### Abstract:

Limited data have been published on the epidemiology and outcomes of breakthrough COVID-19 in patients with hematological malignancy (HM) after anti-SARS-CoV-2 vaccination.

Adult HM who received at least one dose of anti-SARS-CoV-2 vaccine and diagnosed with breakthrough COVID-19 between January 2021 and March 2022 and registered in EPICOVIDEHA were included in this analysis.

A total of 1548 cases were included, mainly with lymphoid malignancies (1181 cases, 76%). After viral genome sequencing in 753 cases (49%), Omicron variant was prevalent (517, 68.7%). Most of the patients received at least two vaccine doses before COVID-19 (1419, 91%), mostly mRNA-based (1377, 89%). Overall, 906 patients (59%) received specific treatment for COVID-19. After 30-days follow-up from COVID-19 diagnosis, 143 patients (9%) died. The mortality rate in patients with Omicron variant was of 7.9%, comparable to that reported for the other variants. The 30-day mortality rate was significantly lower than in the pre-vaccine era (31%). In the univariable analysis, older age (p<0.001), active HM (p<0.001), severe and critical COVID-19 (p=0.007 and p<0.001, respectively) were associated with mortality. Conversely, patients receiving monoclonal antibodies, even for severe or critical COVID-19, had a lower mortality rate (p<0.001). In the multivariable model, older age, active disease, critical COVID-19 and at least 2-3 comorbidities were correlated with a higher mortality, whereas the administration of monoclonal antibodies, alone (p<0.001) or combined with antivirals (p=0.009), was observed protective.

While mortality is significantly lower than in the pre-vaccination era, breakthrough COVID-19 in HM is still associated with considerable mortality. Death rate was lower in patients who received monoclonal antibodies, alone or in combination with antivirals.

EPICOVIDEHA (www.clinicaltrials.gov; National Clinical Trials identifier NCT04733729) is an international open web-based registry for patients with HMs infected with SARS-CoV-2.

### Conflict of interest: No COI declared

COI notes: All the authors have no disclosures to declare for this submitted paper.

### Preprint server: No;

Author contributions and disclosures: LP served as the principal investigator. JSG and FM served as project manager and research assistant, respectively. LP, JSG, and FM contributed to study design, study supervision, and data interpretation and wrote the paper. AB, PC, MH, PK, AP, FP, AOC and LP conceived the registry idea. LP, JSG and FM did the statistical plan, analysis and interpreted the data. All the authors recruited participants and collected and interpreted data. All authors contributed to manuscript writing and review of the manuscript. All authors agreed to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

Non-author contributions and disclosures: Yes; Collaborators (to be listed in PubMed) Laura SERRANO, José-María RIBERA-SANTA SUSANA, Joseph MELETIADIS, Panagiotis TSIRIGOTIS, Nicola COPPOLA, Malgorzata MIKULSKA, Nurettin ERBEN, Caroline BESSON, Maria MERELLI, Tomás-José GONZÁLEZ-LÓPEZ, Jorge LOUREIRO-AMIGO, Carolina GARCÍA-VIDAL, Elizabeth DE KORT, Annarosa CUCCARO, Sofia ZOMPI, Florian REIZINE, Olimpia FINIZIO, Rémy DULÉRY, Maria CALBACHO, Ghaith ABU-ZEINAH, Sandra MALAK, Przemyslaw ZDZIARSKI, Gina VARRICHIO, Athanasios TRAGIANNIDIS, Gaëtan PLANTEFEVE, Rafael DUARTE, François DANION, Maria Chiara TISI, Ioanna SAKELLARI, Meinholf KARTHAUS, Ana GROH, Monica FUNG, Ziad EMARAH, Omar-Francisco CORONEL-AYALA, Louis Yi Ann CHAI, Mathias BREHON, Valentina BONUOMO, Dominik WOLF, Jana WITTIG, Maria VEHRESCHILD, Mario Virgilio PAPA, Julia NEUHANN, María-Josefa JIMÉNEZ-LORENZO, Jan GROTHE, Eleni GAVRIILAKI, Ramón GARCÍA-SANZ, Nicole GARCÍA-POUTÓN, Shaimaa Saber EL-ASHWAH, Matthias EGGERER, Raul CORDOBA, Gökçe Melis ÇOLAK, Elena ARELLANO

### Agreement to Share Publication-Related Data and Data Sharing Statement: na

**Clinical trial registration information (if any):** EPICOVIDEHA (www.clinicaltrials.gov; National Clinical Trials identifier NCT04733729) is an international open web-based registry for patients with HMs infected with SARS-CoV-2.

### 217 Key points

- Mortality rate in hematologic malignancy patients with breakthrough COVID-19 is about 9%,
- 219 lower than in the pre-vaccination era
- Patients who received monoclonal antibodies, alone or combined with antivirals, show a better clinical outcome

### 222 Abstract

Limited data have been published on the epidemiology and outcomes of breakthrough COVID-19 in patients with hematological malignancy (HM) after anti-SARS-CoV-2 vaccination.

Adult HM who received at least one dose of anti-SARS-CoV-2 vaccine and diagnosed with breakthrough COVID-19 between January 2021 and March 2022 and registered in EPICOVIDEHA were included in this analysis.

228 A total of 1548 cases were included, mainly with lymphoid malignancies (1181 cases, 76%). 229 After viral genome sequencing in 753 cases (49%), Omicron variant was prevalent (517, 68.7%). 230 Most of the patients received at least two vaccine doses before COVID-19 (1419, 91%), mostly 231 mRNA-based (1377, 89%). Overall, 906 patients (59%) received specific treatment for COVID-19. 232 After 30-days follow-up from COVID-19 diagnosis, 143 patients (9%) died. The mortality rate in 233 patients with Omicron variant was of 7.9%, comparable to that reported for the other variants. The 234 30-day mortality rate was significantly lower than in the pre-vaccine era (31%). In the univariable 235 analysis, older age (p<0.001), active HM (p<0.001), severe and critical COVID-19 (p=0.007 and 236 p<0.001, respectively) were associated with mortality. Conversely, patients receiving monoclonal 237 antibodies, even for severe or critical COVID-19, had a lower mortality rate (p<0.001). In the multivariable model, older age, active disease, critical COVID-19 and at least 2-3 comorbidities 238 239 were correlated with a higher mortality, whereas the administration of monoclonal antibodies, alone (p<0.001) or combined with antivirals (p=0.009), was observed protective. 240

While mortality is significantly lower than in the pre-vaccination era, breakthrough COVID-19 in HM is still associated with considerable mortality. Death rate was lower in patients who received monoclonal antibodies, alone or in combination with antivirals.

### 244 Introduction

Coronavirus disease 19 (COVID-19) is a life-threatening infection in patients with 245 246 hematologic malignancies (HM), associated with severe clinical presentation and high risk of death.<sup>1-3</sup> In April 2020, the European Hematology Association – Scientific Working Group 247 Infectious in Hematology (EHA-SWG) opened the EPICOVIDEHA registry to collect all adult 248 249 patients with HM that developed COVID-19. It aimed to describe the epidemiology, risk factors, and reported a mortality rate of 31.2% among 3801 patients.<sup>4</sup> In December 2020, nearly one year 250 251 after the first described COVID-19 case, vaccines against the severe acute respiratory syndrome 252 coronavirus 2 (SARS-CoV-2) were approved and became available first for high-risk patients, including HM.5-8 The recently published recommendations from the European Conference of 253 254 Infections in Leukemia (ECIL-9) identify the critical role of mRNA-based vaccines in the fight 255 against COVID-19 and recommend their use in HM, although they may have more limited efficacy amongst severely immunocompromised patients<sup>9</sup>. 256

257 We collected data on adult HMs who developed breakthrough COVID-19 to assess the 258 vaccine efficacy and the potential role of new emergent treatments against SARS-CoV-2. Our 259 preliminary data, regarding the first 113 patients included, showed a significant decrease in the 260 overall mortality rate in the post-vaccination era (12.4%), which was, however, still remarkably higher compared to the rate observed in the overall population.<sup>10</sup> To date, few reports have been 261 published about severity and outcomes of breakthrough COVID-19 in patients with cancer in 262 general<sup>11-12</sup> and HMs specifically,<sup>13</sup> all showing high rates of severe clinical presentation, 263 264 hospitalization and death among these patients. This suggests that HMs require close monitoring and increased medical attention when COVID-19 is diagnosed, regardless of previous anti-SARS-265 266 CoV-2 vaccine.

In this study, we analyzed the epidemiology and outcome of breakthrough COVID-19 in a
 large cohort of HMs and evaluated anti-SARS-CoV-2 treatment received by the patients.

- 269 Methods
- 270 Study design, patients, and procedures

From January 1<sup>st</sup>, 2021, until March 10<sup>th</sup>, 2022, participating institutions documented 271 272 episodes of COVID-19 in their HMs that received anti-SARS-CoV-2 vaccination. Our analysis 273 comprised data from the EPICOVIDEHA registry. EPICOVIDEHA (www.clinicaltrials.gov; National Clinical Trials identifier NCT04733729) is an international open web-based registry for patients with 274 HMs infected with SARS-CoV-2.<sup>14</sup> EPICOVIDEHA was approved by the local ethics committee of 275 276 the Fondazione Policlinico Universitario Agostino Gemelli - IRCCS, Università Cattolica del Sacro Cuore of Rome, Italy (Study ID: 3226). When applicable, the respective local ethics committee of 277 278 each participating institution have approved the project. EPICOVIDEHA methods have been 279 described elsewhere.<sup>4,14</sup> The electronic case report form (eCRF) is accessible online at www.clinicalsurveys.net (EFS Summer 2021, TIVIAN, Cologne, Germany). Each documented 280 281 patient was reviewed and validated by infectious diseases and hematology experts from the 282 coordination team. Inclusion criteria were: a) active HMs within the last five years before COVID-19 diagnosis, b) patients ≥18 years old, c) laboratory-based diagnosis of SARS-CoV-2 infection, and 283 284 d) last vaccine dose 15 or more days before PCR confirmed SARS-CoV-2 infection. Data on 285 baseline conditions pre-COVID-19 (i.e., age, sex, status of HM at COVID-19 diagnosis, factors 286 predisposing for COVID-19), HM clinical management (i.e., last HM treatment strategy, vaccine 287 type, spike protein concentration at diagnosis of COVID-19, COVID-19 diagnosis and management (i.e., reason for diagnostic test, symptoms at onset, stay during infection, treatments received for 288 289 infection) and outcome (i.e., mortality, attributable mortality [assessed by the medical team in 290 charge of the patient], last day of follow-up) were collected. Status of HM at COVID-19 onset and 291 last follow up was defined as active (onset and refractory/resistant), stable disease or controlled 292 (complete and partial response) based on the reports from the respective participating institution.

293 Study objectives

The primary objective of this study was to assess the epidemiology and the outcome of HMs affected by breakthrough COVID-19. Secondary objectives were: 1) to estimate the relative frequency of disease severity, graded according to international standards in our patient population;<sup>15-16</sup> 2) to evaluate the relative frequency of ICU admission among our patients; 3) to evaluate the overall case-fatality rate; 4) to explore the impact of cancer treatment phase (induction, consolidation, maintenance, palliative, re-induction); 5) to explore the impact of vaccine doses administered to patient outcomes; 6) to explore the impact of COVID-19 treatment on patient outcomes. Moreover, data collected were compared with those reported in our previously published study performed in the pre-vaccine era by using the same registry.<sup>4</sup>

### 303 Sample size and statistical analysis

304 No a priori sample size calculation was performed for this analysis. Categorical variables are 305 presented with frequencies and percentages, and continuous variables with median, interquartile 306 range (IQR) and absolute range. Univariable Cox regression model was performed with variables suspected to play a role in the mortality of HM patients with COVID-19. Variables with a p-value ≤ 307 308 0.1 were considered for multivariable analysis. A multivariable Cox regression model was calculated with the Wald backward method. Mortality was analyzed by using Kaplan-Meier survival 309 310 plots. Log-rank test was used to compare the survival probability of the patients included in the 311 different models. A p-value ≤ 0.05 was considered statistically significant. No a priori sample size 312 calculation was done for this exploratory study. SPSSv25.0 was employed for statistical analyses 313 (SPSS, IBM Corp., Chicago, IL, United States). Patients with missing data in essential fields (i.e. 314 HM, chemotherapeutic program, vaccination status, COVID-19 management or survival status) were considered as not valid and, then, excluded from the final analysis. Among the valid cases, if 315 316 a value in a specific variable was missing or unknown, it is indicated as such in the descriptive 317 analysis. Patients with missing data in a certain variable were excluded from regression analyses in case that variable was included into such analyses. 318

### 321 **Results**

### 322 Study population

323 A total of 94 centers in 26 countries, mainly from Europe, participated and registered 1583 324 cases. A list of enrolled cases from each participating country is available in the supplemental 325 material (Fig. S1 and Fig. S2 panel A). Out of these 1583 cases, 35 were excluded since COVID-326 19 was diagnosed within 14 days from the first vaccine dose. Clinical characteristics of 1548 327 evaluable cases are reported in Table 1. Lymphoid malignancies were the largest subgroup, 328 accounting 1181 cases (76.3%); the most frequently reported diagnosis was non-Hodgkin 329 lymphoma (NHL, 549 cases). Among myeloid malignancies, the most frequent diagnosis was acute myeloid leukemia (AML, 140 cases). We found a significantly different distribution 330 lymphoid/myeloid malignancies with that reported in pre-vaccination era (pre-vaccination lymphoid 331 332 malignancies cases: 67.3% vs post-vaccination: 76.3%, p<0.001). At the time of COVID-19 diagnosis, most patients had a controlled malignancy (n=821, 53%), 322 (20.8%) a stable disease 333 334 and the remaining 365 (23.6%) an active disease with 185 cases registered at HM onset. The most 335 frequently reported last HM treatment was immuno-chemotherapy or immunotherapy alone 336 (n=708, 42%), followed by targeted therapies (n=311, 20.1%) and conventional chemotherapy 337 (n=234, 15.1%); 92 patients (5.9%) had received HSCT within six months before COVID-19 338 (allogeneic: 76; autologous: 16) and 8 had chimeric antigen receptor T cells (CAR-T) therapy. Most 339 patients presented at least one comorbidity (60.7%) and 180 (11.6%) had a history of smoking; a 340 complete list of comorbidities and associated clinical outcomes is available in the supplemental 341 material (Table S1).

### 342 COVID-19 severity, variants and anti-SARS-CoV-2 spike proteins

COVID-19 was mild, severe, or critical in 39%, 32.9% and 9.8% of cases, respectively. Twohundred eighty-three patients (18.3%) were asymptomatic and in most of them the diagnosis was made in screening programs (Table 1). We found a significantly lower rate of severe or critical cases compared to that we reported in pre-vaccination era (pre-vaccination: 2425/3801, 63.8% *vs* post-vaccination: 661/1545, 42.7%; p<0.001). Overall, 823 (53.2%) patients required

hospitalization and amongst them 152 (18.1%) required admission to intensive care (ICU). The 348 349 hospitalization and ICU admission rate was significantly lower than reported in the pre-vaccination 350 era (53.2% vs 73%; p<0.001 and 9.8% vs 18.1%; p<0.001, respectively). The asymptomatic cases 351 percentage was of 18.3% (283/1548), similar to that reported in our previous publication with data from the pre-vaccine era (17.8%, 675/3801).<sup>4</sup> Viral genomes were studied in 753 cases (48.6%), 352 with the different Omicron variant as the most frequent viral strain (517/753, 68.7%). Most patients 353 354 received two or three anti-SARS-CoV-2 vaccine doses (91%), mostly with mRNA-based 355 technology (89%); only few patients (8.6%) received a vector-based vaccine and a minority of them an inactivated vaccine (Table 1, Fig. S2 panel B, C and D). Anti-SARS-CoV-2 spike protein IgG 356 levels were analyzed in 244 (15.8%) fully vaccinated patients, 2-4 weeks after the last vaccine 357 358 dose; among these patients, 109 (44.7%) presented an antibody response (optimal: 75, 30.7%; 359 weak: 34, 13.9%), whereas the remaining 135 (55.3%) were non-responders. Most patients who 360 did not have a serological response to vaccines were affected by lymphoid malignancies, as expected (126/135, 93.3%; Fig. 1). 361

### 362 COVID-19 treatments and risk factors for mortality

363 Overall, 906 patients (58.5%) received a specific treatment for COVID-19, whereas 642 364 (41.5%) were not treated, or received symptomatic therapies (non-steroidal anti-inflammatories, 365 painkillers, antipyretics). Among patients who received a specific treatment for COVID-19, 311 366 (34.3%) were treated with monoclonal antibodies only, 246 (27.1%) with corticosteroids only, 218 367 (24.1%) with antivirals only, 108 (11.9%) with antiviral plus monoclonal antibodies and the remaining 23 with convalescent plasma. Details on COVID-19 treatments and outcomes are 368 displayed in the supplemental material (Table S2). Overall day-30 mortality (i.e., from COVID-19 369 370 diagnosis) was 9.2% (143/1548 patients died); if we consider symptomatic patients only, the day-30 mortality rate was of 10.3% (130/1265 symptomatic patients died). The primary cause of death 371 372 was COVID-19 in 97 patients (67.8%), a combination of both, COVID-19 and progressive HM in 39 373 cases (27.2%) and HM alone or combined with other reasons in the remaining 7 patients (4.8%). 374 The mortality rate was significantly lower than that reported in pre-vaccine era (pre-vaccine 31.2%

vs post-vaccine 9.2%; p<0.001). Looking at two of the largest patient cohorts (i.e. chronic 375 376 lymphocytic leukemia, CLL and NHL) we evaluated the potential role of chemotherapeutic 377 treatment type on mortality rate. In CLL patients, we did not observe any significant difference in 378 terms of 30-days mortality rate among patients who had received immune-chemotherapy (13.4%), 379 immunotherapy alone (12.5%) or new targeted therapies (16.1%). On the contrary, in NHL we did observe a slightly higher mortality rate for patients recently treated with CAR-T (20%), compared to 380 381 those treated with immune-chemotherapy (8%), immunotherapy alone (14.3%) or targeted 382 therapies (9.5%). The outcome of patients according to clinical characteristics, vaccine received 383 and specific treatments against SARS-CoV-2 is detailed in Table 2. As shown in Fig. 2, we did not 384 find any significant difference in terms of 30-day mortality rate among the different HM (p=0.693). 385 in contrast to that observed in the pre-vaccination era in which we reported a higher number of 386 fatalities in acute myeloid leukemia/myelodysplastic syndrome patients. In univariable analysis, the 387 factors associated with a worse mortality rate were older age (p<0.001), active HM disease (p<0.001), and presence of 2-3 comorbidities (p<0.001) severe and critical COVID-19 (p=0.007 388 389 and p<0.001, respectively) (Table 3). Referring to the age, patients younger than 60 years showed 390 a more favorable outcome (30-days mortality rate: 2.6%), compared with patients aged 60-69 391 years (7%), 70-79 years (14.8%) and 80 years or more (19.6%) (p<0.001). Conversely, we observed a better clinical outcome for patients who received monoclonal antibodies (with or without 392 393 antivirals; Fig. 3). Analyzing the severity of COVID-19 presentation, a better clinical outcome was observed in patients treated with monoclonal antibodies alone for asymptomatic, mild, or severe 394 395 disease and with monoclonal antibodies combined with antivirals in critical cases (Fig. 4). We did not find differences in terms of outcome according to the number of vaccine doses received; 396 however, a slightly better clinical outcome was evident among patients who received three to four 397 398 doses versus one to two doses (p=0.040, Table 3). We did not observe differences in survival when sorting patients according to viral strain detected (p=0.664; Fig. 5), or post-vaccine anti-spike 399 400 IgG levels (Table 2).

In the multivariable model older age, active disease, critical COVID-19 and 2-3 comorbidities
 were the factors significantly correlated with a higher mortality, whereas receiving anti-SARS-CoV-

2 treatment with monoclonal antibodies alone or combined with antivirals was independently
associated with a lower mortality (HR: 0.155, 95%CI: 0.077-0.313; p<0.001 - HR: 0.407, 95%CI:</li>
0.206-0.803; p=0.010, respectively) (Table 3). Survival and severity according to vaccine doses
administration and post-vaccine anti-spike IgG levels are shown in Fig. 6 and Fig. 1, respectively.

### 407 **Discussion**

In the pre-vaccination era, several studies reported a high COVID-19 mortality in HM.<sup>1-4</sup> From December 2020, anti-SARS-CoV-2 vaccines have been administered in cancer patients, including those with HM.<sup>7-8</sup> Most published studies in HMs confirmed the efficacy and safety of vaccines, particularly those using mRNA, however, most showing less efficacy in patients with lymphoid malignancies treated with immunosuppressive drugs.<sup>17-22</sup>

413 The current study was performed in a large cohort of vaccinated HMs to evaluate 414 epidemiology, risk factors for adverse clinical outcome and treatments of breakthrough COVID-19. 415 We found a predominance of lymphoid malignancies, higher than observed in our previous survey during the pre-vaccine era; this difference might be explained by the lower efficacy of vaccines in 416 this patient population, as further suggested by the high rate of serological non-responders among 417 418 patients with lymphoid malignancies when evaluating anti-spike IgG levels These data are consistent with those in a recent report describing COVID-19 breakthrough infections in a large HM 419 patient cohort, mostly consisting of patients with lymphoid malignancies.<sup>13</sup> Advanced age, 420 presence of comorbidities and active HM were confirmed in the present study as factors that 421 negatively influenced clinical outcome and survival; these were the same risk factors that had 422 previously been reported in the pre-vaccination era.<sup>1-4</sup> Interestingly, in our study, the underlying 423 424 malignancy did not have a significant impact on survival, which was different from our previous experience in non-vaccinated patients, where AML and myelodysplastic syndrome were 425 associated with higher mortality risk.<sup>4</sup> A potential explanation for this difference might be the better 426 efficacy of anti-SARS-CoV-2 vaccines in myeloid malignancies,<sup>23-25</sup> than in lymphoid 427 malignancies;<sup>17-22</sup> however, we may hypothesize new specific anti-SARS CoV-2 drugs and better 428 429 COVID-19 management to be particularly important for patients with AML at risk of increased mortality if urgent chemotherapy is delayed. Similarly, as reported by other studies<sup>13</sup>, we did not 430 find any significant difference in terms of mortality among different treatments received for HM. As 431 432 expected, severe and critical COVID-19 had a worse clinical outcome than mild ones, showing a 433 strong correlation with an increased mortality rate both in univariable and multivariable analysis. 434 Given the vaccine protection, the occurrence of respiratory symptoms, hospitalization rate and 19

435 severe-critical clinical presentations were significantly lower than in the pre-vaccination era, even though still strongly higher compared to the overall population.<sup>26-29</sup> However, it is worth underlining 436 437 that about 20% of patients were asymptomatic and SARS-CoV-2 infection was detected in 438 screening programs. Interestingly, this percentage is analogous to that reported in our published study referring to the pre-vaccination era.<sup>4</sup> Unfortunately, it is not possible to estimate the true 439 incidence of breakthrough infections nor the true number of asymptomatic patients with our data as 440 441 only patients with COVID19 were included in the registry: we are of course aware this is a potential 442 selection bias, hypothetically hampering the reliability of our results. To the best of our knowledge, only few studies evaluated the incidence and cumulative COVID-19 risk among vaccinated cancer 443 patients, thus showing an increased risk in HM patients compared with the overall population.<sup>30-32</sup> 444 445 In particular, Lee and coworkers recently published a nice population-based test-negative case-446 control study in the United Kingdom, evaluating COVID-19 breakthrough infections among a huge 447 number of vaccinated cancer patients and healthy controls. The authors showed that the vaccine effectiveness at 3-6 months after the second dose was lower in the cancer cohort than in the 448 449 control population and among cancer patients was lower in HM patients, especially those affected 450 by leukemia and lymphoma. Very recently, an Italian study evaluated the immunogenicity and 451 clinical efficacy of anti-SARS-CoV-2 vaccine in HM patients on 365 patients. The authors showed an overall incidence of breakthrough infections of 2.98 per 10000 person-days, significantly lower 452 453 in post-vaccine seropositive patients, whereas a clear correlation between T-cellular immunity 454 response and risk of post-vaccine infection has not been found.<sup>33</sup>

In our study, we reported an overall 30-day-mortality rate of 9.2%, mainly driven by COVID-455 19 infection as a direct or contributing factor which is significantly lower than in the pre-vaccination 456 457 era.<sup>1-4</sup> Moreover, the 30-days mortality rate in symptomatic patients only was of 10.3%. The 458 success of vaccination strategies is likely a major factor in the reported improvement, but not the 459 only factor: a better COVID-19 management and the less severity of newer variants may have 460 played a significant role as well. Previous reports suggest that COVID19 management (e.g., steroids, etc.) have also impacted outcomes. Newer variants may be less severe. Data reported in 461 462 our study are coincident to other recently published reports that showed a significant mortality rate of COVID-19 breakthrough infections amongst cancer patients<sup>11-12</sup> or more specifically among
 those affected by HM.<sup>13</sup>

465 In our study, we collected data about viral genotyping in about half of patients; among those, the most prevalent variant was Omicron, accounting for more than 2/3 of patients. These data are 466 not surprising if we consider the large number of registered patients between late 2021 and early 467 2022, months in which the Omicron variant was rapidly spreading throughout Europe.<sup>34</sup> 468 Interestingly, we did not find any significant difference in terms of severity of clinical presentation 469 and mortality rate between Omicron and other variants, matching to other small recently published 470 471 reports on HMs,<sup>35-36</sup> but different to reports in immunocompetent patients in which Omicron presents with better outcome than other variants.<sup>34,37</sup> 472

473 The vast majority of patients enrolled in our study received two or three vaccine doses; 474 comparing clinical presentation and outcomes, we did not find consistent data supporting a better 475 clinical outcome for patients who had received a higher number of vaccine doses, even though a 476 slight difference in deaths proportion was observed comparing those who received 1-2 vs 3-4 477 doses. However, in multivariable analysis, the number of doses did not significantly impact on the overall 30-day-mortality. Several studies highlighted the role of a third vaccine dose as capable of 478 restoring the immune response in serologically less responsive HM patients.<sup>38-39</sup> However, there 479 480 are insufficient data to consider patients with low anti-spike antibody titers at high risk of worse 481 outcomes. Indeed, in our study we did not find any differences in terms of outcomes stratifying 482 patients according to serological response after 2-4 weeks from the last vaccine dose. By using World Health Organization international standards (BAU/mL), we did not find a significantly better 483 484 survival for patients with optimal response, compared to those with weak or no response, although 485 these data were only available in a small percentage of patients (16%). This lack of direct correlation between serological response and survival might be at least in part explained by the 486 putative role of anti-SARS-CoV-2 induced cellular immunity, as suggested by several studies, 23-24,40 487 since the presence of memory T-cells might control the infection and prevent severe COVID-19 488 even if high titers of long-lasting neutralizing antibodies are not elicited.<sup>41</sup> However, since a recently 489

490 published study did not find a clear correlation between post-vaccine T-cell immunity and vaccine clinical efficacy,<sup>33</sup> further studies are warrant to better understand this aspect. Another possible 491 492 explanation is related to the role of the specific anti-SARS-CoV-2 treatments (i.e. monoclonal 493 antibodies, antivirals) that could have partially balanced the lack of protection of serological non 494 responders. Indeed, from our survey, monoclonal antibodies with or without antivirals showed a high clinical activity irrespective of COVID-19 severity, showing the best efficacy when 495 496 administered as single agents in asymptomatic mild and severe patients, and when administered in 497 combination with antivirals in critical ones. The role of monoclonal antibodies in mitigating the negative impact of weak vaccine responses is supported by a recent randomized trial evaluating 498 their role in immunocompetent people without serological response.<sup>42</sup> Moreover, our multivariable 499 500 model confirmed the positive impact on 30-day mortality risk for patients who had received 501 monoclonal antibodies alone or combined with antivirals. We are aware that the present study has 502 limitations due to the retrospective observational design and the possible selection bias due to the 503 large number of participating institutions. Moreover, viral genotyping and serological data were not 504 available for all enrolled patients and we did not know whether COVID-19 was first diagnosed in 505 hospital or in the community, a potential key information for discriminating patient risk and infection 506 natural history. Further prospective studies better evaluating the role of vaccine response in HM 507 are needed.

In conclusion, our survey has shown that vaccination and novel COVID-19 treatments have brought significant improvements in terms of mortality in HMs. To further improve the prognosis of these patients, the role of additional booster vaccine doses, and the role of prophylactic monoclonal antibodies in patients with an ineffective response to vaccination should be investigated.

### 513 Acknowledgments

514 The authors thank Dr. Janina Leckler and all contributors for their utmost contributions and support 515 to the project during a pandemic situation.

### 516 Author contribution

517 LP served as the principal investigator. JSG and FM served as project manager and research 518 assistant, respectively. LP, JSG, and FM contributed to study design, study supervision, and data 519 interpretation and wrote the paper. AB, PC, MH, PK, AP, FP, AOC and LP conceived the registry idea. LP, JSG and FM did the statistical plan, analysis and interpreted the data. All the authors 520 recruited participants and collected and interpreted data. All authors contributed to manuscript 521 522 writing and review of the manuscript. All authors agreed to be accountable for all aspects of the 523 work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved. 524

### 525 Disclosure of conflicts of interest

526 All the authors have no disclosures to declare for this submitted paper.
