# STEREOSELECTIVE SYNTHESIS OF $\alpha$-AMINO ACIDS $\beta$-SUBSTITUTED WITH A 4,5 DIHYDROISOXAZOLE NUCLEUS AND OF TERTIARY AND QUATERNARY ALLYLSILANES 

Tesi di Dottorato di:<br>Maddalena GALLANTI<br>Matricola: R08363

Tutor:Prof. Piero DALLA CROCE<br>Co-tutor: Concetta La ROSA<br>Coordinatore del Dottorato:<br>Prof. Dominique ROBERTO

A Mamma e Papà,
con un grande grazie per l'amore, il supporto e l'incoraggiamento in questi tre anni.

## PREFACE

During the second year of PhD, I spent six months at Bristol University, in Prof. Varinder Aggarwal's laboratory. In order to broaden my skills and competences in a wide science such as Organic Chemistry, there I developed a topic that was different from the one I was studying in Milan. For this reason, the thesis will be articulated in two principal parts (namely Section A and Section B) corresponding respectively to the work performed in Milan ("Stereoselective synthesis of $\alpha$-amino acids $\beta$-substituted with a 4,5-dihydroisoxazole nucleus") an the one performed in Bristol ("Stereoselective synthesis of tertiary and quaternary allylsilanes").

## TABLE OF CONTENTS

SECTION A ..... 1
1 INTRODUCTION ..... 3
1.1 Synthetic Methodologies for the Synthesis of $\beta$-Hydroxy- $\alpha$-amino Acids ..... 8
1.2 Previous Work Overview ..... 15
1.3 PhD Thesis Program ..... 23
2 RESULTS AND DISCUSSION ..... 26
2.1 Synthesis of 4,5-Dihydroisoxazole-3-carbaldehydes 31c, d, f ..... 26
2.2 Synthesis of Enantiomerically Pure 5-Phenyl-4,5-dihydroisoxazole-3-carbaldehyde 31f. ..... 28
2.2.1 Organocatalyzed Synthesis ..... 28
2.2.2 Classical Chemical Resolution ..... 29
2.2.3 Enzimatic Resolution ..... 30
2.3 Synthesis of 3-Acyl-4,5-dihydroisoxazoles 39a-d ..... 36
2.4 Synthesis of 3-Substituted-5-Acetyl-4,5-dihydroisoxazoles 41 and $\mathbf{4 2}$ ..... 40
2.5 Synthesis of Enantiomerically Pure 3-Substituted-5-Acetyl-4,5-dihydroisoxazoles 41and 4242
2.5.1 Chemical Resolution ..... 42
2.5.2 Enzimatic Resolution ..... 43
2.6 Study of the Reaction with Schöllkopf's Reagent. ..... 46
2.6.1 Addition of Schollköpf's Reagent Anion to ( $R$ )-5-Phenyl-4,5-dihydroisoxazole-3- carbaldehyde ( $\boldsymbol{R}$ )-31f. ..... 46
2.6.2 Hydrolysis of Adducts 60 and 61 and Isoxazoline Cleavage of $\mathbf{6 6}$ ..... 50
2.6.3 Addition of Schollköpf's Reagent Anion to 3-Acyl-4,5-dihydroisoxazole ..... 51
2.6.4 Addition of Schöllkopf's Reagent Anion to 5-Acetyl-4,5-dihydroisoxazoles. ..... 56
2.6.5 Models of the Addition of Schöllkopf's Reagent Anion to Ketones (5S)- and (5R)-41 ..... 61
2.6.6 Hydrolysis of Adducts $\mathbf{8 1 - 8 3}$ ..... 64
2.7 Study of the Cleavage of 2-Isoxazoline Ring ..... 66
2.8 Preliminary Studies on Addition of Schöllkpof's Reagent Anion to Imines ..... 71
3 CONCLUSION ..... 74
4 EXPERIMENTAL ..... 76
4.1 General informations ..... 76
4.2 General procedure for the synthesis of compounds $\mathbf{3 2 c} \mathbf{c} \mathbf{- f}$ ..... 77
4.2.1 Oxa-2-aza-spiro[4.5]dec-2-ene-3-carboxylic acid ethyl ester 32c ..... 77
4.2.2 Ethyl 5-cyclohexyl-4,5-dihydroisoxazole-3-carboxylate 32d ..... 77
4.2.3 Ethyl 4,5-dihydro-5-(pyridin-2-yl)isoxazole-3-carboxylate 32e ..... 78
4.2.4 5-Phenyl-4,5-dihydroisoxazole-3-carboxylic acid ethyl ester 32f ..... 78
4.3 General procedure for the synthesis of compounds $\mathbf{3 3 c}, \mathbf{d}, \mathbf{f}$ ..... 78
4.3.1 (1-Oxa-2-aza-spiro[4.5]dec-2-en-3-yl)-methanol 33c ..... 79
4.3.2 (5-cyclohexyl-4,5-dihydroisoxazol-3-yl)methanol 33d ..... 79
4.3.3 5-Phenyl-4,5-dihydroisoxazol-3-yl]-methanol 33 f ..... 80
4.4 General procedure for the synthesis of compounds $\mathbf{3 1} \mathbf{c}, \mathbf{d}, \mathbf{f}$ ..... 80
4.4.1 1-Oxa-2-aza-spiro[4.5]dec-2-ene-3-carbaldehyde 31c ..... 80
4.4.2 5-cyclohexyl-4,5-dihydroisoxazole-3-carbaldehyde 31d ..... 81
4.4.3 4,5-dihydro-5-phenylisoxazole-3-carbaldehyde 31f ..... 81
4.5 Enzimatic resolution of $(\mathbf{\pm}) \mathbf{- 3 2 f}$ ..... 81
4.5.1 (5R)-5-Phenyl-4,5-dihydroisoxazole-3-carboxylic acid ethyl ester ( $\boldsymbol{R}$ )-32f ..... 81
4.5.2 [(5R)-5-Phenyl-4,5-dihydroisoxazol-3-yl]-methanol (R)-33f ..... 82
4.5.3 (5R)-4,5-dihydro-5-phenylisoxazole-3-carbaldehyde (5R)-31f ..... 82
4.6 General procedure for the synthesis of compounds 50a-d ..... 83
4.6.1 1-(1-oxa-2-azaspiro[4.5]dec-2-en-3-yl)ethan-1-ol 50a ..... 83
4.6.2 1-(1-oxa-2-azaspiro[4.5]dec-2-en-3-yl)propan-1-ol 50b ..... 83
4.6.3 2-methyl-1-(1-oxa-2-azaspiro[4.5]dec-2-en-3-yl)propan-1-ol 50c ..... 84
4.6.4 1-(1-oxa-2-azaspiro[4.5]dec-2-en-3-yl)prop-2-en-1-ol 50d ..... 84
4.7 General procedure for the synthesis of compounds 39a-d ..... 85
4.7.1 1-(1-oxa-2-azaspiro[4.5]dec-2-en-3-yl)ethan-1-one 39a ..... 85
4.7.2 1-(1-oxa-2-azaspiro[4.5]dec-2-en-3-yl)propan-1-one 39b ..... 85
4.7.3 2-methyl-1-(1-oxa-2-azaspiro[4.5]dec-2-en-3-yl)propan-1-one 39c ..... 86
4.7.4 1-(1-oxa-2-azaspiro[4.5]dec-2-en-3-yl)prop-2-en-1-one 39d ..... 86
4.8 Synthesis of 5-Acetyl-4,5-dihydroisoxazole 41 and 42 ..... 87
4.8.1 1-(4,5-dihydro-3-methylisoxazol-5-yl)ethanone ( $\pm$ )-41 ..... 87
4.8.2 Synthesis of 5-(1-Hydroxyethyl)-4,5-dihydro-isoxazole-3-carboxylic acid ethyl ester ( $\pm$ )-syn/anti- 55 ..... 87
4.8.3 Synthesis of 5-Acetyl-4,5-dihydro-isoxazole-3-carboxylic acid ethyl ester ( $\pm$ )-42. ..... 88
4.9 Enzymatic resolution of ( $\mathbf{\pm}$ )-41 and ( $\mathbf{\pm}$ )-42 ..... 89
4.9.1 (1S,5S)-1-(3-Methyl-4,5-dihydro-isoxazol-5-yl)-ethanol ((+)-syn-56) ..... 89
4.9.2 (1S,5R)-1-(3-Methyl-4,5-dihydro-isoxazol-5-yl)-ethanol (-)-anti-56. ..... 90
4.9.3 (1S,5S)-5-(1-Hydroxyethyl)-4,5-dihydro-isoxazole-3-carboxylic acid ethyl ester (+)-syn-55 ..... 90
4.9.4 (1 $S, 5 R$ )-5-(1-Hydroxyethyl)-4,5-dihydro-isoxazole-3-carboxylic acid ethyl ester (-)-anti-55 ..... 91
4.10 General procedure for synthesis of (R)- and (S)-41 and (R)- and (S)- 42 ..... 91
(5S)-1-(3-Methyl-4,5-dihydro-isoxazol-5-yl)-ethanone (S)-41 ..... 92
4.10.1 (5R)-1-(3-Methyl-4,5-dihydro-isoxazol-5-yl)-ethanone ( $\boldsymbol{R}$ )-41 ..... 92
4.10.2 (5S)-5-Acetyl-4,5-dihydro-isoxazole-3-carboxylic acid ethyl ester ( $\boldsymbol{S}$ )-42 ..... 92
4.10.3 (5R)-5-Acetyl-4,5-dihydro-isoxazole-3-carboxylic acid ethyl ester (R)-42 ..... 93
4.11 General procedure for the synthesis of compounds $\mathbf{6 0 - 6 3}$ ..... 93
4.11.1 (S)-[(2S,5R)-5-Isopropyl-3,6-dimethoxy-2,5-dihydropyrazin-2-yl]-[(5R)-5- phenyl-4,5-dihydroisoxazol-3-yl]-methanol 60 ..... 94
4.11.2 $(R)$-[(2R,5R)-5-Isopropyl-3,6-dimethoxy-2,5-dihydropyrazin-2-yl]-[(5R)-5- phenyl-4,5-dihydroisoxazol-3-yl]-methanol 61 ..... 95
4.11.3 (R)-[(2S,5R)-5-Isopropyl-3,6-dimethoxy-2,5-dihydropyrazin-2-yl]-[(5R)-5- phenyl-4,5-dihydroisoxazol-3-yl]-methanol 62 ..... 95
4.11.4 (S)-[(2R,5R)-5-Isopropyl-3,6-dimethoxy-2,5-dihydropyrazin-2-yl]-[(5R)-5- phenyl-4,5-dihydroisoxazol-3-yl]-methanol 63 ..... 96
4.12 General procedure for the synthesis of compounds 65-68 ..... 97
4.12.1 (2S)-Amino-(3S)-hydroxy-3-[(5R)-phenyl-4,5-dihydroisoxazol-3-yl]-propionic acid methyl ester 65 ..... 97
4.12.2 (2S)-[(2R)-Amino-3-methyl-butyrylamino]-(3S)-hydroxy-3-[(5R)-5-phenyl-4,5- dihydroisoxazol-3-yl]-propionic acid methyl ester 66 ..... 98
4.12.3 ( $2 R$ )-Amino-[(3R)-hydroxy-3-(5R)-5-phenyl-4,5-dihydroisoxazol-3-yl]-propionic acid methyl ester 67 ..... 98
4.12.4 (2R)-[(2R)-Amino-3-methyl-butyrylamino]-(3R)-hydroxy-3-[(5R)-5-phenyl-4,5- dihydroisoxazol-3-yl]-propionic acid methyl ester 68 ..... 99
4.13 Synthesis of (2S,3S,6R)-2-[(2R)-2-Amino-3-methyl-butyrylamino]-3,6-dihydroxy-4- oxo-6-phenyl-hexanoic acid methyl ester 69 ..... 100
4.14 General procedure for the synthesis of compounds $74 \mathrm{a}, \mathrm{b}$ and $75 \mathrm{a}, \mathrm{b}$ and 76 ..... 101
4.14.1 1-[(2S,5R)- 5-Isopropyl-3,6-dimethoxy-2,5-dihydropyrazin-2-yl]-1-(1-oxa-2- azaspiro[4.5]dec-2-en-3-yl) ethan-1-ol 74a/75a ..... 101
4.14.2 1-[(2S,5R)-5-(Isopropyl)-3,6-dimethoxy-2,5-dihydropyrazin-2-yl]-1-(1-oxa-2- azaspiro[4.5]dec-2-en-3-yl)propan-1-ol 74b/75b ..... 102
4.14.3 3-[(2S,5R)-5-(Isopropyl)-3,6-dimethoxy-2,5-dihydropyrazin-2-yl]-1-(1-oxa-2- azaspiro[4.5]dec-2-en-3-yl)propan-1-one 76 ..... 104
4.15 General procedure for the synthesis of $\mathbf{7 9}$ and $\mathbf{8 0}$ ..... 104
4.15.1 Methyl (2S)-2-amino-3-hydroxy-3-(1-oxa-2-azaspiro[4.5]dec-2-en-3-yl)butanoate 79/80 ..... 105
4.16 General procedure for synthesis of compounds 81-84 ..... 105
4.16.1 (1R)-1-[(2S,5R)-5-Isopropyl-3,6-dimethoxy-2,5-dihydro-pyrazin-2-yl]-1-[(5S)-3- methyl-4,5-dihydro-isoxazol-5-yl]ethanol 81 ..... 106
4.16.2 (1S)-1-[(2S,5R)-5-Isopropyl-3,6-dimethoxy-2,5-dihydro-pyrazin-2-yl]-1-[(5S) 3- methyl-4,5-dihydro-isoxazol-5-yl]ethanol 82 ..... 107
4.16.3 (1S)-1-[(2S,5R)-5-Isopropyl-3,6-dimethoxy-2,5-dihydro-pyrazin-2-yl]-1-[(5R)-3- methyl-4,5-dihydro-isoxazol-5-yl]ethanol 83 ..... 107
4.16.4 (1R)-1-[(2S,5R)-5-isopropyl-3,6-dimethoxy-2,5-dihydro-pyrazin-2-yl]-1-[(5R)-3- methyl-4,5-dihydro-isoxazol-5-yl]ethanol 84 ..... 108
4.17 General procedure for synthesis of compounds 86-88 and 89-91 ..... 109
4.17.1 (2S)-Amino-(3R)-hydroxy-3-[(5S)-3-methyl-4,5-dihydro-isoxazol-5-yl]-butyric acid methyl ester 86. ..... 109
4.17.2 (2S)-Amino-(3S)-hydroxy-3-[(5S)-3-methyl-4,5-dihydro-isoxazol-5-yl]-butyric acid methyl ester 87 ..... 110
4.17.3 (2S)-Amino-(3S)-hydroxy-3-[(5R)-3-methyl-4,5-dihydro-isoxazol-5-yl]-butyric acid methyl ester $\mathbf{8 8}$ ..... 110
4.17.4 (2S)-[(2R)-Amino-3-methyl-butyrylamino]-(3R)-hydroxy-3-[(5S)-3-methyl-4,5- dihydro-isoxazol-5-yl]-butyric acid methyl ester 89 ..... 111
4.17.5 (2S)-[(2R)-Amino-3-methyl-butyrylamino]-(3S)-hydroxy-3-[(5S)-3-methyl-4,5- dihydro-isoxazol-5-yl]-butyric acid methyl ester 90 ..... 112
4.17.6 (2S)-[(2R)-Amino-3-methyl-butyrylamino]-(3S)-hydroxy-3-[(5R)-3-methyl-4,5- dihydro-isoxazol-5-yl]-butyric acid methyl ester 91 ..... 112

SECTION A

## 1 INTRODUCTION

$\beta$-Hydroxy- $\alpha$-amino acids are an important class of amino acids. They are found within the twenty natural amino acids (threonine, serine, and $\beta$-hydroxy proline) and as constituents of more complex natural products. For example, $\beta$-hydroxy tyrosine and $\beta$ hydroxyphenylalanine derivatives are found in clinically important glycopeptide antibiotics, such as Vancomycin, discovered in 1956 by Eli Lilly, and Teicoplanin (Figure 1). ${ }^{1,2}$

Figure 1: Structure of Vancomycin and Teicoplanin

Vancomycin and Teicoplanin are the progenitors of glycopeptides antibiotics and elucidation of their structures led to the development of new antibiotics. ${ }^{2}$ Today, both Vancomycin and Teicoplanin are used in the treatment of patients infected with drugresistant Gram-positive bacterial strains. Glycopeptides antibiotics are toxic for bacteria because they interfere with the synthesis of peptidoglycan layer of the bacterial cell wall. Peptidoglycan is a polymer consisting of sugars and amino acids that forms a mesh-like layer outside the plasma membrane of eubacteria. The sugar component consists of alternating residues of $\beta$-(1,4) linked $N$-acetylglucosamine (NAG) and N acetylmuramic acid (NAMA) residues. Attached to the $N$-acetylmuramic acid is a peptide chain of three to five amino acids. The peptide chain can be cross-linked to the peptide chain of another strand forming the 3D mesh-like layer. Peptidoglycans serve an
important role in the bacterial cell wall, especially in Gram-positive organisms, giving structural strength as well as counteracting the osmotic pressure of the cytoplasm.

In Gram-positive bacteria the glycopeptides antibiotics easily diffuse through the peptidoglycan layer and reach the periplastic space where the peptidoglycan polymerization takes place. By binding onto the L-Lys-D-Ala-D-Ala tails of the monomers the antibiotic positions itself to inhibit the transglycosidase from joining the carbohydrate ends as shown in Figure 2. ${ }^{2}$

Figure 2: Mechanism of action of Vancomycin

Other $\beta$-hydroxy- $\alpha$-amino acids can be found in antibiotics: D-threonine is present in Katanosins (Figure 3), ${ }^{3,4}$ while $\beta$-hydroxyleucine in lysobactin. ${ }^{5}$ Both are highly active against Gram-positive bacteria that have shown resistance to Vancomycin. ${ }^{6}$

Figure 3: Structure of Katanosins $A$ and $B$

Another $\beta$-hydroxy- $\alpha$-amino acid, L-threo- $\beta$-(3,4 dihydroxyphenyl) serine, acts itself as a drug, being used in the treatment of Parkinson's disease. ${ }^{7}$
$\beta$-Hydroxy- $\alpha$-amino acids have also played a key role in the synthesis of other important compounds. For example, Miller and co-workers ${ }^{8}$ used $\beta$-hydroxy- $\alpha$-amino acid $\mathbf{1}$ in the synthesis of carbacephem 2, a $\beta$-lactam (Figure 4(a)), Vederas and coworkers ${ }^{9}$ converted protect $\beta$-hydroxy- $\alpha$-amino acids $\mathbf{3}$ into $\beta$-fluoro amino acids (Figure 4(b)) 4, and Corey and co-workers ${ }^{10}$ used a $\beta$-hydroxy- $\alpha$-amino acids 5 as a chiral building block for the synthesis of $\alpha$-Methylomuralide (Figure 4(c)).

Figure 4: Use of $\beta$-Hydroxy- $\alpha$-amino acids in synthesis

Within the twenty human amino acids, two of them, tryptophan and histidine, are $\beta$ substituted with an heterocyclic ring (Figure 5). Also in the natural product this is a common scaffold, and amino acid $\beta$-substituted with an heterocycle can be found, for instance, in the structure of (-)-Kaitocephalin (Figure 5), ${ }^{11}$ a molecule active on glutamate receptors.

Tryptophan

Histidine

Figure 5: Structures of $\alpha$-amino acids $\beta$-substituted with an heterocycle

Among the different heterocycles, isoxazole and isoxazoline rings play a pivotal in molecule that show activity towards glutamate receptors. ${ }^{12-14}$ As shown in Figure 6, isoxazole ring is found in both agonists and antagonists of AMPA receptor, one of the ionotropic glutamate receptors.

The acidic amino acid glutamate (Glu) is the major neurotransmitter of the fast excitatory synapses in the central nervous system (CNS) and plays a key role in physiological processes ranging from learning and memory to control of movements and pain sensitivity. ${ }^{15,16}$ Several mental diseases like epilepsy, cerebral ischemia, Parkinson and Alzheimer are due to overstimulation of Glu receptors by endogenous or exogenous substances. Glu activity is mediated by different type of receptor and for this reason it is really important to develop molecules that are selective only towards one type, in order to minimize the side effects. For example compounds $\mathbf{6}$ and $\mathbf{7}$ reported in Figure 7 show a neuroprotective activity, due to their action as antagonists of NMDA receptors, one of the ionotropic glutamate receptors. ${ }^{17}$ In both molecules it is identifiable the chain of glutamate, one atom longer in the case of $\mathbf{6}$ and two in the case of 7 .

### 1.1 Synthetic Methodologies for the Synthesis of $\beta$-Hydroxy- $\alpha$ amino Acids

As a consequence of the essential role played by $\beta$-hydroxy- $\alpha$-amino in biological systems and their utility as synthetic building blocks, a number of useful strategies have been devised for their preparation in enantiomerically pure form. These include Sharpless asymmetric epoxidation, ${ }^{18-20}$ Sharpless asymmetric dihydroxylation, ${ }^{21-23}$ electrophilic amination, ${ }^{24}$ hydroxylation, ${ }^{25}$ stereoselective hydrolysis of aziridine carboxylate esters, ${ }^{26-30}$ and the aldol reaction. ${ }^{31,32}$ Among these methods, the focus of this section will be on aldol reactions of glycine equivalents with aldehydes. This reaction, in fact, provides an effective and direct access to $\beta$-hydroxy- $\alpha$-amino acids derivatives, because the process involves the formation of a C-C bond and construction of vicinal stereogenic centres. There are two possible methods to synthesize enantiomerically pure $\beta$-hydroxy- $\alpha$-amino acids through aldol reaction. One utilises a chiral catalyst, whilst the other uses a chiral auxiliary often build into the glycine equivalent.

A few elegant methods for the aldol strategy have been described employing only catalytic amount of chiral sources. In 1999 Corey and co-workers used the cinchonidine-derived bifluoride salt 8, shown in Figure 8, as catalyst in the reaction between the silyl enol ether $\mathbf{9}$ and different aldehydes, obtaining the desired $\beta$-hydroxy-$\alpha$-amino acids in good yield, good d.r. (up to 13:1 syn:anti) and excellent enantioselectivity (e.e.: 95\%). ${ }^{33}$

Figure 8: Corey's synthesis of $\beta$-hydroxy- $\alpha$-amino acids

In 2001 Evans and co-workers reported the aldol reaction of aromatic aldehydes and 5alkoxyoxazoles $\mathbf{1 0}$ catalyzed by the chiral aluminium complex $\mathbf{1 1}$ shown in Figure 9. ${ }^{34}$ This methodology allows the synthesis of masked $\beta$-hydroxy- $\alpha$-amino acids in excellent yield, d.r.(up to 99:1 cis:trans) and e.e. (up to $99 \%$ ).

Figure 9: Evan's synthesis of masked $\beta$-hydroxy- $\alpha$-amino acids

The first direct aldol condensation for the synthesis of $\beta$-hydroxy- $\alpha$-amino acids was reported by Shibasaki in 2002. ${ }^{35}$ Heterobimetallic asymmetric complex ( $\boldsymbol{S}$ )-LLB catalyzed the reaction between glycinate Schiff base 12 with different aliphatic aldehydes with a moderate d.r. (up to $86: 14$ anti:syn) and e.e. (up to $76 \%$ of the anti diastereoisomer) (Figure 10).

Figure 10: Shibasaki's synthesis of $\beta$-hydroxy- $\alpha$-amino acids
A big improvement in the direct aldol reaction was made in 2004 by Maruoka and coworkers. ${ }^{36}$ The use of their chiral phase transfer catalyst $\mathbf{1 3}$ under organic/aqueous biphasic conditions (Figure 11), provided the $\beta$-hydroxy- $\alpha$-amino acids in excellent diastereoselectivity (96:4 anti:syn ratio) and enantioselectivity (e.e. 98\%).

Figure 11: Maruoka's synthesis of $\beta$-hydroxy- $\alpha$-amino acids

Another possibility for synthesizing $\beta$-hydroxy- $\alpha$-amino acids involves an aldol type reaction between a chiral glycine synthon and an aldehyde. Several glycine chiral equivalent have been described in the literature. ${ }^{37}$ Evans and co-workers were the first describing the chiral oxazolidinone $\mathbf{1 4}$ as a chiral glycine equivalent. ${ }^{38}$ The isothiocyanate unit build in the molecule acts as a masked amino group, while the stereochemical control is provided by the oxazolidinone unit. The aldol reaction
between this chiral auxiliary and different aldehydes proved to be highly diastereoselective, providing the desired syn adduct in a d.r. up to 99:1. ${ }^{38}$ Several $\beta$ -hydroxy- $\alpha$-amino acids were synthesized using this useful chiral auxiliary, ${ }^{39-41}$ including MeBmt shown in Figure 12. ${ }^{38}$

Figure 12: Evan's synthesis of MeBmt
Recently Frank ${ }^{42}$ and co-workers proposed a modification of the isothiocyanate unit of oxazolidinone 14. In fact in the reaction with aldehydes, the isothiocianate group reacts with the newly formed alcolate, providing the oxazolidin-2-thione 15, that has to be hydrolysed in order to release the free $\beta$-hydroxy- $\alpha$-amino acids. However hydrolysis is not a straightforward step, as prior transformation of the oxazolidin-2-thione $\mathbf{1 5}$ into the more easily hydrolyzed oxazolidin-2-one 16 is needed (Figure 12). ${ }^{38}$ For this reason, in order to avoid laborious steps, Frank and co-workers envisaged that the isothiocyanate group could be replaced by an azido group. In particular they showed how the reaction between the enolate derived from azide 17, and differently substituted aldehydes provided the syn aldol products $\mathbf{1 8}$ in good yield and diastereoselectivities (Figure 13). The transformation of the $\beta$-hydoxy- $\alpha$-azido ester into the desired amino esters 19 is
more straightforward, requiring only the removal of thiazolidin-2-thione followed by the reduction of the azido group.

Figure 13: Frank's synthesis of $\beta$-hydroxy- $\alpha$-amino esters
Xu and co-workers ${ }^{43}$ developed an aldol reaction between aldehydes and the enolates of tricyclic iminolactones 20 and 21, which are derived from natural ( $1 R$ )-(+)-camphor as chiral glycine templates to generate optically pure $\beta$-hydroxy- $\alpha$-amino acids in good yield and high diastereoselectivity (d.r. up to $>25: 1$ ) (Figure 14). The formation of just two of the four possible diastereoisomers is due to the exclusively endo addition of the nucleophile to the aldehyde with the $\mathrm{C}_{12}$-methyl blocking the attack from the exo-face of the enolate. The $\beta$-hydroxy- $\alpha$-amino acids was then easily released through an acid hydrolysis and the chiral auxiliary recovered in excellent yield. ${ }^{43}$

Figure 14: Xu's synthesis of precursors of $\beta$-hydroxy $\alpha$-amino acids

Within the different chiral glycine equivalents, Schöllkopf's bislactim ether $\mathbf{2 2}$ is particularly attractive because it has proved to be highly diastereoselective in aldol-type reactions and is commercially available in both enantiopure $(R)$ - and ( $S$ )-forms. ${ }^{44-46}$ Schöllkopf's reagent is selectively deprotonated at C-2 providing the azaenolate 23 The attack of this latter to an electrophile compound, such as an alkyl halide, occurs only
from the face opposite to the isopropyl group, leading to products where C-2 and C-5 substituents are in trans relationship (Figure 15).

Figure 15: Reaction between Schöllkopf's reagent and alkyl halides
When the electrophile is a carbonyl group of an aldehyde, a second stereocenter is formed on C-1'. However, in this case the formation of the epimer 2,5-trans-2,1'-syn is preferred over the 2,5-trans-2,1'-anti ones (Figure 16).

Figure 16: Reaction between Schöllkopf's reagent and aldehydes

This is due to a more favourable transition state, in which the aldehyde substituent is far from the methoxy group and from the metal atom (Schöllkopf's model) (Figure17). ${ }^{44}$

Figure17: Schöllkopf's model

The acid catalyzed opening of pyrazine ring leads to the formation of enantiomerically pure amino esters (alanines or serines) in high yields (Figure 18). At this stage the valinate methyl ester can be easily recovered through distillation and used to synthesise new Shöllkopf's reagent.

Figure 18: Synthesis of $\alpha$-amino acids using Schöllkopf's reagent

### 1.2 Previous Work Overview

The research group where I performed the PhD , has been interested for several years in the stereoselective synthesis of non-proteinogenic $\alpha$-amino acids containing an heterocyclic ring using the Schöllkopf's reagent as chiral glycine equivalent. In particular, our early interest concerned the synthesis of alanine and serine type amino acids bearing in position 3 an heteroaromatic ring. Initial studies looked at the reaction between the Schöllkopf's reagent and halogenomethyl derivatives of heteroaromatic systems, as shown in Scheme $1 .{ }^{47}$ The reaction proved to be highly stereoselective, providing only two of the four possible diastereoisomers with a anti:syn ratio of up to 91:9. This stereochemical outcome was explained considering the model shown before (Figure 15). The two adducts were easily separated through chromatographic column, to give, after the hydrolysis of pyrazine ring, enantiomerically pure 3-heteroaromatic-substituted-alanines.

Scheme 1: Synthesis of 3-heteroaromatic-substituted-alanines

In order to synthesise the more synthetically useful $\beta$-hydroxy- $\alpha$-amino acids, we started studying the reaction between heteroaryl aldehydes and Schöllkopf's azaenolate 23. Again just two of the four possible diastereoisomers were formed as shown in Scheme $2 .{ }^{48}$ These products were epimers on the newly formed alcoholic carbon, while the C-2 and C-5 substituents maintained a trans relationship, as previously described.

Scheme 2 Synthesis of $\beta$-hydroxy- $\alpha$-amino acids $\beta$-substituted with an heterocyclic ring

| Heterocycle | anti:syn ratio | Yield (\%) | Counterion |
| :---: | :---: | :---: | :---: |

| $\mathbf{2 6}$ | $100: 0$ | 43 | Ti |
| $\mathbf{2 7}$ | $70: 30$ | 87 | Ti |
| $\mathbf{2 8}$ | $80: 20$ | 60 | Ti |
| $\mathbf{2 9}$ | $87: 13$ | 95 | Ti |

Table 1: Optimization of reaction of heteroaldehydes with Schöllkopfs reagent

The syn/anti ratio depends on the nature of the counterion (Table 1). The titanium derivative of azaenolate $\mathbf{2 3}$ reacts with high diastereoselectivity giving a preference for syn attack product owing to a tight transition state ${ }^{44}$ promoted by coordination of titanium to the aldehyde oxygen. Moreover, the predominance of the $(R)$-epimer of the alcoholic carbon atom comes from an energetically more favored transition state in which the aldehyde substituent R is far from the methoxy group and the metal atom.

To evaluate the effect of a stereocenter at the $\alpha$ position of the aldehyde on the stereochemical course of the reaction, we studied the reaction between Schöllkopf's reagent and non-aromatic enantiopure aldehydes 30a-c (Scheme 3). ${ }^{49}$

Scheme 3: Reaction of Schöllkopf's reagent and non-aromatic enantiopure aldehydes

| Entry | Aldehyde 30 | Counterion | Yield (\%) | Ratio syn:anti |
| :---: | :---: | :---: | :---: | :---: |
| 1 | a | Li | 66 | $75: 25$ |
| 2 | a | Ti | 31 | $84: 16$ |
| 3 | b | Li | 56 | $61: 39$ |
| 4 | b | Ti | -- | -- |
| 5 | $\boldsymbol{( S ) - 3 0 c}$ | Li | 75 | $64: 36$ |
| 6 | $\boldsymbol{( S ) - 3 0 c}$ | Ti | 27 | $51: 49$ |
| 7 | $(\boldsymbol{R})-\mathbf{3 0 c}$ | Li | 63 | $64: 36$ |

Table 2: Optimization of the reaction between Schöllkopf's reagent and enantiopure aldehydes

Also in these cases both lithium and titanium were used as counterion. However, unlike the previous results, ${ }^{48,50}$ the diastereoselectivity was not enhanced except in one case (Table 2, entry 2) and at the expense of the yield. In the other cases, no reaction occurred in the presence of titanium (Table 2, entry 4), or it occurred with a decreased yield and, surprisingly, also less stereoselectivity (Table 2, entry 6). These findings differ from our previous results obtained using heteroaromatic aldehydes ${ }^{48}$ and $\beta$ -heteroaryl- $\alpha, \beta$-unsaturated aldehydes, ${ }^{50}$ presumably because, in this case, titanium may competitively interact also with the carbonyl group of the Boc-protecting group.

The stereochemical outcome at the C-1' and C-2 of the pyrazine ring is in line with the previous results ${ }^{48,50}$ and the widely accepted model for the aldol-type addition of $\mathbf{2 2}$ to aldehydes (Figure17). As chiral aldehydes have diastereotopic carbonyl faces, the reactions of Schöllkopf's reagent with aldehydes 30a-c raise the problem of "double asymmetric induction". In our case, the stereodifferentiation due to the chiral aldehyde (substrate control) clearly does not have a greater effect than Schöllkopf's pyrazine (reagent control) as both $(\boldsymbol{S})-\mathbf{3 0 c}$ and $(\boldsymbol{R})-\mathbf{3 0 c}$ lead to similar stereochemical results with a syn:anti ratio of 1.8:1 (Table 2 entry 5 and 7). This result was quite surprising, because, considering the transition states, we would have presumed a better diastereoselectivity for the reaction between ( $\boldsymbol{R}) \mathbf{- 2 2}$ and $(\boldsymbol{R})-\mathbf{3 0}$. In this case, we predicted the major diastereoisomer would have derived from a positive combination of both Felkinh-Ahn ${ }^{51}$ and Schöllkopf models (Figure 19, transition state A) whereas the minor diastereoisomer would have been the result of an unfavourable transition state, where the more cumbersome substituent is pseudoaxial (Figure 19, transition state B).

Figure 19: Models for the reaction between aldehyde ( $\boldsymbol{R}$ )-30c and Schöllkopf's reagent

Conversely, we expected the reaction between ( $\boldsymbol{R}$ )-22 and (S)-30c should have been less diastereoselective because both the major (Figure 20, transition state A) and the minor (Figure 20, transition state B) diastereoisomers would have derived from half-matched transition states. ${ }^{44}$

A)

B)

Figure 20: Models for the reaction between aldehyde (S)-30c and Schöllkopf's reagent

However, it is well-known that the lithium salts of the $\alpha$-azaenolates are generally not very selective. ${ }^{44,52,53}$ It is therefore very difficult to rationalise the observed stereochemical results fully. The only clear thing that can be deduced is that the azaenolate reacts through the standard Schöllkopf model.

More recently we have focus our attention on 4,5 dihydroisoxazole-3-carbaldehydes. The choice of this heterocycle stems from its peculiar features. In fact it is easy to synthesise through a 1,3-dipolar cycloaddition reaction between nitrile oxides and alkenes (Scheme 4). ${ }^{54}$

Scheme 4: Synthesis of $\Delta^{2}$-isoxazolines through 1,3-dipolar cycloaddition

From the synthetic point of view, the 4,5-dihydro-isoxazole ring proves to be a very versatile heterocycle: in fact it can be converted into a number of useful synthetic units, such as $\beta$-hydroxy ketones ${ }^{55-57}$ or $\beta$-amino alcohols, ${ }^{58}$ depending on the experimental conditions used for reductive ring cleavage.

Initial studies concerned the reaction between Schöllkopf's reagent and aldehydes 31a-c 5,5-disubstituted with two identical groups. ${ }^{59}$ The absence of a racemic stereocenter in the isoxazoline ring allowed us to minimise the total number of diastereoisomers that
result from the reaction with Schöllkopf's reagent. These substrates were synthesised according to a recently reported method ${ }^{60}$ that involves a base-catalysed condensation between ethyl nitroacetate and alkenes 34 (vide infra). The methodology was extended to 1,1-disubstituted alkenes in this study. ${ }^{59}$ The esters 32a-c were then converted into the corresponding aldehydes (Scheme 5)

$\mathrm{a}: \mathrm{R}=\mathrm{R}^{\prime}=\mathrm{Ph}$
$\mathrm{b}: \mathrm{R}=\mathrm{R}^{\prime}=\mathrm{CH}_{3} \quad \mathrm{DABCO}=$
$\mathrm{c}: \mathrm{R}=\mathrm{R}^{\prime}=-\left(\mathrm{CH}_{2}\right)_{5}{ }^{-}$
Scheme 5: Synthesis of aldehydes 31a-c

Aldehydes 31a-c underwent reaction with Shöllkopf's anion 23 (Scheme 6), providing just two of the possible four diastereoisomers, with an excellent d.r as reported in Table 3. The reaction was extremely diastereoselective despite the use of lithium as counterion. The structures of the major diastereoisomers $\mathbf{3 5}$ were determined using NMR analysis and on the base of Schöllkopf model.

Scheme 6: Reaction between Schöllkopf's reagent and aldehydes 31a-c

| Aldehyde 31 | Total yield (\%) | d.r. |
| :---: | :---: | :---: |
| a | 66 | $93: 7$ |
| b | 64 | $90: 10$ |
| c | 68 | $95: 5$ |

Table 3: Yields and d.r of the reaction between Schöllkopf's reagent and aldehydes 31a-c

Adducts 35a-c were hydrolysed under mild conditions, which allowed the isolation of the $\beta$-hydroxy- $\alpha$-amino esters 36a-c and the dipeptides 37a-c (Scheme 7 and Table 4).

Scheme 7: Hydrolysis of pyrazine ring

| $\mathbf{3 5}$ | $\mathbf{R}$ | Yield (\%) |  |
| :---: | :---: | :---: | :---: |
|  |  | $\mathbf{3 6}$ | $\mathbf{3 7}$ |
| a | Ph | 20 | 48 |
| b | $\mathrm{CH}_{3}$ | 20 | 63 |
| c | $-\left(\mathrm{CH}_{2}\right)_{5^{-}}$ | 28 | 42 |

Table 4: Hydrolysis of pyrazine ring

The formation of these dipeptides was due to the partial hydrolysis of the pyrazine ring that often occurs during the hydrolysis reaction. ${ }^{49,61-63}$ We were unable to avoid this despite changing solvent (methyl alcohol, acetonitrile or THF), temperature (from $0{ }^{\circ} \mathrm{C}$ to room temperature), the acid ( HCl or TFA) or its concentration (from 0.2 N to 2 N ). Products $\mathbf{3 6}$ and 37 were easily separated by means of column chromatography and their structure was assigned using exhaustive NMR analysis. Finally, we carried out a hydrogenolysis-hydrolysis of the 4,5-dihydroisoxazole ring of the amino esters $\mathbf{3 6}$ and of the dipeptides $\mathbf{3 7}$ using 1 atmosphere of hydrogen and Raney-Ni as the catalyst. ${ }^{64}$ Hydrogenolysis of $\mathbf{3 6 b}$ and $\mathbf{c}$, was not successful due to a complete degradation of the starting material. The same result was observed using HCl instead of $\mathrm{B}(\mathrm{OH})_{3}$ or $\mathrm{Pd} / \mathrm{C}$ as a catalyst. On the contrary, cleavage of dipeptides $\mathbf{3 7 b}$ and $\mathbf{c}$ allowed us to obtain the corresponding $\beta, \varepsilon$-dihydroxy- $\gamma$-oxo $\alpha$-amino acid derivatives $\mathbf{3 8 b}$ and $\mathbf{c}$ in good yields (Scheme 8). In no case we were able to detect any loss of stereochemical purity. These
$\alpha$-amino acids derivatives have a highly functionalized structure which makes them extremely attractive as potential peptidomimetics.

Scheme 8: Synthesis of polifunctionalized dipeptides through $\Delta^{2}$-isoxazoline ring opening

### 1.3 PhD Thesis Program

In connection with previous results and with the aim of synthesizing new $\beta$-hydroxy- $\alpha$ amino acids $\beta$-substituted with an isoxazoline ring, the program of this PhD thesis tackles the following points:
A) Study of the synthesis of enantiomerically pure 5 -substituted- $\Delta^{2}$-isoxazoline-3carbaldehydes and of the reaction with Schöllkopf's reagent ( $\boldsymbol{R}$ )-22 in order to obtain $\beta$-hydroxy- $\alpha$-amino acids with a supplementary stereocenter on isoxazoline ring (Scheme 9).

Scheme 9: Reaction between Schöllkopf's reagent and 5-substituted- $\Delta^{2}$-isoxazoline-3carbaldehydes
B) Extention of the methodology to the more challenging reaction between Schöllkopf's reagent (R)-22 and 3 -acyl- $\Delta^{2}$-isoxazolines. In particular initially we will focus our attention on achiral ketones as 39 (Scheme 10). The presence in position 5 of the isoxazoline of two identical groups, avoids the doubling of the number of the stereoisomers in the reaction with Schöllkopf's reagent. After reaction with Schöllkopf's reagent and hydrolysis of pyrazine ring, $\beta$-hydroxy-$\alpha$-amino acids 40, with a $\beta$ quaternary stereocentre, will be obtained (Scheme 10). The choice of different R groups on the ketones is made in order to evaluate the steric encumbrance on diastereoselectivity.

Scheme 10: Synthesis of $\beta$-hydroxy- $\alpha$-amino acids through reaction between Schöllkopf's reagent and 3 -acyl- $\Delta^{2}$-isoxazolines
C) Further investigation of the reaction with ketones bearing an acetyl group in position 5 of isoxazoline ring. The presence of a stereocenter in the molecule will require the investigation of a suitable method to obtain 5-acetyl- $\Delta^{2}$ isoxazolines $\mathbf{4 1}$ and $\mathbf{4 2}$ as single enantiomers before reaction with Schöllkopf's reagent ( $\boldsymbol{R}$ )-22 (Scheme 11).

41: $\mathrm{R}=\mathrm{CH}_{3}$
42: $\mathrm{R}=\mathrm{COOEt}$

Scheme 11: Synthesis of $\beta$-hydroxy- $\alpha$-amino acids through reaction between Schöllkopf's reagent and 5-acetyl- $\Delta^{2}$-isoxazolines
D) Study of the best cleavage conditions of $\Delta^{2}$-isoxazolines, in order to use them in the cleavage of more complex substrates as $\mathbf{4 3}$ to obtain polifunctionalized $\beta$-hydroxy- $a$-amino acids 44 (Scheme 12).

Scheme 12: Synthesis of polifunctionalized $\beta$-hydroxy- $\alpha$-amino acids through isoxazoline ring opening
E) Preliminary study will be run on the reaction between simple imines 45 and Schöllkopf reagent (R)-22 (Scheme 13). This will allow us to obtain, after pyrazine cleavage, $\alpha, \beta$-diamino acids 46.

Scheme 13: Study of the reaction between imines and Schöllkopf's reagent

## 2 RESULTS AND DISCUSSION

### 2.1 Synthesis of 4,5-Dihydroisoxazole-3-carbaldehydes

## 31c, d, f

As previously mentioned, aldehyde 31c was synthesised starting from the corresponding ester 32c obtained by means of a base-catalysed condensation between ethyl nitroacetate and methylencyclohexane in accordance with a recently reported method. ${ }^{60}$ The same methodology was also applied in the synthesis of new isoxazolines 31d-f monosubstituted in position 5. According to the described procedure, a mixture of alkene $\mathbf{3 4} \mathbf{c}$-f and ethylnitroacetate reacted in presence of DABCO to give the desired isoxazolines in excellent yields and with total regioselectivity (Scheme 14 and Table 5). The esters 32c, d, f were converted into the corresponding aldehydes 31 through a reduction ${ }^{65}$-oxidation sequence (Scheme 14 and Table 5).

$\mathrm{c}: \mathrm{R}=\mathrm{R}^{\prime}=-\left(\mathrm{CH}_{2}\right)_{5}$
d: $\mathrm{R}=-\mathrm{C}_{6} \mathrm{H}_{11}, \mathrm{R}^{\prime}=\mathrm{H}$

Table 5: Yields of esters 32, alcohols 33 and aldehydes 31

The proposed mechanism by De Sarlo and co-workers, reported in Figure 21, discards the formation of nitriloxide as intermediate. ${ }^{60}$ The tertiary amine, present in the reaction in a catalytic amount, promotes the dehydration of the nitrocompound that is already formed upon addition to alkene (intermediate $\alpha$ ).

Figure 21 Proposed mechanism for the synthesis of $\Delta^{2}$-isoxazolines via base-catalyzed condensation reaction

### 2.2 Synthesis of Enantiomerically Pure 5-Phenyl-4,5-dihydroisoxazole-3-carbaldehyde 31f

### 2.2.1 Organocatalyzed Synthesis

In order to minimize the number of diastereoisomers deriving from the reaction between Schöllkopf's reagent and aldehyde 31f, it was necessary to study an enantioselective synthesis of it. Because of the good results obtained with the base catalyzed reaction between styrene and ethyl nitroacetate (Scheme 14), we thought that the use of a chiral tertiary amine could preferentially form a single enantiomer. However the temperature required for this reaction $\left(60-70{ }^{\circ} \mathrm{C}\right)$ doesn't match with a possible organocatalysis. Therefore we started studying the feasibility of the reaction at lower temperature using DABCO as base. As shown in Table 6 the reaction run at room temperature doesn't afford the desired product (Table 6 entry 2), neither when it is carried out using ultrasound or molecular sieves in order to try to shift the dehydration equilibrium (Table 6 , entry 3 and 4 ).

|  |  | $\begin{gathered} \mathrm{Ph} \\ 34 \mathrm{f} \end{gathered}$ |  |  | Base, <br> conditions, <br> Metal additives <br> 32f |  |  |  |

Table 6: Attempts of synthesis of enantiomerically pure 32 f using organocatalysis

Despite these results, we tried to use quinine as chiral base. When the reaction was
carried out at $80^{\circ} \mathrm{C}$, the product was isolated, racemic, in $10 \%$ yield (Table 6 , entry 5). The reaction at room temperature led to the formation of trace of product that was optically active (Table 6 , entry 6 ). However because the results were not encouraging we used other approaches to obtain the isoxazoline 31f as single enantiomer.

### 2.2.2 Classical Chemical Resolution

Our next approach was to use classical chemical resolution. Through the transformation of the two enantiomers into separable diastereoisomers we could obtain the enantiomerically pure 31f. We tried three different procedures, in order to obtain a mixture of diastereoisomeric salts, amides or esters as shown in Scheme 15. Firstly ester 32f was hydrolysed to the corresponding carboxylic acid ${ }^{66} 47$ and this was treated with $(R)$ - or ( $S$ )-1-phenyl-ethylamine. However the resulted diastereoisomeric salts were not separable by crystallisation under a number of different solvent condition.

Ester 32f was then transformed into a couple of diastereoisomeric esters 48a,b by means of trans-esterification with different chiral alcohols such as L-menthol or (S)-2-methyl-1-butanol. However it was not possible to separate the obtained diastereoisomeric mixtures by chromatography. The same problem was encountered in transforming acid 47, after activation by the Mukaiyama's reagent, into a couple of diastereoisomeric amides 49 by means of a reaction with ( $S$ )-methyl-(1-phenyl-ethyl)amine.

Scheme 15: Attempts of classical chemical resolution of $( \pm)-32 f$

### 2.2.3 Enzimatic Resolution

After these approaches to enantiomers separation, we directed our attention to an enzymatic resolution. This work was conducted in collaboration with Dott.ssa Gandolfi from Dipartimento di Scienze Molecolari Applicate ai Biosistemi that provided us the more suitable microorganisms or enzymes.

To obtain the enantiomerically pure aldehyde 31f it is possible to use two different biocatalytical approaches based on kinetic resolution: the reduction of aldehyde ( $\mathbf{\pm}$ )-31f catalysed by yeasts or the hydrolysis of ester ( $\pm$ )-32f operated by the same microorganisms or isolated hydrolases (Scheme 16)

Scheme 16: Enzimatic startegies for resolution of ( $\pm$ )-32f
In the case of aldehyde reduction, the fifteen yeasts of different species used showed good activity but the alcohol $\mathbf{3 3 f}$ was obtained in racemic mixture.

The hydrolysis of ester ( $\mathbf{\pm}$ )-32f was preliminary screened using different types of microorganism or enzymes known to be able to hydrolyze racemic esters in good selectivity. ${ }^{67}$ All the biocatalysts tested hydrolysed the substrate with a good rate, but only pancreatic porcine lipase (PPL), Pichia etchellsii MIM and Saccaromyces cerevisiae Zeus enantioselectively hydrolysed the ester function of 32f (Table 7). Evaluation of the progress of the reaction showed that the enantiomerically pure ester could only be obtained by driving the reaction over $50 \%$ of molar conversion (Table 7).

| Biocatalyst | e.e. 32f | e.e. 47f | Molar conversion <br> $(\%)$ | $\mathbf{E}^{\text {a }}$ | Time |
| :--- | :---: | :---: | :---: | :---: | :---: |
| PPL | 60 | 75 | 44 | 12 | 30 min |
| PPL | 96 | 52 | 65 | 11 | 45 min |
| Pichia etchellsii MIM | 44 | 47 | 48 | 4.2 | 2 h |
| Pichia etchellsii MIM | 70 | 45 | 61 | 5.3 | 3.5 h |
| Saccharomyces | 23 | 46 | 33 | 3,4 | 4 h |
| Cerevisiae Zeus |  |  |  |  |  |
| Saccharomyces | 92 | 33 | 74 | 5.7 | 24 h |
| cerevisiae Zeus |  |  |  |  |  |

${ }^{\text {a }}$ Conversion and enantioselectivity factor (E) were calculated from the ee of the substrate and the product
Table 7: Screening of biocatalysts for enzymatic hydrolysis of $( \pm)$ - $\mathbf{3 2 f}$

The best results were obtained using PPL, which was also most active at a low concentration $\left(5 \mathrm{gL}^{-1}\right) .{ }^{68}$ In this case it was possible to obtain the enriched unreacted ester (-)-32f with $65 \%$ of molar conversion and $96 \%$ e.e. The absolute configuration of ester (-)-32f was not assigned at this stage, but was determined by means of X-ray analysis of the major adduct obtained after reaction with Schöllkopf's reagent (vide infra) and proved to be ( $5 R$ ). Ester ( - )-32f was then reduced by sodium borohydride ${ }^{65}$ into the alcohol ( - )-33f, and oxidation of the latter with manganese dioxide led to aldehyde (-)-31f (Scheme 14).

The e.e. obtained using PPL was quite surprising, considering that the stereocentre is far from the functionality that is subjected to the action of the enzyme. For this reason we were interested in studying the influence of the substituent in position 5 of isoxazoline. In particular we envisaged to maintain the six member ring and, taking in consideration the commercial availability of alkenes necessary to synthesize the isoxazolines, we prepared the esters 32d and 32e (Figure 22) as previously described (see Scheme 14). In
this way we could evaluate the influence of a non planar ring as ciclohexyl and, through the isoxazoline substituted with pyridine, the influence of an heteroatom in the cycle.

Figure 22: Structure of esters ( $\pm$ )-32d and ( $\pm$ )-32e

Different microorganisms were used in the hydrolysis of esters 32d,e. Some of them proved to be able to hydrolyze the esters with a high reaction rate, even employing a very low concentration of biocatalyst, but unfortunately without any enantioselectivity. The only positive result in term of racemate resolution was obtained using Saccharomyces cerevisiae Zeus. Table 8 and Table 9 show how by using this yeast and stopping the reaction after $50 \%$ of molar conversion, we were able to obtain the esters 32d,e and the corresponding acids 47d,e enantiomerically enriched. The presence of R substituent in position 5 with different geometry and electronic properties than phenyl seems to influence the selectivity. In fact if we consider the $e . e$ of the leftover ester after 24 hours, in the case of $\mathbf{3 2 d}$ and $\mathbf{e}$, this is lower than the one of $\mathbf{3 2 f}$ (see also Table 7). Moreover in the case of ester 32e we observed a very low hydrolysis rate, presumably due to the presence of the heteroatom in the cycle, that may cause a change in the polarity of the molecule making the substrate less accessible to the enzymes.

The enantiomeric excess and molar conversion were determined through chiral HPLC.
After having studied the reaction of hydrolase on esters 33d-f, being again supported by Dott.ssa Gandolfi, we wanted to explore if biocatalysts could selectively oxidize alcohols 33d, $\mathbf{f}$ to the corresponding acids (Scheme 17). In particular we were interested in testing as biocatalyst whole cells of Acetobacter aceti MIM 2000/28 In fact this microorganism, isolated in Dott.ssa Gandolfi's laboratories, showed previously a certain efficiency in the transformation of primary alcohols. ${ }^{69,70}$ Acetobacter aceti oxidizes the
alcohols into the corresponding acids in two steps: in the first one the enzyme alcohol dehydrogenase (ADH) converts the alcohol into the aldehyde (+)- or (-)-31d,f that is subsequently transformed into the corresponding acid by aldehyde dehydrogenase (ALDH) (Scheme 17).

Scheme 17: Enzimatic oxidation of ( $\pm$ )-33d,f

The reactions were carried out in water using Acetobacter aceti grown 48 hours. Table 10 summarizes the results obtained for the oxidation of $\mathbf{3 3 f}$ : the acid $\mathbf{4 7 f}$ was obtained with a very high e.e., while the leftover alcohol is racemic. Because, as previously said, the oxidation proceeds through two steps, we can hypothesize that the stereoselective one is the oxidation of the aldehyde to the acid.

| Entry | e.e. 33f | e.e. 47f | Time |
| :--- | :---: | :---: | :---: |

| 2 | 11 | 98 | 6 h |
| 3 | 17 | 98 | 24 h |
| 4 | 22 | 98 | 72 h |

Table 10: Optimization of enzymatic oxidation of $( \pm)-33 f$
A similar outcome was observed for the alcohol 33d bearing a cyclohexyl in position 5 . Table 11 shows that also in this case the acid $\mathbf{4 7 d}$ is obtained with a good e.e (even if lower than the corresponding 5 -phenyl- $\Delta^{2}$-isoxazoline 47f) while, similarly as before the leftover alcohol is racemic.

| Entry | e.e. 33d | e.e. 47d | Time |

| 3 | 86 | 6 h |  |
|  | 4 | 83 | 24 h |
|  | 2 | 86 | 48 h |

Table 11: Optimization of enzymatic oxidation of $( \pm)$-33d

In both cases it was not possible to isolate the intermediate aldehydes 31d,f and therefore evaluate their e.e. For this reason it was not possible to evaluate the conversion of the reaction. However the HPLC traces run after 72 hours and 48 hours, showed a large amount of leftover alcohol, suggesting that the reaction proceded very slowly. This may be due to the accumulation of the intermediate aldehydes 31d,f, that, even in small amount, are toxic for the microorganism and may cause an inhibition of the enzymatic activity.

### 2.3 Synthesis of 3-Acyl-4,5-dihydroisoxazoles 39a-d

For the synthesis of compounds 39a-d, we envisaged three possible retrosynthetic approaches described in Figure 23.

Figure 23: Retrosynthetic approaches for the synthesis of 39a-d

The synthesis of 39a-d by strategy A was based on the cycloaddition between methyleneciclohexane and different nitro ketones. However these latter compounds are not commercially available and requires a four step synthesis to be obtained. ${ }^{71}$ In the strategy B the key intermediate aldehyde 31c, could undergo reaction with various Grignard, providing the alcohols 50a-d with different R group. Oxidation would give the corresponding ketones. This strategy, however, required 5 steps synthesis. The third possibility (C) envisaged the direct conversion of the ester of the isoxazoline 32c into the ketone via the corresponding Weinreb amide. This strategy was the more appealing because it would allow the synthesis of ketones 39a-d in just two steps.

Our investigations started using strategy C with significant results summarized in Table 12. Initially we thought that converting one pot the isoxazoline 32c, into the corresponding vinyl ketone 39d without isolating Weinreb amide would have been advantageous. For this reason we used an excess (8.3 equivalents) of vinylmagnesium bromide, ${ }^{72}$ which would act to neutralize the HCl salt and to deprotonate the amine
itself, and then act as nucleophile once the intermediate amide as been formed. The desired product 39d was not formed but instead from the complex reaction mixture, $\mathbf{5 1}$ was isolated in $11 \%$ yield. This compound derived from the attack of one molecule of vinyl magnesium bromide on the intermediate vinylketone 39d. In addition, ketone 52 in $26 \%$ yield arising again from the attack of the amine on the highly reactive $\alpha, \beta$ unsaturated ketone (Scheme 18 and Table 12, entry 1).

Scheme 18: Attempted transformation of ester 32c into vinyl ketone 39d
We therefore tried to isolate the Weinreb amide, using methylmagnesium bromide as base. In a first attempt we mixed 3.5 equivalents of Grignard's reagent ${ }^{73}$ with amine and ester 32c. However this procedure led to isolation of the corresponding methyl ketone in $70 \%$ yield (Table 12 entry 2 and Scheme 19). Given this result, we decrease the equivalent of methylmagnesium bromide to 2.35 and inverted the order of the addition. We sought that allowing the formation of the deprotonated amine by mixing the Grignard reagent and $\mathrm{N}, \mathrm{O}$-dimethylhydroxilamine hydrochloride, would have favoured the formation of the amide. In fact we managed to isolate the desired amide $\mathbf{5 3}$ in 49\% yield (Table 12 entry 3).

Scheme 19: Synthesis of Weinreb amide 53

However the subsequent reaction of the amide $\mathbf{5 3}$ with vinylmagnesium bromide led to isolation of ketone $\mathbf{5 2}$ in $92 \%$ yield.

| Entry | Equiv of <br> $\mathbf{C H}_{3} \mathbf{N O C H}_{3} \cdot \mathbf{H C l}$ | $\mathbf{R M g B r}$ (equivalents) | Conditions | Product (\%) |
| :---: | :---: | :--- | :--- | :--- |
| 1 | 1.25 | $\mathrm{CH}_{2}=\mathrm{CHMgBr}$ | $(8.3$ | $-5{ }^{\circ} \mathrm{C}$ for 45 |

Table 12: Results obtained in the synthesis of ketones 39 using strategy $C$

We then turned our attention to strategy B (Scheme 20). As shown in Table 13 the reaction of 32c with various Grignard's reagents occurred with moderate to good yields. In particular when ethylmagnesium bromide and isopropylmagnesium bromide (Table 13 , entry 2 and 3) were used, the Grignard's reagent acted as reducent ${ }^{74}$ on the aldehyde and it was possible to isolate the corresponding primary alcohol 33c, which, in one case, was also the main product. However the two products could be easily separated by column chromatography.

Scheme 20: Synthesis of ketones 39 through strategy B

| Entry | RMgBr | Yield (\%) 50a-d | Yield (\%) 39a-d |
| :---: | :---: | :---: | :---: |
| 1 | $\mathrm{CH}_{3} \mathrm{MgBr}$ | $73 \%$ | $88 \%$ |
| 2 | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{MgBr}$ | $46 \%+19 \% \mathbf{3 3 c}$ | $83 \%$ |
| 3 | $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHMgBr}$ | $25 \%+43 \% \mathbf{3 3 c}$ | $59 \%$ |
| 4 | $\mathrm{CH}_{2}=\mathrm{CHMgBr}$ | $58 \%$ | $53 \%+26 \% \mathbf{5 4}$ |

Table 13: Yields of the reactions shown in Scheme 20

The oxidation was carried out using $\mathrm{MnO}_{2}$ in good to excellent yield. In the reaction of of 39d the yield was not as high compared to the other examples due to the formation of side product 54 (Scheme 21 and Table 13, entry 4).

Scheme 21: Oxidation of 50d

### 2.4 Synthesis of 3-Substituted-5-Acetyl-4,5-dihydroisoxazoles 41 and 42

The racemic 5-acetyl-3-methyl-2-isoxazoline 41 was regioselectively synthesised by means of the 1,3-dipolar cycloaddition of acetonitrile oxide (generated from nitroethane) with methyl vinyl ketone (Scheme 22). ${ }^{54}$

Scheme 22: Synthesis of 41 through 1,3-dipolar cycloaddition

In the case of ketone 42, as the analogous 1,3-cycloaddition between ethyl nitroacetate and methyl vinyl ketone afforded the desired product in very poor yield, it was necessary to find an alternative route. Initially we tried to use the same base catalyzed methodology ${ }^{60}$ described above, between ethyl nitroacetate and methyl vinyl ketone. However the reaction run in presence of DABCO led to the isolation of just the Michael adduct (Scheme 23, pathway a). According to De Sarlo and co-workers, the same reaction carried out in presence of $N$-methyl-morpholine as base and $5 \%$ of $\mathrm{Cu}(\mathrm{OAc})_{2}$, shifted the reaction towards the desired isoxazolines (Scheme 23, pathway b). ${ }^{75}$ However the autors reported also that the little amount of Michael adduct formed during the reaction proved not to be separable from the desired isoxazoline even after several columns.

Scheme 23: Base catalyzed reaction between ethyl nitroacetate and methyl vinyl ketone
For this reason we discarded this route and we decided to follow the same base catalyzed reaction but using the 3-buten-2-ol instead of the corresponding ketone. This reaction afforded the desired mixture of syn/anti (57/43) isoxazolines 55 that was then
transformed into racemic 5-acetyl-isoxazoline $\mathbf{4 2}$ by oxidation of the alcohol function (Scheme 24). ${ }^{76}$

Scheme 24: Synthesis of 42

### 2.5 Synthesis of Enantiomerically Pure 3-Substituted-5-Acetyl-4,5-dihydroisoxazoles 41 and 42

### 2.5.1 Chemical Resolution

Due to the presence of a stereocentre in position 5 of isoxazoline, 41 and $\mathbf{4 2}$ needed to be resolved into their enantiomers, in order to minimize the number of stereoisomers after reaction with Schöllkopf's reagent. We envisaged to convert the racemic ketone 41 into a couple of diastereoisomeric ketals that could have been then separated by chromatography (Scheme 25). Ketone 41 was treated with diethyl L-tartrate but no reaction occurred. The reaction with $(R, R)$-1,2-diphenyl-1,2 ethandiol gave a mixture of starting material and desired ketals 57b and $\mathbf{5 7}^{\mathbf{\prime}} \mathbf{b}$. Unfortunately the diastereoisomers were not separable by column chromatography.

Scheme 25: Chemical resolution of 41 through formation of diastereoisomeric ketals

Another chemical method to resolve 41 was attempted using the enantioselective CBS (Corey-Bakshy-Shibata) reduction of ketones. ${ }^{77,78}$ This would give anti-56 and syn-56, which, after chromatographic separation, would have been oxidised into the corresponding enantiomerically pure ketones. However the treatment of $\mathbf{4 1}$ with 10 mol \% of (S)-(-)-o-tolyl-CBS-oxazaborolidine and 1.8 equivalent of $\mathrm{BH}_{3} \cdot \mathrm{THF}$ led to a mixture of the racemic alcohols syn and anti-56 (Scheme 26).

Scheme 26: Attempted enantioselective reduction of 41

### 2.5.2 Enzimatic Resolution

Because of the lack of success using chemical approaches, once again we shifted our attention to the enzymatic resolution. Ticozzi ${ }^{79}$ in 1988 reported an enzymatic reduction of 41 and 42 into the corresponding alcohols, though he did not report either the $\alpha_{D}$ or the enantiomeric excess of the products. Therefore, following their procedure, racemic isoxazolines 41 and 42 were treated with commercial baker's yeast at $35{ }^{\circ} \mathrm{C}$, in phosphate buffer, $\mathrm{pH} 5.5-6.0$, in the presence of glucose. After continuous extraction of the aqueous solution with dichloromethane, 1:1 mixtures of the corresponding syn/anti diastereoisomeric alcohols $\mathbf{5 5}$ and $\mathbf{5 6}$ were obtained in $\mathbf{6 6 - 7 8 \%}$ yield (Scheme 27). ${ }^{76}$

Scheme 27: Enzymatic resolution of ( $\pm$ )-41 and ( $\pm$ )-42 using baker's yeast
The two synlanti alcohols $\mathbf{5 5}$ were separated by means of flash chromatography on silica gel, whereas the two syn/anti alcohols 56 required flash chromatography and a semi-preparative HPLC separation. Ticozzi reported that, if the reduction of the analogous isoxazoline $\mathbf{5 8}$ was performed in a mixture of 2-propanol/water, the kinetics and the stereoselectivity of the reaction was strongly dependent on the alcohol/water
ratio. ${ }^{80}$ In particular when the reduction of $\mathbf{5 8}$ was performed using a ratio of 2 propanol/water of 4/1, it was possible to obtain the enantiomerically pure syn alcohol 59 and the enantiomerically pure leftover ketone 58 (Scheme 28).

Scheme 28: Kinetic enzymatic resolution proposed by Ticozzi ${ }^{80}$
Based on these results and in order to avoid the laborious purification of syn/anti 56, we studied the enzymatic reduction of $\mathbf{4 1}$ using different ratio of 2-propanol /water. It was found that depending on the 2-propanol:water ratio used with our substrate, the reactions led either to the unreacted ketone or the completely reduced alcohol (Table 14). However also Bhaduri and co-workers reported that reduction of 5-acetyl-3-phenylisoxazoline 58 performed in different 2-propanol/water ratio led to recovery of unreacted starting material.$^{81}$

| Entry | $\mathbf{H}_{2} \mathbf{O}$ | $\boldsymbol{i} \mathbf{P r O H}$ | 41 recovered | $\mathbf{5 6}$ |

| 2 | 1 | 4 | 100 | 0 |
| 3 | 1 | 5 | 100 | 0 |
| 4 | 1 | 6 | 100 | 0 |
| 5 | 3 | 1 | 100 | 0 |
| 6 | 4 | 1 | 100 | 0 |
| 7 | 5 | 1 | 0 | 100 |

Table 14: Study of the kinetic enzymatic resolution of $( \pm)-41$ using different $\mathrm{H}_{2} \mathrm{O} / \mathrm{PrOH}$ ratio
The relative syn/anti configuration of compounds $\mathbf{5 5}$ and $\mathbf{5 6}$ was assigned using ${ }^{1} \mathrm{H}$ NMR spectra from the value of the coupling constant between H-5 and H-1 ( $J=5.2-5.7$ for syn-55 and $\mathbf{5 6}$ and $3.3-3.2 \mathrm{~Hz}$ for anti-55 and 56). The enantiomeric excess of each alcohol was determined by HPLC to be $>98 \%$. Absolute configurations were not assigned at this stage, but were determined by means of an X-ray analysis of the adducts
obtained in the following reaction with Schöllkopf's reagent (vide infra), which allowed the assignment of configuration $(1 S, 5 S)$ to alcohols syn-55, $\mathbf{5 6}$ and $(1 S, 5 R)$ to anti-55, 56. Finally, oxidation of the syn and anti alcohols 55 and 56 with $\mathrm{PCC} / \mathrm{Al}_{2} \mathrm{O}_{3}$ respectively led to (5S)- and (5R)- 42 and 41 (Scheme 27). The enantiomeric excess of the final ketones $\mathbf{4 2}$ and $\mathbf{4 1}$ was confirmed to be respectively > 98\% and $92 \%$.

### 2.6 Study of the Reaction with Schöllkopf's Reagent

### 2.6.1 Addition of Schollköpf's Reagent Anion to (R)-5-Phenyl-4,5-dihydroisoxazole-3-carbaldehyde ( $R$ )-31f

As previously said, after having studied the reaction between Schöllkopf's reagent and 5,5-disubstituted-4,5-dihydroisoxazole-3-carbaldehydes (Scheme 6), ${ }^{59}$ we decided to extend this protocol to aldehyde $(\boldsymbol{R})$-31f. ${ }^{68}$

In accordance with the general procedure, a solution of aldehyde $(\boldsymbol{R})$-31f was added to Schöllkopf's anion (R)-23 generated by $n \mathrm{BuLi}$ in THF at $-78^{\circ} \mathrm{C}$. To evaluate the influence of the counter-ion on diastereoselectivity, the reaction was also performed in a parallel experiment in which the lithium azaenolate $(\boldsymbol{R}) \mathbf{- 2 3}$ was treated with triisopropoxytitanium (IV) chloride ${ }^{82}$ to give the corresponding titanium azaenolate ( $\boldsymbol{R}$ )23' before the addition of aldehyde ( $\boldsymbol{R}$ )-31f. ${ }^{1} \mathrm{H}-\mathrm{NMR}$ of the crude showed the presence of a mixture of diastereoisomers $\mathbf{6 0 - 6 3}$, whose ratio was determined by means of HPLC analysis ( Table 15).

(R)-22
(R)-23

| Counterion | Total | Diastereomer Ratios |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Yield | $\mathbf{6 0}$ | $\mathbf{6 1}$ | $\mathbf{6 2}$ | $\mathbf{6 3}$ | $\mathbf{6 0 + 6 2 /}$ | $\mathbf{6 0 / 6 2}$ |
|  | $(\%)$ | $\left(2 \mathrm{~S}, 1^{\prime} \mathrm{S}\right)$ | $\left(2 \mathrm{R}, 1^{\prime} \mathrm{R}\right)$ | $\left(2 \mathrm{~S}, 1^{\prime} \mathrm{R}\right)$ | $\left(2 \mathrm{R}, 1^{\prime} \mathrm{S}\right)$ | $\mathbf{6 1 + 6 3}$ |  |
| $\mathbf{L i}$ | 60 | 56.8 | 21.9 | 19.5 | 1.8 | $3 / 1$ | $3 / 1$ |
| $\mathbf{T i}$ | 60 | 76.8 | 4.5 | 18.7 | 0.0 | $21 / 1$ | $4 / 1$ |

Table 15: Optimization of the reaction between Schöllkopf's reagent and aldehyde (R)-31f

When the reaction temperature was raised to $-20^{\circ} \mathrm{C}$, the yield of the adducts $60-63$ was lower and compound $64^{83}$ was isolated in $20 \%$ yield (Figure 24). Therefore we hypothesised that, similarly to the reported decarboxylative ring-opening reaction of 3carboxyisoxazolines, ${ }^{56}$ the anion of the alcohol evolves and a fragmentation, via ringopening of the isoxazoline ring, takes place as shown in Figure 24.

Figure 24: Formation of side product 64

The structures $\mathbf{6 0 - 6 3}$ were assigned by NMR. The ( $2 S$ )-configuration of compounds $\mathbf{6 0}$ and 62 was established using the ${ }^{5} J_{\mathrm{H}-2 / \mathrm{H}-5}$ coupling constant whose value of 3.6 Hz , corresponds to a trans relationship between the $2-\mathrm{H}$ and $5-\mathrm{H}$ protons of the pyrazine ring. ${ }^{84,85}$ The absolute configuration of the major adduct $\mathbf{6 0}$ was determined through X-
ray crystallographic analysis (Figure 25). This allowed the assignment of ( $R$ ) configuration to $\mathrm{C}-5$ of isoxazoline ring and therefore the configurations of compounds 32f, 33f, 31f by analogy. The X-ray analysis assigned also the $(S)$ configuration to both $1^{\prime}-\mathrm{C}$ and $\mathrm{C}-2$ of pyrazine ring. As a consequence, the $(R)$ configuration was assigned to the $1^{\prime}-\mathrm{C}$ of the epimer 62.

Figure 25: X-ray of 60
On the contrary, the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra of diastereoisomers 61 and 63 showed a ${ }^{5} \mathrm{~J}_{\mathrm{H}-2 / \mathrm{H}-5}$ coupling constant value of 5.6 Hz , which corresponds to a cis relationship between the H-2 and H-5 protons of the pyrazine ring. The cis relationship was also confirmed by a positive NOE effect between the two protons. The $\left(1^{\prime} R\right)$ and $\left(1^{\prime} S\right)$ configurations were respectively assigned to diastereoisomers 61 and 63 taking into account the accepted model for the aldol-type addition of Schöllkopf's enolate to aldehydes, ${ }^{44}$ which has also been extensively confirmed in our previous studies. ${ }^{49,59}$ On the strength of this model, the azaenolate-pyrazine attacks the aldehyde by means of a more favourable transition state in which the aldehyde substituent is far from the methoxy group and the metal atom (Figure 26a). According to this model, the more cumbersome substituent of the aldehyde (the isoxazoline ring) occupies the equatorial position in a six member ring chair like transition state. This led to a predominance of the adduct ( $\mathbf{1}, \boldsymbol{S}) \mathbf{- 6 0}$ when the attack takes place from the opposite side of the isopropyl group (Figure 26a). On the contrary, when the attack takes place from the same side as the isopropyl group, the most favourable transition state leads to compound ( $\mathbf{1}^{\boldsymbol{\prime}} \boldsymbol{R}$ )-61 (Figure 26b). This is the
first time we have observed the formation of products arising from an attack of the aldehyde from the more hindered side of the azaenolate (adducts 61 and 63). ${ }^{44,53}$ The formation of adduct $\mathbf{6 1}$ in a comparable amount to $\mathbf{6 2}$ when Li is used as counterion (see Table 15) may be explained taking in consideration the two transition states. As shown in Figure 26c the transition state that leads to the formation of product $\mathbf{6 2}$ is more encumbered than the one that leads to $\mathbf{6 1}$ (Figure 26b), because of the phenyl pointing toward the pyrazine ring. We hypothesized the two transition states having comparable energy, leading to the formation of the two adducts in the similar amount

60

61

62

Figure 26: Transition states for the formation of adducts $\mathbf{6 0 , 6 1}$ and 62

As shown in Table 15 the diastereoisomeric ratio increases when titanium is used as counterion. It is thought that titanium promotes a tight transition state ${ }^{84}$ and so the reaction proceeds more selectively than the one using lithium. As shown in Table 15, diastereofacial selectivity with respect to the pyrazine anion is enhanced $(\Sigma(2 S): \Sigma(2 R)=$ $21: 1 \mathrm{vs} 3: 1$ ) as is the facial preference of the carbonyl addition, albeit in a less marked manner (ratios $\left(1^{\prime} S\right):\left(1^{\prime} R\right)=4: 1$ vs $\left.3: 1\right)$.

An involvement of the isoxazoline ring in the complex intermediate can be expected especially when $\mathrm{TiCl}(\mathrm{OiPr})_{3}$ is used. ${ }^{86,}{ }^{87}$ However, in this case, the additional coordination of the titanium atom with the isoxazoline nitrogen should involve a less stable $s$-cis $\mathrm{O}=\mathrm{C}-\mathrm{C}=\mathrm{N}$ conformation of the aldehyde, as well as a more encumbered transition state with the isoxazoline arrangement on the same side as the methoxy group. If a coordination would have taken place, the yield of $\mathbf{6 2}$ would have risen when
titanium was used as counterion. However the amount of product $\mathbf{6 2}$ was practically the same with the two counterions (Table 15), suggesting that the potential metalisoxazolidine coordination had a poor effect.

### 2.6.2 Hydrolysis of Adducts 60 and 61 and Isoxazoline Cleavage of 66

Adducts 60 and 61 were hydrolysed under controlled conditions, leading to the formation $\beta$-substituted serine methyl esters 65, 66 and the dipeptides 66, 68 (Scheme 29). These dipeptides, formed by a partially hydrolysis of pyrazine ring, were isolated in variable amounts during hydrolysis reaction, independent of the conditions used. ${ }^{59}$ However they were separated by means of column chromatography and their structure was assigned using ${ }^{1} \mathrm{H}$-NMR analysis. ${ }^{59,} 62,63$

Scheme 29: Hydrolysis of adducts 60 and 61

Finally, the hydrogenolysis-hydrolysis of the 4,5-dihydroisoxazole ring of dipeptide $\mathbf{6 6}$ using three equivalents of $\mathrm{B}(\mathrm{OH})_{3}$ in a mixture $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$, with $\mathrm{H}_{2}$ and Raney-Ni as catalyst, ${ }^{57}$ led to the corresponding $\beta, \varepsilon$-dihydroxy- $\gamma$-oxo $\alpha$-amino acid derivative 69 in good yield (Scheme 30). This $\alpha$-amino acid derivative, like the $\varepsilon, \varepsilon$-disubstituted derivatives previously obtained by us, has a highly functionalised structure with a further stereocentre that makes it extremely attractive as a potential peptidomimetic.

Scheme 30: Synthesis of polifunctionalized dipeptide 69

### 2.6.3 Addition of Schollköpf's Reagent Anion to 3-Acyl-4,5dihydroisoxazole

With the aim of obtaining new $\beta$-hydroxy- $\alpha$-amino acids, $\beta$-substituted with a 2 isoxazoline ring that is potentially susceptible to further transformation, and containing an asymmetric, enantiomerically pure quaternary carbon in the $\beta$ position, we extended the protocol previously studied for aldehydes, to ketones. One of the most interesting goals of organic synthesis is the asymmetric synthesis of quaternary carbon centres, and one of the most useful means of achieving it is the asymmetric addition of nucleophiles on ketones. ${ }^{88-90}$ In particular, the aldol reaction between a glycine equivalent and prochiral ketones provides access to $\beta, \beta$-disubstituted- $\beta$-hydroxy- $\alpha$-amino acids, which are of considerable interest in the synthesis of peptidomimetics because of their sterically constrained structure. ${ }^{91}$ There are very few published examples of the reaction between Schöllkopf's reagent and prochiral ketones, most of which have involved acetophenone, chloroacetone and chloroacetophenone (Scheme 31). ${ }^{92-96}$ In all cases there is a completely stereocontrol in the formation of the stereocentre at C-2. Moreover when the ketone has two very different size substituents, a good syn/anti ratio can be achieved, as in the case of products 70/71 and 72b/73b.

Scheme 31: Literature examples of reaction between Schöllkopf's reagent and ketones
We decided to start our studies using 3-acyl-4,5 dihydroisoxazole 39a-d 5,5disubstituted with two identical group, in order to avoid the presence of a stereocentre that would have doubled the number of diastereomers after reaction with the

Schöllkopf's reagent. Therefore compounds 39a-d were synthesised as previously described. We envisaged that having ketones substituted with different $R$ groups (eg. methyl, ethyl, isopropyl), would give us the possibility of studying the influence of the steric encumbrance on diastereoselectivity. The vinyl ketone 39d was chosen to allow the synthesis of the pharmacologically interesting vinyl amino acids. Moreover this substrate gave us the possibility of studying the behaviour of Schollkopf's reagent in the presence of two electrophilic carbons.

Following the general procedure, a solution of ketone 39a-d was added to the anion of the bislactim ether $(\boldsymbol{R}) \mathbf{- 2 3}$ generated by $n \mathrm{BuLi}$ in THF at $-78^{\circ} \mathrm{C}$.

Table 16: Reaction between Schöllkopf's reagent and 3-acyl-4,5-dihydroisoxazole 39a-c

As shown in Table 16, the reaction occurred in good yield in the case of ketone 39a and in lower yield for compound 39b. In both cases ${ }^{1} \mathrm{H}-\mathrm{NMR}$ analysis of the crude material revealed the presence of two diastereoisomers in 1:1 ratio. However there was not reaction with ketone 39c. In this case the reaction didn't occur presumably due to the large steric hindrance given by the isopropyl group.

The products 74a/75a and 74b/75b were separated through a chromatographic column and their structures were confirmed by NMR analysis. Through ${ }^{1} \mathrm{H}-\mathrm{NMR}$ analysis it was possible to assign the $S$ configuration to $\mathrm{C}-2$ of pyrazine. In fact for all the adducts the ${ }^{5} J_{\mathrm{H}-2 / \mathrm{H}-5}$ coupling constant had a value of 3.5 Hz , that corresponded to a trans relationship between the $2-\mathrm{H}$ and $5-\mathrm{H}$ protons of the pyrazine ring. ${ }^{84,85}$ The Schöllkopf reagent attacks the carbonyl group exclusively from the opposite side of the isopropyl group, however without any stereocontrol of the newly formed tertiary alcohol. Ongoing X-ray analysis will allow to determine the absolute configuration also at C-1'.

In order to improve the diastereoselectivity, we studied the reaction between ketone 39a and Schöllkopf's azaenolate with counterions other than lithium. Because in the reactions with aldehydes we observed an increased d.r. when titanium was used as the counterion, ${ }^{48,50}$ we thought this metal might be suitable also in this case. However, as shown in Table 16, the reaction run with $\mathrm{TiCl}(i \mathrm{PrO})_{3}$ led to the recovery of unreacted starting material. The same result was obtained when tin was used as counterion. The lack of reactivity in the reaction with titanium, is presumably due to a too hindered transition state occurring when this metal is used. ${ }^{44}$

The reaction of the vinylketone 39d led to the formation of inseparable diastereoisomers 74d and 75d in a $1: 1$ ratio and in $29 \%$ yield. Together with these two expected adducts, ketone 76 derived from the 1,4 addition of Schöllkopf's anion to $\alpha, \beta$-unsaturated ketone, was isolated in $47 \%$ yield (Scheme 32).

Scheme 32: Reaction between Schöllkopf's reagent and vinyl ketone 39d
${ }^{1}$ H-NMR analysis showed that attack of Schöllkopf's anion to the carbonyl group of 39d occurred only trans to isopropyl group, leading again to the formation of adducts with $S$ configuration at C-2 of pyrazine. Similarly, exclusive trans attack occurred in the case of 1,4 addition with product 76 having a ${ }^{5} J_{\mathrm{H}-2 / \mathrm{H}-5}$ coupling constant of 3.5 Hz , confirming a trans relation between the two protons. The only other reported example of a similar 1,4 addition is the reaction of Schöllkopf's azaenolate with nitroethylene, described by Schöllkopf himself. ${ }^{84}$ However in this case both diastereoisomers 77 and 78 were isolated in a ratio of $65: 35$, showing that the attack of the anion on the double bond occurred from both sides of the isopropyl group (Scheme 33).

Scheme 33: 1,4-addition of Schöllkopf's reagent to nitroethylene
Finally the two adducts $\mathbf{7 4 a}$ and $\mathbf{7 5 a}$ were separately hydrolyzed with 0.2 N HCl in THF providing the corresponding amino esters $\mathbf{7 9}, \mathbf{8 0}$ in moderate yield (Scheme 34).

Scheme 34: Hydrolysis of adducts 74a and 75a

### 2.6.4 Addition of Schöllkopf's Reagent Anion to 5-Acetyl-4,5dihydroisoxazoles

After we found that the reaction between prochiral ketone 39a-d and Schöllkopf's reagent occurred without any stereocontrol of the newly formed tertiary alcohol, we were interested in studying the influence of a stereocenter $\alpha$ to the ketone on diastereoselectivity. ${ }^{76}$ Therefore the keto group was moved from position 3 to position 5 of 2-isoxazolines and the two enantiomerically pure 5-acetyl-4,5-dihydroisoxazoles $(5 R)$ - and (5S)-41 and (5R)- and (5S)-42 were synthesized as previously described (Scheme 27). The methyl ketone is chosen to minimise the steric hindrance around the carbonyl group. We select the 3-methyl and 3-carbethoxy derivatives because the resolution of their corresponding racemate was approximately described as previously mentioned. ${ }^{79}$ Moreover the carbethoxy group, in addition to introducing another important functional group, allow us to consider the possible competition between the two carbonyl groups in the reaction with Schöllkopf's reagent.

Various experimental conditions were examined to optimise yields and evaluate the diastereoselectivity of the addition reaction. Under the best conditions, a THF solution of ketone 41 was added to the anion of the bislactim ether ( $\boldsymbol{R}$ )-23 at $-78{ }^{\circ} \mathrm{C}$, and maintained at this temperature for four hours. It was found that longer times or higher temperatures led to lower yields due to the reversibility of the addition, as previously observed by ourselves and by Hayashi. ${ }^{68,97}$ With the ( $5 S$ )- or ( $5 R$ )-3-methyl derivatives 41, the reaction gave mixtures of two diastereoisomeric adducts $\mathbf{8 1 / 8 2}$ or $\mathbf{8 3 / 8 4}$ in ratios of respectively $76: 24$ and $69: 31$, as determined by integrating the doublet of the isopropyl groups in the ${ }^{1} \mathrm{H}$-NMR spectra of the crude reaction mixtures (Scheme 35 and Table 17).

Table 17: Optimization of the reaction between Schöllkopf's reagent and (S)- or (R)-41

To evaluate the influence of the counter-ion on diastereoselectivity, the lithium azaenolate ( $\boldsymbol{R}$ )-23 was treated with triisopropoxytitanium (IV) chloride ${ }^{82}$ to give the corresponding titanium azaenolate before the addition of $\boldsymbol{( S )}$ ) $\mathbf{4 1}$ (Table 17, entry 2 ). However a mixture of adducts $\mathbf{8 1 / 8 2}$ was obtained only in trace amounts. In another experiment in order to make the carbonile more reactive, titanium (IV) chloride was added to a THF solution of ketone ( $\mathbf{S}$ ) $\mathbf{- 4 1}$ before it was added to the anion of the bislactim ether (Table 17, entry 3). Compounds $\mathbf{8 1 / 8 2}$ were obtained with better diastereoselectivity (87:13) but a lower yield (48\%).

A different result was obtained using the $(S)$ - and $(R)$ - ketone 42 (Scheme 36). In this case, under the best experimental conditions, the reaction led to a mixture of
unidentified compounds and varying amounts ( $20-40 \%$ ) of unreacted ketone 42. The ${ }^{1} \mathrm{H}$-NMR spectra of this mixture indicated the presence of a pair of adducts $\mathbf{8 5}$, but only in trace amounts. This different behaviour may have been due to competition between different electrophilic carbons, such as the ketone and the carbethoxy group, despite this latter should be less reactive than the ketone group.

Scheme 36 Reaction between Schöllkopf's reagent and (S)- or (R)-42

Diastereoisomers $\mathbf{8 1 / 8 2}$ and $\mathbf{8 3} / \mathbf{8 4}$ were purified by means of flash chromatography on silica gel, and their structures were confirmed on the basis of mono and bi-dimensional ${ }^{1} \mathrm{H}$-NMR and X-ray analysis. The configuration at C-2 of pyrazine of compounds 82-84 was established being $S$ using the ${ }^{5} \mathrm{JH}_{2} / \mathrm{H}_{5}$ which was $3.5-4.0 \mathrm{~Hz} .{ }^{84,85}$ Adducts $\mathbf{8 1}$ and $\mathbf{8 2}$ were obtained as crystalline solids and underwent X-ray crystallographic analysis, which made possible to assign the configuration at $\mathrm{C}-1$ ' and at $\mathrm{C}-5$ " of both products and the configuration at $\mathrm{C}-2$ of $\mathbf{8 1}$, which could not be determined through ${ }^{1} \mathrm{H}-\mathrm{NMR}$ analysis. As shown in Figure 27, the $S$ configuration was assigned at C-5" and C-2 of both 81 and 82. The configuration at C-1' was found to be $R$ for $\mathbf{8 1}$ (Figure 27a) and $S$ for 82 (Figure 27b), showing that the two diastereoisomers are epimer at C-1'.

QA006
$\overline{\bar{~}}$

QA007

b)

Figure 27: X-ray of adducts 81 and 82
By analogy, we assigned the same $(S)$ configuration to compound (+)-41 and the $(R)$ configuration to (-)-41 (Figure 28).

Figure 28: Absolute configurations of ( - )-41 and (+)-41
Compounds $\mathbf{8 3}$ and $\mathbf{8 4}$ couldn't be obtained as suitable crystals for X-ray analysis, and so their absolute configurations at $\mathrm{C}-1$ ' were assigned by means of exhaustive ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra and NOESY experiments.

The NOESY spectra of the major diastereoisomer $\mathbf{8 3}$ (Figure 29) shows positive effects between $\mathrm{H}-2$ and $1^{\prime}-\mathrm{CH}_{3}$, between isoxazolin $\mathrm{H}-5$ and $1^{\prime}-\mathrm{CH}_{3}$, and between the $\mathrm{H}-2$ and one of the $\mathrm{H}-4$ protons. This last effect suggests an $(S)$ configuration at C-1' because, as shown by the Dreiding's ${ }^{98}$ molecular models, these positive effects can't all be observed at the same time with the opposite $(R)$ configuration at $\mathrm{C}-1$ '.

Figure 29: NOESY spectrum of 83
The NOESY spectra of the minor diastereoisomer 84 (Figure 30), shows positive effects between $\mathrm{H}-2$ and $1^{\prime}-\mathrm{CH}_{3}$, and between isoxazolinic $\mathrm{H}-5$ and 1 ' $-\mathrm{CH}_{3}$ but, instead of the positive effect between the $\mathrm{H}-2$ and $\mathrm{H}-4$ proton as in the case of $\mathbf{8 3}$, there is a positive effect between the $\mathrm{H}-4$ protons and the 1 ' $-\mathrm{CH}_{3}$, thus confirming a $(R)$ configuration for 1 '-C.

Figure 30: NOESY spectrum of 84

### 2.6.5 Models of the Addition of Schöllkopf's Reagent Anion to Ketones (5S)- and (5R)-41

As previously mentioned, there are just few reported examples of the reaction between Schöllkopf's reagent and ketones and none using prochiral ketones containing stereocenters. The reactions of Schöllkopf's reagent with chiral ketone 41 raises the question of "double asymmetric induction". The use of the enantiomeric forms of ketone $\mathbf{4 1}$ led to both matched $((\boldsymbol{R})-\mathbf{2 2}$ and $(\boldsymbol{S})-41)$ and mismatched $((\boldsymbol{R})-\mathbf{2 2}$ and $(\boldsymbol{R})-41)$ situations (Scheme 37), allowing us to evaluate the relative influence of both the
carbonyl $\alpha$-stereocentre (substrate control) and the azaenolate-pyrazine (reagent control) on reaction stereoselectivity.

Scheme 37: Matched and mismatched cases for reaction between Schöllkopf's reagent and (S)-41/(R)-41

The reaction between $(\boldsymbol{R})-\mathbf{2 2}$ and the ketone $(\boldsymbol{S}) \mathbf{- 4 1}$ was more diastereoselective than the reaction with the ketone $(\boldsymbol{R}) \mathbf{- 4 1}$, with the ratio of adducts $\mathbf{8 1 / 8 2}$ being 3.2:1 versus 2.2:1 for $\mathbf{8 3 / 8 4}$ (Scheme 37). This result was for us quite surprising, because, considering the transition states, we would have presumed a better d.r. for the reaction between ( $\boldsymbol{R})$-22 and $(\boldsymbol{R})-\mathbf{4 1}$.

Figure 31: Transition state for reaction between Schöllkopf's reagent and ( $\boldsymbol{R}$ )-41

In the reaction between $(\boldsymbol{R}) \mathbf{- 2 2}$ and $(\boldsymbol{R}) \mathbf{- 4 1}$, we proposed the major diastereoisomer $\mathbf{8 3}$ was derived from the preferential attack of the nucleophile from the favoured Si face of ketone ( $\boldsymbol{R}$ )-41 which is favoured in both the Felkin-Anh ${ }^{99,100}$ and Cornforth ${ }^{101}$ models. This situation allowed the less cumbersome methyl group to be in a pseudoaxial position, in agreement with Schöllkopf ${ }^{44}$ and Zimmerman- Traxler ${ }^{102}$ models (Figure 31, transition state $\mathbf{A}$ and $\mathbf{B}$ ). Therefore, in this case, the favoured diastereoisomer $\mathbf{8 3}$ was a result of a positive combination of both substrate and reagent control. However, this favourable situation may be diminished by a negative steric effect between the 2 isoxazoline ring and the pyrazine 3-methoxy group (Figure 31, transition state A), which could give rise to the moderate diastereomeric ratio.

We proposed that in the reaction between $(\boldsymbol{S}) \mathbf{- 4 1}$ and $(\boldsymbol{R})$-22, the major diastereoisomer 81 was derived from the attack of the nucleophile from the $R e$ face, favoured in both the Felkin-Anh and Cornforth models. However this approach places the more hindered isoxazoline ring in a pseudoaxial position, which is opposite to that normally observed in reactions using Schöllkopf's reagent ${ }^{44,49}$ (Figure 32, transition states $\mathbf{E}$ and $\mathbf{F}$ ). However, in the Cornforth-like transition state $\mathbf{F}$, the unfavourable steric interaction between the pyrazine 6 -methoxy and the 2 -isoxazolinic ring can be minimised by making this the preferred conformation. The attack from the Si face, which puts the more cumbersome isoxazoline ring in a pseudoequatorial position (Figure 32, transition states $\mathbf{G}$ and $\mathbf{H}$ ), suffers from steric repulsions between the nucleophile and the 2 isoxazoline ring. This negative interaction suggested that the transitions states $\mathbf{E}$ and $\mathbf{F}$ were favoured over $\mathbf{G}$ and $\mathbf{H}$, thus explaining the preferential formation of adduct $\mathbf{8 1}$ over 82. In conclusion, the diastereoselectivity of this mismatched case was presumably influenced to a greater effect by the chiral ketone than the Schöllkopf's reagent as the reaction with the ketone ( $\boldsymbol{S}$ )-41 leads to the "substrate control" adduct $\mathbf{8 1}$ as the major diastereomer.

Figure 32: Transition state for reaction between Schöllkopf's reagent and (S)-41

### 2.6.6 Hydrolysis of Adducts 81-83

Adducts 81-83 were hydrolysed under mild conditions to give $\beta$-substituted Lthreonines methyl esters 86-88 and the dipeptides 89-91 (Scheme 38). Amino esters 86$\mathbf{8 8}$ were easily separated from their corresponding dipeptides $\mathbf{8 9 - 9 1}$ by means of column chromatography and their structure was assigned using ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}-\mathrm{NMR}$ analysis. ${ }^{59,}$ 62, 63

Scheme 38: Hydrolysis of adducts 81-83

### 2.7 Study of the Cleavage of 2-Isoxazoline Ring

In order to obtain polyfunctionalyzed $\beta$-hydroxy- $\alpha$-amino acids, we planned to cleave the isoxazoline ring of $\mathbf{8 8}$. Initially Ni-catalyzed hydrogenolysis, that we previously used, ${ }^{59,}{ }^{68}$ run in hydrolytic conditions (a methodology developed by Curran), ${ }^{64}$ led to a mixture of undefined products (Scheme 39).

Scheme 39: Isoxazoline ring opening using Curran conditions

This result prompted us to study the cleavage on more simple substrates. Although the opening of 2-isoxazolines has been extensively studied, ${ }^{103}$ this reaction remains still quite substrate-dependent. As a test substrate we chose the isoxazoline 32f. Therefore this compound was subjected to different set of reaction conditions as summarized in Table 18.

| Entry | Conditions | Result |
| :---: | :---: | :---: |
| 1 | $\mathrm{H}_{2} / \mathrm{Ni}$-Raney, $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O} 5 / 1, \mathrm{~B}(\mathrm{OH})_{3}$ | Complex mixture |
| 2 | $\mathrm{NiSO}_{4}(1 \mathrm{eq}) / \mathrm{NaBH}_{4}(4.5 \mathrm{eq})$ | Complex mixture |
| 3 | $\mathrm{NiCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ (3eq), $\mathrm{NaBH}_{4}$ (10eq), $\quad \mathrm{Boc}_{2} \mathrm{O}$ (3eq), MeOH/THF 3/1 | Complex mixture |
| 4 | DIBALH (3.3.eq), THF, $-78{ }^{\circ} \mathrm{C} \rightarrow 60^{\circ} \mathrm{C}$ | Mixture of $\mathbf{3 3 f}$ and 31f |
| 5 | $\mathrm{Mo}(\mathrm{CO})_{6}(1 \mathrm{eq}), \mathrm{CH}_{3} \mathrm{CN} / \mathrm{H}_{2} \mathrm{O}$, reflux | Decomposition |
| 6 | PMHS (4 eq), $\mathrm{Boc}_{2} \mathrm{O}$ (1.1 eq), $\mathrm{Pd}(\mathrm{OH})$ (cat 2\%), EtOH, reflux | Complex mixture |
| 7 | $\mathrm{H}_{2} / \mathrm{Ni}$-Raney, AcOEt | 94+95 ( $\sim 10 \%$ ) |
| 8 | $\mathrm{H}_{2} / \mathrm{Ni}$-Raney, $\mathrm{AcOEt}, \mathrm{Boc}_{2} \mathrm{O}$ (1.1 eq) | Starting material recovered |

Table 18: Attempted cleavage of isoxazoline ring
Initially, we tested again the conditions developed by Curran, ${ }^{64}$ that lead to $\beta$-hydroxyketone. However, also in this case we isolated a mixture of undefined products (Table 18, entry 1). We therefore thought to change the reductant system, using a nickel salt/borohydride system. Using the conditions previously reported by Lakhvich, ${ }^{104}$ we again isolated a mixture of undefined products (Table 18, entry 2). By carrying out the same reaction in the presence of $\mathrm{Boc}_{2} \mathrm{O}$ anhydride (Table 18, entry 3) ${ }^{105}$ we thought that protection of the newly formed alcohol and amine might prevent subsequent reaction of polymerisation with the ester functionality. Unfortunately also in this case, although the thorough analysis carried out, we were not able to identify any useful product in the reaction mixture.

Scott and co-workers in 2006 reported a very simple method for the cleavage of the N O bond of isoxazolines. ${ }^{106}$ They found that DIBALH could reduce the C-N bond and cleave the $\mathrm{N}-\mathrm{O}$ one, leading to amino alcohol in high yield and high diastereoselectivity. However when isoxazoline $\mathbf{3 2 f}$ was subjected to the same conditions, a mixture of aldehyde 31f and alcohol 33f was formed from reduction of ester (Scheme 40 and Table 18 , entry 4).

Scheme 40: Cleavage of isoxazoline ring using DIBALH

Another reagent widely used and studied for the cleavage of 2-isoxazoline is $\mathrm{Mo}(\mathrm{CO})_{6}{ }^{107,}{ }^{108}$ Treatment of our substrate with $\mathrm{Mo}(\mathrm{CO})_{6}$ in acetonitrile led to decomposition of the starting material (Table 18, entry 5). Kobayashi ${ }^{109}$ and co-workers reported some difficulties in the cleavage of 5-phenyl- $\Delta^{2}$-isoxazolines as well. In fact they only obtained the dehydrated product 93 and the benzaldehyde (Scheme 41).

Scheme 41: Kobayashi's cleavage of isoxazoline ring with $\mathrm{Mo}(\mathrm{CO})_{6}$

A more recent method used $\mathrm{Pd}(\mathrm{OH})_{2}$ as catalyst and the polimer polymethylhydrosiloxane (PMHS) as the reductant. ${ }^{110}$ This methodology is used also in presence of Boc anhydride to protect the newly formed amine. However, when reacting ester 32 f under these conditions, complex mixture was obtained (Table 18, entry 6).

Finally we decided to go back to the Ni-catalyzed hydrogenolysis but run in anhydrous conditions. The reaction afforded a mixture of the two expected syn and anti amino alcohols 94 together with the two cyclic products $\mathbf{9 5}$ deriving from the lactonization between the alcohol and the ester functionality (Scheme 42 and Table 18, entry 7). The amount of $\mathbf{9 5}$ rose from $10 \%$ to $30 \%$ after the column chromatography, due to the acidity of the silica that catalyzed the lactonization.

Scheme 42: Cleavage of isoxazoline ring with $\mathrm{H}_{2} / \mathrm{Ni}$ Raney in anhydrous conditions
In order to avoid the formation of the close product, we tried running the hydrogenation reaction in presence of Boc anhydride to protect the newly formed alcohol and amine. Unfortunately we were able to recover just the unreacted starting material (Table 18, entry 8 ).

It was possible to avoid lactonization due to column chromatography by treating the crude material after hydrogenation with two equivalents of acetic anhydride. Surprisingly we obtained the amino alcohol protected just on the amine functionality 96 (Scheme 43). The amount of lactone detected in the crude NMR after hydrogenation ( $\sim 10 \%$ ) remained constant after acetylation and column chromatography, despite the alcohol not being protected.

Scheme 43: Hydrogenation of isoxazoline of 32 f ring followed by acetilation
The Ni-catalyzed hydrogenolysis reaction was tested also on isoxazoline 32c (Scheme 44). Also in this case, together with the expected amino alcohol 98, it was possible to identify the lactone $99(\sim 36 \%)$ in the crude NMR after hydrogenation. However, in this case, the treatment of the crude mixture with acetyl chloride was less successful. It was possible to isolate the $N$-acetylated lactone $\mathbf{1 0 0}$ and the $N$-acetylated amino ester 101, thought the latter proved not to be stable and cyclised to give $\mathbf{1 0 0}$.

Scheme 44: Hydrogenation of isoxazoline of 32c ring followed by acetilation
Finally we used Ni-catalyzed hydrogenolysis in anhydrous condition to open the ring of isoxazoline 88, obtaining $\gamma$-hydroxy-3-amino-L-threonine derivative $\mathbf{9 2}$ in $25 \%$ yield (Scheme 45). In the ${ }^{1} \mathrm{H}$ NMR spectra of crude reaction mixture it was possible to detect only one diastereoisomer. Spectroscopic data and HRMS (FT-ICR) confirmed the structure but it was not possible to obtain suitable crystals for X-ray analysis necessary to assign the absolute configuration of the newly formed stereocentre C-6. Despite the low yield of compound $\mathbf{9 2}$, this remains the only method to obtain this highly functionalized molecule.

Scheme 45: Cleavage of isoxazoline ring of amino ester 88 with $\mathrm{H}_{2} /$ Ni Raney in anhydrous conditions

### 2.8 Preliminary Studies on Addition of Schöllkpof's Reagent Anion to Imines

After having studied the reaction between Schöllkopf's reagent and aldehydes and ketones, in the last part of my PhD we focussed our attention on a different electrophile, imines. Only one example has been reported in the literature by Schöllkopf himself about this reaction (Scheme 46). ${ }^{111}$ In that case azaenaolate $(\boldsymbol{S})$-105 reacted with the imine functionality of $\mathbf{1 0 2}$, providing the intermediate $\mathbf{1 0 3}$, that cyclised into product 104. The attack on the imine occurred on the opposite face of isopropyl group. However nothing was reported about the diastereoselectivity of the newly formed $\mathrm{C}-\mathrm{N}$ bond.

Scheme 46: Reaction of azaenolate (S)-105 with an imine group

In order to do a preliminary screening, we chose three imines 106-108, all commercially available, bearing three different R group on the nitrogen. Following the general procedure, a solution of imine $\mathbf{1 0 6}$ or $\mathbf{1 0 7}$ was added to the anion of the bislactim ether $(\boldsymbol{R})$ - $\mathbf{2 3}$ generated by $n \mathrm{BuLi}$ in THF at $-78^{\circ} \mathrm{C}$. In the case of sulphonyl imine $\mathbf{1 0 6}$, the reaction occured with a low yield and provided all the four possible diastereoisomers (Scheme 47). Adducts 109 derived from the favourite attack of the Schöllkopf's azaenolate ( $\boldsymbol{R}$ )-23 from the opposite group of isopropyl, while for adducts $\mathbf{1 1 0}$ the attack occurred from the same side of isopropyl. However the four products couldn't be separated by column chromatography.

Scheme 47: Reaction between Schöllkopf's reagent and sulphonyl imine 106

The reaction between benzyl imine $\mathbf{1 0 7}$ and Schöllkopf's anion ( $\boldsymbol{R}$ )-23 didn't occur because ( $\boldsymbol{R}$ )-23 deprotonated the benzylic hydrogen of $\mathbf{1 0 7}$, providing the unreactive poly-conjugated system 111 (Scheme 48).

Scheme 48: Reaction between Schöllkopf's reagent and sulphonyl imine 107

The reaction between phenyl imine $\mathbf{1 0 8}$ and Schöllkopf's azaenolate ( $\boldsymbol{R}$ )-23 occurred in good yield and provided just two of the four possible diastereoisomers, 112 and 113. ${ }^{1} \mathrm{H}-\mathrm{NMR}$ of the products shown a trans relationship between $\mathrm{H}-2$ and $\mathrm{H}-5$, confirming the attack of Schöllkopf's anion from the side opposite to isopropyl group. However the diastereoselection in the formation of the new stereocenter at $\mathrm{C}-1$ ' proved to be relatively low, as the two products were formed with a d.r. of 60:40. Ongoing X-ray analysis will assign the absolute configuration at C -1'of $\mathbf{1 1 2}$ and $\mathbf{1 1 3}$ allowing to establish which of the two is the major one.

Scheme 49: Reaction between Schöllkopf's reagent and phenyl imine 108

The hydrolysis of pyrazine ring to obtain the desired $a, \beta$-diamino acids is object of ongoing researches.

## 3 CONCLUSION

In summary, a simple method to obtain enatiomerically pure $\beta$-hydroxy- $\alpha$-amino acids $\beta$-substituted with a 4,5-dihydroisoxazole nucleus was developed. This involved the reaction between Schöllkopf's reagent and $\Delta^{2}$-isoxazoline ring bearing a carbonyl group (aldehyde or ketone) in position 3 or 5 of the ring (Scheme 50). Reaction between Schöllkopf's reagent and enantiomerically pure 5 -acetil- $\Delta^{2}$-isoxazolines was throughly studied in order to explain the stereochemical outcome of the reaction.
$\Delta^{2-i s o x a z o l i n e ~ r i n g ~ w a s ~ f u r t h e r ~ e x p l o i t e d ~ a n d ~ i t s ~ c l e a v a g e ~ l e d ~ t o ~ t h e ~ f o r m a t i o n ~ o f ~}$ polifunctionalized amino acids or dipeptides (see Scheme 50) that can be potentially incorporated in polypeptides with biological interest.

Scheme 50: Transformation of $\Delta^{2}$ - isoxazoline ring bearing a carbonyl group into polifunctionalized amino acids or dipeptides

Moreover strategies to obtain enantiomerically pure 5-substituted isoxazoline through enzymatic resolution were developed (Scheme 51).

Scheme 51: Enzymatic resolution of 5 -substituted- $\Delta^{2}$-isoxazolines

A preliminary study on the synthesis of $\alpha, \beta$-diamino acids using the reaction between Schöllkopf's reagent and imines was also started. The development of this project, with the aim to extend the methodology to more complex imines, is now ongoing.

## 4 EXPERIMENTAL

### 4.1 General informations

Melting points were measured using a Büchi B-540 apparatus and are uncorrected. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$-NMR spectra were recorded in $\mathrm{CDCl}_{3}$ (unless otherwise specified) on a Bruker AMX 300 spectrometer; chemical shifts ( $\delta$ ) are given in ppm relative to TMS and all of the coupling constants are in Hertz. Optical rotation values were measured at $25^{\circ} \mathrm{C}$ on a Jasco P-1030 polarimeter. The MS spectra were determined using a VG Analytical 7070 $E Q$ mass spectrometer with an attached $V G$ analytical 11/250 data system. The IR spectra were determined using a Jasco FT-IR-4100 spectrometer, in $\mathrm{cm}^{-1}$.

### 4.2 General procedure for the synthesis of compounds 32c-f

A solution of alkene $\mathbf{3 4 c} \mathbf{- f}$ ( $5 \mathrm{mmol}, 1$ equiv.), ethyl nitroacetate ( $10 \mathrm{mmol}, 2$ equiv.) and DABCO ( $0.5 \mathrm{mmol}, 0.1$ equiv.) in ethanol $(20 \mathrm{~mL})$ was heated at $80^{\circ} \mathrm{C}$ for five days in a sealed tube. The organic solvent was evaporated off and the products were purified by column chromatography on silica gel (hexane/ethyl acetate: 80/20).

### 4.2.1 Oxa-2-aza-spiro[4.5]dec-2-ene-3-carboxylic acid ethyl ester 32c

Colourless liquid (70\%);
${ }^{1} \mathrm{H}$ NMR: $\delta 1.37\left(3 \mathrm{H}, \mathrm{t}, J=7.1, \mathrm{CH}_{3}\right) ; 1.40-1.90\left(10 \mathrm{H}, \mathrm{m},-\left(\mathrm{CH}_{2}\right)_{5}\right)$; $2.89(2 \mathrm{H}, \mathrm{s}, \mathrm{H}-4)$; $4.31\left(2 \mathrm{H}, \mathrm{q}, J=7.1, \mathrm{CH}_{2}\right)$.
${ }^{13} \mathbf{C}$ NMR: $\delta 13.79\left(\mathrm{CH}_{3}\right) ; 22.82,24.48,35.94\left(-\left(\mathrm{CH}_{2}\right)_{5}\right) ; 43.0(\mathrm{C}-4) ; 61.4\left(\mathrm{O}-\mathrm{CH}_{2}\right)$; 90.36 (C-5); 150.48 (C-3); 160.77 (C=O).

MS-EI (m/z): $211\left(\mathrm{M}^{+}\right)$.
IR (nujol): 1717 ( $v_{C=N}, \mathbf{C}=\mathrm{N}$ ), $1740\left(v_{C=O}, \mathbf{C}=\mathrm{O}\right)$.

### 4.2.2 Ethyl 5-cyclohexyl-4,5-dihydroisoxazole-3-carboxylate 32d

White solid ( $n$-hexane) (77\%)
m.p.: $48.6-49.5^{\circ} \mathrm{C}$
${ }^{1} H$ NMR: $\delta 1.38\left(3 \mathrm{H}, \mathrm{t}, J=7.1, \mathrm{CH}_{3}\right) ; 2.00-2.09\left(11 \mathrm{H}, \mathrm{m}, \mathrm{C}_{6} \mathrm{H}_{11}\right) ; 2.94(1 \mathrm{H}, \mathrm{dd}, J=$ $9.2,17.6 \mathrm{H}-4$ isox $) ; 3.16(1 \mathrm{H}, \mathrm{dd} ; J=11.1,17.6, \mathrm{H}-4$ isox $) ; 4.35\left(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.1, \mathrm{OCH}_{2}\right)$; 4.59 ( 1 H , ddd, $J=9.2,11.1, \mathrm{H}-5$ isox)
${ }^{13} \mathbf{C}$ NMR: $\delta 14.04\left(\mathrm{CH}_{3}\right) ; 25.54-26.13-28.02\left(\mathrm{CH}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{11}\right)\right) ; 35.74$ (C-4isox); 42.08 $\left(\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{11}\right)\right) ; 61.78\left(\mathrm{OCH}_{2}\right) ; 88.19(\mathrm{C}-5$ isox $) ; 151.26(\mathrm{C}=\mathrm{N}) ; 160.80(\mathrm{O}-\mathrm{C}=\mathrm{O})$.

MS-EI (m/z): $225\left(\mathrm{M}^{+}\right), 152,83$
IR (nujol) $1711\left(v_{C=O}, \mathbf{C}=\mathrm{O}\right)$.

### 4.2.3 Ethyl 4,5-dihydro-5-(pyridin-2-yl)isoxazole-3-carboxylate 32e

Brown solid (diisopropyl ether) (55\%)
Spectroscopic and analytical data are in agreement with those previously reported. ${ }^{112}$

### 4.2.4 5-Phenyl-4,5-dihydroisoxazole-3-carboxylic acid ethyl ester 32f

Oil (84\%)
Spectroscopic and analytical data are in agreement with those previously reported. ${ }^{65}$

### 4.3 General procedure for the synthesis of compounds 33c, d, $f$

A solution of ester 32c, d, $\mathbf{f}$ ( $10 \mathrm{mmol}, 1$ equiv.) in ethanol ( 10 mL ) (ethanol $/ \mathrm{CH}_{2} \mathrm{Cl}_{2}$ : $1 / 1$ for 32c) was added dropwise to suspension of $\mathrm{NaBH}_{4}$ ( $26 \mathrm{mmol}, 2.6$ equiv.) in ethanol $(20 \mathrm{~mL})$ at $0^{\circ} \mathrm{C}$. The reaction was stirred at room temperature for 6 hours. The organic solvent was evaporated off and the residue was poured into water. Acetic acid was added until $\mathrm{pH}=6$, and the mixture was extracted with several portions of ethyl acetate. The combined extracts were dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ and concentrated at reduced pressure. The crude alcohols were purified by column chromatography on silica gel (Hexane/AcOEt 6/4).

### 4.3.1 (1-Oxa-2-aza-spiro[4.5]dec-2-en-3-yl)-methanol 33c

Colourless liquid (89\%);
${ }^{1}$ H NMR: $\delta 1.46-1.82\left(10 \mathrm{H}, \mathrm{m},-\left(\mathrm{CH}_{2}\right)_{5}-\right) ; 2.54(1 \mathrm{H}$, broad, OH$) ; 2.78(2 \mathrm{H}, \mathrm{s}, \mathrm{H}-4$ isox); 4.39 ( $2 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{2}-\mathrm{O}$ ).
${ }^{13}$ C NMR: $\delta 23.81,25.4,36.74\left(-\left(\mathrm{CH}_{2}\right)_{5}-\right) ; 45.33\left(\mathrm{C}-4\right.$ isox); $58.86\left(\mathrm{CH}_{2}-\mathrm{O}\right) ; 87.47(\mathrm{C}-5$ isox); 158.51 (C-3).

MS-EI (m/z): $169\left(\mathrm{M}^{+}\right)$.
IR (nujol): $3374\left(v_{O-H}, \mathrm{OH}\right), 1625\left(v_{C=N}, \mathrm{C}=\mathrm{N}\right)$.

### 4.3.2 (5-cyclohexyl-4,5-dihydroisoxazol-3-yl)methanol 33d

White solid (diisopropyl ether) (77\%)
m.p: $69.5-70.5^{\circ} \mathrm{C}$
${ }^{1}$ HNMR: $\delta$ 2.0-2.09 $\left(11 \mathrm{H}, \mathrm{m},-\mathrm{C}_{6} \mathrm{H}_{11}\right) ; 2.17(1 \mathrm{H}, \mathrm{s}$ broad, OH$) ; 2.77(1 \mathrm{H}, \mathrm{dd}, J=8.9$, 17.1, H-4 isox); 3.00 ( $1 \mathrm{H}, \mathrm{dd}, J=10.5,17.1, \mathrm{H}-4$ isox); 4.38 ( $1 \mathrm{H}, \mathrm{dd}, J=8.9,10.5, \mathrm{H}-5$ isox); $4.39\left(2 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{2} \mathrm{OH}\right)$
${ }^{13}$ C-NMR: $\delta 25.65-26.20-28.40\left(\mathrm{CH}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{11}\right)\right) ; 37.44(\mathrm{C}-4$ isox $) ; 42.21\left(\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{11}\right)\right)$; $57.96\left(\mathrm{CH}_{2} \mathrm{OH}\right) ; 85.37$ (C-5 isox); $158.57(\mathrm{C}=\mathrm{N})$.
MS-EI (m/z): $183\left(\mathrm{M}^{+}\right)$.
IR (nujol): 3377 ( $v_{O-H}, \mathrm{OH}$ ), $1623\left(v_{C=N}, \mathrm{C}=\mathrm{N}\right)$.

### 4.3.3 5-Phenyl-4,5-dihydroisoxazol-3-yl]-methanol 33f

Colourless solid (85\%). Spectroscopic and analytical data are in agreement with those previously reported. ${ }^{65}$

### 4.4 General procedure for the synthesis of compounds

## 31 c, d, f

Following a reported procedure, ${ }^{59} \mathrm{MnO}_{2}(5 / 1 \mathrm{w} / \mathrm{w})$ was added to a solution of alcohol 33c, $\mathbf{d}, \mathbf{f}(10 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(15 \mathrm{~mL})$, and the reaction mixture was stirred at room temperature for 12 hours. The $\mathrm{MnO}_{2}$ was filtered through celite, and the organic solvent was evaporated off. The resulting aldehydes were purified through column chromatography (Exane/AcOEt 80/20) to remove $\mathrm{MnO}_{2}$ residues.

### 4.4.1 1-Oxa-2-aza-spiro[4.5]dec-2-ene-3-carbaldehyde 31c

Colourless liquid (79\%);
${ }^{1}$ H NMR: $\delta 1.50-1.90\left(10 \mathrm{H}, \mathrm{m},-\left(\mathrm{CH}_{2}\right)_{5}\right)$; $2.84(2 \mathrm{H}, \mathrm{s}, \mathrm{H}-4$ isox); $9.95(1 \mathrm{H}, \mathrm{s}, \mathrm{CHO})$.
${ }^{13}$ C NMR: $\delta 23.09,24.71,36.28\left(-\left(\mathrm{CH}_{2}\right)_{5}\right)$ ) 40.13 (C-4 isox); 92.43 (C-5); 158.01 (C-3 isox); 186.43 (CO).

MS-EI (m/z): $167\left(\mathrm{M}^{+}\right)$.
IR (nujol): 1695 ( $v_{C=O}, \mathrm{C}=\mathrm{O}$ ), $1573\left(v_{C=N}, \mathrm{C}=\mathrm{N}\right)$.

### 4.4.2 5-cyclohexyl-4,5-dihydroisoxazole-3-carbaldehyde 31d

Oil (60\%)
${ }^{1}$ H NMR: $\delta 2.00-2.09\left(11 \mathrm{H}, \mathrm{m}, \mathrm{C}_{6} \mathrm{H}_{11}\right) ; 2.83(1 \mathrm{H}, \mathrm{dd}, J=9.1,17.5, \mathrm{H}-4), 3.07(1 \mathrm{H}, \mathrm{dd}$, $J=11.2,17.5 ; \mathrm{H}-4) ; 4.61$ (1H, ddd, $J=9.1,11.2, \mathrm{H}-5), 9.91$ ( $1 \mathrm{H}, \mathrm{s}, \mathrm{CHO}$ )
${ }^{13}$ C-NMR: $\delta 25.56-26.14-28.09\left(\mathrm{CH}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{11}\right)\right) ; 32.51(\mathrm{C}-4$ isox $) ; 42.22\left(\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{11}\right)\right)$; 89.49 (C-5 isox); 159.39 (C=N); 185.84 (CHO).

MS-EI (m/z): $181\left(\mathrm{M}^{+}\right)$.
IR (nujol): 1669 ( $v_{C=O}, \mathrm{C}=\mathrm{O}$ )

### 4.4.3 4,5-dihydro-5-phenylisoxazole-3-carbaldehyde 31f

Oil (83\%). Analytical and spectroscopic data are in agreement with those previously reported. ${ }^{65}$

### 4.5 Enzimatic resolution of ( $\pm$ )-32f

### 4.5.1 (5R)-5-Phenyl-4,5-dihydroisoxazole-3-carboxylic acid ethyl ester (R)-32f

Compound ( $\boldsymbol{R}$ )-32f was obtained by biotransformation, with 3.57 g of ester ( $\mathbf{\pm} \mathbf{)} \mathbf{- 3 2 f}$ dissolved in DMSO and 3.75 g of Lipase from hog pancreas (PPL) being added to 700 ml of 0.1 M phosphate buffer, pH 7 . The biotransformation was carried out at $30^{\circ} \mathrm{C}$ under magnetic stirring. After 45 min (HPLC monitoring), the reaction was extracted
three times with ethyl acetate to recover ester ( $\boldsymbol{R}$-)-32f. The aqueous phase was brought to pH 2 with HCl and extracted three times with ethyl acetate to recover the acid $(\boldsymbol{S})$ 47f. The organic extracts were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the solvent was removed under reduced pressure. The crude ( $\boldsymbol{R}$ )-32f was purified by means of flash chromatography on silica gel (hexane/ethyl acetate: 90/10). Colourless oil (30\%);
$[\alpha]_{\mathrm{D}}^{25}-285.3\left(c 0.95, \mathrm{CHCl}_{3}\right)$.

### 4.5.2 [(5R)-5-Phenyl-4,5-dihydroisoxazol-3-yl]-methanol (R)-33f

Alcohol ( $\boldsymbol{R})$-33f was prepared starting from the ester $(\boldsymbol{R})$-32f as previously described for the racemic compound. Analytical and spectroscopic data are in agreement with those previously reported for the racemic compound.

$$
[\alpha]_{\mathrm{D}}^{25}-166.3\left(c \quad 1.05, \mathrm{CHCl}_{3}\right)
$$

### 4.5.3 (5R)-4,5-dihydro-5-phenylisoxazole-3-carbaldehyde (5R)-31f

Aldehyde ( $\boldsymbol{R}$ )-31d was prepared the ester ( $\boldsymbol{R}$ )-32f as previously described for the racemic compound. Analytical and spectroscopic data are in agreement with those previously reported for the racemic compound.
Colourless oil (83\%);
$[\alpha]_{\mathrm{D}}^{25}-459\left(c 1.29, \mathrm{CHCl}_{3}\right)$.

### 4.6 General procedure for the synthesis of compounds 50a-d

A solution of the appropriate Grignard reagent ( $7.5 \mathrm{mmol}, 2.5$ equiv) was added dropwise at $-78{ }^{\circ} \mathrm{C}$ to a solution of aldehyde $\mathbf{3 1 c}$ ( 3 mmol ) in 5 mL of anhydrous THF. The reaction mixture was stirred for 3 hours and allowed to warm at $-20^{\circ} \mathrm{C}$. A saturated solution of $\mathrm{NH}_{4} \mathrm{Cl}(10 \mathrm{~mL})$ was added to the reaction and the mixture was allowed to warm to room temperature. THF was removed under reduced pressure and the aqueous layer was extracted with AcOEt $(3 \times 3 \mathrm{~mL})$. The combined organic phases were dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ and the solvent removed under reduced pressure. The product were purified by column chromatography (hexane/AcOEt: 75/25) to give alcohols 50a-d.

### 4.6.1 1-(1-oxa-2-azaspiro[4.5]dec-2-en-3-yl)ethan-1-ol 50a

Oil (73\%)
${ }^{1}$ H NMR $\delta: 1.4\left(3 \mathrm{H}, \mathrm{d}, J=6.6 \mathrm{CH}_{3}\right) ; 1.8-1.4(10 \mathrm{H}, \mathrm{m}$. cyclohexyl $) ; 2.02(1 \mathrm{H}$, s broad, $\mathrm{OH}) ; 2.68(1 \mathrm{H}, \mathrm{d} J=16.97, \mathrm{H}-4) ; 2.75(1 \mathrm{H}, \mathrm{d} J=16.97, \mathrm{H}-4) ; 4.65(1 \mathrm{H}, \mathrm{q}, J=6.6 \mathrm{CH})$
${ }^{13} \mathbf{C}$ NMR $\delta: 20.70\left(\mathrm{CH}_{3}\right) ; 23.27,24.87,36.10\left(-\left(\mathrm{CH}_{2}\right)_{5}\right) ; 43.12(\mathrm{C}-4) ; 63.75(\mathrm{CH})$; 86.55 (C-5); 161.5 (C=N)

IR (nujol): 3397 ( $v_{\text {o-H }}, \mathrm{OH}$ ), 1624 ( $v_{C=N}, \mathrm{C}=\mathrm{N}$ ).
MS-EI (m/z): $183\left(\mathrm{M}^{+}\right), 166$.

### 4.6.2 1-(1-oxa-2-azaspiro[4.5]dec-2-en-3-yl)propan-1-ol 50b

Liquid (46\%)
${ }^{1}$ H NMR $\delta: 0.95\left(3 \mathrm{H}, \mathrm{t}, J=6.2, \mathrm{CH}_{3}\right) ; 1.4-1.8(10 \mathrm{H}, \mathrm{m}$, cyclohexyl $) ; 2.1(1 \mathrm{H}, \mathrm{d}, J=4.5$, $C H O H), 2.6(1 \mathrm{H}, \mathrm{d}, J=17.0, \mathrm{H}-4) ; 2.75$ ( $1 \mathrm{H}, \mathrm{d}, J=17.0, \mathrm{H}-4$ ); 4.45 ( $2 \mathrm{H}, \mathrm{dq}, J=4.5$, $6.2 \mathrm{CH}_{2}$ )
${ }^{13} \mathbf{C}$ NMR $\delta: 9.32\left(\mathrm{CH}_{3}\right) ; 23.27,24.89\left(-\left(\mathrm{CH}_{2}\right)_{5}\right) ; 27.56\left(\mathrm{CH}_{2}\right) ; 36.20\left(-\left(\mathrm{CH}_{2}\right)_{5}\right) ; 43.14$ (C-4); $68.89(\mathrm{CHOH}) ; 86.29(\mathrm{C}-5) ; 160.61(\mathrm{C}=\mathrm{N})$
IR (nujol): 3394 ( $v_{O-H}, \mathrm{OH}$ ), $1623\left(v_{C=N}, \mathrm{C}=\mathrm{N}\right)$.
MS-EI (m/z): $197\left(\mathrm{M}^{+}\right), 140$

### 4.6.3 2-methyl-1-(1-oxa-2-azaspiro[4.5]dec-2-en-3-yl)propan-1-ol 50c

White solid (25\%)
m.p: $54-56{ }^{\circ} \mathrm{C}$

### 4.8 Synthesis of 5-Acetyl-4,5-dihydroisoxazole 41 and 42

In the case of 5-acetyl-4,5-dihydoisoxazole 41 and 42 a general procedure was not followed. Below are reported the single procedures that have been used in the synthesis of these compounds.

### 4.8.1 1-(4,5-dihydro-3-methylisoxazol-5-yl)ethanone ( $\pm$ )-41

Compound 41a was prepared starting from 3-buten-2-one and nitroethane, according to the known procedure. ${ }^{54}$ Spectroscopic data were in agreement with those reported.

### 4.8.2 Synthesis of 5-(1-Hydroxyethyl)-4,5-dihydro-isoxazole-3-carboxylic acid ethyl ester ( $\pm$ )-syn/anti- 55

A solution of 3-buten-2-ol ( $1.04 \mathrm{~mL}, 12 \mathrm{mmol}$ ), ethyl nitroacetate ( $2.64 \mathrm{~mL}, 24 \mathrm{mmol}, 2$ equiv) and DABCO ( $269 \mathrm{mg}, 2.4 \mathrm{mmol}, 0.5$ equiv) in ethanol ( 30 mL ) was heated at 80 ${ }^{\circ} \mathrm{C}$ for five days in a sealed tube. The organic solvent was evaporated under reduced pressure and the mixture of diastereoisomers was purified and separated by means of flash chromatography $\left(\mathrm{SiO}_{2}\right.$, hexane/ethyl acetate: 3/1), affording 1.7 gr of product (76\%).

### 4.8.3 Synthesis of 5-Acetyl-4,5-dihydro-isoxazole-3-carboxylic acid ethyl ester ( $\pm$ )-42

$\mathrm{PCC} / \mathrm{Al}_{2} \mathrm{O}_{3}$ (3 equiv) was added to a solution of syn/ anti- 55 ( $1.7 \mathrm{~g}, 9.1 \mathrm{mmol}, 1$ equiv) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(40 \mathrm{~mL})$, and the reaction mixture was stirred at reflux temperature for 24 h . The PCC was filtered through Celite, and the organic solvent was removed under
reduced pressure. The crude ketone was purified by column chromatography ( $\mathrm{SiO}_{2}$, hexane/ethyl acetate: 8/2). Oil ( $1.5 \mathrm{~g}, 90 \%$ ). Spectroscopic data of compound 42 were in accord with those reported. ${ }^{75}$

### 4.9 Enzymatic resolution of ( $\pm$ )-41 and ( $\pm$ )-42

Ketone $\mathbf{4 1}{ }^{54}$ or $\mathbf{4 2}(1 \mathrm{mmol})$ dissolved in the minimum amount of ethanol, was added to a suspension of commercial fermenting yeast ( 5 g ) in tap water ( 30 mL ) containing $\mathrm{KH}_{2} \mathrm{PO}_{4}(60 \mathrm{mg}), \mathrm{Na}_{2} \mathrm{HPO}_{4}(30 \mathrm{mg}), \mathrm{MgSO}_{4}(30 \mathrm{mg})$ and glucose ( 10 g ). If necessary, the pH of the mixture was kept at 5.5-6.0 by addition of diluted aqueous NaOH . The reaction was carried out at $35^{\circ} \mathrm{C}$ under magnetic stirring for 24 h and monitored by TLC. The suspension was stirred with celite at $0{ }^{\circ} \mathrm{C}$ for 15 min and then filtered. The filtered water was extracted in continuous with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The organic phase was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the solvent was evaporated at reduced pressure. The mixture of syn/anti-alcohols 56 ( $78 \%$ total yield) was purified by means of flash chromatography ( $\mathrm{SiO}_{2}$, hexane/ethyl acetate: 8/2) and separated by semi-preparative HPLC (WatersMicropack, $10 \mu \mathrm{SiO}_{2}$, hexane $/ \mathrm{i}-\mathrm{PrOH}: 95 / 5$, flow rate: $7 \mathrm{~mL} / \mathrm{min}$ ). The mixture of syn/anti-alcohols 55 ( $66 \%$ total yield) was purified and separated by means of flash chromatography ( $\mathrm{SiO}_{2}$, hexane/ethyl acetate: 85/15).

### 4.11 General procedure for the synthesis of compounds 60-63

Butyllithium ( 0.81 mL of a 1.6 N solution in hexane, $1.3 \mathrm{mmol}, 1.05$ equiv.) was added to a solution of ( $\mathbf{2 R} \mathbf{R} \mathbf{- 2 2}(0.22 \mathrm{~mL}, 1.23 \mathrm{mmol}, 1$ equiv.) in anhydrous THF ( 5 mL ) cooled at $-78^{\circ} \mathrm{C}$, and the mixture was stirred for 45 min . A solution of triisopropoxytitanium (IV) chloride ${ }^{82}$ ( $1.33 \mathrm{mmol}, 1.075$ equiv.), prepared by mixing titanium tetraisopropoxyde ( $1.0 \mathrm{mmol}, 0.3 \mathrm{~mL}$ ) in anhydrous hexane ( 2 mL ) and titanium tetrachloride ( $0.33 \mathrm{mmol}, 0.32 \mathrm{~mL}$ of a 1 M solution in toluene), was added and stirring was continued for a further 45 min . Aldehyde (-)-31f ( $0.216 \mathrm{~g}, 1.23 \mathrm{mmol}, 1$ equiv.) in THF ( 4 mL ) was added, and the mixture was stirred at $-78^{\circ} \mathrm{C}$ for 6 h . The reaction mixture was allowed to warm to $-10^{\circ} \mathrm{C}$, after which a $\mathrm{pH}=7$ phosphate buffer solution ( 10 mL ) was added, and the mixture was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The organic phase was separated and dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and the solvent was evaporated in vacuo. Compounds $\mathbf{6 0 - 6 3}$ were purified by means of flash cromathography on silica gel (hexane/ethyl acetate: 80/20) and subsequently separated by means of flash cromathography on silica gel (Supelco, Versaflash ${ }^{\circledR}$ station, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /ethyl acetate: 95/5). The diastereoisomeric ratio of compounds $\mathbf{6 0 - 6 3}$ was determined by means of HPLC analysis (Supelco Ascentis ${ }^{\circledR}$ Si column, hexane/isoPrOH: 95/5, flow: $0.7 \mathrm{~mL} \mathrm{~min}{ }^{-1}$ ).

### 4.11.1 (S)-[(2S,5R)-5-Isopropyl-3,6-dimethoxy-2,5-dihydropyrazin-2-yl]-[(5R)-5-phenyl-4,5-dihydroisoxazol-3-yl]-methanol 60

### 4.12General procedure for the synthesis of compounds 65-68

Adducts $\mathbf{6 0}$ and $\mathbf{6 1}(0.5 \mathrm{mmoli})$ were dissolved in THF ( 7.5 mL ) and a 0.2 N solution of $\mathrm{HCl}(7.5 \mathrm{~mL}, 1.5 \mathrm{mmoli}, 3$ equiv.) was added. The mixture was stirred for 24 h at room temperature, and then extracted with diethyl ether in order to remove non-basic organic compounds. It was then treated with $25 \%$ ammonia solution under stirring until $\mathrm{pH}=8$ 10 , and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5 \times 20 \mathrm{~mL})$. The combined organic layers were dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and the solvent was removed in vacuo. Compounds 65,66 and 66,68 were separated by means of flash chromatography $\left(\mathrm{SiO}_{2}\right.$, ethyl acetate:methanol: 98:2, developer: $I_{2}$ ).

### 4.14General procedure for the synthesis of compounds 74a,b and 75a,b and 76

Butyllithium (1.6 N solution in hexane, 1.05 equiv.) was added to a solution of ( $\boldsymbol{R}$ )-22 ( 1 equiv.) in anhydrous THF ( 5 mL ) cooled at $-78^{\circ} \mathrm{C}$, and the mixture was stirred for 45 min. Ketone 39a or $\mathbf{b}$ or $\mathbf{d}$ (1 equiv.) in THF ( 4 mL ) was added, and the mixture was stirred at $-78{ }^{\circ} \mathrm{C}$ for 4 h . The reaction mixture was allowed to warm to $-10^{\circ} \mathrm{C}$, after which a $\mathrm{pH}=7$ phosphate buffer solution ( 10 mL ) was added, and the mixture was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The organic phase was separated and dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and the solvent was evaporated in vacuo. Compounds $\mathbf{7 4 a} / \mathbf{b}, \mathbf{7 5 a} / \mathbf{b}$ and 76 were purified by means of flash column chromatography.

### 4.15General procedure for the synthesis of 79 and 80

Adducts 74a and 75a ( 0.2 mmoli ) were dissolved in THF ( 3 mL ) and a 0.2 N solution of HCl ( $3 \mathrm{~mL}, 1.5 \mathrm{mmoli}, 2$ equiv.) was added. The mixture was stirred for 24 h at room temperature, and then extracted with diethyl ether in order to remove non-basic organic compounds. It was then treated with $25 \%$ ammonia solution under stirring until $\mathrm{pH}=8$ 10 , and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5 \times 20 \mathrm{~mL})$. The combined organic layers were dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and the solvent was removed in vacuo. Compounds $\mathbf{7 9}$ and $\mathbf{8 0}$ were purified by means of flash chromatography ( $\left.\mathrm{SiO}_{2}, \mathrm{AcOEt} / \mathrm{MeOH}: ~ 96: 4\right)$.

### 4.16General procedure for synthesis of compounds 81-84

Butyllithium ( 1.6 N solution in hexane, 1.05 equiv) was added to a solution of ( $\mathbf{2 R} \mathbf{R}$ )-22 (1 equiv) in anhydrous THF ( 5 mL ) cooled at $-78^{\circ} \mathrm{C}$, and the mixture was stirred for 45 min . Ketone ( $\mathbf{5 S}$ ) or ( $\mathbf{5 R}$ )-41 (1 equiv) in THF ( 4 mL ) was added, and the mixture was stirred at $-78{ }^{\circ} \mathrm{C}$ for 4 h . The reaction mixture was allowed to warm to $-10^{\circ} \mathrm{C}$, after
which a pH 7 phosphate buffer solution ( 10 mL ) was added, and the mixture was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The organic phase was separated and dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and the solvent was evaporated in vacuo. Compounds 81 and 82 and 83 and $\mathbf{8 4}$ were purified by means of column chromatography ( $\mathrm{SiO}_{2}$, hexane/ethyl acetate: 8/2) and (hexane/ethyl acetate: 7/3), respectively. They were subsequently separated by means of flash chromatography ( SiO 2 , Supelco-Versaflash ${ }^{\circledR}$ station, hexane/ethyl acetate: 75/25).

### 4.17General procedure for synthesis of compounds $\mathbf{8 6 - 8 8}$ and 89-91

Aqueous $\mathrm{HCl} 0.2 \mathrm{~N}(2.5 \mathrm{~mL}, 5.5 \mathrm{mmoli}$, 2 equiv.) was added to a solution of adduct $\mathbf{8 1}$, 82, 83 ( 0.25 mmoli, 1 equiv.) in THF ( 1.5 mL ). The mixture was stirred for $16-24 \mathrm{~h}$ at room temperature and then extracted with diethyl ether in order to remove non-basic organic compounds. It was then treated with $25 \%$ ammonia solution under stirring until $\mathrm{pH}=8-10$, and extracted with $\mathrm{AcOEt}(4 \times 5 \mathrm{~mL})$. The combined organic layers were dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and the solvent was removed in vacuo. Compounds 86, 87,88 and 89, 90,91 were separated by means of flash chromatography $\left(\mathrm{SiO}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeOH}\right.$ : 98/2, for 86/89 and 87/90; AcOEt/MeOH: 98/2, developer: $\mathrm{I}_{2}$ for 88/91).

### 4.184 ${ }^{2}$-Isoxazoline ring opening

### 4.18.1 2-acetamido-4-hydroxy-4-phenylbutanoate 96

A spatula of Raney-Ni was added to a solution of compound $\mathbf{3 1 f}(218 \mathrm{mg}, 1 \mathrm{mmol})$ in ethyl acetate ( 4 mL ). The mixture was stirred vigorously under hydrogen at room temperature for 24 h , then filtered through celite. The solvent was removed in vacuo. The residue was dissolved in dichloromethane ( 5 mL ) and acetic anhydride ( 2.2 equiv, 0.22 mL ), pyridine ( 1.5 equiv, 0.13 mL ) and 4-dimethylaminopyridine ( 01. equiv, 12 $\mathrm{mgr})$ were added. The reaction mixture was stirred at room temperature for 12 hours. The reaction mixture was washed with water $(3 \times 1.5 \mathrm{~mL})$, dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the solvent removed under reduced pressure. Column chromatography (hexane/AcOEt: 30/70) afforded the syn and anti 96 in $51 \%$ total yield.

A spatula of Raney-Ni was added to a solution of compound 31c ( $210 \mathrm{mg}, 1 \mathrm{mmol}$ ) in ethyl acetate ( 4 mL ). The mixture was stirred vigorously under hydrogen at room temperature for 15 hours, then filtered through celite. The solvent was removed in vacuo. The residue was dissolved in dichloromethane ( 5 mL ) and acetyl chloride ( 2 equiv, 0.13 mL ), triethylamine ( 2 equiv, 0.250 mL ) were added. The reaction mixture was stirred at room temperature for 12 hours. The reaction mixture was washed with water $(3 \times 1.5 \mathrm{~mL})$, dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the solvent removed under reduced pressure. Column chromatography (dichloromethane/MeOH: 97/3) afforded 100 in $41 \%$ total yield

## SECTION B

## 5 INTRODUCTION

Chiral allylsilanes are very useful intermediates in organic synthesis and they have been used as building blocks and as versatile intermediates for the synthesis of complex molecules. ${ }^{113-116}$ Their reactivity is due to the peculiar properties of the C-Si bond. The lower electronegativity of silicon (1.8) compared to carbon (2.5) ${ }^{117}$ causes a rise in the HOMO, making the allylsilane reactive nucleophiles. Moreover Si has a large atomic radius ( 110 pm versus 70 pm of C ) and the bulkiness of a silyl group can control the stereochemistry of the reactions occurring in its immediate vicinity. In addition, silicon can be easily removed from the molecule after it exerted its influence on a synthetic sequence. Protodesilylation ${ }^{118}$ and oxidation ${ }^{119,} 120$ of the C-Si bond occur through initial reaction at silicon by electronegative atoms like oxygen and fluoride, with which it forms very strong bonds.

Chiral allylsilane can react with a broad range of electrophiles leading to the formation of more complex products. Some of the more important and useful reactions are shown in Figure 33. ${ }^{114}$ Depending on the experimental conditions, reactions with carbonyl compounds and imines, can lead to the formation of carbocycles and five members ring heterocycles. However reactions with the same electrophiles, under different reaction conditions, provide homoallylic alcohol and amines.

Figure 33: Reactions of allylsilanes

### 5.1 Synthetic Methodologies for the Synthesis of Chiral Allyl Silanes

Due to the importance of allylsilanes in organic synthesis, many research groups have studied different approaches to obtain them in high enantiomeric and diastereomeric purity. Hayashi and co workers in 1982 described for the first time an efficient synthesis of enatiomerically pure allylsilanes using a palladium-catalyzed asymmetric Grignard cross-coupling. ${ }^{121}$ As shown in Scheme 52, reaction between different allylbromides 114 and Grignard reagent 115 was catalyzed by $\operatorname{PdCl}_{2}[(R)-(S) \mathrm{PFA}]$, led to the formation of allylsilanes $\mathbf{1 1 6}$ in moderate to good yields and excellent e.e.

Scheme 52: Synthesis of allylsilanes proposed by Hayashi ${ }^{121}$

Other Pd catalyzed reaction that have been developed for the synthesis of chiral allylsilanes include the hydrosilalation of 1,3 dienes, ${ }^{122,123}$ silylation of allylic chlorides ${ }^{124}$ and silaborations of allenes. ${ }^{125}$ However, in many cases products are obtained with less than $90 \%$ e.e.

More recently, Oestrich described the synthesis of chiral allyl silanes through a copper catalyzed allylic substitution of an enantiomerically pure carbamate or carbonate 118a or $\mathbf{b}$ with bis(triorganosilyl) zinc $\mathbf{1 1 7}$ (Scheme 53). ${ }^{126}$ Allylsilanes were obtained in moderate to good yield and in high e.e., but this methodology was only applied to a limited number of substrates.

Scheme 53: Syntheis of allylsilanes proposed by Oestrich ${ }^{126}$
Hoveyda and co-workers developed the synthesis of tertiarty and quaternary allylsilanes using catalytic asymmetric allylic alkylation of organozinc reagents to Si substituted allyl phosphates 120. ${ }^{127}$ This transformation is catalyzed by chiral Cu complexes generated in situ from $N$-heterocyclic-carbenes ligands $\mathbf{1 2 1}$ (Scheme 54). Tertiary allylsilanes $\mathbf{1 2 2}$ were obtained in high yields and excellent enantioselectivity. Moreover the reaction proved to have a broad scope, with allylsilanes containing different alkyl groups as methyl, ethyl, isopropyl, $\mathrm{AcO}\left(\mathrm{CH}_{2}\right)_{4}$ - formed without any reduction in the enantioselctivity.

Scheme 54: Synthesis of tertiary allylsilanes proposed by Hoveyda ${ }^{127}$

Moreover the same metal-ligand complex can be used for the synthesis of the more challenging quaternary allylsilanes starting from the sterically congested trisubstituted olefin 123. The quaternary allylsilanes 124 were again obtained in high yields and excellent e.e. ${ }^{127}$

Scheme 55: Synthesis of quaternary allylsilanes proposed by Hoveyda ${ }^{127}$

In this work we aim to study a new route to enantiomerically enriched allylsilanes through the lithiation/borylation reaction developed within the Aggarwal group. The base of lithiation/borylation methodology is the study of the lithiation of carbamates, firstly developed by Hoppe. Therefore in the next section Hoppe's work will be reviewed together with the functionalities allowed by the system.

### 5.2 Hoppe Carbamates and Functionalities Allowed

Hoppe and co-workers first reported the asymmetric deprotonation of an $O$-alkyl carbamates in $1990 .{ }^{128}$ The carbamate $\mathbf{1 2 5}$ is easily synthesised through reaction of the corresponding alcohol with carbamoyl chloride in presence of a mild base as triethylamine ${ }^{129}$ or pyridine. ${ }^{130}$ The carbamate obtained may be deprotonated using or $s \mathrm{BuLi}$ at $-78{ }^{\circ} \mathrm{C}$, in presence of a diamine ligand. After a four hours deprotonation, the lithiated species $\mathbf{1 2 6}$ can react with a variety of electrophiles. This traps the lithiated intermediate with retention of configuration, providing the corresponding secondary alcohols $\mathbf{1 2 7}$ after deprotection of carbamate group (Table 19). ${ }^{131}$

Table 19: Examples of the deprotonation of alkyl carbamates followed by trapping with an electrophile ${ }^{131}$

The presence of the carbamate group has two important effects in the deprotonation reaction. Firstly, it acts as an electron withdrawing group making the alpha proton more acidic. Secondly it helps stabilize the lithiated intermediate, through the coordination of oxygen with lithium, as shown in Table 19. The lithiated carbamate is also stabilized by the diamine that chelates with the lithium.

Hoppe and co-workers mainly used two carbamates groups (Figure 34). While the diisopropyl carbamate ( OCb ) can be removed with $\mathrm{LiAlH}_{4}$ or an excess of DIBALH, the oxazolidines carbamates ( OCby and OCbx ) can be removed through a easier $\mathrm{acid} /$ base hydrolysis using a mixture of $\mathrm{MeSO}_{3} \mathrm{H}$ and MeOH followed by $\mathrm{Ba}(\mathrm{OH})_{2}{ }^{131}$

Figure 34: Carbamate groups employed by Hoppe, et al.

A wide range of electrophiles have been used in this reaction, as $\mathrm{MeI}, \mathrm{CH}_{2} \mathrm{~N}_{2}, \mathrm{Me} 3 \mathrm{SiCl}$, acid chlorides, esters, ketones, aldehydes, allyl bromide an epoxides. ${ }^{132}$ In all cases the electrophile traps the lithiated carbamate with retention of configuration (Figure 35).

Figure 35: Mechanism of electrophile trapping by lithiated alkyl carbamates

As previously mentioned, the presence of a secondary diamine, such as $N, N, N^{\prime}, N^{\prime}$ tetramethylethyldiamine (TMEDA, Figure 36), is needed for the stabilisation of the intermediate lithiated carabamate. When an achiral amine as TMEDA is used, the product obtained is in racemic form. However when a chiral diamine, like (-)-sparteine (Figure 36) is used, enantioselective deprotonation can be induced.

TMEDA

(-)-sparteine

Figure 36: Diamines Employed in the Deprotonation of Alkyl Carbamate

In the case of primary alkyl carabamates, treatment with $s \mathrm{BuLi}$ in presence of $(-)$ sparteine, leads to the preferential deprotonation of pro-S proton of $\mathbf{1 2 5}$, affording the product with an e.r. up to 99:1 (Scheme 56). ${ }^{133}$ Lithiated alkyl carbamates proved to be configurationally stable at $-70^{\circ} \mathrm{C}$ and so no equilibrium due to racemisation of the
organolithium occurs. Therefore the origin of enantioselectivity is a kinetically controlled process. It has been shown by quantum chemical DFT calculation that the transition state for pro- $S$ deprotonation of ethyl carbamate by ( - )-sparteine-sBuLi complex is $2.75 \mathrm{kcal} / \mathrm{mol}$ lower in energy that the transition state fro pro- $R-\mathrm{H}$. This difference of energy at $-78{ }^{\circ} \mathrm{C}$ corresponds to the observed enantiomeric ratio of 99:1. ${ }^{134}$

Scheme 56: Enantioselective deprotonation of alkyl carbamates with (-)-sparteine•sec-BuLi complex

The synthesis of the opposite enantiomer is achieved using (+)-sparteine surrogate (Figure 36), a ligand developed by O'Brien and co-workers. ${ }^{135}$ In fact, while (-)sparteine is commercially available, its enantiomer is not. The use of (+)-sparteine surrogate in lithiated carbamate reactions leads to the exclusively deprotonation of pro$R$ proton of $\mathbf{1 2 8}$, affording the product $\mathbf{1 2 9}$ with an e.r. of 95:5. ${ }^{133}$

Scheme 57: Use of O'Brien's (+)-sparteine surrogate in lithiated carbamate chemistry
Unlike the case of $O$-alkyl carbamates, the lithiated primary $O$-benzyl ones are not configurationally stable at $-78^{\circ} \mathrm{C}$. Therefore when the deprotonation of $\mathbf{1 3 0}$ reaction is run in presence of $(-)$-sparteine, the product $\mathbf{1 3 1}$ is recovered in racemic form (Scheme 58). ${ }^{136,137}$

Scheme 58: Deprotonation of benzyl carbamate in the presence of $(-)$-sparteine ${ }^{136}$
Conversely, secondary benzyl carbamates proved to be configurationally stable at -78 ${ }^{\circ} \mathrm{C}$. ${ }^{137}$ Starting from enantiomerically enriched secondary benzylic carbamates $\mathbf{1 3 2}$, the electrophiles react with the lithiated form with complete retention or complete inversion of stereochemistry, depending on the nature of the electrophile (Table 20). ${ }^{130}$ Electrophiles containing a Lewis basic site usually react with retention of configuration. This is thought to be due to precomplexation between the Lewis basic group and lithium which is Lewis acidic. Electrophiles without a Lewis basic site cannot precomplex with lithium and so reaction occurs with inversion of stereochemistry. In both cases, however, the products are obtained with e.e. up to $95 \%$.

132

Table 20: Electrophiles which react with inversion and retention of configuration ${ }^{130}$

### 5.3 Lithiation/Borylation Methodology

In 1980 Matteson and co-workers reported a breakthrough in the synthesis of chiral boronic esters. ${ }^{138}$ They found that treatment of chiral boronic ester 133 with dichloromethyllithium led to the stereoselective formation of a boron "ate" complex. This intermediate, upon warming to room temperature, underwent a stereospecific 1,2metallate rearrangement to give $\alpha$-chloro-boronic ester 134. When the $\alpha$-chloro-boronic ester 134 was treated with another nucleophile, such as Grignard reagent, a second homologation occurred, providing 135 (Scheme 59). The presence of a chiral diol (eg. pinane diol) as the ester substituent causes both homologations to proceed in an excellent diasteresoselctivity. ${ }^{138}$ The stereochemistry of the "ate" complex is in fact controlled by the chiral environment provided by the boronic ester (substrate control) for the homologation of dichloromethyl lithium. Moreover the diastereomeric ratio can be improved up to $>99: 1$ by adding zinc chloride to the solution. ${ }^{139,140}$

Scheme 59: Homologation of pinane diol derived boronic esters ${ }^{138}$

The homologation of the $\alpha$-chloro boronic ester with a nucleophile is a stereospecific reaction. The migrating group in the boron "ate" complex must be antiperiplanar to the leaving group (the chloride) for 1,2-metallate rearrangement to occur (Figure 37).

Figure 37: Mechanism of 1,2-metallate rearrangement. $X=$ leaving group

The Matteson homologation has been used in total synthesis to form enantiomerically enriched secondary alcohols ${ }^{141-146}$ and allyl boronates for subsequent allylboration. ${ }^{\text {147-150 }}$

A complementary method to the substrate controlled Matteson homologation, was first developed by Hoppe and co-workers. ${ }^{151}$ In this case they obtained the chiral boronic
ester $\mathbf{1 3 6}$ after reacting the chiral lithiated carbamate $\mathbf{1 2 8}$ with triisopropyl borate followed transesterification with pinacol. The lithiated carbamate dictated the stereochemistry of the product. Treatment of the boronic ester with Grignard reagents at $-78{ }^{\circ} \mathrm{C}$ led to the formation of the "ate" complex 137. Upon warming at room temperature, this underwent 1,2-metallate rearrangement, with the expulsion of the carbamate moiety, affording to give the secondary boronic ester $\mathbf{1 3 8}$ (Scheme 60). ${ }^{151}$ The corresponding alcohol $\mathbf{1 3 9}$ is obtained in excellent yield and e.r.

Scheme 60: Formation of secondary boronic ester from chiral lithiated carbamate and subsequent 1,2 -metallate rearrangement ${ }^{151}$

This methodology was used in the total synthesis of (-)-N-acetylcolchinol by Kocienski and co-workers (Scheme 61). ${ }^{152}$ During this work, it was found that the lithiated carbamate could be directly trapped with an aryl boronic ester to form the boron "ate" complex. 1,2-metallate rearrangement, promoted by magnesium bromide in refluxing 1,2-dimethoxyethane (DME) provided the boronic ester, that was oxidized into alcohol 140 in excellent enantioselectivity.

Scheme 61: Synthesis of (-)-N-Acetylcolchinol using lithiation/borylation

Aggarwal and co-workers generalised this methodology making reactions directly the lithiated carbamates with boranes or boronic esters. ${ }^{129}$ Carbamate $\mathbf{1 2 5}$ was enantioselectively deprotonated with $s \mathrm{BuLi}$ in presence of $(-)$-sparteine, leading to the formation of the chiral carbenoid 141. Addition of boranes or boronic esters afforded the boron "ate" complex with retention of configuration which underwent 1,2 metallate rearrangement upon warming. Subsequent oxidation of 142 led to the secondary alcohols $\mathbf{1 4 3}$ in excellent yield and e.r. (Table 21) . ${ }^{129}$

Table 21: Lithiation/Borylation reaction with alkyl carbamates. ${ }^{\text {a }}$ No $\mathrm{MgBr}_{2}$ added. ${ }^{129}$
As shown in Table 21, a broad range of alkyl carbamates can be employed together with a broad range of aryl and alkyl boronic esters, providing easy access to a wide variety of secondary alcohols. When boronic esters are employed, the addition of $\mathrm{MgBr}_{2}$ in $\mathrm{Et}_{2} \mathrm{O}$ at reflux is required to make the 1,2 -metallate rearrangement to occur. Moreover it was shown that iterative homologation could be performed, with alcohols $\mathbf{1 4 5}$ obtained in excellent e.r. and d.r. (Scheme 62). The strength of this methodology lies in the possibility of obtaining all the fours alcohols stereoisomers through the appropriate choice of ( - )-sparteine or (+)-sparteine surrogate during deprotonation of the carbamate.

Scheme 62: Iterative homologation reaction of boronic esters 144 and ent- 144

The lithiation/borylation of primary $O$-alkyl carbamates methodology was then applied in the synthesis of enantioenriched allyl boranes 146 (Scheme 63). These, however, were not isolated but underwent an in situ allylboration with aldehydes providing homoallylic alcohols 147 in high e.r. and d.r. ${ }^{153}$

Scheme 63: Lithiation/borylation/allylboration methodology to form homoallylic alcohols ${ }^{153}$
A further application of this methodology was found in the synthesis of $\beta$-hydroxy allysilanes 153. ${ }^{154}$ Lithium-tin exchange of stannane 148 afforded the lithiated carbamate 149. This reacted with retention of configuration with $\beta$-silyl vinyl borane 150 giving the "ate" complex 151, that upon warming underwent 1,2 - metallate rearrangement. However, because the allyl boranes were not stable, $\mathbf{1 5 2}$ was trapped with aldehyde in situ, affording $\beta$-hydroxy allysilanes 153 (Scheme 64). ${ }^{154}$ This versatile methodology has been applied in the formal synthesis of (-)-decarestrictine D ${ }^{154}$ and the total synthesis of solandelactone E. ${ }^{155}$

Scheme 64: Lithiation/borylation to form $\beta$-hydroxy-allylsilanes ${ }^{154}$

The lithiation/borylation methodology was also extended to the use of secondary benzylic $O$-lithiated carbamate. ${ }^{156}$ Reaction of the lithiated carbamate $\mathbf{1 5 4}$ with boron reagents formed the corresponding boron "ate" complex. Upon warming to room temperature 1,2-metallate rearrangement occurred to give the tertiary borane or boronic ester. Oxidative workup afforded tertiary alcohols $\mathbf{1 5 5}$ in excellent yields and e.r (Table 22). The secondary alcohols, precursors of the carbamate, were easily made enantioselectively by Noyori transfer hydrogenation ${ }^{157}$ of the corresponding ketones or by enzymatic resolution ${ }^{158}$ of the racemic alcohols in an e.r. of up to $>99: 1 .{ }^{156}$

Table 22: Lithiation/Borylation of secondary aryl carbamates ${ }^{156}$
The lithiation/borylation methodology proved to be even more useful, because starting from the same enantioenriched carbamate, both enantiomers of the tertiary alcohol can be obtained. The reaction of boronic esters proceeded with retention of configuration of the lithiated carbamate whereas when boranes were used, the reaction occurred with
inversion of stereochemistry. This stereochemical outcome can be so explained: in the case of boronic ester, the oxygen of the ester complexes with the lithium of the metallated carbamate and so it is delivered from the same face as the carbanion (Figure 38). In case of borane, precomplexation cannot occur and so the electrophile attack the face opposite to the lithium where there is significant electron density owing to the nature of the carbanion being between tetrahedron and trigonal biplanar (Figure 38). ${ }^{156}$

Figure 38: Explanation of whether electrophile reacts with retention or inversion of stereochemistry ${ }^{156}$

### 5.4 Aim of the Work

On the base of the results previously obtained with lithiation-borylation methodology, we envisaged to extend it in the synthesis of tertiary and quaternary allylsilanes with high d.r. and e.r. In particular we thought that the lithiation-borylation of carbamate 156 could afford intermediate 157, that could have been transformed into allylsilanes by means of Zweifel olefination (Scheme 65).

Scheme 65: Proposed used of lithiation/borylation in the synthesis of chiral allylsilanes

Zweifel and co-workers in 1967 described the synthesis of substituted alkenes via iodination of vinylboranes. ${ }^{159}$ It was proposed that initial addition of iodine to the double bond was followed by the migration of a R-group from the boron to the adjacent carbon atom to provide organoborane 158 (Scheme 66). Elimination to give alkene 159 proved to be highly stereoselective and occurred when the boron group and the iodine were in a trans relationship .

Scheme 66: Zweifel olefination mechanism ${ }^{159}$

## 6 RESULTS AND DISCUSSION

The first attempt in using lithiation/borylation methodology for the synthesis of allylsilanes envisaged the use of an $\alpha$-silyl carbamate. ${ }^{\text {a }}$ We thought that trapping the enatioenriched lithiathed carbamate $\mathbf{1 6 0}$ with a boronic ester would have given, after formation of "ate" complex and 1,2-metallate rearrangement, the product $\mathbf{1 6 1}$ (Scheme 67). Zweifel olefination of the newly formed boronic ester would have provided the allysilane 162. However this strategy proved unrewarding, because the intermediate lithiated silyl carbamate 160 was configurationally unstable, ${ }^{160}$ even when the reaction was performed at $-100^{\circ} \mathrm{C}$, and led to racemic 161 .

Scheme 67: Lithiation/borylation of silyl carbamate to synthesise chiral allylsilanes 162
We therefore considered an alternative approach. The lithiation of alkylcarbamate 128a,b was carried out in the presence of chiral diamine $(-)$-sparteine and provided the enantioenriched lithiated carbamate 163a,b configurationally stable at $-78{ }^{\circ} \mathrm{C}$. The subsequent addition of the silaboronate 164 as the electrophile led to the formation of a boron "ate" complex" 165a,b, that upon warming underwent 1,2-metallate

[^0]rearrangement with migration of the silyl group and the expulsion of the carbamate group, providing the 1,1 -silaboronates 166a,b (Scheme 68). Despite there being few reported examples ${ }^{161-163}$ of the migration of a silyl group in the literature, this strategy proved to be successful.

Scheme 68: Synthesis of silaboronates 166a,b through lithiation/borylation of carbamates 128a,b

The reaction was performed using two different R groups, the isopropyl group and the phenylethyl group. In both cases 166 was obtained in very good yields. Despite the silaboronate 164 being commercially available, we found that when the reactions were carried out using freshly synthesised $\mathbf{1 6 4}$ the yields were dramatically improved (from $26 \%$ to $68 \%$ ). Silaboranate 164 was synthesised according to the procedure reported by Suginome and co-workers (Scheme 69). ${ }^{164}$ Silyllithium 167 was prepared treating the corresponding chlorosilane with lithium. The resulting solution was then added to borane 168 and the desired silaboronate 164 was obtained in good yield after distillation.

Scheme 69: Synthesis of silaboronate $164{ }^{164}$

In order to synthesise the desired allylsilanes, we applied modified condition of Zweifel olefination. ${ }^{159,} 165,166$ It was found that $\mathrm{I}_{2} / \mathrm{MeOH}$ was superior to the more commonly employed conditions $\mathrm{I}_{2} / \mathrm{MeONa} / \mathrm{MeOH}$. Initially we focused our attention on the synthesis of vinylsilanes 172a,b. Treatment of silaboronates 166a,b with vinlyllithium
led to the formation of "ate" complex 169a,b (Scheme 70). The addition of iodine in methanol provided iodonium intermediate 170. This, upon warming, rearranged into intermediate 171. Anti elimination led to the formation of 172a,b in good yield and excellent e.r.

Scheme 70: Synthesis of allysilanes 172a,b through Zweifel olefination

It should be noted that, in the case of boronate ester 166a, vinylmagnesium bromide was sufficiently nucleophilic to effect the "ate" complex formation but for the more hindered 166b vinyllithium was required.

Encouraged by this result we directed our attention on the synthesis of more challenging crotylsilanes. Therefore silaboronates 166a,b were treated with Z-propenyllithium 173 or $E$-propenyllithium 174 providing, respectively $E$-crotylsilanes 175a,b and Zcrotylsilanes 176a,b in excellent yields, e.r and d.r.(Scheme 71).

Scheme 71: Synthesis of crotylsilanes $\mathbf{1 7 5 a}, \mathrm{b}$ and $\mathbf{1 7 6 a , b}$ through Zweifel olefination

In the case of the crotylsilanes, the fact that the elimination occurred exclusively when boron and iodine are in anti was important as it prevents the formation of a mixture of cis and trans isomers. Only in the synthesis of highly hindered Z-crotylsilane 176b was the $E$ isomer visible in the crude NMR (d.r.: 85:15). In this case, the minor $E$-olefin presumably arose due to the severe steric clash in the conformation required for antielimination which gives the Z-olefin. Therefore some syn-elimination occurs, providing the small amount of $E$-isomer (Scheme 72).

Scheme 72: Conformations that lead to the formation of cis-crotylsilane 176a and trans crotylsilane 175b

All of the allysilanes synthesized were not able to be analyzed by chiral HPLC or chiral GC. Therefore, it was necessary to derivatize them without losing the e.r. achieved in the previous steps. While hydroboration ${ }^{154}$ and oxidation of the allyl silanes to the alcohol 177a,b (Scheme 73) proved to be a successful strategy for determine the e.r. of allilsilanes $\mathbf{1 7 2 a}, \mathbf{b}$, this was not the case for crotylsilanes $\mathbf{1 7 5 a}, \mathbf{b}$ and $\mathbf{1 7 6} \mathbf{a}, \mathbf{b}$.

Scheme 73: Hydroboration of allylsilanes 172a, b
Therefore, we applied the Tamao-Fleming oxidation of organosilane. ${ }^{119,167}$ This reaction allows the conversion of the dimethylphenylsilyl group to an alcohol functionality with retention of configuration (Scheme 74). The authors propose that the phenyl ring is protonated giving the intermediate $\mathbf{1 7 8}$ and the trifluoroacetate anion attacks the silicon leading to the expulsion of benzene. Subsequently, fluorine attacks silicon kicking out the trifluoroacetate anion. Oxidation occurs when the peroxide anion attacks silicon providing the intermediate $\mathbf{1 7 9}$. This undergoes a stereospecific intramolecular rearrangement with retention of configuration which, after hydrolysis gives alcohol 180.

Scheme 74: Mechanism of Tamao-Fleming oxidation ${ }^{119,167}$
All the crotylsilanes previously synthesized were separately reduced to the saturated organosilanes 181a,b in presence of tosylhydrazide and triethylamine, ${ }^{164}$ before oxidation to the corresponding alcohols 182a, b (Scheme 75). The yields of these reactions were not optimised.

Scheme 75: Tranformation of allysilanes 175a,b and 176a into alcohols 182a,b

In case of the more encumbered crotylsilane 176b, hydrogenation reaction using $\mathrm{PtO}_{2}$ as catalyst was carried out (Scheme 76). ${ }^{168}$ All of the allylsilanes synthesised proved to have an excellent e.r as shown in Scheme 71.

Scheme 76: Reduction of allylsilane 176b

Two PhD students in the group, Dr. Binanzer and Dr. De Ceglie, proved that the lithiation-borylation methodology could be extended to the synthesis of the more challenging quaternary allylsilanes. In this case, the sequence started with lithiation and silylation of carbamate 128a in presence of (-)-sparteine as previously described by Hoppe, ${ }^{169,170}$ providing intermediates 183a,b (Scheme 77). Subsequent deprotonation with $s \mathrm{BuLi} / \mathrm{TMEDA}$ followed by the addition of boronic ester $\mathbf{1 8 4}$ gave intermediate 185. This intermediate was converted to the corresponding quaternary allylsilane 186, using the modified Zweifel olefination (see Scheme 70) in good yields and excellent e.r. (Table 23). The e.r. was determined by HPLC analysis, of the product derived from hydroboration/oxidation of 186a-c. The absolute configuration was assigned by X-ray analysis of the alcohol obtained from 186c by hydroboration/oxidation. All other assignments were made by analogy.

Scheme 77: Lithiation/borylation followed by Zweifel olefination for the synthesis of quaternary allylsilanes 186a-c

|  | $\mathrm{R}^{1}$ | $\mathrm{R}^{2}$ | Yield of $\mathbf{1 8 5}$ | Yield of $\mathbf{1 8 6}$ | e.r. of $\mathbf{1 8 6}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| a | Me | Et | $94 \%$ | $73 \%$ | $97: 3$ |
| b | Ph | Me | $52 \%$ | $73 \%$ | $97: 3$ |
| c | Ph | Et | $76 \%$ | $60 \%$ | $97: 3$ |

Table 23: Yields and e.r for lithiation/borylation/Zweifell olefination sequence

Roush previously showed that quaternary allylsilane 187 can react with aldehydes through a [3+2] cycloaddition reaction, leading to the formation of a tetrahydrofuran 188 in good yield and excellent diastereoselctivity (Scheme 78). ${ }^{171}$

Scheme 78: Cyclization of quaternary allilsilane ${ }^{171}$
This prompted us to synthesise quaternary allylslilane 193 (Scheme 79), according to the methodology shown in Scheme 77. Quaternary allylsilane 193 was obtained racemically starting from carbamate $\mathbf{1 8 9}$ (using TMEDA instead of ( - )-sparteine in the deprotonation step) in very good yield.

Scheme 79: Synthesis of quaternary allylsilane 193 through lithiation/borylation/Zweifel olefination sequence

We thought that allylsilane 193 could undergo cyclization ${ }^{114,172,173}$ reaction with different electrophiles, providing natural product precursors (Scheme 80). For instance, reaction of 193 with benzaldehyde would provide 194, a motif that is found in the molecule of Iritectol B. Reaction with chlorosulphonyl isocyanate would lead to the formation of $\mathbf{1 9 5}$ that could be oxidized to the antifungal compound 196 or to lactam 197.

Scheme 80: Cyclization of allysilane 193 to provide useful molecules

Therefore, we reacted allysilane $\mathbf{1 9 3}$ with benzaldehyde in presence of different Lewis acids ${ }^{171,172,174}$ to obtain 194. However when $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}$ or tris(pentafluorophenyl)borane were used, the reaction didn't occur at low temperature and led to a mixture of undefined products when the temperature was raised (Table 24).

| Lewis Acid | PhCHO | Solvent | Temperature | Time | Comment |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{BF}_{3} \mathrm{OEt}_{2}(1.3 \mathrm{eq})$ | 1.3 eq | DCM | $-78{ }^{\circ} \mathrm{C}$ | 2 h | No reaction |  |
| $\mathrm{BF}_{3} \mathrm{OEt}_{2}(1.3 \mathrm{eq})$ | 1.3 eq | DCM | $-45^{\circ} \mathrm{C}$ | 3 h | No reaction |  |
| $\mathrm{BF}_{3} \mathrm{OEt}_{2}(1.3 \mathrm{eq})$ | 1.3 eq | DCM | $-30^{\circ} \mathrm{C}$ | 24 h | No reaction |  |
| $\mathrm{BF}_{3} \mathrm{OEt}_{2}(1.3 \mathrm{eq})$ | 1.3 eq | DCM | $-20^{\circ} \mathrm{C}$ | 20 h | Complex mixture | reaction |
| tris(pentafluorophe nyl)borane | 1.3 eq | DCM | $-78{ }^{\circ} \mathrm{C}$ | 3 h | No reaction |  |
| tris(pentafluorophe nyl)borane | 1.3 eq | DCM | $-30^{\circ} \mathrm{C}$ | 12 h | No reaction |  |
| tris(pentafluorophe nyl)borane | 1.3 eq | DCM | $-20^{\circ} \mathrm{C} \rightarrow 0^{\circ} \mathrm{C}$ | 8 h | Complex mixture | reaction |

Table 24: Attempted cyclization of 193 with benzhaldehyde using different Lewis acids
Using $\mathrm{SnCl}_{4}$, the only product recovered from the complex reaction mixture was $\mathbf{2 0 1}$ (Scheme 81). This product presumably derives from an initial $\mathrm{Si}-\mathrm{Sn}$ exchange. ${ }^{175}$ The allylstannane 198 undergoes an internal rearrangement, providing 199. This latter reacts with benzaldehyde providing 200 and the alkoxide is trapped by silylchloride, giving 201.

Scheme 81: Proposed mechanism for the formation of 201
We then turned our attention to the reaction with chlorosulphonyl isocyanate (CSI). This reaction between an allylsilane and CSI can give two possible products: the lactam 204, if annulation occurred across the $\mathrm{C}=\mathrm{N}$ bond of CSI , and the lactone 206 if cyclization occurred across the $\mathrm{C}=\mathrm{O}$ bond (Scheme 82). Woerpel and co-workers proposed that electrophilic attack by CSI occurs antiperiplanar to the silyl group of allylsilane leading to $\beta$-silyl carbocation 202. ${ }^{173}$ A subsequent 1,2 -silyl migration occurs providing intermediate 203, that cyclises anti to the silyl group to give 4,5-trans-204 or 205. According to Woerpel and co-workers, ${ }^{176}$ the steric size of the $\alpha$-substituent of the allylsilane exerts a strong influence on the annulations. The steric interaction between the $\alpha$-substituent $\mathrm{R}_{2}$ and the $\mathrm{NSO}_{2} \mathrm{Cl}$ group disfavours the $N$-cyclization intermediate 203b. However, intermediate 203b is favoured by repulsion between $\mathrm{NSO}_{2} \mathrm{Cl}$ and $\mathrm{R}_{1}$. On the other hand, $O$-cyclization intermediate 203a is favoured by steric repulsion between the $\alpha$-substituent $\mathrm{R}_{2}$ and the $\mathrm{NSO}_{2} \mathrm{Cl}$ group but disfavoured by interaction of $\mathrm{NSO}_{2} \mathrm{Cl}$ and $\mathrm{R}_{1}$. Therefore an allyl silane with a large $\mathrm{R}_{2}$ group and a small $\mathrm{R}_{1}$ group prefers the $O$-cyclization pathway, leading to lactone precursor 205. In contrast, an allylsilane with a small $\mathrm{R}_{2}$ group and a large $\mathrm{R}_{1}$ group favours the $N$-cyclization pathway, to provide the lactam 204.

Scheme 82: Proposed mechanism of annulation and origin of the competion between $\mathrm{C}=\mathrm{N}$ and $\mathrm{C}=\mathrm{O}$ annulations ${ }^{176}$

On the basis of this consideration, we reacted allylsilane 193 with CSI, expecting the lactone $\mathbf{2 0 8}$ as the main product. Instead, a mixture of lactam 207 and lactone 208 were formed. However, although different reaction conditions were tested ${ }^{176,177}$ it was not possible to direct the reaction towards just one of the two products (Table 25). In all the reactions, the crude weight was less than the theoretical yield, suggesting that protodesilylation may have occurred in the reaction.

Table 25: Attempted cyclization with CSI

At this point, my stay in Bristol ended. Due to the highly challenging nature of the cyclisation reactions investigated, no further work was carried out on this project.

## 7 CONCLUSION

In summary, a simple method to obtain tertiary allyl- or crotyl silanes in excellent e.r and $d . r$ was developed. This involved the extension of the lithiation borylation reaction developed within the Aggarwal group through reaction of primary lithiated alkyl carbamates with silaboronate $\mathbf{1 6 4}$ (Scheme 83). Zweifel olefination of the intermediate secondary silaboronate led to allyl and crotyl silanes. It was found necessary to derivatise the allyl silanes using either hydroboration/oxidation or Fleming-Tamao oxidation to obtain material which could be analysed by chiral HPLC.

Scheme 83: Synthesis of tertiary allyl- and crotylsilanes through lithiation/borylation/Zweifel olefination

Using a related strategy, a unique reaction sequence that leads to quaternary allylsilanes in similarly high e.r. was developed. This involved reaction of lithiated silacarbamate 183a,b with alkyl boronic esters to give tertiary boronic esters (Scheme 84). Zweifel olefination led to quaternary allylsilanes in excellent e.r. and yield.

Scheme 84: Synthesis of quaternary allylsilanes through lithiation/borylation/Zweifel olefination

Attempts to react quaternary allyl silane $\mathbf{1 9 3}$ with aldehydes in the presence of a Lewis acid were unsuccessful. The allyl silane 193 did react with CSI, however, to give a mixture of lactam and lactone products.

Scheme 85: Attempted cyclization with benzaldehyde and with CSI

## 8 EXPERIMENTAL

### 8.1 General information

All reactions were carried out in oven-dried $\left(180{ }^{\circ} \mathrm{C}\right)$ glassware and under an Ar atmosphere using standard Schlenk techniques. Anhydrous solvents were prepared using anhydrous solvent drying columns. ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}-\mathrm{NMR}$ spectra were acquired at various field strengths as indicated, and were referenced to $\mathrm{CHCl}_{3}$ or TMS. ${ }^{11}$ B NMR spectra were recorded with complete proton decoupling using $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}$ as an external standard. Low- and high-resolution mass spectra were recorded using Electron Impact (EI), Chemical Ionization (CI) or Electron-Spray Ionization (ESI) techniques. For CI, methane or $\mathrm{NH}_{4} \mathrm{OAc} / \mathrm{MeOH}$ were used. Analytical TLC: aluminium backed plates precoated ( 0.25 mm ) with silica gel 60 F 254 . Compounds were visualized by exposure to UV-light or by staining with $5 \%$ solution of $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Mo}_{7} \mathrm{O}_{24} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ in EtOH followed by heating. Flash chromatography was carried out using Merck silica gel 60, 0.040-0.063 mm particle size. Melting points were determined with a Boetius hot stage apparatus and were not corrected. All IR data were obtained on a Perkin-Elmer Spectrum One FTIR spectrometer. $N, N, N^{\prime}, N^{\prime}$-Tetramethylethylenediamine (TMEDA) was purchased from Aldrich and (-)-sparteine was purchased from Alfa Aesar or Aldrich. Both were distilled under reduced pressure over $\mathrm{CaH}_{2}$ prior to use. Anhydrous methanol was purchased from Acros and used without further purification. $s$ BuLi was purchased from Acros or Aldrich.

## 8.2 (R)-Dimethyl(phenyl)(3-phenyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)propyl)silane 166a

Phenylpropyldiisopropylcarbamate 128a ( $0.50 \mathrm{~mL}, 1.89 \mathrm{mmol}$ ) and (-)-sparteine ( $0.45 \mathrm{~mL}, 1.89 \mathrm{mmol}$ ) were dissolved in diethyl ether ( 8 mL ) and cooled to $-78{ }^{\circ} \mathrm{C}$. $s$ BuLi ( $1.4 \mathrm{~mL}, 1.3 \mathrm{M}$ solution in cyclohexane $/$ hexane ( $92: 8$ ), 1.89 mmol ) was added dropwise and the mixture was stirred at $-78{ }^{\circ} \mathrm{C}$ for 5 hours. Silylboronic ester $\mathbf{1 6 4}$ ( $0.35 \mathrm{~mL}, 1.32 \mathrm{mmol}$ ) was added dropwise and the resulting mixture was stirred at $78^{\circ} \mathrm{C}$ for 1 hour, allowed to warm to $23^{\circ} \mathrm{C}$ and stirred for an additional 18 hours. Water was added, the phases were separated, the aqueous phase was extracted three times with diethyl ether and the combined organic phases were washed with brine, dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, filtered and concentrated. Column chromatography (silica gel, $5 \%$ diethyl ether in petroleum ether) gave boronic ester 166a ( $344 \mathrm{mg}, 69 \%$ ) as a colourless oil. The racemate was obtained with TMEDA instead of $(-)$-sparteine.
$R_{\mathrm{f}}\left(5 \%\right.$ diethyl ether in petroleum ether): $0.2 ;[\alpha]_{\mathrm{D}}^{23}=+24.0\left(c=1.0, \mathrm{CH}_{3} \mathrm{Cl}\right) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 500 \mathrm{MHz}\right): \delta[\mathrm{ppm}] 7.51-7.10(\mathrm{~m}, 10 \mathrm{H}), 2.70(\mathrm{ddd}, J=13.4,9.7,5.0 \mathrm{~Hz}, 1 \mathrm{H})$, 2.46 (ddd, $J=13.4,9.7,6.8 \mathrm{~Hz}, 1 \mathrm{H}), 1.89$ (dddd, $J=13.1,12.0,9.7,5.0 \mathrm{~Hz}, 1 \mathrm{H}), 1.64$ (dddd, $J=13.1,9.7,6.8,2.9 \mathrm{~Hz}, 1 \mathrm{H}), 1.23(\mathrm{~s}, 6 \mathrm{H}), 1.20(\mathrm{~s}, 6 \mathrm{H}), 0.71$ (dd, $J=12.0$, $2.9 \mathrm{~Hz}, 1 \mathrm{H}), 0.32(\mathrm{~s}, 3 \mathrm{H}), 0.31(3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $\left.\mathrm{CDCl}_{3}, 126 \mathrm{MHz}\right): \delta[\mathrm{ppm}]=142.6$, $138.8,133.8,128.8,128.5,128.2,127.6,125.6,82.8,39.4,28.0,25.2,24.7,-2.3,-3.4$; ${ }^{11} \mathrm{~B}\left(\mathrm{CDCl}_{3}, 96 \mathrm{MHz}\right) \delta[\mathrm{ppm}]=33.7$; HRMS (ESI): calculated for $\mathrm{C}_{23} \mathrm{H}_{33} \mathrm{BO}_{2} \mathrm{Si}$ $\left([\mathrm{M}+\mathrm{Na}]^{+}\right): \mathrm{m} / \mathrm{z}=403.2235$, found: $\mathrm{m} / \mathrm{z}=403.2224$; $\mathrm{MS}(\mathrm{ESI}): \mathrm{m} / \mathrm{z}=221.1,303.2$, 373.2, 403.2; IR ( $\widetilde{v} / \mathrm{cm}^{-1}$, neat): 3026, 2977, 2927, 2858, 1350, 1306, 1248, 1143, 1111.

## 8.3 (R)-Dimethyl(2-methyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)propyl)(phenyl)silane 166b

Isobutyl diisopropylcarbamate $\mathbf{1 2 8 b}(1.41 \mathrm{~g}, 2.03 \mathrm{mmol})$ and (-)-sparteine ( 0.46 mL , $2.03 \mathrm{mmol})$ were dissolved in diethyl ether $(30 \mathrm{~mL})$ and cooled to at $-78^{\circ} \mathrm{C} . s \mathrm{BuLi}$ ( $1.56 \mathrm{~mL}, 1.3 \mathrm{M}$ solution in cyclohexane/hexane ( $92: 8$ ), 2.03 mmol ) was added dropwise and the mixture was stirred at $-78^{\circ} \mathrm{C}$ for 5 h . Boronic ester $164(0.45 \mathrm{~mL}$, 1.57 mmol ) was added dropwise and the resulting mixture was stirred at $-78{ }^{\circ} \mathrm{C}$ for 1 hour, allowed to warm to $23^{\circ} \mathrm{C}$ and stirred for an additional 18 hours. Water was added, the phases were separated and the aqueous phase was extracted three times with diethyl ether. The combined organic phases were washed with brine, dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated. Column chromatography (silica gel, $4 \%$ diethyl ether in pentane) gave boronic ester $\mathbf{1 6 6 b}(339 \mathrm{mg}, 68 \%)$ as a colourless oil. The racemate was obtained with TMEDA instead of $(-)$-sparteine.
$R_{\mathrm{f}}$ (4 \% diethyl ether in pentane): $0.4 ;[\alpha]_{\mathrm{D}}^{23}-5.0\left(\mathrm{c}=0.63, \mathrm{CHCl}_{3}\right) ;{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right.$, $400 \mathrm{MHz}) \delta[\mathrm{ppm}]=7.57-7.32(\mathrm{~m}, 5 \mathrm{H}), 1.91(\mathrm{dqq}, J=7.8,6.7,6.6 \mathrm{~Hz}, 1 \mathrm{H}), 1.20(\mathrm{~s}, 6$ H), $1.15(\mathrm{~s}, 6 \mathrm{H}), 0.99(\mathrm{~d}, J=6.7 \mathrm{~Hz}, 3 \mathrm{H}), 0.89(\mathrm{~d}, J=6.7 \mathrm{~Hz}, 3 \mathrm{H}), 0.66(\mathrm{~d}, J=7.8$ $\mathrm{Hz}, 1 \mathrm{H}), 0.36(\mathrm{~s}, 3 \mathrm{H}), 0.34(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $\left.\mathrm{CDCl}_{3}, 101 \mathrm{MHz}\right): \delta[\mathrm{ppm}]=140.0$, 133.9, 128.5, 127.5, 82.6, 27.0, 26.4, 25.2, 24.9, 24.8, $\left.-1.3,-1.5 ;{ }^{11} \mathrm{~B}^{( } \mathrm{CDCl}_{3}, 96 \mathrm{MHz}\right)$ : $\delta[\mathrm{ppm}]=32.6$; HRMS $(\mathrm{CI}):$ calculated for $\mathrm{C}_{18} \mathrm{H}_{31} \mathrm{BO}_{2} \mathrm{Si}\left([\mathrm{M}+\mathrm{H}]^{+}\right): 319.2265$, Found: 319.2257; MS (CI): $m / z=303.3$ (85), 241.3 (100), 157.1 (80); MS (CI): $\mathrm{m} / \mathrm{z}=157.1$, 241.3, 303.3; $\operatorname{IR}\left(\tilde{v} / \mathrm{cm}^{-1}\right.$, neat): 2977, 1304, 1247, 1142, 1110, 836, 815.

## 8.4 (S)-Dimethyl(phenyl)(5-phenylpent-1-en-3-yl)silane 172a

Vinylmagnesium bromide ( 2.1 mL of 1 M solution in tetrahydrofuran, 2.1 mmol ) was added dropwise to a stirred solution of boronic ester $166 \mathbf{a}(0.19 \mathrm{~g}, 0.5 \mathrm{mmol})$ in tetrahydrofuran $(4 \mathrm{~mL})$ at $-78^{\circ} \mathrm{C}$. The reaction mixture was stirred for 30 minutes at $-78{ }^{\circ} \mathrm{C}$, and then a solution of iodine $(0.54 \mathrm{~g}, 2.1 \mathrm{mmol})$ in methanol ( 4 mL ) was added dropwise. The mixture was stirred for a further 30 minutes, and then allowed to warm to $0^{\circ} \mathrm{C}$. Sodium thiosulfate ( 15 mL of $5 \%$ aqueous solution) was added, and the solvents were removed from the reaction mixture in vacuo. The mixture was then extracted with diethyl ether ( $3 \times 20 \mathrm{~mL}$ ) and the combined organic phases were washed with brine ( 60 $\mathrm{mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. The crude product was purified by flash chromatography ( $100 \%$ petroleum ether)) to give allylsilane 172a $(0.114 \mathrm{~g}, 81 \%$ ) as a colourless oil.

## 8.5 (S)-Dimethyl(4-methylpent-1-en-3-yl)(phenyl)silane 172b

$n \mathrm{BuLi}(1.35 \mathrm{ml}, 1.6 \mathrm{M}$ in hexanes, 2.12 mmol ) was added dropwise to tetravinyltin $(0.20 \mathrm{ml}, 1.07 \mathrm{mmol})$ at $23^{\circ} \mathrm{C}$. The mixture was stirred for 30 minutes during which white vinyllithium precipitated. The hexane was removed carefully by syringe, the solid was washed three times with hexane, dissolved in tetrahydrofuran $(0.5 \mathrm{~mL})$ and cooled to $-78{ }^{\circ} \mathrm{C}$. Then a solution of $\mathbf{1 6 6 b}(170 \mathrm{mg}, 0.53 \mathrm{mmol})$ in tetrahydrofuran $(4 \mathrm{~mL})$ was added dropwise and the reaction mixture was stirred for one hour. Iodine ( $538 \mathrm{mg}, 2.12$ mmol ) in methanol ( 5 mL ) was added dropwise, the reaction mixture was stirred for an additional 30 minutes at $-78{ }^{\circ} \mathrm{C}$ and then warmed to $0{ }^{\circ} \mathrm{C}$. The reaction was quenched by the dropwise addition of a $5 \%$ aqueous solution of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ until the solution became colourless. The solvent mixture was removed in vacuo and the resulting residue was dissolved in ethyl ether. Water was added, the phases were separated and the aqueous layer was extracted three times with diethyl ether. The combined organic layers were washed with brine, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. The crude product was purified by flash chromatography ( $100 \%$ petroleum ether) to give $\mathbf{1 7 2 b}$ ( 69 mg , $60 \%$ ) as a colourless oil.

### 8.10(1S)-3-Phenyl-1-(trimethylsilyl)propyl diisopropylcarbamate

## 183a

3-Phenylpropyl diisopropylcarbamate $\mathbf{1 2 8 a}(1.16 \mathrm{~g}, 4.4 \mathrm{mmol})$ and (-)-sparteine ( 1.31 $\mathrm{mL}, 5.72 \mathrm{mmol})$ were dissolved in diethyl ether ( 25 mL ) and the solution was cooled to $-78{ }^{\circ} \mathrm{C}$. sBuLi ( $4.4 \mathrm{~mL}, 5.72 \mathrm{mmol}, 1.3 \mathrm{M}$ in cyclohexane) was added dropwise and the reaction mixture was stirred for 5 h at $-78{ }^{\circ} \mathrm{C}$ before $\mathrm{TMSCl}(0.73 \mathrm{~mL}, 5.72 \mathrm{mmol})$ was added dropwise. The mixture was allowed to warm to room temperature, stirred overnight and water ( 20 mL ) was added. The layers were separated and the aqueous layer was extracted with diethyl ether ( $3 \times 20 \mathrm{~mL}$ ). The combined organic layers were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. The crude product was purified by flash chromatography (silica gel, $5 \%$ ethyl acetate in petroleum ether) to give $\mathbf{1 8 3 a}$ ( 1.12 g , $76 \%$ ) as a colourless oil. The racemate was obtained with TMEDA instead of (-)sparteine.
$R_{\mathrm{f}}=0.7(10 \%$ diethyl ether in pentane $) ;[\alpha]_{D}^{25}=-5\left(\mathrm{c}=1.0, \mathrm{CHCl}_{3}\right) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right.$, $400 \mathrm{MHz}): \delta[\mathrm{ppm}]=7.30-7.26(\mathrm{~m}, 2 \mathrm{H}) ; 7.19-7.16(\mathrm{~m}, 3 \mathrm{H}) ; 4.80(\mathrm{dd}, J=10.8,3.5$ $\mathrm{Hz}, 1 \mathrm{H}$ ); 4.16 (br s, 1 H ); 3.76 (br s, 1 H ), 2.75 (ddd, $J=13.6,11.3,4.8 \mathrm{~Hz}, 1 \mathrm{H}$ ); 2.61 (ddd, $J=13.6,10.8,5.9 \mathrm{~Hz}, 1 \mathrm{H}) ; 2.01-1.80(\mathrm{~m}, 2 \mathrm{H}), 1.25$ (br s, 12 H ), 0.07 (s, 9 H ); ${ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}, 100 \mathrm{MHz}\right): \delta[\mathrm{ppm}]: 156.3,142.4,128.3,125.7,68.5,46.5,44.9$, 33.9, 33.8, 21.8, 20.6, -3.3 ; HRMS (CI, $\mathrm{C}_{19} \mathrm{H}_{34} \mathrm{NO}_{2} \mathrm{Si}$ ): calculated: $\mathrm{m} / \mathrm{z}=336.2359$ $(\mathrm{M}-\mathrm{H})^{+}$, Found: 336.2347; MS (CI): m/z = 336 (64), 320 (97), 292 (70), 244 (22), 218 (59), 202 (83), 191 (21), 146 (86), 128 (44), 93 (25), 86 (26), 73 (100); IR ( $\tilde{v} / \mathrm{cm}^{-1}$, neat): 2965, 1682, 1430, 1331, 1298, 1281, 1248, 1219, 1157, 1132, 1048, 1034, 871, 745, 697; The enantiomeric purity was determined by HPLC analysis (Daicel Chiralpak IB column; hexane: $\mathrm{iPrOH}=99.5: 0.5,0.3 \mathrm{~mL} / \mathrm{min} ; \mathrm{t}^{1}=16.2 \mathrm{~min}($ minor $), \mathrm{t}^{2}=18.1 \mathrm{~min}$ (major): er $>$ 99:1. ### 8.13Dimethyl[(1S)-1-methyl-3-phenyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)-propyl]phenylsilane 185b

(1S)-1-[Dimethyl(phenyl)silyl]-3-phenylpropyl diisopropylcarbamate 183b (996 mg, $2.0 \mathrm{mmol})$ and TMEDA ( $0.42 \mathrm{~mL}, 2.8 \mathrm{mmol}$ ) were dissolved in diethyl ether ( 10 mL ) and cooled to $-78{ }^{\circ} \mathrm{C}$. $s \mathrm{BuLi}$ ( 1.3 M in cyclohexane, $2.1 \mathrm{~mL}, 2.8 \mathrm{mmol}$ ) was added dropwise and the mixture was stirred for 5 hours at $-78{ }^{\circ} \mathrm{C}$. MeBpin ( $398 \mathrm{mg}, 2.8$ mmol ) was added dropwise and the reaction mixture was stirred for 1 hour at $-78{ }^{\circ} \mathrm{C}$, allowed to warm to $23^{\circ} \mathrm{C}$, and stirred for an additional hour. Then magnesium bromide diethyl etherate (prepared by stirring 144 mg magnesium and 0.34 mL dibromoethane in 10 mL diethyl ether for 4 hours) was added dropwise and the reaction mixture was stirred overnight. Saturated ammonium chloride was added, the phases were separated and the aqueous phase was extracted with diethyl ether $(3 \times 50 \mathrm{~mL})$. The combined organic phases were washed with brine, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo.

Flash column chromatography (silica gel, $10 \%$ ethyl acetate in pentane) gave boronic ester $\mathbf{1 8 5 b}$ ( $410 \mathrm{mg}, 52 \%$ ) as a colourless oil.

### 8.15(1S)-1-Ethyl-1-(2-phenylethyl)prop-2-en-1yl](trimethyl)silane 186a

Boronic ester 185a ( $50 \mathrm{mg}, 0.14 \mathrm{mmol}$ ) was dissolved in tetrahydrofuran ( 1 mL ) and cooled to $0{ }^{\circ} \mathrm{C}$. A freshly made solution of vinyllithium (see below) was added dropwise. After stirring for 30 minutes at $0^{\circ} \mathrm{C}$, a solution of $\mathrm{I}_{2}(179 \mathrm{mg}, 0.70 \mathrm{mmol})$ in methanol ( 6 mL ) was added dropwise over 10 minutes. The mixture was then allowed stirred at $0{ }^{\circ} \mathrm{C}$ for 20 min before a $5 \%$ aqueous solution of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ was added until the red colour disappeared. The reaction mixture was concentrated in vacuo and the residue was taken up into diethyl ether $(25 \mathrm{~mL})$ and washed with $\mathrm{H}_{2} \mathrm{O}(3 \times 10 \mathrm{~mL})$. The organic layer was dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. The crude product was purified by flash chromatography (silica gel, $100 \%$ petroleum ether) to give $\mathbf{1 8 6 a}(25 \mathrm{mg}, 73 \%$ ) as a yellow oil.

Preparation of vinyllithium solution: $n \mathrm{BuLi}(1.6 \mathrm{~m}$ in hexane, $350 \mu \mathrm{~L}, 0.56 \mathrm{mmol}$ ) was added dropwise at room temperature to tetravinyltin ( $51 \mu \mathrm{~L}, 0.28 \mathrm{mmol}$ ). After stirring
for 30 minutes, the liquid was removed and the white solid was dissolved in tetrahydrofuran.
$R_{\mathrm{f}}=0.6(100 \%$ pentane $) ;[\alpha]_{D}^{25}=-28\left(\mathrm{c}=1.0, \mathrm{CHCl}_{3}\right) ;{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}, 400 \mathrm{MHz}\right) \delta$ $[\mathrm{ppm}]=7.32-7.28(\mathrm{~m}, 2 \mathrm{H}), 7.21-7.17(\mathrm{~m}, 3 \mathrm{H}), 5.81(\mathrm{dd}, J=17.6,11.0 \mathrm{~Hz}, 1 \mathrm{H}), 5.02$ (dd, $J=11.0,1.5 \mathrm{~Hz}, 1 \mathrm{H}), 4.80(\mathrm{dd}, J=17.6,1.5 \mathrm{~Hz}, 1 \mathrm{H}), 2.55-2.51(\mathrm{~m}, 2 \mathrm{H}), 1.92-$ $1.84(\mathrm{~m}, 1 \mathrm{H}), 1.80-1.57(\mathrm{~m}, 3 \mathrm{H}), 0.95(\mathrm{t}, J=7.5 \mathrm{~Hz}, 3 \mathrm{H}), 0.02(\mathrm{~s}, 9 \mathrm{H}),{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}, 100 \mathrm{MHz}\right): \delta[\mathrm{ppm}]=144.9,143.6,128.4,128.3,125.6,110.8,34.2,30.8,24.2$, 9.2, -2.9 ; HRMS (CI, $\left.\mathrm{C}_{16} \mathrm{H}_{26} \mathrm{Si}\right)$ : $246.1804\left(\mathrm{M}^{+}\right)$, found: 246.1807; MS $\left(\mathrm{CI}, \mathrm{C}_{16} \mathrm{H}_{26} \mathrm{Si}\right)$ : 246 (7), 231 (48), 173 (5), 155 (26), 191 (6), 73 (100); IR ( $\widetilde{v} / \mathrm{cm}^{-1}$, neat): 3083, 3027, 2962, 2863, 1619, 1454, 1247, 895, 749, 699; The enantiomeric purity was determined by HPLC analysis of the alcohol, obtained by hydroboration of the olefin with 9-BBN, followed by oxidation with $\mathrm{H}_{2} \mathrm{O}_{2}$. Daicel Chiralpak IB column, hexane: $i \mathrm{PrOH}=95: 5$; $0.7 \mathrm{ml} / \mathrm{min}, \mathrm{t}_{1}=13.9 \mathrm{~min}$ (minor), $\mathrm{t}_{2}=15.8 \mathrm{~min}$ (major): $e r=98: 2$.

### 8.16Dimethyl[(1S)-1-methyl-1-(2-phenylethyl)prop-2-en-1yl]phenylsilane 186b

Boronic ester 185b ( $34 \mathrm{mg}, 0.09 \mathrm{mmol}$ ) was dissolved in tetrahydrofuran ( 1 mL ) and cooled to $0{ }^{\circ} \mathrm{C}$. A freshly made solution of vinyllithium (see above) was added dropwise. After stirring for 30 minutes the mixture, a solution of $\mathrm{I}_{2}(140 \mathrm{mg}, 0.54$ mmol ) in methanol ( 3 mL ) was added dropwise over 10 minutes. The mixture was stirred for an additional 20 min before $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ ( $5 \%$ in water) was added dropwise until the red colour disappeared. The reaction mixture was concentrated in vacuo and the residue was taken up into water ( 5 mL ) and extracted with diethyl ether $(3 \times 25 \mathrm{~mL})$. The combined organic layer was washed with brine, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. The crude product was purified by flash chromatography (silica gel, $100 \%$ pentane) to give $\mathbf{1 8 6 b}$ ( $19 \mathrm{mg}, 73 \%$ ) as a colourless oil.

### 8.17(1S)-1-Ethyl-1-(2-phenylethyl)prop-2-en-1yl](dimethyl)phenyIsilane 186c

Boronic ester $\mathbf{1 8 5}$ ( $100 \mathrm{mg}, 0.24 \mathrm{mmol}$ ) was dissolved in tetrahydrofuran ( 1 mL ) and cooled to $0{ }^{\circ} \mathrm{C}$. A freshly prepared solution of vinyllithium (see above) was added dropwise and after 30 minutes at $0^{\circ} \mathrm{C}$, a solution of $\mathrm{I}_{2}(305 \mathrm{mg}, 1.20 \mathrm{mmol})$ in methanol $(10 \mathrm{~mL})$ was added dropwise over 10 minutes. The mixture was then stirred at $0^{\circ} \mathrm{C}$ for 20 min before a $5 \%$ aqueous $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$-solution was added dropwise until the red colour disappeared. The reaction mixture was concentrated in vacuo and the residue was taken up with diethyl ether $(25 \mathrm{~mL})$, washed with $\mathrm{H}_{2} \mathrm{O}(3 \times 10 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. The crude product was purified by flash column chromatography (silica gel, $100 \%$ petroleum ether) to give the product ( $44 \mathrm{mg}, 60 \%$ ) as a yellow oil.

### 8.181-[Dimethyl(phenyl)silyl]ethyl diisopropylcarbamate 190

Ethyl disopropylcarbamate $\mathbf{1 8 9}(1.88 \mathrm{~mL}, 10.0 \mathrm{mmol})$ and TMEDA $(1.97 \mathrm{~mL}, 13.0$ mmol ) were dissolved in diethyl ether ( 50 mL ) and cooled to $-78{ }^{\circ} \mathrm{C} . s \operatorname{BuLi}(10.0 \mathrm{~mL}$, $13 \mathrm{mmol}, 1.3 \mathrm{~m}$ in hexane/cyclohexane) was added dropwise and the reaction mixture was stirred at $-78{ }^{\circ} \mathrm{C}$ for 5 hours. Then $\mathrm{PhMe} e_{2} \mathrm{SiCl}(2.85 \mathrm{~mL}, 17.0 \mathrm{mmol})$ was added dropwise and the mixture was allowed to warm to $23{ }^{\circ} \mathrm{C}$ overnight. After the addition of saturated aqueous ammonium chloride solution the phases were separated and the aqueous phase was extracted with diethyl ether $(3 \times 25 \mathrm{~mL})$. The combined organic layers were washed with brine, dried (magnesium sulfate) and concentrated in vacuo. Flash column chromatography (short silica plug, $100 \%$ pentane) gave carbamate 190 $(2.971 \mathrm{~g}, 91 \%)$ as a colourless oil.
The silane was dissolve in dry toluene and the solvent was removed in vacuo to remove traces of water. This process was repeated two times and then a 0.2 m solution in dry diethyl ether was prepared and stored over activated $4 \AA$ Á molecular sieves.
$R_{\mathrm{f}}=0.2\left(5 \%\right.$ ethyl acetate in pentane); $[\alpha]^{22}{ }_{\mathrm{D}}=-24\left(\mathrm{c}=3.2, \mathrm{CH}_{2} \mathrm{Cl}_{2}\right) ;{ }^{13} \mathrm{C}$ NMR (100 $\mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta[\mathrm{ppm}]=155.9,136.3,134.0,129.2,127.2,63.6,46.0$ (br), 45.1 (br), 21.1 (br), 16.3, -5.0, $-5.4 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta[\mathrm{ppm}]=7.56-7.50(\mathrm{~m}, 2 \mathrm{H})$, $7.38-7.50(\mathrm{~m}, 3 \mathrm{H}), 4.88(\mathrm{q}, J=7.4 \mathrm{~Hz}, 1 \mathrm{H}), 4.01$ (br, 1 H ), 3.72 (br, 1 H ), 1.24 (d, $J=7.4 \mathrm{~Hz}, 3 \mathrm{H}), 1.16(\mathrm{~d}, J=1.0 \mathrm{~Hz}, 6 \mathrm{H}), 1.14(\mathrm{~d}, J=1.0 \mathrm{~Hz}, 6 \mathrm{H}), 0.35(\mathrm{~s}, 3 \mathrm{H})$, $0.34(\mathrm{~s}, 3 \mathrm{H})$; HRMS ( $\mathrm{CI}, \mathrm{C}_{17} \mathrm{H}_{29} \mathrm{NO}_{2} \mathrm{Si}$ ): calc. $\left[\mathrm{M}+\mathrm{H}^{+}\right]: \mathrm{m} / \mathrm{z}=308.2046$, found: $\mathrm{m} / \mathrm{z}=308.2032 ; \mathrm{MS}\left(\mathrm{CI}, \mathrm{C}_{17} \mathrm{H}_{29} \mathrm{NO}_{2} \mathrm{Si}\right): 39.1$ (15), 128.1 (15), 220.1 (20), 230.2 (100), $292.2(30), 308.2(20) ; \operatorname{IR}\left(\widetilde{v} / \mathrm{cm}^{-1}\right.$, neat $)=2965,1683,1428,1288,1046,771,699$;

### 8.19[1,5-Dimethyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hex-4-en-1- yl](dimethyl)phenylsilane 192

A mixture of (1S)-1-[dimethyl(phenyl)silyl]ethyl diisopropylcarbamate ( 0.2 M in diethyl ether, $10 \mathrm{~mL}, 2.0 \mathrm{mmol}$ ) 190 and TMEDA ( $0.43 \mathrm{~mL}, 2.8 \mathrm{mmol}$ ) was cooled to $-78^{\circ} \mathrm{C}$, $s \operatorname{BuLi}(1.3 \mathrm{M}$ in cyclohexane, $2.15 \mathrm{~mL}, 2.8 \mathrm{mmol}$ ) was added dropwise and the mixture was stirred for 5 hours at $-78^{\circ} \mathrm{C}$. Boronic ester $191(1.0 \mathrm{M}$ in diethyl ether, $2.8 \mathrm{~mL}, 2.8$ mmol ) was added dropwise and 5 minutes after the end of the addition the reaction mixture was allowed to warm to $23^{\circ} \mathrm{C}$ and was stirred overnight. Water was added and the aqueous phase was extracted with diethyl ether $(3 \times 25 \mathrm{~mL})$. The combined organic layers were washed with brine, dried (magnesium sulfate) and concentrated in vacuo. Flash column chromatography (silica gel, $5 \%$ ethyl acetate in pentane) gave the title compound ( $610 \mathrm{mg}, 84 \%$ ) as a colourless oil.
$R_{\mathrm{f}}=0.4$ (5 \% ethyl acetate in pentane); ${ }^{11} \mathrm{~B}$ NMR ( $128 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta[\mathrm{ppm}]=35.0$; ${ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta[\mathrm{ppm}]=137.7(\mathrm{C}), 134.8(\mathrm{CH}), 130.9(\mathrm{CH}), 128.7$ $(\mathrm{CH}), 127.3(\mathrm{CH}), 125.3\left(\mathrm{Me}_{2} \mathrm{C}=\mathrm{CH}\right), 82.8(\mathrm{BOC}), 33.6\left(\mathrm{CH}_{2}\right), 26.1\left(\mathrm{CH}_{2}\right), 25.7\left(\mathrm{CH}_{3}\right)$, $25.2\left(\mathrm{CH}_{3}\right), 25.0\left(\mathrm{CH}_{3}\right), 17.6\left(\mathrm{CH}_{3}\right), 15.5\left(\mathrm{CH}_{3}\right),-4.5\left(\mathrm{CH}_{3}\right),-4.7\left(\mathrm{CH}_{3}\right) ;{ }^{1} \mathrm{H}$ NMR (400 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta[\mathrm{ppm}]=7.54-7.50(\mathrm{~m}, 2 \mathrm{H}, \mathrm{Ph}), 7.34-7.30(\mathrm{~m}, 3 \mathrm{H}, \mathrm{Ph}), 5.10-5.04(\mathrm{~m}$,

### 8.203,7-Dimethylocta-1,6-dien-3-yl)dimethyl(phenyl)silane 193

Tetravinyl tin ( $0.15 \mathrm{~mL}, 0.84 \mathrm{mmol}$ ) was cooled to $0^{\circ} \mathrm{C}$ and $n \mathrm{BuLi}(1.6 \mathrm{~m}$ in hexane, $1.05 \mathrm{~mL}, 1.68 \mathrm{mmol}$ ) was added dropwise. After 30 minutes the precipitating vinyl lithium was dissolved in tetrahydrofuran ( 1 mL ) and added dropwise to a solution of [(1R)-1,5-dimethyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hex-4-en-1-yl](dimethyl)phenylsilane $192(100 \mathrm{mg}, 0.28 \mathrm{mmol})$ in tetrahydrofuran $(2 \mathrm{~mL})$ at $0{ }^{\circ} \mathrm{C}$. After stirring for 40 minutes at $0{ }^{\circ} \mathrm{C}$, a solution of $\mathrm{I}_{2}(426 \mathrm{mg}, 1.68 \mathrm{mmol})$ in $\mathrm{MeOH}(4 \mathrm{~mL})$ was added dropwise over 10 minutes. The mixture was then allowed to stir at $0^{\circ} \mathrm{C}$ for 25 min and $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$-solution ( $5 \%$ in water) was added dropwise until the red colour disappeared. The organic solvents (hexane, tetrahydrofuran and methanol) were removed in vacuo and the concentrate was taken up into diethyl ether ( 25 mL ). The aqueous phase was extracted with diethyl ether ( $3 \times 25 \mathrm{~mL}$ ). The combined organic layers were washed with brine, dried (magnesium sulfate) and concentrated in vacuo. Flash column chromatography (silica gel, pentane) gave the title compound 63 mg , $93 \%$ ) as a colourless oil.
$R_{\mathrm{f}}=0.3(100 \%$ pentane $) ;{ }^{13} \mathrm{C}$ NMR ( $\left.100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta[\mathrm{ppm}]=144.4(\mathrm{CH}), 137.0$ (C), $134.8(\mathrm{CH}), 131.1(\mathrm{C}), 128.9(\mathrm{CH}), 127.3(\mathrm{CH}), 125.1\left(\mathrm{Me}_{2} \mathrm{C}=\mathrm{CH}\right), 110.9$ $\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{CH}\right), 35.4\left(\mathrm{CH}_{2}\right), 30.8(\mathrm{C}), 25.7\left(\mathrm{CH}_{3}\right), 22.2\left(\mathrm{CH}_{2}\right), 17.6\left(\mathrm{CH}_{3}\right), 16.9\left(\mathrm{CH}_{3}\right),-6.1$ $\left(2 \times \mathrm{CH}_{3}\right) ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta[\mathrm{ppm}]=7.51-7.46(\mathrm{~m}, 2 \mathrm{H}, \mathrm{Ph}), 7.38-7.30$ (m, $3 \mathrm{H}, \mathrm{Ph}$ ), 5.74 (dd, $\left.J=17.4,10.7 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{H}_{2} \mathrm{C}=\mathrm{C} H\right), 5.02$ (dd, $J=7.2,7.2 \mathrm{~Hz}, 1 \mathrm{H}$,

## ACKNOLEDGEMENT

Giunta alla fine di questi tre anni, desidero ringraziare le persone che mi hanno seguita più da vicino.

Innanzi tutto un grazie a Tina, per avermi guidata e sostenuta con pazienza, per avermi dato suggerimenti ma anche per essere stata aperta al dialogo e avermi lasciata libera di "sperimentare". Un grande grazie anche per avermi permesso di trascorrere sei mesi, davvero decisivi per la mia formazione, a Bristol, città che ora posso un po' considerare la mia seconda casa.

Grazie anche al Prof. Dalla Croce, per essere stato al mio fianco in laboratorio davvero fino all'ultimo secondo. Penso davvero che i "trucchetti" imparati nell'osservarla lavorare siano qualcosa di prezioso che porterò con me.

Grazie anche ai ragazzi con cui ho condiviso il laboratorio: Beppe, per avermi introdotto nel mondo della chimica organica pura, per i consigli e la PAZIENZA! Ciccio, per le risate e per aver reso davvero indimenticabili alcuni momenti trascorsi in labo. Enrica, con cui ho condiviso studio e labo in questo ultimo anno e mezzo, per tutte le chiacchierate, dalle reazioni che non venivano alle ricette di cucina! Grazie anche Giacomo e Marta. In particolare un grazie speciale a Marta per l'aiuto in questi ultimi due mesi e un in bocca la lupo per il proseguimento dello studio sulle immine: sono sicura che farai un ottimo lavoro!

Un grande grazie anche al Prof. Varinder Aggarwal, per avermi accolta nel suo gruppo e avermi dato la possibilità di ampliare le mie conoscenze nella chimica organica. E grazie anche a tutto il VKA group, persone davvero speciali, che hanno reso i miei sei mesi a Bristol davvero indimenticabili.

Questa tesi è dedicata a loro, ma desidero rivolgere un pensiero e un ringraziamento ai miei genitori e alla mia famiglia. Grazie per il sostegno in ogni mia decisione, davvero prezioso in ogni momento, specialmente in quelli più difficli.

A last big thank goes to Ben. We both "delivered our babies" this year and I think I couldn't be more lucky to have by my side someone who really understand what the all PhD process and writing up mean. I really want to thank you for having been so encouraging, for having motivated me not to give up, for having helped me face the reality being un po' more positive, showing that every problems can be solved. I really thank you for your love and support, that I can feel so close despite the Ocean or the English Channel between us.

[^0]:    ${ }^{\text {a }}$ This work was published in Org. Lett. 2011, 13, 1490 by Aggarwal, V. K.; Binanzer, M.; De Ceglie, M. C.; Gallanti, M.; Glasspoole, B. W.; Kendrick, S. J. F.; Sonawane, R. P.; Vazquez-Romero, A.; Webster, M. P. Therefore this section is the result of the work of several persons. To be complete I included it all, even if I focused my attention on the derivatization of the allylsilanes and on their cyclization
