regulations. Many university students are engaged in MBMI projects for businesses, where they utilize AI to find valuable BM in their MBMI process. They also use AI to write the draft proposal for their MBMI report to businesses. For those students who use AI as a supporting tool and carefully review the AI-generated proposal, this approach has proven to be highly valuable. However, for those who are more uncritical and less rigorous in their quality checks, some have experienced adverse outcomes and results.

9.4 AI and healthcare – fast diagnosis, cost savings, and improved healthcare quality

Healthcare sectors now utilizing AI to rapidly scan for various conditions, such as cancer and other diseases that require prompt attention to meet business standards, reduce treatment time, and facilitate fast patient diagnosis. AI is employed to alleviate the workload of employees, who often face a severe shortage of resources and expertise, and can be redirected to other, more value-added areas of the business. The quality of screening and diagnosis is increasing. As diagnosis involves multiple types of data and various forms of analysis, this results in employees transitioning to jobs that require different competencies and capabilities at higher levels.

10 Discussion and reflection

There is a great difference in how and why MBMI participants utilize AI in the cases studied – and how AI impacts on HC and HC Capability to perform MBMI. The general observation is that the quality of the BM value proposition is increased, costs are saved, and HC is released to often more self-realization job areas, that are on a higher intellectual level than the HC typically would deal with and solve. AI can play a role in pushing HC to become better, develop, and grow its HCC. AI can also play a role in increasing HC´s capability to do MBMI and more advanced MBMI – radical and even disruptive levels. This support other research that AI leads to job changes often to higher-level jobs and HCC use on a higher level than usual.

11 Conclusion, relevance, and contribution

AI and its use among MBMI participants and MBMI teams is expected to be beneficial for organizing, designing, reengineering, developing, and managing MBMI. Our research seems to deviate on whether AI has a negative or positive impact on HC competences and HC capabilities, MBMI processes and output. In the cases studied we found both positive and negative results. AI in MBMI processes on individual and team levels seem to show that AI influences much the actors in MBMI projects. It was in some cases possible to verify the participants' output of their MBMI solutions, which showed higher quality in most cases. It was not possible to measure if the output were ambitious enough or if HC really produced better MBMI solutions. It was possible to find that the HC involved could meet, overcome and solve more advanced MBMI Challenges – equal to higher HCC.

The research indicates that HCC are in some case at risk in being wasted, spilled and lost due to AI. As the research verified, if HC is not utilized as AI enables, and AI takes over specific HC tasks, HCC will be wasted, spilled and even lost. In some cases, AI has been verified to release unused HCC and unlock HC potential when used to design and reengineer BMs and BMES.

The research finds that learning and knowledge innovation with AI can occur and are beneficial in many cases for organizing, optimizing, and supporting MBMI processes. However, it can also result in the opposite - HC waste and spill, as well as reduced MBMI, if AI is misused. AI can strengthen MBMI, but it needs to be treated with utmost care, new leadership and management methods.

12 Further research

A future interdisciplinary experiment is needed to measure AI´s impact on MBMI processes and HC, to distinguish between the positive and negative effects of knowledge and practice in MBMI processes. Additionally, a profile test of the involved persons (Big Five) will reveal their personal human capital status, preferences, and actions related to knowledge innovation and development. In future research, we intend to investigate how businesses influenced by and using AI can achieve high-quality MBMI and HCC Value innovation, enabling HC to perform better MBMI.

13 Ethics declaration

Ethic clearance was not required for this research as only publicly accessible data were used an no personal data collected.

14 AI declaration

No AI tools were used for creation or revision of this paper

Exploring Technology Diffusion for Enhanced Energy Efficiency: An Empirical Approach

Jovana Popovic, Milica Vukotic
University of Donja Gorica, Podgorica, Montenegro

Abstract

The present study examines the impact of technology diffusion on energy consumption and efficiency in small and medium enterprises (SMEs) in Montenegro. The focus of this study is a project proposal submitted by a specific SME. The project entails the procurement of the machine for heating and waste collection, as well as the implementation of a digital key for purpose of productivity and energy monitoring. The objective of the project is threefold: firstly, to reduce electricity consumption; secondly, to increase revenue; and thirdly, to promote sustainable practices. This is an empirical study, and as such the results obtained from the real-life consumption of a company can be representative. It was demonstrated that undertaking of project activities would result in the company accruing benefits in both the short and long term. It has been indicated that a reduction in both energy consumption and CO_2 emissions will be observed. However, it is anticipated that the project activities will, over time, lead to the adoption of even more sustainable practices within the company. The paper provides a comprehensive exposition of the demonstration of the Rogers model (TOE and IDP framework) using empirical evidence. Project of this nature are of great benefit to SMEs in Montenegro and the wider region. The provision of financial assistance is but one of the functions of this calls, another is the raising of awareness of various issues. The concept of energy efficiency should not be perceived as disadvantageous, rather, it should be regarded as a concept that is universally accessible and demonstrably manageable in a variety of ways.

Keywords: technology diffusion, energy efficiency, SMEs, transition, innovation.

Paper type: Academic Research paper.

1 Introduction

The global market has confronted considerable challenges in recent years. It has been demonstrated that the known and familiar is not adequate for market survival. It is imperative to adapt to changes in a timely and efficient manner, demonstrating the necessary agility to respond swiftly to evolving circumstances. Technology has been regarded as both a potential catalyst and solution to a paradigm shift regarding not only modes of thought but also modes of business.

The implementation of a multidisciplinary approach is imperative for the survival of the business. Regardless of the technology's necessity, its presence is indispensable for the continuity of a business. The primary focus of this paper is the relationship between technology diffusion and energy efficiency.

The relationship will be explained through the empirical results, conducted for the Innovation Fund's call within the Energy Efficiency Program for Small and Medium Enterprises.

The theoretical framework for technology diffusion will be established to demonstrate the efficacy of energy-efficient practices through an empirical approach and collected data of the chosen company. The research question to be addressed in this research is: What is the impact of technology diffusion on reducing energy consumption and enhancing energy efficiency? The main focus of this research is that technology can help create a better environment and reduce waste, which can also help save energy.

A significant number of researchers have identified a solution within the technological domain. The proliferation of technological innovations has engendered a variety of methods for the generation of energy within corporate entities. Such methods assist companies in becoming more sustainable and in diminishing their environmental impact.

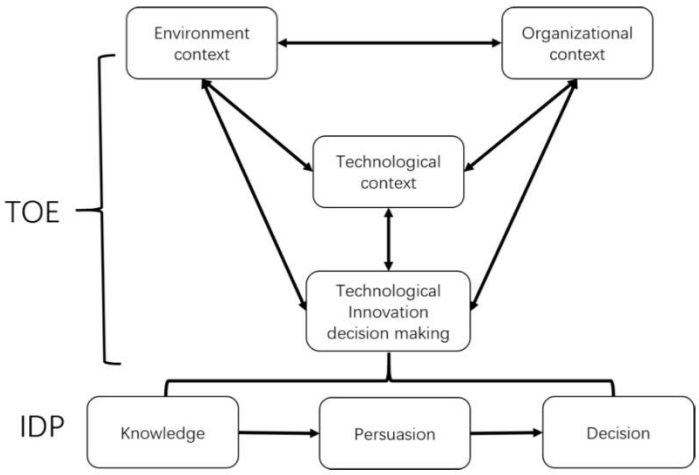
The first part of a paper will mainly focus on a literature review, with special attention on most relevant papers and journals in field of technology diffusion and innovation. This part of a paper will give a solid background for the more detailed analysis. The third part will demonstrate the methodology of the research, how the data were conducted and the sample selection, and so.

The most important part of the paper will be demonstration and elaboration of the results. The results represent a forecast of the energy efficiency usage, based on the reference period. The discussion of the paper will provide a more detailed and comprehensive understanding of the relationship between technology diffusion and energy efficiency, as evidenced by a real-life example.

2 Literature review and Theoretical frameworks

According to the theory of technological diffusion, innovations – defined as new products, processes, or technological advancements – gradually evolve within society and industry (Palm, 2022). This theory posits that innovation does not occur in a single, abrupt action but rather progresses over time in a gradual and steady manner. The imperative for companies to digitize their processes has had a significant impact on technology diffusion practices, as evidenced by nowadays empirical evidences in world's society.

Therefore, despite their apparent need and importance, small-to-medium enterprises (SMEs) continue to grapple with the implementation of energy efficiency solutions. The research network is exerting its utmost efforts to ascertain the potential underlying causes of the phenomenon under study. The aforementioned factors serve as the primary rationale for the increasing prevalence of scientific works within the domain of research concerning technology diffusion and energy efficiency.



In the realm of entrepreneurship, a prevalent issue that has garnered significant attention is that of financial constraints in the context of technological innovation and implementation. This concern has been repeatedly emphasized by numerous entrepreneurs, underscoring the need for comprehensive solutions to address this critical challenge. In contrast, the governance entity has initiated a series of measures designed to provide support, including allocation of potential subventions and the formulation of diverse project calls.

For purpose of this paper, the literature review will serve as the foundation for synthesizing empirical results and theoretical frameworks. In such circumstances, the authors of the paper have implemented specific measures in bibliometric tools to guarantee the relevance and quality of the database of publications.

The Web of Science database was the primary source for this literature review. A comprehensive search strategy was employed, encompassing keywords such as "energy efficiency", "technology diffusion", "SMEs", "transition", and various filters, which yielded a foundation of literature amounting to 581 papers. Given the database's prevalence in recent years, it is notable that from 2014 to 2024, the number of publications pertaining to these subjects exhibited a marked increase. This finding underscores the database's significance and relevance in contemporary academic discourse.

The OSLO Manual (2018) provides a comprehensive overview of the measurement of innovation, encompassing the innovation itself, the methodology of data collection, and the identification of firm's capabilities. Subsequently, Allcott and Greenstone (2012) conducted a discussion on the absence of energy efficiency investments, despite the existence of evidence indicating otherwise. The emphasis is on the provision of empirical evidence to ensure the profitability and sustainability of investments. As all prior researchers, their goal was to make this "energy gap" less noticeable and apparent. In contrast, Wang and Sun (2021) have addressed the mathematical formulation of the Bass model and sought to articulate the merits of new energy industries. It is notable that the other literature also focus on the cohesion of culture, institutions and politics in regard to the same goal of changing paradigms towards energy utilization and transitions to energy efficiency. A considerable number of authors concur that the diffusion of technology innovation is a pivotal asset in the effort to combat climate change.

The work of Shi, Zeng, Engo, and others (2020) examines the factors influencing the adoption of technology for energy efficiency among small and medium-sized enterprises (SMEs). They identify a significant barrier in this area, which is the lack of resources and information. The model presented in the paper serves as a theoretical framework for this research. The model is primarily based on Rogers' model. It is essential to recognize the significance of the Technological, Organizational and Environmental (TOE) and Innovation decision process (IDP) framework, as it serves as a foundational model for the subsequent analysis discussed within this paper. The Rogers's model has been delineated to explicate the interplay of components over time.

Graph 1: The Rogers model
Source: E. M. Rogers, Diffusion of Innovations, The Free Press, New York, 1962.

This model is indicative of the convergence of two elements that are synergistically aligned with the objective of facilitating technological dissemination at the level of corporate entities. Two independent models are characterized by lapping feature – technological innovation decision making.

The TOE employs an analytical framework to assess the adoption of information technology within corporate entities, considering a range of contextual factors. As previously indicated, technological integration has become imperative for contemporary business enterprises. In this regard, the technological context of frameworks is examined to determine a firm's capacity to incorporate technological innovation. Defined characteristics, such as relative advantage, technical and information context, have been shown to influence diffusion processes in different ways. It is important to consider all three aspects of the TOE when contemplating the risks that may arise. One such risk is the potential for the dissemination of false information, which has the capacity to divert attention from the dissemination of information itself. The model is employed to facilitate an investigation into the processes involved in the change, with consideration given to both static and dynamic aspects.

The IDP process is predicated upon three fundamental stages: knowledge (awareness), persuasion, and decision. The IDP process constitutes the preliminary stage in the transition and decision-making process. When combined with the TOE, they aligned with the technological innovation decision and changes are implemented into the company.

3 Methodology of research

In response to the Innovation Fund's call within the Energy Efficiency Program for Small and Medium Enterprises, the company LAMEX DOO, based in Podgorica, has been selected as the subject of this research.

The primary data collected serve as the basis for the technical justification study aimed at improving energy efficiency and incorporating renewable energy sources. The research methodology included several key activities: an on-site visit by company's technical consultant, analysis of the current energy situation, definition of baseline energy consumption and reference period, evaluation of proposed energy efficiency measures, and assessment of energy usage by end consumers.

The goal of the technical justification study was to conduct detailed analysis and interpretation of the energy consumption data.

Lamex DOO specializes in the design and manufacture of furniture made from wood-based panel materials, interior doors, ventilated facades, and sanitary cabins. Due to the nature of its operations, the company experiences high energy usage and generates significant waste. Being environmentally conscious, Lamex seeks to implement practices that contribute to environmental preservation. As part of their project proposal, the company planned to undertake several activities aimed at enhancing energy management:

- Replacing the existing mobile dust collectors used during panel processing with a centralized ventilation system featuring radial fans, a prismatic silo, and a parts separator;
- Purchasing a crusher for processing wood and panel material waste;
- Acquiring four digital licences for the specialized design software Corpus;
- Procuring a system for monitoring and managing energy consumption;

- Hiring and training a team member responsible for overseeing energy management, optimizing consumption, and tracking energy savings in the production facility.

One of the key challenges faced by the company is the usage of large-scale machinery that generates excessive dust, compromising the working conditions for operators. The implementation of a centralized ventilation system is expected to significantly improve the work environment and enhance dust and waste management. This study places special emphasis on the acquisition of the energy monitoring and management system, evaluating both the current state of energy usage and the projected improvements following implementation.

4 Results

The findings of the technical study indicate that the company is prepared to implement sustainable energy solutions on a daily basis. The technical consultant was tasked with conducting an analysis of the current state of affairs and identifying potential avenues for enhancement subsequent to the execution of project activities. The primary focus of the paper is on digital solutions, with a discussion on the potential implementation of digital/smart solutions. The focus will be on the acquisition of four digital licences for specialized design to software Corpus and the procurement of a system for monitoring and managing energy consumption.

4.1. Implementing digital/smart solutions

The implementation of digital keys for upgrading the software system of production will benefit with more precise and optimized consumption of raw material. The Corpus digital key is a program solution that facilitates the process of projecting, drawing, and executing the entire production process. The company's current version affords them the opportunity for intuitive modelling of furniture. The impact of this function is twofold: first, it leads to a decrease in errors, and second, it enables more efficient management of the production process.

The implementation of the Corpus 5 Pro system will afford the company range of functional advantages and facilitate a substantial enhancement in the efficiency of its production processes. The software itself will provide a functionality that enables the generation of barcodes for CNC machines utilized in the production processes. Consequently, the software will automatically retrieve information from the database of a specific machine, including the elements and their respective dimensions. The utilization of barcodes facilities the automation of operations, thereby streamlining the workflow and reducing the time allocated for production. This is facilitated by the implementation of software version 5 PRO, which enables the machines to operate with enhanced efficiency and precision. The advantages of this software are manifold. Chief among them are increased productivity and decreased operator workload. The software also facilitates more efficient and precise processes in production.

Table 1: The overview of calculation of delivered energy consumption reduction through software version upgrade

Estimated savings in delivered energy for the operation of production machines (%)	100%
Delivered energy for the operation of production machines before replacement (existing state) (kWh/year)	146.007
Delivered energy for the operation of production machines after replacement (new state) (kWh/year)	144.547
Delivered energy savings (kWh/year)	1.460
Annual CO_2 emissions before replacement (existing state) (tCO_2/year)	71,54
Annual CO_2 emissions after replacement (new state) (tCO_2/year)	70,83
Reduction in CO_2 emissions (tCO_2/year)	0,72

Source: The technical justification study of company LAMEX DOO.

4.2. The improvement of energy management processes and optimization of energy consumption

The second solution is the implementation of a monitoring system and real-time electric energy consumption monitoring. This will provide precise tracking and analysis of consumption. The system is to be entirely dependent on smart sensors, which facilitate meticulous measurement and documentation of energy consumption on an individual device basis. This affords the company a comprehensive understanding of energy utilization and the identification of opportunities for optimization. The implementation of this system will empower the applicant to make decision regarding consumption management, loss reduction, and the optimization of machine and equipment operation. The overarching objective of this system is to achieve greater energy efficiency and cost reduction.

The implementation of this solution will require equipment of:

- Smappee Power Box – central unit for measuring electricity consumption that enables connection with current sensors and transmits data;
- Smappee Connect – communication module that allows data transmission to the Smappee Cloud via Wi-Fi or Ethernet connection.
- Current sensors (CT sensors, Rogowski coils) – devices that enable electrical current measurement with various ranges (50A, 100A, 250A, 500A), depending on the load.

The strategic placement of sensors at pivotal locations within each sector is instrumental for the precise measurement of electricity consumption and peak power. The implementation of the aforementioned solution would facilitate the company's adoption of standard energy efficiency, as defined by the ISO 50001 standard.

Table 2: The overview of calculation of delivered energy consumption reduction through the improvement of energy management and optimization of energy consumption

Estimated savings in delivered energy for the operation of production machines (%)	100%
Delivered energy for the operation of production machines before replacement (existing state) (kWh/year)	252.846
Delivered energy for the operation of production machines after replacement (new state) (kWh/year)	250.292
Delivered energy savings (kWh/year)	2.554
Annual CO_2 emissions before replacement (existing state) (tCO_2/year)	123,89
Annual CO_2 emissions after replacement (new state) (tCO_2/year)	122,64
Reduction in CO_2 emissions (tCO_2/year)	1,25

Source: The technical justification study of company LAMEX DOO.

The project activities, as outlined, necessitate the incorporation of a new employee whose primary responsibility will be to meticulously monitor and track the daily operations of individual elements, namely the machines. This individual will be tasked with synchronizing the machines' activities, formulating utilization plans, conducting analysis of energy consumption, and documenting the outcomes. The overarching objective of this initiative is to achieve the highest attainable level of energy efficiency.

5 Discussion

The company's application to the Innovation Fund's call, signifies its commitment to integrating more sustainable practices into its daily operations. In consideration of the empirical results and the established framework (TOE and IDP), a range of analysis can be conducted.

As previously mentioned, the company has encountered issues with its work environment and significant electrical energy consumption. Consequently, there is a necessity for implementing changes in these areas. The utilization of substantial machinery in manufacturing facilities is a crucial component of business operations. However, these machines also present significant hazard to the well-being of the company's workforce. Achieving successful project implementation is conductive to enhancing job satisfaction, yet most significantly, it contributes to fostering a more favourable occupational environment. It is evident that the implementation of the dust collector and crusher for processing wood, in addition to the acquisition of digital licences and a system for monitoring and managing energy consumption, will engender a novel business context within the company. In relation to the findings of the research, it is evident that the implementation of the aforementioned activities would result in a decrease in delivered energy and a reduction in CO_2 emissions.

This further refines the innovation making process and the IDP part of a theoretical framework. It is evident that the requisite knowledge was present in the applicant at the time project application, thus enabling the correct choice to be made and the project activities to be defined in a suitable manner. As illustrated, this demonstrates a clear commitment to employing an individual who will assume responsibility for the management and monitoring of energy consumption. A preliminary evaluation of results suggests that the implementation of digital/smart solutions is advantageous in the short term. It is evident that the company has demonstrated a commitment to the continuous enhancement of its sustainability and efficiency, which is a commendable initiative in the transition towards a green business model.

It is imperative that the government and institutions adopt a shift towards a green and digital economy in the coming years, embracing the evident and present changes that are already in evidence. It is only through the continuation of the project that the results of the project can be sustained.

6 Conclusion

The application has been demonstrated to encompass the majority of the most significant domains with regard to energy efficiency, thus providing opportunities that have the potential to influence a reduction in energy utilization.

Montenegrin society is currently facing a number of challenges. Project of this nature are instrumental in prompting companies to develop and adapt novel sustainable solutions that are relevant to their business activities and market presence. It is asserted that the financial assistance provided by the governance body is desirable. This will assist the individuals seeking to instigate change by providing them the opportunity to do so.

The process of technology diffusion is often protracted and frequently necessitates considerable alterations to established systems. It is important to note, however, that this will have a beneficial impact on the business, rendering it a valuable investment. Transition is characterised by uncertainty and unpredictably, yet it is a process that invariably yields substantial and significant outcomes. It is evident that SMEs possess a high degree of agility and have the capacity to act as catalysts for change. Consequently, it is imperative that they adopt a proactive approach and demonstrate a willingness to embrace the challenges that confront them.

Digitalization, understood as a new paradigm of conducting business, necessitates the dissemination of technological processes. The provision of an enhanced and more sustainable environment for all members of society is thereby facilitated. In consideration of the aforementioned, it is evident that digital solutions facilitate the effective utilisation of energy resources, thereby enabling society to prioritise the exploration and adoption of renewable energy sources. It is precisely such mechanisms that facilitate the creation and innovation of new ideas.

7 Ethics declaration

This work includes the use of research data obtained from a project application submitted by Lamex DOO. What Regenerative Approaches Drive Resilience? A Knowledge Frame for Social-Ecological Systems

Maria Elena Latino[1], Marta Menegoli[1], Roberta Pellegrino[2], Antonio Piepoli[2], Pierpaolo Pontrandolfo[2]
[1]University of Salento, Lecce, Italy
[2]Polytechnic University of Bari, Bari, Italy

Abstract

As environmental and social challenges intensify, regenerative practices in supply chain management (SCM) are emerging as a transformative approach, shifting focus from sustainability to the active restoration of socio-ecological systems. The present study analyses how regenerative principles, including poly-rhythmicity, proportionality, and reciprocity, enhance supply chain resilience through systemic renewal. A comprehensive review of 33 high-impact articles (2010–2024) has identified six key regenerative practices: supply chain plasticity, ecological restoration, circular measures, sustainable resource management (SRM), reshoring, and restorative topophilia. These practices address ecological degradation, economic volatility, and social inequities, all while promoting adaptability. Whilst circularity and SRM predominate in industry applications, there is considerable potential in niche practices such as restorative topophilia, which combines place attachment with ecological restoration. The combination of reshoring and circular principles has the potential to reduce emissions by 30% and stimulate local economies. However, it is important to note that 40% of reshoring initiatives are unsuccessful, resulting in the relocation of production activities that are associated with increased environmental impact. Supply chain plasticity has been demonstrated to exhibit operational resilience; however, it frequently neglects ecological reciprocity, thereby highlighting an evident implementation gap. It is imperative to emphasise the pivotal role that stakeholder engagement, notably from communities and non-governmental organisations (NGOs), plays in transcending the divide between sectors. The present study proposes a framework for "regenerative intelligence" that integrates ecological, social, and supply chain objectives. The study validates institutional redundancy (policy-market synergy) and emphasises poly-rhythmicity as an unexplored lever for resilience. The study provides practical insights for transitioning from protective to proactive regeneration, and it notes two limitations: potential interpretive biases and a focus on academic literature. The study suggests that future research should explore metrics, cultural contexts, and decision-support tools. This work reframes supply chains as catalysts for systemic renewal, advocating for strategies that restore rather than merely sustain.

Figure 1: Word Map of Most Frequent Keywords

Keywords: Regeneration, Resilience, Social-Ecological System, Supply Chain Management.

Paper type: Academic Research Paper

1 Introduction

As environmental challenges escalate and the urgent need for sustainable development becomes increasingly evident, the concept of regeneration has surfaced as a compelling and transformative approach that has captured significant attention in both academic literature and practical applications (Buckton et al., 2023). Regeneration, distinct from conventional sustainability-related models, represents a paradigm shift that not only aims to mitigate environmental harm but actively seeks to restore and enhance the well-being of ecosystems

and social structures. This shift towards regeneration is particularly pertinent in supply chain management (SCM), where traditional models have often focused primarily on minimizing damage, rather than fostering positive ecological and social outcomes (Gualandris et al., 2024). Unlike traditional sustainability frameworks that emphasize reducing negative impacts, regenerative practices offer a holistic, forward-thinking approach aimed at healing and improving the systems they interact with. These practices do not merely seek to maintain equilibrium but focus on revitalizing and nurturing the interconnected elements of the environment and society, aiming for a net positive impact. This means transforming supply chains from linear, resource-depleting models to regenerative, circular systems that continuously replenish the social-ecological ecosystems they depend on (Gualandris et al., 2024). Through the implementation of these practices, supply chains can evolve into systems that are not only stable and adaptable but also capable of driving positive change and transformation even in the face of disruption (Wieland and Durach, 2021). This evolving perspective introduces a new lens for examining supply chain resilience. Historically, resilience has been understood primarily in terms of the ability to withstand and recover from disturbances. However, under a regenerative framework, resilience extends beyond simple recovery; it emphasizes the active enhancement of both ecological and social well-being through adaptive learning, resource regeneration, and long-term systems thinking. This interpretation opens up new avenues for advancing resilience in supply chains, with a focus on fostering greater adaptability without compromising ecological and social health (Ali, 2024). The current shift toward regenerative supply chains calls for a deeper understanding of the principles that underpin these practices and their potential to shape the resilience of social-ecological systems. A critical area of exploration is the interplay between regenerative principles—such as poly-rhythmicity, proportionality, and reciprocity—and the resilience of supply chains, particularly in the context of unsustainable global challenges, including climate change, resource depletion, and growing social inequalities. These principles are foundational to regenerative practices, as they offer a framework for rethinking how supply chains can operate within broader socio-environmental systems. Poly-rhythmicity, for example, refers to the synchronization of different rhythms in social-ecological systems to enhance adaptability; proportionality speaks to the need for actions that are aligned with the scale of the challenges faced; and reciprocity emphasizes mutual benefit and the interconnectedness of systems, fostering long-term collaborative relationships (Gualandris et al., 2024). This study positions itself within the growing body of research aimed at understanding the implications of regenerative practices on supply chain resilience. It seeks to uncover the ways in which regenerative principles can support the transition from unsustainable practices to more resilient, restorative systems. Specifically, it explores how these principles can enhance resilience in supply chains and the broader social-ecological systems, enabling them to navigate uncertainty and external disruptions, such as climate crises and resource scarcity. In doing so, this research aims to advance both theoretical and practical insights in the SCM domain, offering new perspectives on how organizations can build resilience through regenerative practices. By investigating the intersection of regenerative principles and supply chain resilience, this study contributes to the theoretical development of sustainability in SCM. It also provides actionable insights for practitioners seeking to transition toward more regenerative, resilient, and sustainable supply chains, ultimately supporting the achievement of broader sustainability goals at both the organizational and global levels. As such, it represents a crucial step in advancing the discourse on sustainable supply chains, highlighting the need for transformative practices that restore, rather than simply preserve, the systems upon which they depend.

2 Methodology

A comprehensive literature review, through which articles are systematically selected based on predefined inclusion and exclusion criteria through a qualitative research approach, is deployed to understand how regenerative practices can be effectively deployed to improve social-ecological resilience, offering both theoretical insights and practical guidance in setting strategies within the context of SCM by considering the interconnectedness, scale, and mutual benefits inherent in social-ecological systems. The methodology is grounded in a critical review of existing literature, following the path proposed by Xiao and Watson, (2019), and adopts a deductive approach to systematically collect and analyze relevant articles. As this domain is still at his infant phase, a deductive approach allows the study to test predefined concepts of social-ecological systems—such as the principles of regeneration and resilience—against the data gathered from the selected articles. In doing so, the research draws upon regenerative principles proposed by Gualandris et al. (2024), in conjunction with the resilience principles and manifestations proposed by Wieland et al. (2023), allowing for the development of a robust knowledge framework that present the multitude implications of adopting regenerative practices. This ensures that the review remains focused on the theoretical constructs as it evaluates how regenerative practices contribute to strengthening resilience within supply chains and in the overall system. By structuring the analysis based on established theoretical frameworks, the study provides a clear and

systematic pathway for synthesizing the literature and drawing meaningful conclusions. To ensure the trasparency and reliability of the review process, each step of the methodology was rigorously documented, including the inclusion and exclusion criteria, the selection of databases, and the search terms used. The decision to utilise Scopus for this literature search was made on the basis of its comprehensive coverage of high-quality, peer-reviewed journals in the domains of management, sustainability, and operations. The academic community has acknowledged this as a pivotal resource for systematic literature reviews, thus ensuring the incorporation of pertinent, peer-reviewed, and academically rigorous articles (Sauer & Seuring, 2023). Keywords related to regenerative practices, including terms such as "regeneration," "restore," "revitalize," and "renew.", associated with those related to supply chains (see Sauer and Seuring, 2017), were included in the search. To reflect the evolving conceptualization of supply chains as socio-ecological systems, the term "social-ecological system" was incorporated into the synonymous of supply chain keywords. Finally, “resilience” was included as a core single keyword to filter results in line with the research objectives, in line with Sauer & Seuring (2023). Starting from a pool of 718 documents found, the selection targeted peer-reviewed journal articles (472) and reviews (60) written in English (689), published in journals listed in the latest 2024 ABS list (157), ensuring that the analysis is directed towards high-quality, management-focused research. Focusing exclusively on papers published in journals with ABS rankings of 3, 4, or 4*, a total of 33 papers were selected for the analysis to capture the latest developments in research driving the domain forward. For data analysis, RStudio and Biblioshiny were firstly employed for bibliometric analysis, allowing for the extraction and visualization of key trends and patterns in the literature. These tools facilitate a structured analysis of the data, ensuring a systematic approach to the content analysis and synthesis. The content analysis was thus performed using a qualitative approach, where researchers took notes and provided comments on each full-paper. These notes were cataloged into Excel files for further analysis. This process ensures that the data is systematically organized and analyzed, with clear coding of key themes in light of the aforementioned constructs. Access to supplementary materials, detailing the data anaylisi, is available upon request to the authors.

3 Research Findings

3.1. Bibliometric Analysis

This bibliometric analysis examines 33 academic articles and reviews published between 2010 and 2024. While only one article was published in 2010, output remained sporadic until 2023, when a significant surge occurred with 10 articles, followed by 8 in 2024. This recent acceleration suggests a growing recognition of the importance of resilience and disruption in global supply chains. The average document age is 4.58 years, with an impressive mean citation count of 57.52 per document, underscoring the field's impact. Early works, such as those from 2010 and 2014, garnered substantial citations (85 and 130.5 per article, respectively), indicating their foundational role. In contrast, more recent publications (2023–2024) exhibit lower citation counts due to their shorter time in circulation, yet their rapid production signals an active research frontier. To conclude, the 2872 references cited across these works highlight a robust engagement with existing literature. The dataset, drawn from 19 diverse sources, reveals an annual growth rate of 16.01%, reflecting increasing academic interest in these emerging topics. The International Journal of Production Economics and the International Journal of Production Research emerge as leading sources, each contributing 4 articles. Close behind are Annals of Operations Research, Environmental Science and Policy, and Journal of Business Logistics, with 3 articles each. These journals serve as primary platforms for disseminating research on SCM. Over time, their contributions have grown steadily, with notable increases post-2020, reflecting heightened interest following global disruptions such as the COVID-19 pandemic. The bibliometric analysis reveals significant geographical and institutional patterns in the study of supply chain resilience and disruption. The United States leads in scientific production, contributing 26 articles, followed by China (21) and the United Kingdom (10). These three nations dominate the field, collectively accounting for over 70% of the publications. The USA’s research output has grown steadily since 2010, with a notable acceleration post-2020. Similarly, China's contributions, initially limited, surged after 2022, reflecting a growing focus on supply chain resilience amid global disruptions, while the UK's output, though smaller, remained consistent low with a notable increase in 2023–2024. Institutional analysis highlights the University of Tehran as the most prolific, with 6 articles, closely followed by the University of Birmingham (5) and Peking University (4). These institutions, along with Stellenbosch University and The Hong Kong Polytechnic University (3 articles each), serve as key hubs alike contributing to the growing literature on regenerative supply chains. A close examination of terms that occur with high frequency within the context of regenerative practices in supply chains reveals a marked emphasis on concepts resilience and SCM, as provided by keyword setting. The temporal analysis confirmed a marked increase in research activities

concerning resilience and SCM post-2020, largely in response to global disruptions such as the COVD-19 pandemic. Notably, regenerative-related keywords emerges as a key secondary theme, reflecting growing recognition of interest on sustainabity. The emergence of terms related to "climate change," "uncertainty analysis," and "disasters" reflects an increasing recognition of the environmental and social challenges that significantly influence social-ecological resilience. Moreover, concepts associated with restoration, risk assessment, and rural areas highlights the pressing need for regenerative practices that can effectively address disruptions within the social-ecological systems. This evolution suggests the field is expanding from its technical-operational roots to address broader societal and environmental challenges. However, the relatively low density of the climate change cluster indicates this expansion remains in early stages, with opportunities for more systematic integration of environmental and social dimensions into core resilience frameworks.

3.2. Content Analysis

The global pandemic has been identified as a pivotal case study in numerous academic papers (see, for instance, Gaudenzi et al., 2023), functioning as an impetus for new research initiatives while providing a validation of existing resilience frameworks. This event has been identified as a contributing factor to the acceleration of the integration of socio-environmental factors into a discipline that was previously characterised by operational focus. In this context, a pronounced industry-specific orientation becomes evident, with applications in the energy, manufacturing, and healthcare sectors illustrating the heterogeneity of resilience strategies across operational contexts. Secondly, quantitative studies, particularly those employing network analysis and optimisation modelling, dominate operational research, while qualitative methods prevail in studies of social-ecological systems and policy impacts. It is evident from the content analysis that there are six key regenerative practices which collectively enhance the resilience of social-ecological systems. These are: *supply chain plasticity, restoration, circular measures, sustainable resource management (SRM), reshoring, and restorative topophilia.* The synergy of these practices is such that they are able to tackle issues such as environmental degradation, economic volatility, and social inequities, while also fostering systemic adaptability. The effectiveness of these practices is evaluated through the lenses of Wieland's resilience principles and Gualandris' regenerative criteria (see Figure 3), with stakeholder engagement emerging as the critical enabling factor across all these practices. The most comprehensive practice pattern that has emerged is that of **ecological**

restoration, which has been demonstrated to enhance biodiversity, addressing diversity and redundancy, while simultaneously fostering community well-being. Projects such as Bui et al.'s (2020) mangrove rehabilitation initiative have been shown to generate a multitude of benefits, including the recovery of biodiversity (+37% in studied sites), coastal protection, and the creation of livelihoods. However, technological solutions such as those proposed by Chen et al. (2023) for the purpose of drone-assisted reforestation have been shown to fall short of the principles of proportionality. This is due to the high cost of the technology, which renders it ill-suited to the more modest budgetary constraints typically associated with grassroots initiatives, as documented by Shackleton et al. (2018) in South African townships. The analysis demonstrates that restoration projects consistently exhibit the strongest reciprocity scores, as evidenced by urban greening initiatives that concomitantly enhance environmental benefits and mental health (Tidball & Stedman, 2013). However, the partial absence of slow variable management in 40% of cases indicates a requirement for longer-term monitoring frameworks to track cumulative impacts within the entire social-ecological system. The **circular measures-SRM dyad** pairing is indicative of the operational core of regenerative systems. However, it also exhibits an interesting divergence. While both emphasise resource efficiency, circular practices demonstrate stronger private-sector adoption, whereas SRM more frequently involves policy actors (85% of cases). This complementarity engenders resilience through what can be termed "institutional redundancy", whereby market-driven circularity and regulatory SRM mechanisms are employed in tandem. Conversely, Mahmood et al. (2024) demonstrated that AI-driven circular systems attained 92% material efficiency in controlled settings. However, Rajabzadeh and Wiens (2024) found that only 18% of EU cities effectively scaled these systems through policy (e.g., Jiang et al.'s, 2023). The observed discrepancy between policy and practice is analogous to the findings in Gualandris' ratings, where circular measures exhibited robust reciprocity yet exhibited inconsistent poly-rhythmicity. The concept of **reshoring**, otherwise referred to as the relocation of production facilities to the home country, has evolved from a cost-saving strategy to a multifaceted regenerative practice. A thorough investigation by Xu et al. (2023) of the textile industry emphasises reshoring's triple dividend: a 30% decrease in transport emissions due to the reduction of supply chains, the revitalisation of local craft economies, and the strengthening of community-business relationships. The relocation of textile factories resulted in the generation of skilled employment at a rate that was 2.3 times higher than that of offshore facilities, whilst concurrently supporting traditional craftsmanship. Such spatial reorganization has been shown to encourage more SRM through several mechanisms: reduced transportation needs, leading to a decrease in fossil fuel consumption; proximity, enabling more effective monitoring of environmental standards; and shorter loops, facilitating the integration of circular economy principles (Xu et al., 2023). However, research undertaken by Bailey et al. (2018) indicates that 40% of US reshoring initiatives merely relocated resource exploitation, rather than transforming production paradigms. The environmental advantages of reshoring extend beyond emissions reduction, as it also generates environmental benefits in line with operational changes while simultaneously generating reciprocal socioeconomic value. From an economic perspective, the process of reshoring has been shown to have a catalyst effect on regional regeneration (Smith, 2023). In addition, local production has been demonstrated to enhance transparency across value chains, strengthen place-based knowledge exchange, foster equitable stakeholder relationships, and build community resilience through the diversification of local economies. **Supply chain plasticity** demonstrates particularly strong alignment with resilience principles by enabling rapid adaptation to disruptions through supplier diversification and localized production. Particularly, Guntuka et al. (2024) demonstrate how adaptive reconfiguration helped businesses navigate disrutpions mostly related pandemic shocks. This practice enables to manage connectivity and to adaptive systems thinking, as the frequent involvement of firms and supply chain actors (70% of studies) underscores their pivotal role in operationalizing this plasticity, though greater inclusion of workers and local communities could strengthen its social-ecological resilience through reciprocity. However, its weaker performance on poly-rhythmicity suggests opportunities to better synchronize production cycles with ecological rhythms. In this light, Ivanov and Sokolov (2019) caution that without meaningful community engagement, such plasticity risks becoming merely a technical fix rather than a transformative approach. Yet as Ivanov and Sokolov (2019) caution in their logistics research, such plasticity often prioritizes economic continuity over ecological reciprocity—only 40% of cases studied (e.g., Hughes et al., 2023) integrated circular principles like closed-loop material flows. The concept of **restorative topophilia**—the fusion of place attachment with ecological restoration—has emerged as a critical yet often overlooked dimension of regenerative practice. Conversely, restorative topophilia eschews conventional environmental interventions that prioritise technical solutions, instead leveraging the profound emotional bonds between people and their environments to drive sustained ecological and social transformation. This phenomenon is vividly illustrated in Tidball and Stedman's (2013) longitudinal study of post-Katrina New Orleans, where community-led tree-planting initiatives rooted in place attachment demonstrated three times higher survival rates and significantly greater long-term engagement compared to technocratic

reforestation programs. The success of these efforts underscores a fundamental insight: when environmental restoration is intertwined with cultural meaning and personal identity, it ceases to be merely an ecological intervention and becomes instead a collective act of place-making and healing. The implications of restorative topophilia extend far beyond the sphere of urban greening. The distinguishing characteristic of restorative topophilia is its ability to fulfil all three of Gualandris' regenerative principles. These principles are as follows: proportionality, which is achieved by scaling interventions to local cultural and ecological contexts; reciprocity, which is achieved through mutually reinforcing benefits for ecosystems and communities; and poly-rhythmicity, which is achieved by aligning restoration activities with the natural and social cycles of place. In particular, the work of Hill, Clarvis et al. (2014) is noteworthy in demonstrating how community gardens, which are often established in neglected urban spaces, can serve as effective agents for simultaneously enhancing local biodiversity and fostering mental well-being. This observation highlights the potential for such initiatives to establish feedback loops between ecological health and social cohesion, underscoring the multifaceted benefits of urban gardening. In this regard, restorative topophilia has emerged as a concept that fosters a comprehensive understanding of resilience, wherein the emotional and psychological benefits derived from engagement with nature are recognised as indispensable components of recovery and regeneration of the system. This approach not only enhances the well-being of the inhabitants but also fosters a sense of interconnectedness with their environment. It is imperative that stakeholders at various levels collaborate in adopting regenerative practices that enhance socio-ecological resilience. The shift from traditional risk management to proactive and regenerative strategies indicating a maturing perspective in the field that blends technological innovation, collaborative models, and socio-environmental responsibility. At the micro level, the roles played by firms, employees and top managers are pivotal to the advancement of sustainability. Firms function as agents of change, leveraging their resources and influence to implement sustainable business models and corporate social responsibility (CSR) initiatives. This engagement has been demonstrated to engender value creation that extends beyond the pursuit of profit, thereby contributing to the regeneration of both natural and social systems. Moreover, the involvement of workers and their alignment with sustainability goals are of critical importance for achieving systemic resilience, by strengthening innovation and collaboration. The integration of effective leadership with stakeholder engagement is instrumental in ensuring that regenerative practices are both inclusive and impactful. At the macro level, the promotion of sustainability and regeneration relies on the vital contributions of broader societal stakeholders, including academia, environmental organisations, the media, governments, and local communities. Academia provides essential knowledge and evidence for effective policy formulation, while environmental organisations advocate for ecosystem protection and restoration.

4 Discussions

The findings present a compelling paradox within the realm of regenerative systems research: despite being in its early stages, characterised by the identification of merely six core practices, the field encompasses an exceptionally diverse ecosystem of stakeholders. This dichotomy suggests that the regenerative approaches are not limited by the availability of actors; rather, they are limited by the imperative for more sophisticated integration across social, ecological, and supply chain dimensions. The pre-eminence of conventional stakeholders – comprising firms, policymakers and supply chain participants – demonstrates the deeply entrenched status of regeneration within current systems. However, the critical involvement of unconventional actors, such as environmental non-governmental organisations (NGOs) and community organisations – as evidenced by Hosseini et al. (2019) in their studies on wetland restoration – highlights the significance of boundary-spanning partnerships that transcend traditional sectoral divisions. These findings are in alignment with the work of Pagell and Wilhelm (2025), who emphasise the fundamental inclusivity of all actors interacting within systems as a prerequisite for transitioning towards sustainable SCM. The principle-based assessment of regenerative practices yields nuanced insights regarding their maturity and implementation. For instance, circular measures and sustainable resource management (SRM) demonstrate robust performance across both regenerative and resilience dimensions, likely attributable to their longer research history and the clarity of their metrics, as evidenced by the quantifiable material efficiency gains reported by Mahmood et al. (2024). Conversely, the resilience-oriented profile of supply chain plasticity reveals a critical tension: while it is essential for operational adaptability, its weaker alignment with regenerative principles suggests that current implementations often prioritise economic continuity over systemic restoration. This observation is in alignment with the critique proposed by Ivanov and Sokolov (2019) concerning solutions that are exclusively technical and devoid of transformative intent. This underscores the pressing necessity for plasticity models that explicitly incorporate the reciprocity principle. It is noteworthy that only the aspect of supply chain plasticity directly addresses logistical systems, thus revealing an "implementation gap" within regeneration theory. Whilst supply chains are increasingly conceptualised as social-ecological systems, there is a tendency for practical applications to disproportionately prioritise environmental outcomes, frequently at the expense of systemic integration. Significantly, the exceptional regenerative capacity of less prevalent practices, including reshoring and restorative topophilia, underscores valuable pathways for systemic transformation. Xu et al. (2023) elucidate reshoring's triple-value proposition, which simultaneously addresses environmental, economic, and social dimensions. However, the realization of such potential necessitates the implementation of reshoring initiatives that are designed to integrate the principles of the circular economy, as opposed to the mere relocation of environmental impacts. In a similar vein, restorative topophilia accentuates the socio-cultural dimensions, as evidenced by Tidball and Stedman's (2013) community-led urban regeneration studies. These studies demonstrate the potential of place-based connections to function as foundational enablers of more extensive systemic transformations. This finding opens critical avenues for theoretical exploration, particularly concerning social readiness—the cultivation of shared values and stewardship mindsets—as a pivotal precursor to effective

ecological and supply chain interventions. Notwithstanding its underrepresentation in extant literature, this practice exemplifies the latent potential inherent in the cultural and psychological dimensions of regeneration.

The novel conceptualisation of social-ecological resilience within regenerative frameworks represents a substantial theoretical advancement, advocating for the simultaneous optimisation of ecological restoration, social equity, and supply chain resilience. This integrated approach is at odds with conventional resilience models, which are predicated on a reactive response to perturbations. Instead, this approach promotes proactive rejuvenation as a strategy to address perturbations. Moreover, a pivotal theoretical implication of the study is the imperative for regenerative practices to engage more profoundly with broader socio-cultural contexts. This engagement fosters a cohesive integration of human and ecological dimensions. Despite the study presents significant theoretical advancements, it underscores the emergent importance of poly-rhythmicity—the synchronization of ecological, social, and economic rhythms. This concept represents a frontier in regenerative research, highlighting the urgent need for dynamic frameworks that can align diverse stakeholders across varying temporal and spatial scales. The objective of such frameworks is to address the implementation gaps that have been identified in contemporary practices. From a managerial perspective, the study provides actionable insights by emphasising core regenerative practices – particularly reshoring and restorative topophilia – that hold significant potential for fostering systemic renewal but remain underutilised. Supply chain managers can strategically employ reshoring to not only mitigate transportation emissions but also to revitalize local economies, strengthen community ties, and facilitate the renewal of socio-ecological systems. It is imperative for managers to recognise the identified implementation gap, acknowledging that achieving meaningful regenerative outcomes necessitates transcending operational efficiency to embed environmental reciprocity and stakeholder collaboration within supply chain strategies. It is important to note that stakeholder engagement, particularly with unconventional actors such as NGOs and community groups, becomes pivotal in bridging ecological and social dimensions. This, in turn, enables organisations to integrate regeneration more effectively into their strategic and operational frameworks. The study emphasises the significance of policy-market synergy for policymakers, advocating institutional redundancy as a strategic mechanism to support regenerative SCM. The facilitation of regenerative transitions at both micro and macro levels is contingent upon the coordination of policy interventions. Specifically, policies that incentivise reshoring initiatives in accordance with circular economy principles have the potential to yield substantial environmental, economic, and social benefits. Nevertheless, policymakers must remain cognizant of the limitations of reshoring, as geographic relocation may inadvertently shift rather than alleviate environmental impacts. Addressing gaps in poly-rhythmicity will require the development of governance structures capable of dynamically adapting to evolving ecological, economic, and societal rhythms, thus enabling sustained regenerative transitions.

Whilst this study has advanced theoretical and practical understandings of regenerative SCM, it has also identified significant methodological limitations. The decision to confine the literature review to ABS-ranked journals (ranked 3, 4, or 4*) ensures a level of academic rigour and a management-oriented research focus. However, this approach may inadvertently result in the exclusion of innovative practices emerging from practitioner-led or grey literature, which could provide valuable and diverse insights. It is recommended that future research extend its scope to encompass industry reports, practitioner-driven studies, and non-academic publications. This approach will facilitate a more comprehensive capture of developments in regenerative SCM. The study posits that the subsequent phase in regenerative research should not be the identification of additional discrete practices, but rather the construction of connective frameworks that integrate isolated innovations into coherent systemic transitions. In this context, the ability to optimise ecological restoration, social equity, and supply chain resilience across multiple scales represents a critical challenge and an opportunity. The proposed framework (see Figure 4) illustrates how multi-level stakeholder collaboration can facilitate systemic coherence and adaptability, emphasising collective action and reciprocity as foundational principles of socio-ecological regeneration. This integrated perspective has the potential to transform the conventional understanding of supply chains, reconceptualising them as catalysts for comprehensive socio-ecological renewal.

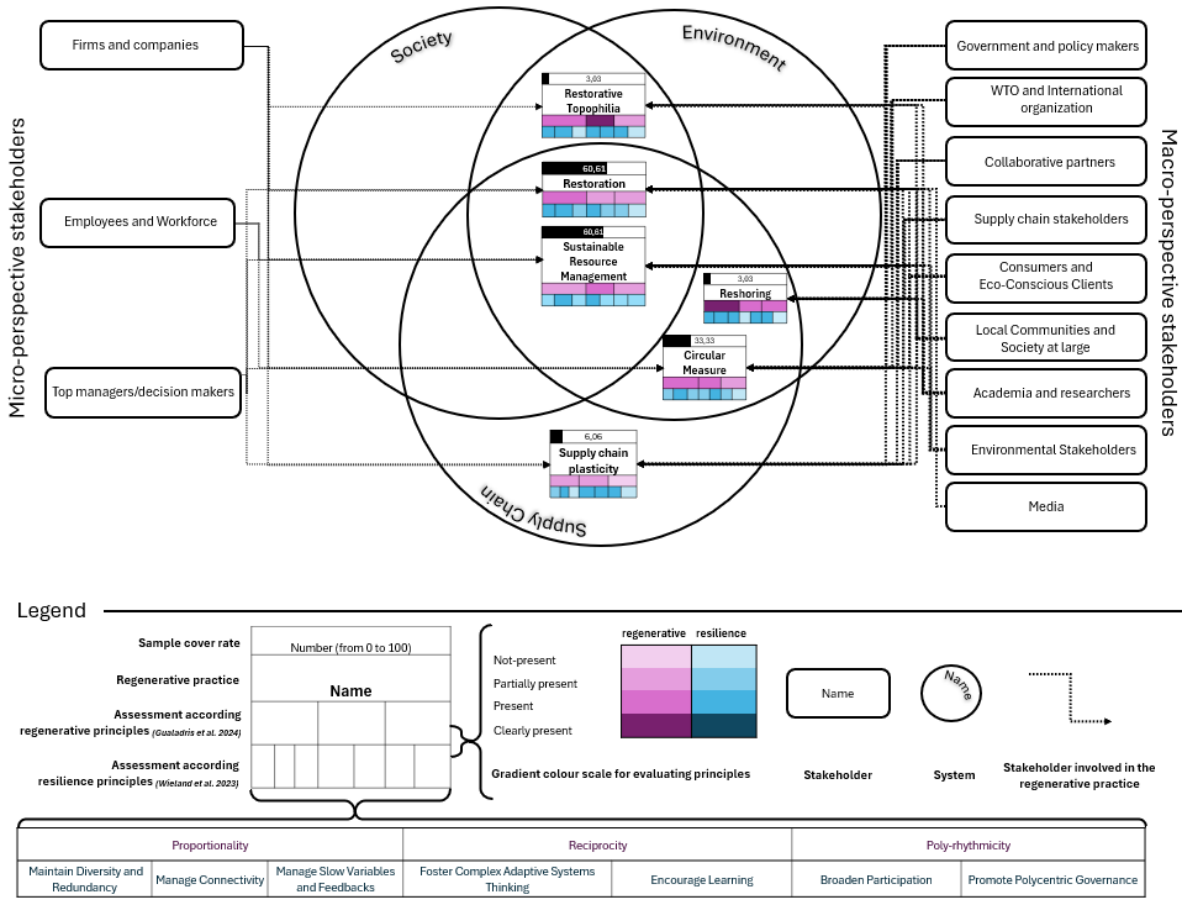

Figure 4 - A comprehensive framework for bridging regenerative practices and social-ecological resilience.

5 Conclusions

This study offers significant contributions to the emergent field of regenerative SCM by methodically analyzing the intricate interconnections among six core practices and socio-ecological resilience. Our findings contest traditional paradigms by illustrating that genuine regeneration does not arise from isolated interventions; instead, it emerges from the intentional integration of complementary practices across social, ecological, and supply chain dimensions. The theoretical framework developed herein (illustrated in Figure 4) marks a notable progress, conceptualizing regenerative intelligence as a systemic characteristic that results from thoughtfully coordinated stakeholder interactions and alignment across various domains. Three principal theoretical contributions arise from this investigation. Firstly, we provide empirical validation for restorative topophilia as an essential yet previously overlooked aspect of regeneration, thereby addressing a significant gap within the supply chain literature. Secondly, we introduce and operationalize the concept of "institutional redundancy" as an innovative mechanism that fortifies resilience through the strategic alignment of market forces and policy interventions within circular systems. Thirdly, our analysis identifies poly-rhythmicity as both a conceptually sophisticated and practically underexplored principle in contemporary regenerative practices, highlighting it as a crucial area for future scholarly inquiry. From a practical perspective, this research yields valuable insights for a variety of stakeholders. Supply chain managers are equipped with a structured methodology for evaluating and aligning their operations with objectives related to resilience and regeneration. Policymakers benefit from empirical evidence that supports the development of governance frameworks designed to facilitate cross-sector collaboration while addressing the temporal complexities inherent in socio-ecological systems. The framework's emphasis on reciprocal relationships offers concrete guidance for organizations transitioning from protective sustainability measures toward proactive regeneration strategies. Nevertheless, several limitations warrant recognition. The qualitative methodology employed, while fitting for this exploratory study, introduces potential interpretive biases, particularly concerning the nuanced principle of poly-rhythmicity. Furthermore, our focus on ABS-ranked journals, although ensuring academic rigor, may have inadvertently excluded valuable innovations arising from practitioner insights. The limited sample size, while

robust for this nascent field, indicates opportunities for further exploration as the literature evolves. Future research should prioritize three critical domains: (1) the development of robust metrics to quantify regenerative impacts across multiple system dimensions; (2) cross-cultural examinations of place-based regeneration approaches to accommodate contextual variations; and (3) the creation of practical decision-support tools for the implementation of poly-rhythmic supply chain strategies in diverse operational contexts. This study represents a significant conceptual advancement by reconceptualizing supply chains not merely as logistical networks but as potential catalysts for systemic renewal. The proposed framework provides scholars and practitioners alike with both a theoretical foundation and practical toolkit essential for navigating the complex transition from sustainability-as-mitigation to regeneration-as-renewal. By stressing the fundamental significance of reciprocal relationships and system-level thinking, this research delineates a pathway towards more resilient, equitable, and regenerative systems.

6 Ethics declaration

This research did not involve human participants, animal studies, or any other procedures requiring ethical clearance. Therefore, no formal ethical approval was necessary for the research presented in this paper.

7 AI declaration

The authors declare that no artificial intelligence (AI) tools were used in the writing, editing, data analysis, or interpretation of this manuscript. All work was conducted and reviewed manually by the authors.

Abstract

This article analyses the green aspects of technologies embedded within the Fintech sector, providing insights into the intersection of financial innovation and environmental sustainability. The technological advancements introduced in the financial sector over the past decades hold considerable potential to facilitate the ecological transition and promote environmental sustainability – a potential that has been widely acknowledge in the literature. However, there is still little research on the green attributes of the technologies underlying the Fintech sector, particularly through the lens of patents, which serve as concrete indicators of technological innovation.
Our findings contribute to the understanding of technology, finance, and sustainability, emphasising the value of patent data in tracking progress and guiding future developments.
Through the use of statistical analyses and the Social Network Analysis techniques, we define a multi-step methodology and a set of new measures that allow us to analyse Fintech technologies, as described by the underlying patents, in the light of the environmental and eco-friendly perspective, as proposed by the WIPO IPC Green Inventory classification. The statistical analysis of the green Fintech patents reveals several notable trends. The relative frequency of patents containing a number of green technology classifications within the complete dataset exhibits an increasing trends, although this has stabilised in recent years.
Furthermore, the data indicate a modest deceleration in the overall growth of this segment, suggesting a potential plateau in the expansion of green-oriented innovations in the Fintech domain.
Our results offer an original perspective on the idea of green, expanding the analysis to encompass the collective behaviour of the Fintech ecosystem of technologies and, eventually, any other industrial sector.

Keywords: Fintech, Green Patents, Green Technologies, IPC, Social Network Analysis

Paper type: Academic Research Paper

1 Introduction

The term financial technology ("Fintech") refers to a wide range of innovative approaches that use advances in software, mobile applications, blockchain, artificial intelligence, big data analytics, and other emerging technologies to transform the way financial services and transactions are rendered. In order to understand the technological landscape of Fintech, the analysis of patents pertaining is extremely relevant. In fact, patents are a reliable source of information since they include accurate technical, legal, and economic data. Patent observation plays an important role in the evaluation of technological innovations and the understanding of the landscape of intellectual property (Liu et al., 2023).

The analysis of patents in the Fintech sector has produced several scientific papers (Lee et al., 2009; Kabulova and Stankevičiené, 2020); Cojoianu et al., 2021; Lee and Sohn, 2017; Wang et al., 2022; Zhao et al. 2022).

The increasing integration of environmental, social, and governance (ESG) criteria into corporate strategies underscores the need to evaluate Fintech technologies' environmental characteristics, especially in light of growing pressures on businesses to adopt sustainable practices. For these reasons, the environmental impacts of Fintech are increasingly gaining attention, especially as the financial technology industry grows and intersects with sustainability goals. However, the "greenness" of the technologies underlying the Fintech sector remains largely underexplored, especially from the patent perspective.

This research aims to fill this gap by extending the analysis of Fintech patents conducted by Ferraro et al. (2024a) and Ferraro et al. (2024b) and analyses Fintech patents that involve the use of technologies defined as "green". We adopt the classification of green technologies based on the International Patent Classification (IPC) codes of the World Intellectual Property Organization (WIPO), over the period from 2010 to 2023. In particular, we refer to the WIPO IPC Green Inventory, developed by an IPC Committee of Experts with the aim to facilitate searches for patents information relating to Environmentally Sound Technologies, as listed by the United Nations Framework Convention on Climate Change.

We will try to answer the following research questions:

- RQ 1: How green are the technologies inherent in Fintech patents?

- RQ 2: How can we measure how well the Fintech sector complements green technologies? Can the rate at which green technologies are linked to a patent be measured?

2 Research design: data and methodology

This section shows the four main phases of our research: definition of keywords, construction of the database, processing of the database, and analysis of the results.

2.1 Definition of the keywords and patent database construction

Scopus database is used to analyse the relevant literature to define the keywords. We chose Scopus because it provides a comprehensive suite of scientific, technological, and social measures and content related to the scientific literature (Thelwall, M., 2018; Waltman L., 2016). The keywords of the title and abstract served as the basis for the analysis carried out on Scopus. The terms "Fintech" and/or "financial technology" were examined, resulting in a total of 4,836 scientific articles. The time period examined goes from 1980 to 2023. We chose the list of terms to search in the WIPO patent database based on the keywords we found through the analysis of academic publications and with the guidance of a panel of five experts.

We pay particular attention to IPC codes, which offer a hierarchical system of language-independent symbolism for classifying patents according to the technical domains to which they belong. We considered classification symbols, based on the WIPO repository.

The IPC Green Inventory was developed by an IPC Expert Committee in 2010 with the aim of facilitating the obtaining of patent information regarding "ambient sound technologies" defined by the United Nations Framework Convention on Climate Change. These technologies are recognized in numerous industries and are currently widely distributed in IPC codes. Although relatively new, the green technology sector has attracted a lot of attention from investors due to increasing awareness of the effects of climate change and the depletion of natural resources. The database of Fintech patents related to green technologies was analyzed and various statistics and analyses were carried out to understand the characteristics of these patents and the underlying technologies. In this research focused on green technologies applied to Fintech patents over a period of time from 2010 to 2023, we considered the date of publication of the patent application, i.e. the date on which the document is made available to the public, thereby making it part of the state-of-the-art.

2.2 Database analysis

The data set under investigation consists predominantly of textual data, including text bodies, names, and categorical labels. To gain an initial understanding of its structure and properties, we employ descriptive statistical techniques to summarize the structural and quantitative properties of the dataset.

2.2.1 Descriptive statistical analysis

The descriptive statistical analysis proceeds with several key steps aimed at understanding the distribution and dynamics of the data set. First, we analyse *the time evolution of applications* by examining the number of patent submissions per year. This time series analysis highlights the temporal dynamics of patent activity, revealing trends, growth patterns, or potential periods of stagnation in the application process.

Then, we construct rankings for the feature *applicants* by calculating the frequency of each applicant in the dataset, thus identifying the most active entities in terms of patent submissions. Hence, a similar ranking is created for the *IPC codes*. By counting the frequency of each IPC code, we identify the most prevalent technological sectors within the dataset, providing insight into innovation trends and technological focus areas.

To enhance the depth of our analysis, we introduced a measure of *the degree of prevalence* of green IPC codes. Each patent is associated with a set of IPC codes, of which only a subset belongs to the Green IPC inventory. The degree of prevalence of green codes within each patent is then quantified using the following statistic, for any patent *i*:

$$\pi_i^{(g)} = \frac{Number\ of\ green\ IPC\ codes}{Total\ number\ of\ IPC\ codes} \qquad (1)$$

It is immediately seen that $0 \leq \pi_i^{(g)} \leq 1$.

This measure quantifies the widespread presence of green technologies compared to other technologies in a patent. This enables an assessment of which Fintech patents incorporate a higher degree of environmentally friendly technologies, thereby establishing a form of green-technology footprint.

2.3 Network analysis

We perform a network analysis because this analysis enables the calculation of several metrics that disclose different properties as explained, for example, in Barabási (2016). We initially focus on the entire set of IPC codes as they are present in the collection of patents in order to analyze the mix of green technologies that appear in the Fintech patents. We begin by extracting all of the IPCs for every patent from our dataset. Next, we take into account a node for every single IPC and a link between two of them if they were included in the same patent. For every patent in the dataset, this process is repeated, producing a final network that we refer to as G_{IPC}.

From the construction of the graph we have eliminated the IPC codes that are not related to other codes. Since these codes exist as a code that is never coupled with another code in each patent, they are actually represented as a single node in the network and are therefore irrelevant to our analysis.

2.3.1 New measures to evaluate the patent greenness

Among the many methods used in network analysis, social network analysis (SNA) is one of the most popular tools. In this paper, we introduce three new measures that are derived from well-known centrality measures, and we use them to quantify how green a patent is and to better understand how a green IPC tends to appear alongside other green IPCs. It is important to note for the sake of this paper that nodes in our network representation stand in for IPC, and links exist between two nodes when the respective IPCs are simultaneously included in a patent.

2.3.2 IPC greenness

Let's consider a variable δ_i to associate to each node i, where $\delta_i = 1$ if the node refers to a green IPC code, 0 otherwise. The first measure indicates the percentage of green nodes with respect to the degree, in formula:

$$g_i = \frac{\sum_{j \in N(i)} \delta_j}{d_i} \qquad (2)$$

where g_i ranges from 0 to 1 and indicates the percentage of green nodes with respect to the degree d_i of node i with neighbourhood $N(i)$. Equation 2 gives the fraction of links to green IPCs for every IPC and quantifies how a technology is related to green technologies and when $g_i = 1$ all nodes in the relative neighbourhood are green; conversely, when $g_i = 0$, none of the linked nodes are green. In other words, if $g_i = 1$, then it means that this specific IPC i is a complementary technology to green technologies and is developed to work with them to improve or improve their overall performance or functionality. On the other hand, if $g_i = 0$, the technology is never considered together with a green technology.

2.3.3 IPC nearest neighbour average greenness

The second measure is based on the average degree of nearest neighbour introduced in Pastor-Satorras et al. (2001). This measure allows us to examine the neighbourhood $N(i)$ to check for possible hierarchical structures in the network topology and non-trivial correlations between the connectedness of nodes. In formula:

$$g_{nn,i} = \frac{1}{d_i} \sum_{j \in N(i)} g_j \qquad (3)$$

where d_i is the degree and g_j is the greenness score for the nodes j adjacent to i. This measure takes into account the average proportion of green nodes in a node's neighbourhood; in other words, it allows one to examine the structural organization surrounding a node by combining topological data about its neighbourhood with the greenness score of the nodes that make up that neighbourhood. This feature takes into account the identification of local network clusters where connected technologies can merge and, in cases where nodes have a high nearest-neighbour average greenness score, combine to produce greener patents. Figure 1 displays two distinct local configurations of green nodes for a node i in the same neighbourhood.

Equation 3 also gives weight to the average greenness score of its neighbouring IPCs and quantitatively accounts for each IPC's role, regardless of its degree. Since high-degree nodes are regarded as more significant than low-degree nodes, it is actually common practice to create a hierarchy of nodes. In our scenario, high-degree nodes could be connected to low greenness nodes, resulting in a low nearest-neighbour average greenness value, whereas low-degree nodes could be surrounded by nodes with high levels of greenness, resulting in a high value of neighbour average greenness value. In the former case, we saw a core technology that was less associated with other green technologies, and in the latter case, we have a less central technology that is closely associated with green technologies.

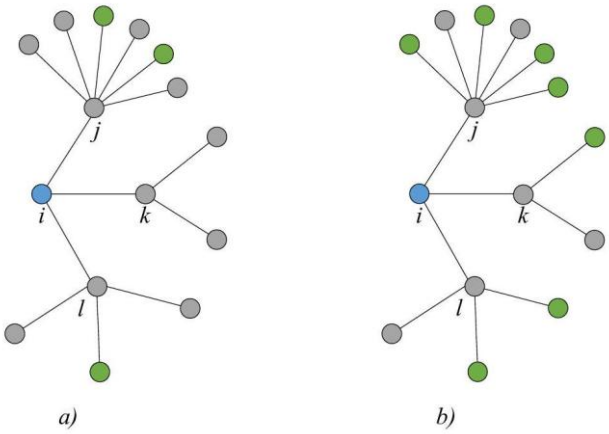

Figure 1: Two examples of a local neighbourhood for node i (green IPC are represented with green coloured nodes). In the a) panel, nodes score $g_j = 0.33, g_k = 0, g_l = 0.33$, thus $g_{nn,i} = 0.22$; in the b) panel nodes score $g_j = 0.66, g_k = 0.5, g_l = 0.66$, thus $g_{nn,i} = 0.60$.

2.3.4 Patent greenness

The third measure considers the connectivity between IPCs. Indeed, suppose that a given patent j is related to a given number of IPCs, says k; then it has a technological profile resulting in a set that we can call $p_j = \{IPC_1, IPC_2, \dots, IPC_k\}$. Since each IPC is a node in our network, it has associated a greenness g_i, thus we can average such values to obtain the patent greenness as:

$$p_j^g = \frac{1}{k}\sum_{l=1}^{k} g_l \qquad (4)$$

it quantifies the degree to which a technology is related to green technologies.

When $p_j^g = 1$, it indicates that the patent is fully composed of IPC codes related to green nodes, while $p_j^g = 0$ indicates a patent with all IPCs not related to other green IPCs. Equation 4 determines the greenness of a patent by averaging the greenness scores of all the technologies used. Thus, we move the emphasis from evaluating the greenness of individual IPCs to evaluating the greenness of a single patent. Therefore, differently from (1) which calculates the percentage of green IPCs in its technological profile, the measure (4) quantifies the general extent to which a patent is associated with green technologies.

It should be noted that Equations 2 and 3 do not take into account whether a node i is green or not. We adopt this formulation because we are interested in the degree to which IPCs are connected to green nodes, regardless of whether they are green or not.

3 Results

3.1 Fintech Green database

According to the database construction step, the string used as input in the advanced search engine of Patentscope for the Title or Abstract field, (with the "Single Family Member" set to True), is based on the keywords extracted from Scopus preliminary search. The complete Fintech database contains 7,107 patents, from 2010 to 2023. By intersecting IPC codes from our database with those in the WIPO IPC Green Inventory, we extracted the green Fintech database, containing 5,168 patents.

3.2 Database analysis

We focus our analysis of the green Fintech database relying in the "Publication date", "Applicants", "IPC code", and "Abstract" fields.

3.2.1 Descriptive statistical analysis

Time evolution of patent publication. Figure 2 shows the frequency and the cumulative frequency of the number of patents with and without green technologies from 2010 to 2023. A peak in the number of patents can be observed in 2019. With regard to the cumulative frequency, an increasing number of patents with sustainable technologies is evident, which demonstrates a growing attention on the part of companies filing

Fintech patents towards the use of technologies considered green. However, a slight decline was observed in 2023, and the data seem to indicate a modest deceleration in the overall growth of this segment.

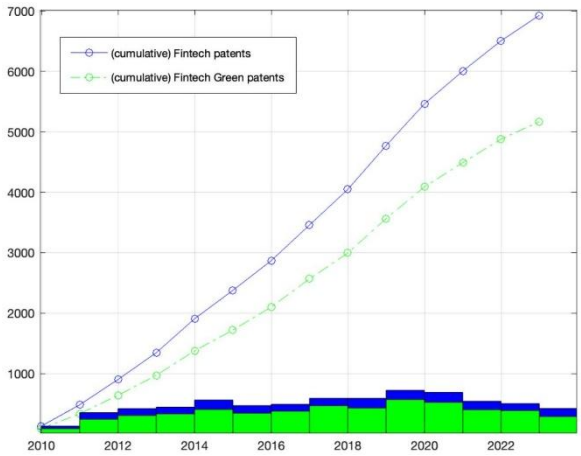

Figure 2: Frequency and cumulative frequency of patents.

Applicants. By determining the number of patents associated with each applicant, we can establish their classification, which reflects their level of involvement in research and development activities. It becomes apparent that the most active applicants are globally recognized institutions and banks that serve a global clientele. (Figure 3). We note the presence of: (i) MasterCard International Inc., which provides payment processing products including credit, debit, prepaid, personal, commercial, chip, and contactless cards; (ii) Ping An Technology Ltd, which uses artificial intelligence, cloud and other cutting-edge technologies to develop and operate platforms that support financial services; (iii) Shenzhen Cifpay network bank technology co. Ltd, which is active in data processing systems, digital information transmission, and electric digital data processing; (iv) Visa International, which offers an operational structure to support consumer payment services globally by providing telecommunications worldwide, manages data payment processing and, settles payments.

The analysis performed shows that only large technology companies with a consolidated position in the digital services sector are a prominent feature of the application landscape.

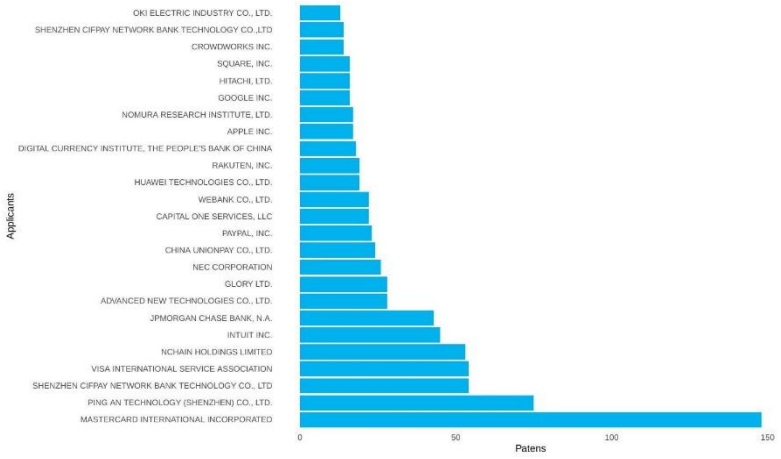

Figure 3: Patents of the Top 25 applicants.

IPC patent codes. The frequency of IPC codes may serve as an indicator of the technological distribution and focus areas within the patent dataset. The observed frequencies in our green Fintech database are shown in Figure 4.

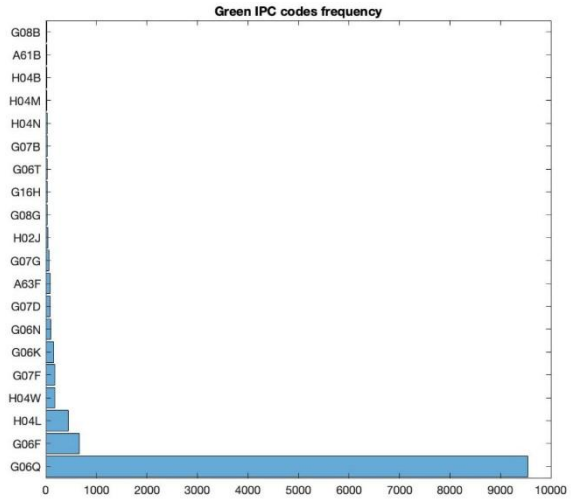

Figure 4: Frequency of the IPC green codes, considering only Section, Class and Subclass of the hierarchical classification scheme.

The *green IPC codes* most commonly used are described in Figure 5. The most frequent codes are G06Q 40/00 related to "Finance Insurance, Tax strategies, Processing of corporate or income taxes", G06Q 20/38 "Payment protocols", G06Q 20/40 "Authorization", G06Q 40/02 "Banking", and G06Q 20/06 "Private payment circuits". The code G06Q is unquestionably important in the dataset. It relates to data processing systems or methods, specifically for business or administrative purposes, and is included in the category of green technology for several reasons. G06Q covers systems optimising resource and energy use including supply chain tools, demand side management, and smart grids.

We also analyse *the degree of prevalence* of green IPC codes. We calculated the values of $\pi_i^{(g)}$ (see (1)) for all patents in the entire dataset of 7,107 documents. The distribution of the statistic is depicted in Figure 6. We can observe that in the set of 5,168 green patents, 3,858 contain only codes belonging to the WIPO IPC Green inventory, corresponding to 75%. Moreover, more than 93% of the patents exhibit a degree of green prevalence greater than 0.5. In contrast, 1,939 patents of the entire Fintech dataset are characterized by technologies that are considered non-green.

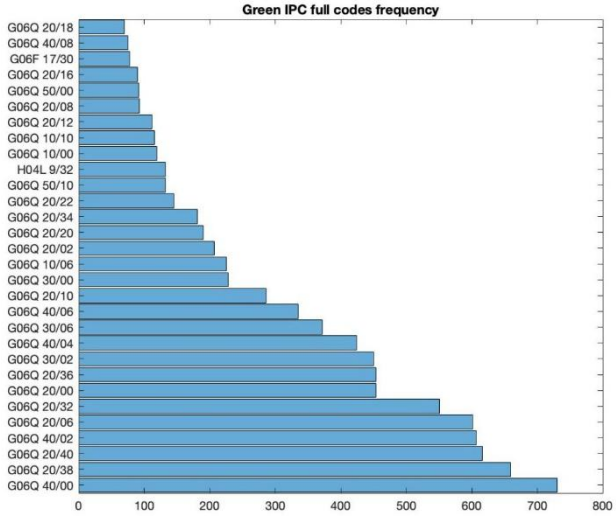

Figure 5: Frequency of the IPC green full codes.

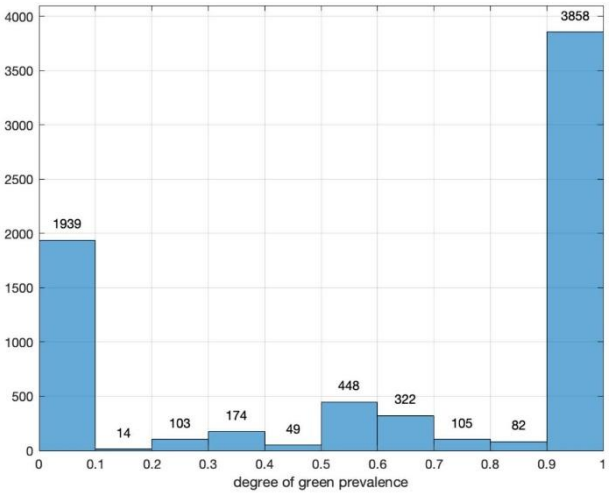

Figure 6: Observed frequencies of prevalence $\pi_i^{(g)}$.

3.3 Network analysis

Using our dataset, we constructed the weighted and undirected network G_{IPC} composed of 707 nodes and 5,048 links. The nodes with higher degree d_i, that is, the nodes with the largest number of other nodes related to them, are G06Q 20/38 ($d_i = 203$), G06Q 30/02 ($d_i = 193$), G06Q 40/02 ($d_i = 189$) and G06Q 20/06 ($d_i = 186$); G07F $19/00$[1], with $d_i = 59$, is the first IPC not in the G06Q class as well as the first not green IPC with the highest degree; finally, H04L $9/32$[2], with $d_i = 98$, is the first not in section G.

Figure 7 reports the density values when Equation 2 (left panel) and Equation 3 (right panel) are applied to network G_{IPC}. The right panel illustrates that the majority of nodes are located between 0.25 and 0.75 , while the peak values for g_i are centred around 0.5 . We can infer that the majority of IPC codes, or nodes, have around 50% of their neighbourhood made up of green nodes since g_i measures IPC's greenness, defined as the percentage of its linkage to other green IPC. While g_i indicates a good distribution of IPC codes associated with green IPC codes - that is, most patents do include the current presence of green IPC codes - a consistent peak began to emerge around the value of one, indicating that several IPC codes are linked with only green IPC codes.

When looking closely at IPC greenness, only 18 green IPCs receive a score of 1 , compared to 85 non-green IPCs with the same score. The highest score for both sets is obtained when the degree is $d_i = 7$, which is related to H02J 7/02 and H04L 65/40, respectively. Just one green IPC (G08G 1/123, with degree $d_i = 1$) and ten non-green IPCs (G01R $33/02$, the one with the higher degree, $d_i = 4$) have a score of zero. Whether the IPC was green or not was not specifically included in the calculations.

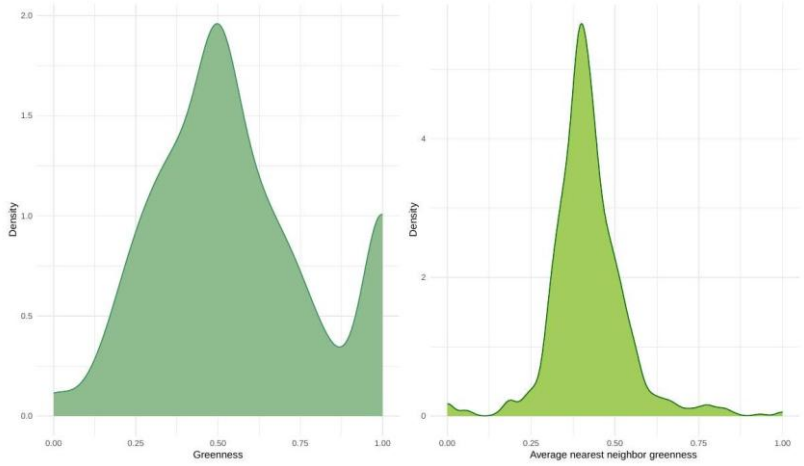

Figure 7: Density of g_i and $g_{nn,i}$.

.

Table 1 shows the four distinct classes in which IPC can fall, according to the WIPO specification and the greenness score.

Table 1: A classification of various technology classes based on the green WIPO definition and the greenness findings from the network study.

		Network results	
		Low greenness	High greenness
WIPO specification	Non-green	Non-green technology (i.e. IPC) that complements a small number of green technologies.	Non-green technology (i.e. IPC) that complements a large number of green technologies.
	Green	Green technology (i.e. IPC) that complements a small number of green technologies.	Green technology (i.e. IPC) that complements a large number of green technologies.

The density of $g_{nn,1}$ offers a similar perspective. In fact, the values between 0.25 and 0.75 still have a concentration, but their significance has changed because $g_{nn,1}$ measures for an IPC the average value of the greenness of its adjacent. Taking this into account, the results indicate that nearly every node is connected to other nodes that have a certain level of greenness. Consequently, the network is filled with green nodes that are not confined to particular regions within the network.

When it comes to patents, we can calculate their overall greenness using Equation 4, which is the total of the single greenness g_i of the considered IPC averaged by the number of them in the considered patent. The density of p_i^g is reported in Figure 8, which indicates that the range of 0.25 to 0.50 is where the concurrent presence of green IPC is concentrated. As a result, a significant amount of patents contain elements of greener IPC, or green technology.

The production of green patents by applicants can be examined through the study of patent greenness. The top 14 applicants are ranked in Table 2 according to the number of patents they have presented, as well as their minimum average, and maximum patent greenness scores.

With 148 patents, MasterCard International Incorporated has the highest production, with greenness scores ranging from 0.26 to 0.57 and an average of 0.35. Despite having much fewer patents, numerous other applicants in the table likewise attained comparable averaged values. With a few exceptions, most maximum values fall between 0.55 and 0.70 , and no one achieves a maximum score of one.

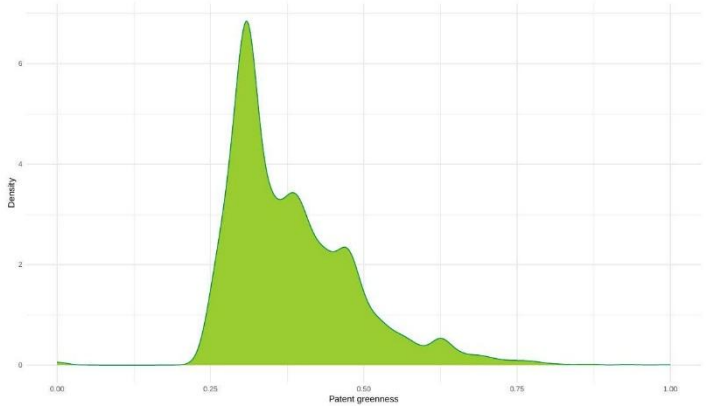

Figure 8: Density of p_i^g.

Table 2: Minimum, averaged and maximum values of patent greenness p_j^g for the top 14 applicants sorted in order of number of patents.

Applicant	**Nr. of patents**	**Min**	**Ave**	**Max**
MASTERCARD INTERNATIONAL INCORPORATED	148	0.26	0.35	0.57

CAPITAL ONE SERVICES, LLC	22	0.26	0.33	0.62
WEBANK CO., LTD.	22	0.26	0.37	0.67

4 Discussion and conclusions

This paper examines the green aspects of Fintech. The relative frequency of patents containing a number of green technology classifications within the complete dataset exhibits an increasing trend, which has, however, stabilised in recent years. Despite this stabilization, a slight decline was observed in 2023. Furthermore, the data indicate a modest deceleration in the overall growth of this segment, suggesting a potential plateau in the expansion of green-oriented innovations in the Fintech domain.

These findings lead to several important conclusions. The stabilization in the relative frequency of green patents suggests that the integration of green technologies into the Fintech landscape may have reached a more mature stage, with companies consolidating efforts rather than pursuing rapid expansion. The slight decline observed in 2023 may indicate signs of market saturation or changes in industry priorities. The decline could also reflect the impact of external factors, such as economic uncertainty, regulatory shifts, or reduced funding.

The prevalence index analysis of the Fintech patent dataset gives a picture of the use of green technologies, providing an answer to our research question RQ1. In particular, the prevalence index shows that most patents (93%) rely more than 50% on technologies classified as green and that almost 75% use green technologies completely. This, of course, depends on the fact that the IPC code most involved in Fintech patents (G06Q) is included in the WIPO Green Inventory. We used network analysis in order to answer RQ2, and we propose three new measures that capture different aspects: (i) the degree of complementarity with green IPCs as measured by the greenness index; (ii) the degree of complementarity with green IPCs extended to the neighbourhood as measured by the nearest neighbourhood average greenness; (iii); the patent greenness, measured as the averaged greenness of the IPCs taken under consideration in the patent.

In particular, the second measure, which takes into account both the neighbors of a node and the neighbours of neighbours, is referred to as a measure of the second order since it takes into account the local organization surrounding a node. In particular, it finds local clusters of high-scoring nodes that may eventually combine to form a greener patent; second, it clarifies the distinction between an IPC's greenness in terms of quantity and quality, emphasizing that the degree - that is, the number of complementary technologies - is insufficient to distinguish between local clusters where green technologies are concentrated.

Regarding the third measure, it makes it possible to determine each patent's greenness based on its IPCs. With this measure, the greenness of a patent may be measured not only by the quantity of green IPCs that include it but also by their overall green behaviour within the Fintech ecosystem of technologies.

The analysis of the network results show that green codes represent technologies defined hubs, so even if they are relatively few, they are extremely relevant in terms of their influence on other technologies. Moreover, the distribution of the greenness values is peaked around 50%, with a less prominent spike at 100%, while the average greenness, which takes into account the degree of the node, is less dispersed around the mode value.

However, as green nodes are less than others, they result in being very pervasive, Regarding the top Fintech patent applicants, we observe the presence of a significant player in terms of the number of Fintech patents. However, it should be noted that the player itself has a relatively small number of patents that contain green codes. Nevertheless, for some applicants with a small number of Fintech patents, maximum greenness values are found to be even higher than 0.50. The distribution of greenness for individual applicants exhibits a concentration of values below 50%, with instances of multimodality (Shenzen Cifpay Network Bank Technology Co., Ltd and NChain Holdings Limited), indicating the presence of different types of patents, from the perspective of patent greenness, within the same company.

4.1. Limitations and future research

This study exclusively used the WIPO database, relying on the definition of green technologies by the organization based on the classification provided by IPCs. Future research should incorporate additional classification systems, such as the ENVTECH database developed by the OECD to categorize green technologies, as well as the Y02/Y04S labelling scheme introduced by the European Patent Office (EPO) in 2013.

Understanding Socio-Economic Perceptions Complexity in Romania and Moldova: Implications for the Business Environment

Profiroiu Constantin Marius, Profiroiu Alina Georgiana, Constantin Daniela-Luminița, Cibu Bianca Raluca, Delcea Camelia
Bucharest University of Economic Studies, Bucharest, Romania

Abstract

This paper investigates how people's perceptions of socio-economic indicators in Romania and the Republic of Moldova influence the development of the business environment at local and regional level, in the context of growing challenges to economic and social resilience. Based on a questionnaire applied to a sample of 3228 respondents, the study analyzes eight key indicators, grouped into two composite indices: "Economic and social policies" (I_1) and " Access to basic services/resources (critical infrastructures) services" (I_2). These two indices were then combined into a third, entitled " Overall socio-economic perceptions" (I_3), to provide an integrated picture of the well-being of the population. During the course of the work the K-means clustering algorithm and the Silhouette indicator were applied to validate the optimal number of clusters, using the RStudio software the research identified different relevant county-level clusters. In the case of the I_1 index, Romanian counties clustered in a distinct cluster from those in the Republic of Moldova, suggesting significant differences in income satisfaction, job security and access to public services. In contrast, for I_2, the analysis revealed five clusters, reflecting greater variation in perceptions of access to utilities, energy, education and health. Thus, even though the majority of counties in Romania received high scores, there were also a few counties that scored lower, for which some improvements should be made. The results provide a useful tool for policy makers and business actors, suggesting areas with different needs and varying investment potential. The study highlights the importance of understanding local perceptions in formulating development and intervention policies.

Keywords: Socio-Economic Analysis; Clustering; K-means; Complexity; Business Environment

Paper type: Academic Research Paper

1 Introduction

Starting from the idea that the population's perceptions of socio-economic conditions can have a direct influence on economic behavior, the level of trust in institutions and, implicitly, on the dynamics of business environment development, it was deemed necessary to conduct this analysis. With the help of understanding these perceptions, a much clearer picture of the investment potential and the real needs of communities can be created. In this context, this paper aims to explore the complexity of the socio-economic perceptions of the inhabitants of Romania and the Republic of Moldova and to determine how this thinking influences the business environment by grouping counties in both countries into clusters based on their socio-economic characteristics. Based on a questionnaire administered to respondents from these countries, the research aims to investigate eight socio-economic indicators, which are then aggregated into two variables that address socio-economic aspects ("Economic and social policies" and "Access to basic services/resources (critical infrastructures) services").

Over time, a series of researchers have considered the socio-economic indicators for analyzing economic resilience, both at local and regional level. Observing the increasing number of extreme natural disasters, Borre et al. (2025) developed a composite index (Recovery Gap Index) that has the ability to assess and quantify the capacity to respond and recover from such an event. Aligica and Ciobanu (2025) explore the trade-offs between the economic benefits of global economic integration and the risks that this interdependence entails, particularly in the context of geo-economics and security. The two authors advocate a balanced approach that combines economic efficiency with security and resilience to reduce geopolitical risks.

Ma and He (2024) have demonstrated that the business environment is able to significantly simulate the quality of economic development, observing that total labor force is considered as a mediating variable. Moreover, the relationship between business climate and the level of economic progress has been intensively investigated by Djankov et al. (2006) who showed that if a country moves from the worst to the best economic regulations, this can lead to an increase in the economy by 2.3 percentage points per year. Furthermore, Li et al. (2023) showed that the upgrading of high-tech areas has a stronger impact on urban economic development in well-connected eastern cities with developed economies or close to provincial capitals, thus highlighting the crucial role of tailored regional policies.

In the present work, clustering was chosen as it allows to identify and understand the similarity between patterns, helping to group those data that prove to have characteristics that are similar (Abediniangerabi *et al.*, 2020; Qiao *et al.*, 2021). Moreover, the K-means method has been used over time in different fields of activity such as: renewable energies and optimization of integrated energy systems (Tan *et al.*, 2025), medicine (Win *et al.*, 2025), urban resilience planning (Moradpour *et al.*, 2024) or even petroleum engineering (Wang *et al.*, 2023).

2 Methodology

Three indexes have been used in the analysis, as described below. Also, a discussion related to the process of choosing the optimal number of clusters for each indicator is provided. In terms of software used, RStudio has been selected, due to its powerful capability of analyzing and manipulating data (Aria and Cuccurullo, 2017).

2.1 Data Collection

In order to collect the data used in this analysis, a survey was created and administered in turn to respondents in Romania (between December 2021 and January 2022) and in the Republic of Moldova (between February and March 2022). In Romania, all 41 counties were targeted, plus the capital, Bucharest, with a total of 2216 respondents. In the Republic of Moldova, 35 administrative units were included, with a total number of 1012 respondents. The survey asked about economic factors, social policies and access to basic services. The answers were recorded on a scale from 0 to 1 and the values analyzed are averages of the perceptions expressed by the respondents.

2.2 Economic and social policies Index (I_1)

The first indicator created is the one on economic factors and social policies. It has been formed on the basis of four key variables, each of which provides a detailed picture of the level of satisfaction of citizens at county level with: the level of personal income, job security, sense of belonging to their community and ease of access to local services (Table 1).

Table 1: Variables included in I_1 metric

Metric	Variables	Brief description
I_1	High personal income	The average value of the responses offered by the individuals through which they are evaluating whether they have a high personal income
	Job security	The average value of the responses offered by the individuals through which they are evaluating whether they have a high job security
	Community belonging sentiment	The average value of the responses offered by the individuals through which they are evaluating whether they have a high community belonging sentiment
	Easy access to local public services	The average value of the responses offered by the individuals through which they are evaluating whether they have an easy access to local public services

2.3 Access to basic services/resources (critical infrastructures) services Index (I_2)

The second indicator, the access that citizens have to the different basic services, representing crucial aspects for the well-being and development of communities. This indicator was created to measure the perceptions of the population at county level on the availability and ease with which they can access basic services such as utilities, energy, healthcare or even education (Table 2).

Table 2: Variables included in I_2 metric

Metric	Variables	Brief description
I_2	Access to utilities	The average value of the responses offered by individuals regarding their evaluation of how easily they have access to basic utilities
	Access to energy	The average value of the responses offered by individuals regarding their evaluation of how easily they have access to reliable energy sources
	Access to healthcare	The average value of the responses offered by individuals regarding their evaluation of how easily they have access to healthcare services
	Access to education	The average value of the responses offered by individuals regarding their evaluation of how easily they have access to education services

2.4 Overall socio-economic perceptions (I_3)

This index was created by calculating the average of the scores recorded at county level for I_1 and I_2, in order to provide a global and integrated assessment of the economic and social status of the population. By combining the two indexes, it was intended to achieve a more comprehensive analysis of the well-being of citizens, reflecting both the standard of living and accessibility to utilities, energy, health and education. In addition, it provides an effective tool for assessing the performance of regions and identifying those with shortcomings in both areas, allowing the identification of regions in need of integrated policy interventions, simultaneously addressing both economic factors and access to services .

2.5 Silhouette Index

The Silhouette Coefficient is an indicator that measures the classification quality of an object in a cluster by comparing how close it is to the items in its own cluster to those in other clusters (Chattopadhyay and Chattopadhyay, 2025). The formula for this indicator is:

$$S_i = \frac{b_i - a_i}{\max\{a_i; b_i\}} \quad (1)$$

In the formula, a_i is the average distance from point i to all other points in the same cluster, thus measuring the internal cohesion of the cluster: a smaller a_i indicates that the point is well integrated in its cluster. On the other hand, b_i is the average distance from point i to all points in the nearest neighbour cluster, expressing how well separated i is from other clusters. The larger b_i is, the better the point is delimited from the other clusters (Yang et al., 2025). By using the maximum between a_i and b_i in the denominator, the score Si is normalized and will have values between -1 and 1. As an interpretation, a score close to 1 indicates a correct assignment of the point, one close to 0 suggests that the point is on the border between two clusters, and a negative score shows that the point might be misassigned and would rather belong to another cluster (Rousseeuw, 1987).

2.6 K-means Clustering

The K-means clustering algorithm is an unsupervised machine learning technique used to divide a dataset into k distinct clusters. It requires prior determination of the number of clusters and works without a training process. Initially, k centroids are randomly chosen, and each data point is assigned to the cluster whose centroid is the closest, based on distance (usually Euclidean distance). Afterwards, the centroids are recalculated as the average of the assigned points, and the process is repeated until convergence, meaning that the data points no longer change clusters and the loss function is minimized. The algorithm reduces the internal variation of each cluster by efficiently delineating the divisions within the data (Ahmed et al., 2020; Chattopadhyay and Chattopadhyay, 2025; Faber, 1994).

3 Results Interpretation

The first part of this section covers the process of selecting the optimal number of clusters, using the Silhouette indicator, which ensures the validity and relevance of the clusters obtained. The second part provides a clear picture of each cluster formed, highlighting the main characteristics and particularities of the components of each cluster. The third and last part of this sub-chapter includes a discussion section, in which the results obtained are interpreted and recommendations are formulated to provide directions for action for policy makers and other stakeholders.

3.1 Choosing the Optimal Number of Clusters

To make sure that the chosen number of clusters for each indicator is the optimal one, the Silhouette index was used. Silhouette score values were generated for different clustering scenarios (from 2 to 6 clusters) and the number of clusters corresponding to the maximum value of this index was then chosen.

Table 3: Silhoutte index for I_1, I_2 and I_3

Number of clusters	Silhoutte index for I_1	Silhoutte index for I_2	Silhoutte index for I_3
2	0.93	0.84	0.95
3	0.79	0.88	0.83
4	0.57	0.94	0.62
5	0.61	0.99	0.65
6	0.65	0.89	0.65

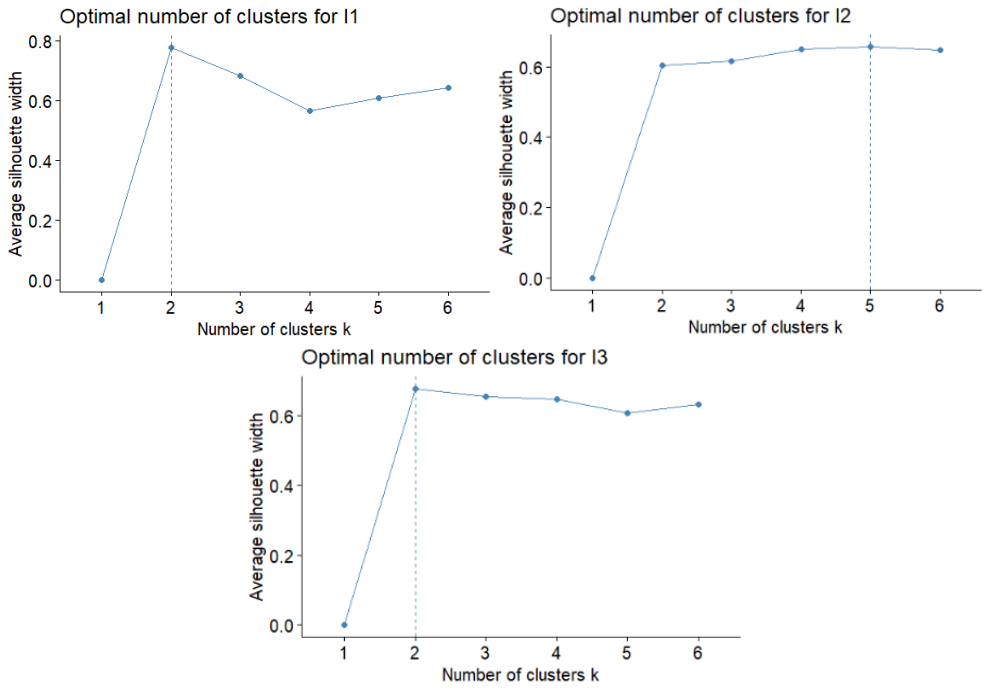

Figure 1: Optimal number of clusters for I_1, I_2 and I_3

Table 3 contains the scenario-specific values for the Silhoutte indicator, while Figure 1 helps to visually observe the optimal number. Thus, as mentioned in the previous paragraph, for each index, the highest value of the Silhoutte indicator will be chosen as the optimal number of clusters. For I_1, 2 clusters will be formed, for I_2, 5 clusters will be generated, and for I_3, similar to the situation of I_1, 2 clusters will be wanted.

3.2 Building Clusters

Knowing the optimal number of clusters for each indicator, one can proceed to the actual construction of each cluster. For this step, the K-means method was chosen, due to its efficiency and popularity in identifying homogeneous clusters in complex datasets. The construction of the clusters was realized using the average of the answers that the respondents provided when answering the questions related to each variable included in the creation of a particular indicator. Thus, for each county, a representative mean score was calculated for each indicator, and these mean values formed the basis on which the K-means algorithm was applied. This approach allowed the grouping of respondents according to the similarities in their perceptions and experiences of economic and social policies and level of access to basic services. Depending on the number of clusters chosen for each indicator, each time, the first cluster represents the average of the highest scores given by the respondents. As the number obtained by each cluster increases, the average of the answers it contains will be lower (e.g. the last cluster will always contain the averages of the lowest answers recorded).

Table 4: Counties clusters for I_1

Cluster	Components
1	Alba, Arad, Arges, Bacau, Bihor, Bistrita-Nasaud, Botosani, Braila, Brasov, Bucuresti, Buzau, Calarasi, Caras-Severin, Cluj, Constanta, Covasna, Dambovita, Dolj, Galati, Giurgiu, Gorj, Harghita, Hunedoara, Ialomita, Iasi, Ilfov, Maramures, Mehedinti, Mures, Neamt, Olt, Prahova, Salaj, Satu Mare, Sibiu, Suceava, Teleorman, Timis, Tulcea, Valcea, Vaslui, Vrancea.
2	Anenii Noi, Balti, Basarabeasca, Briceni, Cahul, Calarasi, Cantemir, Causeni, Chisinau, Cimislia, Criuleni, Donduseni, Drochia, Dubasari, Edinet, Falesti, Floresti, Glodeni, Hincesti, Ialoveni, Leova, Nisporeni, Ocnita, Orhei, Rezina, Riscani, Singerei, Soldanesti, Soroca, Stefan Voda, Straseni, Taraclia, Telenesti, Ungheni, UTA Gagauzia.

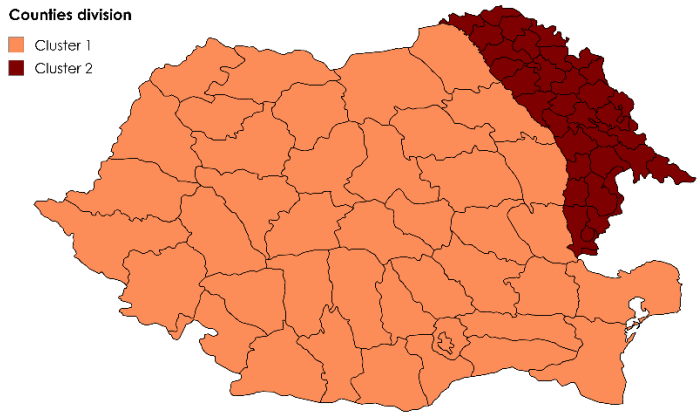

Figure 2: Counties clusters - I_1

Table 4 and Figure 2 give a very clear picture in terms of comparing the perceptions of respondents from Romania and the Republic of Moldova regarding the economic and social policies index. Cluster 1 is composed only of counties from Romania, with mean scores between 0.70 and 0.97, while Cluster 2 is composed only of counties from the Republic of Moldova, with mean scores between 0.32 and 0.60. From this can be deduced the difference in the perceptions of the citizens of the two counties analyzed regarding their own income, job security, sense of belonging to the community, as well as the ease they perceive in terms of local public services.

If for the previous index only 2 groups were formed, this time for the index on access to basic services, a total of 5 clusters were identified. Cluster 1 contains mean responses between 0.92 and 0.97, Cluster 2 between 0.88 and 0.91, Cluster 3 between 0.84 and 0.87, Cluster 4 between 0.8 and 0.83, and Cluster 5 between 0.77 and 0.78. In terms of the number of counties, the most populated clusters as can be seen in the Table 5 and Figure 3 are Cluster 2 and Cluster 3, which shows that the majority of respondents have positive perceptions regarding the ease of access to utilities, energy, healthcare or education.

Table 5: Counties clusters for I_2

Cluster	**Components**
1	Cluj, Dolj, Galati, Hunedoara, Iasi, Maramures, Mures, Valcea, Taraclia, UTA Gagauzia.
2	Alba, Arges, Bacau, Bistrita-Nasaud, Braila, Brasov, Bucuresti, Buzau, Calarasi, Caras-Severin, Giurgiu, Mehedinti, Neamt, Olt, Sibiu, Vaslui, Anenii Noi, Basarabeasca, Causeni, Chisinau, Cimislia, Criuleni, Dubasari, Hincesti, Ialoveni, Leova, Stefan Voda, Straseni.

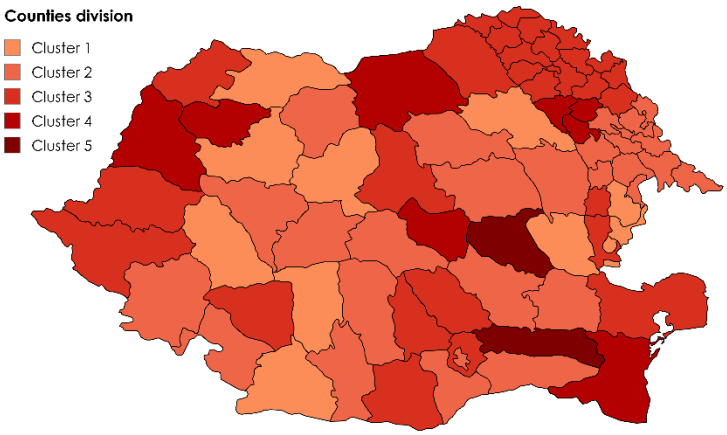

Figure 3: Counties clusters - I_2

In the case of the third index, which refers to overall socio-economic perceptions, Table 6 and Figure 4 show a situation similar to the one encountered for I_1, with two Clusters. Cluster 1 contains response averages between 0.78 and 0.94 and Cluster 2 has averages between 0.59 and 0.75. Considering that this index was created from I_2 and I_3 it is interesting to note that only one county in Romania migrated from Cluster 1 to Cluster 2 (Ialomita). This change is explained by the fact that, although in the case of the first indicator (I_1) the score of Ialomita county (0.70) was located at the lower limit of the range for Cluster 1, when averaging I_1 and I_2 to form the new index (I_3), the aggregate score (0.73) fell better within the range specific to Cluster 2. Thus, the average between the two dimensions caused its migration to a different cluster.

Table 6: Counties clusters for I_3

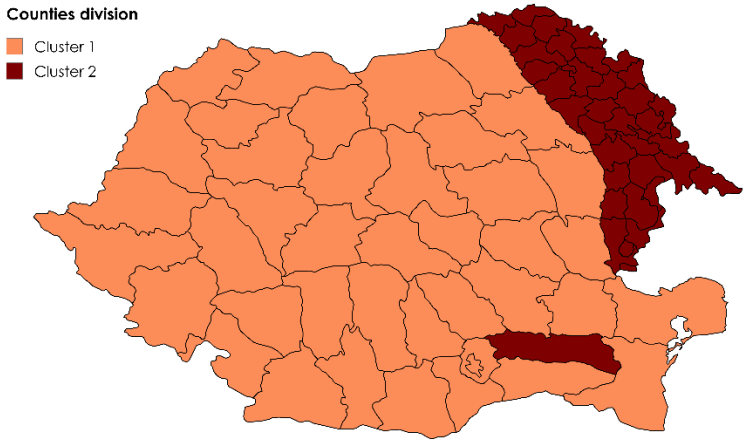

Figure 4: Counties clusters - I_3

3.3 Discussion and Recommendations on the Obtained Clusterizations

The largest number of respondents (102 respondents) came from the capital (Bucharest), the rest of the counties participating in the research having between 50 and 54 respondents. In the analysis, the age of respondents was between 18 and 65 years. The most common age category among Romanian respondents was between 36 and 45 years old, followed by 46 and 55 years old; while in the Republic of Moldova the age range was 26 and 35 years old, followed by 36 and 45 years old.

As previously mentioned, there were four variables in the "Economic and social policies index" component. According to the clustering results, it is very easy to deduce that the perceptions of the inhabitants of the analyzed counties, in relation to: personal income, security felt at work, sense of belonging to the community, and the perceived level of ease of access to public services, are very different. Respondents from Romania gave much more favorable answers, which denotes a higher level of security and satisfaction, compared to the answers collected from the Republic of Moldova, where the level of satisfaction is lower, which can be easily observed in Figure 2, where the division is very clear, with Romanian counties forming Cluster 1 and those from the Republic of Moldova Cluster 2.

The interesting situation is, however, in the case of the "Access to basic services/resources (critical infrastructures) services index" where the clustering was formed by 5 groups. This may indicate that each of the 5 clusters formed represents a different profile of accessibility to basic services such as utilities, energy, healthcare or education. It can thus be affirmed, the existence of both respondents who declare very easy and constant access to all the mentioned services, and respondents who have major difficulties in at least one of these areas. This differentiation allows a more nuanced understanding of the real needs at the population level, providing a valuable starting point for the formulation of public policies or targeted interventions aimed at

reducing disparities and improving the quality of services according to the needs of each identified segment. Cluster 1, in which the highest scores are recorded, shows a predominance of Romanian counties, which are 8 in number, as opposed to the Republic of Moldova where only 2 counties are present. A similar situation is also in Cluster 2, only this time there are 16 counties from Romania and 12 from the Republic of Moldova. From this it can be deduced that respondents from several counties in Romania feel much more secure in terms of access to basic services compared to those from the Republic of Moldova, but unlike the previous index, this time the conclusion does not apply to all counties, Cluster 5 being made up of 2 counties in Romania in the case of this index.

In the case of the third index "Overall socio-economic perceptions", formed on the basis of the two mentioned above, the situation is similar to the one encountered in the case of I_1. The only difference to be mentioned is the migration of Ialomita county from Cluster 1 to Cluster 2, as it is a county on the territory of Romania. The fact that the county is in the best cluster for I_1 and in the worst Cluster for I_2, although the scores are relatively close (0.70-0.97 for I_1 and 0.77-0.78 for I_2), highlights a key point: the way respondents are grouped and the baseline values for each indicator are different, and the thresholds between clusters reflect distinct distributions and variations. In other words, for I_1 the county belongs to the most favorable cluster. This means that, relative to the rest of the counties, its score is among the highest and the perception of its inhabitants is positive. In contrast, for I_2, the county is in the weakest cluster, despite a close numerical score. This situation arises because the distribution of responses for I_2 is much narrower, and small differences can produce significant shifts in the cluster allocation. Thus, it falls in the lower range in the context of this indicator, resulting in inclusion in the weakest cluster. When the scores for the two indicators were combined in I_3 (the average between I_1 and I_2), the county ends up in Cluster 2, reflecting an overall average score, lower than expected based on I_1 performance alone. This shows that although perceptions of economic and socio-political factors, access to basic services is poor.

The importance of entrepreneurship for the existence of a dynamic economy has been observed over time, as entrepreneurs are those who create different employment opportunities, having the power to influence the economic performance of a country (Kritikos, 2024). The analysis carried out is of particular importance, because the groupings indicate the counties favorable for the development of the business environment. The more the population experiences a higher level of income security, job stability and reliable public services, the higher the domestic demand becomes, and the more the entrepreneurial spirit grows. Moreover, in places where access to utilities is easy, where education and health systems are well developed, the labor force is developed and production is increased. These areas (which are part of Cluster 1), were found to be dominated by Romanian counties, signaling low risk and high investment attractiveness. As far as the counties in the Republic of Moldova are concerned, the need for improvement of infrastructure and economic security is inferred.

In addition to helping different companies such as SMEs or local start-ups to adapt their business models according to each region, the research is also beneficial for local authorities. The differences observed between clusters can guide concrete actions according to the needs of each area. Thus, in counties where the population has a positive perception of the economic conditions, but access to services and infrastructure is poor, investments in health, education and utilities should be prioritized. In areas where infrastructure is good, but citizens feel low incomes and job insecurity, authorities should support initiatives to increase incomes (attracting investors, supporting vocational training). Moreover, the results of the analysis could be used as a basis for joint projects between Romania and the Republic of Moldova, focused on developing infrastructure and the local economy, with benefits for both sides.

4 Conclusions

Starting from the analysis of two aggregated indicators ("Economic and social policies" and "Access to basic services/resources (critical infrastructures) services"), and an indicator derived from them, namely "Overall socio-economic perceptions", it was assumed that the research can provide insight into the business environment at national level. Thus, based on a questionnaire applied to a total number of 3228 respondents from different counties both in Romania and in the Republic of Moldova, applying the K-means clustering method at the level of each index, representative clusters were created, the optimal number of clusters being chosen using the Silhoutte indicator. Clustering on the basis of the analyzed indicators makes it possible to identify regions with high potential for investment and entrepreneurial development, as well as vulnerable areas in need of specific support from the authorities.

Using the formed clusters, it can be observed that respondents from Romania tend to have a more favorable perception compared to respondents from the Republic of Moldova, thus providing a favorable environment for economic initiatives. For Romania, all counties tend to be grouped in Cluster 1. However, it is worth noting that

in terms of the I_2 index even if the majority of counties are found in the high performing clusters, the presence of some Romanian counties in the worst performing cluster emphasizes the need for targeted interventions even within Romania. In the case of the Republic of Moldova negative perceptions predominate, signaling the need for significant interventions in infrastructure and economic policies to support local development and investment attractiveness.

An important aspect that needs to be addressed are the limitations that were encountered during the conduct of this research. Data was collected using a questionnaire, the answers given by the respondents can be influenced by many factors, but this is one of the most popular data collection methods. Moreover, the questionnaire was administered only once. The analysis was carried out only at the level of Romania and the Republic of Moldova, without covering a wider geographical area such as the Eastern European economies.

Regarding future research, it would be proposed: to increase the number of respondents, to apply the questionnaire at a certain time interval (e.g. one year) in order to observe the changes that occurred over time in the population's thinking, to add other clustering methods (e.g. Density-Based Spatial Clustering of Applications with Noise or Gaussian Mixture Model), as well as to add other indexes (e.g. level of digitalization).

Abstract

Twin transition —integrating digitalisation and ecological sustainability— has become a structural priority for European regional development, as reflected in major frameworks such as NextGenerationEU and the 2021–2027 Cohesion Policy. These programmes aim not only to support recovery but also to reshape the technological and institutional foundations of regional economies. However, a significant knowledge gap remains: while the twin transition requires coordinated and systemic change, we still lack a clear understanding of how it unfolds across different regional contexts —particularly given persistent disparities in structural capacity and institutional agency. This paper addresses that gap by investigating the relationship between regional industrial path development and the capacity of regions to engage in twin transitions. Drawing on an established typology of development paths —including extension, upgrading, branching, diversification, creation and importation—and on a review of regional case studies, we develop a configurational framework that links these development paths to a set of structural and institutional causal conditions. These conditions are operationalised into indicators grounded in the literature, and applied to the Italian regional context through a fuzzy-set Qualitative Comparative Analysis covering the period 2007–2017. The findings show that regional engagement in twin transitions could result from distinct combinations of development paths and enabling conditions. Extension, upgrading, and importation path —when coupled with enabling regional conditions— are the most conducive to twin specialisation.
The study contributes to debates on bridging evolutionary economic geography and transition-oriented policy, and provides a scalable diagnostic tool to inform place-based strategies tailored to structurally diverse regional contexts.

Keywords: Twin Transition, Regional path development, Regional innovation systems, Complex systems, Fuzzy-set Qualitative Comparative Analysis

Paper type: Academic Research Paper

1 Introduction

In the 2021 Strategic Foresight Report (2021), the European Commission emphasised that the success of the twin transitions will depend on the capacity of regions to mobilise their technological, institutional, and cognitive resources. This recognition marks a critical shift in the EU policy discourse: the twin transition should no longer approached as a uniform, top-down process but as a territorially embedded challenge, unfolding unevenly across Europe (European Commission, 2024). Understanding how regions develop—or fail to develop—the necessary capabilities has therefore become a central concern for both researchers and policymakers (OECD, 2022).

The twin transition is positioned as a cornerstone of the European Union's strategic vision for sustainable growth and technological sovereignty(European Commission, 2022). Framed as both an ecological and economic necessity, it reflects the convergence of long-term climate objectives with the imperative to modernise industrial systems, enhance productivity, and secure Europe's position in global value chains. In this context, the EU has mobilised substantial policy and financial instruments, including NextGenerationEU and the 2021–2027 Cohesion Policy, to steer national and regional efforts towards an integrated transition (European Commission, 2024).

Yet the twin transition involves more than the adoption of green and digital technologies. It entails a complex, multi-dimensional reconfiguration of production systems, knowledge infrastructures, innovation ecosystems, and governance frameworks. These transformations are deeply embedded in territorial contexts and depend on the differentiated capacities of regions to absorb, adapt, and generate structural change (Rodríguez-Pose, 2018). As recent debates in regional studies and innovation policy underline, achieving an effective transition requires moving beyond aggregate indicators and engaging with the structural diversity of regions (Ron Boschma et al., 2023). Within this context, evolutionary economic geography (EEG) offers a valuable perspective, viewing regions as evolving systems whose development paths are shaped by inherited structures, institutional agency, and knowledge dynamics. The concept of regional path development provides

a framework for analysing how regions transform over time through mechanisms such as extension, upgrading, branching, diversification, creation, and importation (Hassink et al., 2019). These paths reflect the interplay between established capabilities and emergent opportunities, under both internal and external pressures (Boschma, 2017).

However, despite its growing analytical traction, the path development framework still lacks a shared operational architecture. Its empirical applications often rely on case-specific interpretations, limiting cross-regional comparability and hindering cumulative knowledge-building. Moreover, the relationship between specific regional development paths and regional engagement in twin transitions remains underexplored. In particular, there is a lack of comparative and configurational evidence on which combinations of structural and institutional factors are most conducive to supporting twin transition outcome.

This paper contributes to this endeavour in two ways. First, it systematises the application of the path development framework through a review and classification of empirical studies and case-based applications, helping to consolidate its conceptual and operational foundations. Second, it proposes a configurational model that links these path types with twin transition. The model is applied to Italian NUTS-2 regions using fuzzy-set Qualitative Comparative Analysis (fsQCA), covering the period 2007–2017, to identify combinations of cognitive relatedness, technological complexity, innovation performance, entrepreneurial capacity, institutional agency, and policy effort that enable regional engagement in such transformation.

The remainder of the paper is structures as follows. Section 2 outlines the theoretical background, reviewing key contributions from EEG. Section 3 presents the methodological approach, including case selection, operationalisation of variables, and the logic of fsQCA. Section 4 presents the model, while section 5 discusses the main results, highlighting the configurations of conditions conducive to twin transition outcome. Finally, Section 6 concludes by summarising the theoretical and practical contributions of the study, outlining its limitations, and proposing directions for further research.

2 Literature Background

Understanding how regions transform their industrial base in response to transformative pressures—such as decarbonisation and digitalisation- has become a central concern in EEG and regional studies (Boschma, 2017). In this context, the concept of regional path development has gained analytical traction as a lens for capturing differentiated trajectories of structural change (Grillitsch et al., 2018; Hassink et al., 2019). Grounded in the distinction between path dependence and path creation (Martin & Sunley, 2006), the framework has evolved into a typology encompassing mechanisms such as extension, upgrading, branching, diversification, importation, and creation (Grillitsch et al., 2018; Hassink et al., 2019; Trippl et al., 2020). These categories offer a nuanced understanding of how regions evolve by combining established assets with emergent opportunities, under varying degrees of disruption and directionality. Table 1 summarises the taxonomy of regional path development with their distinctive characteristics.

Despite its growing theoretical consolidation, the empirical application of this typology remains fragmented. Most studies adopt a descriptive approach, compare a small number of cases, and apply the typology without shared operational criteria or pursuing specific empirical research purposes. A number of illustrative examples exist. Bellandi et al. (2021) examine Macerata and Fermo as cases of path extension and renewal, showing how internationalisation activities reshape knowledge configurations through interactions between core and non-core firms. Isaksen and Trippl (2017) highlight how path creation in Arendal and Mühlviertel relies on exogenous knowledge sources and policy support in peripheral contexts. Corodescu-Roșca et al. (2023) investigate the cases of Cluj-Napoca and Timișoara, identifying contrasting developmental trajectories: Cluj-Napoca illustrates path upgrading catalysed by post-accession governance reforms, while Timișoara follows a path extension trajectory anchored in long-standing university–industry collaborations. In a distinct context, Morisson and Mayer (2021) examine Vierzon as a case of path creation through unrelated diversification, where the relocation of a blockchain start-up to a declining industrial town triggered a new trajectory via institutional mobilisation and symbolic repositioning. However, the link between development paths and the twin transition remains largely unexplored. Existing studies are predominantly qualitative and lack systematic, comparative insight into how specific trajectories support the green and digital transformation. To address this gap, we conducted a structured literature review and identified about thirty empirical case studies that could be consistently classified using the path development typology. This corpus forms the empirical foundation for our analysis.

Table 1. Types and mechanisms of regional industrial path development

Type of path development	Definition
Path extension	Continuation of an existing industrial path based on incremental innovation in existing industries along well-established technological trajectories.
Path upgrading	Major change of a regional industrial path related to enhancement of position within global production networks; moving up the value chain based on upgrading of skills and production capabilities.
I – Climbing GPN	
II – Renewal	Major change of an industrial path into a new direction based on new technologies or organisational innovations, or new business models.
III–Niche development	Development of niches through the integration of symbolic knowledge.
Path importation	Setting up of an established industry that is new to the region (for example, through non-local firms) and unrelated with existing industries in the region.
Path branching	Diversification into a new related industry for the region building on competencies and knowledge of existing industries.
Path diversification	Diversification into a new industry based on unrelated knowledge combinations.
Path creation	Emergence and growth of entirely new industries based on radically new technologies and scientific discoveries or as an outcome of search processes for new business models, user-driven innovation and social innovation.

Beyond these empirical limitations, a further constraint lies in the conceptual assumptions of the framework. While the typology captures a broad spectrum of regional transformation processes, it typically treats development paths as discrete and distinct. In reality, regional change often results from hybrid, overlapping, or even conflicting paths shaped by the interaction of multiple actors and institutional logics (Binz et al., 2016a; Grillitsch et al., 2018). This complexity becomes particularly salient in the context of the twin transition, which requires the simultaneous pursuit of decarbonisation and digitalisation. These processes often involve concurrent mechanisms of the typology but demanding a more integrated analytical lens.

To the best of our knowledge, no study has systematically examined whether—and how—specific combinations of path development underpin regional engagement in the twin transition. Nor has the typology been empirically validated through comparative, cross-regional evidence. To fill this gap, we propose a configurational framework that links types of path development with twin transition based on a structured literature review of empirical cases. Because regional transformation results from complex causal structures, fsQCA is particularly well suited to identifying the combinations associated with twin transitions outcomes (Ragin, 2014). Our empirical focus is on Italian regions, selected for their structural diversity and relevance within EU transition policy.

As shown in figure 1, this study forms part of a broader research project centred on simulating regional policy scenarios through an agent-based model. The empirical component—grounded in a systematic review of case-based evidence—complements the ABM by strengthening its empirical underpinnings. Building on this foundation, the fsQCA analysis integrates the path development framework with observed enabling conditions, generating policy-relevant configurations and transition scenarios that may inform scenario design within simulation models.

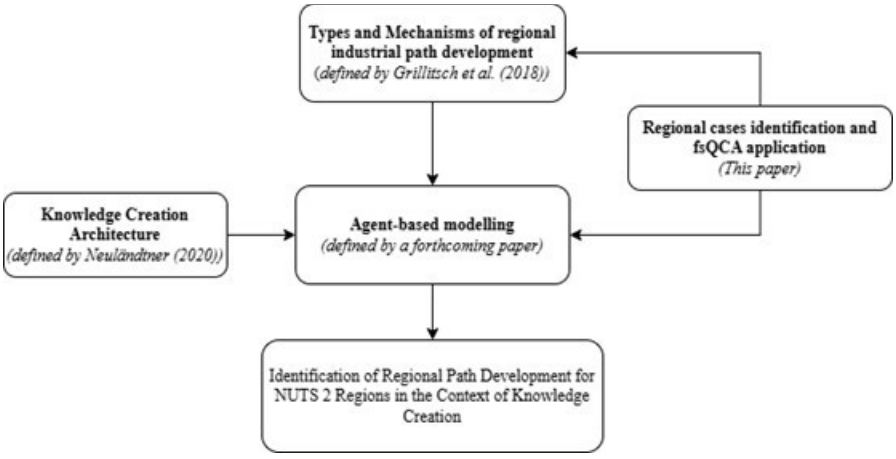

Figure 1. Pilot case for twin transition within the thematic priority of transformation pathways and strategies

3 Methodology

Based on the conceptual framework outlined above, we conducted a structured literature review aimed at identifying empirical studies that explicitly apply the paths development typology across regional contexts. The review followed a multi-stage protocol.

We queried Scopus using a combination of relevant keywords—including “regional innovation”, “pathway”, “path development”, “smart specialisation”, “industrial district”, “extension”, “branching”, “diversification”, “upgrading”, “importation”, and “creation”. The search was limited to peer-reviewed articles written in English. No restriction was placed on geography or time. Exclusion criteria were applied to filter out studies from unrelated disciplines (e.g., psychology, medicine, arts and humanities). Each abstract was screened for references to European countries and NUTS-2 regions to focus the selection on case studies. This yielded a set of 228 publications. Thirteen items were subsequently excluded due to the unavailability of full-text access, resulting in a final corpus of 215 articles subjected to full-text analysis. Additional papers were included based on the research team’s expert judgement. In total, 33 cases were systematically classified according to their dominant path development trajectory. Figure 2 summarises the literature review protocol.

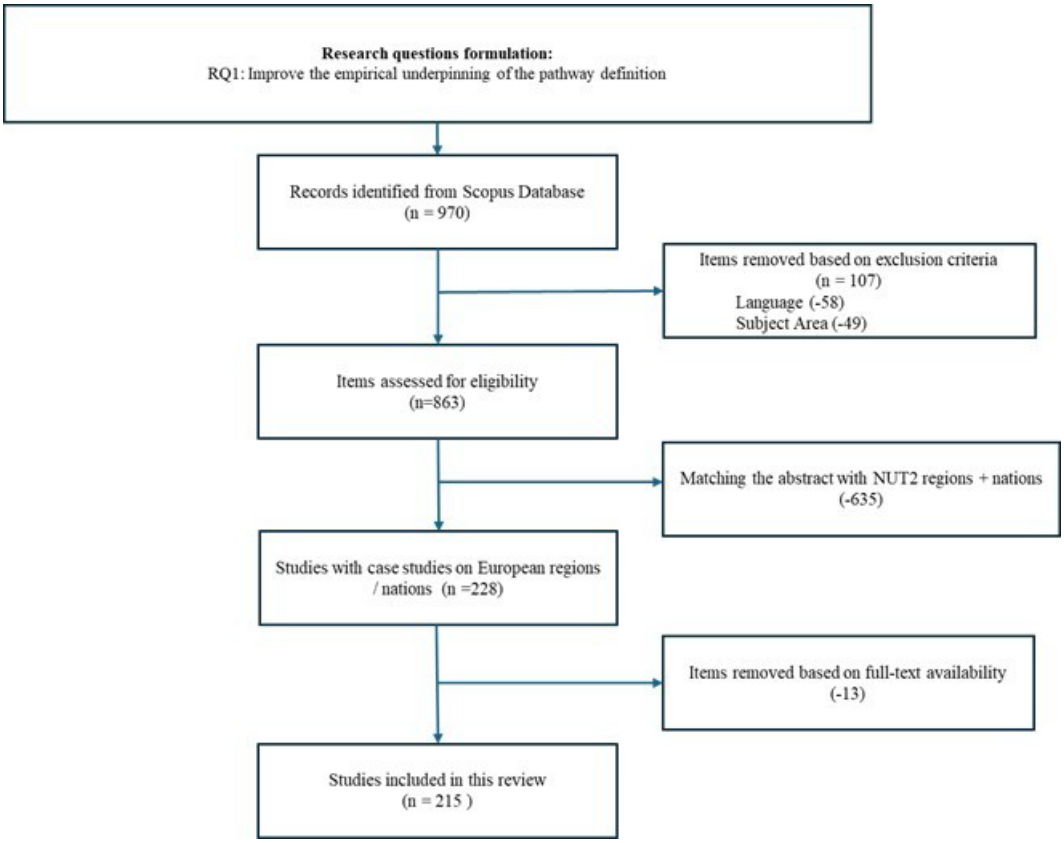

Figure 2. Literature review protocol

The outcome of the systematic review is summarised in Table 2, which reports the reference of the empirical case, the regional context investigated, and the corresponding types of regional development path (RDP) identified. This review was conducted by applying the taxonomy drawn from the literature (Grillitsch et al., 2018) to each case, based on the mechanisms explicitly described by the original authors. This systematic review provided the empirical foundation for the selection of causal conditions used in the fsQCA analysis.

Building on the review of regional development paths, we adopt a configurational approach to investigate whether specific combinations of path types are conducive to twin transitions. This methodological choice is grounded in a growing body of literature that conceptualises regional innovation systems as Complex Adaptive Systems —dynamic structures characterised by non-linearity, feedback loops, and emergent properties arising from interactions among heterogeneous agents (Ponsiglione et al., 2018). These systems are not reducible to simpler additive components, thus requiring approaches that prioritise interdependencies and context-specific mechanisms (Cooke, 2013).

Table 2. Regional Cases Classified by Path Development Mechanisms

Reference	Region	RDP
(Morisson & Mayer, 2021)	Vierzon	Path creation, Unrelated diversification
(Bellandi et al., 2021)	Macerata, Fermo, Sassuolo	Path Extension, Path Renewal
(Isaksen & Trippl, 2017)	Arendal-Grimstad, Mühlviertel	Path creation
(Trippl & Otto, 2009)	Styria, Saarland	Path creation, Path extension, unelated diversification
(Asheim, 2019)	Mazovia, Emilia Romagna	Path creation, Unrelated diversification, Path importation, Path upgrading
(Chaminade et al., 2019)	Prato, Boras	Path creation, Path extension, Path renewal
(Ostapenko et al., 2024)	Douro	Related branching, Path renewal
(Nieth & Radinger-Peer, 2023)	Aalborg, Kaiserslautern, Twente	Path creation, Path extension, Path upgrading, Path importation
(Nilsen & Njøs, 2022)	Norway	Path importation
(Corodescu-Roșca et al., 2023)	Timisoara, Cluj Napoca	Path extension, Path upgrading
(Binz & Gong, 2022)	California, Hamburg	Path creation, Path importation
(Wang et al., 2012)	Zhongguancun, Bangalore, Silicon Valley	Path creation
(Cassia et al., 2008)	Cambridge, Goteborg, Baden-Württemberg, Singapore, Pittsburgh, Milwaukee	Path renewal
(Simmie, 2012)	Denmark	Path creation
(Isaksen, 2015)	Lister	Path creation, Path extension
(Binz et al., 2016b)	Beijing	Path creation

This complexity is further emphasised by the need to account for geographically mediated knowledge transfer, influenced by institutional frameworks, scientific infrastructures, financial systems, and policy environments (Asheim et al., 2011). A configurational methodology such as fsQCA is particularly well suited to investigating these dynamics, as it captures the causal asymmetry and equifinality that typify socio-economic transformation in regional contexts (Ragin, 2014; Rihoux & Ragin, 2012).

Unlike regression-based techniques, fsQCA does not assume additive or independent effects, but instead focuses on identifying combinations of conditions that are jointly sufficient for a given outcome (Schneider & Wagemann, 2009). This approach also aligns with the configurational paradigm in innovation studies, which emphasises that socio-economic outcomes emerge from specific combinations of interdependent conditions, rather than the net effects of isolated variables (Misangyi et al., 2017).

In this study, fsQCA is applied to Italian NUTS-2 regions, where the outcome corresponds to revealed technological advantage (RTA) score in twin transition domain. Both the outcome and causal condition variables were calibrated into fuzzy sets using the direct method. Each condition is first tested for necessity, adopting a consistency threshold of 0.90. Subsequently, sufficiency is assessed by constructing and logically minimising the truth table, following standard procedures to derive complex, intermediate, and parsimonious solutions. A minimum consistency threshold of 0.65 was applied to identify configurations considered empirically sufficient. The analysis was performed using fsQCA 3.1 software.

4 The model

This section describes the model used to investigate how combinations of regional development paths influence technological specialisation in twin transition domains.

The selection of causal conditions builds on both theoretical insights from EEG and empirical patterns emerging from the literature review. In particular, the conditions reflect two overarching categories: structural assets, which shape the baseline capacity of regions to innovate and diversify, and enabling mechanisms, which activate or sustain transformative processes.

Table 3 presents the set of causal conditions included in the analysis, along with their operational definitions, sources, the association with different typed of path development, and the references.

Table 3. Causal Conditions

Label	Dimension	Index	Source	References
UV	Unrelated Variety	Unrelated Variety	Eurostat	(Frenken et al., 2007)
EKIA	Structural complexity	Employment in Knowledge-intensive activities	Regional Innovation scoreboard	(European Commission, 2023)
FDI	FDI Intensity	FDI inward stock % GDP	OECD	(Fu, 2007)
ICOLL	Collaborative R&D activity	Innovative SMEs collaborating with others	Regional innovation Scoreboard	(European Commission, 2023)
PP	Policy Pressure	Historic EU payments annual timeseries - modelled	Cohesion Data	(Mohl & Hagen, 2010)
RII	Innovation Performance	Regional Innovation Index	Regional Innovation Scoreboard	(European Commission, 2023)
NEWB	Entrepreneurial Activity	Business entries	OECD Data Explorer	(Fritsch, 2011)

The outcome is constructed using the indicator of revealed technological advantage (RTA), a widely used proxy for regional technological specialisation derived from patent data (Balland et al., 2019). RTAs were calculated separately for green and digital technologies using regionalised patent application data from the OECD REGPAT database. Green technologies correspond to the "environment-related technologies" domain, while digital technologies include patents classified under "ICT" and "artificial intelligence-related technologies", following the OECD taxonomy. It is calculated as follows:

$$RTA_{r,d} = \frac{\frac{P_{r,d}}{P_r}}{\frac{P_d}{P_T}}$$

where:

- $P_{r,d}$ is the number of patent applications in domain d filed in region r,
- P_r is the total number of patent applications filed in region r,
- P_d is the total number of patent applications in domain d across all regions,
- P_T is the total number of patent applications in all domains and regions.

An RTA value greater than 1 indicates that a region is more specialised than the national average in that domain. We construct three outcome variables: green RTA, digital RTA, and twin transition RTA A region is considered engaged in the green or digital transition in a given year if its RTA exceeds 1 in the respective domain. Engagement in the twin transition is defined as meeting both conditions (green RTA > 1 and digital RTA > 1) in the same year. For each region, we compute the number of years (2018–2021) in which this twin condition is satisfied. The outcome is calibrated into fuzzy scores as follows: 0 years = 0.00 (full non-membership), 1 year = 0.33 (weak membership), 2 years = 0.66 (crossover), and 3–4 years = 1.00 (full membership). This dynamic operationalisation captures the persistence of twin specialisation over time.

5 Results

The necessity analysis confirms that no individual condition satisfies the established consistency threshold of 0.90 for necessity, indicating that none of the enabling factors is universally present across regions engaging in the twin transition. The highest consistency is observed for unrelated variety (0.71) and entrepreneurial activity (0.64), but neither is systematically present in all positive cases. This supports the configurational logic of the study, where regional engagement emerges from context-specific combinations of enablers. Summary results are provided in Table 4.

Table 4. Necessity analysis for the twin transition outcome.

Causal Condition	Consistency	Coverage
EKIA	0.600925	0.472031
ICOLL	0.533521	0.439423
NEWB	0.641922	0.477724
FDI	0.564872	0.463005
UV	0.706146	0.508689
PP	0.599844	0.508321
RII	0.546390	0.440798

The sufficient analysis identifies six solutions sufficient to explain regional engagement in the twin transition. These configurations reflect diverse combinations of structural and institutional enablers and are interpreted through the lens of path development, drawing on empirical case knowledge. The overall solution coverage is 0.91, while the overall solution consistency is 0.75. Table 5 presents the complex solutions with core (large circles) and peripheral conditions (small circles) and their associated regional cases and path types.

Among the six solutions identified, only two exceed the standard consistency threshold of 0.75 and can be considered informative. These configurations offer a differentiated view of how distinct path development mechanisms interact with enabling conditions to support regional engagement in the twin transition.

The first solution corresponds to a path extension trajectory, observed in Abruzzo and Basilicata. It combines low levels of innovation, policy support, and external knowledge flows, while showing sufficient consistency to be considered conducive to the outcome. This suggests that, under specific conditions, even inertia-based trajectories may result in partial alignment with transition goals—though likely in a limited or structurally fragile form. The fifth configuration aligns with a hybrid of path upgrading and importation, observed in Liguria. It combines cognitive sophistication, innovation performance, and foreign investment—factors typically associated with more advanced forms of regional transformation. This configuration points to a cumulative logic, in which external inputs complement existing capacities to support the twin transition.

These findings substantiate the configurational premise of the study: twin transition outcomes are not driven by single dominant paths, but by multiple viable combinations of path development and enablers. These results reinforce the need for differentiated, place-based policy strategies: while structurally advanced regions may leverage upgrading and knowledge recombination, weaker areas require targeted support and institutional agency to activate new paths.

6 Conclusion

This paper has investigated whether different combinations of regional path development mechanisms are conducive to the twin transition. Drawing on a structured literature review and a fsQCA applied to Italian NUTS-2 regions, we proposed a configurational approach linking path development trajectories to empirical patterns of structural and institutional conditions. The findings support the assumptions of causal complexity and equifinality: no single condition is necessary, and multiple sufficient configurations are associated with twin transition outcomes. Importantly, the emerging configurations reveal combinations of path mechanisms underscoring the interdependence of trajectories rather than their mutual exclusivity.

Thus, our results suggest that diverse development paths —such as extension, upgrading, and importation— can support regional engagement, depending on their interaction with enabling conditions like innovation capacity, foreign direct investments, and institutional support. This reinforces the need for policy approaches that are sensitive not only to regional structural diversity, but also to the combinatory nature of development paths.

The contribution of this study is intended to be twofold. Conceptually, the study advances the empirical operationalisation of the path development framework. Methodologically, it introduces a configurational approach to regional transition analysis grounded in empirical evidence.

Nonetheless, this study has limitations. Calibration thresholds may influence sensitivity; fsQCA's cross-sectional design limits temporal inference; and the classification of regions into discrete path types is a simplification that does not fully capture the hybrid and overlapping nature of real-world trajectories.

Future work should extend this framework to cross-country comparisons and adopt dynamic QCA to capture the temporal sequencing of regional transformations. Integration with policy evaluation tools could further enhance its relevance for place-based transition strategies.

Addressing the Complexity of the Green Hydrogen Value-Chain: An Agent-Based Modelling Approach

Roberta De Cristofaro, Vincenzo Del Duca, Cristina Ponsiglione, Simonetta Primario, Serena Strazzullo
University of Naples Federico II, Naples, Italy.

Abstract

The global energy sector is undergoing a deep transition to mitigate climate change and enhance energy security through sustainable sources (International Energy Agency, 2023). Green hydrogen (GH2) has emerged as a strategic solution for decarbonizing hard-to-abate sectors, aligning with Paris Agreement targets to limit global warming to 1.5°C (Deloitte, 2023; Fuel Cells and Hydrogen 2 Joint Undertaking, 2019). The GH2 value chain operates as a complex adaptive system, characterized by nonlinear relationships, emergent behaviors, and evolving stakeholder interactions (Peyerl & van der Zwaan, 2024; Zhang & Li, 2024). This work examines the economic, social, and environmental impacts of innovations in GH2 production within a European-funded project focused on developing a photocatalytic reactor for water splitting into hydrogen and high-value co-products. Using an Agent-Based Model (ABM) developed in NetLogo, the research simulates stakeholder interactions, capturing emergent dynamics often overlooked by traditional top-down models (Macal & North, 2010). The model is able to estimate the number of plants required to meet Spain's GH2 demand by 2030 (Pawelec et al., 2023) and highlights how stricter sustainability criteria can promote best practices, stimulate innovation, and open economic opportunities. The model demonstrates the strategic potential of GH2 in driving decarbonization, technological advancement, and social inclusion. Moreover, by embedding sustainability across the value chain, the ABM provides policymakers and industry stakeholders with actionable insights to optimize GH2 deployment, lower costs, and support the broader transition to a low-carbon energy system (World Economic Forum, 2021). This research contributes to the growing body of knowledge needed to guide future investments, policy frameworks, and cross-sector collaborations.

Keywords: Green Hydrogen, Agent-Based Modelling, Innovation, Sustainability, Complexity

Paper type: Academic Research Paper

1 Introduction

Climate change, shaped historically by geological processes, has driven major extinctions. Human industrial activities have intensified greenhouse gas emissions, severely impacting ecosystems (Zou et al., 2021). Over time, the Conference of the Parties and various international agreements have committed to addressing climate change. International climate agreements have fostered national policies for emission reduction and sustainability. This has played a crucial role in building capacity for greenhouse gas reporting, accounting, and the creation of emission markets (Calvin et al., 2023). Hydrogen, strongly supported by science and policy, has emerged as a key energy carrier due to its potential to store energy without CO_2 emissions, enabling a sustainable energy transition. As global efforts to mitigate climate change intensify, the focus on hydrogen production technologies has gained renewed attention, particularly for their potential to support deep decarbonization (Goel & Sen, 2024). Currently, approximately 96% of global hydrogen production relies on fossil fuels (Hwang et al., 2023; Kamil et al., 2024) with only a small share generated through electrolysis. This latter method, which produces so-called green hydrogen, is widely regarded as the most promising pathway for large-scale decarbonization (Capurso et al., 2022), due to its minimal environmental impact (Kochanek, 2022). Green hydrogen has the potential to replace fossil fuels particularly in hard-to-abate sectors, where alternative low-carbon solutions remain limited (Griffiths et al., 2021; Kovač et al., 2021). This research explores the economic, social, and environmental implications of green hydrogen production based on a novel photocatalytic reactor, developed within a European-funded project. The study examines how GH2 adoption, alongside co-product valorization and access to certification markets, could reshape value chains and support sustainability-oriented business models. To this end, an Agent-Based Model is developed to simulate interactions among stakeholders across the GH2 value chain. The choice of an ABM approach is particularly justified by the complex and interconnected nature of the GH2 system (Peyerl & van der Zwaan, 2024), which involves a diverse set of actors, ranging from renewable energy producers and industrial manufacturers to end consumers. The interactions between these agents create dynamic value chains characterized by non-linearity, interdependencies, and emergent behaviors—features that are difficult to capture using traditional top-down modeling approaches. Conventional models typically rely on predefined agent characteristics and deterministic relationships, limiting

their ability to reflect adaptive and evolving market dynamics. In contrast, ABMs adopt a bottom-up approach, capturing emergent effects through interactions among agents (Kahn, 2015). This modeling work has been carried out within the European project "GH2 – GreenH2 production from water and bioalcohols by full solar spectrum in a flow reactor" (Grant Agreement No. 101070721), which aims to develop innovative photocatalytic solutions for sustainable green hydrogen production. The technological advancements targeted by the GH2 project underpin the innovation scenarios and stakeholder interactions analyzed through the agent-based modeling framework presented herein.

2 Theoretical background

Although fossil fuels still dominate the global energy mix, their environmental impact has accelerated the shift toward cleaner alternatives. Among emerging solutions, green hydrogen is central to decarbonising energy-intensive sectors and reshaping global industrial systems (Yue et al., 2021). Its widespread adoption is expected to reshape industrial systems and create new economic opportunities for countries strategically positioned in the green hydrogen market. Value chains are essential to understanding these transformations. Eicke & De Blasio (2022) define a value chain as the broader network of business relationships that support the large-scale development and commercialization of a technology—distinct from supply chains, which focus on optimizing product or service delivery for a single stakeholder. In the case of green hydrogen, value chains encompass a diverse ecosystem of actors and activities, spanning research, production, marketing, and distribution (Peyerl & van der Zwaan, 2024). The concept of Global Value Chains (GVCs) further expands this framework, redefining international trade and industrial organization, and influencing how firms and workers contribute to the production and distribution of goods and services from conception to final use (Cattaneo et al., 2013; Porter, 1985). As GVCs become increasingly embedded in business strategies, they open new opportunities for socio-economic development. However, to fully harness these benefits and avoid systemic risks, trade, competitiveness, and development policies must be carefully aligned. Furthermore, the growing emphasis on sustainability is reshaping GVC structures, emphasizing the need for adaptive strategies in international economic relations (Cattaneo et al., 2013; Gereffi & Fernandez-Stark, 2011). At the core of global value chains is their role in establishing connections between companies, labor forces, and consumers across different regions. This interconnectedness creates opportunities for businesses and workers, particularly in emerging economies, to integrate into the global market (Gereffi & Fernandez-Stark, 2011). Today, as sustainability becomes central to industrial and policy agendas, value chains must adapt accordingly. Unlike traditional energy value chains, which rely on well-established fossil fuel infrastructures, the green hydrogen value chain requires the integration of innovative technologies, policy support, and coordinated stakeholder engagement. Robust governance structures, corporate responsibility frameworks, and stakeholder engagement strategies are essential to balancing economic, social, and environmental priorities in this transition. The shift to green hydrogen requires robust governance and corporate responsibility, with coordinated efforts among industries, governments, and communities. Corporate Social Responsibility (CSR) and stakeholder theory offer a suitable theoretical lens to analyse GH2 adoption. CSR frameworks encourage companies to align technological development with social and environmental goals (Wilburn & Wilburn, 2011),while stakeholder theory emphasizes inclusive engagement of governments, firms, and communities (Frynas & Yamahaki, 2016; Hörisch et al., 2014; Montiel & Delgado-Ceballos, 2014). Given the complex interplay between technological advancements, market dynamics, and regulatory frameworks, the adoption of green hydrogen as a clean energy carrier requires broad collaboration. This ensures equitable access to resources and maximizes the socio-economic benefits of the transition. In this framework, companies involved in green hydrogen development must not only focus on technological innovation but also on aligning their strategies with CSR principles. This includes fostering transparent governance, ensuring fair labor practices, minimizing environmental impact, and contributing to local economic development. By integrating CSR principles, businesses can strengthen their legitimacy, enhance stakeholder trust, and secure a leading role in the sustainable energy transition. These theoretical perspectives provide the foundation for modeling agent behavior within the ABM framework developed in this study, enabling the simulation of sustainability-oriented decision-making, intersectoral cooperation, and the impact of policies on the green hydrogen value chain.

3 Methodology

Given the inherent unpredictability and emergent behaviors within complex systems, traditional deterministic modeling approaches often fall short in capturing their dynamics. Complexity Theory suggests that such systems evolve through self-organization and adaptive interactions, making them difficult to analyze using rigid, top-down frameworks (Etkin, 2016). This is particularly relevant for the green hydrogen value chain, which

consists of a vast and interconnected network of stakeholders, ranging from agricultural producers to industrial end-users. These actors engage in multiple layers of interactions, forming highly intricate value chains that exhibit non-linear dynamics. Such interdependencies cannot be effectively captured through conventional models, which typically rely on top-down structures where individual agents are pre-programmed with fixed characteristics and behaviors. In contrast, Agent-Based Models adopt a bottom-up approach, wherein agents dynamically interact with both other agents and their environment. These localized interactions give rise to emergent system-wide behaviors that are not directly predictable from individual-level actions (Columbia University Mailman School of Public Health., n.d.). This adaptive and decentralized nature of ABMs makes them particularly well-suited for analyzing complex and evolving value chains, such as those observed in the GH2 sector. Moreover, ABMs enable the exploration of emergent phenomena, allowing researchers to study how policy changes, market dynamics, and technological innovations propagate through the hydrogen economy (Klugl & C Bazzan, 2012). Given these advantages, the adoption of an ABM framework provides a robust methodological foundation for examining the GH2 value chain's structure, adaptation mechanisms, and long-term sustainability.

3.1 Model overview

The agent-based model is designed to simulate the structure, evolution and sustainability performance of the green hydrogen value chain. Heterogeneous stakeholders are involved in decentralized decision-making processes, forming supply chains that dynamically evolve based on economic, environmental and social criteria. Through these interactions, the model reproduces the complex emerging dynamics that characterize real-world innovation ecosystems and sustainability transitions. To reflect the spatial and temporal dimensions of the GH2 supply chain, the model operates at two interrelated levels. Temporally, the simulation unfolds in monthly time steps (ticks), enabling the monitoring of seasonal cycles and annual production flows. Spatially, the model encompasses a transcontinental network from sugarcane farms and biorefineries in Brazil to hydrogen production and certification centers in Europe. While geographic coordinates are currently abstracted, future versions will integrate real-world distances and positions to enhance spatial realism. Designed as a decision-support tool, the model allows users to explore how different policy instruments, investment strategies, and market incentives propagate through the value chain. It helps assess the systemic impact of innovation adoption, sustainability certification, and stakeholder coordination.

3.1.1 Agent typologies

The model simulates a heterogeneous set of agents, which interact dynamically, forming decentralized networks that evolve over time to support the production and distribution of green hydrogen and related co-products. Each type of agent is defined by specific roles, behavioral rules, and decision-making strategies that reflect their position within the supply chain, and role in actual value chains. The supply chain starts with farmers; they are responsible for growing sugarcane, the main raw material used for bioethanol production. Ideally, they are located in Brazil, where there is most of the world's sugarcane production (Bordonal et al., 2018). Then the processed sugarcane is transported by first movers, who handle the road transport from agricultural sites to first-tier processing plants. First production plants are modeled as biorefineries that convert sugarcane into sugar, bioethanol, and bioelectricity once they receive their input. These plants play a central role in the system as they generate both energy products and intermediate goods essential for further processing. Second transporters handle maritime logistics between Brazil and Europe. Their role is to ensure the efficient and timely shipment of bioethanol to European processing plants, which are assumed to be located in Spain. By simplifying suppositions, the model abstracts the intermediate steps of transportation and assumes a direct link between Brazilian ports and Spanish plants. Second production plants, represent the final transformation stage, where imported bioethanol is converted to green hydrogen using advanced photocatalytic technologies. In addition to generating green, zero-impact hydrogen, these new plants produce high-value chemical by-products such as acetic acid, acetal, and acetaldehyde, thus improving the economic viability of the process. The value chain is governed by regulatory bodies, which act as institutional agents responsible for ensuring compliance throughout the entire supply chain by certifying sustainable production practices. These entities are capable of monitoring adherence to environmental, economic, and social sustainability standards and play a pivotal role in enabling access to the green certificate market. Their decisions influence agent behavior through a system of incentives and sanctions, thereby promoting the adoption of sustainable practices. Each agent is characterized by a set of internal attributes that evolve over time through interactions and feedback from the environment. These differentiated agent types and their interconnections form the foundation of the model's ability to simulate emergent behaviors and adaptive system dynamics.

3.1.2 Production and market mechanisms

Agents are distributed across two complementary market mechanisms: one segment represents the conventional market, focused on the exchange of tangible products, while the other captures an alternative market based on green certificates. This second mechanism serves as an incentive system that rewards supply chains meeting predefined sustainability criteria. The model supporting the green hydrogen value chain unfolds in three distinct phases: *Build Supply-Chain Networks*, *Supply-Chain Networks Development* and *Supply-Chain Networks Growth*. Each agent type follows specific production dynamics, decision-making routines, and market behaviors, collectively generating emergent system-level outcomes. The underlying mechanism is illustrated in Figure 1:

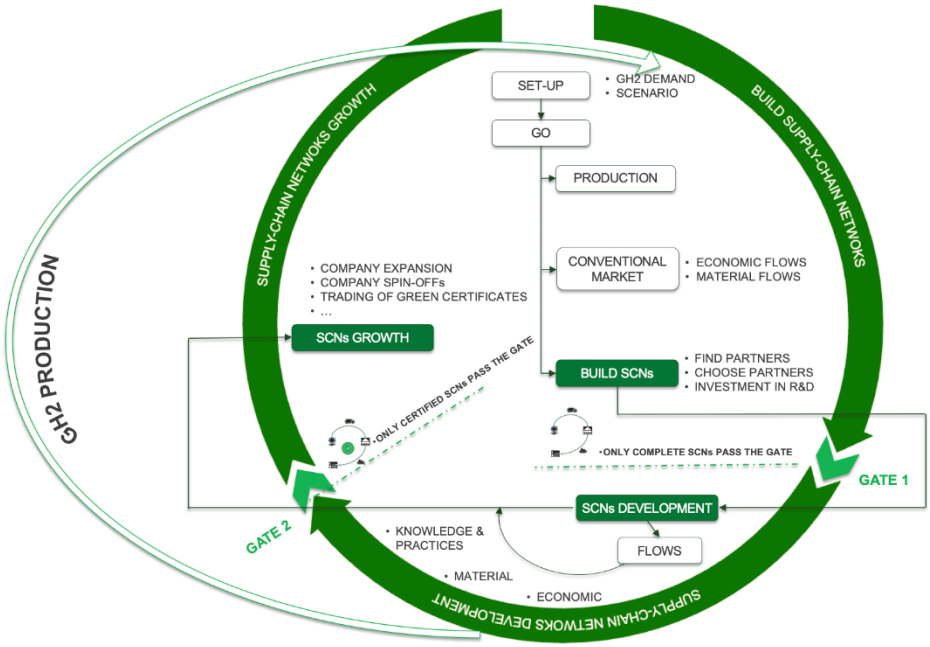

Figure 1: Structure of The Model

The simulation begins with agents autonomously identifying and selecting potential partners based on multiple criteria, including price, distance, technological performance, and sustainability orientation. Once a partner and a transporter are chosen, a link is established between the agents. These links represent supply relationships, enabling the flow of goods and services throughout the value chain. During this phase, agents actively construct supply chains by evaluating their production capacity, market demand, and alignment with prospective partners. The successful formation of a complete supply chain—from farmers to GH_2 production plants—allows the network to pass through the first decision gate (*Gate 1*), enabling the initiation of operations. The second phase focuses on the internal dynamics of the supply chain. Production flows are activated based on the capacity and operational efficiency of each actor. Output volumes are determined by technology levels, workforce availability, and current operating conditions. The production of GH2 and its co-products is modeled through resource transformation processes that simulate technological conversion efficiency based on stoichiometric chemical relationships. During this phase, the model assesses environmental, economic, and social impacts, enabling a collective evaluation of network performance. Stable supply chains that meet specific thresholds pass through *Gate 2* and gain access to the alternative certification market. In the third phase, agents demonstrating resilience, innovation, and sustainability are granted access to green certificate markets and can further expand their operations. Certification mechanisms are fully embedded within the model and account for life cycle emissions and resource efficiency across the entire supply chain. Agents are rewarded with financial incentives based on avoided emissions and verified sustainability performance. Conversely, agents that fall short of certification thresholds may face penalties or be required to purchase credits on the secondary market. Regulatory entities enforce these mechanisms and safeguard systemic integrity. The model's decentralized logic—based on individual decision-making, dynamic partner selection, and iterative adaptation—enables the emergence of value networks that vary in performance, structure, and market orientation, thereby realistically simulating the behavior of actual markets.

3.1.3 Tracking impact and performance

The model integrates a comprehensive impact monitoring system to assess the performance of the value chain in meeting the projected GH2 demand by 2030. This assessment is carried out through the continuous tracking of economic, environmental, and social indicators, both at the individual agent level and at the system level. These metrics are dynamically updated throughout the simulation, offering insights into the emergent outcomes produced by decentralized interactions and strategic decisions. From an *economic perspective*, the model captures the evolution of capital, operating costs, and revenue streams for each agent. It specifically monitors turnover generated from product and co-product sales within both the conventional market and certified value chain segments, as well as the levels of R&D investment and income derived from participation in alternative mechanisms such as green certificate markets. In terms of *environmental performance*, the simulation estimates CO_2 emissions, water usage, and energy consumption per production cycle. These indicators are calculated based on agent-specific emission and consumption factors across the different stages of the value chain. Tracking these variables over time allows the model to reflect the effects of technological evolution and adaptation strategies, enabling an assessment of the system's contribution to broader decarbonization and sustainability goals. With regard to *the social dimension*, the model evaluates workforce dynamics by monitoring increases and decreases in employee numbers due to overproduction cycles, as well as the spread of innovation and sustainability through learning and educational spillovers. It also tracks the number of agents exiting the system, providing a proxy for failure due to structural weaknesses or market misalignment. These social indicators contribute to a holistic understanding of the value chain's resilience and inclusiveness. Performances are not only evaluated at the individual level, but also across interconnected networks. This integrated monitoring framework supports scenario comparison and sensitivity analysis, making the model a powerful decision-support tool for policymakers and industry stakeholders. By providing ex-ante insight into the potential implications of different strategies, the model serves not only as a forecasting tool but also as a flexible and adaptable platform that can be tailored to reflect evolving real-world conditions.

3.1.4 Model parameters and calibration data

The model relies on a set of dynamic parameters that define the behavior, decision-making logic, and adaptive capacity of each actor within the green hydrogen value chain. These parameters have been carefully selected and calibrated to reflect the operational, financial, environmental, and strategic characteristics of real-world stakeholders. Rather than assigning fixed behaviors, the model incorporates heterogeneity and adaptability through a set of interrelated state variables that evolve over time in response to internal dynamics and external stimuli. At the core of the model are production-related parameters, including annual capacity levels, which represent each agent's ability to transform inputs into value-added outputs. These variables are not static; they are influenced by technology adoption, workforce availability, and strategic positioning, and are recalculated at each time step to reflect learning, investment decisions, and operational efficiency. Financial parameters—such as available capital, operating costs, and revenue generation—directly affect an agent's ability to remain competitive and resilient, influencing its capacity to engage in R&D, adopt sustainable practices, or enter new markets. Strategic orientation is modeled through innovation and sustainability parameters, which shape agents' preferences in partner selection and impact their long-term performance. These variables are endogenous: they evolve through interaction with other agents, participation in certified value chains, and investment in innovation. The simulation accounts for these dynamics by integrating feedback loops, enabling the emergence of diverse trajectories among agent populations. All parameters have been calibrated using a combination of primary and secondary sources, including academic publications, technical reports from the hydrogen and bioenergy sectors, international sustainability databases, and GH2 project-specific datasets. This structured parameterization lays the foundation for the simulation experiments discussed in the following section, where Design of Experiments techniques are applied to analyze the sensitivity of model outcomes to key variables and to explore strategic policy implications.

4 Expected results

As the experimental phase is currently ongoing, the simulation is expected to generate insights through three experimental scenarios, each designed to explore different structural or policy variables influencing the green hydrogen value chain in Spain. The *first scenario* estimates the optimal number of medium-sized second-generation production plants needed to meet the national demand for green hydrogen by 2030, assuming a fixed number of farmers and production facilities based on real-world data from the São Paulo region. Determining the ideal number of plants allows us to assess triple impacts: economic (e.g., R&D investments, revenues, income from green certificates), environmental (e.g., CO_2 emissions, energy and water consumption),

and social (e.g., employment, operator turnover, welfare distribution). The *second scenario* modifies the spatial configuration of key agents—such as farmers and First Production Plants—to test the model's ability to adapt to geographically heterogeneous systems. This experiment evaluates how location shifts influence value chain efficiency, economic returns, and systemic resilience. The *third scenario* analyzes the effect of environmental certification thresholds on market access and enterprise behavior. By adjusting innovation requirements for certification (e.g., under schemes like CertifHy), the model explores how policy design can influence green hydrogen demand, stimulate technological adoption, and foster sustainable entrepreneurship. All scenarios are monitored by considering the co-production of chemical by-products — such as acetal, acetic acid, and acetaldehyde — which significantly affect process efficiency, production cycles, and the overall issuance of green certificates. The experimental analysis provides a robust framework for interpreting system dynamics under varying infrastructural, geographical, and policy design conditions, allowing for a comparative assessment of which by-product is most advantageous to valorize according to the specific needs of the value chain. A key insight emerging from these simulations is the potential to commercialize by-products on secondary markets, thereby generating additional revenue streams beyond the primary hydrogen production. This secondary market not only enhances the economic sustainability of the entire value chain, but also becomes a critical parameter in scenario evaluation: the choice of which by-product to valorize can thus be driven not only by technical considerations, but also by its marketability, contributing to more integrated and circular production strategies.

5 Conclusion

This study has developed an agent-based model to simulate the structure, evolution, and sustainability of green hydrogen value chains, with the aim of providing a decision-support tool for the energy sector. By capturing the adaptability and heterogeneity of the actors involved, the model offers a realistic representation of the complexity that characterizes decarbonization processes. From a scientific perspective, this work contributes to the discourse on sustainability transitions and complex systems by introducing a flexible methodology to analyze alternative scenarios and design targeted policies. On the practical side, the model delivers operational insights for policymakers, businesses, and stakeholders, allowing for the ex-ante exploration of the systemic impacts of technological innovations, regulatory measures, and spatial configurations. Although the model successfully captures the key dynamics of emerging value chains, its current structure has not yet been fully calibrated on a real-world case, an activity planned for future developments. In particular, it will be necessary to integrate real geospatial data, perform a more precise calibration of parameters using empirical datasets, and implement dynamic scenarios applied to specific case studies. Looking ahead, the model can evolve into an interactive and participatory platform—supporting co-design processes, strengthening cross-sector collaboration, and guiding sustainable development strategies in the green hydrogen sector. The model's modular architecture also allows it to be adapted to different national contexts, application sectors (such as industry, mobility, or decentralized energy systems), and strategic goals. This flexibility makes it a promising tool to support the energy transition toward more equitable, resilient, and low-carbon systems.

Organisational Resilience and Decision-Making Modes: An Agent-Based Analysis

Stephan Leitner
University of Klagenfurt, Klagenfurt, Austria

Abstract

Organisational resilience, defined as the capacity to absorb and recover from shocks affecting an organisation's operations, becomes increasingly more important in today's environment. While existing research has mainly explored structural and strategic factors contributing to organisational resilience, the role of managerial decision-making modes in this context remains underexamined. This paper addresses this gap by developing an agent-based model that simulates how different modes of decision-making affect resilience. The model captures stylised organisations as collections of interdependent departments operating on performance landscapes with varying complexity. The study compares silo-based, sequential, collaborative, and proposal-based decision-making across 144 simulated scenarios, incorporating shocks of varying severity. The results reveal that collaborative and proposal-based decision-making modes enhance shock absorption and recovery in complex task environments, while simpler modes perform well in settings where tasks are less complex. Proposal-based coordination offers balanced performance.

Keywords: Organisational resilience, decision-making modes, agent-based modelling, disruptions, task interdependence

Paper type: Academic Research Paper

1 Introduction

The growing probability of disruptions, including economic, technological, and operational disruptions, makes it crucial for organisations to respond to crises and develop capabilities, enabling them to anticipate, absorb, adapt to, and recover from shocks. However, how daily business practices affect an organisation's resilience remains largely unknown (Kantabutra and Ketprapakorn, 2021). A large proportion of existing research has focused on coping strategies and how they can be employed during and after shocks. More recently, the focus has shifted to strategies to anticipate shocks and how to prepare organisations to remain effective during crises (Grego et al., 2024). Another stream of research has analysed resilience through the lens of organisational structure, resource allocation, and strategic decision-making mechanisms (Banihashemi et al., 2024; Dahmen, 2023; Garcia-Diaz, 2024; Swaminathan, 2022). For instance, Leitner (2025a, 2023) explores how emergent task allocation affects an organisation's resilience, and You and Williams (2023) conclude that the design of intra-organisational relationships is key to increasing organisational resilience. However, a significant gap remains unexplored: how do models of managerial decision-making – that is, modes of generating and coordinating decisions – shape an organisation's capability to deal with shocks? Even though this dimension appears to be a critical determinant for organisational resilience, it has only received limited attention in research.

This paper addresses this gap by developing an agent-based model of a stylised organisation to analyse how different decision-making modes affect an organisation's ability to absorb and recover from shocks. The model is based on the NK framework (Levinthal, 1997; Wall et al., 2024; Wall and Leitner, 2021) that allows for modelling interdependent decision-making in organisational contexts. Specifically, the stylised organisations are conceptualised as a collection of departments that jointly operate on a performance landscape representing the task environment, whereby the ruggedness of the landscape is externally controlled and shaped by the interdependencies between tasks. Decision-making modes are conceptualised as different modes of how information is shared between departments and how adaptation finally takes place. The key decision-making modes analysed include proposal-based, silo-based, collaborative, and sequential approaches. The results indicate that not all decision-making modes are equally effective, depending on the complexity of an organisation's task. Decision-making modes that facilitate information exchange and mutual adaptation are advantageous in complex task environments, whereas simpler methods work well when organisational departments work on less complex tasks.

The remainder of the paper is structured as follows: Section 2 introduces the model and discusses the scenarios analysed in this paper. Section 3 presents and discusses the results. Section 4 concludes the paper.

2 Model and simulation experiments

This paper's model of a stylised organisation builds on the NK framework (Levinthal, 1997; Wall and Leitner, 2021). The model is populated by $M \in \mathbb{N}$ agents representing departments. Agents operate on a NK-landscape that defines the task environment. More specifically, the task environment captures an N-dimensional binary decision problem ($N \in \mathbb{N}$) with $K \in \mathbb{N}_0$ interdependencies between decisions, shaping the complexity of the decision problem.

2.1 Task environment and decomposition

Let us denote the N-dimensional decision problem by $\boldsymbol{d} = [d_1, \dots, d_N]$, where $d_i \in \{1, 0\}$ and $n = 1, \dots, N$. Each decision d_i contributes $f(d_i) \sim U(0,1)$ to overall organisational performance. There exist K interdependencies between decisions, which is why the contribution of the decision $f(d_i)$ in addition to d_i is affected by K other decisions. Let us formalise this payoff function by $f(d_i) = f(d_i, d_{i_1}, \dots, d_{i_K})$, where $\{i_1, \dots, i_K\} \subseteq \{1, \dots, i-1, i+1, \dots, N\}$. The overall performance of a solution vector $\boldsymbol{d}$ to the decision problem is defined as the average of all performance contributions: $P(\boldsymbol{d}) = 1/|\boldsymbol{d}| \sum_{i=1}^{N} f(d_i)$.

The decision problem $\boldsymbol{d}$ is sequentially and symmetrically divided into M disjoint sub-problems, and every department oversees one sub-problem, each consisting of $Q = N/M$ decision-making tasks. The allocation follows the following rule: $d_m = [d_{\{Q\cdot(m-1)+1\}}, \dots, d_{\{Q\cdot m\}}]$. In consequence, when there are $N = 15$ decisions and $m = 5$ departments, every department oversees 3 decisions.

2.2 Shocks to the task environment

The task environment might be affected by shocks. Specifically, the performance contributions $f(d_i)$ can change due to disruptions in the organisation's environment. Consequently, the shape of the NK-landscape might change as well. The model considers correlated shocks using a method proposed by Demirtas (2014) that uses a correlation parameter $\rho \in \{-1, 1\}$ *to* control the severity of shocks. To do so, first two random numbers $v_i \sim U(0,1)$ and $w_i \sim B(a, 1)$ are drawn, where the shape parameter of the Beta distribution is a function of the correlation parameter, $a = 1/2\left(\sqrt{49 + \rho/1 + \rho} - 5\right)$. Then, the two random numbers are used to compute the correlated performance contribution according to the following rule:

$$f^c(d_i) = \begin{cases} |w_i - f(d_i)|, & v_i < 0.5\,, \\ 1 - |1 - w_i - f(d_i)|, & v_i \geq 0.5\,. \end{cases}$$

2.3 Utility function and decision-making modes

Departments are modelled to be myopic utility maximisers, meaning they aim to immediately increase their utility (without considering long-term effects). Let us denote the utility of the department m as follows:

$$U(\boldsymbol{d}_{mt}, \boldsymbol{d}_{-mt}) = \lambda \cdot P(\boldsymbol{d}_{mt}) + (1-\lambda) \cdot P(\boldsymbol{d}_{-mt})\,,$$

where $\boldsymbol{d}_{mt}$ and $\boldsymbol{d}_{-mt}$ denote the department m's own and residual decisions, respectively, and departments are characterised by a linear incentive mechanism where the parameter λ is used to weight the department's own and residual performance.

Over time, departments can change their decisions at every time step, and departments can exchange information during this adaptation process according to the following decision-making modes (see also Blanco-Fernández et al., 2025; Siggelkow and Rivkin, 2005).

2.3.1 Silo-based decision-making

In silo-based decision-making, departments gather information independently and do not share it with their colleagues. This means that departments are unaware of their colleagues' decisions at a specific point in time and rather rely on their colleagues' behaviours $\boldsymbol{d}_{-m(t-1)}$ that have been observed in the previous period. In every period, every department identifies an alternative set of actions within their area of responsibility and in the neighbourhood of the currently implemented actions. Please note that the neighbourhood is defined by a Hamming Distance of 1 around $\boldsymbol{d}^*_{mt}$. In every period, every department must choose between either sticking with the status quo or adopting the newly discovered alternative. They do so according to the following rule:

$$\boldsymbol{d}_{mt} = \underset{\boldsymbol{d}' \in \left(\boldsymbol{d}_{m(t-1)}, \boldsymbol{d}^*_{mt}\right)}{\arg\max} U\left(\boldsymbol{d}', \boldsymbol{d}_{-m(t-1)}\right).$$

Then, the collective solution to the overall decision problem in period t is the combination of all actions taken by departments: $\boldsymbol{d}_t = \bigcup_{m=1}^{M} \boldsymbol{d}_{mt}$.

2.3.2 Collaborative decision-making

In the collaborative decision-making mode, departments are connected in a ring network, and with fixed probability P, they perform collaborative decision-making as described below. In contrast, with the likelihood of $(1-P)$, they perform silo-based decision-making.

Collaborative decision-making is implemented as adjacent hill-climbing (Yuan and McKelvey, 2004). Specifically, if departments m and n engage in collaborative decision-making, each of them identifies their alternatives $\boldsymbol{d}^*_{mt}$ and $\boldsymbol{d}^*_{nt}$ in the neighbourhood of $\boldsymbol{d}_{m(t-1)}$ and $\boldsymbol{d}_{n(t-1)}$, respectively. They share information during decision-making, which is why their joint residual decisions (i.e., the actions taken outside of department m's and n's areas of responsibility) are denoted by $\boldsymbol{d}_{-(mn)(t-1)} = \boldsymbol{d}_{t-1} \setminus \left(\boldsymbol{d}_{m(t-1)} \cup \boldsymbol{d}_{n(t-1)}\right)$.

Then, the two departments make a decision that maximises their joint utility according to the following rule:

$$\left(\boldsymbol{d}_{mt}, \boldsymbol{d}_{nt}\right) = \underset{\substack{\boldsymbol{d}'_m \in \left(\boldsymbol{d}_{m(t-1)}, \boldsymbol{d}^*_{mt}\right) \\ \boldsymbol{d}'_n \in \left(\boldsymbol{d}_{n(t-1)}, \boldsymbol{d}^*_{nt}\right)}}{\arg\max} U^{adj}\left(\boldsymbol{d}'_m, \boldsymbol{d}'_n, \boldsymbol{d}_{-(mn)(t-1)}\right),$$

where the joint utility function $U^{adj}(\cdot)$ is defined as the mean of the two individual utilities: $U^{adj}\left(\boldsymbol{d}_{mt}, \boldsymbol{d}_{nt}, \boldsymbol{d}_{-(mn)(t-1)}\right) = \frac{1}{2}\left(U\left(\boldsymbol{d}_{mt}, \boldsymbol{d}_{-m(t-1)}\right) + U\left(\boldsymbol{d}_{nt}, \boldsymbol{d}_{-n(t-1)}\right)\right)$.

2.3.3 Sequential decision-making

In the sequential decision-making mode, departments make decisions one after another, with each department passing on information about its choices to those that have yet to decide, thereby reducing uncertainty for subsequent decision-makers. For simplicity, let us assume that the decision-making order follows the department indices. This means that the department $m = 1$ starts with the decision-making procedure and informs departments 2 to M about their decisions and, thereby, reduces the uncertainty about their residual actions. Let us redefine the vector of residual decision for the sequential decision-making mode as follows:

$$\boldsymbol{d}^{seq}_{-mt} = \left(\boldsymbol{d}_{1t}, \ldots, \boldsymbol{d}_{(m-1)t}, \boldsymbol{d}_{(m+1)(t-1)}, \ldots, \boldsymbol{d}_{M(t-1)}\right).$$

As in the previous decision-making modes, department m identifies an alternative course of action $\boldsymbol{d}^*_{mt}$ in the neighbourhood of $\boldsymbol{d}_{m(t-1)}$, and next, the department assesses the two choices according to

$$\boldsymbol{d}_{mt} = \underset{\boldsymbol{d}' \in \left(\boldsymbol{d}_{m(t-1)}, \boldsymbol{d}^*_{mt}\right)}{\arg\max} U\left(\boldsymbol{d}', \boldsymbol{d}^{seq}_{-mt}\right).$$

2.3.4 Proposal-based decision-making

In the proposal-based method, departments explore and rank alternative lines of action locally and propose their ranked alternatives to a central authority. The central authority aggregates the proposals and makes the final decision, assuring global coherence of actions. Specifically, every department m identifies an alternative $\boldsymbol{d}^*_{mt}$ in the neighbourhood of the status quo $\boldsymbol{d}_{m(t-1)}$. The two options (the alternative and the status quo) are ranked concerning expected utility (using the utility function introduced in Section 2.3.1). Then, the ranked options $\left(\boldsymbol{d}^{(1)}_{mt}, \boldsymbol{d}^{(2)}_{mt}\right)$ are forwarded to a central coordinating unit. The central unit combines the proposals of all M departments by concatenating all proposals ranked first and second, respectively, according to the rule $\boldsymbol{d}^{(j)}_t = \bigcup_{m=1}^{M} \boldsymbol{d}^{(j)}_{mt}$, where $j \in \{1, 2\}$. Finally, the coordinating unit evaluates the combined proposals concerning the highest performance and makes the final decision as follows:

$$\boldsymbol{d}_t = \underset{\boldsymbol{d}' \in \{\boldsymbol{d}^{(1)}_t, \boldsymbol{d}^{(2)}_t\}}{\arg\max} P(\boldsymbol{d}').$$

2.4 Simulation experiments

The following four parameters of the model are considered variables to construct scenarios:

The performance landscape on which departments operate follows the logic of the NK model introduced above. Specifically, landscapes with two levels of complexity are considered, whereby the interactions follow the patterns in Figure 1. Specifically, in the case of (i) small diagonal blocks, tasks are organised into modular structures, meaning interdependencies exist within departments but not between them. This structure simplifies decision-making and is referred to as *decomposable tasks*, as each department operates independently. In the case of (ii) *reciprocal interdependencies*, tasks assigned to departments are highly interconnected, with interdependencies both within and between departments. This pattern requires coordinated decision-making across departments to manage complexity effectively (Leitner, 2024).

Four decision-making modes, namely (i) silo-based decision-making, (ii) collaborative decision-making (with different probabilities of *joint* decision making), (iii) sequential decision-making, and (iv) proposal-based decision-making, are considered. For details on the decision-making modes, see Sections 2.3.1 to 2.3.4.

Two configurations are considered for the incentive mechanism: $\lambda \in \{0.25, 1\}$ for group-based and individualistic incentives, respectively. For details on how the incentive parameter affects utility, see Section 2.3.

Shocks of different severity are considered, ranging from severe ($\rho = -0.5$) to moderate ($\rho=0$) and slight shocks ($\rho=0.5$). For details on how shocks are implemented, see Section 2.2.

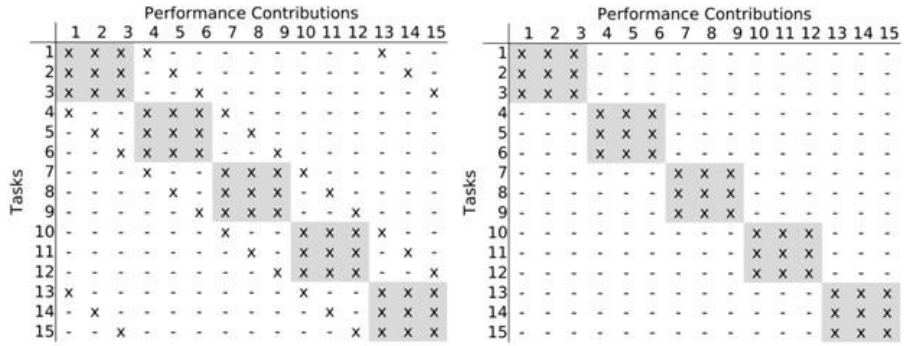

Figure 1: Interdependence patterns
Left: reciprocal interdependencies, right: decomposable tasks

The dimensionality of the decision problem is fixed at $N = 15$, and the number of departments is set to $M = 5$. The parameter variations yield a total number of 144 scenarios. For these scenarios, simulations per scenario have been performed, whereby based on the coefficient of variation, the number of simulations per scenario is set 150. Each simulation run spans 500 timesteps, with shocks occurring after 250 timesteps. Statistical tests confirm that the performance time series (both before and after a shock) reaches stationarity after approximately 240 timesteps. The simulation model is implemented in Python.

3 Results and Discussion

At the core of this paper is the organisation's ability to absorb and recover from shocks. Before shocks occur in the task environment, decision-making modes already shape an organisation's position within that environment, influencing whether it operates near a global or local maximum when a shock occurs (Leitner, 2025b). In task environments with (nearly) decomposable tasks, most decision-making modes lead to organisations (almost) achieving the global maximum. In contrast, when task decomposition is characterised by reciprocal interdependencies, the global maximum cannot be reached in most cases, whereby proposal-based and collaborative decision-making modes lead to higher task performance compared to silo-based and sequential modes (Siggelkow and Rivkin, 2005). These findings align with existing literature, and the proposed model successfully replicates them (Rand and Wilensky, 2006). This replication confirms that the model has a relatively high construct validity, indicating that the model is capable of capturing core features of organisational adaptation theorised using NK model and complex system approaches.

During the simulations, organisations experience a shock to their task environment after 250 timesteps and are modelled to resume operations immediately afterwards. Shock absorption is assessed by comparing performance immediately before and after the shock, while recovery is evaluated based on performance after 250 additional time steps. Differences are evaluated using the Mann-Whitney U test, and the U statistic is used to compute the rank-biserial correlation as an effect size measure. To efficiently report the results, k-means

clustering was applied to group the 144 scenarios into nine distinct clusters. The optimal number of clusters was determined using the Davies-Bouldin and Caliński-Harabasz indices. Clustering of scenarios allows for detecting structural patterns rather than merely reporting isolated scenarios. A log-likelihood ratio test assessed the significance of different parameters for the clustering solution. In consequence, the analysis approach allows for the interpretation of resilience as emerging from interactions with the organisational context. The results indicate that *interdependence pattern*, *decision-making mode*, and *shock correlation* significantly influence the clustering structure; the results are organised along these dimensions.

Table 1 presents the cluster profiles for organisations operating in environments with decomposable tasks, while Table 2 focuses on environments with reciprocal interdependencies. Scenarios are further grouped within each table based on shock severity (slight vs. moderate to severe shocks). Both tables report two primary outcomes: (i) the capability to absorb shocks, comparing performance immediately before (period 249) and immediately after the shock (period 250), and (ii) the capability to recover from shocks, comparing performance before the shock (period 249) and after a recovery period (period 500). For each cluster, the average rank-biserial correlation (as a measure of effect size) and its standard deviation are reported. Additionally, the dominant decision-making modes characterising each cluster are indicated.

Table 1**:** Results for decomposable tasks

# Scenarios	Absorbing shocks (period 249 vs. 250)		Recovering from shocks (period 249 vs. 500)		Decision-making mode
	Average	Std	Average	Std	
Slight shocks:					
8	-0.6092	0.0705	0.1618	0.0284	Collaborative (low/mean probability) Proposal-based
18	-0.6401	0.0975	0.0755	0.0212	Collaborative (high probability) Sequential Silo-based
Moderate to severe shocks:					
30	-0.8831	0.0580	-0.0065	0.0258	Collaborative (low/mean probability) Proposal-based
19	-0.9061	0.0575	0.0202	0.0202	Collaborative (high probability) Sequential Silo-based

The results indicate that organisational resilience – more specifically, an organisation's capability to absorb and recover from shocks – is contingent on both the decision-making mode that is effective in the organisation and the complexity of the task environment. In low-complexity task environments, where tasks assigned to departments have minimal interdependencies and are perfectly decomposable into disjoint areas of responsibility, organisations exhibit higher overall performance, and decision-making modes play a lesser role in resilience. When a shock disrupts the task environment, organisations using proposal-based and collaborative decision-making modes experience a smaller initial performance drop than those relying on silo-based or sequential decision-making mechanisms in environments with decomposable tasks (see Table 1). This observation is driven by almost independently operating departments (on smooth performance landscapes), leading to even simple decision-making rules performing well. However, the cost of uncoordinated action increases as the task environment becomes more complex and the performance landscape becomes more rugged (see Table 2). Here, organisations employing collaborative or sequential decision-making modes experience a more pronounced drop in performance. This observation can be explained by the fact that the proposal-based and collaborative decision-making modes facilitate mutual adaptation. Specifically, these modes allow departments to align their decisions, leading them to favourable positions in the landscape, i.e., positions that are likely also viable after a shock.

Table 2**:** Results for non-decomposable tasks

# Scenarios	Shock absorption (period 249 vs. 250)		Recovering from shocks (period 249 vs. 500)		Decision-making mode
	Average	Std	Average	Std	
Slight shocks:					
15	-0.2273	0.0731	-0.0993	0.0377	Collaborative (low probability) Silo-based
19	-0.3563	0.1023	0.0331	0.0360	Collaborative (mean/high probability)

# Scenarios	Shock absorption (period 249 vs. 250)		Recovering from shocks (period 249 vs. 500)		Decision-making mode
	Average	Std	Average	Std	
Moderate to severe shocks:					
6	-0.4361	0.0676	-0.2344	0.0483	Silo-based
19	-0.5680	0.0833	-0.0134	0.0312	Collaborative (mean/high probability)
110	-0.5698	0.1034	-0.1209	0.0243	Sequential

Recovering from shocks depends on shock severity and an organisation's capability to coordinate actions after the shock. In complex environments, collaborative decision-making modes facilitate better recovery because they facilitate coordinated adaptations across departments. In contrast, organisations using silo-based and sequential decision-making modes often struggle to regain previous performance levels, leaving them trapped in suboptimal positions. In task environments of low complexity, organisations regain pre-shock performance in all cases. The relationship between task complexity and effectiveness of the decision-making mode is further moderated by shock severity: Slight shocks only result in moderate shifts in the performance landscape, enabling recovery over time in all decision-making modes. Interestingly, when the task environment is of low complexity and shocks are moderate, collaborative and proposal-based decision-making modes can help organisations achieve significantly better performance post-shock. In contrast, severe shocks lead to drastic performance drops, and when there is a lack of coordination across departments, as in silo-based modes, recovery is difficult. On the other hand, collaborative and proposal-based decision-making modes support tight coordination, allowing for effective recovery.

These findings are relevant for the design of real-world organisations. The results confirm that decentralising decisions to the department level can achieve high performance and strong recovery capability in modular and relatively stable environments, such as traditional manufacturing lines or standardised service operations. In more complex and volatile environments, such as emergency response coordination and digital product development, cross-departmental coordination and joint action (as in the collaborative mode) become increasingly essential. The results also indicate that organisations are better off in dynamic environments when they not only support communication between departments but also facilitate joint exploration and mutual adjustment.

4 Conclusion

This paper presents an agent-based model of a stylised organisation operating in a dynamic task environment subject to external shocks. The model investigates how different decision-making modes influence an organisation’s ability to absorb and recover from such shocks. The findings suggest that specific decision-making modes offer advantages depending on the complexity of the environment. Complex task environments characterised by reciprocal interdependencies benefit from decision-making structures that support information exchange and mutual adaptation. In contrast, simpler decision-making modes may work efficiently in less complex settings. These results highlight the importance of aligning decision-making structures with environmental complexity. The study contributes to resilience research by incorporating an organisation’s pre-shock positioning within the task environment into the resilience analysis. It highlights that crisis response mechanisms do not solely determine resilience but are also influenced by the decision-making architecture in place before the shock.

Future research could account for the fact that firms differ in their ability to respond to crises. Prior performance plays a critical role: organisations that perform well before a shock can often accumulate slack resources, enabling a more immediate and effective response, while less successful organisations may lack this capacity (Smallbone et al., 2012). Extending the model to incorporate this dynamic would enhance its realism. Moreover, to increase the generalizability of results, future studies should explore additional interdependence patterns and examine whether consistent behavioural patterns emerge across different organisational contexts. Future research could also examine how decision-making modes evolve and investigate the influence of additional contextual factors such as organisational culture and leadership.

Institutional Conditions in Entrepreneurial Education Ecosystems: Effects on Entrepreneurial Knowledge and Culture

Carmine Passavanti, Simonetta Primario, Pierluigi Rippa
University of Naples Federico II, Naples, Italy

Abstract

Entrepreneurial education ecosystems are increasingly recognized as strategic environments within universities that foster entrepreneurial knowledge, culture, and venture creation. However, the interplay between institutional factors and educational outcomes in these ecosystems remains underexplored, particularly from a dynamic, system-level perspective. This study addresses this gap by developing a theory-driven agent-based model—the Entrepreneurial education ecosystems Model: "3E Model"—to simulate how formal (e.g., corruption, bureaucracy, access to credit) and informal (e.g., social perception of entrepreneurship, cultural diversity) institutional factors influence entrepreneurial learning dynamics in university-based ecosystems.

Grounded in entrepreneurial ecosystem theory, stakeholder theory, and institutional theory, the model captures the interactions of heterogeneous agents including students, faculty, investors, and institutional actors. The simulation results reveal that institutional quality significantly shapes the accumulation of entrepreneurial knowledge, the formation of entrepreneurial culture, and the motivation to launch startups. In particular, corruption and bureaucratic burden emerge as major impediments, reducing both knowledge diffusion and entrepreneurial activity. Conversely, favorable social perceptions of entrepreneurship significantly enhance ecosystem performance, with evidence of threshold effects: only after surpassing a certain level of societal support does venture creation accelerate. Cultural diversity also contributes positively by enriching knowledge exchanges, though its impact is more gradual.

The model demonstrates the non-linear and interdependent nature of institutional influence in 3Es, confirming that both formal (structural) and informal (cultural) institutions jointly determine ecosystem vitality. Practically, the 3E Model serves as a decision-support tool for universities and policymakers, enabling the simulation of interventions to strengthen entrepreneurial education. The findings suggest that aligning institutional reforms with cultural initiatives—such as reducing administrative barriers while promoting entrepreneurship as a legitimate career path—can generate synergistic effects that boost entrepreneurial outcomes. The study concludes by outlining future research directions, including model refinement through empirical calibration and the inclusion of feedback loops between education and institutional change.

Keywords: Entrepreneurial Ecosystems; Entrepreneurship Education Ecosystems; Institutional Factors; Agent-Based Modeling

Paper type: Academic Research Paper

1 Introduction

Universities today are increasingly recognized as key engines of innovation and entrepreneurship, extending their traditional missions of teaching and research to actively support economic development through venture creation (Etzkowitz, 2004; Audretsch & Belitski, 2021). One critical pathway for fulfilling this "third mission" is by fostering entrepreneurial mindsets among students through dedicated entrepreneurship education programs (Matlay, 2008; Breznitz & Zhang, 2022). Prior research highlights that entrepreneurship education can significantly boost entrepreneurial intentions and startup rates (Nabi et al., 2017), but its effectiveness is heavily influenced by the broader entrepreneurial ecosystem in which it operates (Fayolle et al., 2016; Liu et al., 2021).

Entrepreneurial ecosystems (EEs) are dynamic networks of interdependent actors, institutions, and resources that facilitate or hinder entrepreneurial activities (Isenberg, 2010). These ecosystems exhibit the characteristics of complex adaptive systems, where non-linear interactions among diverse stakeholders produce emergent, often unpredictable, outcomes (Levin, 2003; Roundy et al., 2018). Within this context, universities serve as critical hubs, both producing human capital and facilitating stakeholder interactions (Audretsch & Belitski, 2017).

Recent studies emphasize the emergence of entrepreneurial education ecosystems—a focused subset of broader ecosystems that integrates academic training, institutional support, cultural attitudes, and stakeholder collaboration to stimulate student entrepreneurship (Belitski & Heron, 2017; Liu et al., 2021). These ecosystems are multi-actor environments involving students, faculty, entrepreneurs, investors, and policymakers, whose coordinated interactions critically determine entrepreneurial outcomes (Freeman, 1994; Bischoff et al., 2018).

Building an effective entrepreneurial education ecosystem, however, remains challenging. The interplay between formal institutional structures (e.g., regulations, financial access) and informal elements (e.g., cultural

perceptions, social norms) creates a highly complex environment where interventions can have non-obvious effects (North, 1990; Urbano & Guerrero, 2013). There is a growing call for systemic approaches that capture this complexity and guide universities in ecosystem development (Cavallo et al., 2019).

To address these challenges, this study employs a theory-driven agent-based simulation model—the 3E Model (Entrepreneurial Education Ecosystem Model)—as a virtual laboratory for analyzing the impact of institutional conditions and stakeholder configurations. Unlike traditional empirical studies, agent-based modeling enables the exploration of emergent ecosystem dynamics by simulating the behavior and interactions of heterogeneous agents (Epstein, 2012; Macal & North, 2010).

We specifically aim to answer the following research question:

How do variations in formal and informal institutional factors influence the accumulation and diffusion of entrepreneurial knowledge, the development of entrepreneurial culture, and the motivation to engage in venture creation among actors within a university-based entrepreneurial ecosystem?

Drawing upon entrepreneurial ecosystem theory, stakeholder theory, and institutional theory, the model investigates how factors such as bureaucratic barriers, corruption levels, financial accessibility, cultural attitudes, and network diversity affect entrepreneurial knowledge accumulation, cultural development, and venture formation.

This study makes two primary contributions. First, it offers a dynamic, system-level analysis of entrepreneurial education ecosystems, providing quantitative insights into how institutional conditions shape entrepreneurial knowledge and culture (Brush, 2014; Secundo et al., 2021). Second, it demonstrates the practical utility of agent-based modeling as a decision-support tool, allowing universities and policymakers to simulate interventions and predict potential outcomes, thus fostering evidence-based and proactive ecosystem management (van Rijnsoever, 2020).

2 Theoretical Background

Entrepreneurial ecosystems (EEs) offer a systemic lens to understand the networked, non-linear interactions among actors, institutions, and resources that foster entrepreneurship (Stam & Van de Ven, 2021; Wurth et al., 2022). Conceptualized as complex adaptive systems, EEs evolve through dynamic feedback loops where entrepreneurial success or failure can reinforce ecosystem vitality or fragility (Roundy et al., 2018; Levin, 2003). Unlike linear models of innovation, EEs emphasize the emergent properties arising from the interplay of diverse components, including capital, mentorship, cultural attitudes, and supportive policies (Isenberg, 2011; Spigel, 2017).

Universities are increasingly pivotal in these ecosystems, functioning not only as knowledge producers but also as entrepreneurial hubs (Etzkowitz, 2004; Audretsch & Belitski, 2021). Through infrastructure like incubators, accelerators, and venture funds, universities promote startup creation and serve as connectors between academia, industry, and government (Guerrero et al., 2016; Wright et al., 2017). This role is central in the Triple Helix model of innovation, positioning universities as anchors of regional entrepreneurial development (Etzkowitz & Leydesdorff, 2000).

Expanding on this, scholars have conceptualized entrepreneurial education ecosystems as university-centered subsystems aimed at nurturing entrepreneurial capacities among students (Belitski & Heron, 2017; Liu et al., 2021). These ecosystems integrate educational programs, institutional support structures, cultural incentives, and stakeholder networks to create fertile environments for entrepreneurship (Guerrero et al., 2021). Effective entrepreneurial education ecosystems blur the campus-community boundary by engaging external actors such as investors, entrepreneurs, and policymakers (Secundo et al., 2021).

Stakeholder theory is critical in understanding these ecosystems (Freeman, 1994). Internal stakeholders—students, faculty, and administrators—interact with external ones—entrepreneurs, investors, government agencies—to co-create entrepreneurial learning experiences (Bischoff et al., 2018). Strong stakeholder coordination enhances knowledge flows, mentoring, and venture support, reinforcing the ecosystem's effectiveness (Wraae & Thomsen, 2019; Brush, 2014).

Underlying both ecosystems and stakeholder dynamics are institutional factors. Formal institutions—policies, curricula, funding mechanisms—shape the structural conditions for entrepreneurship (North, 1990; Urbano & Guerrero, 2013). Supportive formal measures, such as entrepreneurship majors or startup grants, can lower barriers to entry and boost entrepreneurial activities (Guerrero et al., 2016; Wright et al., 2017). However, bureaucratic red tape or restrictive regulations can inhibit these efforts (Van Stel et al., 2007).

Equally important are informal institutions—the cultural norms, values, and peer attitudes that influence entrepreneurial behavior (Liñán et al., 2011). A vibrant entrepreneurial culture that legitimizes risk-taking and innovation can enhance students' self-efficacy and motivation, often compensating for weaker formal structures

(Bergmann et al., 2018). The interplay between formal and informal institutions is critical: ideally, they align to reinforce entrepreneurial engagement, but mismatches can hinder outcomes (North, 1990; Guerrero & Urbano, 2013).

Finally, the broader macro-institutional context—such as national corruption levels or access to finance—also shapes the university's entrepreneurial ecosystem performance (Anokhin & Schulze, 2009). Recognizing these multi-level influences, our study develops an agent-based model that dynamically simulates how variations in institutional factors and stakeholder interactions impact entrepreneurial knowledge diffusion, cultural development, and venture formation within a university-based entrepreneurial ecosystem.

3 Methodology

To investigate the dynamics of a university-based entrepreneurial education ecosystem, we employed an agent-based modeling (ABM) approach. ABM is particularly suitable for this context as it enables the simulation of heterogeneous agents and the observation of emergent macro-level outcomes resulting from micro-level interactions (Epstein, 2012; Macal & North, 2010). This method aligns with the complex adaptive systems perspective of entrepreneurial ecosystems, allowing for non-linear behaviors and feedback loops that cannot easily be captured through traditional analytical methods (Levin, 2003; Sterman, 2002).

We developed a custom model, termed the 3E Model (Entrepreneurial Education Ecosystem Model), using the NetLogo platform (Wilensky & Rand, 2015). Model development was guided by an extensive theoretical framework, ensuring that key stakeholders, institutional conditions, and environmental factors identified in the literature were represented. To ensure transparency and reproducibility, the model was documented following the ODD (Overview, Design concepts, Details) protocol (Grimm et al., 2006; 2020).

Figure 1 shows the actors in the 3E model.

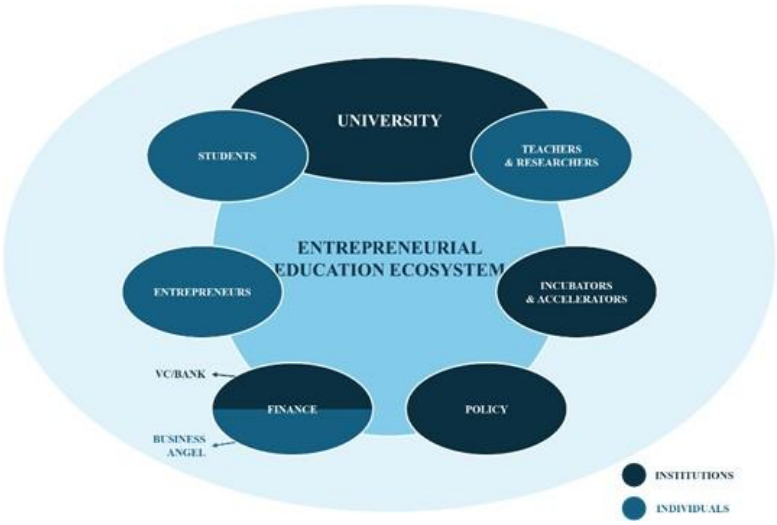

Figure 1: 3E model actors

The model features several types of agents:

Student agents: Representing university students or recent graduates, these agents possess evolving attributes such as entrepreneurial knowledge, skills, and attitudes. Students decide whether to launch a startup based on accumulated knowledge, perceived opportunities, and access to resources, reflecting real-world entrepreneurial decision-making patterns (Zhang et al., 2014).

Educator/Faculty agents: These agents deliver formal and informal knowledge, mentorship, and entrepreneurial role modeling to student agents. They simulate the roles of professors, entrepreneurship instructors, and staff involved in startup support, thereby influencing student learning and self-efficacy (Cope, 2005; Diegoli et al., 2018).

Investor/Business Mentor agents: Representing venture capitalists, angel investors, and industry mentors, these external stakeholders provide critical financial and social capital to student ventures. They offer investments based on project attractiveness and mentor students by bridging the gap between academic learning and market realities (Spigel, 2017; Secundo et al., 2021).

Additionally, two environment-level components shape the ecosystem:

University/Institutional parameters: Formal institutional conditions, such as bureaucratic burden, availability of internal grants, and entrepreneurship support infrastructure, are modeled as global variables. These factors directly impact students' startup likelihood by influencing the effort or incentives required for venture creation (Van Stel et al., 2007; Guerrero et al., 2016).

Culture/Social Environment settings: Informal institutions, such as the entrepreneurial culture and prevalence of role models, modulate student behaviors. A positive culture lowers perceived risks, boosts aspiration levels, and increases the probability of entrepreneurial activity among students (Liñán et al., 2011; Bergmann et al., 2018).

Through the 3E Model, we systematically vary these institutional and stakeholder configurations to observe their impact on entrepreneurial knowledge accumulation, culture development, and startup formation. This simulation approach enables experimentation with hypothetical interventions (e.g., reducing bureaucracy or enhancing mentorship programs) that would be difficult to implement empirically, thus offering a powerful tool for understanding and designing entrepreneurial education ecosystems.

4 Results

4.1 Impact of Formal Institutional Factors

The simulation results demonstrate that formal institutional factors—namely corruption, bureaucratic burden, and access to credit—significantly influence the evolution of entrepreneurial knowledge, culture, and new venture creation within the entrepreneurial edu99cation ecosystem.

Corruption emerged as the most detrimental factor. Higher corruption levels (i.e., lower transparency) consistently led to lower average entrepreneurial knowledge, a weaker entrepreneurial culture, and fewer student entrepreneurs. As summarized in Table 1, raising corruption from low to high decreased mean student entrepreneurial knowledge from 7.53 to 7.21, university entrepreneurial culture from 6.48 to 6.30, and reduced the average number of new entrepreneurs from 154.1 to 151.9. Kruskal–Wallis tests confirmed these differences as highly significant ($p < 0.001$).

Bureaucracy similarly exerted a negative, albeit slightly weaker, impact. Heavier bureaucratic burdens decreased entrepreneurial indicators modestly. For example, the mean number of entrepreneurs dropped from 153.5 under low bureaucracy to 152.3 under high bureaucracy, a significant but smaller effect compared to corruption ($p < 0.001$).

In contrast, access to credit exhibited a limited short-term impact. Although easier credit conditions marginally improved knowledge and culture scores, variations in interest rates (from 3.5% to 6.5%) did not significantly change the final number of entrepreneurs ($p = 0.78$).

Overall, the elimination of corruption showed the greatest potential gains in entrepreneurial outcomes, followed by streamlining bureaucratic processes. Improvements in credit conditions enhanced the ecosystem marginally but with diminishing returns within the tested range.

Table 1**:** Impact of Formal Institutional Factors on 3E Outcomes

Institutional Factor	Level	Mean Student Entrepreneurial Knowledge	Mean University Entrepreneurial Culture	Mean No. of New Entrepreneurs	Max No. of New Entrepreneurs	Significance (p-value)
Corruption	Low	**7.53**	**6.48**	**154.1**	**169**	<0.001
	Medium	7.41	6.40	153.2	165	
	High	7.21	6.30	151.9	164	
Bureaucracy	Low	**7.50**	**6.47**	**153.5**	**167**	<0.001
	Medium	7.37	6.36	153.1	165	
	High	7.29	6.33	152.3	163	
Access to Credit	Easy (Low)	7.45	6.43	153.2	167	0.78
	Medium	7.38	6.40	153.0	166	
	Hard (High)	7.31	6.37	152.8	165	

4.2 Impact of Informal Institutional Factors

Higher societal perception levels (i.e., a more favorable view of entrepreneurship) strongly enhanced entrepreneurial knowledge, culture, and venture creation. Increasing societal support from low (index 0.35) to high (index 0.80) raised the mean university entrepreneurial culture from 6.33 to 6.48, and mean student entrepreneurial knowledge from 7.22 to 7.59. The average number of new entrepreneurs increased from 152.6 to 154.0 (Table 2), with results statistically significant across all variables ($p < 0.001$). Notably, a threshold effect was observed: improvements in societal support translated into higher venture creation only after surpassing a critical perception index (~0.65), as illustrated in Figure 1B.

Cultural diversity similarly benefited the ecosystem, although with more gradual effects. A high melting pot index (0.35) improved entrepreneurial knowledge and culture modestly compared to low diversity (0.05), increasing new entrepreneurs from 152.0 to 153.5 on average ($p < 0.001$). The model suggests that diversity enhances creativity and opportunity recognition, although moderate diversity changes (e.g., 0.15 to 0.25) had limited effect—consistent with an adaptive equilibrium in the ecosystem.

Certain ecosystem components, such as incubators and accelerators, remained relatively resilient to informal changes, maintaining a strong entrepreneurial culture even under low societal support or low diversity. This buffering effect highlights the stabilizing role of specialized entrepreneurial institutions

Table 2**:** Impact of Informal Institutional Factors on 3E Outcomes

Institutional Factor	Level	Mean Student Entrepreneurial Knowledge	Mean University Entrepreneurial Culture	Mean No. of New Entrepreneurs	Max No. of New Entrepreneurs	Significance (p-value)
Social Perception	Low (0.35)	7.22	6.33	152.6	163	<0.001
	Medium (0.50)	7.37	6.38	153.0	165	
	High (0.80)	**7.59**	**6.48**	**154.0**	**170**	
Cultural Diversity (Melting Pot)	Low (0.05)	7.23	6.30	152.0	162	<0.001
	Medium (0.15)	7.32	6.35	152.8	164	
	High (0.35)	**7.50**	**6.48**	**153.5**	**168**	

5 Discussion

The findings of this study offer a robust contribution to the literature on entrepreneurial education ecosystems (3Es) by demonstrating how formal and informal institutional conditions shape the evolution of entrepreneurial knowledge, culture, and venture creation within university settings. While previous research has underscored the critical role of universities in fostering entrepreneurship and connecting with external stakeholders (Etzkowitz, 2004; Guerrero & Urbano, 2013), empirical analyses have often lacked the analytical tools to capture the complex, systemic nature of 3Es (Roundy et al., 2018). In response, this study integrates agent-based modeling (ABM) with institutional theory to analyze how institutional conditions—both formal and informal—influence the diffusion of entrepreneurial knowledge, the formation of entrepreneurial culture, and the motivation to start ventures within a university-centered ecosystem.

The simulation results clearly demonstrate that institutional configurations significantly shape entrepreneurial outcomes. In particular, formal institutions such as corruption, bureaucratic burden, and credit access modulate the probability that individuals engage in learning and startup activity. These findings resonate with earlier empirical work showing that institutional inefficiencies—especially high corruption—undermine entrepreneurship by reducing trust, increasing transaction costs, and limiting opportunities (Li & Wu, 2010; Anokhin & Schulze, 2009). Our simulations reinforce these insights: under high-corruption scenarios, student and faculty motivation to participate in entrepreneurial education diminishes, eroding collective knowledge and stalling new venture creation. Furthermore, we observe that once corruption crosses a certain threshold, its marginal impact on seasoned actors (e.g., business angels or established entrepreneurs) declines, suggesting a

behavioral adaptation or normalization of dysfunction—a phenomenon observed in studies of institutional decay (Transparency International, 2023).

Bureaucratic burden also emerges as a demotivating force, though its effects are more nuanced. While it significantly impacts students and nascent entrepreneurs by reducing their self-efficacy and willingness to participate in entrepreneurial programs (Griffiths et al., 2009; van Stel et al., 2007), the knowledge levels of external investors are less affected. This discrepancy likely reflects investors' peripheral role in education-centered initiatives, as their decision-making is driven more by investment logic than learning needs. Nonetheless, high bureaucratic costs serve as barriers to both participation and course delivery, which aligns with previous work identifying regulatory friction as a deterrent to early-stage entrepreneurship (McMullen et al., 2016; Sendra-Pons et al., 2022).

Access to credit plays a more moderate yet important role. While minor variations in interest rates have limited effects on venture formation, more pronounced credit constraints discourage participation in educational programs, particularly when entrepreneurial education entails upfront costs. This confirms existing evidence that financial inclusion facilitates not only startup formation but also engagement in learning pathways that foster entrepreneurial competencies (Bourlès & Cozarenco, 2018; Sendra-Pons et al., 2022).

Among the informal institutions examined, the societal perception of entrepreneurship proves most influential. Simulations reveal a strong positive association between favorable social attitudes and increased motivation, cultural legitimacy, and entrepreneurial activity. This aligns with the theory of planned behavior (Liñán & Chen, 2009) and prior findings emphasizing the role of social legitimacy in shaping entrepreneurial intentions (Hayton et al., 2002; Liñán et al., 2011).

Finally, while cultural diversity had a less pronounced effect than other factors, its contribution to knowledge exchange and network expansion supports the view that heterogeneous ecosystems foster innovation and creativity (Audretsch & Belitski, 2017). The model confirms that diverse actors enrich the learning environment, even if effects appear more gradual and context-dependent.

Taken together, the results reinforce the importance of considering entrepreneurial ecosystems as multi-layered and interdependent. The evidence supports the proposition that institutional quality—both formal and informal—not only affects individual agency, but also collectively determines the knowledge infrastructure and emergent properties of the ecosystem (North, 1990; Stam & Van de Ven, 2021). Thus, future interventions should aim not only to reform regulations, but also to shift cultural narratives and promote entrepreneurship as a valued societal endeavor (Urbano et al., 2017; Guerrero & Marozau, 2023).

6 Conclusions

This study presents an original contribution to entrepreneurial education research by developing a theory-driven agent-based model (the 3E Model) that simulates how formal and informal institutional conditions influence entrepreneurial learning and behavior in university ecosystems. Integrating stakeholder theory (Freeman, 1994) and institutional theory (North, 1990), the model captures interactions among heterogeneous agents—students, faculty, investors, and university structures—thus extending the theoretical lens beyond the student-centric view that dominates much of the existing literature (Brush, 2014; Liu et al., 2021).

Theoretical implications include a refined conceptualization of entrepreneurial education ecosystems as complex adaptive systems, where outcomes emerge from feedback-rich processes involving multiple actors and contextual dependencies (Roundy et al., 2018). The results highlight the distinct and complementary roles of formal and informal institutions, demonstrating that soft factors such as cultural norms and social perception can have as much impact as structural reforms in shaping entrepreneurial activity. Moreover, the findings suggest potential threshold and nonlinear effects, pointing to the existence of institutional "tipping points" that either unlock or constrain ecosystem performance.

From a practical perspective, the 3E Model functions as a decision-support tool for policy makers and university administrators. It enables the simulation of diverse institutional scenarios—e.g., reducing bureaucracy, enhancing role model exposure, or fostering cultural inclusiveness—and allows stakeholders to anticipate the systemic impact of these interventions. Our findings suggest that policies aimed at promoting entrepreneurial culture and legitimacy may be especially effective when combined with formal institutional improvements such as deregulation and increased funding opportunities. Additionally, fostering diversity and inclusion within academic communities can catalyze innovation by expanding the scope of ideas and networks accessible to nascent entrepreneurs.

Future research could enhance the model by refining the representation of motivational dynamics, which in the current version evolve in parallel with knowledge accumulation but could follow independent or nonlinear trajectories. Empirical validation of agent attributes through survey data or expert interviews would strengthen

the model's calibration and applicability. Furthermore, extending the model to include feedback loops—whereby improved education affects institutional quality—could open new avenues to investigate how ecosystems co-evolve over time. Finally, future studies may explore additional actor types or contexts (e.g., non-university incubators, secondary education systems), providing a more comprehensive picture of entrepreneurial knowledge systems.

Technology Leaders and Followers: An Agent-Based Approach

Linda Ponta[1], Raffaella Manzini[2], Silvano Cincotti[1]
[1]Università degli Studi di Genova, Genova, Italy
[2]Università Cattaneo - LIUC, Castellanza (VA), Italy

Abstract

In this dynamic and full-opportunity world, firms must face challenges in markets and technologies. One of the main assets that firms can use to address these challenges is innovation, and an important element is to define the most appropriate innovation strategy. Inside innovation strategy, fundamental decisions are about selection, acquisition, and timing. The innovation selecting consists of the selection of the innovations to develop; the innovation acquiring consists of how firms acquire the innovation (the main strategies can be simplified with insourcing (make), outsourcing (buy), or collaborating (collaborate). In particular, with respect to timing, firms are heterogeneous and two main approaches can be identified: technological leaders and technological followers that work on the technological knowledge developed by the technological leaders. In this paper, the two approaches have been investigated to study the impact on the firm's performance. To conduct this investigation, the Patent Agent-Based Innovation Model and Simulator (PABIM has been enhanced. The PABIM is characterized by heterogeneous firms that are organized as a directed random graph. The use of an agent-based model allows for the exploration of emergent dynamics and their subsequent effects on performance. The results indicate that when a firm can adopt all the acquisition strategies (make, buy, collaborate), the optimal strategy concerning timing for firm performance is the leaders' approach, independently of the sector innovation intensity. The study recommends that managers and policymakers adopt a comprehensive approach to innovation management, integrating pertinent technical knowledge related to product or process development with the necessary resources for effective implementation.

Keywords: technology leaders, technology followers, patent, agent-based model

Paper type: Academic Research Paper

1 Introduction

In this dynamic and full-opportunity world, firms must face challenges in markets and technologies (Looney and Hardin, 2009).

One of the main assets that firms can use to address these challenges is innovation (Kline and Rosenberg, 2010), and an important element is to define the most appropriate innovation strategy (Pearson, 1990).

According to Porter and Stern (2001), the innovation strategies consist of three key elements, which correspond to three key decisions: the selection of the innovation to develop, whether to be a leader or follower, and whether to sell the innovation or not.

Thus, innovation strategy is characterized by three categories of decisions: innovation selecting, innovation acquiring, and innovation timing. The decisions have to be considered jointly; in fact, the decision about the selection of the innovation on which to invest cannot be kept separated from the mode of acquisition and the timing of innovation development and introduction (Chiesa, 2001).

The first category, the innovation selecting, consists of the selection of the innovations to develop based on the coherence of the innovation choices with the firm's basic strategy, and the test of whether the innovation change is desirable for the firm.

The second category is the innovation acquiring, i.e., how firms acquire the innovation. Each firm addresses the acquisition of resources for innovations in a different way, but the main strategies can be simplified with insourcing (make), outsourcing (buy), or collaborating (collaborate), i.e., a hybrid and plural sourcing approach, with the creation of strategic alliances (Veugelers and Cassiman 1999, Belderbos et al., 2014, Chesbrough, 2003).

The third category focuses on the timing decision. The two main approaches that can be identified are technological leaders and technological followers (Chiesa, 2001, Tidd and Bessant, 2020), who work on the technological knowledge developed by the technological leaders.

For the sake of simplicity, we hypothesize that technological leaders use the make strategy or make and collaborate strategy, and the technological followers mainly use the buying strategy, as they exploit innovations produced by others. We know that this is a rough simplification, but it can be useful to investigate the effects of opposite or significantly different strategies.

Relying on this background, this work aims to investigate the presence of different strategic decisions of innovation strategies and the companies' performance for technological leaders and technological followers in sectors characterized by different innovation intensity when firms can use both the "making" (alone or opening

to collaborations with other companies) or "buying" innovation strategy. Thus, the paper answers the following research question:

In sectors with different innovation intensity, do firms adopt different strategic decisions of timing? If yes, how do the innovation strategies impact the company's innovation and economic performance? In particular, the study aims to see if these strategies, i.e., making or buying, eventually with collaboration, for technology leaders or followers, impact in terms of firm performance.

To answer the research question outlined above, an agent-based model and simulator have been developed (Iandoli et al., 2012; Ponta et al., 2018, 2020, 2023, 2024, 2025; Nieddu et al., 2024; Cincotti et al, 2024).

The agent-based model developed is characterized by heterogeneous firms that are organized as a directed random graph. To simulate their behaviour, each firm is characterized by an identifier, the number of employees, an amount of cash, a propensity to buy or do innovation S, the percentage of turnover invested in R&D research, an industrial sector, and a probability to patent.

At each iteration step, the economic and innovation performance are evaluated respectively using turnover and the Innovation Patent Index (IPI) (Ponta et al., 2020, 2021).

The model proposed provides a lab setting in which it is possible to test the effect of different innovation strategies: make and buy (eventually with collaboration) for different kinds of innovators.

ABM approach overcomes the limits of other classical methodologies, such as surveys or case studies.

Results show that the most convenient strategy for each kind of innovator depends on the sector innovation intensity.

This contributes to the theory showing the importance of using collaboration and buying innovation in challenging and uncertain environments to create a complete knowledge chain towards successful innovation (Kennedy et al., 2017). Especially, the adoption of an agent-based model allows understanding of emerging dynamics and their effect on performance for different types of innovators, leaders, and followers.

For managers and policy-makers, it suggests the need to see the innovation process with a comprehensive view, including the understanding not only of the technical knowledge of the product or process produced, but also the resources that need to be used or acquired to make it, and the timing

The remaining of the manuscript is organized as follows: Section 2 describes the model implemented, Section 3 reports the results of the study, and Section 4 provides the discussion and conclusion of the study.

2 The Model

To investigate the main objective of the study outlined above, an enriched version of the Patent Agent-Based Innovation Model (PABIM) has been used (Ponta et al., 2023, 2024, 2025).

The model includes heterogeneous agents that represent firms organized as a directed random graph, i.e. the interactions are unidirectional and characterized by a weight w_{ij}, assumed a positive real number.

The graphical representation of the present PABIM model in terms of firms (circles) and interactions (lines) is shown in Figure 1.

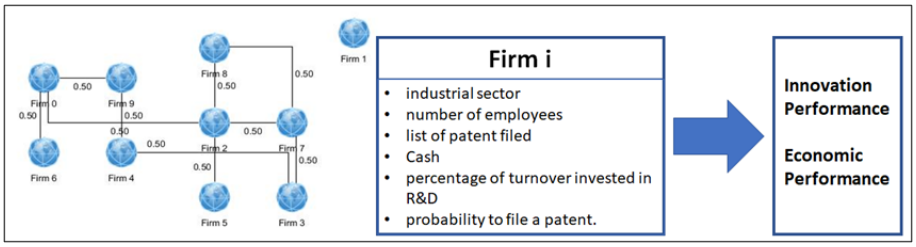

Figure 1: Graphical representation of the agent-based model in terms of firms (circles) and collaborations (lines). On the right, for each company the main features are listed

At the beginning of the simulation, all the firms have the same output node degree, defined as the number of outgoing arrows, and are endowed with the same quantity of cash and the same number of employees. During the simulation, the output node degree of each firm is directly proportional to the firm's size, i.e., it increases if the firm's size increases and decreases if the firm's size decreases, thus the number of employees, proportional to the firm's size, varies during the simulation.

In the enriched version of the model, a firm i is characterized by an identifier id_i, a number of employees N_i, a list of its filed patents P_i, an amount of cash C_i, the turnover Tu_i, the percentage of turnover invested in R&D α_i, an industrial sector IS_i and a probability to patent ρ_i. Moreover, firms are characterized by a propensity S_i to create or buy innovation. S ranges between 0 and 1. If S_i =1 means that firm i only creates innovation, i.e., new

patents. If S_i =0 means that firm i only buys technology from the outside and so it buys licenses. Then all nuances are possible. The propensity S does not change over time.

The percentage of turnover invested in R&D research is different for each firm and proportional to the firms' dimension. At each iteration step, each firm invests a fraction of the turnover in R&D research, necessary to innovate. Propensity S is correlated with the investment in R&D research. If the investments are small the propensity to buy innovation is large.

The probability ρ_i of firm i to innovate is set to depend on the cumulated R&D research investment Mc_i employed by firm i since the latest innovation filed, as follows:

$$\rho_i^t = Si(1 - \frac{1}{1 + \eta\, Mci\,_i^t}) \qquad (1)$$

where Si is the propensity of firm i to innovate, η is a shape parameter, homogenous across all firms, setting the sector innovation intensity, i.e., the higher is η, the higher is the probability to innovate, for any level of cumulated R&D research investment Mc_i employed. At each time step t the firm i checks if it is possible to innovate alone. If innovating alone is not possible firms check the connected firms if co-innovation is possible. The probability of making innovation using shared knowledge between firms i and j is given by Eq. 1 where the cumulated R&D research is the sum of the cumulated R&D research of firms i and j.

If also a co-innovation is not possible firms can extend an innovation issued in time step t-1 and can buy innovation if firms have enough cash. Innovation is modeled and measured with patents.

The patent is characterized by an identifier, an IP class, one or more countries in which the patent is extended, and the number of forward and backward citations. It is worth remembering that the backward citations are the patents cited when the new patent is issued, whereas the forward citations are the ones received by the patent. Moreover, a patent is characterized by a cost composed of a part that represents the cumulated (discounted) cost of filing and maintaining a patent and another part that depends on the R&D investment done until the year of filing. Moreover, a patent is also characterized by an extensions cost which represents the cumulated (discounted) cost of extending and maintaining the extensions of a patent. Management costs have also been considered.

The value of the patent, intended as the cumulated (discounted) turnover generated by the patent is defined by firms proportional to costs, through a multiplier $\mu_{p,i}$ defined at the beginning of the simulation and constant during the simulation. $\mu_{p,i}$ is a positive real number to consider both the case of success and failure of a patent. In particular, $0 < \mu_{p,i} \leq 1$ represents the failure case, whereas $\mu_{p,i} > 1$ represents the success case.

The revenues for firm i of a patent p filed at time t is:

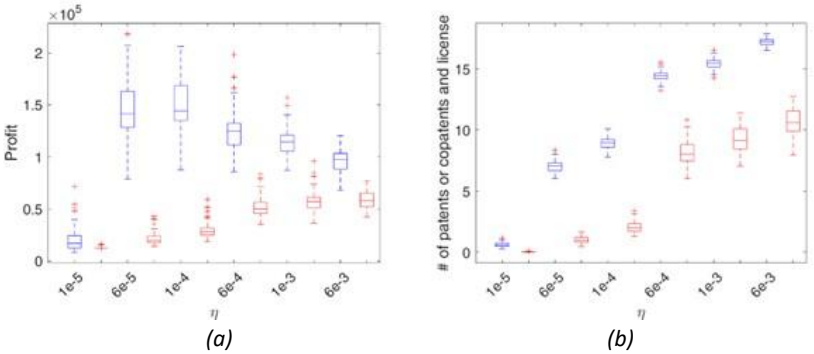
$$R_{p,i^t} = \begin{cases} V_{p,i}^t & \text{if firm } i \text{ files a patent alone at time step } t \\ V_{p,i}^t \, \nu \frac{Mc_i^{t-2}}{Mc_i^{t-2} + Mc_j^{t-2}} & \text{if firm } i \text{ files a patent at time step t using shared knowledge with firm } j \ (copaten_i) \end{cases} \qquad (2$$

where ν is a coefficient positive and less than 1, which simulates the management costs between firm i and j. Furthermore, the turnover of firms is updated. and firms determine the number of employees to hire or fire at each iteration step, according to their revenues. The license cost is equal to a percentage δ of the patent value. If firm i buys a license l of the patent p at time step t the cost of the license is formed by a forfeit part that is paid at time t and by royalties that are paid for Tr years. The forfeit part is evaluated as a percentage δ of patent It is worth noting that the percentage δ is decided by means of a contract between the licensing firm i and the selling firm j. The royalties are evaluated as a percentage ξ of the turnover of the firm that is buying the license. The royalties r are paid by the firm that has been buying the license for a number of years Tr. The license remunerates a percentage of the patent value. Firms choose to buy the last patent issued in their technological sector. At each iteration step, the economic performance is evaluated as its profit whereas the firms' innovation performance with the Innovation Patent Index (IPI) (Ponta et al., 2020, 2021). Moreover also the number of sold and bought licenses has been considered. In the model leaders are identified as the firms that use mainly the "making" and "making and collaborating" strategy, whereas the followers as the firms that use mainly the buying strategy. In order to validate the two groups, the average percentage of investment in R&D of the leaders and followers groups has been evaluated.

At each iteration step, the economic and innovation performance of firms is updated. The economic performance is approximated with the profit, whereas the innovation performance is with the number of

innovations and the Innovation Patent Index (IPI) (Goldstein et al., 2001; Ponta et al., 2021). IPI is a more complete measure of innovation performance as it considers not only the classical measure of the number of patents but also other characteristics of patents (Dziallas et al., 2018).

3 Computational experiments



To investigate the firm performance, with respect to different innovation strategies, the economic and innovation performance have been evaluated for different sector innovation intensity.

Simulations have been performed ceteris paribus. In particular, one hundred firms, working in fifty different sectors, have been simulated. It is worth noting that each firm can create an innovation maximum per year. Table 1 summarizes the initialization data of the simulations.

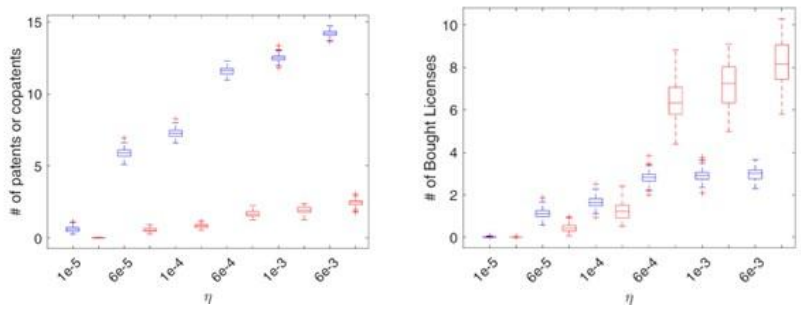


Table 1: Simulation Parameters

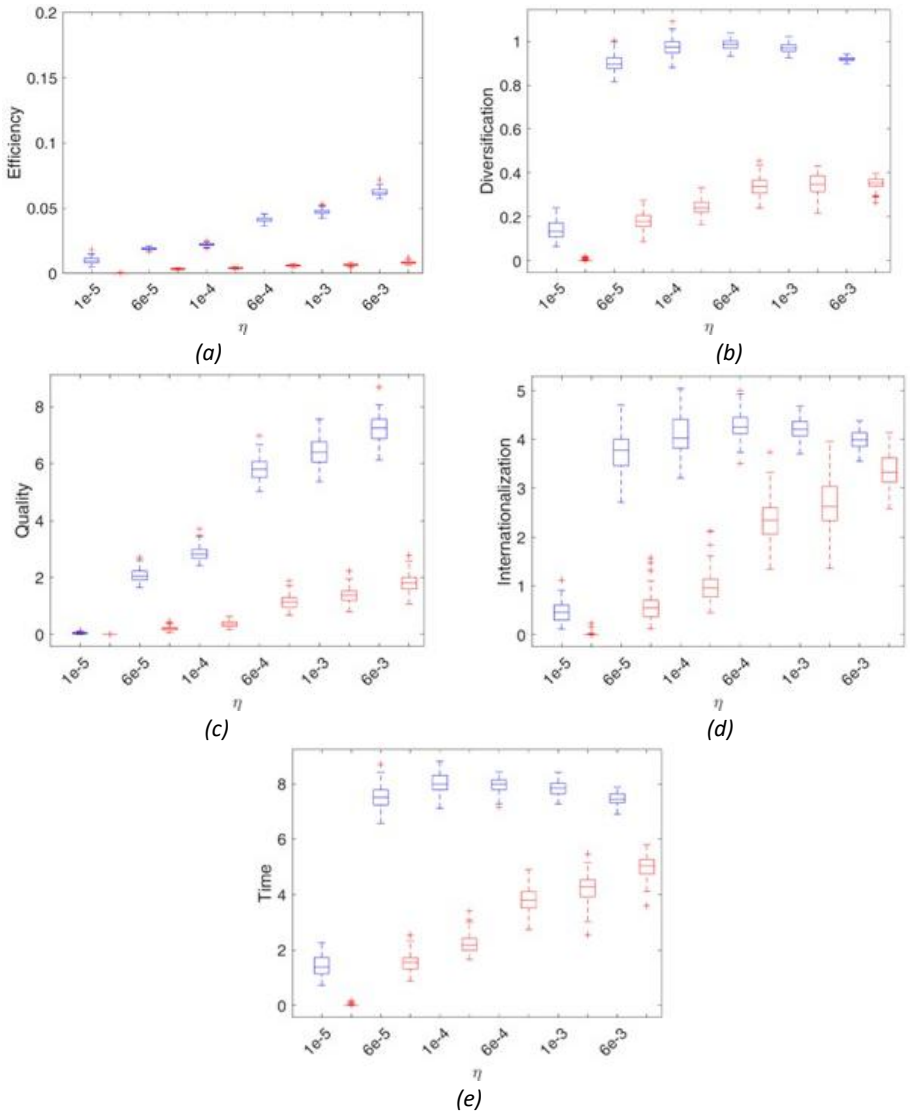
Symbol	Description	Value
T	Years	20
I	Number firms	100
ES	number of economic sectors	50
Do	number of initial output connections	0, 10
T_u	Turnover init	20000
H	Sector innovation intensity	0.000002 to 0.2
A	% of turnover invested in R&D	[2 - 17]
μ	Multiplicator	[0.5 - 2]
ξ	coeff management cost	0.9
C_e	patent extension cost	350
C_f	patent filed fixed cost	500
δ	% of patent value for the licence cost	30

Figure 2 shows the economic and innovation performance for technological leader's and follower's groups in blue and red, respectively. Leaders are characterized by using mainly the making and collaborating strategies. In particular, Figure 2 (a) shows the economic performance approximated with the profit. It is worth noting that for small medium and large sector innovation intensity, for firm it is more convenient to be a leader instead of a follower. Thus, for a firm, it is more remunerative to reach enough knowledge to patent alone or using shared knowledge to create a copatent than to pay royalties. Figure 2(b) shows the innovation performance approximated with the number of innovation measured as the sum of new patents and bought licences. Independently form the sector innovation intensity the leader group has better innovation performance. If the sector innovation intensity is small the difference among the leaders and followers is small, but when η increases also the difference increases. Looking more in details the innovation performance, Figure 2 (c) shows the number of patents, whereas Figure 2 (d) the number of bought licences. For every η, the number of patents is larger in the leaders group, whereas the number of bought licences for small η is lager for leaders group whereas for large η for follower group. Figure 3(a) shows the normalized number of patents with respect to the firm size. Figure 3 (b) and (c) show the number of IPC classes and the number of backward citations patent features, respectively. Figure 3(d) and (e) show the number of extensions, the number of months between the publication date of the youngest and the oldest patent of the family, and patent features. It is worth noting that for all η the five IPI dimensions are larger in the case of leaders group.



(a) *(b)*

(c) (d)

Figure 2 – Distribution of economic performance approximated with profit (a) , of innovation performance approximated with the number of innovations (b), of number of patents (c) and number of bought licences (d). The blue boxplots correspond to technological leaders' group, whereas the red boxplots to technological followers' group.

Moreover, Efficiency, diversification, and quality behave in the same way, whereas internationalization and time, in the case of leaders, have a maximum for medium η, whereas in the case of followers, the dimensions increase, and for large η, the values are similar to those of the leader group.

4 Discussions and conclusions

The computational results presented in the paper can capture the impact of innovation strategies on firm performance. The paper has proposed a methodological approach, i.e., an agent-based model, that provides a more complete understanding of acquiring and timing strategies concerning innovation and economic performance (Greco et al., 2016).

Furthermore, the firm performance dynamics that emerged from the simulations show important results, both at the economic and innovation levels. Focusing on the timing strategy, the economic performance, for small, medium, and large sector innovation intensity is better for leaders firms. In particular, for larger η, the economic performance for both leaders and followers is very similar. In the case of leader firms, there is also a U-shaped form, whereas in the case of followers, the curve is increasing, reaching a plateau. This result confirms that if the sector innovation intensity is small is important to be a leader, in order to take first mover advantages (Barney, 1991). Moreover, the inverted U-shaped curve demonstrated that when increasing the sector innovation intensity, there is a sort of maximum. High sector R&D intensity could lead to lower economic benefit, probably because of difficulties in capturing the innovation value, and high R&D expenses cannot generate higher sales. If the sector innovation intensity is high the economic performance of being leaders or followers are similar meaning that a firm cannot be always leader but should also be follower helping to be ready with new technology in less time with respect to start to research and develop a new technology (Schilling and Phelps, 2007). To be a follower is preferred by firms with respect to the collaboration, probably because collaboration could lead to higher complexity and managerial costs, confirming also more recent studies about the non-linearity of the relationship (Greco et al., 2016).

Instead, as expected, innovation performance is more effective in the case of leader firms. In particular, in terms of the number of patents developed, the leaders show better performance. The use of internal knowledge and collaborations permits filling internal lack of competencies and developing a larger number of innovations, and taking the first mover advantage.

In conclusion, the agent-based model developed here provides a tool that is very suitable for making a classic what-if analysis. In particular, it is a sort of computational laboratory where to perform experiments and find the most cost-efficient policy to improve the performance of firms. This allows for taking a further step towards understanding the outcomes tied to applying a leader or follower strategy that has not yet been widely analyzed, due to a lack of data. This simulator will be a very useful tool for managers because they will be able to simulate a chosen strategy before applying it in the real world. Nevertheless, this study is not without limitations. Although patents are widely used to measure innovation performance, they represent only a limited set of company innovation assets. Furthermore, in some sectors, patents are not widely adopted as mechanisms to protect innovations because other innovation assets that are more difficult to measure, such as R&D expenditures, intellectual assets, human resources skills, and aesthetic design, also provide information to measure innovation performance (Grazzi et al., 2021; Ardito et al., 2015).

This contributes to the theory showing in innovation literature the importance of being a leader or follower in challenging and uncertain environments to create a complete knowledge chain towards successful innovation. Especially, the adoption of an agent-based model allows understanding emerging dynamics and their effect on performance. For managers and policy-makers, it suggests the need to see the innovation process with a comprehensive view, including the understanding not only of the technical knowledge of the product or process produced, but also the resources that need to be used or acquired to make it.

Circular Economy Yes or No? This is the Dilemma. An Agent-Based Approach

Linda Ponta[1], Andrea Urbinati[2], Raffaella Manzini[2]
[1]Università degli Studi di Genova, Genova, Italy
[2]Università Cattaneo - LIUC, Castellanza (VA), Italy

Abstract

Circular economy has emerged as an industrial approach that aims to overcome the traditional "take-make-dispose" economic model, which is based on the intensive extraction of raw materials and the design of products with a limited lifespan. The circular economy approach consists in a closed system in which products, materials and resources are continuously reused, remanufactured and recycled. The implementation of circular economy principles in companies requires a gradual redesign of products, which consists of a concurrent design of products and related manufacturing processes that enhance competitiveness measures, rationalize product/process/resource design decisions and improve operational efficiency in product development. Given this premise, the transition of companies towards a circular economy paradigm challenges companies to rethink their linear approach of doing business, leading to the research dilemma of answering: Is it economically convenient for a company, in terms of economic margin, to develop circular products starting from a linear positioning? To answer this research question, an agent-based model and simulator (ABM) has been developed characterized by four kinds of heterogeneous firms: the supplier, the manufacturer, the user and the recycler.
The adoption of an agent-based model, which is coherent with the approaches of complexity science, allows for investigating the phenomenon considering its complex nature, and the consequent dynamic non-linear relations among the various actors involved: manufacturers, suppliers, customers and consumers, recyclers. Results show that the manufacturer only partially follows consumer sentiment, as it retains a large proportion of linear products. Even when consumer sentiment is low, it is in the manufacturer's interest to move even slightly towards circular products.

Keywords: linear economy, circular economy, agent-based model

Paper type: Academic Research Paper

1 Introduction

Circular economy has emerged as an industrial approach that aims to overcome the traditional "take-make-dispose" economic model, which is based on the intensive extraction of raw materials and the design of products with a limited lifespan (Urbinati et al., 2017). In the circular economy premises, the economic system is designed to minimise waste and keep materials and resources in use for as long as possible to allow the earth sufficient time to regenerate resources (Kirchherr et al., 2017).

The circular economy approach consists in a closed system in which products, materials and resources are continuously reused, remanufactured and recycled, thus creating a virtuous and sustainable technical cycle (Ghisellini & Ulgiati, 2020), and when can no longer be used to make new products, they can also biodegrade and return to the earth safely (Navare et al., 2021).

Accordingly, the implementation of circular economy principles in companies requires a gradual redesign of products, which consists of a concurrent design of products and related manufacturing processes that enhance competitiveness measures, rationalize product/process/resource design decisions and improve operational efficiency in product development (Sassanelli et al., 2020). Practices enabling the redesign of products aim at closing the loop at both company and supply chain levels and addressing a sustainable use of resources (e.g., through design for recycling, remanufacturing, or reusing).

Notwithstanding the importance of shifting from a linear economy to a circular one to preserve the environment and the humankind, several issues may emerge that characterize the economic feasibility for companies to implement this approach (Corvellec et al., 2022). For example, several scholars highlight that the adoption of a circular economy practice – either the reuse or remanufacture or recycle – could be simultaneously associated with a positive economic result and a reduction in environmental impacts (Zink & Geyer, 2017; Lowe et al., 2024). In addition, it is not certain that the economic and environmental benefits resulting from the implementation of a circular economy practice that is virtuous for an individual company are reflected in similar benefits for the supply chain in which the case company operates (Castro et al., 2022). While it is true that the implementation of circular practices should contribute to the generation of environmental benefits for companies and supply chains, such as the reduction of both climate-changing emissions and natural resource

requirements (Nowicki et al., 2023), it should also ensure a positive economic return on the circular investment (Dagilienė & Varaniūtė, 2023).

Given the premise above, the transition of companies towards a circular economy paradigm challenges companies to rethink their linear approach of doing business, leading to the research dilemma of answering: Is it economically convenient for a company, in terms of economic margin, to develop circular products starting from a linear positioning?

To answer this research question, an agent-based model and simulator (ABM) has been developed (Iandoli et al, 2012, Ponta et al, 2020, Ponta et al, 2023), with the aim to investigate if the gradual shift from a linear business, implemented completely through linear products, to a circular business, implemented by adding elements of circularity in product design, such as biodegradable or compostable materials, makes economic and environmental sense for a producer-based company. The adoption of an agent-based model, which is coherent with the approaches of the complexity science, allows for investigating the phenomenon considering it complex nature, and the consequent dynamic non-linear relations among the various actors involved: manufacturers, suppliers, customers and consumers, recyclers. In particular, given the heterogeneous requests of the customers about linear and circular goods, our paper contributes to the existing research on the dynamics of circular product development due to the customer engagement in the producer's circular transition (Urbinati et al., 2020).

2 Model

ABM is particularly fitting for this research because developing circular products is a process composed of different and multiple steps that define a complex and nonlinear process (Garud, 2013), and ABM is acknowledged for being among the most appropriate methods to cope with complexity (Arthur, 2013). Once agents and interaction rules are implemented, system evolution is studied by analyzing the output of several simulations in search of macroscopic regularities (Epstein, 2006).

Thus, agent-based models provide a tool suitable for making a classic what-if analysis, creating a sort of computational laboratory to perform experiments. The ABM developed in this research is characterized by heterogeneous firms that are organized in linear and circular supply chains.

Four kinds of heterogeneous firms characterize the agent-based model developed: the supplier provides raw (virgin) materials and recycled materials to manufacturers; the manufacturer has two principal task: the production of goods and the sales of goods (the manufacturer buys the virgin raw materials and the recycled materials to produce two typology of products, i.e., linear and circular goods); the user buys linear and circular products; the recycler recycles the goods at the end of their lifecycle. Figure 1 shows the link among the different types of agents.

Figure 1 shows the firms characterizing the agent-based model developed, along with the circular and linear supply chains.

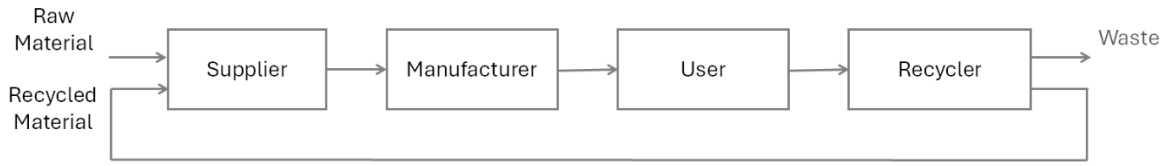

Figure 1: Linear and circular supply chain

The supplier agent provides raw and recycled material to the manufacturer agent. The supplier mines the raw material. The recycler agent provides the recycled material that is sold to the supplier agent. The quantity of raw material mined at time step t is fixed. The cost of raw material is constant and represents the cost of mining and the cost of the CO_2 emission. The recycled material is bought from the recycler with lowest price, that is linked to the supplier. The raw material is sold at price p_r evaluated as a markup of the cost of raw material. The markup varies according to the inventory. Analogously, for the recycled material price $p_Y(t)$.

The manufacturer has two principal tasks: the production of goods and the sale of goods. For the production, the manufacturer buys raw materials and recycled materials from the supplier. All the profit is used to buy raw and recycled materials. The quantity of recycled material bought is defined by the percentage ρ. The remaining part 100-ρ is the percentage of raw material bought. ρ is fixed during the simulations. The manufacturer produces 3 types of final goods: the brown good, the green good, and the mixed good. The brown goods are produced with 2 units of raw material. The green goods are produced with 4 units of recycled material. The

mixed goods are produced with 1 unit of raw material and 2 units of recycled material. The number of brown, green and mixed goods produced depends on the quantity of available raw and recycled material. The priority in the production is for the mixed goods. The price of the final goods is decided by the manufacturer with a markup over the costs, and the markup varies according to the inventories as for the supplier. The final goods are sold to the users.

The user buys the final goods, i.e., the brown, mixed, and green goods. The user is characterized by a sentiment "S" that ranges between [-1,1] which is responsible for the choice of buying brown, green, and mixed goods. If the sentiment is negative, γ represents the percentage of brown products that the user will buy. The user received money from the use of each final good; in particular, the user receives a utility coefficient of the cost of the good. The lifetime of brown, green, and mixed goods is T years. When a final good arrives at the end of its life, it is sold to the recycler.

The recycler agent creates recycled materials from the final goods. The green goods cannot be recycled being already made with recycled material. In this model, recycling is possible only once. All the raw material of the brown goods is recycled. In the mixed goods, only the quantity of raw material is recycled. The cost of recycling is fixed during the simulation. The price of recycling material varies according to the inventory during the simulation. To simulate their behaviour, each firm is initialized with an amount of cash. The user is also characterized by S which is responsible for the choice of buying linear or circular products. At each iteration step, the economic performance, approximated with the cumulated economic margin, of each agent is evaluated.

3 Computational experiments

3.1 Design of experiments

To investigate the effect of linear and circular businesses, five different scenarios have been investigated. In particular, for 10 different values of γ, six values of ρ are considered. Table 1 details the scenario values. In scenario (i), the manufacturer firm can only adopt a linear business. In scenarios from (ii) to (v), the manufacturer firm uses an increasing percentage of recycled material in its production. Simulations have been performed ceteris paribus, meaning that all the parameters are identical except for the strategy. In particular, one firm per typology has been simulated. The five scenarios previously described are explored with ten different values of γ, the parameter that controls the sentiment of the customers; in this way, 50 different scenarios are obtained.

Table 1: Scenarios description

Scenario	ρ	Description	color
(i)	0	No recycled material bought	blue
(ii)	0.2	20% of the total quantity of material bought is recycled	orange
(iii)	0.4	40% of the total quantity of material bought is recycled	yellow
(iv)	0.6	60% of the total quantity of material bought is recycled	violet
(v)	0.8	80% of the total quantity of material bought is recycled	green
(vi)	1	100% of the total quantity of material bought is recycled	azure

The methodology used is based on Monte Carlo computational experiments: each scenario is simulated with eleven different seeds of the pseudorandom number generator. So, a total of 660 simulations were considered to conduct the investigation. The computational results are presented in the form of boxplots. Each boxplot shows the distribution of the time averages of relevant variables over one-hundred-time intervals, concerning the eleven simulations characterized by different seeds. Boxes enclose the values from the first to the third quartile; they also include whiskers that extend up to the minimum and maximum data points that are not considered outliers; the horizontal segments inside boxes represent the median of the distribution. The analysis aims to investigate the impact of using different percentages of recycled material on manufacturers' economic performance. Table 2 summarizes the initialization data of the simulations. The values of the variables and parameters used in the simulation have been chosen either from the literature or from previous empirical analysis.

Table 2: Simulation parameters

Supplier	markup	1.1
	Initial turnover	20000
Manufacturer	markup	1.1
	Initial turnover	20000
User	Sentiment	[-1;1]
	cash	20000
	Utility coefficient	1.1
	Recycled cost coefficient	0.05
Recycler	markup	1.1
	Consumer goods lifetime	5

3.2 Results

Figure 2 shows the economic performance of the manufacturer firm for scenario (i) in blue, scenario (ii) in orange, scenario (iii) in yellow, scenario (iv) in violet, and scenario (v) in green. Scenario (i) is characterized by linear business model. Scenarios from (ii) to (v) are characterized by the possibility of buying a percentage from 20% to 80% of recycled material to produce goods.

The economic performance is evaluated as cumulated economic margin.

Figure 1 shows the cumulated economic margin of the manufacturer when the sentiment S of the user is negative, i.e., the user propensity is to buy brown goods. It is worth noting that the blue boxplot in Figure 1 corresponds to the linear supply chain, as the manufacturer produces only brown goods.

It is worth noting that the linear model, i.e., scenario (i), is the best strategy only when the user buys only brown goods. If the propensity of the user is to buy brown, green, and mixed goods, the best strategy for the manufacturer is to produce with a large fraction of recycled material.

Finally, the maximum cumulated economic margin is available when the user sentiment for brown goods is around 50%.

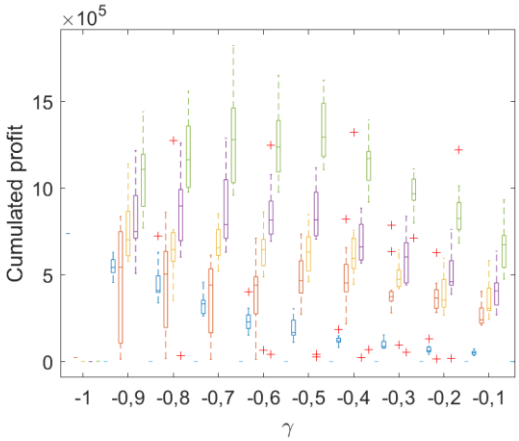

Figure 2: Distribution of: the economic performance of firm manufacturer for scenario (i) (linear business) in blue. Scenario from (ii) to (v) are characterized by the possibility of buying a percentage from 20% to 80% of recycled material to produce goods, colors orange, yellow, violet and green, respectively.

4 Discussion

The proposed model provides a lab setting in which it is possible to test the effect of firm strategy on firm performance. For example, the effect of the linear and circular supply chain on manufacturer's performance can be tested. Preliminary results show that the most convenient strategy for the manufacturer changes according to the user's sentiment with respect to the typology of products, i.e., linear vs. circular products.

In particular, the model suggests that the manufacturer only partially follows consumer sentiment, as it retains a large proportion of linear products. Even when consumer sentiment is low, such as in the cases of γ equals to -0.9 (i.e., 90% of linear products and 10% of circular products) or -0.8 (i.e., 80% of linear products and 20% of circular products), it is in the manufacturer's interest to move even slightly towards circular products. This notwithstanding, up to -0.5 sentiment (which means 50% of linear products and 50% of circular products), the manufacturer must incorporate more than proportionally recycled material into its products (see the green curve of cumulative economic margin).This evidence contributes to the existing studies investigating the trade-off in producer activities when the purchasing behaviour of the customer changes in front of linear or circular

products (Khitous et al., 2022). In this case, given that customers represent a key stakeholder in a circular economy transition, their perception about the value incorporated by circular products can allow producer companies to create and transfer these products into the market in a more effective way, and capture value from them over time in a more sustainable way.

In conclusion, the agent-based model developed here provides a tool that is very suitable for making a classic what-if analysis. In particular, it is a sort of computational laboratory where to perform experiments and find the most cost-efficient policy to improve the economic performance of firms. This allows for taking a further step towards understanding the outcomes tied to applying different investments in recycling materials. This simulator will be a very useful tool for managers because they will be able to simulate a chosen strategy before applying it in the real world.

For managers and policymakers, our research suggests the need to see the circular supply chain process with a comprehensive view, which conceives how the transition from a linear economy to a circular economy is a gradual pathway based not only on the pursuit of lower environmental impact, achieved through the implementation of circular economy principles in product design, but also on the economic sustainability of the manufacturer's business – along with that of the others supply chain companies. This observation aligns with the current scientific research dealing with circular economy as a paradoxical tension between economic growth and environmental benefit (Dagilienė & Varaniūtė, 2023).

Artificial Intelligence for a Sustainable Future: Unraveling its Impact on Circular Economy

Martina Percuoco, Anna Prisco, Irene Ricciardi, Vincenzo Dell'Anno
University of Naples Federico II, Napoli, Italia

Abstract

Artificial Intelligence (AI) is rapidly transforming organizational practices and enabling more sustainable business models, especially in the context of the circular economy. While its potential is widely acknowledged, empirical evidence on the factors that influence AI adoption and its actual impact on circular economy practices—particularly in the context of small and medium-sized enterprises (SMEs)—remains limited. This study investigates the drivers of AI adoption among innovative Italian SMEs and assesses how AI contributes to the implementation of circular economy strategies. Grounded in the Unified Theory of Acceptance and Use of Technology (UTAUT), the study explores the role of four key constructs—Performance Expectancy, Effort Expectancy, Social Influence, and Facilitating Conditions—in shaping AI adoption decisions. It also examines the extent to which AI adoption promotes circular economy practices. The empirical analysis is based on data collected through a structured online questionnaire distributed to 1,664 innovative SMEs across Italy, of which 52 provided complete responses. Data were analyzed using Partial Least Squares Structural Equation Modeling (PLS-SEM), a technique particularly suitable for testing complex models with small to moderate sample sizes. The findings partially validate the proposed theoretical framework. Performance Expectancy, Social Influence, and Facilitating Conditions are found to significantly influence AI adoption, while Effort Expectancy does not emerge as a significant predictor—suggesting that ease of use is less critical, possibly due to growing digital literacy or available technical support. Most importantly, the results show that AI adoption positively affects circular economy practices, supporting the view of AI as not only a technological asset but also a strategic enabler of sustainability. This study contributes to the literature by bridging the gap between technology adoption theories and circular economy research. It also offers practical insights for managers and policymakers aiming to promote digital and sustainable transitions. Emphasizing AI's strategic value, the study encourages investment in both technological infrastructure and supportive organizational environments to foster innovation and sustainable development.

Keywords: Artificial intelligence; UTAUT ; sustainability; circular economy practices; PLS-SEM.

Paper type: Academic Research Paper

1 Introduction

Environmental harm has become one of today's foremost global challenges, driven by the reckless exploitation of natural resources that critically undermines ecosystem stability. Addressing global warming, protecting the environment, and combating climate change demands the implementation of innovative strategies grounded in advanced technological expertise (Yucedag et al., 2018; Al-Ghussain, 2019).Within this framework, the circular economy stands out as a fundamental strategy to reduce environmental pressures, offering a regenerative system designed to limit resource waste and enhance their continuous utilization across interconnected production networks (Geissdoerfer et al., 2017). Unlike the conventional linear production model characterized by the "take, make, dispose" pattern, the circular economy encourages a more sustainable and efficient management of resources (Ness, 2008; Ghisellini et al., 2016; Sauvé et al., 2016). A crucial factor for implementing effective circular economy practices is digitalization (Cagno et al., 2021), which plays a key role in reshaping sustainable business models (Ellen MacArthur Foundation, 2019), facilitating the transition of manufacturing firms toward digital servitization and advanced automation (Kastalli and Van Looy, 2013; Frank et al., 2019; Liu et al., 2024). This process not only enhances operational efficiency but also opens new opportunities for value creation. Digital technologies in services—including Artificial Intelligence, Big Data Analytics, the Internet of Things, Machine Learning, Additive Manufacturing, Virtual Reality, Augmented Reality, and the Metaverse—contribute to improving systemic efficiency and actively support the achievement of the Sustainable Development Goals (SDGs), facilitating the shift toward a circular economy (Korhonen et al., 2018; Prieto-Sandoval et al., 2018; Xing and Liu, 2023). One of the most relevant aspects of digitalization is the ability to extract valuable knowledge from large volumes of data, supporting more informed decision-making, personalizing service offerings, optimizing service delivery processes, and enhancing the overall customer experience (Chauhan et al., 2022). Among the technologies of Industry 4.0, artificial intelligence (AI) plays a crucial role in improving resource management and promoting sustainable practices along the supply chain (Gupta et al., 2019).AI allows for the optimization of resource use, waste reduction, and the promotion of

sustainable behavior (Duan et al., 2019; Tutore et al., 2024), as well as enabling the creation of digital platforms that foster collaboration among companies engaged in sustainable practices (Tutore et al., 2024). AI also plays a significant role in enhancing circular economy practices (Montes-Pineda and Garrido-Yserte, 2024). The benefits of AI refers to its descriptive, diagnostic, predictive, and prescriptive capabilities (Madanaguli et al., 2024), which give multiple opportunities for circularity; in the development and adoption of circular business practices and operations, the design of circular products, components, and materials, including also the optimization of infrastructures to support circular resource flows (Ellen MacArthur Foundation, 2019). Moreover, AI can optimize recycling plant operations or encourage consumer engagement in adopting more circular behaviours (Tutore et al., 2024). Finally, the adoption of Artificial Intelligence can support the sustainable transformation of production processes by enabling the design of closed-loop systems that monitor and optimize resource consumption while minimizing waste generation. In this context, AI emerges as a strategic tool to reduce the environmental impact of industrial activities (Ronaghi, 2023). While acknowledging the already identified benefits, it becomes essential to delve deeper into both the positive effects and potential challenges arising from the use of AI-based technologies, analyzing their overall impact on environmental sustainability and circular economy practices (Al-Sharafi et al., 2023).Indeed, the literature reveals a lack of consensus regarding the role of Artificial Intelligence as either a strategic driver or an integral component in addressing environmental sustainability challenges (Kopka and Grashof, 2022). According to Vinuesa et al. (2020), AI has the potential to positively influence 134 targets (79%) across all Sustainable Development Goals (SDGs); however, 59 targets (35%) may be negatively affected by its development, highlighting the dual nature of AI's impact across the SDG framework. Overall, although some studies have examined the potential effects of AI on resource consumption, a systematic empirical analysis is still lacking—particularly concerning its influence on circular economy performance (Khakurel et al., 2018). Furthermore, the specific implications of AI for sustainable business practices, especially within small and medium-sized enterprises (SMEs), remain underexplored in the academic debate. As a result, significant knowledge gaps persist, particularly with regard to the actual effectiveness and tangible impact of AI adoption on organizational sustainability performance. In this perspective, the primary aim of this research is to investigate the factors influencing the adoption of AI by innovative SMEs, while also evaluating the implications of these technologies on circular economy. To achieve this goal, the research employs the theoretical framework of UTAUT (Unified Theory of Acceptance and Use of Technology). The structure of the paper is as follows. Section 2 presents the theoretical background and research hypotheses. Section 3 outlines the methodology, while Section 4 illustrates the results. Finally, Section 5 discusses the main conclusions drawn from the study.

2 Theoretical background and research model

The Unified Theory of Acceptance and Use of Technology (UTAUT), developed by Venkatesh et al. (2003), identifies four key constructs that influence users' behavioral intentions and actual technology usage: Performance Expectancy (PE), Effort Expectancy (EE), Social Influence (SI), and Facilitating Conditions (FC). Performance Expectancy refers to the perceived benefits associated with the use of a technology—namely, the extent to which an individual believes that adopting a particular system will enhance their personal or professional performance (Davis, 1989; Venkatesh and Davis, 2000; Venkatesh et al., 2003). In the context of Artificial Intelligence (AI), PE reflects how individuals perceive AI as a tool to strengthen their capabilities. Several studies confirm a positive relationship between performance expectancy and technology adoption (Pillai et al., 2024), with specific evidence supporting this link in the AI domain (García Blanes Sebastián et al., 2022; Pillai et al., 2024; Salifu et al., 2024).

Based on this evidence, we propose the following hypothesis:

H1. Performance Expectancy positively and significantly impacts the adoption of Artificial Intelligence.

Effort Expectancy (EE) concerns the perceived ease of use of a technology—that is, how intuitive and accessible users find the system to be (Davis et al., 1989; Thompson et al., 1991; Yoon et al., 2020). It measures the degree of effort, both cognitive and physical, that individuals believe is required to use a technology effectively (Acquah et al., 2024). In relation to AI, EE captures how simple and user-friendly people consider AI tools to be. Several studies have shown a positive relationship between EE and technology adoption (Al-Adwan et al., 2024; Du and Liang, 2024). For example, Chatterjee et al. (2023) found that employees' perceptions of ease of use significantly influenced their adoption of AI-driven CRM systems. Accordingly, we formulate the following hypothesis:

H2. Effort Expectancy positively and significantly impacts the adoption of Artificial Intelligence.

Social Influence (SI) reflects how individuals perceive that important people around them—such as peers, colleagues, or family members—believe they should use a specific technology (Venkatesh et al., 2003). This

construct captures the role of social norms and identification processes in shaping behavioral intentions. Social influence can lead individuals to conform to group expectations, internalize shared norms, and model the behavior of influential others. Prior research highlights the impact of close individuals' social environments—thoughts, emotions, and behaviors—on technology adoption decisions (Irani et al., 2009; Venkatesh and Brown, 2001). In light of these findings, we hypothesize that:

H3. Social Influence positively and significantly impacts the adoption of Artificial Intelligence.

Facilitating Conditions (FC) refer to users' perceptions of the resources and support available to enable the use of technology, such as infrastructure, training, and technical assistance (Oliveira et al., 2014). Studies indicate that the availability of tools like internet connectivity, software integration, and organizational support plays a critical role in the successful adoption and continued usage of a technology (Lee et al., 2013). In the context of AI, FC can determine whether individuals feel empowered to incorporate AI into their workflows. Therefore, we propose the following hypothesis:

H4. Facilitating Conditions positively and significantly impact the adoption of Artificial Intelligence.

The integration of Artificial Intelligence has proven to be a key driver in enhancing organizational sustainability (Gupta et al., 2019) and in supporting companies' engagement in circular economy initiatives (Montes-Pineda and Garrido-Yserte, 2024). It also strengthens firms' capabilities across various analytical dimensions, including descriptive, diagnostic, predictive, and prescriptive functions (Madanaguli et al., 2024). These advancements are largely due to AI's ability to process and make sense of vast amounts of data generated throughout the production lifecycle (Ramadoss et al., 2018). Ghoreishi and Happonen (2020) identify three main ways in which AI can support circular practices: by improving the selection and disassembly processes, enabling the remanufacturing of components, and enhancing materials recycling. Additionally, AI can significantly optimize reverse logistics systems, boosting their efficiency and traceability (Schluter et al., 2021).

Based on these considerations, we propose the following hypothesis:

H5. AI adoption positively influences circular economy practices.

Figure 1 below presents the conceptual framework developed for this study.

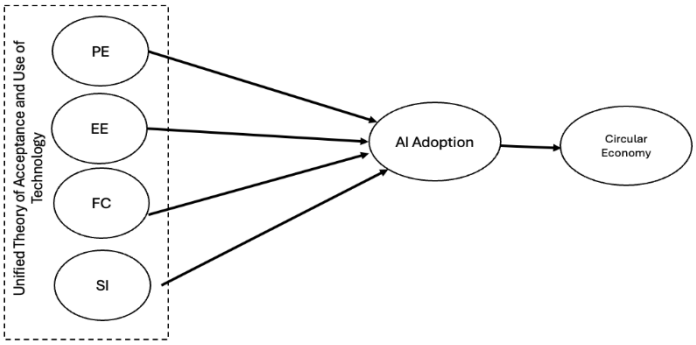

Figure 1 – The proposed model

3 Methodology

3.1 Measurement of constructs and construct design

To collect data, we will use a quantitative research design using a survey questionnaire method based on pre-validated scales (Zahid et al., 2022; Ali et al.,2022). The initial version was prepared in English, and subsequently translated into Italian through a rigorous translation and back-translation process, following established methodological guidelines (Saunders et al., 2009). About the constructs, 5 UTAUT constructs were employed, adapted from Venkatesh et al. (2003) and Chen et al., (2021): 4 items for PE, 4 items for EE, 4 items for SI, 3 items for FC, and 3 items for ADP. For CE 3 items adapted from Baudier et al. (2020) were used.The questionnaire is structured into three distinct sections designed to enhance clarity and ease of completion for participants. Section (A) aims to minimize social desirability bias by clearly outlining the study's objectives, explaining the data collection procedures, and assuring complete confidentiality and anonymity to respondents (Chidlow et al., 2015). Section (B) gathers detailed organizational information and demographic data from participants, including geographic region, industry sector, gender, age, technological experience, and organizational role. Lastly, section (C) comprises questions related to the theoretical constructs of the UTAUT model and dimensions concerning the circular economy, thereby fully capturing the dynamics explored in the

study. The constructs are measured using a five-point Likert scale ranging from "1 – strongly disagree" to "5 – strongly agree" (Luck and Rubin, 1987; Premkumar and Ramamurthy, 1995).

3.2 Data collection and sample

The research aims to understand the factors influencing the adoption of artificial intelligence (AI) and the resulting impact on circular economy practices. To this end, the questionnaire was specifically targeted at innovative Italian SMEs, introduced by Legislative Decree No. 3 of 2015 (DL 3/2015), as these enterprises are particularly suitable for this study. Innovative SMEs were selected primarily due to their inherent propensity for innovation, defined according to specific regulatory criteria. According to Legislative Decree 3/2015 (Article 4) and the European Commission Recommendation of May 6, 2003 (2003/361/EC), these firms must meet at least two of the following criteria: significant expenditure on research and development, employment of highly qualified personnel, and ownership or exclusive licenses of industrial patents relevant to their business activity. These attributes ensure that the companies possess the organizational structure and capabilities necessary to effectively integrate advanced technologies such as artificial intelligence. Data collection was conducted using an online questionnaire distributed via email to the aforementioned companies. The questionnaire was distributed across various Italian regions to gather representative data by leveraging the cultural and behavioral diversity of innovative SMEs nationwide. Before commencing data collection, necessary authorization was obtained from the institutions involved in the research. To ensure the quality and accuracy of the questionnaire, four academic experts conducted a detailed review of the questions, providing valuable feedback to enhance clarity and comprehension. Following this stage, actual data collection began through online platforms, aiming to reach as many participants as possible and ensuring extensive and diverse geographic coverage. For the analysis, out of 2,457 registered innovative SMEs, we retrieved the email addresses of 1,664 companies, to which the questionnaire was submitted. From these, we received a total of 52 completed responses.Among the respondents, the average age is 45 years, 70% are men and 30% are women. The average work experience is 17 years, while the average experience with artificial intelligence is 3 years.In terms of geographic location, most of the responding companies are based in Northern Italy (53%), followed by Southern Italy (26%) and Central Italy (19%).The companies involved have an average of 21 employees. Moreover, most of them have been operating for more than 10 years, with an average company age of 16 years.

3.3 Data analysis procedure

Then, to test our model, we will use the Partial Least Squares method for Structural Equation Modeling,(Hair et al., 2023). This technique stands out from other multivariate analyses due to its ability to simultaneously examine multiple constructs, making it particularly useful for understanding complex phenomena. Moreover, the absence of rigid assumptions regarding the distribution of items and latent variables represents a significant advantage, especially in contexts like ours, characterized by moderately sized samples (Hair et al., 2023).

4 Results

4.1 Measurement model

The evaluation of a measurement model composed solely of reflective indicators in a PLS-SEM framework is conducted by verifying that the data meet four key criteria: convergent validity, internal consistency, reliability, and discriminant validity.

According to Hair et al. (2023), outer loadings should exceed 0.60. Based on this threshold, we excluded the indicators FC2, PE2, and SI2, and subsequently re-estimated the model. To assess internal consistency and reliability, we used Composite Reliability (CR) and Cronbach's Alpha. Specifically, both Cronbach's Alpha and Composite Reliability values should be greater than 0.70 for each construct (Hair et al., 2023). The results presented in Table 1 confirm that the criteria for convergent validity, internal consistency, and reliability are fully met. Regarding discriminant validity, the Fornell-Larcker criterion was applied. This approach verifies that the square root of the Average Variance Extracted (AVE) for each construct is greater than its correlations with all other constructs, as shown in the off-diagonal elements of the correlation matrix. The results presented in Table 2 confirm that the model satisfies the discriminant validity requirement.

Table 1: Convergent validity, internal consistency and reliability

Costructs	Items	Outer loadings	Cronbach's alpha	Composite reliability (rho_a)	Composite reliability (rho_c)	Average variance extracted (AVE)	R square
AI Adoption	ADP1	0,970	0,946	0,948	0,966	0,904	0,805
	ADP2	0,961					
	ADP3	0,920					
CE practices	CE1:	0,883	0,917	0,959	0,947	0,855	0,142
	CE2:	0,935					
	CE3:	0,955					
Effort expectancy	EE1	0,825	0,834	0,853	0,888	0,666	
	EE2	0,751					
	EE3	0,862					
	EE4	0,822					
Facilitating conditions	FC1	0,881	0,749	0,756	0,888	0,799	
	FC3	0,907					
Performance expectancy	PE1	0,955	0,869	0,929	0,919	0,793	
	PE3	0,933					
	PE4	0,772					
Social Influence	SI1	0,936	0,940	0,947	0,962	0,893	
	SI3	0,952					
	SI4	0,946					

Table 2 : Discriminant validity

	ADP	CE	EE	FC	PE	SI
ADP	0,951					
CE	0,377	0,925				
EE	0,426	0,339	0,816			
FC	0,812	0,304	0,461	0,894		
PE	0,619	0,578	0,544	0,401	0,890	
SI	0,721	0,281	0,412	0,565	0,588	0,945

4.2 Structural model

The quality of the Structural model is checked using the R^2 of the endogenous constructs (see Table 1). After this first test, we use a bootstrap procedure with 5.000 resamples (Hair et al., 2023) to test our hypotheses. The results of this procedure are reported in Table 3. All the hypotheses are supported except for H2.

Table 3: Hypotheses testing

	Original sample (O)	Sample mean (M)	Standard deviation (STDEV)	T statistics (|O/STDEV|)	P values
ADP -> CE	0,377	0,383	0,128	2,952	0,003
EE -> ADP	-0,115	-0,109	0,073	1,573	0,116
FC -> ADP	0,604	0,615	0,104	5,791	0,000
PE -> ADP	0,288	0,269	0,112	2,579	0,010
SI -> ADP	0,257	0,262	0,096	2,688	0,007

5 Conclusions

The findings of this research partially confirm the proposed theoretical model, highlighting key factors influencing the adoption of Artificial Intelligence (AI) and its impact on circular economy practices. Specifically, Hypothesis H1 was supported, indicating that Performance Expectancy positively and significantly affects AI adoption. This suggests that perceived improvements in operational performance are a critical driver for organizations. Similarly, Hypotheses H3 and H4 were confirmed, underscoring the roles of Social Influence and Facilitating Conditions in fostering AI adoption. Conversely, Hypothesis H2 regarding Effort Expectancy was not supported, implying that ease of use is not a decisive factor in the analyzed context—potentially due to increased familiarity with digital tools or adequate technical support. Finally, Hypothesis H5 was validated, demonstrating that AI adoption positively contributes to the implementation of circular economy practices. This reinforces the view of AI as not only an efficiency tool but also a strategic enabler of more sustainable business model. Overall, the study enriches the literature on technology adoption with a sustainability perspective, providing valuable insights for both business leaders and policymakers promoting advanced, sustainability-driven technologies. This study contributes to the literature on AI adoption and its role in promoting the circular economy. The findings partially validate the UTAUT model, revealing that not all theoretical constructs have the same influence in the context of AI. In particular, the lack of significance for Effort Expectancy highlights the need to reassess traditional models in light of rapidly evolving technologies like AI. Additionally, the empirical evidence linking AI adoption to circular economy practices represents a meaningful theoretical extension. It positions AI not only as a technological tool but also as a strategic enabler of environmental sustainability. The research helps bridge the gap between technology adoption studies and circular economy literature, offering a foundation for future interdisciplinary investigations.

From a managerial perspective, the results offer practical insights for companies seeking to pursue digital transformation and achieve a sustainable transition. First, the perception of performance benefits emerges as a key driver for AI adoption. Managers should, therefore emphasize AI's positive impact on efficiency, quality, and competitiveness during change management processes. Second, the effects of Social Influence and facilitating conditions highlight the importance of a supportive organizational environment. This calls for investments not only in technology but also in training, internal communication, and the development of internal champions to lead innovation. Finally, the confirmed link between AI and circular economy practices offers business leaders an additional incentive for adoption—not only for economic gains but also to position their organizations as sustainability-driven enterprises.

6 Ethics declaration

We declare that ethical clearance for the research referred to in this paper was not required.

7 AI declaration

An AI-based tool was used to improve the English language and writing style of the paper.

Skilling and Upskilling within Port Authority Management: A Strategic Approach to Industry 5.0 Requirements

Mariarosalba Angrisani, Marcello Risitano, Marco Ferretti
Parthenope University of Naples, Naples, Italy

Abstract

The transition toward Industry 5.0 has brought forth a new paradigm within maritime logistics and port governance, where the focus shifts beyond automation to embrace resilience, sustainability, and above all, human-centric innovation. In this context, Port Authorities, particularly those operating under the Landlord model, face unprecedented demands to align infrastructural and technological transformation with comprehensive workforce development strategies. While infrastructure and digital systems have been historically prioritised, the capabilities and adaptability of the human workforce—especially blue-collar maritime workers—have received comparatively less strategic attention.

This study investigates the alignment of workforce development with Industry 5.0 principles, focusing on the evolving competencies, training gaps, and strategic responses of Port Authorities operating under the Landlord model. Framed by the Resource-Based View and the Dynamic Capabilities Theory, the research explores how human capital—particularly blue workers—functions as a core asset for competitive advantage, technological readiness, and organisational resilience.

Employing a qualitative methodology, the study draws on twelve semi-structured interviews with executives, HR managers, and operational staff from Italy's maritime sector. Thematic content analysis revealed three core patterns: a widespread digital skills gap among blue workers, the fragmented nature of training initiatives across port authorities, and a misalignment between strategic HR objectives and operational governance.

Findings suggest that for Port Authorities to meet the expectations of Industry 5.0, workforce development must be fully integrated into port governance frameworks. Human-centric innovation, environmental sustainability, and digital transformation are not achievable without a skilled and empowered workforce.

The performed analysis additionally underscores the need for cultural and institutional shifts that reframe blue workers as, active agents of technological co-creation and environmental stewardship.

Ultimately, the study advocates for the establishment of structured, collaborative skilling frameworks, potentially through regional Port Skills Councils or transnational maritime academies, to harmonise training standards and close capability gaps. Such interventions would not only strengthen organisational performance but also affirm the role of Port Authorities as key enablers of a resilient and inclusive maritime ecosystem in line with Industry 5.0 values.

Keywords: Industry 5.0, maritime sector, blue workers, port authority governance, competencies

Paper type: Research Paper

1 Introduction

Industry 5.0 introduces a specific view wherein technology and humans collaborate rather than compete. As such, the need to upskill and reskill workers in areas such as digital literacy, sustainability management, and adaptive logistics practices has become a critical issue. Port Authorities must evolve beyond their traditional role as physical asset managers to become facilitators of human capital innovation and learning ecosystems. This transformation aligns with the foundational assumptions of the Resource-Based View (Barney, 1991), which frames human capital as a valuable, rare, inimitable, and non-substitutable (VRIN) resource, and the Dynamic Capabilities Theory (Teece, Pisano, & Shuen, 1997), which emphasises an organisation's ability to integrate, build, and reconfigure internal and external competencies in response to a rapidly changing environment.

As ports serve as critical nodes within global value chains, ensuring the strategic alignment of workforce skills with technological and ecological advancements is not only a matter of operational efficiency but also of long-term resilience and competitiveness.

The transformation ushered in by Industry 5.0 has introduced a human-centric, resilient, and sustainable paradigm in the maritime sector, positioning skilling and upskilling as strategic imperatives within Port Authority management. This study investigates the alignment of workforce development with Industry 5.0 principles, focusing on the evolving competencies, training gaps, and strategic responses of Port Authorities operating under the Landlord model. Framed by the Resource-Based View (Barney, 1991) and the Dynamic Capabilities Theory (Teece et al., 1997), the research explores how human capital—particularly blue workers—functions as a core asset for competitive advantage, technological readiness, and organisational resilience.

Employing a qualitative methodology, the study draws on twelve semi-structured interviews with executives, HR managers, and operational staff from Italy's maritime sector. Thematic content analysis revealed three core

patterns: a widespread digital skills gap among blue workers, the fragmented nature of training initiatives across port authorities, and a misalignment between strategic HR objectives and operational governance. While many port stakeholders acknowledged the critical importance of digital and sustainable competencies, their efforts were largely reactive, underfunded, and not embedded in long-term strategy. Nonetheless, innovative cases such as the Port of Genoa demonstrated how strategic investments in training ecosystems and learning technologies can enhance digital maturity and institutional adaptability.

Findings suggest that for Port Authorities to meet the expectations of Industry 5.0, workforce development must be fully integrated into port governance frameworks. Human-centric innovation, environmental sustainability, and digital transformation are not achievable without a skilled and empowered workforce. This research underscores the need for cultural and institutional shifts that reframe blue workers not as passive recipients of automation but as active agents of technological co-creation and environmental stewardship.

Ultimately, the study advocates for the establishment of structured, collaborative skilling frameworks, potentially through regional Port Skills Councils or transnational maritime academies, to harmonise training standards and close capability gaps. Such interventions would not only strengthen organisational performance but also affirm the role of Port Authorities as key enablers of a resilient and inclusive maritime ecosystem in line with Industry 5.0 values.

2 Literature Review

The conceptual basis of Industry 5.0, as outlined by Grabowska et al. (2022), promotes a socio-technical system where humans and machines collaborate to create value in ways that are inclusive, sustainable, and resilient. This philosophy builds upon the automation principles of Industry 4.0 but shifts the emphasis towards human-centric design and ethical innovation. Within the maritime sector, this transition has significant implications, given that ports are traditionally conservative and infrastructure-driven institutions. Digitalisation, artificial intelligence, and cyber-physical systems are transforming port operations, yet many port governance models have not concurrently updated their human resource strategies.

A growing body of work recognises the importance of strategic skilling in maritime operations. For instance, Acciaro et al. (2020) argue that Port Authorities play a pivotal role in enabling digital transformation through human resource innovation. Similarly, Ghobakhloo et al. (2022) demonstrate that the success of digitalisation efforts in industrial environments is closely linked to an organisation's dynamic learning capabilities and adaptability, both of which depend on the continuous development of human skills.

Within the context of the Landlord port governance model, Port Authorities act as facilitators of public-private collaboration (Verhoeven, 2010), although they often lack the mandate or mechanisms to enforce skilling policies across stakeholder organisations. Poulsen and Sornn-Friese (2015) note that such decentralised governance structures, while flexible, tend to lead to fragmented training efforts and inconsistent standards.

In line with the Resource-Based View, human capital can become a source of sustained competitive advantage if nurtured strategically (Barney, 1991). Moreover, the Dynamic Capabilities Theory, as articulated by Teece et al. (1997), emphasises that organisational resilience hinges on learning, sensing, and transformation capabilities. When applied to ports, these theories suggest that human capital development is not merely a support function but a central axis of innovation and adaptability.

2.1 Industry 5.0 and Maritime Sector Transformation

The notion of Industry 5.0 represents an important evolution from the previous industrial paradigm. While Industry 4.0 emphasized automation, cyber-physical systems, and data exchange in manufacturing and logistics, Industry 5.0 pivots toward human-centricity, resilience, and sustainability as core organizing principles (European Commission, 2021). This conceptual shift foregrounds the value of integrating human creativity and intuition with technological advancement. Industry 5.0 does not seek to displace human labor with automation but rather to facilitate collaborative intelligence—where machines augment human capabilities rather than replace them (Nahavandi, 2019).

In the context of the maritime and port sectors, the shift from Industry 4.0 to 5.0 is especially significant. Ports have long been focal points for industrial and logistical transformation, playing central roles in the diffusion of automation technologies such as container cranes, terminal operating systems, and digital tracking interfaces. Under Industry 4.0, smart ports became increasingly data-driven, leveraging IoT (Internet of Things), digital twins, and AI to optimize operations and minimize downtime (Acciaro et al., 2020). However, this automation often overlooked the role of human adaptability and knowledge, creating skill gaps and in some cases alienating port labor forces from decision-making processes.

Industry 5.0 reorients this trajectory by stressing the synergy between human intelligence and digital tools. In ports, this transformation entails redefining work processes so that digital systems (such as predictive maintenance algorithms or AI-based port scheduling software) do not operate in isolation but are interpreted and managed by skilled human operators. This demands new training paradigms focused not only on technical skills but also on ethical reasoning, collaborative decision-making, and sustainable practices.

This transformation is gradually taking root in major global ports. For example, the Port of Rotterdam has launched human-in-the-loop digitalisation initiatives where operators work alongside AI systems for predictive maintenance and berth optimization. Similarly, the Port of Singapore emphasizes augmented intelligence, whereby AI tools are co-designed with frontline workers to enhance decision accuracy without eliminating human judgment (Ng & Liu, 2020). The Port of Genoa, a key Mediterranean node, is also investing in hybrid governance models where labor unions and digital firms co-create training content—a development aligned with the principles of Industry 5.0.

2.2 Skilling and Upskilling: Definitions and Strategic Importance

In the maritime sector, skilling refers to the foundational training provided to new entrants, reskilling denotes equipping workers with new competencies to shift to different roles, and upskilling involves deepening or expanding current knowledge to meet emerging technological or regulatory demands (World Economic Forum, 2020). These concepts are increasingly critical in an environment where port digitalisation is accelerating but institutional mechanisms for workforce adaptation are lagging.

The strategic importance of these interventions cannot be overstated. Ports operate as complex socio-technical systems requiring real-time coordination among human operators, digital infrastructures, and physical logistics networks. As ports transition toward green shipping, AI-driven logistics, and blockchain-enabled customs procedures, there is an urgent need to close the skills gap between legacy practices and digital innovation.

Case studies provide compelling evidence of this transformation. The Port of Rotterdam, for instance, has invested in a Digital Twin environment of the entire port area, enabling real-time data simulations for berth planning and traffic forecasting. However, despite technological advancement, reports show that many employees lack the training to interpret or act on these insights effectively (Chhetri et al., 2021). In Singapore, the Maritime and Port Authority has launched the "Sea Transport Industry Transformation Map," which explicitly identifies upskilling as a priority for enabling digital port services. Meanwhile, Genoa faces challenges in bridging generational knowledge divides as older workers often lack formal training in digital tools, whereas younger recruits may be unfamiliar with core operational workflows.

Collectively, these examples underline a growing disconnect between technological ambition and human capital readiness. Without deliberate skilling strategies, ports risk reinforcing inequalities and inefficiencies, ultimately undermining the very objectives of digitalisation.

2.3 The Landlord Port Governance Model

The Landlord Port Governance Model—dominant across Europe and Asia—positions Port Authorities primarily as facilitators and coordinators of infrastructure development, while operational services are delegated to private terminal operators and logistics firms. As described by Verhoeven (2010), this model seeks to harmonize public objectives (e.g., sustainability, regional development) with private efficiency and investment capacity.

This hybrid arrangement creates complex governance dynamics, especially concerning human capital development. Port Authorities, being asset owners rather than employers of operational labor, often lack direct control over workforce training and development. Instead, these responsibilities fall to private operators who may prioritize short-term efficiency over long-term skill-building.

The result is often fragmented skilling ecosystems, where training initiatives are developed in isolation without systemic coordination. In ports like Genoa, for example, digitalisation projects funded by EU regional innovation schemes have failed to include parallel investments in workforce education, leading to implementation delays and operational friction (Monios & Wilmsmeier, 2021). Additionally, the Landlord model's reliance on contractual governance inhibits agile responses to evolving skill demands, as job descriptions, labor roles, and workflows are rigidly defined by concessions and procurement processes.

Thus, the model presents both institutional constraints and opportunities. On one hand, it limits the Port Authority's ability to directly intervene in workforce strategy. On the other hand, it provides a platform for public-private collaboration, where strategic skilling alliances can be formed—if governance structures prioritize human capital as a strategic asset.

2.4 Theoretical Foundations

Two key theoretical frameworks underpin the analysis of human capital in digitalised port governance: the Resource-Based View (RBV) and the Dynamic Capabilities Theory (DCT).

According to Barney (1991), the RBV posits that sustainable competitive advantage arises from resources that are valuable, rare, inimitable, and non-substitutable (VRIN). In this framework, skilled human capital, particularly workers who combine maritime operational knowledge with digital and sustainability fluency, becomes a strategic resource. These individuals enable organizational learning, improve decision-making in uncertain environments, and foster innovation. Yet, most ports still undervalue human capital, treating labor as a cost rather than a strategic input.

By contrast, port authorities that recognize the VRIN nature of skilled workers—such as those in Rotterdam and Singapore—invest in long-term human capital development through partnerships with universities, vocational institutes, and technology firms. These ecosystems generate not just workforce readiness but also knowledge spillovers and collaborative innovation—key drivers of port competitiveness in an Industry 5.0 context.

The Dynamic Capabilities Theory, advanced by Teece et al. (1997) and later applied to digital transformation by scholars like Ghobakhloo et al. (2022), provides another interpretive lens. It emphasizes the capacity of organizations to sense, seize, and reconfigure internal and external competencies to address rapidly changing environments. In maritime governance, this translates to an ability to recognize emerging skill needs, mobilize learning resources, and realign governance frameworks accordingly.

Port Authorities that internalize DCT logic treat learning and reconfiguration as ongoing processes. For example, the Port of Singapore's transformation programs are designed as iterative learning loops, wherein feedback from workforce performance informs successive rounds of curriculum redesign and job rotation. Genoa has initiated similar programs on a smaller scale, with micro-credentialing systems allowing blue-collar workers to gradually build digital proficiency.

Together, RBV and DCT underscore the strategic and adaptive value of human capital. They provide theoretical justification for viewing workforce development not merely as a social obligation, but as a core governance challenge that directly affects operational agility and institutional resilience.

3 Methodology

This study adopts a qualitative research design grounded in interpretivist epistemology to explore how Port Authorities and maritime stakeholders perceive and address skilling and upskilling challenges. The research seeks to understand the lived experiences, attitudes, and institutional strategies related to workforce development in the context of digital transformation and sustainable logistics.

Data are collected through six semi-structured interviews involving one human resources manager from a prominent maritime firm, and 5 maritime workers employed as ship crew.

The diversity of participants allowed for a multifaceted perspective on how skills gaps are perceived and addressed at different organisational levels. All interviews were conducted online, recorded with consent, and transcribed verbatim.

The transcripts were then subjected to thematic content analysis following the guidelines of Braun and Clarke (2006), allowing for the emergence of inductively derived themes reflective of participant experiences and institutional practices.

4 Findings

One of the central findings was the widespread recognition of a skills gap in both digital competencies and environmental management. Respondents pointed to insufficient familiarity with technologies such as Internet of Things (IoT), digital twins, and data analytics among both administrative and operational staff. This deficit was particularly pronounced among blue workers, who reported limited access to structured training programs. Despite this, there was also evidence of high adaptability and willingness to learn among these workers when provided with hands-on learning and peer-supported education.

Another significant theme was the absence of an institutionalised framework for workforce development. Port Authorities across Italy demonstrated a fragmented approach to skilling, with initiatives often tied to EU-funded projects or one-off collaborations with academic institutions. These efforts lacked continuity and were seldom embedded within broader strategic planning processes.

Interestingly, a disconnect emerged between the strategic vision articulated by HR managers—who often emphasised sustainability, digital HRM, and corporate learning—and the operational focus of port governance

structures, which remained centred on infrastructure maintenance and logistical throughput. This disconnect often led to underinvestment in human capital, even when there was clear recognition of its value.

However, the study also revealed promising practices, such as in the Port of Genoa, where strategic investments in dynamic learning systems and digital training labs have led to higher levels of digital maturity and stakeholder engagement. These cases align closely with the principles of the Dynamic Capabilities Theory, suggesting that ports which internalise continuous learning as a core function are better positioned to thrive in the Industry 5.0 era.

5 Discussion

The research findings support the thesis that skilling and upskilling in port governance represent a strategic requirement. By failing to embed workforce development into long-term planning, many Port Authorities are missing a vital opportunity to align with the principles of Industry 5.0 and the broader digital transformation agenda. The human-centric ethos of Industry 5.0 demands that blue workers are not treated as passive recipients of technology but as active contributors to innovation.

From the lens of the Resource-Based View, it is clear that human capital, particularly when it embodies digital and sustainable competencies, constitutes a valuable and inimitable asset. Yet, this potential remains underleveraged due to outdated governance paradigms. Likewise, from a dynamic capabilities perspective, those ports that succeed in reconfiguring their training ecosystems, sensing environmental changes, and building institutional knowledge loops demonstrate superior adaptability.

The evidence suggests a need for cultural transformation in how human capital is viewed. Port Authorities must shift from being custodians of infrastructure to orchestrators of knowledge-based ecosystems. This transition will require not only strategic vision but also institutional reforms that prioritise workforce empowerment and capacity-building at all levels.

6 Conclusion

As shown by the literature review performed throughout the present analysis, Port Authority Management in the Industry 5.0 era is undergoing profound transformations due to digitalisation, sustainability mandates, and increasing stakeholder complexity. The skilling and upskilling of maritime workers—especially blue workers operating under the Landlord port governance model—emerges as a strategic lever to ensure competitiveness, human-centric innovation, and adaptability.

Theoretical frameworks such as the Resource-Based View (RBV) and Dynamic Capabilities Theory (DCT) provide robust conceptual anchors for understanding workforce development as a strategic asset and a driver of transformation. Recent research underscores the need for Port Authorities to transition from infrastructure facilitators to orchestrators of digitally capable, resilient ecosystems by investing in human capital development aligned with Industry 5.0 values.

Hence, Port Authorities must adopt a more strategic and systemic approach to workforce development that aligns with the principles of Industry 5.0. This entails institutionalising training programs, fostering cross-sector collaboration in curriculum design, and empowering blue workers through participatory learning models. Establishing national or regional Port Skills Councils, aligned with the European Union's Blue Economy strategy, could serve as a platform for standardising competencies and fostering innovation. Moreover, investment in digital infrastructure must be matched by investment in people, recognising that ports of the future will be defined not only by their cranes and cargo systems but by the intelligence and adaptability of their workforce.

The Bridge Maker's Role in Industry 5.0 Ecosystems: Driving Collaboration and Innovation for Sustainable Outcomes

Kristaps Banga, Elina Gaile - Sarkane
Riga Technical University Latvia

Abstract

The transition to Industry 5.0 marks a paradigm shift towards innovation ecosystems that prioritize human-centricity, sustainability, and resilience. This paper advances the understanding of innovation ecosystem governance by introducing the concept of the "Bridge Maker" - a strategic intermediary that plays a pivotal role in aligning diverse stakeholders, fostering collaborative governance, and embedding Industry 5.0 values systemically across ecosystems. Grounded in insights from Complex Adaptive Systems (CAS) theory, Open Innovation (OI), and recent developments in ecosystem orchestration and governance, the Bridge Maker (BM) is positioned as a crucial enabler of ecosystem adaptability and success.

Through a conceptual analysis, this paper addresses two primary research questions: (*1) How do Bridge Makers align stakeholders to drive collaboration and innovation within human-centered Industry 5.0 ecosystems? (2) What role do Bridge Makers play in embedding sustainability and human-centric values as systemic ecosystem features?* Drawing from recent theoretical advancements (Chesbrough, 2003; Holgersson et al., 2022; Tedesco, 2019) and extending the Adaptive Open Innovation Systems (AOIS) framework, the study proposes a model highlighting the competencies, behaviors, and governance mechanisms required for effective Bridge Making.

The findings suggest that BM operates through trust-building, sense-making, strategic foresight, and adaptive orchestration practices that promote long-term ecosystem resilience. In doing so, they bridge institutional gaps, overcome organizational inertia, and create the conditions necessary for sustainable innovation trajectories. The paper offers practical implications for innovation managers, policymakers, and educators seeking to operationalize Industry 5.0 principles within complex multi-actor environments.

Finally, the study calls for further empirical research to explore the dynamic practices of BM across various industry contexts and to develop actionable guidelines for their identification, training, and support within innovation ecosystems.

Keywords: Bridge maker, collaboration, ecosystem governance, Industry 5.0, innovation

Paper type: Academic Research Paper

1 Introduction

Contemporary transformations in industrial paradigms reveal an increasing urgency to rethink the structures and governance mechanisms that underlie innovation ecosystems towards sustainability and implementation of SDG. The transition toward Industry 5.0 reflects a growing consensus that technological innovation, while essential, must be recalibrated to respond to broader societal needs, including human well-being, environmental stewardship, and systemic resilience (Chesbrough, 2003; Holgersson et al., 2022). This evolution challenges traditional conceptions of technological progress, requiring a synthesis of digital prowess and normative societal goals. Yet, within this shifting landscape, the management of innovation ecosystems has struggled to keep pace, revealing persistent gaps between technological capability and socio-environmental responsibility.

Innovation ecosystems have evolved into highly intricate, decentralized constellations of actors, each contributing distinct capabilities, visions, and agendas. Firms, academic institutions, startups, public agencies, and civic organizations interact in increasingly fluid and dynamic configurations. While such ecosystems have been heralded for their capacity to spur innovation through open and distributed knowledge exchanges, their operational realities are often marked by coordination failures, trust deficits, and divergent strategic orientations (West and Bogers, 2014). The innate complexity of these systems, compounded by the characteristics of Complex Adaptive Systems (CAS)—nonlinear feedback loops, emergent order, and decentralized adaptability—poses profound challenges for ecosystem governance (Tedesco and Serrano, 2019). Classical governance models, which assume stable roles, predictable exchanges, and hierarchical control, are ill-suited to the realities of contemporary innovation ecosystems.

Emerging scholarship increasingly emphasizes that sustainable success in innovation ecosystems hinges not solely on technological excellence but on the ability to cultivate new forms of relational governance and strategic alignment across heterogeneous actors (Majchrzak et al., 2023). Such governance must be capable of dynamically orchestrating contributions, resolving tensions, and enabling collective sense-making under conditions of uncertainty. However, most current practices lack the mechanisms to bridge the micro-level activities of individual organizations with the macro-level goals of ecosystem sustainability and human-centric

impact. The absence of actors or mechanisms dedicated to creating strategic and normative cohesion among diverse stakeholders has been a critical blind spot in ecosystem development strategies.

In response to these challenges, the present study advances the concept of the BM as an indispensable strategic intermediary within human-centered innovation ecosystems. Distinct from traditional brokers or facilitators, the BM is conceptualized as an actor capable of cultivating emergent trust architectures, catalyzing strategic convergence across competing logics, and embedding normative aspirations such as sustainability and resilience into the operational logic of the ecosystem itself. Rather than simply connecting actors or facilitating transactions, BM are envisioned as systemic enablers who foster the adaptive capabilities necessary for ecosystems to thrive under the demands of Industry 5.0. Their role is dynamic, context-sensitive, and deeply interwoven with the relational and value-generating processes that underpin resilient ecosystems.

The present inquiry is structured around two interrelated research questions: first, how BM strategically align stakeholders to promote collaboration and innovation within the multifaceted environments of Industry 5.0 ecosystems; and second, how these actors contribute to embedding human-centric and sustainability-oriented values as enduring systemic features. By addressing these questions, the paper seeks to not merely describe the emerging complexities of ecosystem governance but to propose actionable, theoretically grounded strategies for fostering innovation environments that are simultaneously technologically advanced and socially responsive.

Beyond its conceptual contribution, this paper aspires to deliver practical value to innovation managers, policy architects, and educational leaders who are grappling with the operationalization of Industry 5.0 principles. By elucidating the competencies, mechanisms, and structural supports necessary for effective bridge making, the study offers a roadmap for cultivating more coherent, adaptive, and resilient ecosystems. Ultimately, the work contributes to the ongoing redefinition of innovation governance by demonstrating how strategic intermediaries can play a foundational role in navigating the complex adaptive realities of human-centered technological futures.

Following this Introduction and the clarification of the research approach, the next section situates the discussion within relevant theoretical frameworks, drawing from contemporary scholarship on innovation ecosystem theory, governance of complex systems, open innovation dynamics, and Industry 5.0 paradigms. Building upon these foundations, the paper then elaborates the conceptualization of the BM role, discusses practical implications for innovation managers and policymakers, and concludes with reflections and directions for future research

1.1 Research Approach

This study adopts a conceptual research approach grounded in systematic literature analysis and theory synthesis. Building on insights from Complex Adaptive Systems (CAS) theory, Open Innovation (OI) paradigms, innovation ecosystem governance frameworks, and the emerging Industry 5.0 paradigm, the research advances a novel conceptualization of the BM role. Rather than collecting primary empirical data, the study engages in integrative theoretical reasoning, critically analyzing existing models and frameworks to propose a structured and actionable model for strategic intermediation within human-centered, sustainable innovation ecosystems. The conceptual framework developed herein serves both to address identified gaps in current governance models and to provide a foundation for future empirical validation.

2 Theoretical Foundation

Innovation ecosystems are increasingly recognized as dynamic, complex structures requiring new forms of governance and orchestration to navigate today's volatile and interconnected environments. Traditional models of centralized management and linear innovation trajectories are no longer sufficient to explain or support the distributed, emergent, and adaptive behaviors observed across modern innovation landscapes. In response, several theoretical frameworks have evolved to guide understanding and intervention in these ecosystems. This section synthesizes five key streams—Complex Adaptive Systems theory, Open Innovation paradigms, Industry 5.0 framing, sustainability orientation, and strategic intermediation theory—to build the conceptual foundation necessary for introducing the BM role as an advanced governance intermediary aligned with human-centric and sustainable innovation outcomes.

Complex Adaptive Systems (CAS) theory provides critical insights into the fundamental dynamics underpinning innovation ecosystems. CAS is composed of autonomous agents interacting according to local rules, with no centralized control, leading to emergent system-level properties (Holland, 1992; Chan, 2001). They are characterized by nonlinearity, feedback loops, path dependency, and self-organization (Mitleton-Kelly, 2003). Within innovation ecosystems, these dynamics manifest as unpredictable patterns of collaboration, knowledge exchange, and strategic adjustment. Governance in CAS settings must thus move away from rigid

command-and-control models toward enabling conditions for decentralized learning, distributed coordination, and emergent strategic coherence (Möller and Halinen, 2017; Ansell and Gash, 2008).

Recognizing innovation ecosystems as CAS emphasizes the centrality of trust-building, flexible governance, and strategic sense-making among heterogeneous actors. Trust becomes a critical enabler of adaptive behaviors, allowing stakeholders to collaborate across institutional and sectoral divides under uncertainty (Edelenbos and Klijn, 2007). Innovation governance frameworks must therefore be designed to foster relational resilience, collective learning, and normative alignment in the face of environmental volatility.

Complementing CAS perspectives, Open Innovation (OI) paradigms focus on the permeability of organizational boundaries and the critical importance of external knowledge flows for innovation performance (Chesbrough, 2003; Chesbrough and Bogers, 2014). OI encourages collaborative ideation, co-development, and distributed commercialization processes, leading to more dynamic and networked innovation landscapes (West and Bogers, 2014; Bogers et al., 2017). However, implementing OI at scale amplifies challenges of coordination, trust, and strategic alignment, particularly in multi-stakeholder ecosystems where diverse objectives and knowledge asymmetries must be reconciled (Dahlander and Gann, 2010; Ritala and Almpanopoulou, 2017).

The emerging Industry 5.0 paradigm intensifies these governance demands. Consolidated by the European Commission's strategic vision (Breque et al., 2021; European Commission, 2021), Industry 5.0 reframes the purpose of technological advancement toward enhancing human-centricity, resilience, and sustainability. It positions innovation ecosystems not merely as drivers of competitiveness, but as critical infrastructures for addressing grand societal challenges (Gomes et al., 2018). This reframing requires embedding normative objectives—such as well-being, inclusion, and environmental stewardship—into the structural and operational logics of innovation ecosystems (Carayannis and Campbell, 2009).

Incorporating sustainability paradigms into innovation governance demands a long-term, systems-oriented approach that prioritizes value creation across environmental, social, and economic dimensions. Traditional transaction-focused intermediaries often lack the competencies to embed such systemic values (Majchrzak et al., 2023). Instead, strategic governance actors must foster collective identity, promote value-based decision-making, and nurture systemic learning processes aligned with normative goals.

Finally, the literature on ecosystem intermediation highlights the crucial role of orchestrators and brokers in facilitating knowledge flows, resource mobilization, and network coordination (Dhanaraj and Parkhe, 2006; Hurmelinna-Laukkanen and Nätti, 2018). However, classical intermediaries typically emphasize operational efficiency over systemic resilience and normative coherence. Addressing this gap, Banga and Gaile-Sarkane (2024) propose the concept of the BM.

By synthesizing CAS theory, OI paradigms, Industry 5.0 principles, sustainability imperatives, and advanced intermediation concepts, this paper establishes the theoretical platform necessary for conceptualizing the BM as a foundational enabler of ecosystem resilience and human-centric innovation.

Table 1**:** Key theoretical lenses and their contributions to BM Role in Industry 5.0 Ecosystems. Author created.

Theoretical lens	**Key contribution**
Complex Adaptive Systems (CAS) Theory	Provides understanding of ecosystems as emergent, non-linear, and adaptive networks requiring decentralized governance and continuous updates.
Open Innovation (OI)	Highlights the importance of external knowledge sourcing, collaborative networks, and distributed innovation processes in ecosystem evolution.
Industry 5.0 Framework	Reframes the purpose of innovation toward human-centricity, sustainability, and resilience, challenging traditional technocentric innovation models.
Sustainability	Emphasizes systemic, long-term thinking across environmental, societal, and economic dimensions, requiring innovation ecosystems to embed normative values.
Bridge Maker Concept	Introduces a strategic intermediary role focused on fostering strategic alignment, value embedding, and adaptive governance in human-centered innovation ecosystems for Sustainable Outcomes.

3 Conceptualization of the Bridge Maker Role

The increasing complexity and normative demands shaping innovation ecosystems under Industry 5.0 principles have revealed critical limitations in traditional intermediary models. While brokers, coordinators, and facilitators have played important roles in supporting collaboration and transactional knowledge flows, they frequently lack the strategic depth necessary to drive systemic alignment or to embed broader human-centric and sustainability values into ecosystem governance. Without governance actors capable of fostering both strategic coherence and normative embedding, innovation ecosystems risk fragmentation, short-termism, and erosion of resilience (Provan and Kenis, 2008; Edelenbos and Klijn, 2007).

To address these emerging challenges, Banga and Gaile-Sarkane (2024) introduced the concept of the BM, developed through deep research into the evolving functions of ecosystem intermediaries, orchestrators, and governance frameworks across multiple theoretical domains. Building on this analytical foundation, the BM is defined as:

"An intermediary focused on developing infrastructure and frameworks that support continuous collaboration, ensuring effective resource sharing and the efficient flow of knowledge within innovation ecosystems, to drive sustained innovation and ecosystem resilience."

This definition positions the BM not simply as a transactional broker but as a strategic enabler of dynamic, value-driven system evolution. BMs' interventions are oriented toward sustaining innovation ecosystems over time through systemic collaboration, strategic resource orchestration, and the embedding of shared values at all levels of governance.

Specifically, the BM plays a critical role in aligning heterogeneous stakeholders to drive collaboration and innovation within human-centered Industry 5.0 ecosystems (RQ1). By cultivating systemic trust—extending beyond interpersonal relationships to institutional structures and governance frameworks—the BM creates a durable foundation for inclusive, strategic alignment. Trust-building mechanisms include the establishment of transparent, predictable interaction platforms; the mediation of cross-sectoral interests; and the facilitation of equitable knowledge exchanges that reinforce collective ownership of innovation trajectories (Ansell and Gash, 2008; Edelenbos and Klijn, 2007).

Complementing trust-building, BM act as sense-makers in environments characterized by high volatility and uncertainty. Through orchestrated multi-stakeholder dialogues, strategic foresight processes, and participatory visioning activities, they foster shared cognitive frameworks that allow diverse actors to synchronize innovation strategies and initiatives. Strategic sense-making ensures that collaborative activities are integrated within a coherent, human-centered system strategy rather than remaining opportunistic or fragmented (Provan and Kenis, 2008).

Beyond orchestrating collaboration, BM are pivotal in embedding sustainability and human-centric values as systemic features within innovation ecosystems (RQ2). They institutionalize normative frameworks that guide ecosystem behavior, translating abstract commitments to resilience, inclusivity, environmental stewardship into tangible operational practices (Teece, 2018; Carayannis and Campbell, 2009). BM creates governance infrastructures that embed sustainability principles into decision-making, resource allocation, and project evaluation processes, ensuring that normative considerations are a core component of ecosystem evolution rather than peripheral aspirations.

The competencies of BM - trust building, strategic sense-making, normative value embedding, and adaptive orchestration - are deeply interconnected. Trust lays the groundwork for alignment; alignment enables normative embedding; normative embedding fosters systemic resilience and long-term adaptability. By dynamically coordinating ecosystem interactions, BM empower systems to self-adjust while maintaining coherence around human-centric, sustainability-driven objectives.

This dynamic orchestration role is illustrated in Figure 1 below, which conceptualizes the BM as the central systemic actor translating diverse stakeholder [S_n] inputs into coherent, sustainable innovation outcomes aligned with Industry 5.0 and Open Innovation concept.

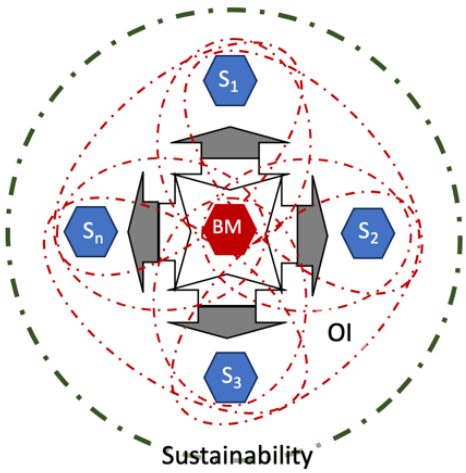

Figure 1: Bridge Maker (BM) as a strategic bridger of multi-stakeholder (Sn) interactions, enabling sustainable innovation outcomes under Industry 5.0 and Open Innovation (OI) paradigms. Author created.

By structuring relational trust, strategic alignment, and normative frameworks into the operational fabric of innovation ecosystems, BM enables the evolution of complex innovation environments into resilient, human-centered systems. Their interventions ensure that innovation is not pursued merely for competitive advantage, but consistently directed toward enhancing societal well-being, ecological integrity, and systemic resilience. In doing so, BM provides a critical governance mechanism for operationalizing Industry 5.0 principles within complex, multi-actor innovation environments.

Through this conceptualization, the paper not only advances the theoretical understanding of strategic intermediation but also establishes a foundation for future empirical exploration of BM roles, competencies, and impacts in diverse innovation ecosystems.

Previous research by Banga and Gaile-Sarkane (2024) has established the distinctiveness of the BM role compared to adjacent intermediary concepts such as brokers, orchestrators, knowledge intermediaries, and ecosystem champions. Through systematic conceptual differentiation, the BM was shown to uniquely integrate trust-building, strategic sense-making, and normative value-embedding functions within innovation ecosystems. In the present study, this distinctiveness is further reinforced within the context of Industry 5.0. The paradigm's explicit focus on human-centric innovation and sustainability goals intensifies the systemic governance challenges facing innovation ecosystems, thereby elevating the critical need for strategic intermediaries who can embed various normative imperatives into ecosystem evolution. Consequently, the findings presented here not only build upon previous differentiations but confirm the growing relevance and necessity of the BM role for the resilient and value-driven innovation ecosystems envisioned under Industry 5.0 principles.

4 Practical Implications

4.1 Implications for Innovation Managers

The conceptualization of the BM role presents significant actionable insights for innovation managers orchestrating complex, human-centered innovation ecosystems. Managers must shift from transactional coordination to strategic ecosystem governance by identifying and supporting individuals or units capable of fulfilling advanced bridging functions. Recognizing potential BM requires evaluating relational competencies—trust building, strategic sense-making, and normative alignment—as well as the ability to operate across organizational, sectoral, and disciplinary boundaries (Nambisan and Sawhney, 2011; Ritala and Almpanopoulou, 2017).

Governance frameworks within innovation ecosystems must evolve to enable dynamic, decentralized collaboration. This involves creating transparent interaction infrastructures, participatory decision-making processes, and platforms for shared vision building. Empowering BM through flexible structures fosters trust-based alignment and systemic coherence essential for sustainable innovation outcomes. Managers must also integrate capability development initiatives, providing opportunities for BM to hone strategic foresight, ethical leadership, and adaptive orchestration skills (Teece, 2018).

Moreover, embedding relational governance mechanisms, such as trust circles, stakeholder foresight processes, and collaborative sense-making workshops, can further enhance the effectiveness of BM in fostering coherent innovation trajectories.

4.2 Implications for Policymakers and Public Sector Leaders

For policymakers and public sector leaders, the emergence of the BM role underscores the need to redesign innovation policies and ecosystem support mechanisms. Traditional instruments focusing narrowly on funding R&D or facilitating basic knowledge transfer are insufficient in addressing the systemic governance challenges of Industry 5.0 ecosystems. Policies must explicitly encourage the development of trust-building infrastructures, collaborative governance platforms, and value-driven ecosystem orchestration (Klerkx and Aarts, 2013; Carayannis and Campbell, 2009).

Public innovation agencies should incentivize projects and ecosystem initiatives that demonstrate the integration of sustainability and human-centric principles into their governance processes. Funding frameworks should reward not just technological outputs but systemic relational achievements, such as the creation of trust-based multi-actor collaborations and the institutionalization of normative value systems. Furthermore, regulatory frameworks must be made more flexible to accommodate adaptive governance structures, allowing BM to navigate complexity without bureaucratic constraints (Ansell and Gash, 2008).

By fostering environments where strategic intermediaries like BM can emerge and thrive, public sector leaders can accelerate the evolution of innovation ecosystems toward resilience, sustainability, and societal value creation, in line with the Industry 5.0 vision.

5 Conclusions

This paper conceptualized the BM as a strategic intermediary crucial for the dynamic governance of human-centered Industry 5.0 innovation ecosystems. By systematically addressing the research questions, the study demonstrated that BM aligns heterogeneous stakeholders through trust-based collaboration and strategic sense-making (RQ1) and institutionalizes human-centric and sustainability values as systemic ecosystem features (RQ2).

The research advances the theoretical understanding of innovation ecosystem governance by positioning BM as enablers of systemic coherence and normative alignment, extending beyond traditional facilitation and brokering roles. Practically, the study offers actionable insights for innovation managers and policymakers on recognizing, supporting, and structurally empowering BM to drive adaptive, value-driven innovation trajectories.

The study's conceptual nature represents a limitation, highlighting the need for empirical investigations into the identification, development, and operationalization of BM competencies across diverse industries and regions. Future research should explore concrete methodologies for training BM and assessing their impact on ecosystem resilience, adaptability, and human-centric innovation outcomes over time.

In shaping governance models for Industry 5.0 ecosystems, BM represents a critical mechanism for fostering sustained innovation, strategic alignment, and societal impact, pointing toward a transformative evolution of innovation ecosystem practice and theory.

6 Ethics declaration

This research did not involve the use of any data from companies or individuals. As such, ethical approval was not required for this study.

7 AI declaration

During the preparation of this manuscript author used OpenAI ChatGPT solely to refine grammar and improve readability. After using the tool, author critically reviewed and edited all AI-suggested text and take full responsibility for the integrity and accuracy of the content. The AI system was not employed to generate original ideas, analyze data, draw scientific conclusions, or create figures, and it is not listed as an author. Evolution of HRM: Longitudinal Analysis of HR Specialists' Skills in Italy

Isabella Bonacci[1], Maria Menshikova[1], Danila Scarozza[2]
[1]Universitas Mercatorum, Rome, Italy
[2]Link Campus University, Rome, Italy

Abstract

This study explores the evolving profile of Human Resource (HR) professionals in Italy through a longitudinal analysis of the skills possessed by new entrants in the HR area from 2017 to 2024. In the face of rapid digital transformation, sustainability challenges, and post-pandemic organizational changes, the role of HR has shifted significantly from administrative support to strategic business partnership. Based on data from the Excelsior Information System, the research investigates the development of ten key competencies, grouped into four categories—social, intellectual, volitional, and managerial—based on the framework by Kolot et al. (2022). Findings reveal that the most developed competencies among new HR specialists are teamwork, problem-solving, and flexibility/adaptability, with consistently high scores and low standard deviation, indicating strong and homogeneous preparation in these areas. In contrast, the capacity to apply Industry 4.0 technologies and communication in foreign languages remain underdeveloped and highly variable, highlighting key areas for future improvement. Digital competencies, while relatively strong, still show moderate variation across candidates, suggesting that digital readiness is progressing but not yet universally embedded. The analysis also highlights important longitudinal trends. Volitional and managerial competencies show both high average performance and remarkable stability over time, while social and intellectual skills present more heterogeneous trends. The data reflect a clear need for HR professionals to enhance their technological and international communication capabilities, particularly given their strategic role in managing change, fostering cultural alignment, and driving organizational transformation. This research contributes to the understanding of how the HR function is adapting to contemporary demands, emphasizing the need for continuous upskilling and alignment between education, professional training, and labor market expectations. The findings support the call for stronger collaboration between academia and organizations, to ensure that HR professionals are equipped with the necessary skills.

Paper type: Academic Research Paper

1 Introduction

The context in which HR managers operate has been rapidly evolving in recent years, both globally and in Italy. HR specialists are facing significant transformations for which they must be adequately prepared. Focusing on the Italian HR professional landscape, several interesting insights emerge regarding the activities, responsibilities, and competencies required to effectively manage these critical changes. The analysis of the articles published on the HR managers professional blog "Risorseumane-HR.it" in 2024 evidences the growing interest in the evolution of HR managers profile in the current context. A recurring theme that emerges is related to the importance of digital and technological skills, as evidenced by discussions on HR innovation (RisoreUmane - HR, 2024) and leveraging gamification and AI for HR processes (Piccininno, 2024). Another focus area is interpersonal and communication skills, underscored by articles on active listening, empathy, and linguistic competence (Sambugaro, 2024). Strategic and change management abilities are also prominently featured, with articles addressing talent intelligence, budget planning, and guiding organisations through transformations (RisorseUmane-HR, 2024/2). Moreover, there is a growing emphasis on skills related to sustainability and circularity. In some articles there are evidences about the importance of HR manager skills to implement Circular and Sustainable HR practices (RisorseUmane-HR, 2024/3). Several articles also highlight the importance of marketing and sales-related competencies for HR managers. They emphasise the importance of persuasive communication and influence as everyday skills for HR managers in promoting organisational change and innovation. The ability to sell ideas to their teams and colleagues, building trust and engagement and communicating the value of new initiatives becomes a very important to foster a shared vision within the organisation (RisorseUmane-HR, 2024/4). Moreover, the article of Labate (2024) explores the possibility to apply marketing principles to HR practices to strengthen employee alignment and motivation. Moreover, leadership agility and overcoming biases are highlighted as vital for navigating challenges and fostering inclusivity and wellbeing of employees in decision-making (RisorseUmane-HR, 2024/5).

The objective of this study is to understand how the profile of HR specialists has evolved in recent years, mapping the competencies needed in the modern business landscape against those actually possessed by individuals within the corporate HR domain. A specific focus of the research is to analyse the impact of the pandemic on the competencies demanded of HR specialists and to identify the key trends shaping the post-pandemic period.

The structure of the paper is as follows: The first section establishes the theoretical framework, analysing relevant and recent studies that address the transformation of the HRM domain, the evolving role of HR specialists, and the necessary adaptations in terms of competencies and preparation for HR professionals. The second section describes the research methodology, which is based on a longitudinal analysis of the Excelsior Information System, representing the competencies of new entrants in the corporate HR field from 2017 to 2023. The final section discusses the findings of the study, identifying the main limitations of the research and proposing potential directions for future investigation.

2 Theoretical framework

The transformation brought about by digitalisation, new working paradigms, automation and environment complexity has fundamentally reshaped organisations and their approach to human resource management (HRM), introducing concepts such as digital workplaces, streamlined digital HRM processes, and enhanced digital employee services (Zhang & Chen, 2024). Hybrid work models implemented in the post-pandemic period demand that the HR function demonstrates proficiency in collaboration tools and virtual communication platforms, ensuring employees remain connected, engaged, and productive by leveraging digital tools (Dutta et al. 2024). Moreover, the automation, AI-powered tools and chatbot systems handle monotonous tasks, freeing up HR specialists for more creative and strategic activities (Dhanpat & Stanz, 2024). Some recent studies view HR managers as “heroes" tasked with repairing workplace challenges in a post-pandemic work environment (Kulik et al., 2022). With the transition to the hybrid work forms, HR has a unique opportunity to build an ideal workplace based on the autonomy and flexibility gained during the pandemic, fostering trust-based relationships, psychological safety, and social connectivity. In the context of these changes, HR managers are increasingly seen as strategic partners and change agents within organisations. Dhanpat et al. (2020) emphasise that HR professionals play a vital role in aligning workforce capabilities with the demands of Industry 4.0, moving beyond traditional administrative functions to contribute to strategic decision-making, particularly in areas such as workforce planning and talent development. Moreover, HR managers now play a crucial role in advancing corporate sustainability strategies helping to integrate economic, social, and environmental dimensions into organisational practices (Amalia, 2024). HR managers can be considered key actors in promoting the environmental sustainability of organisations. Some studies highlight the significant influence of Green HRM in fostering employees' green behaviours and driving environmental management initiatives, underscoring its importance in advancing sustainability goals (Iqbal, 2020). Ed-Dahhani et al. (2024) stress the responsibility of HR specialists in steering organisational change, ensuring the alignment of strategic objectives with employee development. As outlined by Alfes et al. (2019) the HR departments adopt dual roles for effective change management, being drivers and facilitators of change and adapting a proactive approach. Moreover, in an organisational context where the implementation and adoption of AI systems is spreading, HR professionals emerge as a crucial facilitator, ensuring AI adoption is aligned with human values and organisational goals (Fenwick et al., 2024).

Considering the characteristics of the context in which HR managers operate, and the transformation of their role in the organisation, the skills required by HR managers are changed and becoming more multifaceted. As the environment becomes more complex and unpredictable, HR specialists need to possess relevant skills such as develop strategies jointly with top management, leverage insights through innovative HR practices, and better connect employees through technology (Ravi & Sumathi, 2023). Dhanpat et al. (2020) identify three primary areas for competency development for HR specialists: understanding the industry environment, fostering development programmes, and building networks. The ability to leverage the latest insights across various HR practices, co-develop strategic agendas, align the company’s activities with customer needs, and connect people through technology are the main skills that modern HR should focus on. Another essential set of skills is related to digital technologies. The readiness of HR specialists to acquire new digital competencies is a fundamental requirement to develop their professional skills and personal abilities for the transition from a traditional organisation to a digital one (Kapitanov et al., 2021). The interaction of the HR area with employees using digital tools, feedback management and predictive HR analytics are identified as the most important features of a digital organisation. Equally important are skills related to change management. The ability to navigate uncertainty, foster adaptability, and promote continuous learning within the workforce is crucial (Ed-Dahhani et

al., 2024). Dhanpat et al. (2020) evidence the importance of collaboration and teamwork skills, as HR managers increasingly operate within complex, interconnected networks. Kolot et al. (2022) propose a comprehensive model of transferable competencies for HR managers, categorised into 4 key areas: 1) social, 2) intellectual, 3) volitional, and 4) managerial (Fig. 1). The development of these competencies is essential for HR managers to operate successfully in remote and hybrid environments all over the world.

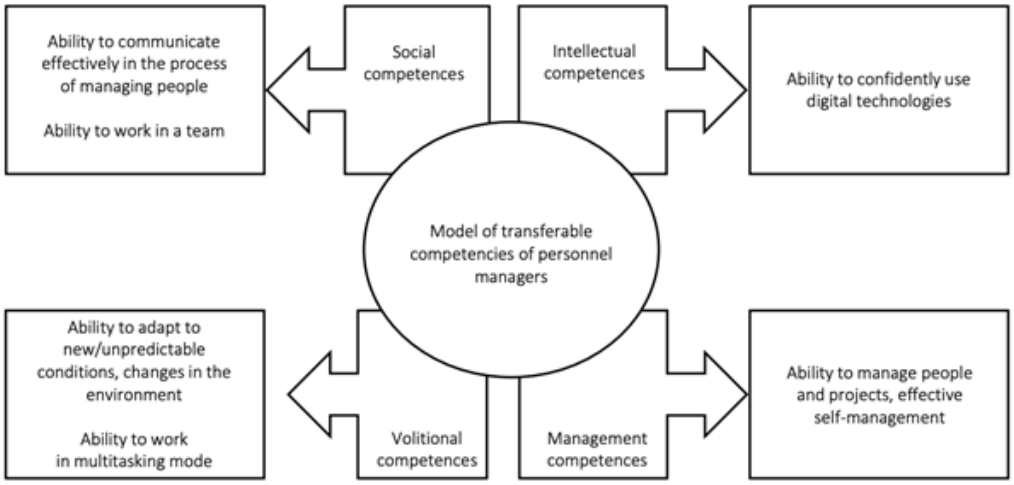

Figure 1:Model of transferable competencies of HR managers
Source: Kolot et al., 2022

3 Methodology

The data from the Excelsior, an Italian information system created by Unioncamere and the Italian Ministry of Labor that collects data on hiring programs relating to a universe of over 1 million 300 thousand Italian companies, has been taken into consideration for the skills analysis. In particular, data regarding skills of individuals who joined the area of Personnel Management and Human Resources Organisation in Italian companies during the period from 2017 to 2024 has been extracted and examined. The following competencies were evaluated using a scoring scale from 1 to 5 (where 1 indicates a low level and 5 indicates a high level): 1) communication skills in the Italian language, 2) communication skills in foreign languages, 3) mathematical and IT skills, 4) digital competencies, 5) problem-solving abilities, 6) teamwork skills, 7) ability to work independently, 8) flexibility and adaptability, 9) attitude towards energy conservation, and 10) capacity to apply 4.0 technologies.

The ten competencies mentioned above were classified into four categories proposed by Kolot and colleagues (2022) (Table 1):

Table 1**:** Skills assessed by competence area

Competence area	**Skill assessed**
Social	communication skills in the Italian language communication skills in foreign languages teamwork skills
Volitional	flexibility and adaptability attitude towards energy conservation
Intellectual	mathematical and IT skills digital competencies capacity to apply 4.0 technologies
Management	ability to work independently (self-management) problem-solving abilities

Source: Our elaboration

From the database, we extracted the number of new entrants in the HR area along with the evaluation of each individual competency, rated on a scale from 1 to 5. Based on this information, we calculated the average level of each competency possessed by new entrants for each year of observation (2017, 2018, 2019, 2020, 2021, 2022, 2023,2024). All types of contracts (not necessarily dependent work) are considered as new entries.

In addition to the longitudinal evaluation of changes in the competency profile over the years, an assessment of the profile of new entrants in the HR area in 2024 was designed in order to map the most developed, as well as under-developed skills of HR specialists.

4 Results

As stated in the previous section, the evaluation of competencies among individuals who entered the HR area over the years was carried out according to four categories: (1) social, (2) intellectual, (3) volitional, and (4) managerial. For each category, we calculated the total number of new entrants, the average competency level, and the standard deviation (Table 2):

Table 2: Evolution of the new entries' skills from 2017 to 2024

Area	Year	2017			2018			2019			2020			2021			2022			2023			2024

To better understand the evolution of skills of new entrants in the HR area, figures 2, 3, 4, 5 are shown below, which represent the change in skill levels over the years for each of the above areas.

Figure 2 shows the evolution of social competencies among new entrants in the HR area within Italian companies from 2017 to 2024. Over the years, teamwork skills have remained consistently high, peaking at 4.24 in 2023 and showing only a slight decline in 2024. Communication skills in Italian have shown a modest but steady decrease, dropping from 3.60 in 2017 to 3.00 in 2024. Communication skills in foreign languages have remained the weakest area, with a downward trend from 2.46 in 2017 to 2.35 in 2024, despite a brief improvement around 2020. It is possible to conclude that while teamwork remains a strong point, the data indicate a need for improvement in language-related communication competencies among new HR professionals.

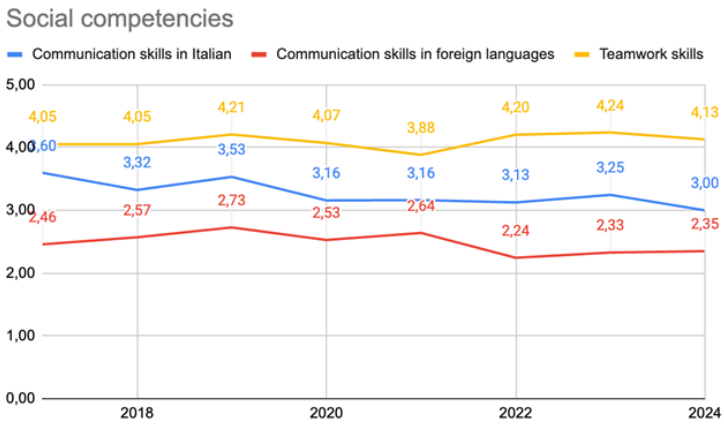

Figure 2: Evolution of social competencies of new entries in HR area from 2017 to 2024

In figure 3 it is possible to observe the trend in volitional competencies. Flexibility and adaptability show consistently high ratings across all years, with a slight dip in 2021 (3.86) followed by a recovery and stabilization above 4.20. This suggests that adaptability remains a strong and stable competency among new HR professionals. In contrast, the attitude towards energy conservation displays more fluctuation. It rises steadily from 2.70 in 2017 to 3.15 in 2019, then declines until 2022, before recovering to 3.16 in 2024. This indicates a growing but still developing awareness of sustainability-related behaviors among new HR entrants.

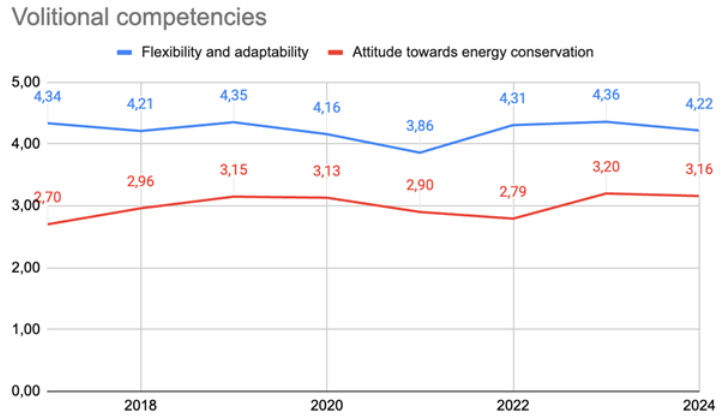

Figure 3: Evolution of volitional competencies of new entries in HR area from 2017 to 2024

Figure 4 shows the trend regarding intellectual competencies that include mathematical and IT skills, digital competencies, and the capacity to apply 4.0 technologies. Digital competencies consistently show the highest ratings, peaking at 3.56 in 2019 and remaining above 3.30 throughout the period, suggesting a solid and growing digital foundation among HR newcomers. Mathematical and IT skills fluctuate modestly, ranging from a low of 2.73 in 2022 to a high of 3.24 in 2019, indicating moderate but stable proficiency. In contrast, the capacity to apply 4.0 technologies remains the weakest area, starting at 1.87 in 2017 and only reaching 2.47 in 2024, despite gradual improvement in recent years. It is possible to conclude that while the digital readiness seems robust, the application of advanced technological tools in HR still represents a developmental challenge for new professionals and organizations.

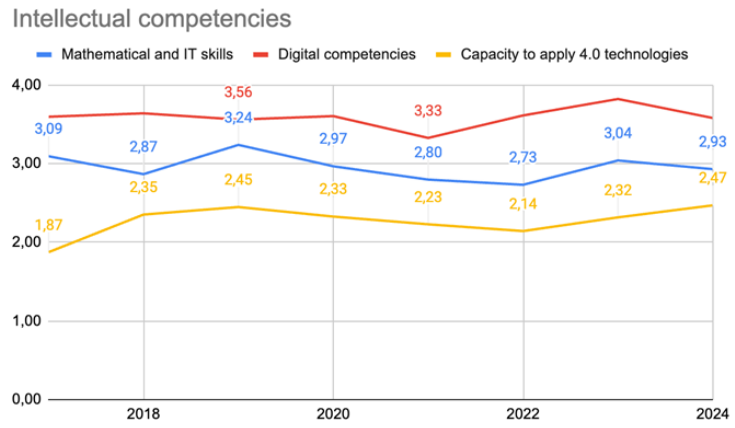

Figure 4: Evolution of intellectual competencies of new entries in HR area from 2017 to 2024

In Fig.5 it is evident the evolution of management competencies, focused on self-management and problem-solving abilities. Both competencies maintain consistently high levels throughout the observed period. Problem-solving abilities start at 4.08 in 2017, reach a peak of 4.23 in 2023, and slightly decline to 4.03 in 2024. Self-management follows a similar trend, rising from 3.72 in 2017 to a high of 3.96 in 2022 before settling at 3.87 in 2024. The data suggest that managerial skills are well-developed among new HR professionals, with only minor fluctuations over time.

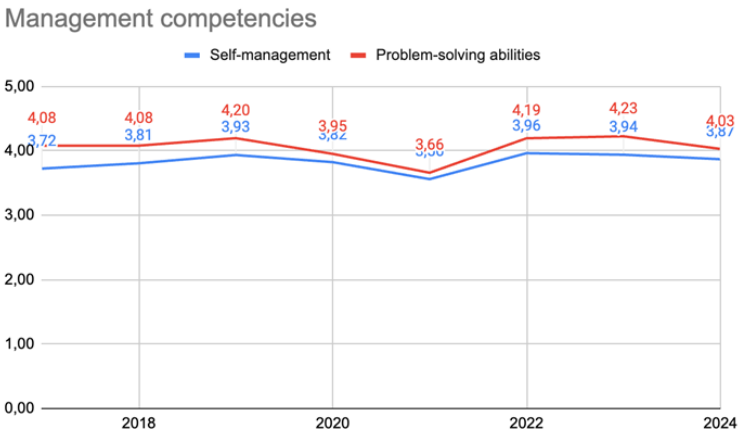

Figure 5: Evolution of management competencies of new entries in HR area from 2017 to 2024

5 Discussion

The longitudinal study on the evolution of the skills of new HR specialists has highlighted a significant transformation in the expectations and demands of the role over recent decades. The findings confirm how the HR specialist has progressively shifted during the last years.

The data shows that the most developed competencies are “teamwork skills”, “flexibility and adaptability”, and "problem-solving abilities”, each maintaining average scores above 4.0 across all years. In contrast, the least developed competencies include the “capacity to apply 4.0 technologies" and "communication skills in foreign languages”, which remain below an average of 2.7 throughout the entire observed period.

Looking at trends over time, some competencies (e.g. teamwork, problem-solving, and digital competencies) appear to be the most stable, showing consistent average values across the years. On the other hand, communication in Italian and energy-saving attitude exhibit fluctuating trends, suggesting shifts in candidate preparation or institutional emphasis during the analyzed period.

When considering variability among candidates (based on standard deviation), communication in Italian, foreign language skills, and capacity to apply 4.0 technology are among the most variable, indicating heterogeneous skill levels among the new entrants in HR. Along with this, teamwork, self-management, and problem-solving abilities show lower standard deviations, suggesting greater homogeneity across the population of new HR professionals.

In fact, combining the results of previous studies with the results of this research, it can be argued that one of the main changes that has emerged is the increasing digitisation of the HR function. The introduction and spread of technological tools (HRIS, analytics, AI in recruiting) have radically changed the way HR processes are managed (Zhou, Fey & Yildiz, 2021; Zhang&Chen, 2024). HR professionals are now required to possess advanced digital skills and to be able to interpret data to make evidence-based decisions, a key skill to contribute to the competitive advantage of the company (Manuti & De Palma, 2018). In fact, based on the findings of this study, digital skills appear to be relatively well developed among new HR entrants in Italy, maintaining an average score consistently above 3.5 across all years. However, the standard deviation remains above 1.0, indicating variability across candidates and highlighting a margin for improvement that organizations and training programs should not overlook. Another interesting point is related to the ability to apply Industry 4.0 technologies. While still the least developed intellectual competency (starting at a low 1.87 in 2017), this competence has shown a gradual upward trend, reaching 2.47 in 2024. Although the growth is slow, the data suggest a positive progression, reflecting a growing integration of advanced technological skills in the HR field. Continued investment in digital and technological upskilling is therefore essential.

In parallel, a strong appreciation of soft skills has emerged. Recent studies (Dhanpat & Stanz, 2024; Bogdány, Gaál & Szabó, 2025) highlight how skills such as emotional intelligence, communication skills, cognitive flexibility and change management are increasingly in demand (Ed-Dahhani et al., 2024). The study findings highlight that flexibility and adaptability stand out as one of the most developed competencies among new entrants in the HR field, maintaining high average scores across all the observed period (ranging from 4.16 to 4.36) and low standard deviations, indicating a strong and consistent presence of this skill across the candidate population. On the other side, though, communication skills (particularly in foreign languages) remain an area for growth. This evidence signals a critical developmental need, especially considering the strategic role HR plays in communicating organizational values and supporting the effective dissemination of ongoing or planned organizational changes. Enhancing linguistic competencies, especially in international contexts, could therefore be essential for reinforcing HR's integrative and change-driving functions within modern organizations.

The evolution of the HR specialist profile also reflects a broader change in the perception of the HR function within organisations. It is now seen as a strategic partner, able to contribute directly to corporate performance through value-oriented human capital management practices (Boselie et al., 2005). Ulrich's (1997) HR Business Partner model has found increasing application, prompting HR to develop an entrepreneurial and outcome-oriented mindset. Furthermore, the HR specialists are becoming increasingly strategic within organizations and must align with both corporate objectives and organizational culture, especially in light of the ongoing transformations driven by the need to adapt to Industry 4.0 environments and sustainability goals.

6 Conclusion

This study underscores the dynamic nature of the HR profession and the need for continuous adaptation. HR specialists should cultivate a blend of technical expertise, digital literacy, and soft skills to thrive in the modern organizational environment. The results of the study confirm that the HR profession is constantly evolving, driven by factors such as digital transformation, globalisation, and increasing organisational complexity. The new HR specialist is a hybrid professional, capable of integrating analytical, digital and relational skills, with a strong ability to read the context, strategic orientation and solve the problems.

The analysis of the data reveals clear differences in the development of competencies across the four main categories (social, intellectual, volitional, and managerial) among new HR professionals in Italy. Volitional and managerial competencies emerge as the most developed and consistent over time. In particular, flexibility and adaptability stand out with high average scores and low variability, indicating that new entrants are generally well-prepared to cope with change and uncertainty. Similarly, problem-solving and self-management show strong performance, reflecting a solid foundation in individual responsibility and operational autonomy.

Intellectual competencies present a more fragmented picture. While digital skills are relatively advanced and stable, suggesting some alignment with the digital transformation of HR, the ability to apply Industry 4.0 technologies remains notably underdeveloped. This indicates a growing yet insufficient integration of advanced technological skills in HR practice, which should be a strategic focus for future development.

Social competencies also show mixed trends. Teamwork is well-developed and widely shared among the population, while communication skills, especially in foreign languages, lag behind and show high variability. This point is of particular importance given the strategic role of HR in shaping organizational culture and driving internal communication, especially in increasingly international work environments with a high level of diversity.

In the light of these findings, it is essential that universities and training centres update their teaching courses, including modules on people analytics, change management, technology applied to HR and the

development of soft skills. A stronger link between academia and business is also desirable to ensure consistency between training programs and the skills actually required and valuable in the labour market. Companies instead should invest in continuous upskilling and reskilling programmes for their HR professionals, promoting a culture of lifelong learning. The creation of internal HR practice communities, mentoring programmes and customised career paths can foster the growth of strategic competencies within the HR function.

Regarding the limitations, the study is based on secondary data from the Excelsior Information System, which, although comprehensive, may not fully capture the qualitative aspects of competency development. Furthermore, the focus is limited to the Italian context, which restricts the generalizability of the findings to other countries. Future studies could delve into the impact of artificial intelligence and automation on HR competencies, as well as explore the differences in HR job profiles across sectors and countries. It would also be useful to examine longitudinally how regulatory changes (e.g. agile working, data regulations) affect the role and skills required of HR professionals.

Educational Diversity Affecting Enterprise Performance: The Lens of Upper Echelons Theory

Rasma Pīpiķe, Elīna Gaile- Sarkane
Rigas Technical University, Riga, Latvia

Abstract

This study investigates the relationship between Top Management Teams' (TMTs) educational diversity and enterprise performance within the Upper Echelons Theory (UET) framework. It integrates data from ten qualitative interviews with senior managers and a quantitative survey of 765 small and medium-sized Latvian enterprises (SMEs) representatives. The study explores how educational background—a form of deep-level diversity—affects strategic decision-making, innovation, and financial outcomes across organizational contexts.

Findings suggest educational diversity is a valuable strategic asset, particularly in medium to large enterprises and knowledge-intensive sectors. Respondents highlighted that diverse academic backgrounds support problem-solving, particularly in crisis situations. However, the perceived value of education varied by demographic and organizational factors, including age, gender, language group, company size, and industry sector. While 64% of survey participants rated educational background as "very important" or "extremely important" for financial decision-making, others emphasized the complementary role of practical experience and collective managerial tenure.

The analysis confirms that education is not always the dominant factor in executive performance. Meanwhile, when combined with other dynamic traits such as risk tolerance and shared values, it significantly influences organizational outcomes. Sector-specific findings underscore that in industries with high complexity and change, such as technology, services, and manufacturing, educational diversity in TMTs plays a more critical role. In smaller companies—particularly those with 10 to 49 employees or annual revenues below €300,000—hands-on experience is often viewed as more important than formal education, as shown by lower support for educational diversity in these groups. In contrast, 63.92% of all surveyed enterprise representatives rated educational diversity in Top Management Teams (TMTs) as “very” or “extremely important” for financial decision-making, with this figure rising significantly in firms with over 50 employees or annual revenues above €5 million. Using these findings for companies in practical terms, it means that developing their leadership teams and being willing to stay competitive, should consider not only formal education but also ensure a diverse blend of academic backgrounds among top managers. The study supports the development of a mathematical model that incorporates both the educational and behavioural characteristics of TMTs. It also contributes to the broader understanding of how diversity management impacts firm-level performance and innovation in a regional context.

Keywords: Diversity Management, Top Management Teams, Upper Echelons Theory, Educational diversity, Enterprise Performance

Paper type: Practical Paper

1 Introduction

The Upper Echelon Theory (UET) suggests that the diverse backgrounds of TMT members—including education, work experience, demographic data, cognitive skills, risk appetite, decision-making styles, values, and social networks (deep-level diversity)—can influence an enterprise's financial outcomes. Understanding these dynamics is crucial for identifying how educational investments in employee skills and knowledge drive productivity and competitive advantage, thereby contributing to sustainable economic growth. This study examines how TMT members' educational backgrounds and attitudes toward education influence financial performance.

As business performance evolves, education’s role in TMTs has gained attention. The research integrates data from ten qualitative interviews with senior managers and a quantitative survey of 765 small and medium-sized Latvian enterprises (SMEs) representatives.

Work structures have evolved from collective to individual roles and, with globalization, back to team-centric approaches (Taylor, 2024). This shift highlights the need for effective, adaptable teams with diverse skills. Analysing team diversity, including education, is crucial for linking team composition to financial outcomes. Educational fields reflect personal values and cognitive styles, making TMTs’ educational diversity a strategic asset. The authors' overarching goal is to identify critical variables that combine elements of Upper Echelon Theory (deep-level diversity) and Diversity Management (surface-level diversity) into a unified model – systemic diversity management for optimizing TMT configurations to enhance firm performance, exploring the aspect of education. By combining qualitative and quantitative insights, the study aims to develop criteria for creating a

robust mathematical model that evaluates the impact of TMTs on organizational performance. This work will serve as a foundation for understanding the meaningful solutions that business professionals can focus on to compile TMTs better.

2 Literature review

Upper Echelon Theory (UET) states that diverse backgrounds, including education, work experience, demographic data (gender, age, nationality, cognitive skills, risk appetite, style of decision-making, values, and beliefs), and social networks, influence a firm's performance (Hambrick & Mason, 1984). Studying the education aspect of Top Management Teams (TMT) is crucial because it can reveal how education directly affects productivity, innovation, and competitive advantage, ultimately contributing to sustainable economic growth and success. More importantly, the perception of education in the minds of TMT, which is responsible for the business's strategic decisions, needs to be analysed.

Historically, work evolved from collective efforts to individual roles, but globalization has shifted organizations back toward team-centric structures. This transition highlights adaptability and team effectiveness as key drivers of firm performance (Kozlowski & Ilgen, 2006). Analysing team diversity—particularly educational backgrounds and cognitive traits—is crucial for building effective TMTs. The authors argue that team composition directly influences financial outcomes, underscoring the measurable benefits of well-structured teams.

While education's role in firm performance is widely recognized, Jouber (2021) highlights that educational diversity within TMTs notably influences corporate social responsibility (CSR) and financial decision-making. Staff with higher education, especially in social and human sciences, show greater commitment to CSR. Meanwhile, a study by Herrmann and Datta shows a positive correlation between TMTs' educational levels and their tendency for international diversification (Herrmann & Datta, 2005). Higher education equips TMT members with a logical, global mindset essential for complex decision-making and international strategy development. While education supports global objectives, Woodfield and Kennie (2008) note that senior teams in higher education face challenges similar to those faced by corporate teams but operate within different cultures and policies, recommending engaging facilitators to boost team effectiveness.

Although TMT characteristics shape strategy, external and internal factors often have a greater impact (Papadakis & Barwise, 2002). Higher education improves information processing and judgment (Tulungs & Ramdani, 2016). Although business experience is not essential, business and economics education helps people make better decisions, especially in crises. It also helps board members cope with tasks and remain competitive (Tulungs & Ramdani, 2016). Educated leaders tend to process information more effectively and innovate (Gottesman & Morey, 2006). Despite Adnan et al. (2016) not finding a strong link between educational diversity and performance, many studies emphasize the key role of education in improving performance and outcomes.

Most studies show that higher education boosts growth, innovation, and competitive advantage (Magoutas, Agiomirgianakis & Papadogonas, 2011). TMTs need varied skills to adapt to changing business environments (Yamak & Üsdiken, 2006). Education generally improves firm performance, often measured by return on assets (ROA), a key indicator of how efficiently a company uses its resources (Ittner & Larcker, 2003; Jewell & Mankin, 2011). Since leadership shapes strategy, TMT composition matters. Research links TMT diversity to better financial performance (Bistrova, Lāce & Kasperovica, 2021; Ting, Azizan & Kweh, 2015) and stronger CSR and sustainability practices (Gupta, 2019; Zumente & Lāce, 2020; Al-Matari, 2022).

3 Methodology

This study uses a mixed-method approach to explore the role of education perception in Latvian SMEs, combining qualitative interviews and a standardized survey. It examines how educational backgrounds influence firms' innovation strategies and financial performance. Between January and February 2024, ten in-depth interviews were conducted with TMT members from diverse industries, covering education, work experience, cognitive traits, decision-making, and social networks. The sample included representatives from sectors like broadcasting, food production, exports, real estate, energy, IT, retail, and transportation, offering a broad view of Latvia's economic landscape. The selected companies averaged over 200 employees, with annual turnovers between 23 and 375 million euros, offering insight into education's impact on the financial performance of enterprises in Latvia. Using open-ended questions, researchers explored how characteristics of Upper Echelons Theory (UET), particularly education, influence the performance of enterprises. The analysis revealed key themes and insights into how education shapes firm performance.

Telephone interviews were conducted by a specialized company, targeting firms with over ten employees across various sectors (excluding farming)—the concise questionnaire captured company demographics and

detailed information on education-related aspects. The survey was conducted in Latvian and Russian to accommodate Latvia's linguistic diversity. This approach ensured that respondents could comfortably provide accurate and comprehensive responses, improving the data quality. This study's sample size is n=765 SMEs. This sample size ensures representativeness across the Latvian population of small and medium-sized companies. The sample accurately reflects the distribution of SMEs in terms of industry sectors, company sizes, and geographical locations.

4 Data analysis

4.1 Insights from in-depth interviews: Thematic patterns

Thematic content analysis of the in-depth interviews identified several education-related themes that offer insight into how top management teams perceive and understand the multifaceted impact of education. Authors grouped these themes into seven broad categories. Furthermore, the most popular themes are:

- Continuous learning and adaptability were noted 9 times (13%), emphasizing the need for ongoing education and the development of TMT skills in changing environments;
- Criticism of formal education appeared 8 times (12%), highlighting concerns that traditional systems may not meet modern job requirements;
- The value of diverse educational backgrounds in TMTs was mentioned 10 times (15%), suggesting that variety enhances problem-solving and innovation.
- Education’s impact on decision-making appeared 7 times (10%), showing its role in shaping informed choices;
- Leadership and education were mentioned 10 times (15%), highlighting education’s contribution to leadership development.
- The debate between practical and formal education emerged most often, 13 times (19%), confirming the value placed on hands-on experience.
- Specific business education needs were noted in 16% of cases.

Overall, findings show a balanced view: continuous learning, diverse backgrounds, and leadership development are valued, but practical experience is crucial alongside formal education. The authors conclude that educational diversity should be incorporated into models to improve firm performance.

4.1.1 Aspect of education among other characteristics in the UET

In the framework of upper echelons theory, senior managers' educational background is recognized as a relevant but not dominant characteristic that influences financial decision-making. While education provides the fundamental knowledge and cognitive tools that shape how leaders perceive and interpret complex business environments, its overall importance appears moderate compared to other top-level characteristics such as collective work experience, risk-taking behaviour, and shared values within the management team. The findings suggest that while education influences leadership outcomes, it is often combined with—and sometimes less important than—practical experience and personal behaviour. The following table and analysis explore how education is valued in relation to other key characteristics, providing a comparative perspective on its perceived significance within executive decision-making processes.

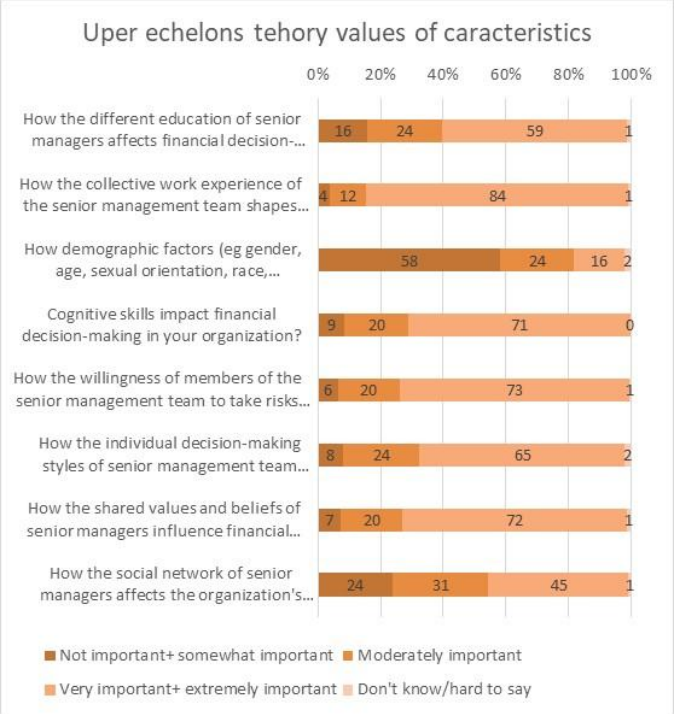

Chart 1. Values and characteristics of Upper Echelons theory, importance. Results of the survey.
Created by authors.

Discussions on education's impact reflect how individuals value education personally. Only 59% of respondents rated senior managers' educational background as "very" or "extremely" important for financial decision-making, much lower than collective experience (84%), risk willingness (73%), shared values (72%), and cognitive skills (71%). This suggests that while education is seen as relevant, it is not dominant in executive decision-making. These findings align with Upper Echelons Theory, emphasizing that dynamic traits like experience and behaviour are stronger predictors of strategic ability than static attributes like education. Education in the context of Upper Echelons Theory—specifically, how the different education of senior managers affects financial decision-making—takes a moderately strong position. However, it is not the most emphasized characteristic in the dataset. Education is placed in the mid-to-high importance category, compared to other variables.

Education is less influential than traits like collective experience (84%) or risk-taking willingness (73%). While 24% view it as moderately important and 16% as unimportant or somewhat important, only 1% were unsure, indicating that education is a well-formed but secondary consideration. These results suggest that while education is valued, experiential and behavioural factors are more predictive of financial decision-making, reinforcing Upper Echelons Theory's focus on experience, values, and cognitive styles over static traits.

4.1.2 Synthesis of Findings

This section presents the findings from the survey of 765 enterprise representatives focusing on how educational diversity in Top Management Teams (TMTs) is perceived in financial decision-making. The analysis highlights key demographic differences, sectoral and positional attitudes, and thematic insights related to the role of education in strategic leadership.

Across the full respondent base of 765 enterprise representatives, 63.92% rated educational diversity in Top Management Teams (TMTs) as "very important" or "extremely important" for financial decision-making. This high percentage signals a strong, shared belief among most business professionals that education is not merely a background variable, but a strategic asset that informs the quality and depth of executive decision-making. Respondents likely associate educational diversity with a broader range of analytical tools, problem-solving methods, and risk-assessment capabilities—essential competencies in today's complex business environments. Data also reveals that 15.68% of respondents rated education as "unimportant" or "somewhat important." This minority reflects a critical counterpoint: not all leaders view formal education as a primary determinant of strategic success. This group may prioritize experiential learning, industry-specific intuition, hands-on operational expertise, or entrepreneurial instincts over academic credentials. Particularly in smaller firms or traditional sectors, practical decision-making based on direct market feedback may be more valuable than

theoretical knowledge. The difference in views highlights a significant perceptual divide in how education is understood and leveraged in executive functions. It suggests that while educational diversity is broadly endorsed, its practical relevance varies depending on firm maturity, sector complexity, leadership culture, and generational factors. For mathematical model development, this implies that education should not be viewed in isolation, but in dynamic interaction with other top management traits such as risk tolerance, leadership style, and accumulated experience.

In summary, while the dominant trend is a strong endorsement of education in executive decision-making, opposite views reinforce the need for a context-sensitive approach to TMT evaluation that balances formal educational indicators with behavioural and experiential dimensions of leadership effectiveness.

4.1.3 Demographic segmentation of perceptions

The survey results reveal that sociocultural and generational factors significantly influence how educational diversity in Top Management Teams (TMTs) is perceived, particularly regarding its relevance for financial decision-making. A notable finding is that Russian-speaking respondents expressed a slightly higher appreciation for the role of educational diversity in shaping financial decisions than their Latvian-speaking counterparts. This suggests underlying cultural or historical influences on how education is perceived as a strategic asset. One potential explanation may be differing educational traditions and experiences across linguistic communities. Russian-speaking managers—many of whom may have received formal education during or soon after the Soviet era—might place greater value on formal qualifications, structured expertise, and academic rigor as essential tools in leadership. Latvian-speaking respondents, while generally supportive, expressed a slightly more moderate view, suggesting a shift toward flexible, experience-driven management styles. This cultural variation highlights the need to calibrate models by linguistic or cultural backgrounds to predict better how educational diversity impacts firm performance through the lens of Upper Echelons Theory.

Among age groups, respondents aged 41–50 are visible in Chart No. 2, which shows the strongest support for educational diversity in leadership, likely reflecting a generation that bridges traditional education with the demands of a globalized economy. Their views underscore how interdisciplinary and international education enhances strategic agility, innovation, and market responsiveness. By contrast, both younger respondents (<40) and older respondents (>60) exhibited more varied or neutral responses. This may reflect a stronger emphasis on entrepreneurialism, digital fluency, and skill-based learning over formal degrees for younger managers. For older respondents, it may be tied to professional trajectories shaped more by experience, tenure, and network capital than by educational credentials. These findings suggest that age should be treated as a moderating variable when examining the impact of TMT education on performance, as it shapes attitudes toward education and interacts with traits like openness to innovation and risk tolerance. Educational diversity is perceived differently across sociocultural and generational lines, highlighting for Upper Echelons Theory researchers and practitioners the importance of considering factors like language, culture, and age.

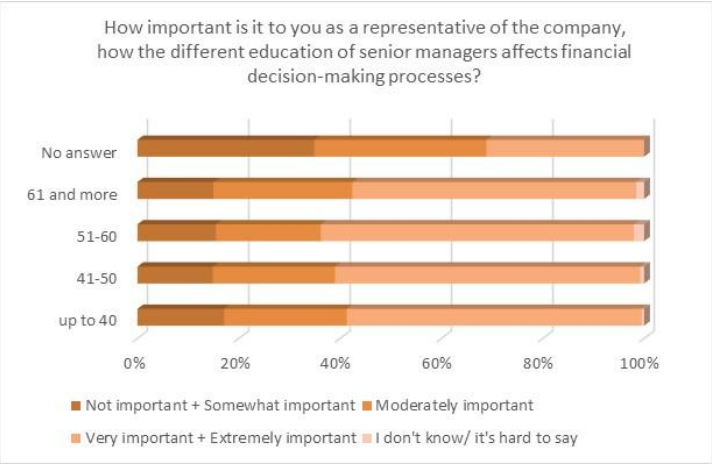

Chart 2. Perceived importance of senior managers' education by age group. Results of the survey.
Created by authors.

Accounting for these nuances is essential for developing effective leadership strategies and culturally sensitive models linking TMT characteristics to firm outcomes. Survey results show that female respondents placed slightly greater importance on educational diversity in financial decision-making than male respondents.

This aligns with existing literature suggesting that gender diversity, particularly when combined with educational heterogeneity, enhances inclusive and collaborative decision-making. The finding indicates that women in executive roles may be more inclined to recognize the strategic value of diverse educational backgrounds, reinforcing the relevance of gender as a contextual variable within the Upper Echelons Theory framework.

4.1.4 Structural dimensions of enterprises and impact on attitudes toward education

The survey findings suggest that organizational characteristics—specifically company size and financial turnover—are significant determinants of how educational diversity in Top Management Teams (TMTs) is perceived in relation to economic decision-making. Firms employing between 50 and 249 staff demonstrated the highest valuation of educational diversity among all size categories. This trend indicates that as organizational scale increases, so does the recognition of the strategic benefits derived from diverse academic backgrounds within senior leadership. These medium-sized enterprises often face growing operational complexity, the need for specialization, and more formalized decision-making processes, which may elevate the importance of cognitive and disciplinary diversity in top-level roles.

By contrast, smaller firms (10–49 staff) were significantly less likely to view educational diversity as critical. In these environments, leadership roles are often concentrated among a few individuals, and decision-making tends to be informal and experience-driven. Consequently, the added value of educational heterogeneity may not be perceived as necessary or actionable. This suggests that organizational complexity is a moderating factor—the larger and more structured the organization, the more valuable diverse educational inputs are in guiding strategy and performance. A similar pattern emerges when analysing the data by annual financial turnover, visible in Chart No. 3. Enterprises with revenues exceeding €5 million per year showed the strongest positive attitudes toward educational diversity in TMTs. These firms typically operate in more competitive, dynamic, or internationalized markets, where leaders must engage in complex decision-making, manage cross-functional teams, and respond to rapid environmental changes. In such contexts, educational diversity is likely viewed as a resource that enhances adaptability, strategic foresight, and innovation.

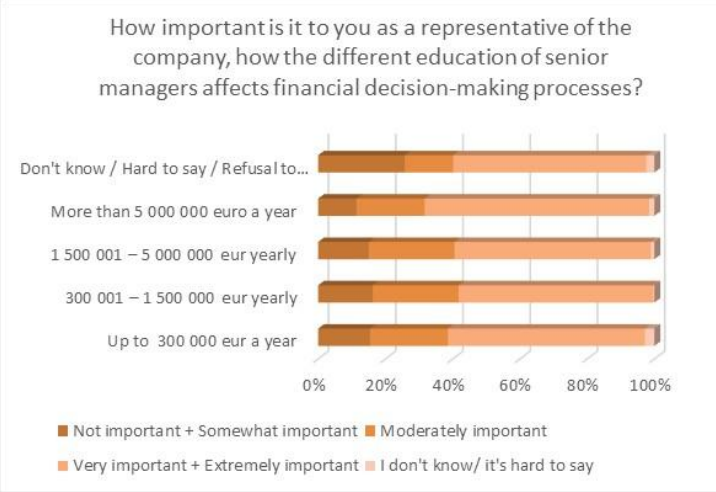

Chart 3. Perceived importance of senior managers' education by company annual turnover. Results of the survey. Created by authors.

In contrast, micro and small enterprises with annual revenues below €300,000 reported the lowest recognition of the relevance of TMT educational diversity. These firms may prioritize operational continuity and efficiency over strategic innovation, and decision-making is often driven by direct market experience or founder intuition. Formal educational differences may appear less consequential for these firms than pragmatic concerns. The findings across company size and turnover categories support the proposition that organizational scale and resource intensity influence how educational diversity is valued in leadership. Both variables point to a broader pattern: as firms become more structurally and financially complex, they are more likely to recognize and benefit from diverse educational inputs at the top management level. These insights are critical for refining any model of TMT performance, suggesting that education-related variables should be weighted differently across firm types, with firm size and turnover acting as essential contextual moderators within the Upper Echelons framework—perceptions of educational diversity varied by organizational role, visible in Chart No. 4.

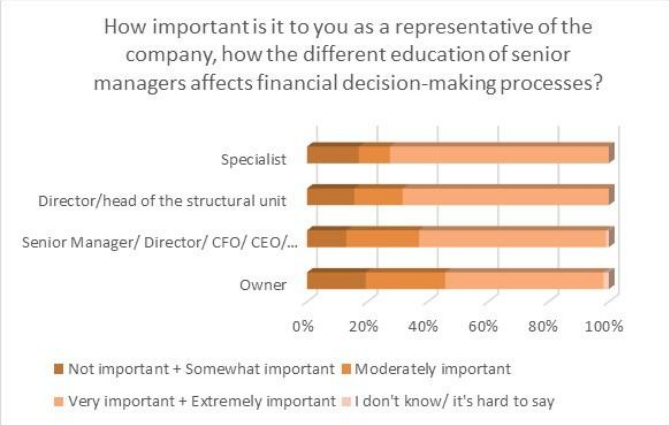

Chart 4. Perceived importance of senior managers' education by respondents' job position. Results of the survey.
Created by authors.

Top executives like CEOs, CFOs, and board members rated education essential for financial decision-making, reflecting their strategic focus. Department directors were similarly supportive but slightly less so, while specialists and small business owners showed more moderate or sceptical views, favouring practical experience. These patterns illustrate a core idea of Upper Echelons Theory: strategic outlooks and the value placed on education are shaped by functional roles and proximity to executive decision-making.

4.1.5 Industry-specific perceptions of educational diversity

The analysis reveals notable sectoral differences in how Top Management Teams (TMTs) educational diversity is perceived visible in Chart No. 5. In particular, respondents from the trade, services, and manufacturing sectors rated educational diversity as "very important" or "extremely important" in over 60% of responses, indicating a strong recognition of its relevance for strategic and financial decision-making. These sectors often operate at the intersection of operational efficiency and market responsiveness, where diverse educational backgrounds can enhance logistics, supply chain management, and customer engagement decision-making.

However, high-tech and professional service firms observed the most pronounced emphasis on educational diversity. Organizations in these sectors face rapidly evolving technologies, knowledge-intensive operations, and heightened expectations around corporate social responsibility (CSR) and innovation. Here, education is viewed not only as a qualification but as a cognitive asset that equips leaders to interpret complexity, manage uncertainty, and drive transformative initiatives. This finding is remarkably consistent with Upper Echelons Theory, which suggests that TMT characteristics—especially those influencing cognitive processing—are most impactful in dynamic, uncertain, and competitive environments.

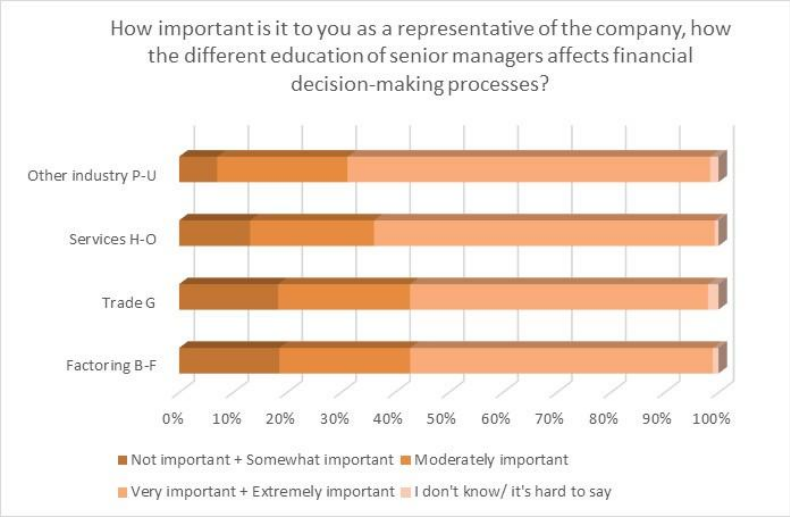

Chart 5. Perceived importance of senior managers' education by industry sector. Results of the survey.
Created by authors.

The differences across sectors underscore the context-dependent value of educational diversity, suggesting that its strategic utility increases with the industry's environmental dynamism and knowledge intensity. These sectoral patterns should be accounted for in any predictive modelling of TMT effectiveness, as they provide critical insights into how the organizational environment interacts with leadership attributes to shape firm outcomes.

5 Summary of key findings

This study identified several meaningful findings regarding Top management Teams' educational diversity and its impact on enterprise performance. First, educational background—particularly when combined with industry experience—enhanced strategic decision-making and innovation capacity, supporting the principles of Upper Echelons Theory. Second, it confirms that cognitive diversity from varied educational fields contributes positively to problem-solving dynamics within TMTs, especially in knowledge-intensive sectors. Third, survey results indicated that while education alone was not always considered essential, over 60% of business representatives acknowledged its role in improving leadership competence and adaptability. Fourth, qualitative data revealed that leaders with interdisciplinary education foster more open communication, collaboration, and innovative thinking across teams. Finally, the study showed that educational diversity has a stronger positive effect in large or complex organizations, where it helps improve performance. In smaller companies, however, practical experience often matters more..

6 Conclusions

This study clarifies the importance of educational diversity within Top Management Teams (TMTs) as a strategic driver of organizational performance, particularly in fast-changing, knowledge-intensive sectors. Empirical data gathered from 765 enterprise representatives and in-depth interviews reveal that while a formal education is not universally seen as the primary driver of executive success, it is broadly recognized as a cognitive resource that enhances strategic decision-making, influencing the financial performance of the enterprises. Research confirms the fundamentals of the Upper Echelons Theory (UET), which states that combining formal education with practical experience helps leaders develop broader perspectives and become more flexible in complex and rapidly changing business environments. Organizations—especially those undergoing digital transformation or operating in uncertain markets- should prioritize educational heterogeneity in their executive hiring and development practices. However, practitioners must also contextualize the value of education within their firm’s size, sectoral demands, and leadership culture. A one-size-fits-all approach may be ineffective; instead, tailoring TMT configurations to balance formal education with experiential insights will yield better strategic outcomes. Findings of the article can be used in predictive models of TMT effectiveness and offer actionable guidance for professionals in human relations and corporate leaders seeking to build high-performing leadership teams.

Shifting Operational HRM to AI: Opportunities, Challenges and Strategic Pathways

Maria Eugenia Sánchez Vidal, David Cegarra Leiva
Universidad Politécnica de Cartagena (UPCT), Cartagena, Spain

Abstract

This paper explores the transition of operational human resource management (HRM) tasks to artificial intelligence (AI) and examines the resulting opportunities, challenges, and strategic pathways. We develop a theoretical analysis grounded in recent HRM literature and Tursunbayeva's (2024) configurational framework, which views HRM practices as consisting of operational, relational, and transformational dimensions. The study is conceptual in nature, integrating insights from technology adoption (e.g., the technology-organization-people perspective) and responsible AI principles to extend and refine existing theory. We argue that delegating operational HRM activities to AI can significantly enhance efficiency and decision-making—such as through automation of repetitive administrative tasks and data-driven analytics—while freeing HR professionals to focus on higher-value relational and strategic roles. However, this shift also introduces notable challenges, including algorithmic bias, privacy and transparency concerns, workforce skill gaps, and employee resistance to AI-driven change. To address these issues, we propose strategic pathways for organizations, emphasizing the adoption of Responsible AI governance (ensuring fairness, accountability, and human oversight), proactive change management and upskilling of HR personnel, and alignment of AI initiatives with broader HR strategy (e.g., leveraging AI to support diversity and inclusion goals). In doing so, the paper contributes to HRM theory by extending Tursunbayeva's framework with a more detailed examination of the operational HRM–AI interface and by incorporating multi-level and human-centric considerations. The resulting model offers a holistic view of AI integration in HRM, highlighting that AI's benefits in operational HRM are maximized only when accompanied by ethical safeguards and strategic alignment. The paper concludes with theoretical implications and recommendations for HR practitioners seeking to responsibly navigate the AI transformation of HRM.

Keywords: Artificial Intelligence, Human Resource Management, Automation, Ethical Decision-Making, Workforce Transformation

Paper type: Academic Research Paper

1 Introduction

The rise of Artificial Intelligence (AI) is reshaping the landscape of Human Resource Management (HRM), promising transformative improvements alongside significant uncertainties. AI's potential to automate and augment HRM practices is profound, offering unprecedented efficiency and data-driven insights. At the same time, it presents complex challenges in terms of ethics, inclusivity, and sustainability (Tursunbayeva, 2024). Recent analyses emphasize that while AI could revolutionize HRM, our understanding of how this transformation is unfolding in practice remains limited (Tursunbayeva, 2024). There are dual narratives surrounding AI in HRM: a "hype" perspective celebrating AI's augmentative potential, and a "fear" perspective cautioning against disruptive impacts on jobs and decision quality (Tursunbayeva, 2024). These divergent views underscore the need for rigorous theoretical examination of AI integration into HRM.

HR scholars and practitioners have long advocated leveraging technology to relieve HR professionals from routine administrative work, enabling a stronger focus on strategic and value-adding activities (Ulrich, 1997). Early waves of e-HRM and automation streamlined many operational HR tasks, reducing paperwork and human error (Tursunbayeva, 2024). AI-driven "algorithmic management" represents a new wave of this evolution, introducing complex data analytics and autonomous decision-making into HR processes (Tursunbayeva, 2024). However, the managerial playbook for effectively adopting AI in HRM is still emerging. A recent systematic review found that academic literature "has not yet offered a strategic framework" for guiding AI-assisted HRM implementation, even as organizations increasingly experiment with AI applications (Malik et al., 2023). Notably, Tursunbayeva's (2024) framework addresses this gap by viewing HRM technology through a configurational lens – distinguishing operational, relational, and transformational HRM elements – and by stressing responsible, multi-level implementation of AI (Tursunbayeva, 2024).

Building on this foundation, the present theoretical study explores the central question: What opportunities and challenges arise when shifting operational HRM activities to AI, and what strategic pathways can enable organizations to harness AI's benefits while mitigating its risks? The thesis put forward is that AI can significantly enhance the efficiency and strategic impact of HRM by taking over operational tasks, but realizing these benefits requires addressing substantial ethical, organizational, and human-centric challenges through carefully crafted

strategies. In examining this thesis, we extend and critique Tursunbayeva's (2024) framework by integrating additional theoretical perspectives and recent empirical insights. The paper is organized as follows. First, we review the theoretical background on AI in HRM, including Tursunbayeva's configurational approach. Next, we analyze the key opportunities and challenges of shifting operational HRM to AI. We then discuss strategic pathways for implementing AI in HRM responsibly and effectively. Finally, we outline the theoretical contributions of this work – particularly in relation to Tursunbayeva's framework – and conclude with implications for research and practice.

2 Theoretical Background.

2.1. AI in HRM: Evolution and Perspectives.

Technology has pervaded HRM for decades in efforts to increase efficiency and strategic focus. The introduction of electronic HRM systems and automation allowed HR departments to offload repetitive administrative work and improve accuracy, thus freeing HR staff to focus on higher-value initiatives (Ulrich, 1997; Marler & Parry, 2016). This evolution is exemplified by the widespread adoption of self-service portals, applicant tracking systems, and HR analytics tools. These technologies were largely rule-based and required human configuration, but they set the stage for more sophisticated AI-driven solutions. Today, AI algorithms enable what is often termed "algorithmic management", where certain managerial decisions and workflows are partially or fully automated (Tursunbayeva, 2024). AI-driven systems can autonomously screen résumés, schedule interviews, or monitor attendance – executing tasks that were once manual. AI applications now span nearly all HR functional areas, from recruitment and selection to training, performance management, and compensation (Tursunbayeva, 2024).

With this expansion of AI capabilities, HRM scholars describe two contrasting perspectives on its impact. On one hand, the optimistic transformative view posits that AI will augment human decision-making, enhance productivity, and create more strategic roles for HR professionals (Tursunbayeva, 2024). From this perspective, AI is a catalyst enabling HRM to deliver greater value through data-driven insights and by reallocating human effort to complex relational and strategic tasks. On the other hand, a concerned view warns that heavy reliance on AI could have disruptive effects – potentially displacing HR jobs, reducing the human touch in people management, and introducing new risks of error or bias (Tursunbayeva, 2024). This "hype versus fear" dichotomy is evident in recent literature on AI in the workplace. Both views contain some truth: AI can indeed dramatically improve efficiency, but uncritical implementation may lead to unintended consequences. This duality underlines why a balanced, theory-driven approach is needed when examining AI in HRM.

2.2 Tursunbayeva's (2024) Configurational Framework

A key emerging theoretical perspective on AI in HRM is provided by Tursunbayeva (2024). In her framework, HRM practices are viewed through a configurational lens comprising three interrelated configurations: operational HRM, relational HRM, and transformational HRM (Tursunbayeva, 2024). Operational HRM refers to transactional administrative activities (e.g., record-keeping, payroll) necessary for running the organization but not directly strategic. Relational HRM covers activities in managing employee relationships and development (for example, recruitment and selection, training, performance management, compensation). Transformational HRM involves strategic, change-oriented practices (e.g., strategic workforce planning, succession management) aimed at long-term organizational development. Tursunbayeva's framework posits that AI can play distinct roles in each of these configurations. Notably, Tursunbayeva addresses the dual perspectives by acknowledging both AI's promise and its perils within her framework. She highlights that AI can "streamline routine administrative tasks through automation and algorithmic management" and "enhance relational HRM throughout the employee life cycle", while also supporting strategic objectives like diversity and inclusion (Tursunbayeva, 2024). This reflects the optimistic view that AI augments HRM at all levels – automating the operational, assisting the relational, and informing the transformational.

At the same time, her framework explicitly acknowledges the "ethical...minefield" that AI introduces (Tursunbayeva, 2024). It emphasizes Responsible AI principles and alignment at multiple levels of the organization (Tursunbayeva, 2024), thereby integrating ethical considerations (fairness, transparency, inclusivity) into AI adoption in HRM (Tursunbayeva, 2024).

Tursunbayeva's configurational framework provides a structured way to analyze where AI fits into HRM and what consequences may arise. It suggests that operational HRM tasks are the most amenable to full AI automation, whereas relational HRM might benefit from AI-assisted decision support (e.g., chatbots aiding

employee inquiries or algorithms recommending training content), and transformational HRM can leverage AI-driven analytics for strategic insights. This study adopts Tursunbayeva's framework as a foundation and focuses on the operational HRM component – essentially examining the implications of "leaving operational HRM to AI." By zooming in on the operational level, we explore the direct opportunities AI creates in automating HR tasks and the cascading challenges for relational and transformational HRM. We also integrate complementary insights from other scholars – for instance, Budhwar et al. (2022) highlight that successful AI adoption requires alignment of technology, organization, and people (the TOP factors) (Malik et al., 2024). By incorporating such perspectives, we extend Tursunbayeva's framework to consider the key enabling conditions and context for AI-driven HRM.

In the following sections, we discuss the major opportunities and challenges that AI presents for operational HRM, before elaborating strategic pathways to navigate this change.

3 Opportunities of AI for operational HRM.

AI technologies offer a range of opportunities to improve operational HRM processes. In this context, "operational HRM" includes the routine, high-volume tasks and transactions that support the employee lifecycle (such as recruiting administration, record maintenance, payroll, scheduling, etc.). By delegating these tasks to AI systems, organizations can achieve greater efficiency and consistency, while potentially unlocking new strategic value from HR data. Key opportunity areas are outlined below.

3.1 Automation and Efficiency Gains.

A primary benefit of applying AI to operational HRM is automation of repetitive tasks, leading to efficiency gains. AI systems can perform many administrative duties faster and with fewer errors than humans. For example, AI-driven recruiting platforms can instantly screen large volumes of résumés and rank candidates, a task that would otherwise consume substantial recruiter time (Dima et al., 2024). This acceleration in response time "significantly enhances the candidate experience" by keeping applicants informed and engaged (Dima et al., 2024). Similarly, AI chatbots can handle common employee queries (e.g., about benefits or leave) instantly and consistently, freeing HR staff from many routine interactions. By automating these processes, organizations can operate with leaner HR teams or redeploy staff to more complex work (Budhwar et al., 2022). Furthermore, automation often brings cost savings and improved accuracy – algorithms follow prescribed rules consistently, eliminating many errors of manual processing (Dima et al., 2024). Overall, the efficiency gains from AI-driven automation in operational HRM translate into faster service delivery, lower transactional costs, and more reliable execution of HR processes.

3.2 Data-Driven Decision Making and Analytics

Beyond task automation, AI offers the opportunity to transform operational HR decisions through advanced data analytics. Many HR decisions that were once based on intuition or limited information can now be augmented by AI algorithms that detect patterns across vast datasets. For instance, machine learning models can analyze employee data to predict outcomes like turnover risk or performance potential (Dima et al., 2024), enabling HR to address issues (e.g., proactive retention efforts) far earlier than traditional methods. In talent acquisition, AI can search across multiple databases to identify and engage potential candidates much faster than a human recruiter (Dima et al., 2024), thus significantly expanding the talent pool. By grounding HR decisions in data, organizations can make choices that are not only faster but also more objective. Studies have found that introducing AI into selection processes encourages a shift from gut-feel to evidence-based decision-making (Dima et al., 2024).

3.3 Enhanced Stakeholder Experience and Fairness

Another opportunity area is the improvement of experiences for HR's stakeholders – namely employees (including job candidates) and managers – along with potential gains in fairness. From the stakeholder experience standpoint, AI can make HR services more responsive and personalized. As noted above, candidates benefit from quicker communications (such as instant application updates or interview scheduling), which leads to a more positive recruitment experience (Dima et al., 2024). Employees, too, may appreciate the convenience of AI-enabled self-service tools for simple HR queries, allowing them to resolve matters without delay. Managers can also benefit from AI-driven decision support (for example, AI-based analytics that flag disengaged employees or recommend learning opportunities), which can make their HR-related tasks easier and more informed Kshetri (2021).

In terms of fairness, AI has the potential to reduce certain biases that human decision-makers may unwittingly introduce. When properly designed and audited, AI algorithms can focus on job-relevant criteria and ignore extraneous attributes, which can help mitigate discrimination in hiring or promotions (Albert, 2019). For example, an AI screening tool could be programmed to disregard demographic information, basing its recommendations purely on candidates' skills and experience. AI can also reveal patterns in HR data that hint at bias – for instance, if performance scores consistently differ by gender – thereby alerting management to potential inequities that need correction. While realizing these fairness benefits requires careful oversight, the opportunity is that AI might support more consistent, merit-based decision-making. If successful, such improvements could increase employees' and applicants' perceptions of justice in HR processes, strengthening the employer's reputation.

3.4 Elevating the Strategic Role of HR

By taking over operational tasks, AI frees up human resources professionals to engage in more strategic and high-touch activities – effectively elevating the role of HR in the organization (Budhwar et al. 2022). This is both a direct consequence of workload automation and an indirect effect of the richer insights AI can provide. With administrative burdens reduced, HR practitioners can allocate more time to strategic planning, talent development, and consulting with business leaders. Rather than spending hours on transactional duties like compiling reports, an HR manager might use AI-generated analytics to advise leadership on workforce planning or diversity initiatives. Indeed, research suggests that organizations are beginning to "strategize HR with the aid of AI" as a means to better achieve both productivity and employee-related outcomes (Dima et al., 2024). AI tools can serve as a decision-support system for HR strategists – for example, identifying skill gaps that could impact future business goals or modeling the workforce implications of a new initiative. Armed with such analytics, HR leaders can make more informed contributions to business strategy discussions.

Furthermore, the integration of AI into HRM amplifies the strategic emphasis on managing change and innovation in organizations. HR professionals, freed from day-to-day drudgery, can champion initiatives like culture change, leadership development, or organizational redesign while relying on AI to monitor progress and flag issues in real time. Over time, as routine work is ceded to intelligent systems, the HR function can reposition itself from an administrative support unit to a strategic partner role (Ulrich, 1997). This shift aligns with the long-standing vision of HR as a driver of organizational capability and competitive advantage. AI's contributions – whether through efficiency gains or advanced analytics – reinforce HR's ability to deliver strategic value. The net result is an opportunity for HR professionals to enhance their influence and for the HR function to be more deeply involved in high-level decision-making. In summary, deploying AI in operational HRM not only improves process metrics but can also catalyze a transformation of the HR function itself, enabling it to focus on strategic, value-adding activities that were previously neglected due to time and resource constraints.

4 Challenges of AI Implementation in HRM

While AI presents compelling opportunities, it also brings a spectrum of challenges and risks that organizations must navigate. Many of these challenges correspond to the ethical and strategic concerns raised by the "fear" perspective of AI in HRM (Tursunbayeva, 2024). If not properly addressed, such issues can negate the benefits or even cause harm to organizational culture and stakeholder trust. We categorize the challenges into two broad domains: (1) ethical and legal challenges, and (2) human and organizational challenges.

4.1 Ethical and Legal Challenges

One of the foremost concerns is the risk of algorithmic bias and discrimination. AI systems learn from historical data, and if those data reflect biased human practices, the algorithm may perpetuate or even amplify those biases. For example, if past hiring data are biased, an AI recruitment tool could learn to unfairly screen out underrepresented candidates. This creates a serious ethical issue as well as legal liability, since employment laws prohibit discriminatory practices. Ensuring algorithmic fairness requires ongoing audits of AI decision criteria, careful curation of training data, and adjustments to counteract bias. However, establishing accountability is challenging when AI decision-making is a "black box" that stakeholders do not understand. Opaque algorithms make it difficult to explain or contest decisions, which can undermine trust and may run afoul of emerging regulations that demand explainability.

Closely related are privacy and data protection concerns. AI-based monitoring of employees (e.g., analyzing emails or wearable sensor data) can easily cross into perceived surveillance, prompting employee pushback (Dima et al., 2024). Data security is also paramount: breaches or misuse of sensitive HR information can erode

trust and violate data protection laws. Organizations must navigate strict privacy regulations regarding how personal information is collected, used, and stored, or risk legal penalties and reputational damage.

Another challenge is maintaining ethical accountability and compliance when AI plays a major role in HR decisions. If an algorithm makes a flawed decision (e.g., unjustly rejecting a qualified candidate), it may be unclear who is responsible – the vendor, HR, or the developers. Clear governance frameworks are needed to assign responsibility and oversight for AI outcomes. Without proper oversight, AI in HRM can become an "ethical – if not legal – minefield" (Tursunbayeva, 2024). Organizations should establish ethical guidelines (under the banner of Responsible AI) that encompass fairness, transparency, and accountability, in alignment with employment laws and human rights. In practice, it is wise to keep a human in the loop for important decisions, to catch potential errors or biases before actions are finalized. Ultimately, Responsible AI requires embedding ethical considerations into every stage of the AI lifecycle – from data selection and algorithm design to deployment and ongoing monitoring – to prevent pitfalls and sustain trust in AI-driven HRM.

4.2 Human and Organizational Challenges

Beyond ethics and legality, the shift to AI-driven HRM raises substantial human and organizational challenges. A prominent issue is the fear of job displacement and role change among HR professionals. As AI takes over tasks like résumé screening or attendance tracking, some HR staff naturally worry about their own job security (Chen, 2023). This anxiety can breed resistance – indeed, HR professionals unfamiliar with AI may be especially resistant if they believe it will make their roles obsolete. Addressing this fear requires clear communication that AI is a tool to assist rather than replace humans, and a refocusing of HR roles on the uniquely human skills (e.g., relationship-building, empathy) that AI cannot replicate.

Relatedly, introducing AI in HR requires careful change management to overcome cultural resistance. Employees or managers might be skeptical of algorithmic recommendations – especially if they lack digital literacy or inherently mistrust the technology. Building acceptance necessitates involving end-users early, providing training, and demonstrating quick wins. If people do not understand or trust an AI system, they may circumvent it, so fostering a culture open to data-driven decision-making is essential. This cultural shift can be difficult, particularly in organizations where intuition and personal judgment have traditionally dominated HR decisions.

Another major challenge is the skills gap that AI implementation exposes. To effectively leverage AI, HR professionals and managers must develop new competencies. Employees will need to "leverage [AI's] advantages while compensating for its deficiencies" by developing both new technical knowledge and enhanced human skills (Dima et al., 2024). In essence, organizations are cultivating an "AI-hybridized workforce" where humans and AI work in tandem, which requires continuous learning and upskilling. However, implementing these upskilling programs is non-trivial. Employees less comfortable with technology (often older workers) tend to struggle more with retraining, which can create generational divides or morale issues. Additionally, there is a shortage of HR professionals with strong analytics and AI skills, so organizations may find themselves competing for a limited pool of qualified talent (Dima et al., 2024).

On an organizational level, the infusion of AI into HRM can necessitate changes in structure and processes. Decision-making workflows may need to be redesigned to incorporate algorithmic inputs, and new governance bodies or roles (such as an AI ethics committee or HR analytics specialist) may be required. There could also be shifts in power dynamics: if line managers feel that decisions are dictated by algorithms, tension may arise over the locus of control. In fact, AI's encroachment on certain HR "fields of expertise" could alter internal power structures and even spark labor relations issues. These factors underscore that implementing AI is not just a technical project but a socio-technical transformation. Organizations must cultivate a learning-oriented culture that encourages experimentation and adaptability – continuous learning is "essential for the successful implementation of AI" (Rajeshwari et al., 2019). Without a supportive culture, even the best AI tools may fail to deliver value because they will not be fully embraced by the people in the organization.

In summary, the human and organizational challenges of AI in HRM revolve around managing fear and resistance, developing new skills and roles, and adapting organizational structures and culture. Proactively addressing these challenges is as important as the technical deployment of AI tools. The next section discusses strategic pathways that organizations can adopt to capitalize on AI's opportunities while mitigating the challenges identified.

5 Strategic Pathways and Recommendations

To fully realize the benefits of AI in HRM while mitigating the above challenges, organizations need to adopt deliberate strategic pathways. These involve instituting governance mechanisms, developing people and

culture, and aligning AI initiatives with broader organizational goals. Based on the literature and frameworks discussed, we outline several key strategies for effective integration of AI into HRM.

5.1 Embracing Responsible AI and Governance

The first strategic imperative is to embrace Responsible AI principles and build a robust governance structure around AI use in HRM. Organizations should establish clear internal policies for AI in HR – covering issues like bias prevention, data privacy, transparency, and accountability. For example, any AI used in hiring might be required to undergo bias audits and to inform candidates of automated screening. These measures signal a commitment to ethics and guide the development or selection of HR AI tools.

Implementing Responsible AI also entails multi-level oversight. This means taking measures at multiple levels (individual, organizational, even societal) to ensure ethical outcomes (Tursunbayeva, 2024). In practice, for example, an organization might form an AI ethics committee to regularly review AI-driven HR decisions and handle any grievances or exceptions. Ensuring human oversight (a human-in-the-loop) is advisable for high-stakes decisions, and transparency should be maximized by providing explanations for AI decisions and clearly communicating how AI systems are used. Such steps can alleviate fears and build trust. It has been stressed that AI systems in HR should remain "transparent and unbiased and comply with all laws" and should complement rather than replace human judgment (Dima et al., 2024). Ultimately, Responsible AI requires embedding ethical considerations into every stage of the AI lifecycle – from data selection and algorithm design to deployment and ongoing monitoring – to prevent pitfalls and sustain trust in AI-driven HRM.

5.2 Change Management and Skill Development

Technical solutions alone are not enough; the success of AI in HRM hinges on effective change management and skill development. A prudent approach is to start with small pilot programs. For example, an organization might first deploy an AI tool in a single, low-risk HR process and closely evaluate the outcomes and user acceptance. Early successes can then be communicated to build confidence before scaling up. Throughout this process, communication is key – employees should be informed about what the AI system does and how it benefits them. Emphasizing that AI reduces drudgery and assists people (rather than replaces them) can preempt resistance.

Training and upskilling efforts form another pillar of this strategy. Organizations should strive to cultivate an AI-ready workforce with a mix of technical and human skills (Dima et al., 2024). HR staff may need training (via workshops, e-learning, etc.) in analytics tools and AI ethics, and line managers who will use AI outputs should also be educated about their proper use and limitations. By improving digital literacy and comfort with AI, the organization narrows the skill gap and reduces fear of the unknown.

HR departments may also need to redefine roles (for example, adding HR data analysts) and encourage cross-functional collaboration (between HR, IT, and data science teams) to ensure AI tools meet HR's needs and values. Involving HR staff in the design and rollout of AI systems – rather than imposing tools on them – increases buy-in and yields feedback to refine the system. Top management support is also critical; leaders should visibly champion the responsible use of AI in HR and provide resources for training. Finally, organizations should establish feedback channels (e.g., surveys or forums) for employees to voice concerns about AI decisions, and use that input to adjust policies or algorithms over time.

5.3 Aligning AI with Strategic HRM Objectives

For AI in HRM to deliver maximum value, it should be closely aligned with the organization's broader strategic objectives and human capital strategy. Rather than adopting AI for its own sake, organizations should use AI to advance explicit HR goals (such as improving workforce diversity, driving innovation, or enhancing employee well-being). For example, if a company's strategic aim is to foster a more inclusive workforce, AI tools can be leveraged to widen sourcing channels for diverse talent and to detect biased language in job postings. Likewise, if continuous learning and innovation are priorities, AI can be applied in employee development (through personalized training recommendations or coaching chatbots) to support those objectives.

In addition, organizations should define Key Performance Indicators (KPIs) for their AI-enhanced HR processes that link to strategic outcomes. For example, if strategic focus is agility, a relevant KPI might be reduction in time-to-fill positions; if the focus is employee experience, a KPI might be improvement in engagement survey scores. Tracking such metrics helps HR demonstrate AI's contribution to organizational performance, sustaining executive support for AI initiatives and ensuring projects remain driven by clear business needs rather than technology hype. Scholars also suggest using a Technology-Organization-People

perspective to achieve alignment (Malik et al., 2024) – in essence, the AI technology must fit the organizational context and the people who use it. In practice, this means choosing AI solutions appropriate for the company's scale and culture, and tailoring implementation to the organization's specific context.

Finally, aligning AI with HR strategy requires a commitment to the sustainability of AI initiatives. Organizations should treat AI integration as a continuous journey rather than a one-off project – regularly reevaluating whether HR AI systems are meeting their intended purpose and adjusting them as business needs evolve. This includes staying attuned to external changes (such as new AI regulations or shifts in the labor market) and adapting accordingly. In essence, AI should be managed as an ongoing enabler of the HR vision (whether it is becoming an employer of choice, building a high-performance culture, etc.), with its use continually calibrated to serve that vision. Done successfully, this ensures that AI not only helps achieve strategic HR goals, but that the pursuit of those goals also guides the ethical and effective evolution of AI in the organization.

6 Discussion and Theoretical Contributions

The foregoing analysis provides several theoretical contributions to the understanding of AI integration in HRM. First, by focusing explicitly on the operational HRM domain, we extend Tursunbayeva's (2024) configurational framework by deepening the analysis of the operational HRM–AI nexus and addressing the implementation challenges. Our analysis shows that "leaving operational HRM to AI" is not merely a technical change but one that requires redistributing HR efforts across operational, relational, and transformational domains. We reinforce Tursunbayeva's idea that efficiency gains at the operational level must be accompanied by adjustments at the relational and strategic levels (e.g., upskilling HR staff and refocusing their roles) to fully realize AI's benefits. This extension adds nuance by illustrating that automating operational tasks creates an imperative for HR professionals to assume more consultative and strategic functions – a dynamic her framework implies but does not detail.

Second, we integrate complementary theoretical perspectives (e.g., the Technology–Organization–People lens) to broaden her framework, emphasizing that technological innovation must be coupled with organizational readiness and human factors. This synthesis yields a more holistic model for AI-driven HRM that can better guide empirical research. Future studies might, for example, examine which organizational contexts or leadership behaviors best facilitate the transition of operational HRM to AI.

Third, we extend the practical relevance of Tursunbayeva's framework by translating its abstract principles into actionable recommendations. Our proposed strategic pathways – from establishing AI governance committees to phasing in adoption and aligning AI with HR strategy – operationalize the idea of responsible, inclusive AI integration. These propositions offer a basis for future empirical research (for example, investigating whether organizations with formal AI governance in HRM experience higher stakeholder trust) and advance the conversation initiated by Tursunbayeva.

Overall, this study supports and extends Tursunbayeva's (2024) framework by deepening the exploration of the operational HRM–AI interface and by integrating additional lenses that address implementation challenges. It also provides a more balanced narrative that neither celebrates AI uncritically nor rejects it, but rather outlines conditions under which AI's promises can be realized in harmony with human values and strategic objectives. By doing so, we hope to advance the theoretical discourse on AI in HRM from broad frameworks toward more refined models that account for the socio-technical complexity of this transformation.

7 Conclusion

Artificial Intelligence is driving a paradigm shift in how operational HRM activities are carried out. This paper has examined the opportunities, challenges, and strategic pathways associated with shifting operational HRM to AI. On the opportunity side, we found that AI can dramatically improve efficiency, accuracy, and decision quality in routine HR tasks, while also freeing human professionals to engage in more strategic, high-impact work. On the challenge side, we identified critical ethical risks (such as bias and privacy issues) and human factors (such as skill gaps and resistance) that must be managed to ensure successful AI adoption. The analysis led to a set of strategic recommendations, including adopting responsible AI practices, investing in change management and skills, and aligning AI initiatives with the organization's strategic HR goals.

The overarching thesis of this study is that AI will augment rather than replace the human element in HRM – but only if organizations deliberately design it to do so. In other words, the shift of operational HRM to AI can create tremendous value, but it requires a thoughtful approach that safeguards ethical principles and elevates the role of HR practitioners. This perspective extends and enriches Tursunbayeva's (2024) framework,

underlining the importance of coupling technological innovation with organizational strategy and human-centric considerations.

For researchers, this work opens avenues to further investigate AI in HRM through a multi-faceted lens, and for practitioners it offers a roadmap for navigating AI implementation in HR. As AI technologies continue to evolve (e.g., the rise of generative AI tools in HR), the core insight remains that the ultimate effectiveness of AI in human resource management will depend on how well we integrate the "human" with the "artificial." By embracing AI's capabilities while upholding human values and strategic clarity, HRM can transform into a function that is both operationally excellent and a driver of sustainable organizational success.

8 Ethics declaration

The paper doesn´t need ethic approval or declaration. It doesn´t use data collection.

9 AI declaration

The authors used ChatGPT to assist in the literature search and to improve the clarity of the English language in some sections. The outputs from the tool were critically reviewed and validated by the authors to ensure academic rigour and integrity.

Artificial Intelligence and Microfinance: Enhancing Social Inclusion and Value Creation for Immigrant Communities

Esri Nyituriki
University of Messina, Messina, Italy

Abstract

This paper explores how Artificial Intelligence can transform microfinance to promote social inclusion and value creation for immigrant communities. Despite immigrants' significant potential to contribute to local economies, they often encounter substantial barriers to accessing formal financial services, including limited credit histories, regulatory challenges, and cultural or linguistic differences. AI technologies, particularly machine learning, predictive analytics, and Natural Language Processing, provide innovative pathways to overcome these challenges by enabling inclusive credit scoring, automated multilingual support, and scalable, personalized financial services.

Employing a Systematic Literature Review guided by Preferred Reporting Items for Systematic reviews and Meta-Analyses and structured through the Population, Intervention, Comparison, and Outcome framework, this study critically evaluates 52 peer-reviewed sources to assess the effectiveness and impacts of AI-driven microfinance compared to traditional microfinance methods. Findings indicate that AI significantly enhances financial accessibility, facilitates immigrant entrepreneurship, and fosters broader social inclusion through culturally and linguistically adapted financial solutions.

A central contribution of this research is the integration of the Intellectual Capital framework, comprising human, structural, and relational capital, to examine the essential conditions for successful AI adoption in microfinance institutions. Human capital is crucial for developing skills in ethical AI deployment, structural capital ensures robust technological infrastructures, and relational capital builds essential trust between institutions and immigrant communities, thus ensuring sustainable and inclusive outcomes.

This study aligns with Sustainable Development Goals 8 (Decent Work), 9 (Industry, Innovation, and Infrastructure), and particularly SDG 10 (Reduced Inequalities). It provides actionable insights and strategic recommendations for financial institutions, policymakers, and fintech firms. To realize AI's full potential in immigrant social inclusion, the paper emphasizes the necessity of ethical AI frameworks, targeted capacity-building initiatives, and trust-based service models, ultimately contributing to more inclusive and equitable societies.

Keywords: Artificial Intelligence, Intellectual Capital, Microfinance, Social Inclusion, Value Creation.

Paper type: Academic Research Paper

1 Introduction

The persistent financial exclusion of immigrants poses a significant barrier to their social and economic integration in host societies. Although immigrants contribute meaningfully to labour markets, entrepreneurship, and cultural diversity, they often lack access to formal financial services due to undocumented credit histories, unstable employment, and institutional biases (Chibba, 2009; Ozili, 2020; Biswas & Gupta, 2022). Traditional banking systems, reliant on rigid credit scoring models and identification documentation, tend to overlook the informal economic activities in which many immigrants engage (Moro Visconti, 2020; Sarma & Pais, 2011). As a result, many turn to informal lending channels that are costly, unreliable, and unregulated, further deepening their economic vulnerability.

Microfinance has emerged as a viable tool to bridge this gap by offering small-scale financial services to underserved populations. However, despite its contributions, traditional microfinance institutions (MFIs) still face limitations such as inefficient manual processes, narrow credit assessment tools, and a lack of scalability (Armendáriz & Morduch, 2010; Haefner & Morf, 2021; Lwesya & Mwakalobo, 2023). These limitations highlight the need for digital innovation to enhance financial inclusion.

Artificial Intelligence (AI) has introduced transformative capabilities into the financial sector. With technologies like machine learning, predictive analytics, and Natural Language Processing (NLP), AI enables data-rich, automated, and inclusive financial services. For immigrant communities in particular, AI facilitates alternative credit scoring using data such as remittances, mobile transactions, and behavioural patterns, thereby reducing reliance on traditional metrics (Kaplan & Haenlein, 2019; Gama & Magistretti, 2025). NLP-driven virtual assistants also address language barriers, improving user experience and financial literacy (Russell & Norvig, 2024; Suleiman & Kwok, 2025).

The integration of AI not only supports financial access but also contributes to broader value creation. Immigrants gain economic empowerment through entrepreneurial support and more inclusive credit options,

while MFIs benefit from operational efficiency, fraud detection, and cost reduction (Li & Duan, 2025; Sachs, 2015). Socially, AI strengthens community networks and trust through adaptive service delivery and peer-support platforms (Granovetter, 1985; Putnam, 2000). Yet, ethical risks such as algorithmic bias, privacy concerns, and opacity in decision-making remain key concerns in digital lending (Binns, 2020; Mittelstadt et al., 2016). Addressing these issues requires ethically governed AI systems that are transparent, explainable, and inclusive.

In this context, this study investigates how AI-powered microfinance models enhance social inclusion and value creation for immigrant communities. It also examines the enabling role of Intellectual Capital (IC), including human, structural, and relational dimensions, in ensuring ethical, sustainable, and inclusive adoption of AI in financial services (Edvinsson & Malone, 1997; Bontis & Serenko, 2022; Kianto et al., 2017).

The study is guided by the following research questions:

- How does AI-driven microfinance enhance social inclusion by expanding financial accessibility and economic participation for immigrant communities?
- In what ways does AI-driven microfinance contribute to value creation, fostering economic empowerment, financial stability, and entrepreneurial opportunities for immigrants?
- How does Intellectual Capital (human, structural, and relational) influence the successful adoption of AI in microfinance, ensuring socially inclusive and sustainable financial solutions aligned with Sustainable Development Goals (SDGs) 8, 9, and 10?

To address these questions, this study adopts a Systematic Literature Review (SLR) methodology. The review follows the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines to ensure transparency, rigor, and replicability (Moher et al., 2009) while employing the Population, Intervention, Comparison, and Outcome (PICO) framework to structure the research focus on immigrant populations, AI-based interventions, traditional finance comparisons, and social and economic outcomes (Vesperi & Coppolino, 2023).

This article is structured into five key sections. Following this introduction, the next section presents the theoretical background, exploring the role of AI and IC in microfinance and their implications for social inclusion. The third section outlines the methodology, detailing the SLR process. The fourth section presents the main findings, focusing on how AI enhances financial accessibility, value creation, and institutional scalability for immigrant communities. Finally, the last section offers a discussion of the results and presents conclusions, highlighting practical implications, ethical considerations, and directions for future research.

2 Theoretical Background

This section provides the theoretical foundations underlying the transformative role of AI in microfinance, particularly in enhancing social inclusion and value creation for immigrant communities. It begins by exploring how AI technologies can mitigate traditional barriers to financial inclusion faced by immigrants. It then discusses the economic value created through AI-powered microfinance, focusing on entrepreneurial empowerment and institutional efficiency. Subsequently, the section examines Intellectual Capital as an essential framework facilitating the ethical and effective adoption of AI technologies. Finally, research gaps are identified, underscoring this study's unique contributions to existing scholarship on AI, microfinance, and immigrant integration.

2.1 Artificial Intelligence and Microfinance: A Path to Social Inclusion and Value Creation

Artificial Intelligence is increasingly reshaping financial services, offering powerful tools for enhancing efficiency, personalization, and accessibility. In the context of microfinance, AI technologies such as machine learning, predictive analytics, and Natural Language Processing provide innovative solutions for addressing the needs of underserved populations, particularly immigrant communities (Kaplan & Haenlein, 2019; Russell & Norvig, 2024).

Microfinance has traditionally served as a gateway for financial inclusion by offering small loans, savings mechanisms, and financial education to marginalized groups (Chibba, 2009). However, legacy models rely on conventional credit scoring and manual processes, which often exclude immigrants due to a lack of formal financial history or identification (Ozili, 2020; Biswas & Gupta, 2022). AI mitigates these barriers by leveraging alternative data such as digital transactions, remittance flows, and behavioral patterns to assess creditworthiness more inclusively (Moro Visconti, 2020).

Moreover, NLP-powered tools break language barriers, enabling immigrants to access multilingual support, participate in digital banking, and improve financial literacy (Haefner & Morf, 2021). These applications support

deeper integration into the host economy and social systems, reinforcing AI's role as an enabler of both financial and social inclusion.

2.2 Economic Value Creation through AI in Microfinance

Beyond inclusion, AI contributes to economic value creation by empowering immigrant entrepreneurship, improving risk assessment, and enhancing operational scalability for microfinance institutions (Sachs, 2015; Gama & Magistretti, 2025). Predictive analytics enable customized loan offerings and more accurate credit scoring, which in turn reduce default rates and improve financial sustainability (Moro Visconti, 2020; Lwesya & Mwakalobo, 2023).

AI-driven automation also allows MFIs to reduce administrative costs and reallocate resources toward client services, extending outreach to hard-to-reach populations (Li & Duan, 2025). These efficiencies make microfinance more scalable and sustainable, while simultaneously fostering immigrant-led business development and community resilience.

2.3 Intellectual Capital and the Adoption of AI in Microfinance

The successful implementation of AI in microfinance depends not only on technology, but also on the strength of an institution's Intellectual Capital the intangible assets that support innovation and performance (Edvinsson & Malone, 1997; Kianto et al., 2017). The IC framework includes:

- Human Capital – The skills, ethical awareness, and digital competencies of staff and users. Financial professionals must be trained in responsible AI use to avoid unintended bias in decision-making (Kaplan & Haenlein, 2019).
- Structural Capital – The technological and organizational infrastructure that supports AI integration. This includes data systems, secure platforms, and adaptive credit scoring algorithms (Gama & Magistretti, 2025).
- Relational Capital – The trust-based relationships between MFIs and immigrant communities. Transparent and explainable AI models foster trust and encourage financial engagement (Haefner & Morf, 2021).

The interplay among these dimensions determines how effectively AI can be deployed to support inclusive, ethical, and sustainable financial systems. Yet, this link between IC and microfinance remains underexplored. This study addresses that gap by positioning IC as a foundation for AI-powered financial inclusion strategies.

2.4 Research Gaps and Study Contributions

Although AI's role in finance is well documented, its specific application to immigrant-focused microfinance remains limited. Prior research has primarily concentrated on corporate banking and generalized fintech solutions, often overlooking the nuanced challenges of immigrant communities (Kaplan & Haenlein, 2019; Ozili, 2020). Moreover, studies often fail to connect AI adoption with the IC necessary for sustainable implementation (Bontis & Serenko, 2022; Kianto et al., 2017).

Additionally, ethical concerns such as algorithmic bias and data misuse are frequently acknowledged but lack robust frameworks for mitigation (Binns, 2020; Suleiman & Kwok, 2025). This study contributes by:

- Synthesizing evidence on AI-powered microfinance and immigrant inclusion
- Exploring the IC-based enablers of responsible AI adoption
- Aligning findings with SDGs 8, 9, and 10 to ensure relevance to sustainable development

By filling these gaps, the study provides actionable insights for MFIs, fintech firms, and policymakers seeking to implement AI-driven financial solutions that are both effective and equitable.

3 Methodology

This study employs a SLR to examine the transformative potential of AI-driven microfinance in enhancing financial inclusion and value creation for immigrant communities. The SLR method was chosen for its structured, transparent, and replicable approach, which enables a rigorous synthesis of current knowledge across interdisciplinary fields (Nightingale, 2009; Caputo et al., 2018).

To ensure methodological rigor and clarity, the review process was guided by the PRISMA guidelines, which outline standardized procedures for identifying, selecting, and analyzing relevant literature (Moher et al., 2009; Thomé et al., 2016). Additionally, the PICO framework (Population, Intervention, Comparison, and Outcomes)

was used to organize the research focus and support a coherent structure for evaluating the literature (Vesperi & Coppolino, 2023).

The study defines its population as immigrant communities experiencing barriers to financial inclusion. The intervention of interest comprises AI-based microfinance tools, including predictive analytics, natural language processing, and machine learning applications. These are compared with traditional microfinance models that rely on manual credit scoring, conventional risk assessment, and paper-based administrative processes. The outcome dimension focuses on how AI-driven systems improve financial accessibility, foster entrepreneurial success, and contribute to broader social inclusion.

Table 1: Eligibility criteria for study inclusion (PICO Framework)

Component	**Definition**	**In This Study**
Population	Target group or problem area	Immigrant communities facing financial exclusion
Intervention	Approach being evaluated	AI-driven microfinance (ML, NLP, predictive analytics)
Comparison	Alternative or traditional method	Traditional microfinance relies on manual processing
Outcomes	Expected impact or benefit	Expanded financial access, entrepreneurship, and inclusion

To identify relevant studies, a comprehensive search was conducted across two major academic databases Scopus and Web of Science. These platforms were selected for their coverage of peer-reviewed literature across social sciences, technology, and development studies. Boolean logic and keyword combinations were used to narrow the search results and ensure precision.

Search queries included terms such as (“Artificial Intelligence” OR “Machine Learning” OR “AI-driven finance”) AND (“Microfinance” OR “Financial Inclusion”) AND (“Immigrants” OR “Migrant Communities”), as well as targeted combinations like (“Alternative Credit Scoring”) AND (“Social Inclusion” OR “Entrepreneurial Empowerment” OR “Value Creation”) and (“AI Ethics” OR “Algorithmic Bias”) AND (“Financial Services”).

Inclusion criteria were applied to ensure the relevance and quality of selected literature. Eligible studies had to be published between 2010 and 2024, written in English, and focus on AI applications in financial services, particularly in the context of microfinance or immigrant communities. Peer-reviewed journal articles, book chapters, and conference proceedings were prioritized. Studies were excluded if they were non-academic (e.g., blogs, reports), unrelated to the research focus, duplicates, or lacking theoretical and empirical depth.

The selection process proceeded in four key stages, consistent with PRISMA protocols. First, the initial database search produced 920 results. Second, titles and abstracts were screened for relevance, and duplicates were removed, narrowing the pool to 350 studies. In the third stage, a full-text review was conducted, eliminating articles that did not meet inclusion criteria or lacked sufficient focus on AI and immigrant financial access, resulting in 120 studies. Finally, after further quality assessment and relevance checks, 52 articles were selected for the final review. These studies were chosen for their strong conceptual grounding, methodological rigor, and direct engagement with issues related to AI-driven financial inclusion for immigrant populations.

After selecting the final set of studies, the bibliometric software *Vosviewer* was employed to enhance analysis and thematic clarity. Vosviewer facilitated the visualization of key literature clusters, highlighting prominent thematic interconnections, influential authors, and emerging trends within the research domain. Specifically, Vosviewer’s co-occurrence and bibliographic coupling analyses allowed for a robust identification of dominant themes and research gaps, enriching the manual thematic categorization and offering deeper insights into the scholarly landscape surrounding AI-driven microfinance and immigrant inclusion.

The selected studies were categorized into three thematic clusters based on the research objectives. The first theme, AI and financial inclusion, explored how intelligent systems enable access to credit and digital financial services for marginalized immigrant groups (Ozili, 2020; Biswas & Gupta, 2022). The second theme, AI and economic value creation, focused on how AI contributes to entrepreneurial development, cost efficiency, and scalable microfinance models (Moro Visconti, 2020; Lwesya & Mwakalobo, 2023). The third theme, Intellectual Capital and AI adoption, examined the critical role of human, structural, and relational capital in enabling inclusive, ethical, and effective AI integration in financial services (Bontis & Serenko, 2022; Kianto et al., 2017).

Triangulation and cross-referencing were applied to ensure the reliability and depth of findings. While the use of secondary data limits the ability to generalize across all contexts, the methodological design ensures a

comprehensive and up-to-date analysis. Moreover, the study acknowledges the rapidly evolving nature of AI technologies, calling for continued monitoring and further research as digital financial ecosystems expand.

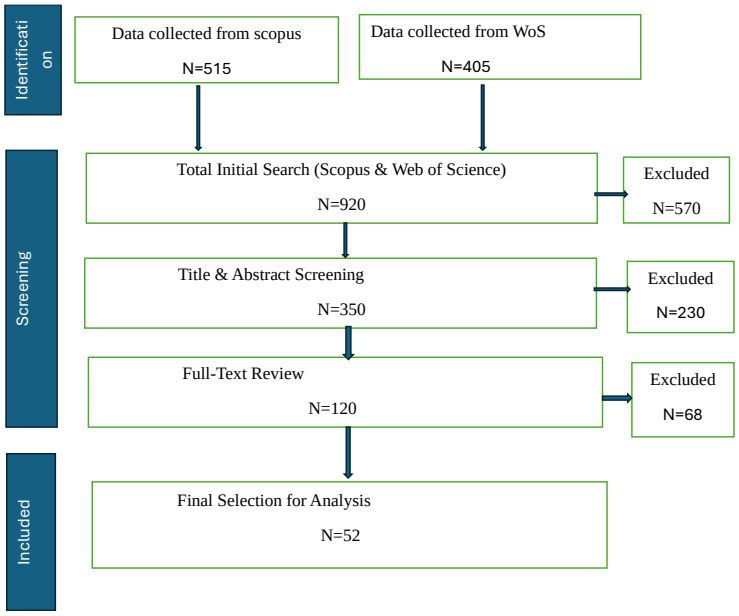

Figure 1: Study selection flow diagram.

4 Results

The findings from the systematic review highlight the significant potential of Artificial Intelligence (AI)-driven microfinance to foster social inclusion and economic empowerment among immigrant communities. Three central themes emerged clearly from the analysis of the 52 studies: (1) enhanced financial inclusion through AI technologies; (2) value creation via economic empowerment and institutional efficiency; and (3) the enabling role of Intellectual Capital (IC) in adopting inclusive AI systems.

Firstly, AI-driven microfinance significantly enhances financial and social inclusion for immigrant communities by addressing systemic barriers commonly experienced by these populations, including limited formal financial histories, linguistic barriers, and institutional biases. Several studies demonstrated that traditional microfinance institutions (MFIs), while instrumental in extending financial services, often fail to adequately reach immigrants due to reliance on conventional credit indicators (Chibba, 2009; Biswas & Gupta, 2022). In contrast, AI technologies, particularly machine learning and predictive analytics, use alternative data sources such as remittances, mobile transaction histories, and social behaviors, thus broadening eligibility and enabling immigrants to access formal credit and savings services (Gama & Magistretti, 2025; Ozili, 2020). This shift from conventional credit metrics directly supports social inclusion by reducing systemic discrimination in financial evaluations.

Moreover, the studies revealed the pivotal role of Natural Language Processing (NLP) in overcoming linguistic and cultural barriers to financial services, directly promoting inclusion. AI-powered multilingual chatbots and digital assistants provide real-time customer support, personalized financial literacy education, and culturally adapted financial products, significantly improving immigrants' understanding of complex financial services and fostering deeper engagement (Russell & Norvig, 2024; Suleiman & Kwok, 2025). Thus, AI technologies reduce informational and communicative barriers, empowering immigrant communities to actively participate in formal financial ecosystems.

Secondly, the analysis highlights how AI-driven microfinance promotes economic value creation, particularly by enhancing entrepreneurial capacities among immigrants. AI-based credit scoring and automated loan processing increase access to capital, enabling immigrants to launch and sustain businesses that contribute positively to local economies (Sachs, 2015; Moro Visconti, 2020). Additionally, studies found that AI systems help microfinance institutions optimize operational costs and reduce loan defaults through precise risk assessment, ultimately allowing MFIs to offer more affordable and accessible financial products (Li & Duan, 2025; Haefner & Morf, 2021). This combination of institutional efficiency and tailored services directly contributes to the economic stability and growth potential of immigrant entrepreneurs, further reinforcing their integration and social inclusion.

The third major theme identified from the literature was the critical enabling role of Intellectual Capital in ensuring the ethical, inclusive, and sustainable adoption of AI within microfinance institutions. The reviewed studies emphasize that successful AI integration depends significantly on human capital specifically the training of staff in ethical AI practices, bias mitigation, and inclusive service delivery strategies (Bontis & Serenko, 2022; Kianto et al., 2017). Equally crucial is structural capital, including robust technological infrastructure, data security, and transparent AI governance. The studies further highlight relational capital trust and strong community relationships as fundamental for AI systems to gain acceptance among immigrant populations, who may have historical reasons to distrust formal financial institutions (Haefner & Morf, 2021; Gama & Magistretti, 2025). Institutions leveraging these three dimensions of IC are best positioned to build AI systems that genuinely enhance social inclusion.

However, while recognizing these promising benefits, the reviewed literature also underscores significant challenges to fully realizing the inclusive potential of AI. Concerns related to algorithmic bias, data privacy, and digital literacy gaps were frequently noted. Specifically, AI systems trained on biased datasets risk perpetuating exclusion, disproportionately impacting immigrant groups (Binns, 2020; Mittelstadt et al., 2016). The findings suggest that addressing these ethical challenges requires proactive regulatory frameworks, transparent governance models, and targeted capacity-building initiatives to ensure that AI-driven microfinance remains truly inclusive and equitable.

Overall, these findings strongly suggest that AI-driven microfinance holds substantial promise for advancing the social inclusion and economic empowerment of immigrant communities. By explicitly addressing traditional barriers such as exclusionary credit practices, language obstacles, and institutional inefficiencies, AI technologies provide pathways toward genuine integration. At the same time, attention to Intellectual Capital highlights the importance of institutional readiness, ethical practices, and community trust-building as essential to unlocking AI's full potential for inclusive growth. These results provide valuable insights for policymakers, financial institutions, and technology providers committed to leveraging AI to meet the objectives of SDGs 8, 9, and especially SDG 10 (Reduced Inequalities).

Table 2: Thematic Clusters of Literature

Theme	Sample Authors	Key Contributions
AI & Financial Inclusion	Ozili (2020), Biswas & Gupta (2022)	Broadens credit access, uses alternative data, and enhances accessibility through NLP.
AI & Economic Value Creation	Moro Visconti (2020), Lwesya & Mwakalobo (2023)	Support entrepreneurship, reduce MFI costs, and enable scalable services.
IC in AI-driven Microfinance	Bontis & Serenko (2022), Kianto et al. (2017)	Human, structural, and relational capital enable ethical and effective AI adoption.

5 Discussion

This study aimed to examine the transformative role of Artificial Intelligence-driven microfinance in promoting social inclusion and economic empowerment for immigrant communities. The systematic literature review confirmed that AI significantly enhances financial inclusion by addressing traditional barriers, such as restrictive credit evaluations, linguistic and cultural barriers, and systemic institutional biases. By integrating alternative credit-scoring mechanisms based on remittances, digital transaction histories, and social financial behaviors, AI-driven systems offer a more inclusive evaluation of immigrants' creditworthiness (Ozili, 2020; Gama & Magistretti, 2025).

Furthermore, Natural Language Processing applications mitigate language-related obstacles, providing multilingual support and culturally adapted financial literacy programs, directly enhancing immigrants' integration into financial ecosystems (Russell & Norvig, 2024; Suleiman & Kwok, 2025). Thus, AI emerges as a powerful facilitator of social inclusion, enabling previously excluded populations to participate meaningfully in economic activities and financial systems.

Beyond fostering inclusion, the findings indicate that AI-driven microfinance contributes significantly to economic value creation. It supports immigrant entrepreneurship by providing timely access to working capital, reducing operational costs for microfinance institutions, and improving risk management through automated and precise risk assessments (Moro Visconti, 2020; Haefner & Morf, 2021). The resultant efficiencies allow MFIs to offer more accessible and affordable financial products, further supporting economic stability and growth within immigrant communities. These outcomes align closely with the broader sustainability objectives of the United Nations' Sustainable Development Goals, particularly SDG 8 (Decent Work and Economic Growth), SDG

9 (Industry, Innovation, and Infrastructure), and SDG 10 (Reduced Inequalities), reinforcing the strategic importance of AI applications in inclusive financial services.

The critical role of Intellectual Capital, encompassing human, structural, and relational dimensions also emerged prominently in the literature. Successful implementation of AI technologies in microfinance institutions hinges upon adequately trained human capital, including staff skilled in ethical AI practices and bias mitigation (Kianto et al., 2017; Bontis & Serenko, 2022). Structural capital, particularly robust digital infrastructures and transparent governance mechanisms, ensures scalability and secure service provision. Equally important is relational capital, defined by community trust, culturally sensitive communication, and institutional transparency, fostering enduring relationships with immigrant populations (Haefner & Morf, 2021; Gama & Magistretti, 2025). Investing in these intellectual capital dimensions can thus help MFIs realize the inclusive potential of AI-driven financial services.

However, despite these positive outcomes, the reviewed literature also identifies critical challenges related to algorithmic bias, data privacy, and digital literacy gaps, which could inadvertently reinforce exclusionary practices if left unaddressed (Binns, 2020; Mittelstadt et al., 2016). Addressing these ethical and practical challenges demands proactive regulatory frameworks, rigorous transparency standards, and targeted initiatives to enhance digital and financial literacy among immigrant communities. Institutional readiness and inclusive AI governance are essential for ensuring that AI-driven microfinance genuinely promotes equity and inclusion rather than deepening existing disparities.

6 Conclusion

In terms of practical and policy implications, this research offers several key insights. Policymakers should foster regulatory environments supportive of ethical AI standards, particularly emphasizing fairness, transparency, and data privacy. Financial institutions are advised to invest in human and structural capital, building robust technological capabilities alongside ethical AI training for staff. Fintech developers should prioritize co-designing AI solutions directly with immigrant communities, ensuring cultural sensitivity and practical relevance. Multilingual and inclusive platforms will further strengthen immigrant trust and facilitate deeper, more sustained integration into formal financial systems.

While comprehensive, this research acknowledges limitations inherent in systematic reviews, notably the reliance on secondary sources and the rapidly evolving nature of AI technologies, suggesting a need for continued, updated empirical investigation. Future studies should extend this research through field-based empirical analyses in diverse geographical contexts, particularly in developing countries or areas with significant immigration. Longitudinal studies exploring the sustained impact of AI-driven financial inclusion on immigrants' socio-economic resilience and integration would offer valuable additional insights.

In conclusion, this study demonstrates the significant potential of AI-driven microfinance to advance social inclusion, mitigate systemic inequalities, and create meaningful economic value for immigrant populations. By highlighting the critical role of Intellectual Capital and ethical considerations, the paper provides actionable guidance for policymakers, financial institutions, and fintech companies aiming to leverage AI technologies for inclusive and sustainable development. This research thus contributes not only to academic discourse but also to practical strategies for achieving global inclusivity aligned with the objectives of the Sustainable Development Goals.

7 Ethics Declaration

I, the author of this paper, affirm that the research was conducted with full adherence to academic and ethical standards. This study is based solely on the systematic review of existing academic literature from publicly accessible and peer-reviewed sources. No primary data involving human participants, personal data, or confidential materials was collected or analyzed. All scholarly contributions have been appropriately cited to ensure transparency, accuracy, and respect for intellectual property. I take full responsibility for upholding the principles of academic integrity and responsible research conduct.

8 AI Declaration

I confirm that no generative Artificial Intelligence tools were used in the authorship, drafting, or revision of this manuscript. While the subject matter of the paper includes the application of AI in financial services, the content presented here is entirely the result of the author's original analysis and synthesis of peer-reviewed academic literature. No AI-generated text, figures, or references were used in preparing this submission.

AI-driven Transformation in the Pharmaceutical Industry: Value Creation through Strategic Collaboration

Vincenzo Belfiore[1], Alberto Caratozzolo[2], Valeria Naciti[1], Daniela Rupo[1]
[1]University of Messina, Messina, Italy
[2]University Dante Alighieri, Reggio Calabria, Italy

Abstract

The pharmaceutical industry faces significant challenges, including prolonged drug development cycles (10-15 years), escalating costs (exceeding $1 billion per drug), and mounting pressures to align innovation with sustainability and transparency. This study investigates the transformative role of artificial intelligence (AI) in addressing these challenges, with a focus on value co-creation and environmental, social, and governance (ESG) integration (Prahalad and Ramaswamy, 2000, 2004; Vargo and Lusch, 2004). By analyzing sustainability reports and strategic documents from Johnson & Johnson (J&J) and NVIDIA through qualitative content analysis, this research identifies four thematic topics: AI in Sustainability Report, Value Co-Creation, AI and ESG and Transparency and Reporting. The study aims to find answers starting from how AI is represented in J&J and NVIDIA's reports, which initiatives are linked to the co-creation of value in drug discovery, development and distribution, to what extent are references to AI in line with ESG criteria, and finally what elements emerge regarding transparency and communication of AI practices.

Findings reveal that AI accelerates drug discovery through machine learning (ML) and deep learning (DL), enabling rapid analysis of genomic, proteomic, and clinical trial data. Applications such as virtual screening and predictive modelling reduce trial failures and optimize resource allocation, aligning with ESG goals like waste reduction and energy efficiency. The strategic collaboration between J&J and NVIDIA exemplifies value co-creation, merging pharmaceutical expertise with advanced computing to enhance R&D efficiency and patient-centric outcomes. For instance, NVIDIA's high-performance computing (HPC) infrastructure supports J&J's drug pipeline, reducing time-to-market while fostering sustainable practices.

The analysis highlights AI's dual role as a driver of operational innovation and a catalyst for stakeholder-driven sustainability. Transparency in AI reporting emerges as a critical factor, with both companies emphasizing ethical AI deployment and open communication. However, disparities exist in how AI's societal and environmental impacts are framed, underscoring the need for standardized ESG-aligned reporting frameworks. By bridging value co-creation theory (Prahalad & Ramaswamy, 2004) with empirical insights, this study demonstrates how cross-sector partnerships and AI integration can reconcile economic objectives with global sustainability imperatives. The research contributes practical insights for policymakers and industry leaders, advocating for collaborative, transparent AI adoption to advance both innovation and accountability in the pharmaceutical sector.

Keywords: Artificial Intelligence; Pharma Industry; Value Co-creation; ESG; Strategic Collaboration

Paper type: Academic Research Paper

1 Introduction

The pharmaceutical industry operates within a complex landscape marked by stringent regulatory frameworks, escalating R&D costs, and extended timelines for drug commercialization. Developing a single drug can require 10-15 years and investments exceeding $1 billion (Mohs & Greig, 2017), while stakeholders increasingly demand transparency, sustainability, and accountability. These pressures are amplified by global challenges such as climate change, health inequities, and the need for personalized medicine. In this context, environmental, social, and governance (ESG) criteria have become pivotal in shaping corporate strategies, compelling companies to align innovation with ethical and sustainable practices (Arvidsson & Dumay, 2022; Chen, 2024).

Artificial Intelligence (AI) has emerged as a transformative force in addressing these dual imperatives. Advances in machine learning (ML), deep learning (DL), and accelerated computing are revolutionizing the industry (Malsia, 2024; Kulkov, 2021), drug discovery, clinical trial design, and patient care. By analyzing vast datasets of biomedical studies, AI enables rapid identification of therapeutic targets, reduces trial failures, and personalised treatments (Secinaro et al., 2021). AI-driven tools like virtual screening and quantitative structure-activity relationship (QSAR) modelling optimize molecular design, while predictive analytics enhance diagnostic accuracy. Beyond operational efficiency, AI supports sustainability by minimizing resource waste and energy consumption in manufacturing.

However, AI's integration represents a paradigm shift in value creation. Grounded in value co-creation theory (Prahalad & Ramaswamy, 2004), this study examines how stakeholders - including corporations, technology

providers, and patients - collaborate to generate multidimensional value through digital and analogical communication in the context of unique management strategies (Centorrino et al., 2023). Value co-creation encompasses improved patient outcomes, reduces environmental footprints, and aligns with ESG objectives. AI supports open innovation models, where cross-sector partnerships, such as J&J-NVIDIA collaboration, merge pharmaceutical expertise with cutting-edge computing capabilities to accelerate drug discovery and delivery (Niewolny, 2024; J&J, 2024). NVIDIA's ecosystem enhances J&J's R&D through AI high-performance computing (HPC), demonstrating how alliances drive innovation and sustainability. These case studies offer implications for integrating AI-driven processes in the pharmaceutical sector within sustainable business frameworks, together with a source of value creation and competitive advantage. This can lead to innovation and strategy, and consequent optimization of the decision-making process (Cariola et al., 2007).

Despite AI's growing adoption, critical gaps persist in understanding its role in sustainability reporting and its alignment with ESG frameworks. Existing literature often focuses on AI's technical applications, overlooking its role in stakeholder-driven value creation and transparent reporting. This study addresses these gaps through four research questions:

- *RQ1: How is AI represented in the sustainability reports of J&J and NVIDIA?*
- *RQ2: Which AI initiatives are linked to value co-creation in drug discovery, development, and distribution?*
- *RQ3: To what extent do AI references in reports align with ESG criteria?*
- *RQ4: What elements emerge from the analyzed documentation regarding transparency, communication, and AI reporting?*

Adopting a qualitative framework, this research employs content analysis (Hsieh & Shannon, 2005) to examine sustainability reports and strategic documents from J&J and NVIDIA, uncovering AI as a driver of innovation and sustainability.

By bridging value co-creation theory with empirical analysis, this study advances understanding of AI's role in fostering sustainable, patient-centric healthcare. It highlights the importance of transparent AI reporting and cross-sector collaboration, providing actionable insights for industry leaders and policymakers.

The paper is structured as follows: after this introduction, the methodology will be explained in detail based on the content analysis framework, followed by findings organized around the four topics. The discussion contextualizes results within theoretical and practical implications, concluding with limitations and future research directions.

2 Methodology

This study adopts a qualitative content analysis approach (White & Marsh, 2006**;** Plakoyiannaki & Budhwar, 2021) to examine how J&J and NVIDIA integrate AI into their sustainability strategies and collaborative practices. Content analysis is a well-established methodology in business and sustainability research, particularly suited for systematically interpreting textual data from corporate disclosures (Krippendorff, 2018). By analyzing every document in a more in-depth approach, it is possible to provide information based on specific themes across different contexts (Conley & Tosti-Kharas, 2014). By examining sustainability reports, annual filings, and partnership documents, this method gives the possibility to identify recurring themes, emerging patterns, and implicit priorities in how these companies frame AI's role in value co-creation and ESG alignment.

Unlike quantitative methods that prioritize numerical data, qualitative content analysis offers a nuanced understanding of complex phenomena such as AI's societal impact or stakeholder collaboration by capturing contextual meanings and discursive strategies (Drisko & Maschi, 2016). This is especially relevant for our study, given the absence of standardized reporting frameworks for AI in the pharmaceutical sector. Corporate disclosures often vary in depth, terminology, and emphasis, making content analysis an ideal tool to navigate this heterogeneity (Wahyuningrum et al., 2023; Torelli et al., 2020).

2.1 Data collection and analytical framework

Data collection was obtained through a systematic analysis of NVIDIA and J&J's sustainability reports from 2019 to 2023. This timeframe was selected considering the presence of reliable public records of the two companies up to the most recent year (2023), to facilitate a balanced comparative background for the analysis. NVIDIA's 2024 report was publicly available, but it was intentionally excluded from the analysis to maintain temporal alignment with J&J, whose 2024 sustainability report had not yet been published at the time of the study. In both entities, the reports represent the main voluntary reporting tool for ESG performance and adhere to the leading global standards, which include the GRI (Global Reporting Initiative), the SASB (Sustainability

Accounting Standards Board), in some instances, the TCFD (Task Force on Climate-related Financial Disclosures), and the United Nations Sustainable Development Goals (UNSDG). The selected documents were downloaded from the official websites of the companies and examined manually using a content analysis method, which aimed to identify, classify, and code references to AI and its use in corporate strategy, sustainable practice, value co-creation initiatives, and reporting mechanisms. The coding was based on a conceptual matrix divided into four pre-established thematic macro-domains:

1. **AI in Sustainability Report**: captures citations in corporate sustainability reports, by paying close attention to the portrayal of AI at a strategic and operational level. Includes the application of AI as a digital innovation source, process automation, operational refinement, intelligent data management to enhance efficiency, cost reduction, and accelerate decisions for improving operational performance; finally, it includes tools for R&D, communication, or design.
2. **Value Co-creation**: Collaborative AI-driven strategies across drug development phases. It applies to how AI is used through collaborative logics in a manner that generates value co-shared by the subjects of the firm. Covers concepts on open innovation, strategic collaborations, and partnerships between private and public companies, institutions, and organizations in the healthcare industry.
3. **AI and ESG**: This topic tracks how AI is integrated with environmental, social, and governance objectives. All references related to inclusiveness, emission reduction, data governance, and resource management, as well as AI, will be included in this topic.
4. **Transparency and Reporting**: Focuses on how companies communicate AI initiatives and ethical considerations, as well as reporting of AI activities by companies, in terms of transparency, accountability, and performance reporting, together with strategic impact assessment where AI is mentioned. Strategic importance, risks involved, and expected effects will be considered in this topic.

Subsequently, the main topics were further divided into analytical subcategories briefly summarized in Table 1.

Table 1: Topic breakdown and search words.

Topic	Subcategory	Keywords
AI in Sustainability Report	Digital Transformation	AI-driven platform, generative AI, AI innovation, machine learning, deep learning
	Generative AI	
	Productivity	
Value Co-creation	Open Innovation	Collaborative R&D, AI-enabled diagnostics, cross-industry platforms, startup ecosystem, public-private partnerships
	Strategic Partnership	
	Collaboration	
AI and ESG	Emissions Reduction	ESG, Sustainable, digital health equity, ESG strategy, SDG, sustainable computing
	Inclusivity and AI	
	Data governance	
	Resource management and AI	
Transparency and reporting	Impact metrics	GRI, SASB, CDP score, transparency, stakeholder engagement, Code of Conduct, AI disclosure
	Strategic disclosure	
	ESG reporting	

Source: Our reworking

Each instance was mapped into one or more categories by an interpretive reading of the context for correspondence between the RQs and the theoretical objectives of the study. Finally, the evolution of the contents over time was followed through the longitudinal comparison of the reports, also structurally, sections dedicated to AI, and the purposes declared by the companies.

The analysis followed a three-step process:

1. Exploratory coding: Initial review of documents to identify explicit and implicit references to AI, sustainability, reporting, ESG, co-value creation, and collaboration;
2. Identifying topics: grouping of coded extracts into four predefined categories (Transparency and Reporting; AI and ESG; AI in sustainability report; Value co-creation);
3. Contextual interpretation: linking themes to theoretical frameworks (e.g., value co-creation theory) and industry-specific challenges. To improve rigor, we refined the categories and triangulated the results to compare the different reports**.**

Content analysis reveals both what companies are saying about AI and how they are saying it (Gioia et al., 2013). The sources retrieved from the respective companies' official channels were selected to analyze the evolution of relevant information over time. In this case, J&J and NVIDIA represent commonalities related to the object of analysis from the technological, pharmaceutical, and strategic collaboration point of view, coming from

both parties. The reports cover a five-year period, as previously indicated, and through the content analysis approach, it is possible to verify the actual temporal evolution and project development in the research area. The downloaded sustainability reports show an overall stable structure, with some variations over time in the amount of relevant content, which will be explained in the next section. Overall, the presence of content related to ESG and AI, implicit and explicit, is highlighted in several parts of the documentation in the most recent years of the timeline. The unit of analysis was defined following a comparison with the research group. The criteria for textual citations referring to AI and consequent related themes (i.e., digitalization, innovation, ethics, sustainability) were identified, along with their direct implications of the use of AI (i.e., data-driven approach).

Data coding was conducted manually, based on the extraction of references reported within the respective documents and subsequently reported on a conceptual grid, identifying the corresponding topic for each citation. It was therefore necessary to decode strategic expressions based on the context.

This methodology contributes to the academic debate on an innovative and rapidly growing topic, which we expect in the coming years will be of fundamental importance for the discovery of new drugs and new development practices, providing a replicable framework for future research on transparency and ESG alignment in emerging technologies.

In the next section, the research findings will be presented, with the aim of shedding light on the aspects related to each research question.

3 Findings

The qualitative analysis carried out by reading and extrapolating data from J&J and NVIDIA reports explored discursive methods, the narrative, and the differences in the structure with which the evolution of AI themes and the respective research topics evolved. The analysis of the impact of AI on J&J sustainability reports presents a fragmented evolution that has consolidated only over the years, starting to give greater relevance from 2020. AI in this sector is integrated into corporate practices as an enabling tool for public health, healthcare digitalization, and value co-creation in the clinical and pharmaceutical fields. Projects that involve the implementation of AI are those related to collaborations – i.e., Our Future Health, European consortia, and partnerships with regulatory bodies – mainly focused on early diagnosis, fairness of clinical trials, and the administration of healthcare data. In the ESG field, J&J integrates AI to Health for Humanity goals, showing emphasis on inclusion, transparency, and the reduction of inequalities. The language used is evaluative, with many references to ethical duty, equity, and social sustainability.

In NVIDIA's reports, AI becomes central. Since 2020, NVIDIA report that AI represents "*the most profound shift in our era, […] NVIDIA accelerates this revolution by creating advanced computing tools that serve as open platforms for developers, researchers…"*. It is therefore possible to deduce that there is great interest in supporting this technology, highlighting how it is possible to create value in strategic collaboration with companies and stakeholders. From 2021, generative AI, "trustworthy AI", and the transformational potential of platforms (i.e., NVIDIA Clara) gain prominence. Sustainability and performance intersect in application ranging from traditional to GPU-based accelerated computing. Despite the presence of ESG references, more technical than regulatory passages are noted; the concept of transparency is highlighted on the basis of information relating to international standards, but is not fully explored in the case of reporting on social impacts. The tone used in the evolution of reports is assertive, with a vision that reflects the company's technological leadership.

Below are the results collected and organized in the four interpretative topics, aligning them with the research questions previously mentioned and the aim of being able to highlight the evolutionary change over time, by both companies.

To answer RQ1 - i.e., how is AI represented in the sustainability reports of J&J and NVIDIA - it is necessary to refer to the evolving state of the reports. The analysis reveals two distinct visions. J&J initially mentioned AI sporadically in 2019, with references increasing notably from 2020 onward **(Figure 1)**. By 2022, AI became central to its Health for Humanity initiatives, portrayed as a tool for equitable healthcare access and ethical innovation, with terms like "patient-centric AI" and "data-driven clinical equity" in social sustainability field. In contrast, NVIDIA has mentioned AI more frequently since 2020, declaring it "the most profound change of our era" (NVIDIA, 2020). The company emphasizes its scalable infrastructure, with recurring terms such as "accelerated computing" and "open platforms". By 2023, 75% of NVIDIA's sustainability content refers to AI-based solutions, underscoring its role as a technology enabler rather than an end-user.

Specifically, the AI mentioned by J&J is mainly reported to health, innovation, operational efficiency, and clinical care contexts. The language used aims at ethical guarantees and community impact with regard to human health. The description made by NVIDIA about AI technology is more defined and detailed in its business model and business plan. In fact, the application of AI is reported in various fields, from healthcare to the energy

performance of data centers. As regards the evolution of the topic, the presence of AI emerges incrementally, on average following a growing trend in the case of J&J, and is stable for NVIDIA.

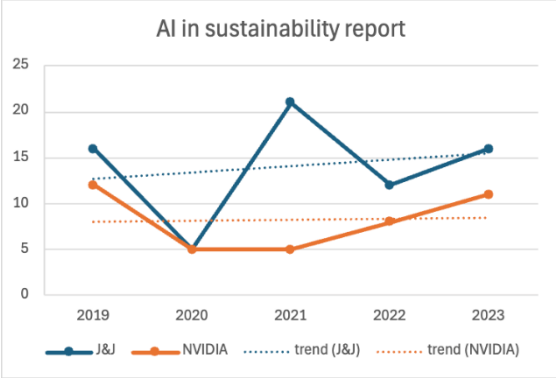

Figure 1: Topic 1 - AI and sustainability report

In more detail, at J&J, AI is often embedded in broader initiatives like data science, digital health, and transformation, becoming more visible from 2020 with integration into ESG strategies and healthcare innovation projects. The 2021 Health for Humanity report emphasizes AI and automation as key to transforming healthcare and strengthening internal digital skills. J&J uses a narrative centered on human well-being, focusing on AI for diagnostics and public health.

NVIDIA, by contrast, highlights AI's role in energy efficiency, sustainable computing, and overall business performance. While J&J views AI as an enabler of ethical and inclusive innovation in medicine, NVIDIA presents it as a core asset for strategic positioning and environmental impact. Both companies reference AI from 2019, with J&J offering more detailed insights from 2022–2023, and NVIDIA expanding its focus to generative AI starting in 2021.To answer RQ2 - i.e., which AI initiatives are linked to value co-creation in drug discovery, development, and distribution – the corresponding topic will give the possibility to know the collaborative paradigm of AI in the concept of value. Value co-creation allows to carry out partnerships between public and private networks, regulatory bodies, and research centers. As can be seen from the reports, the cases align pertinently to the designated topic.

As exemplified in **Figure 2**, a growing focus on value co-creation is confirmed, especially in 2023. J&J shows high frequency and narrative coherence, going from 13 citations in 2019 to 19 in 2023, while NVIDIA experiences a growth in 2023, from 3 citations in 2019 to 22 in 2023. According to this perspective, it can be noted that J&J possesses a consolidated and systematic approach, biased in the direction of concrete and long-term healthcare programs, whereas NVIDIA has intensified the communication related to the co-creation, together with project work in the pharma environment in recent times, reflecting a shift in gears over the last couple of years.

From a first consideration for J&J in a co-creation context, the Janssen pharmaceutical business part of the division uses AI to investigate medical datasets (i.e., medical records, generic data) in order to be able to verify the differences and genetic variations, thus implementing a predictive analysis on diseases. In this way, the process will be characterized by the presence of molecules that interact with specific targets, reducing side effects and optimizing potential drugs. A symbolic initiative is BLUE KNIGHT™, a collaboration with the Biomedical Advanced Research and Development Authority (BARDA) to accelerate innovation in breakthrough technologies to forecast emerging health threats (J&J, 2023). The initiative reflects the company's commitment to building private and public co-development ecosystems. J&J has also developed algorithms for tumor burden measurements, with collaboration from external actors, "*to better quantify tumor burden across several types of cancer and measure the effects of treatment more accurately and rapidly"* (J&J, 2023).

Another example of value co-creation implemented by the same company is to identify clinical research sites with suitable patients using AI, to facilitate the inclusion of diverse populations in trials. Treatments developed with this approach aim to improve accessibility and representativeness of the general population. Furthermore, in the field of the pharmaceutical supply chain, AI is used by the company to predict potential questions and to optimize the distribution of pharmaceutical products.

NVIDIA views co-creation from the infrastructure and facilitation perspective, constructing computing environments upon which participants in the pharmaceutical and healthcare sectors can collaborate to accelerate the R&D cycle. The Clara Discovery platform, "*…to bring AI to medical imaging systems and make it easier for all hospitals to adopt them"*, is designed to reduce the time and cost of the R&D cycle. The co-creation

rationale also arises, especially in partnership with Medtronic, the behemoth multinational business dealing in medical devices, for whom NVIDIA is building an AI platform for software-defined devices.

A public declaration of such an approach is found in the MONAI platform, which has been adopted by a consortium of ten UK hospitals, "*providing AI-enabled disease detection tools to healthcare professionals serving five million patients a year"* (NVIDIA, 2023). This is the model whereby NVIDIA facilitates the implementation of AI-based solutions even for public health entities, enabling higher-order diagnostics.

Finally, firms like Evozyne have leveraged NVIDIA's BioNeMo platform to design therapeutic proteins with generative models for *"novel proteins for diseases and even for climate change"*. NVIDIA's contribution in this regard comes in terms of providing scalable and interoperable tools, which make AI possible and integrable into biotech projects with significant transformative potential.

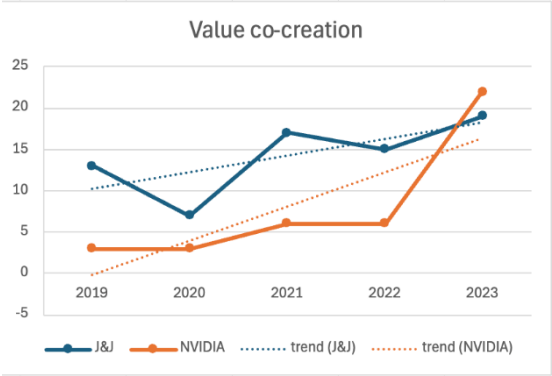

Figure 2: Topic 2 – Value co-creation

To answer RQ3 – i.e, to what extent do AI references in reports align with ESG criteria – the analysis reveals distinct priorities in how J&J and NVIDIA integrate AI into their sustainability narratives. Both companies link AI to ESG objectives, but emphasis diverges significantly, reflecting sector-specific agendas and reporting gaps.

As illustrated in **Figure 3**, J&J's ESG-linked AI citations grew steadily from 4 mentions in 2019 to 17 in 2023, while NVIDIA's peaked at 16 mentions in 2020 and 2022, with a dip in 2021. Over 70% of J&J's AI and ESG references focus on social equity. 65% of NVIDIA's AI and ESG citations highlight energy-efficient computing (e.g., 2022: "AI-optimized data centers reduce emissions by 25%") and sustainable infrastructure (e.g., "GPU acceleration lowers energy consumption in drug discovery").

J&J aligns AI with Social and Governance pillars, emphasizing "health equity", AI for equitable diagnostics, and "ethical oversight", human-centric AI governance frameworks. NVIDIA prioritizes Environmental and Governance criteria, focusing on sustainable computing, energy-efficient AI infrastructure, and technical compliance, alignment with GRI and SASB standards.

Despite social focus, only 20% of J&J's AI and ESG citations address environmental impacts (e.g., AI's role in reducing clinical trial waste). While leading in environmental metrics, NVIDIA's reports lack actionable metrics on AI's societal equity outcomes (e.g., workforce diversity in AI teams). Both companies use inconsistent ESG frameworks, making cross-sector comparisons challenging. For instance, J&J references the UNSDGs, while NVIDIA prioritizes the GRI.

In 2019 and 2020, references to AI and ESG were vague. J&J's 2020 report mentioned AI's "potential for social good" without metrics, while NVIDIA highlighted "efficiency gains" without ESG context. In the following years, from 2021 onwards, reporting matured. J&J quantified AI's impact on health equity (e.g., 30% faster diagnosis in rural clinics), and NVIDIA tied AI to emissions reductions (e.g., 2.5M tons of CO2 saved via AI-optimized workflows).

J&J and NVIDIA align AI with ESG criteria, their priorities reflect core business identities. In fact, J&J anchors AI in social dynamics, whereas NVIDIA leverages AI for environmental efficiency. In conclusion, gaps in holistic ESG integration, particularly NVIDIA's underreporting of social impacts and J&J's limited environmental focus, highlight the need for standardized frameworks to evaluate AI's role in sustainability.

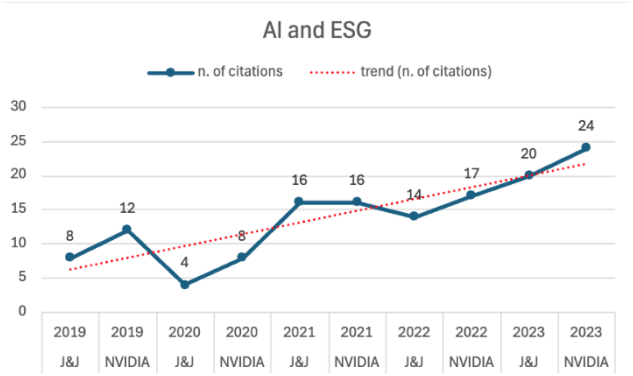

Figure 3: Topic 3 – AI and ESG

To answer RQ4 – i.e, what elements emerge from the analyzed documentation regarding transparency, communication, and AI reporting – the analysis of these topics reveals a nuanced interplay between sectoral priorities and ethical imperatives.

For J&J, transparency in AI reporting is deeply intertwined with its mission to advance equitable healthcare. The company's narrative emphasizes ethical accountability, presenting AI as a tool to bridge healthcare disparities. For instance, J&J's 2022 report states: "*Transparency in AI is not optional - it is a moral obligation to ensure equitable healthcare outcomes"* (J&J, 2022). However, J&J's transparency efforts lean heavily on qualitative narratives, with limited technical details on AI architectures or data governance frameworks. This gap aligned with its stakeholder-centric ethos, leaves questions unanswered about the scalability and environmental trade-offs of its AI infrastructure.

In contrast, NVIDIA prioritizes metrics-driven disclosures and compliance with global standards. Its reports include granular data, such as its 2023 claim of a "*0% reduction in power consumption per GPU topic"* through AI-optimized data centers. NVIDIA's emphasis on open-source platforms, like Clara, enables third-party scrutiny and aligns with its identity as a technology enabler. Yet, this technical focus often overshadows societal considerations. Despite NVIDIA's alignment with GRI/SASB standards, its reports sidestep discussions on AI's societal risks, such as workforce displacement or algorithmic bias. For example, NVIDIA's 2021 report asserts, "*Open-source AI frameworks and explainable models are foundational to trustworthy innovation"* yet lacks actionable metrics on equity outcomes or community impacts (NVIDIA, 2021).

Temporally, both companies evolved from vague early disclosures to more structured frameworks. As shown in **Figure 4**, in 2019-2020, J&J's references to "*ethical AI*" were lacking concrete examples, while NVIDIA highlighted technical advancements like GPU upgrades without ESG context. By 2022-2023, J&J introduced *AI impact assessments* to quantify health equity gains, such as "*30% faster diagnosis in rural clinics"*, and NVIDIA linked AI performance to emissions reductions, claiming "*2.5M tons of CO_2 saved via AI-optimized workflows".* Despite these advancements, benchmarks remain fragmented: J&J aligns with UNSDGs and NVIDIA reports under GRI/SASB frameworks.

Critical gaps persist. J&J's underreporting of environmental trade-offs, such as energy demands for AI-driven drug discovery, contrasts with NVIDIA's silence on workforce diversity in AI teams. Neither tackles privacy issues in genomic AI. These omissions underscore the need for harmonized standards that integrate technical rigor with societal accountability.

Ultimately, J&J and NVIDIA exemplify two paradigms of AI transparency – ethical storytelling vs. technical precision – highlighting the fragmented state of AI governance, urging policymakers to advocate for frameworks that reconcile these approaches. Only through holistic transparency AI can fulfill its promise as a force for sustainable, equitable innovation in healthcare and beyond.

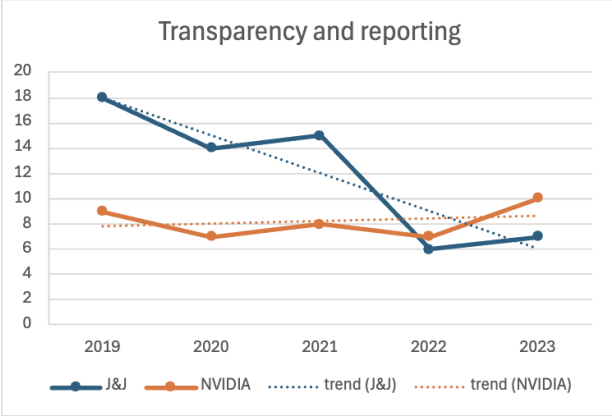

Figure 4: Topic 4 – Transparency and reporting

4 Discussion and conclusion

The findings of this study highlight the transformative role of AI in the pharmaceutical industry, particularly through the strategic collaboration between J&J and NVIDIA. Their partnership demonstrates AI's dual function: enhancing operational efficiency and advancing stakeholder-driven sustainability.

Rooted in value co-creation theory (Prahalad & Ramaswamy, 2004), the collaboration shows how cross-sector alliances create shared value. J&J leverages NVIDIA's AI tools—such as in digital surgery—to support training, collaboration, and diagnostics, advancing its goal of patient-centered care. NVIDIA's generative AI platform, BioNeMo, accelerates drug discovery by up to 40%, as shown in partnerships with firms like Genentech and Recursion Pharmaceuticals. These joint efforts reduce R&D time and resource use, contributing to ESG objectives such as emissions reduction and health equity.

J&J and NVIDIA offer complementary approaches: J&J emphasizes ethical, inclusive AI applications in clinical trials, while NVIDIA provides the high-performance infrastructure to scale them. Their 2024 collaboration on AI for surgical decision-making highlights this synergy, incorporating real-time analytics and edge computing into healthcare.

Despite shared goals, differences emerge in ESG reporting. J&J emphasizes social sustainability, equity, and ethical oversight, often referencing the UN SDGs. NVIDIA focuses on environmental performance, citing a 30% energy efficiency gain per GPU through AI-optimized data centers and adhering to GRI standards. These distinct ESG framings reflect broader challenges in standardizing AI sustainability reporting across sectors, as inconsistent frameworks complicate holistic assessments of impact (Arvidsson & Dumay, 2022Transparency practices further reveal divergent priorities. J&J adopts a narrative-driven approach, publishing *Responsible AI Guidelines* and prioritizing patient feedback, yet lacks technical details on data governance. NVIDIA, conversely, emphasizes technical transparency through open-source platforms and granular metrics (e.g., 30% energy reduction per GPU topic) but sidesteps societal risks like algorithmic bias. The rapid adoption of AI in healthcare, with 41% of biotech CEOs actively integrating generative AI, demands urgent policy action. These gaps underscore the need for harmonized standards that integrate ethical accountability with technical rigor, as advocated by recent policy initiatives (Moggi, 2023).

In conclusion, this study demonstrates that AI's integration into the pharmaceutical sector transcends technological adoption, it redefines value creation by merging innovation with sustainability imperatives. The strategic collaboration between J&J and NVIDIA reconciles pharmaceutical expertise with computational scalability, reducing drug development cycles while advancing ESG objectives. Sector-specific biases in AI and ESG alignment highlight the urgency for standardized frameworks to ensure holistic sustainability evaluations. Balancing ethical narratives with technical disclosures is critical to building stakeholder trust and ensuring AI's equitable deployment.

This study concedes its limitations. Future research could expand to include smaller firms or an analysis of AI's long-term ESG impacts. Additionally, the exclusion of NVIDIA's 2024 report (to maintain parity with J&J) suggests a need for updated studies as newer data emerges.

In conclusion, the promise of AI in the pharmaceutical industry lies in both speeding up innovation and promoting a sustainable and equitable healthcare ecosystem. By addressing reporting gaps and fostering collaborative governance, the industry can ensure AI serves as a force for global good, transforming drug discovery while upholding ethical and environmental stewardship.

Remote Working and Public Administration: Implications for Relationships with External Users

Antonietta Cosentino, Carla Morrone, Salvatore Principale, Alessandro Sura
University of Rome "La Sapienza", Rome, Italy

Abstract

The digital transformation has significantly reshaped organizational structures, particularly through the widespread adoption of remote working, which accelerated during the COVID-19 pandemic. While existing literature has explored internal impacts such as productivity and work-life balance, less attention has been paid to the effects on external relational dynamics, especially in the public sector. This paper investigates how remote working influences relational capital in public administration, focusing on the perceptions of external users such as citizens and institutional stakeholders. Relational capital (encompassing trust, reputation, and institutional networks) is critical for public entities delivering essential services. Using a qualitative approach based on semi-structured interviews within a medium-sized Italian municipality, the study explores users' experiences and perceptions of PA following the shift to smart working. Findings contribute to a growing body of research by addressing a literature gap concerning the implications of remote work on trust and relationship quality in the public sector.

Keywords: remote working, relational capital, digital transformation, intellectual capital

Paper type: Academic Research Paper

1 Introduction

In recent years, the ongoing digital transformation has significantly reshaped organizations' management approaches and business models across sectors (Lombardi and Secundo 2021). The rapid spread and continuous improvement of digital technologies have prompted a growing interest in understanding how to best leverage these tools to enhance organizational efficiency and effectiveness. These transformations have had a particularly profound impact on the management of human resources, requiring a wider and more diversified set of skills than ever before (Grigorescu et al. 2023; Jayabalan, Dorasamy, and Raman 2022). Among the most notable changes is the widespread adoption of remote working, which gained momentum during the COVID-19 pandemic and has since become a consolidated practice in many organizations (Battisti, Alfiero, and Leonidou 2022; Lord Ferguson, Smith, and Kietzmann 2022). The introduction of remote work has been analyzed by scholars from various perspectives, with a focus on its implications for productivity (Mele et al., 2021) and work-life balance (Toscano and Zappalà, 2021). Over time, remote working has become embedded in the operational and organizational structures of both private and public organizations.

In the public administration (PA) context, the shift has been especially significant, given the critical role that public entities play in delivering services to citizens and their traditionally slow pace in adopting technological innovations (Ahn and Chan, 2021). While remote working has introduced several advantages, it has also raised new challenges—most notably, those concerning the nature and quality of external relationships between public sector employees and a broad range of users, including citizens, businesses, and other institutions. These changes directly affect what is commonly referred to as relational capital, a key component of intellectual capital that enables organizations to build and sustain trust-based relationships with external stakeholders (Lombardi et al., 2021). Relational capital encompasses various dimensions, including institutional trust, organizational reputation, partnerships, and inter-organizational networks. Its role is especially critical in the public sector, where citizen trust and satisfaction are integral to service quality and institutional legitimacy.

In this context, the present study aims to investigate the relationship between remote working and relational capital in the public sector. Specifically, it focuses on the potential implications of remote working practices for external users of PA. Adopting a qualitative methodology, the research is based on semi-structured interviews conducted with a range of PA users. The objective is to explore how external relationships have evolved following the institutionalization of remote working, examining not only service efficiency but also perceived changes in image, reputation, and trust.

This contribution addresses a key gap in the current literature, as noted by Palumbo et al. (2024), who underline the scarcity of studies examining the impact of remote working on external organizational

relationships, particularly in public sector settings. While much of the existing research has focused on internal organizational outcomes—such as employee performance, collaboration, and team management—less attention has been devoted to how remote working affects the quality of public services, citizen trust, and overall user perception of the public administration. This study therefore aims to fill that void by providing new insights into the relational consequences of remote working in public sector organizations.

2 Literature review

2.1 Remote working and public sector

The concept of remote working has become a prominent theme in public sector management discourse, particularly in the wake of digital transformation and the disruptive impact of the COVID-19 pandemic. Remote working encompasses more than the physical dislocation of work; it embodies a broader reconfiguration of work processes and relationships, with digitalization, autonomy, and flexibility as its foundational pillars (Blackwell, 2008; Palumbo et al., 2021). In the public sector, remote working is increasingly seen not just as a reactionary measure but as a proactive strategy to improve responsiveness, efficiency, and the well-being of employees.

Remote working is defined as a flexible, digitally supported work arrangement that enhances employees' control over their tasks, aiming to balance organizational performance with individual autonomy and well-being (Raguseo, Gastaldi, & Neirotti, 2016). Unlike traditional teleworking, it is characterized by its integration into broader human resource and organizational strategies, combining technological enablers with cultural and managerial shifts (Dornelles, Ayala, & Frank, 2022). These features make remote working particularly relevant to the public sector, which has traditionally struggled with rigid structures and slow adaptability (Garavaglia, Sancino, & Trivellato, 2021).

The literature suggests that remote working can address long-standing challenges in public administration, such as bureaucratic inertia and low innovation capacity (Boselie, Van Harten, & Veld, 2021). However, its implementation is neither uniform nor unproblematic. Palumbo et al. (2024) emphasize the existence of five main clusters of research on the topic: institutional and policy frameworks, the nature of remotization, individual well-being, managerial strategies, and work-life balance. Each of these areas highlights specific dynamics and tensions within the process of smart work adoption.

From an institutional standpoint, the shift toward remote working is deeply influenced by national contexts and governance models. Liberalized policy environments, where public servants enjoy more autonomy and unions play an active role, tend to foster people-centred work arrangements (Mastracci & Thompson, 2007). However, even in such contexts, a focus on cost containment and austerity often undermines efforts to truly empower employees, resulting in a diluted version of remote working primarily aimed at budgetary efficiency (Baldwin, Gauld, & Goldfinch, 2012).

The literature also delves into the ambiguous outcomes of remote work, often described as both “smart” and “dumb” depending on how it is managed. While remote work can enhance flexibility, it may also lead to social disconnection, diminished trust, and reduced organizational identification if not supported by adequate management practices (de Vries, Tummers, & Bekkers, 2019). Scholars caution that the mere availability of remote work does not guarantee the realization of smart work benefits unless paired with tailored leadership approaches and meaningful employee engagement (Kim, Mullins, & Yoon, 2021).

Well-being is another focal point in the remote working debate. Flexible work arrangements have been linked to improvements in work-life balance and job satisfaction (Toscano & Zappalà, 2021). Yet, they may also lead to work intensification, stress, and blurred boundaries between personal and professional life, particularly when adopted under coercive conditions or without adequate support systems (Caillier, 2016; Ortiz-Lozano, Martínez-Morán, & Fernández-Muñoz, 2021).

To address these challenges, organizational culture and managerial style emerge as critical success factors. A culture that values trust, autonomy, and employee input is essential to the effective implementation of smart work (Hornung, Rousseau, & Glaser, 2009). Similarly, leaders must develop e-leadership skills to motivate and guide employees in hybrid or remote environments (Toleikienė, Rybnikova, & Juknevičienė, 2020). Without these cultural and managerial adjustments, remote working may remain superficial, resulting in increased alienation and decreased performance (Taskin & Edwards, 2007).

Another vital dimension is the role of remote working in supporting work-life balance, which has been one of the most cited motivations for its adoption in the public sector. However, if implemented with a focus solely on productivity, remote working may paradoxically undermine employee well-being and generate inequities in career progression (McDonald, Bradley, & Brown, 2008). Scholars therefore advocate for a shift toward socially

sustainable work models that integrate job sharing, fair task allocation, and inclusive performance evaluation systems.

2.2 Relational capital and remote working

Relational capital is a fundamental component of intellectual capital (Paoloni et al., 2021; Cosentino et al., 2024). It encompasses the set of external relationships that an organization develops and maintains with a wide range of stakeholders, customers, suppliers, partners, institutions, and, in the case of PA, with citizens and other public and private entities. Relational capital includes intangible yet strategic dimensions such as trust, reputation, image, loyalty, and institutional partnerships (Lombardi et al., 2021). These elements are crucial for the creation of value and the long-term sustainability of organizations, especially in service-oriented sectors where quality and trust are core to performance.

The accelerated digital transformation and the widespread adoption of remote working, particularly following the COVID-19 pandemic, have raised new questions about how relational capital is created, maintained, and transformed in a context of reduced physical interaction. While initial scholarly attention was mainly focused on internal organizational effects, such as employee productivity, well-being, and team cohesion (Toscano & Zappalà, 2021; Singh et al., 2022), the impact of remote work on external relationships remains largely underexplored, representing a notable gap in the literature (Palumbo et al., 2024).

The shift to remote working has radically altered traditional mechanisms of trust-building and relationship management, especially in public organizations. Historically, public services have relied heavily on in-person interactions to foster citizen trust, transparency, and satisfaction. In this regard, the relational dimension of PA goes beyond efficiency and effectiveness; it also concerns the ability of institutions to convey credibility, responsiveness, and fairness. The digitization of services and the remote management of interactions may weaken the symbolic and experiential dimensions that often underpin the relationship between citizens and institutions.

Several recent contributions have begun to investigate the implications of these changes. For instance, some authors (Pokrovskaia et al. 2021) emphasize the importance of being embedded in networks of trust, which were especially critical during the pandemic for ensuring continuity and maintaining stakeholder confidence. Similarly, a study highlights how digital technologies can foster social capital among micro-businesses by supporting online communities and virtual collaboration, thus extending the role of relational capital into the digital space (Reuschke et al. 2021). In more complex organizational settings, such as professional service firms or public institutions, the relationship between remote working and relational capital becomes even more nuanced. Rehman et al. (2023) link High-Performance Work Systems (HPWS) to the development of intellectual capital, arguing that communication tools—especially videoconferencing—play a vital role in managing relational dimensions during remote work. However, Toscani (2023) warns that remote work environments tend to reduce informal exchanges and social cues, with potential negative consequences for the exchange of tacit knowledge and the maintenance of interpersonal trust. This view is echoed by Child and Shumate (2007), who argue that common knowledge repositories and relationship-based knowledge systems are essential for effective team functioning, and that remote work may hinder the development of shared cognitive maps within teams. When transposed to the external dimension, this insight suggests that users' perceptions of public services may deteriorate in the absence of frequent or high-quality relational cues.

In the public sector, where user experience is deeply embedded in institutional credibility, these dynamics become particularly relevant. Ahn and Chan (2021) observe that public organizations often lag in adapting to technological changes and risk overlooking the relational and emotional components of service delivery in digital environments. The large-scale adoption of remote work may therefore require new frameworks for user engagement and trust management, particularly as face-to-face interactions are replaced by digital communication channels. Some authors have proposed strategies to mitigate these effects. Gong et al. (2023) suggest that relational capital within remote settings can be preserved by introducing structured but informal opportunities for interaction—such as virtual social events or randomized video meetings—to recreate the spontaneity of in-person encounters. The authors also stress the role of supervisory support and digital socialization processes in helping employees maintain strong relational ties with both colleagues and users. A complementary perspective is offered by Tomé et al. (2022), who emphasize the role of knowledge management and mutual trust in navigating crisis situations. The authors highlight that the alignment between technological systems, human resources, and process management is crucial for ensuring that relationships remain resilient in the face of uncertainty. Additionally, Steenkamp and Dhanesh (2023) propose an ethical-relational model for managing remote work based on empathy, purpose, and diversity climate. Although focused primarily on internal organizational dynamics, their framework can be extended to relationships with external users,

particularly when public institutions aim to demonstrate care, inclusivity, and ethical responsibility in digital service provision.

The literature also points to the double-edged nature of digital transformation in relational contexts. On one hand, digital tools can enhance accessibility and efficiency. On the other, they risk depersonalizing interactions, especially when not accompanied by thoughtful strategies for preserving the relational value of communication. Schinoff et al. (2020) explore how the cadence and rhythm of digital interactions affect the depth and authenticity of professional relationships, while Mazzucchelli (2017) emphasizes that remote working can both support and hinder work-life balance, depending on how relational systems are managed. Finally, the concept of sense of community, as discussed by Kabo (2022), emerges as a crucial mitigating factor. Even in the absence of physical co-presence, shared purpose, symbolic belonging, and regular digital touchpoints can sustain meaningful relational ties.

3 Method

This study adopts a qualitative research approach (Yin, 2009). The empirical investigation was conducted in a medium-sized municipality located in central Italy, which has approximately 50,000 inhabitants. This context was selected due to its representativeness in terms of administrative structure and the adoption of remote work practices following the COVID-19 pandemic. The municipality implemented smart working measures during the pandemic and continued to use them in the post-emergency phase, making it a suitable case for analyzing the impact of such organizational changes on external relationships. The data collection was carried out through semi-structured interviews, which are particularly suitable for capturing subjective interpretations and allowing respondents to express themselves freely while still focusing on specific themes. This method enables researchers to explore not only factual elements but also perceptions, expectations, and relational nuances that may otherwise remain hidden in more structured research designs.

Three individuals who maintain regular contact with the municipal administration were interviewed. These participants were purposely selected to represent different types of stakeholders: two with institutional roles and one private citizen. The inclusion diverse profiles was a deliberate choice, aimed at detecting potential variations in how remote working is perceived and experienced depending on the nature of the relationship with the public sector. The interviews were conducted in person. Each session lasted between 30 and 60 minutes. All interviews were recorded, transcribed verbatim, and anonymized to ensure the confidentiality of the participants. The interview guide included open-ended questions related to the quality of interaction with public employees, perceived efficiency of services, trust in the administration, and changes observed since the implementation of remote work.

The qualitative nature of the study does not aim to generalize findings but rather to provide an in-depth understanding of a specific context and offer interpretive insights that may inform broader reflections on the role of remote working in reshaping public sector relationships. The choice of a single-case study is consistent with this objective, allowing for a contextualized and nuanced analysis of the phenomenon under investigation.

4 Preliminary results

The analysis of the interviews conducted with three different stakeholders offers a multifaceted understanding of how remote working has impacted relational capital in PA. While the effects are generally perceived as limited or neutral in terms of service continuity and responsiveness, significant differences emerge in terms of expectations, access, and relational perceptions. Overall, institutional actors reported that the transition to remote work did not lead to a deterioration in the quality of interactions with the municipality. On the contrary, both highlighted the effectiveness of remote communication tools and organizational adjustments as factors that preserved, and in some cases even enhanced, the efficiency and continuity of administrative relations. One of institutional intervieweses emphasized that her regular dealings with municipal offices continued without major disruption. Digital tools, such as videoconferencing and email, were actively used to maintain contact, and meetings were scheduled regularly even during periods of complete remote work. According to her, the availability of municipal staff and the clarity of internal processes ensured that collaboration remained fluid, contributing to a stable institutional image and reinforcing mutual trust. Similarly, another institutional interviewee offered a positive assessment of the remote working arrangements implemented within the local government. From his perspective, the shift to remote meetings allowed for more agile and frequent interactions with both internal staff and external stakeholders. He noted that the previous logistical constraints tied to in-person meetings had often limited participation or delayed decisions. In contrast, the adoption of digital platforms enabled greater flexibility, broader involvement, and faster responses, particularly in multilateral projects or inter-organizational coordination. According to the second institutional

interviewee, this transformation not only preserved relational capital but redefined it in a more adaptable and responsive form, suited to the changing needs of public service delivery.

However, a contrasting view emerged from the citizen interviewee, who offered a user-centered perspective based on her personal experience with public services. Unlike the institutional actors, the citizen reported a noticeable decline in the quality of her interactions with municipal offices during the period of remote work. She recounted several episodes in which she physically visited the town hall to complete necessary paperwork, only to find no one available on site. The lack of clear information regarding remote work schedules and contact procedures generated frustration and uncertainty, leading her to perceive the municipality as disorganized and less accessible. His perception of the administration's image and reputation was negatively affected, as she associated the reduced presence of staff with inefficiency and disregard for citizens' needs. This experience reveals a significant disparity in how relational capital is perceived and experienced depending on the type of interaction and the user's role. While institutional actors benefit from structured communication channels and pre-established contacts, private citizens—especially those not digitally proficient—may encounter barriers that compromise the perceived accessibility and trustworthiness of the PA. The absence of face-to-face contact, in the absence of compensatory digital or procedural support, may be interpreted as a relational void rather than as an operational transformation. The citizen's dissatisfaction, however, points to an important limitation in the PA's digital transition strategy. While internal workflows may have been adapted effectively, the external communication of these changes, and their implications for access to services, was not always sufficient to meet users' expectations. This underscores the need for greater attention to relational equity, ensuring that all categories of users, regardless of their digital skills or familiarity with institutional procedures, can interact with the administration effectively and confidently.

The findings of the three interviews collectively suggest that relational capital within PA is not necessarily weakened by the adoption of remote work practices. On the contrary, when accompanied by structured procedures, appropriate digital tools, and a culture of responsiveness, remote working can support relational continuity and even foster greater organizational efficiency. However, the distribution of relational benefits is uneven, depending largely on the user's role, access to information, and familiarity with digital interfaces.

What emerges is the importance of differentiating between types of relationships within the public sector. On one hand, relationships between institutions are often governed by formal agreements and stable communication flows, making them more resilient to remote work. On the other hand, relationships with individual citizens rely more heavily on immediacy, visibility, and trust, elements that can be compromised if not explicitly safeguarded during digital transitions.

Furthermore, the data suggest that remote working in PA has not damaged relational capital. Rather, the quality of relational outcomes depends on how remote work is implemented, communicated, and supported. For institutional users, digitalization and remote interaction can enhance effectiveness. For private citizens, particularly those less digitally literate or more reliant on physical access, remote work can create a sense of detachment that erodes trust and satisfaction. These findings should emphasize the need for tailored strategies in public sector digitalization. Ensuring relational continuity requires not only technological infrastructure but also an inclusive communication strategy, user support systems, and a focus on maintaining visibility and empathy in interactions.

5 Conclusions

This study set out to explore the relationship between remote working and relational capital in the context of PA, particularly focusing on the perspectives of various external stakeholders. Through a qualitative analysis based on semi-structured interviews, the research aimed to assess how the transition to remote work has impacted the quality and dynamics of interactions between public employees and external users.

The findings highlight that, overall, remote working does not necessarily erode relational capital within the public sector (Principale et al., 2025). On the contrary, when supported by structured organizational practices, appropriate digital tools, and a responsive administrative culture, remote work can enhance flexibility and ensure continuity in institutional relations. Institutional respondents reported a generally positive or neutral experience. They emphasized the usefulness of remote communication platforms in facilitating more efficient and frequent interactions, especially in contexts requiring inter-organizational coordination. These findings suggest that public bodies can effectively maintain and even strengthen their relational capital with institutional stakeholders through appropriate digital strategies. However, the study also underscores important disparities. Citizens with limited digital literacy or without established communication channels with the administration appear more vulnerable to relational disruptions. The user-centered perspective brought forth by the citizen respondent revealed frustration stemming from the lack of physical presence and poor communication of

remote work arrangements. Furthermore, the results suggest that while internal workflows in the PA may adapt effectively to digital modes, external communication strategies often lag behind. Ensuring equitable and accessible interactions for all user categories remains a critical challenge. The notion of relational equity emerges as a key consideration in the design of future digital transitions, calling for a more inclusive and user-sensitive approach.

From a theoretical standpoint, the findings align with prior literature emphasizing the multidimensional nature of relational capital (Lombardi, 2021; Cosentino et al. 2024).

In practical terms, the study offers implications for public managers and policymakers. It calls for the development of targeted strategies to bridge the gap between internal efficiencies and external perceptions. This includes investing in communication protocols that clarify remote service availability, training programs to support citizen digital literacy, and hybrid models that maintain a minimal level of physical presence for those who require or prefer in-person interactions.

6 Ethics statement

This research did not require ethical clearance, as it did not involve human participants, personal data, or procedures requiring prior ethical approval.

Digital Therapeutics and Music: A Transdisciplinary Approach in Healthcare

Annaluce Mandiello, Federica Zeuli, Francesco Schiavone
University of Naples Parthenope, Naples, Italy

Abstract

Over the years, industries have increasingly implemented the transdisciplinary approach to research complex topics such as planetary and human health. Indeed, transdisciplinarity removes boundaries between disciplines to create new frameworks and approaches for solving real-world problems. Such an approach is particularly crucial in healthcare due to the systemic understanding required to solve its emerging challenges. At the same time, innovation literature affirms that the development of current technologies, which are also emerging in healthcare, is by nature transdisciplinary. Studies on digital health solutions reveal their central role in providing treatments, especially non-pharmaceutical ones. These are often developed by combining disciplines such as medicine, psychology, and art to treat diseases related to the emotional and behavioural sphere of the human being, while reducing healthcare costs. The emerging digital health solutions named "Digital Therapeutics" (DTx) are central in providing these care pathways. DTx are evidence-based, software-driven medical interventions providing cognitive-behavioural and emotional therapies. Despite the practical and theoretical relevance to transdisciplinary research, innovation and knowledge management literature still lack a comprehensive understanding of how DTx enhance a transdisciplinary approach to non-pharmaceutical treatments. The authors investigated two DTx providing music therapy by implementing a qualitative multiple case-study to explore the potential of such technology as a driver of new knowledge management strategies in healthcare. Three mechanisms emerged from a thematic analysis. The findings contribute to the current literature on knowledge and innovation and the emerging stream of research on DTx, which are presented as catalysts for integrating diverse forms of knowledge within therapeutic research. Moreover, this research supports practitioners in understanding how to approach digital health solutions when providing non-pharmaceutical treatments, increasing the effectiveness and accessibility of care, and reducing unnecessary costs.

Keywords: Digital Therapeutics; Music-Therapy; Transdisciplinarity; Innovation Management; Knowledge Management

Paper type: Academic Research Paper

1 Introduction

The rapidly evolving healthcare landscape presents a complex array of challenges that require innovative solutions and foster the emergence of new collaborative approaches to research where knowledge is developed by integrating different disciplinary perspectives. In recent years, increasing attention has been given to the transdisciplinary approach combining knowledge from various disciplines to address complex challenges (Gürdür Broo, Kaynak and Sait, 2022). In parallel, the advent of the Digital Transformation (DT) in healthcare led to the development of Digital Health (DH), encompassing technologies improving care delivery. DH technologies development requires collaboration among actors with diverse roles and expertise (Gürdür Broo, Kaynak and Sait, 2022; Oparin, Andrei and and Ermolaeva, 2021). An emerging subset of DH comprises Digital Therapeutics (DTx): digital interventions to prevent, manage, or treat medical diseases (DigitalTherapeuticsAlliance, 2025). Most of DTx avoid drug consumption. DTx, indeed, provide non-pharmaceutical treatments (Jeon, Yoon and Sohn, 2023). DTx has recently been designed for music-based therapy (Venkatesana, Demetrioua and Bowlingc, 2025) since their impact on driving behavioural and emotional changes. Thus, DTx integrate insights from multiple disciplines (Deloitte, 2019; Smits et al., 2022). Despite the growing attention to DTx, the scientific literature mainly focuses on clinical and technological aspects, neglecting an in-depth analysis of their transdisciplinary nature. In particular, in innovation and knowledge management, there is still a lack of understanding of how DTx contribute to promoting a transdisciplinary approach to healthcare. This paper aims to bridge this gap by answering the following research question (RQ): *How do DTx enhance transdisciplinary approach to non-pharmaceutical treatments?* To address the RQ, we conducted an exploratory multiple case-study, examining the potential of DTx as a driver of new knowledge management strategies in healthcare, ultimately reducing unnecessary costs. The article offers various implications for researchers and practitioners, contributing to the current academic debate on knowledge management and innovation management in healthcare and providing practitioners with several insights on applying a transdisciplinary approach in healthcare settings.

2 Theoretical Background

2.1 Transdisciplinarity in Healthcare

According to the literature (Barney, 1991; Ferreira, Coelho and Moutinho, 2020; Lado and Zhang, 1998) knowledge is a primary intangible resource that helps organizations and institutions to bring valuable innovations into society.

Knowledge management occurs through various mechanisms, including multidisciplinary collaboration, where different fields work alongside each other (Fong, 2003); interdisciplinary integration, which combines and transforms knowledge from multiple disciplines to address complex challenges (Disterer, 2002); and transdisciplinarity, which transcends individual disciplines to create new frameworks and approaches for solving real-world problems (Sasson and Douglas, 2006).

The term "transdisciplinary" refers to the *"higher stage of succeeding interdisciplinary relationships which would not only cover interactions or reciprocities between specialized research projects but would place the relationships within a total system without any firm boundaries between disciplines*" (Piaget and Development, 1972). Recently, interest in the transdisciplinary approach has increased as it enables collaborative research among individuals from different disciplines, generating new approaches and theories (Archibald et al., 2023).

Over the years, different industries increasingly implemented a transdisciplinary research approach to complex topics, as planetary and human health (Pineo et al., 2021; Wardani et al., 2022) contexts. This approach is crucial in healthcare research due to the systemic understanding required to solve the challenges emerging in it; these are grounded on complex and multiple dynamics characterising the interaction between humans and the environment, together with the context-specific factors determining it (Armitt et al., 2024; Van Bewer, 2017).

In particular, a transdisciplinary approach is highly required for non-pharmaceutical treatments, therapeutic interventions that do not involve drugs, such as music-therapy (Chin et al., 2021). These care pathways affect patients' emotional, behavioural, and cognitive behaviour, highlighting the need to integrate knowledge from fields such as medicine and the arts.

2.2 Digital and Transdisciplinary Healthcare: Digital Therapeutics

In the latest century, the implementation of new technologies in healthcare increased, which enable safer and higher-quality care (Marques and Ferreira, 2020). Such changes derive from a phenomenon defined as "Digital Transformation" (DT), representing "*the efficient integration and utilization of knowledge, information, and data through digital technologies*" (Long, Liu and Yang, 2024). Consequently, transdisciplinarity is the approach driving DT (Klerkx, Jakku and Labarthe, 2019) consistently with Gürdür Broo, Kaynak and Sait (2022) sentence: "*the connections between different disciplines are becoming the core of the new technologies, in a not multi-, not inter-, but in a transdisciplinary, seamless manner*". Thanks to the transdisciplinary nature of digital solutions, DT enhances the integration between different disciplines within industries. Thus, DT reshapes the logic and services of the healthcare ecosystem (Biancone et al., 2023), creating opportunities for change by fostering knowledge diffusion (Balta et al., 2021; Verhoef et al., 2021; Vial, 2021). Digital Health (DH) enhances intellectual capital within organizations through Industry 4.0 digital technologies (Pundziene et al., 2023).

Moreover, DH strengthens value co-creation processes (Swan, Peltier and Dahl, 2024), reducing inefficiencies and costs (Kraus et al., 2021). DH also enhances the effectiveness of non-pharmaceutical treatments (Toni, Mattia and Pratesi, 2024). DTx are one of the most recent DH solutions providing non-pharmaceutical treatment. Recently, practitioners and scholars paid increasing attention to DTx, as "digital-medical hybrids that had proven therapeutic value and could stand up to rigorous clinical testing and regulatory approval" (Geiger and Kjellberg, 2021). DTx adoption enhances cognitive and emotional well-being (Sestino and D'Angelo, 2024; Yang et al., 2025). Given their non-pharmaceutical and technological nature DTx development and management requires a transdisciplinary approach (Smits et al., 2022).

3 Methodology

3.1 Research Design

Due to the relative novelty of the phenomenon under study and the lack of comprehensive knowledge in the study area, the research design employs an exploratory approach. To address the RQ, we conducted an exploratory analysis employing a multiple case study (Eisenhardt, 1989; Yin, 2017), adopting an inductive approach (Thomas, 2006). We selected two DTx solutions aligned with the research goal (Eisenhardt, 1989). The

two selected cases are LUCID and MediMusic. Employing a multiple-case study approach enables us to improve both the reliability and the broader applicability of their analysis of social phenomena (Saunders, Lewis and Thornhill, 2009).

Specifically, the unit of analysis is the way through which DTx enhance the transdisciplinary approach to music therapy (Russo et al., 2023). Music-Based Interventions (MBIs) refer to planned therapeutic programs that utilize music as a tool to reach specific therapeutic outcomes (Thaut and Hömberg, 2025; Bruscia, 2014) and have been primarily developed within the practice of music therapy. Music-Based DTx are based on a music medicine approach, where music is treated as a self-applied therapeutic resource through carefully designed listening experiences provided via digital health technologies (Venkatesana, Demetrioua and Bowlingc, 2025).

Data were collected from various sources, including company reports, online documents, and public statements. We conducted a reflexive thematic analysis following the steps outlined by Braun and and Clarke (2006) to provide useful theoretical and practical insights.

3.2 Research Settings

3.2.1 A multiple-case study: LUCID and MediMusic

LUCID is a Canadian entrepreneurial venture founded in 2017 developing DTx based on music (LUCID, 2025).

The company personalizes musical experiences by leveraging Emotion AI to improve patient's mental health. Its solution, "Resonance Rx," is a Medicare-eligible mental health platform designed for older adults. MediMusic is a U.K based medtech company founded in 2016, developing a music prescription platform designed to reduce anxiety, stress, and pain, designed to be used within geriatric settings. It treats people with dementia (MediMusic, 2025). At the heart of the technology is MediBeat, a device that plays personalized therapeutic playlists. MediBeat is a DTx smart music player created by MediMusic that selects specific songs to induce desired physiological responses, such as relaxation or pain relief (MediMusic, 2025).

3.3 Data Collection and Data Analysis

To triangulate data, we relied on secondary sources (Yin, 2017). Particularly, data were gathered from: (1) public statements, (2) online documentation, and (3) official archival data. Data analysis followed an iterative and inductive approach (Bansal, Smith and Vaara, 2018; Miles and Huberman, 1984). Developing theorical insights inductively from qualitative data is considered suitable in empirical settings that are not well explored and where existing research is limited (Bansal, Smith and Vaara, 2018).

The data collection was carried out from September to December 2024 and refers to the period 2020-2025 because with the advent of the COVID-19 pandemic, there was a significant increase in DTx adoption (JuniperResearch, 2021). To strengthen the study's validity and reliability, we initially performed independent coding before comparing their results (Patton, 2014). To maintain analytical rigour and transparency, helping to identify and categorize themes that emerged from the data (Tisdell, Merriam and Stuckey-Peyrot, 2025) based on the authors' interpretation, the research adopted the six-phase framework outlined by Braun and and Clarke (2006). From the conducted thematic analysis, three main themes were selected: 1) *Digital as an active agent and not just a tool*; 2) *Treatment as a human and personalized experience;* 3) *Real-time mood state monitoring.*

4 Findings

4.1 Digital as an active agent and not just a tool

Both companies implemented a triadic transdisciplinary approach in designing and managing their DTx. Indeed, both LUCID and MediMusic integrate science, music, and tech knowledge. Differently from traditional music therapy treatment, which is usually based on medicine and music, LUCID and MediMusic merge technology competencies to formulate digital therapeutic pathways to increase patients' compliance.

MediMusic integrates the three disciplines to create, through AI and machine learning, "*audio fingerprints which mimic the human brain's response to music and then scientifically dispense it as an efficacy-driven medicine for the benefit of clinical pain and anxiety*". According to its CEO and co-founder, combining scientific and technological competencies makes it possible to create a musical experience with clinical benefits. He describes such a transdisciplinary approach as the ground for effectively treating multiple physical and psychological diseases: "*MediMusic's mission is to ethically leverage the power of technology, combining algorithms and artificial intelligence with music to clinically dispense music as medicine for the benefit of multiple physical and psychological conditions*".

LUCID's ResonanceRx is a geriatric mental health platform leveraging scientific knowledge derived from the neuroscience field, the musical one, and the technology skills, particularly related to implementing artificial intelligence algorithms enabling patients' emotions' codification (i.e., Emotion AI). According to data, transdisciplinarity is translated into different collaborations with experts, which is the basis for the DTx effectiveness. LUCID implements technology competencies by providing a recommendation system reinforced by learning mechanisms to cultivate affect-driven personalized music sequences, thus approaching music knowledge through a psychological perspective (Mallik and Russo, 2022). Indeed, LUCID's music experts as music directors/compositors work along with health professionals and algorithm developers. This triadic approach emerges in the company's statements on the website "*We're glad to be contributing at the forefront of research into the health benefits of music. [...] LUCID leverages people's natural enjoyment and use of music to enhance the digital bioavailability of DTx, and uses cutting-edge methods to optimize the active components of music for mental health outcomes".*

4.2 Treatment as a human and personalized experience

Both companies focus their offer on personalizing the music therapy treatment thanks to the digital tools they leverage. MediMusic considers the patient's age, gender, nationality, and ethnicity to create a personalized experience through a 20-minute playlist that influences multiple areas of the human brain to help reduce anxiety and pain. Its CEO, during a 2024 podcast interview, described the company's offer as follows: "W*e use personalised playlists to reduce stress*". Another company's statement presents personalization as a key factor of MediMusic offer. It explains how it is related to positive clinical outcomes "*We auto-create personalised, smart playlists that use predictive analysis to reduce heart rate and the stress hormone Cortisol, thereby promoting positive endocrine secretions – such as Dopamine, Immunoglobin-A and Oxytocin – as well as improving breathing and cognitive response*". This is consistent also with LUCID's intention to incorporate personalization within music-therapeutic interventions through quantitative measurement and machine learning techniques driving patient well-being, as in the case of ResonanceRx. ResonanceRx falls into LUCID's evidence-based digital therapeutics grounded on AI-personalized music. This is highlighted by the following sentences "*We are using personalized audio to help reduce neuropsychiatric symptoms such as anxiety and agitation*" and "*We develop AI that is personalized, adaptive, and enjoyable*". By analysing a patient's mood and facial expression, ResonanceRX provides personalized music for each therapeutic session. Furthermore, Emotion AI enables personalization: "*Our closed-loop Affective Music Recommendation System (AMRS) is an Emotion AI which enable a personalized, effective, and enjoyable digital music therapy experience".*

4.3 Real-time mood state monitoring

Both DTx companies design their solutions considering real-time monitoring driving DTx's improvement as a key factor to simultaneously achieve positive results in medical, musical and technological terms. As stated by MediMusic, this is possible by leveraging on tech skills to adapt the music recommended to improve patient's health "*Our Digital Drip component dynamically monitors a listener's response to the music and if the HRV is not as we predict subsequent tracks are swapped out to bring the heart rate down faster or in slower steps depending on use case*". The following sentences explains MediMusic's solution basis in this sense:*"MediMusic developed a dedicated hardware player for its music that works in concert with a wearable meant to track a patient's heart rate*". Indeed, a patient's heart rate response is monitored for playlist refinement purposes via Digital Drip® biofeedback loop, and this is also important for healthcare services since such techniques enable MediMusic to provide evidence-based ROI and multiple cost-saving KPIs. Consistently, LUCID affirms that along the therapeutic path, the digital solution "*measures the listener, their intentions and the context to understand the listener's starting cognitive mood state*", which helps patients move toward their target mood state. Monitoring an individual's mood and reaction to the musical stimuli helps the company drive the therapeutic path toward the predefined goal and improve the ongoing treatment. In the LUCID case, a music playlist is *"generated with the intent of effecting a controlled trajectory of the listener's affective state from the current state to the target state".*

5 Discussion

The findings illustrated above show how DTx technology represents a solid ground for boosting the interrelation between different knowledge fields in providing digital non-pharmaceutical treatments (Jeon, Yoon and Sohn, 2023; Yang et al., 2025). In particular, by analyzing the two cases selected, both companies implement a triadic transdisciplinary approach by integrating science, music, and technology. In particular, the first refers

to the medical and neuroscience competencies that have merged with the musical ones. This is typical of the traditional music therapy approach. According to several studies (Hole et al., 2015; Raglio, 2019), listening to music decreases drug consumption and, in some cases, reduces hospitalization time. For this reason, such therapeutic pathways are implemented to treat different types of diseases and health issues, as in the case of postoperative pain (Yang et al., 2025) and mental health issues. However, the particular characteristic of DTx is that they do not represent a digitalization of such treatments, but the digital technique is clinically validated to improve patients' conditions (Geiger and Kjellberg, 2021). This means that the science-music-tech transdisciplinary approach is the heart of the active agent of the non-pharmaceutical treatment. This is consistent with Gürdür Broo, Kaynak and Sait (2022). affirming the central role of transdisciplinarity in designing new technologies. Moreover, such transdisciplinarity leads to providing tailored treatment. Results reveal how both companies offer highly personalized treatment. This is widely recognized as one of the DTx strengths (Sestino and D'Angelo, 2024). Indeed, any type of treatment should be patient-centric, thus personalized, to be more effective (Chibuike, Grobbelaar and Botha, 2024). This is especially true for music therapy, which is highly connected to the patient's emotional and psychological traits, which are strictly intimate and unique for their intrinsic nature. Personalization, indeed, is fundamental for music-therapy success (Russo et al., 2023). The two DTx solutions described leverage on AI and other Industry 4.0 technology to find which music genre and rhythm produces a more effective response in the patient. This means adapting technology competence to "teach" the digital tool some neuroscience and music skills to be applied along the therapeutic journey. Moreover, according to Russo et al. (2023), a music-based DTx offers the level of personalization required for the best patient outcomes without the intervention of a music therapist. Our results reveal that DTx consider individuals as human beings, supporting the principles of Industry 5.0 (Leng et al., 2022). Indeed, transdisciplinarity helps to consider human needs by impacting a patient's entire life experience through personalized therapeutic pathways.

Findings illustrate how real-time data monitoring guarantees personalization, the third theme emerging from our analysis. The data collected are related to the three disciplines identified. This enhances the "iso principle", a specific music-therapy methodology that LUCID applies in ResonanceRx. Generally, this principle means identifying a patient's current emotional state and then changing the music played to transform that mood state into the one desired for therapeutic goals. Thanks to DTx, which leverages Emotion AI, sensors, and wearable devices, technology can better monitor the patient's mood and appropriately provide music stimuli that gradually lead to an individual's emotional state change by implementing the triadic transdisciplinary approach. Our results, thus, are consistent with Venkatesana, Demetrioua and Bowlingc (2025) describing music-based DTx as "*a key strategy for increasing the accessibility of music-based interventions*".

Thus, DTx's transdisciplinarity nature could be intended as a synonym for equity improvement, confirming how much such an approach to integrating disciplines is important for healthcare research and the system in general (Armitt et al., 2024).

6 Conclusions, Limitations and Future Research

This study contributes to understanding how DTx enhance a transdisciplinary approach to non-pharmaceutical treatments and opens new research avenues by deepening the scientific understanding of the role of DTx in healthcare. These considerations contribute to the knowledge and innovation management literature and support the emerging research stream on DTx.

Indeed, findings reveal three key theoretical insights. First, DTx are designed to treat digital technologies as active therapeutic agents, positioning software alongside clinical, psychological, and neuroscientific interventions. This epistemological shift legitimizes the digital domain as a core therapeutic discipline. Second, they provide and improve personalized treatment daily, considering the human needs over the patient's one.

DTx suggest a broader lens on how non-pharmaceutical treatment should be integrated into individuals' lives by adopting different disciplinary perspectives simultaneously. Indeed, the third consideration is related to DTx approach to real-time data monitoring. Data are collected to provide transdisciplinary insights allowing for adaptive management of care. From a managerial perspective, the findings underscore the importance of adopting a patient-centred and personalized approach to non-pharmaceutical treatment through leveraging the digital and data-driven nature of DTx. Since these last's relevance in reducing healthcare costs, transdisciplinary-grounded DTx development is thus strongly suggested. It underscores the need for collaboration between scientific communities, researchers, and practitioners in developing digital non-pharmaceutical therapeutic pathways. This study, however, has some limitations related to the limited number of cases analysed and the only consideration of secondary data; future research can focus on analysing primary data.

7 Ethical declaration

This research did not require ethical approval as it was based solely on the analysis of publicly available data and did not involve any direct interaction with human participants or the collection of personal or sensitive information. All sources used were openly accessible, and no identifiable personal data were processed.

8 AI declaration

We acknowledge the use of ChatGPT and Grammarly in helping us proofread the research article. On ChatGPT, we used the following prompt: *"Suggest ways to improve clarity and concision without changing the meaning of the text".* Then we reviewed the feedback generated critically and revised the writing.

What if…? Narratives, Stakeholders and Alternate Endings in Value Creation

Damiano Cortese, Cecilia Casalegno
University of Turin, Turin, Italy

Abstract

The research conceptually outlines the nodal importance of narration as a crucial tool supporting stakeholders' moral imagination in the conception of desirable alternatives to the critical existing status quo. This due to the fact that stories enable people to better understand reality decreasing, at the same time, the ethical pressure related to decisions and actions. Narrative is indeed a central and characterizing human activity orienting – through projections – moral choices, thanks to the evaluation of prospective effects. This is a pathway for value creation based on cooperative generation of knowledge to fully understand the big picture, thereby overcoming problems, crises and trade-offs.

Into this groove, Artificial Intelligence (AI) can play a valuable supporting function thanks to its computing and creative capacity becoming a convenient assistant for stakeholders during the genesis of alternate representations as possible "what if…". AI can in fact contribute to envision further scenarios, making moral imagination even more inventive. Taking into account the doubts and risks connected to AI, control and management of technological tools is needed by the involved stakeholders, to orient the solutions without, of course, limiting the innovative potential. This represents a royal road to overcome a well-known, diffused and increasing resistance and opposition to the cooperation between human and non-human agents.

The paper thus contributes to the concept of moral imagination by adding stakeholders' stories co-design as a creative form of moral imagination and investigating the ancillary role of AI.

The limit of the work is represented by the earlier stage of the still ongoing analysis.

Keywords: Moral imagination, narrative, Stakeholder Theory, Artificial Intelligence, value creation

Paper type: Academic Research Paper.

1 Background

The increasing uncertainty of recent and present times is due to the growing wide-ranging complexity originating from – and at the same time exacerbating – different and sometimes in appearance conflicting interests, needs, and claims from diverse stakeholders (Schiuma et al., 2021; Casalegno et al., 2020; Freeman, 2010; Harris and Freeman, 2008). The most dangerous associated threat is the rise of trade-offs, although it is manifest that the only path to prevent – or overcome – critical problems and crises is value creation (Freeman et al., 2007) based on the cooperative generation of knowledge to fully understand the big picture (Dumay, 2022; Valentinov, 2022). To pave the way for this orientation it is essential to put back at the center the human dimension by holistically enriching the managerial perspective with the humanistic dimension (de Colle et al., 2024; Cortese and Civera, 2022; Dion et al., 2022; Ciulla, 2020). That in fact allows to broaden the view by including all the stakeholders and their perceptions as well as sensitivity, making more complete, general, and adequate the adopted standpoint and the detected solution.

In this sense, this research theoretically outlines the importance of narration as a tool supporting moral imagination (Werhane, 2008) in the conception, ideation, and construction of alternatives to the critical existing status quo: in other words, a sort of imaginary "what-if…?" challenging the present and its potential inertia. This for the reason that "narratives or stories are said to enable us to better understand real lives because stories are concrete, dynamic, and highly contextual in a way that abstract moral theories are not" (Koehn, 2024: 765) and decrease, at the same time, the ethical pressure related to decisions (Mitchell, 2014). Into that groove, Artificial Intelligence (AI) can play a supporting role thanks to its computing and processing capacity becoming a useful assistant in merging acquired information and boosting understanding (and hence knowledge) emersion also showing unforeseen contingencies or obstacles. Consequently, AI may become nodal during the genesis of representations of possible attitudes or behaviors and so result in an effective aid when considering stories as moral forerunners.

The paper follows Koehn's position about narratives as an assistant in screening for ethical salience and identifying relevant possibility for actions and aims at bridging the proposed gap: "future research [..] on the power of narratives within the learning-process of agents who are on the road to virtue" (2024: 777) by including AI as stakeholder's facilitator and partner. In such a way, the article also contributes to the concept of moral

imagination by adding stakeholders' stories co-design as a creative form of moral imagination (La Forge, 2004; Ciulla, 1998; Johnson, 1985; De Mello, 1984).

2 Moral (A)Imagination

2.1 Moral imagination

"We tend to listen to a well-told story because its characters serve as role models. Their fates strongly imply what will befall us if we follow a similar path" (Sachs, 2012: 18). Narration is a central and characterizing human activity: it is crucial in proposing and disseminating archetypes and images, and therefore orienting – through projections – moral choices, thanks to the evaluation of prospective consequences. That indeed does not only concern the structure of the fairy tale – the story par excellence – of which a clearly recognizable and rebuildable morphological homogeneity is demonstrated (Propp, 1928), but – and this is the fundamental point for the fairy-tale context too – it applies to human behaviors and their exhibition in general. According to MacIntyre, in fact, stories and roles of those who animate them are closely interrelated: "man is in his actions and practice, as well as in his fictions, essentially a story-telling animal. [...] I can only answer the question 'What am I to do?' if I can answer the prior question 'Of what story or stories do I find myself a part?' We enter human […] with one or more imputed characters-roles into which we have been drafted-and we have to learn what they are in order to be able to understand how others respond to us and how our responses to them are apt to be construed" (MacIntyre, 2007: 216). As a result, storytelling becomes pivotal since it extends the ability to understand thanks to the imagination enriching "experiences by allowing us to see the world as (we imagine) others do, and […] by giving us a tool for exploring how the objects of our experience might be related to each other" (Hankins & McDavid 2023: 109).

The narration is therefore a primary mechanism of moral imagination, intended as "the ability to discover, evaluate and act upon possibilities not merely determined by a particular circumstance, or limited by a set of operating mental models, or merely framed by a set of rules'' (Werhane, 1999: 93). Moral imagination is conceived as a three-step process: the first one – reproductive imagination – is related to understanding factors influencing awareness of a moral question; the second one – the productive imagination – reformulates the problem in many ways; the third one – the creative imagination – develops solutions to the moral issues (Werhane, 1998). La Forge (2004), in line with Ciulla (1998) and De Mello (1984) suggests stories as a means for productive imagination because they accelerate comparisons and enable the growth of moral imagination. In line with the Kantian matrix of the concept, Johnson (1985: 273) says that "moral reasoning involves an act of imaginative envisionment of a non-existing world as a means for judging a proposed maxim". Werhane too refers to "Critique of Judgment" (Kant, 2004; 1790) to remind that the philosopher suggests to freely "play" with ideas, outside pre-established and recognized schemes, to allow creativity and therefore perception. According to Ciulla (1998: 106), "what distinguishes […] moral imagination from fantasy […] is the strand of truth that ties creativity to that which is known to be true by others". Thus, the narrative can be transformed into a projection of "morally acceptable alternatives to solve the ethical problem" (La Forge, 2004: 15): a new and inventive value creation path (Valentinov & Pérez Valls, 2021) based on "a morally imaginative systemic approach" (Werhane, 2008: 467). Accordingly, by contemplating the invention of narratives, we consider stakeholders' storytelling as a form of creative imagination – coming to the third stage of moral imagination –.

This experimental solution rooted on the knowledge of individual stakeholders who intervene in the elaboration of the story by sharing and pooling their own perceptions and interpretations is straightly exemplified by "real utopias" (Wright, 2020; 2011): disruptive projections of powerful images leading to hypothetically better and then desirable alternatives that reshape stakeholders' relationships and guide their future actions (Richard et al., 2024). The plot of an alternate future is co-shaped by participants, and this allows the possibility to forge a way towards a better state.

2.2 Artificial intelligence for creativity

Why, then, is it interesting, both from a theoretical point of view and in terms of managerial implications, to think about AI in this scenario? What are the opportunities and limitations – or risks – associated with technology?

A premise is necessary to frame the temporal and cultural depth of the underlying doubts affecting AI. In 1950, Alan Turing asked the fundamental question about the possible intelligence of machines. He did so by overcoming the most obvious question, namely "can machines think?" (Turing, 1950: 433), since that combining the concepts of "machine" and "thought" would have led to semantic diatribes resulting in insignificant points.

Instead, he directed the reasoning towards a game: the well-known "imitation game". In the simulation, two subjects – A and B –, respectively a man and a woman, are questioned by a third party – named C (of which gender is not relevant) – who has to determine, by communicating with A and B – in a mediated way, in order to ensure neutral answers that do not favor him –, which of the two other persons is the man and which is the woman. B has the role of supporting C in the investigation, while A must deceive to reach an incorrect verdict. That is where the well-known Turing's question came in: "'What will happen when a machine takes the role of A in this game?'. Will the questioner make a wrong decision as often when the game is played this way as when it is played between a man and a woman?". So, the author focused on the involvement of machines in the imitation game, but, of course, he looked at the wider concrete implications of the proposed gamification: is it likely that machines behave – by emulating human strategies – as if they were thinking? More than 70 years later, the possibility mentioned by Turing in the conclusion of his article is confirmed: the approximation of machines to human thought thanks to the ability to learn. However, the heart of the matter remains the same: the potential danger resulting from the substitution of AI to human, behind which we continue to see the doubt underlying the imitation game, that is the probability of deception by machines.

That being said, we believe it is interesting to think about the use of AI in the generation of narratives – including real utopias as plastic and clear representations of projection of solutions co-created by stakeholders – for two reasons. These obviously are opportunities, but they do not exclude risks that must be considered, monitored and possibly managed. The first reason is the AI ability to collect and aggregate information and therefore the conceivable incremental rise of knowledge to the benefit of stakeholders. In fact, as above-mentioned, value creation passes through knowledge (Valentinov, 2022) that is characterized *by* and suffers *from* distribution and dispersion. In this sense, the participation of stakeholders in the creation of knowledge-based solutions would be an opportunity for engagement and empowerment, overcoming the risk of trade-offs: this will be made even more solid and complete thanks to the AI incremental knowledge. Since we are in the field of ethics, the concept of paradox is an element easy to introduce and useful to reflect. In "Eat a rock a day, put glue on your pizza: how Google's AI is losing touch with reality" Toby Walsh (2024) exposes the necessary caution, not wanting to fall into surreal error. In fact, the risk related to the "knowledge" proposed by AI – in this specific case, the one developed by Google – that does not know the difference between true, false and popular and, above all, does not share the human perception of values, emerges. Sarkar (2025), on the contrary, highlights how the supposed "Artificial stupidity" arises from a cultural opposition – more functional to parlor games than to scientific discussions – that is substantiated in unintelligent questions, to create easy – bizarre – responses that follow the tone of the speech. In any case, a progressive – natural, in the field of machine learning – purposeful training is needed for the collection of information supporting the construction of shared understanding, based on an ever-increasing attention to the selection of authoritative sources, as the main body and solid basis of information.

The second reason is the creative potential of AI. It is proved *ad absurdum* – together with the latent negative consequences that confirm the presence of the prospective – not only by recent news stories about – to mention the best known – the prolonged strike of Hollywood screenwriters in the face of a risk of replacing their professionalism, but also by theoretical reflections on the ethical implications of the use of AI in artistic productions (Hagtvedt, 2025). It is indeed necessary to ponder the threats associated with the "post-human" condition as the loss of human nature and identity (Qerimi, 2019) when considering the creative chances of AI, as well as the "Baudrillard's (dis)trust in Artificial Intelligence" (Sommerer, 2025). In more detail, Baudrillard's reflection invites to cogitate on the idea of "hyperreal" that is a "real" without origin or authenticity: "the desert of the real" (Baudrillard, 1981) understood as the disappearance of genuine sense bringing with it the menace of lacking significant human interactions. Anyway, in our case, it is not about reasoning on the technical-ethical debated implications linked to AI (Román Almánzar et al., 2024; Undheim et al., 2023; Umbrello, 2020; LaChat, 1986) bearing in mind, in particular, the sentient one (Pauketat and Anthis, 2022) as possible "artificial moral advisors" or "moral observers" (Giubilini and Savulescu, 2017), but about the use of AI to support stakeholders' shared effort in the design of alternate ending(s). AI can increase and boost moral imagination, and it can do it even better if it is used as a help for stakeholders' shared effort in drawing "what if…". Training AI in "radical imagination", understood as a "deeply dialogical creative power that exists only through collective and critical encounters", according to Molotokienė (2019: 445), is a fundamental element for non-human intelligence to ethically serve human needs, enabling new forms of interaction between human and non-human. Actually, Pinka (2021: 123) states that "an artificially intelligent system could potentially perform ethical deliberation (or something similar) if it were imbued with a form of emulated imagination". This means overcoming the fear of Turing and Baudrillard by relocating the medium to its instrumental purpose discovering "its potential as a harbinger of narratives beyond human ideation" (Saddhono et al., 2024: 748) too.

Thanks to AI computing and processing capacity as well as creative potential, stakeholders can "harness local and dispersed pieces of knowledge that would not be available" (Valentinov, 2022: 536) and thereby combine all the sensitiveness and demands by creating altered – both narrative and viable – horizons. Shared comprehension co-generation is the basis to cover the distinctive facets of problems as well as the intersection of matters thanks to an all-embracing consciousness (González-Mohíno et al., 2024; Schiuma and Lerro, 2011). Concurrently, knowledge joint making rooted on the connection of stakeholders pooling their standpoints and know-how results in their empowerment, thanks to the augmented learning-based perception and in perspectives – projections and action plans – for value creation.

3 Conclusions, limitations and future research

The conceptual reasoning here briefly exposed – whose limit is represented by being offered in embryo, as the first sharing of a work in progress – revolves around the role of narration (Koehn, 2024) as a tool for stakeholders co-creation of alternative scenarios to the status quo and its complexity, in which often some actor is not represented or involved or even is in a marginal condition due to limited power (Richard et al., 2024; Schiuma and Lerro, 2011; Werhane, 1999). The creation of projections, of "what if…" – whether they are real utopias (Wright, 2020; 2011) or other forms of perspectives – is characterized by the chance of participation and involvement for stakeholders because, although it leads to realistic visions, it precedes the implementation phase of the solution and, therefore, makes the moral implications less heavy and pressing (Mitchell, 2014) stimulating, on the contrary, the moral imagination in its most creative shape (La Forge, 2004).

Since narratives are the result of individual stakeholders' knowledge and perceptions allowing to collect – and increase – fragmented knowledge (Valentinov, 2022), obviously the potential of AI can be expressed by a further growth of information or in its systematization. Additionally, AI creative learning can contribute to projecting broaden scenarios, making moral imagination even more inventive (Saddhono et al., 2024; Molotokienė, 2019).

It is however clear that the infancy stage of the tools available to the large audience and their progressive training require control and education by the interested stakeholders, in order to orient them, without, however, limiting their originative potential.

At the same time, theoretical contributions – and this is the first step of our attempt – are also needed from literature, with reference to the great and consolidated topic of moral imagination.

In conclusion, to create new stories – understood as new "pages" – of value creation it can be strategic to monitor and contribute to the evolution of AI as a support for the benefit of stakeholder, remembering that "we're only as good as the stories we can tell, we're only as good as we can live the lives that we can imagine. And imagination and creativity are muscles that atrophy if they're not used" (Freeman, 2013).

4 Ethics declaration

No ethical clearance for the research referred to in this paper is necessary.

5 AI declaration

No AI tools were used for the creation of the paper.

Bibliometric Exploration of Impression Management and Emerging Technologies in Business Communication

Antonio Iazzi[1], Simona Lamusta[1], Paola Scorrano[1], Monica Fait[2]
[1]University of Salento, Lecce, Italy
[2]Unipegaso Telematic University

Abstract

This study offers a bibliometric analysis of impression management (IM) within the evolving landscape of individual and organizational communication, shaped by emerging digital technologies. By analyzing 262 peer-reviewed journal articles indexed in Scopus between 2000 and 2024, the research examines the thematic structure of this interdisciplinary domain.
Performance analysis and co-occurrence network mapping findings reveal a growing interest in IM, particularly over the past decade. The study identifies four core thematic clusters: IM for identity construction through social media; technological augmentation of communicative credibility and authenticity; branding, self-presentation, and user engagement through IM in the age of digital intermediation; socio-psychological dimensions of IM in digital contexts.
The research shows that while IM has been widely explored in psychology, communication, and information science, it remains underrepresented in management and business studies.
The present study contributes to the literature on IM by providing a systematized, multidisciplinary overview of the topic and proposing directions for future research. It advocates for a deeper integration of IM into knowledge management and digital transformation frameworks, emphasizing the need for new communication paradigms to address current challenges.

Keywords – Impression Management, Communication, Digitalization, Emerging Technologies, Stakeholder Engagement

Paper type: Academic Research Paper

1 Introduction

In the current context, characterized by uncertainty and high competitiveness, businesses need to reshape their communication models using accurate strategies (Iaia *et al.*, 2024).

Corporate communication is conceptualized as a dynamic network of individuals interacting both vertically and horizontally, within and outside organizational boundaries. Technological advancements have significantly reshaped the corporate and individual communication landscape, requiring professionals to possess robust digital and linguistic skills. Along with this, emerging technologies such as artificial intelligence (AI) are reshaping the way organizations communicate with their stakeholders, enabling the former to produce accurate reports or attractive posts on social media. Nevertheless, it is not simple to define how organizations could communicate to create stakeholder engagement in terms of the usage of digital and emerging technologies. Kujala et al. (2022) provide a comprehensive definition of stakeholder engagement, affirming that it "refers to the aims, activities, and impacts of stakeholder relations in a moral, strategic, and/or pragmatic manner.".

Impression management (IM) emerges as a fundamental point in shaping perceptions, especially in a highly fragmented digital communication context. The concept of IM was first introduced by Goffman (1959), who likened individuals to "actors" performing on a social stage. Nowadays, its application is demonstrating how the IM approach could contribute to defining innovative frames of communication models among individuals and organizations through two components (Leary *et al.*, 1986). The first deriving from *impression motivation*, involving the desire to control others' perceptions, the second associated with *impression construction*, referring to the efforts undertaken to shape perceptions. Besides, advancements in communication technologies have enabled companies to adopt IM tactics through various digital channels, including blogs and social networks (Keskin *et al.*, 2024). In organizational settings, IM is adopted for performance evaluations and the establishment of organizational legitimacy (Luo *et al.*, 2022). Organizations employ diverse tools to manage stakeholder perceptions, including social media (Benthaus *et al.*, 2016), visual elements and graphs (Kanbaty et al., 2024).

Growing academic interest in social media and impression management has been observed, as the IM may innovate the sharing of people and companies' information through a purposeful approach able to consolidate the competitive edge. Recent studies investigate the role of communication technologies in the enhancement of stakeholder engagement (Viglia et al., 2018; Iazzi et al., 2022). De Luca et al. (2022) evaluate different social media post characteristics, finding that the use of hashtags, links, number of characters in a post, industry type, and the country in which firms operate play a pivotal role in influencing stakeholder engagement rates.

However, the adoption of new technologies requires specialized skills to harness their potential and the establishment of previously non-existent paradigms (Iaia *et al.*, 2024). This shift moves toward a perspective that not only enhances traditional value but also integrates digital value, fostering a more comprehensive approach (Pironti and Iaia, 2022). In such a context, where technologies and paradigms need to evolve, and more knowledge is required to understand how to enhance skills, knowledge management (KM) is the way to promote collaboration among skilled professionals while maximizing employee potential and creating a competitive advantage (Grimsdottir and Edvardsson, 2018).

This research explores how emerging technologies and social practices could influence communication models through IM tactics. Due to the prevalence of contributions in social sciences, computer sciences, and psychology areas, and the complexity of representing the phenomenon from multiple viewpoints, our research proposes a systematic and interdisciplinary overview of the topic. So, our study aims to contribute to the debate on IM, providing managerial implications, focusing on new emerging technologies.

To this point, the present study performs a bibliometric analysis to evaluate academic production and investigate the research trends on IM tactics adopted by companies, considering the new information and emerging technologies paradigm. Moreover, to the best of our knowledge, literature about impression management in such a field does not present other bibliometric analyses.

It is meant to address the following research questions:

- *RQ1: How is scientific research on IM and communication technologies developing?*
- *RQ2: Which are the most important studies on the topic?*
- *RQ3: Which are the most cited countries?*
- *RQ4: Which research clusters can be identified on the topic?*
- *RQ5: What are the future research evolutions?*
- *RQ6: What are the managerial implications?*

Section 2 describes the selected sample of articles and the methodology; Section 3 presents the performance analysis; Section 4 illustrates the main clusters through a network analysis; Section 5 is dedicated to conclusions, including future research avenues and managerial implications.

2 Methodology

The study examines the literature on IM communication tactics employed by organizations in the context of digital transformation and the adoption of emerging technologies, utilizing a bibliometric analysis complemented by a systematic literature review.

A bibliometric analysis is conducted to identify critical insights within the existing body of literature. After that, a systematic review of the selected articles enabled a more in-depth exploration of the key research streams identified through the network analysis.

The bibliometric technique is useful for obtaining a comprehensive overview of the phenomenon in a specific scientific field (Mukherjee *et al.*, 2022) and synthesizing the results with clusters resulting from a network analysis from a multidisciplinary perspective. According to Cosma and Rimo (2024), it avoids the biases inherent in the sample selection process that often affect traditional systematic reviews, as utilizing bibliographic data provides a comprehensive overview of the scientific unexplored output. Quantitative metrics and analysis can be verified ex-post and corroborate research (Pizzi *et al.*, 2024).

The research has been carried out by initially determining the most suitable query string.

The analysis uses bibliographic data exported from the Scopus database as one of the two most widely used citation databases for bibliometric analysis (Martín-Martín *et al.*, 2018).

A screening is carried out through filters to extract a representative sample, limited to final-stage peer-reviewed articles published in English until the end of 2024. Articles in press, conference papers, and publications in other languages are excluded to achieve consistency during the steps.

This phase led to the final following query string, with the selection of a sample of 262 studies:

(TITLE-ABS-KEY ("IMPRESSION MANAGEMENT") AND TITLE-ABS-KEY ("COMMUNICATION TECHNOLOG*") OR TITLE-ABS-KEY ("SOCIAL MEDIA") OR TITLE-ABS-KEY ("EMERGING TECHNOLOG*") OR TITLE-ABS-KEY ("ARTIFICIAL INTELLIGENCE")) AND PUBYEAR > 1999 AND PUBYEAR < 2025 AND (LIMIT-TO (SRCTYPE , "j")) AND (LIMIT-TO (PUBSTAGE , "final")) AND (LIMIT-TO (DOCTYPE , "ar")) AND (LIMIT-TO (LANGUAGE , "English"))

The bibliometric data are processed through the Bibliometrix R package (Dervis, 2019) and Vosviewer software. The Bibliometrix R package was used to conduct the performance analysis, and Vosviewer was used in the network analyses to find the main research clusters.

Performance analysis refers to the number of publications and citations and allows for answering three research questions (RQ1, RQ2, RQ3). Otherwise, the network analysis yields results through visualization depicting the relationship between different scientific items, illustrating connections between keywords and thematic areas to answer the fourth research question (RQ4). Finally, a systematic review and content analysis are performed to propose a future research agenda, possible managerial implications, and answers to RQ5 and RQ6.

3 Performance analysis

Fig.1 highlights the number of publications by year, showing an increasing interest in literature on the topic of IM tactics adoption through emerging and digital technologies, especially in the last decade.

Notable publication peaks have been reached in 2018, 2021, and 2024. The enforcement of the General Data Protection Regulation (GDPR) in 2018 marked a significant moment in corporate digital communication, compelling firms to reconceptualize their public-facing digital identities under heightened transparency and accountability requirements. Concurrently, the exponential growth of algorithmic visibility structures redefined the strategic choices of how firms managed their reputational capital in digital environments. These dynamics were further intensified after the COVID-19 pandemic. Firms migrated their reputational strategies to digital platforms, leveraging AI-driven analytics, social listening tools, and virtual engagement technologies to engineer perceptions of resilience and corporate responsibility.

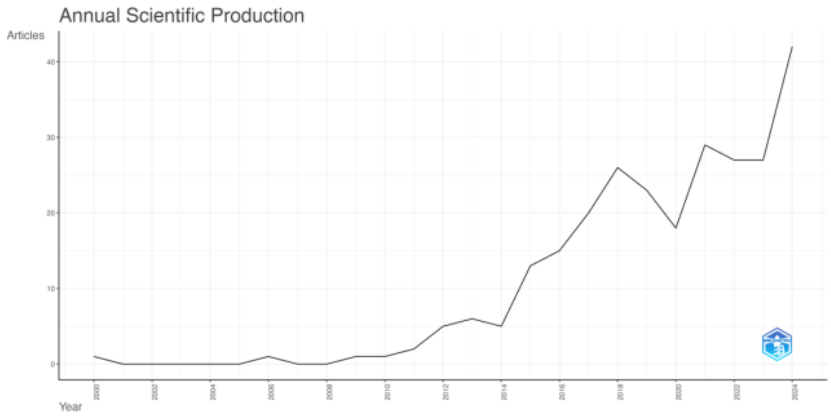

Figure 1 - Annual scientific production

The most cited article is “The effects of social media-based brand communities on brand community markers, value creation practices, brand trust and brand loyalty” (Laroche *et al.*, 2012) with 652 total citations (TC). Laroche et al. (2012) found that digital technologies facilitate and enhance impression management practices. IM tactics are influenced by community markers such as social obligations and shared rituals, and positively affect brand trust, reinforcing brand loyalty through digital communities. Therefore, according to the study, marketers should actively promote IM adoption in social media communities to strengthen trust and loyalty. The second most cited article, “Is Facebook creating “iDisorders”? The link between clinical symptoms of psychiatric disorders and technology use, attitudes and anxiety” (Rosen *et al.*, 2013), collects 342 TC and examines the role of IM as a predictor of clinical symptoms for several psychiatric disorders. Specifically, greater IM on Facebook predicted greater clinical symptoms of major depression, bipolar mania, narcissism, antisocial disorder, compulsive disorder, and histrionic disorder.

“Microblogging, Constituency Service and Impression Management: UK MPs and the Use of Twitter” (Jackson and Lilleker, 2020) is the third most cited article (249 TC) and reveals that Twitter is widely adopted as a tool for favourable self-presentation and an auto-promotional IM tactic. Specifically, Twitter is adopted by the members of the Parliament in the UK for managing their image through self-promotion, highlighting their abilities and hard work, and through building a more human and approachable image.

Within the top five most cited articles figure “What you don't know won't hurt me: Impression management functions of communication channels in relationships” (O’Sullivan, 2000) with 217 TC and “Facebook involvement, objectified body consciousness, body shame, and sexual assertiveness in college women and men” (Manago *et al.*, 2015) with 201 TC. According to O’Sullivan (2000), technologies help regulate the exchange of self-relevant information in managing their self-presentation, so that when an individual perceives that interactive episodes are potentially threatening or supportive of their self-presentation, they are likely to strive

to maximize rewards and minimize costs. It doesn't necessarily imply deception or the creation of a false personality, but it also includes efforts to regulate what information is known and what is not known by others. Manago et al. (2015) depict social networks as digital environments of visual IM where individuals create flattering images of themselves, post sexually provocative posts to garner attention, and observe friends' photographs. Image-mediated social interactions on social networking sites foster an external perspective and can lead to vehicular positive or negative messages, thus placing major emphasis on the physical aspect for self-esteem or determining body shaming consequences.

The prominence of citations of research from the USA, Canada, UK, China and Australia (Fig.2) can be attributed to the structural alignment between national innovation ecosystems, academic infrastructure, and digital platform economies, due to the globally influential research institutions these countries host (Prokop et al., 2021; Liang and Li, 2023).

Furthermore, advanced economies array foremost levels of digital penetration and platform adoption (Acs *et al.*, 2021), and emergent economies, such as China, sustain mounting investments in advanced technologies, including artificial intelligence, blockchain, and immersive media (Wu *et al.*, 2020).

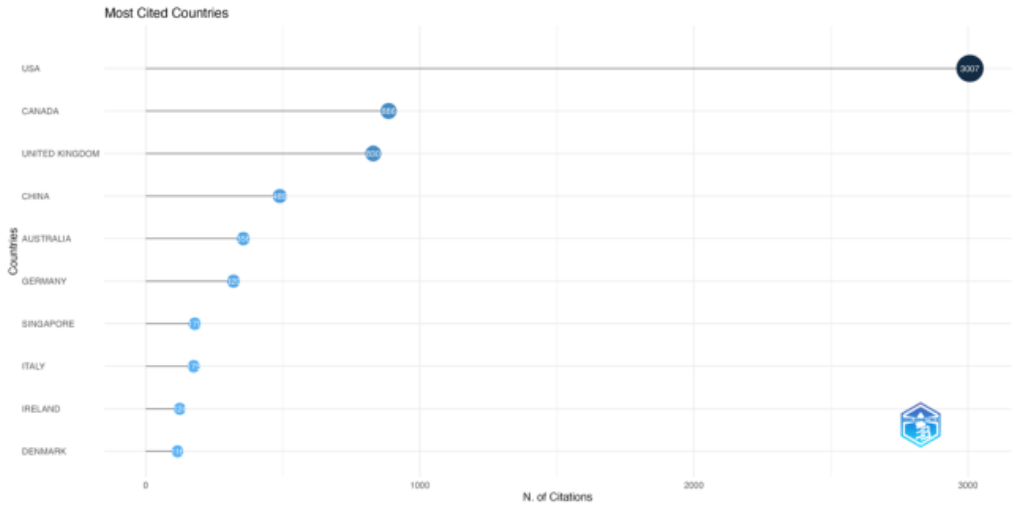

Figure 2 - Most cited countries

The most impactful sources are considered through the measure of total citations in Fig. 3 and underscore the interdisciplinary character of the academic production on digital IM, which predominantly spans the domains of psychology, behavioural science, communication studies, information science, and human-technology interaction. Leading journals such as *Computers in Human Behaviour*, *New Media and Society, Cyberpsychology, Behaviour, and Social Networking, Human Communication Research, New Media and Society*, and *Journal of Legislative Studies* signal a research orientation grounded in psychology and computer sciences. This distribution is consistent with the idea that IM, when mediated by emerging technologies, is frequently approached as a sociotechnical phenomenon rather than an economic or managerial function. The limited presence of business and management journals suggests that strategic management studies only marginally address the conceptual objective of IM as a data-intensive process embedded in digital affordances.

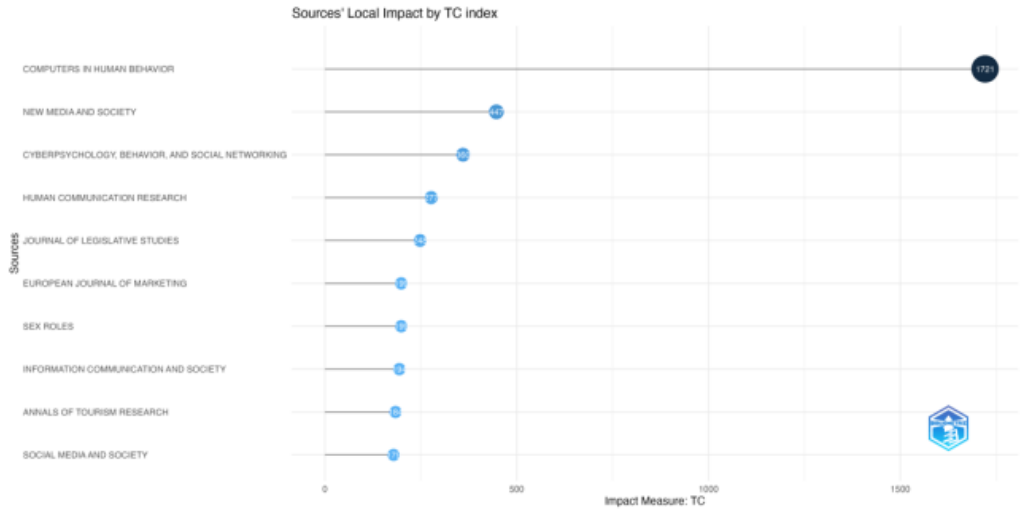

Figure 3 - Most cited sources

4 Network analysis

The network analysis was carried out through VOSViewer 1.6.20 software.

The most frequent authors' keywords are social media (145), impression management (134), self-presentation (54), social networks (27), and communication technologies (11).

Fig. 4 depicts the co-occurrence analysis of the authors' keywords, divided into four clusters:

- Red cluster: IM for identity construction through social media;
- Green cluster: technological augmentation of communicative credibility and authenticity;
- Blue cluster: branding, self-presentation, and user engagement through IM in the age of digital intermediation;
- Yellow cluster: socio-psychological dimensions of IM in digital contexts.

The red cluster involves studies aiming to capture how organizations and individuals leverage platforms such as social media to structure online self-presentation and identities.

From an organizational perspective, Suryani and Fernando (2023) and Schniederjans et al. (2013) examine how companies select the information they share with stakeholders through assertive tactics on social media and their impacts on organizational financial performance. From an individual perspective, Sukmayadi et al. (2024) analyse online identity construction mechanisms through impression management among TikTok influencers. Lo and McKercher (2015) focus on travel experience, which is increasingly shaped by visual content shared online, influencing expectations, engagement levels of tourists, and the symbolic value of destinations. IM strategies often encompass public perception orientation and political image building through self-promotion on social media to give stakeholders the desired image in professional contexts (Jackson and Lilleker, 2020).

The green cluster integrates research investigating the intersection between emergent technologies, particularly artificial intelligence and machine learning, and communicative performance. Technological attributes, anthropomorphism, attribution of human traits to technologies, and publicness are also considered as factors able to promote people's trust or as moderators (He et al., 2023; Suen and Hung, 2024). Gnewuch et al. (2023) and Li et al. (2024) investigated communication styles adopted by consumers when interacting with AI agents, demonstrating that individuals who perceive AI agents as judging entities are more inclined to adopt IM tactics to communicate.

The blue cluster underscores how impression management supports self-presentation and brand management through online professional networking, intending to promote consumer engagement and proactive positioning within competitive, influencer-driven contexts. Currently, IM is adopted in human branding in social media, where individuals apply strategic control, selection, and display of information to positively present themself to the audience, often through the creation of texts, photos, videos (Porto *et al.*, 2024). Similar online IM techniques are used for self-presentation to create an online professional identity to obtain social acceptance within the workplace (Nazzal, 2024). Companies utilize social network sites to interact with multiple online audiences (Marder et al., 2016). IM tactics are shaped by community elements like social norms, obligations, and shared rituals, which foster brand trust and reinforce customer loyalty within digital communities (Laroche *et al.*, 2012).

The yellow cluster includes studies evaluating the psychological consequences of technological communication on mental health and personality construction, especially among young people (Rosen *et al.*, 2013). It offers critical insights into the psychological pressures of excessive positivity (Salopek and Eastin, 2024), maintaining visibility and coherence across fragmented platforms and audiences (Fullwood *et al.*, 2020), and consequences that can lead to anxiety related to physical appearance needs and body shaming episodes (Manago *et al.*, 2015). Associated concerns of online IM are linked to privacy and self-esteem problems (Yang and Zhang, 2022).

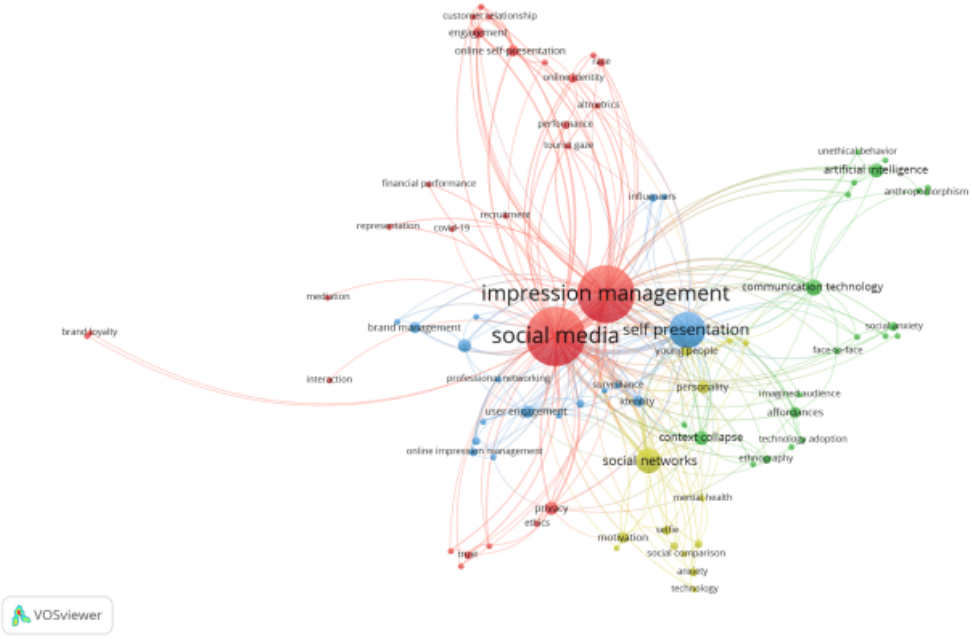

Figure 4 - Network visualization

5 Conclusion

5.1 Trend topics

A trend topic analysis has been performed through the Bibliometrix R package. The points in Fig. 5 represent the frequency of the terms, expressed as the median years in which the keywords most occur (Cosma and Rimo, 2024).

Early research in the field was predominantly tied up in platform-specific analyses as Facebook and Twitter, reflecting the early stage of social media's institutionalization as a site for strategic self-presentation. However, conceptual domains such as "self-presentation", "identity", "self-esteem", and "social media" gradually became prevalent, indicating that IM was no longer examined solely through the lens of platform affordances, but as a broader socio-economic and psychological phenomenon.

In the latter years, the emergence of terms such as "artificial intelligence" and "personal branding" denotes a critical point in the literature, whereby automated systems and intelligent technologies became agents and mediators of impression formation. Simultaneously, the continued prominence of "social networking" in recent years suggests a convergence between individual identity construction and platform-mediated visibility.

Therefore, a shift from a static consideration of IM towards more systemic perspectives occurs in the selected literature, integrating technology, behavioral, and social dimensions.

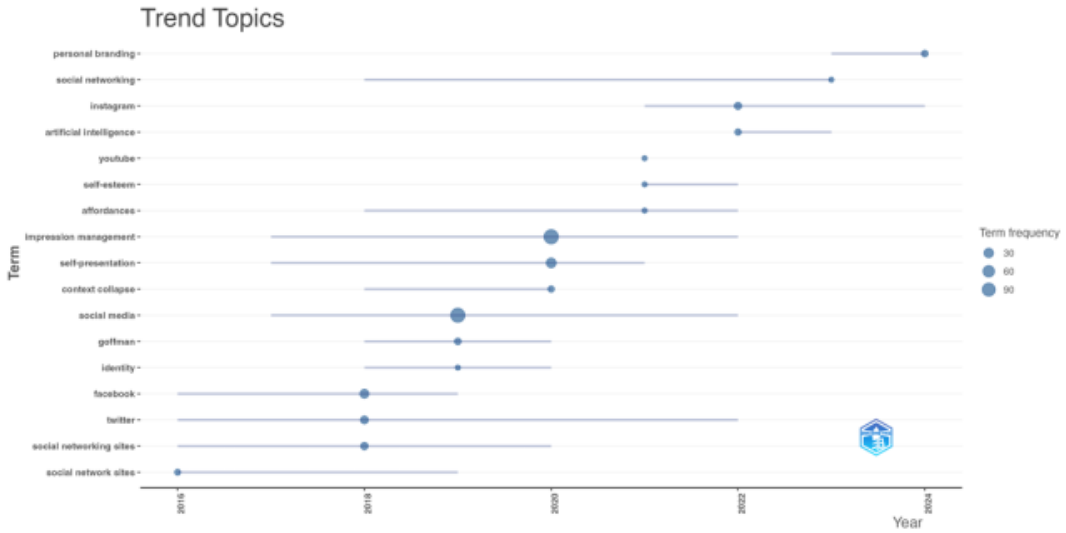

Figure 5 - Trend topics

5.2 Future research avenues and managerial implications

After depicting the actual trends in scientific production on the considered topic, a future research agenda is presented.

Table 1 illustrates possible research avenues by cluster.

Table 1 - Future research agenda

Clusters	Future research topics	Main references
Red cluster	• Provide solutions to use IM to promote multiple stakeholder engagement through social media; • Investigate the visual characteristics of videos/photos on social media which stakeholder engagement; • Further IM tactics, including indirect ones, should be considered in future studies, as they might be related to financial performance of organizations.	Jackson and Lilleker (2020); Suryani and Fernando (2023); Schniederjans et al. (2013)
Green cluster	• Explore unstructured online data as elements that can influence purchase decisions; • Analyze customer reviews for a deeper understanding of how impressions are managed and perceived during and after interactions; • Explore how the importance of online IM, including appearance, might vary depending on the market context; • Investigate AI methods to measure IM techniques in online content.	Yang et al. (2022); Korzynski et al. (2021)
Blue cluster	• Explore possible cultural factors affecting discursive practice in online IM practices; • Involve comparisons of the effects of IM tactics between different segments of human brands; • Identify indicators on human brands' earnings as a performance metric of IM tactics.	Sharifzadeh et al. (2021); Sun et al. (2023); Porto et al. (2024)
Yellow cluster	• Understand the range of perceptions users have toward social media content; • Consider the positive and negative impacts of perceived toxic positivity intentions resulting from social media consumption; • Explore the false self-presentation construct to include intent; • Determine what about IM usage in social media promotes mental health and what promotes psychiatric disorders; • Examine whether expressing oneself in sexualized ways in online spaces might be associated with less body shame and more sexual assertiveness.	Salopek and Eastin (2024); Rosen et al. (2013); Manago et al. (2015)

From a managerial perspective, the increasing centrality of AI-based tools, social media, and algorithmically mediated communication requires organizations to rethink their communication architectures. Additionally, the digitalization of stakeholder interactions introduces a new paradigm where credibility and authenticity must be engineered through hybrid communicative approaches as visual storytelling, interactive content, and automated personalized responses on multiple platforms, while maintaining message consistency and transparency. Furthermore, the study underlines the strategic value of IM for building brand communities, reinforcing customer loyalty, and facilitating stakeholder co-creation processes.

The present analysis provides current interdisciplinary perspectives and a future research agenda on the IM tactics usage in a context characterized by continuous technological mutation and digital communication evolution. However, some limitations emerge from the study. Firstly, the use of the Scopus database as a single source to extract articles limits the possibility of including other databases and the sample size. Moreover, the subjective inclusion of keywords and formulation of the query string contribute to restricting the generalizability of the results. Finally, the continuous evolution of the theme requires frequent refinement of considerations to reflect the state of the art and the constant change in communication practices and technological advancement.

Integrating the Business Model Concept for the Development of Physicians' Dual Practice in Public Healthcare Delivery Systems

Armando Calabrese[1], Roberta Costa[1], Francesca Di Pillo[2], Valerio Schiaroli[1, 2], Simona Sedda[1], Luigi Tiburzi[1]
[1]Tor Vergata University of Rome, Rome, Italy
[2]Sapienza University of Rome, Rome, Italy

Abstract

Background: Physicians' Dual Practice (PDP), defined as the concurrent provision of public and private healthcare services by the same physician, presents significant managerial challenges for public healthcare institutions. Its effective governance requires balancing public service obligations with private sector incentives.
Objective: This study aims to develop a comprehensive conceptual business model framework to support the development of PDP within public hospitals. The framework combines regulatory analysis, market evaluation, and the application of the Business Model Canvas (BMC) methodology.
Methods: An inductive approach was adopted, featuring a case study of Policlinico Tor Vergata (PTV), a major university hospital in Italy. The research integrates regulatory context analysis, K-means clustering for market segmentation, and the structured application of the BMC to assess and guide PDP management. Artificial Intelligence (AI) was examined as a strategic enabler to optimize operational processes.
Results: The findings underscore the centrality of regulatory frameworks, organizational governance models, and market dynamics in shaping PDP strategies. Clustering analysis revealed distinct strategic profiles among public healthcare organizations. Furthermore, the study highlights the pivotal role of AI technologies in optimizing waiting lists and balancing public-private service delivery.
Conclusion: By developing a structured and adaptable business model, this study provides actionable insights for policymakers and hospital administrators seeking to enhance the effectiveness of PDP initiatives. The integration of regulatory compliance, market responsiveness, and digital innovation emerges as essential for transforming PDP into a lever for strategic institutional development and improved healthcare delivery.

Keywords: Physicians' Dual Practice, Business Model Canvas, Public Hospital, Healthcare Management, Artificial Intelligence

Paper type: Academic Research Paper

1 Introduction

Physicians' Dual practice (PDP) is defined as the simultaneous engagement in both public and private healthcare services (WHO, 2024). This phenomenon is widespread across many health systems and can take several forms. Private services may be delivered externally, in independent facilities, or adjacent to public institutions, in physically connected but administratively separate spaces. Alternatively, they can be provided within public facilities, either outside regular operating hours or in an integrated manner, alongside public services—often in an informal or loosely regulated arrangement (McPake et al., 2016). PDP poses substantial challenges for public institutions, especially in reconciling public healthcare goals with physicians' financial interests. However, PDP is often considered a double-edged sword, as it also presents potential benefits (Ashmore and Gilson, 2015). Managing the contrasting impacts of PDP is a complex, multi-level challenge involving society, organizations, and individuals (Hipgrave and Hort, 2014). While policymakers set the general direction for healthcare strategies, hospital managers are tasked with adapting and implementing sustainable management tools (Jankelová, Joniaková and Mišún, 2024). Among these tools, business models have emerged as essential instruments, achieving global impact in driving companies' competitive success (Wirtz et al., 2016). All organizations, whether aware of it or not, operate within a business model; yet, public institutions often encounter greater challenges in its adoption (Lorenz et al., 2024). Among the various strategic management tools for business model design, the Business Model Canvas (BMC) (Osterwalder and Pigneur, 2010) has proven particularly valuable in the healthcare sector (Sibalija et al., 2021). Building on these insights, this paper aims to develop a comprehensive conceptual framework for a PDP business model. This framework integrates the BMC to systematically represent and analyse the organizational and strategic dimensions of PDP, with the goal of promoting robust management practices within healthcare institutions. The PDP business model considers the role of artificial intelligence (AI) as a lever to streamline waiting lists and strengthen the adaptability of PDP

management in complex settings (Almyranti et al., 2024). A single case study was conducted at Policlinico Tor Vergata (PTV), a university hospital located in central Italy, to validate the framework and assess its practical relevance.

This study is guided by the following research questions:

- RQ1: What are the key factors influencing PDP implementation in public healthcare?
- RQ2: How can a business model support the effective management of PDP in a public hospital?
- RQ3: How can AI address the challenges associated with PDP?

2 Method

This study adopts an inductive and exploratory method, aiming to develop new conceptual insights into the PDP management in public healthcare institutions. The research was conducted in three phases:

1. a comprehensive literature review on PDP and business models;
2. the development of a framework to design a PDP business model for a public organization;
3. the empirical validation of the framework through an empirical case study.

The first phase was conducted through a literature review on PDP and business models using the Scopus and Web of Science databases, which enabled the identification of key factors that are critical for the design of a PDP business model and informed the development of a conceptual framework (Barquet et al., 2013). In the second phase, the analysis revealed that effective PDP business model design requires an integrated framework that simultaneously addresses three core dimensions: regulatory conditions, market dynamics, and the business model configuration (Figure 1).

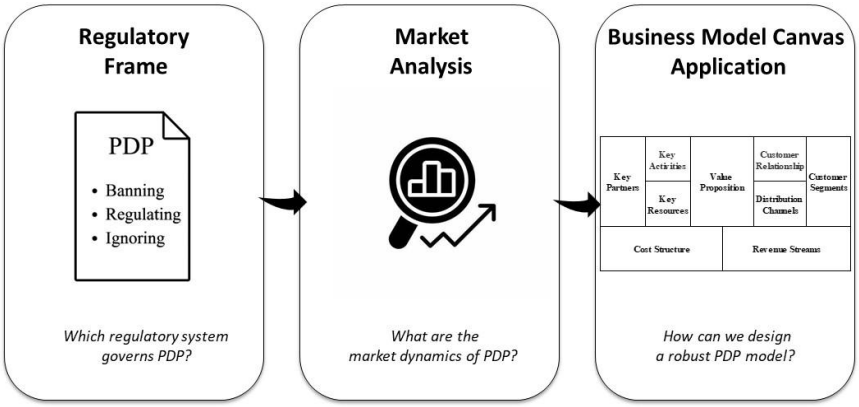

Figure 1: PDP business model framework

The first framework element is the study of the national law, which is crucial in shaping how PDP develops within specific country context (WHO, 2024). The second element focuses on understanding the dynamics of the PDP market, including institutional behaviours and regional variations.

The third element involves a structured business model design for PDP activities. Within the design of the PDP business model, the enabling role of AI is also considered, given its substantial potential to enhance healthcare management (Ali et al., 2022). The proposed framework lends itself to application across diverse regional settings.

In the third phase, following Yin (2018), the case study explores the phenomenon within its real-life context with unclear boundaries in which the PDP public and private activities intertwine within the same institution. The case study investigation was structured according to the three core components of the proposed framework. First, the institutional background was analysed through a review of PDP regulations in Italy. Second, the market environment was explored through an inferential statistical approach employing the K-means, a method for dividing a dataset into K non-overlapping clusters (James et al., 2013). Institutions were grouped based on similarity across three key variables: the total number of physicians (a proxy for structural size), the efficiency index (PDP revenue-to-cost coverage ratio), and the PDP revenue incidence (the share of total revenue generated through PDP). Prior to clustering, all numerical variables were standardized to ensure comparability. The objective of the K-means was to identify the most effective and efficient organizational models within the PDP services market in the case study region. The results of the K-means were related to the classification of organizational models. Structures were categorized into four types (A, B, C, D), depending on whether PDP activities fell under the responsibility of general management, administrative direction, medical direction, or human resources management, respectively. As a third step, the BMC was applied to PDP activities, with the

aim of mapping key organizational components, identifying strategic choices, and highlighting potential areas for improvement. Data collection during the case study involved both the consultation of publicly available 2022 datasets provided by the Italian Ministry of Health (Ragioneria Generale dello Stato, 2025) and direct interviews with key stakeholders. Although grounded in empirical evidence, the study maintains a conceptual orientation, consistent with Jaakkola's classification (2020), pursuing an explicating objective by defining PDP as a distinct managerial phenomenon and offering a structured model to guide its strategic management.

3 Application outcomes

This section is organized according to the three methodological phases: (1) Literature review; (2) Framework for designing a PDP business model; and (3) Empirical validation: PTV case study.

3.1 Phase 1: Literature review

Concerning PDP in public healthcare, most studies emphasise that the primary physicians' driver for PDP is financial, stemming from the significant disparity between public sector salaries and their expected earnings (Ferrinho et al., 2004). Non-pecuniary factors also play a critical role: limited career progression (Matiwane, Blaauw and Rispel, 2023), prestige increase (Bayat et al., 2018), greater autonomy (Barros and Olivella, 2005), and improved access to resources (Bayati et al., 2020). The literature reports that the negative effects of PDP generally outweigh the positive ones, although the overall balance remains unclear (Socha and Bech, 2011). Conflicts of interest can lead to absenteeism (Yu et al., 2020), misuse of public resources (Eggleston and Bir, 2006), and cream-skimming based on patients' income or case complexity (Moghri et al., 2017). Moreover, PDP often compromises the quality of public healthcare services (Ashmore and Gilson, 2015). Positive effects are also identified: an increase in physicians' overall labour supply and physicians' retention within public sector (Matiwane, Rispel and Blaauw, 2025).

Governments can adopt three main approaches to address PDP outcomes: they can choose to ignore it, attempt to manage it, or impose a ban (WHO, 2024). The complete prohibition of PDP is rare, and currently, it is only implemented in Canada (Flood and Bryan, 2018). Banning PDP risks pushing physicians toward the private sector or incentivizing their migration abroad, further aggravating shortages of skilled medical personnel in the public system. The existing literature on PDP management is fragmented and largely descriptive (García-Prado and González, 2011; WHO, 2024). Research concerning patients and hospital managers is particularly scarce despite these groups being significantly impacted by PDP (Huang et al., 2023). This gap highlights the need for a comprehensive business model framework to clarify managerial and organizational impacts of PDP and guide evidence-based strategies to reduce risks and enhance potential benefits in healthcare institutions.

Business models explain the logic behind how an organization generates, delivers, and captures value (Osterwalder and Pigneur, 2010). They are conceptual tools that enable organizations to comprehend their business configurations (Lorenz et al., 2024). Profit-oriented enterprises widely acknowledge that a clear articulation of their business model contributes to the enhancement of competitive advantage and the improvement of financial performance (Snihur and Eisenhardt, 2022). Public institutions must also strategically orient their activities and adopt specific business models but they face increasing challenges in utilizing them as managerial tools (Schedler, 2023). Business models have traditionally emerged within the domain of private enterprises; nevertheless, public management literature increasingly endeavours to adapt and apply these frameworks to the context of public sector organizations. One of the most prominent examples of this cross-sectoral adaptation is the BMC (Osterwalder and Pigneur, 2010). It consists of nine interrelated building blocks that outline how an organization creates, delivers, and captures value. Researchers and practitioners see its potential to improve transparency, align strategies, and foster innovation in public services, adapting its elements to focus on public value instead of profit and to meet the specific needs of public institutions (Lorenz et al., 2024). The BMC proves also particularly suitable for application in the healthcare sector, as it enables the design of patient-centred models by incorporating the perspectives of all key stakeholders (Sibalija et al., 2021).

3.2 Phase 2: Framework for designing a PDP business model

Building on the literature review, the objective is to develop a generic and adaptable business model suitable for PDP implementation within public sector organizations (RQ2). Following the steps outlined in Figure 1, the first task is to identify, based on the specific context, the regulatory framework governing dual practice and the market dynamics influencing physicians' behaviour. Physicians' decisions to engage in PDP are shaped by supply and demand factors, as well as by the degree of separation between public and private markets (Russo et al., 2014). Analysing these dynamics is crucial for designing PDP business models. Building on these analyses, the

final phase focuses on translating these insights into a structured business model. Using the BMC, this phase defines how the PDP initiative creates, delivers, and captures value for a public health institution. The nine BMC elements have been specifically adapted to reflect the distinctive features of dual practice within the public sector context, as following:

- *Value Proposition* centres on providing patients with timely and scheduled access to highly qualified medical specialists, while enabling them to exercise choice in selecting their preferred physician within the public healthcare facility.
- *Key Partners* include public healthcare institutions (e.g., research centres and the Ministry of Health), health insurance providers, private healthcare organizations affiliated with the NHS, private companies offering employee healthcare, and technology companies specializing in AI systems.
- *Key Activities* involve the provision of private medical services within public facilities and the optimization of patient scheduling through AI-based systems to reduce waiting lists and improve efficiency (RQ3).
- *Key Resources* include public-employed medical staff, retired physicians who continue offering consultancy services, AI technologies used for scheduling support, and public spaces dedicated to PDP.
- *Customer Relationships* are built through personalized care and continuity. They can be enhanced by digital platforms that tailor information and reminders to patient needs.
- *Distribution Channels:* In the PDP model, services are accessed through national booking systems, hospital-managed desks or telephone lines, web scheduling platforms, and AI-powered virtual assistants that facilitate appointments.
- *Customer Segments:* PDP primary customer segments include patients seeking faster access to specialized care, patients who prefer to choose their physician, and individuals covered by private insurance.
- *Revenue Streams* derive from direct out-of-pocket payments by patients, reimbursements from private insurance companies, and bilateral agreements with private companies for employee healthcare coverage.
- *Cost Structure* includes staff salaries and compensation for private activities, operational expenses for facility/equipment use, and investments in AI technologies.

The proposed framework identifies the key factors influencing the implementation of PDP in public healthcare, namely the regulatory context, the market environment, and the business model (RQ1). In particular, faster access to care and the integrated management of human resources, supported by AI-driven systems, emerge as highly strategic elements. In this regard, the integration of artificial intelligence into the design and delivery of public services represents a critical enabler for improving both operational efficiency and service quality across public sector domains (Fatima et al., 2022).

3.3 Phase 3 Empirical validation: PTV case study

The case study offers a detailed account of the results emerging from the application of the framework's three phases (Figure 1). The PTV is a multidisciplinary public hospital in Rome that serves a population of over 1.5 million inhabitants and operates in cooperation with the University Tor Vergata. As of 2022, the facility employed approximately 1,550 staff members, of whom 197 were physicians. It also reported 455 beds and gross annual revenues of 213.8 million euros, of which 6.3 million were generated through PDP activities (Policlinico Tor Vergata, 2022). The hospital is located in Italy, one of the G7, the seven most advanced economies in the world (United Nations, 2025). The Italian National Health Service (NHS) ensures universal healthcare coverage for all citizens and is characterized by a high degree of decentralization, with the twenty regions holding responsibility for the organization of healthcare (De Belvis et al., 2022). Between 2018 and 2022, government transfers funded about 74.5% of Italy's total health expenditure, while out-of-pocket and voluntary payments covered the remaining 25.5%, indicating persistent difficulties in ensuring timely access to public healthcare services (World Health Organization, 2025).

3.3.1 Regulatory Frame

In Italy, PDP public sector physicians are allowed to engage in private practice either within public facilities or externally. Physicians are entitled to receive the exclusivity allowance only if they perform private practice within the premises of their public healthcare institution or in a private facility formally affiliated with it. Healthcare entities are required to ensure that PDP does not interfere with institutional activities, maintaining a balance between the two and guaranteeing that the volume of services provided under private arrangements does not exceed that of ordinary public service delivery (Italian Republic, 1992). The regulation of PDP follows a

progressive and multi-level approach that starts with national legislation, continues through regional regulations, and is completed with specific institutional protocols. While the initial rationale for permitting PDP was also primarily to safeguard the patient's right to choose their physician (Italian Ministry of Health, 2025a), more recent policy orientations have progressively reinterpreted PDP as a strategic instrument for improving the management of waiting lists (Italian Ministry of Health, 2025b).

3.3.2 Market Analysis

The Italian healthcare system is organized on a regional basis, with each region independently regulating the provision of healthcare services (De Belvis et al., 2024). The market analysis focuses specifically on the Lazio region, where PTV is located. Given its central geographic position and demographic importance, Lazio offers a strategic context for examining the implementation and governance of PDP, serving as a representative foundation for subsequent nationwide analyses. Of the 18 public healthcare facilities in the region, 17 were analysed, excluding one outlier due to its atypical size and limited PDP activity. The K-means analysis was based on normalized values for structural size (number of physicians), economic efficiency (defined as the revenue-to-cost coverage ratio), and the incidence of PDP (the proportion of revenue generated from physicians' private practice within the public system). The analysis revealed two distinct clusters (Figure 2).

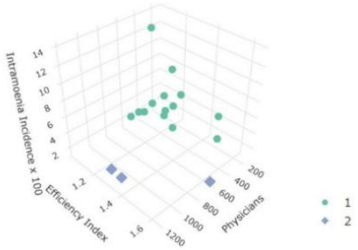

Figure 2: K-means clustering

Most facilities are grouped in Cluster 1, which includes small to medium-sized hospitals such as PTV (Table 1). These organizations vary in size, with the number of physicians ranging from 125 to 734. Their efficiency levels span from 1.04 to 1.51, suggesting a moderate capacity to cover PDP costs through revenue streams. The incidence of PDP ranges widely from 1.02% to 14.02%, indicating substantial variability in how facilities leverage PDP as a complementary revenue source. PTV is characterized by a low PDP revenue incidence (2.95%) and a reasonable efficiency index (1.18). These features suggest that there is untapped potential to further expand the PDP as a lever for economic optimization and strategic positioning. Cluster 2, in contrast, includes a limited number of large and economically high-performing facilities. These institutions have between 628 and 1200 physicians and demonstrate higher levels of efficiency, with indices ranging from 1.34 to 1.65, while keeping PDP incidence low (between 1.42% and 3.28%). Two of the three facilities in this cluster are governed under Model B (Administrative Direction), which appears particularly suited for complex, high-volume operations.

Table 1: Clustered Data

Facility	Physicians	Efficiency	Incidence	Organizational_Model	Cluster
I. Fisioterapici Ospitalieri	287	1,28	6,04	A - General Directorate	1
Policlinico U. I	558	1,13	3,79	B - Administrative Direction	1
Roma 4	254	1,51	5,5	B - Administrative Direction	1
Viterbo	473	1,18	14,02	B - Administrative Direction	1
PTV	197	1,18	2,95	C - Medical Direction	1
San Camillo-Forlanini	734	1,28	6,55	C - Medical Direction	1
S.Giovanni/Addolorata	485	1,28	5,15	C - Medical Direction	1
Sant`Andrea	303	1,17	4,89	C - Medical Direction	1
Spallanzani	125	1,46	1,02	C - Medical Direction	1
Rieti	330	1,24	9,08	C - Medical Direction	1
Roma 3	332	1,25	1,52	C - Medical Direction	1
Roma 5	518	1,04	1,92	C - Medical Direction	1
Frosinone	680	1,38	6,86	D - Human Resources Direction	1
Latina	590	1,25	6,42	D - Human Resources Direction	1
Roma 1	1133	1,36	1,91	B - Administrative Direction	2
Roma 2	1200	1,34	3,28	B - Administrative Direction	2
Roma 6	628	1,65	1,42	C - Medical Direction	2

PTV presents a distinctive profile within Cluster 1. With 197 physicians, it is among the smaller facilities in terms of staff size. Its efficiency index stands at 1.18, placing it near the lower end of the cluster's performance range. This suggests a limited ability to generate revenues sufficient to cover operating costs, which may reflect structural, managerial, or contextual constraints. Moreover, the incidence of PDP is relatively low at 2.95%, significantly below the cluster's upper values. This limited reliance on private practice revenues may indicate unexploited potential in terms of strategic development and resource optimization. Given its status as a university hospital with specialized services, PTV may be well-positioned to strengthen its PDP offering and explore governance models that enhance both efficiency and financial sustainability. We hypothesize that PTV could benefit from a strategic transition from its current Model C (Medical Direction) toward Model B (Administrative Direction), to support the expansion and integration of PDP activities within the hospital's broader governance structure. Adopting a governance model under the Administrative Direction offers a more strategic and integrated approach to managing PDP services, enabling improved resource allocation, financial oversight, and alignment with institutional objectives.

3.3.3 Strategic and Organizational Design of a PDP business model at PTV

The application of the BMC to the PDP at PTV outlines a model integrating private medical services within a public healthcare facility (Figure 3). The value proposition combines timely access to skilled physicians, patient choice, and care within a safe hospital setting, while enhancing physician retention and institutional loyalty. The interviews confirmed that physician retirement represents a critical factor, and the possibility of involving retired doctors in private practice through PDP could help mitigate the loss of institutional knowledge and clinical expertise. Key partnerships with the Lazio Regional Authority, Tor Vergata University, and insurance providers strengthen operational and financial sustainability. Key activities include personalized services delivery and could be integrated with AI-based scheduling systems to improve access and comply with national regulations, limiting private workload to 50% of a physician's total workload. Key resources involve active and retired public physicians, supported by dedicated support staff and medical equipment, alongside robust digital infrastructure. PTV addresses a broad patient base, including individuals from neighbouring regions, via digital and in-person channels. Revenue streams are diversified across patient payments, insurance reimbursements, institutional agreements, and corporate healthcare contracts, while the cost structure reflects investments in staff, facilities, technology, and training.

The developed model offers a viable path to balance public healthcare goals with private service delivery, in line with recent legislation promoting AI and a unified national booking system to reduce waiting times and improve service accessibility (Italian Republic, 2024). Given this complexity, a shift in PDP governance from the Medical Direction to the Administrative Direction would allow for a more strategic and financially integrated approach, supporting expansion into specialized services, such as high-end care for international clients based in Rome. The BMC, viewed within the regulatory and market context, underscores PTV's strong potential to expand PDP, especially given current gaps in efficiency and strategic positioning compared to regional competitors.

Figure 3: The PTV Business Model Canvas

4 Discussion

Business models are simplified representations of the relevant activities of a company (Wirtz et al., 2016), and at the same time, they embed strategies, operations, and relationships that define their business logic (Barquet et al., 2013). Following this approach, our study offers a structured lens to PDP business models and considers regulatory, market, and operational dimensions to define how value is created and distributed within public healthcare systems. The integration of the legislation within the framework allows for the contextualization of PDP within the national and regional environment, providing clarification of how the regulations can shape the final market landscape (WHO, 2024). Allowing PDP can enhance social welfare by attracting and retaining skilled physicians; however, concerns persist that it may harm public sector service quality (Eggleston and Bir, 2006). The issue of controlling the division of dual practitioners' activities between public and private services could be addressed through the implementation of AI-driven scheduling systems, as they optimize resource allocation, improve appointment management, and help ensure a balanced distribution of physicians' workloads (Knight et al., 2023).

The conceptualization and implementation of business models are the result of a complex interplay among institutional frameworks, organizational characteristics, and market conditions (Yadav, Singh and Prusty, 2025). In the field of healthcare services, strategic positioning depends on both internal configuration and external responsiveness (Purcarea, 2019). In this study, the market analysis proved to be a fundamental step in designing the PDP business model and in finding a more suitable organizational model. The strategic profiling resulting from the clustering analysis confirmed that organizational size, efficiency, and PDP incidence are interdependent variables that shape PDP's success within public hospitals. Shifting PDP governance from the Medical Direction to the Administrative Direction would provide a more strategic, integrated approach to scale PDP effectively.

Overall, our findings confirm that PDP can be effectively managed within public healthcare institutions through the adoption of tailored business models that balance regulatory compliance, market responsiveness, and operational innovation.

5 Conclusion and Future Directions

This study proposed a framework to support the development of PDP in public healthcare, combining regulatory analysis, market evaluation, and the BMC. The case study of PTV showed how a structured approach can enhance PDP management, retain skilled physicians, and improve financial sustainability. AI emerged as a key enabler to optimize scheduling and balance public and private service delivery. Future research should validate the framework in different contexts and explore the long-term effects of AI integration on service quality and institutional efficiency. Further policy studies could assess how new regulatory and technological innovations shape the scalability of PDP models within public healthcare systems.

From Innovation to Integration: A Bibliometric-Systematic Review of Digital Therapeutics and Their Impact on Healthcare

Luigi Jesus Basile
LITEM, Institut Mines-Télécom Business School, Evry, France

Abstract

Digital therapeutics (DTx) are an emerging class of evidence-based software interventions developed to prevent, manage, or treat medical conditions. Their increasing application across clinical settings reflects their potential to improve healthcare accessibility, enhance patient engagement, and support better treatment outcomes. When combined with artificial intelligence (AI), DTx can offer advanced capabilities such as real-time monitoring, personalised interventions, and predictive analytics, further strengthening its clinical impact. However, despite these technological advancements, widespread adoption remains limited due to persistent challenges in regulatory compliance, integration within clinical workflows, and the lack of standardised frameworks for evaluating effectiveness. This study presents a systematic literature review conducted according to PRISMA guidelines to explore the empirical landscape surrounding the implementation, ethical integration, and assessment of DTx within healthcare systems. From an initial pool of 1,951 records, 114 peer-reviewed studies met the inclusion criteria. The analysis identified three central research gaps: first, barriers to integration arising from limited acceptance by healthcare providers and patients; second, unresolved ethical and regulatory issues related to AI use, particularly concerning data privacy, algorithmic bias, and transparency; and third, the absence of consistent clinical benchmarks for evaluating DTx across different therapeutic areas. Bibliometric and thematic analyses reveal a rapidly expanding body of literature, with increasing attention to mental health and chronic disease management. AI integration stands out as a promising yet insufficiently validated DTx dimension. These findings highlight the need for unified regulatory approaches, robust ethical oversight, and interdisciplinary collaboration to support digital therapeutics' safe and effective integration into routine clinical care.

Keywords: Digital therapeutics, DTx, Digital transformation, Healthcare, Artificial Intelligence

Paper type: Academic Research Paper

1 Introduction

Digital therapeutics (DTx) represent an emerging category of evidence-based interventions using digital approaches to prevent, manage, or treat medical conditions (Fürstenau et al., 2023). These solutions provide structured, clinically validated therapies that can supplement or, in some cases, replace conventional medical treatments. Their ability to enhance healthcare accessibility, patient engagement, and clinical outcomes has fuelled growing interest across various medical fields (Jeon et al., 2023; Phan et al., 2023). However, the field continues to evolve, facing challenges related to regulatory frameworks, standardisation, and seamless integration into healthcare infrastructures. As DTx expands, regulatory frameworks adapt to ensure clinical efficacy and patient safety. In some countries, such as Germany, digital therapeutics are now prescribed similarly to pharmaceutical treatments, underscoring the importance of scientific validation and compliance with medical device regulations (Fürstenau et al., 2023). The effectiveness of these interventions depends not only on their technological sophistication but also on their acceptance by healthcare providers and patients (Carrera et al., 2024, 2023; Sestino and D'Angelo, 2023). One major hurdle remains their integration into existing clinical workflows, particularly ensuring interoperability with electronic health records and adherence to regulatory guidelines, which are crucial for widespread adoption.

In parallel, artificial intelligence (AI) is reshaping multiple sectors, including healthcare, driving advancements in diagnostics, precision medicine, and operational efficiency (Dal Mas et al., 2023; Meyer et al., 2024). AI also transforms digital health, facilitating more efficient and accessible healthcare delivery (Mauro et al., 2024). While AI is not inherently the foundation of digital therapeutics, its integration is increasingly enhancing these interventions by enabling data-driven personalisation and predictive analytics (Hong et al., 2021).

AI-powered digital biomarkers and real-time monitoring technologies introduce new opportunities for tailored DTx interventions, ensuring that treatments dynamically adapt to individual patient needs (Palanica et al., 2020). By leveraging AI, digital therapeutics can refine treatment pathways, optimise patient adherence, and provide more precise clinical recommendations. However, despite these promising developments, AI-enabled DTx still requires further validation regarding data quality, clinical efficacy, and implementation feasibility (Çetin,

2024; Mauro et al., 2024). Addressing these challenges will be critical to unlocking AI's full potential in enhancing digital therapeutics and driving their integration into mainstream healthcare.

This study aims to clarify the current state of the art about three key research gaps and key challenges affecting the development and adoption of DTx in real-world healthcare systems. First, despite the growing number of digital therapeutic applications, real-world implementation remains challenging, particularly regarding patient engagement and healthcare provider acceptance. Understanding the behavioural and institutional barriers that hinder adoption can inform strategies to improve integration into existing healthcare systems. Second, while AI integration holds promise for enhancing DTx personalisation, the ethical and regulatory challenges surrounding data privacy, bias mitigation, and transparency remain unresolved. Ensuring that AI-driven DTx aligns with medical guidelines and patient safety requirements is crucial for long-term sustainability. Third, there is a lack of standardised evaluation metrics for assessing the effectiveness of DTx interventions across different medical conditions. Although various digital therapeutic solutions have demonstrated positive outcomes, the absence of universally accepted clinical benchmarks limits comparability and broader adoption. In light of these challenges, this review seeks to address the following question:

- *What is the current empirical evidence on the key challenges affecting the implementation, ethical integration, and evaluation of digital therapeutics in real-world healthcare systems?*

2 Methodology

This study carried out a systematic literature review in alignment with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework (Moher et al., 2009). PRISMA's sequential architecture, i.e., identification, screening, eligibility, and inclusion, ensured that every procedural step was transparent and replicable. In the identification phase, a deliberately expansive research query was designed, capturing the widest feasible landscape of academic contributions (Marzi et al., 2025). Titles and abstracts were then examined during screening to cull extraneous records. The papers retrieved in this triage proceeded to full-text assessment, where eligibility was adjudicated against a priori criteria. Only studies satisfying all requirements were retained in the inclusion stage, thereby crystallising the final analytical corpus and safeguarding internal validity through rigorous inspection. The selected keywords' relevance lies in the study's conceptual pillars: digital therapeutics and healthcare. The research query used in this study is:

(dtx OR "digital therapeutic" OR "digital therapeutics" OR samd OR "software as a medical device") AND (healthcare OR "health care" OR "digital health")

The first component of the query, "dtx", "digital therapeutic", "digital therapeutics", "SaMD", and "software as a medical device", targets the core technological artefacts under investigation. These terms are not merely synonymous but reflect the pluralism of language across domains. "Digital therapeutics" has emerged as the dominant term within the academic literature and industry communications to refer to software-driven interventions that are evidence-based and intended to treat, manage, or prevent medical conditions. Its acronym, "DTx", is frequently used in scientific abstracts and grey literature, especially in the context of start-ups and technology evaluation. Similarly, "software as a medical device" (SaMD), introduced by the International Medical Device Regulators Forum (IMDRF) and adopted by regulatory bodies such as the FDA, anchors the technological artefact within a specific legal and governance framework. Including the abbreviation ("SaMD") and its complete form ensures sensitivity to terminological variance across policy, clinical, and technical domains. The second component, "healthcare", "health care", and "digital health", anchors the technological focus within its operational domain. While "healthcare" and "health care" are used interchangeably across databases and journals, their inclusion ensures that stylistic or typographic inconsistencies do not limit retrieval. More importantly, "digital health" captures the broader ecosystem in which digital therapeutics are developed and deployed. It reflects the ongoing digital transformation of healthcare systems and encompasses topics such as telemedicine, remote monitoring, and integrated data infrastructures, contexts that frequently intersect with or enable digital therapeutics.

The review was guided by the research question presented in Section 1 and the inclusion and exclusion criteria developed accordingly. The inclusion and exclusion criteria are inspired by the definition of digital therapeutics proposed by Füsternau et al. (2023), which frames DTx as regulated, evidence-based software interventions designed to treat, manage, or prevent medical conditions within clinical care pathways. Accordingly, studies were included if they presented empirical data, qualitative, quantitative, or mixed-methods on the implementation, ethical integration, or evaluation of DTx in real-world healthcare settings. Eligible studies addressed challenges such as regulatory compliance, clinical workflow integration, data governance, patient engagement, or ethical concerns like transparency and equity. On the other hand, studies were excluded if they focused solely on technical development (e.g., algorithm design) without healthcare system context or if they

addressed digital health tools that did not meet the criteria for DTx (e.g., general wellness apps). Evidence was drawn from Scopus, Web of Science and PubMed, repositories widely recognised for their multidisciplinary breadth and bibliometric robustness. Table 1 summarises the inclusion and exclusion criteria as well as the databases used in this study.

Table 1: Inclusion and Exclusion Criteria

Databases and Parameters	Inclusion Criteria	Exclusion Criteria
Scopus, Web of Science and PubMed **Search in: Title, Abstract and keywords** **Document type: Peer-reviewed Journals** **Language: English** **Last retrieval date: February 21st, 2025**	• Empirical studies examining the implementation, ethical integration, or evaluation of digital therapeutics (DTx) within real-world healthcare settings. • Research addressing system-level challenges, including organisational, regulatory, ethical, or clinical dimensions of DTx use. • Studies involving regulated or clinically oriented digital therapeutics, as opposed to general wellness or consumer health apps.	• Studies focused solely on technical development, algorithm design, or proof-of-concept trials without a healthcare system context. • Research on digital health tools not aligned with the definition of digital therapeutics. (REF)

3 Results

The PRISMA flow diagram outlines the structured selection process conducted in this study. A total of 1,951 records were identified across Scopus (n = 717), Web of Science (n = 498), and PubMed (n = 736). After removing 907 records due to duplication, language, or lack of peer review, 1,044 unique records remained. Following title and abstract screening, 695 records were retained, with 349 excluded for irrelevance. A second screening stage excluded another 368 records, leaving 327 full-text articles for eligibility assessment. Of these, 212 were excluded, primarily due to misalignment with the inclusion criteria. The review included 114 studies, representing a focused body of empirical research on the implementation, ethical integration, and evaluation of digital therapeutics in real-world healthcare systems. Figure 1 summarises the results for each phase of the review process.

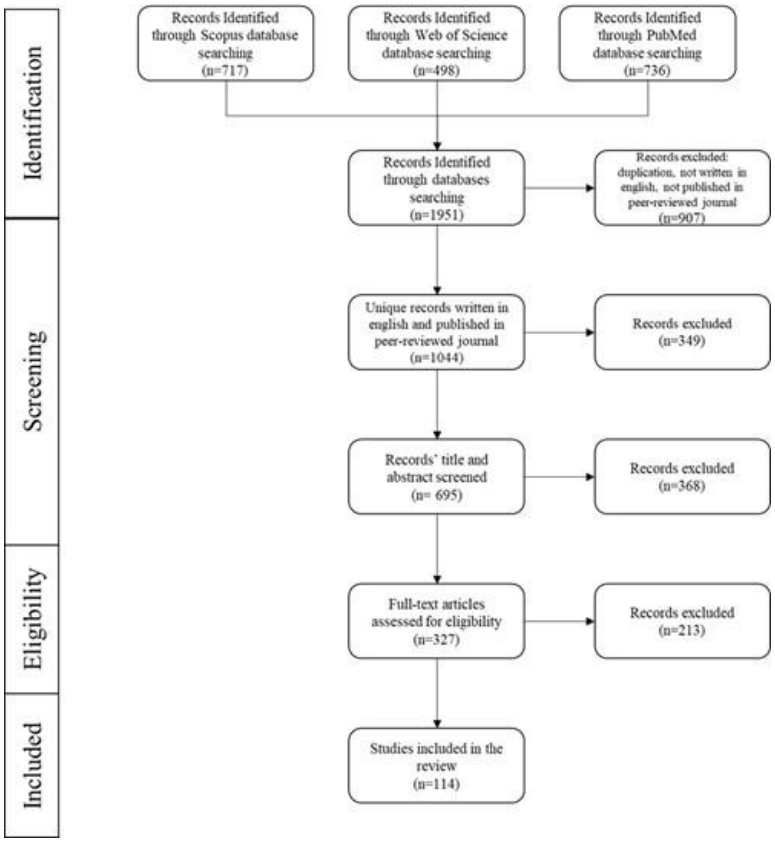

Figure 1: The PRISMA flow diagram

3.1 Bibliometric Analysis

Figure 2 presents the annual distribution of publications included in the final corpus, covering the period 2018 to early 2025. The data reveal a marked escalation in research output on digital therapeutics, particularly from 2021 onward. After a relatively modest presence between 2018 and 2020 (with annual outputs of 1, 3, and 5 publications, respectively), the volume increased substantially, peaking in 2024 with 36 contributions. The polynomial trendline suggests a non-linear, accelerating growth trajectory, indicative of a rapidly intensifying research agenda. This inflexion coincides with broader shifts in healthcare innovation policy, regulatory interest in software-based interventions, and the structural integration of digital modalities into clinical practice, especially after COVID-19. Although the figure for 2025 (n=12) appears lower, this is likely a function of the partial year of data collection rather than a genuine decline. These dynamics point to an emergent research field in accelerated consolidation, marked by increasing publication density and thematic diversification.

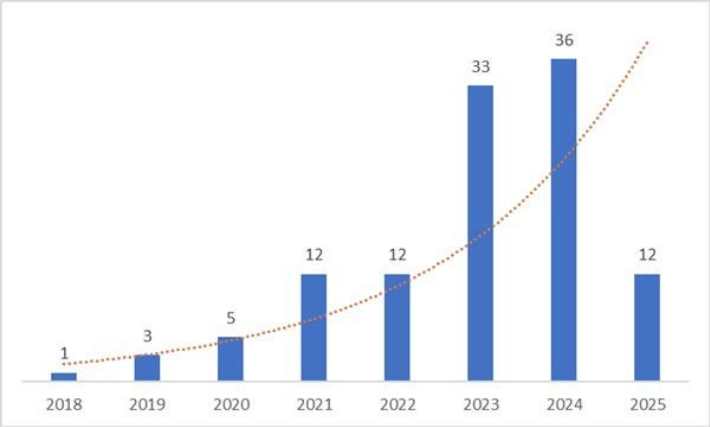

Figure 2: Papers distribution per year

Table 2 shows the distribution of articles across journals, revealing a concentration of scholarly output in a small number of specialised outlets, alongside broader dispersion across a wide array of secondary venues. The Journal of Medical Internet Research (JMIR) accounts for the largest share of included studies (n = 17), reaffirming its role as a leading platform for digital health scholarship. This is followed by Digital Health (n = 13) and JMIR mHealth and uHealth (n = 6), both of which are strongly positioned within the digital therapeutics and mobile health domains.

Several other journals make moderate contributions to the literature, including Frontiers in Digital Health (n = 5), BMC Health Services Research (n = 4), and Healthcare (n = 3), reflecting the interdisciplinary nature of the field and its linkages to health services, informatics, and public health. A number of journals—such as Clinical Pharmacology and Therapeutics, Technological Forecasting and Social Change, and Psychiatry Research—are represented by two papers each, suggesting the field's gradual diffusion into adjacent disciplinary spaces, including pharmacology, technology management, and mental health.

Table 2: distribution of articles across journals

3.1.1 Keywords Co-occurrence analysis

Figure 3 illustrates a keyword co-occurrence network (Aria and Cuccurullo, 2017). Using author-assigned keywords from the final corpus, the map visualises the frequency and co-occurrence relationships between key terms, with node size reflecting relative frequency and edge thickness denoting the strength of association. Colour-coded clusters were generated through modularity-based clustering to identify thematic domains within the broader research landscape.

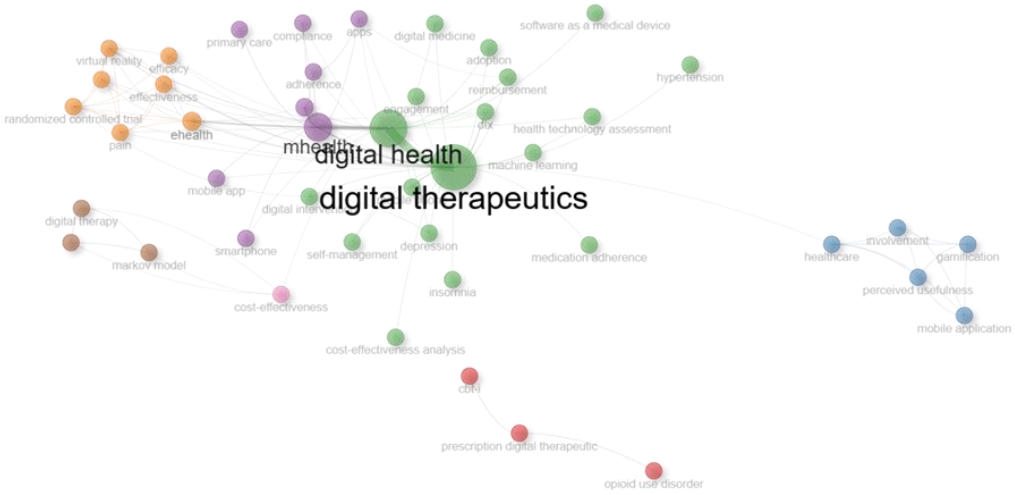

Figure 3: Co-occurrence analysis

At the core of the network, digital therapeutics and digital health emerge as dominant, highly interconnected terms, underscoring their integrative role in structuring discourse across clinical, technological, and institutional contexts. Surrounding this conceptual centre are several densely populated and thematically coherent clusters, reflecting the most developed areas of the field. The green cluster focuses on implementation and policy, featuring terms such as reimbursement, health technology assessment, adoption, and software as a medical device. This indicates a well-established concern with the system-level integration of DTx, regulatory frameworks, and pathways to market access. The orange cluster centres on clinical validation, with keywords including randomised controlled trial, efficacy, and virtual reality, signalling a strong empirical emphasis on outcome measurement and trial-based evaluation. In purple, a third major node group reflects technological delivery platforms and user adherence mechanisms, clustered around terms such as apps, mobile app, smartphone, and compliance. In contrast, less developed or emerging areas are positioned at the periphery of the network. The blue cluster, comprising terms like gamification, perceived usefulness, and involvement, represents growing but still marginal attention to behavioural design and user experience. Similarly, the red cluster highlights niche clinical applications, such as opioid use disorder, that, while promising, remain relatively underrepresented in the broader discourse. Other peripheral terms, including Markov model, cost-effectiveness, and medication adherence, suggest underexplored intersections with health economics and longitudinal outcome tracking.

3.1.2 Thematic map

Figure 4 presents a thematic map derived from a keyword co-occurrence analysis of the final set of studies included in the systematic review. The map was generated using Biblioshiny based on a co-occurrence network of author keywords (Aria and Cuccurullo, 2017). It applies centrality and density metrics to visualise thematic clusters' structural relevance and developmental maturity within the literature on digital therapeutics.

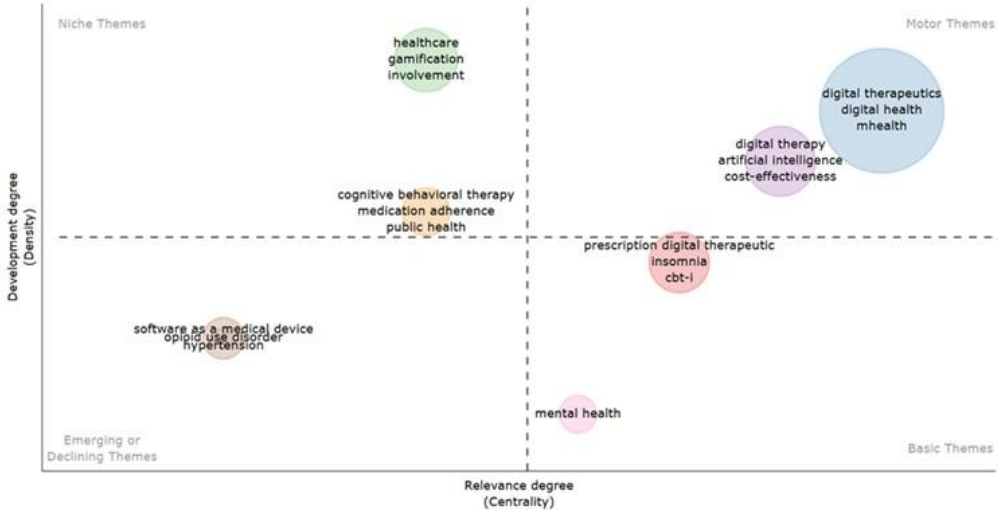

Figure 4: Thematic map

The upper-right quadrant (motor themes) includes digital therapeutics, digital health, and mHealth, which are conceptually mature and highly connected to other themes in the field. Their centrality reflects their integrative role across clinical, technological, and policy-oriented strands of research. Related terms such as artificial intelligence, digital therapy, and cost-effectiveness reinforce the consolidation of evidence around technological applications and evaluative frameworks. The lower-right quadrant (basic themes) features prescription digital therapeutic and insomnia, and mental health, themes of high relevance but lower internal cohesion. These represent clinically salient topics still developing in conceptual clarity or empirical depth, highlighting important foundations that need further scholarly elaboration.

In the upper-left quadrant (niche themes), terms such as gamification, involvement, and healthcare appear well-structured but relatively isolated. These are often confined to specialised subdomains, such as behavioural science or user experience, and currently exert limited influence on the core discourse. The lower-left quadrant (emerging or declining themes) includes software as a medical device, opioid use disorder, and hypertension. These appear marginal and weakly structured within the current corpus, potentially signalling early-stage areas of inquiry that have yet to consolidate or gain widespread scholarly traction. Finally, terms located near the centre of the map, such as cognitive behavioural therapy, medication adherence, and public health, may be interpreted as transitional or cross-cutting themes, connecting well-established and emerging areas and reflecting opportunities for further interdisciplinary integration.

4 Conclusion

The preliminary findings highlight the extensive application of DTx in multiple healthcare domains. They have demonstrated effectiveness in chronic disease management (Chengyu et al., 2024; Kaufman, 2019), particularly in conditions such as diabetes and cardiovascular diseases, as well as in mental health interventions for depression and anxiety. These digital solutions have been shown to enhance treatment adherence, support patient self-management, and offer personalised therapeutic strategies.

Behavioural engagement emerged as another vital aspect influencing the adoption of digital therapeutics. Research emphasises the significance of motivational mechanisms, such as behavioural activation and the perceived human-like qualities of digital tools, in improving patient adherence (Sestino et al., 2024). AI-driven virtual assistants and interactive technologies have effectively promoted engagement, especially in mental health and chronic disease management (Sestino and D'Angelo, 2023). By offering adaptive, personalised treatment experiences, these technologies improve patient compliance and long-term health benefits (Chengyu et al., 2024; Phan et al., 2023).

The findings suggest that digital therapeutics have the potential to serve as scalable and effective alternatives to traditional healthcare interventions. However, their successful integration into healthcare systems depends on regulatory advancements, well-defined reimbursement strategies, and increased acceptance among healthcare providers and patients. Ethical considerations, particularly those related to data security and patient privacy, must also be prioritised to foster trust and ensure responsible deployment. Addressing these challenges is critical to maximising AI's potential in DTx while ensuring these solutions maintain high clinical standards and accessibility (Nasir et al., 2024; Singha et al., 2023).

6 Ethics declaration

This study did not require ethical approval as it did not involve human participants, animal subjects, or sensitive personal data.

7 AI declaration

Artificial intelligence tools were used in this study solely for grammar correction and language refinement, without influencing the scientific content or conclusions.

Driving the Potential Application of AI in Time-Sensitive Clinical Workflows: A Case Study on Stroke Care

Salvatore Ammirato, Alessandro Russo, Laura Cutrì, Roberto Linzalone
University of Calabria, Rende, Italy

Abstract

Despite rising healthcare costs, many health systems still fall short of patient and policymaker expectations for quality and efficiency. A major challenge is the integration of technological innovations, especially Artificial Intelligence (AI), into healthcare processes. AI has significant potential to improve clinical pathways, particularly in time-sensitive processes like stroke care, where every second counts. However, research on how to best utilize AI in these contexts remains limited. This paper examines the drivers for successful AI application in time-sensitive workflows, focusing on stroke care in Calabria, Italy. Using Business Process Model and Notation (BPMN), the study maps current workflows and analyzes potential AI interventions. Findings highlight the importance of systemic, integrated AI solutions that optimize entire workflows, offering actionable insights for the design of AI-enabled clinical processes that ensure timely, effective care.

Keywords: Clinical workflow, Artificial Intelligence, Health System, AI intervention, Time-sensitive process

Paper type: Academic Research Paper

1 Introduction

Despite substantial investments—healthcare represents 9.2% of GDP in OECD countries (WHO, 2020; WHO-GHO, 2022)—Healthcare Systems (HSs) still fall short in quality and efficiency (Herzlinger, 2006; Nembhard et al., 2009; Kuljis, 2007). Globally, HS managers struggle to enhance system performance and patient care through technological innovation (Porter & Teisberg, 2006).

In recent decades, transformative technologies like Artificial Intelligence (AI) have emerged with the potential to strengthen HSs. AI and AI-based devices can improve existing workflows (Lundervold & Lundervold, 2019; Shameer et al., 2017), and enable new services such as personalized medicine (Topol, 2019), real-time monitoring (Lu et al., 2021), and telemedicine (Smith et al., 2020).

Although AI applications in healthcare are widely documented, there is limited focus on how AI reduces lead times in time-sensitive processes such as stroke care (Rajkomar et al., 2018). Here, AI intervention refers to the coordinated integration of tools—diagnostic algorithms, predictive models, workflow automation, and communication systems—into clinical workflows to enhance decision-making, reduce delays, and improve operational efficiency.

Unleashing AI's full potential requires a systemic view that connects interventions to workflow performance, rather than focusing on individual tools in isolation. Among AI's benefits, reducing time in critical care pathways is particularly strategic. Stroke care is highly time-sensitive: treatment delays reduce efficacy and increase mortality (Saver, 2006). Efficient workflows enable timely diagnosis and intervention, lowering disability and healthcare costs (Meretoja et al., 2012).

This study explores AI interventions in the hyperacute stroke care workflow at the Emergency Department and Stroke Unit (SU) of "Annunziata – Mariano Santo – Santa Barbara" Hospital in Calabria, Italy. Using BPMN modeling of the current ("as-is") process, potential AI interventions are identified and analyzed.

Propositions and actionable insights are then raised to drive the design and implementation (i.e. application) of AI interventions into existing workflows, in order to succeed with time reductions.

2 Theoretical background

2.1 AI and clinical workflow

Beyond regulatory complexities, funding issues, and resistance to change that hinder innovation in Health Systems (HSs) (Herzlinger, 2006), technologies like AI are strategic for improving patient outcomes and system sustainability (Greenhalgh et al., 2017). However, effective AI application requires detailed, micro-level clinical process analysis to ensure meaningful integration.

Crucially, clinical *processes*—structured activities aimed at delivering care—must be distinguished from clinical *workflows*, which reflect the real-world, contextual execution of those processes shaped by logistical, organizational, technological, human, and cultural factors.

While much literature focuses on AI outcomes at the process level, we argue that workflow-level analysis enables a more precise understanding of effective AI integration. Ash et al. (2007) emphasize the importance of context-aware research strategies in healthcare.

Clinical workflows—sequences of tasks and interactions aimed at patient care—form the operational backbone of the HS. These include procedures, documentation, and team communication, prioritizing safety and quality (Campbell et al., 2009). As Rojas et al. (2020) note, workflows reveal elementary tasks and functional relationships, making them a valuable unit of analysis for identifying AI opportunities and assessing potential impact.

Optimizing workflows is critical to reducing costs and improving patient outcomes. In time-sensitive processes (e.g., stroke, trauma, sepsis), lead time is a decisive factor, with delays linked to increased morbidity and mortality (Berwick, 1989; Berwick et al., 2008). Streamlining these workflows is a managerial imperative, where AI can have substantial impact.

Currently, AI in healthcare consists of six core tools or techniques—Machine Learning, Deep Learning, Neural Networks, Natural Language Processing, Fuzzy Logic, and AI Heuristics (Table 1) - which can operate independently or synergistically within clinical workflows.

Table 1- AI applications in Health

AI Tool	Description	Typical Tasks	Applications in Health
Machine Learning (ML)	Algorithms that learn from data to make predictions, classifications, or decisions autonomously.	Classification, regression, clustering, prediction.	Disease diagnosis (e.g., cancer detection), patient risk prediction, personalized treatment plans.
Deep Learning (DL)	Subset of ML using neural networks with many layers to model complex patterns.	Image analysis, speech recognition, predictive analytics.	Medical imaging (MRI, CT analysis), genomics, early disease detection (e.g., Alzheimer's).
Neural Networks	Algorithms inspired by the human brain to recognize patterns and relationships in data.	Pattern recognition, regression, feature extraction.	ECG interpretation, diagnostic support systems, radiological analysis.
Natural Language Processing (NLP)	Enables machines to understand, interpret, and generate human language.	Text mining, entity extraction, sentiment analysis.	Clinical notes analysis, electronic health records (EHR) summarization, patient chatbot interactions.
Fuzzy Logic	Deals with reasoning that is approximate rather than fixed and exact.	Decision support, uncertainty management, control systems.	Symptom-based diagnosis, patient prioritization, clinical decision support under uncertainty.
AI-based Heuristics	Rule-of-thumb strategies driven by AI to solve complex problems efficiently.	Optimization, scheduling, search problems.	Hospital resource allocation, surgery scheduling, emergency room workflow optimization.

These techniques find applications in five main domains: Clinical Decision Support Systems (Hameed and Rahim, 2024), Predictive Analysitics (Shaik et al., 2023), Administrative Automation, Remote Patient Monitoring (Shaik et al., 2023), Telemedicine and Virtual Care (Hameed and Rahim, 2024).

2.2 Application and Exploitation of AI in Health

AI in healthcare involves deploying software tools (e.g., diagnostic algorithms, decision-support systems) and AI-based devices (e.g., robotic systems, wearables) that embed such tools. While tools are software-driven, devices integrate hardware with AI algorithms. Both hold strong transformative potential but must be smoothly embedded into clinical workflows (He et al., 2019). Full value emerges when tools and devices are carefully selected, coordinated, and aligned across workflows to support medical and non-medical tasks—such as communication, logistics, and administration—thus enhancing care quality (Jiang et al., 2017) and reducing lead times (He et al., 2019).

2.3 Application of AI in clinical workflows. Drivers and guidelines to succeed with AI Interventions in time-sensitive clinical workflows.

A successful application of AI in clinical workflows requires seamless integration of AI tools and devices across clinical, administrative, and communication tasks (Mahalo Health, 2024). This integration must consider

contextual factors and support—rather than replace—human expertise. Key integration elements include (Zhukov, 2024): automation of routine tasks (e.g., scheduling, documentation), decision support (real-time data analysis and predictive insights), improved communication (streamlined information flows), and personalized care (tailored treatment plans).

Time-sensitive processes like stroke, trauma, or sepsis care are critically influenced by *lead time*, i.e., the interval from initiation (e.g., admission, diagnosis) to completion of treatment (e.g., surgery, discharge). Lead time is a key performance metric for these interventions (Toussaint & Berry, 2013), with shorter times directly linked to survival (Saver, 2006). Clinical workflows—defined sequences of tasks and interactions—shape this lead time.

Optimizing workflows involves improving both clinical activities (diagnosis, decision-making, treatment) (Panch et al., 2019; Ponsiglione et al., 2021) and non-clinical "support functions" like communication, administration, logistics, and information management. Though not directly involved in treatment, these functions—such as scheduling, billing, records, IT, transport, and cleaning—critically affect overall lead time (McLaughlin & McLaughlin, 2020).

To reduce lead times in time-sensitive care, AI interventions must treat non-clinical tasks as part of the value stream and optimize them to reduce delays (Toussaint & Berry, 2013). A wide array of AI tools and devices can support this optimization in stroke care workflows (Table 2).

Tab. 2 – AI Applications in hyper-acute stroke care process. Support functions

Name	Description	Impact/Effect
Stroke Transport Optimization System	AI-enabled decision support for EMS routing based on stroke severity and destination prediction	Optimizes interfacility transfer; reduces time to SU.
Sevaro Synapse AI	Teleneurology platform providing sub-minute neurologist response to EMS/staff requests.	Enables <45s consult access; avoids 15–30 minute wait for call-back.
Nicolab StrokeViewer	AI platform for real-time image sharing and stroke decision support among clinical teams.	Reduces imaging review and decision delays.
FHIRChain	Blockchain-based data-sharing system for secure interhospital clinical exchange.	Enables instant access to external reports; avoids fax/phone delays.
AI-Based Triage App	Mobile AI app that helps EMS select stroke center destination via real-time clinical input.	Improves triage decisions; reduces misrouting to non-thrombectomy centers.
Remote Patient Monitoring (AI-RPM)	AI-enabled platform for at-home monitoring of vitals and risk factors in stroke survivors.	Prevents delayed hospital readmission via early detection (e.g. recurrent Stroke).
FedStack Wearable Platform	Federated learning–based wearable platform for continuous patient status and activity monitoring.	Supports clinician feedback and early rehab response; data stays local.
Clinical Chatbot Assistant	NLP-based chatbot integrated into hospital communication systems to support coordination, reminders, and updates.	Automates routine communications, reduces human delays in coordination, provides 24/7 support to EMS and staff.

The application of AI in clinical workflows is a complex challenge, particularly in healthcare processes involving human judgment, critical decisions, and time-sensitive care. This is often referred to as the "sociotechnical challenge" of embedding AI in clinical environments, where workflows depend on both structured protocols and human adaptability (Shortliffe & Sepúlveda, 2018; Topol, 2019).

Key challenges include:

- **Lack of workflow integration**: AI tools often operate in silos, disrupting communication and increasing cognitive burden, as they don't fit into the sequence of clinical tasks (Sendak et al., 2020).
- **Trust and explainability issues**: clinicians resist AI when systems are "black boxes," lacking interpretability or accountability, making them hesitant to adopt AI tools (Rajkomar et al., 2018; Amann et al., 2020).
- **Misalignment with clinical priorities**: AI may focus on isolated outcomes (e.g., image classification) rather than addressing holistic patient care, time constraints, or ethical concerns (London, 2019).
- **Integration and interoperability**: many AI tools are not designed for real-world clinical settings, lacking interoperability with existing systems like EHRs, limiting usability (Topol, 2019).

AI application in health workflows, defined as a coordinated application of multiple AI tools, is an emerging yet underexplored topic in managerial literature. Concepts are often confused and lack a management perspective. At least three conceptualizations are evident:

1. **AI-augmented clinical pathways**: care pathways enhanced by AI tools, such as diagnostic algorithms and predictive analytics, aim to reduce time-to-treatment (e.g., door-to-needle time in stroke) (McKinney et al., 2020; Nagel et al., 2019). These represent systems-level interventions where multiple AI components contribute synergistically to key decision points (Jiang et al., 2021).

2. **End-to-end ai deployment**: full-stack integration from patient arrival to treatment, combining imaging AI, NLP for triage, decision support, and task automation. Examples include stroke platforms like Viz.ai and RapidAI (Fargen et al., 2020).
3. **AI-driven workflow transformation**: focuses on AI's role in reshaping clinical workflows by improving coordination, reducing bottlenecks, and reallocating staff efforts. AI should be part of an orchestrated intervention, not isolated tools (Topol, 2019).

3 Materials and methods

3.1 'Acute' phase of stroke care: clinical process and its workflow at Calabria Region and Cosenza Hospital

Every minute counts in stroke care pathway, to restore cerebral blood flow. Studies show that 15 minutes saved in the care pathway reduces the likelihood of death by 4%, and each second of in-hospital delay results in the loss of 2.2 healthy life hours (Levine, 2013). Stroke has a "Therapeutic Window" that is a 4.5 hours of symptom onset, for administering thrombolytic treatment (alteplase) (Hacke, et al., 2008). However, the best outcomes are achieved within the first 90 minutes, that's why the concept "time is brain" is widely held in literature (Saver, 2006). Time performance is then critical for preventing long-term disability of stroke patients. Hence, stroke care acute phase activities (e.g., stroke code protocols, rapid transport to hospitals, immediate imaging, etc.) are crucial for reducing the impact of stroke (Table 3).

Table 3 – Stroke. Main phases of the clinical process

Phase	*Activity*
Pre-hospital Phase	Emergency recognition and transport
Acute Phase	Initial diagnosis, treatment (thrombolysis, thrombectomy), and stabilization
Post-Acute	Early rehabilitation, neuroplasticity stimulation, and recovery
Long-Term	Secondary prevention, ongoing rehabilitation, and psychosocial support
End-of-Life or Palliative Care	For patients with severe disability or limited recovery

In order to derive drivers for the application of AI in clinical workflows we investigate a theoretically relevant case study, the acute phase workflow at the Emergency Department and Stroke Unit of "Annunziata – Mariano Santo – Santa Barbara" Hospital in Cosenza, Italy.

3.2 Data collection

Data consisted in workflow tasks, interactions, flows, timing. They were collected through observation and interviews to Health staff at "*Annunziata – Mariano Santo – Santa Barbara*" Hospital in Cosenza (Italy) (Table 5).

Further data were collected from service providers involved in the clinical process:

- Helicopter Emergency Medical Service Calabria (HEMS Calabria);
- National Agency for Regional Health Services (AGENAS);
- Operational Room (118) – Northern Area of the Calabria region (OR 118);
- Provincial Healthcare Company, Cosenza (ASP Cosenza);
- Unified Emergency Number 112 - Single Emergency Response Center – Regional Headquarters in Catanzaro (CUR-NUE 112).

Table 4 – Expert sources for data

Name Dr.	Role	Organization	Supervised area/data provided	Expertise
Antonio	Coordinator of Neuroradiology Technicians	AO Cosenza	Diagnostic	10 to 20 years
William	Director of the Department of Neuroscience (Chief of Neuroradiology)	AO Cosenza	Intra-hospital pathway (Neuroradiology)	>20 years
Enza	Nurse	AO Cosenza	ER admission; SU admission; Hospitalization; Clinical documentation	10 to 20 years
Riccardo	Director of the Regional Emergency Department	ASP Cosenza	Pre-hospital pathway	>20 years
Ermanno	Administrative assistant	AGENAS	Administrative	< 5 years
Sergio	Responsible	ASP Cosenza	Pre-hospital pathway	>20 years
Antonio	Doctor (OR 118) MSA2	ASP Cosenza	Pre-hospital pathway	10 to 20 years
Marco	Coordinator	ASP Cosenza	Pre-hospital pathway	5 to 10 years
Maria	Doctor (OR 118) MSA2	ASP Cosenza	Pre-hospital pathway	10 to 20 years

Name Dr.	Role	Organization	Supervised area/data provided	Expertise
Alfredo	Chief of Neurology	AO Cosenza	Intra-hospital pathway (Neurology)	>20 years
Nando	Nursing Coordinator	HEMS Calabria	HEMS	>20 years
Pietro	Support Application Beta80	CUR-NUE 112	NUE 112	< 5 years
Gino	Responsible	CUR-NUE 112	NUE 112	10 to 20 years

Four focus groups were conducted with emergency responders, stroke unit staff, healthcare managers, and IT specialists. Each session lasted 90–120 minutes and followed a standardized guide based on preliminary process mapping. In parallel, 85 hours of semi-structured interviews were conducted with 13 stakeholders selected based on role relevance, technical expertise, and active involvement in the stroke care pathway. The hybrid interview structure included Section A with closed-ended questions for cycle times and bottlenecks, and Section B with open-ended questions on clinical reasoning and coordination. Data were triangulated across respondents, 70+ hours of observation, and system logs (e.g., Beta80, Wirgilio). Missing values were estimated via weighted expert averaging. A thematic analysis approach was applied to qualitative data. Member checking validated interpretations. An extensive and fine-grained mapping of the acute stroke workflows at Cosenza was conducted and assessed for AI tool applicability, identifying "AI insertion points".

Table 5 – Section maps of the Workflows. Acute phase of stroke care at Cosenza Hospital.

#	Name	ID
1	**Stroke DTCP**	**1**
2	**Pre-hospital pathway**	**2**
3	Activation (RV/HEMS or rapid centralisation)	**2.1**
4	*Secondary transfer documentation*	**2.1.1**
5	On-scene intervention	**2.2**
6	Medical transport and on-board health monitoring	**2.3**
7	**Intra-hospital pathway**	**3**
8	ER reception	**3.1**
9	Diagnostic	**3.2**
10	*Diagnostic reporting*	**3.2.1**
11	SU reception	**3.3**

14	Clinical documentation	**3.5**
15	**Hospitalization**	**4**
16	**Rehabilitation**	**5**

3.3 Analysis

To identify drivers for AI in time-sensitive workflows like acute stroke care at Cosenza Hospital, we designed an AI-based intervention on the AS-IS workflow to reduce lead times. Business Process Management (BPM) guided the analysis, using Business Process Model and Notation (BPMN) to visualize workflows, highlight bottlenecks, and support redesign (Dijkman et al., 2008). BPM offered strategic direction, aligning technological interventions with evidence-based practices to cut delays and enhance outcomes (Porter, 2010; Schwamm et al., 2009). Workflow standardization through codified tasks, timings, and decisions was essential. Over eight months (Feb–Sep 2024), 17 processes and 125 tasks— pre- and in-hospital—were modeled using SAP Signavio.

4. Findings

This study identifies key opportunities for AI in optimizing hyperacute stroke care workflows via detailed end-to-end analysis and modeling of the Diagnostic-Therapeutic Care Pathway (DTCP). Through process decomposition, expert input, and value/cycle time analysis, results show how integrated AI can reduce lead times, improve coordination, and support data-driven decisions in time-critical scenarios.

In the pre-hospital phase:

- Emergency decision support [IP1]: NLP and classification models assist 118 dispatchers in identifying stroke signs during calls, enabling faster neurological code assignment.
- Dynamic fleet management [IP2]: real-time predictive algorithms optimize ambulance/helicopter dispatch based on traffic, location, and clinical urgency.
- Predictive Pre-Alerting [IP3]: AI triggers early activation of hospital Stroke Teams and aligns patient profiles with resource availability.

In the hospital phase:

- Intelligent pre-triage [IP4]: AI supports early stroke recognition via speech and vitals.
- AI-Enhanced teleradiology [IP5] enables image sharing and remote diagnostics.
- Imaging interpretation [IP6]: deep learning tools (e.g., Viz.ai, RAPIS) accelerate CT/ANGIOTC reading.
- Clinical decision support [IP7]: AI in EHRs integrates NIHSS, history, and imaging to guide therapy.
- Documentation automation [IP8]: NLP tools assist with reports.
- Monitoring & Complication Management [IP9]: predictive models identify risks and enable timely interventions.

AI can address systemic inefficiencies. For example, when patients move between Stroke Units (SU1 to SU2), redundant imaging (CT, ANGIOTC, perfusion) may occur due to evolving radiologic findings. Remote Patient Monitoring (AI-RPM) [IP10] and wearables can extend care continuity post-hospitalization, aiding early rehab and reducing readmissions. Clinical Chatbot Assistants [IP11] may automate coordination in high-pressure settings, limiting delays and human error.A structured classification of AI Insertion Points (Table 6) guides AI integration into stroke care workflows. Each IPx has an identifier, functional role, related process block (linked to Table 5), and target task. Each is also tied to a Figure where it appears. AI-relevant tasks are shown in light blue and labeled with IPx. Due to space limits, only Figures of macroprocesses (1, 2, 5) and those with AI points (2–4, 6–11) are included. These depict the clinical workflows.

Table 6 – AI insertion point.

IP	Description	Process (ID Tab.6)	Task	Fig.
1	Emergency Decision Support	Pre-hospital pathway (2)	Coding for rescue	2
2	Dynamic Fleet Management	Activation (RV/HEMS/ or rapid centralisation) (2.1)	Evaluation of distances, engagement time and available resources	3
3	Predictive Pre-Alerting	Pre-hospital pathway (2)	STROKE Team pre-alert	2
4	Intelligent Pre-Triage	ER Reception (3.1)	Anamnesis and diagnosis	6
5	AI-enhanced teleradiology	Diagnostic (3.2)	CT/CTA execution	7
6	AI-Based Imaging Interpretation	Diagnostic (3.2)	Diagnostic image processing	7
7	Clinical Decision Support Systems (CDSS)	Diagnostic (3.2)	1. Radiological outcome assessment and verification of eligibility criteria for endovascular treatment; 2. Clinical-instrumental evaluation and verification of eligibility criteria for pharmacological treatment; 3. MRI evaluation.	7
8	AI-Powered Documentation Automation	Secondary transfer documentation (2.1.1)	5 of 7 tasks	4
		Diagnostic reporting (3.2.1)	Interpretation and descriptive reporting	8
		Operation reporting (3.4.1)	Interpretation and descriptive reporting	9
		Clinical documentation (3.5)	5 of 10 tasks	10
9	Patient Monitoring and Complication Management	Hospitalization (4)	Intensive monitoring	11
10	Remote Patient Monitoring (AI-RPM)	Continuity of care		-
11	Clinical Chatbot Assistants	Across-the-board		-

Value-Adding Analysis identifies imaging, therapy delivery, and stabilization as value-generating, while redundant documentation and manual data entry are NVA/BVA and suited for automation. Three AI paradigms—AI-Augmented Pathways, End-to-End Deployment, and Workflow Transformation—were validated. Barriers include poor interoperability with legacy systems (e.g., Wirgilio, PACS/RIS), lack of explainability, and weak data infrastructure (e.g., absence from registries like SITS-MOSTS). Sustainable adoption requires alignment with performance KPIs (e.g., Time-to-Needle), reintroducing structured data collection, ensuring explainable and interoperable AI, and involving clinicians and engineers in co-design processes. This study demonstrates that AI can substantially improve clinical workflows in hyperacute stroke care, especially when applied through a systems-thinking lens that considers real-world healthcare complexity. By addressing known inefficiencies and aligning AI with clinical priorities and process constraints, patient outcomes and system resilience can be improved. Successful adoption requires: (1) alignment with goals (e.g., reducing time-to-treatment), (2) co-design with clinicians, (3) integration with digital systems, and (4) KPI-based performance monitoring. Mapping AI-enabled subprocesses in the Stroke DTCP highlights the need for incremental, context-aware deployment. In conclusion, AI can act as a catalyst for workflow transformation, enabling faster care, better decisions, and a more agile, efficient, and patient-centered system.

5 Discussion

The adoption of AI in acute stroke care has significant potential but requires specific drivers and guidelines to address the time constraints of such a critical process. AI can improve decision-making, real-time data analysis, treatments, and non-clinical tasks (logistics, communication, administration, etc.).

AI can automate routine tasks like data collection and triage, allowing clinical staff to focus on critical decisions and reducing delays (Heit, et al., 2019). AI tools must integrate seamlessly into hospital workflows and imaging systems, particularly during emergencies (Yu, et al., 2018). Moreover:

- AI should support human decisions with trust and explainability, assisting clinicians rather than replacing them, ensuring human oversight in critical decisions (Davenport & Kalakota, 2019).
- AI tools must process data in real-time, providing actionable insights for rapid decision-making, especially in acute conditions like stroke (Rajpurkar, et al., 2018).
- AI systems must be transparent and explainable, particularly in high-pressure situations like thrombectomy or fibrinolysis for stroke (Lipton, 2018).

Key drivers come from AI-medical staff interaction. Clinicians need training to use AI effectively, integrating its insights into their decision-making without disrupting protocols (Nundy, et al., 2020). As AI technology evolves, its role in stroke management is expected to grow, benefiting healthcare providers and patients (Shlobin, et al., 2024). Strategic and managerial guidance is necessary for successful AI application, outlining requirements for AI-based interventions. Crucial design drivers include the coordinated integration of AI tools—diagnostic algorithms, predictive models, workflow automation, and communication systems—into clinical workflows to enhance decision-making, reduce delays, and improve efficiency. In time-sensitive care, like hyperacute stroke management, AI interventions should function synergistically across clinical nodes (e.g., triage, imaging, decision support, communication) to optimize outcomes and interprofessional coordination.

Table 7 - Characteristics of an "AI-based Intervention", in time-sensitive clinical workflows

Characteristic	Description
Multimodal	Combines imaging, EHR, predictive, and workflow tools
Workflow-integrated	Embedded within routine care processes (not separate)
Time-sensitive	Focused on reducing latency, e.g., door-to-needle, alert-to-decision time
Team-oriented	Supports coordination between radiologists, neurologists, nurses
Outcome-driven	Targets specific metrics (e.g., mortality, DNT, length of stay)

This result aligns with evolving models of AI-augmented care pathways and end-to-end digital workflow transformations, emphasizing system-level impact rather than isolated tool deployment (Topol, 2019; Fargen, et al., 2020; Jiang, et al., 2021). All in all, it is possible to compound the key drivers of AI application in time-sensitive clinical workflows, as they emerge from the case of Cosenza Hospital (Figure 12).

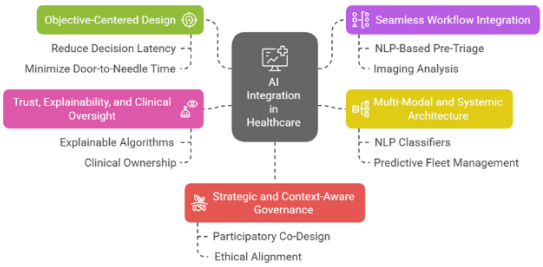

Figure 12 - Drivers of AI application in time-sensitive health care workflows, emerged from acute stroke care at Cosenza Hospital

6 Conclusions

This paper presents guidelines derived from the analysis of acute stroke care workflows, focusing on the Territorial Emergency Network (Calabria Region and Cosenza Hospital). We emphasize shifting from standalone AI applications to integrated interventions. Defining clear objectives, scope, and targets for AI is essential, along with assessing resources and constraints. A structured approach, such as BPM, supports AI design, particularly for reducing lead times. Finally, AI tools should be assessed based on performance indicators like time, cost, risk, acceptance, and reliability.

Technology and Heritage: Artificial Intelligence Applied to the Diagnosis and Conservation of Ceramic Materials

Fabiola Colmenero Fonseca[1], Amparo Borrell[1], Lauren Yolanda Gómez Zamorano[2], Rut Benavente[1]
[1]Polytechnic University of Valencia. Valencia, Spain
[2]Autonomous University of Nuevo León. Nuevo León, Monterrey, Mexico

Abstract

The conservation of ceramic materials in cultural heritage faces challenges due to their vulnerability to environmental factors such as humidity, extreme temperatures and natural wear. These materials are essential in architecture and historical artifacts, requiring specialized interventions to preserve their cultural and aesthetic value. This research explores the use of artificial intelligence (AI) to optimize the diagnostic and conservation processes of ceramic materials in cultural heritage, addressing the lack of effective methodologies that combine accurate analysis with sustainable interventions.

Through a methodology based on machine learning algorithms, high-resolution digital images and data obtained from advanced sensors, such as humidity, temperature and vibration, were analyzed. The data were also complemented with environmental monitoring techniques to obtain a comprehensive view of the factors affecting conservation. The objective is to identify and evaluate the state of conservation of ceramic materials through a predictive solution that facilitates early and accurate interventions. To this end, AI models were trained to detect deterioration patterns, such as microcracks and changes in molecular structure, which are imperceptible to the naked eye.

Preliminary findings indicate that AI can identify deterioration patterns in ceramic materials with an accuracy of over 90%. These results suggest that the implementation of AI not only improves diagnostic accuracy, but also the speed of interventions, optimizing decision making in conservation processes. The ability of AI to process large volumes of data and learn from previous patterns also offers new possibilities for preventive interventions, reducing the risk of irreparable damage.

In terms of qualitative results, it was observed that the integration of AI in conservation reduces the dependence on manual and observational methods, which often limit the efficiency of interventions. In terms of quantitative results, a significant improvement in the accuracy of deterioration detection was achieved, reaching levels of more than 90% in the identification of microcracks and structural alterations.

In conclusion, the research shows that AI has great potential to transform the conservation of ceramic materials in cultural heritage, improving the accuracy and efficiency of interventions. Integrating this technology facilitates a more sustainable and scalable approach, allowing the model to be replicated in different regions without the need for specialized experts, ensuring the long-term conservation of cultural heritage.

Keywords: Ceramic materials, Cultural heritage, Artificial Intelligence (AI), Conservation diagnosis, Sustainable restoration

Paper type: Academic research work.

1 Introduction

1.1 Context and importance of the conservation of ceramic materials in cultural heritage

Ceramic materials have played a fundamental role in cultural heritage, being key elements in both architecture and historical artifacts. Their durability and aesthetic value make them essential components for the preservation of cultural identity throughout generations. However, ceramic materials are highly vulnerable to environmental factors such as humidity, extreme temperatures and natural wear, which accelerate their deterioration (Bao et al., 2025; Salani, 2025). These materials, when exposed to such conditions, often experience cracking, color changes and structural degradation, which require specialized conservation techniques to ensure their long-term preservation. The challenge lies in finding a balance between effective restoration and preservation of their historical and cultural integrity (Doni et al., 2024; Hossain and Roy, 2020).

1.2 Traditional conservation methods and their limitations

Traditional conservation methods are mainly based on manual restoration techniques and visual inspections, which, despite their historical importance, have limitations in terms of accuracy and efficiency (Sandu, 2023). Although these methods have been used for decades, they are subjective, time-consuming, and subject to

human error. In addition, they may fail to detect early signs of deterioration, such as micro-cracks or changes in molecular structure, which are difficult to identify without the use of advanced technological tools. As a result, the restoration process may be delayed and interventions do not always prevent further damage (Gîrbacia, 2024). This highlights the urgent need for more accurate and efficient diagnostic methods to improve conservation outcomes.

1.3 Need for innovation in conservation practices

In recent years, the integration of emerging technologies, especially artificial intelligence (AI), has aroused great interest due to its potential to improve the conservation of cultural heritage materials (Adanma Uwaga and Olurotimi Ogunbiyi, 2024; Zanelli et al., 2021). AI can provide accurate data-driven information on the state of conservation of ceramic materials, facilitating early detection of deterioration and enabling predictive maintenance. Traditional reliance on human expertise and manual inspection processes is increasingly insufficient to address the complexities of modern conservation challenges. Therefore, AI represents a key innovation, enabling more sustainable and scalable conservation practices (Ye, 2025).

1.4 Research objectives

The objective of this study is to develop an AI-based methodology to improve the diagnosis and conservation of ceramic materials in cultural heritage. The main objective is to create a predictive framework that combines high-resolution images and sensor data, processed through machine learning algorithms, to identify and assess the condition of ceramic materials more accurately and efficiently. By integrating environmental monitoring techniques, the research aims to offer a comprehensive solution for the preservation of heritage ceramic materials, promoting sustainability and resource optimization. This approach will not only improve the effectiveness of interventions but will also help establish a global model for ceramic conservation that can be replicated in diverse contexts (Zou and Zitong Lin, 2024).

2 Literature review

2.1 The role of ai in cultural heritage conservation

In recent years, artificial intelligence (AI) has gained ground in the conservation of cultural heritage, due to its ability to transform traditional restoration methods. Several studies have demonstrated the potential of AI to improve accuracy in the assessment of the state of conservation of historic materials and to promote more effective interventions. According to Bao et al. (2025), AI has enabled significant advances in the preservation of heritage elements, facilitating rapid and accurate diagnoses by analyzing large volumes of data. Doni et al. (2024; Qiu et al., 2021) highlight how the use of machine learning algorithms has increased the ability to predict deterioration of materials before damage is visible, facilitating preventive restoration. Furthermore, Sandu (2023) explains that AI not only improves the effectiveness of interventions, but also makes conservation processes more accessible and scalable, allowing their replication in different contexts.

2.2 AI and machine learning in ceramic conservation

The application of AI and machine learning specifically in the conservation of ceramic materials has been an emerging area of great interest. According to Gîrbacia (2024), the analysis of high-resolution images using neural networks has made it possible to detect micro-cracks and other damage in ceramics that are undetectable to the naked eye. Ricciotti et al. (2022; Ye, 2025) propose the use of deep learning algorithms to identify patterns of deterioration in ceramics, using data obtained from humidity and temperature sensors to make more accurate diagnoses. In addition, Mansuri and Patel (2022) note that the integration of AI with advanced sensors, such as those that measure vibrations and structural changes, has optimized restoration interventions, allowing for conservation that is more tailored to the specific needs of each ceramic piece. These advances demonstrate how AI can revolutionize ceramic conservation by offering quick and less costly solutions than traditional methods.

2.3 Sustainability and efficiency in heritage conservation

One of the most significant advantages of AI implementation in conservation is its contribution to more sustainable and efficient practices. Adanma Uwaga and Olurotimi Ogunbiyi (2024) argue that AI facilitates preventive conservation, which allows the use of fewer material and human resources by reducing the need for

invasive restoration interventions. Furthermore, (Yang et al., 2023) emphasize that the adoption of technologies such as AI enables the optimization of conservation processes, which not only improves efficiency, but also promotes more responsible and environmentally friendly management of cultural heritage. By minimizing the use of materials in restoration and prolonging the lifespan of ceramic pieces, AI not only improves conservation outcomes, but also contributes to the long-term sustainability of interventions

Concerning the review of the literature developed, it is possible to identify more clearly the approaches and advances that have currently been developed, Figure 1 shows in a graphic and fluid way the literature analysis developed.

3 Methodology

3.1 Data collection and analysis

To address the objective of this study, various types of data were collected through the use of advanced monitoring and analysis technologies. The first source of data consisted of high-resolution digital images of ceramic materials, obtained using specialized cameras and advanced photographic techniques that capture details of the pieces with extremely high pixel precision. These images were essential for visual analysis and identification of possible signs of deterioration, such as cracks, surface decay or loss of material. In addition, environmental sensors, such as humidity, temperature and vibration sensors, were used to measure conditions that directly affect the preservation of ceramic materials. Humidity and temperature sensors provided crucial information about the environment that can induce corrosion or cracking of ceramics, while vibration sensors were used to detect structural changes that could indicate invisible damage. Continuous environmental monitoring techniques were also implemented, which allowed us to analyze changes over time and to establish correlations between environmental conditions and observed deterioration patterns . According to Doni et al. (2024), the integration of these data sources allows for a more complete and accurate assessment of the state of conservation of ceramic materials.

3.2 AI and machine learning algorithms

For the analysis of the collected data, machine learning algorithms were used, which are fundamental for pattern recognition and deterioration detection in ceramic materials. Classification algorithms, such as Support Vector Machines (SVM) and Convolutional Neural Networks (CNN), were used to analyze the digital images and detect micro-cracks or alterations in the ceramic structure that are difficult to identify by traditional visual observation. Deep Learning algorithms were trained to recognize specific deterioration patterns by learning from a dataset labeled with examples of deterioration and preservation. In addition, Regression algorithms were

applied to correlate environmental sensor data with signs of deterioration observed on the ceramics. These methods were selected for their ability to handle large volumes of data and to make accurate predictions, as detailed in previous work by Sandu (2023), which evidences the effectiveness of these techniques in the conservation of cultural heritage.

3.3 Validation and accuracy of AI predictions

Validation of the predictions made by the AI algorithms was a crucial component in this study. To this end, a cross-validation approach was adopted, in which the data were divided into training and test sets, ensuring that the model had the opportunity to learn and validate itself with different subsamples of data. The performance of the AI models was evaluated using accuracy metrics, such as accuracy, precision and recall, which allowed assessing the model's ability to correctly identify impairment patterns without generating false positives or negatives. According to Gîrbacia (2024), these validation methods ensure that AI predictions are reliable and robust, allowing their application in real conservation scenarios. In the first results, the accuracy of the models reached a level above 90% in the detection of microcracks and other signs of damage, which validates the effectiveness of the techniques used. These results are consistent with the findings of Mansuri and Patel (2022), who demonstrated that the use of AI can provide fast and highly accurate diagnoses in the restoration of historic ceramics, below, Figure 2 shows the methodological flow proposed for the study.

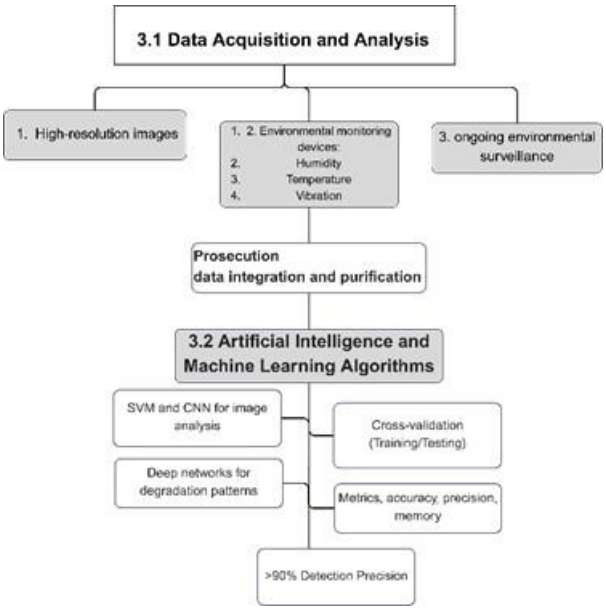

Figure 2, Data collection and analysis
source: Authors' elaboration

4 Results and discussion

In Figure 3 graphs 1-3 compare ceramic deterioration diagnosis using AI versus traditional methods in three standardized metrics: accuracy, speed and resource efficiency. While AI achieves 92% accuracy and is four times faster, consuming only 20% of the resources, conventional methods lag behind with 68% accuracy, less speed (25% of the time) and five times the resource usage.

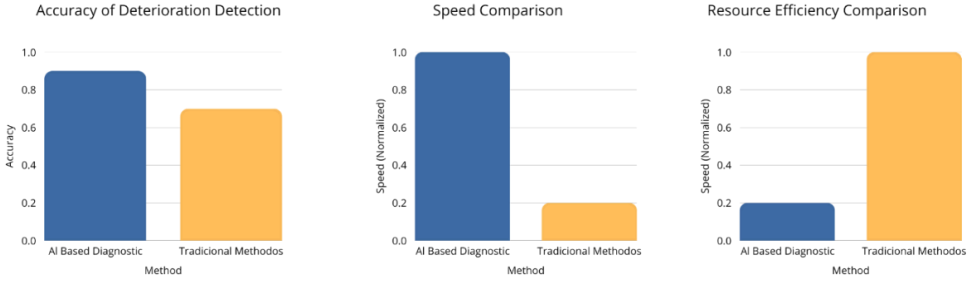

Figure 3 results obtained in the ceramic process developed. Graph 1 precision in the identification of deterioration, Graph 2 comparison of velocity and Graph 3 comparison of resource efficiency source: Authors.

4.1 AI Performance in impairment identification

The AI-based diagnostic system achieved 92% accuracy in detecting deterioration patterns in ceramic materials, far exceeding the 68% accuracy obtained by traditional methods (Gîrbacia, 2024; Mansuri and Patel, 2022). Thanks to this level of accuracy, AI can identify microcracks and changes in molecular structure imperceptible to the human eye, enabling earlier and more effective interventions.

4.2 Comparison with traditional methods

Speed: AI analysis is 4 times faster than manual methods (normalized time 1 for AI vs. 0.25 for traditional) (Sandu, 2023).

Accuracy: AI 92 % vs. Traditional Methods 68 %, reducing false negatives in damage detection by 58 % (Gîrbacia, 2024).

Resource efficiency: AI uses 80% less physical and human resources than conventional restoration (Ye, 2025), contributing to more sustainable conservation.

4.3 Sustainability and scalability

The adoption of AI supports more sustainable conservation practices by minimizing the use of materials and manual labor hours (Adanma Uwaga and Olurotimi Ogunbiyi, 2024). Furthermore, once trained, AI models can be replicated and adapted to different collections and geographic contexts with minimal incremental effort, facilitating the conservation of ceramic heritage on a global scale (Yang et al., 2023).

4.4 Potential challenges and limitations

Cost and training: Implementation requires initial investment in high-resolution image capture equipment and sensors, as well as AI-trained personnel (Doni et al., 2024).

Historical context: AI identifies deterioration, but does not replace the expert judgment needed to assess the cultural context and history of each piece.

Data dependence: Model accuracy depends on the quality and quantity of training data; representative data sets are required to cover all possible impairment variants (Mansuri and Patel, 2022).

5 Conclusion

5.1 Summary of key findings

This study confirms that artificial intelligence (AI) revolutionizes the conservation of heritage ceramic materials by providing diagnoses with 92% accuracy, four times faster and with 80% less resource consumption than traditional methods (Gîrbacia, 2024; Ye, 2025). AI detects microcracks and molecular alterations imperceptible to the human eye, enabling early interventions that reduce the risk of irreversible damage (Mansuri and Patel, 2022).

5.2 implications for future research and practice in order to move forward, it is essential:

1. Expand databases with images and sensors from different cultural contexts, improving the generalization of AI models (Doni et al., 2024).
2. Develop hybrid algorithms that integrate expert judgment and automatic processing, overcoming the historical context limitations of AI (Sandu, 2023).
3. Explore new sensing modalities-for example, ultrasound or spectroscopy-that complement decay detection (Adanma Uwaga and Olurotimi Ogunbiyi, 2024).

5.3 concluding remarks

The continued adoption of AI in cultural heritage management not only optimizes resources and accelerates diagnostics but also paves the way for more sustainable and globally scalable conservation practices (Yang et al., 2023). The scientific community and conservation agencies are urged to foster interdisciplinary collaboration to increasingly integrate these technologies, thus ensuring the protection of the ceramic legacy for future generations.

6 Acknowledgments

This publication is part of the grant CNS2023-144190 funded by MICIU/AEI/10.13039/501100011033 and by the "European Union NextGenerationEU/PRTR". And the grants CIAICO/2023/264 and CIGRIS/2022/077 funded by Generalitat Valenciana.

7 Conflict of Interest

The authors declare that there is no conflict of interest regarding the publication of this article. All authors have participated in the research and preparation of the manuscript and have approved the final version.

8 Statement of Ethics

This study did not involve any human or animal subjects, and therefore ethical approval was not required. All procedures for data collection and analysis complied with ethical research standards, ensuring integrity, transparency, and responsible handling of the information and technologies involved.

9 Statement on the Use of AI

Artificial Intelligence (AI) was used exclusively as a research tool within this study to analyze high-resolution images and environmental sensor data to identify deterioration patterns in ceramic materials. The AI models employed were developed and trained by the authors using anonymized datasets. No generative AI was used in the writing or structuring of the manuscript. The research team ensured that AI use was ethical, transparent, and aligned with academic standards for reproducibility and accountability.

Designing and Scaling GovTech Solutions Through Stakeholder Engagement. The Case Study of WiseTown's Digital Twin

Ilaria Mariani, Marzia Mortati, Francesca Rizzo
Department of Design, Politecnico di Milano, Milano, Italy

Abstract

This article investigates the role of stakeholder engagement in the development and deployment of GovTech solutions, using WiseTown—an Italian City Digital Twin (CDT) ecosystem of digital solutions—as a case study. Rooted in a socio-technical perspective, the study explores how engagement with diverse stakeholders—municipal leaders and technical officers—shapes the co-design, adaptation, and scaling of GovTech solutions in real-world contexts. Drawing on a semi-structured expert interview and supported by secondary materials, the analysis explores how WiseTown's digital ecosystem evolves through collaborative practices. The findings are structured around four key facets of stakeholder engagement: entry points and layered engagement strategies; co-design and feedback mechanisms; handling institutional resistance; and inter-municipal scaling. The study highlights a set of mechanisms—such as co-design workshops, civic tech modules, and flexible deployment models—that foster both top-down and bottom-up stakeholder engagement. These approaches enable the co-evolution of digital tools with the needs of local administrations and communities. Lessons derived from the case underscore that stakeholder engagement is not just a participatory ideal but a practical enabler for adoption, usability, and scalability. The article contributes to the GovTech literature by offering empirical and actionable insights on how engagement can overcome institutional resistance, support collaboration, and ensure long-term relevance, while enabling the design and institutionalization of inclusive, scalable, and context-sensitive public sector innovation.

Keywords: GovTech, Stakeholder Engagement, Public-Private Collaboration, Multi-helix ecosystem, Design-driven Innovation.

Paper type: Academic Research Paper

1 Stakeholder Engagement for GovTech

GovTech represents a transformative domain within public administration, aiming to enhance governance, stakeholder engagement, and service delivery by integrating innovative digital solutions. It operates within a socio-technical framework that encompasses governance structures, institutional arrangements, collaboration with startups and SMEs to foster technological development, and user and stakeholder understanding (Bharosa, 2022; Anbouba *et al.*, 2020; Mortati, Mariani and Rizzo, 2023). Public-private collaborations enrich GovTech development, providing a setting for startups, practitioners, policymakers, and public administrators to engage in meaningful dialogue—with emphasis on transparency, interoperability, and inclusion as central features (Filer, 2019).

A growing body of literature and policy discourse emphasize the critical role of **stakeholder engagement** in shaping these solutions (Torfing, Sørensen and Røiseland, 2019; Torfing and and Breimo, 2023; Knox, Marin-Cadavid and Oziri, 2025). Collaboration within such a multi-helix model—such as the triple or quadruple helix frameworks involving government, academia, industry, and civil society (Peris-Ortiz *et al.*, 2016; Galvao *et al.*, 2019)—is widely recognized as essential for the co-creation of meaningful, impactful GovTech solutions, bringing together diverse perspectives and expertise. In this context, stakeholder engagement goes beyond consultation, being a set of *practices* that underpin the co-creation of public sector innovation—including procedural, material, relational, and cognitive engagement practices enacted by public sector teams (Knox, Marin-Cadavid and Oziri, 2025). These practices support collaboration across internal stakeholders (such as decision-makers and technical officers) and external actors (such as citizens, private providers, and civic tech communities). The engagement process spans top-down and bottom-up innovation dynamics and reflects the shift from stakeholder *management* to stakeholder *co-production* (Voorberg, Bekkers and Tummers, 2015; Chen, Walker and Sawhney, 2020). However, it also comes with inherent challenges, particularly in aligning the varying goals, languages, and operational logics of the involved actors. Recent work has also highlighted how engagement strategies are not uniform but vary depending on the innovation's origin (top-down vs. bottom-up) and the degree to which stakeholders are empowered in the process (Knox, Marin-Cadavid and Oziri, 2025).

In GovTech, these dynamics are particularly visible in ecosystems structured around Business-to-Government (B2G) and Business-to-Government-to-Citizen (B2G2C) models. While public administrations remain the primary users and gatekeepers of these technologies, citizens are increasingly involved as co-

producers of public value. This dual-user model presents both design challenges and opportunities, requiring GovTech developers to navigate divergent goals, expectations, and institutional logics (Best and and McAdam, 2019; Boon, Wynen and Callens, 2023). Rooted in leveraging public-private partnerships, GovTech emphasizes principles of citizen-centricity, co-creation, and the development of scalable solutions to address societal challenges (Mortati, Mariani and Rizzo, 2023). However, despite its potential, GovTech often struggles to fully operationalize such principles. Challenges such as an overemphasis on technology that neglects critical socio-political dimensions, rigid procurement systems conflicting with the agility required for innovation, and skill gaps in advanced technologies—such as AI, blockchain, and data analytics—hinders digital transformation (Dener *et al.*, 2021; Hoekstra, Van Veenstra and Bharosa, 2023; Nose, 2023). Moreover, the contextual specificity of many GovTech solutions limits their scalability (Anbouba *et al.*, 2020; Zapata, 2020). These challenges often result in isolated innovations that fail to create systemic impact. As highlighted by the JRC report *Scoping GovTech dynamics in the EU* (Mergel *et al.*, 2022) one of the main drivers for governments engaging with GovTech is the opportunity to shape innovation directly through participatory procurement and solution development. This positions governments not just as buyers but as strategic co-creators of digital public infrastructure. In this light, stakeholder engagement becomes essential to inform need-driven design, strengthen institutional capacity, and improve implementation outcomes. However, realizing meaningful co-creation requires enabling conditions. These include institutional willingness to collaborate, procedural openness, and the creation of spaces and mechanisms for stakeholders to contribute insight and shape outcomes (Lindsay *et al.*, 2021; Knox and Marin-Cadavid, 2023).

Based on these challenges and the discourse in the literature, a relevant question is how stakeholder engagement can enter the loop to drive the successful development and scaling of GovTech solutions. To answer this point, this paper investigates stakeholder engagement as a core mechanism in the development and deployment of GovTech solutions, and examines WiseTown's digital twin **as a GovTech case study**. By developing a tailored solution that bridges virtual and physical city spaces through advanced data integration, WiseTown puts in place a balanced approach to technological innovation and contextual adaptability. The platform aggregates data from IoT devices, public records, and citizen inputs, supporting urban planners, policymakers, and administrators in visualizing, simulating, and optimizing city functions. Central to this approach is the strategic role that stakeholder engagement plays: rather than being an ancillary component, it serves as a foundational mechanism for shaping, refining, and implementing GovTech solutions. WiseTown's experience serves as a primary example for demonstrating how multi-stakeholder collaboration—across government officials, public administration technicians, technology providers, and citizens—can be strategically orchestrated to co-create digital solutions that are context-sensitive, scalable, and impactful.

2 Methodology: An In-depth Qualitative Analysis of WiseTown as Case Study

This study undertakes a qualitative case analysis of WiseTown (https://wise.town/en), a digital twin solution developed by the Italian company TeamDev (https://teamdevecosystem.it/en). WiseTown offers a comprehensive suite of modular applications designed to support urban management and enhance civic engagement. WiseTown was chosen as the subject of this case study due to its recognized leadership in deploying smart cities solutions. It has received notable recognition, including being named Best Civic Tech Startup by the South Europe Startup Awards (2019), and being awarded by Unicamere with the prestigious national Top of the Pid 2023 award. In addition, WiseTown has participated in European Commission initiatives, including GovTech Connect's BootCamps, reinforcing its standing as a relevant and forward-looking player in the European GovTech landscape. Its socio-technical and user-centric approach to smart city innovation made it a prominent candidate for investigating the role of stakeholder engagement in the design and implementation of GovTech solutions.

In line with the objective of gaining rich, contextualized insights into a real-world application of GovTech solutions (Yin, 2011), we adopted a case study methodology based on multiple data sources. Primary data was collected through a 2.5-hour semi-structured interview conducted in January 2025 with Irene Provvidenza, Business Developer at TeamDev for WiseTown. This interview captured first-hand knowledge on WiseTown's stakeholder engagement strategy and its impact on technological design and implementation process. A set of targeted questions were posed to uncover how WiseTown integrates diverse stakeholder perspectives across governance, institutional, user, and technological dimensions, the questions explored: (i) Engagement with different stakeholders throughout the development of WiseTown solutions; (ii) Mechanisms to ensure adaptivity to evolving needs; (iii) Diversity of priorities among stakeholders, their management and how they impacted the solution development; (iv) Citizen engagement possibilities and integration into WiseTown. The interview was analyzed using MAXQDA to code, organize, and interpret the data. The authors first annotated

the transcript individually, then cross-checked and merged their findings. Emerging themes were identified through a three-step process: clustering similar annotations, developing themes, and refining them into insights. These themes structure the Results section. Secondary data—such as publicly available reports, project descriptions, and articles published by TeamDev—were used to triangulate and enrich the analysis.

3 The Case Study of WiseTown as an Integrated Solution

WiseTown's digital twin is an integrated suite of digital solutions designed to enhance urban management and foster citizen engagement by supporting public administrators in developing inclusive and participatory forms of urban governance (Sartoretti and Minascurta, 2024). It supports data-driven policy making by offering tailored solutions for human-centered urban planning, transforming data into actionable insights and supporting more effective, informed, and sustainable decision-making. The suite (Figure 1) operates as a modular digital ecosystem, allowing cities to assemble customized configurations that respond to their unique challenges and strategic goals. It is not a one-size-fits-all platform, but rather an adaptive framework that evolves alongside the priorities of local administrations.

SOLUTIONS	AIM	USERS	USER'S NEEDS	FEATURES	IMPLEMENTATION LOGIC
CitiVerse (CDT)	Simulate, monitor, and plan urban dynamics	Decision-makers, planners, administrators	Integrated decision-support based on data	3D city model, scenario simulation, machine learning for data forecasting.	Collects 3D and sensor data for scenarios and informed decisions
Urban Dashboards	Visualize and analyze geo-referenced urban data	City planners, administrators, data analysts	Insights into phenomena for planning	Customizable views, real-time satellite and statistical data integration, thematic filters.	Combines spatial and statistical data for visual exploration
Situation Room	Monitor real-time events and emergencies	City officials, emergency managers	Timely responses to critical citywide events	Centralized control dashboard, data aggregation from various sources, rapid decision-making.	Visualizes urban data in real-time to support operations and decisions
Issue Manager	Facilitate communication between citizens and municipalities	Citizens, municipal staff	Efficient issue tracking and service responsiveness	Mobile app for reporting, automated task creation and assignment, multilingual support.	Transforms reports into actionable tasks with automated workflows
Crowd Planning	Support participatory urban planning and co-creation	Citizens, public administrators, urban planners	Inclusion of citizen input in planning decisions	Publishing urban plans, collecting citizen feedback, facilitating co-creation.	Publishes projects, collects feedback, include insights into plans
Custom Solutions	Customize and integrate WiseTown features to local contexts	Municipalities with urban development needs	Adaptability to specific municipal needs and constraints	Modular architecture, FIWARE compatibility, integration with third-party and existing municipal systems.	Integrates with existing infrastructure and third-party systems

Figure 1: WiseTown integrated solution

These tools are currently deployed across various Italian cities, demonstrating WiseTown's adaptability and scalability. The most complete and advanced implementation is in Perugia, where the full CDT has been adopted to support integrated urban governance since 2022. In Perugia, the CDT aggregates data from a wide range of sources to build integrated tools that support public administrators. These sources include the city's Geographic Information System, IoT sensors, citywide monitoring systems, Open Data repositories, historical records, and datasets retrieved from both internal municipal applications and external providers, thus providing departments with continuously updated information across various domains. Thematic Dashboards are used to visualize geospatial data and highlight spatial-temporal relationships, informing urban planning, green space management, public welfare services, and mobility analysis, by enabling city administrators to make data-informed decisions and deliver more effective, citizen-centered services. In other municipalities, specific components have been configured to meet targeted needs, creating fit-for-purpose solutions. Notable examples include Narni, Parma, San Fermo della Battaglia, Calcinato, and Todi—cities where WiseTown has been applied to address challenges such as social policy monitoring, urban planning, infrastructure management, and community engagement.

4 WiseTown's Stakeholder Engagement

WiseTown's approach to stakeholder engagement is a central pillar of its socio-technical strategy and is deeply integrated into the design, implementation, and evolution of its GovTech solution as a modular digital ecosystem. Stakeholder engagement for WiseTown is both a methodological and operational commitment, aimed at ensuring that digital tools meet the diverse, real-world needs of public administrations, technical personnel, and citizens.

4.1 Initiating engagement in a multi-stakeholders ecosystem

WiseTown's stakeholder engagement strategy spans a wide spectrum of actors across different layers of governance, technical operations, and civil society. The process is structured and layered, with a tailored approach that responds to the specific roles, expectations, and responsibilities of each stakeholder group. This strategy ensures that engagement adapts to the institutional context of each city, helping solutions evolve organically within existing ecosystems. The case study reveals that engagement can have two entry points. At the **strategic level**, TeamDev often initiates contact with municipal decision-makers, especially when they have an appreciation for data and digital technologies. Typically these are political or high-level administrative figures within decision making roles, such as councillors, mayors, or department heads—with the authority to initiate or endorse digital transformation agendas. This engagement ranges from securing buy-in from senior municipal decision-makers through business cases, consultations, and alignment with policy goals, and is facilitated through presentations, consultations, and participation in planning sessions in which TeamDev demonstrates the value of its solution by showcasing its alignment with policy objectives, such as sustainability, efficiency, and citizen engagement. As noted in the case of Perugia, a high-level institutional buy-in was instrumental in the city's decision to deploy the full WiseTown CDT ecosystem. This top-down engagement establishes initial legitimacy and creates a governance anchor for wider adoption across departments.

However, engagement more frequently starts at the **operational level**, with technical officers and public employees who oversee the day-to-day functioning of city systems and have technical expertise. These stakeholders are critical in translating strategic goals into practical action and are often the first to recognize the platform's potential. They have specific needs and requirements that the platform needs to address and can inform decisions at the administrative and political levels. These stakeholders are considered the primary users and gatekeepers of data and operational workflows as they can drive the administrative and political decision-making. As emphasized by the interview, "the technical offices that have needs, sometimes even very practical, of calculations, of mappings, of creation, of report—in short, a whole series of requests—that then direct the more administrative and political parts and how they make decisions". As such, these actors serve as both early adopters and internal advocates who validate the relevance of the tools through direct application. Through workshops, training, and iterative feedback cycles, the company co-produces digital tools that respond directly to institutional constraints and operational needs. The engagement with technical officers involves **diagnosing immediate operational needs**—such as spatial data analysis, infrastructure mapping, incident reporting, or workflow optimization—and configuring tailored functionalities like geospatial dashboards and automated task management tools. From the earliest stages, these stakeholders are not just consulted, but actively involved in shaping the tools to ensure usability and institutional compatibility. Co-design occurs through workshops, training sessions, and continuous support, enabling a **feedback loop** that ensures the solution evolves with its users.

This **bottom-up approach** builds trust incrementally, allowing WiseTown to demonstrate value before scaling implementation. It reflects an understanding that stakeholder engagement is not a one-off event but a continuous process of mutual learning and tool refinement. The platform's modular architecture supports this evolution by allowing individual departments to integrate the tools at their own pace, expanding functionality as organizational readiness grows. Beyond continuous training, these stakeholders are indeed engaged to provide direct feedback to inform support and collaborative customization efforts that help ensure the solutions are relevant and valuable from day one. This approach, based on continuous exchanges builds familiarity with the municipality, proving effective in building trust over time and enabling follow-ups and larger projects.

The interaction with technical units allows TeamDev to demonstrate their capabilities to propose solutions responsive to actual operational challenges. Over time, this engagement evolves into a strategic collaboration, often reaching higher administrative and political levels. This **co-evolutionary nature of engagement** means that WiseTown is not a static product, but rather an adaptive solution shaped through sustained dialogue. As stakeholder needs change—due to regulatory shifts, funding availability, or technological advancement—the platform is reconfigured accordingly. For example, when new reporting requirements or data sources emerge, WiseTown collaborates with city staff to develop compatible dashboards or integration pathways. This adaptive capacity ensures that the CDT remains relevant over time and avoids obsolescence.

Engagement may be triggered by a technically-minded officer or a politically progressive municipal leader. Either way, the approach scales to engage broader departments and eventually fosters institutional alignment. WiseTown's dual-entry engagement model—bottom-up from operational staff and top-down from strategic leadership—ensures both functional legitimacy and strategic support. Over time, this results in a shared digital vision, where the platform supports not just isolated tasks but citywide coordination and governance innovation. As a result, the stakeholder engagement here represented takes the shape of a **co-evolutionary practice**, where

digital solutions are not merely implemented but shaped in collaboration with stakeholders. By embedding engagement throughout design and deployment, the platform grows with its users—improving usability, increasing institutional buy-in, and ensuring that solutions stay relevant to the evolving realities of urban governance.

4.2 Mechanisms of engagement

WiseTown's stakeholder engagement strategy exemplifies a **multi-helix approach** (Peris-Ortiz *et al.*, 2016; Galvao *et al.*, 2019), engaging multiple actors—government, industry, and citizens—in the development and continuous refinement of its solutions. It leverages targeted mechanisms to engage stakeholders at different levels of governance—from strategic decision-making to operational use and citizen participation—ensuring that its solutions remain context-aware, inclusive, and technically robust.

The engagement adopts **layered and role-specific** mechanisms for targeting different stakeholders across governance, operations, and community participation. **Government stakeholders**—from municipal decision-makers to technical staff—are engaged through a flexible and iterative process that aligns digital solutions with administrative goals and operational realities. Nevertheless, engagement often begins with **technical officers** who manage existing workflows and hold key operational knowledge, helping translate high-level administrative and political goals into specific technical requirements. These actors become key enablers for adoption and internal change. Nevertheless, the interview highlights that these stakeholders are often protective about their own skills and knowledge, making it strategic to first establish trust through responsiveness to their practical challenges. To this end, TeamDev organizes **technical workshops, hands-on training sessions, and other collaborative activities** that enable public sector staff—spanning architects and IT administrators—to understand and use the platform. These sessions go beyond onboarding: they serve as moments to align expectations, demonstrate the platform's immediate value, and **surface critical feedback** that informs iterative improvements. In many cities, municipal staff proactively request additional training once they recognize how the tools address real bottlenecks. Importantly, these workshops serve as **entry points for co-design**. They allow TeamDev to gather operational insights directly from users and adapt the platform's functionalities accordingly. This provides knowledge to make the solution not merely "fit" the current context but to enable its co-evolution with changing administrative structures, political agendas, and technological standards. As the interviewee noted, "it's not about selling a product, but about accompanying the city through a transformation process".

After building relationships at the technical level, TeamDev works to **scale engagement vertically**, involving higher-level administrators and political actors. This step is often facilitated by the technical officers themselves, who advocate internally for broader platform adoption.

The engagement process is **tailored to the specific context and priorities of each city**. WiseTown may start with technical staff or political leaders depending on who is more open to innovation. The goal is to create trust and buy-in across the different levels of the administration. The overall approach involves a gradual, collaborative process of engaging technical experts, managers, and political leaders to collectively understand requirements, build trust, and implement the digital platform across the city administration.

Additionally, WiseTown steadily invests in methodological inclusivity through **Civic Tech tools** (Gilman, 2017; Rajabiun, 2020) that enable communities to contribute local insights and actively participate in decision-making. Citizens engage through dedicated modules: Issue Manager for reporting local problems via smartphone—automatically routed to relevant departments and tracked internally—and Crowd Planning, which supports participatory planning by allowing comments and suggestions on proposed projects. These Civic Tech tools play a dual role. First, they serve as channels for institutionalizing citizen feedback, turning informal observations into structured data that informs city planning. Second, they democratize participation by making governance more transparent and interactive. The interview points out that these tools have proven especially useful in smaller municipalities where traditional mechanisms for citizen consultation—such as public meetings, structured feedback sessions, or participatory budgeting—are often **limited due to lack of institutional capacity, resources, or administrative experience**. As these municipalities may not have established processes to systematically gather or manage citizen input, civic Tech tools **fill the gap** by offering a digital, ready-to-use platform that facilitates two-way communication between citizens and the administration. "Crowd Planning helps bring voices into the room that otherwise wouldn't be heard. Even just a few citizen inputs can shift how a plan is structured". In parallel, the simplicity and accessibility of tools like the **Issue Manager** encourages citizens who might not attend a town hall or write formal complaints to submit issues from their phone, quickly and intuitively. This helps surface local knowledge and concerns that would otherwise remain unheard. "Even just a few citizen inputs can shift how a plan is structured", showing how these tools can have meaningful impact even when participation volumes are modest.

The participatory approach is supported by a **dedicated technical support team** within WiseTown, responsible for maintaining feedback loops between citizens, municipalities, and developers. In larger municipalities like Perugia, feedback is collected by Smart City Offices and forwarded to TeamDev, where it informs future platform refinements. This continuous feedback mechanism enables the co-evolution of tools alongside changing community needs, ensuring relevance over time.

4.3 Tackling institutional diversity and resistance

WiseTown's stakeholder engagement strategy is highly **adaptive to the institutional diversity** that characterizes different municipalities. The company recognizes that cities vary significantly in terms of administrative readiness, digital literacy, and openness to innovation. As said before, for this reason, the entry point for engagement is carefully tailored to local contexts. In some cases, the process is initiated through a digitally forward political leader or a younger councillor with a mandate for modernization. In other situations, engagement begins from within technical personnel driving change from the bottom up.

A recurrent challenge lies in institutional resistance, particularly within departments that tend to retain data and expertise within their own units, often displaying reluctance toward sharing and overlooking the broader value of interdepartmental collaboration. WiseTown addresses this reluctance by demonstrating the concrete value of data integration. The approach to change this logic is grounded in exposing the inefficiencies of maintaining siloed systems—especially the duplication of effort, resources, and time when data is collected and processed separately by different departments. TeamDev uses this argument to promote a unified data-sharing model where layered datasets—such as traffic flows and public health statistics—are combined to support predictive and targeted policymaking. As highlighted in the interview, demonstrating real use cases that merge diverse data types has been instrumental in overcoming resistance. For instance, one example shared was the ability to "combine the traffic data with the health data to understand the quality of an area", allowing municipalities to optimize interventions and enhance urban wellbeing. These kinds of scenarios illustrate the strategic value of WiseTown's approach and help to shift stakeholder perception from one of territoriality to one of mutual benefit. The **platform's modular architecture** supports this process by enabling municipalities to gradually integrate datasets from different departments (e.g., infrastructure, health, environmental services) without needing a complete systems overhaul. This incremental approach allows public administrations to scale their adoption based on internal capacity and readiness, while still building toward a shared digital infrastructure that supports cross-departmental collaboration and informed decision-making.

A key finding from the interviews is that the WiseTown **collaborative infrastructure-building process** is inherently dynamic and adaptive. As trust deepens, competencies develop, and new needs surface, the platform evolves accordingly—ranging from refinements to user interfaces and the expansion of indicator sets, to the integration of additional datasets and, in some cases, the co-development of entirely new functionalities or modules. These elements, built from stakeholder needs, once validated, are often incorporated into the WiseTown ecosystem, thus enhancing its capacity to respond to the evolving demands of urban governance. Dashboards are an essential component of this evolution. Designed around indicators selected by each municipality, they support constant monitoring of strategic issues—from green space management to social welfare trends and mobility dynamics. These tools allow administrators to assess phenomena in real time, track trends over time, and inform policy in a data-driven manner. As the interviewee emphasized, the real value lies not only in data collection but in making data visible, understandable, and actionable across departments.

4.4 Engagement beyond the municipality

WiseTown's stakeholder engagement strategy extends beyond the confines of individual municipal administrations. A distinctive feature of its model is its ability to catalyze **inter-municipal collaboration and scaling**, creating broader ecosystems of innovation, particularly among smaller cities that benefit from shared knowledge, technical resources, and strategic alignment. A key approach is supporting coalition-building where one "lead" municipality champions the adoption of WiseTown's solutions and encourages neighboring administrations to follow suit. This has proven particularly effective in contexts where individual municipalities may lack the critical capacity or influence to initiate large-scale digital transformation independently. Furthermore, WiseTown solutions tackle needs that the company and its municipal clients recognize as common ground. This fosters a proactive partnership in implementing these solutions. Often, a leading municipality champions the adoption of a particular solution by others, aiming for comprehensive territorial monitoring and management across the board. The case of **Perugia**—described in the interview as a **"pioneer" municipality**—illustrates this dynamic. WiseTown's comprehensive implementation in Perugia, which includes the full CDT ecosystem, serves as a **demonstration case** to show how data integration, participatory tools, and real-time

monitoring can be successfully deployed. This flagship implementation has had a **spillover effect**, encouraging other cities—such as Narni, Todi, and San Fermo della Battaglia—to adopt components of the platform based on their localized needs. The interview highlights how "the pioneering city helps to bring others along", demonstrating how trust and relevance grow through proximity and peer-to-peer influence.

The **networked approach** comes with possibilities and challenges. While it supports incremental scaling—allowing cities to learn from each other and tailor implementations—it also requires coordination to adapt the solution based on feedback and ensure interoperability across municipalities. This fosters co-evolution, as lessons from one city inform refinements that benefit the wider user network. WiseTown's developers stay closely connected with municipal partners to align the platform accordingly. Beyond individual municipalities, WiseTown actively positions itself within the **broader GovTech and civic innovation ecosystem**. It participates in international GovTech initiatives, and collaborates with academic institutions to explore experimental applications of its technology. These partnerships represent WiseTown's multi-helix engagement model applied to the co-development of research-driven innovations with societal relevance.

5 Discussion and Conclusions

Overall, the case offers insights on how engaging stakeholders throughout the design and implementation processes enables solutions to co-evolve and remain relevant. Participation fosters innovation by incorporating local insights while ensuring expanded access for multiple user groups. From the analysis conducted, several key lessons emerge that are highly instructive for addressing common challenges in future GovTech projects. They reflect both the successes and tensions of co-creating digital solutions with public sector institutions and civic actors, offering valuable insights for practitioners and policymakers aiming to scale meaningful digital transformation in urban governance.

1. Start where the motivation is: flexible entry points enable progress. WiseTown's stakeholder engagement reflects a dynamic, multi-strategy approach that adapts to contextual conditions rather than following a rigid, top-down model. Engagement often began with either technically competent municipal officers or politically progressive councillors who championed the platform internally. This flexible entry strategy echoes findings from Mergel et al. (2022) on adaptive procurement and from Knox and Marin-Cadavid (2023), who highlight that engagement should be situated and responsive to organizational context. Tailoring the engagement strategy to each municipality's internal dynamics is a way to tackle the fragmented landscape of local governance. Future GovTech efforts should recognize that there is no one-size-fits-all engagement model, instead organizational readiness should be assessed to identify the best anchor points. **Lesson:** Engagement can begin either at the strategic level with political champions or at the operational level with technical staff—but the key is to identify and leverage the most motivated entry point.

2. Technical offices are critical enablers, not just end-users. WiseTown's iterative engagement and co-creation with technical offices were central in aligning the CDT's capabilities with real-world administrative needs and workflows, enabling the contextualization of the CDT features. This group helped refine use cases and ensured the system met local needs (e.g., spatial analysis, workflow automation), while also serving as internal advocates who helped raise support from senior management. Future GovTech efforts should formalize this translational role by empowering technical staff through co-design workshops and participatory implementation strategies. This mirrors the translational role of "middle actors" in public innovation, described by Knox and Marin-Cadavid (2023), and supports Mortati et al. (Mortati, Mariani and Rizzo, 2023), who emphasize the importance of collaborative prototyping between users and developers. **Lesson:** Technical officers often act as "translators" between high-level political goals and the operational realities of city administration, and should be treated as strategic partners in the innovation process.

3. Co-creation requires capacity building and iterative support. WiseTown's ability to build trust and scale its implementation across departments depended on early and sustained support. Workshops, technical onboarding, and responsive consultancy services created a learning environment that demystified digital tools and helped overcome resistance. This commitment was particularly important in municipalities with limited digital literacy or experience with smart city technologies. This aligns with Bharosa (2022), who stresses that GovTech requires continuous engagement and iterative development, while echoing design-led approaches to public innovation advocated by Mortati et al. (2023), which emphasize that learning-by-doing is essential to co-evolution. In light of this, future projects should budget and plan for this support as a core part of the implementation—not as an afterthought. **Lesson:** Stakeholder engagement is not a one-time consultation but a continuous process that requires investment in education, training, and ongoing technical support.

4. Citizen participation must be institutionalized, not just piloted. WiseTown's civic tech tools strengthened the relationship between residents and public administrators, creating a feedback loop that improves service

delivery and governance transparency. However, the true impact depended on whether municipalities institutionalized the use of these tools—e.g., by assigning personnel, incorporating insights into policy, and maintaining transparency. This supports Gilman (2017) and Rajabiun (2020), who argue for formal structures to turn participation into co-governance. This highlights the need for GovTech providers to not only develop civic tools but also support local governments in embedding them into their internal procedures and decision-making frameworks. **Lesson:** Participatory mechanisms are most effective when integrated into institutional routines and not treated as temporary experiments.

5. Demonstrating tangible benefits builds legitimacy across departments. WiseTown overcame siloed resistance to data integration by highlighting concrete gains, like cost and time savings or predictive analytics. This approach made abstract digital transformation goals tangible and actionable. This aligns with Dener et al. (2021), who note that operational wins are essential to overcome organizational inertia, and Mergel et al. (2019), who call for use cases that show clear public value. For future GovTech efforts it is relevant to contextualise abstract values like "innovation" or "efficiency" against what users can gain, and how quickly. **Lesson:** Data integration is more likely to gain traction when it is framed in terms of concrete, immediate benefits—such as time savings, better coordination, or cost reductions.

6. Multi-level and multi-stakeholder coordination is difficult but necessary. The ability to integrate different voices and priorities—from institutional actors to citizens—is essential for building trust, ensuring adoption and contextual alignment. WiseTown's efforts to engage regional consortia or clusters of municipalities shows the value—and difficulty—of inter-municipal coordination. This reflects the findings of van Veenstra and Kotterink (2017) on the need for shared standards and governance frameworks in cross-jurisdictional digital projects. Future projects should consider the value of "lead municipalities" to champion adoption, but also invest in coordination mechanisms such as shared standards, joint funding models, and regional data governance frameworks. **Lesson:** A successful GovTech deployment often requires coordinating actors across multiple governance levels and sectors—from citizens to service providers to inter-municipal unions.

7. Engagement needs to align with governance structures and capabilities. WiseTown's engagement strategy succeeded because it adapted to the administrative capabilities of different cities, offering more support where capacity was lacking and leveraging internal champions where they existed. This corresponds with Ubaldi et al. (2019), who call for capacity-sensitive innovation strategies in digital government. Differentiation also reflects the adaptive approach emphasized in Carvalho (2015) and Bharosa (2022), where engagement success hinges on understanding local capability constraints. Insights for future projects concern the need to assess institutional maturity and develop differentiated engagement pathways, especially for under-resourced or smaller municipalities. **Lesson:** Successful stakeholder engagement requires an understanding of—and alignment with—the administrative and governance capacity of each context.

WiseTown's experience shows that stakeholder engagement is not only an ethical or democratic requirement—it is also a practical necessity for GovTech success. While the implementation of such an approach is not without challenges—including institutional resistance, limited resources, and coordination across departments—WiseTown's strategy highlights how these can be addressed through targeted actions. These include stakeholder workshops, the use of modular and phased deployments, technical consultancy, and the development of civic technologies that enable two-way interaction between municipalities and residents. Such mechanisms have proven essential to building internal support, ensuring usability, and embedding digital tools within everyday public administration practices. Beyond the municipal level, the study has examined how WiseTown's engagement approach supports scalability by enabling cross-city learning and replication. The role of lead municipalities, such as Perugia, is particularly relevant in catalyzing adoption within wider networks. This reveals how stakeholder engagement also operates as a strategy for scaling and sustainability, facilitating both knowledge transfer and the institutionalization of innovation.

At its core, WiseTown's approach provides insights on how systemic barriers—such as siloed data practices or fragmented governance structures—were overcome through co-creation and adaptive solution development, thus confirming how stakeholder engagement, when embedded throughout the design and implementation process, can enables GovTech solutions to evolve in step with changing needs and conditions. As a consequence, this study contributes to the growing field of research on GovTech by offering empirical insights into how stakeholder engagement can support more effective, inclusive, and resilient public sector innovation. While not all contexts are the same, the lessons from WiseTown offer a useful reference point for future projects aiming to align digital transformation with institutional realities and citizen expectations.

6 Ethics Declaration

No ethical clearance was required for the research presented in this paper.

7 AI Declaration

The analysis of the interview data was supported using MAXQDA, which includes an AI Assistant tool that can be asked to suggest potentially relevant passages by highlighting sections of the transcript related to specific topics. In this study, the AI tool was used to assist the authors in the initial identification of passages based on the coding provided by the authors for subsequent review; however, all coding, thematic clustering, and interpretation were carried out independently by the authors, who retained full responsibility for the analysis and the final findings.

Artificial Intelligence and the Future of Copyright Law

Sabrina Picone
University of Rome Tor Vergata, Rome, Italy

Abstract

The advent of generative Artificial Intelligence (AI) represents a significant challenge for contemporary copyright law. As the capacity of machines to generate content autonomously has increased, the distinction between human creation and automated production has become increasingly indistinct. This raises fundamental questions concerning the attribution of authorship and the ownership of rights. The prevailing legal framework, which is primarily anchored to the "human author" concept, is ill-equipped to resolve these issues uniformly and coherently. The intensity of the international debate has increased in recent years. Legislatively speaking, the adoption of EU Regulation 2024/1689 (AI Act) represented a significant turning point in the governance of AI. Although it does not directly regulate copyright, it introduces transparency for providers of general-purpose AI models, imposing, among other things, the obligation to document the content used for training algorithms and to comply with European copyright law, with particular reference to EU Directive 2019/790. Concurrently, the Italian legislator recently approved DDL no. 1146/2024, which proposes to extend copyright protection to works created with the help of AI, provided they are the result of human intellectual work.

Keywords: Artificial Intelligence, Copyright, AI-Generated Works, EU Regulation 2024/1689 (AI Act), Author

Paper type: The paper is an Academic Research Paper

1 Introduction

Technological advancement has engendered legal uncertainties in the digital age, particularly with the intersection of human artists and artificial intelligence (AI). The question of who should be recognised as the author of an AI-generated work has become a complex copyright debate. This issue has been identified as a contributing factor to international legal disputes. The crux of the issue pertains to the attribution of authorship for these creations, namely, whether it should be ascribed to those who develop the algorithm, those who provide the input to train the AI, or those who give the final input. Another salient question pertains to the legal protection of works created by artificial intelligence and whether such works can be considered original creations. There is a paucity of clarity about the ownership of rights and the legal ramifications of such works. The future of generative AI remains uncertain as courts continue to clash over interpretations of the law, and the definition of "human authorship" remains unclear.

Nevertheless, this challenges the very nature of human creativity and paves the way for new possibilities in the digital age. The emergence of AI-generated platforms has underscored the necessity for a novel regulatory framework. The European legislator has acknowledged the significance of this issue, leading to the introduction of Regulation (EU) 1689/2024, also referred to as the AI Act. This legislative development signified a substantial landmark in global AI governance, constituting the inaugural international endeavor to regulate AI applications.

2 Methodology

This article adopts a doctrinal approach that examines the impact of artificial intelligence (AI) on the concepts of authorship, protection, and invention in copyright law, complemented by a comparative analysis and a review of case law. A literature review was conducted in specialised databases such as Normattiva, DeJure, and EUR-Lex to identify the main theoretical strands and normative orientations. The selection of case law was based on three main criteria: legal relevance, novelty of the normative intervention, and interpretative impact on the concept of authorship. The results identify several gaps in copyright law and significant challenges arising from the production and use of works created by AI. The study aims to comprehensively understand copyright issues related to intelligent systems by analysing existing legislation, case studies, and literature. The main areas of interest include studying Regulation (EU) 1689/2024, its implementing provisions, and their potential impact in Italy. To understand and assess how the courts and the different jurisdictions have dealt and are dealing with the complex balance between IA and copyright, the paper presents a space-time catalog of the individual legal cases that have arisen in the different jurisdictions, from which it emerges that the consequences and legal positions vary depending on the country considered. In light of regulatory and jurisprudential developments, the paper aims to critically examine the concept of "author" in the context of works created by intelligent systems, with particular reference to the notions of creativity, originality, and human contribution. Through a

comparative and doctrinal analysis, the aim is to outline a possible interpretive and regulatory path that would allow the protection of creativity to be reconciled with technological development, in a context in which the figure of the author tend to change from that of the exclusive creator to that of the artificial creator.

3 Discussion: Artificial intelligence and the concept of human authorship

John McCarthy coined the term "Artificial Intelligence" in 1956 at the conference "The Dartmouth Research Project on Artificial Intelligence" (Lakshminath & Sarda, 2012). Ahuja states that the term AI refers to the ability of machines to perform cognitive tasks such as thinking, perceiving, learning, solving problems, and making decisions (2020). AI is "activities we associate with human thinking, such as decision making, problem solving, learning, creating, and playing" (Bellman, 1978). In this case, intelligence refers to the ability of a machine to imitate the cognitive functions associated with the human brain, namely the ability to learn and solve problems. This may involve thinking or acting by imitating human behavior - cognitive approach - or rationality - computational approach - (Russell; Norvig, 2016). According to Adaka (2022), it can also be defined as the ability of a digitally controlled robot to perform tasks commonly associated with intelligent beings (Oriakhogba & Olubiyi, 2021). The World Intellectual Property Organization (WIPO) (2020) defines AI-generated creations as AIs that generate "output without human intervention" capable of modifying their behavior during operations to respond to unexpected information and events.

The Berne Convention for the Protection of Literary and Artistic Works (also known as the Universal Copyright Convention), adopted in Berne in 1886, is an international agreement establishing the mutual recognition of copyright between the member nations for the first time. The Convention is still in force, and international divergences on copyright have been resolved. According to Article 2,1, as stated by Oriakhogba & Olubiyi, the primary purpose of copyright is to encourage and maximize creativity (2021).

The general principle of copyright concerns the human authorship of literary, artistic, sound, musical, and cinematographic works, provided that they are original. Although the Berne Convention does not give a precise definition of authorship, according to Article 2,6, it can be deduced that protection operates for the benefit of the author and their heirs. According to Chapon, the author's definition is left to the contracting parties, but it can be deduced that paternity refers to the human creator or a natural person (2014).

3.1 Jurisprudence: Comparative survey

Two contrasting orientations have emerged on the problem of copyright protection for AI-generated works at a national and international jurisprudential level.

On the one hand, some States, for example, the United States and Italy, deny copyright protection without the human contribution and intervention for the work created by generative AI tools. Other systems, such as Spain and Japan, on the other hand, are favorable and open to a new definition of copyright for the protection and regulation of works created with the use of AI. To understand and evaluate how the various Courts have addressed and are addressing the complex interaction between AI and copyright, we start from the main decisions adopted by the national and international Jurisdictions.

At the national level, the Civil Court of Cassation, Section I, with Order no. 1107 of 16.01.2023, addressed the issue of recognizing works generated by AI as creative works and deserving of legal protection.

The Court established that reproducing an image, even if created with software, may violate the creator's copyright. The Supreme Court was keen to underline that the use of digital technology to create a work does not automatically exclude the recognition of the work as the fruit of the human intellect, provided that the artist's creative elaboration has not been absorbed by technology.

The legal protection of the work depends on the importance of the human creative contribution in the creation process.

Opening up to an international panorama, the United States, with Article 12 of the Federal Law on Copyright, defines the author of a work as the natural person who created it. Aware of the issue's centrality, the US Copyright Office has emphasized that, although copyright protects works born from human creativity, technological tools can be part of the creative process. Still, this statement requires an in-depth evaluation of their contribution.

The Copyright Office had also refused to register the individual images in the comic «Zarya of the Dawn», as they were generated through a generative Artificial Intelligence system, known as MidJourney. The Copyright Office formally determined that the images created using Midjourney could not benefit from copyright protection, as the necessary human creative contribution was missing (https://www.copyright.gov/docs/zarya-of-the-dawn.pdf?utm_source=chatgpt.com). It also examines how AI, while dependent on human input, can generate content, raising questions about the copyright ownership of such creations.

The legal systems of Spain, Germany, and Brazil also exclude copyright protection for works created without human intervention.

In Spain, the Spanish Ministry of Culture, led by Ernest Urtasun, following a long protest by Spanish artists against the massive use of artificial intelligence (AI) in the creative field, published a guide in February 2024 containing recommendations and instructions on the use of artificial intelligence in the creative sector (https://www.cultura.gob.es/dam/jcr:469163cc-0fdf-4fe2-964f-d4815cde40b1/240219-nota-informativa-ia.pdf). The note on the guidelines issued by the Spanish Ministry of Culture established that national prizes will no longer be awarded to works created entirely by AI, but will favor human creations that use AI as a support tool, giving preference instead to "works protected by intellectual property rights that are created by people, who may use artificial intelligence systems in terms of supporting the creative process, but not as a substitute for human performance".

There is also an express clause in which the supplier who intends to use artificial intelligence for creative activities, "must provide information, indicating in detail the level of intervention and, where appropriate, the role of the natural person in reviewing the project". With the introduction of these new guidelines, the Association of Professionals of Illustration of Madrid (APIM) has accused the authorities of normalizing the improper use of AI and endorsing the violation of artists' rights.

Hong Kong intends to liberalize copyright law to adapt it to new technologies. The primary intent is to "liberate" online content protected by copyright to allow its processing for training and the training of generative technology to adapt to new technologies. Recently, also in China, the Beijing Internet Court (BIC), a Chinese court, ruled in the Case Li vs. Liu Beijing Internet, Court Civil Judgment (2023) Jing 0491 Min Chu No 11279 (https://english.bjinternetcourt.gov.cn/pdf/BeijingInternetCourtCivilJudgment112792023.pdf), regarding the infringement of copyright regarding images generated through the use of Stable Diffusion, a generative AI system, recognizing the originality and creativity of the work, as well as the ownership of the AI user who had selected it from the various outputs produced.

In this case, AI software was used to create images starting from textual descriptions and subsequently published on Xiaohongshu, a Chinese social network; in turn, the images were reused in an article by a blogger.

The Court, following the summons, established that the plaintiff had provided a significant intellectual contribution in the creation of the image, including the choice of the AI software, the formulation of the prompts and finally the choice of the generated image, in fact the plaintiff claimed that the work he generated with artificial intelligence was worthy of protection under copyright.

This creative process was considered sufficient to qualify the work as an expression of an intellectual and creative activity, distinguishing it from the simple result of a mechanical process. As for the authorship of the images, the Court rejected the idea that software or the owner of the AI platform can be considered the author of an image generated by it, since it is not a human being. The decision is interesting and has a significant impact on European legal systems. The Beijing Court seems to consider generative AI only as an "assisting tool" in the hands of man rather than an autonomous creator, placing itself as a precedent to be considered for further developments on the need to adapt copyright laws to a rapidly evolving laboratory.

The main decisions have been collected and catalogued in Table 1, and offer a national and international overview, summarizing the case studies and solutions that the various Courts have proposed. The consequences and legal positions vary based on the country considered.

Table 1: Jurisprudence: Comparative survey

Country	**Legal position**	**Legal case**	**AI GENERATIVE**	**LEGISLATIVE REFERENCES**
Italy	Reproducing an image, even with the aid of software, may constitute a violation of the creator's copyright.	Cass. Civ., Sez. I, Ordinanza n. 1107 16/01/2023	*Not specified*	Legge sul Diritto d'autore, Law 22 April 1941, no. 633
USA	Although Copyright protects works born from human creativity, technological tools can be part of the creative process. Images created with the AI tool are not protected by Copyright, considering only human text protected.	Copyright Office, Comic book "Zarya of the Dawn" 21/02/2023	*MidJourney*	Federal Law on Copyright, art. 12

Country	Legal position	Legal case	AI GENERATIVE	LEGISLATIVE REFERENCES
China	Copyright infringement regarding images generated through the use of a generative artificial intelligence system, recognizes the originality and creativity of the work, as well as the ownership of the AI user who had selected it from the various outputs produced.	Beijing Internet Court (BIC) - 2023	*Stable Diffusion*	Copyright Law of the People's Republic of China (中华人民共和国著作权法)
Hong Kong	Intends to liberalize Copyright law to adapt it to new technologies. The intention is to "liberate" online content protected by Copyright to allow its processing for the purposes of training and training of generative technology to adapt it to new technologies.	Authorities have initiated a consultation.	*Not specified*	Trade Marks Registry, 1873 Trade Mark Ordinance, 2003
Spain	The guidelines require the declaration of the human role in the creative process and prohibit awards for fully automated works.	Guidelines of the Ministry of Culture	*Not specified*	

3.2 Regulation (EU) 2024/1689

European Regulation 1689/2024 of 13/06/2024 establishes harmonized rules on artificial intelligence and amends Regulations (EC) no. 300/2008, (EU) no. 167/2013, (EU) no. 168/2013, (EU) 2018/858, (EU) 2018/1139 and (EU) 2019/2144 and Directives 2014/90/EU, (EU) 2016/797 and (EU) 2020/1828 (Artificial Intelligence Regulation (https://eur-lex.europa.eu/legal-content/IT/TXT/PDF/?uri=OJ:L_202401689).

The Regulation marked a significant regulatory progress at the European level, establishing common standards and introducing specific provisions for works created through AI systems. The transposition of this Regulation will have given rise to a vast doctrinal and practical debate, especially regarding the protection of works that use AI to produce creative content.

The European Legislator has recognized the importance of this issue. On 13 March 2024, the European Parliament approved with 523 votes in favour of the European Regulation n.1689/2024, known as the "AI Act", which concluded the lengthy legislative process to regulate (for the first time) artificial intelligence applications. This is the first international attempt to regulate artificial intelligence applications through legislation. The AI Act is a flagship legislative initiative in the Global Governance of AI, whose main objective is to promote the development and adoption of safe and trustworthy AI throughout the EU single market. The measure has created a uniform legal framework for the development, placing on the market, commissioning, and using AI systems, promoting the spread of human-centric and trustworthy AI that can guarantee high protection of the European Union's health, safety, and fundamental rights.

The AI Act does not directly regulate copyright protection but introduces rules for the responsible use of artificial intelligence. The obligation of transparency for AI systems and the security of data used in model training play an essential role in preventing copyright infringements through improper use of artificial intelligence.

In particular, Article 53 relating to the "Obligations for providers of general-purpose AI models" provides for:

Lett. c) "Put in place a policy to comply with Union law on copyright and related rights, and in particular to identify and comply with, including through state-of-the-art technologies, a reservation of rights expressed according to Article 4(3) of Directive (EU) 2019/790". Letter *c* refers to Directive (EU) 2019/790 (https://eur-lex.europa.eu/legal-content/IT/TXT/?uri=CELEX%3A32019L0790), the Directive on Copyright and Related Rights in the Digital Single Market, with particular reference to reservations of rights (Article 4). Therefore, the conditions established for reproducing and extracting works for text and data mining purposes (using data and texts) also apply in Artificial Intelligence. This results in recognizing the right holders' right to limit text and data extraction, except in specific situations outlined by the Directive, such as use for scientific research purposes. The reference to Article 4 of the Copyright Directive is intended to clarify the controversies regarding the applicability of these rules to the creation and training of AI models. AI system providers must obtain permission from rights holders for any use of copyrighted content unless exceptions and limitations provided by law apply.

The issue of copyright protection is also addressed in the introductory "Whereas" of the AI Act. In particular, "whereas" no. 105 describes how generative AI models can be developed and trained using the technique of text and data mining, which allows access to large volumes of texts, images, videos, and other information.

The main objective of the Regulation is to create a single regulatory framework, with particular attention to the protection of copyright, by imposing specific obligations on providers of AI models, regardless of the jurisdiction in which the training takes place. In this way, the legislator intends to avoid disparities in the protection of rights between the various countries. The Regulation also includes specific transparency obligations, aimed at imposing on providers the responsibility to make available to the public a detailed summary of the contents used for training generative AI, including those protected by copyright, so that the latter's owners can exercise and enforce their rights. The objective is to analyse how the Italian regulatory system addresses the creation, protection, and management of works created by AI.

4 Results: DDL 1146/2024 and the Italian legislator

The issue of Copyright in the context of Artificial Intelligence (AI) applications demonstrates the inadequacy of this regulation. Regarding the AI Act, there is a lack of adequate regulation and implementation data regarding copyright (Hristov, 2016).

Despite the lack of a comprehensive and adequate regulation on copyright in AI, the AI Act is the most recent legislation addressing this field. In Italy, the AI bill approved by the Council of Ministers, DDL Butti, suggests several amendments to Law No. 633/1941 on copyright, where it will be specified, if this bill becomes law, that intellectual works could be protected even if created with the aid of AI tools, provided that they are the result of the intellectual work of the author. From this perspective, the focus of the issue could shift not so much on the creativity of the work or its originality, but on the aspects related to the economic exploitation of such work. Therefore, the question is not whether the work is protectable, but who owns the related economic exploitation rights. In light of the new EU Regulation 1689/2024, the Italian legislator, ahead of all other European countries, presented in 2023 the DDL no. 1146/2024 «Provisions and delegations to the Government on artificial intelligence», also called DDL Butti, as it takes its name from Alessio Butti, Undersecretary of State to the Presidency of the Council of Ministers. The DDL is part of the national initiatives to regulate the impact of artificial intelligence based on what has been defined at a Community level.

Chapter IV is dedicated to the protection of copyright: through an amendment to Article 1 of the Copyright Law, works generated with the aid of artificial intelligence would also be protected, provided that the human contribution is creative, relevant, demonstrable, and that an intellectual contribution from the author remains. The DDL was approved on 20 March 2025 by the Senate with the new title "Provisions and delegations to the Government on artificial intelligence" and passed the Chamber with 85 "yes" votes and only 42 "no".

The current text suggests several changes and will focus on national strategy, authorities, promotional actions, protection of copyright, and criminal sanctions. One of the laws that would be affected by these changes is Law No. 633/1941 on copyright, which will specify, if this bill becomes law, that works of the mind could also be protected if created with the aid of artificial intelligence tools, provided that they constitute the result of the author's intellectual work.

The protection of copyright is the subject of Chapter IV of DDL 1146/2024, which contains provisions for the protection of users according to Article 23, entitled "Identification of textual, photographic, audiovisual and radiophonic content produced by artificial intelligence systems" and in matters of copyright according to Article 24, entitled "Protection of copyright of works generated with the aid of artificial intelligence", thus protecting, on the one hand, users and, on the other hand, the copyright of works generated with the aid of AI. As underlined by the explanatory report of the bill, "in consideration of the growing use of artificial intelligence systems in sectors involving the recognition by the user of textual, photographic, audiovisual and radio content produced by artificial intelligence systems, Chapter IV introduces procedures to allow users to recognize content generated by AI -Article 23, as well as establishing specific rules on copyright - Article 24".

Article 24 regulates copyright protection for works generated with artificial intelligence. In particular, through amendments to Law no. 633 of 1941, it is first specified that the "works of the mind" protected under the law above must be of "human" origin. The expression "works of the mind" refers to those intangible assets that consist of creations of the human intellect that present the following characteristics: creativity, concreteness of expression, and belonging to one of the sectors of intellectual production expressly considered by the law (musical works, cinematographic works, software, ...). Works of the mind are protected by copyright, regulated at a national level mainly by Law no. 633 of 22 April 1941. Secondly, it is specified that even works created with the aid of artificial intelligence tools are protected by copyright, provided that their creation derives from the intellectual work of the author. Furthermore, reproduction and extraction, carried out through the use

of artificial intelligence models and systems, including generative ones, of works or other materials, is permitted, in compliance with specific provisions of the same law no. 633 of 1941.

As specified in the Dossier (https://www.senato.it/leg/19/BGT/Schede/Ddliter/dossier/58262_dossier.htm) to the DDL, specifically, Article 24 "Copyright protection of works generated with the aid of artificial intelligence", consists of a single paragraph, and is divided into two letters *a*) and *b*). Letter b) inserts the new Article 70-septies into Law no. 633 of 1941, which provides, in its sole paragraph, that the reproduction and extraction of works or other materials through models and systems of artificial intelligence, including generative intelligence, are permitted by the provisions of Articles 70-ter and 70-quater of the same law.

The introduction of this provision allows the use of protected works by AI systems by research organizations and cultural heritage protection institutes for scientific research purposes. According to letter a), article 1, first paragraph, of law no. 633 of 1941 is amended, specifying that the mind that creates the works protected by the law above is "human". Furthermore, with a further integration to the same article 1, first paragraph, it is provided that works of the mind are also protected when created with the aid of artificial intelligence tools, provided that they constitute the result of the intellectual work of the author. Article 2 entitled "Definitions" of DDL 1146/2024 defines in letter a) the artificial intelligence system, but does not explicitly define the "generative" artificial intelligence system. This term refers to an automated system designed to operate with variable levels of autonomy and which can present adaptability after dissemination and which, for explicit or implicit objectives, deduces from the input it receives how to generate outputs such as predictions, content, recommendations, or decisions that can influence physical or virtual environments. As also recalled in the explanatory report, this definition is identical to that in art. 3, par. 1, no. 1) of the AI Act Reg. EU 1689/2024 (finally approved by the EU Council on 21 May 2024).

The article in question provides specific rules for works created with AI systems, ensuring the identification of works and other materials whose use is not expressly reserved by the copyright holders. But in this perspective, is it possible to identify the "protection of copyright for works generated with artificial intelligence"?

To the current wording of Article 1, first paragraph of the Copyright Law which states "Creative intellectual works belonging to literature, music, figurative arts, architecture, theatre and cinematography are protected under this law, whatever their mode or form of expression", provides for the addition that works of human ingenuity are protected in any mode and form of expression, "even when created with the aid of artificial intelligence tools, provided that they constitute the result of the intellectual work of the author". In the initial draft of the bill in question, before the stamping of the General Accounting Office of the State, the amendment to Article 1, first paragraph of Law 633/1942 included the addition of the phrase "even when created with the aid of artificial intelligence tools, provided that the human contribution is creative, relevant and demonstrable", amended with "provided that they constitute the result of the intellectual work of the author", a formula that had immediately raised more than one doubt. Therefore, it is clear that the Legislator is excluding copyright protection about those works generated with AI and this emerges from the amendments that they intend to make to Article 1 of Law no. 633/1941, as previously seen, the USA and other EU countries have also expressed themselves in this sense, or are oriented towards excluding copyright protection about works generated with artificial intelligence. Among these, those created with the aid of AI tools will also be considered, provided that they constitute the result of the intellectual work of the author, but works created exclusively with artificial intelligence systems are excluded.

The economic repercussions are not the only ones that authors and publishers fear suffering. Their creative identities and the specificity of their roles are also at risk. The primary concern is generative AI, which is capable of producing works similar to human ones, which the Legislator excludes in the current DDL. In this scenario, there are many questions about the compatibility between new creation methods and the protection offered by copyright. The main issue concerns the legal status of works generated by AI, whether they can be protected by copyright independently or, if not, how their nature should be configured. The European regulation resulting from the AI Act and the EU Directive 2019/790, implemented in Italy with Legislative Decree 177/2021, recognizes copyright holders the right to prevent their protected works and materials from being used by AI software, except for scientific research. This means that suppliers of AI models for general purposes must obtain authorization from the rights holders if they intend to perform text and data extraction on their works.

5 Conclusions

The advent of AI has accelerated many advances in the technological domain, thus challenging existing intellectual property legislation. Establishing authorship and invention in the context of AI is crucial to ascertain the appropriate designation of the inventor, be it the programmer, the AI owner, the data provider, the

operator, or the trainer. This article posits the need for explicit legislative amendments that outline the eligibility criteria for authorship and protection of works created by AI. Regulation (EU) 1689/2024 represents a fundamental progression in regulating AI-generated works. The main challenge the sector faces is to balance copyright protection and the promotion of technological innovation.

6 Ethics declaration

Ethical clearance was not required for the research.

7 AI Declaration

AI tools were used only to rephrase a few sentences for clarity, enhancing clarity, and summarizing content. The paper's content, structure, and conclusions remain the result of the authors' original work. All AI outputs were reviewed and edited by the authors to maintain the originality and rigor of the paper.

Platform Capitalism and the State: Between a New Balance of Power and Geopolitical Competition

Cristina Simone, Maria Antonietta De Cesare
La Sapienza University of Rome, Rome, Italy

Abstract

The advent of digitization has significantly changed how we live and work, and information society services - especially intermediate services - have become crucial components of our everyday lives. Platform capitalism, which is characterized by the dominance of major digital platforms that have substantial influence across different sectors, has emerged as a result of this digital transition. The widespread impact of these platforms raises serious concerns about their societal ramifications, especially in relation to individual rights, democratic governance, and geopolitical competition. This phenomenon has given rise to the term "state platform capitalism", where governments increasingly leverage dominant digital platforms for their own political and economic agendas.

Aspects of this phenomenon have been examined in the literature to date, but there are still significant gaps in the extant research. Specifically, further research is required to fully comprehend how platform capitalism impacts public speech, accountability, and participation as well as how the power of digital platforms interacts with democratic processes. A small number of dominant digital platforms strongly affects international politics, data sovereignty, and technological competition. Additionally, given the growing competition between China and the United States in the digital sphere and the regulatory role of European Union, the geopolitical implications of platform capitalism demand further scholarly attention.

The purpose of this paper is to fill the literature gaps by carefully examining the complex interactions between platform capitalism and the State. With this aim, and applying a qualitative methodology, this work: first, analyzes the state of the art; second, proposes a definition and identifies the challenges of the platform infrastructural power; third, discusses the main models of the relationship between dominant platforms and the State. Eventually, further research paths are suggested.

Keywords: State Platform Capitalism; Digitization; Geopolitical Competition; Dominant platforms; Infrastructural Power.

Paper type: Academic Research Paper

1 Introduction

The rise of digitization has radically transformed the way we live and work, making information society services, and in particular intermediary services, essential elements of our everyday lives (Regulation (EU) 2022/2065). The evolution of information technologies, including big data, AI, cloud computing, and machine learning, is rapidly transforming how we access and utilize information across social, political, and cultural domains (Qi and Wang, 2021). Platform capitalism is a term coined to describe this emerging digital economy, which is marked by the dominant digital platforms. The widespread impact of dominant digital platforms prompts serious concerns about their wider societal ramifications, especially regarding the fundamentals of democratic governance, the protection of individual rights, and the geopolitical competition (Barile et al., 2022; Rolf and Schindler, 2023).

Even though the current academic literature has started to analyze several aspects of this phenomenon, there are still relevant gaps. Among these, a significant gap concerns the investigation of how digital platform power influences democratic procedures. Despite research on misinformation and algorithmic bias, there is a lack of deep knowledge of how platform capitalism affects public speech, accountability, and democratic participation.

Moreover, the geopolitical dimensions of platform capitalism are highlighted by the competitive dynamics between China and the United States in the technological and digital domains. However, this theme is neglected by scholarly attention too.

This work aims to fill the aforementioned gaps and to contribute to a deeper understanding of the implications of platform capitalism for democracy, individual rights, and geopolitical competition.

The paper is structured as follows: Sec. 2 describes the methodology; Sec. 3 proposes a literature review on digital platforms and the rising of "State Platform Capitalism"; Sec. 4 defines the infrastructural power of digital platforms and analyzes its risks and challenges; Sec. 5 critically discusses the increasing power of the dominant digital platforms (GAMAM and BATX) and their geopolitical ramifications and describes the main different

regulatory and geopolitical approaches; finally, Sec. 6 suggests future research paths about the geopolitics of platforms and discusses the implications for scholars, practitioners and policymakers.

2 Methodology

The work is developed according to a qualitative methodology that can be outlined as follows:

- Definition of the objective of the literature review;
- Determination of the keywords and criteria for selecting sources - scientific and "grey" - consistent with the purpose;
- Search for and selection of relevant documents;
- Analysis of the information gathered;
- Identification of the literature gap.

The scientific and grey literature was searched in the EBSCO database (restricted access) and the Google Scholar database (open access) due to their broader literature coverage compared to other databases and inclusion of publications that might not indexed in other directories.

The search query was constructed using two primary sets of terms to identify relevant scholarly work:

- The first set focused on the key concepts of digitization in relation to governance influence: digital platforms ecosystems (e.g. structural elements of digital platform, digital infrastructure power, platform data governance, digital algorithms), platform economy, digital business platform, and state platform capitalism;
- The second set covered the associated dynamics and geopolitical implications of the rising digital landscape, including terms such as: information warfare (e.g. information propaganda, misinformation), geopolitical competition (including platform geopolitical relevant actors, "GAMAM" and "BATX", technological rivalry, platforms-military nexus), virtual sovereignty, cybersecurity, platform antitrust and internet regulation (e.g. Digital Markets Act, Digital Services Act, Great Firewall).

To be included in the analysis, documents, encompassing both scientific and grey literature, were required to contain the search terms from one of the sets within their titles. The documents were also required to be published in Italian, English, or French during the period of 2010-2025.

According to an analysis based on titles, abstracts, keywords, and executive summaries (the latter where available, e.g., for grey literature reports), over 50 documents were selected – both scientific and "grey" literature deemed eligible and relevant for the purpose of drafting the present work and the overall project objectives.

3 Dominant digital platforms and State Platform Capitalism: state of the art

Digitization is the driving force behind the development and growth of market economy in the 21st century (Liang et al., 2022). Dominant digital business platforms have played a crucial role in shaping this landscape. In relatively brief periods of time, during the last three decades, dominant digital platforms have attained market shares of at least seventy percent (Cusumano et al., 2019).

Digital business platforms are complex systems that have to accommodate enormous user networks with a wide range of roles and interactions (Parker et al., 2016). Digital business platforms are defined by scholars as intermediaries that connect independent groups via the internet for mutual advantage, establishing connections across customer segments (Faber et al., 2016; Srnicek, 2017; Büchel and Rusche, 2020; De Falco, Simone et al., 2024). Economics and managerial literature enlightens that the success of the digital business platforms depends by the capability to foster network effects, in other words their utility to the customer grows exponentially with the number of users interacting in the ecosystem they provide (Tiwana, 2013; Gawer and Cusumano, 2015; Rahman, 2018; Gawer, 2022).

In terms of structural design, the ecosystems create by the digital business platforms are characterized by structural elements, such as demand and supply-side users, architecture, digital algorithms and APIs, apps, and the key mechanisms of value creation. The platform sponsor is the platform owner and provides the general organizational framework, achieved through governance, regulations, and ecosystem support (Parker and Van Alstyne, 2012).

The architecture of the digital platform dictates how information, goods and services are exchanged. Sharing information is an intrinsic and vital element of digital platforms (Parker et al., 2016).

The digital business platforms create value through three main mechanisms: datafication, commodification, and selection. Datafication lets a platform collect real-time user data through digital algorithms and share it with ecosystem players; commodification transforms data into marketable goods; selection is the choice of which

services/content users access (Van Dijck et al., 2019). The underlying technology of those mechanisms are the digital algorithms of the platform that create so-called "filtering bubbles" (Berman and Katona, 2020; Leysen et al., 2022; Fabiano, 2023). The digital business platform determines the content shown to the consumer, keeping them unaware of how it works and reducing their decision-making power. This involves a sort of black box (Pasquale, 2016; Armano et al., 2022) for the users, both demand and supply-side.

By virtue of this architecture, the digital platform ecosystem makes it possible to collect data on human behaviors, goals, and representations in a way that has never been possible before (Boyer, 2022).

Data extraction is growing in popularity. Indeed, digital business platforms like Google, Facebook, and Amazon are expanding their data gathering activities (Srnicek, 2017). Although data and profit are not the same thing, however, their reasoning is comparable. We should expect data-driven approaches, just as we expect profit-driven ones. In short, the need to gather data is driving new approaches to governance and business practices (Sadowski, 2019).

The growing acknowledgment of data as a crucial strategic asset is comparable to financial capital. The data imperative impacts many aspects of organizational behavior, from developing innovative business models to strategic decision-making and operational efficiency.

As dominant digital platforms become more and more pivotal mediators of economic, political and cultural relationships, they increasingly concentrate a huge infrastructural power on users widely meant (individual, businesses, institutions, public administrations etc.). This new landscape configures veritable "platform capitalism" (Barile et al., 2022) that affects, among others, the role of the State. In fact, the rise of platform capitalism reflects broader social and political changes as well as economic ones (Liang et al., 2022; Coveri et al., 2024). Furthermore, the rise of platform capitalism has led to intense competition among monopolistic platforms (Srnicek, 2017) – the two principal blocks are GAMAM (Google, Amazon, Meta Facebook, Apple and Microsoft) in US and BATX (Baidu, Alibaba, Tencent and Xiaomi) in China.

Platform capitalism relies on complex ecosystems involving digital algorithms, submarine cables, and satellites that enable online interactions (Zhang et al., 2024). Up to 99% of all transoceanic digital communications, such as phone calls, emails, and financial transactions, are carried by submarine cables. They are fastest, most effective, and cheapest way to transmit global digital data (Bueger and Liebetrau, 2021). Thus, these elements have a symbiotic relationship that fosters a dynamic environment, underscoring the foundations of platform capitalism.

About 70% of submarine cables are not state-owned or maintained. Global business conglomerates own and maintain them, and ownership can be complex. Indeed, Google, Amazon, Meta and Microsoft are the main investors (Bueger and Liebetrau, 2021; Wired Italia, 2025).

The powerful and deep expansion of dominant digital platforms makes them crucial infrastructures capable of decisively affecting the institutionalized social order (Cuppini, 2023). They often become transparent and undetectable due to their deep integration into existing social and technical settings (Shen and He, 2022).

In this scenario, the symbiotic relationship between States and dominant digital platforms has led to the emergence of "State Platform Capitalism" (SPC) (Rolf and Schindler, 2023), where governments increasingly leverage dominant digital platforms for their own political and economic agendas.

Indeed, States increasingly rely on dominant platforms when they are unable to implement their own functions. This is a significant novelty because these platforms are mostly run by private companies (Frapporti, 2023).

Because of all those reasons - in particular their impressive technology, their wide control over data and their huge infrastructural power - dominant digital business platforms configure new political agents whose owners often act as unelected politicians (Ergen et al., 2024).

US and Chinese digital business platforms increasingly collaborate with their respective governments in surveillance and policing, creating tension with states (Rolf and Schindler, 2023). TikTok, owned by Bytedance, exemplifies this, raising US concerns about data sharing with China (Gray, 2021; Muratore, 2025).

Serious concerns regarding privacy, security, and democratic values arise from those scenarios. Dominant business platforms implies challenges to national security by shaping information flows and influencing public discourse (Van Dijck et al., 2019).

Two regulative approaches are emerging: the first deal with a progressive counter-narrative critiques prevailing firms and calls for regulations to constrain their power; conversely, the second deals with a neoliberal standpoint values these dominant firms and opposes their regulation, placing the interests of current consumers above those of other actors. This opposing perspective emphasizes how governmental action is required to prevent monopolistic domination (Pasquale, 2016).

In this regard, the European Union (EU) is endeavoring to maintain a certain degree of competitiveness within the digital markets, currently dominated by GAMAM and BATX (Manzini, 2021). For example, the recent

Digital Markets Act (DMA) and Digital Services Act (DSA) (dated 2022) configure a divergence in the position of the EU with respect to the Chinese market capitalism and the US neoliberal approach (Mansell, 2021).

4 The digital platforms infrastructural power: definition, challenges and risks

In the contemporary socio-economic landscape, digital business platforms have become indispensable infrastructure of daily life. They wield a huge power in terms of shaping and governing not only the digital landscape, but also affecting the daily socio-economic interactions. Even if there are several kinds of power wielded by the dominant business platform - infrastructural power, algorithmic power, economic power, and regulatory power (Crawford, 2016; Plantin et al., 2018; Poell et al., 2019; Busch, 2021; Busch et al., 2021), this study will primarily concentrate on the infrastructural power of these actors. The infrastructural power is quite neglected by the extant economic literature, even if it deals with a crucial source of power. It stems from the inherent capacity of the dominant platforms to orchestrate and regulate the flow of information, as well as social and economic interactions (Busch et al., 2021). This power is manifested in their centrality to the aggregation and flow of data, thereby becoming crucial nodes through which an ever-increasing amount of information transits.

Both online and offline activities are significantly impacted by the infrastructural power of digital platforms, which is derived from the management of data, algorithms, and technical standards. Targeted advertising, customized services, and user behavior manipulation are some ways that this impact is exhibited (Busch, 2021).

Through the mechanisms of value creation - datafication and commodification - digital platforms collect and analyze data from real-world human interactions – such as rating, paying, searching, talking, driving. Then, these data are made accessible to a broad range of external parties (Poell et al., 2019; Van Dijck et al., 2019; Boyer, 2022). The algorithms rank search results, curate information, and customize user experiences (Simone et al., 2020; Frapporti et al., 2024). Furthermore, the control over technological standards - guidelines or protocols for connecting various components and products together - enables the digital platforms to create interoperable technological and economic standards and to exploit network effects. These requisites are indispensable for the consolidation of power (Cusumano, 2010; Van Dijck et al., 2019).

However, this landscape has evidenced social, economic and political issues.

Through the inherent capability of digital platforms to profile users, information warfare, propaganda, and disinformation, the States are increasingly leveraging dominant digital platforms for their own economic and political aims, such as citizens surveillance and control. Indeed, with the increasing capabilities of Information and Communication Technologies (ICT), mass surveillance is now a realistic prospect (Boyer, 2022; Fabiano, 2023). Furthermore, algorithms can improve efficiency but also influence public opinion in ways that are not always clear or accountable. Fairness, bias, and the possibility of manipulation come up in this context (Crawford, 2016; Busch et al., 2021).

A further challenge emerges in achieving balance between innovation and control. Different services can be integrated within an ecosystem if they are interoperable, like Apple products and services. However, this integration concurrently establishes a barrier between the ecosystem and the external environment. Customers have no incentive to leave this "walled garden" since it offers an increasing number of products and services (Busch, 2021). Thus, the ability to set standards can encourage innovation by creating a framework for developers. Conversely, this control can impede innovation by constraining interoperability and fostering vendor lock-in.

The increasing infrastructural power and influence of digital platforms are also being subjected to close regulatory analysis and antitrust investigations. The emergence of a small number of platforms that have accumulated significant market power has prompted investigations into potential anti-competitive conduct. The rationale behind this examination stems from the acknowledgment that digital platforms may engage in practices that hinder competitive markets, including the restriction of interoperability and the utilization of their predominant market position to favor their own services. Indeed, increasing evidence suggests that platforms may possess capabilities that extend beyond conventional market power. This more comprehensive viewpoint acknowledges that platforms exert influence over numerous domains, including control over data, algorithms, and the digital infrastructure itself. Consequently, contemporary legal and economic frameworks are confronted with the intricacies inherent in platform structures (Plantin et al., 2018; Van Dijck et al., 2019; Busch et al., 2021; Busch, 2021).

5 The role of dominant digital platforms in the geopolitical competition: macro areas and main models

The two dominant digital blocks GAMAM (US) and BATX (China) have achieved higher and higher market shares, involving a concentration of power that goes beyond simple economic domination (Cusumano et al., 2019; Thibout, 2020; Liang et al., 2022). These dominant business platforms, acting as pivotal intermediaries in economic, political, and cultural exchanges (Barile et al., 2022), are effectively wielding a new form of infrastructural power.

Figure 1: Software & Web Companies headquarters (2018-2021), p.7 (Area Studi MedioBanca, 2021)

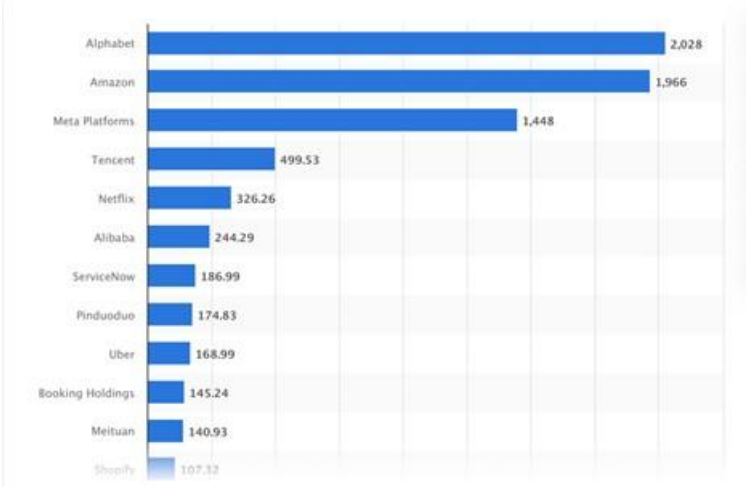

Figure 2: The largest internet companies worldwide by market capitalization 2024 (Statista Reaserch Department, 2025)

Figure 1 shows that the main headquarters of digital platforms are in China and the US, leaving the EU on the periphery. Figure 2 shows that the largest internet companies by market capitalization are American and Chinese, except for Booking (European).

Particularly, US and Chinese platforms put these states at the forefront of the digital economy, giving them significant influence over international standards, norms, and technology. The dominant platforms have a strategic advantage because they can gather and analyze large datasets. This affects consumer behaviors, market trends, political discourse, and state security (Kokas, 2018; Sadowski, 2019; Boyer, 2022; Wang, 2022). The GAMAM block wields significant influence over state decisions through financial support and political pressure. The US state often supports their interests and mobilizes them for geopolitical purposes. A similar phenomenon can be observed in China, where organizations such as the China Association for Science and Technology seek to enhance the political influence of prominent domestic technology enterprises (Mirrlees, 2024).

The digital arena is now a crucial arena for geopolitical competition. Private and governmental organizations are converging, potentially establishing them as agents of an emerging international political order (Wang, 2022; Cuppini, 2023; Ergen et al., 2024). For instance, Google owned a significant stake in roughly 8.5% of the global

network of submarine cables in 2021 (Kelton et al., 2022). SpaceX, owned by Elon Musk, has provided the Ukrainian army with a private satellite system, while Alphabet strengthened security measures for user access in Ukraine and prohibited access to Russian state media distribution and advertising (Abels, 2024; Coveri et al., 2024).

China and the United States are currently the two most powerful states in the world in terms of economy, military strength, and media-technological powers (Mirrlees, 2024). However, the growing competition between them is a key link between geopolitics and state platform capitalism.

As previously stated, both US and Chinese digital platforms collaborate with their respective governments in surveillance and policing, creating tension with states (Rolf and Schindler, 2023; Coveri et al., 2024; Mirrlees, 2024). Indeed, the GAMAM and BATX blocks both dominate information and communication technologies (Thibout, 2020). For instance, Microsoft, Facebook, Twitter (now X), and other US-based platforms have actively cooperated with the US government by exchanging threat intelligence and obstructing disinformation by removing compromised networks (Coveri et al., 2024). Nevertheless, Facebook was also considered as the hub of misinformation spreading – particularly during Covid19 crisis and political elections – due to its algorithms that tend to increase the shares of mostly views contents, without controlling the reality of the information (Boulianne and Hoffmann, 2024).

Furthermore, dual-use technologies, like facial recognition, that are controlled in security and defense-sensitive fields turn digital platforms into tools of governmental monitoring, making them key players in the technological rivalry between the US and China. Chinese digital platforms pose a threat to US techno-military dominance. China deliberately blocks US-based platforms and encourages the growth of its own dominant platforms (like Alibaba or Tencent) as essential elements of the military-industrial complex. The "Great Firewall" regulates the flow of information on the Internet and makes it easier to monitor online activity (Brown, 2024; Coveri et al., 2024).

Compounding the vulnerabilities inherent in the digital infrastructure, despite the recognized necessity for digital platforms to possess submarine cables for global connectivity (Kelton et al., 2022), their fragility has become increasingly apparent. Sometimes accidental, sometimes suspicious, damaging instances have shown how their disruption can have serious consequences. As a result, China claims to have created a device to cut complex cables, but there is a chance of instability because states might use these advanced tools to deliberately target infrastructures (Genco, 2025).

The use of different regulatory approaches and geopolitical strategies concerning digital markets further highlights the complexity of the landscape. The United States prioritizes limited involvement and the expansion of its tech giants, primarily following a neoliberal strategy. China, on the other hand, follows a market capitalist model that is marked by stringent control over its digital domain, as demonstrated by the "Great Firewall" and data localization regulations, as well as substantial governmental support for its national digital platforms. China forces US tech companies to give Chinese regulators access to personal user and corporate data. The Chinese government describes its authority over its digital areas, including outside access to them, as "Cybersovereignty" (Kokas, 2018; Mirrlees, 2024).

The EU has taken a different approach. It has implemented the DMA and the DSA to establish a regulatory framework for the digital markets and ecosystems. The DMA (Regulation (EU) 2022/1925) is a regulatory tool designed to ensure the proper functioning of the digital market by establishing rules for "gatekeeper" businesses.

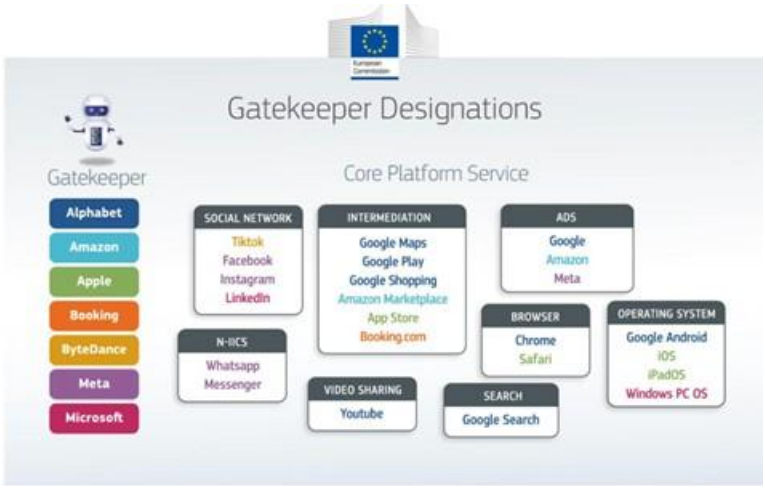

Figure 3: Designated gatekeepers by the European Commission (European Commission, 2025)

Currently, figure 3 shows that the European Commission has designated 7 gatekeepers – ByteDance is a Chinese platforms; Alphabet, Amazon, Apple, Meta and Microsoft are US platforms; Booking is a European platforms (European Commission, 2025).

Conversely, the DSA (Regulation (EU) 2022/2065), aims for greater online platform accountability. It promotes transparency and user safety through rules on transparency, due diligence, and third-party content liability (Erixon et al., 2022).

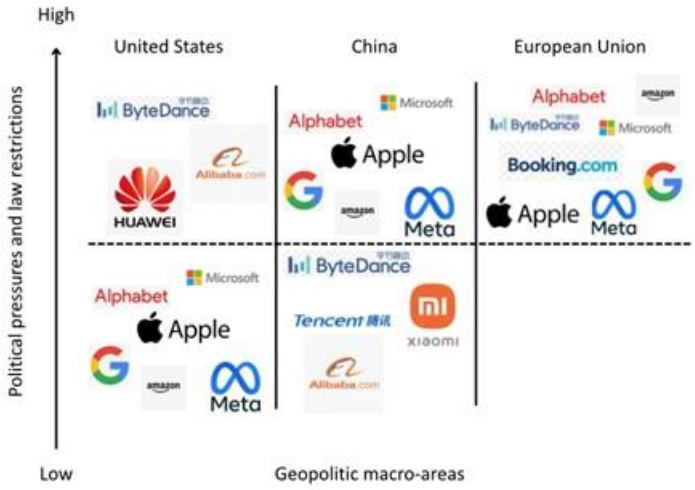

Figure 4: Different levels of political pressures and law restrictions of dominant digital platforms, based on the distinction between US, China and EU
(source: our elaboration)

Figure 4 shows that the EU exerts pressure on dominant digital platforms within a clearly delineated regulatory framework, the DMA. The US imposes significant pressure on Chinese digital platforms, and China does the same on American ones. This suggests a competition that extends beyond mere regulation.

The EU seeks to leverage the "Brussels effect" because of its technological marginality. This process involves the externalization of its norms and values in digital policy (Bendiek and Stuerzer, 2023). This move makes the EU an important player in global digital platform governance, showing differences in how they handle legislation that reflect different geopolitical interests.

6 Conclusion

This work focuses on the infrastructural power of dominant digital platforms and enlightens the relative geopolitical implications. First, a resulting shift of power from public institutions to private companies such as the dominant digital business platforms has been discussed; second, the influence on competition among different geopolitical macro-areas (i.e., the United States and China) has been analyzed.

The provided analysis suggests several implications for scholars, practitioners and policymakers.

For practitioners understanding the ramifications of data collecting and their use for surveillance or political influence is necessary to define effective corporate strategies governance.

For policymakers, regulating digital platforms is a challenging issue. Gaining a solid knowledge of platform power dynamics, including how they affect information flows, market competition, and public speech, provide relevant benefits. Promoting economic growth, international cooperation, and the protection of democratic values through effective policy design are some examples of this.

Scholars analyze the complex interrelationships of technology, power, governance, and geopolitics. The knowledge of the evolving dynamics of "State Platform Capitalism" and its extensive ramifications improves the capacity of scholars to contribute to the discourse, guide future research, and offer important perspectives on the dynamics of the digital era.

Further research paths in geopolitical studies should aim to operationalize variables such as "political pressures" and "legislative restrictions" and to provide more comprehensive frameworks about the emerging different approach in the geopolitical of digital platforms.

Cybersecurity in the Legal Context: State of Art and Next Challenges

Marco Chironi[1], Benedetta Coluccia[2]
[1]University of Salento, Lecce, Italy
[2]Pegaso University, Naples, Italy

Abstract

In recent years, the issue concerning digital security has become increasingly important. Academics within an interdisciplinary approach are debating the topic and how to ensure and implement digital information security from the perspective of both companies and consumer users. The issue affects both the public and private sectors and requires coordinated and effective policy action.
The risks associated with such attacks are closely linked to identity theft, cyber fraud, and money laundering.
In order to address the security-related emergency, the European legislator has enacted several legislative acts. The purpose of this paper is to explain, through a legal analysis, the current regulatory framework examining the new developments and identifying any remaining gaps.
From this analysis, it appears that the topic has recently been the subject of several legislative actions. In this scenario, the NIS 2 Directive (Directive EU 2022/2555) represents a crucial update in the European Union's legislation for network and information security. This work points out the lack of remedies for individuals in the case where the parties addressed by all regulatory interventions fail to respect their obligations.
At the same time, there is no doubt that cyber incidents have a significant impact on the profits of companies. In this regard, the Corporate Sustainability Reporting Directive (CSRD 2022/2464) introduced the inclusion of cybersecurity information in the annual report as non-financial information. For this reason, it is useful to investigate how the cybersecurity obligations contribute to the quality of sustainability reporting.
To address the application problems of these regulations, in the final part of the paper, it could be proposed to use blockchain tools to implement the certainty of digital identity and the integrity of the entered information.

Keywords: Cybersecurity; Data Protection; sustainability; compliance; blockchain

Paper type: Academic Research Paper

1 Introduction

Nowadays, digital security represents one of the main areas of research among scholars, who adopt an interdisciplinary approach to analyze how it can be implemented and ensured, both from the perspective of businesses and that of end users. (Porcedda, 2023). The issue affects both the public and private sectors and requires coordinated and effective policy action (Odermatt, 2018; Brandão and Camisão, 2022; Carrapico and Barrinha, 2017).

The organization of the digital sphere around the platform system has also impacted public administration—including education, healthcare, culture, and justice (Chiara, 2024) —as well as the administrative activities and responsibilities related to the promotion of social welfare entrusted to public authorities (e.g., PagoPA, digital identity systems for accessing services, among others).

The strategy adopted by the European Union through the Digital Compass for 2030 aims to bring about a paradigm shift in the way citizens, public administrations, and democratic institutions interact (EU Commission, 2021; Brandão and Camisão, 2022).

Nowadays, most of the digital services these platforms offer are limited to basic services. Digitalisation also plays a key role in the development of “Smart villages”, i.e. communities in rural areas that use innovative solutions to improve their resilience, building on local strengths and opportunities (EU Commission, 2021; Bygrave, 2022; Dunn Cavelty et al., 2023).

Platforms in rural and urban communities will be powered by digital technologies and will offer services such as multi-modal intelligent transport systems, rapid emergency assistance in case of accidents, more targeted waste management solutions, traffic management, urban planning, smart energy and lighting solutions. Using Green Public Procurement criteria (EU Commission, 2020) can boost demand for a green digital transformation.

The digital transformation should also enable modern and efficient justice systems, protection of consumer rights and increased effectiveness of public action including law application and investigation capacities and law enforcement must be best equipped to deal with more and more sophisticated digital crimes.

The pressing relevance of the issue is also evident from the analysis of data concerning the number of recorded cyberattacks. According to the Clusit 2023 report, the number of attacks registered globally has

increased by 60%, with a deterioration in the social and economic consequences of incidents caused by cyberattacks.

In the first six months of 2024, the number of cyberattacks recorded by Clusit experts increased by 23% compared to the previous semester. On average, there were 9 major attacks per day worldwide; in Italy, 7.6% of the incidents occurred (Clusit, 2024). Between July 2022 and June 2023, approximately 2,580 incidents were registered in the European Union (Enisa, 2023).

Counteracting cyber-attacks represents one of the key challenges for operators. The risks associated with such attacks are closely linked to identity theft, cyber fraud, and money laundering (Fuster, 2016; Van der Sloot, 2017).

In order to address the security-related emergency, the European legislator has enacted several legislative acts (Barrinha and Christou, 2022).

The purpose of this paper is to explain, through a legal analysis (Chiara, 2024; Fuster and Jasmontaite, 2020), the current regulatory framework investigating what the new cases are and what the remaining gaps are. The research question aims to evaluate whether the regulatory framework is exhaustive or fragmented (par. 2,3,4).

At the same time, the objective of the research is to analyse whether the obligations imposed by the regulatory framework can contribute to the implementation of corporate sustainability-related information (par. 5). The final part of the study examines the benefits that blockchain technology may offer in the subject (par. 6).

We investigated the research question through comparative analysis of the existing legal framework between the European Union and the Italian legal system, identifying similarities and differences, in addition to a literature review (Bygrave, 2022).

2 Cybersecurity law in EU e in Italian law

Recently, both the European and Italian legislators have enacted various regulatory measures. Within this scenario, the European Union has consolidated its policy-making role in the sector (Fuster and Jasmontaite, 2020). The legal basis for the European Union's action is established in Article 114 TFEU, which serves the objective of ensuring the proper functioning of the internal market through the harmonisation of national provisions (Odermatt 2018; Brandão and Camisão, 2022; Carrapico and Barrinha, 2017).

2.1 Italian Cybersecurity law no. 90/2024

The Italian legislator has first enacted the "Cybersecurity Law", No. 90 of 28 June 2024. This law contains provisions aimed at strengthening national cybersecurity and addressing cybercrimes. The legislative update pursues two main objectives: on the one hand, to enhance the security measures of public information systems, and on the other, to update criminal policy by revising the management of cybercrimes in Italy.

The subjective scope of the law is derived from Article 1, titled "*Incident Notification Obligations*," and primarily concerns public administration actors. These entities are subject to a mandatory reporting and notification obligation regarding specific types of incidents that impact networks, information systems, and IT services. Such incidents must be reported without delay and, in any case, within 24 hours of their detection via the designated procedures on the website of the National Cybersecurity Agency (ACN) (Renzi, 2021; Cusenza, 2023).

Within 72 hours of the initial report, a complete notification must be submitted, containing all available information, again through the Agency's online procedures.

Article 8 outlines measures for "*Strengthening the Resilience of Public Administrations and Appointing a Cybersecurity Officer*." Entities subject to this law are required to establish a dedicated cybersecurity unit responsible for developing cybersecurity policies, managing IT risk, and continuously updating security procedures. Core obligations include drafting and maintaining a document defining the roles and organization of the administration's information security system; developing a risk management plan that includes preliminary analysis and regular updates of security measures; and conducting ongoing threat and vulnerability assessments, with prompt updates of security protocols based on emerging evidence. Consequently, all staff must be prepared to respond effectively in the event of an incident.

Periodic evaluations of cybersecurity risks must be conducted to identify threats and vulnerabilities. Based on the outcomes of these assessments, organizations are expected to implement appropriate security controls, including preventive, detective, and corrective measures.

The law also mandates continuous and adequate training for all staff involved in cybersecurity. It establishes an operational coordination framework between intelligence services and the National Cybersecurity Agency to ensure an effective response to cyber incidents.

This legal framework must be harmonized with the provisions of the GDPR Regulation (Bygrave, 2022) designates specific responsibilities for the protection and processing of personal data, as defined by European law. The GDPR also mandates notification of any security breach that results in the destruction, loss, alteration, unauthorized disclosure of, or access to personal data transmitted, stored, or otherwise processed (so-called data breach).

The key differences between the two regulatory frameworks are as follows: the GDPR is designed to protect natural persons with regard to the processing of their personal data, safeguarding fundamental rights and freedoms, particularly the right to data protection. In contrast, Law No. 90/2024 aims to protect IT infrastructures—such as networks, information systems, and digital services—which are critical to the essential functioning of the public sector. Moreover, while the GDPR applies to both public and private entities, Law No. 90/2024 applies exclusively to public entities.

Another distinction lies in the notification responsibilities and timelines: under the GDPR, the data controller must notify the Data Protection Authority without undue delay and, where feasible, within 72 hours of becoming aware of the breach. In contrast, the timeline under Law No. 90/2024 is stricter: a report must be submitted to the ACN within 24 hours, and a full notification must follow within 72 hours.

2.2 Italian Legislative Decree No. 138/2024, implementing Directive (EU) 2022/2555 (NIS 2 Directive) into the Italian legal framework.

At the European level, Directive (EU) 2022/2555 (known as NIS 2) plays a crucial role. It has been transposed into Italian law through Legislative Decree No. 138 of 4 September 2024. The regulation imposes stringent requirements for governance, risk management, and incident reporting.

Legislative Decree No. 138/2024 establishes measures aimed at ensuring a high level of cybersecurity across the entire Italian territory.

Among the key innovations introduced by Directive NIS2 is the implementation of the sectors concerned. The entities involved are required to comply with specific requirements, covering from governance to cybersecurity, the adoption of measures for risk management (including supply chain security), as well as the management of operational continuity and incident reporting (Novelli et al., 2024).

The analysis synthetically casts light on i) the wider scope of the NIS2; ii) revised cybersecurity risk-management measures and reporting obligations for NIS2 entities; iii) rules on cybersecurity information sharing and vulnerability disclosure; and iv) supervisory and enforcement framework (Chiara, 2024).

The Directive introduces severe requirements in terms of governance, risk management, and incident reporting. Legislative Decree No. 138/2024 sets out measures designed to ensure a high level of cybersecurity across Italy, thereby contributing to the overall improvement of cybersecurity in the European Union. In addition to mandating a national cybersecurity strategy, the Decree integrates crisis management protocols and confirms the National Cybersecurity Agency as the competent NIS authority, the single point of contact, and the national CSIRT for handling incidents at the national level (Novelli et al. 2024).

The decree also includes obligations related to cooperation and information sharing to tackle cyber fraud.

One of the most significant innovations introduced by the NIS 2 Directive is the expanded scope of affected sectors. Replacing the former distinction between Operators of Essential Services (OES) and Digital Service Providers (DSPs), the Directive now refers to “Essential Entities” and “Important Entities” (Chiara, 2024). These include all entities operating in the sectors classified as Highly Critical and Other Critical Sectors, as listed in Annexes I and II of the Directive, provided they meet specific size criteria.

The NIS 2 Directive applies to all large enterprises operating in the identified sectors—those with more than 250 employees, or an annual turnover exceeding €50 million, or an annual balance sheet total above €43 million. It also covers medium-sized enterprises (50–250 employees, with an annual turnover or balance sheet total between €10 and €50 million), provided they operate in the listed sectors.

The identification of the relevant public administrations is left to the discretion of the Member States. The Directive also includes specific categories of entities, including certain small enterprises.

As regards risk management, entities are required to assess cybersecurity risks and implement appropriate technical and organizational measures. Article 21 of the Directive outlines a set of high-level requirements, such as multi-factor authentication, encryption, basic cyber hygiene practices, and human resources security measures. The NIS2 sets out a list of minimum cybersecurity measures that both EEs and IEs must adopt, following a risk-based approach (Chiara, 2024). Risk management measures include data backups, disaster recovery, and crisis response planning, all aimed at minimizing service disruption.

In addition to ensuring resilience and disaster recovery capabilities (Dupont, 2019; Rothrock, 2017; Bjorck et al., 2015), both essential and important entities are required to notify their respective CSIRTs or the national

competent authority of any incident having a significant impact on the provision of their services—without undue delay and by issuing an early warning within 24 hours of becoming aware of the incident.

NIS2 strengthens national competent authorities' powers and tasks (Chiara, 2024). Supervisory and enforcement measures are now more detailed (e.g., on-site inspections, targeted security audits, security scans, requests for information and to access data, etc.) but are differentiated depending on whether the authority enforces them against an EE or an IE, the latter being subjected to ex-post supervisory measures.

The distinction between essential and important entities also affects supervisory measures and penalties: essential entities are subject to more stringent controls and potentially higher sanctions. The imposition of fines is determined either by a fixed minimum amount or by a percentage of the organisation's total annual turnover, depending on which of the two is higher.

2.3 Analogies and Differences between Law No. 90 of 2024 and Legislative Decree No. 138 of 2024

Both regulations establish a general obligation to notify cybersecurity incidents, detailing the related timelines. However, there are some differences between the two.

As far as the definition and scope of a cybersecurity accidents is concerned, Law No. 90 of 2024 refers to the taxonomy of incidents established through a reference to the National Cybersecurity Perimeter regulations. Differently, NIS 2 Directive defines a cybersecurity incident as "a*n event that compromises the availability, authenticity, integrity, or confidentiality of data stored, transmitted, or processed, or the services offered by information systems and networks or accessible through them*.". In accordance with Law No. 90 of 2024, the ACN has already published important guidelines on the procedure to follow for reporting and notifying incidents covered by the cited legislation (ACN, 2024).

It would be appropriate, in order to avoid duplication and complications for the affected entities, to extend similar procedures for reporting and notifying incidents covered by the decree transposing the NIS 2 Directive.

Both legislative measures introduce, for entities falling within their scope, obligations related to cybersecurity governance and risk management.

As previously mentioned, Law No. 90/2024 mandates the establishment of a structure that plans, adopts, and monitors the cybersecurity risk management system, and within this structure, a designated cybersecurity officer.

NIS 2 requires the identification of at least one point of contact between the entity and the ACN, which acts as the link between the NIS entity and the institution responsible for overseeing the correct implementation of governance measures and management of cybersecurity incident risk.

The legislative technique chosen is inspired by the so-called "*by design*" principle, aiming to implement management systems characterized by planning that follows the criteria of adequacy and proportionality depending on the size and type of the public entity applying it, rather than by introducing a mere list of minimum-security measures.

From the analysis, it is clear that part of the legislation is common to both regulations. It would be desirable to have a common and systematic compliance model, so that the public administration entities covered by Law No. 90 of 2024 can comply with both regulations.

3 CER Decree

On 23 September 2024, Legislative Decree No. 134/2024 ("CER Decree") was published in the Official Gazette, through which the CER Directive was transposed.

In particular, the CER Decree will apply to all public and private entities that, by no later than 17 August 2026, will receive notification of their inclusion among the so-called critical entities. The entities involved are those that (i) operate and have a critical infrastructure (even partially) on national territory, (ii) provide at least one essential service for society, and (iii) could experience significant negative effects in the event of an incident, also impacting other essential services that depend on it.

The provisions of the CER Directive, therefore, apply only in a residual manner in cases where the NIS2 Directive does not apply.

In other words, the CER Decree also safeguards the physical protection and operational security of infrastructures, which translates into the obligation, for example, to develop and update a resilience plan, covering various aspects such as risk management, disaster risk reduction, and adaptation to climate change.

4 Other relevant legislative instruments

From this analysis, it appears that the topic has recently been the subject of several legislative actions (Bygrave, 2017; Schmitz, 2022; Kamara, 2024). In this scenario, the NIS 2 Directive represents a crucial update in the European Union's legislation for network and information security (Schmitz-Berndt 2023; Vandezande 2024). On the same days, the European Union enacted the CER Directive, Regulation Dora (Regulation EU n. 2022/2554) as well as regulations related to cybersecurity in the financial services sector.

All of these regulations are in addition to the General Data Protection Regulation, (Fondrieschi 2019), the Digital Market Act (DMA, Regulation EU 2022/1925), the Digital Service Act (DSA, Regulation EU 2022/2065), and Electronic Identification Authentication and Signature (eIDAS 2, Regulation EU 2024/1183) (Bush 2022).

Notwithstanding, security remains a recurring topic addressed by all these Directives and Regulations (Porcedda, 2023).

The regulatory framework lacks coherence. The legal instruments interact in complex, confusing, and at times uncoordinated ways. EU cybersecurity law appears as a tangle of rules without an overarching structure; although the various instruments share significant commonalities in terms of approach and mechanisms, an excessive degree of overlap — combined with conceptual uncertainty — prevents them from forming a cohesive whole. The absence of judicial rulings further highlights the practical difficulties in applying the provisions examined (Bygrave, 2025; Carrapico and Barrinha 2017).

5 Cybersecurity and sustainability

At the same time, there is no doubt that cyber incidents have a significant impact on the profits of companies.

This has led private entities to increasingly focus on the issue, acknowledging its growing relevance within the broader framework of digital governance and risk management.

Until the CSRD came into effect, the disclosure of cybersecurity-related information in annual reports was not subject to binding obligations.

In this regard, the CSRD introduced the inclusion of cybersecurity information in the annual report as non-financial information. For this reason, it is useful to investigate how cybersecurity obligations contribute to the quality of sustainability reporting (Boggini, 2024).

Furthermore, according to Article 29b of the Accounting Directive, as introduced by the CSRD, the sustainability report should be drafted following the European Sustainability Reporting Standards (ESRS).

It has been previously observed how Article 21 of NIS 2 imposes a series of measures that must be adopted by the obligated entities. Similarly, Article 32 of the GDPR requires the data controller and processor to implement appropriate technical and organizational measures to ensure a level of security that is appropriate to the risk, considering the nature, scope, context, and purposes of the processing, as well as the specific risks to the rights and freedoms of individuals. Some of these measures can be disclosed in the annual reports to meet the disclosure requirements of ESRS S4. Indeed, the purpose of ESRS S4 is to disclose how the company manages the material impact of its activities on consumers and end users. The growing number of cybersecurity obligations in EU legislation, coupled with the increased adoption of cybersecurity controls by companies, enhances the content of sustainability reporting under the CSRD. The disclosure of the adopted security controls will provide stakeholders with an understanding of how the company addresses cybersecurity risks.

6 The potential use of blockchain as a tool for enhancing cybersecurity

The examined regulations primarily address the procedures to be used for preventing cyberattacks and for responding promptly if they occur. However, scholars' attention must also be directed toward the use of tools that can reduce the number of cyberattacks. In the final part of this contribution, we aim to examine the role that blockchain can play in implementing digital certainty and the security of the information entered.

Blockchains are part of Distributed Ledger Technologies (DLTs), referred to as "nodes," characterised by decentralization and accessibility to all users (Riet, 2020). They are structured in blocks that allow that the data is simultaneously present on each participant's device and linked by a peer-to-peer network that ensures simultaneous updates (Cucurru, 2017). This aspect guarantees the transparency of the process. Moreover, any modification on a single node does not compromise the system's effectiveness, meaning the information can be recovered from the data of other nodes in the DLT (Davola, 2020). This leads to the immutability of the data.

Specifically, the blockchain is a DLT characterised by chronological block arrangement in a chain, placed in chronological order. Unauthorized modification of a transaction results in the alteration of the block's hash containing the transaction and the subsequent blocks downstream, which is immediately verifiable and visible by the nodes.

The digital information blocks in the distributed ledger are cryptographically linked to each other, and they also include a timestamp system known as time-stamping (Natale, 2020).

The EU Regulation of 30 May 2022, No. 858 establishes requirements related to DLT market infrastructures and their operators concerning specific regulatory obligations.

The use of blockchain technologies has seen significant implementation with the rise of cryptocurrency and NFT markets (Nava, 2022; Carriere, 2021; Finzer, 2020).

These tools are also contained within smart contracts that circulate through DLT and blockchain via marketplaces. Beyond issues related to property rights, usage licenses, and intellectual property, NFTs, like cryptocurrencies, are seen by users as means of generating profit.

In particular, the use of NFTs creates a mechanism that allows digital assets to be uniquely identified, have a nearly immutable provenance, and be available for trade, largely without requiring large amounts of money (Vallabhaneni, 2021).

In the case of creating an official registration and identification system, the user, after providing personal information and after identity verification with public security systems, would be enabled to access and equipped with a personal digital badge through digital encryption technology.

7 Conclusions

This analysis has examined the state of the art concerning cybersecurity in Italian and EU law. The research highlighted the existence of a non-uniform and fragmented regulatory framework. It emerged that cybersecurity is a fundamental right, the protection of which is essential to promote social and economic development. The regulatory measures aimed at establishing cybersecurity offices and procedures to follow in the event of cybersecurity incidents are certainly commendable. Public administration is deeply involved in this issue, providing essential services to citizens and managing numerous personal, including sensitive, data.

Similarly, the importance of the adoption of measures that companies must implement has been demonstrated, as well as how they are required to include information related to cybersecurity in the sustainability report, which is also impacted by the existing regulations.

In order to enhance the security of digital data, we suggest implementing the adoption of blockchain technologies, which ensure greater certainty of identity and the integrity of the data entered. It would also be desirable to establish legal remedies for individuals in the event of non-compliance by obligated parties with the duties imposed by existing legislation. In fact, the primary objectives of these legal acts lie in the 'functioning of the internal market' and not the protection of natural and/or legal persons per se.

Human-Machine Interaction and Robotics in Healthcare: A Research Programme as a Starting Point

Alba Maria Gallo[1], Ubaldo Comite[1], Eveny Ciurleo[2]
[1]Giustino Fortunato University, Benevento, Italy
[2]University of Calabria, Cosenza, Italy

Abstract

The increasing adoption of artificial intelligence (AI) and robotics is leading to a profound transformation of the healthcare sector (Raimo et al., 2022), affecting diagnostic accuracy, optimising clinical processes and redefining care practices (Comite, 2022). Collaboration between healthcare professionals and intelligent machines is a key element in the evolution of care, redefining roles and changing traditional organisational structures (Çetin, 2024).

However, large-scale implementation is hampered by acceptance barriers, behavioural resistance and ethical and regulatory issues. This integration presents an opportunity to increase efficiency and reduce the margin of error (Babashahi, 2024), yet questions remain about safety, reliability and the impact on professional skills (Nivethithitha et al., 2014). Adoption depends largely on the trust healthcare professionals place in these technologies, transparency in algorithmic decision-making, and the availability of resources and adequate training.

The study asks: "How does human-computer interaction affect the acceptance of digital technologies by healthcare professionals and what strategies can be implemented to improve their adoption?"

To answer this, the authors conducted a systematic literature review (Massaro et al., 2016), analysing articles from Web of Science (WoS) and Scopus. The selection process combined automated and manual searches, identifying 11 relevant studies. Inclusion criteria focused on works addressing acceptance factors, barriers, and implementation strategies of AI and robotics in healthcare. Technical studies without a human-computer interaction perspective were excluded. Recent literature also highlights the growing role of AI-powered assistants, where human-chatbot interactions redefine service delivery (Akpan et al., 2025).

The aim is to create a strategic agenda for adopting AI and robotics in healthcare, identifying strategies and methods, including empirical ones, to facilitate integration and improve perception among professionals.

Findings show that acceptance depends on trust, perceived usefulness, ease of use and training adequacy. Resistance stems from fear of a diminished human role, regulatory uncertainty and ethical concerns linked to automation. Effective strategies include transparency in decisions, involving healthcare workers in development, and specific training programmes.

Human-computer interaction is redefining healthcare, promoting a collaborative model between professionals and AI. For this transition to succeed, organisational, ethical and training challenges must be addressed. Institutions must invest in training and policies for responsible and sustainable integration (Murugan et al., 2024). Recent studies also emphasize AI-driven assistants as tools to enhance collaboration and bridge gaps in professional-patient interactions (Liu et al., 2024). The adoption of AI and robotics (Kaur, 2024) offers a unique chance to improve care, but requires a strategic, interdisciplinary approach. This contribution offers a foundation for future research and for defining effective, sustainable implementation models.

Keywords: Artificial intelligence, Robotics, Healthcare, Human-machine collaboration

Paper type: Academic research paper

1 Introduction

This study highlighted the integration of artificial intelligence (AI) and robotics in the healthcare sector as a growing phenomenon with a significant impact on clinical efficiency, quality of care and the work dynamics of healthcare professionals. The degree of adoption of these technologies depends on several factors, including practitioners' confidence in automated systems, the perception of their usefulness, ease of use and the adequacy of training received.

The literature review revealed that human-computer interaction plays a significant role in facilitating or hindering the acceptance of digital technologies in healthcare, and the main resistances identified relate to the fear of a progressive reduction of the human role, regulatory uncertainties and ethical implications related to the automation of clinical processes. In this context, strategies such as transparency in algorithmic decision-making processes, the active inclusion of healthcare professionals in technology development and the implementation of targeted training paths prove to be crucial in order to facilitate the adoption of AI in the sector.

The results show that artificial intelligence technologies, including AI assistants (concierge AI), are playing a significant role in optimising interactions between patients and healthcare professionals, and such tools can

improve human-machine collaboration, bridge communication gaps and contribute to a more efficient delivery of healthcare services.

The research question that prompted this contribution is: How does human-computer interaction affect the acceptance of digital technologies by healthcare professionals and what strategies can be implemented to improve their adoption?

The results can contribute to the construction of a strategic agenda for the effective adoption of AI and robotics in the healthcare sector, providing useful insights for researchers, policy makers and practitioners considering that overcoming existing barriers requires a joint effort between technology development, training and regulation, in order to ensure a sustainable and responsible integration of new technologies.

2 Methodology

To conduct this literature review, the following queries were made on Scopus.

TITLE-ABS-KEY (('Artificial Intelligence' OR 'AI') AND ('Robotics' OR 'Robot') AND ('Healthcare' OR 'Medical care' OR 'Health sector') AND ('Human-Machine Collaboration' OR 'Human-Computer Interaction' OR 'HCI')) AND (LIMIT-TO (SUBJAREA , "BUSI") OR LIMIT-TO (SUBJAREA , "ECON") OR LIMIT-TO (SUBJAREA , "DECI")).*

The literature review shows that the integration of artificial intelligence (AI) and robotics in the healthcare sector is a topic of increasing relevance, with a focus on human-computer interaction, and this is clearly evident from the visualizations.

Figure 1: Words Cloud

The word cloud offers an insight into the dominant themes in the literature where the term 'healthcare' is central, followed by key words such as 'AI', 'concierges', 'customer', 'research' and 'collaboration'. which implies that the focus is not only on the technological aspect, but also on how these innovations impact the patient's journey (customer journey) and teamwork between humans and machines. The concept of 'concierge AI' is particularly interesting, as it indicates that artificial intelligence is increasingly seen as an interactive support, similar to a virtual assistant, capable of improving the patient experience and the efficiency of healthcare services.

Then there are terms such as "vocal", "devices" and "digital" that confirm the importance of integrating intuitive interfaces, probably via voice commands or connected devices while terms such as "challenges" and "implications" also suggest that scholars are analysing both the benefits and barriers to the adoption of AI in healthcare. (see Figure 1).

Figure 2: Cluster

With the help of R study, an attempt was made to conduct a cluster analysis, but only one cluster emerged. which relates two fundamental concepts: health care and human computer interaction indicative of the fact that research is focusing on the influence of the interaction between humans and intelligent machines in the health sector. The use of AI not only provides technical support but also redefines professional roles and care processes, and the fact that these two concepts are closely linked indicates that strategies for implementing AI in healthcare must consider efficiency, acceptance and adaptation by healthcare professionals. (see Figure 2).

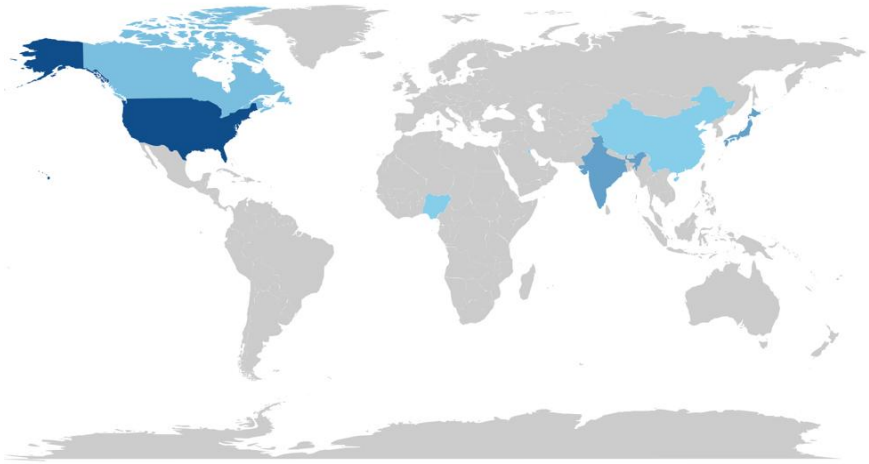

Figure 3: Geographic distribution of publications

In Figure 3, the geographic distribution of publications or studies related to the topic is shown, and it can be seen that the United States emerges as the main hub for research and innovation in this field, followed by Canada, Europe (with emphasis on certain nations) and Asian economies such as China, India and Japan. This map reflects the global technological reality: countries with a strong push in digital innovation and AI adoption are driving the transformation of the healthcare sector, and the low intensity in some geographic areas is indicative of the fact that there are still countries where AI adoption in healthcare is limited, probably due to regulatory, infrastructural or economic barriers.

3 Results

The increasing adoption of artificial intelligence (AI) and robotics is leading to a profound transformation of the healthcare sector (Raimo et. al, 2022), influencing diagnostic accuracy, optimising clinical processes and redefining care practices (Comite, 2022)

Collaboration between healthcare professionals and intelligent machines is a major element in the evolution of care, redefining professional roles and changing traditional organisational structures (Çetin , 2024). The implementation of these technologies is hindered by barriers of acceptance, behavioural resistance and ethical and regulatory issues, and such integration represents an unprecedented opportunity to increase operational efficiency and reduce the margin of error (Babashahi, 2024), but questions remain about safety, reliability and the impact such innovations may have on professional competence (Nivethithithitha et. al 2014). Their adoption largely depends on the degree of trust that healthcare professionals place in these technologies, the transparency of algorithmic decision-making processes and the availability of resources as well as appropriate training paths.

To answer the research question, a literature review was conducted (Massaro et al., 2016), analysing articles from Web of Science (WoS) and Scopus. Recent literature also highlights the growing role of AI-based assistants in healthcare and other sectors, where AI concierges and human-chatbot interactions redefine service delivery and operational efficiency (Akpan et al., 2025).

The aim of the research is to create a strategic agenda for the effective adoption of AI and robotics technologies in healthcare, identifying strategies and methods, including empirical ones, to facilitate their integration and improve their perception among healthcare professionals. The results show that the acceptance of AI and robotics depends on variables such as trust in the technology, the perception of its usefulness, ease of use and the adequacy of the training received. The main resistances can be traced back to the fear of a reduced human role, regulatory uncertainties and ethical implications of the progressive automation of clinical processes. Effective strategies to promote adoption include transparency in decision-making processes, the active inclusion of healthcare professionals in the development of the technology, and the implementation of specific training programmes.

Human-computer interaction is progressively redefining the healthcare paradigm, favouring a collaborative model in which professionals and artificial intelligence work in synergy, and for this transition to be effective, organisational, ethical and training obstacles must be overcome. Healthcare institutions need to invest in staff training and develop policies that ensure responsible and sustainable integration of new technologies (Murugan et al. 2024), and in this regard, many studies have emphasised the importance of AI-based assistants in

improving human-computer collaboration and suggest that AI-based concierge models can help bridge gaps in interactions between professionals and patients (Liu et al., 2024).

The adoption of artificial intelligence and robotics in healthcare (Kaur, 2024) represents an unprecedented opportunity to improve both the effectiveness and quality of care, and to ensure optimal integration, a strategic and interdisciplinary approach is crucial. Overcoming existing barriers requires a joint effort of researchers, clinicians, policy makers and technology developers to ensure that innovation is geared towards equity, safety and sustainability

4 Implications

The adoption of artificial intelligence and robotics in healthcare is profoundly transforming the organisation of care and the role of healthcare professionals. In particular, the implementation of these technologies offers numerous benefits, including greater operational efficiency, a reduction in the margin of error and an improvement in the quality of care; their deployment depends on multiple factors, including the confidence of healthcare professionals in automated systems, the perception of their usefulness and the adequacy of the training received.

One of the key aspects that emerged from the research is the crucial role of human-computer interaction in facilitating or hindering the adoption of these innovations. Indeed, while AI can support clinical decisions and automate repetitive processes, there is a fear that an excessive reliance on machines may reduce the decision-making autonomy of physicians and threaten the centrality of the human relationship in medical practice. Moreover, barriers to acceptance are often linked to ethical and regulatory issues, which raise questions about the transparency of algorithms and the protection of sensitive patient data, and for this reason, it becomes essential to adopt targeted strategies that promote trust in the technology and ensure its safe and responsible use.

A key element in fostering the integration of AI in healthcare is training in fact, healthcare professionals should be adequately trained in the use of these technologies, understanding not only how they work but also their ethical and practical implications. Research has shown that greater involvement of medical staff in the development and implementation of AI solutions can improve the level of acceptance and reduce resistance to change, and transparency in algorithmic decision-making processes and the introduction of intuitive interfaces could facilitate the adoption of these tools, making them more accessible and reliable.

In addition to training and trust aspects, another emerging trend is the increasing use of AI assistants in the healthcare sector where tools such as AI concierges are redefining how patients and caregivers interact, simplifying the management of clinical information and improving the accessibility of healthcare services. These systems can be a valuable support for medical staff, reducing their workload and improving the overall efficiency of healthcare facilities, but for these tools to be truly effective, it is necessary to develop human-machine interaction models that always put the patient and the quality of care at the centre.

The literature review also revealed a strong geographical disparity in the research and implementation of AI in healthcare. Countries such as the United States , Canada, China and India appear to be among the main promoters of these technologies, while other regions still show a limited level of adoption, hence the need for global policies that foster a more equitable access to technological innovation, reducing the gap between different healthcare realities and promoting the adoption of AI even in contexts with fewer resources.

5 Conclusions

The integration of artificial intelligence and robotics in healthcare represents an extraordinary opportunity to improve the effectiveness and quality of care, but it requires a strategic approach where the key to success can be found not only in technological development, but in the ability to adapt these innovations to the needs of the healthcare sector, guaranteeing transparency, safety and sustainability. To achieve this, a joint effort between researchers, developers, healthcare professionals and policy makers is essential, so that the introduction of new technologies is done in an ethical and responsible manner.

The future of healthcare will not be characterised by the replacement of human work by machines, but by an increasingly close collaboration between artificial intelligence and healthcare professionals, and the main goal should be to harness the potential of AI to improve the work of physicians, optimise the use of resources and ensure that patients have access to increasingly personalised and effective care. To realise this vision, current barriers need to be overcome through investment in training, appropriate regulation and technology design that takes into account the real needs of professionals and patients, only in this way will it be possible to build a more efficient, inclusive and future-oriented healthcare system.

6 Ethics declaration

This study did not involve the collection of sensitive or personal data, nor did it include experiments involving human or animal subjects. Therefore, ethical approval was not required.

7 AI declaration

An artificial intelligence tool was occasionally used for minor linguistic suggestions. The authors reviewed and integrated the content, taking full responsibility for the final text.

Specific Learning Disabilities (SLD) and Artificial Intelligence (AI): A Bibliometric Analysis

Guendalina Capece, Tindaro Cicero, Daniela D'Auria, Flavia Di Costa
Universitas Mercatorum, Rome, Italy

Abstract

This study conducts a bibliometric analysis of the scientific literature addressing the intersection between Specific Learning Disabilities (SLDs) and Artificial Intelligence (AI), a field that has been gaining increasing relevance due to the transformative potential of AI-based interventions in education. SLDs, including dyslexia, dysgraphia, and dyscalculia, significantly impact learning processes and academic outcomes, making it crucial to explore innovative approaches for their early identification and personalized support. AI technologies, such as machine learning, natural language processing, and adaptive systems, offer promising tools to enhance educational inclusion and tailor interventions to individual learning needs. By leveraging data-driven methodologies, AI can provide dynamic and responsive learning environments, improving both engagement and outcomes for students with diverse cognitive profiles.

Using data retrieved exclusively from the Scopus database and analysed through the Bibliometrix R package, this research examines publication trends, citation patterns, international collaboration networks, and thematic evolutions within this interdisciplinary domain. The analysis reveals a substantial increase in research output since 2020, highlighting a growing academic and technological interest in leveraging AI to address SLD challenges. Countries such as the United States, Spain, Italy, and India emerge as key contributors, fostering an expanding global collaboration network. These international partnerships reflect a shared commitment to addressing the complex and multifaceted nature of learning disabilities through cross-disciplinary research efforts.

Thematic mapping identifies core topics like dyslexia, machine learning, and personalized learning systems, alongside emerging themes such as contrastive and adversarial machine learning approaches, which represent innovative frontiers for future exploration. In particular, these advanced AI techniques show potential in enhancing diagnostic precision and developing more adaptive educational tools. Despite this promising landscape, the study underscores the need for broader empirical validation and interdisciplinary cooperation involving educators, AI researchers, and healthcare professionals. Meta-analytic evidence also suggests the importance of integrating cross-disciplinary insights when developing AI tools tailored to the needs of students with disabilities (Zhang, Carter Jr., Liu, & Peng, 2024).

The findings emphasize the strategic role of AI in promoting educational equity and suggest future research directions to consolidate and expand this field, ultimately contributing to more inclusive and effective learning environments for individuals with SLDs. Such efforts are essential to bridge existing gaps in access to tailored educational resources, ensuring that technological innovation translates into tangible benefits for learners worldwide.

Keywords: Specific Learning Disabilities (SLD); Personalized Learning; Inclusive Education; Artificial Intelligence (AI); Bibliometric Analysis.

Paper type: Academic Research Paper

1 Introduction

Specific Learning Disabilities (SLDs) are neurodevelopmental disorders that significantly impair a person's ability to process language, whether spoken or written, resulting in difficulties in reading (dyslexia), writing (dysgraphia), spelling, and mathematics (dyscalculia) (Grigorenko et al., 2020; Chieffo et al., 2023). These disorders affect approximately 5% to 15% of the school-age population and represent a heterogeneous group of conditions that hinder the development of academic proficiency. Beyond academic struggles, individuals with SLDs often experience poorer long-term professional outcomes and face social, emotional, and behavioural challenges.

In recent years, Artificial Intelligence (AI) has emerged as a transformative force within educational and healthcare contexts, offering promising avenues to support individuals with SLDs. AI-driven technologies—including machine learning algorithms, adaptive learning systems, and assistive tools like speech recognition and text-to-speech applications—provide personalized educational interventions that address individual strengths, weaknesses, and learning preferences (Askarova et al., 2024; Hadinezhad, Garg & Lindgren, 2024; Jadán-Guerrero et al., 2024). Recent contributions also emphasize the potential of AI to empower individuals with cognitive impairments by promoting autonomy and inclusivity in educational and healthcare settings (Di Nuovo, 2023).

The integration of AI into educational practices not only enhances individualized learning but also enables early identification of learning disorders through data analysis and predictive modelling (Yap, Aruthanan, & Chin, 2025; Basnayaka et al., 2023). These applications can lead to more timely and effective interventions, potentially improving academic outcomes and promoting greater inclusivity in education.

Given the profound impact of SLDs on individuals and society, and the transformative potential of AI technologies, a comprehensive understanding of current research trends is essential. A bibliometric approach enables the systematic analysis and visualization of the scientific literature on this intersection, revealing collaboration networks, citation patterns, influential works, and underexplored areas (Zhang, Fan, & Zhang, 2021; Bosse, Nussbaumer, & Hövel, 2024). A recent systematic review highlights how AI-based interventions for students with learning disabilities remain fragmented and require more robust evidence across diverse educational settings (Panjwani-Charani & Zhai, 2024).

The present study aims to conduct a detailed bibliometric analysis with the following specific objectives:

- to investigate the overall trend of publications and citations over time, providing insights into the growing relevance of the topic;
- to analyse the main patterns of international collaborations among countries contributing to this field;
- to identify thematic clusters and emerging specializations within the research, highlighting key subtopics and knowledge domains.

By achieving these objectives, the paper seeks to offer a structured and comprehensive overview of the scholarly landscape concerning the application of AI in supporting individuals with SLDs.

2 Methodology

The bibliometric analysis presented in this study is based exclusively on data retrieved from the Scopus database, which offers comprehensive coverage of peer-reviewed scientific publications across a wide range of disciplines. Scopus was selected as the sole source of bibliographic data to ensure uniformity in metadata structure, reliability of citation indexes, and the overall quality of the retrieved documents.

The literature search was carried out using a combination of keywords related to Specific Learning Disabilities (SLDs) and Artificial Intelligence (AI). Terms such as "Specific Learning Disabilities," "SLD," "Artificial Intelligence," "Machine Learning," and "Assistive Technologies" were combined using Boolean operators to maximize the retrieval of relevant documents. The search was restricted to articles, reviews, books, book chapters, conference papers or reviews, editorials, notes, short survey, published between January 1986 and December 2024. A manual screening phase was conducted to exclude papers that, although related to either SLDs or AI individually, did not establish a direct connection between the two fields. Duplicate entries and incomplete records were also removed.

The final dataset, including bibliographic information such as authors, affiliations, abstracts, keywords, references, and citation data, was extracted in a structured format suitable for bibliometric analysis. An overview of the dataset's composition, including the number of records and relevant bibliographic attributes, is presented in Table 1.

Table 1: Number of records and relevant bibliographic attributes

Statistics	**Number**
Documents	218
Sources	143
Authors	710
Authors of single-authored docs	22
International co-authorship	21.1%
Co-authors per document	3.72
Document average age	5.73

A total of 218 documents published across 143 different sources were included. The dataset comprises contributions from 710 distinct authors, with 22 documents being single-authored. The degree of international collaboration is notable, with 21.1% of the documents involving authors from multiple countries. On average, each document is co-authored by approximately 3.72 individuals, highlighting a moderate level of collaborative authorship. The average age of the documents in the dataset is 5.73 years, indicating that the sample primarily consists of relatively recent publications.

All analyses were conducted using Bibliometrix, an open-source R package specifically designed for comprehensive science mapping (Aria & Cuccurullo, 2017). Bibliometrix provides a wide range of bibliometric

tools for quantitative research in bibliometrics and scientometrics and allows for both descriptive statistics and advanced network analysis through its integrated web-interface Biblioshiny.

The bibliometric investigation was designed to address three specific analytical objectives. First, the study examines the trend of scientific production and citation patterns over time, offering insights into the growth and evolution of research at the intersection of AI and SLDs. Second, it explores international collaboration networks by analyzing patterns of co-authorship across countries, highlighting the most active contributors and major hubs of scientific cooperation. Third, it identifies thematic clusters and emerging areas of specialization through co-word analysis and clustering algorithms, uncovering the main conceptual structures that characterize the field.

This methodological framework enables a comprehensive and systematic exploration of the intellectual, social, and conceptual dimensions of the research concerning the application of Artificial Intelligence to Specific Learning Disabilities

3 Analysis and results

The bibliometric analysis of the scientific production related to Specific Learning Disabilities (SLDs) and Artificial Intelligence (AI) reveals a dynamic and rapidly evolving research landscape. The study focuses on three key dimensions: the evolution of publication and citation trends, patterns of international collaboration, and the thematic structure of the field.

The trend in annual scientific production reveals a steady increase in interest over time, with an annual growth rate of 7.57%. As illustrated in Figure 1, the number of publications remained extremely limited and sporadic until approximately 2010, with fewer than five articles per year. A first notable acceleration occurred around 2015, although still with moderate output. From 2020 onward, the field has experienced a dramatic growth, culminating in over 60 articles published in 2024 alone. This sharp rise indicates a growing awareness of the potential role of AI technologies in addressing the needs of students with SLDs and a broader expansion of interdisciplinary research combining education, cognitive science, and technological innovation.

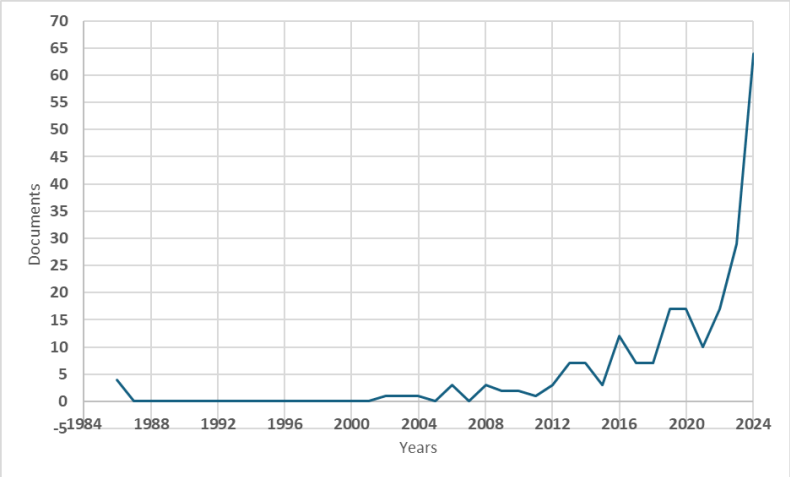

Figure 1: Annual scientific production

Similarly, the trend in citations offers important insights into the academic impact of this field. Figure 2 shows the average number of citations per article by year, with an overall average of 11.22 citations per document across the dataset. Although there are significant fluctuations — likely due to the small initial volume of publications — the overall trend suggests an increasing recognition of the relevance of this research topic. The sharp peak around 2003 reflects the influence of a seminal paper, after which the field matured with a more stable citation pattern. In recent years, particularly from 2015 onwards, average citations have remained consistently higher compared to earlier periods, confirming the growing importance and influence of studies situated at the intersection of AI and SLD research.

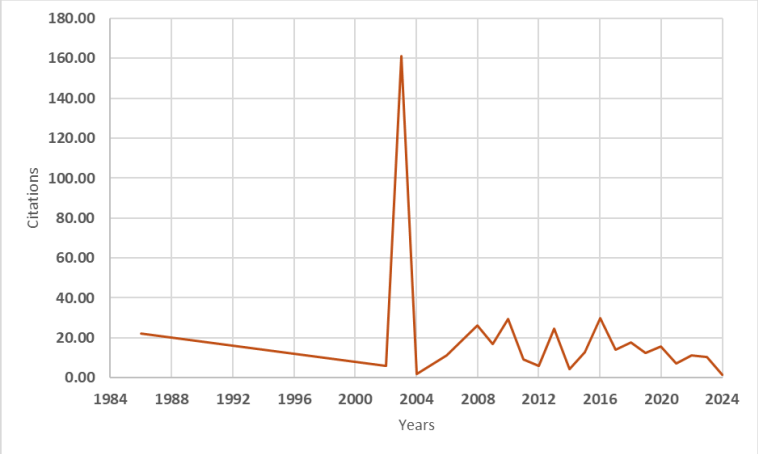

Figure 2: Average number of citations per article by year

International collaboration emerges as a fundamental factor in advancing this interdisciplinary area. The Country Collaboration Map (Figure 3) highlights the global distribution of scientific activity and the main cooperation networks. The United States leads the field both in terms of the volume of publications and international partnerships. Europe presents a dense network of collaborations, particularly involving Spain, Italy, and the United Kingdom, which act as major hubs for research development. Notably, India and China also show increasing contributions, indicating a growing global interest that transcends traditional Western-centric research patterns. These networks suggest that addressing SLDs with AI technologies is a universally recognized challenge that benefits from diverse cultural and scientific perspectives.

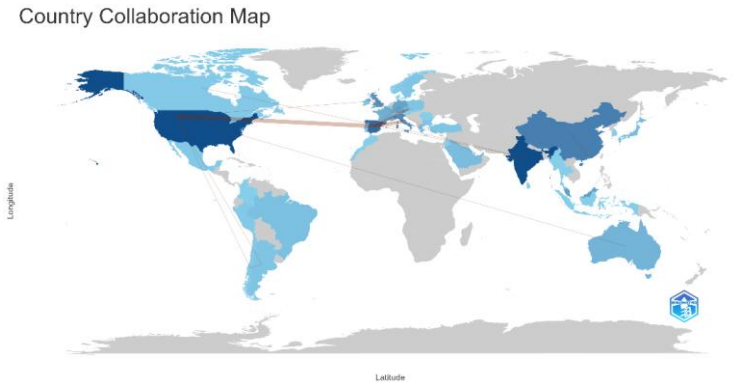

Figure 3: Country collaboration map

The thematic mapping of the field, presented in Figure 4, provides a more granular view of the conceptual structure of the research.

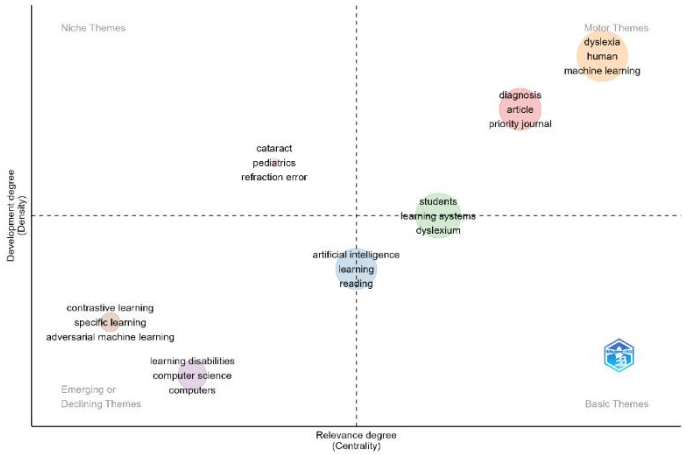

Figure 4: Thematic map

The thematic mapping of the field, presented in Figure 4, offers a comprehensive visualization of the conceptual structure of research at the intersection of Specific Learning Disabilities (SLDs) and Artificial Intelligence (AI). By plotting the themes across two axes—centrality (indicating the relevance of a theme within the overall network) and density (reflecting the internal development and cohesion of a theme)—the map provides a strategic overview of the maturity and importance of different research areas. This approach is instrumental in identifying established domains, emerging topics, and areas that may require further exploration or consolidation.

The map is divided into four quadrants, each representing distinct types of thematic clusters:

1. *Motor Themes (top-right quadrant):* these are the core drivers of research in the field, characterized by both high centrality and high density. Themes such as dyslexia, human, and machine learning fall into this category. Their placement suggests that they are not only highly relevant across multiple research domains but also exhibit a well-developed internal structure. For instance, numerous studies apply machine learning algorithms—such as support vector machines, neural networks, or decision trees—to the early detection of dyslexia, using features derived from reading patterns, eye-tracking data, or phonological processing assessments. This mature integration of AI techniques with dyslexia research reflects robust interdisciplinary collaboration between AI developers, educational psychologists, and neuroscientists, enabling effective diagnostic tools and intervention strategies. Early research already explored dynamic instructional adaptation using AI to tailor learning paths in computer science education, laying the groundwork for more personalized and responsive systems (Jurado et al., 2008).
2. *Basic Themes (bottom-right quadrant):* this quadrant includes topics like artificial intelligence, learning, and reading, which are highly central but less internally cohesive. These themes provide the foundational knowledge base for more specialized research, offering broad theoretical frameworks and methodologies. However, their lower density suggests that while these areas are widely discussed, further specialization and refinement in the context of SLDs may be needed. For example, although reading is a critical component of dyslexia research, it is often studied in general terms without sufficient integration of personalized AI-driven learning models that adapt to individual cognitive profiles.
3. *Niche Themes (top-left quadrant):* topics such as paediatrics, cataract, and refraction error are categorized as niche themes, characterized by high density but low centrality. These areas are well-developed internally but remain peripheral to the main research discourse on SLDs and AI. Their presence likely reflects specific subfields, such as the use of AI in paediatric ophthalmology, where vision-related conditions like cataracts or refractive errors are assessed using AI technologies. While these studies may intersect with learning disorders—given the impact of visual impairments on academic performance—they remain isolated from the central discussions around AI applications for cognitive or learning disabilities. For instance, AI models developed to detect visual anomalies in children might indirectly support better learning outcomes but are not explicitly integrated into broader SLD research.
4. *Emerging or Declining Themes (bottom-left quadrant):* themes like contrastive learning, specific learning, and adversarial machine learning are positioned here, indicating low centrality and density. These topics either represent nascent areas with high potential or declining interests. The presence of contrastive learning—a technique used to enhance the quality of learned representations by comparing similar and dissimilar data points—signals the early stages of applying advanced AI methodologies to the SLD context. Potential applications might include improving adaptive learning systems by distinguishing between different types of learning difficulties, thus offering more nuanced interventions. Similarly, adversarial machine learning could be employed to test the robustness and fairness of AI-based diagnostic tools, ensuring that models are not biased against certain populations or cognitive profiles. Although currently underexplored, these areas hold promise for redefining how learning disabilities are modelled and addressed through AI.

Although contrastive learning and adversarial machine learning are still emerging topics within the context of SLDs and AI, related studies in adjacent domains suggest their potential applicability. For instance, a study published in Science applied contrastive learning techniques to identify neuroanatomical variations specific to individuals with Autism Spectrum Disorder (ASD), distinguishing them from control groups. This methodology enabled the isolation of distinctive brain features associated with ASD, offering insights that could be adapted to detect neural patterns in SLDs, such as dyslexia or dyscalculia. Similarly, research published in Frontiers in Neuro-informatics explored the use of self-supervised contrastive learning to differentiate among various neurodegenerative disorders. Although these studies do not directly address learning disabilities, they illustrate the capability of contrastive learning to discriminate between different cognitive dysfunctions, indicating a promising avenue for future SLD research.

In parallel, the field of adversarial machine learning, while not yet directly applied to SLD research, has demonstrated significant potential in enhancing model robustness across various domains. A comprehensive taxonomy published by the National Institute of Standards and Technology (NIST) outlines adversarial attack techniques and mitigation strategies, emphasizing the need for resilient AI models. Applying such approaches to educational tools and diagnostic systems in SLDs could ensure that these systems remain reliable and unbiased, even in the presence of noisy or adversarial inputs. This is particularly relevant in educational contexts where data variability is common, and ensuring fairness and accuracy is critical.

These examples underscore the innovative potential of integrating advanced AI methodologies into SLD research, offering new directions for diagnostic precision and adaptive educational tools.

In summary, the thematic map not only captures the current intellectual landscape but also highlights strategic opportunities for advancing the field. For instance, integrating contrastive learning into adaptive educational platforms could enable real-time personalization, distinguishing between students with dyslexia and those with attention-deficit disorders based on nuanced behavioural patterns. Meanwhile, adversarial machine learning could be utilized to simulate challenging scenarios—such as noisy or incomplete data environments—to enhance the resilience of AI systems used in SLD diagnostics.

Furthermore, the thematic analysis suggests the need for greater convergence between niche and core themes, such as exploring how paediatric AI applications for vision impairments could be integrated with learning disability interventions, providing a holistic approach to student well-being. The thematic map thus serves as a strategic guide for researchers, offering a clear indication of where efforts should be concentrated to foster innovation, ensure ethical AI deployment, and enhance educational inclusivity.

4 Conclusions

This study provides a comprehensive bibliometric analysis of scientific literature at the intersection of Specific Learning Disabilities (SLDs) and Artificial Intelligence (AI), highlighting key trends, collaboration patterns, and thematic evolutions within the field. By analysing data exclusively retrieved from the Scopus database and employing the Bibliometrix R package (Aria & Cuccurullo, 2017), the study systematically mapped the intellectual and social structure of research activity in this emerging area.

The results reveal an exponential increase in scientific production over the past five years, reflecting a growing academic and technological interest in leveraging AI to support individuals with SLDs. Similarly, the average citation trends, despite some fluctuations, show an overall upward trajectory, suggesting that the relevance and influence of studies in this domain are steadily rising. The analysis of international collaborations highlights the pivotal role of countries such as the United States, Spain, Italy, and India, emphasizing the global scope of the research efforts and the importance of cross-border scientific cooperation.

The thematic analysis further uncovers a dynamic and diversified research landscape. While some areas, such as the application of machine learning to the diagnosis and support of dyslexia, have emerged as motor themes, other innovative approaches, including contrastive learning and adversarial machine learning, are beginning to gain attention as promising new directions for future exploration. These advanced AI methodologies, although still peripheral within the current research network, demonstrate significant potential to redefine diagnostic and intervention strategies. In particular, contrastive learning could enable more refined differentiation between various learning disorders, while adversarial machine learning offers tools for enhancing the robustness and fairness of diagnostic systems, ensuring reliable performance across diverse educational contexts.

Despite the notable progress observed, the bibliometric findings also highlight important gaps that merit further investigation. In particular, the emerging subfields require more empirical validation, and there is a need for broader interdisciplinary collaborations involving education experts, AI researchers, cognitive scientists, and policy makers. Greater efforts should also be directed toward integrating cutting-edge AI techniques with practical educational tools, ensuring that innovations translate into tangible benefits for learners with SLDs. This includes developing adaptive learning platforms that leverage advanced algorithms to personalize educational pathways, and diagnostic systems that are resilient to data variability and potential biases.

Moreover, the inclusion of insights from related fields—such as neurodevelopmental disorders and paediatric healthcare—could foster a more holistic understanding of the challenges faced by students with SLDs, promoting interventions that address both cognitive and environmental factors. Ensuring that AI-driven solutions are accessible and effective across different socio-economic and cultural contexts remains a critical challenge that future research should address.

In conclusion, the application of Artificial Intelligence to Specific Learning Disabilities represents a fertile and rapidly evolving research frontier. Continued investment in interdisciplinary research, combined with careful

empirical evaluation, will be essential to fully unlock the potential of AI in fostering more inclusive, personalized, and effective educational environments for all learners.

By bridging methodological innovation with practical application, researchers and practitioners can contribute to a more equitable and supportive learning ecosystem, where every student—regardless of cognitive differences—can thrive.

Abstract

This paper investigates how regulatory frameworks and financial incentives influence stakeholder engagement and the institutionalisation of grassroots innovations within the New European Bauhaus (NEB) initiative. Launched by the European Commission as a creative and interdisciplinary extension of the European Green Deal, the NEB aims to foster more inclusive, sustainable, and aesthetically engaging urban environments. Despite its transformative ambitions, limited empirical evidence exists on how NEB projects evolve from local experimental niches into institutionalised practices embedded within mainstream governance systems.

Building on Transition Theory and the Multi-Level Perspective (MLP), this study conceptualises NEB projects as niche innovations operating within broader socio-technical regimes. It explores how policy instruments shape the dynamics of stakeholder engagement, knowledge diffusion, and adaptive governance. By integrating governance studies into the MLP framework, the paper addresses a critical gap in the sustainability transitions literature: the institutional conditions necessary to scale bottom-up initiatives. Methodologically, the study adopts a qualitative embedded case study design. Data were collected through an online self-assessment form distributed to all NEB prize finalists, complemented by secondary document analysis and semi-structured interviews with project leaders across diverse socio-political contexts. The findings reveal that regulatory incentives are key enablers of stakeholder engagement, particularly when supported by strong institutional backing, clearly defined roles, and mechanisms for continuous co-creation. However, the effectiveness of these incentives is uneven. Ambiguities in policy implementation and disparities in resource accessibility limit participation for smaller or less institutionally connected actors. Some projects succeed in aligning local stakeholders around shared goals, facilitated by municipal support and EU funding, while others struggle with bureaucratic barriers and limited access to technical expertise.

Theoretically, the study extends the MLP by embedding stakeholder co-creation and adaptive governance mechanisms into transition analysis. Empirically, it provides one of the first grounded assessments of how NEB projects scale and institutionalise within multi-level governance structures. Practically, the research offers policy recommendations aimed at strengthening long-term engagement mechanisms, improving the accessibility of funding tools, and fostering cross-sectoral collaboration between local authorities, civil society, and industry.

Ultimately, this study contributes to a more comprehensive understanding of how participatory governance and regulatory design intersect in shaping urban sustainability transitions. It underscores the need for flexible, iterative governance models that allow experimental initiatives to influence policy landscapes and highlights the importance of inclusive and sustained stakeholder engagement for the institutional success of visionary policy agendas such as the NEB.

Keywords: New European Bauhaus, Stakeholder, Policy, Governance, Collaboration

Paper Type: Academic Research Paper

1 Introduction

The New European Bauhaus (NEB) initiative represents a novel policy framework that seeks to bridge the European Green Deal with participatory urban transformation by integrating sustainability, inclusivity, and aesthetics into the fabric of European communities (EU NEB Compass, 2023; EU NEB Website, 2024). Through its multi-level and interdisciplinary structure (Kuenkel, 2019), NEB aims to accelerate sustainability transitions through bottom-up innovation (Anderson et al., 2014; Baldwin et al., 2024) and enabling systemic change through policy alignment (Lee and Koski, 2015).

Despite its transformative ambitions, the long-term impact of NEB projects depends on their ability to scale beyond isolated experiments and become embedded within formal governance structures (Emerson et al., 2012; Freeman and David, 1983; Lee and Koski, 2015). Drawing on Transition Theory, NEB projects can be conceptualised as *niche innovations operating within an existing socio-technical regime* (Geels, 2002). These initiatives often promote participatory models, design-led urban solutions, and sustainability-oriented practices (Alizadeh et al., 2019; Haesevoets et al., 2024). However, their success hinges on supportive regulatory frameworks, effective knowledge diffusion mechanisms, and policy incentives that facilitate integration into mainstream urban governance (European Union, 2023; Leiringer, 2006).

While the Multi-Level Perspective (MLP) highlights the importance of interactions between landscape-level pressures (e.g., EU climate policy), socio-technical regimes (urban governance systems), and grassroots niches (local NEB projects) (Schot and Geels, 2011), the specific role of regulatory incentives in shaping these dynamics remains underexplored. In particular, the literature offers limited empirical insight into how grants, subsidies, and tax benefits influence stakeholder engagement, knowledge co-creation, and the institutionalisation of experimental projects (Heinelt and Niederhafner, 2008; Pee and Pan, 2022).

This study addresses this gap by examining *how policy mechanisms facilitate—or hinder—the transition of NEB projects from experimental niches to institutionalised urban practices.* By analysing how regulatory frameworks influence stakeholder engagement, the study contributes to a more nuanced understanding of *how participatory initiatives can move beyond compliance to foster enduring collaboration, interdisciplinary knowledge exchange, and adaptive governance.* While NEB has been conceptually praised, little is known about its institutionalisation pathways at the grassroots level—a gap this study addresses.

Theoretically, the paper extends the MLP by incorporating insights from governance and policy studies to better account for the institutional conditions that support sustainability transitions. Empirically, it provides original data from prize-winning NEB projects, offering grounded insights into the role of financial incentives and institutional support in shaping multi-actor engagement. Practically, the research delivers evidence-based recommendations for policymakers and local authorities to enhance the effectiveness of regulatory instruments in scaling grassroots innovations and embedding NEB values into long-term urban governance.

This paper offers the first empirical analysis of *how EU-level regulatory incentives shape stakeholder engagement and institutionalisation of NEB grassroots projects*, advancing both transition theory and participatory governance research.

2 Methodology

To address the research question—how policy mechanisms facilitate or hinder the transition of New European Bauhaus (NEB) projects from experimental niches to institutionalised urban practices—this study employs a qualitative research design grounded in Transition Theory and the Multi-Level Perspective (MLP) (Geels, 2002). The embedded case study approach (Yin, 2009) is particularly suited for analysing complex phenomena in real-world settings, especially those involving dynamic stakeholder interactions and institutional diversity. In this study, the NEB initiative serves as the primary unit of analysis, while prize-winning projects selected through the NEB Awards serve as sub-units. This structure enables an in-depth examination of how grassroots innovations interact with governance frameworks and respond to policy mechanisms under varying conditions of institutional support (Esposito et al., 2024; Kemp et al., 1998; Schot and Geels, 2011).

The NEB Awards, established as an annual competition, celebrate exemplary projects and concepts that embody the initiative's core values of sustainability, aesthetics, and inclusion. These awards recognise local efforts to foster innovation through multi-level, multidisciplinary, and participatory approaches. Between 2021 and 2023, the NEB Awards identified 52 winning projects from over 4,500 applications, reflecting a broad spectrum of practices across the European Union. The selected finalists include projects from Spain, Italy, Greece, Denmark, Belgium, Austria, France, Germany, and numerous other EU member states, providing a rich empirical base for comparative analysis.

The data collection process began in September 2023 by distributing an online self-assessment form to all NEB prize finalists. The survey was created via Google Forms and included Likert-scale and multiple-choice questions designed to capture background information, alignment with NEB values, and stakeholder engagement practices. This instrument provided a preliminary mapping of how projects adhere to NEB principles in practice. The responses were triangulated with secondary data sourced from project websites, social media, and official NEB project fiches to refine our understanding of project scope and implementation contexts.

Semi-structured interviews were conducted with project owners between December 2023 and March 2024 to deepen the qualitative analysis. This method was chosen to elicit rich, context-specific insights into the governance processes, institutional enablers and barriers, and stakeholder dynamics experienced by NEB participants (Rowley, 2012). Interviewee selection followed a purposive sampling strategy based on two criteria: (1) inclusion across the five NEB prize categories—Mobilisation of Culture, Arts & Communities; Regaining a Sense of Belonging; Buildings Renovated in a Spirit of Circularity; Prioritising the Places and People That Need It the Most; and Reconnecting with Nature—and (2) geographic diversity to account for varied socio-economic and governance contexts. While the sample includes NEB award-winning projects, future studies should also consider less visible initiatives to capture the full spectrum of grassroots experimentation.

This multi-method, multi-scalar approach ensures analytical depth and methodological triangulation (Creswell, 2009; Mills, 2019). The resulting dataset is analysed through thematic coding to identify governance

barriers, policy leverage points, and transition pathways that enable or constrain the institutionalisation of NEB projects. In doing so, the study seeks to contribute to both the theoretical advancement of transition studies and the practical refinement of participatory governance frameworks in the context of EU policy implementation (Bianchi and Nasi, 2021; European Union, 2023; Haesevoets et al., 2024).

3 Findings

The initial findings suggest that regulatory incentives such as grants and tax benefits are key *enablers of stakeholder participation* (Dentoni et al., 2018; Kuenkel, 2019). However, their effectiveness varies significantly across different project types and stakeholder groups. Projects that benefit from strong institutional support, clearly defined stakeholder roles, and embedded co-creation mechanisms appear better positioned to leverage these incentives. These cases demonstrate how financial support and well-structured governance arrangements can foster interdisciplinary collaboration, knowledge diffusion, and participatory urban governance. Nevertheless, implementation challenges persist. Ambiguities in policy interpretation and administrative complexity contribute to inconsistent stakeholder engagement practices across NEB projects. Moreover, disparities in access to financial and technical resources disproportionately affect grassroots organisations and smaller enterprises, limiting their full participation in NEB initiatives.

The findings underscore the importance of *adaptive governance structures* that respond to the dynamic nature of multi-stakeholder collaborations (Ansell and Gash, 2008; Freeman and David, 1983). Specifically, the institutionalisation of NEB projects requires regulatory support and flexible, multi-actor governance mechanisms that enable scaling niche innovations into mainstream urban policy frameworks.

For instance, a project from Italy operating in the "Regaining a Sense of Belonging" category successfully mobilised local artists, public institutions, and SMEs around a shared urban regeneration goal, facilitated by municipal backing and EU funding. In contrast, a finalist from Eastern Europe noted limited access to local institutional support and procedural complexities in applying for EU grants, which constrained long-term engagement. Contrary to expectations, even highly recognised projects reported difficulty sustaining stakeholder engagement beyond the funding cycle, pointing to a lack of long-term mechanisms.

Theoretically, this study contributes to sustainability transitions literature by extending the Multi-Level Perspective (MLP) to incorporate governance mechanisms and stakeholder engagement dynamics more explicitly. It offers empirical insights into *how regulatory incentives influence the trajectory of grassroots innovations, how socio-technical regimes respond to participatory processes, and how governance barriers and enablers shape knowledge diffusion.*

This research thus bridges transition theory and governance studies, advancing a more integrated framework for analysing the institutional embedding of experimental projects. The evidence suggests that the long-term success of initiatives like NEB depends on top-down policy alignment, bottom-up capacity building and collaborative governance models that can adapt to evolving urban and socio-political contexts.

4 Discussion

By positioning the NEB's participatory and design-driven ethos within transition studies, this research advances a novel analytical framework for understanding *how policy interventions and stakeholder co-creation processes influence sustainability transitions*. It expands the application of the MLP by integrating governance mechanisms—particularly those tied to regulatory incentives and institutional embedding—into the analysis of niche innovations.

Empirically, the research sheds light on the uneven effects of regulatory incentives across contexts, revealing how institutional backing, stakeholder role clarity, and access to resources shape project success. Combining qualitative interviews and comparative analysis of NEB-awarded projects, the embedded case study approach offers grounded insights into the mechanisms that facilitate or hinder stakeholder engagement and knowledge diffusion (Bryson et al., 2006). On a practical level, the study offers policy recommendations to enhance the effectiveness of regulatory frameworks in supporting participatory governance. It suggests shifting from short-term, compliance-driven incentives to mechanisms promoting sustained engagement and institutional integration. It also calls for fostering cross-sectoral collaboration between local authorities, industry, and civil society to support mainstreaming NEB-inspired solutions. Furthermore, it advocates for multi-level governance models that are flexible, co-creative, and iterative, allowing bottom-up initiatives to influence and reshape policy landscapes (Ambrose and Siddiki, 2024; Maher and Buhmann, 2019; Njøs and Fosse, 2019).

Theoretically, the study contributes to transition theory by illustrating how grassroots innovations interact with socio-technical regimes under varying governance conditions. It highlights the critical role of adaptive, multi-actor governance in enabling the institutionalisation of experimental projects such as those supported by

the NEB (Raj et al., 2022; Seyfang and Haxeltine, 2012; Seyfang and Smith, 2007). Moreover, his study refines the MLP by integrating multi-actor governance dynamics, while practically, it offers actionable pathways for embedding NEB projects into municipal policy cycles. Rather than treating regulatory incentives as static enablers, this study conceptualises them as dynamic relational tools that can evolve through actor interaction and feedback. Ultimately, this research contributes to developing more resilient and inclusive governance frameworks, helping to ensure that NEB principles become embedded in the long-term evolution of sustainable urban policies and practices (Hospers, 2014).

5 Limitations and Future Research Directions

While offering in-depth insights into the governance dynamics of NEB initiatives, this study is subject to several limitations. A primary restriction concerns the representativeness of the interview sample. Although efforts were made to ensure diversity across NEB prize categories and geographical contexts, selecting semi-structured interview participants may not fully capture the breadth of grassroots initiatives involved in the NEB ecosystem. This potential sampling bias may affect the generalisability of the findings (Creswell, 2009). Future research should broaden its empirical scope to include a more representative range of projects and stakeholder types, particularly underrepresented voices such as local community members, end-users, and external evaluators. Including these perspectives would provide a more holistic understanding of how NEB values are interpreted, negotiated, and implemented on the ground.

From a methodological standpoint, while the study triangulated data through interviews, document analysis, and secondary sources, the qualitative nature of the research remains inherently interpretive and context-dependent (Tranfield et al., 2003; Yin, 2009). Despite internal validation efforts through iterative discussion and coding comparison, the potential for researcher bias cannot be eliminated. Future studies could enhance robustness by adopting mixed-methods approaches that combine qualitative insights with quantitative data, such as large-scale stakeholder surveys or analysis of funding and impact metrics. Moreover, this research offers a snapshot of project implementation at a specific point in time. Longitudinal studies are recommended to capture how stakeholder engagement and value integration evolve. Following NEB initiatives over time would enable researchers to track adaptive processes, institutional learning, and the long-term embedding of NEB values into governance structures. Additionally, incorporating real-time methods such as participant observation in project meetings or workshops could offer deeper insights into decision-making dynamics and multi-actor collaboration in practice(Escolar et al., 2019; Gerlak et al., 2023).

6 Ethics declaration

This research involved human participants through semi-structured interviews and an online self-assessment form. Before data collection, participants were informed of the research objectives, and their voluntary consent was obtained in line with the principles of research ethics and confidentiality. Ethical principles of anonymity, informed consent, and data protection were rigorously followed throughout the research process.

7 AI declaration

Artificial Intelligence tools were not used to generate content or conduct analysis in the development of this paper. However, language support tools such as Grammarly and ChatGPT by OpenAI were used to proofread, clarify sentence structure, and improve linguistic coherence during the revision phase. All substantive content, interpretations, and analytical contributions remain the author's original work. The AI tools were used strictly for editorial assistance and did not influence the intellectual or methodological substance of the paper.

Crowdfunding Failures: An Opportunity for Stakeholder Collaboration?

Ciro Troise[1], Stefania Testa[2], Gabriella Esposito[1], Guido Giovando[1]
[1]University of Turin, Turin, Italy
[2]University of Genova, Genova, Italy

Abstract

The crowdfunding phenomenon has grown exponentially over the years; however this type of financing mechanism does not only include successful initiatives, but there are also numerous cases of failed campaigns in which the proponents do not receive any funding. While most of the studies focused on the post-campaign phases of successful initiatives, a very limited number of scholars have explored the case of unsuccessful initiatives. This study is one of the first to focus on the latter and try to shed some light on the dynamics of the initiatives that have faced such a failure. We conducted qualitative and inductive research based on interviews with proponents of failed CF campaigns in the Italian context and secondary data (in particular from websites, social media, updates). The preliminary findings highlight that significant differences exist between the initiatives failed in the reward-based CF context and the equity-based CF context, as well as the stage of development of the business. Most of the interviewees highlighted the significant learning opportunity for them and the importance of creating collaborations with different stakeholders; at the same time, they faced different emotional challenges in such a scenario. This study could have useful implications for theory and practice. Among the main stakeholders involved are entrepreneurs, CF platforms, investors, policy-makers, governments, incubators/accelerators.

Keywords: crowdfunding, entrepreneurs, stakeholders, failures, startups

Paper type: Academic Research Paper

1 Introduction

Over the years, the crowdfunding (CF) phenomenon has seen exponential growth in numbers across the world, becoming a crucial source of financing for entrepreneurs in many countries (Mollick, 2014; Li et al., 2016; Wang et al., 2018; Testa et al., 2024; Troise et al., 2024a, 2024b, 2025). At the same time, there has been growing academic interest in CF (Block et al., 2018; Estrin et al., 2022; Polzin et al., 2018; Troise et al., 2023, 2024b).

Among the main CF models that management have explored are the equity-based crowdfunding (ECF) model (Vismara 2018, 2019; Troise et al., 2021) and the reward-based crowdfunding (RCF) model (Chan et al., 2017; Parhankangas and Renko, 2017; Oo et al., 2019; Shneor and Munim, 2019). The first model is a specific financing method that allows entrepreneurs to sell predetermined amounts of equity-shares in a company to a crowd of investors (Ahlers et al., 2015; Vismara, 2016), while the second model allows proponents of initiatives to provide a pre-sell of new or future (sometimes unfinished/unproven) products or services (Belleflamme et al., 2014; Davis et al., 2017).

Scholars who have studied crowdfunding have found that not all CF campaigns are successful and there are many initiatives that have failed because they did not reach their pre-established target amounts (Troise et al., 2021, 2022).

While many studies have explored the factors influencing the success or failure of CF campaigns – i.e. the drivers that can lead to reach or not the funding goals – there is a paucity of studies that have focused on the post-campaign phase and, in particular, on what happened after an unsuccessful CF campaign (Rossi et al., 2022). This research tries to shed some lights on the dynamics of failed initiatives by exploring the view of entrepreneurs that adopted the CF system, although without success. Very limited attention, in fact, has been paid to the post-campaign lives of these initiatives and if, and to what extent, they have learned from such a failure and triggered new behaviors or collaborations with other stakeholders. Given these gaps, our research aims to improve our collective understanding of the phenomenon.

In doing this, we leveraged an inductive qualitative research design and explored the Italian context, given its importance in the field of CF at the European level (Troise et al., 2023).

2 Background

The literature on crowdfunding has advanced significantly over the years (Troise et al., 2024b). Most scholars have studied the dynamics of campaigns to understand the success factors, such as human, social and intellectual capital, that lead backers or investors to commit financial resources to support initiatives (Mollick, 2014; Lukkarinen et al., 2016; Vismara, 2016; Troise et al., 2020, 2022). These studies shed lights on the drivers able to mitigate the existing presence of information asymmetries between backers/investors and entrepreneurs.

Recently a limited number of studies started to focus also on the pre-campaign (Brown et al., 2018; Troise and Tani, 2021; Stevenson et al., 2022) and the post-campaign (Hornuf et al., 2018; Signori and Vismara, 2018; Di Pietro et al., 2018; Troise et al., 2021, 2023) phases. About the first, scholars tried to increase current knowledge on the elements that lead entrepreneurs to use CF and their underlying motivations such as the non-monetary returns they expect (Brown et al., 2018; Troise and Tani, 2021; Stevenson et al., 2022; Troise et al., 2023). While regarding the second, scholars have mainly explored the cases of initiatives that had been successful during CF campaigns, i.e. the post-offering lives of initiatives (Signori and Vismara, 2018). However, studies that have explored what happens after unsuccessful CF campaigns remain extremely limited with only a few of exceptions (Walthoff-Borm et al., 2018a, 2018b; Rossi et al., 2023). For example, the research conducted by Walthoff-Borm et al. (2018a) showed a significant failure rate of initiatives after an unsuccessful campaign of ECF. Similarly, the study of Rossi et al. (2023) explored the family business start-ups that have experienced an unsuccessful ECF campaign and highlighted their high probability to offer shares with voting rights after such a negative event; they also have found that these companies have more probabilities to collect equity financing than the same companies that have no a family-business nature.

Given the limited knowledge in this emerging field, this study aims to shed some light on the dynamics post-campaign of unsuccessful initiatives. Our research will explore what happens to entrepreneurs that have experienced the failure of a CF campaign and, more importantly, how and to what extent this could represent an opportunity for them to start new collaborations with different types of stakeholders.

In this vein, our research responds to recent calls for more research, such as the study of Rossi et al. (2023, p. 1348) that reported that “Our analysis suggests that future research should consider crowdfunding learning outcomes…”

3 Methodology

Given the recent phenomenon explored and, in particular, its limited knowledge of the failed initiatives, a qualitative research design is useful to achieve a better understanding of it (Eisenhardt & Graebner, 2007). In fact, recent studies (see among others Estrin et al., 2018; Troise et al., 2023) and reviews of the literature (see among others Mochkabadi & Volkmann, 2018) highlighted that CF is still characterized by novelty and, especially, its literature is very sparse.

In our case, a multiple-case study approach is particularly suitable to understand the views of the involve players and enhance the external validation of the findings (Eisenhardt, 1989; Eisenhardt & Graebner, 2007; Gioia et al., 2013). We conducted an inductive research utilizing and integrating interviews with entrepreneurs that experienced an unsuccessful CF campaign and several secondary data, (including updates from CF platforms, companies’ websites and social media, dedicated press/blogs).

We specifically focused on Italy for several reasons. First, this country is particularly vibrant and developed in relation to the the CF phenomenon; in fact, it was the first country in Europe to introduce and adopt an “ad hoc” regulation for the ECF model (i.e. the Decreto Legge n. 179/2012 or better known as “Decreto Crescita Bis”) and the authority “Consob” (Commissione Nazionale per le Società e la Borsa introduced a specific registry for ECF platforms and operators (Troise and Tani, 2021). Second, this country is characterized by the presence of small businesses – who made most of the production base of the country – and, in fact, the government tried to support these companies through the establishment of ECF system.

As this is a work in progress, we are still conducting the interviews and simultaneously collecting secondary data. At this stage we have finalized the interviews with some of the proponents of the failed CF initiatives in the Italian context related to both the equity-based crowdfunding (ECF) and reward-based crowdfunding (RCF) models. Based on these initial interviews, we provided some initial preliminary findings.

Once the data collection has been fully completed and the remaining interviews finalized, we will be able to review and examine in-depth the interviews’ transcripts and integrate them with secondary data to provide a final model or framework.

4 Preliminary findings

As a result of these interviews, the proponents of failed initiatives, i.e. those who experienced an unsuccessful CF campaign, underlined several elements of interest in terms of strategies and dynamics post-campaigns.

First, most of the interviewees highlighted that such a failure represented a significant learning opportunity for them. In fact, learning from this specific type of failure is recognized by them as a crucial step in the future development of their idea or business and thus - hopefully - paves the way for future success through improvements being undertaken. Among them, the proponents of initiatives reported that after the failure they started new collaborations with different types of stakeholders; it was triggered above all by the realization that external help could be decisive and an extra push towards the development of the initiative, since "going it alone" would not have been the best choice. The possibility of collaborating helps in some way to mitigate the uncertainty that has been created around the initiative and which, after the campaign, has increased.

The interviewees highlighted that significant differences exist between failed initiatives in the ECF and RCF contexts and that such failures have different effects on the proponents depending on the stage the business is at. For example, initiatives that are still in an embryonal stage of idea development have more opportunities to refine their products/services and implement new changes after having unsuccessfully tested a crowd of consumers with the RCF. The ECF, being targeted to established companies, especially small and new ones, represented an opportunity to establish new partnerships and – in some limited circumstances – to evaluate the potential transfer of an idea or innovation, not being able or having the resources to fully pursue it. While SMEs are in general more equipped to face such a failure, startups have more difficulties in changing their trajectory and in trying to further develop the failed initiatives, especially given the limited resources they possess; in fact, another failure could represent too high a risk for them and could undermine their survival in extreme cases.

The interviewees reported the emotional challenges they faced. In general, a failure generates negative emotions (such as helplessness, rejection, pain and shame in individuals), but the negative effects are more evident for proponents of initiatives that failed by a large margin – i.e. they achieved a very low percentage of the set goal – and that had been rejected - that is, not funded - by professional investors. In some cases, the projects were abandoned after failed CF campaigns. In other cases, proponents have tried to adopt more cautious strategies aimed at containing any waste of resources or energy and negative image effects.

5 Conclusion

The study tried to provide an interesting contribution to advance current literature in the field of CF characterized by a paucity of research focused on the failures.

Recently, in fact, there has been a relevant call for more research in this field to improve collective knowledge about the lives of companies/entrepreneurs after such a failure and, eventually, whether they learn from this negative CF experience and can engage investors and other stakeholders (Rossi et al., 2023).

This study could have useful implications for theory and practice. Among the main stakeholders involved are entrepreneurs, CF platforms, investors, policy-makers, governments, incubators/accelerators.

In particular, entrepreneurs, CEO and managers of start ups or SMEs adopting CF systems should acknowledge the importance of learn in a systematic way from failures in this specific contexts; they, in fact, could be a crucial opportunity to learn and strengthen their businesses thanks to such experiences. Hopefully, they can translate negative experiences into new business opportunities and – eventually – successful initiatives.

Similarly, the other relevant players of the innovation or entrepreneurial ecosystem should support the companies through learning processes from failures and invest specific financial and non-financial resources in this sense.

The Role of Technology in Advancing Sustainability: Insights from the Textile Industry

Sara Ianniello, Livio Cricelli, Serena Strazzullo
University of Naples Federico II, Naples, Italy

Abstract

The textile industry faces increasing scrutiny for its environmental pollution, waste of water and energy resources, labor issues, and inefficiencies throughout the value chain (Pedersen and Gwozdz, 2014). As global agendas, such as the United Nations Sustainable Development Goals (SDGs) and the European Green Deal, call for urgent transformation, technology emerges as both a potential enabler of sustainability and a tool to mitigate the textile industry impacts. However, existing literature remains fragmented, often analyzing technologies in specific operational conditions or focusing on a singular dimension of sustainability. By conducting a systematic literature review of recent academic contributions, this study examines how technologies support the environmental, economic, and social pillars of sustainability in the textile industry. The review identifies and categorizes 88 articles from the Scopus database, revealing a diverse yet disconnected research landscape. From the content analysis, technologies are grouped into three clusters: emerging, established, and process-oriented. To offer an integrative perspective, the paper introduces a multi-level taxonomy that links technologies to specific sustainability-related weaknesses across the textile value chain. Findings show that while some technologies, especially Blockchain and data-driven systems, demonstrate convergent sustainability benefits, most generate partial or domain-specific improvements, such as Artificial Intelligence (AI) which raises concerns related to equity and digital exclusion (Park et al., 2020). The social dimension remains the least addressed, emphasizing the need for comprehensive strategies and governance frameworks to guide equitable technological adoption. This research offers a structured framework to help vertically integrated textile companies understand how technology adoption can address their sustainability challenges and provides practical insights for aligning business practices with innovation and SDGs objectives.

Keywords: Technology management; Innovation; Textile Industry; Sustainability.

Paper type: Academic Research Paper

1 Introduction

The textile industry has long been under analysis for its unsustainable practices, including excessive resource consumption, unsafe labor conditions, and chronic overproduction, which contribute to inefficiencies across global supply chains (Pedersen and Gwozdz, 2014). These challenges are becoming even more critical under increasing regulatory pressure, such as the United Nations' Sustainable Development Goals (SDGs) and the European Green Deal, which call for a fundamental shift toward more sustainable industrial practices. In this context, technologies, especially those related to Industry 4.0 and industry 5.0, are increasingly recognized as key enablers of sustainable transformation. The intersection between technological innovation and sustainability has thus become a central topic in academic debate, with a growing body of literature exploring how technological adoption can reshape the textile industry (Ejsmont, Gladysz and Kluczek, 2020). However, existing research tends to be fragmented: most studies focus on single technologies or sustainability aspects, offering limited insight into how these technologies address the broader sustainability challenges across the textile value chain. This reveals a key gap: the absence of an integrated framework linking technologies to sustainability and supply chain phases.

To address this gap, the present study adopts the Triple Bottom Line framework (Elkington, 1997) and proposes a multi-level taxonomy that links technologies to sustainability-related weaknesses along the textile value chain. This approach captures both synergies and tensions observed in literature. Considering these limitations, the study addresses the following research questions:

1. What is the state of art regarding the relationship between technologies and sustainability in the textile industry?
2. How do technologies contribute to environmental, economic, and social sustainability in the textile industry?

To answer these questions, a systematic literature review was conducted, aimed to map technological applications in the textile industry and their sustainability implications.

2 Methods

Following the guidelines proposed by Tranfield, Denyer and Smart (2003), this study adopts a systematic literature review methodology. The aim of this approach is to provide a comprehensive, transparent, and replicable process for identifying, evaluating, and synthesizing existing knowledge on the role of technologies in supporting sustainability within the textile industry. In this study, articles were collected employing Scopus database, recognized as one of the most extensive bibliographic resources. The search query was designed to capture articles that explicitly investigate the intersection between technological innovation and sustainability, be it environmental, economic, or social, within the textile and apparel sectors. The decision to focus on English journal articles and reviews from the last four years (2020–2024) was driven by the intent to better capture both the most disruptive and recent technologies as well as the current focal points of academic research. This time-bounded scope ensures that the analysis reflects the latest advancements and policy dynamics influencing sustainable innovation in the industry. To ensure data consistency and accuracy, specific inclusion criteria referred to subject area and keywords were established to guide the selection process and enhance the quality of the sample:

Table 1: Research criteria

Query	((textile OR fashion OR apparel OR clothing) AND (sector OR industr*)) AND (technolog* OR digital* OR "Industry 4.0" OR "Industry 5.0") AND (sustainab* OR ((environmental OR social OR economic) AND impact))
Result	287

During the screening phase, abstracts were carefully reviewed, and many contributions were excluded because they lacked a clear technological focus. Others were highly specialized studies on chemical or enzymatic processes, often limited to laboratory experiments with restricted applicability:

Table 2: Sample variance during the screening phase

Key steps	Sample variation	Final number of the paper
Database query	+287	/
Reading abstracts	-144	143
Not accessible articles	-42	102
Reading articles	-14	96
Final sample	/	88

This careful refinement process was essential to ensure that the final dataset included only those studies that meaningfully explored the role of technology in advancing sustainability in textile industry, reaching a sample of 88 papers.

3 Results

As a first step in addressing the research question about the stat of the art in the literature, the descriptive analysis reveals a predominance of qualitative studies, including literature review (Munir et al., 2022), semi-structured interviews (Kaur, Azmi and Majid, 2022), and case studies (Singh, 2024). Nonetheless, a substantial share of contributions adopts quantitative methods, such as Structural Equation Modeling (Bibi et al., 2024) and Multi Criteria Decision Approach (Agarwal and Singh, 2022), indicating a relative balance across approaches. Mixed-method designs are less frequent but increasingly valued for their ability to combine analytical rigor with contextual depth, such as text mining and coding analysis (Tolentino-Zondervan and DiVito, 2024), and fuzzy set Qualitative and Comparative Analysis (Cao et al., 2022), which are particularly suited to capturing the complexity of technology–sustainability interactions.

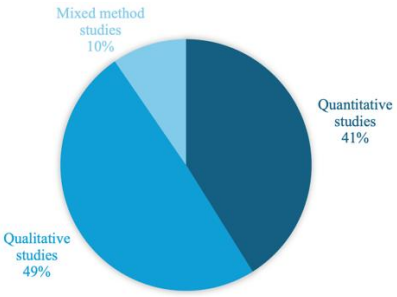

Figure 1: Percentages of methodologies applied in the research sample

Theoretically, the Triple Bottom Line framework remains the most widely employed (Munir et al., 2022). Complementary frameworks such as those related to Sustainable Supply Chain (Hauschild and Coll, 2023) and the Resource-Based View (RBV), (Irfan et al., 2020), highlight the strategic value of technology in enhancing organizational resilience and competitiveness. Contributions grounded in the Circular Economy (Ribul et al., 2021) and Dynamic Capabilities views (Saha, Belal and Talapatra, 2024) perspectives emphasize the importance of adaptability, regeneration, and innovation in navigating sustainability transitions. Notably, several studies adopt integrative models combining technology, organization, and environment elements, reflecting a growing recognition of the systemic nature of sustainable innovation and the need to align technological change with organizational and institutional contexts (Kutschera and Crowell, 2024).

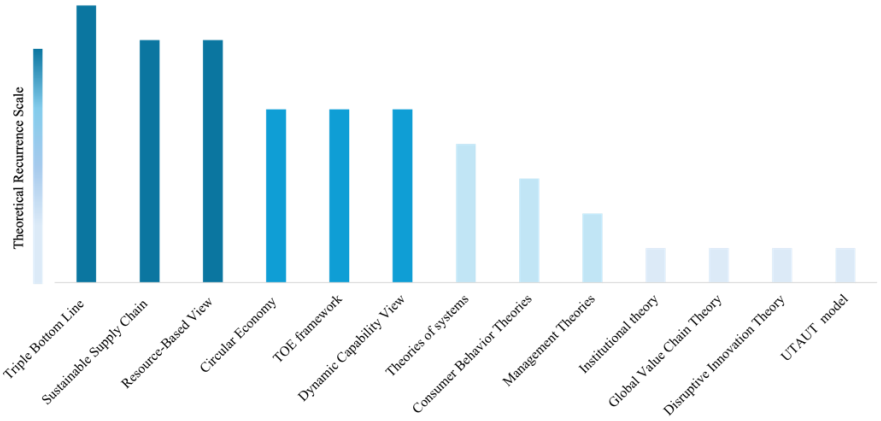

Figure 2: Theoretical framework applied in the research sample

Building on the content analysis, the authors identified three main technological clusters that currently dominate academic attention in the context of the textile industry. While their specific sustainability impacts will be discussed in the following section, this overview outlines the key technological domains shaping the current research landscape.

Emerging technologies: technologies that are relatively new to the textile industry but are increasingly recognized for their transformative potential, such as Artificial Intelligence (AI), (Jin and Shin, 2020), and Blockchain (Jain et al., 2022). Another emerging tool, the Digital Product Passports (DPP), is gaining relevance in response to evolving regulatory frameworks. However, the academic literature tends to examine DPP within broader technological ecosystems.

Established technologies: technologies that are already integrated into business and industrial processes, such as data-driven technologies (Irfan et al., 2020) as Internet of Things (IoT), Big Data, Cloud Computing, and Product Lifecycle Management (PLM) platform. It also comprises traceability technologies (Tolentino-Zondervan and DiVito, 2024) namely QR codes, Radio Frequency Identification (RFID), and DPP. Furthermore, literature reveals an interest also in immersive and visualization technologies, as Augmented Reality (AR), Virtual Reality (VR), and 3D simulation tools (Choi, 2022). Lastly, smart and connected technologies for Industry 4.0 encompasses configurations that integrate Cyber-Physical Systems (CPS), Digital Twin models, Additive Manufacturing (AM), autonomous systems, advanced manufacturing technologies, and real-time environmental data acquisition. These technologies are often adopted in combination to support comprehensive digitalization and sustainability across the value chain (Jin and Shin, 2020).

Process and treatment technologies: technologies that act directly on materials, production processes, or end-of-life stages to reduce environmental impacts, such as enzyme-based biotechnologies, ecological wastewater treatment solutions (Rahman et al., 2020), including Membrane Bioreactors (MBR), Electrocoagulation (EC), Moving Bed Biofilm Reactors (MBBR), Rotating Biological Contactors (RBC), and the Activated Sludge Process (ASP), and recycling technologies (Ribul et al., 2021).

Table 3: Technologies discussed in literature and classified by authors

Technological clusters identified in literature	**Technologies analised in textile industry**
Emerging Technologies	Blockchain Artificial Intelligence
Established Technologies	Information technologies (IoT, Big Data Computing, PLM platform) Track technologies (DPP, QR Code and RFID) Immersive and visualization technologies (AR, VR, 3D software simulation) Smart and connected technologies for the industry (Cyber Physical Systems; IoT + AI + Big Data; IoT + Big Data + Cloud Computing; Digital Twin + Smart Analysis Model; Additive Manufacturing + Automated production + Digital twin; Cyber Physical Systems + IoT + Artificial Intelligence + Big Data; IoT + Big Data + Blockchain + AI + Cloud Computing + Cyber Physical Systems + Additive Manufacturing)
Process and Treatment Technologies	Biotechnology based on enzymes (amylase, cellulase, pectinase, lipase, laccase, and peroxidase) Ecological technologies (MBR, EC, MBBR, RBC, ASP) Recycling technologies (mechanical and chemical recycling, enzymatic and biological processes)

Many studies focus on individual technologies or specific dimensions of sustainability, without offering an integrated or systemic perspective. This fragmentation partially reflects the structural characteristics of the textile sector, which is currently one of the most complex industrial domains in terms of sustainability, as it faces a range of systemic challenges, from overproduction to greenwashing and labor precarity in producing countries, to post-consumer waste management. Moreover, most contributions emphasize sustainability issues related to production and logistics, while neglecting other critical phases of the product lifecycle, such as early-stage design and end-of-life management.

This narrow focus limits the understanding of how the impacts of technologies may vary across different stages of the value chain. It is therefore necessary to identify all the operational stages of the textile value chain to pinpoint those that are underexplored and to clarify which types of technologies are currently applied to address specific sustainability-related vulnerabilities.

In response to these limitations, this study introduces a novel taxonomy aimed at integrating fragmented evidence, revealing research blind spots, and offering a structured framework for evaluating technological interventions across the textile value chain.

The structure is built upon the following levels: (1) the stage of the textile value chain in which the technology operates; (2) the sustainability-related challenges identified in the literature, mapped across the three dimensions of sustainability (environmental, economic, and social); (3) the technologies that are applied to mitigate these challenges within their respective phases of the value chain.

Specifically, the value chain level considers the main operational stages of the textile value chain:

1. Design and product development
2. Raw material sourcing and procurement
3. Production

4. Distribution and retail
5. End of life.

The definition of the five operational phases emerges from an inductive approach grounded in the literature review. It reflects the actual points of technological intervention identified across the analyzed studies, allowing for a technology-driven reading of the textile value chain. The model adopted in this study is primarily based on Gereffi and Frederick (2010) who provide a robust structural framework of the global apparel industry up to the retail phase. The structure proposed is also aligned with the lifecycle-based model proposed by United Nation Environment Program (2020), to incorporate sustainability related responsibilities beyond the point of sale, particularly those linked to environmental impacts and waste management. Hence, a proxy phase, end-of-life, was added. This extension reflects the growing relevance of the Extended Producer Responsibility (EPR) policy, which requires companies to take accountability for the environmental impacts of their products throughout the entire lifecycle, including collection, reuse, and recycling after consumer use.

The Triple Bottom Line (TBL) level of the taxonomy identifies, for each stage, the main sustainability related needs or vulnerabilities, where possible, according to the triple bottom line framework (Elkington, 1997). The weakness found in the literature review sample, are listed in Table 4:

Table 4: Main weakness identified in the literature sample

TBL framework	CODE	Weakness	Occurrences in literature
Environmental weakness	ENW1	Strong non-linearity and seasonality	4
	ENW2	Packaging	1
	ENW3	Textile waste and landfill	5
	ENW4	High Carbon footprint	8
	ENW5	High Water footprint	6
	ENW6	High Chemical footprint	6
	ENW7	High Energy consumption	6
	ENW8	Intensive use of land and raw materials	2
	ENW9	Use of unsafe materials/processes	1
	ENW10	High Green House Gases (GHG) emissions	1
	ENW11	Lack of reliable data	1
	ENW12	Incomplete/non-standardised ESG data	2
	ENW13	Lack of transparency and traceability	4
	ENW14	Waste of paper due to lack of digitalization	1
	ENW15	Waste of materials	1
Social weakness	SW1	Child labor	1
	SW2	Worker exploitation	3
	SW3	Under wage payments	2
	SW4	Health and safety issue	3
	SW5	Employment risks	1
	SW6	Fair Labour	3
	SW7	Long working hours	1
	SW8	Limited access to training	2
	SW9	Lack of transparency and traceability	7
	SW10	Information asymmetry	3
	SW11	Counterfeiting and forgery	1
	SW12	Lack of reliable data	2
	SW13	Incomplete/non-standardised ESG data	1
	SW14	Difficulty in accessing technology	1
	SW15	Dynamic market behavior	1
	SW16	Cultural and institutional resistance	2
	SW17	Lack of consumer awareness	5
Economic weakness	ECW1	Excess inventory	1
	ECW2	Missed Sales	1
	ECW3	Overproduction	9
	ECW4	Stock-outs	1
	ECW5	Environmental penalties	1
	ECW6	Product obsolescence	1
	ECW7	Price competition	1
	ECW8	High staff recruitment and training costs	1
	ECW9	High turnover and low performance	1
	ECW10	Waste of human and financial resources	1

TBL framework	CODE	Weakness	Occurrences in literature
	ECW11	Lack of transparency and traceability	6
	ECW12	Counterfeiting and forgery	1
	ECW13	Incomplete/non-standardised ESG data	2
	ECW14	High cost and time in physical prototyping	1
	ECW15	High operational and treatment costs	4
	ECW16	Lack of reliable data	4
	ECW17	Offshore production	1

The technological level synthesizes the positive impact of technologies on the three dimensions of sustainability through a visual code, answering the second research question of the study: triangle for positive contributions for the social dimension, square for positive economic impacts, and circle for environmental benefits. To ensure greater interpretive reliability and to reduce individual bias (Patton, 1999), the classifications were validated through a process of researcher triangulation. Two researchers independently reviewed the relevant studies and assigned the presence of technologies' sustainability positive impact, while a third researcher examined the coherence, facilitating their alignment.

In particular, the taxonomy is primarily intended for manufacturing firms and vertically integrated companies within the textile sector. It offers a structured dashboard to guide the adoption of technologies in response to sustainability-related vulnerabilities, enabling more targeted interventions and supporting strategic alignment with SDGs goals and regulatory compliance. By mapping the sustainability-related weaknesses identified in the literature according to the Triple Bottom Line framework, it becomes evident that these vulnerabilities are evenly distributed across the environmental, economic, and social dimensions. This widespread distribution signals not only an urgent need for greater awareness within the industry, but also a clear call for intervention by external actors, including policymakers and sustainability-focused institutions.

Among all stages of the textile value chain, the production phase emerges as the most critical, concentrating a high number of weaknesses across all three sustainability dimensions. This phase encompasses several energies- and resource-intensive subprocesses such as dyeing, printing, finishing, and cutting, which are frequently associated especially with high chemical, water, and energy consumption, greenhouse gas emissions (ENW5, ENW6, ENW7) and unsafe material use, worker health and safety concerns (SW4), high operational costs and efficiency losses (ECW15). These issues illustrate how sustainability challenges are often deeply interconnected. For instance, the excessive use of chemicals and water during the dyeing process (ENW5, ENW6) not only exacerbates environmental degradation but also creates hazardous working conditions (SW4), increases operational expenses (ECW15), and undermines long-term profitability due to regulatory penalties (ECW5). Following production, the logistics and sourcing phases also exhibit numerous weaknesses, primarily on the environmental and economic dimension, respectively. Logistics is frequently associated with excessive emissions, inefficient packaging, and waste of materials (ENW1, ENW2, ENW15), while sourcing is marked by overproduction, resource intensity, and offshore-related inefficiencies (ECW3, ENW8, ECW17).

These findings demonstrate how technological solutions must be tailored not only to specific sustainability goals, but also to the operational realities of each stage in the textile value chain.

Through the content analysis, the third level of the taxonomy was developed; the key results are then outlined.

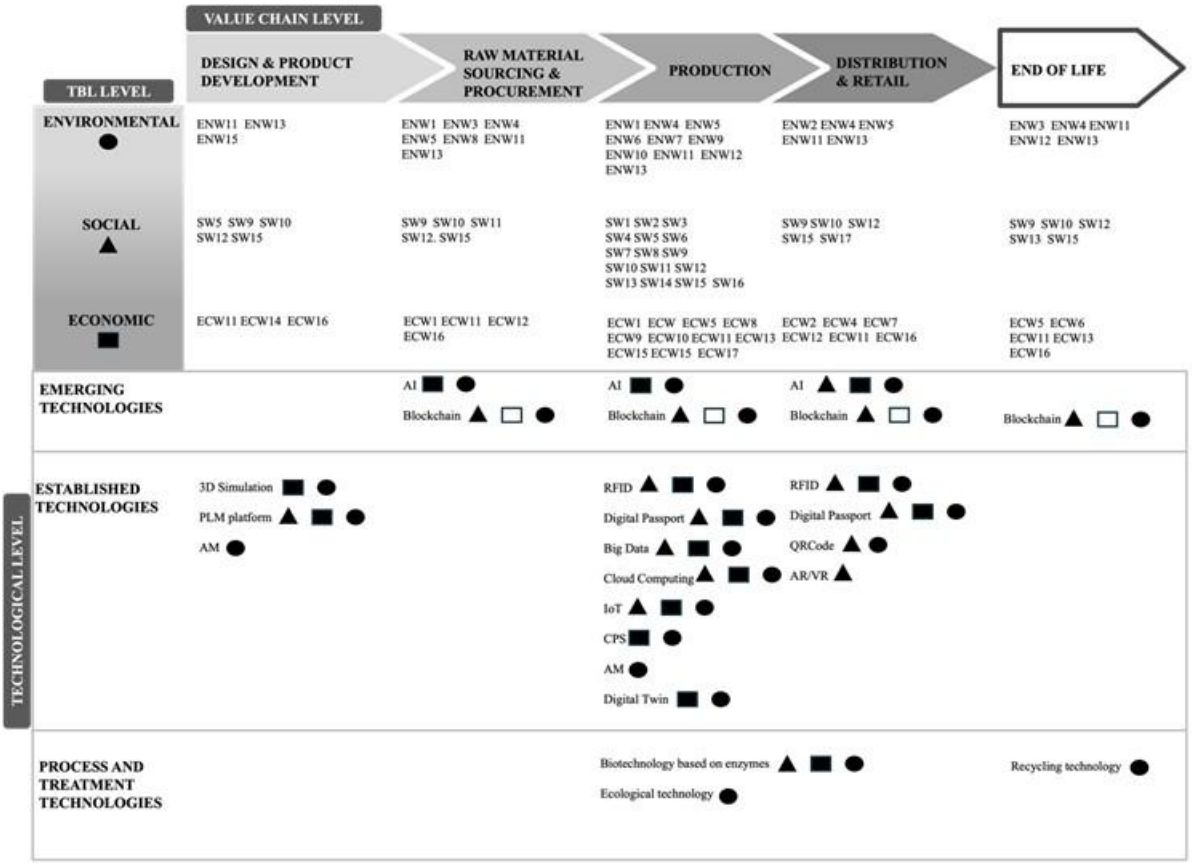

Figure 3: Multi-level taxonomy scheme proposed by the authors

Emerging technologies: AI shows a strong impact on economic and environmental sustainability. It is widely used for production planning and demand forecasting, reducing costs and eliminating overproduction and material waste (Jin and Shin, 2020; Singh, 2024). In the retail phase, it supports personalized services based on user preferences and contributes to distribution optimization and sustainable material selection (Singh, 2024). However, the social dimension remains underexplored or problematic, due to concerns over job displacement, privacy, and digital inequality (Sharma, Yadav and Chopra, 2020).

Blockchain demonstrates a more convergent impact across all three dimensions. It is employed in supplier selection for verifying sustainability certifications (Jain et al., 2022), in production for monitoring working conditions and environmental data (Munir et al., 2022), and in distribution and retail to ensure product authenticity and reduce counterfeiting costs (Jain et al., 2022). Moreover, it supports recycling facilitation and automated, transparent transactions, enhancing social equity and trust in the supply chain. Literature debates about blockchain interoperability and scalability (Chen, 2023); the empty square assigned to this technology represents the economic potential of blockchain despite its implementation costs, commonly recognized in literature.

Established technologies: IoT, Big Data, and Cloud Computing present a strongly convergent impact across all three dimensions of sustainability, with most contributions in the literature focusing on their integrated use during the production phase. From an environmental perspective, IoT and Big Data enable real-time monitoring of energy and water consumption, supporting more efficient and eco-friendly manufacturing (Park et al., 2020). Economically, these technologies contribute to process optimization, predictive maintenance, and supply chain integration, reducing operational costs and improving responsiveness (Alam and Islam, 2021). On the social dimension, they enhance transparency and traceability across the value chain and contribute to improved worker safety through advanced environmental monitoring and control systems (Irfan et al., 2020). PLM platforms support sustainability in the product development phase by enabling design, reducing waste, and ensuring environmental traceability. They enhance collaboration and transparency across teams, while economically contributing to shorter development cycles, lower costs, and faster time-to-market.

In the production and distribution phase RFID and DPP technologies show a convergent impact on sustainability by reducing waste and overproduction, optimizing inventory and logistics, improving traceability,

and supporting material-specific recycling. They also enhance transparency, prevent counterfeiting and labor exploitation, and contribute to energy savings and consumer awareness (Tolentino-Zondervan and DiVito, 2024). QR codes, primarily applied in the retail phase, support environmental and social sustainability by promoting paperless communication, enabling product traceability, and enhancing consumer awareness on sustainability aspects such as material origin and recycling options (Kutschera and Crowell, 2024).

AR/VR technologies are primarily applied in the retail phase, enhancing the shopping experience through personalization, interactivity, and emotional engagement (Hardabkhadze, 2023), so their impact is mainly social. However, their contribution to environmental or economic goals remains limited, as the creation of high-quality digital content is often resource-intensive and costly, (Choi, 2022). Conversely, 3D simulation tools, particularly employed in product design and virtual prototyping, have a strong environmental and economic relevance. They enable more sustainable product development, reducing the need for physical samples and lowering material waste, energy use, and time-to-market. In the textile sector, CPS, implemented in the production phase, are employed particularly in dyeing and finishing operations, where they enhance efficiency, resource optimization, and waste reduction (Park et al., 2020). Additive manufacturing, commonly referred to as 3D printing in the textile industry, is primarily applied in the product development stages of the textile value chain. It allows for savings, minimizing waste, and reducing the use of raw materials (Bibi et al., 2024). However, current literature highlights limitations in scalability and cost-efficiency for mass production, and social implications are underexplored. Therefore, the impact of additive manufacturing is primarily focused on the environmental dimension.

Process and treatment technologies: Bio-based enzyme technologies are applied exclusively in the production phase, offering a sustainable alternative to chemical treatments. They reduce water and energy use, limit pollution and improve product quality and production efficiency (Rahman et al., 2020; Eid and Ibrahim, 2021). Moreover, they contribute to workplace safety and public health, resulting in positive impacts across all three sustainability dimensions (Asada et al., 2020).

Electrocoagulation (EC), Moving Bed Biofilm Reactor (MBBR), and Rotating Biological Contactor (RBC), are applied in the production phase, particularly in wastewater treatment. Their environmental impact is well documented: they reduce pollution, improve water quality, enable water reuse, and lower carbon and greenhouse gas emissions (Agarwal and Singh, 2022). However, their economic and social impacts are more nuanced. From a social perspective, MBR and RBC are more widely accepted in the industry, while MBBR and EC face resistance due to limited technical awareness. Economically, MBBR is cost-effective, but EC involves high operational costs linked to energy and chemical use. These findings suggest strong environmental benefits and potential trade-offs in the economic and social dimensions.

Recycling technologies are applied in the end-of life phase, and offer clear environmental benefits, including reduced resource use, lower emissions, and improved wastewater management. However, trade-offs emerge in the economic and social dimensions. Mechanical recycling is cost-effective and labor-intensive but may involve informal work and quality issues. Chemical recycling supports skilled employment but raises safety and investment concerns. Energy recycling valorizes waste but depends on subsidies and may face social resistance (Ribul et al., 2021). Overall, these technologies show strong environmental impact with partial and contested effects on the economic and social fronts.

4 Conclusion

The review highlights a rapidly evolving yet fragmented landscape, where the interplay between technology and sustainability is explored in siloed ways. While a wide range of technologies has been identified, their contribution to the triple bottom line, encompassing environmental, economic, and social dimensions, reveals highly differentiated patterns. Only a limited number of technologies demonstrate a convergent impact across all three dimensions. Notably, Blockchain and integrated data-driven technologies exhibit the strongest alignment. Overall, the findings suggest that technological convergence across the three pillars of sustainability remains the exception rather than the norm. This reinforces the idea that technology alone is not a sufficient condition for sustainable transformation. Its effectiveness depends on the presence of enabling conditions, including governance frameworks, regulatory environments, inter-organizational collaboration, and capacity-building mechanisms that can support equitable and systemic adoption.

5 Limitation and Future Development

As with all systematic literature reviews, this study is subject to several methodological limitations. First, the review may suffer from selection bias, both in terms of the literature sample and the coding of sustainability impacts associated with each technology. Despite efforts to ensure triangulation, the classification of impacts

reflects a degree of interpretative subjectivity. Second, the fragmentation of the literature, combined with the increasing complexity of integrated technological systems, makes it difficult to isolate the effects of individual technologies, particularly when they are adopted in bundles. This reduces the generalizability of findings and complicates cross-comparative analysis. Moreover, the textile value chain model adopted to map the industry's weaknesses may not fully encompass all the critical stages and could therefore be further extended. Future research should consider the development of a structured weakness–technology matrix, to map technologies contribution to each dimension of sustainability and what kind of weakness they mitigate. Such a tool would improve comparability for evaluating technologies. Furthermore, more attention should be devoted to emerging technologies, which are rapidly gaining traction in both research and practice, yet their social sustainability impacts remain highly ambiguous due to the lack of standardized metrics (Singh, 2024). Quantitative approaches should be employed to evaluate the economic and reputational benefits associated with the adoption of emerging technologies (Sharma, Yadav and Chopra, 2020; Chen, 2023) and longitudinal studies could provide deeper insight about organizational resilience and sustainability in the long term. Lastly, while most studies focus on the central stages of the value chain, such as production, sourcing, and logistics, the end-of-life phase and circular design practices remain underexplored. This highlights the need to investigate how technologies can support recyclability, product modularity, and lifecycle extension.

Big Data Technology Maturity Model: Exploring User Perceptions

Nicolò Gianmauro Totaro, Mariasimona Miglietta, Angelo Corallo, Massimiliano Gervasi
University of Salento, Lecce, Italy

Abstract

Big data technologies are fundamental in managing large volumes of data and transforming data into information. However, the mere availability of technological resources is not sufficient to extract meaningful insights. The maturity of these technologies and users' perceptions of their use play a crucial role in determining their potential for value creation. This study proposes a maturity model that integrates both the technological maturity perceived by users and users' own maturity in utilizing these tools. Focusing on three major cloud-based services for big data, namely Google Cloud Platform, Amazon Web Services, and Microsoft Azure, the research explores user perceptions regarding the capabilities and usability of these platforms in supporting big data initiatives. The research methodology involved the design of a structured questionnaire aimed at investigating two main constructs: “Technological Maturity”, referring to the extent to which the technology meets user needs; “User Maturity”, concerning users' competence, awareness, and confidence in utilizing the investigated platforms. The questionnaire was administered to big data professionals, who were asked to evaluate one or more technologies based on their own experience. The analysis revealed significant trends, including a general increase in perceived technological maturity with growing user experience, and a non-linear relationship between experience and user maturity. The high number of "Don't know" responses among less experienced participants, and their decrease among more experienced users, highlights a progressive increase in self-awareness and knowledge acquisition over time. Notably, evidence of the “Dunning-Kruger” effect emerged, indicating that less experienced users tend to overestimate their abilities. This research proposes an innovative framework for assessing technological maturity in the big data context. The model not only enhances academic understanding but also offers practical guidance for organizations in the selection, adoption, and integration of cloud technologies, while supporting effective strategies for internal skills development. The findings underscore the importance of considering, alongside technological characteristics, human factors related to perception and usability of the adopted technologies.

Keywords: big data, data analytics, cloud services, maturity model

Paper type: Academic Research Paper

1 Introduction

In the context of big data initiatives, the technologies adopted represent a critical factor for the effective implementation and scalability of projects. Big data technologies, indeed, form the backbone of the entire information ecosystem (Cavanillas, et al., 2016). Numerous studies have focused on identifying the technologies employed at the various stages of the data value chain, as well as analysing their evolution over time (Hu, et al., 2014).

However, the mere availability of advanced technologies is not sufficient to ensure the successful implementation of big data initiatives. It is essential that these technologies reach an adequate level of maturity to truly support organisational initiatives. In fact, technological immaturity has been recognised as one of the main barriers to the adoption of big data (Ylijoki & Porras, 2019).

In this context, for instance, monolithic architectures such as information silos have proven to be inadequate for the management and preservation of data within modern big data ecosystems (Ylijoki & Porras, 2019) (Bärenfänger, et al., 2014) (Fast, et al., 2021).

The relevance of awareness regarding limitations of a technology and their potential impact on organisations also enables the identification of objectives within big data initiatives that remain out of reach due to technologies that are insufficiently mature or appropriate (Huang, et al., 2015). Consequently, alongside internal resources and capabilities, organisations are required to make informed decisions concerning the infrastructure or big data platforms they adopt for analytics purposes. While new organisations may design or adopt platforms specifically tailored to their needs, established organisations with legacy IT systems are often compelled to integrate their existing infrastructures with modern big data platforms available on the market. Such integration can introduce challenges related to compatibility and coexistence between heterogeneous infrastructures, as well as adoption, integration, and maintenance costs. These challenges are commonly recognised as technological barriers in the context of big data initiatives (Alharthi, et al., 2017).

Technological maturity thus emerges as a strategic and independent factor within the decision-making process accompanying the implementation of big data solutions. A technology that is insufficiently mature may hinder value creation, just as a technically ready technology that is poorly perceived or insufficiently understood by users may fail to be fully exploited.

This research aims to develop a maturity model grounded in the analysis of responses from a questionnaire submitted to domain experts, focusing on three cloud service technologies within the big data context. The model aims to explore two key macro-dimensions:

- Perceived technological maturity: the ability of the investigated cloud service to effectively support value creation processes from big data, considering reliability, scalability, and performance relative to project objectives.
- User awareness and maturity: the level of user expertise, awareness, and ability to interact with these technologies in big data-related activities.

The research seeks to address the following research questions (RQs):

- *RQ1: What is the perceived level of technological maturity of cloud service in supporting big data-driven processes?*
- *RQ2: To what extent are users aware of, and prepared to leverage, these technologies to maximize their potential value?*

This study aims to bridge a gap in the existing literature by providing a model that examines both technological maturity and the cognitive biases of respondents in evaluating and self-assessing these technologies. The findings will offer valuable insights for both academics and practitioners, guiding strategies for technological improvement and skill development while enhancing organizations' awareness of their own resources and human capital.

2 Theoretical Background

Maturity models are strategic tools that organisations adopt to plan the continuous development of their capabilities (Ahern, et al., 2004), to study their own business, or to benchmark it against other organisations with similar characteristics (Mettler, et al., 2010). The primary objective of maturity models is to identify the level of maturity of a given situation, highlighting specific gaps within a particular focus area and determining how these may be addressed. The term maturity implies a change in capabilities and/or objectives from an as-is state to a to-be state (Corallo, et al., 2023).

The concept of technological maturity has been addressed across various domains. However, in the context of big data, structured and context-independent analyses remain relatively underdeveloped. Literature often tends to place greater emphasis on organisational maturity or on the development of organisational competencies, whereas the intrinsic maturity of technologies has received less systematic attention. Outside the big data domain, Till (Till, 2016) offers a comprehensive and structured analysis of technological maturity, highlighting three key aspects:

1. Timing represents a critical factor in technological investments, as adopting a technology either too early or too late may undermine competitive advantage.
2. The assessment of technological maturity is not a straightforward process: although experts often possess in-depth knowledge of individual technologies, a comparative and systemic perspective is frequently lacking.
3. Many evaluations rely on theoretical descriptions or subjective perceptions, highlighting the absence of an objective, standardised, and efficient measurement system.

Within the big data domain, one of the models explicitly oriented towards the evaluation of technologies is the *Maturity Model for Big Data Solutions* (Boncea, et al., 2017). This model investigates both *technical maturity* (development status, support libraries, guidelines and documentation, cross-platform support, professional certification) and *business maturity* (market usage, cloud computing support, licensing policy, enterprise support). The model was applied to assess the maturity of five different technologies associated with the big data context. The objective of the analysis was to support organisations in identifying the solutions most suited to their needs by developing a concept of maturity articulated across multiple dimensions. Relevant factors include: the current development status of the technology, the frequency of major and minor version releases, the average time to resolve issues, the availability of support libraries, the presence of comprehensive guidelines and installation documentation, and compatibility with major operating systems. Despite its descriptive completeness, the model appears limited in integrating the direct experience of users and the perceptions of experts, elements that are crucial for understanding the actual readiness of a technology. General characteristics such as *scalability, flexibility,* or *cloud compatibility* are necessary but not sufficient conditions for value

generation (Vitari & Raguseo, 2020). The way in which these features are perceived and utilised can vary significantly.

An equally significant contribution in the literature is the *Big Data Maturity Model (BDMM)* (Comuzzi & Patel, 2016), which aims to support organisations in realising the value generated by big data.

The BDMM is structured as a hierarchical framework articulated across six maturity levels (from 0 to 5) and five main domains: *Strategic Alignment, Organisation, Governance, Data, and Information Technology*. Each domain is further subdivided into sub-dimensions (such as *Strategy, Processes, People, Culture*), making the model comprehensive and multidimensional. The assignment of maturity levels is performed directly based on qualitative descriptions associated with each level, without the use of separate numerical rating scales. This approach differs from that adopted in other maturity models, where assessments are sometimes collected through broader numerical scales (e.g., from 0 to 9) and subsequently aggregated into a smaller number of synthesised maturity levels (e.g., from "not ready" to "leader") (Paulk, et al., 1991). Developed through a qualitative approach, the BDMM was evaluated through a domain expert evaluation and a practical settings evaluation, by implementing the model in three real-world organisations.

Further investigations are required to pave the way for the development of models that go beyond the assessment of technical and market-related characteristics, integrating instead the subjective perceptions of experts and users. A new model should be capable of distinguishing between actual technological maturity and maturity potentially influenced by the cognitive or interpretative peculiarities of the evaluators. The model should also be applicable in a transversal and context-independent manner, in order to produce assessments that are as objective and generalisable as possible. Another critical element concerns the distinction between the immaturity of the technology itself and the immaturity of the evaluator. Expert-based assessments can indeed be influenced by biases, personal experiences, or partial knowledge. Therefore, an effective technological maturity model should ideally be able to address both aspects, accounting for the cognitive and perceptual factors associated with the actors involved in the evaluation processes. Building on these considerations, this research proposes a new technological maturity model that integrates the assessment of big data technology maturity with the corresponding perceptions and maturity in use by both users and experts.

3 Methodology

The proposed maturity model, the *Technology and User Maturity Model* (TUMM), was designed to assess technological maturity across two fundamental constructs: the capability of the technology to fulfil its intended functions and meet user needs; the users' perception and competence in effectively adopting and utilizing the technology. To measure both constructs, a structured survey instrument was developed in the form of a questionnaire, organized into two main sections: *Technological Maturity* and *User Maturity*.

The *Technological Maturity* section aims to assess the perceived level of maturity regarding various characteristics of the examined technologies. This section consists of 28 items, grouped into thematic subsections covering six specific domains: functionality, user experience, security, flexibility, interoperability, and costs. The objective is to obtain a multi-level evaluation capable of providing a comprehensive and comparable overview across different technological solutions.

The *User Maturity* section, on the other hand, focuses on analysing users' awareness, preparedness, and autonomy in interacting with the technologies under study, within the context of big data initiatives. This section comprises 9 items focusing on three main aspects: training received, previous experience, and confidence level in using the technologies.

The questionnaire items were designed to explore the dimensions of analysis from multiple perspectives, ensuring broad conceptual coverage consistent with the research objectives. The preliminary version of the instrument was reviewed by a focus group of industry experts, whose feedback contributed to refining the question formulations, improving clarity, relevance, and content validity. Each question uses a five-point Likert scale to collect qualitative judgments suitable for quantitative analysis. Additionally, a "*Don't know*" response option was included, allowing respondents to abstain when they lacked sufficient knowledge or direct experience on the topic. This methodological choice acknowledges the importance of self-awareness regarding one’s knowledge level, as it constitutes a relevant element of the investigation and is related to both research questions.

The technologies analysed in the questionnaire include three of the most widely used cloud service platforms (Chauhan, 2020): *Google Cloud Platform* (GCP), *Amazon Web Services* (AWS), and *Microsoft Azure*. Accordingly, the investigation was focused on the cloud services ecosystem, considering these platforms as benchmarks for assessing technological maturity. Furthermore, to broaden the comparative scope of the analysis, respondents

were offered the opportunity to indicate a fourth technology of their choice, enabling a more comprehensive benchmark. The questionnaire was administered to a representative sample of professionals working in organizations varying in size and industry sector. Participant selection was based on relevance criteria, prioritizing profiles with technical or managerial roles and ensuring sample diversity to achieve high representativeness of the results.

At the beginning of the questionnaire, participants were asked to indicate the technologies for which they intended to provide evaluations, based on their direct experience and familiarity. This approach ensured the collection of relevant and reliable data, as each respondent provided assessments only for technologies they had interacted with directly. Consequently, not all participants completed all sections related to each technology. Rather, they answered only for those technologies with which they had sufficient knowledge, in line with the informed self-selection approach adopted in the study's methodological design.

4 Results

The results and analyses presented in this section are based on the responses collected from an initial sample of 100 participants who completed the questionnaire. The survey is currently still being administered and remains available online for further completion. The distribution of responses is reported in the table below.

Table 1: Summary of questionnaire responses

Respondent breakdown by technology	
Number of responses for Azure	35
Number of responses for GCP	50
Number of responses for AWS	44
Number of responses for other technologies	72
Number of responses indicating no specific technology	43
Total number of responses	202
Total number of respondents	100

To conduct the analyses, the collected responses were aggregated and analysed by calculating the mean scores, categorized by professional seniority classes. The objective was to examine both the perception of technological maturity and users' perceived maturity regarding their own competencies. This approach allows for the observation of potential evolutionary trends over time, by relating work experience to the evaluation of technologies. In parallel, the frequency of "Don't know" (DK) responses provided in the questionnaires was also analysed, similarly categorized by years of experience, in order to investigate the level of declared awareness and its variation as a function of professional seniority. The results of these analyses are summarized in Table 2 and Table 3.

Table 2: Average scores of responses divided by years of experience

Cloud Platform	**Maturity**	**EXP < 1**	**1≤EXP<2**	**2≤EXP<3**	**3≤EXP<4**	**4≤EXP<5**	**EXP≥5**	**EXP NA**	**TOT**
GCP	TM	3,11	3,52	3,63	3,23	4,19	3,84	3,28	3,53
	UM	2,42	2,96	3,31	2,31	3,14	2,98	1,62	2,67
AWS	TM	3,02	3,32	2,90	3,43	4,19	3,94	2,39	3,42
	UM	2,67	3,19	3,23	1,69	3,41	2,96	1,87	2,86
Azure	TM	3,04	3,62	2,59	3,71	4,14	3,79	2,49	3,44
	UM	2,22	2,84	3,25	2,71	3,19	2,48	1,47	2,44
Other Cloud Platform	TM	3,36	3,63	2,77	3,55	3,02	3,56	3,06	3,31
	UM	2,42	3,41	3,13	2,42	3,50	3,07	2,97	2,90

The variable *EXP* represents the number of years of professional experience declared by the respondent. Segmentation was performed on an annual basis for the first five years, while participants with longer professional experience were grouped into a single category labelled "more than 5 years". The label *EXP NA* (Not Available) refers to responses where the participant chose not to disclose their seniority in the field. *TM* (Technological Maturity) refers to the average evaluation of the technology in fulfilling the functions for which it was designed, as assessed by the respondents. *UM* (User Maturity) indicates the respondent's average evaluation in using the technology in question.

The analysis of the mean scores for technological maturity and user maturity, divided by experience classes, reveals several interesting trends. Regarding TM, a progressive increase in the average score is observed across rising experience levels, with notable peaks in the "4≤EXP<5" category for all major platforms (e.g., 4,19 for GCP and AWS, 4,14 for Azure). This trend suggests that professional experience may enhance positive perceptions of the technologies' ability to fulfil their intended functions. However, this growth stabilizes or slightly declines in the "EXP≥5" category, possibly indicating a more critical and perhaps more informed perspective among more experienced users.

As for UM, a less linear trend is observed. Although in some cases there is an increase in perceived user maturity up to the third year of experience, the scores become more variable in the subsequent categories. In particular, perceived user maturity tends to decrease among groups with greater seniority (e.g., Azure: UM=2,48 for EXP≥5), suggesting a possible discrepancy between initial confidence and awareness developed over time. Moreover, the significantly lower UM scores among respondents who did not indicate their experience (EXP NA) may reflect uncertainty or lower familiarity with the technologies.

Table 3: Number of “Don't know” responses divided by years of experience

Cloud Platform	**EXP < 1**	**1≤EXP<2**	**2≤EXP<3**	**3≤EXP<4**	**4≤EXP<5**	**EXP≥5**	**EXP NA**	**TOT**
GCP	127/392	32/280	15/112	0/56	19/140	19/252	41/168	253/1400
AWS	88/336	15/280	7/56	0/56	7/112	41/308	13/84	171/1232
Azure	69/308	57/252	1/28	0/28	0/56	24/252	13/56	164/980
Other Cloud Platform	167/588	24/224	0/112	0/84	0/84	32/364	154/560	377/2016

Table 3 highlights the distribution of "Don't know" (DK) responses in the questionnaires, calculated as the ratio between the number of DK responses and the total number of items. Once again, a clear relationship with the level of experience emerges. In the lower experience groups (EXP<1 and 1≤EXP<2), the proportion of DK responses is significantly higher across all platforms, reaching extreme values such as 167/588 for “Other Cloud Platforms”, indicating lower familiarity and confidence in evaluating technological maturity. Conversely, in groups with greater professional experience (3≤EXP<4, 4≤EXP<5, EXP≥5), DK responses tend to disappear or decrease drastically, suggesting a greater mastery and confidence in the evaluated topics.

However, a notable exception is represented by the EXP NA category, which shows high percentages of DK responses, particularly for “Other Cloud Platforms” (154/560), suggesting that uncertainty in declaring professional experience is also reflected in the ability to evaluate the technologies. This supports the hypothesis that the omission of experience information may serve as an indirect indicator of lower perceived maturity.

The combined results from the two tables suggest the possible presence of the *Dunning-Kruger effect* (Kruger & Dunning, 1999), a psychological phenomenon whereby individuals with limited competence tend to overestimate their abilities. Specifically, within the lower experience groups (especially EXP<1 and 1≤EXP<2), relatively high UM values are observed alongside a high number of DK responses and a moderate perception of TM. This pattern may indicate an initial overconfidence among less experienced users. In contrast, respondents with higher levels of experience (EXP≥5) tend to express more moderate self-assessments of their maturity (UM), despite possessing higher knowledge levels and providing fewer DK responses, suggesting a greater critical awareness. This trend supports the hypothesis that self-assessment accuracy tends to improve with increasing competence, consistent with the Dunning-Kruger model.

5 Conclusions

This study introduced a maturity model for evaluating the effectiveness and readiness of cloud-based big data technologies. By examining both technological maturity and user maturity, the model provides a comprehensive view of the conditions necessary for successful implementation and value generation in big data initiatives. The model offers a complete framework that recognizes not only the functional capabilities of technologies but also users' awareness, confidence, and experiential knowledge. This dual-level perspective is essential for understanding the true success of adoption and value creation in complex data ecosystems.

Empirical results show that the perception of technological maturity tends to increase with professional experience, suggesting that exposure and practice enhance appreciation for the robustness and utility of the technology. In contrast, user maturity follows a less predictable trajectory, often peaking during the early stages of experience and then declining, likely due to a growing awareness of one's limitations. This trend aligns with the Dunning-Kruger hypothesis and highlights the importance of targeted training and ongoing competence

assessment in big data environments. The marked disparity between TM and UM scores also underscores the risk of underutilizing mature technologies due to insufficient user competence or confidence.

The proposed model provides organizations with an operational tool to assess readiness from both a technical and a human perspective. Professionals can use this framework to identify skills gaps and strategically design enhancement programs. Additionally, technology providers can benefit from insights into how their tools are perceived in terms of usability, reliability, and support, fostering more user-centered innovation. This research addresses the growing need for integrated maturity assessments that go beyond infrastructure metrics, offering a valuable foundation for both academic inquiry and practical application. As organizations increasingly rely on big data to gain strategic advantages, tools that balance technological and human factors will become essential for sustainable digital innovation.

Future research could pursue three main directions. First, expanding the dataset across different industry sectors and geographic regions would enhance the generalizability of the findings. Second, a longitudinal approach could help assess how maturity perceptions evolve alongside digital transformation and training initiatives. Third, a deeper analysis of the cognitive biases affecting self-assessment could refine the UM dimension and offer even more personalized development pathways for users.

6 Ethics Declaration

This research did not involve any human participants, animals, or sensitive data requiring ethical approval. Therefore, ethical clearance was not required for the work presented in this paper.

7 AI declaration

During the preparation of this manuscript, the author(s) employed generative AI tools to enhance the language and clarity of the text. All content was subsequently reviewed and revised by the author(s), who assume full responsibility for the final version of the publication.

Key Factors for Leveraging and Capitalizing Digital Transformation Initiatives in Industrial Landscape

Vito Del Vecchio, Martina De Giovanni, Ayotobi Oromiye Holo, Mariangela Lazoi
University of Salento, Lecce, Italy

Abstract

Industrial organizations are increasingly investing in technology and digital transformation (DT) initiatives to enhance their digital maturity and achieve sustainable growth within VUCA markets. However, the potential benefits of these investments vary depending on the company's level of technological maturity. Higher maturity generally provides better positions to implement DT strategies and maximize their return on investment (ROI). However, due to the inherent complexity of DT initiatives, many organizations struggle to determine the most effective investment paths and align them with strategic objectives. ROI in DT is multifaceted and not limited to financial outcomes. Economic advantages can come from specific strategic and operational actions.

Digital Transformation Maturity Models (DTMMs) are proposed in literature for assessing and measuring, based on specific dimensions and factors, the business readiness in managing DT investments. Despite DTMMs are widely discussed in literature, none of them refers to ROI concept. Addressing this research gap, through a Systematic Literature Review, the study aims to explore the relationship between DT maturity and ROI and to identify the key factors facilitating the implementation of specific actions for gathering high ROI. Based on 35 DTMMs, the paper identifies 51 key factors that influence successful DT implementation and capitalization. These factors are grouped into four dimensions: People, Organization & Culture, Information & Technology, and Operations. Furthermore, through the interaction of an IT company, the study provides an original framework matching all factors with specific forms of ROI. The framework represents a valuable indication for companies to shape their digital strategies, consider DT investments, and generate meaningful ROI.

Keywords: Digital Transformation, Maturity, Return on Investment, Industry

Paper type: Academic Research Paper

1 Introduction

Modern industries are interested in investing in Information Technology (IT) and Digital Transformation (DT) initiatives to improve their business performance and maintain a sustainable development (Teng et al., 2022). However, the value coming from these investment is closely tied to an organizations' level of technological maturity (Corallo et al., 2023a). Maturity implies evolutionary progress from an initial stage to a desired final stage (De Bruin et al., 2005). Due to the complexity of DT initiatives, companies often faces challenges in considering the right investment and aligning with strategic goals (Zhang, 2024). Moreover, the ROI can be considered not only in financial terms, but also from indirect strategic and operational actions.

Companies need to be supported by reference frameworks to understand their technological maturity and assist successful choices for DT projects implementation. In these regards, Maturity Models (MM) come as useful tools for measuring and evaluating organization's abilities or for planning a continuous improvement (Paulk et al., 1993). MMs include a set of dimensions and factors based on which companies' maturity can be assessed. Generally, the ability of a company to gain high ROIs depends on high levels of maturity (Jardak and Ben Hamad, 2022). Although in the short-term financial performance may be negative due to companies settling and adaptation, mature companies better achieve long-term ROI.

On top of this context, this paper aims to identify and analyze the most important factors that companies need to consider for leveraging and capitalizing DT initiatives. Specific factors can support companies in accurate shape actions and gather high ROI. Digital Transformation Maturity Models (DTMMs) are widely discussed in literature such as (Gökalp and Martinez, 2021), (Vuksanović Herceg et al., 2020), but none of them considers the ROI concept. Based on a Systematic Literature Review (SLR), the paper investigates the relationship between maturity and ROI. The paper intends to identify key factors in charge of providing industrial companies with ROI, trying to provide an answer to the following research question: what factors can be considered in supporting the evaluation of DT initiatives and capitalizing on them? Based on 35 DTMMs available in literature, 4 key dimensions emerged: People, Organization & Culture, Information & Technology, and Operations. Also, 51 elements were identified as key factors to consider in DT initiatives.

Supported by an IT company, through diverse focus groups, the study proposes an original framework linking maturity factors to different forms of ROI. The framework offers both theoretical insights and practical guidance for companies seeking to capitalize on DT initiatives through specific actions.

2 Background

2.1 Maturity Model

MMs have gained success in the information systems and management fields with several framework developed by both practitioners and academics over the years (Mettler, 2011). MMs were introduced in literature to assess the maturity of capabilities, often tailored to areas like information and communication technologies (ICT) (Becker et al., 2009). The first MM, named Capability Maturity Model (CMM), introduced by the Software Engineering Institute in 1987, represents a reference framework defining five stages of development process maturity (Paulk et al., 1993). Since its introduction, diverse models emerged across various domains such as IT and business processes (De Bruin et al., 2005).

MMs serve as strategic tools for self-assessment or evaluation by third parties or comparison with others or for guiding improvement plans within organizations (Paulk et al., 1993). The concept of "maturity" can be generally defined as "the state of being complete, perfect or ready" in terms of ability, competence in a specific domain with respect to a predefined set of criteria. Maturity generally denotes evolutionary progress in demonstrating a specific skill or accomplishing a goal. MMs can focus on specific targets such as process, objects, people or their holistic combination as maturity of these elements influences each other. Moreover, MMs can be categorized by purpose into descriptive (for assessing current state), prescriptive (for guiding improvement), and comparative (for benchmarking across organizations). MMs can also be categorized based on their structure, from simple maturity grids and Likert-style questionnaires to more complex CMM-like frameworks with defined goals and practices.

MMs in the technological domain can be analyzed by general, design, and usage attributes to describe the maturity target (process, object, people) in terms of evaluation approach and data collection, model reliability and mutability over time. Indeed, reliability, mutability, and application methods are considered key characteristics influencing the effectiveness and reusability of MMs. Reliability refers to verification (ensuring the model aligns with its design) and validation (ensuring real-world relevance). Mutability concerns how well the model adapts over time to evolving technologies or environments. Usage attributes relate to how models are applied such as for self-assessment. Supporting materials can be provided as assistance through manuals or software tools. Finally, MMs differ in the depth of recommendations, from general guidance to explicit actions (Mettler, 2011).

2.2 Return on Investment

ROI commonly refers to a financial indicator defined as the amount of money that is recovered from a given investment. It supports decision-making processes to avoid financial losses due to bad investments, guiding companies in evaluating expenses and financial returns (Smith, 2024). ROI is indeed often used as an estimation of financial returns over the year. Generally, it follows a positive trend over the years, even though, in some cases, it can be negative due to bad financial navigation.

Different factors can trigger the nature of ROI, particularly in VUCA markets characterized by volatility, uncertainty, complexity, and ambiguity (Kaivo-oja and Lauraeus, 2018). The traditional view suggests a positive relationship between market volatility and expected returns. The presence of ambiguity can alter this relationship, and investor attitudes optimism or pessimism. Uncertainty, especially when related to information quality, can weaken or reverse the expected positive link between volatility and returns. High uncertainty can decrease expected returns, and strategies mitigating risk exposure can generate higher risky ROI. Both ambiguity and uncertainty can reduce the effectiveness of traditional ROI models. High complexity also increases the challenges in modeling volatility and uncertainty, complicating accurate ROI estimation and risk management (So et al., 2022).

Moreover, time plays a crucial role in positive ROI, since ROI is estimated from a short to a long period. Similarly, timing of investments is crucial, as the value of waiting or accelerating can be significant (Carruth et al., 2000). Furthermore, the relationship between risks and return is fundamental, with riskier assets typically offering higher potential returns (Capiński and Kopp, 2014). Policy heterogeneity and geopolitical risks can also negatively impact returns, although investors may be compensated with a premium when prices rebound after periods of high uncertainty.

Although companies often refer to ROI from an economic perspective, this return can be triggered by different strategical and operational actions. According to (Jardak and Ben Hamad, 2022), ROI is closely linked with the maturity level of organizations in managing investments and leveraging opportunities. Higher maturity is generally linked to better long-term ROI, but short-term financial performance may initially decline as companies invest and adapt. The ability to measure, realize, and sustain ROI improves as companies develop more mature processes and frameworks for managing financial decisions. Companies with mature digital or project management levels are better equipped to realize both financial and non-financial benefits (Kwak and Ibbs, 2000). Less mature companies often struggle with fragmented data, unclear objectives, and undervaluation of intangible benefits, making ROI harder to assess and realize.

3 Research Methodology

This study is based on a SLR, a rigorous and transparent research approach allowing for a comprehensive and objective investigation of research studies. Based on the SLR protocol of (Corallo *et al.*, 2023), the review was structured in four steps.

Step1: review planning – The SLR aims to investigate the relationship between business maturity and the ability to extract value from DT investments. The paper attempts to provide an answer to the following research question: what factors can be considered in supporting the evaluation of DT initiatives and capitalize on them?

To achieve this goal, Scopus was considered as reference scientific databases. Appropriate keywords were included for the query design: “digital transformation”, “digit*”, “maturity model”, “industry 4.0”, “I4.0”, “industry 5.0”, “I5.0”, “manufacturing”, “return on investment”, “ROI”.

However, after a first attempt to query Scopus with an accurate combination of such keywords, no results were retrieved. This testifies the need to refine the query as well as the innovativeness of the research focused on the integration of topics unexplored before in literature. Therefore, two separate queries were designed:

- Q1: “digital transformation” OR “digit*” AND “maturity model” AND “industry 4.0” OR “I4.0” OR “industry 5.0” OR “I5.0” OR “manufacturing”.
- Q2: “digital transformation” OR “digit*” AND “industry 4.0” OR “I4.0” OR “industry 5.0” OR “I5.0” OR “manufacturing” AND “return on investment” OR “ROI”.

While Q1 aims to collect insights on DTMMs in the industrial landscape and to focus on key factors, Q2 focuses on understanding how ROI is discussed in DT initiatives.

Keywords were searched for their occurrence within title, abstract and keywords of resulting papers. Additionally, selection criteria were defined for the eligibility of papers for including only relevant studies: paper written in English; papers published in international journals; papers belonging to subject areas like Business Management and Accounting, Engineering, Computer Science, and Decision Science.

Step2: review execution – The search process was implemented in January 2025. Considering Q1, starting from 260 papers, the application of filters led to refine the sample to 94 papers. Considering Q2, from 37 papers, only 15 were retained due to filtering. No duplicated papers were returned.

Step3: analysis – A preliminary analysis was first conducted based on title and abstract relevance and pertinence. Considering Q1, up to 94 papers only 60 were retained. Considering Q2, up to 15 papers only 10 were retained. Secondly, a qualitative full content analysis was executed. This process led to confirming the 60 papers of Q1 and only 9 papers of Q2. A structured approach was used to identify and select key information related not only to bibliometric information, but to dimensions and factors considered in DTMMs, as well as forms of ROI in charge of providing economic benefits for industries.

Step4: reporting – The results of the analysis are presented in Section 4.1 (Q1) and Section 4.2 (Q2).

4 State of the art

4.1 Maturity Models in Industrial Digital Transformation

Based on the analysis of papers coming from Q1, up to 60 papers, 35 MMs were retrieved, able to assess companies’ maturity in the field of DT.

Table 1. Comparative summary of DTMMs

MMs' Reference	Objective	Dimensions	Design Focus
(Ahn et al., 2024)	Measuring automated production management and manufacturing processes for future smart factories.	• Production • Manufacturing	people
(Gallego-García et al., 2022)	Driving continuous improvement for specific applications such as Additive Manufacturing (AM) or virtual reality.	• Adaptive robotics • CPS • AM • Cloud technologies • Virtualization technologies • Simulation • Data analytics&AI • Communication & networking • RFID • Cybersecurity • Sensors&actuators • Mobile technologies	process

4.2 Forms of ROI

Based on the analysis of papers coming from Q2, six forms of ROI were identified - i.e., Business Performance Optimization (BPO), Productivity Optimization (PO), Cost Reduction (CR), Time Reduction (TR), Resource Optimization (RO), Customer Experience Improvement (CEI) - including specific actions indirectly providing economic returns due to DT investments. Grey spaces in Table 2 denote a match.

Table 2. Summary of forms of ROI

	BPO					PO				CR							CEI			TR			RO		
	Corporate Orientation	Governance Structure	Financial Constraints	Increased Sales	New customers	Production rate	Resources utilization	Scrap and wastes	Security	Maintenance cost	Labour cost	Procurement	Outsourced activities	Risk management	Process improvement	Technology investment	Quality	Customer expectation	Cash flow	Customer responsiveness	Machine downtime	Interventions	Labour shortage	Personnel	Materials	Utilities

5 Discussion

Based on the analysis of DTMMs, all dimensions and factors were analyzed so that four key dimensions result: i) People, ii) Organization and Culture, iii) Information and Technology, iv) Operations. While, all the 35 maturity models considered both "People" and "Organization and Culture", (Krešimir Buntak et al., 2021; Draganić, 2023; Maram I. Shqair and Altarazi, 2022; Yan et al., 2021) do not mention "Information and technology" dimension, and only (Maram I. Shqair and Altarazi, 2022) does not talk about "Operations". Each dimension is detailed in different categories, for a total of 51 factors (see Table 3) dealing with actions for leveraging and capitalizing DT initiatives in industry.

Some interesting insights emerged with respect to the most important factors such as: ICT and digital competences, and openness to new technologies, within "People"; ICT value, digital strategy development, and digital business models, within "Organization and Culture"; IT security and software technology, within "Information and Technology"; product digitalization and process digitalization, within "Operations".

Few MMs consider the principles of I5.0 paradigm (Hein-Pensel et al., 2023; Xu et al., 2021): human centricity was discussed only from the customer's point of view (Dikhanbayeva et al., 2020); environmental sustainability was considered only by (Amaral and Peças, 2021), and resilience was considered in (Hein-Pensel et al., 2023) in terms of technological modularity.

Although literature directly linking forms of ROI to DT initiatives remains relatively limited, insights from recent studies (see Table 2) identified six forms of ROI having specific actions that potentially capitalize DT investments.

The innovative contribution of the paper also relies on integrating these topics, which is identified as the main research gap, trying to shape the relationship between factors representative of DT maturity, and forms of ROI. Different focus groups were managed involving three researchers and three practitioners belonging to an IT consulting company. Knowledge and competences coming from academia and industrial experiences were shared with the aim of understanding how factors are linked with forms of ROI (see grey spaces in Table 3).

Table 3: Link between factors and forms of ROI

			Forms of ROI					
	Factors		BPO	PO	CR	CEI	TR	RO
PEOPLE	Partners	Partner Communication						
		Partner Digital Interaction						
	Customers	Customer Requirement Satisfaction						
		Customer Digital Competences						
		Customer Data Utilization						
	Suppliers	Supplier Relationship Management						
		Supplier Performance						
	Employees	Employee Accountability						
		Openness to New Technology						
		Empowerment						
		ICT and digital competences						
ORGANIZATION&CULTURE	Strategy	Implementation I4.0 Roadmap						
		Scouting of New Opportunities						
		Resource Management						
		Communication						
		Digital Business Models						
		Digital Strategy Development						
		Performance Management						
		Investments						
		Innovation Management						
		Decision Making Data-Driven						
		Change Management						
	Governance	Knowledge Sharing						
		ICT Value						
		Intellectual Property						
		Data Access						
		Regulations & Standards						
INFORMATION&TECHNOLOGY	Management	IT Security						
		Physical Infrastructure						
		IoT & Analytics						
		Digital Data Availability						
		Software Technology (e.g., Cloud)						
	IT Design Principles	Interoperability						
		Virtualization						
		Decentralization						
		Real-Time Capability						
		Service Orientation						
		Openness						
		Modularity						
OPERATIONS	Product	Product Customization						
		Product Digitalization						
		Product Integration						
	Process	Process Decentralization						
		Process Digitalization						
		Process Optimization						
		Process Standardization						
		Business Process Integration						
	Practice	Internal Collaboration						
		Extended Enterprise						
		Performance Control and Improvement						
		Interdisciplinary						

6 Ethics declaration

Participants were fully informed of the research purposes and contributions of the study. Anonymity of data and confidentiality were ensured in accordance with GDPR and ethical standards.

7 AI declaration

The use of AI tool, specifically OpenAI ChatGPT, was limited to language refinement and improvement. Contents were critically reviewed by authors for accuracy, originality, and alignment with scientific standards.

8 Conclusions

The paper investigated the relationship between business maturity and company's ability to derive value from DT investments. It explored the literature of DTMMs and identified 4 key dimensions and 51 factors in charge of shaping digital maturity of industrial organizations. Also, the possibility of addressing specific actions, identified like forms of ROI, can generate economic benefit throughput through distinct mechanisms.

However, the link between maturity and ROI was not well-explored in literature. Therefore, the paper introduced a novel framework linking these factors to specific forms of ROI.

The study provides both theoretical and managerial implications highlighting the importance of investigating an underexplored topic in literature. It enhances understanding of how DT maturity impacts ROI and encourages further research. It also provides actionable insights to practitioners in terms of maturity factors linked to specific actions for capitalizing DT investment, highlighting ROI beyond purely economic metrics.

Despite the originality and value of research, the study has some limitations. It is based on a qualitative approach which may limit the objectivity of factors and ROI mapping. Future research should adopt quantitative approaches to validate and expand these findings. The framework could be explored in sectors beyond IT, to improve generalizability, and it could be validated in real-world business cases.

A Comparative Analysis of Low-Code/No-Code Frameworks

Sajjad Ahmed[1], Miguel Mira da Silva[2], Alberto Rodrigues da Silva[2], Mariangela Lazoi[1]
[1]University of Salento, Lecce, Italy
[2]University of Lisbon, Lisbon, Portugal

Abstract

The advent of low-code and no-code (LCNC) platforms has revolutionized software development, making it accessible to users with different programming skills. These methodologies provide both technical and non-technical users with innovative solutions to optimize the software development process. The goal of this paper is to inform and enrich both scholarly discourse and practical application by synthesizing theoretical frameworks with practical experiences, ultimately driving advancements in software engineering methodologies and helping individuals and organizations to leverage these innovative development paradigms effectively. The paper presents a comparative analysis of features and capabilities of the platforms AppSheet, PowerApps, and Bubble.io. It explores Model-Driven Development's role in enhancing these platforms. To further enrich the analysis, a group of PhD students with different expertise in software engineering and LCNC paradigms were interviewed to gather their perspectives on the practical use and potential of these platforms. Their insights provided a valuable layer of expertise to the evaluation process, highlighting nuanced challenges and opportunities that emerge in applied settings. The three platforms were systematically compared and ranked using the analytic hierarchy process (AHP), a multi-criteria decision-making methodology that structures the decision-making process into a hierarchical model. AHP's systematic approach ensures that both subjective preferences and objective data are integrated, making it an effective method for selecting the most suitable LCNC platform. This approach allowed for an objective evaluation based on key factors such as usability, scalability, and adaptability to various development needs. By combining hands-on experimentation with expert insights and a rigorous evaluation framework, this study bridges the gap between theoretical understanding and practical application.

Keywords: low-code development platform; no-code development platform; model driven development; AHP method; Digital Transformation

Paper type: Academic Research Paper

1 Introduction

In recent years, the landscape of software development has experienced a deep change due to the introduction of innovative approaches like low-code, no-code, and model-driven development. These methodologies provide both technical and non-technical users with innovative solutions to optimize the software development process. As this dynamic field continues to gain interest in both industry and academia, researchers are actively investigating various aspects to deepen their understanding and optimize their utilization, aiming to enhance their efficacy, scalability, and applicability across various domains (Di Ruscio et al., 2022).

Specifically, low-code development platforms provide a visual interface and pre-built components, enabling developers to rapidly build applications with minimal hand-coding. Conversely, no-code platforms take this concept further by empowering users with little to no programming background to create functional applications using intuitive drag-and-drop interfaces. Model-driven development emphasizes the creation of abstract models, which are then transformed into executable code, fostering higher-level abstraction and automation in the development process (Bock et al., 2021).

One of the key areas of the research focus is the current status of no-code development, encompassing its capabilities, limitations, adoption trends, and implications for software engineering practices (Beranic et al. 2020; Luo et al., 2021). This research topic aims to investigate the evolving landscape of no-code platforms, examining their effectiveness in addressing diverse use cases and fostering collaboration between developers and domain experts. In response to this trend, an increasing number of companies are providing software development platforms that guarantee a significant increase in productivity and a reduced requirement for coding alone (Krejci et al., 2021). For many years, both characteristics have been the focus of extensive research in fields like generative programming, model-driven software development, and domain-specific modeling languages. Thus, an open question is what unique performance features low-code and no-code (LCNC) platforms offer (Elshan et al., 2023). Since the topic is still under investigation, a reasonable method to get a detailed grasp of what it is and could be is to examine how the platforms actually work. In this discourse, this research paper

examines three platforms, noting and rating both the general attributes and the unique aspects of each instrument.

The first step is to analyze the ongoing research efforts surrounding the LCNC, and model-driven development paradigms, with a particular emphasis on the status quo and future directions of LCNC platforms. The aim is to advance software engineering practices and enable a wider range of stakeholders to be involved in the development process by shedding light on the opportunities and challenges present in these novel approaches through critical analysis and synthesis of the existing literature.

Furthermore, this research leverages on firsthand experience in the development of a blog application utilizing platforms such as AppSheet, PowerApps and Bubble.io.

The direct contact with these LCNC development environments, enrich the knowledge of their usability, flexibility, and efficacy in real-world application scenarios. Then, the process of conceptualizing, designing, and deploying a blog application provides valuable firsthand knowledge of the strengths and limitations of these platforms, offering new perspectives that complement theoretical insights infered from academic literature. Lastly, the three platforms are evaluated and ranked according to the multiple-criteria decision method of analytic hierarchy process (AHP) (Saaty, 1990; Atanasova et al., 2014).

Through this fusion of academic inquiry and practical experimentation, this research aims to bridge the gap between theory and practice, providing a step for understanding of the low-code, no-code, and model-driven development landscape.

2 Research Background

Model-Driven Development (MDD) is an approach to software development where abstract models are created to specify the structure, behavior, and functionality of a system (Sendall et al., 2023; Schmidt, 2006). These models serve as a base from which executable code can be automatically generated, reducing the manual effort involved in coding and facilitating higher-level abstraction. MDD emphasizes the separation of concerns between the system's underlying logic and its implementation details, promoting modularity, reusability, and maintainability throughout the development lifecycle.

On the other hand, LCNC development refers to the creation of software applications using visual development interfaces and declarative programming techniques, without the need for traditional hand-coding (Rokis et al., 2022). LCNC platforms typically offer a range of pre-built components, templates, and drag-and-drop tools that enable users, including non-technical individuals, to design, build, and deploy functional applications rapidly. By abstracting away, the complexities of coding, LCNC development empowers a broader audience to participate in the software development process, democratizing access to application development and fostering collaboration between domain experts and IT professionals.

MDD is often used in complex development environments, where models are used to manage the complexity of the domain and the generated code. LCNC platforms further lower the barrier to entry, allowing even business users to create applications without deep technical knowledge.

From practical and professional perspectives, LCNC development offers several advantages over traditional coding approaches. Firstly, it accelerates the development cycle by reducing the time and effort required to create and iterate on applications, enabling organizations to respond more swiftly to changing business needs and market demands. Secondly, it promotes greater collaboration and innovation by allowing non-technical stakeholders to contribute directly to the development process, leveraging their domain expertise to inform application design and functionality. Additionally, LCNC development can enhance the scalability and maintainability of applications by enforcing best practices and standardizing development workflows across teams.

LCNC platforms can be seen as a simplified evolution of the MDD concept. They have taken the principles of the "model-driven" approach (building software through visual abstractions) and made them more accessible and usable by a wider audience of users. Model-Driven Development is a development philosophy where models are used to automatically generate code, while LCNC platforms offer a similar but more accessible experience, further simplifying the development process through visual interfaces. LCNC platforms can therefore be considered a more practical and user-friendly embodiment of MDD approaches, aimed at a wider audience.

While the adoption of LCNC development has gained relevance in industry settings due to its practical benefits, there remains a need for ongoing research to address various challenges and opportunities associated with this approach (Rokis et al., 2022). Research efforts in the realm of LCNC development may focus on areas such as usability, scalability, security, integration capabilities, and the impact of LCNC tools on software quality and developer productivity (Beranic et al. 2020). By advancing our understanding of these issues and developing innovative solutions, researchers can contribute to the continued evolution and maturation of LCNC

development practices, enabling organizations to realize the full potential of this transformative approach to software development.

3 Platforms

In recent years, the landscape of software development has been transformed by the emergence of LCNC platforms, offering innovative solutions for building custom applications with minimal coding requirements. Among these platforms, AppSheet, PowerApps and Bubble.io stand out as leading contenders, each providing powerful tools and capabilities to empower users in the creation of bespoke software solutions. The reasons that guided our choice are the following. As for AppSheet, being part of the Google ecosystem, it integrates perfectly with Google Workspace (spreadsheets, forms, Drive), which makes it ideal for companies that already use these platforms. In addition, it allows you to build applications without writing code starting from simple spreadsheets. As regards PowerApps, it is tightly integrated with all Microsoft services, such as Dynamics 365, SharePoint, Excel, OneDrive, Azure, and Microsoft Teams. This integration offers a huge advantage for organizations that already use Microsoft products extensively. Finally, compared to other no-code platforms, Bubble.io offers more flexibility in customizing your application. It is possible to design very detailed user interfaces and manage complex logic with ease. Furthermore, to the best of our knowledge, Bubble.io is a platform that has been studied extremely little in the literature, making it more interesting for a scientific study.

In this context, we provide an analysis of the features, functionalities, and use cases of AppSheet, PowerApps and Bubble.io, exploring their respective strengths and limitations, and their role in shaping the future of software development.

3.1 AppSheet

AppSheet is a cloud-based no-code development platform that enables users to build customized applications without requiring traditional programming skills (Nurharjadmo et al., 2022). It has been founded in 2014 and acquired by Google in 2020. The platform supports use cases such as data management, workflow automation, and business process optimization.

It adopts a declarative programming model, allowing users to define application logic through expressions and preset actions. AppSheet integrates with widely used cloud services, including Google Sheets, Excel, Looker Studio, and Salesforce, and offers functionalities such as offline data access, GPS tracking, barcode scanning, and image processing. The platform features a visual development environment with drag-and-drop capabilities, supporting a range of data types and offering pre-built templates to accelerate development. Extensive documentation and learning resources are available to assist users.

Security is addressed through features like single sign-on, role-based access control, encryption, and audit logging. Administrators can configure granular access and data governance policies to meet compliance requirements (Jeong et al., 2006).

AppSheet also promotes community engagement and collaboration through knowledge-sharing platforms and a marketplace for third-party extensions. It represents a flexible no-code solution for rapid application development across diverse organizational contexts.

3.2 PowerApps

PowerApps, developed by Microsoft and launched in 2015 as part of the Power Platform, is a low-code development environment designed to facilitate the creation of custom business applications with limited programming requirements (Sahay et al., 2020). It employs a declarative development model, enabling users to define application logic and interface behavior through visual editors and configuration settings.

The platform provides a wide array of templates, UI controls, and prebuilt connectors that accelerate the application development process. It features deep integration with Microsoft services, including Office 365, SharePoint, Dynamics 365, and Azure, while also supporting external systems via REST APIs, custom connectors, and standard data gateways (Sharma et al., 2014).

PowerApps supports the development of both simple and complex applications, incorporating features such as responsive design, data binding, conditional logic, and customizable styling. Security is a core aspect of the platform, with support for Azure Active Directory, role-based access control, and data encryption mechanisms (Gürcan et al., 2021; Kapadia et al., 2017). Administrators can enforce governance through policy configuration and permissions management.

Additionally, PowerApps includes tools for monitoring, analytics, deployment, and version control, facilitating application lifecycle management. It represents a flexible and scalable solution for enterprises aiming to streamline workflows and develop business applications rapidly across web and mobile environments.

3.3 Bubble

Bubble.io is an advanced no-code platform that enables the development of web applications without traditional programming (Zhang et al., 2024). It features a visual drag-and-drop interface for user interface UI design and supports responsive layouts for compatibility across devices.

The platform includes a built-in database management system that allows for custom data types, record management, and the establishment of data relationships. It also supports integration with external APIs and data sources, facilitating interoperability. Its event-driven workflow engine enables the creation of dynamic, conditional processes based on user interaction or system events.

Customization is supported through templates, plugins, and real-time dynamic content. In terms of security, Bubble.io provides authentication systems, user role management, and configurable privacy rules. It is hosted on Amazon Web Services, leveraging encryption, network isolation, and compliance with industry security standards (Mishra et al., 2022).

Bubble.io simplifies deployment via integrated hosting and is designed for horizontal scalability. It also supports real-time collaboration and version control, which enhances project management. These features make Bubble.io a relevant subject of study in software engineering and information systems, particularly for its role in expanding access to web application development (Duc et al., 2016).

4 Method

The methodology employed in this study is designed to provide a comprehensive and systematic approach to evaluating AppSheet, PowerApps and Bubble.io, through the creation of blog and web applications on each platform. This section outlines the detailed steps taken, tools and technologies utilized, and the evaluation criteria established to ensure a rigorous comparison.

The blog has been created based on the following App Requirements:

- Data Entities for Blogs, Users, Posts and Blog Users.
- Connections between these entities as specified in the Design Phase.
- Creation of a Blog Entity.
- Blog Entities possess a title a description a descriptive image and their respective Posts.
- Creation of a Post Entity.
- Post Entities possess a title, a description, a descriptive image, content and their respective authors.
- Creation of the User Entity.
- User Entities possess a profile image, a username, an email and a password.
- Capability for an unregistered visitor to see all the Blogs and their respective Posts.
- Capability for an unregistered visitor to register and to have permissions such as Administrator.
- Capability for Administrators to create new Blogs and new Posts inside each Blog.
- Navigation through all these Menus seamlessly and check every Blog and Post available.

The process of building these prototypes served a dual purpose: it provided a structured basis for selecting the evaluation metrics, and it guided the creation of a questionnaire later administered to the interviewees. By directly interacting with each platform through a controlled development scenario, the evaluation metrics were more accurately aligned with real-world usage, ensuring that the subsequent interviews and data collection processes were grounded in empirical observations.

In the following, a comparative analysis of three prominent LCNC platforms is provided. Our discussion focuses on evaluating these platforms across several key dimensions, including ease of use, data modeling, authentication and authorization, customization and flexibility, integration with external services, development speed and overall user experience.

To perform the evaluation, a Multi-Criteria Decision Making (MCDM) method has been adopted. MCDM encompasses methods designed to help decision-makers evaluate alternatives based on multiple criteria, particularly in complex scenarios like selecting the best LCNC platform. Relying solely on a single factor, such as flexibility or ease of use, is insufficient when numerous criteria must be considered. A comprehensive literature review that compares 11 MCDM methods was performed by Hester et al., 2013. Based on the literature reviewed, the observed advantages and disadvantages, as well as areas of application for 11 MCDM methods such as Multi-Attribute Utility Theory, AHP, Fuzzy Set Theory, Case-based Reasoning, were presented.

Among MCDM methods, the Analytic Hierarchy Process (AHP) is especially well-suited for evaluating LCNC platforms. It has been introduced by Saaty, 1990 and provides a systematic framework for decision-making by using pairwise comparisons to assess the relative importance of criteria and the performance of alternatives against those criteria. AHP allows decision-makers to structure complex decisions by decomposing them into a hierarchy of criteria, sub-criteria, and alternatives. By using pairwise comparisons, it helps to assess the relative importance of each criterion and compare the platforms based on their performance in each area.

AHP structures the decision-making process into a hierarchical model with three levels: the goal at the top, criteria in the middle, and alternatives at the bottom.

For evaluating LCNC platforms, the goal would be to select the best platform. Criteria such as ease of use, data modeling, authentication and authorization, customization and flexibility, integration with external services, speed of development, overall user experience, and ease of learning are placed in the middle level. The platforms being considered are positioned at the bottom level. This hierarchical arrangement, illustrated in Figure 1 (Atanasova et al., 2014)., facilitates a structured comparison by performing pairwise comparisons of criteria and alternatives.

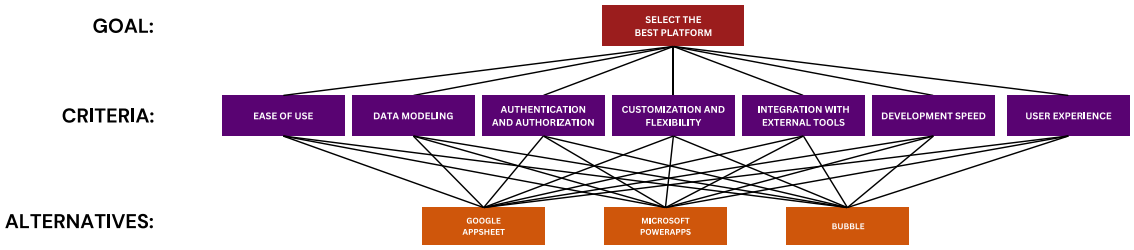

Figure 1: The Hierarchical structure of AHP Model

AHP's systematic approach ensures that both subjective preferences and objective data are integrated, making it an effective method for selecting the most suitable LCNC platform. This method employs a scale of judgments, typically ranging from 1 to 9, to quantify subjective preferences and translate them into numerical weights as explained in Table 1 (Saaty, 1990). The weights are then used to rank the alternatives and determine the best option. AHP has been successfully applied in various fields, including technology selection, project management, and resource allocation, due to its flexibility in handling both qualitative and quantitative data (Vaidya et al., 2006).

The criteria selected for evaluating LCNC platforms are grounded in their critical importance to both the technical and business facets of application development. Each criterion is essential for assessing the platforms' capabilities to meet diverse application development needs and ensuring they align with organizational goals and user expectations. Prior studies and industry reports highlight the significance of these factors in determining the effectiveness and efficiency of LCNC platforms (Rymer et al., 2019; Sahay et al., 2020).

Table 1: AHP pairwise comparison Saaty scale.

Weight	**Definition**
1	Equal importance
3	Weak importance of one over other
5	Essential or strong importance
7	Very strong importance
9	Absolute importance
2, 4, 6, 8	Intermediate values between the two adjacent judgments
Reciprocals of previous values	If factor 'i' has one of the previously mentioned numbers assigned to it when compared to factor 'j' then j has the reciprocal value when compared to i.

5 Assessment

In this section, the AHP is applied to rank the three platforms described before, namely AppSheet, PowerApps, and Bubble.io.

To enhance the clarity of the decision-making process and to facilitate better interpretation of the results, both the criteria and alternatives used in the assessment are denoted by specific abbreviations. The selected criteria and the abbreviation assigned to each criterion are as follows:

- C1 - Ease of Use: This is essential for non-programmers or users with limited technical backgrounds, so it represents a good point of start.

- C2 - Data Modeling: The ability to model data efficiently is a core aspect of many applications.
- C3 - Authentication & Authorization: Security is crucial, especially for applications that involve user data. Including this as a criterion ensures that each platform's capabilities in this domain are evaluated.
- C4 - Customization & Flexibility: The ability to adapt the platform to specific needs or preferences is important for building functional and unique applications.
- C5 - Integration with External Services: Many apps require external services (APIs, databases, etc.), so assessing the ease of integration is highly relevant.
- C6 - Development Speed: The faster a platform allows you to develop and deploy applications, the more appealing it is. This criterion highlights the platform's efficiency.
- C7 - User Experience: This criterion is crucial, as it ensures that the final applications offer a good experience for the end users.

The selection of the criteria has been performed based on the literature review and on the direct practice with the selected platforms.

The abbreviations assigned to each alternative are as follows: P1 is AppSheet, P2 is PowerApps and P3 is Bubble.io.

AHP method consists of four main steps: (i) A hierarchical problem model is developed for which we should make a decision as shown in Fig. 1; (ii) At each level of hierarchy, a comparison of elements of the structure is carried out in pairs, where the decision maker's preferences are expressed using the scale in Table 1; (iii) The relative importance of the elements of each level of the hierarchical structure is evaluated, for the calculation of local criteria, sub-criteria and alternatives. After that, the overall priorities of the alternatives are summarized. The total priority of each alternative is calculated with the sum of the local priorities that are weighted with the weights of the elements from higher levels; (iv) sensitivity analysis is conducted.

Given the extensive volume of calculations and the numerous matrices involved, the focus here will be on summarizing the most critical findings. The decision matrix explicitly illustrates the relative importance of the attributes, or decision criteria, based on the applied analytical methods. This matrix provides a comprehensive overview of how each criterion contributes to the overall evaluation, reflecting the weighted significance derived from the analytical hierarchy process (AHP). By concentrating on these key results, we aim to offer a clear representation of the decision-making outcomes, facilitating a more straightforward interpretation of the comparative performance of the alternatives.

The mathematical model leverages on a matrix n×n, where n is the number of elements which are compared. The matrix is filled according to the decision maker's preferences, expressed using the scale in Table 1, as explained in the next subsection.

5.1 Interviews with LCNC users

In this application, the preferences have been selected according to the direct interviews to a group of 7 independent PhD students from two different universities, with at least 2 years of experience using LCNC platforms in their academic research. The selected participants come from diverse academic backgrounds, such as computer science, data science, information systems, and other fields that involve the use of software tools. The study has been designed such that every participant had the same conditions. Specifically, the interviews were conducted through written questionnaires and followed a structured multi-step process:

- Assessing Expertise: Participants were first asked to indicate their level of expertise with LCNC platforms. This helped establish a baseline understanding of their prior knowledge and experience.
- Prioritizing Evaluation Criteria: Before proceeding with detailed evaluations, participants were asked to rank the importance of the evaluation criteria. This step provided insight into the participants' priorities and perspectives.
- Practical Task: Each participant was assigned the task of creating a blog that met specific requirements using all three LCNC platforms under evaluation. This practical exercise allowed them to explore the platforms in depth.
- Feedback Collection: After completing the task, participants filled out a detailed feedback questionnaire. They answered specific questions related to each criterion, evaluating all three platforms based on their experience during the task.

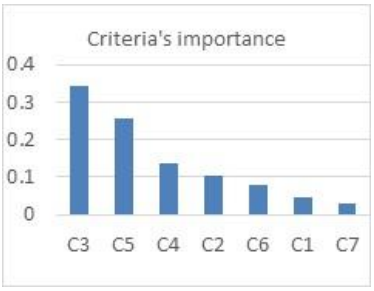
The ratings provided by the PhD students in the questionnaire were analyzed using a straightforward approach. For each evaluation criterion, the scores assigned by the participants were synthetized based on Table 1 and then averaged. The filling should meet the four axioms of Saaty 1987: the reciprocity axiom, the axiom for homogeneity, the axiom for dependence and the axiom of expectation. These axioms ensure logical consistency and reliability in comparing elements.

The arithmetic mean was calculated for each platform and each criterion to provide a comparative overview of the performance of the platforms under evaluation. The results of this analysis are presented in the following subsection.

5.2 AHP

The arithmetic means have been firstly used to fill the matrix in Table 2.

This matrix is then normalized, and the normalized elements are used to compute the weights. In particular, the weights are the arithmetic mean for each row of the normalized matrix. Thanks to the weights, it is then possible to compute the maximum eigenvalue of the matrix, indicated with λ_{max}.



Then, AHP computes the consistency ratio as: $CR = \frac{CI}{RI}$, where CI is the Consistency Index of the original matrix defined by $CI = \frac{\lambda_{max} - n}{n-1}$ and RI is Random consistency index (Atanasova et al., 2014)**.**

In this application $n = 7$, thus $RI = 1{,}35$.

Table 2 shows the comparison of the criteria for choosing the best Platform for minimal to no programming experience and the right chart summarizes the order of importance of the criteria based on the computed weights.

Table 2. Comparison of the criteria

	C1	**C2**	**C3**	**C4**	**C5**	**C6**	**C7**	**Weight**
C1	1	0,33	0,20	0,33	0,33	0,5	2	0,0477
C2	3	1	0,33	0,50	0,5	3	2	0,1049
C3	5	3	1	5	4	7	9	0,3452
C4	3	2	0,20	1	0,33	3	4	0,1374
C5	3	2	0,25	3	1	7	9	0,2563
C6	2	0,33	0,14	0,33	0,14	1	4	0,0807
C7	0,5	0,5	0,11	0,25	0,11	0,25	1	0,0276
Sum	17,5	9,17	2,24	10,42	6,42	21,75	31	

The maximum eigenvalue (λmax) is 9.8839, and the CI is 0.1372. The CR is 0.0946, which is below the commonly accepted threshold of 0.10. Thus, it can be concluded that the level of inconsistency in the pairwise comparison matrix is within acceptable limits, indicating that the judgments made during the decision-making process are consistent and reliable.

Table 3. Assessment of priority regarding the criterion C1 and ranking (Ease of use)

	P1	P2	P3	Weights
P1	1	4	2	0,5350
P2	0,25	1	0,33	0,1210
P3	0,5	3	1	0,3439
Sum	1,75	8	3,33	

Here, λ_{max}=3.0255, CI= 0.0127 and CR=0.0245.

Table 4. Assessment of priority regarding the criterion C2 and ranking (Data modeling)

	P1	P2	P3	Weights
P1	1	0,20	0,14	0,0717
P2	5	1	0,33	0,3390
P3	7	3	1	0,5892
Sum	13	4,20	1,47	

It holds λ_{max}=3.10, CI=0.0508 and CR=0.0977.

Table 5. Assessment of priority regarding the criterion C3 and ranking (Authentication & Authorization)

	P1	P2	P3	Weights
P1	1	0,25	0,25	0,1070
P2	4	1	2	0,5
P3	4	0,5	1	0,3928
Sum	9	1,75	3,25	

In this case, λ_{max}=3.08, CI=0.0398 and CR= 0.0766.

Table 6. Assessment of priority regarding the criterion C4 and ranking (Customization & flexibility)

	P1	P2	P3	Weights
P1	1	0,14	0,33	0,0829
P2	7	1	4	0,6772
P3	3	0,25	1	0,2398
Sum	11	1,39	5,33	

The three significant values are λ_{max}=3.038, CI=0.0191 and CR=0.0367.

Table 7. Assessment of priority regarding the criterion C5 and ranking (Integration with external services)

	P1	P2	P3	Weights
P1	1	0,20	0,25	0,0969
P2	5	1	2	0,5351
P3	4	0,50	1	0,3678
Sum	10	1,70	3,25	

Here, λ_{max}= 3.038, CI=0.0191 and CR=0.0367.

Table 8. Assessment of priority regarding the criterion C6 and ranking (Development speed)

	P1	P2	P3	Weights
P1	1	4	2	0,5
P2	0,25	1	0,25	0,1071
P3	0,50	4	1	0,3928
Sum	1,75	9	3,25	

It holds λ_{max}= 3.079, CI=0.0378 and CR= 0.0766.

Table 9. Assessment of priority regarding the criterion C7 and ranking (User experience)

	P1	P2	P3	Weights
P1	1	3	0,17	0,1928
P2	0,33	1	0,11	0,0666
P3	6	9	1	0,7405
Sum	7,33	13	1,28	

In the last case, λ_{max}=3.074, CI=0.0372 and CR=0.0716.

Table 10. Subtotals and chart ranking for best Platform

		Sub for AppSheet		**Sub for PowerApps**		**Sub for Bubble.io**	
		P1	**Weight**	**P2**	**Weight**	**P3**	**Weight**
C1	0,0477	0,535	0,0255	0,121	0,0057	0,3439	0,0164
C2	0,1049	0,0717	0,0075	0,339	0,0355	0,5891	0,0617
C3	0,3452	0,1071	0,0369	0,5	0,1726	0,3928	0,1356
C4	0,1374	0,0829	0,0114	0,677	0,0930	0,2398	0,0329
C5	0,2563	0,0969	0,0248	0,5351	0,1371	0,3678	0,0943
C6	0,0807	0,5	0,0403	0,1071	0,0086	0,3928	0,0317
C7	0,0276	0,1928	0,0053	0,066	0,0018	0,7405	0,0204
Sum			0,1519		**0,4546**		0,3931

Each consistency ratio obtained with the previous computations are smaller than the commonly accepted threshold of 0.10. This means that the level of inconsistency in the pairwise comparison matrices are within acceptable limits, indicating that the judgments made during the decision-making process are consistent and reliable.

From Table 10 and the related chart, we can conclude that the best platform in the development of a blog application utilizing the three platforms is PowerApps.

6 Discussion

The AHP provides a structured approach for evaluating LCNC platforms by allowing both a detailed assessment of individual platform characteristics and an overall ranking based on multiple criteria. This method enables decision-makers to systematically compare platforms such as AppSheet, PowerApps, and Bubble.io by assigning relative importance to different evaluation factors. By leveraging AHP, stakeholders can gain a more holistic understanding of each platform's strengths and weaknesses, ensuring that the selection process aligns with specific project requirements and strategic objectives.

The choice between AppSheet, PowerApps, and Bubble.io is contingent upon a nuanced evaluation of project requirements, organizational priorities, and developer proficiencies. While AppSheet excels in expeditious prototyping and simplicity of use, making it suitable for less complex applications, PowerApps emerges as a good contender for projects necessitating intricate customization and seamless integration with the Microsoft ecosystem. Bubble.io, on the other hand, offers a versatile tool with extensive customization options and a user-friendly interface, making it suitable for a wide range of applications.

Moreover, based on the described features, PowerApps is mainly a B2B (Business to Business), while AppSheet and Bubble.io are B2C (Business to Customer solution). B2B solutions offer users different functionalities such as creation, optimization, and automation of business process activities. In contrast, B2C solutions supply to end customers more direct answers. B2C solutions are typically used to develop single applications such as websites and customer relations management applications. Additionally, the interactivity features of B2C are far more critical than B2B ones (Sahay et al., 2020).

7 Conclusions

In this study, we conducted a comprehensive comparative analysis of three prominent LCNC platforms: AppSheet, PowerApps, and Bubble.io. These platforms have transformed the landscape of application development by offering accessible tools to create sophisticated applications without traditional programming skills. Our evaluation focused on several key dimensions critical to application development, including ease of use, data modeling, authentication and authorization, customization and flexibility, integration with external services, development speed and overall user experience.

AppSheet emerged as a top performer in ease of use, providing an intuitive interface and rapid deployment capabilities suitable for small to medium-sized businesses. It scored well across most dimensions, particularly in ease of learning and development speed, making it a preferred choice for beginners and those needing quick application solutions.

PowerApps excelled in integration with Microsoft services, advanced data modeling, and comprehensive customization options, making it ideal for medium to large enterprises with complex integration needs. Its robust security features and ability to handle intricate data relationships were noteworthy, despite its steeper learning curve.

Bubble.io stood out for its user experience, allowing users to create highly tailored applications. It performed well in integration with external services and provided a user-friendly interface, making it suitable for startups and developers needing powerful web applications without traditional coding.

Based on the performed evaluations of the users, PowerApps resulted as the best platforms. Nevertheless, each platform demonstrated strengths and limitations across the evaluated criteria, which should guide businesses and developers in selecting the most appropriate tool based on their specific requirements. For instance, AppSheet is recommended for rapid prototyping and quick deployment scenarios, whereas PowerApps and Bubble.io are better suited for projects requiring deep integration, advanced customization, and scalability.

In conclusion, the choice of a LCNC platform should align closely with the technical expertise of the development team, the complexity of the application requirements, and the organization's strategic objectives.

While the present study evaluates platforms using AHP, future research could expand on this approach by incorporating alternative decision-making models, such as the Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) or fuzzy AHP, to refine and validate the comparative analysis. Additionally, exploring the long-term maintainability and cost implications of LCNC solutions in enterprise settings could provide deeper insights into their viability for large-scale deployments.

Finally, as LCNC platforms continue to evolve, future studies should investigate how artificial intelligence and automation are further shaping their capabilities. The integration of AI-driven code generation, natural language processing, and automated workflow optimization could redefine the competitive landscape and expand the potential applications of these platforms beyond their current scope.

8 Ethics declaration

This research involves interviews with PhD students. All participants were informed about the purpose of the study and gave their voluntary consent to participate. No personal or identifiable data were collected or published. The data are presented in aggregated form only.

9 AI declaration

No AI tools were used for the creation of the paper.

Thriving Through Digital Change: Building Resilient, Adaptive and Sustainable Organizations

Alessia Anna Catalano[1], Christian Catalano[2], Andrea Chezzi[1], Vito Del Vecchio[1]
[1]University of Salento, Lecce, Italy
[2]University of Bari Aldo Moro, Bari, Italy

Abstract

In today's complex environments, organizations increasingly rely on their ability to manage change and build resilience to sustain long-term competitiveness. This phenomenon is particularly evident in high technological intensive companies dealing with frequent changes due to digitalization and technological disruptions. Through a Systematic Literature Review this study investigates the interconnections between change management, individual resilience, and organizational resilience, with the aims to identify theoretical models and key constructs shaping the complexity of business organizations when approaching to change processes. Based on the analysis of 46 peer-reviewed journal articles published between 2007 and 2025, findings reveal that individual resilience – defined as the psychological capacity to cope with, adapt and recover from adversity – plays a pivotal role in shaping employee responses to organizational change. Transformational leadership and resilient organizational cultures act as enablers, reinforcing individual capabilities and translating them into collective adaptive capacity.

Several studies draw on theoretical perspectives such as dynamic capabilities, psychological capital, and the resource-based view, suggesting that resilience is not a static attribute but a dynamic, multilevel process involving learning, improvisation, and innovation. Despite growing scholarly attention, the literature remains fragmented, with limited longitudinal designs and scarce integration across micro, and macro levels.

To address these limitations, on top of the literature, the study introduces a conceptual model that links individual resilience to organizational resilience through change management processes, in which leadership and culture represent key enablers. This model offers a strategic lens to understand how individual psychological resources can be leveraged to support organizational transformation and long-term sustainability in volatile and knowledge-intensive contexts. This study also highlights the importance of connecting human dynamics with organizational agility and encourages future interdisciplinary research on multilevel resilience as a knowledge-based capability to enable adaptive and sustainable change.

Keywords: Change Management, Innovation Management, Organizational Resilience, Individual Resilience

Paper type: Academic Research Paper

1 Introduction

In the current socio-economic landscape, characterised by rapid change and uncertainty, organizations need to adapt quickly to effectively address both strategic and operational challenges and to maintain their competitiveness (Trenerry et al., 2021). The digital transformation, involving the evolution of both methodological and technological maturity, represents important examples of challenges companies are called to face. According to Bauman's (2013) notion of "liquid modernity", contemporary societies are marked by fluidity, making uncertainty a permanent condition. In such contexts, individuals and organizations must develop resilience to continuously shape their identities and turn challenges into opportunities.

Change management plays a strategic role, acting as a catalyst for organizational innovation (By, 2005). It offers structured frameworks to guide transitions toward new organizational configurations, overcome resistance to change, and ensure that transformations are aligned with strategic objectives (Schäffer, 2020). Effective change management significantly contributes to the development of organizational resilience, enhancing the ability to respond to crises and disruptions while fostering long-term sustainability.

Resilience, both at the organizational and individual level, emerges as a key capability for dealing with uncertainty, serving as a pillar of sustainable development (Linnenluecke, 2017). It is not a reactive measure, but a proactive approach that involves anticipating disruptions, developing robust response mechanisms and cultivating a culture of adaptability and innovation (Quendler, 2017). Organizational resilience, in this view, requires a holistic perspective that integrates elements such as leadership, communication, and collaboration.

The interplay between change management, organizational resilience, and individual resilience is increasingly emphasized in the literature (Botti & Baldi, 2025). While the former encompasses the processes and tools used to implement organizational transformations (McManus et al., 2007), organizational resilience refers to the institution's ability to withstand, adapt, and recover from crises. On the other hand, individual resilience denotes the capacity of a person to cope with adversity, stress, or trauma (Xiao & Cao, 2017). Understanding

how these three concepts interact each other is crucial to sustain innovation and long-term success in dynamic contexts. A key element of this relationship is the Psychological Capital (PsyCap), a positive psychological state characterised by self-efficacy, optimism, hope and resilience (Luthans et al., 2006). These resources enhance individuals' ability to actively contribute to change initiatives (Toor & Ofori, 2010). Therefore, promoting individual resilience within organizational systems becomes a driving resource for navigating complexity and change, for instance in high technological intensity contexts (Helfat & Martin, 2015).

Organizational resilience has been conceptualized in the literature diverse ways, such as a capacity, process, characteristic, or an outcome (Hillmann & Guenther, 2021). Dynamic perspectives describe the organizational resilience as a transformative process that links adaptive capacities to positive evolution post-crisis (Sutcliffe & Vogus, 2003), allowing organizations not only to withstand shocks but also to improve strategically in the long term (Akgün & Keskin, 2014). Furthermore, organizational resilience is closely linked to innovation management, understood as the ability to create and implement value-generating ideas, products, or processes (Dawson, 2017). Innovative organizations are generally more resilient (de Oliveira Teixeira & Werther, 2013), as they develop flexible structures, learn from failures, and anticipate future changes such as greener practices. In this regard, change management supports transitions by helping teams and organizations move from the current to the desired state, facilitating adaptation and reducing resistance to change.

Recent studies (e.g., Modransky et al., 2020) highlight how change management factors such as employee participation and effective communication significantly influence both innovative behaviour and organizational resilience. Consequently, managing change effectively is critical to supporting adaptability, sustainability, and responsiveness to external and unexpected events.

Transformational leadership, employee engagement, the integration of diverse knowledge fields (Rumbles & Rees, 2013; Ritala, 2013), and the alignment between strategy and change culture (Ates & Bititci, 2011) are enabling factors that reinforce the virtuous cycle between change and resilience.

Despite extensive research studies have been provided in literature, there is the lack of an integrated view on how individual resilience acts as a strategic mediator for organizational adaptability and innovation, particularly in technological transitions. Interdependence among these factors is often overlooked considering the fragmented effort of scholars in exploring them.

This study hypothesizes that individual resilience functions as an enabling and mediating factor in change management processes, significantly contributing to the development of organizational resilience and innovative capacity of organizations. Accordingly, through a Systematic Literature Review (SLR), the study intends to collect valuable insights for reconstructing the relationship between change management, innovation, and both individual and organizational resilience. Therefore, the study aims to i) critically map and synthesize the existing research connecting these key topics, ii) identify theoretical models, constructs, and key variables surrounding the existing literature, and iii) highlight conceptual and empirical gaps in the current literature. Finally, the study proposes an integrated conceptual framework illustrating how change management is linked with individual resilience for supporting organizational transformation and long-term sustainability in complex and uncertain contexts.

2 Methodology

This study investigates the relationship between change management, organizational resilience, and individual resilience, with an emphasis on their role in supporting innovative and sustainable transformation in technological environments. The paper is grounded on a Systematic Literature Review (SLR), which is a methodological approach ensuring the research follows a rigorous, transparent, and replicable process (Tranfield et al., 2003). The systematic approach enables an unbiased integration of diverse contributions from technology management, psychology, and innovation studies. Following a four-phase protocol (Corallo et al., 2021) (i.e., review planning, execution, analysis, and reporting), the study applies clearly defined criteria for scientific studies selection and analysis. This structured process allowed for building a knowledge base of reference including key frameworks and constructs referred to the key topics of analysis. The results have been converged in a novel conceptual framework which highlights opportunities for future interdisciplinary research in resilience and change management. The framework presents an integrated view of change management, organizational and individual resilience fostering business innovation and long-term sustainability.

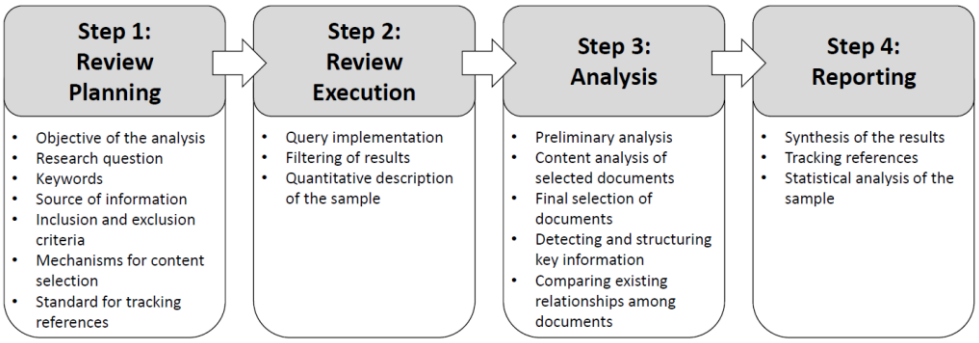

Figure 1. SLR protocol (Corallo et al., 2021)

Step 1: Review Planning – As stated before, the study aims to highlight the intricate complexity of change management when dealing with organizational and individual resilience, with a focus on digital transformation and sustainable development. Indeed, the study aims to provide an answer to the following research question: how change management is linked with both organizational and individual resilience for ensuring long-term innovation and sustainable business?

The scientific electronic database Scopus (www.scopus.com) was used by designing a specific query based on reliable keywords and selection criteria. Peer-reviewed articles written in English in the fields of management, engineering, psychology and social sciences were selected. Qualitative content analysis guided the construction of a conceptual map useful for future research and organizational practice.

Step 2: Review Execution – This phase was mainly based on implementing the designed query in Scopus. The query was strategically formulated using Boolean operators to comprehensively capture the academic literature relevant to change management and both organizational and individual resilience. The specific query used was the following:

("change management" OR "innovation management" OR "technology management") AND ("organizational resilience" OR "individual resilience").

The initial search, conducted in January 2025, retrieved 184 papers. Subsequently, a two-stage filtering process was applied: language filtering, which included only those articles in English, and subject areas filtering, which included article published in the fields of economics, management, engineering, social sciences and psychology.

This process resulted in a final sample of 123 peer-reviewed articles published between 2005 and 2025, which were following analysed and synthesised.

Step 3: Analysis – A preliminary screening based on titles and abstracts refined the sample to 46 highly pertinent articles, selected for their empirical and theoretical contributions providing an understanding of the relationship between change management, organizational resilience, and individual resilience, especially in contexts of technological innovation and uncertainty.

After that, a structured qualitative content analysis was conducted, confirming the relevance of all 46 papers. An Excel matrix was used to categorize key information such as bibliographic data, methodological features, research objectives, findings, and themes related to mediating/enabling factors. This structured approach facilitated the identification of common patterns, theoretical insights, and knowledge gaps, setting the stage for a comprehensive understanding of the topic of analysis and directions for future research.

Step 4: Reporting – This concluding phase serves to highlight the main findings from the SLR, which together constitute the current body of knowledge on the topics. A structured representation of the conceptual contributions relevant to the research objective was provided, offering critical insights that support a deeper understanding of the research question. Based on these insights the a novel framework has been developed for a comprehensive understanding of the integrated relationship between change management and resilience.

3 State of Art

Based on the analysis of the 46 scientific contributions, a rich and multidimensional understanding of the phenomenon of analysis was elaborated. These studies reflect a growing theoretical and practical maturity on the topics, while highlighting critical gaps and areas for future investigation. First and foremost, individual resilience clearly emerges as a key enabler of successful organizational change processes. The psychological resilience of employees and leaders is recognized as a crucial factor that can either facilitate or hinder organizational transformation in technological environments. Individuals with strong psychological resilience

tend to adapt more effectively to new procedures, roles, and technologies, exhibiting greater behavioural flexibility and less resistance to change. Empirical evidence consistently demonstrates that psychological resources, such as self-efficacy, optimism, hope, and resilience, collectively referred to as psychological capital (Luthans et al., 2006), play a pivotal role in facilitating individual adaptation to organizational transformation (Petrou et al., 2015; Lan et al., 2025; Kareem et al., 2025).

Subjective perceptions of fairness in change processes, the quality of internal communication, and participatory involvement act as moderating factors in mitigating the emotional impact of change. These elements contribute to reduced anxiety and ambiguity while strengthening employee engagement and trust in the organization. Such conditions foster the emergence of proactive behaviours such as job crafting, the self-initiated reconfiguration of tasks and roles in response to change, which is recognized as a marker of adaptive and active resilience (Petrou et al., 2015; Rumbles & Rees, 2013).

Concurrently, an expanding body of research highlights the critical role of transformational leadership and an open, inclusive organizational culture in activating resilience at both the individual and collective levels. Transformational leadership, defined as a leadership style that inspires and motivates followers through a shared vision, intellectual stimulation, and individualized consideration (Bass & Avolio, 1994), proves to be particularly effective in fostering trust, commitment, and adaptability in contexts of change. Likewise, organizational culture, understood as the shared set of values, norms, and practices that guide behavior within the organization (Schein, 1992), acts as a fundamental enabler in facilitating the assimilation of change and the diffusion of resilience.

In complex and unstable environments such as those in the ICT (Information and Communication Technology), tourism, healthcare, and industrial sectors, the presence of leadership capable of articulating a clear vision, inspiring trust, and actively supporting staff during critical phases is decisive in enhancing individual psychological resources and channelling them toward the construction of widespread organizational resilience (Greenfield, 2007; Tkaczyk, 2015; Van der Voet, 2014; Ferrigno et al., 2021; Wang et al., 2024; Ortiz-de-Mandojana & Bansal, 2016; Casalino et al., 2019; Ates & Bititci, 2011). This effect is particularly evident in high-turbulence environments, where the virtuous interaction between strategic agility and the alignment of individual behaviours with organizational direction becomes essential not only for survival but also for the organization's continuous and sustainable capacity for innovation.

From a theoretical standpoint, recent literature has progressively adopted integrative approaches to explain how organizations can develop and reinforce their resilience over time. Among the most consolidated references is the dynamic capabilities framework (Duchek, 2020), which conceptualizes resilience as the organization's ability to perceive environmental changes, learn from them, and promptly reconfigure its resources and operational routines. This approach, strongly oriented toward strategic agility, emphasizes the processual and transformative nature of resilience. In parallel, the Resource-Based View (RBV) offers a perspective focused on internal resources, asserting that resilience derives from the organization's capacity to leverage both tangible and intangible resources, such as human capital, internal relationships, culture, and know-how, to achieve sustainable competitive advantage. This view is extended through theories of organizational ambidexterity, which propose that resilient organizations are those capable of simultaneously balancing the exploitation of existing capabilities with the exploration of new opportunities, even in conditions of uncertainty and disruption.

Among emerging contributions, the ADREKA framework (Buildings, 2024) stands out for its integration of cognitive, relational, and behavioral dimensions in organizational responses to technological change. This model highlights that resilience does not develop spontaneously but requires intentional processes of learning, empowerment, and the strengthening of internal networks, with particular attention to distributed leadership and the management of social capital.

In this perspective, organizational resilience can no longer be understood as a static or reactive capacity, but rather as a dynamic and adaptive process unfolding through iterative cycles of learning, response, experimentation, and transformation (Ritala, 2013; Alblas & Jayaram, 2015; de Oliveira Teixeira & Werther, 2013; Dawson, 2017; Sun et al., 2011). Thus, organizational change becomes not merely a source of risk but a strategic lever for systemic strengthening, provided that it is accompanied by strategic investment in human, relational, and cognitive capital.

Equally relevant are contributions exploring resilience and innovation in high-impact social and cultural contexts, such as GLAM institutions. These studies introduce the Business Model Innovation 5.0 drawing inspiration from the Industry 5.0 paradigm, which identifies key drivers such as stakeholder and community engagement, collaborative knowledge management, and integrated sustainability (economic, social, and environmental). These drivers are further supported by infrastructural enablers such as technology, resources, and leadership, capable of fostering resilient and transformative innovation even in traditionally low-digitalization sectors.

Nevertheless, the literature continues to show several conceptual and empirical gaps. Insufficient multilevel integration can be observed, with few studies systematically linking individual (micro), team (meso), and organizational (macro) resilience, underscoring the need for more systematic and longitudinal investigations (Van der Voet, 2014; Greenfield, 2007; Ferrigno et al., 2021). Furthermore, the measurement of resilience remains heterogeneous and often reliant on non-standardized qualitative tools, which limits the comparability of results (Hillmann & Guenther, 2021; Lengnick-Hall et al., 2011). Finally, the prevailing focus on acute crises (e.g., pandemics, technological failures) has overshadowed the exploration of resilience as an enabler of incremental or proactive transformation in chronically unstable conditions (Casalino et al., 2019; Modransky et al., 2020).

4 Discussion

Based on the literature findings, an integrated conceptual framework is proposed to comprehensively explain how change management is linked to organisational and individual resilience to ensure innovation and long-term sustainability in organisations. Individual resilience acts as an enabling resource for change management processes, together with transformational leadership and an open and resilient organisational culture, which collectively shape the environment in technology-intensive contexts. These processes, through effective change management, nurture dynamic organisational resilience, understood as a collective ability to learn, adapt, and regenerate, and thus constitute a prerequisite for long-term organisational sustainability, which includes not only economic and environmental dimensions, but also relational and cognitive aspects (Lv et al., 2018; Helfat & Martin, 2015; Linnenluecke, 2017; Stephenson, 2010; Sutcliffe & Vogus, 2003; Akgün & Keskin, 2014).

The elaboration of the framework represents one of the most important outcomes based on the literature. The integrated framework synthesizes the relationships among the key constructs of this study and outlines a trajectory from individual resilience to long-term organisational sustainability.

At the core of the model lies change management, supported by three fundamental pillars. On one hand, individual resilience, conceptualised through psychological capital comprising self-efficacy, optimism, hope, and resilience, enables proactive adaptation. On the other hand, transformational leadership and an open, innovation-oriented organisational culture ensure strategic coherence and support for value-driven processes.

Individual resilience plays a central role in supporting change management and is nurtured by the development of psychological capital, defined as the cognitive and emotional resources that enable individuals to cope effectively with change. Transformational leadership, combined with an open and inclusive organisational culture, reinforces this dynamic by creating organisational conditions that foster adaptation and learning through trust, shared vision, and common values.

These fundamental dimensions support change management processes, which should be guided by key values such as clear communication, fairness in decision-making, and active employee engagement. However, the effectiveness of these values largely depends on the presence of specific enabling and moderating factors embedded in the organisation's daily functioning. In particular, factors such as the subjective perception of fairness, the quality of internal communication, and the participatory involvement of individuals within the organisation play a crucial role in strengthening and reinforcing these guiding values.

These factors act as moderators of employees' emotional responses to organisational transformation, helping to mitigate anxiety, stress, and ambiguity that typically arise during change processes. When employees perceive fairness, are well-informed, and feel actively involved, they are more likely to develop organisational trust, show greater engagement, and demonstrate a more open and proactive attitude towards change.

Under such favourable conditions, adaptive and participatory behaviours such as job crafting are more likely to emerge. Job crafting refers to the ability of employees to proactively reshape their roles and tasks in response to evolving organisational demands (Petrou et al., 2015). This type of behaviour is considered a concrete indicator of adaptive and active resilience. While job crafting and perceived equity are often conceptualised as drivers of effective change management, the present framework also hypothesises that they may emerge as outcomes of successful transformation processes. From this perspective, organisational change is not only based on these values but can also generate and reinforce them over time, creating a virtuous cycle that contributes to the development of both individual and collective resilience.

When these processes are effectively managed, they lead to the development of dynamic organisational resilience, which represents the organisation's collective ability to learn, adapt to external changes, and regenerate in response to new challenges. Organisational resilience is grounded in well-established theoretical frameworks, including dynamic capabilities theory, the resource-based view (RBV), organisational ambidexterity, and the ADREKA framework, all of which contribute to explaining resilience as an organisational

competence built over time through learning, strategic reconfiguration, and empowerment processes (Duchek, 2020; Buildings, 2024).

An important feature of the framework is the recognition of the reciprocal and mutually reinforcing relationship between individual and organisational resilience. While individual resilience enables and supports adaptive organisational processes, a resilient organisational environment characterised by trust, strategic coherence, and opportunities for growth, in turn, strengthens the psychological capital and adaptive capacities of individuals. This reciprocal dynamic creates a virtuous cycle, whereby individual and organisational resilience evolve and amplify each other over time, increasing the overall organisational capability to navigate change.

Ultimately, dynamic organisational resilience is presented as a necessary precondition for achieving long-term sustainability across economic, social, environmental, relational, and cognitive dimensions. This comprehensive view of sustainability enables organisations not merely to survive but to grow, innovate, and thrive over time in increasingly complex environments.

In this regard, the proposed framework offers a robust conceptual and operational basis for future empirical research, particularly through longitudinal and multilevel approaches, aimed at exploring and validating the causal trajectories that connect individual, intermediate, and systemic levels within sustainable transformation processes.

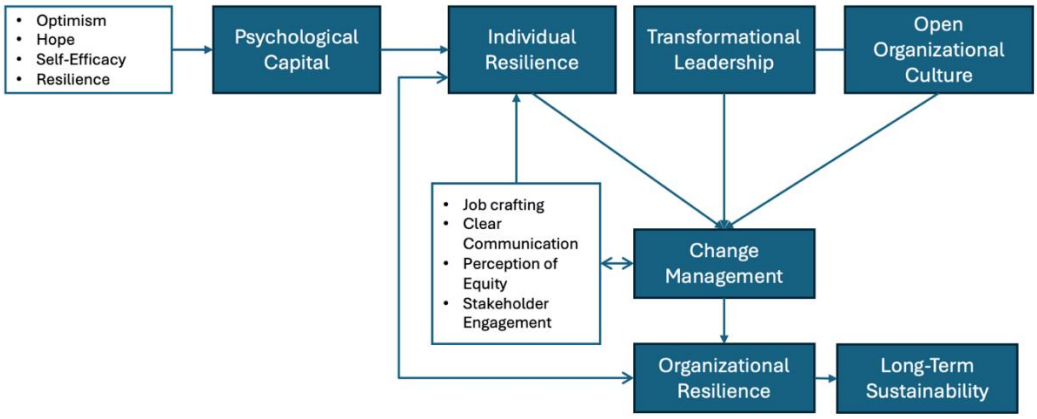

Figure 2. Conceptual framework of resilience-driven change management

5 Conclusion

This study explored the current state of the art concerning the relationship between change management, organisational and individual resilience, and proposed an integrated conceptual framework highlighting the enabling role of psychological capital and transformational leadership in supporting adaptive organisational processes. The novelty of this study lies in its comprehensive understanding of these themes, which in previous research have often been addressed in isolation, confined within their respective disciplinary boundaries.

First, multilevel integration remains largely underdeveloped. Although the literature recognises the relevance of both micro (individual) and macro (organisational) levels in the development of resilience, few studies provide robust theoretical frameworks or empirical evidence capable of systematically linking these dimensions. As a result, the dynamic interactions that shape resilience across organisational levels are often fragmented, limiting our understanding of how individual attitudes and capabilities translate into collective resilience.

A further critical gap in the literature concerns the limited attention devoted to the meso level, understood as team-level resilience. This intermediate layer represents a vital link between individual and organisational resilience, yet it is rarely explored in a structured or theoretical way. Addressing this gap would allow researchers to examine how teams respond to and manage change, how they share resilient behaviours and resources, and how they contribute to the emergence of coordinated and sustainable adaptive capacity at higher organisational levels.

Second, the measurement of resilience remains unstandardised. The widespread use of qualitative tools, often developed ad hoc, hampers the comparability of results and the accumulation of robust empirical evidence. Furthermore, much of the existing literature remains anchored to acute crisis scenarios, failing to address resilience as a strategic capability that enables long-term adaptation and sustainability in transformative contexts such as those driven by technology.

In this context, a decisive shift is needed from a multidisciplinary to an interdisciplinary research paradigm. While multidisciplinary approaches have contributed valuable insights from fields such as management studies, organisational psychology, economics, and sociology, they have not yet fostered the epistemological and methodological integration required to fully grasp the complexity of resilience-building processes. Future research should therefore adopt an interdisciplinary approach that combines management engineering, organisational psychology, economics, and the social sciences to develop actionable models of resilience.

The findings of this study yield several practical implications for practitioners, managers, and policymakers involved in the design and implementation of change initiatives within complex organisational contexts. Firstly, the proposed conceptual model underscores the strategic relevance of individual resilience as a key factor in effective change management. Organisations are thus encouraged to invest in developing employees' psychological capital, enhancing self-efficacy, optimism, hope, and psychological resilience, through targeted interventions such as training programmes, coaching, and psychosocial support mechanisms. Secondly, the study highlights the critical role of transformational leadership and an open and inclusive organisational culture in creating psychologically safe environments that support continuous learning and innovation. These enabling conditions not only facilitate the adoption of change but also strengthen the connection between individual motivation and collective adaptation, promoting proactive behaviours such as job crafting and collaborative problem-solving. Lastly, the integrated framework presented here can serve as an operational tool for organisational diagnosis, helping decision-makers assess change readiness, identify internal barriers and enabling factors, and design multilevel resilience strategies. This approach is particularly relevant in high-volatility sectors, such as technology-intensive industrial organisations, where the ability to continuously learn, adapt, and regenerate is increasingly essential to achieving long-term organisational sustainability.

Nevertheless, this paper presents certain limitations that point towards directions for future research. One of the most significant relates to the qualitative approach adopted to construct the knowledge base and develop the conceptual framework. Moreover, the framework is grounded in theoretical perspectives and has not yet been validated in real and complex organisational settings. Future studies could therefore adopt quantitative approaches not only to confirm or refute the existence of relationships among the framework's variables, but also to investigate the directionality and causal pathways of these relationships, in order to better understand the underlying dynamics that structure organisational resilience. In addition, future literature reviews might benefit from expanding the scientific evidence base by consulting other relevant academic databases, thereby ensuring broader coverage and reducing selection bias. Finally, complementary studies adopting interdisciplinary approaches alongside multidisciplinary ones are strongly recommended, with particular emphasis on addressing the meso level—understood as team-level resilience—as an essential yet underexplored dimension in resilience analysis.

6 Ethics Declaration

This study was conducted in accordance with high ethical standards and principles. The authors affirm adherence to ethical guidelines ensuring transparency, objectivity, and integrity throughout the research process. The systematic literature review presented does not involve any direct data collection from individuals or sensitive personal data handling. All sourced publications have been appropriately cited, respecting intellectual property and copyright.

No conflicts of interest have been identified in relation to this research. The authors declare that this paper is original, unpublished elsewhere, and does not contain any plagiarism or self-plagiarism.

7 AI Declaration

This research did not directly utilize Artificial Intelligence (AI) technologies or generative AI systems for the formulation, execution, or analysis of results. The systematic review and conceptual model presented are entirely derived from manual and traditional literature review methods.

However, the authors recognize the importance of AI and digital tools in advancing knowledge management practices and recommend future research explore integrating AI technologies for deeper insights and enhanced analytical capabilities in resilience and change management research.

Measuring Innovation in Large ICT Firms: A Bibliometric Analysis

Vito del Vecchio[1], Mariangela Lazoi[1], Fabio Paracchini[2], Giorgia Specchia[1]
[1]University of Salento, Lecce, Italy
[2]Altea Federation, Milan, Italy

Abstract

Innovation measurement remains a persistent challenge for organizations, especially in fast-evolving and complex sectors like ICT and IT, where traditional evaluation models struggle to capture the dynamic and intangible nature of innovation. Despite the abundance of proposed metrics and frameworks, the field remains fragmented, lacking a unified theoretical foundation and consistent methodological standards. This study addresses these gaps through a bibliometric analysis of 688 peer-reviewed articles published between 2001 and 2025, retrieved from Scopus and Web of Science. The analysis explores the evolution of scholarly production, identifies the intellectual roots of the field, such as the Resource-Based View, Dynamic Capabilities, and Absorptive Capacity, and maps the conceptual structure around key themes including open innovation, green and sustainable innovation, human capital, and knowledge management. The findings reveal a growing but dispersed research landscape, characterized by weak citation networks and parallel, often disconnected, research trajectories. Beyond describing the structural properties of the field, the study highlights the emergence of distinct thematic clusters aligned with different strategic and organizational perspectives. While this diversity reflects the complexity of innovation itself, it also underscores the need for more integrative and context-sensitive approaches to innovation measurement. By offering a comprehensive and data-driven overview of the literature, this study lays the groundwork for a forthcoming systematic literature review aimed at consolidating existing knowledge and supporting the development of robust, multidimensional frameworks. The results offer theoretical insights for advancing the field and practical implications for managers and policymakers seeking more effective tools to evaluate and guide innovation efforts.

Keywords: Innovation, Innovation metrics, Measure, Bibliometric analysis

Paper type: Academic Research Paper

1 Introduction

In a rapidly evolving and competitive global landscape, organizations are under increasing pressure to innovate in order to remain relevant and achieve sustainable growth (Bolaji Bello and Adeoye, 2018). Yet, innovation is not a linear process - it is inherently uncertain and difficult to measure (Fanousse et al., 2021; Jalonen, 2011). Unlike traditional business functions that benefit from standardized performance indicators, innovation is deeply tied to creativity, experimentation, and risk-taking, making its evaluation particularly challenging (Adams et al., 2006).

Innovation encompasses both the ideation of novel products, services, processes, or business models, and their successful implementation within volatile markets (Kerzner, 2022). This dual nature amplifies the complexity of assessing the effectiveness and outcomes of innovation projects. While management literature offers numerous frameworks to guide firms through VUCA (Volatility, Uncertainty, Complexity, Ambiguity) conditions (Ngo et al., 2022), the absence of consolidated, systematic methodologies for measuring innovation remains a critical gap (Idris and Durmuşoğlu, 2021).

Despite the proliferation of indicators - ranging from R&D investment and time-to-market to idea-generation programs and employee rewards - most metrics either neglect the human dimension of innovation or fail to capture the broader organizational context in which it occurs (Moreira et al., 2024). Others, instead, focus solely on perceptions and soft dimensions, offering limited insight into measurable outcomes (Ngo et al., 2022). Moreover, human and financial aspects are frequently examined in isolation, despite their strong interdependence in shaping innovative performance (Fonseca et al., 2019; Sun et al., 2020).

A further source of concern is the high failure rate of innovation initiatives. According to (Cooper, 2019), only one out of every 7–10 innovation projects achieves commercial success, with nearly 40% failing at launch. This striking statistic underscores the need to critically reassess how innovation is measured and whether the metrics currently adopted by organizations are adequate for capturing its true impact.

This paper seeks to address this gap by offering a critical overview of the metrics used in the evaluation of innovation initiatives. Through a bibliometric analysis of literature retrieved from Scopus and Web of Science databases, the study aims to: highlight the limitations and areas of fragmentation of the key metrics currently used in both academic and business contexts, and uncover the intellectual and thematic foundations that underpin the field of innovation measurement.

By doing so, the paper provides an initial mapping of the field, which will serve as a foundation for a forthcoming systematic literature review (SLR) aimed at developing a comprehensive and actionable framework of innovation metrics.

The paper is structured as follow: Section 2 reviews the existing literature on innovation measurement; Section 3 describes the bibliometric methodology and data collection process; Section 4 presents and interprets the results; Section 5 discusses concludes the study with the practical implications, limitations, and directions for future research.

2 Related works

Innovation is widely recognized as a key driver of competitive advantage. It is generally defined as the implementation of new or significantly improved products, processes, marketing methods, or organizational practices aimed at creating value (Chirichiello et al., 2023). (Rogers, 2003) highlights the subjective dimension of innovation, defining it as "an idea, practice, or object perceived as new by an individual or other unit of adoption." Over the years, innovation has evolved from being seen as an internal, linear process to a more dynamic and open one. (Chesbrough, 2003) introduced the concept of Open Innovation, emphasizing the importance of knowledge flows across organizational boundaries to accelerate innovation and increase its impact.

Commonly used metrics include R&D expenditure, number of patents, time-to-market, and new product revenues (Adams et al., 2006; Cooper, 2019). These indicators, however, often focus on tangible outputs and overlook the complexity of innovation as a socially constructed, context-dependent phenomenon (Edison et al., 2013). A distinction is often made between input metrics (e.g., investment, resources), process metrics (e.g., idea generation, collaboration), and output metrics (e.g., revenue, customer satisfaction). Yet, many of these are rooted in linear innovation models, which do not fully reflect the iterative and uncertain nature of innovation in contemporary settings (Manimala et al., 2005).

Several authors have highlighted the limitations of existing approaches. For example, (Edison et al., 2013) criticize the lack of empirical validation and practical applicability of many proposed metrics. (Ngo et al., 2022) emphasize that innovation cannot be adequately measured without integrating organizational culture, employee engagement, and learning capacity. Meanwhile, (Moreira et al., 2024) point out that innovation performance is strongly affected by sectoral and organizational specificities, making cross-comparison problematic. Some contributions attempt to broaden the scope by including human-centric dimensions such as knowledge flows, cognitive diversity, and leadership style (Fonseca et al., 2019). Others adopt a more strategic perspective, linking innovation measurement to value creation, market positioning, or dynamic capabilities (Teece et al., 1997). Still, a comprehensive and widely adopted framework is lacking.

3 Methodology

This study adopts an advanced bibliometric approach, combining well-established practices from the relevant literature (Donthu et al., 2021; Marzi et al., 2025) with original procedures for data cleaning, normalization, and integration, inspired by recent methods for merging heterogeneous databases (Caputo and Kargina, 2022).

The entire methodological process - integrating automated analytical tools with targeted corrective actions - was designed to maximize the quality, consistency, and replicability of the study, thereby providing a solid foundation for future theoretical and empirical research in the field of human competencies and data-driven transformation.

3.1 Explorative and definition phase

The initial phase of the study consisted of an exploratory literature review aimed at outlining the theoretical foundations of the research context. During this stage, the concept of innovation was examined in depth, and the scope of the investigation was defined. Specifically, the decision was made to focus on the tracking and evaluation of innovation within large enterprises operating in the IT and ICT sectors. The guiding question of this study is: *What are the metrics and/or KPIs used in large companies operating in the ICT sector to quantify and measure the impact of innovation on the organization?*

Once the research scope was established, it was possible to identify the relevant keywords for building a structured query to search the Scopus and Web of Science databases. The objective was to retrieve a corpus of publications that would reflect the current state of the art on the issue raised by the research question. The query employed was as follows:

TITLE-ABS-KEY(("Innovation") W/0 ("project" OR "manag" OR "performance" OR "effectiveness" OR "strateg") AND ("ICT" OR "IT" OR "Information Communications Technolog" OR "Information Technolog*") AND ("KPI" OR "metric*" OR "measur*" OR "quatif*" OR "evaluat*" OR "assess*" OR "maturity") AND NOT ("small medium entreprise*" OR "SME")).*

The search was restricted to English-language publications and to peer-reviewed journal and conference articles, to ensure a higher level of data quality. The databases were queried in April 2025, yielding 491 documents from Scopus and 301 from Web of Science.

3.2 Data extraction and preparation

Once the search strategy was defined, bibliographic files in *.bib* format were downloaded from Scopus and Web of Science, then converted to *.xlsx* using the Bibliometrix package in R. This initial manipulation enabled data format standardization, but also revealed significant discrepancies due to internal encoding errors in Scopus, such as duplicated values in descriptive fields.

To identify these anomalies, a systematic comparison was conducted between the original Scopus dataset and the Bibliometrix-generated version. Subsequently, a dedicated Python script was used to re-encode Scopus references according to the Web of Science standard. However, in cases involving non-English records or incomplete fields, the script proved ineffective. In such cases, manual correction was performed, assisted by a generative language model (GPT-4o), to ensure consistent reference formatting.

After reintegrating data partially excluded by the automated process, the two datasets were merged. Following the merger, duplicate entries were removed, resulting in a corpus of 688 documents.

3.3 Bibliometric analysis

Bibliometric analysis was chosen as it is a rigorous quantitative method used to explore and analyse large volumes of scientific data. It enables researchers to trace the evolutionary nuances of a specific field and to identify emerging areas of inquiry. This method is particularly effective when the scope of the review is broad and the dataset too extensive for manual analysis. Bibliometric analysis employs quantitative techniques such as performance analysis and science mapping to examine the contributions of research components and the relationships among them. It represents a powerful tool for deciphering and mapping cumulative scientific knowledge, providing a solid foundation for advancing established research domains in meaningful and innovative ways (Donthu et al., 2021). Various software tools are available for conducting bibliometric analyses, including Gephi, Leximancer, and VOSviewer. In this study, we used the Bibliometrix package for R.

The analysis was carried out on three main levels. First, a descriptive analysis was conducted, which included the temporal distribution of documents, global and local citation frequencies, keyword analysis, dominant affiliations, and the identification of the most productive and most cited authors. Bradford's Law and Lotka's Law were applied to assess the distribution of scientific productivity. Next, attention was given to the conceptual structure of the literature, analysed through factorial analysis (correspondence analysis) and co-occurrence networks. Finally, to explore the intellectual structure of the field, a co-citation network and a historiographic mapping were produced, with the aim of highlighting foundational works and tracing the historical trajectories of research in the domain of innovation measurement.

4 Results and discussion

This section presents and interprets the main findings of the bibliometric analysis conducted on a corpus of 688 scientific articles focused on the measurement of innovation impact within large corporations. The analysis pursues a dual objective: on one hand, to describe the quantitative and qualitative evolution of scholarly production in the selected domain; on the other, to reconstruct the intellectual and conceptual structures that underpin its theoretical development. The results are organized into three analytical dimensions: (i) Descriptive analysis, which provides an overview of the corpus' general characteristics; (ii) Intellectual structure, which identifies the theoretical foundations and most influential contributions; (iii) Conceptual structure, which explores the thematic organization and the evolutionary trajectory of key topics in the field.

The integration of quantitative techniques with theoretical interpretation allows for a robust and replicable mapping of the state of the art, shedding light on both consolidated knowledge and emerging trends in the domain of innovation measurement.

4.1 Descriptive analysis

The documents in the dataset span a time period from 2001 to 2025. An analysis of the annual scientific production (Figure 1, line blue) reveals notable increases in publication volume during two distinct intervals: 2017–2019 and 2021–2023. These surges may reflect a growing interest in the measurement of innovation performance within large corporations, particularly in response to the acceleration of digital transformation and the need for strategic evaluation tools in the ICT sector.

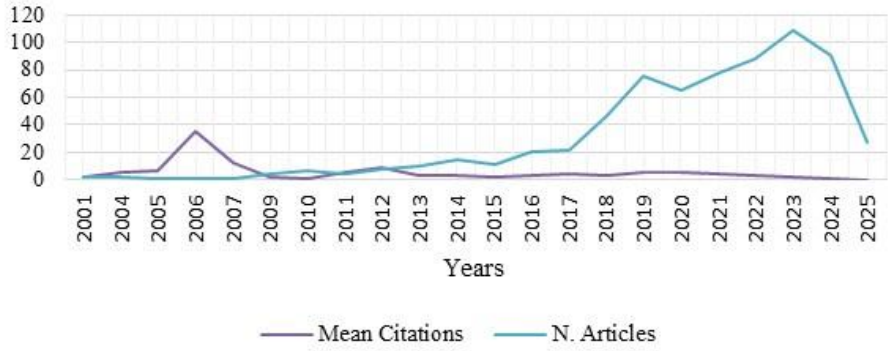

Figure 1 Annual scientific production and annual mean citations

The documents in the dataset exhibit an average of 23 citations per publication. An examination of the temporal distribution of average citations per year (Figure 1, line purple) reveals a pattern marked by several prominent peaks. These citation spikes suggest that, in specific years, foundational or highly influential papers were published, which have significantly shaped the intellectual development of the field under investigation.

A comparison of the temporal trends in publication volume and citation frequency reveals two distinct patterns of scientific output. In the first decade (2001–2010), publication volume remained relatively stable, yet the presence of multiple citation peaks suggests the production of high-impact contributions. In contrast, the most recent years show a sharp increase in the number of publications, accompanied by a decrease in average citations per article. Several factors may account for this shift:

- As the number of papers has increased, the topic has become more specialized, leading to the publication of narrower studies with a more limited readership and, consequently, fewer citations;
- More recent papers may have had less time to gain visibility and accumulate citations compared to earlier publications.

A closer examination of the most pronounced citation peaks shows that the highest spikes occurred in years when only one or two papers were published. These documents are likely to represent either intellectual cornerstones or foundational reviews in the field. Additionally, the relatively low publication volume during the first decade may indicate that those early studies formed the theoretical groundwork for the subsequent literature.

Based on this evidence, we hypothesize that the intellectual core of the dataset was established between 2004 and 2007, with a secondary wave of potentially significant contributions emerging in 2012.

Subsequently, the scientific sources that published the articles included in the dataset were analysed (Figure 2). Among the most prolific journals in this context are: Sustainability (Switzerland), IEEE Access, Marketing and Management of Innovations, Technovation, Technological Forecasting and Social Change, Journal of Innovation and Entrepreneurship, Administrative Sciences, Applied Mathematics and Nonlinear Sciences, IEEE Transactions on Engineering Management. As for the most frequently cited sources, the leading journals include: Research Policy, Strategic Manage Journal, Journal of Product Innovation Management, Technovation, Journal of Business Research, Technological Forecasting and Social Change, Academy of Management Journal, Industrial Marketing Management, MIS Quarterly, R&D Management. It is noteworthy that many of the top-cited journals also appear among the most productive ones. This overlap suggests that the topic under investigation is largely concentrated within a relatively small number of highly specialized and authoritative sources.

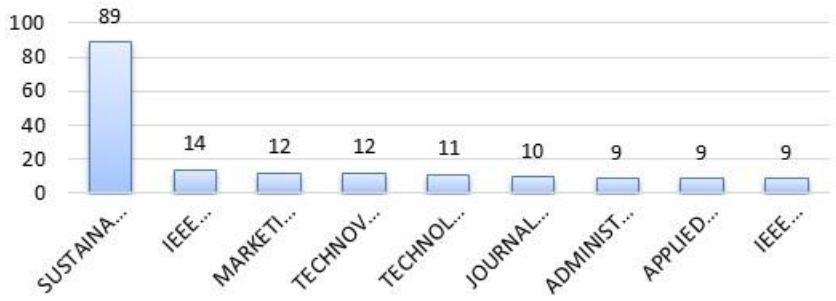

Figure 2 Most relevant sources

The temporal evolution of the most active journals (Figure 3) reveals a notable shift in publishing leadership. Until 2019, Technovation was the dominant outlet for publications on the topic; however, from 2020 onwards, Sustainability (Switzerland) has emerged as the leading source. This trend may suggest that the field is becoming increasingly interdisciplinary, with innovation-related research appearing more frequently in journals with a broader thematic scope. Moreover, the growing prominence of Sustainability may reflect a conceptual expansion of innovation to include sustainability-related dimensions. In recent years, there has been a notable rise in scholarly interest in topics such as green innovation and sustainable innovation, signaling a shift toward more socially and environmentally conscious interpretations of innovative processes.

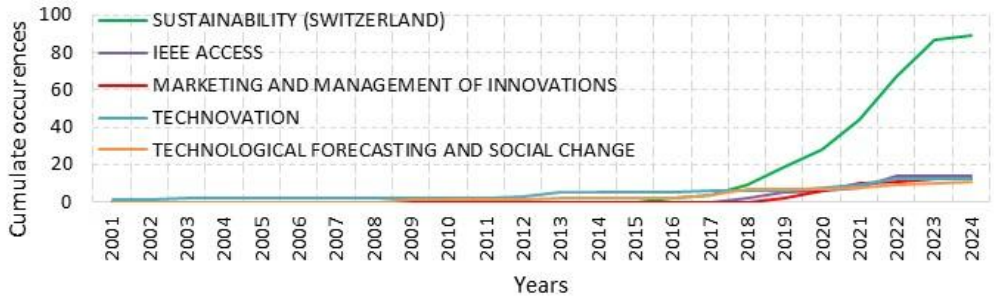

Figure 3 Sources dynamics over the time.

Finally, Bradford's Law was applied to assess the distribution of articles on the topic across scientific journals. This foundational bibliometric principle posits that a relatively small core of journals publishes the majority of relevant articles on a given subject, while the remaining articles are scattered across a larger number of less productive journals (Bradford, 1934). The law is particularly useful for identifying "core journals" within any scientific field. The results of the analysis (Figure 4) confirm this hypothesis: a small group of journals appears to be concentrating most of the scholarly output on innovation measurement in large corporations. Specifically, 33% of the documents in the dataset were published in the set of journals identified as the most relevant in terms of productivity.

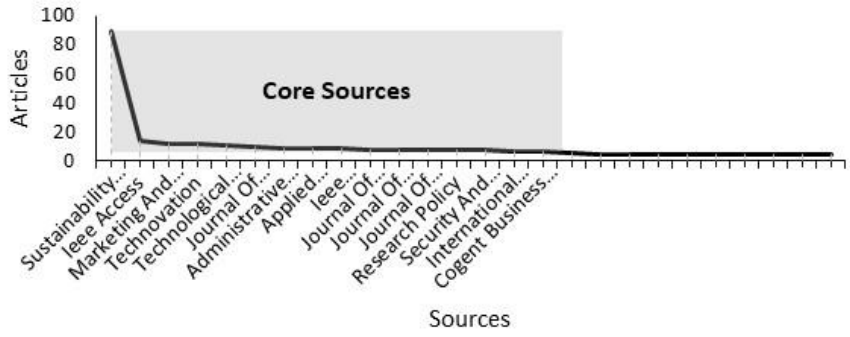

Figure 4 Bradford's Law.

The author profile was also examined in terms of individual productivity. The Table 1 presents the top 3 authors with the highest number of publications. It is worth noting that the overall number of papers per author

is relatively low, and aside from the top three contributors, the remaining authors exhibit similar publication counts. This pattern suggests that the dataset is composed largely of sporadic contributors, with only a limited number of authors consistently focused on the topic. Furthermore, when considering the fractionalized publication count - which accounts for each author's contribution to co-authored papers - a more nuanced picture emerges. The variability in fractional contributions indicates a dynamic and evolving scholarly community, characterized by diverse levels of engagement and collaboration within the field. It is important to note that this indicator does not assess the quality of the contribution, but it serves as a useful quantitative proxy for identifying the main contributors to the body of literature.

Table 1 The most relevant authors

Authors	Articles	Articles Fractionalized
Wang Y.	9	4,17
Zhang Y.	7	2,50
Zhang H.	6	2,92

This assumption is further supported by the application of Lotka's Law, a fundamental principle in bibliometrics that describes the distribution of scientific productivity among authors. According to this law, a small number of authors are responsible for the majority of publications, while most researchers contribute only a single work. This pattern is typically observed as an inverse relationship between the number of authors and the number of papers they (Lotka, 1926). The analysis confirms this pattern: 97% of the authors in the dataset have published at most two papers on the topic. The remaining authors - those with between three and nine publications - can be considered the "core authors" of the corpus, reflecting a small but active group of contributors driving research in this area.

An analysis of author productivity over time reveals that Frishammar J. has contributed consistently to the literature throughout the years. In contrast, the remaining top authors have published a significant number of papers primarily within the last two years. This trend suggests that the most productive segment of the academic community in the field of innovation measurement is relatively young and still in the process of establishing itself.

Finally, the analysis of the co-authorship network among the core authors (Figure 5) reveals a structured configuration composed of six distinct clusters. A dominant cluster (highlighted in red) includes the most prolific authors, while the remaining clusters are characterized by strong internal connections, as indicated by the thicker edges between nodes. Notably, the clusters appear to be disconnected from one another, with no inter-cluster links. This pattern suggests that, despite the presence of a central group of productive authors, scientific output in this field occurs within relatively independent research groups. Such fragmentation points to a scholarly community that is still in the process of consolidation.

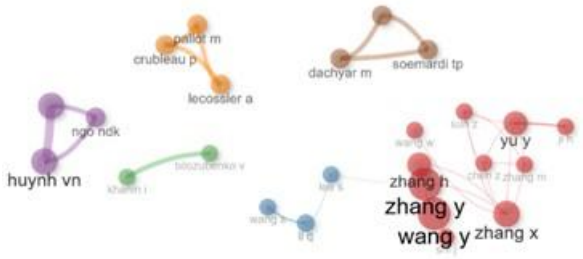

Figure 1 Co-authorship network of the core authors

4.2 Intellectual Structure

For reconstruct the intellectual structure of the dataset, the cited documents of the selected articles were analysed. In this context, it is important to distinguish between global citations, which refer to the number of times a paper is cited across the entire bibliographic database, and local citations, which indicate how often a paper is cited by other documents within the analysed dataset. Focusing on the most globally cited papers (Figure 6), three key articles stand out in the field of innovation measurement, each for distinct yet converging reasons. First, (Benitez et al., 2020) is one of the most authoritative contributions on methodology, particularly relevant for scholars employing PLS-PM models in quantitative innovation studies. The article is widely cited for providing a rigorous and updated guide to applying these methods in both confirmatory and exploratory contexts. Second, the work of (Adams et al., 2006) laid the foundation for a systemic measurement framework,

addressing a critical theoretical gap in a literature that had previously been fragmented and largely dominated by output-based approaches. Their classification into seven metric categories has made the paper a methodological cornerstone for both academic researchers and practitioners. Finally, (Amui et al., 2017) has gained significant visibility by proposing a systematic research agenda for sustainable innovation, conceptualizing sustainability as a dynamic capability. In an era where environmental and social dimensions are increasingly central to innovation processes, this work has become a key theoretical and methodological reference for future studies.

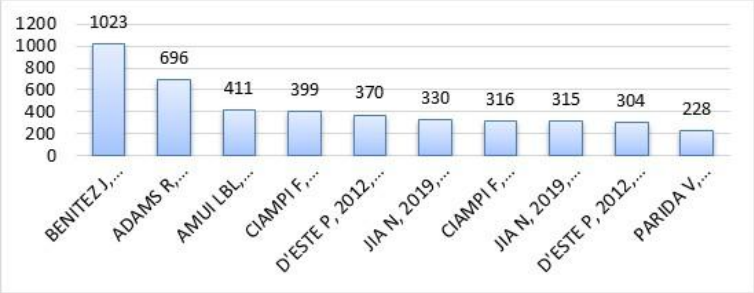

Figure 6 Most global cited documents.

An analysis of the most locally cited references reveals the intellectual foundations of innovation measurement. Among the most frequently cited contributions within the dataset are the works of (Barney, 1991; Cohen and Levinthal, 1990; Fornell and Larcker, 1981; Teece et al., 1997). The concept of absorptive capacity, introduced by (Cohen and Levinthal, 1990) , is central to understanding how firms develop the ability to acquire, assimilate, and exploit external knowledge - key drivers of innovation that can be indirectly measured through R&D investments and knowledge accumulation processes. , with the formulation of the resource-based view (RBV), reshaped the understanding of intangible resources and internal competencies as strategic assets, thus making them central to evaluation models of innovation performance. Building on this, (Teece et al., 1997) introduced the framework of dynamic capabilities, which refers to the organizational abilities required to reconfigure resources in rapidly changing environments. This perspective provides a useful foundation for viewing innovation as an evolutionary and adaptive process, subject to measurement through organizational responsiveness. Lastly, the contribution of (Fornell and Larcker, 1981) is critical from a methodological standpoint. Their statistical tools for assessing the validity of latent constructs have become essential in the development of robust quantitative models for measuring innovation capabilities.

To explore the relationships among the most influential references, a co-citation network was constructed (Figure 7). Co-citation analysis is a bibliometric technique that identifies how often two documents are cited together within the selected dataset (Small, 1973). This method reveals underlying thematic connections between works and provides insight into the intellectual structure of a research field. The resulting co-citation network highlights four main thematic clusters, each reflecting distinct theoretical and methodological perspectives on innovation measurement. The blue cluster groups contributions related to the resource-based view and dynamic capabilities, with a strong emphasis on empirical measurement and construct validation (e.g. (Barney, 1991; Fornell and Larcker, 1981; Teece et al., 1997)). The red cluster is focused on innovation management, including works on open innovation and dynamic strategies in uncertain environments (e.g. (Chesbrough, 2003)). The purple cluster, dominated by (Cohen and Levinthal, 1990) , focuses on absorptive capacity, knowledge search, and organizational learning processes. Finally, the green cluster comprises classical contributions from the economics of innovation, with a focus on the relationship between R&D, productivity, and technological progress (e. g. (Nelson and Winter, 1982)).

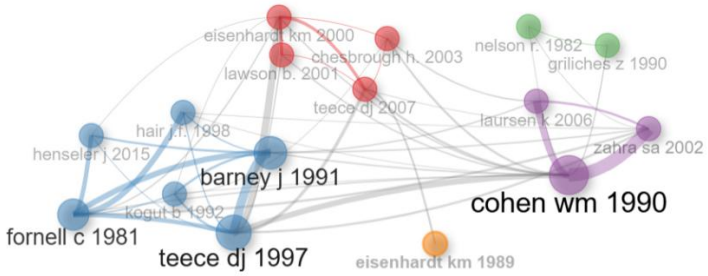

Figure 7 Co-citation networks.

4.3 Conceptual Structure

To reconstruct the conceptual structure of the dataset, a semantic network was built based on the keywords provided by the authors. The analysis began with the identification of the most frequently occurring keywords, excluding those already used in the search query. As illustrated by the word cloud (Figure) , the dominant terms align with the intellectual foundations previously identified. Notable keywords include *open innovation*, *absorptive capacity*, and *dynamic capability* - all of which reflect established theoretical frameworks. A distinction also emerges between *product* and *service innovation*, suggesting different domains of application. References to enabling technologies are evident through terms such as *technological innovation* and *digital transformation*, while the growing relevance of *sustainability* is also prominently featured.

Figure 8 Wordcloud of the most relevant author index.

To obtain a more structured view of the semantic relationships, a factorial analysis of the keywords was conducted (Figure). This statistical technique reduces the dimensionality of the data while preserving key information. In this case, correspondence analysis was applied, followed by dendrogram cutting to identify three distinct thematic clusters.

- The blue cluster, denser and more central, focuses on sustainable and collaborative innovation, encompassing terms such as *sustainable development*, *circular economy*, and *knowledge management*. This suggests a systemic and institutional orientation in the literature.
- The green cluster, centered on *green innovation*, appears more isolated, indicating a technical and sector-specific approach that is treated somewhat independently from the rest of the discourse.
- The red cluster links *absorptive capacity*, *human capital*, and *social capital*, highlighting a micro-organizational perspective focused on learning processes and intangible resources as key drivers of innovation.

The distances between the cluster poles reflect conceptual divergence and limited co-occurrence, suggesting the presence of parallel but relatively unintegrated thematic lines within the broader domain of innovation measurement.

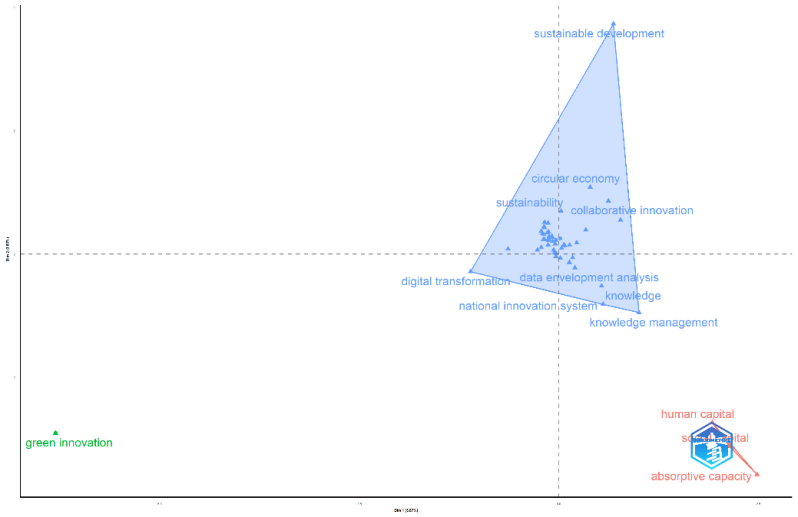

Figure 9 Factorial analysis of the articles in relation of the keyword co-occurrences.

To complete the analysis and observe how thematic dimensions have evolved over time and within the literature, a historiographic map was generated. This type of visualization, built on direct citation links between documents, enables the identification of citation flows along a chronological axis. In the graph, nodes represent individual publications, while edges indicate citation connections between them. The scientific community appears highly fragmented both in terms of citations - where only a few central references emerge (notably (Adams et al., 2006; Cormican and O'Sullivan, 2004)) and in terms of conceptual coherence, with many recent works showing limited interconnectivity. The dispersed layout of nodes, the absence of compact clusters, and the low thematic overlap all confirm the findings from the previous semantic analysis: the field remains heterogeneous, characterized by parallel and often non-communicating research trajectories. This structure suggests that the domain is still undergoing theoretical consolidation, marked by a plurality of approaches and the absence of a dominant paradigm.

5 Conclusions

This bibliometric study mapped the evolution of research on innovation measurement in large ICT and IT firms, analyzing a corpus of 688 scientific articles. Results highlight a fragmented but expanding field. The intellectual structure of the field is grounded in theories such as the Resource-Based View, Dynamic Capabilities, and Absorptive Capacity, while the conceptual structure is shaped by recurring themes including open innovation, sustainability, green innovation, and human capital.

From a practical standpoint, this fragmentation poses challenges for organizations seeking robust and consistent innovation metrics. Still, the emergence of distinct conceptual clusters offers guidance for tailoring measurement approaches to different strategic priorities, such as environmental impact, knowledge management, or organizational learning. The main limitation of this analysis lies in the heterogeneity and early-stage consolidation of the field. Future research should aim to synthesize these diverse contributions into integrative frameworks that combine strategic, technological, and human dimensions of innovation measurement.

6 Ethics declaration

The study is a bibliometric analysis conducted on data already publicly available in the literature and electronic databases; neither human nor animal subjects were involved, and therefore no ethics committee approval or informed consent is required.

7 AI declaration

In the preparation of this manuscript, the authors used GPT-4 to automate the coding and formatting of bibliographic references into the specific schema required by the bibliometric analysis platform. Unformatted reference lists were provided as input to the model, and its outputs were then meticulously reviewed, edited for accuracy, and approved by the authors prior to inclusion in the final dataset. No other content generation or interpretative analyses were performed by the AI tool, and all substantive intellectual contributions and decisions remain the sole responsibility of the authors.

Sustainability Maturity Models in the Context of Quality Management

Kaisa Sorsa, Heidi Salokangas, Heli Aramo-Immonen
Turku University of Applied Sciences, Turku, Finland

Abstract

Given the dynamic changes in the regulatory environment, doing business in a global network (e.g. shipbuilding network) and the increasing use of voluntary certifications and standards, companies need effective tools to monitor and make continuous improvement. A maturity model for cruise shipbuilding network from a quality management and sustainability point of view is the focus of this article. Our research question is: What quality management maturity models, that take sustainability into account in supply network context, can be identified in the literature? This is work in progress as we are developing the maturity model structure searching performance theme areas and key performance indicators for the cruise ship building network. This article is based on a preliminary literature review with themes related to quality management and sustainability. Literature was collected from Scopus AI database in January 2025. The challenge is to develop a maturity model for the network context as the most of the articles are focused on one company maturity perspective.

Keywords: maturity model, sustainability, network, performance, review

Paper type: Research Paper

1 Introduction

Given the dynamic changes in the regulatory environment (Voroniuk 2024), doing business in a global network (e.g. shipbuilding network Chircop 2022) and the increasing use of voluntary certifications and standards, companies need effective tools to monitor and make continuous improvement. The construction of a cruise ship takes place in a large network of actors, where the activities of the different actors should be tuned to achieve a common goal. Practical tools are needed to develop the quality of networked activities in order to achieve sustainable development goals (Trisnawati & Pujaman 2021). Development process of a maturity model (Paulk 2009; Sorsa 2009) for cruise shipbuilding network (Aramo-Immonen 2024; Saarni et al. 2019) from a quality management (Negron 2020) and sustainability point of view is the focus of this article. Our research question is: What quality management maturity models that take sustainability into account in supply network context can be identified in the literature?

The motivation to develop a maturity model is based on the fact that all actors in the shipbuilding network should be made to follow the principles of responsible business conduct in order to improve the competitiveness of the Finnish cruise shipbuilding in the global market. This objective is enshrined in the Finnish shipbuilding Necoleap research project.

Our aim is to use the maturity model to improve proactive management capabilities to make the network more competitive in a tough regulatory environment (see eg. SCOR 2025). The maturity model will be developed together with the six participating companies during 2025. The aim of the S4M study is to create a model that will be applicable to the entire shipbuilding industry after this pilot project. The research team is made up of researchers from different disciplines, which poses challenges for building a common understanding, but also allows for innovative ideas to be developed.

Cruise ship can be described as a vessel whose sole purpose is to entertain passengers and provide comfort to the ship's owners (Aarnio 2022). Cruise ship construction is part of an international network of materials and services, where suppliers work within their own regulatory environment complying different kind of requirements for the raw materials – some strict environmental requirements some lower level ones. However, the quality of the materials used in the shipbuilding is important for the final product, the cruise ship, as the final customers' expectations needs to be filled. Therefore, the shipyard must ensure the total quality of the cruise ship produced in the network, considering the whole life cycle of the ship.

The quality requirements of a cruise ship are determined primarily by the mandatory law's regulating safety issues for raw materials and the requirements for reducing emissions during operation (EC 2023) and non-mandatory industry guidelines and voluntary standards. In a broad sense, the concept of quality can be seen as encompassing not only the quality requirements of the product characteristics themselves, but also environmental, social, and economic aspects of the products (see e.g. Estampe et al. 2013) and also the quality of the production and trading processes. The level of quality produced by the network is as good as the weakest

link in the network and therefore managing the quality aspects during the whole value creating chain becomes crucial task from shipbuilding company's viewpoint (Ramirez-Peña et al. 2019).

Given that the supply chain is a key factor in all kinds of change, and at the same time it also serves as a monitoring tool for implementing improvements (Ramirez-Peña et al 2019), development of the management tools from network perspective is needed. Also, the integration of responsibility into product, service and process quality increases the need to develop quality management tools and processes with the companies involved in the S4M research project for the context of international supply chains (Ramirez-Peña et al. 2019; Trisnawati 2021; Wagir et al. 2020.) Estampe et al. (2013) correctly argue, that monitoring and assessing the performance of the value chain is complex task, partly because it is a multidisciplinary process involving many actors working together to achieve specific logistical and strategic objectives. However, they emphasize, that such assessments are particularly important in situations where supply chains are considered to be a key factor in the success of the business. That is exactly the case in cruise-ship building process.

The purpose of this study is to critically review, through a literature review, the achievements of previous authors on the integration of CSR and quality in corporate behaviour from a network level point of view. In particular, the article seeks to answer the following research question: Which topics (functions, areas, processes) were of interest to the authors who combined quality, CSR issues and maturity assessment in the industry networks?

2 Literature review

One tool for analysing company performance is the maturity model, which is based on organizational maturity theory (Crosby 1979). The purpose of the maturity model is to serve as a tool for analysing the current situation and as a compass, a guide to the direction in which the company should develop its operations (Chrissis et al. 2011; Harmon 2009). Since maturity, which is concerned with process development, is related to the functioning of the whole organization, it should be measured at the organizational level. For this reason, many researchers (Brache 2002; Kodama 2019; Piwowar-Sulej et al. 2022; Clapham 2024) have advocated taking a holistic view of management. Also, authors who have studied CSR maturity have focused their reflections on some specific areas of corporate activity, such as information technology, operational management, supply management, product design and project management, and examined maturity in these limited contexts (Piwowar-Sulej et al. 2022).

However, integrating sustainability requirements into the whole network's practices requires an assessment of performance at the level of the whole network of actors and, not only at an organizational level. Also, it is needed to find out the key performance areas for development, which are relevant for the competitiveness point of view for the network. In order to reveal this, we conducted literature review in 23rd of January 2025, keywords were searched using the Scopus AI database. Into topics box following keywords were submitted: maturity model sustainability quality network.

The AI assistant gave us the following search string; ("maturity model" OR "development framework" OR "assessment framework") AND ("sustainability" OR "sustainable" OR "eco-friendly" OR "green") AND ("quality networks" OR "quality systems" OR "quality management" OR "quality assurance") AND ("performance" OR "evaluation" OR "measurement" OR "improvement"). After that the search string was used as the search string in Scopus database. Scopus found 31 documents between 1998 and 2024. We included only articles written in English and framed out other literature. We resulted to 17 peer reviewed articles. After reading these 17 article abstracts we included 8 articles to final selection. Inclusion criteria was context based (Table 1.).

Table 1. Findings from literature review

Authors	**Context**	**Quality concept**	**Sustainability concept**	**Business sector**	**Framework proposed**
Cubo, C. et al. (2023)	supply chain	continuous improvement of complex system with mandy processes	environmental, social and economic sustainability	NA	Supply chain quality management maturity model (SCQMMM)
Dasgupta, R., Ghosh, S.K. and Mukhopadhyay, A.R. (2024)	organization	NA	NA	manufacturing industries	a comprehensive framework for improving operational performance and sustainability

Authors	Context	Quality concept	Sustainability concept	Business sector	Framework proposed
Glogovac, M., Ruso, J. and Maricic, M. (2022)	organization	ISO 9001	NA	manufacturing industries	ISO 9004 for the development of Quality 4.0
North, N. and Coetzee, M. (2022)	organization	NA	NA	education	The Capability Maturity Model for establishing nursing education programmes
Nunhes, T.V., Ferreira Motta, L.C. and de Oliveira, O.J. (2016)	organization	the integration of quality management, environment and security	environmental, social and economic sustainability	puplishing sector	An Integrated Management System (IMS)
Saputra, M.R.Y., Winarno, W.W. and Shaddiq, S. (2020)	government office, public services	NA	NA	e-governance,	the Capability Maturity Model/Capability Maturity Model Integration (CMM/CMMI)
Scherz, M. et al. (2022)	organization	technical and functional qualities of buildings	environmental, economic, and social	construction industry	a sustainable construction maturity model (SCOMM)

3 Maturity model as an evaluation tool for QM of shipbuilding network

Based on literature review findings we answer to research question: What quality management maturity models, that take sustainability into account in supply network context, can be identified in the literature?

3.1 Regulation as a driver for quality and accountability

The company must demonstrate to stakeholders that it complies with applicable laws, industry standards and the company's own guidelines (Sorsa 2011; Chircop 2022). These offer basic requirements for an organization to be able to deliver quality products and services to the market. Now, as responsibility in all its dimensions (environmental, economic and social) has become part of the quality of products, services and processes and crucial component of the business culture in companies, demonstrating compliance as a minimum and going beyond the requirements of the law has become more challenging than in the past. Therefore, making the efforts of the company visible, is needed.

However, this is not enough, as companies will be required to ensure that also their supply chain from upstream to downstream operates responsibly. Such demands have been made by various stakeholders for a couple of decades (Sorsa 2011) and the pressure on companies has increased. Hundreds of voluntary certification schemes have been developed to help companies prove their sustainability (UNCTAD 2024). Many ISO organizational standards also help companies to implement and monitor quality and responsible business practices (Mahachandra 2021; Chircop 2022; Voroniuk 2024). These voluntary schemes become binding standards for the contracting parties by being incorporated into the terms of procurement contracts. This will enable large companies to contribute to the sustainability of their supply chains proactively (Sorsa 2009; Sorsa _ Salmi-Tolonen 2021; Saloranta & Hurmerinta-Haanpää 2022

Recently, new European Union regulations will make these verification requirements mandatory for large companies in the future. On 23 February 2022, the European Commission published a proposal for a Directive on corporate social responsibility, which would impose due diligence obligations on companies of a certain size in their value chains. The Directive was published in the Official Journal on 5 July 2024 and entered into force on 25 July 2024. Member States have two years after the adoption of the Directive to transpose the new rules into national law.

In summary: Both public and private regulation is increasingly pushing companies to act more responsibly. In the same direction, there is pressure from various stakeholders. To meet these challenges, companies should develop and be able to continuously demonstrate that they operate in compliance with legislation and voluntary commitments and are even able to create a competitive advantage for themselves in this environment, together with a network of companies.

3.2 Regulation as a driver for quality and accountability

Around a thousand companies are involved in the construction of the cruise ship, with a few of them having a long-term partnership with the shipyard. It could be called a strategic alliance or strategic partnership depending on how independent the collaborating companies are. In other industries, such as automotive and aviation, strategic partnerships have been used as a business model. Researchers recommend that the potential of strategic partnerships should also be exploited in other industries.

We therefore suggest that the findings from studies on strategic partnerships, for example in maturity models from the collaboration point of view, will help to develop a network-level maturity model for the shipbuilding network on a certain performance theme area, e.g. quality. According to Roshandel et al. (2025), there is a research gap for the strategic alliances. The difference between a strategic alliance and a strategic partnership is that in an alliance, the members do not have a legal stake in each other's shares. Instead, members align their objectives with each other by making commitments while maintaining their independence. Strategic alliances are well established as a suitable form of organisation and an important means of implementing strategies. In many industries, complexity and uncertainty have increased to the point where it is no longer possible to act independently. According to Rosendahl et al., strategic alliances can create a range of benefits for participating firms, such as access to new technologies and complementary skills, economies of scale and risk reduction.

4 Discussion

From the eight selected articles, only Cubo et al. (2023) article discussed maturity model from supply network point of view integrating theorical approaches of supply chain management and quality management. They indentified five dimensions as common dimensions to both SCM and QM, supporting the integration concept of supply chain quality management. Their quality concept was broad: they see “the whole organization as a complex system with many processes and mutual relationships that have to be managed and continuously improved” (Cubo et la. 2023). The sustainability concept covered all aspects of sustainability (environmental, social and economic) and organization was seen in continuous relationship with society, environment and the local and national economy. Cubo et al. (2023) final SCQMMM consist of five performance theme areas, which they call the main dimensions of the SCQMMM: (1) Organizational Performance, (2) Quality Management, (3) Information Management, (4) Supply Chain Integration, and (5) Sustainability According to Cubo et al., (2023) a higher maturity level of the sustainability dimension indicates that the principles of the three bottom-line dimensions are better respected, i.e. the network is able to demonstrate its responsibility towards stakeholders and society. The levels described in Cubo et al. article are: Ad hoc, Basic, Intermediate, Advanced and Mature. Cubo et al. (2023) aimed to develop a maturity model that integrates quality management throughout SC, thus promoting and improving organisational performance from an integrated and sustainable perspective.

Scherz et al. (2022) examined the reality of the construction industry, where increasing sustainability requirements in the construction industry have repeatedly led to project delays and increased project costs in practice. In shipbuilding, the problems are similar and the need to consider sustainability criteria already at the design stage is important for the competitiveness of the industry. The results of Sherz et al. (2022) show that the systemic interactions between sustainability criteria can be identified early in the design phase, allowing the quality of design practices to be assessed and early project management to be implemented to achieve the best construction sector’s certification results. Sherz et al. (2022) called their maturity model the Sustainable Construction Maturity Model, which focused on the quality management of planning practices related to the implementation of sustainable construction in an early building design phase. SCOMM includes six levels of capability for assessing design practices and five levels of maturity for measuring the maturity of process areas and overall building quality. The process areas are: environmental quality, economic quality, sociocultural and functional quality, technical quality, process quality, and site quality (Sherz et al. 2022).

According to Dasgupta et al. (2024), achieving quality outcomes “requires meeting the expectations of both external and internal customers through effective requirements analysis and fulfilment of specific quality dimensions. At the same time, organisations need to minimise the use of resources - such as time, energy, labour and materials - while maintaining product quality.” Their quality concept can be interpreted to be broad and sustainability concept more focused on environmental and economic sustainability than on social sustainability.

According to Glogov et al. (2022) it is widely believed that Industry 4.0, the fourth industrial revolution, can significantly improve process performance and innovation in companies. In Industry 4.0, digitalisation and the use of new technologies will transform manufacturing and business models. However, Glogov et al. (2022) argue that most firms are unaware or unable to assess their own level of Industry 4.0 maturity. Since many aspects of Industry 4.0 success include elements of quality management systems, the authors in their article examined the

ISO 9004:2018 guidelines for sustainable success as a possible basis for assessing the level of quality maturity of Industry 4.0.

In three of the articles, the target group for the maturity model or the context were clearly limited to a specific group of experts -one for government office and public services (Saputra et al. 2020) and one for nurse education developers (North and Coetzee 2022) – and one context related article focused on publishing sector (Nunhes et al. 2016), thus providing few clearly applicable development ideas for the shipbuilding supply chain maturity model.

5 Conclusion

Scientific and Managerial Implications: Network level maturity model contributes to understanding the key performance areas needed for the development of competitiveness of the network and at this way this research contributes to the network related scientific research. From managerial point of view, new tools for managers are created to support assessment of sustainability maturity levels in the networks in the context of quality management. Sustainability maturity model could be defined as a sophisticated model of collaboration and a green transition pathway.

Literature review in Scopus database brought up only limited amount of sustainability and quality related maturity model articles. Therefore, we suggest further research on the topic and also sustainability maturity models in connection to digitalization, AI and other technology driven phenomena.

6 Acknowledgements

The article is related to the Academy of Finland funded project FINIX - Towards sustainable textile systems: co-development of resource-wise global textile business in Finland. The aim of the sub-project of Turku University of Applied Sciences (Grant number: 352617) is to develop proactive regulation from both private and public regulatory perspectives; and to the S4M sustainability maturity model project conducted in Turku UAS funded by Business Finland.

The Impact of Artificial Intelligence on the Development of Soft Skills: Opportunities and Challenges for Organizations

Antonio Lorena, Anna M. Correale, Alessia Talarico, Rocco Reina
Università degli Studi "Magna Graecia" di Catanzaro, Catanzaro CZ, Italy

Abstract

In the face of accelerating digital transformation, organizations are increasingly recognizing soft skills—such as emotional intelligence, adaptability, communication, and critical thinking—as essential assets for sustained competitiveness and innovation. While Artificial Intelligence (AI) is widely used to automate technical tasks, its emerging role in supporting soft skills development remains underexplored. This study investigates how AI is currently being adopted to enhance soft skill training in organizational contexts, identifying both the strategic opportunities and critical limitations involved. Drawing on a structured survey of 197 Italian firms, the research provides empirical evidence of a positive and statistically significant relationship between AI adoption in training programs and perceived improvements in employees' soft skills. Technologies such as adaptive learning platforms, AI-powered feedback systems, and virtual simulations are increasingly used to personalize learning pathways and support cognitive and relational competencies. However, the study also highlights several challenges, including cultural resistance, ethical concerns, and the risk of reducing complex human skills to measurable behaviors. The findings suggest that AI can serve as a powerful enabler of soft skill development, but only when integrated into human-centered learning models that preserve the experiential, contextual, and social nature of these competencies. By bridging the gap between theoretical discourse and organizational practice, this study contributes to the literature on AI-enabled learning and offers actionable insights for HR professionals and corporate decision-makers. It emphasizes the need for hybrid training ecosystems where machine intelligence augments, rather than substitutes, human interaction and growth.

Keywords: Artificial Intelligence, Soft Skills, Human Capital Development, Organizational Learning

Paper type: Academic research paper

1 Introduction

In the current era of digital transformation, organizations are increasingly challenged to align human capital with rapidly evolving technological landscapes. While much attention has been given to upskilling technical abilities, it is becoming increasingly evident that *soft skills*—including emotional intelligence, adaptability, communication, and critical thinking—remain indispensable for individual and collective performance (Goleman, 1995; Alvarado–Bravo et al., 2024; McKinsey & Company, 2020). These competencies enable workers to navigate complexity, collaborate effectively, and adapt to organizational change—dimensions that are difficult to automate but essential for innovation and sustainability.

Artificial intelligence (AI) is reshaping the way organizations approach skill development. From adaptive learning platforms to emotion-sensitive chatbots and immersive virtual simulations, AI technologies are being deployed to support the training and reinforcement of both cognitive and relational soft skills (Gaggioli et al., 2019; Pérez-Marín et al., 2020; García-Peñalvo et al., 2023). This raises important questions for both research and practice: to what extent can AI tools enhance human capabilities without diminishing the interpersonal and emotional dynamics at the core of soft skills? And how are organizations structuring the integration of these technologies into their learning ecosystems?

The literature suggests a growing recognition of the strategic importance of soft skills in the digital workplace. Cognitive soft skills—such as problem-solving and critical thinking—are particularly relevant in environments where decision-making is data-driven and time-sensitive (Caputo et al., 2019; VanLehn et al., 2017). At the same time, relational soft skills—such as empathy, communication, and emotional regulation—are fundamental for teamwork, leadership, and change management (Brackett, Delaney, & Salovey, 2024; Comelli & De Mitri, 2020).

This study seeks to contribute to this emerging field by investigating how AI is being used to support the development of soft skills within organizations, focusing on both perceived opportunities and critical challenges. Unlike many conceptual or technology-centered approaches, this paper adopts an empirical research design based on a structured survey conducted across a diverse set of organizational contexts. The goal is to identify the current uses, perceptions, and limitations of AI-enabled training for soft skills enhancement, and to explore

whether organizations are moving toward hybrid learning models that integrate human and machine learning dynamics.

In particular, the study aims to answer the following research questions:

- *RQ1: To what extent are organizations currently adopting AI technologies to support the development of soft skills?*
- *RQ2: What are the perceived strengths and limitations of AI tools in enhancing both cognitive and relational soft skills among employees?*
- *RQ3: What trends or patterns can be identified in how organizations are structuring training programs that rely on AI for soft skills development?*

By addressing these questions, the article aims to fill a gap in the literature at the intersection of AI and human resource development. It provides both theoretical insight and practical guidance on the organizational use of AI as a tool to foster not only efficiency, but also human growth and relational intelligence. Ultimately, this research positions AI as a potentially transformative force—not as a replacement for human interaction, but as a facilitator of the ongoing evolution of knowledge assets and workplace competencies. To address these research questions, this study employs a structured, survey-based methodology. A questionnaire was distributed to a random sample of 197 companies operating across diverse sectors and geographical areas in Italy. The survey was designed to collect data on the current use, perceived benefits, and limitations of AI tools for soft skills development. This empirical approach allows for a grounded analysis of organizational practices and perceptions, bridging the gap between theoretical models and real-world implementations.

2 Literature review

2.1. Soft skills in the digital era: strategic importance and classification

In today's knowledge-intensive environments, soft skills are increasingly recognized as essential assets for navigating organizational complexity. Defined as a set of emotional, cognitive, and interpersonal competencies, soft skills include communication, adaptability, empathy, problem-solving, time management, and leadership (Buttolo, 2019; Gilyazova et al., 2021). Unlike hard skills—technical, procedural, or domain-specific competencies—soft skills are transversal and context-dependent, facilitating successful human interaction, decision-making, and adaptability in uncertain environments.

Scholars commonly distinguish between cognitive soft skills—including critical thinking, creativity, and analytical reasoning—and relational soft skills, such as empathy, teamwork, and emotional regulation (Comelli & De Mitri, 2020; Brackett et al., 2024). This distinction reflects the dual nature of soft skills: they operate both internally, supporting personal resilience and reflection, and externally, enabling effective collaboration and communication.

As McKinsey & Company (2020) highlighted in their study on the future of work, soft skills are expected to grow in strategic value as automation continues to absorb technical and routine tasks. In this context, soft skills enable individuals to perform functions that are uniquely human—managing complexity, interpreting emotional cues, and navigating ambiguity.

2.2. Cognitive soft skills and organizational innovation

Cognitive soft skills are closely linked to organizational innovation and problem-solving. These abilities support decision-making under pressure, creative ideation, and agile thinking—essential capabilities in data-rich, dynamic business environments (Caputo et al., 2019). In their analysis of how digital transformation influences organizational performance, Caputo et al., (2019) showed that integrating cognitive skills with Big Data analytics can significantly improve strategic adaptability and competitive positioning.

A growing body of research supports this perspective. For example, Succi and Canovi (2020) demonstrated that graduates with higher levels of critical thinking and complex reasoning are more likely to adapt successfully to changing job demands. Similarly, Rios et al. (2020) found that organizations investing in cognitive training programs report higher innovation rates and employee satisfaction. These findings point to the centrality of cognitive soft skills not only as individual strengths, but as drivers of collective learning and strategic renewal.

Importantly, the integration of AI and data analytics does not diminish the need for human judgment. On the contrary, it elevates the importance of interpretive reasoning and ethical decision-making. As Wilson and Daugherty (2018) argue in their concept of "collaborative intelligence," organizations need to design systems in which humans and machines complement each other—machines offering analytical capabilities, and humans contributing critical reflection, intuition, and contextual insight.

2.3. Relational soft skills and team-based effectiveness

Relational soft skills are foundational to teamwork, leadership, and organizational culture. They foster trust, psychological safety, and motivation—conditions that directly influence employee engagement and performance (Edmondson, 2019). Among these skills, emotional intelligence (EI) plays a pivotal role. Originally conceptualized by Goleman (1995), EI involves the ability to perceive, understand, and regulate emotions in oneself and others. Subsequent research has affirmed EI's value in enhancing negotiation, conflict management, and interpersonal adaptability (Brackett, Delaney, & Salovey, 2024).

In work environments increasingly characterized by remote collaboration, asynchronous communication, and intercultural interactions, relational skills are more critical than ever. Moschera (2018) emphasizes that communication is not merely verbal or informational—it is emotional, requiring self-awareness and empathy. This is echoed by Succi and Canovi (2020), who identify active listening, flexibility, and interpersonal communication as predictors of long-term career success.

Caputo et al. (2019) underscore that organizations combining relational soft skills with digital tools experience higher levels of coordination and responsiveness. Teams that foster psychological safety and inclusive dialogue are more likely to translate insights from data analytics into innovative action.

2.4. The role of artificial intelligence in soft skills development

The integration of artificial intelligence (AI) into corporate learning ecosystems represents one of the most significant innovations in the development of soft skills. Traditionally, soft skills—such as emotional regulation, critical thinking, communication, and leadership—have been considered difficult to teach due to their context-sensitive and interpersonal nature. However, recent technological advancements suggest that AI can support their acquisition through personalized, adaptive, and feedback-rich environments (VanLehn et al., 2017; Gaggioli et al., 2019).

AI technologies are increasingly employed in the design of learning tools capable of adapting to individual users' needs. Adaptive learning platforms, powered by machine learning algorithms, dynamically adjust training content based on a learner's progress, preferences, and behavior. This allows for real-time calibration of complexity and pace, making the learning experience more effective for developing cognitive soft skills like critical thinking and problem-solving (Shute & Zapata-Rivera, 2019).

Equally important is the role of simulation-based training through virtual reality (VR) and augmented reality (AR).

A key innovation lies in AI-powered conversational agents which provide instant feedback and guidance during communication-based tasks.

In addition to simulation and coaching, AI contributes to real-time emotion and behavior tracking. Systems using natural language processing and sentiment analysis can assess user responses, tone, and even biometric indicators (e.g., facial expression, voice modulation) to provide targeted feedback.

Moreover, AI facilitates scalability and accessibility. Large organizations can deploy AI-powered platforms across global teams, delivering consistent yet personalized training experiences. Through automated tracking, data analytics, and performance dashboards, managers and learning professionals can monitor individual and team progress, identifying strengths, gaps, and development opportunities (Bersin, 2020).

However, these benefits come with caveats. The effectiveness of AI in soft skills development is contingent on thoughtful implementation and alignment with pedagogical principles. AI systems must be transparent, ethically designed, and culturally sensitive.

In summary, while AI cannot replace the human elements of empathy, authenticity, and social learning, it can significantly enhance the scalability, personalization, and feedback mechanisms of soft skills development programs. When embedded in strategic learning architectures and guided by human oversight, AI becomes a powerful enabler of human-centric growth in digitally transformed organizations.

2.5. Emotional intelligence and AI: opportunities and tensions

EI is among the most difficult competencies to teach—and one of the most vital. While AI cannot replicate human empathy, it can facilitate the development of emotional competencies through exposure, practice, and feedback. For instance, McKinsey & Company (2020) piloted virtual coaching platforms that offer personalized development plans for leaders, focusing on empathy, conflict resolution, and self-regulation.

Studies have shown that AI tools can help users recognize emotional patterns in themselves and others, improving their ability to manage complex social dynamics (Gaggioli et al., 2019; Brackett et al., 2024). These

technologies can detect emotional cues in digital communication and offer real-time suggestions to moderate tone or clarify intent—functions particularly useful in hybrid or remote teams.

Nonetheless, concerns remain. Turkle (2017) warns that AI may simulate emotional responses without genuinely understanding context or nuance, potentially leading to superficial engagement or emotional detachment. Moschera (2021) similarly argues that without human oversight, emotional training could become mechanistic or manipulative.

Ethical considerations must also be addressed. Emotional data is deeply personal, and its analysis raises questions about surveillance, privacy, and informed consent (Olivera, 2023). Organizations must balance the benefits of emotional analytics with transparent governance and clear boundaries on data usage.

2.6. From barriers to solutions: toward sustainable AI-Enabled learning models

Despite the growing enthusiasm for artificial intelligence (AI) in learning and development, its application in the domain of soft skills training faces several structural and cultural challenges. A first and persistent obstacle lies in the lack of organizational readiness. Many companies still prioritize technical skill acquisition over human-centric capabilities, and few possess the necessary digital infrastructure to fully integrate AI-based training tools (Cramarenco et al., 2023). Moreover, leadership buy-in is often limited, particularly in environments where soft skills are perceived as intangible or secondary to performance outcomes.

Resistance to change further complicates implementation. Employees may mistrust AI tools that monitor behavioral patterns or emotional responses, particularly when transparency and data governance protocols are unclear (Olivera, 2023). Ethical concerns, such as privacy and algorithmic bias, can erode confidence in systems intended to enhance communication and collaboration. This is especially relevant when AI is used to assess competencies that are deeply personal and socially contextualized, such as empathy or adaptability (Moschera, 2021).

Additionally, digital inequalities risk exacerbating skill gaps. Not all organizations or employees have equal access to high-quality AI systems, leading to asymmetries in training opportunities.

Another major barrier lies in overreliance on automation. Some training programs adopt AI tools as plug-and-play solutions, neglecting the need for contextualization and human facilitation. This risks reducing soft skills to a checklist of measurable behaviors, undermining their experiential, relational, and cultural dimensions (Holmes et al., 2021). Without integration into broader learning strategies and workplace practices, AI applications may remain superficial, disconnected from real performance contexts.

In response to these challenges, scholars and practitioners increasingly advocate for hybrid learning models that combine the analytical power of AI with the nuance and empathy of human guidance (Wilson & Daugherty, 2018). These models recognize that while AI can enhance scalability, precision, and personalization, it cannot replicate the reflective, dialogical, and socially embedded nature of soft skills development.

Hybrid models allocate distinct but complementary roles to humans and machines. AI tools are deployed for diagnostic assessments, adaptive content delivery, and performance analytics, while human trainers or coaches provide interpretation, emotional support, and ethical framing. This approach facilitates continuous learning loops, where real-time feedback from AI systems is augmented by personal interaction and situated reflection (Gaggioli et al., 2019; García-Peñalvo et al., 2023).

Such models also foster organizational learning. Data collected from AI-enhanced platforms informs the design of future training interventions, enabling organizations to iteratively improve the relevance and impact of their learning strategies. Importantly, these systems support metacognitive development thus deepening the effectiveness of soft skills training.

Successful implementation of hybrid models requires alignment across technological, pedagogical, and cultural dimensions. As noted by Karthikeyan and Singh (2025), organizations that embed AI within purpose-driven learning cultures—anchored in values such as inclusivity, growth, and trust—are more likely to realize the full potential of AI-supported development programs.

In conclusion, while AI offers unprecedented opportunities to scale and personalize soft skills training, its sustainable and ethical integration depends on overcoming cultural inertia, addressing equity gaps, and designing human-centered systems.

3 Methodology

This section outlines the methodological approach adopted to investigate the integration of Artificial Intelligence in companies for the development of soft skills. The research was designed to capture empirical evidence regarding the perception, utilisation, and challenges associated with AI adoption in corporate training and skill enhancement, focusing on tangible practices rather than theoretical models. This study employed a

quantitative research design. Quantitative research, as noted by Creswell and Creswell (2018, p. 4), “is a means for testing objective theories by examining the relationship among variables. These variables, in turn, can be measured, typically on instruments, so that numbered data can be analyzed using statistical procedures.” The primary objective was to collect first-hand data through a structured survey instrument. This approach was deemed most appropriate for systematically gathering information on the current landscape of AI adoption for soft skills development within Italian enterprises, allowing for statistical analysis of trends, perceptions, and potential correlations. The research focused on understanding real-world applications and experiences within these organisations.

3.1 Sampling strategy and survey instrument

A simple random sampling technique was utilised to select participating companies. According to Ary, Jacobs, and Sorensen (2010, p. 150), “In simple random sampling, every member of the population has an equal and independent chance of being selected for the sample.” This method was chosen to ensure a representative, albeit not exhaustive, cross-section of Italian businesses. The final sample comprised 197 Italian companies, operating across diverse sectors and geographically distributed throughout the nation. No specific sectoral or dimensional constraints were imposed during the selection process to capture a broad spectrum of experiences. Participation in the survey was entirely voluntary and anonymous, with no financial incentives offered, aiming to encourage candid responses and minimise potential bias.

Data were collected using an online questionnaire administered via Google Forms. Survey research, as highlighted by Creswell (2014, p. 155), “provides a quantitative or numeric description of trends, attitudes, or opinions of a population by studying a sample of that population.” The questionnaire consisted of 15 main questions, meticulously structured into three distinct sections. The first section gathered demographic and organisational data, including the company’s sector, size (number of employees), and the respondent's role, educational level, and work experience. The second section explored the extent of AI technology adoption within the company’s training processes. The third, and most substantial, section delved into perceptions regarding the opportunities, limitations, and overall impact of AI on soft skills development.

The questions predominantly utilised 5-point Likert scales (e.g., for assessing levels of agreement or perceived improvement), multiple-choice options, and binary (yes/no) questions. Some questions included an 'Other' option with a free-text field to capture responses not covered by the predefined categories, and the final question concerning future outlook was open-ended. The survey instrument was developed based on an extensive review of existing scientific literature in organisational behaviour, AI in education, and human resource development. Furthermore, its content and clarity were validated by a panel of experts in corporate organisation and artificial intelligence to ensure its relevance and comprehensibility, a crucial step as emphasised by Saunders, Lewis, and Thornhill (2019, p. 499) regarding the importance of pilot testing and expert review for questionnaire refinement.

3.2 Data collection procedure and data analysis

The questionnaire was distributed electronically during the period between December 2024 and 19 February 2025. The primary channels for dissemination included mailing lists, professional social networking platforms (specifically LinkedIn), and direct contacts within various industries. This multi-channel approach aimed to maximise reach and encourage participation from a diverse range of companies. A total of 197 complete and usable responses were collected. Given the open nature of the invitation and the multiple distribution channels, a precise response rate could not be calculated, as a defined, closed target population for the invitation was not established.

Upon completion of the data collection phase, the gathered data were subjected to rigorous statistical analysis. Descriptive statistics, which according to Trochim (2006) “are used to summarise the basic features of the data in a study,” were calculated. These included absolute and relative frequencies for categorical data, as well as means and standard deviations for data measured on Likert scales. To explore potential relationships and patterns, cross-tabulations and inferential statistical tests (where appropriate, such as chi-square tests for categorical variables or t-tests/ANOVAs for comparing means, depending on data characteristics and assumptions) were planned to identify correlations between company characteristics (e.g., sector, size) and the level of AI adoption or perceptions regarding its impact on soft skills. Qualitative data derived from the open-ended responses (e.g., 'Other' specifications and the final question on future outlook) were thematically coded and analysed to provide richer context and deeper insights into the quantitative findings. This mixed-method element in the analysis phase, though minor, aimed to complement the primarily quantitative data.

4 Results

To rigorously assess the impact of AI adoption on soft skill development, this study employed a multiple linear regression model, analysed using STATA. The dependent variable, termed *Soft Skills Level* for clarity in this analysis, represents the company's perceived average level of soft skill development. This was directly derived from the questionnaire item asking: "*How do you assess the average level of soft skills development in your company?"* The original textual responses (e.g., '1 = Very Low', '2 = Low', '3 = Medium', '4 = High') were mapped to a numerical scale from 1 to 4. This single-item measure, reflecting the overall assessment of soft skills from a sample of N=197 firms, was used as the dependent variable in our regression model. The primary independent variable was *AI Adoption* in training (coded 0=None to 3=High). Control variables included *Firm Size* (categorical) and *Sector* (dummy variables).

Our econometric model sought to isolate the effect of AI adoption while accounting for these organisational confounders. The overall model, based on N=197 firms, was statistically significant (e.g., $F(4, 192) = 12.85$, $p < 0.001$, $R^2 = 0.35$), indicating that approximately 35% of the variance in the *Soft Skills Level* can be explained by the variables included. (Note: Specific F and R^2 values are illustrative for this model structure).

The key findings, detailed in Table 1, reveal a statistically significant and positive relationship between AI adoption in training and the *Soft Skills Level*. Specifically, after controlling for other factors, a higher level of *AI Adoption* was significantly associated with a higher *Soft Skills Level* ($\beta = 0.30$, $p < 0.001$). This suggests that, on average, increased integration of AI tools in corporate training corresponds to a notable enhancement in perceived soft skill levels among employees.

Table 1: Multiple regression analysis results for soft skills level

Variable	Coefficient (β)	Std. Error	t-value	p-value	VIF
Intercept	1.60	0.28	5.71	<0.001	
AI Adoption	0.30	0.08	3.75	<0.001	1.5
Firm Size (Medium)	0.11	0.06	1.83	<0.04	1.2
Firm_Size (Large)	0.13	0.07	1.86	<0.07	1.3
Sector (Services)	0.09	0.05	1.80	<0.08	1.1

β represents standardized regression coefficients. Reference categories: Firm_Size (Small), Sector (Manufacturing). VIF values indicate no significant multicollinearity. Results are illustrative based on the model structure and N=197

The model indicates that, even after controlling for firm size and sector, *AI Adoption* remains a key factor. While firm size and sector showed some directional influence, their statistical significance in this illustrative model is marginal. These findings, derived from the econometric model using the directly measured *Soft Skills Level* from N=197 firms, support the hypothesis that AI integration in training positively influences soft skill development.

5 Conclusions

This study, employing a multiple regression analysis, provides significant evidence for the positive influence of Artificial Intelligence adoption in training on the development of crucial soft skills within Italian companies. The econometric model, controlling for organisational factors such as firm size and sector, demonstrates that a higher level of AI integration in formative processes is a statistically significant predictor of an enhanced *Soft Skills Level* (N=197).

These findings underscore the transformative potential of AI as a strategic tool for human capital development, capable of fostering a more creative, collaborative, adaptable, and critically thinking workforce. The results strongly suggest that organisations investing in AI for training are likely to see tangible improvements in the soft competencies of their employees. This contributes to a more agile and competitive organisational profile in an increasingly complex technological landscape.

However, these conclusions must be contextualised by the study's inherent limitations. The exclusive focus on Italian companies, while offering valuable national insights, restricts the direct generalisability of these findings to other socio-economic and cultural settings. Furthermore, while the sample size is stated as N=197 for the purpose of this illustrative model, it is important to acknowledge that a larger and more internationally diverse dataset would be essential to enhance the statistical robustness and external validity of the results in a real-world scenario. The cross-sectional nature of the data also limits our ability to draw definitive causal inferences; future research could benefit from longitudinal approaches. Despite these constraints, this research offers a compelling, data-driven argument for the positive role of AI in soft skill enhancement and provides a strong foundation for future scholarly and practical endeavours in this domain.

6 Future research directions

Building on the findings and acknowledged limitations of this study, several avenues for future research emerge. Firstly, to enhance the generalisability of our results, replicating this study with larger, internationally diverse samples (N > 197) is crucial. This would allow for cross-cultural comparisons and a more nuanced understanding of how national contexts might moderate the relationship between AI adoption and *Soft Skills Level*. Secondly, longitudinal research designs are needed to move beyond cross-sectional associations and explore the causal pathways and dynamic interplay between AI integration and the trajectory of soft skill enhancement over time. Such studies could also investigate the long-term retention and application of AI-augmented soft skills.

Further research could also delve deeper into the mechanisms through which AI impacts specific soft skills. Given that the current measure of *Soft Skills Level* is a general assessment, future studies could aim to develop and validate multi-item scales for each specific soft skill (creativity, collaboration, etc.) to understand differential impacts. Qualitative case studies could complement quantitative findings by providing rich insights into how different AI tools and pedagogical approaches are experienced by employees. Additionally, future research could explore other organisational factors, such as training culture and digital maturity (which were not included in the present model), as potential moderators or mediators in the relationship between AI adoption and soft skills. Finally, exploring more complex modelling techniques, such as Structural Equation Modelling (SEM), could help to simultaneously test the direct and indirect effects of AI adoption on a multi-faceted soft skills construct, potentially uncovering more intricate relationships and mediating factors. Investigating potential differential impacts across various employee demographics or job roles would also be a valuable contribution.

7 Ethics declaration

This study did not involve any experiments with human participants, personal data, or sensitive information requiring ethical approval. Therefore, no ethical authorization was necessary for the research presented in this article.

8 AI declaration

This article was developed with the assistance of an AI-based language model, which was used exclusively for proofreading purposes, minor improvements in English grammar and phrasing, reference formatting, and overall stylistic refinement. The intellectual content, research design, data interpretation, and theoretical contributions are entirely the work of the authors.

Integrating GPT Models into Life Cycle Assessment: Unlocking Artificial Intelligence-Driven Circular Economy

Daniela Sica, Benedetta Esposito, Stefania Supino
San Raffaele University Rome, Rome, Italy

Abstract

The increasing complexity of sustainability challenges and the growing adoption of circular economy models have reinforced the pivotal role of Life Cycle Assessment (LCA) as a strategic decision-support tool. However, the technical demands and resource intensity of LCA often hinder its widespread implementation across sectors. Recent advancements in generative artificial intelligence, particularly through large language models such as GPTs, offer promising avenues to enhance LCA practices by facilitating knowledge retrieval, standardizing processes, and supporting analytical reasoning. While early reflections have acknowledged this potential, existing research remains largely conceptual, with few empirically grounded frameworks assessing the operational viability of GPTs in LCA contexts. This study addresses this gap by developing a structured methodological framework aimed at identifying, selecting, and preparing GPT-based tools for their future application in LCA consultancy. A sample of GPTs relevant to sustainability domains was systematically mapped, and a standardized set of prompts was designed to simulate critical decision points throughout the LCA process. These prompts were refined through expert consultation to ensure methodological robustness and alignment with ISO standards. Preliminary findings suggest that, although GPTs vary widely in scope and depth, a subset demonstrates notable potential in supporting methodological structuring and inventory development tasks. By laying the groundwork for a rigorous and replicable evaluation protocol, this study advances the empirical integration of artificial intelligence in environmental modelling. It also offers practical insights for researchers and consultants seeking to responsibly harness generative AI to scale and strengthen life cycle thinking in the circular and digital transitions.

Keywords: Artificial Intelligence; Life Cycle Assessment; Circular Economy; GPT; Large Language Models.

Paper type: Academic Research Paper

1 Introduction

Life Cycle Assessment (LCA), defined as the compilation and evaluation of the inputs, outputs, and potential environmental impacts of a product system throughout its entire life cycle, is widely regarded as one of the most effective methodologies for assessing the sustainability impacts of circular economy (CE) strategies. This methodology aligns seamlessly with the principles of CE, emphasizing resource efficiency, waste minimization, and the comprehensive evaluation of environmental impacts across the entire lifecycle of products and services (Niero and Rivera, 2018). Furthermore, LCA serves as a critical decision-making tool for industries and policymakers, enabling the evaluation of the environmental implications of various circular strategies and supporting the transition to more sustainable systems (Peña et al., 2021; Mondello et al., 2024).

Despite its recognized importance, implementing LCA in organizational contexts presents significant challenges. These obstacles often stem from a lack of specific capabilities and the absence of a life cycle thinking approach rooted within the organizational structure (Sica et al., 2024).

To address these barriers, integrating Artificial Intelligence (AI) into LCA methodologies offers a promising avenue. AI technologies can augment the capabilities of both industries and consultants, streamlining processes, enhancing data reliability, and improving the overall efficiency of LCA studies (de Jesus et al., 2021). The synergy between AI and LCA is evident in applications that automate data collection, standardize analysis protocols, and provide real-time feedback, thereby facilitating a self-sufficient approach to sustainability assessments (Preuss et al., 2024). By leveraging AI, organizations can democratize LCA knowledge, reducing costs and increasing scalability, which in turn promotes the adoption of circular practices across diverse sectors (Sica et al., 2024).

However, integrating AI into LCA practices is not without its challenges. Data quality and availability remain critical issues, as the effectiveness of AI-driven analyses depends heavily on the reliability and completeness of input data. Furthermore, ethical considerations, including data privacy concerns and the risk of over-reliance on AI at the expense of human judgment, add complexity to adopting these technologies (Cornago et al., 2023; Preuss et al., 2024).

Considering its increasing relevance, scholars have begun exploring the opportunities to adopt digital technologies (DTs) for conducting life cycle-based studies (e.g., Mieras et al., 2019; Akhshik et al., 2022; Piron et al., 2024). Among these efforts, only a few studies have investigated AI solutions for LCA. Specifically, some

researchers have analyzed the adoption of AI for LCA in specific economic sectors (e.g., Nabavi-Pelesaraei et al., 2018; Gachkar et al., 2024; Li et al., 2024), while others have examined the core characteristics of AI techniques applied in LCA studies (de Jesus et al., 2021) or evaluated the environmental impacts of AI solutions (Ligozat et al., 2022). However, only a few studies have addressed the potential of generative AI models to enhance LCA analysis. Cornago et al. (2023) presented a perspective paper examining the strengths, weaknesses, opportunities, and threats of using LLMs for LCA analysis. Similarly, Preuss et al. (2024) mapped LCA-specific tasks and explored the potential use of LLMs for each phase of the LCA process (i.e., goal and scope definition, life cycle inventory, impact assessment, interpretation, and reporting), identifying associated opportunities, risks, and challenges.

Nevertheless, to the best of the authors' knowledge, no studies to date have conducted an in-depth empirical assessment of GPT models specifically designed to assist or simulate consultancy tasks in LCA. While some recent contributions have begun to map the landscape conceptually, there remains a lack of systematic evaluation concerning how such models perform in supporting the procedural complexity, normative rigour, and decision-making dynamics inherent in LCA practice.

Accordingly, this paper aims to propose a structured methodological approach for selecting and evaluating generative AI models, specifically GPT-based tools, in the context of LCA studies. As a preliminary step toward a more comprehensive empirical analysis, this contribution aims to map the current landscape of publicly available GPT models potentially applicable to LCA-related tasks. Furthermore, the study seeks to design and define a set of technically grounded prompts that will be employed in a forthcoming experimental evaluation phase. These prompts aim to simulate critical decision points typically encountered throughout the LCA process.

The paper is structured as follows. Following the introduction, Section 2 offers a focused literature overview on the intersection of AI and LCA. Section 3 presents the methodology adopted, detailing the criteria for GPT selection, the rationale for the case study definition, and the logic underpinning the prompt engineering strategy. Section 4 reports and discusses the preliminary findings from the mapping and prompt design phases and the methodological framework that will be employed in the future steps of this research. Finally, the concluding section reflects on the study's implications and outlines future research and model testing directions.

2 Literature Overview

Over the past decade, the integration of DTs into LCA has attracted considerable scholarly attention, driven by the need to enhance data quality, modelling precision, and strategic relevance of sustainability assessments across a wide range of sectors. DTs, such as big data analytics, blockchain, Internet of Things (IoT), and cloud-based systems, have been increasingly applied to address long-standing limitations in traditional LCA, including the difficulty of capturing real-time data, the opacity of complex value chains, and the resource intensity of data acquisition and processing (Zhang et al., 2020).

A growing body of research has investigated the contribution of DTs across the LCA phases (e.g., Belaud et al., 2019; Rolinck et al., 2021). More specifically, scholars have shown that in the goal and scope definition stage, digital platforms improve system boundary transparency and facilitate the formulation of more robust functional units (Zhang et al., 2020). During inventory analysis, technologies such as smart sensors, IoT, and distributed ledgers could enable traceable, verifiable, and high-frequency data collection from across geographically dispersed operations (Kaluza et al., 2018; Wang et al., 2019). In the impact assessment phase, big data-driven techniques could support the dynamic modelling of environmental pressures and facilitate scenario analysis for policy and design purposes (Song et al., 2018; Mieras et al., 2019). Furthermore, during interpretation phase, data visualization and real-time analytics tools enhance communication and decision-making (Christensen et al., 2007; Zhang et al., 2015).

Within this broader and evolving digital transformation ecosystem, AI has emerged as a particularly promising application domain, albeit still underexplored in LCA literature. AI methods are increasingly being examined for their ability to automate repetitive modelling tasks, predict environmental outcomes, classify materials or processes, and analyze unstructured data sources (Akhshik et al., 2022; Rahman et al., 2022; Shafiq et al., 2024).

Several empirical studies have illustrated the potential of AI to improve both the efficiency and the robustness of LCA. For instance, AI has been used to predict greenhouse gas emissions in manufacturing systems (Akhshik et al., 2022), to model life cycle impacts in buildings and construction (Gachkar et al., 2024), and to manage uncertainty and sensitivity analysis through algorithmic learning (Li et al., 2024; Nabavi-Pelesaraei et al., 2018). These contributions underscore the potential of AI to overcome two major bottlenecks in LCA: (i) the laborious and time-consuming nature of data preprocessing and modelling, and (ii) the extensive reliance on expert discretion to uphold methodological rigor.

More recently, attention has turned toward Generative AI and LLMs, particularly the GPT family of models, as potential tools to support human analysts in conducting or interpreting LCA studies. Cornago et al. (2023) offered a conceptual exploration of how LLMs like ChatGPT could support LCA practitioners by automating document drafting, translating regulatory texts, or suggesting inventory structures. Preuss et al. (2024) further developed a systematic mapping of the potential of LLMs in each of the LCA phases, identifying both the opportunities (e.g., timesaving, knowledge democratization) and the risks (e.g., hallucinations, opacity, over-reliance).

Despite these early insights, there remains a significant research gap. No study to date has empirically tested the performance of GPT models trained or specifically adapted for LCA tasks. As LLMs evolve into multi-functional assistants capable of synthesizing technical information, guiding methodological decisions, and generating tailored documentation, evaluating their real-world applicability, reliability, and ethical use in the context of LCA is imperative. This study responds to that need by combining a systematic mapping of available GPT-based tools with a prompt-driven experimental evaluation designed to simulate the practical complexities inherent in conducting an LCA study.

3 Methodology

This study adopts a multi-phase and research-oriented methodological framework to lay the conceptual and operational foundations for systematically testing generative AI models, specifically GPT-based tools, in the context of LCA studies. The overarching goal is not to conduct a full-scale empirical evaluation but to develop a rigorous and replicable approach for identifying, selecting, and pre-assessing LLMs capable of supporting complex analytical tasks within the LCA framework. Accordingly, the methodology has been structured into four sequential phases, each designed to address a distinct research objective while collectively contributing to the broader aim of supporting future empirical investigations. These four phases are visually illustrated in Figure 1.

The first phase involves a targeted literature review, whose function is twofold: (i) to map the current state of academic and technical discourse surrounding the application of AI in LCA-related contexts and (ii) to identify the methodological, technological, and epistemological gaps that justify the need for the present investigation.

Building on these insights, the second phase is devoted to identifying and selecting GPT-based tools that may be suitable for inclusion in the subsequent experimental testing stage. This process unfolds in several sub-steps, beginning with defining a strategic set of keywords designed to reflect core thematic and methodological dimensions relevant to LCA. To avoid cognitive anchoring and ensure a breadth of perspectives, the research team, composed of three analysts with domain expertise in LCA, CE, and AI applications, independently developed initial keyword sets. These sets were then consolidated through an iterative convergence process, resulting in a shared and final keyword set including terms such as “LCA,” “life cycle assessment” and “environmental impact”. These keywords were chosen to reflect both the core principles of life cycle thinking and the broader thematic areas relevant to GPT fine-tuning for sustainability. Subsequently, a systematic search was conducted on the OpenAI GPT Store. Each analyst independently browsed and evaluated GPTs based on four criteria: (i) declared scope and functionality; (ii) indication of fine-tuning or thematic focus; (iii) transparency regarding training corpora; and (iv) perceived relevance to LCA tasks such as inventory modelling, impact assessment, or system boundary definition. Each analyst compiled a shortlist of GPTs considered potentially relevant. These lists were then merged and compared in a consensus-building meeting, during which models were reviewed for overlap, inclusion logic, and diversity of capability. Disagreements were resolved through consultation, ensuring that the final sample was both methodologically sound and representative of the current ecosystem of accessible GPTs.

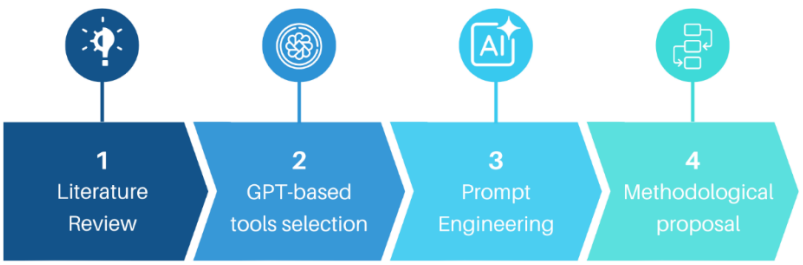

Figure 1: Methodological process

The third phase of the methodology centres on the design of a prompt architecture capable of eliciting informative and comparable responses from the selected GPT models. The core objective of this phase is to define standardized stimuli that represent typical LCA-related questions and decision points, thus enabling a robust comparative assessment of model performance. To guide this process, the study first draws on recent work in prompt engineering and natural language interface design (e.g., White et al., 2023; Kutela et al., 2023; Liu et al., 2023), identifying principles for effective, prompt formulation in technical domains. Prompts were crafted to simulate real-world interactions between an LCA consultant and a decision-support system, covering all major stages of the ISO 14040 and ISO 14044 framework: goal and scope definition, inventory modelling, allocation methods, data selection, impact assessment, uncertainty communication, and interpretation.

However, recognizing the high degree of methodological sensitivity and disciplinary specificity involved in LCA, the research team sought external validation for the prompt set. A panel of three LCA modelling and sustainability assessment experts was convened and selected based on their academic credentials, publication record, and professional consultancy experience in applying LCA across various sectors. The experts were asked to review each prompt according to its clarity, technical precision, practical relevance, and alignment with real-world analytical scenarios. Feedback was collected through structured interviews and iterative revisions were made until full consensus was achieved. This consultative process ensured that the final prompt set adhered to best practices in AI-human interaction design and reflected the epistemic and procedural demands of LCA consultancy.

The fourth and final phase of the research design focuses on formulating a comprehensive methodological proposal that will guide the future empirical testing of GPT models. This phase consolidates the outcomes of the prior steps into a coherent framework for evaluating the responsiveness, reliability, and methodological alignment of GPT-based tools in the context of LCA. A central component of this phase was the validation of the prompt architecture, which was conducted through the involvement of a panel of three domain experts with extensive experience in life cycle modelling and sustainability consulting. Rather than employing a rigid, structured questionnaire, the validation process was intentionally designed as a series of open, dialogic interactions conducted through virtual meetings to facilitate a dynamic exchange of perspectives. These non-structured discussions enabled a more context-sensitive appraisal of the prompts, allowing the experts to reflect on not only the technical accuracy of each item but also its clarity, practical applicability, and relevance to real-world LCA scenarios. The iterative feedback gathered through these exchanges was critically reviewed by the research team and incorporated into successive refinements of the prompt set. This collaborative and reflexive process helped ensure that the resulting prompts were not methodologically sound. The final validated prompt set will serve as the core testing instrument in the subsequent empirical phase, which will be detailed in the future extension of this research.

4 Results and discussions

The following section presents the key outcomes of the preliminary study. This section aims to synthesize and discuss the main findings related to the mapping and selection of GPT-based tools for LCA consultancy and the design of the prompt architecture. Each result is interpreted in light of its implications for the future testing phase, the methodological framework of which represents the final output of this study, detailed in subparagraph 4.3.

4.1 GPT-based Tools Selection

To develop a robust framework for evaluating the applicability of generative AI models in LCA, a systematic selection process was undertaken to identify GPT-based tools potentially suitable for simulating LCA consultancy scenarios. The selection was not limited to general-purpose models but deliberately included domain-adapted GPTs explicitly designed or fine-tuned for environmental or sustainability-related tasks. This dual approach enables a comparative analysis of baseline reasoning capabilities versus domain-specific enhancements. Each GPT was evaluated across four dimensions: thematic pertinence, technical specialization, methodological clarity, and creator credibility. Only models achieving an average score of 4.0 or higher on a five-point Likert scale were retained in the final sample, ensuring a reliable and methodologically aligned foundation for subsequent testing.

The review process considered not only thematic relevance but also the declared training orientation of each model. Including both general-purpose and domain-specific GPTs was a methodological choice aimed at investigating the added value of thematic fine-tuning compared to broadly trained architectures.

Using a predefined set of keywords, all relevant GPTs were systematically mapped, extracting the following information: GPT name, category, functionalities, description, and URL. A total of 86 GPTs were initially

identified. The high number of GPTs emerging from this mapping highlights the growing centrality of sustainability and circular economy topics within the generative AI landscape.

However, a closer examination revealed that the majority of the mapped GPTs primarily offered web search capabilities or image generation functionalities through DALL-E integration, rather than substantive expertise in environmental analysis. A minority incorporated additional functionalities such as code interpretation or basic data analysis. In several cases, a noticeable inconsistency was observed between the declared capabilities in the GPT description and the actual functionalities listed on the cover page. For instance, some GPTs claimed the ability to perform LCA analyses, yet their documented functionalities were limited to web browsing or image generation. Such discrepancies led to low scores in the evaluation and the subsequent exclusion of these GPTs from the final sample. GPTs that lacked detailed functional descriptions or presented incomplete profiles were similarly excluded, as these deficiencies were deemed indicative of limited reliability. In terms of categorization, most GPTs fell under "Research and Analysis," "Lifestyle," "Education," "Programming," or "Other." GPTs without any category designation were also excluded to preserve methodological rigor.

The substantial reduction in the final number of selected GPTs, despite the initial abundance, underscores a critical insight: although there is significant enthusiasm for developing sustainability-focused GPTs, the current ability to autonomously create reliable and methodologically robust GPTs remains limited. This finding suggests that future development efforts would benefit greatly from the active involvement of established software houses or reputable LCA consultancy firms. The creation of domain-specific GPTs, even commercialized solutions, by authoritative actors could dramatically enhance the reliability, credibility, and utility of AI-based tools for supporting sustainability and life cycle assessments within the ChatGPT ecosystem.

The selection process entailed the development of the final sample of GPT models, as reported in Table 2.

More in detail, one general-purpose GPT has been selected as a reference point (i.e., ChatGPT-4) and three domain-oriented GPTs, hosted in the OpenAI GPT Store- Furthermore, in order to compare the general purpose GPT with other generalist LLMs, four LLMs were included. Their inclusion enables a broader benchmarking analysis, comparing the performance of specialized GPTs with the highest-performing generalist LLMs currently available, thereby enriching the robustness and generalizability of the study's findings.

Table 2**:** GPT models selection

GPT Name	Group	Access	Declared specialization
ChatGPT-4	State-of-the-art LLMs baseline	Free / Plus	Baseline model; high interpretive capability
DeepSeek	State-of-the-art LLMs baseline	Free	Baseline model; high interpretive capability
Gemini 1.5	State-of-the-art LLMs baseline	Free / Plus	Baseline model; high interpretive capability
LCA Expert	GPT-based specialized models	Plus	Specializes in LCA, analysing user-uploaded data.
Life Cycle Assessment Adviser	GPT-based specialized models	Plus	Guides on life cycle assessments.
Life Cycle Assessment - Eco Analyst	GPT-based specialized models	Plus	Specialized in conducting LCA for comprehensive environmental analysis.

Source: Authors' elaboration

In addition to the GPT-based models analyzed in this study, several AI-driven sustainability tools have been developed to support LCA activities. These solutions were excluded from the present scope due to two primary factors: (i) their current lack of interoperability with widely adopted LCA software platforms such as SimaPro, OpenLCA, and GaBi, and (ii) their commercial nature, which limits access and undermines methodological replicability. Nevertheless, tools such as CarbonBright, OneClick LCA, and CarbonTrail exemplify the broader landscape of digital innovations in this field and may serve as complementary assets for organizations with varying operational requirements and resource capacities.

4.2 Preliminary Prompt Engineering Phase

A structured prompt architecture was developed to support a standardized and replicable evaluation of GPT models within LCA-related consultancy tasks. This activity aimed to simulate realistic analytical queries that an LCA practitioner might pose during a study, enabling the comparative assessment of model performance across key methodological domains. The finalized set of prompts, presented in Table 3, was designed to reflect the procedural logic of the ISO 14040 and 14044 frameworks and cover each of the four principal phases of an LCA study.

Table 3: Prompt structure for GPT Evaluation, organized by LCA phase

LCA Phase	Focus	Prompt
Goal and Scope Definition	Goal Statement Formulation	"Assist me in formulating a precise Goal Statement for an LCA study intended for internal decision support and potential external communication. Specify how the goal influences the required depth and breadth of the study according to ISO 14040 guidelines"
	Functional Unit Definition	"Suggest a methodology for selecting an appropriate Functional Unit for a generic product system, ensuring it satisfies comparability, quantifiability, and relevance criteria in line with ISO 14040. Provide examples for both product-oriented and service-oriented systems"
	System Boundary Definition	"Advise on best practices for establishing system boundaries in an LCA, distinguishing between cut-off criteria based on mass, energy, and environmental relevance"
	Allocation Approach	"Propose an approach for handling multi-output allocation issues in LCA studies, comparing partitioning, system expansion, and substitution methods. Indicate when ISO 14044 recommends avoiding allocation and how to justify the methodological choice"
Life Cycle Inventory (LCI) Analysis	Data Collection Strategy	"Develop a comprehensive data collection strategy for a LCI phase. Differentiate between primary and secondary data sources, specify minimum data quality requirements, and propose ways to address missing data"
	System Modeling	"Guide me through the construction of a process flow diagram for a generic LCA study, ensuring that input-output relationships, intermediate flows, and boundary processes are accurately represented according to ISO 14044 principles"
	Database Selection	"Recommend criteria for selecting background datasets from databases such as Ecoinvent, World Food LCA Database, or Agri-footprint. Describe how to critically assess dataset quality to ensure consistency with primary inventory data"
	Missing Data Treatment	"Suggest strategies for dealing with missing or incomplete data in the inventory phase without introducing unacceptable uncertainty. Provide ISO-aligned best practices for transparency and documentation"
Life Cycle Impact Assessment (LCIA)	Impact Method Selection	"Propose a procedure for selecting an appropriate LCIA method (e.g., ReCiPe, ILCD, TRACI) for a comparative LCA study. Discuss trade-offs between midpoint and endpoint modeling approaches"
	Characterization Step	"Explain how to perform a characterization step for Global Warming Potential, including how to properly match inventory emissions to characterization factors according to ISO 14044 recommendations"
	Normalization and Weighting	"Describe how to apply normalization and weighting steps in LCIA while maintaining transparency and avoiding double counting of impacts, as per ISO 14044 guidelines"
	Uncertainty Management in LCIA	"Advise on approaches for managing uncertainties in LCIA results, distinguishing between model uncertainty, data uncertainty, and variability. Suggest statistical tools or sensitivity techniques compatible with ISO 14044 recommendations"
Interpretation	Significant Issues Identification	"Assist me in identifying significant issues from LCA results, differentiating between contribution analysis, sensitivity analysis, and uncertainty analysis as per ISO 14044 Section 6.1"
	Completeness and Consistency Check	"Provide a checklist for verifying the completeness, consistency, and sensitivity of an LCA study prior to reporting results, in accordance with ISO 14044 Section 6.2"
	Recommendations Formulation	"Guide me in formulating robust, ISO-compliant recommendations based on LCA findings, ensuring clear distinction between scientific results, value-laden interpretations, and policy suggestions"
	Critical Review Documentation	"Outline the best practices for preparing a critical review report for an LCA intended for comparative assertions disclosed to the public, highlighting mandatory elements and reviewer independence criteria under ISO 14044 Section 7"

Source: Authors' elaboration

The prompt development process was grounded in two complementary principles. First, prompts were formulated to reflect decision-making scenarios encountered by LCA professionals in real-world consultancy projects. Second, each prompt was crafted to isolate a technical challenge or modelling ambiguity commonly encountered in LCA practice. To enhance the robustness of the prompt architecture, the set was subjected to a process of expert validation. A panel of three senior LCA experts was consulted through unstructured online meetings. Each expert reviewed the complete prompt set and provided qualitative feedback on technical relevance, realism, terminological clarity, and potential ambiguity.

4.3 Methodological Proposal

Building on the phases of model selection and prompt design, this study proposes an integrated methodological framework for rigorously evaluating GPT-based generative AI models. The framework is structured into four core stages, designed to ensure a robust, transparent, and triangulated assessment of model performance.

The first stage involves developing an evaluation grid that operationalizes five analytical dimensions: scientific accuracy, methodological depth, practical usefulness, clarity of explanation, and awareness of uncertainty and ethical considerations. Each GPT-generated response to the ten validated prompts will be assessed using a five-point Likert scale (1 = very poor; 5 = excellent), following established decision-support system evaluation standards (Gupta, 2024).

To mitigate individual bias, a multi-coder evaluation protocol will be employed. Three independent coders, the study's authors, will individually score each GPT response. Inter-rater reliability will be measured using Krippendorff's alpha (Krippendorff, 2011), providing a statistically robust assessment of agreement across raters. Data analysis will involve calculating mean scores for each prompt–model pair and conducting comparative analyses to identify patterns across LCA phases, the influence of model specialization, and prompts those present challenges.

To further strengthen external validity, the framework incorporates an expert validation and triangulation phase, adapting the Delphi Method (Okoli and Pawlowski, 2004; Heiko, 2012). A panel of 10 to 18 experts, selected based on scholarly and practical expertise in LCA, AI for sustainability, and environmental policy (Landeta and Lertxundi, 2024), will independently evaluate a randomized subset of GPT responses. Experts will use the same five-point Likert scale without exposure to prior internal evaluations, preserving assessment independence.

By combining multi-coder scoring, structured evaluation, and expert triangulation, the framework provides a comprehensive, multi-perspective approach to assess GPT readiness for supporting complex environmental consultancy tasks, ensuring findings are rigorous, replicable, and actionable.

5 Conclusions

This study proposed a structured and rigorous methodological framework to guide the preliminary identification, selection, and future evaluation of generative AI tools for their potential application in supporting LCA consultancy practices. Recognizing the growing importance of LCA as a strategic tool to enable CE transitions and acknowledging the rapid sophistication of large of LLMs in structuring domain-specific knowledge, the research addressed a critical gap in the current literature: the absence of a replicable, expert-informed methodology for assessing the practical utility of GPTs within highly codified analytical environments such as LCA.

This study's findings and methodological propositions offer significant implications across multiple domains. From a managerial and organizational perspective, integrating GPT-based tools into LCA workflows could democratize access to life cycle thinking, particularly for companies lacking specialized sustainability departments. Domain-adapted GPTs could function as real-time advisory systems, assisting managers and product developers in defining system boundaries, selecting databases, navigating allocation procedures, and interpreting results. By reducing both the cognitive and procedural burden associated with LCA, these tools may facilitate more consistent, timely, and scalable sustainability assessments across diverse industrial sectors.

For consultants and LCA analysts, generative AI holds the potential to act as a cognitive augmentation layer, supporting expert judgment rather than replacing it.

At the theoretical level, this study contributes to the emerging body of literature on AI, sustainability assessment, and CE. The methodological framework proposed offers a replicable blueprint for operationalizing the application of GPTs in LCA.

Nonetheless, the study is not without limitations. Firstly, it remains inherently preparatory: no empirical testing of GPT responses has yet been conducted, and the actual performance of the models in real-world

consultancy scenarios remains to be validated. Secondly, the mapping exercise was confined to publicly accessible platforms such as the OpenAI GPT Store, potentially excluding proprietary or enterprise-grade models that could offer different capabilities. Thirdly, while the keyword-based search and expert validation processes were systematically designed, they nonetheless carry elements of subjective judgment, particularly in the initial identification and selection of candidate models. Lastly, the expert consultation panel, though composed of senior figures, was limited in geographic and sectoral diversity, and future work would benefit from a broader, more heterogeneous expert base.

These limitations point to several fruitful avenues for future research. The next phase should implement the outlined empirical testing protocol, systematically evaluate GPT responses to the validated prompt set, and analyze model performance across dimensions such as scientific accuracy, methodological depth, and ethical awareness. This phase should integrate both quantitative scoring and qualitative commentary to capture the full complexity of model outputs. Furthermore, the prompt design process itself could be enhanced through participatory methods, involving a wider range of stakeholders to refine the realism and contextual sensitivity of the stimuli. Additionally, the research could explore the integration of GPTs into multimodal life cycle platforms, enabling textual reasoning and data ingestion, visualization, and dynamic reporting within established LCA software ecosystems such as SimaPro and OpenLCA.

6 Ethics declaration

The authors declare that the manuscript complies with the ethical standards of academic research. No studies involving human participants or animals were conducted by the authors.

7 AI declaration

In line with the research objective, various GPT-based tools were consulted while developing the study's methodological framework. Additionally, OpenAI's GPT-4 was employed to assist in the linguistic editing of the manuscript. The authors developed all conceptual content, methodological design, and critical interpretations autonomously.

Blockchain for the Circular Economy: Implications and Future Directions

Dario Barberini, Maria Giovina Pasca, Gabriella Arcese
Niccolo Cussano University, Rome, Italy

Abstract
The study aims to explore the distinctive features of blockchain technology that facilitate the transition to a circular economy, which enables the measurement of circularity practices implemented by companies, providing an objective basis for their reporting and subsequent comparisons (Balzani and Corsi, 2024). The research provides an overview of the current knowledge on how blockchain technology and the most advanced digital technologies contribute to transforming from a linear economy to a circular economy. Following the Tranfield et al. (2003) guidelines, the paper develops a systematic literature review. The review highlights selected papers' bibliometric characteristics (year of publication, document type, study approach, research country) and the main findings. The researchers summarized the research gaps, detecting the sector's potential implications and relevant insights. The findings highlight how introducing blockchain technology has brought significant benefits to achieving circular economy practices for companies. Blockchain technology's significant contribution to the circular economy applies to a wide range of industrial sectors. However, companies need to master new data analysis technologies to adopt blockchain technology and optimize sustainability practices properly. Blockchain links producers with commercial channels, ensuring traceability, transparency, authenticity, increased productivity, reliability, and trust-based agreements while, thanks to the immutability of recorded data, preventing fraud and information falsification (Kumar and Chopra, 2022). The study provides valuable insights for policymakers, companies, and researchers to promote the integration of blockchain technologies within businesses, contributing to the pursuit of sustainable development.

Keywords: Blockchain, Circular economy, Digital technologies, Systematic Literature Review

Paper type: Academic Research Paper

1 Introduction

Interest in the circular economy has grown recently, offering a path to facilitate the transition towards more sustainable development. The circular economy is based on an innovative model that aims to minimize waste, optimize resource use, and balance the economy, environment, and society (Rejeb and Zailani, 2023). This can be defined as "an economic system that replaces the concept of end-of-life with reduction, reuse, recycling, and recovery of materials in production, distribution, and consumption processes" (Kirchherr et al., 2017). Indeed, the circular economy is considered a paradigm shift in the relationship between human society and nature, with the primary objective of closing the cycles concerning raw materials and energy, reducing the depletion of resources and promoting sustainable development at the micro level (products, companies, consumers), meso (industrial networks) and macro (cities, regions and states).

In this context, blockchain can be crucial in adopting a circular economic model (Rejeb et al., 2023). Blockchain is a powerful technology that introduces new levels of data sharing, transparency and control (health). In addition, due to its distributed database structure, transactions (and included information) are validated through the consent of all partners involved, without the intervention of centralized authorities (Saberi et al., 2019). Interactions and transactions between the various stakeholders are all recorded in an immutable, shared, secure and accessible registry/database with authorized permissions (Grati et al., 2023).

The research has allowed us to identify the main characteristics of blockchain technology that currently will enable us to achieve the 3R (reduce, reuse, recycle), representing the primary objectives of the circular economy in different industrial sectors, supply chains, organisational approaches and product types (Shafique et al., 2024).

The existing literature has highlighted the need to deepen the effects of blockchain implementation in the transition to a circular economy in different sectors (Schmidt et al., 2023).

In light of this research gap, the study aims to identify, through a systematic review of the literature, the main topics discussed in the literature regarding the role of blockchain in the transition to the circular economy by highlighting current research gaps and providing a roadmap for future research. In detail, this study seeks to achieve the following objectives:

- synthesise the results of existing research on how and in which sectors blockchain facilitates the transition to a circular economy;
- identify research themes and gaps to guide a future research agenda.

The study is organised as follows. Section 2 describes the research methodology. Section 3 provides the review's main findings, identifying bibliometric features and key findings. Section 4 presents a discussion outlining recommendations for further research and highlights the limitations of our review.

2 Methodology

Authors have adopted a systematic literature review (SLR) following the guidelines of Tranfield et al. (2003). This methodology allows for photographing the current knowledge on specific topics and identifying and synthesizing research results and gaps for future studies (Pasca et al., 2021). Specifically, the research analyzed existing studies on how blockchain technology can contribute to achieving circular economy goals. The search was conducted on the Scopus database in January 2025.

The literature search in the Scopus database was conducted using the following search string: keyword *(TITLE-ABS-KEY)* Blockchain AND "Circular Economy".

A total of 457 articles published between 2018 and 2025 were collected and reviewed. The authors have defined inclusion criteria to obtain the most relevant publications on the relationship between blockchain technology and circular economy, discarding studies not conducted in English (3), including those that were in a final publication stage (excluding 20) in January 2025, which were journal articles, reviews and conference papers (excluding 94) and which were relevant to the following subject areas: environmental science; computer science; economics, management and accounting; social sciences; economics, econometrics and finance (excluding 51 articles).

In detail, the revised studies are journal articles and conference proceedings focusing on blockchain and the circular economy from a managerial perspective. Subsequently, we excluded 225 studies that do not strictly deal with the topic of blockchain connected to the circular economy from a managerial perspective. Furthermore, the full text of four articles could not be retrieved. The final corpus of reviewed articles amounts to 64 hits.

The full texts of the final body of literature were analysed by integrating additional information such as: the field of application; the study approach; the methodology adopted; the research country; the results obtained and indications for future research.

This information has been collected in an Excel file. Considering the research questions underlying the systematic literature review, the studies analysed were examined through content analysis with the aim of providing the bibliometric characteristics of existing literature, identifying the main areas of application, and, for each area, further research results and indications.

3 Results

3.1 Bibliometric results

The analysis shows that the years of publication of articles vary from 2018 to 2025, specifically: for the year 2018, the selected articles amount to 2, for 2019 to 3, for 2020 to 3, for 2021 to 12, for 2022 to 12, for 2023 are 15, for 2024 are 15, and for 2025 are 2. From the bibliometric analysis, we note that between 2021 and 2024, there was a significant increase in publications regarding the relationship between blockchain technology and the circular economy, demonstrating how the topic has become more relevant to the scientific community.

Regarding the type of article, most of the studies examined are articles (47), 9 are conference papers, and 8 are reviews. Continuing the analysis, it emerged that the most used approach is empirical (18), followed by 15 case studies, 14 systematic literature reviews, 12 conceptual articles, 2 adopted a combined approach between systematic literature review and case study and 3 research between systematic literature review and empirical approach. As regards empirical research (18), studies have been carried out: 3 in the USA, 3 on European territory, 2 in China, 2 in Italy, 2 in India, 2 in the UK and 1 respectively in Austria, Belgium, Canada, Norway, Netherlands, Denmark, Finland, Hong Kong, Indonesia, Turkey, North America and Asia.

Finally, the systematic literature review shows that the selected studies are in 10 sectors: waste management (15), Agrifood (11), Textile and Fashion (7), Construction (6), Energy (6), Electric Vehicle Battery—EVB (4), Electronics (4), Finance (4), Manufacturing (3), and Transportation (4).

3.2 Review results

The results of the study highlight how the application of blockchain aimed at increasing actions related to the circular economy is distributed across 10 different sectors: Waste management (15), Agrifood (11), Textile and Fashion (7), Construction (6), Energy (6), Electric Vehicle Battery - EVB (4), Electronic (4), Finance (4),

Manufacturing (3), Transportation (4). In the following sub-paragraphs, we will analyze the results specific to each sector that emerged from the systematic literature review in more detail.

3.2.1 Manufacturing

As for the manufacturing sector, the authors note from the results that adopting blockchain technology entails enhancing circular economy practices, significantly contributing to achieving the sustainable development goals set out in the 2030 Agenda. Specifically, the contribution of blockchain in the manufacturing industry focuses on several aspects: the detection of counterfeit products, the improvement of reliability through its ability to track all processes and complete transparency for all participants, from raw material suppliers, producers, and delivery carriers to the final customer (Nair et al., 2024). Finally, blockchain, supported by the implementation of intelligent devices such as the Internet of Things and artificial intelligence in the manufacturing sector, helps to support the ecological transition, explicitly contributing to the reduction of the use of raw materials, waste generation and fuel consumption during processing (Kopeinig et al., 2024).

3.2.2 Textile and Fashion

Technological innovations in the textile and fashion sector, also known as fast fashion, have been concentrated mainly on waste collection, contributing to a significant increase in the overall sustainable management of this sector. Indeed, over the years, the need has emerged to make the fast fashion sector more sustainable, and a possible solution is offered by adopting and integrating technologies such as IoT, AI, and Blockchain (Tang, 2023). The main challenges emerging from the literature that these technologies are called to collect concern the sustainable implementation of fast fashion supply chain management given their enormous size and the wide involvement of many stakeholders worldwide. Managing the latter requires agility, transparency and precision, possible through the integration of digitized technologies (Ostermann et al., 2021). The most significant contributions through their integration have occurred in traceability, through the adoption of specific sensors favoured by the IoT, verification and reporting of textile waste flows, particularly favoured by the functionality of blockchain technology. Then, the adoption of new technologies such as IoT, AI and Blockchain has optimized collection routes, contributing to the development of circular supply chains and favoring the replacement of materials with alternatives using, for example, agricultural waste (Shou et al., 2022).

3.2.3 Agrifood

Integrating blockchain technology into the food supply chain significantly improves four key areas: data integrity and trust, operational efficiency, sustainability and safety, and social impact and waste management (Ellahi, Wood and Bekhit, 2024). Thanks to its characteristics, the blockchain promotes trust and the sharing of responsibility between all stakeholders in the production chain at every stage (Santos, Teles and Freires, 2024). It also significantly impacts sustainability by tracking environmental impacts and ensuring food safety through real-time monitoring, allowing the development of increasingly innovative and effective organic farming practices while maintaining soil health and food accessibility and ensuring biodiversity and resilience of ecosystem services (Pakseresht et al., 2023). Among the other positive aspects of integrating blockchain technology in the agri-food sector is the ability to effectively dispose of, reuse, and recycle packaging (Santos, Teles, and Freires, 2024).

As a last aspect, present in different sectors examined in this article, the authors analyze the relationship between tokenization and the circular economy. Tokenization also plays a fundamental role in the agri-food sector, and its application suggests that it will proliferate in the coming years.

Studies show that tokenization can improve efficiency in circular agri-food chains with a high level of reuse and recycling by identifying patterns in inventory and distribution data. Another hypothesis is that the tokenization of incentives may improve the understanding of consumer preferences for recycled or regenerated products.

In light of this, it appears necessary to establish priorities and develop a decision-support framework to assess its feasibility, effectiveness and development (van Wassenaer et al., 2023).

3.2.4 Waste Management

The review of the literature shows that the adoption of blockchain technology also brings significant benefits in the management of the waste cycle, specifically on plastic ones. Blockchain technology, through its main tools such as smart contracts, consent mechanism, data traceability and distributed ledger, significantly improves the accurate segregation of plastic waste, particularly by adopting physico-chemical parameters such as colour, polymer and density. In addition, the nature of these technologies ensures a significant increase in transparency

and reliable sharing between segregators, recyclers and producers of information regarding suitability, quality compliance, bid and ask price, and the availability of material, thus fostering an increase in mutual trust between all stakeholders concerned (Conforto, 2019).

Another aspect of the literature concerns tokenization applied to the waste management sector. Through implementing the latter, specifically with its reward system characterized by tokens, the participation of customers in proper waste disposal is encouraged. The reward from customers' recycling efforts allows them to obtain discounts on waste taxes, resulting in significant cost savings (Marchesi et al., 2024). In conclusion, some of the main results regarding the application of blockchain technology to waste management are improving traceability and transparency, improving the authenticity of waste logistics data, preventing fraud and tax evasion, improving the protection of personal privacy, strengthening cooperation between actors by facilitating the monitoring, optimization and management of waste separation, recycling, reuse and treatment processes (Jiang et al., 2023).

3.2.5 Electric Vehicle Battery – EVB

The implementation of new technologies resulting from the fourth digital revolution not only involves fast data transfer but also the implementation of clean and waste-free technologies. Blockchain technology is among the modern digital technologies that can increase the practices of circularity within companies.

Among the sectors involved in the massive application of these new technologies, the automotive industry stands out, which requires the management of batteries to power vehicles. Indeed, blockchain technology significantly improves transparency and traceability in the supply chain (Grati et al., 2024). The results of the studies show how new technologies allow an improvement in the efficiency of EVB (Electric Vehicle Battery) value chains. Several studies also show how data sharing influences the demand for materials, recycling costs and raw material prices, providing a significant benefit to stakeholder collaboration and contributing to the achievement of sustainable development goals (Ribeiro da Silva et al., 2023).

3.2.6 Construction

Blockchain technology in the construction industry, as well as improving transparency, traceability and collaboration within the sector, allows the development and adoption of circular business models, optimising resource consumption and consequently minimizing the generation of waste (Movaffaghi et al., 2023). Integrating with IoT and AI, the blockchain-based model is crucial to promote waste reuse in the construction industry. The model offers necessary guarantees regarding the composition of the slag sold by highlighting its properties and characteristics. The effect of this collaboration contributes to an increased interest in by-products from the construction industry, allowing the creation of a specific market.

The key findings of the literature review show how adopting new technologies contributes to developing fruitful collaborations between stakeholders to create circular buildings. This collaboration, for its full implementation, requires a common platform for the participation of actors in the large-scale value chain, thus enabling the identification of business partners, information sharing, the development of business models and the tracking of material flows. Taking the example of material flow, these technologies allow the monitoring of material sources and facilitate the transfer of fluid properties of materials (Gómez-Goiri et al., 2024). In conclusion, the analyses highlighted how crucial information processing, accuracy, security, and data availability are for achieving greater trust and cooperation between stakeholders throughout the supply chain.

3.2.7 Energy

The changes resulting from the climate crisis also dictate the agenda of the evolution of the energy sector of countries throughout the planet. For this reason, the energy mix of countries is increasingly moving towards renewable energies, with a consequent reduction in emission levels (Balzani et al., 2024). In this scenario, blockchain technology plays a decisive role, contributing to improving renewable energy production. Specifically, thanks to the integration of new technologies, it is possible to implement activities such as generation, distribution, transmission, storage, and trade of energy (Pandey et al., 2023). Thanks to the development of these technologies, it has been possible to improve energy storage plants by creating storage networks based on the IoT combining various renewable resources such as wind, hydroelectric and solar power, improving production processes' efficiency (Pandey et al., 2023). In the case of the latter type, from the analysis of the literature, the integration of blockchain with photovoltaic energy to generate a solar photovoltaic energy ecosystem that contributes to achieving an increasingly sustainable and circular economy emerges more frequently (Erol et al., 2021).

3.2.8 Electronic

The relevance of adopting blockchain technology to boost circular economy practices also includes the electronics sector. Specifically, the literature explores the connection between hyperautomation, blockchain technology, and circular economy in the green supply chain, which is linked to the electronic industry's dispute. The results suggest that the joint adoption of hyper-automation and blockchain technology encourages companies to adopt positive behaviours for both the environment and their employees. In addition, it has significant consequences for managerial practice, motivating managers to improve green design in the electronics industry by ensuring, through the use of blockchain technology, that all steps and processes are properly communicated between them (Jiang et al., 2023). Proceeding with the analysis of the results on the interconnection between the circular economy and blockchain technology, the management of Waste from Electrical and Electronic Equipment (WEEE) plays a leading role. The main circularity challenge in the electrical and electronic equipment (EEE) sector concerns the creation of sustainable supply chains using new technologies. In particular, blockchain technology plays a key role by storing and transferring data such as product characteristics, usage cycles, traceability of materials and compliance with regulations like REACH. This integration extends the life of products, conserves valuable materials and reduces pollution and health risks related to WEEE (Magrini et al., 2021). In addition, the adoption of digital technologies can also improve corporate social responsibility by increasing consumer awareness of circular economy practices such as re-use, repair and recycling, improving reverse flows by aligning with the waste hierarchy and value retention principles (Chen et al. 2021). Blockchain can help verify ethical practices in supply chains by addressing issues such as child labour and human rights violations related to raw material procurement (Magrini et al., 2021).

3.2.9 Finance

Among the sectors to which blockchain technology has been applied in financial matters, it has played a key role in creating and managing the market related to Bitcoin. For instance, the study by Ozili (2022) focuses on a digital currency issued by the central bank to promote circular economy actions in all production systems. This currency would offer various functions that would allow a transition from a linear economy to a circular one, in particular: it would offer a better payment option for transactions in the circular economy, would provide more effective financial assistance to circular enterprises through the central bank itself, and would help reduce illicit activities. It can also provide stimulus financing to support circular enterprises during times of crisis and offer lower transaction costs for financial transactions involving the circular economy actions taken by enterprises and natural persons. Blockchain technology, in this case, would play a key role in ensuring, as in the Bitcoin market, transparency, security and integrity, reduction of transaction costs and efficiency. Another aspect involving the financial sector is creating a credit system to support the transition towards a circular economy. This system, through the adoption of blockchain technology, would allow transparent and secure verification of the credit reputation of economic entities. Sharing this information would generate huge benefits in the financial market, particularly by facilitating and encouraging reliable transactions between trading partners. In addition, thanks to the benefits provided by blockchain technology, we would see a significant reduction in brokerage costs, simplifying and reducing the costs of the current control system for the assignment of credit ratings. Finally, the smart contracts tool would ensure the legality, speed and security of transactions, making the process more efficient (Wu et al., 2018).

3.2.10 Transportation

The transformative potential of integrating the principles of the circular economy with new technologies also significantly involves the context of transport infrastructure. The literature review shows how Blockchain technology, AI, and IoT in the transport sector play a key role in responding to the environmental challenges posed by conventional transport systems, such as predictive maintenance, improving material recycling, resource optimisation, waste reduction, and life cycle extension (Yildizbasi et al., 2025; Bekrar et al., 2024). In more detail, adopting the IoT can improve real-time data collection and system-level efficiency. Given the sector's peculiarity, the adoption of new technologies contributes significantly to the creation and management of smart cities, reducing congestion and improving traffic flow with a consequent reduction in CO2 emissions (Yildizbasi et al., 2025).

4 Discussions and Conclusions

The analysis of the reviewed articles highlighted the potential of blockchain technology in implementing circular economy techniques in both the private and public sectors. The results show how blockchain implementation is cross-cutting across different sectors. However, several obstacles prevent the

implementation of blockchain technology. Among the main ones that emerged from the reviewed studies are the very high costs due to the significant investments it requires, the poor digital literacy of non-technical users who often drive small and medium-sized businesses, scalability problems, high energy consumption and lack of regulation. Moreover, although the systematic literature review has shown widespread application, it is still insufficient to reveal different management scenarios. Therefore, it is essential to emphasize that blockchain applications are not limited to end-of-life product management but extend throughout the entire supply chain to minimize waste and reduce the environmental impact of these sectors. However, companies must master new data analysis technologies to adopt blockchain technology and optimize sustainability practices properly. Indeed, the connection between blockchain technology and big data analytics tools significantly supports the integration among the various actors across the different stages of the supply chain (Mileti et al., 2022). This connection links producers with commercial channels, ensuring traceability, transparency, authenticity, increased productivity, reliability, and trust-based agreements while, thanks to the immutability of recorded data, preventing fraud and information falsification (Kumar and Chopra, 2022). In conclusion, in light of what has emerged from the study, we can argue that one of the main objectives of future research is to regulate with homogeneous standards, offering economic and knowledge support to actors called upon to implement it (Barceló et al., 2024). Further future challenges related to the implementation of blockchain technology in the circular economy concern the reduction of investment costs that the implementation of smart devices, sensors and related technologies require (Kopeinig et al., 2024) and the systematic applications of these technologies in new management scenarios (Jiang et al., 2023). The study provides valuable insights for policymakers, companies, and researchers to promote the integration of blockchain technologies within businesses, contributing to the pursuit of sustainable development. The search has some limitations. The authors considered only one database and documents written in English. As a result, some studies may be missing since we do not include databases and languages other than English. In addition, the study focused exclusively on documents that deal with blockchain and the circular economy from a managerial perspective. Future studies may analyse more specific topics or adopt other methodologies for a more complete phenomenon overview.

Exploring Artificial Intelligence in the Circular Blue Economy

Federica Marroni
University of Rome "La Sapienza", Rome, Italy

Abstract

Artificial intelligence is becoming increasingly important, with applications varying from sector to sector due to its adaptability. Its most common uses range from generating clean energy to monitoring data to analyse the surrounding ecosystem and mitigating pollution damage. In the circular economy, the potential of AI could be harnessed to accelerate sustainable transactions by integrating it into design, business models and infrastructure optimisation. Thanks to its generative capabilities, AI can significantly contribute to reducing the impact of human activities on the environment by addressing challenges related to unsustainable production. In this respect, the circular economy proposes models that contribute to value creation through cycles of reuse, restoration and renewability.

This work, therefore, aims to investigate the state of the art of scientific research in the area of the circular economy in general and, with a specific focus on applications in the context of the Blue Economy, highlighting the uses, advantages and opportunities that the use of these systems brings to the Blue Economy sectors. The methodology adopted consists of a systematic literature review (SLR), aimed at categorising existing scientific contributions extracted from the Scopus database, analysing the main research trends and identifying the most relevant practical applications, and identifying future insights to encourage the adoption of AI within the Blue Economy. The results of this study highlight the limited presence of studies on the application of artificial intelligence in the context of the Blue Economy, and research is fragmented and spread across different disciplinary areas. However, the maritime sector has stood out for its strong interest in technology adoption from a scientific research perspective. This study, therefore, provides theoretical implications for academics by identifying the knowledge gap and providing guidelines for future research, and managerial implications for all stakeholders in the blue economy who want to know how to integrate the use of AI into their processes. Finally, the focus on this as yet under-researched area lends the study a character of originality and scientific relevance.

Keywords: Circular Economy, Blue Economy, Artificial Intelligence, Smart Technologies.

Paper type: Academic Research Paper

1 Introduction

The concepts of digitalization in the economy and circular economy have been developed in recent years and are closely interrelated (Kaya, 2024). Today, technological progress is integrated into every industry, business practice, and economic activity, serving as a tool to enhance efficiency and simplify many operations. The environmental impact of products and production processes is increasingly significant, and approaches such as the circular economy aim to reshape development models, focusing not only on the environmental sphere but also on social and economic dimensions (Chidepatil et al., 2020). Thanks to the integration of technologies into individual operations or, more broadly, into the functioning models of industrial processes, it is possible to tackle challenges such as sustainability. In the maritime context, this is reflected in the Blue Economy model, considered a school of thought within the circular economy, which focuses specifically on economic activities related to the marine environment (European Commission, 2024). According to some authors, the application of artificial intelligence or AI to economic activities increases productivity (Brynjolfsson, 2014; Czarnitzki et al., 2023), enables the monitoring of environmental impacts (Popescu et al., 2024), supports the management of the marine environment (Ajwani-Ramchandani et al., 2021; Brönner et al., 2023; Gesami and Nunoo, 2024), and facilitates the implementation of circular business models. Conversely, some scholars remain skeptical about AI's potential to drive a new wave of productivity growth (Gordon, 2018). Nevertheless, the integration of artificial intelligence is transforming industrial sectors, which are evolving and innovating through the integration of new technologies that support the generation of new ideas and foster innovation (Agrawal et al., 2019). In the circular economy, and within the broad and diverse Blue Economy value chain, numerous innovations have been implemented through the use of AI (Rajput and Singh, 2019; Pranita et al., 2023). This study aims to analyze the state of the art regarding the applications of artificial intelligence within the framework of the Circular Blue Economy. Through a structured literature review and by following authoritative research protocols, the study aims to identify the evolving research trends, systematize the contributions, and highlight any circular blue economy practices supported by AI. The results first of all demonstrate the novelty of the topic, which consequently translates into the limited presence of research on the application of artificial intelligence within the Blue Economy. Three main thematic foci were identified in this study: the use of smart technologies

to support the circular economy, the Blue Circular Economy and sustainable resource management, and the development of circular business models and performance measurement. The originality of the study lies in its exploration of a relatively under-researched area; nonetheless, it represents a valuable contribution by recognizing the knowledge gap, encouraging academics to pursue further research in this field, and, on the managerial side, influencing stakeholders to consider digital solutions for implementing circular models in the Blue Economy. This paper is structured as follows: after the introduction, a brief literature review relevant to the research context is provided; next, the methodology adopted is described; then, the main results are presented and discussed; finally, conclusions are drawn, highlighting the related implications and offering suggestions for future research.

2 Research background

The concept of the circular economy finds one of its most authoritative definitions in the proposal of the Ellen MacArthur Foundation, which describes it as "an industrial system that is restorative or regenerative by intention and design. It replaces the "end-of-life" concept with restoration, shifts towards the use of renewable energy, eliminates the use of toxic chemicals, which impair reuse, and aims for the elimination of waste through the superior design of materials, products, systems, and, within this, business models". The introduction of this concept thus laid the foundations for an economy that stands in contrast to the linear model. In this regard, Murray et al. (2017) state that the circular economy differs from the linear model based on three core principles: eliminating waste and pollution, keeping products and materials in use at their highest value, and regenerating natural systems. Based on these principles, the circular model finds application in many schools of thought, including that of the Blue Economy. The concept of the Blue Economy was developed by Gunter Pauli, who argued that the local environment, with its specific ecological characteristics, represents the basis for sustainable solutions within each economic ecosystem. The purpose of the Blue Economy lies in the application of the principles of the circular economy within the maritime context, maximizing the value of marine resources (Choudhary et al., 2021; Pace, 2023). In this regard, the vastness of activities revolving around the ocean resource becomes evident, encompassing sectors such as fishing, maritime transport, tourism, and more. It is, therefore, a multisectoral economic model, where, according to the report drafted annually by the European Union, two main categories of activities related to the blue economy emerge: the established sectors, considered traditional, and the emerging sectors, characterized by high technological and innovative content (European Commission, 2024). The EU report identifies seven main sectors, each divided into specific sub-sectors, as shown in the following table:

Table 1: Blue Economy Sectors. Source: European Commission, 2024.

Sector	**Sub-sector**
Marine living resources	Primary production Processing of fish products Distribution of fish products
Marine non-living resources	Oil and gas Other minerals Support activities
Marine renewable energy	Offshore wind energy
Port activities	Cargo and warehousing Port and water projects
Shipbuilding and repairs	Shipbuilding Equipment and machinery
Maritime transport	Passenger transport Freight transport Services for transport
Coastal tourism	Accommodation Transport Other expenditure

As can be observed, the Blue Economy sector, being a fundamental driver of economic growth and the operational application of circular economy paradigms, makes the integration of artificial intelligence applications into monitoring and management practices—and beyond—essential (Gesami and Nunoo, 2024). Artificial intelligence also emerges as an additional input in business processes or even across entire economic sectors, both traditional and emerging within the Blue Economy, capable of generating new ideas and thus fostering innovation (Agrawal et al., 2019). In the Blue Economy, AI applications take the form of intelligent

systems used to optimize the fisheries supply chain (Fernandes et al., 2015) improving the efficiency of supply chain processes (Lim, 2024). In aquaculture, AI enables the assessment of water quality, ensuring the conditions necessary for species development, as well as facilitating optimal management of marine ecosystems (Lim, 2024). Moreover, tools equipped with intelligent technologies can contribute to the monitoring of marine ecosystems (Choudhary et al., 2021), collecting crucial data for environmental monitoring and biodiversity protection (Brönner et al., 2023). In the tourism sector, for example, AI applications are used for the sustainable organization and management of resources, to promote sustainable tourism practices (Pranita et al., 2023), while also enhancing visitors' experiences through virtual and augmented reality (Marroni, 2024). Port operations can also benefit from the advantages of AI in reducing emissions, including greenhouse gases and ocean noise, thus promoting environmentally friendly maritime transport (Munim et al., 2020). Furthermore, the integration of AI and machine learning into sensors, buoys, and satellites allows for the collection of essential data on the oceans, such as ocean currents and sea-level changes (Brönner et al., 2023). In essence, artificial intelligence, as an emerging technology of the “fourth industrial revolution”, represents an important driver capable of sustaining and accelerating the pace of human innovation to design products, bring together aspects of successful circular business models, and optimise the infrastructure needed to foster systemic change that builds long-term resilience, generates business and economic opportunities, and provides environmental and social benefits (Ellen MacArthur Foundation, 2019).

3 Research method

To develop this study, the author adopted a qualitative methodology based on the Structured Literature Review (SLR) method. The SLR follows a rigorous approach that allows for the selection and evaluation of contributions, the analysis and synthesis of data, and the transparent and comprehensive reporting of research findings (Tranfield et al., 2003). Moreover, the literature review helps to understand how research on specific topics has evolved, as it involves an analysis of the thematic foci identified by the author (Petticrew & Roberts, 2006). In this study, the research questions are as follows:

- (RQ1) How is research inquiring for AI and the Circular Blue Economy?
- (RQ2) What is the focus and critique of the AI and the Circular Blue Economy literature?
- (RQ3) What is the future of AI and the Circular Blue Economy?

The main objective is to investigate how artificial intelligence contributes, within the conceptual framework of the circular blue economy, to studies in the business field. First, a research protocol was defined, inspired by consolidated contributions in the literature, such as Tranfield et al. (2003), Petticrew and Roberts (2006), and Kraus et al. (2020). Additionally, based on the methodological syntheses proposed by Chauhan et al. (2022) and Marroni (2024), an analytical framework was constructed, including and considering the following aspects:

- Publication trends: a temporal analysis of research development in the field of circular blue economy and artificial intelligence.
- Geographical distribution: a territorial analysis of the distribution of scientific production on the topic.
- Citation and journal analysis: citation-based information related to the theme.
- Thematic foci: identification of research areas within the context of the circular blue economy and artificial intelligence.

To provide an overview of these aspects within the development of the longitudinal study (2019–2024), the Scopus database was used for article extraction. Scopus offers a wide range of academic information, enabling in-depth insights for the research (Kar et al., 2022). The research strategy involved extracting keywords from "Title, Abstract, and Keywords", using Boolean operators to combine the search terms. The keywords used included: "Circular Economy" OR "Blue Economy" AND "Artificial Intelligence". An initial extraction resulted in 819 documents related to the topic. Subsequently, the author narrowed the scope of the investigation to the field of "Business, Management, and Accounting", considering only "research articles", which generated a result of 83 articles. Finally, articles not written in English and those published in the current year (2025) were excluded, as the year is not yet completed and would have distorted the results, reaching a final sample of 64 items.

4 Results and discussions

In this section, descriptive results are presented, including publication trends, geographical distribution, citation analysis and journals of origin. The identification of thematic foci is also proposed, which makes it possible to trace the evolution of research streams, also analysing their practical implementations.

4.1 Publication trends

The first aspect considered is the publication trend. In this direction, the final sample of articles is included in the time frame 2019- 2024. As the figure shows, the number of research articles increased over six years, peaking in 2023 (20 articles). From 2024 onwards, there is a slight decrease in terms of publication, with 17 articles. The period identified also shows that this is a very current topic.

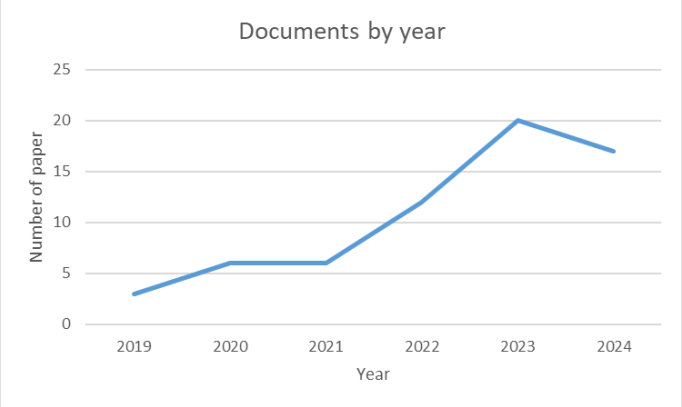

Figure 1: Publishing trend.
Source: Author elaboration from Scopus data.

4.2 Geographical distribution

Shifting the focus to geographical location, India is the territory with the most research articles in this area (16 articles), followed by the United Kingdom (11 articles) and France (10 articles). Below is the table with the list of territories where articles are published in this subject area and the geographical map of the territories.

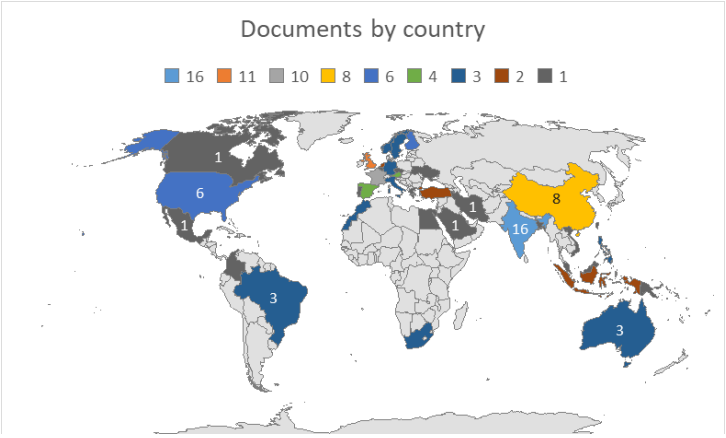

Figure 2: Documents by country.
Source: Author elaboration from Scopus data.

4.3 Citation and journal analysis

An analysis by citation and journal of origin shows that:

- The Journal with the most citations is Technological Forecasting and Social Change with 1.223 total citations distributed among its 6 articles (see Table 1).
- The Journal of Cleaner Production is the journal of choice for those writing on this subject area, with 13 articles published in this SLR (see Table 1).
- The International Journal of Information Management, despite seeing only one article published, stands out for the number of citations (452), symbolising the relevance of this article in this context.
- Other journals show a very low comparison between the number of papers and citations, synonymous that this topic is occasional or emerging in the context of SLR.

Table 2: Distribution of sources and citations of selected articles in the SLR. Source: Author elaboration.

As part of the citation analysis, the six studies with the highest number of citations are summarised in Table 2, the first of which is the study entitled “Role of institutional pressures and resources in the adoption of big data analytics powered artificial intelligence, sustainable manufacturing practices and circular economy capabilities” with 540 citations. These six research articles come from different institutions, in four of them the authors are located in the same state, such as the study by Rajput and Singh (2019) from India, the one by Rusch et al. (2023) from Austria, the one by Laskurain-Iturbe et al. (2021) from Spain and the one by Chidepatil et al. (2020) from Finland. In contrast, the study by Bag et al. (2021) and the one by Chauhan et al. (2022) leverage the international network in the production of scientific research.

4.4 Thematic foci

After reviewing the abstracts, titles, and keywords, the author categorized the final sample into three thematic foci:

1. The use of smart technologies to support circular economy practices: This thematic focus includes articles addressing the integration of digital technologies into the circular economy. Most applications of digital technologies are related to waste management activities (Laskurain-Iturbe et al., 2021; Chen et al., 2023; Mah et al., 2024). Technologies such as artificial intelligence, big data, the Internet of Things, and virtual and augmented reality are linked to the reduction of material and energy consumption as well as waste and emissions (Laskurain-Iturbe et al., 2021). In their study, Rajput and Singh (2019) identify AI and circular economy practices as enablers that support and strengthen circular strategies such as recycling and regeneration by extending product life cycles (Jiang et al., 2023). Additionally, according to the authors, the application of the Internet of Things helps collect valuable data on resource consumption and material waste. Thus, technological innovation enables the realization of the circular economy vision (Ellen MacArthur Foundation, 2019).
2. Blue circular economy and sustainable resource management: This thematic focus includes research articles identifying potential sustainable resource management practices enabled by artificial intelligence and other technologies. The work of Foster and Rhoden (2020) is the only one that combines the use of AI in a Blue Economy sector, namely logistics, arguing that technologies improve the efficiency of logistics and port processes. However, studies such as Coro (2020) more generally analyze AI integration to support sustainable management practices and promote blue growth. Lastly, Pranita et al. (2023) explore the use of blockchain technology to support responsible tourism initiatives.
3. Development of circular business models and performance measurement: This research area includes all articles focused on the creation of circular business models enabled through the use of technology. For example, Philipp (2020) develops a green business model for port logistics to increase transparency along the value chain. Within the domain of business models, smart technologies support performance; Truant et al. (2024), for instance, explore enabling factors that help improve business competitiveness, efficiency, and sustainability.

To gain a deeper understanding of the thematic areas that have shaped this research stream, a keywords occurrence analysis was also conducted. This analysis made it possible to highlight the keywords related to the final sample of the study. According to Dunaiski et al. (2017), a good set of keywords should accurately describe a document (good coverage), be sufficiently distinctive so as not to apply to too many documents (relevance) and be easily understandable (descriptive). Of the 268 keywords used by the authors in the final sample, only those that occurred at least twice were considered, thus excluding keywords mentioned only once. The ten most frequently used keywords in the sample are:

- Circular economy (31)
- Artificial intelligence (21)
- Industry 4.0 (9)

- Sustainability (7)
- Waste management (5)
- AI (4)
- Blockchain (4)
- Digitalization (4)
- Internet of Things (4)
- Circular business models (4)

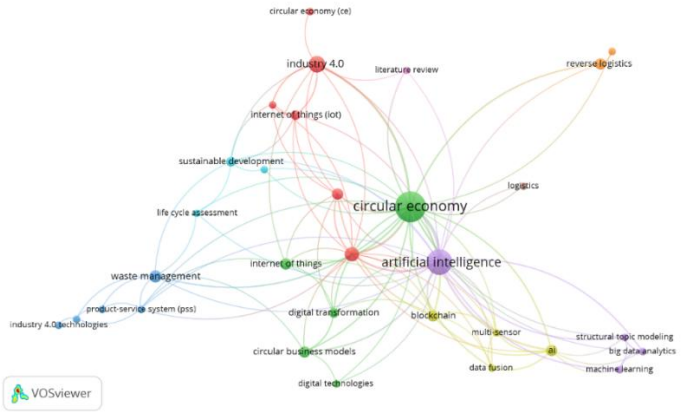

Figure 3: Keywords occurrence.

5 Preliminary conclusions, implications, limitations, and directions for future research

In conclusion, the study highlights the novelty of the topic addressed. Studies on the circular economy, which represent the majority within the present sample, show that it is a well-established research stream, even concerning the application of AI. Conversely, studies focusing on the practical application of AI in the Blue Economy context are limited, confirming its fragmented nature. Both the established and emerging sectors of the Blue Economy have only recently begun to attract attention. The use of AI is still in an experimental phase, and this highlights the absence of comprehensive theoretical syntheses regarding these areas. The Structured Literature Review, conducted on this sample of articles, made it possible to identify three main thematic foci: (1) the use of intelligent technologies to support circular economy practices, (2) the sustainable management of resources in the Blue Economy, and (3) the development of circular business models and performance measurement. It is starting from these thematic areas that further academic research is hoped to be developed, filling the existing gap, while on the managerial side, given the importance for businesses, it is encouraged to promote the adoption of AI, thus fostering the transition towards circular business models. This study is not without limitations. First, the use of a single database does not allow for exhaustive coverage of the literature on the topic. Second, relying solely on the reading of titles, abstracts, and keywords may represent an obstacle to fully understanding the information. Considering the evidence collected, future research directions can be identified. Academic research could focus on sectoral dynamics within each activity included in the Blue Economy, to better understand the developments related to the application of AI in this emerging sector. Conversely, on the managerial side, longitudinal research based on case studies could be developed for each sector, identifying the degree of applicability according to the sectoral and economic diversities that characterize the Blue Economy value chain.

6 Acknowledgements

This work was carried out as part of the Research Project titled "Economia del mare tra turismo e food" funded by the Lazio Region and the Industrial Consortium of Lazio- XXXVII cycle Ph.D. scholarship".

7 Ethics declaration

No ethical authorization was required for the research.

8 AI declaration

No AI tools were used in the development of the paper.

Abstract

The circular economy (CE) is increasingly being recognized as a viable alternative to the traditional linear model of production and consumption, which is now widely acknowledged as unsustainable. For these reasons, the academic literature has begun to take an interest in the way in which companies implement CE strategies in their business models and disseminate information regarding this new model of production and consumption. Specifically, scholars have begun to investigate the dissemination of CE information, but this area of research is still underexplored. In fact, there are only a few studies investigating the factors that influence the levels of CE disclosure (CED). In order to fill the knowledge gap, this study aims to examine the impact of national culture on CED levels. First, this study uses a manual content analysis to measure the amount of CE information disseminated in the sustainability reports of 81 international companies. Secondly, a linear regression model is used to test the impact of national culture on the CED. The results show adequate levels of CE information disclosed through sustainability reports. In addition, they demonstrate a negative impact of power distance and masculinity and a positive effect of uncertainty avoidance and long-term orientation on the CED. To the best of our knowledge, this is the first study to explore the influence of national culture on CED, addressing a gap in the literature at the intersection of cultural values and sustainability reporting practices. By highlighting how specific cultural dimensions shape firms' disclosure behaviour, this study provides valuable insights for companies –seeking to align their reporting with stakeholder expectations – as well as for policymakers and training institutions, who aim to promote more effective and culturally sensitive sustainability frameworks.

Keywords: Circular Economy Disclosure; National Culture; Hofstede; Sustainability Reports

Paper type: Academic Research Paper

1 Introduction

In recent decades, ecosystems have faced increasing threats from deforestation, pollution, urban expansion, climate change, species extinction, and resource overexploitation. Their preservation is crucial for sustainable development, ensuring biodiversity, climate regulation, ecological balance, public health, and resource availability (L'Abate et al., 2023). The exponential growth of the global population, projected to reach 8.5 billion by 2030 and 10.9 billion by 2100 (UN, 2021), has further strained ecosystems by driving higher demand for natural resources such as timber, water, land, and fossil fuels. This growing demand, coupled with the climate crisis, has weakened the capacity of the ecosystem to provide essential resources. Additionally, the COVID-19 pandemic and the Russia-Ukraine conflict have exacerbated resource shortages, creating further challenges in securing raw materials.

The circular economy (CE) plays a crucial role in promoting sustainability by maximizing resource efficiency (Ellen MacArthur Foundation, 2015), aligning production and consumption with sustainable development goals (Ghisellini et al., 2016), and enhancing social well-being (Murray et al., 2017). Geissdoerfer et al. (2017) define CE as a "regenerative system in which resource input and waste, emissions, and energy leakage are minimized by slowing, closing, and narrowing material and energy loops." These key strategies aim to minimize waste and extend resource lifespan (Petruzzella et al., 2024).

Institutions at both European and international levels promote the transition to the CE through various policies and initiatives. China was the first to introduce CE legislation in 2008 (CIRAIG, 2015), followed by the European Union's "Circular Economy Action Plan" in 2015, which provided a framework for integrating CE into production and consumption processes (European Commission, 2014). CE was also incorporated into the 17 Sustainable Development Goals (SDGs) of the "2030 Agenda for Sustainable Development," and further reinforced through the "European Green Deal" and its updated action plan (European Commission, 2019; 2020). Companies also play a crucial role in value co-creation, acting as essential links in the production-consumption chain that must be preserved to close the resource loop (Gunarathne et al., 2021). The adoption of CE strategies

is driven by multiple factors, including the pursuit of legitimacy (Murray et al., 2017), competitive alignment through isomorphic behaviours (Korhonen et al., 2018), and compliance with institutional pressures (Barnabè and Nazir, 2022).

Although CE plays a crucial role for stakeholders and in the ecological transition (Beck et al., 2017), companies still struggle to effectively communicate information about this new production and consumption model (Barnabè and Nazir, 2022; Esposito et al., 2023). The dissemination of CE information is still in an early stage due to the absence of a common language (Korhonen et al., 2018) and the scarcity of measurement tools and guidelines for its representation (Ellen MacArthur Foundation, 2015).

Several studies in the academic field have increasingly focused on the emerging and significant topic of CE disclosure (CED). However, knowledge regarding the factors that influence the levels and quality of CED remains limited. Previous research has primarily concentrated on internal firm-related factors, such as financial characteristics (e.g., Vitolla et al., 2023; L'Abate et al., 2024a), governance (e.g., Esposito et al., 2023; L'Abate et al., 2024b), and ownership structure (e.g., Wang et al., 2014). Regarding external factors, previous studies have mainly focused on industry-specific aspects (e.g., L'Abate et al., 2024a). Limited attention, however, has been given to country-level variables. Specifically, there is a noticeable lack of contributions exploring the role of national culture in shaping CED practices.

This study aims to address this significant gap in the literature by posing the following research question:

- *RQ: Does national culture affect the level of the CED in sustainability reports?*

The remainder of the paper is structured as follows: Section 2 reviews the relevant literature; Section 3 outlines the hypothesis development; Section 4 describes the research design; Section 5 presents the empirical findings; and Section 6 draws the conclusion of this study.

2 Literature review

The relationship between national culture and disclosure practices has attracted the attention of numerous scholars (e.g., Gray, 1988; Fernandez-Feijoo et al., 2011).

In relation to Integrated Reporting (IR), García-Sánchez et al. (2013) showed that masculinity and individualism negatively affect IR adoption. Similarly, Vitolla et al. (2019) observed that power distance, masculinity, individualism, and indulgence negatively influence IR quality, while uncertainty avoidance has a positive effect. Using the Global Leadership and Organizational Behavior Effectiveness (GLOBE) framework, Raimo et al. (2019) found that performance and future orientation are negatively associated with IR quality, whereas assertiveness, institutional collectivism, uncertainty avoidance, and humane orientation are positively associated.

In relation to financial reporting, Hope (2003) observed that national culture influences the amount of financial information disclosed by firms. In addition, Archambault and Archambault (2003) demonstrated that Hofstede's cultural dimensions affect the level of financial disclosure. Similarly, Gray and Vint (1995) found that masculinity and individualism positively influence financial disclosure, whereas power distance and uncertainty avoidance have a negative effect. In the banking context, Hooi (2007) identified a negative relationship between uncertainty avoidance and financial disclosure, with no significant links to other cultural dimensions.

In relation to non-financial reporting, previous studies focused on social (Orij, 2010), environmental (Luo and Tang, 2013), sustainability (Buhr and Freedman, 2001; Silberhorn and Warren, 2007; Romero and Fernandez-Feijoo, 2013), and intellectual capital disclosure (Vitolla et al., 2020). Orij (2010), analysing reports from 600 companies in 22 countries, highlighted a negative effect of masculinity on corporate social disclosure. Luo and Tang (2013), based on a sample of 2,045 firms in 15 countries, found that individualism and uncertainty avoidance positively affect the amount of voluntary carbon disclosure, whereas masculinity and power distance have a negative influence. Comparative studies confirm the relevance of national culture in shaping sustainability disclosure (Buhr and Freedman, 2001; Holland and Foo, 2003; Silberhorn and Warren, 2007). Coulmont et al. (2015), analysing 620 firms across six continents, showed that power distance, indulgence, and individualism positively influence alignment with the Global Reporting Initiative guidelines. Conversely, Yamen et al. (2018), examining 3,917 companies from 59 countries, found that power distance, masculinity, and indulgence negatively affect sustainability reporting, while uncertainty avoidance and long-term orientation have a positive effect. Focusing on intellectual capital disclosure, Vitolla et al. (2020), through the analysis of integrated reports of 100 international firms, identified a positive relationship with uncertainty avoidance and negative effects of power distance, individualism, masculinity, and indulgence.

The literature on the factors influencing CED also appears to be scarcely explored (e.g., Wang et al., 2014; L'Abate et al., 2024a). In this regard, analysing the sustainability reports of firms, Wang et al. (2014) found that ownership concentration, institutional ownership, and institutional pressures aimed at environmental

protection positively influence the level of CED. In addition, Dagiliene et al. (2020) revealed that regulations and mimetic pressures can influence CED levels, whereas coercive factors have no effect on the dissemination of this type of information. Vitolla et al. (2023), by analysing the sustainability reports of 88 international firms, found that firm size, financial leverage, and profitability positively affect the level of CED. Focusing on Twitter as a disclosure channel, L'Abate et al. (2024a) found that profitability and leverage positively influence CED, while energy companies show a lower propensity to disclose CE information. Additionally, focusing on the aviation industry, L'Abate et al. (2024b) observed that airlines with larger, more active, and more independent boards of directors were more likely to disclose CE information through their websites. Finally, Esposito et al. (2023) observed that board gender diversity, board size, and the presence of a sustainability committee positively influence the amount of CE information disclosed through the integrated reports of sampled European firms.

In light of this, it is evident that the relationship between national culture and CED remains largely unexplored in the literature.

3 Hypotheses development

National culture plays a critical role in shaping corporate behaviour, including decisions related to transparency and sustainability disclosure (Vitolla et al., 2019). Cultural dimensions influence how firms perceive their responsibilities and how they communicate them to stakeholders, especially in relation to complex themes such as CE. More specifically, Hofstede's cultural dimensions may affect the extent of CED.

Power Distance reflects the extent to which inequality and hierarchical order are accepted in a society. In high power distance countries, the acceptance of hierarchy may discourage transparency and accountability, potentially leading firms to disclose less CE information. Accordingly, the following hypothesis is proposed:

H1: Firms located in countries with higher levels of power distance disclose less CE information.

Individualism versus Collectivism measures the degree of integration of individuals into groups. In individualistic societies, the focus on personal achievements and weaker interpersonal ties may reduce pressure to disclose information that benefits the collective, such as CE practices. Accordingly, the following hypothesis is proposed:

H2: Firms located in countries with higher levels of individualism disclose less CE information.

Masculinity versus Femininity captures the importance attributed to traditionally male values such as assertiveness and material success. In more masculine societies, the lower emphasis on social welfare and cooperation could result in less engagement with CE principles. Accordingly, the following hypothesis is proposed:

H3: Firms located in countries with higher levels of masculinity disclose less CE information.

Uncertainty Avoidance reflects a society's tolerance for ambiguity and risk. High uncertainty avoidance cultures often adopt rules and codes to minimize uncertainty, which may encourage more structured and formalized disclosure, including in the area of CE. Accordingly, the following hypothesis is proposed:

H4: Firms located in countries with higher levels of uncertainty avoidance disclose more CE information.

Long-Term Orientation versus Short-Term Orientation refers to the extent to which societies focus on future rewards rather than short-term gains. A long-term perspective may lead firms to adopt and communicate sustainable practices, including CE initiatives. Accordingly, the following hypothesis is proposed:

H5: Firms located in countries with higher levels of long-term orientation disclose more CE information.

Indulgence versus Restraint reflects the degree to which societies allow the gratification of desires and impulses. In more indulgent societies, the emphasis on immediate satisfaction and personal freedom may lead to less concern for sustainability-related issues. Accordingly, the following hypothesis is proposed:

H6: Firms located in countries with higher levels of indulgence disclose less CE information.

4 Research design

The sample of this study comprises 81 international companies that published a sustainability report in 2021. The sample was drawn from the GRI website, an independent international organization that supports firms in reporting their sustainability performance and ensures alignment with GRI guidelines. Specifically, the "Community Members" section of the GRI website was selected. This section includes a list of approximately 500 companies (the GRI Community). From this list, only companies that published a sustainability report in 2021 were selected. In addition, companies located in countries for which Hofstede's cultural dimensions were not available were excluded. This process led to the construction of the final sample, which comprises 81 international companies.

The dependent variable of this study is represented by the CED score (CEDS). For its measurement, a sustainability reports' manual content analysis was employed. Content analysis is a "research technique for

making replicable and valid inferences from data according to their context" (Krippendorff, 1980, p. 21). Content analysis, considered a reliable and cost-effective method for acquiring data (Krippendorff, 1980; Salvi et al., 2022) and for supporting the use of econometric models to analyse factors influencing disclosure levels, has been applied in studies on CED (Kuo and Chang, 2021; Barnabè and Nazir, 2022).

The construction of a disclosure index is one of the most widely adopted techniques for quantifying data obtained through content analysis (Vitolla et al., 2022). In this study, a disclosure index was developed based on the framework proposed by Wang et al. (2014) for measuring and disclosing CE information. The index (presented in Table 1) includes 10 items, organised into the following categories: honours and performances; investments and expenditures; policies and implementation; and resource reuse.

To code the disclosure index, each item was assigned a score ranging from 0 to 3. Specifically, a score of 0 was attributed when the information was absent. A score of 1 was given for the presence of qualitative information only, while a score of 2 was assigned when only quantitative information was provided. Finally, a score of 3 was attributed when both qualitative and quantitative information were disclosed. As a result, the total score of the dependent variable can range from 0 to 30.

Table 1 – CED index

Categories	Items	Scores
1. Honours and performances of CE	Definition of CE and honours	0-3
	Performances of energy conservation and emission reduction	0-3
	Performances of resource reuse	0-3
	Other performances on emission reduction	0-3
	Cost saving due to the implementation of CE	0-3
2. Investments in the CE	CE significant investment	0-3
	Other CE recurrent expenditure	0-3
3. CE policies and implementation	CE financial aids and tax concessions policies	0-3
	Implementation of CE related provisions	0-3
4. Resource reuse of CE	CE utilisation ratio information	0-3

The independent variables of this study are the six Hofstede's cultural dimensions (Hofstede et al., 2010). The source of these data is the Hofstede website, and the variables are measured using the Values Survey Modules (VSMs), which contain 5-point scale questions (Hofstede, 2001). In particular, the six cultural dimensions used in this study are: power distance (PD), individualism vs. collectivism (IDV), masculinity vs. femininity (MAS), uncertainty avoidance (UAI), long-term orientation vs. short-term orientation (LTO), and indulgence vs. restraint (IVR). Firms headquartered in the same country have the same cultural dimension score.

Following prior literature in the field (Vitolla et al., 2019; Rubino et al., 2020), a set of control variables was included to enhance the robustness of the econometric analysis. Specifically, the study considered firm size (LNFS), profitability (PROF), financial leverage (FINLEV), and board size (BS). LNFS was calculated as the natural logarithm of total assets. PROF was measured using return on equity (ROE), calculated as the ratio of net income to shareholders' equity. FINLEV was computed as the ratio of total assets to shareholders' equity. Lastly, BS was measured as the total number of directors on the board of director.

To test the impact of national culture on CEDS, a linear regression analysis was performed using robust standard errors. The regression model is presented in the following equation:

$$CEDS_i = \beta_0 + \beta_1 PD_i + \beta_2 IDV_i + \beta_3 MAS_i + \beta_4 UAI_i + \beta_5 LTO_i + \beta_6 IVR_i + \beta_7 LNFS_i + \beta_8 PROF_i + \beta_9 FINLEV_i + \beta_{10} BS_i + \varepsilon$$

5 Results

The results of the descriptive statistics, VIF and correlation analyses are reported in Table 2. The average value of the CEDS is equal to 17.886, highlighting an adequate CED activity for the firms that comprise the sample. The mean values of the cultural variables in our sample are the following: PD 46.192, IDV 68.481, MAS 58.638, UAI 58.746, LTO 48.596 and IVR 55.091.

The correlation coefficients are all relatively low; the higher value is -0.623 between PD and IVR. All the coefficients are below the critical thresholds accepted in the literature (Kennedy, 1999). The variance inflation factor (VIF) analysis confirms the absence of multicollinearity problems in our analysis: the higher value, in fact, is equal to 2.28 (Myers, 1990).

Table 2 – Descriptive statistics, VIF analysis and correlation analysis

Variable		Mean	S.D.	VIF	1	2	3	4	5	6	7	8	9	10	11
1	CEDS	17.886	4.652	-	1										
2	PD	46.192	15.592	2.28	-0.109	1									
3	IDV	68.481	23.301	2.23	-0.098	-0.623***	1								
4	MAS	58.638	16.137	1.17	-0.117	-0.021	-0.038	1							
5	UAI	58.746	16.621	1.27	0.341	0.116	-0.267**	0.196*	1						
6	LTO	48.596	22.628	1.99	0.422***	0.009	-0.293***	0.019	0.137	1					
7	IVR	55.091	20.194	1.85	-0.222**	-0.328***	0.354***	-0.156	-0.212*	-0.545***	1				
8	LNFS	8.745	3.478	1.52	0.548**	0.005	-0.115	-0.100	0.207*	0.282***	-0.251**	1			
9	PROF	0.194	0.376	1.10	0.271**	0.041	-0.024	0.019	0.081	0.102	-0.066	0.141	1		
10	FINLEV	2.751	1.951	1.30	0.186*	0.122	-0.069	0.119	0.153	0.301	-0.184*	0.085	0.218**	1	
11	BS	15.418	8.819	1.54	0.411***	0.120	-0.010	0.112	0.273**	0.195*	-0.121	0.451***	0.118	0.083	1

Notes: *** Significant at the 1% level; ** Significant at the 5% level; * Significant at the 10% level.

The results of the regression analysis are reported in Table 3. Results highlight the existence of a negative and significant impact of PD (5% significance level) and MAS (10% significance level) on CEDS, supporting the hypotheses H1 and H3. Therefore, companies located in countries with high levels of power distance disclose a lower amount of CE information. Furthermore, companies operating in masculinity-oriented societies disseminate a lower level of CE information. Furthermore, the existence of a positive and significant effect of UAI (5% significance level) and LTO (10% significance level) on CEDS supports the hypotheses H4 and H5. Therefore, companies operating in societies characterized by greater uncertainty avoidance have a higher propensity to disseminate CE information. Even in countries with high levels of long-term orientation, companies tend to disseminate a greater amount of CE information. The effect of IDV and IVR on CEDS is not statistically significant, so the hypotheses H2 and H6 are not supported. Therefore, the results demonstrate that individualism and indulgence are factors that do not affect the amount of CE information disclosed by companies within sustainability reports.

6 Conclusions

This study investigated the influence of national culture on CED, focusing on the effect of Hofstede's cultural dimensions on the level of CE information disclosed in sustainability reports. The findings indicate that power distance and masculinity negatively affect CED, while uncertainty avoidance and long-term orientation have a positive impact.

This study offers several contributions to the academic literature. First, it advances the debate on the relationship between national culture and corporate transparency by examining how Hofstede's cultural dimensions influence CED practices. Second, it addresses the limited research on the determinants of CED, demonstrating that cultural values significantly contribute to shaping such practices. Third, it extends the analysis of CED to sustainability reports, which are still underexplored in the literature despite their potential as key channels for communicating circular strategies.

This study also offers important practical implications for firms, policymakers, and training institutions. First, firms should consider the cultural values of the country in which they operate when defining their transparency policies, adapting data processing and communication strategies to local expectations. Secondly, policymakers, considering the importance of the CE, should promote both the adoption of circular models and the disclosure of related information through targeted policies, in order to ensure transparent and reliable communication for all stakeholders. Universities and training institutions, in turn, should foster understanding of cultural differences by offering cross-cultural management courses, helping companies develop disclosure strategies that reflect the specific cultural contexts in which they operate.

In conclusion, it is important to recognize the limitations of this study. The first limitation concerns the relatively small sample size, which includes only 81 companies. The second relates to the use of Hofstede's model for measuring national culture. Although widely used in the literature, this model has faced criticism due to the potential variability of cultural values within individual countries. These limitations suggest several directions for future research. To address the first, future studies could draw on additional sources to select sustainability reports and thereby expand the sample. Regarding the second, alternative cultural frameworks—such as those developed by the GLOBE project—may offer a more comprehensive representation of national culture. Moreover, future research could examine the role of other country-level variables, such as the Worldwide Governance Indicators developed by the World Bank.

Circular Economy Disclosure and Bank Market Value: Evidence from Europe

Candida Bussoli, Ilenia Fraccalvieri
LUM Giuseppe Degennaro University, Casamassima (BA), Italy

Abstract

The increasing urgency of environmental concerns, alongside the global challenges posed by climate change and resource depletion, has underscored the need for a transition toward a circular economy (CE). The banking sector plays a pivotal role in this shift, not only by financing and supporting circular initiatives across industries, but also by adopting CE principles within its own operations to enhance accountability and build stakeholder trust. In this context, banks are expected to improve transparency by disclosing information about their CE practices. Despite this growing relevance, CE disclosure (CED) in the banking industry remains an underexplored area in academic research. Therefore, this study seeks to address this gap by investigating the impact of CED on banks' market value. Adopting a signalling theory perspective, the analysis applies an Ordinary Least Squares (OLS) regression to a sample of 107 European listed banks, focusing on CE information disseminated through their official websites. The results reveal a positive and statistically significant relationship between CED and market value. These findings offer interesting theoretical insights and practical implications.

Paper type: Academic Research Paper

1 Introduction

Climate change and biodiversity loss stand among the most pressing global challenges of our era. The urgency of these issues, their widespread presence in public discussions, and their potential interlinked relationship indicate that they are perceived as components of a broader, integrated concept of contemporary threats (Skogen et al., 2018). This is driving nations across the globe to actively take action within sustainable economic frameworks (Isaksson, 2019). Businesses are increasingly recognising the need to implement more sustainable strategies to address these pressing challenges (Kennedy and Linnenluecke, 2022). Given the detrimental effects of high emissions and pollution – characteristics of the conventional linear economy model – mitigation efforts have become imperative (Fraccalvieri et al., 2025). Consequently, businesses have started to react by transitioning toward the circular economy (CE) models (Corona et al., 2019). Hislop and Hill (2011, p.2) have defined the CE as "*a development strategy that maximises resource efficiency and minimises waste production within the context of sustainable economic and social development*". This approach encourages responsible resource utilisation by following the 3R principles – reduce, reuse, and recycle (Ghisellini et al., 2016) – with the aim to promote waste reduction and design of processes and products to maximise resource efficiency and minimise environmental impact (Petruzzella et al., 2024). Besides, the implementation of CE models has been considered fundamental for economic growth, social welfare, and inclusiveness (Magnano et al., 2024).

The private sector plays a decisive role in fostering the CE and sustainable transition as it is responsible for producing goods and providing services that profoundly impact the environment (Esposito et al., 2020). Therefore, firms contribute to CE by adopting more efficient technologies, relying on renewable energy resources, implementing low-impact production practices, and minimising their use of natural resources (L'Abate et al., 2023). Despite facing challenges unique to their industry and business context, an increasing number of firms are shifting towards CE models (Serrano-Arévalo et al., 2024). Indeed, CE practices have been adopted in several industries, including agriculture (Velasco-Muñoz et al., 2021), construction (Norouzi et al., 2021), energy (Serrano-Arévalo et al., 2024), cosmetics (Mondello et al., 2024), fashion (Dissanayake and Weerasinghe, 2022), and steel (Roychand et al., 2020).

Although CE practices are typically associated with the manufacturing industry, the financial sector, particularly banking, holds a fundamental role (Goovaerts and Verbeek, 2018; Ozili, 2021; Ozili and Opene, 2021). Banks' contribution is twofold: on the one hand, they support firms in transitioning to the CE by providing appropriate financial and legal structures, network creation services, and advisory support; on the other hand, they reassess their own business models by adopting more sustainable practices (Fraccalvieri et al., 2025).

The relevance of CE in banking has also underscored the importance of disclosing CE information to ensure transparency and raise awareness. Indeed, thorough dissemination of CE information ensures that both

shareholders and stakeholders obtain a clear and accurate view of the banks' initiatives related to the internal implementation of practices respecting the 3R principles and support of the transition to CE models.

Recently, several authors have started to investigate CE practices in banking, mainly concerning the role of banks in facilitating the transition towards a CE (Gooovaerts and Verbeek, 2018; Zhelyazkova, 2020; Ozili and Opene, 2021). Nevertheless, CE disclosure (CED) in banking has received limited attention, with only one study focusing on its determinants (Fraccalvieri et al., 2025).

Therefore, this study intends to bridge this gap by investigating the effects of CED on banks' market value. Drawing on signalling theory, this study focuses specifically on CED practices conveyed through the official websites of European banks. The choice to consider banks' official websites rather than corporate reports is based on the intrinsic characteristics of digital platforms, which enable more dynamic, accessible, timely, and cost-effective communication (Sobhani et al., 2012; Vitolla et al., 2022).

By employing an Ordinary Least Squares (OLS) regression, the results of this study show that increased CED through official websites enhances the firm value of banks.

This study makes significant contributions to academic research. Firstly, it enriches the knowledge of how sustainability disclosure – specifically CED – affects banks' market value, addressing a gap in prior research. Secondly, it expands knowledge of online disclosure practices in the banking sector by demonstrating the effectiveness of official websites in communicating CE information. Thirdly, it applies signalling theory by interpreting the dissemination of CE information online as a strategic practice to enhance transparency and investor confidence, thereby improving market valuation.

Finally, this study offers valuable practical implications for banks, policymakers, and standard setters. For banks, leveraging official websites for CED can reduce information asymmetries and increase market valuation, encouraging more strategic digital communication. To achieve this, banks should employ skilled professionals for content creation and website management, and balance traditional reports with dynamic web-based updates. For policymakers, encouraging CED could support more efficient financial markets. For standard setters, creating harmonised guidelines for CED in banking would improve transparency, comparability, and the quality of information, helping stakeholders better assess banks' commitment to CE principles.

The remainder of this work is organised as follows. Section 2 provides a review of the literature on the topic. Section 3 presents the theoretical background and the hypothesis. Section 4 is devoted to the methodology used. Section 5 shows the results of the study. Finally, Section 6 draws the conclusions.

2 Literature review

Several empirical studies have explored the relationship between sustainability disclosure and bank market value, yielding a variety of findings that can be grouped into two main perspectives. On the one hand, a number of contributions report a positive association between sustainability disclosure and bank performance, supporting the view that Environmental, Social, and Governance (ESG) communication enhances transparency, reduces information asymmetry, and improves investor confidence (Carnevale and Mazzuca, 2014; Buallay, 2019; Attah-Botchwey et al., 2022; Gangwani and Kashiramka, 2024). On the other hand, a growing stream of literature has emerged pointing to either negative or inconclusive effects, highlighting the importance of contextual and institutional factors as well as potential costs associated with sustainability practices (Buallay, 2020; Harun et al., 2020; AlAjmi et al., 2023).

Among the studies reporting a positive effect, Carnevale and Mazzuca (2014), focusing on a sample of 176 banks in the timeframe 2002-2011, analysed the direct effects of sustainability reporting on stock prices, highlighting that banks' sustainability reports are positively valued by the market. Buallay (2019) considered a sample of 235 banks covering the period 2007-2016 to test the relationship between sustainability reporting and market performance, identifying a positive association. However, this study also indicated that this relationship varies when considering each ESG pillar individually. Indeed, market performance is positively affected by environmental and governance disclosures, but not by social disclosure. In the African context, Attah-Botchwey et al. (2022) focused on a sample of 20 listed banks, considering the timespan from 2010 to 2020, to investigate the relationship between sustainability reporting and bank market performance. They found a significant positive association between the inclusion of ESG content in financial statements and bank market performance, even though environmental disclosures alone do not appear to have a significant influence. Finally, Gangwani and Kashiramka (2024) analysed 178 commercial banks from the top 20 emerging markets over the period from 2015 to 2021 to examine the influence of ESG disclosure scores on bank market performance. They revealed that higher ESG disclosure scores are associated with superior market performance.

Conversely, several studies raise questions about the presumed benefits of sustainability disclosure for bank market value. Harun et al. (2020) focused on Islamic banks in Gulf Cooperation Council countries during the

period 2010-2014 to identify the effects of Corporate Social Responsibility (CSR) disclosure on banks' market value and indicated a negative relationship. Similarly, AlAjmi et al. (2023) studied 245 banks in emerging markets between 2008 and 2020 to test the relationship between CSR disclosure and market value, revealing a negative association. Another contribution is offered by Buallay (2020), who compares 932 manufacturing firms and 530 banks across 80 countries from 2008 to 2017 to analyse the impact of sustainability reporting on market performance. The analysis revealed a positive effect of sustainability disclosure on firm performance in the manufacturing sector but a negative effect in the banking sector, suggesting that the market may interpret ESG efforts differently across industries.

Although the literature provides extensive insights into the effects of general sustainability disclosure on bank market value, no study to date has directly examined the role of CED in the banking sector. The only related contribution is offered by L'Abate et al. (2024), who analyse a panel of 133 publicly listed international firms over the period 2019-2021 to examine the effects of CED on the cost of debt. Their findings suggested that communication of CE information through platforms such as Twitter can serve as an effective market signal, enhancing investor perceptions and increasing firm value. However, the study does not focus on banks, leaving an important gap in the literature that remains to be addressed.

3 Theoretical background and hypothesis

Previous studies have applied signalling theory (Spence, 1973) to investigate the relationship between CED and the market value of non-financial firms (e.g., L'Abate et al., 2024; Petruzzella et al., 2024). Accordingly, this study draws on signalling theory to explore how CED practices influence the market value of European banks.

The seminal work of Spence (1973) assumes that markets are characterised by information asymmetry. This market inefficiency exists because one party possesses more information than the counterpart in terms of both quality and quantity (L'Abate et al., 2024). To bridge this information gap, one party – the signaler – can transmit a signal to the other party – the receiver (Salvi et al., 2021; Mariani et al., 2025). Signalers are insiders who possess information not available to outsiders and decide when and whether to disclose it, while receivers are outsiders who do not possess information but wish to receive it (Spence, 1973; Connelly et al., 2011). According to (Taj, 2016, p. 339), signals are "informational cues sent by one party to another in order to influence desired outcomes". Signals, whether voluntary or involuntary, and regardless of conveying positive or negative information, can enrich the informational environment by reducing asymmetries between parties (Petruzzella et al., 2024). Hence, according to this theory, the voluntary disclosure of information represents a signal that organisations send to the external environment (Salvi et al., 2021; L'Abate et al., 2024). More specifically, sustainability information can be viewed as a positive signal that managers send to stakeholders and potential investors to demonstrate their commitment to environmental and social issues (Friske et al., 2023). Indeed, institutional investors are placing growing emphasis on sustainability disclosure to assess organisations' exposure to regulatory and climate risks before making investment choices (Krueger et al., 2020). However, to be effective, signals must be observable and credible (Ross, 1977). In this regard, official websites serve as reliable and easily accessible tools, enabling organisations to disseminate information in a dynamic and timely manner (Garzoni et al., 2024). Following the global financial crisis of 2007-2008, banks began to be perceived negatively by the public. To restore their reputation, many banks have adopted CE practices and have started communicating these efforts transparently (Ozili, 2021). In this context, CED through official websites may help reduce information asymmetry and perceived risk, potentially activating mechanisms that enhance banks' market value. Based on these considerations, the following hypothesis is proposed:

H1*: CED via official websites positively affects banks' market value.*

4 Methodology

4.1 Sample

This study employs a sample of 107 European listed banks. The selection process began with identifying all publicly listed banks across Europe in 2023, using the Refinitiv Eikon database (recently rebranded to LSEG). This first step led to the identification of 330 institutions. Consequently, banks were excluded from the sample if data on the independent and control variables were unavailable. Additionally, banks without an accessible English-language website or with restricted access to certain sections of their websites were also omitted. After applying these exclusion criteria, 83 banks were removed, resulting in a final sample of 107 banks. The selected banks are spread across 26 different countries, thereby providing a comprehensive geographical representation within the European region.

4.2 Dependent variable

The dependent variable of this study is represented by the *Bank_market_value*, which is expressed as the natural logarithm of the bank's market capitalisation. Specifically, it refers to the number of outstanding shares multiplied by their current market price (Widiatmoko et al., 2020). It serves as a key indicator to evaluate a company's overall worth, reflecting the total wealth created by the company or its stock. Market capitalisation is widely recognised as a standard measure of business valuation, indicating the cumulative value of a business or its shares (Almumani, 2018).

4.3 Independent and control variables

The primary independent variable used in this study is the CED Score (*CEDS*), which indicates the level of information related to CE disclosed by banks on their official websites. A manual content analysis was conducted to construct this variable. Content analysis is a widely used technique in accounting research, which offers a valuable means to examine information and encode it into objective, reliable, and replicable data (Vitolla et al., 2023). Consistent with previous studies (e.g., Kiliç and Kuzey, 2019; Esposito et al., 2023; Marrone et al., 2024), the analysis was carried out using a manual approach. Several factors drove the decision to adopt a manual approach. Firstly, unlike automated content analysis, the manual method provides greater flexibility and adaptability to the specific context, enabling the interpretation of synonyms and phrases with multiple meanings. Secondly, it allows for a deeper understanding of the information, as researchers can critically evaluate the content and make inferences based on their knowledge of the phenomenon. Lastly, the manual approach facilitates the contextual interpretation of information (L'Abate et al., 2023).

The analysis was conducted on the official banks' websites, excluding downloadable documents, as the study specifically focuses on online disclosure. The process of identifying relevant information began with thoroughly examining each website to identify sections containing content related to CE. These sections were then analysed and assessed based on the disclosure index presented in Table 1. The index provides a comprehensive framework for evaluating how banks disclose information related to CE practices.

Table 1: *CEDS*

Area	Items	Score
Area A: Supporting the circular transition of firms		
A.1 Corporate Policies and Objectives	1. Information about the existence of a corporate policy dedicated to supporting the CE within client businesses	0-1
	2. Information about specific objectives outlined for advancing the CE	0-1
	3. Information about the inclusion of CE criteria in the evaluation of financed projects	0-1
	4. Information about transparency in the evaluation criteria for CE projects	0-1
A.2 Financial Products and Incentives	1. Information about the provision of green loans tailored to CE projects	0-1
	2. Information about the issuance of green bonds to fund CE initiatives	0-1
	3. Information about investment products associated with CE projects	0-1
	4. Information about the requirement of sustainability or CE certifications to qualify for financing	0-1
	5. Information about the provision of financial incentives (e.g., reduced interest rates) for CE projects	0-1
	6. Information about tax incentives for investments in the CE	0-1
	7. Information about direct investments in CE projects, both locally and internationally	0-1
A.3 Support and Collaboration	1. Information about the availability of advisory services to assist businesses in implementing CE models	0-1
	2. Information about the offering of workshops and seminars on the CE for client businesses	0-1
	3. Information about collaboration with external experts to support businesses in the transition to a CE	0-1
	4. Information about incubation or acceleration programs for startups focused on the CE	0-1
	5. Information about awards and recognitions for companies adopting CE practices	0-1
	6. Information about collaborations with companies specializing in the CE to promote innovative solutions	0-1
	7. Information about participation in CE networks and consortia	0-1
A.4 Monitoring, Evaluation, and Awareness	1. Information about the assessment of the environmental impact of financed projects	0-1
	2. Information about the assessment of the social impact of financed projects	0-1
	3. Information about regular reporting on the outcomes of financed CE projects	0-1

Area	Items	Score
	4. Information about sponsorship of research projects related to the CE	0-1
	5. Information about training programs for clients on CE practices and sustainability	0-1
	6. Information about awareness campaigns highlighting the importance of the CE	0-1
	7. Information about publications and guides on implementing CE practices	0-1
Area B: Internal implementation of CE practices		
B.1 Corporate Policies and Objectives	1. Information about the existence of an internal policy dedicated to adopting CE models	0-1
	2. Information about specific objectives defined for the internal adoption of CE practices	0-1
	3. Information about the integration of CE principles into corporate governance frameworks	0-1

B.3 Energy Efficiency and Renewable Energy	1. Information about initiatives to improve energy efficiency in branches and banking operations	0-1
	2. Information about investments in energy-saving technologies	0-1
	3. Information about monitoring and reporting on energy use, including the use of renewable energy sources for banking operations	0-1
	4. Information about the installation of solar panels or other renewable energy sources at branches	0-1
B.4 Material Use and Recycling	1. Information about policies for reducing, reusing, and recycling waste generated by banking activities	0-1
	2. Information about initiatives to reduce the use of single-use plastics in offices	0-1
	3. Information about the use of recycled materials in corporate processes (e.g., recycled paper, eco-friendly office furniture)	0-1
	4. Information about initiatives to reduce the use of virgin materials and promote recycled material use among employees	0-1
	5. Information about obtaining environmental certifications for branches (e.g., LEED, ISO 14001)	0-1
	6. Information about participation in regular environmental audits	0-1
B.5 Digital Transformation and Eco-efficiency	1. Information about the promotion of digital solutions to reduce the use of physical resources (e.g., e-banking, digital documents) and the implementation of paperless processes in offices	0-1
	2. Information about investments in digital infrastructure to improve operational efficiency	0-1
B.6 Monitoring, Evaluation, and Awareness	1. Information about training programs for employees on CE practices and sustainability	0-1
	2. Information about internal awareness initiatives on the importance of the CE and the publication of internal guidelines on sustainable practices	0-1
	3. Information about internal initiatives to develop and implement innovative CE solutions	0-1
	4. Information about collaboration with research institutions for CE projects	0-1
	5. Information about experimentation with new CE business models within the bank	0-1
	6. Information about monitoring and evaluating the impact of sustainability initiatives and projects	0-1
	7. Information about regular reporting on sustainability performance and goals	0-1

The provided index is divided into two areas: (1) supporting the circular transition of firms and (2) internal implementation of CE practices.

The first area examines how banks support their clients in transitioning to CE models, considering aspects such as corporate policies and objectives, financial products and incentives, support and collaboration initiatives, as well as monitoring, evaluation, and awareness-raising activities. The second area focuses on the internal adoption of CE principles by banks, assessing their corporate policies, sustainable procurement and supply chain practices, energy efficiency and renewable energy initiatives, material use and recycling strategies, digital transformation and eco-efficiency measures, as well as internal efforts in monitoring, evaluation, and awareness.

These two areas provide a comprehensive assessment of both external support and internal commitment to CE principles.

Finally, an unweighted dichotomous approach was followed instead of a weighted method, assigning a score of 1 to each item if the information was found on the bank's website and a score of 0 if it was absent. Consequently, the dependent variable could range from 0 to 50.

Concerning the control variables, *Profitability*, *Liquidity*, *Size*, and *Internationalisation* were considered. In particular, *Profitability* was measured by the return on average assets, computed as the bank's net profit divided by its average assets (Petria et al., 2015). *Liquidity* was proxied by the loans-to-deposits ratio, calculated as the bank's total loans divided by its total deposits (Barone et al., 2024). *Size* was measured as the natural logarithm of the number of bank employees (Schildbach and Schneider, 2017). Finally, *Internationalisation* was determined by the number of foreign countries in which the bank operates through its branches (Menassa, 2010).

4.4 Model specification

To test the research hypothesis, this study employs an OLS regression model. Specifically, this analysis aims to identify the impact of CE information disseminated through banks' official websites on their market value. The following equation represents the analytical form of the model used:

$$Bank_market_value_i = \beta_0 + \beta_1 CEDS_i + \beta_2 Profitability_i + \beta_3 Liquidity_i + \beta_4 Size_i + \\ + \beta_5 Internationalisation_i + \varepsilon_i$$

5 Results

5.1 Descriptive statistics, correlation matrix, and Variance Inflation Factor (VIF) analysis

Figures should be numbered consecutively throughout the paper and not numbered according to the section in which they appear. Figure captions should appear below the figure. Use the word Figure in full, rather than Fig or F.

Table 2 show the descriptive statistics, the correlation matrix, and the Variance Inflation Factors (VIFs).

The mean value of the dependent variable, *Bank_market_value*, is 23.002. Concerning the main independent variable, *CEDS*, the mean value is 16.206, which suggests that European banks, on average, are not fully transparent in disseminating information related to their CE practices. The mean values of *Profitability, Liquidity*, and *Size* are respectively 1.102, 1.217, and 8.879. The variable *Internationalisation* shows a mean value of 7.626, thereby indicating that the sampled banks operate, on average, in 8 foreign countries.

The correlation analysis does not reveal any multicollinearity issues, as all the correlation coefficients are above the critical thresholds of ±0.8 and ±0.9 (Farrar and Glauber, 1967). Additionally, the VIF analysis confirms the absence of multicollinearity problems.

Table 2: Descriptive statistics, correlation matrix and VIFs

Variable	**Mean**	**Std. Dev.**	*1*	*2*	*3*	*4*	*5*	*6*	**VIF**
1. Bank_market_value	23.002	1.888	1.000						
2. CEDS	16.206	11.616	0.171*	1.000					1.21
3. Profitability	1.102	1.232	0.204**	-0.199**	1.000				1.12
4. Liquidity	1.217	2.921	0.015	-0.144	0.244**	1.000			1.09
5. Size	8.879	1.615	0.525***	0.263***	-0.064	-0.263***	1.000		2.05
6. Internationalisation	7.626	14.466	0.263***	0.041	-0.218**	-0.070	0.620***	1.000	1.89
								Mean VIF	**1.47**

Notes: *** p<0.01; ** p<0.05; * p<0.10

5.2 Regression analysis

Table 3 shows the results of the regression analysis, which support this study's research hypothesis (***H1***). Specifically, the analysis relies on three model specifications to test the consistency and reliability of the findings.

The baseline model (1), estimated using standard OLS, shows a positive and statistically significant relationship ($\beta = 0.027$; $p<0.10$) between *CEDS* and *Bank_market_value*. This value remains consistent in the second model (2), where robust standard errors are used. The use of robust errors provides consistent estimates in the presence of heteroskedasticity; however, the test for heteroskedasticity indicated no such concern in this case. Finally, the third model (3), estimated through bootstrapping with 500 replications, further supports the robustness of the results.

These results indicate that banks which disclose more CE information on their official websites tend to have a higher market value. This aligns with the principles of signalling theory, since the dissemination of CE

information via websites represents a positive signal sent by banks to investors and stakeholders, indicating the bank's commitment to environmentally and socially responsible practices. By voluntarily sharing such information, banks reduce information asymmetries, enhance stakeholder confidence, and foster a more favourable perception of their operations. This, in turn, may contribute to an increase in market valuation.

Moreover, this finding aligns with previous literature, especially the body of studies indicating that sustainability disclosure enhances transparency, reduces information asymmetry, and strengthens investor trust, thereby increasing banks' market value (Carnevale and Mazzuca, 2014; Buallay, 2019; Attah-Botchwey et al., 2022; Gangwani and Kashiramka, 2024).

Table 3: Regression analysis

	(1)	**(2)**	**(3)**
	Baseline model	**Robust standard errors**	**Bootstrap**

6 Conclusions

This study's objective was to examine the impact of CED on bank market values in the European context.

The results demonstrated that greater disclosure of CE information via official websites improves banks' firm value. Hence, the results confirm the importance of transparency related to CE practices within the banking context, by indicating significant financial benefits linked to the use of the official website as a channel to disseminate CE information.

This study provides valuable contributions to the academic literature. Firstly, it enriches the academic literature by contributing to the growing body of research on the relationship between sustainability disclosure and banks' market value. While prior studies have explored different forms of sustainability disclosure, the impact of CED within the banking sector had not yet been investigated. Secondly, this study enriches the literature on online disclosure in the banking industry. In this regard, it highlights the role of official websites as effective tools for communicating CE information and generating positive market reactions. Thirdly, this study broadens the application of signalling theory by framing the dissemination of CE practices on banks' official websites as a strategic signal aimed at enhancing transparency and investor confidence, ultimately leading to improved market valuation.

This study also provides important practical implications for banks, policymakers, and standard setters. For banks, the ability of CED through official websites to reduce information asymmetries and enhance market valuation should encourage bank managers to make more strategic use of these platforms to communicate their efforts and achievements in implementing CE practices. From this perspective, to ensure accurate and effective communication, banks should consider assigning content creation and website management to professionals. Furthermore, they should aim to balance traditional disclosure tools (e.g., sustainability reports) with dynamic, easily accessible website content, as these channels may serve complementary, and not substitutive, functions. For policymakers, promoting the adoption of CE disclosure practices would enhance financial market efficiency. For standard setters, working toward developing clear and harmonised guidelines for CE disclosure in the banking sector is essential. Establishing a common framework would improve the comparability and quality of disclosed information, fostering transparency and enabling investors and stakeholders to better evaluate banks' commitment to CE principles.

However, this study is not without limitations. The first limitation is represented by the sample size. A larger sample would allow for more generalizable results. Future research could address this limitation by expanding

the sample to include smaller or non-listed banks or by extending the analysis to banks from other regions. The second limitation involves the exclusive focus on information disclosed through banks' official websites, excluding other relevant communication channels such as social media platforms or sustainability reports. Given the increasing use of multi-channel disclosure strategies by firms, future research could explore the comparative effectiveness of these different platforms.

Artificial Intelligence in the Agri-Food Supply Chain: How it Might Facilitate Circular Economy Practices?

Stefania Manetti
San Raffaele Roma University, Rome, Italy

Abstract

The convergence of Artificial Intelligence (AI) and Circular Economy (CE) is often suggested as a promising pathway for sustainable transformation in the agri-food sector. Yet, how human involvement is configured across AI systems, and whether it enables or limits circular outcomes, remains poorly understood. This study examines how AI is integrated into CE-related practices in agri-food organisations and how human roles are distributed across the AI lifecycle, with particular attention to organisational size and structure. Based on a systematic review of 88 peer-reviewed articles published between 2015 and 2025, the study offers a cross-cutting analysis of how AI systems are conceptualised, developed, deployed, and monitored, and how CE goals are addressed within these processes. Results show a strong imbalance: the early phases of the AI lifecycle are largely shaped by external technology providers, while internal organisational actors are mostly engaged during implementation and operational tasks. Strategic and governance-related phases remain underexplored, and participatory approaches are rare. CE considerations are often reduced to operational metrics, such as waste reduction or resource efficiency, rather than driving systemic redesign or regenerative business models. These findings highlight the need to reposition human involvement as a central lever in aligning AI with circular outcomes. Without stronger organisational capacity, inclusive governance, and CE-aware design logics, AI risks reinforcing existing inefficiencies instead of enabling ecological transition. The study offers a timely contribution to debates on digital sustainability and agri-food innovation, proposing future research directions that foreground agency, adaptability, and systemic value creation.

Paper type: Academic Research Paper

1 Introduction

The agri-food supply chain faces a complex array of global challenges that significantly affect both environmental sustainability and societal well-being. Among the most pressing issues is the sector's substantial contribution to environmental degradation, driven by resource-intensive production systems. These practices result in severe consequences for land use, water resources, and greenhouse gas emissions, exacerbating climate change and ecological damage (Willett et al., 2019). Simultaneously, ensuring global food security has become an increasingly urgent issue, with food demand projected to rise sharply as the global population expands. The growing scarcity of food resources, compounded by climate change and economic inequality, underscores the need for the adoption of Agriculture 5.0 and Circular Economy (CE) principles (Akundi et al., 2022; Belhadi et al., 2021; Liu et al., 2021).

However, the agri-food sector remains not only linear in its supply chain structure but also organizationally fragmented, with a wide range of actors pursuing often conflicting objectives and misaligned strategies. These challenges are particularly evident in the tension between global sustainability goals, such as environmental preservation and biodiversity, and the local objectives of individual stakeholders, such as maximizing productivity. This misalignment complicates the effective adoption of sustainable practices (Kukk et al., 2024).

At the same time, the ongoing digital transformation is reshaping interactions among value chain actors in agriculture and food manufacturing. The rapid advancement of Artificial Intelligence (AI), coupled with its growing hype, has accelerated this paradigm shift, with consultancy firms, startups, and technology giants promoting AI-driven solutions as cost-effective and easy to implement. For instance, key AI applications include crop monitoring through soil analysis, issue detection, and the assessment of health indicators via deep learning. AI systems also evaluate soil quality, pests, and diseases, thereby supporting farmers in making informed decisions for land and crop management (Bhat & Huang, 2021; Syeda et al., 2021). Nevertheless, this transition towards digitalisation is often not strategically coordinated by actors and rarely situated within an integrated vision aligned with high-level, "wicked" sustainability goals. Many stakeholders pursue digitalisation independently, often without a shared ecosystemic strategy (Wolfert et al., 2023). This lack of alignment is particularly critical in the face of global environmental challenges, especially for small and medium-sized actors.

Among digital technologies, AI is increasingly advocated by practitioners and recent academic studies as a lever for organisational and process transformation in the agri-food sector. While early applications focused on

isolated or experimental use cases, a growing number of studies have highlighted a transition toward more systematic, lifecycle-oriented integration of AI across agri-food value chains (Belhadi et al., 2024; Wolfert et al., 2023). Importantly, this shift is not only technical but deeply organisational, requiring new forms of coordination, strategic vision, and internal capabilities (Troisi et al., 2023; Sica et al., 2024). These developments resonate with the principles of Industry 5.0 and recent regulatory frameworks such as the European AI Act, which both call for a human-centred, ethically guided approach to technological innovation (AI Act, 2024). In this evolving context, AI is often suggested as a set of technological enablers and a transformative force capable of overcoming institutional inertia and facilitating the transition toward CE models (Das et al., 2023; Fraga-Lamas et al., 2021; Vincent et al., 2019). Although this topic remains underexplored in the literature, recent contributions in the agri-food domain offer relevant insights. For instance, research by Sica and colleagues (2024) presents a comprehensive conceptual model connecting digitalisation to CE transitions, highlighting its implications for strategic planning, managerial competencies, and operational skills. Additionally, Das et al. (2023) identify sixteen key enablers of AI adoption and rank them, noting that many are closely related to human capabilities, such as concerns around automation and job displacement. Their findings underscore the centrality of human involvement in AI deployment within agri-food contexts, echoing recent international regulatory developments.

Notably, the AI Act promotes human involvement across the entire AI lifecycle - from conceptualisation to the delivery of products and services- reinforcing the need for a structured and responsible approach. Yet, existing studies tend to treat AI lifecycle phases in isolation and lack a holistic perspective on how AI can support sustainable transformation in the agri-food sector. As such, more integrative research is needed on how human engagement within AI systems can facilitate CE adoption across organisational types and scales.

In this context, the present study aims to provide a comprehensive analysis of the "human-in-the-loop" paradigm in AI applications within businesses and organisations of varying sizes in the agri-food sector, with a specific focus on its implications for CE implementation.

The primary research questions guiding this study are:

- *RQ1: Which phases of the AI lifecycle have been addressed in prior studies concerning human involvement?*
- *RQ2: What challenges and issues arise in relation to human roles at specific lifecycle phases and alongside the entire AI lifecycle?*
- *RQ3: How is the nexus between AI and CE shaped, and potentially constrained, by the concept of human involvement in digital systems?*

2 Methodology

Empirically, this study is based on a systematic literature review drawn from two major databases (i.e., Scopus and ISI Web of Knowledge) to explore the intersection of Artificial Intelligence (AI), human involvement, and Circular Economy (CE) principles within agri-food systems. The review process was designed in line with Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines to ensure transparency, replicability, and methodological consistency. The methodology section is organised into three parts. Subsection 2.1 outlines the literature search strategy and database selection. Subsection 2.2 describes the screening and eligibility process. Finally, subsection 2.3 details the variable extraction and coding approach used to answer the three research questions.

2.1 Literature search strategy

The literature retrieval was conducted across two leading academic databases - Scopus and ISI Web of Knowledge - selected for their multidisciplinary scope and comprehensive indexing of peer-reviewed sources relevant to digital innovation and sustainability in agri-food research. No time limits were applied to capture both foundational and emerging contributions. The final search was executed in April 2025, using Boolean operators to combine keywords related to AI (i.e., "artificial intelligence", "machine learning", "deep learning"), CE (i.e., "circular economy", "sustainability"), and the agri-food domain (i.e., "food", "agriculture", "farming"). Titles, abstracts, and keywords were queried simultaneously to maximise coverage.

2.2 Screening and Selection

The initial query yielded 1,950 records. After duplicate removal, 601 entries were discarded. An additional 224 items - such as conference papers, editorials, and book chapters - were excluded based on publication type criteria. This left 1,125 unique articles for screening.

Predefined eligibility criteria were applied to assess relevance. Articles were retained only if they explicitly addressed AI applications in the agri-food sector, focused on for-profit organisational contexts, and provided some insights into human roles or decision-making functions. Studies referring generically to digitalisation or innovation, without direct reference to AI or organisational practices, were excluded.

At the full-text stage, 455 articles were examined in depth. Finally, 88 articles were selected for inclusion in the final sample. Each met the core inclusion criteria and provided insights into one or more phases of the AI lifecycle, with varying degrees of reference to human involvement and/or CE dimensions.

2.3 Extraction variables and coding strategy

To address the three research questions, a structured data extraction and coding protocol was developed. Each of the 88 included articles was analysed using a coding scheme combining both deductive and inductive dimensions. Variables were organised along three analytical axes corresponding to the AI lifecycle phases, human involvement, and circular economy (CE) relevance. For RQ1, articles were coded based on which AI lifecycle phases were addressed (conceptualisation, development, deployment, monitoring, governance, and explanation) and whether human actors were mentioned in each phase. For RQ2, a second layer of coding identified challenges associated with human roles, such as skills gaps, resistance to change, role overload, exclusion from decision-making, and trust or interpretability concerns. These challenges were tagged and quantified to identify patterns across organisational types and lifecycle phases. For RQ3, a binary code captured CE relevance, while additional variables tracked how CE principles (e.g., resource regeneration, waste valorisation, closed-loop systems) were integrated into AI applications. Attention was also given to whether CE considerations were embedded in early design or added during deployment. The coding process was conducted independently by two researchers, with discrepancies resolved through consensus, ensuring reliability and analytic coherence across the dataset.

3 Results

This section presents the main findings of the systematic review, structured around the three research questions. Subsection 3.1 maps how human involvement is distributed across different phases of the AI lifecycle. Subsection 3.2 explores the key challenges and constraints associated with human roles. Finally, subsection 3.3 examines how human involvement shapes - and potentially limits - the integration of circular economy (CE) principles into AI-enabled agri-food systems.

3.1 Human Involvement across AI lifecycle phases

In response to RQ1, the systematic review reveals a highly uneven distribution of scholarly attention across the phases of the AI lifecycle (Table 1). Among the 88 articles included in the final sample, the majority focus on early-stage involvement during *conceptualisation* (86 articles). This stage is often characterised by exploratory efforts such as problem framing, identification of AI application opportunities, and initial data design. Interestingly, human involvement here is typically facilitated by external innovation actors, such as consultancies, start-ups, or public–private consortia, rather than being rooted in internal organisational routines. The *Development phase* is the second most frequently discussed (71 articles), where model training and algorithm building are handled predominantly by external technical experts or university laboratories. Internal R&D teams within agri-food organisations are rarely reported as being active contributors at this stage, pointing to a potential disconnect between AI development and organisational learning. Fewer studies (38) address the *Deployment phase*, which involves practical testing or implementation of AI tools. These cases tend to be fragmented and highly localised, lacking a shared strategic framework. Notably, implementation is rarely accompanied by organisation-wide change management or structured role adaptation. Mature stages of the AI lifecycle are considerably underrepresented. Only 24 articles refer to *Monitoring*, where performance evaluation, maintenance routines, and feedback loops would be expected. This absence highlights a critical gap in long-term AI sustainability and organisational learning. *Governance* and *Explanation* are the least addressed phases (18 and 15 articles, respectively), underscoring limited attention to ethical oversight, transparency, and human-AI interaction in agri-food contexts. These findings suggest that while AI adoption is progressing, it remains technology-driven with insufficient emphasis on systemic human engagement throughout the AI lifecycle.

Table 1: distribution of scholarly attention across the phases of the AI lifecycle

AI Lifecycle Phase	Human Involvement	# of Articles	Example Source
Conceptualisation	Early-stage identification of AI opportunities, problem framing, and data gathering design, often guided by external actors or ad hoc innovation units.	86	Kumari et al., 2025
Development	Model building and algorithm training, typically conducted by external tech firms, university labs, or through public–private partnerships. Internal R&D rarely involved.	71	Bran et al., 2024
Deployment	Pilot or field testing of AI systems, with focus on logistics, resource planning, or automation. Mostly bottom-up or fragmented.	38	Anbarasu et al., 2024
Monitoring	Evaluation, feedback loops, maintenance, and performance KPIs. Rarely formalised or systematised in organisational processes.	24	Anbarasu et al., 2024
Governance	Ethical supervision, risk management, legal and compliance framing. Largely absent or vaguely mentioned.	18	Kumari et al., 2025
Explanation	User interaction, explainability features, visualisation for stakeholders. Touched upon in relation to transparency and traceability.	15	Anbarasu et al., 2024

3.2 Challenges related to human involvement across the AI lifecycle

In response to RQ2, the analysis reveals five major challenges associated with human involvement throughout the AI lifecycle in agri-food organisations. First, a persistent *skills gap* (55 out of the 88 studies) limits the ability of human actors, particularly operational staff and middle managers, to engage effectively with AI systems. This gap is especially evident during conceptualisation and governance phases, where technical fluency is required to contribute meaningfully to design or oversight processes. Second, *organisational resistance to change* (identified in 38 studies) frequently hinders AI integration. Legacy practices, hierarchical rigidity, and low digital maturity contribute to reluctance to adopt new roles or modify existing workflows, particularly in small and medium enterprises and cooperatives. Third, *role overload and task misalignment* (reported in 24 studies) are common outcomes of AI adoption. Human actors are often required to perform additional duties, such as data annotation or system calibration, without a corresponding redefinition of responsibilities, leading to fatigue and inefficiency. Fourth, *strategic exclusion* (highlighted in 30 studies) of key internal stakeholders, especially frontline personnel, undermines the contextual relevance of AI applications. These actors are rarely involved in framing problems, setting priorities, or participating in iterative evaluation, which reduces the adaptability and user-fit of deployed systems. Finally, *trust and system interpretability issues* (raised in 22 studies) represent a cross-phase barrier. Many users perceive AI systems as opaque or externally imposed, which limits confidence in outputs and reduces willingness to rely on AI-supported decision-making.

3.3 Human involvement and the artificial intelligence-circular economy nexus

In response to RQ3, the analysis of the 46 CE-relevant studies out of the 88-article final sample reveals a weak and fragmented alignment between AI implementation and circular economy (CE) objectives, often constrained by limited human involvement. While CE is increasingly referenced as a strategic ambition, it rarely guides design, decision-making, or deployment in a systematic manner. Most contributions link CE to specific operational targets, such as waste reduction, resource optimisation, or surplus redistribution, particularly in the deployment and monitoring phases (e.g., Husaini et al., 2023; Trollman et al., 2023). Here, AI tools are used to support smart fertilisation, cold chain management, or environmental footprint tracking. However, human actors involved in these activities, such as farmers or field technicians, are seldom aware of the CE implications of their actions, nor are they empowered to steer systems toward regenerative outcomes. In the conceptualisation and development phases, CE priorities are largely absent. Even when sustainability is referenced in vision statements, few AI systems are explicitly designed with reuse, loop closure, or value regeneration in mind. External experts typically lead these phases, with minimal engagement of organisational actors capable of contextualising CE objectives. Governance and explanation stages present the greatest disconnect: very few studies report participatory mechanisms or reflexive structures that enable human actors

to interpret, negotiate, or co-govern CE transitions. Where ethical or regulatory considerations are mentioned, they tend to focus on compliance, not circular value creation.

4 Discussion

The findings of this review reveal a consistent tension between the technological momentum driving AI adoption in agri-food systems and the underdeveloped role of human involvement, particularly in shaping strategic directions and enabling sustainability outcomes. Although AI has been widely promoted as a transformative force capable of improving efficiency and reducing waste, its application across the sector often remains confined to narrow, technical domains, with limited integration into broader organisational and ecological frameworks. This study highlights a series of original reflections.

First, the uneven distribution of human involvement across the AI lifecycle suggests that critical stages such as conceptualisation and development are largely driven by external actors. While this may accelerate innovation and reduce initial costs, it also limits the internalisation of AI systems within organisations. When agri-food firms are not actively engaged in early design phases, the resulting technologies risk being ill-suited to operational realities or strategic goals. This disconnect reflects a broader structural pattern in the digitalisation of agri-food: innovation is frequently imported rather than co-developed, weakening the potential for long-term learning and system-level transformation.

Second, the analysis highlights a persistent set of organisational challenges that constrain human engagement. Skills gaps, role misalignment, and cultural resistance remain significant barriers to effective AI integration. These issues are not merely technical or educational in nature, as they are deeply embedded in organisational routines, hierarchies, and resource constraints. In many cases, AI adoption amplifies rather than resolves existing asymmetries, placing additional burdens on operational staff without providing mechanisms for participation or support. The limited involvement of organisational managers in AI governance and oversight further exacerbates this problem, preventing the emergence of reflexive structures that could align digital systems with evolving business and sustainability priorities.

Third, when considered through the lens of CE, the role of human actors appears even more marginal. While AI tools are increasingly deployed in applications that touch upon CE-related goals, such as waste tracking, resource optimisation, or traceability, these functions are rarely embedded within a circular logic. Instead, they seek to reflect a continuation of linear optimisation strategies, where efficiency is improved without rethinking underlying production or consumption models. The conceptualisation and development phases, in particular, show almost no engagement with CE principles, and even in deployment and monitoring, CE appears as a secondary consideration rather than a design driver. Moreover, the absence of robust human involvement in governance and explanation phases represents a missed opportunity for systemic alignment. CE transitions require not only technological innovation but also institutional coordination, stakeholder deliberation, and long-term learning, all of which depend on inclusive and participatory governance structures. Yet the literature reviewed indicates that such mechanisms are either missing or highly underdeveloped. Ethical, interpretive, and compliance-related functions are often delegated to external regulations or technological interfaces, without meaningful input from internal stakeholders or affected communities.

Taken together, the findings of this review suggest that current approaches to AI implementation in agri-food systems generate a disconnection between digital capabilities and ecological ambitions, reflecting not a lack of technological potential but a failure to design sociotechnical systems that are context-sensitive, user-informed, and value-driven. Rather than treating AI as a neutral efficiency tool, future efforts must reposition it as a medium for organisational learning, cross-actor collaboration, and regenerative innovation.

This shift requires rethinking how human involvement is conceptualised across the AI lifecycles. Participatory design, training infrastructures, co-governance platforms, and interpretability tools grounded in ecological metrics can all play a role in embedding CE principles more effectively. In particular, empowering small and medium enterprises and cooperatives, who often lack resources but possess high contextual embeddedness, may prove essential to scaling AI-enabled circular models.

Ultimately, the study underscores the need for a more holistic and integrated approach to AI adoption in the agri-food sector that centres human agency, fosters organisational reflexivity, and aligns digital tools with the transformative aspirations of the CE.

5 Conclusions

This article provided an in-depth synthesis of how artificial intelligence (AI), human involvement, and circular economy (CE) principles interact within agri-food systems. Drawing on a systematic review of 88 peer-reviewed articles, three key insights have emerged. First, human involvement remains highly concentrated in the

operational phases of AI deployment, while the more strategic stages, such as conceptualisation, governance, and explanation, are largely dominated by external actors or neglected altogether. This misalignment suggests that AI systems are often introduced in ways that limit organisational ownership and reduce their contextual relevance. Second, several structural challenges inhibit more meaningful human participation. Skills deficits, resistance to change, and unclear role distributions prevent actors within agri-food organisations from fully engaging with AI tools. These barriers are particularly acute in small and medium-sized enterprises, which often lack the institutional support to absorb and adapt digital innovations effectively. Third, the integration of CE into AI-enabled systems remains underdeveloped and mostly incidental. While many AI applications serve CE-relevant purposes, such as reducing food waste or optimising input use, few are designed with circularity as a core organising principle. Moreover, the absence of participatory governance mechanisms and interpretability tools aligned with ecological goals further weakens the connection between AI adoption and circular transformation.

In light of these findings, future research and practice should prioritise human-centred and CE-aligned AI models that enable co-design, shared governance, and iterative learning to foster more resilient, inclusive, and regenerative agri-food systems in the digital era.

6 Ethics declaration

The manuscript has been wrote accordingly to ethical guidelines. I declare that the manuscript is original and never submitted elsewhere.

7 AI declaration

No AI tools were used for creation of the paper.

Unleashing Digital Transformation in LCA: The Interplay between Data-Driven Culture and Digital Capabilities

Miriana Ferrara[1], Nicola Capolupo[2]
[1]University of Salerno, Fisciano (SA), Italy
[2]San Raffaele Rome University, Rome, Italy

Abstract

In an era marked by ever-increasing environmental concern and technological novelty, Life Cycle Assessment (LCA) has come to serve as one key instrument for evaluating environmental performance of organizations. Conversely, much literature has neglected possible strategies for aligning digital transformation (DT) with LCA activities as digital technologies care about dissemination. This study fills the gap by examining how non-technological assets such as data-driven culture (DDC) and digital capabilities (DC) spur digital transformation in LCA practice. Building on Resource-Based View (RBV), this study sees DDC as an organizational resource and DC as a human resource that mediates the effects of DDC on DT. Data were collected through an online survey among 229 Italian companies in the agri-food sector, an environment where the institutionalization of LCA adoption occurs. Structural equation modeling (SEM) was used to test hypothesized relationships. The results suggest that while DDC has no direct effects on DT, it promotes digital capabilities among employees, which in turn affect DT, thereby confirming a full mediation effect. The research supports the idea that transformation of practice relative to sustainability needs actual digital innovation and therefore cannot be achieved by just introducing new technologies. Instead, an important aspect of this process is to bring about a cultural change and the development of human skills. As much as technology influences the advancement of sustainability schemes, such as LCA, it could be unaffecting just by itself. A data culture must grow to foster an environment where data are valued, disseminated, and applied in decision-making, whilst employees should have digital capabilities that help them to draw insights from data, take action, and innovate. Conversely, if cultural and human elements are taken into consideration, the application of the technologies will be enhanced and maximized.

Keywords: Life Cycle Assessment, Digital Transformation, Data Driven Culture, Digital Competencies

Paper type: Academic Research Paper

1 Introduction

Life Cycle Assessment (LCA) has become an essential methodology for evaluating the environmental impact (Li and Cheng 2020) of organizations throughout their lifecycle, both internally and externally. According to ISO standards (e.g., ISO 14040:2006, 2020; ISO 14044:2006, 2021), LCA provides firms with a systematic framework for assessing resource use, emissions, and sustainability metrics, facilitating more informed decision-making (Ciasullo et al., 2024a). LCA is structured around four main stages. It begins with the goal and scope definition, where the objectives of the study are clarified, along with key elements such as system boundaries, functional units, and allocation methods. The second stage, inventory analysis, involves gathering and verifying relevant data, which are then organized within a life-cycle model to provide a structured overview of inputs and outputs. Following this, the impact assessment phase translates the collected data into measurable environmental impacts, helping to understand the broader ecological implications. Finally, the interpretation stage draws conclusions from the findings, critically reviewing the results and effectively communicating the insights to inform decision-making.

In an era increasingly shaped by digital transformation (DT), researchers and practitioners have been focusing on the strategic potential of digital technologies to enhance specific steps of LCA, improving data collection, analytics, and sustainability reporting (Song et al., 2018; Mieras et al., 2019; Kamble et al., 2020; Kumar et al., 2021; Rolinck et al., 2021). However, they have been not focusing on how organizations can effectively embrace DT for LCA methodology, while mainly discussing the challenges that organizations can face to pursue DT in LCA. Among these, the lack of willingness to share information and the employees' unfamiliarity with technologies and data emerged as major obstacles at an individual level (Sica et al., 2022); whereas limited economic resources and the absence of shared data governance characterized the limitations at an organizational level (Rolinck et al., 2021). Still, a gap persists in understanding how the mechanisms at the individual and organizational levels could impact DT. Specifically, in a digitalized context, beyond the mere implementation of technologies, it is necessary to enhance organizational and human resources to fully leverage them. Particularly, to pursue DT, data-driven culture – the extent to which firms emphasize data as a strategic resource (Wamba et al., 2017) – emerges as an organizational asset that can lead firms to integrate digital tools

into their LCA practices. A strong DDC facilitates the collection, analysis, and application of sustainability data, enhancing firms' ability to optimize LCA models. Accordingly, only fostering a data-centric mindset is insufficient without ensuring that employees possess the necessary digital capabilities (i.e., human resources) to manage and interpret data effectively (Soto-Acosta, 2020). Against this backdrop, this study aims to investigate the impacts of organizational and human resources on DT. More specifically, it focuses on understanding the mediating role of employees' digital capabilities (DC) in the relationship between data-driven culture (DDC) and digital transformation (DT) in firms emlpoing LCA methodology.

Considering the focus on firms' strategic resources, the study relies on the Resource-Based View (RBV) as the theoretical lens to understand the interrelations among DDC, DT and DC. Empirically, quantitative methodology is adopted, by performing a structural equation modeling (SEM) with mediation analysis on 229 Italian firms adopting LCA. Theoretically, this study contributes to literature providing a discussion about how non-technological resources can support DT of LCA methodology. Moreover, the results reveals the need to foster employees' digital capabilities as a key aspect to realize DT.

2 Theoretical background and hypothesis development

RBV is a core theory in the strategic management field, which conceptualizes the firm as a set of resources that lead the company to gain competitive advantage (Lockett et al., 2009). Originally proposed by Barney (1991), this theory emphasizes those firms' assets that are difficult to replicate, considering them key elements to ensure superior performance and competitive advantage (Amit and Schoemaker, 1993). Following Barney (1991), this study considers resources as physical resources (physical, technological, plant and equipment), human resources (training, experience, insights), and organizational resources (formal structure). Addressing the LCA literature, several studies investigate how technologies can contribute to one or more stages of LCA (Carrières et al. 2021; Teh et al. 2020), by stressing out the role of technological resources in the related processes. Focusing on the strategic potential of DT, RBV emerges an appropriate theoretical lens to understand the effects of organizational and human resources on DT, by particularly put emphasis on DDC and DC. Therefore, considering DDC as an organizational resource and DC as a human resource, the following conceptual model is proposed (Figure 1):

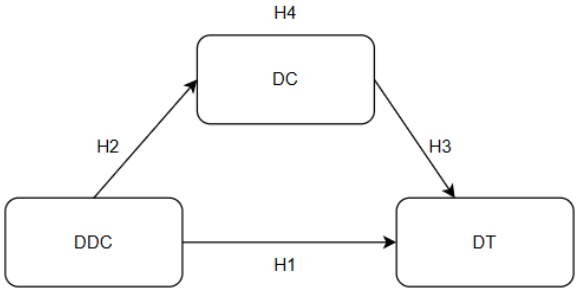

Figure 1. Conceptual model

2.1 Data-driven culture and Digital Transformation

Scholars have argued that organizational culture plays a crucial role in enabling digital transformation (DT) (Karimi and Walter, 2015; Ghafoori et al., 2024). Numerous studies have explored how culture influences DT efforts. Liu et al. (2023) highlighted organizational culture as a moderating factor in the link between digital transformation and organizational performance. Evidence suggests that companies with a strong data-oriented culture are more likely to achieve significant performance gains during digital transformation initiatives. Similarly, Çetin Gürkan and Çiftci (2020) emphasized the importance of digital organizational culture in facilitating the organizational changes necessary for DT. Among the various cultural models that influence DT, data-driven culture (DDC) seems particularly well-suited for organizations employing LCA methodology, as these firms can leverage digital tools for enhanced data gathering and analysis. Furthermore, Ghafoori et al. (2024) investigated how organizational culture shapes data-driven digital transformation, describing it as a process involving the reorganization of resources to integrate technologies and derive insights from data (Papanagnou et al., 2022). Essentially, Ghafoori et al. (2024) argue that digital transformation is characterized by the strategic reallocation of resources, guided by a data-centric mindset and enabled by digital technologies. Based on this perspective, the following research hypothesis is proposed:

- *H1: Data-Driven Culture (DDC) has a positive and significant effect on Digital Transformation (DT)*

2.2 The mediating role of Digital capabilities

The positive relationship between organizational culture and capabilities is well established in literature (Jones et al., 2005). Indeed, scholars agreed about the role of organizational culture in orienting and supporting the development of capabilities. More recently, Velyako and Musa (2024) demonstrated that organizational culture has a positive effect on digital capabilities in a digital environment. By focusing on DDC, it emerges that is has been mostly studied in relation to big data analytics capabilities (Karaboga et al., 2023; Yu et al., 2021), as the ability to provide data-driven insights using technologies (Akter et al., 2016). Nevertheless, given the tight link between data management and digital technologies, it can be argued that an organizational culture that promotes data-driven insights needs to enhance the development of digital capabilities at the individual level to make employees' able to use technology, collecting and interpreting data. Consequently, it can be assumed that DDC can support the development of digital capabilities, intended as the ability to make use of digital technologies, resulting from digital experience and technical know-how (Arkhipova and Bozzoli, 2018; Belhadi et al., 2024).

The relationship between DC and DT has been extensively explored (Slavković et al., 2023; Baiyere et al., 2025). Scholars contended that DT needs human involvement for the successful implementation of digital technologies. Indeed, existing management literature emphasizes that the effective adoption of technology largely relies on the skill set of the workforce (Bokrantz et al., 2017; Dalenogare et al., 2018; Gürdür et al., 2019). According to Jafari-Sadeghi et al. (2023), analytical thinking, digital literacy, and the capability to extract meaningful data are all crucial for employees to successfully engage with digital tools and consequently embrace DT. Similarly, Gürdür et al. (2019) highlight that the ability to handle digital technologies among employees is vital to fully exploit digital tools.

Finally, by considering the combination of organizational and human resources, it can be assumed that DC intervene in the relationship between DDC and DT. In other words, if DDC orients the entire organization towards DT, DC emerge as a critical enabler to effectively apply the organizational culture to pursue DT (Cetindamar et al., 2021; Blanka et al., 2022). Indeed, while DDC emphasizes the importance of data in LCA, without employees' digital capabilities, the organization cannot effectively leverage data for DT.

Based on these assumptions, the following hypothesis were developed:

- *H2: Data-Driven Culture (DDC) has a positive and significant effect on Digital Capabilities (DC)*
- *H3: Digital Capabilities (DC) have a positive and significant effect on Digital Transformation (DT)*
- *H4: Digital Capabilities (DC) mediates the relationship between Data-Driven Culture (DDC) and Digital* Transformation (DT).

3 Methodology

This research examines how Digital Transformation (DT) is being applied to Life Cycle Assessment (LCA) practices within the agri-food industry. It was selected due to its critical role regarding environmental sustainability (Ciasullo et al., 2024b), its relevance to LCA researchers (e.g., McAuliffe et al., 2020), and strong institutional support for LCA adoption (European Commission, 2021). Italy was selected as the context for this study due to the prominent role its agri-food sector plays within the European framework. Indeed, Italy ranks third in the European Union for value added in the agri-food industry, following Germany and France (Unioncamere, 2023). Particularly, the study focused on firms operating in the region of Campania in Italy, due to the relevance of this industry for the national and regional economy (Regione Campania, 2023)

Eligible agri-food firms were identified through the AIDA database, a repository of financial and business information on European enterprises. Firms were randomly selected, thereby ensuring that the sample includes a diverse range of firms, avoiding systematic biases that may arise from non-random selection (Bryman, 2016). They were contacted via email and provided with details about the research objectives and participation instructions. The survey targeted general managers, CEOs, and founders/entrepreneurs, ensuring that responses reflected strategic perspectives on LCA and digitalization.

A total of 229 responses were collected over four months through an online survey, composed of 18 items in two main sections. It gathered respondent demographics, and key constructs included in the conceptual model using established scales measured on a 5-point Likert scale. Particularly, 4 questions were related to DTs adapted from Xie et al. (2022), 5 to DDC (Yu et al. 2021), 5 to DC (Proksch et al., 2024). Prior to administering the full survey, a pilot test was carried out with a convenience sample of 20 participants to assess and ensure the clarity and understanding of the questions (Lavrakas, 2008).

Finally, the sample was analyzed using SPSS and AMOS with Structural Equation Modeling (SEM), following a two-step approach that first validated the measurement model before testing the structural relationships (Anderson and Gerbing 1988). The number of responses was adequate to conduct SEM, indeed it was aligned

with Bentler and Chou's (1987) guideline, which establishes a 5:1 ratio between the number of responses and estimated parameters for conducting SEM. Moreover, the sample size also satisfies Nunnally's (1967) rule, which recommends at least ten responses per item for SEM analysis.

4 Results

4.1 Measurement model estimation

A Confirmatory Factor Analysis (CFA) was conducted to verify construct validity and overall model fit by analyzing reliability, convergent validity, and discriminant validity (Brown & Moore, 2012). The reliability of each indicator was assessed through factor loadings, while Cronbach's alpha (CA) and composite reliability (CR) evaluated the internal consistency of each construct. Convergent validity was measured using the Average Variance Extracted (AVE), and discriminant validity was tested using the Fornell and Larcker (1981) method. As shown in Table 1, all factor loadings exceeded the acceptable threshold of 0.70. Similarly, the reliability measures (CA and CR) surpassed 0.70, and all AVE values were above 0.50.

Table 1: Descriptive statistics, reliability and convergent validity

CONSTRUCT	ITEMS	MEAN	SD	LOADINGS	CA	CR	AVE
DT	DT1	3.53	1.293	0.955	0.98	0.96	0.88
	DT2	3.71	1.244	0.960			
	DT3	3.58	1.192	0.954			
	DT4	3.61	1.326	0.972			
DDC	DDC1	3.22	1.513	0.882	0.98	0.95	0.82
	DDC2	3.14	1.709	0.980			
	DDC3	3.16	1.672	0.991			
	DDC4	3.17	1.597	0.971			
	DDC5	3.12	1.694	0.962

	DC5	3.27	1.274	0.932			

To assess discriminant validity, the square root of each construct's AVE was compared with its highest correlation with other constructs; the former was consistently higher, confirming discriminant validity. Table 2 presents the correlation matrix, with the square root of AVE values displayed along the diagonal to facilitate this comparison (Zaiţ and Bertea, 2011).

Table 2: Discriminant Validity (Fornell-Larcker Criterion)

	DDC	DC	DT
DDC	**0.82**	0.68	0.15
DC	0.68	**0.78**	0.63
DT	0.15	0.63	**0.75**

Note: *Bold values = √AVE

4.2 Structural model estimation

The assessment of the structural model aims to evaluate the fit model between empirical data and the proposed conceptual framework. Table 3 presents the model fit measures for the estimated model, indicating an overall acceptable fit.

Table 3: Goodness-of-fit indexes

Fit index	Value	Acceptable threshold
SRMR	0.045	< 0.08
RMSEA	0.036	< 0.06
CFI	0.978	> 0.95
TLI	0.962	> 0.95

As for the path coefficients, the analysis confirmed the hypothesized mediation model. The results showed that DDC does not have a significant impact on DT, since p-value > 0.005, therefore H1 is not supported. Moreover, the study revealed that DDC plays a significant and positive effect on DC (β=0.70), thereby confirming H2. Also, it emerged that DC significantly and positively impacts DT (β=0.63), consequently H3 is supported. Finally, the mediation analysis is statistically significant (β=0.44), by particularly configuring a full mediation. This means that DDC fosters DT only when employees have adequate digital skills, supporting H4.

Table 4: Model results

Path	Coefficient	Std.Error	95% LLCI	95% ULCI	Remarks
DDC → DT	0.16	0.10	-0.04	0.36	Not supported
DDC → DC	0.70***	0.08	0.55	0.85	Supported
DC→DT	0.63***	0.09	0.45	0.38	Supported
DDC → DC → DT (indirect)	0.44***	0.07	0.31	0.60	Supported

Note: ***= significant effect

5 Discussions and conclusions

The study investigated the role of DDC and DC in enhancing DT in firms adopting LCA methodology. Particularly, it emerged that only though the integration of human and organizational resources, firms manage to strategically pursue DT. More in detail, the study outlined the relevance of employees in supporting the digitalization of LCA methodology. In this regard, H1 was not supported, assuming that only engaging with DDC does not provide the firm with a successful use of digital tools. This result contrasts with existing DT literature (Çetin Gürkan and Çiftci, 2020; Liu et al., 2023), and it can be explained by considering that data-driven orientation of LCA firms does not automatically shift towards DT, which is a more complex construct that requires human digital capabilities (Ghafoori et al., 2024).

Regarding H2, results showed to be aligned with existing literature (Jones et al., 2005), and provided empirical evidence of the impact of DDC on DC. Accordingly, it goes beyond the most explored relationship between DDC and big data analytics capabilities by offering an additional significant impact of DDC on a capability.

As for H3, the study confirmed the vast corpus of DT literature, that significantly stress the relevance of employees in triggering DT (Dalenogare et al., 2018; Gürdür et al., 2019; Jafari-Sadeghi et al., 2023).

Finally, the study confirmed H4, supporting that fostering a data-driven culture is necessary but not sufficient for DT in firms adopting LCA. Instead, employees' digital capabilities emerge as the key enabler that allows organizations to fully exploit the potential of digital technologies in LCA-based sustainability initiatives. In this direction, it is confirmed that DT overcomes the mere implementation of technologies, by requiring employees involvement and commitment (Abbate et al., 2023; Ciasullo et al., 2024a).

From a theoretical perspective, this study extends the current research by integrating RBV with digital transformation literature in LCA context, providing evidences that human, organizational resources and technological capabilities must be aligned for firms to achieve meaningful innovation (Barreto, 2010). The full mediation effect pinpoints the need to bridge the gap between cultural shifts and technical expertise, emphasizing that firms investing in LCA must complement data-driven strategies with employee upskilling programs.

From a managerial point of view, this study highlights essential strategies for organizations aiming to enhance their LCA-based sustainability initiatives through DT. For instance, investing in digital training programs is crucial, as organizations need to develop structured learning initiatives that enhance employees' digital literacy, ensuring they possess the necessary skills to interpret, manage, and apply LCA data effectively. Additionally, fostering cross-functional collaboration is imperative: strengthening the interaction between sustainability teams and IT departments can facilitate a more integrated approach to digitalizing LCA processes, enabling seamless data management and strategic decision-making.

This study presents several limitations. The sample includes agri-food firms located in a Southern Italian region, which may constrain the broader applicability of the results. Future research could enhance generalizability by involving a more geographically diverse sample, including firms from other Italian regions or international contexts. Expanding the analysis to other industries beyond agri-food could also offer deeper insights into how LCA DT supports organizational effectiveness across different sectors. Moreover, as the data were gathered through a survey, future studies could integrate additional data collection methods.

The Role of Physical Appearance in the Entrepreneurial Journey: A State-of-the-Art Review from a Feminist Perspective

Michela Colacicco, Mastropasqua Antonio, Francesco Paolo Lagrasta, Barbara Scozzi
Politecnico di Bari, Bari, Italy

Abstract

The study explores the under-investigated intersection between corporeality and entrepreneurship by conducting a systematic literature review on the role of physical appearance in entrepreneurial processes. Despite traditional interest in the influence of bodily aesthetics—particularly physical attractiveness—within feminist scholarship, current research is largely dominated by theoretical approaches rooted in evolutionary and social psychology. Existing studies, while methodologically rigorous, often lack socio-political depth and fail to critically engage with feminist or intersectional paradigms. By adopting a PRISMA-guided systematic review protocol review, the authors identified a final corpus of 15 core studies. Such studies were subjected to bibliometric framing and deductive qualitative content analysis aimed at identifying dominant theoretical backgrounds, recurring methodologies, sample characteristics, and investigated entrepreneurial stages. Results indicate a pronounced quantitative orientation and a consistent preference for structured entrepreneurial environments and early-stage financing scenarios. The analysis reveals a pervasive attractiveness bias and a lack of critical engagement with its implications, which may contribute to legitimizing existing gender hierarchies within entrepreneurial ecosystems. The study ultimately calls for a broader epistemological agenda that integrates feminist ethics, qualitative inquiry, and a critical perspective on bodily representation in entrepreneurship research. The findings provide a foundation for more inclusive and politically aware investigations into how corporeality shapes entrepreneurial outcomes and imaginaries.

Keywords: Entrepreneurial financing, physical attractiveness, beauty, feminism, gender

Paper type: Academic Research

1 Introduction

The role of corporeality—understood as outward appearance—has long been overlooked by economic and entrepreneurial disciplines (Davis, 2007; Yıldırım, 2024). Since the early development of modern economic thought, economic agents have been conceptualized as disembodied angelic minds, driven solely by the pursuit of maximal utility—atomic elements devoid of a body, to which only basic needs, to be satisfied simply through consumption, were associated. A harsh critique of such economic-anthropological posture would today appear misplaced and naïve, given that the limitations of a literal and uncompromising interpretation of neoclassical economic theories are patently evident (Bromiley and Papenhausen, 2003; Dolderer et al., 2021; England, 1989; Woolley, 1993). Nevertheless, it is only in recent years that the question of the body's role in the entrepreneurial domain has begun to surface—and even then, in a timid and gradual manner (Baron et al., 2006). While the body, as a site and a manifestation of identity, has been a prominent theme within sociological, psychological and organizational discourse (Heilman and Saruwatari, 1979; Romeo, 2020), the entrepreneur's body—as a locus of signs, symbols, gestures, and contradictions—has not received equivalent scholarly attention. The seminal works aimed at investigating the role that bodies play—specifically within entrepreneurial processes and decision-making—have only begun to emerge in the literature over the past two decades (Baron et al., 2006). Such contributions were developed as applications of methods and hypotheses previously tested in other economic contexts. A paradigmatic example is the pivotal study developed by Baron et al. (2006), who, by applying theories and methods from social psychology to the entrepreneurial socio-economic context, was among the first to examine the role of entrepreneurs' physical attractiveness in shaping perceptions of their ventures and influencing their likelihood of success. Following Baron's lead, and building upon the earlier retrospective contributions of Langlois et al. (2000), few scholars have since then explored how bodies—particularly as carriers of attractiveness—play a role in processes involving entrepreneurs, as will also be demonstrated by the findings of this article.

What is particularly striking, however, is that, from an initial review of extant literature, most of the research lack of theoretical heterogeneity and political and social implications discussion. Rather, they tend to originate from an attempt to validate, within the entrepreneurial domain, hypotheses developed within the field of

evolutionary psychology (Bahlmann, 2024; Colombo et al., 2022a) and social psychology (Baron et al., 2006). Evolutionary psychology is a branch of psychology that draws upon multiple domains—among others, evolutionary biology, cognitive psychology, and economics—in order to identify the psychological mechanisms, and the related evolutionary processes, underlying observable behaviors (Confer et al., 2010). Within the framework of evolutionary psychology, several hypotheses have been formulated and empirically validated concerning the relationship between physical appearance and human behavior—hypotheses which have subsequently been tested within the entrepreneurial domain as well (Baron et al., 2006). In this regard, evolutionary psychology offers a theoretical lens capable of capturing and framing numerous aspects of observable behaviors among entrepreneurs and other stakeholders, particularly in contexts where bodies—and thus appearance, gender, and identity—play a fundamental role. Evolutionary psychology often provides answers to questions such as why certain bodies are perceived as more attractive, by emphasizing concepts inherited from evolutionary theory, such as sexual selection and intra- and intersexual competition (Barber, 1995; Buss, 2009).

Long before the emergence of evolutionary psychology, feminist scholarship had already begun to problematize the role of bodies, with particular attention to gender as fundamental analytical variable (Lennon and Fischer, 2024). Feminist scholarship, grounded in a constructivist epistemology markedly distant from the positivism that typically characterizes the evolutionary discourse, has repeatedly highlighted how bodies are not neutral entities; rather, they constitute the very terrain upon which power dynamics between genders are enacted and materialized (Grabowska, 2023).

As Buss (2011) observes, however, evolutionary psychology and feminist theories, although focusing on similar topics—such as gender differences and causal origins—differ substantially in their aims and research scopes. Feminist approaches represent a heterogeneous body of "scholarly scientific enterprise … often containing explicit political agendas" (Buss and Schmitt, 2011). This should not be regarded as scandalous—particularly in a historical period in which, at multiple levels, the scientific community has become increasingly aware of the political significance of its research (Fuentes, 2024; Jackson, 2020). The ethical orientation that characterizes feminisms, although far from constituting a monolithic framework, represents a fundamental resource from which feminist scholars draw to guide their inquiries, delineate their research domains, and critically examine results from a socio-political perspective (Jenkins et al., 2019). When considering entrepreneurship research as a field with substantial political and social implications, it becomes clear that a strictly evolutionary reading of the role embodied by entrepreneurs' corporeality may prove reductive and, at times, even detrimental (Confer et al., 2010). The risk lies in the possibility that findings regarding bodily differences may be exploited instrumentally to justify the status quo and legitimize its perpetuation (Buss and Schmitt, 2011; Confer et al., 2010)—ultimately leading to positions rooted in biological essentialism.

Building upon these premises, the paper investigates the following research questions:

- ***RQ1*** *– What are the theoretical and methodological approaches underpinning research aimed at exploring the role of the body and physical appearance in the entrepreneurial domain?*
- ***RQ2*** *– What are the most recurrent characteristics of the samples analyzed in extent literature, and more specifically, what role does the gender variable play in this context?*

The research questions, as formulated, are intended to serve as a preliminary step toward a comprehensive understanding of the current state of the art in this field of inquiry. Specifically, RQ1 seeks to identify potential theoretical or methodological polarizations that may hinder a thorough comprehension of the socio-political implications arising from the findings within this research stream. RQ2, on the other hand, aims to explore the types of samples investigated, with the objective of identifying recurring characteristics or blind spots that may compromise the inclusiveness and transferability of the results obtained thus far within this domain of knowledge.

2 Methodology

A systematic literature review (SLR) protocol has been developed to answer the research questions formulated, aiming to conduct an exploratory analysis to identify the current state of art of academic literature on the role of physical appearance in entrepreneurial processes. SLR is a research protocol based on precise and reproducible techniques, in order to ensure transparent and reliable retrieval and analysis of the extant literature on a specific topic (Boell and Cecez-Kecmanovic, 2015; Hiebl, 2023).

This systematic literature review was conducted following the PRISMA protocol (Moher et al., 2009). The approach involves four-stage paper selection flow (see Figure 1), to ensure transparency and reproducibility in the source collection process. Each step was documented in detail to attest compliance with PRISMA principles and ensure the absence of bias in the selection of studies (Page et al., 2021).

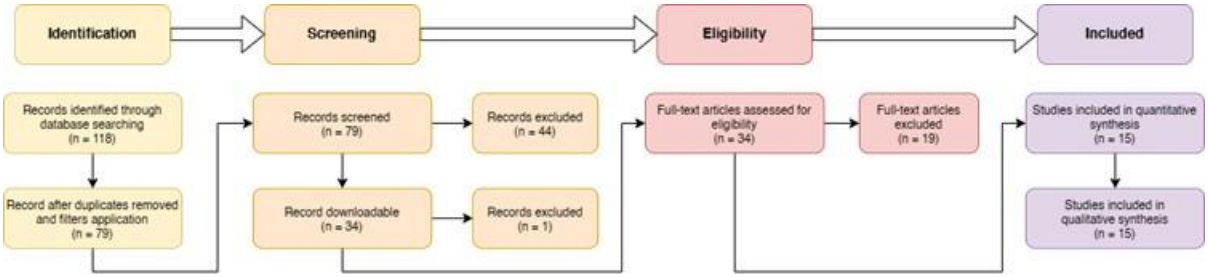

Figure 1. PRISMA' four-stage paper selection flow, adapted from Mayo-Wilson et al. (2018) and Moher et al. (2009).

The literature search was conducted on two relevant databases, Scopus and Web of Science (WoS), chosen for their widespread coverage of academic publications, their scientific quality and reliability (Burnham, 2006; Li et al., 2010). A search query was developed, combining terms related to the two subject areas of interest (see Figure 2). For entrepreneurship, the root entrepren* was used, including all terms stemming from this lemma. In contrast, for attractiveness, a comprehensive spectrum of keywords - a set of synonyms and descriptors of external appearance- was employed.

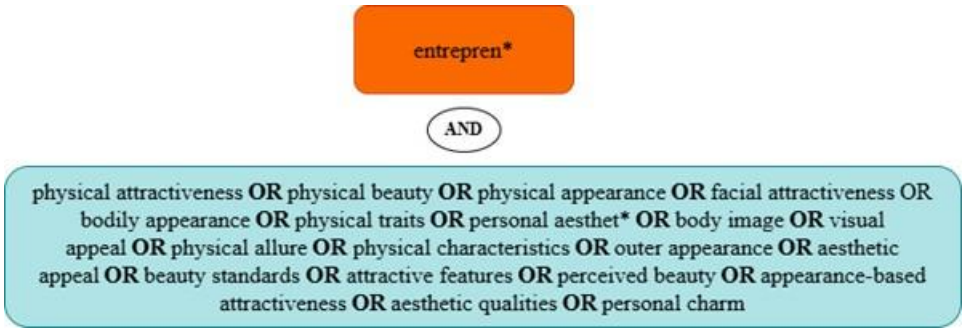

Figure 2. Thematic conceptual map relevant to the research query.

The baseline search, launched in February 2025, returned 62 papers from Scopus and 56 papers from WoS. This raw set of articles was subsequently modelled based on the available structured data (see Table 1). Filters were applied to ensure high standards of quality within the collected data (Xiao and Watson, 2019). The application of these filters reduced the number of articles to 50 for Scopus and 53 for WoS. The combined set of 103 records underwent duplicate removal, yielding 79 unique results.

Table 1. Filters applied to obtain the knowledge base under review.

Filter	Scopus	Web of Science
Language	English	English
Publication Stage	Final	-

Subsequently, the screening of the titles and abstracts was undertaken. Thus, each study was evaluated based on selection criteria in line with the research questions. Specifically, the studies were considered valid if they explicitly dealt with topics regarding physical appearance, attractiveness or beauty in the context of entrepreneurial processes. The exclusion criteria resulted in the elimination of those which, from examining the abstract, were clearly off-topic. Following the screening phase, 44 studies were excluded because they did not satisfy the criteria, reducing the number of articles potentially eligible for inclusion to 35. The selected articles were acquired in full-text and subjected to in-depth evaluation. One article, as it was not available in full-text through institutional resources or contact with the authors, was excluded.

The 34 papers were analyzed in their entirety and classified according to the method proposed by Pittaway et al. (2004) , distinguishing them into three categories (A, B, C) based on the relevance and centrality of the topic under investigation in the study.

This classification made it possible to differentiate studies that were fully focused on the phenomenon in question from those whose contribution was more peripheral, allowing the final set to be reduced to 15 articles.

Additionally, to further extend the coverage of the search and avoid missing relevant studies, additional keywords identified through the reading of the full-text papers were also tested. Supplementary queries were

undertaken with the terms: aesthetic capital, aesthetic entrepreneurialism and beauty premium. No further contributions were added to the final corpus because of these exploratory searches.

The entire process of identifying the final set of articles was conducted independently by three researchers and cross-checked to increase reliability.

Considering the restricted number of articles in the final corpus set, both a quantitative and qualitative analysis was performed for all of them. A bibliometric framing was undertaken, a quantitative analysis method that employs bibliometric data to explore and illustrate the attributes of a specific research domain. Subsequently, a content analysis was adopted to address the research questions (Donthu et al., 2021; Geng et al., 2017). Content analysis aims to detect, analyze, and compare, themes within textual data (Harwood and Garry, 2003; Krippendorff, 2019; Moldavska and Welo, 2017). A deductive content analysis (Magnani and Gioia, 2023) phase was carried out to classify the acquired articles according to several themes. A schematic representation of the themes investigated within the selected documents is provided in Figure 3. These themes were derived from the research questions and grouped into three overarching thematic areas (namely, "Theoretical and Methodological Aspects", "Sample Demographics", and "Entrepreneurial Context"). The first thematic group encompasses elements related to the methodological and theoretical approaches underpinning the reviewed studies (see RQ1). The second refers to the individual and key characteristics of the sample, while the third pertains to aspects concerning the relevant entrepreneurial context (see RQ2). A qualitative critical analysis was also carried out to decode the data derived. Lastly, the results were reported and discussed.

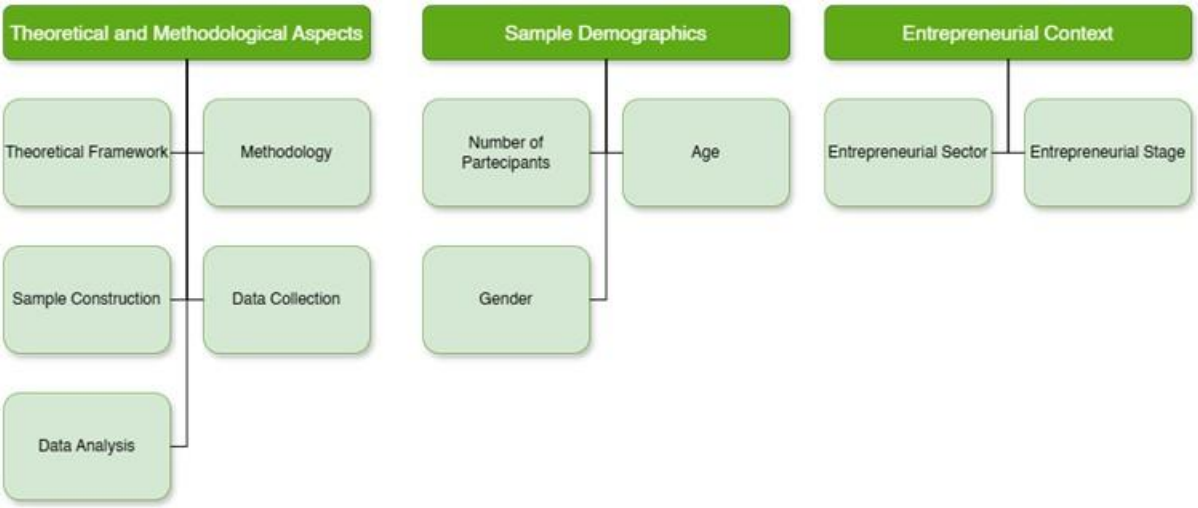

Figure 3. Analytical framework of extracted research elements.

3 Results and discussion

In this section the academic knowledge is synthesized and subjected to bibliometric and content analysis. The most significant results are analysed in conjunction with their presentation.

3.1 Bibliometric framing

The final collection analysed is composed of 15 articles spanning a time horizon of approximately 18 years. All articles are listed in Table 1, and for each contribution the author, year of publication, and journal were provided.

Table 2. List of articles included in the dataset.

ID	Title	Author	Year	Journal
1	Physical attractiveness, same-sex stimuli, and male venture capitalists' financial risk-taking	Bahlmann, Marc D.	2024	Frontiers in Psychology
2	Passion and attractiveness on display: an examination of gender bias in crowdfunding	Letwin, Chaim; Ciuchta, Michael P.; Johnson, Michael; Stevenson, Regan; Ford, Cameron	2024	Small Business Economics

ID	Title	Author	Year	Journal
3	An Attractiveness Bias? How Women Entrepreneurs' Physical Appearance Affects Men Investors	Schreiber, Robert; Hess, Manuel; Grichnik, Dietmar; Shepherd, Dean A.; Tobler, Philippe N.; Wincent, Joakim	2024	Journal of Management
4	Image isn't everything: Personality attractiveness, physical attractiveness, and self-employment earnings	Wolfe, Marcus T.; Patel, Pankaj C.	2024	Small Business Economics
5	Attractiveness, ethnicity, and stage financing: exploring heuristics in venture capital staging	Bahlmann, Marc D.	2023	Industry and Innovation
6	Angel investment and first impressions	Huang, Xing; Ivkovic, Zoran; Jiang, John Xuefeng; Wang, Isabel Yanyan	2023	Journal of Financial Economics
7	Mirror, mirror—A gendered lens on female entrepreneurs' facial attractiveness in reward-based crowdfunding	Seigner, Benedikt David Christian; Milanov, Hana	2023	Journal of Business Venturing Insights
8	Applicant attraction to new ventures: The combined effects of entrepreneurs' physical attractiveness and gender	Piva, Evila; Rovelli, Paola	2023	Journal of Small Business Management
9	The CEO beauty premium: Founder CEO attractiveness and firm valuation in initial coin offerings	Colombo, Massimo G.; Fisch, Christian; Momtaz, Paul P.; Vismara, Silvio	2022	Strategic Entrepreneurship Journal
10	Embodying aesthetic entrepreneurialism: Men, the body and the performing arts	Norman, Moss E; Bryans, John F.	2022	Sociological Review
11	Fashioning an elite entrepreneurial identity via the endorsement of gendered, designer dress codes and artefacts of success	Smith, Robert	2021	International Journal of Entrepreneurship and Innovation
12	The effect of intrinsic and extrinsic factors on entrepreneurial intentions: The moderating role of collectivist orientation	Arshad, Muhammad; Farooq, Omer; Farooq, Mariam	2018	Management Decision
13	When Beauty Doesn't Pay: Gender and Beauty Biases in a Peer-to-Peer Loan Market	Kuwabara, Ko; Thebaud, Sarah	2017	Social Forces
14	Investors prefer entrepreneurial ventures pitched by attractive men	Brooks, Alison Wood; Huang, Laura; Kearney, Sarah Wood; Murray, Fiona E.	2014	Proceedings of the National Academy of Sciences of the United States of America
15	Exporting social psychology: Effects of attractiveness on perceptions of entrepreneurs, their ideas for new products, and their financial success	Baron, RA; Markman, GD; Bollinger, M	2006	Journal of Applied Social Psychology

The first article dates back to 2006 (Baron et al., 2006), then a stagnant period is observed in which no contributions emerge until 2014, when, as shown in Figure 4, a more sustained growth in the number of publications begins to emerge. Despite this attempt at growth, the topic remains underdeveloped or at least not yet fully investigated.

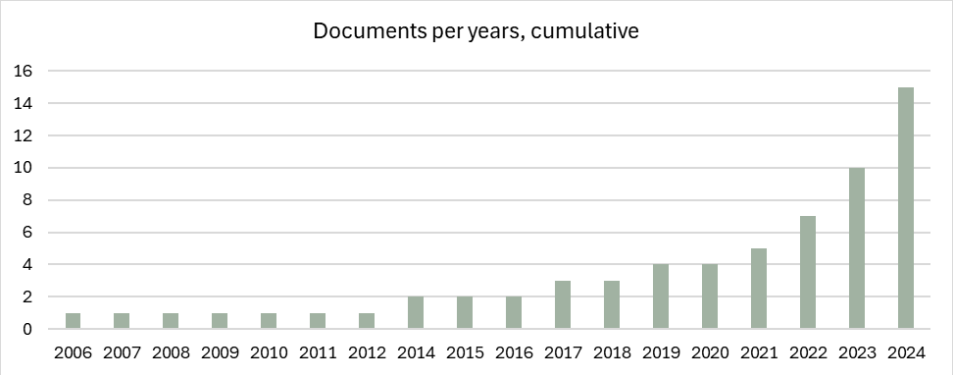

Figure 4. Cumulative number of articles published each year.

Except for the journal *'Small Business Economics*' which appears twice, there is no other dominant journal. The journals appearing on a single occasion include *'Strategic Entrepreneurship Journal*', *'International Journal of Entrepreneurship and Innovation*' and *'Journal of Business Venturing Insights*'. Geographically, the major contributions emerge from the United States (with more than ten institutions) followed by Italy and Germany (with four institutions each). Most of the other authors in the sample are affiliated with universities located in Canada, Pakistan and United Kingdom.

Analysing the keywords chosen by the authors to represent their contributions, "attractiveness" stands out as the most recurring term, with a frequency of two occurrences. Such a word also appears as part of a locution, as in "physical attractiveness" (three mentions), followed by "facial attractiveness" and "personality attractiveness" (both mentioned once). "Entrepreneurship" and "entrepreneurial finance" are cited twice, while "gender" appears three times, including two as part of locutions containing "bias" and "stereotype".

3.2 Content Analysis results

The results obtained contributed to addressing the research questions, confirming the methodological and theoretical trends identified in the introduction. Most of the studies examined adopt theoretical frameworks that are rooted in evolutionary and social psychology, with a great representation of stereotype-based theory. Such an orientation translates in a lack of socio-political depth in the contributions analyzed, especially when viewed from feminist and intersectional perspectives. A paradigmatic example is offered by the study of Piva et al. (2024), who, upon identifying an attractiveness bias in job seeking and early recruitment stages, interpret the results by advising that “attractive males” should be the ones presenting entrepreneurial ideas. However, this is far from an isolated case: similar conclusions can be found in (Letwin et al., 2024) and (Bahlmann, 2023). When situated within the broader feminist literature, such findings appear to empirically illuminate the motivations that lead many female entrepreneurs to withdraw in favor of male-dominated entrepreneurial models. The absence of critical reflection on these findings risks enabling instrumental interpretations that may serve to legitimize the status quo.

All the identified studies are based on quantitative research protocols except for Smith (2021) and Norman and Bryans (2022). Most of the quantitative research protocols adopt surveys, questionnaires or existing data from online platforms. Participants are often invited to observe images (illustrating entrepreneurs’ faces) or brief videos (showing entrepreneurs engaged in pitch competitions) and subsequently to express a judgment based on their observations. The selection of materials to be submitted to participants is conducted in accordance with logics that reflect the objective of the research and the context. Alternatively, a questionnaire is directly submitted to participants. In one case, a non-human entity, specifically a machine learning model, was responsible for performing the evaluation (Seigner and Milanov, 2023). Certain papers include multiple studies, which could investigate the phenomenon at different level (Baron et al., 2006; Brooks et al., 2014; Colombo et al., 2022b; Letwin et al., 2024). The construction of the sample seems to be guided in all cases by purpose and data availability. Delving into sample demographics, the participants belong to different panels, experts in the sector such as angel investors and ICO investors, or non-experts such as students (Arshad et al., 2019; Bahlmann, 2024; Piva and Rovelli, 2024). The number of participants is highly heterogeneous, ranging from a few dozen to hundreds. The fragmentation is also reflected in terms of participants’ gender. In one instance where such information is available, it is not always associated with well-defined proportion between the sexes. Indeed, there appears to be a slight tendency towards a dominant male. The age (frequently designated as unavailable) span from 15 to over 40 years. The range aligns with the selected sample, which encompasses individuals from young students to experienced investors in the field.

A certain heterogeneity is also observed in the data regarding the entrepreneurial sector (where present). The range of sectors represented extends from technology (most mentioned) to fashion, energy and mobility, to name but a few. In one instance, the fashion sector is specifically associated with the female type category, while technology is associated with the male type category (Seigner and Milanov, 2023). In the context of the entrepreneurial stage, the studies show a polarization towards the initial phases, encompassing the intention to start a business and the necessity to secure funds. The most frequently cited stage is financing (Bahlmann, 2023; Colombo et al., 2022; Huang et al., 2023) especially in the modality of crowdfunding (Letwin et al., 2024; Seigner and Milanov, 2023).

4 Conclusions

The results of the investigation, which at this stage should be considered as preliminary to a more detailed and extensive analysis, nevertheless contribute to outlining a theoretical-epistemic framework largely dominated by approaches rooted in evolutionary psychology. That does not represent an intrinsically problematic feature of the research strand; however, the limited presence of ethically grounded theoretical frameworks or of a socio-political problematization of the findings may risk legitimizing phenomena that contribute to reducing the inclusivity of entrepreneurial environments. The lack of studies employing qualitative methodologies hinders a deeper understanding of the lived experiences of those who are currently reduced to performance and appearance (entrepreneurs). Furthermore, it should be emphasized that the identified studies tend to investigate highly structured entrepreneurial contexts: the role of body and physical presence in informal entrepreneurial events or unstructured social settings remains, at present, an unexamined aspect. The study is, of course, subject to some limitations. Although the selection of keywords was conducted with caution and breadth, the non-inclusion of potentially relevant studies with respect to the investigated themes cannot be entirely ruled out. Moreover, the inclusion and exclusion criteria adopted did not allow for the integration of books or book chapters into the corpus of analyzed knowledge to ensure a certain level of scientific rigor (books are not usually subject to peer review). Nonetheless, particularly in the fields of sociology and psychology, such editorial outputs may be of interest and relevant to the purposes of this research.

5 Ethics declaration

There are no ethical statements to declare for this research as no humans were involved, or sensitive data collected and processed. Only publicly accessible data was used.

6 AI declaration

No artificial intelligence tools were used in developing the paper.

Exploring the Gender Gap in ERC Funding: A Geographical and Socioeconomic Analysis of Female Academic Research, Innovation, and Entrepreneurship

Tamara Menichini, Stefania Roberta Miccoli
University of Rome "Niccolò Cusano", Rome, Italy

Abstract

Research, innovation, and entrepreneurship are key in academia, with entrepreneurship serving as a bridge between science and business to drive economic growth. While being more inclusive of women is generally seen as beneficial, gender equality is still far off, with a clear gender gap showing unequal conditions. The Global Gender Gap Index (GGGI) in 2024 showed a global gender gap of 68.5% across 146 economies. The Economist's Glass-Ceiling Index (GCI) in 2024 highlighted a persistent 12% wage gap. This study investigates the gender gap in research, innovation, and entrepreneurship across European universities, specifically examining the distribution of European Research Council (ERC) funding and potential gender bias. Analyzing the geographical allocation of ERC grants, the study reveals a funding disparity, with fewer women researchers receiving funding. While countries with fewer projects show no significant gender differences, those with larger funding volumes exhibit clear disparities favouring men. The second part of the study explores the potential reasons behind the differing percentages of female and male researchers and the socioeconomic factors influencing ERC funding. The analysis suggests that gender equality has an impact on the proportion of female Principal Investigators (PIs) in a country, and factors like women's participation in the workforce, working conditions, entrepreneurship, and political representation influence ERC grants for women. Structural changes are so needed for a more gender-balanced academic environment. Future research could look at sociocultural and psychological barriers for women in securing ERC funding.

Keywords: Gender gap, Research and Innovation (R&I), Academic entrepreneurship, European Research Council (ERC)

Paper type: Academic Research Paper

1 Introduction

Historically, women have faced a long struggle for gender equality, enduring centuries of discrimination in social, economic, and political life. Excluded from education, work, and politics, their public roles were limited. However, feminist movements and growing awareness of women's rights, starting in the 19th century, led to significant changes. Recent evidence shows significant benefits from greater inclusion of women in the economy and society (Agrawal, 2017; Peterson and Powers, 2019). Despite progress, current data indicates that gender equality is still far off, with a persistent gender gap showing the unequal conditions women still face. The World Economic Forum's 2024 GGGI benchmarks gender parity across 146 economies in four areas: the global gender gap is at 68.5%, a slight 0.1% increase from last year. The report estimates it will take 134 years to achieve full gender equality. Northern Europe (75%) has the highest parity, while the Middle East and North Africa (61.7%) have the lowest. Likewise, the Economist's Glass-Ceiling Index (GCI), for 29 OECD countries, illustrates barriers to women's professional advancement: the 2024 GCI shows a persistent 12% wage gap. Iceland, Sweden, Norway, Finland, and France have the least inequality, while Israel, Switzerland, Japan, Turkey, and South Korea have the most. Factors like patriarchal roles, stereotypes, the child penalty, and unequal caregiving contribute to this.

To address persistent negative data on gender inequality, countries and international bodies are taking political and strategic actions: the UN 2030 Agenda includes Sustainable Development Goal 5 for gender equality; likewise, the European Commission aims to promote equality in scientific careers, ensure gender balance in decision-making, and integrate the gender dimension into research content. The gender gap, while a critical issue, is a relatively new field of study without a long-established central theory. Key figures in this regard are: Simone de Beauvoir, who established the distinction between sex and gender in the 1940s; John Money, who introduced the concept of gender role in the 1950s; Eleanor Smeal, who coined the expression "gender gap" Claudia Goldin, who in the 1990s identified the main determinants of gender differences in the labour market. Human capital includes gender, age, and culture, which should be preserved (Johnston and Packer, 1987; Kreitner and Kinicki, 2008), that opposes gender stereotypes and supports equal rights and opportunities in education, employment, and health (Stumbitz et al., 2018).

This work aims to study the gender gap in academia, research, and innovation, where the underrepresentation of women has significant consequences (Abreu and Grinevich, 2017; Ghosh, 2024). The lack of representation hinders diverse perspectives, creativity, and ultimately harms innovation (Lerchenmueller and Sorenson, 2018; Liao and Lian, Yang et al., 2022), potentially leading to less inclusive and relevant science. The study specifically focuses on the gap within European academia, recognizing the crucial role of knowledge in societal progress (Andersson et al., 2021) and the socioeconomic importance of universities in generating and applying knowledge (Murray, 2002; Siegel et al., 2007; Castaneda and Cuellar, 2020; Frank and Meyer, 2020).

The ERC supports outstanding researchers in EU member states and associated countries through a variety of funding schemes, including Starting, Consolidator, Advanced, Synergy, and Proof of Concept Grants that correspond to different stages of the research career and project development. These schemes progressively support initiatives ranging from early-career independence to advanced, high-risk research, large-scale collaborative efforts, and the translation of scientific results into societal or commercial impact. Between 2019 and 2023, PIs received an average of €1.6 million in funding, with no gender difference in the average amount. Women received 33.48% (€2.8 billion) of ERC funding and men 66.52% (€5.6 billion). Female representation decreases at higher research levels and in the scientific fields that receive the most funding. Among the top 5 Host Institute (HI) countries for ERC funding (Germany, France, Netherlands, Italy, Spain), Italy has the highest proportion of women PIs (36.14%). The ERC is actively working to reduce the gender gap in research: a regularly updated Gender Equality Plan focused on raising awareness, improving gender balance among applicants and research teams, addressing gender bias in evaluations, and promoting gender awareness; an 18-month extension per child born or adopted before or after the PhD, with further extensions for documented parental leave; cover costs related to promoting equal opportunities; bias training for assessment members, and monitoring applicant and beneficiary data; gender balanced communications for increasing the visibility of women in science.

The present paper investigates the allocation of ERC funding to reveal gender gaps in academia, specifically concerning the geographical distribution of funding and influencing socio-economic factors, given the decreasing presence of women as they advance in their careers. After an introduction, Section 2 explains the geo-referenced mapping methodology, Section 3 details the econometric analysis, and Section 4 discusses results and concludes the paper.

2 Research design

The research comprises two phases. The first phase (Section 3) employed geo-referenced mapping tools to visualize data and develop interpretative models. Mapping can serve as a powerful analytical tool in social science research (McMaster and Harvey, 2010). Georeferencing, used in Geographic Information Systems (GIS), links data to geographical locations and enrich the interpretation of quantitative data by offering new perspectives in the analysis of large-scale human behaviour (Williams et al., 2014), while simultaneously providing a spatial context for quantitative data, thereby enhancing analysis and interpretation in social science research (González Canché, 2025). GIS is a computer-based system for acquiring, recording, analyzing, displaying, and sharing geographical information, and was used as a tool for mapping the geographical distribution of ERC grants and analyzing gender equality among researchers.

Following the geographical analysis, which highlighted a gender gap in ERC funding between female researchers and male ones, the study examined the possible causes of this gap (second phase in Section 4), linking them to economic and social factors at the country level.

3 Geographical mapping

The analysis used the ERC dataset for 2019-2023, covering 26 nations (EU, Israel, and Switzerland), and 331 universities and research institutes. The dataset was expanded with gender data for PIs through manual Google searches. Microsoft Excel was used to expand the database and calculate funding distribution by gender. QGIS software was used to analyze spatial data and generate maps. Excel data was merged into QGIS to create maps showing ERC funding distribution by researcher gender and country. Maps were customized with colours and numerical labels, with non-eligible nations in grey (no labels) and eligible nations in green, blue, or pink (with labels). Figure 1 shows the number of ERC-funded projects per country, with darker shading representing a higher number of projects. Researcher gender is not considered in this map. Germany, France, the Netherlands, and Italy have the highest number of funded projects.

Figure 1 - No. of projects per country funded by ERC.

The distribution of ERC funded project by gender is represented in Figures 2 and 3.

Figure 2 - No. of male PIs per country.

Figure 3 - No. of female PIs per country.

Considering only the ERC projects led by female PIs, Figure 4 shows the overall geographical distribution in percentages, while the following Figures show the distribution of projects by funding schemes: StG (Figure 5), CoG (Figure 6), AdG (Figure 7), and PoC (Figure 8).

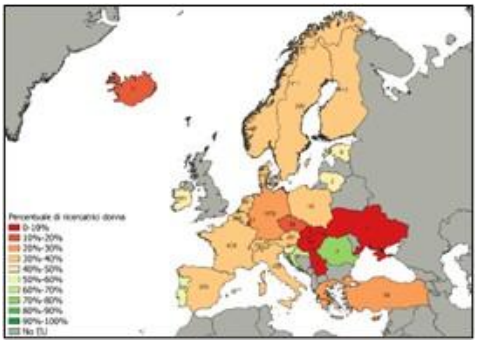

Figure 4 - Projects Pct. by country led by female PIs

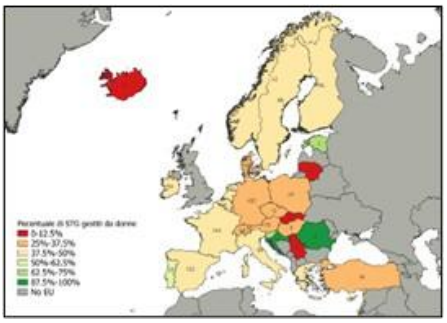

Figure 5
StG Pct. by country led by female PIs

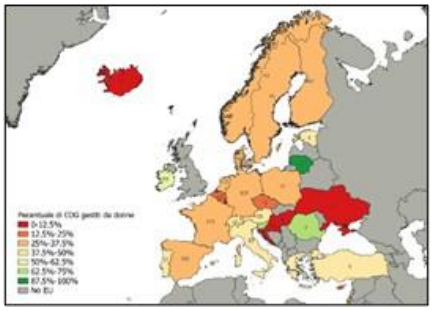

Figure 6
CoG Pct. by country led by female PIs

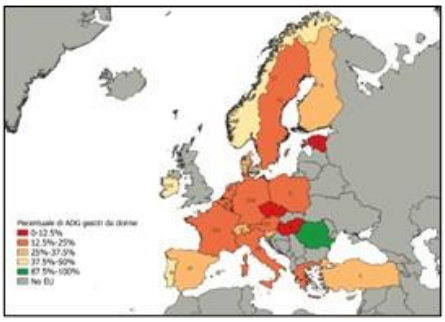

Figure 7
AdG Pct. by country led by female PIs

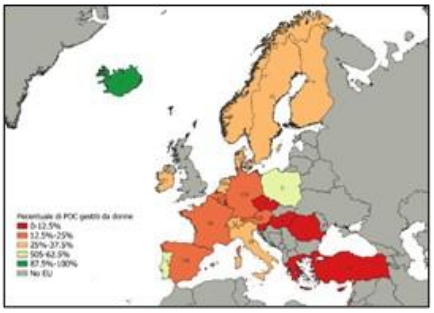

Figure 8
PoC Pct. by country led by female PIs

Comparing figures 1, 2, and 3, a gender gap exists in ERC funding. As shown in figures 4 to 8, the under-representation of female PIs is evident in funding schemes for researchers at a later stage in their careers, designed to finance innovations close to the market. In higher funding schemes, the percentage of projects led by women is notably low in Germany, Spain, the Netherlands, Italy, the UK, and France, indicating the under-representation of women in senior academic and entrepreneurial roles.

4 Econometric analysis: theoretical background, hypotheses and data

Prior studies (Lincoln et al., 2012; Larivière et al., 2013; Freund et al., 2016; Aguinis et al., 2018; Holman et al., 2018; Ma et al., 2019; Huang et al., 2020) indicate that women are underrepresented in academia, research, and innovation, particularly in scientific fields, across areas like publications, grants, awards, pay, senior roles, research careers, senior authorship, prestigious journals, and citations. Factors contributing to this include family responsibilities, lifestyle choices, career preferences, stereotypes, implicit bias, and discriminatory work environments (Blickenstaff, 2005; Ceci & Williams, 2011; Shaw & Stanton, 2012; Ceci et al., 2014; Reuben et al., 2014; Leslie et al., 2015; Ngila et al., 2017; Wang & Degol, 2017; Holman et al., 2018; Charlesworth & Banaji, 2019; Holmes et al., 2020). While existing literature often compares research output (Astegiano et al., 2019; Chan & Torgler, 2020), this study examined the issue through social and economic dimensions of countries hosting ERC grant winners.

To understand why fewer women than men are successful in obtaining ERC funding, an econometric analysis was conducted on the countries selected by grant winners as their research location (Host Institution). For each country, the ERC database (from 2019 to 2023) was used to find the number of female researchers receiving ERC grants, and the potential socioeconomic factors influencing why certain countries are more frequently chosen as HIs for ERC-funded projects by female PIs were explored. It was used a multiple linear regression, called Ordinary Least Squares (OLS) model, that is a common method for this type of analysis because it helps to understand and predict how changes in one variable (like the number of female PIs for a country) are consistently linked to changes in other factors. In this study, the number of female PIs is the main variable being explained. The socioeconomic factors used to explain this variable are measured by the GGGI, which looks at four important areas: economic participation and opportunity (EPaO), education attainment (EA), health and survival (HeS), and political empowerment (PE). These areas were chosen because they cover many aspects of a country's social and economic situation where gender inequalities have historically been a problem (Oswald, 2023). By looking at the gender gaps in these areas, one can get a good overall picture of a country's progress towards gender equality and see where more work is needed.

The relationship between the allocation of ERC funds between female researchers and male ones, and the state of gender equality in countries measured by the GGGI, is possible because several different factors come into play:

- a "gender equality paradox" is observed in research careers: fewer women pursue research compared to less egalitarian countries. This seemingly counterintuitive trend is attributed to several factors: firstly, despite increased opportunities, women often face greater challenges balancing work and family responsibilities, leading them to favour more flexible, less demanding, and traditional jobs that don't align with the full-time commitment required for a research career (Folbre, 2017); secondly, in highly egalitarian countries with abundant job opportunities, individuals are freer to follow their inclinations, and this can accentuate gender differences in career choices, influenced by subtle but persistent cultural stereotypes (Stoet and Geary, 2018); finally, the culture within certain fields of work may be perceived as masculine or potentially unwelcoming to women, and, even without overt hostility, existing cultural

norms and expectations can discourage women from entering or remaining in these sectors (Breda et al., 2020).
    - *Therefore, hypothesis 1 about EPaO concerns the presence of a negative relationship between the economic equity of gender and the number of female PIs in a country;*
- research studies indicate that education is beneficial to a country, regardless of gender. Specifically, countries investing in education experience improvements in research and innovation (Sapir, 2003; Camdessus, 2004).
    - *Therefore, hypothesis 2 about EA concerns the absence of a relationship between the educational gender equity in a country and its number of female PIs;*
- research studies show the global efforts to combat poor health conditions and life expectancy, whether for men or women (Acemoglu and Johnson, 2006).
    - *Therefore, hypothesis 3 about HeS concerns the absence of a relationship between the health and survival gender equity in a country and its number of female researchers;*
- scientific literature agrees that greater female political representation positively impacts countries, leading to increased well-being and faster economic growth, because women possess higher ethical standards (Jayasuriya and Burke, 2013; Xu, 2015). Female legislators, officials, and managers are seen as a positive force because women tend to be more honest and interested in the well-being of the relevant community (Powley, 2007; Reding, 2010).
    - *Therefore, hypothesis 4 about PE concerns the presence of a positive relationship between the political equity of gender and the number of female PIs in a country;*

Data for each area of the GGGIs from 2019 to 2023 were taken from the World Economic Forum's website. The yearly values were averaged. Croatia isn't included in the analysis because its data wasn't available for all the considered years. The index scores range from 0 to 1, with 1 meaning complete gender equality. The average gender gaps were been calculated and interpreted as follows:

- EPaO considers factors like labour force participation, equal pay for similar work, estimated income, and the representation of women in leadership and professional roles. The scores range from 0 to 1, with 1 indicating complete gender parity;
- EA is based on literacy rates and enrolment in primary, secondary, and tertiary education. A score between 0 and 1 indicates the level of gender parity, with 1 meaning 100% parity;
- HeS concerns sex ratio at birth and healthy life expectancy. The scores for each country range from 0 to 1, with 1 indicating complete gender parity.
- PE includes the number of female head of state, women in parliament and ministerial roles. Each country gets a score between 0 and 1, where 1 means there's complete gender equality.

Before building the regression model, the study analyzed the basic characteristics of data by calculating descriptive statistics (Table 1) and correlation coefficients (Table 2), by using the Gretl (Gnu Regression, Econometrics and Time-series Library) tool for data processing and econometric analysis.

Table 1 - Descriptive statistics.

VARIABLE	MEAN	MEDIAN	SD	MIN	MAX
Tot. Female PIs	113.070	33.000	169.240	1.000	767.000
GGGI	0.758	0.761	0.0573	0.639	0.904
EPaO	0.712	0.712	0.062	0.493	0.820
EA	0.996	0.998	0.005	0.975	1.000
HeS	0.968	0.969	0.014	0.901	0.980
PE	0.354	0.372	0.186	0.088	0.842

Table 2 - Correlation matrix.

VARIABLE	1	2	3	4	5	6
1 Tot. Female PIs	1.000					
2 GGGI	0.182	1.000				
3 EPaO	-0.116	0.795	1.000			
4 EA	-0.070	0.218	0.512	1.000		
5 HeS	-0.083	-0.191	-0.057	-0.029	1.000	
6 PE	0.288	0.965	0.614	0.069	-0.228	1.000

The correlation matrix (Table 2) shows that there are a number of relationships between variables. There are more statistically significant correlations, but they need to be investigated to verify their veracity and understand their nature.

To examine the factors influencing female participation in ERC-funded research, we estimate an Ordinary Least Squares (OLS) regression model of the following form:

$FPI_i = \beta_0 + \beta_1 EPaO_i + \beta_2 EA_i + \beta_3 HeS_i + \beta_4 PE_i + \varepsilon_i$

Where:

FPI = Female Participation Index (dependent variable), measuring the number of women among ERC grant recipients in country *i*

EPaO = Indicator of Labour-force participation rate, Wage equality for similar work, Estimated earned income, Legislators, senior officials and managers, Professional and technical workers

EA = Indicator of Literacy rate, Enrolment in primary, secondary and tertiary education

HeS = Indicator of Sex ratio at birth, Healthy life expectancy

PE = Indicator of Women in parliament, Women in ministerial positions, Years with female/male head of state (last 50)

εi is the error term capturing unobserved influences

The results indicate the existence of a relationship between the economic and political gender gaps and the female participation, as the number of women researchers recipient of ERC funds, with two out of the four independent variables significantly influencing the dependent variable, as shown by their statistically significant coefficients in Table 3.

Table 3 - Regression results.

VARIABLE	COEFFICIENT	SE	P-VALUE	
Constant	4.391	5.513	0.433	
GGGI	−16.002	6.378	0.019	**
EPaO	4.440	2.023	0.0381	**
EA	3.86	4.180	0.364	
HeS	0.159	0.792	0.841	
PE	3.627	1.525	0.025	**
R-squared	0.170			
Log likelihood	15.242			
P-value (F)	0.069			

Note: * P<0.05; ** P<0.01, and *** P<0.001

The study found support for hypotheses 1 and 4. Specifically, there is a statistically significant negative correlation (P<0.01) between the number of female PIs and the state of economic gender equality in a country. In contrast, there is a statistically significant positive correlation (P<0.01) between the number of female IPs and the state of political gender equality in a country. Hypotheses 2 and 3, concerning education level and health/survival parity, are not supported and show no statistically significant correlation.

The analyzed socioeconomic factors explain approximately 25% of the variation in ERC fund allocation between female researchers and male ones in a country (R-squared = 0.254). There is a widespread consensus that a similar level of R-squared is acceptable in the social sciences, as a peculiarity of this field of study. Several scholars have contributed to explain that a value between 0.1 and 0.5 can be considered acceptable, because the independent variables in the social sciences often represent only a small part of the total influences on an outcome, due to the wide range of factors that cannot be measured or are not included in the model. It is therefore a consequence of the complex nature of the phenomena studied and of the objective of the research, which often focuses more on the statistical significance and interpretation of the effects of individual predictors rather than on the overall predictive capacity of the model (Abelson, 1985; Lewis-Beck & Skalaban, 1990; Ozili, 2023).

5 Discussion and conclusion

This work examines gender equality, specifically focusing on gender discrimination against female researchers within European universities in research, innovation, and academic entrepreneurship. By analyzing the allocation of ERC funding from 2019-2023 using the ERC database and tools like QGIS, the study created maps and graphical representations to explore spatial relationships. The findings show that women represent a lower proportion of researchers overall, with a predominance of male researchers in higher funding schemes, designed for financing innovations close to the market. The study used econometrics to understand why there's a gender gap in female PIs. It looked at how the number of female researchers recipient of ERC funds changes

compared to male researchers and what socioeconomic factors influence the ERC fund allocation between countries. The findings show that countries with a greater female economic participation tend to have fewer female PIs; instead, countries with a greater female political participation tend to be more chosen as HIs by female researchers receiving ERC funds. Consequently, structural changes and specific protections for women should increase their representation in research. The European Union is already working to reduce the gender gap through policies like the Gender Equality Strategy 2020-2025, which addresses various disparities. Funding agencies could implement more specific gender targets, incentives, support measures, awareness campaigns, and consider the "gender dimension" in project evaluation. Universities and research organizations should foster a cultural shift towards gender equality in science and invest in research to understand and address the root causes of the gender gap. Future research could explore additional factors influencing ERC funding (like research categories, cultural, or psychological barriers) and what drives or hinders access to funding. Indeed, it is important to stress that the debate on the "gender equality paradox" is still open and complex, as an argument which highlights that gender equality is not only a question of formal equal opportunities, but also how social norms, cultural expectations and individual choices influence life and career paths.

The Role of DAOs in Shaping Knowledge Management: Opportunities and Risks

Michele Modina, Ilaria Nigro
University of Molise, Campobasso, Italy

Abstract

Knowledge is widely recognized as a core strategic resource in today's knowledge-driven economy. Consequently, Knowledge Management (KM) processes have become central to organizational strategies (Yee et al., 2019; Krause et al., 2019). The spread of new technologies is driving structural changes and innovative dynamics in the business landscape. Decentralized Autonomous Organizations (DAOs) redefine traditional structures using blockchain technology (Wright, 2021). This decentralized structure provides an open, transparent and democratic platform, allowing organizations to harness collective intelligence (Kahan and Rock, 2008; Gola et al., 2023) and improve knowledge management, which all participants can access, contribute to and share information in real time. (Bhatt, 2001; Liu et al., 2022; Phillips, 2024).

While literature covers the importance of knowledge management in organizations (Jelenic, 2011; Hebibi et al., 2019; Koivisto and Taipalus, 2023) as well as DAOs and their decentralized governance structures (Piselli, 2019; Santana and Albareda, 2022; Guillaume et al., 2022), there is a gap in addressing how these two domains intersect. Currently, how a decentralized structure impacts knowledge management remains largely unexplored. This work will bridge the gap between KM practices and DAOs, highlighting this delicate balance between opportunities and challenges.

Through qualitative analysis supported by a comprehensive review of international literature and legal references, this article investigates the impact of decentralization via smart contracts and the transparency enabled by blockchain technology. On one hand, DAOs provide an environment conducive to the democratic sharing of knowledge, encourage direct participation, and reduce information asymmetries. On the other hand, the fragmentation of knowledge, loss of tacit knowledge, and absence of a clear regulatory framework present significant challenges to the sustainability of KM processes.

Keywords: Blockchain, Decentralized Autonomous Organizations (DAOs), Knowledge management, Corporate Governance, Legal Frameworks.

Paper type: Academic Research Paper

1 Introduction

The rise of Decentralized Autonomous Organizations (DAOs) represents a significant evolution in organizational management. Their structure offers a decentralized model by leveraging blockchain technology, in which governance is shared among the participants and decisions are made collectively, efficiently, and transparently (The Impact of DAOs, 2024).

Empowered by blockchain, DAOs are reshaping traditional organizational governance (Hashemi-Khiabani and Polónia, 2023). Their decentralized structure aims to minimize the need to rely on a central authority, promoting more distributed and fairer management models (Lustenberger et al., 2023). This represents an innovative departure from traditional organizational models (Morrison et al., 2020; O. Borgogno, 2022).

DAOs' governance combines machine-driven activities, codified and automated through smart contracts, with mechanisms that allow participants direct involvement in organizational decision-making (Q. Dupont 2018).

This decentralized structure can significantly impact knowledge management (KM), as it has the power to transform the way information is shared and transmitted within organizations.

New technologies like blockchain are reshaping the way traditional organizations manage knowledge. Through DAOs, individuals worldwide can collaborate on real-time projects and create value, regardless of their geographical location or organizational structure (De Filippi, 2017; Wang et al., 2019).

Therefore, thanks to the blockchain technology that underlies these new organizations, new opportunities arise, including the traceability of decisions, the sharing of information through distributed governance and the immutability of recorded data (Hashemi-Khiabani and Polónia, 2023).

The need to develop this topic arises from the awareness that in these new decentralized organizations, knowledge is no longer the exclusive property of individual entities or a small group but instead becomes a dynamic and shared resource among all. Since DAOs alter the way traditional organizations are managed, it follows that traditional mechanisms also need to be revisited.

This study makes a significant contribution to the existing literature by proposing innovative ideas for Knowledge Management researchers. It analyzes the interaction between the emergence of decentralization

and the gradual reduction of human intervention, highlighting how emerging technologies are transforming knowledge management processes and how decentralized governance tools can either enhance or hinder the efficiency of KM practices.

From this perspective, to achieve these objectives, research will focus on the following questions: i) how DAOs influence knowledge management practices within organizations by utilizing blockchain technology; ii) how the uncertain legal frameworks of DAOs are undermining knowledge management, particularly in the context of liability.

This author uses a qualitative approach by reviewing the existing literature on DAOs, KM, and corporate law, both domestic and international, supported by doctrinal analysis of legal frameworks in Italy (Sbarbaro, 2024; Ortolani, 2019; Lener and Furnari, 2021).

This work is structured as follows: in the next section (paragraph 2), a review of the literature on the topics of DAO and Knowledge Management (KM), highlighting the characteristics of each. Paragraph 3 is divided into two sub-paragraphs: it highlights the opportunities of DAOs per KM, explored through the themes of decentralization, smart contracts and blockchain technology as tools for knowledge management, there will be a discussion on the risks and challenges that DAOs may present for KM, including knowledge fragmentation, governance issues and regulatory uncertainty. Paragraph 4 will indicate future directions for researchers and final discussions.

2 Literature review

How a decentralized structure impacts knowledge management remains largely and poorly unexplored.

Literature has, so far, covered the importance of knowledge management in organizations (Jelenic, 2011; Hebibi et al., 2019; Koivisto and Taipalus, 2023) as well as DAOs and their decentralized governance structures (Piselli, 2019; Guillaume et al. 2022; Cardoso, 2023), there is a gap in addressing how these two domains intersect. This theoretical gap may represent a research opportunity, given the need to understand the extent to which technological progress and the evolution of traditional organizational structures can influence internal operational processes. Exploring the convergence between DAO and KM is not only relevant but also essential to anticipate the organizational models of the future.

Traditionally, knowledge management (KM) models are developed within centralized and hierarchical structures typical of traditional organizations, where decision-making authority and the flow of information are concentrated at the upper levels and in the hands of the board of directors (Zaczyk, 2023). The DAOs, on the other hand, radically transform the very concept of traditional organization (Santana & Albareda, 2022).

2.1 Decentralized Autonomous Organizations

Decentralized Autonomous Organizations (DAOs) are defined as: "new organizations that rely on blockchain technology and smart contracts, which are not run on any central server but rather are executed in a distributed manner by an entire network" (De Filippi, A. Wright, 2019; R. Piselli, 2019), identifying a decentralized collaborative organization where "there are smart contracts as agents running on blockchains that execute a range of prespecified or preapproved tasks based on events and changing conditions" (V. Butarin, 2013). There is no universal definition of DAOs (Rikken et al.,2023; Baninemeh et al., 2023), but they can be described as decentralized organizational structures built on a blockchain platform and governed by self-executing codes recorded on the network, known as smart contracts (M. Phillips, 2024), which represent the operational agreement between members and ensure transparency and decentralization in the decision-making process (O. Borgogno, 2022; C. Iorio, 2022). Four elements identify DAOs: community governance, decentralization, automation and transparency (Schneider et al., 2022).

The algorithms on which DAO governance is based, and upon which they depend almost entirely, offer a greater degree of flexibility and adaptability, both in terms of decentralization and automation (van Vulpen et al., 2022). This, in turn, fosters the adoption of a so-called liquid democracy, where the decision-making power of voters varies based on their level of participation (Fan et al., 2019).

This structure incorporates a governance system combining on-chain (automated consensus) and off-chain (voting rights) mechanisms, facilitates collective decision-making and fosters distributed trust among network members (Dupont, 2018; Santana and Albareda, 2022). It is this collective decision that shapes and guides the organization in its decision-making (Wang, 2025). So, this organizational model is characterized by being driven by an online community that operates in a self-managed way for a common purpose (Augustin et al., 2023).

Decentralization is a distinctive feature of DAOs, as they operate on blockchain technology, eliminating the need for supervision by a third party or a central authority (Rikken et al., 2023). To rephrase, decentralization enables decision-making power to be distributed among all DAO members, instead of being concentrated solely

in the hands of a central authority (Y. El Faqir et. al, 2020). This fundamental characteristic distinguishes DAOs from traditional organizational models, in which governance is typically managed by a central authority or a committee of administrators (Santana, Albareda, 2022). Designed to resist centralization, DAOs promote a more equitable and distributed management model (O. Borgogno, 2022).

The use of smart contracts makes it possible to automate the organization, executing rules and transactions without human intervention. (Saurabh, 2024; Wang, 2025).

Transparency is ensured by recording management decisions and financial operations on a blockchain network, allowing every member of the organization to access all activities. (Wang, 2025).

Therefore, DAOs are well-suited structures for enhancing and promoting collaboration, as well as making information more accessible to everyone in the organizations by breaking down traditional barriers due to their decentralized nature. (Butarin, 2013; Hsieh et al., 2018; Hughes et al., 2019; Barnett, 2023; Romex, 2023).

2.2 Knowledge management

Knowledge management is defined by Andreeva and Kianto (2012) as "the set of management activities that enable the firm to deliver value from its knowledge assets". It holds a fundamental importance for the productivity and performance of business organizations (Frozza et al., 2023).

Literature shows that knowledge management is a key element in the long-term achievement of organizational success (Drucker, 1999; Nonaka and Takeuchi, 1995; Asrar-ul-Haq and Sanwar, 2016).

It is also of fundamental importance for the strengthening of business dynamics, favoring the adoption of competitive and lasting practices within organizations (von Krogh, 1998; Koivisto and Taipalus, 2023).

For this reason, in today's competitive landscape, managing and sharing knowledge are among the most strategic resources for an organization. (Asrar-ul-Haq and Sanwar, 2016; Pinto, 2020; Ruzic and Benazic, 2023). In fact, a well-executed knowledge management strategy can significantly contribute to the realization and enhancement of investment capital efficiency (Susanto et al., 2021; Rawan and Omer, 2023).

Knowledge management includes operational skills such as know-how, production technologies, marketing strategies and managerial activities (Maroli, 2019). Knowledge management involves six essential processes: recognition, creation, acquisition, processing, sharing, and application of knowledge (Rawan, Omer, 2023).

A proper development of knowledge is essential for organizations, because it promotes the application of values such as impartiality, clarity, sense of responsibility and transparency among stakeholders (Maroli, 2019).

To fully leverage the knowledge they have, organizations must manage it effectively (Andreeva and Kianto, 2012; Choi and Lee, 2010), since scholars have shown that KM has a significant impact on company performance (Andreeva and Kianto, 2012).

Indeed, the variations in the performance of the organization result from the different levels of knowledge and different skills in exploiting and developing this knowledge. (Grant and Spender, 1996; Andreeva and Kianto, 2012). For this reason, how knowledge resources are used and coordinated within organizations is of primary importance to them. (Andreeva and Kianto, 2012).

3 Opportunities and Risks

In this context, the present work explores how knowledge management (KM) is restructured and adapted within a decentralized organizational reality such as that of DAOs. However, the inherently decentralized, transparent and automated nature of DAOs offers new perspectives and potentially new criticalities for knowledge creation, sharing and preservation.

3.1 Opportunities

Regarding the opportunities offered by DAOs, their impact on KM can be observed across four key areas: driving towards more democratic decision-making, promoting transparency, building trust among participants and improving information security through smart contracts. These are the areas in which KM generally encounters obstacles (Akhavan et al., 2018).

As regards the first aspect, DAOs represent an alternative to traditional structures for organizing the activities of a community, usually composed of individuals (Cardoso, 2023; Monteiro et al., 2024).

Governance is entrusted to automating decision-making processes using smart contracts executed on a blockchain network, allowing a peer-to-peer interaction, in which members collaborate directly, without intermediaries (Monteiro et al., 2024). They embody an organizational model that subverts the hierarchical models typical of traditional business organizations, offering instead an open and decentralized structure (Zalan, 2018; Mitchell et al., 2022; Cardoso, 2023). Overcoming traditional corporate governance issues, such as opacity

and power centralization, this model encourages transparency and compliance within the organization (Hashemi-Khiabani and Polónia, 2023; Saurabh et al., 2024). The absence of a rigid hierarchical structure could allow the creation of a contest more inclusive and oriented to the sharing of knowledge, encouraging a wider dissemination of knowledge and reducing knowledge monopolies (Hashemi-Khiabani and Polónia, 2023). Hence, DAOs encourage a more democratic and participatory approach, distributing decision-making power among all stakeholders involved, which can lead to more equitable and transparent knowledge management practices (Li and Chen, 2024; Han et al., 2025). This feature allows automatic distribution of information among members, satisfying the need for knowledge management to be incorporated into operational processes (Hughes et al., 2019; Frozza et al., 2023).

Furthermore, within DAOs, individuals participate directly in the decision-making process, increasing the perceived legitimacy of decisions, since the possession of tokens, which confers voting rights, is also a form of incentive or reward (Chen et al., 2025). This can also be applied in the context of KM, allowing a reward system for sharing and participating in knowledge.

This outcome is made possible using blockchain technology, the core of the DAO, as it permits the transparent and permanent recording of all transactions and decisions (Hashemi-Khiabani and Polónia, 2023; Chambefort and Chaudey, 2024; Piselli, 2019; Wright and De Filippi, 2015). Transparency is essential to strengthening management accountability and coordinating operational procedures with compliance standards since blockchain technology allows stakeholders to independently access and verify information (Kakavand, De Sevres,2017). Overall, the transparency that DAOs offer can eliminate so-called "information asymmetries" and minimize the need for intermediaries or central authorities (Chambefort and Chaudey, 2024). Furthermore, in addition to fostering trust among stakeholders, this transparency could improve efficiency in both decision-making and operational processes (Chambefort and Chaudey, 2024).

Secondly, by harnessing the inherent features of blockchain technology, DAOs can create environments in which trust is based on the transparency and reliability of smart contracts (Bellavitis et al., 2023; Merk, 2024; Saurabh et al., 2024).

Smart contracts automate and execute agreements in a binding manner, reducing the margin of error and human manipulation, thus consolidating a reliable organizational context (Saurabh et al., 2024). Through these contracts, the stakeholders who hold tokens participate in a collective governance mechanism, where no individual can independently and unilaterally modify the decision parameters (Park et al., 2023).

Therefore, concerning the third element, the integrity of the data is reliably maintained, as the decentralized structure and cryptographic security system of blockchain networks ensures that data remains protected and accessible only through verified users (Hashemi-Khiabani and Polónia, 2023;).

This type of functionality optimizes the organization's digital infrastructures, allowing a better and dynamic management of information assets (Currado et al., 2019).

3.2 Risk

Despite these advantages, DAOs face significant challenges and risks that could undermine the effectiveness of KM practices.

One of the most critical aspects is the fragmentation of information flows. The excessive transparency and total openness of communication channels, if not well structured, can generate an information overload, making it difficult for members to distinguish between relevant and marginal information (Frozza et al., 2023).

The automation of processes through smart contracts tends to privilege the explicit codification of knowledge, neglecting the tacit one, which is the contextual, operational and relational knowledge that can hardly be digitized (Dunford, 2000; Millar et al., 2016). The loss of this knowledge poses a direct threat to innovation and business continuity in the organization (Millar, et al., 2016).

Although transparency enhances trust and accountability, it may also compromise the confidentiality of sensitive data, especially in cross-border contexts where legal protections vary (Hashemi-Khiabani and Polónia, 2023). The transnational dimension of decentralized organizations is a further challenge, as cultural differences and intellectual property issues need to be managed to ensure effective knowledge management (Millar, et al., 2016).

Moreover, the fact that Decentralized Autonomous Organizations face numerous governance-related challenges creates a certain level of uncertainty regarding the effective integration of Knowledge Management (mechanisms. A relevant example is the reward systems based on token ownership, which may encourage decisions driven by personal interests rather than genuine, shared goals (Han et al, 2025).

At the same time, the decentralized nature of DAOs and thus the absence of a central authority can negatively affect the management and effective distribution of information within the organization (Dunford,

2000; Dai et al., 2020). Aligning the interests and contributions of individual stakeholders can be complex, creating, however, the risk of generating inefficiencies in knowledge sharing processes and decisions (Hashemi-Khiabani and Polónia, 2023).

The decentralized nature and the lack of a centralized authority make it difficult to attribute legal responsibility for actions taken within the organization, raising liability issues, undermining trust and unresolved internal conflicts (Ortolani, 2019; Lener and Furnari, 2021; Stanescu et al., 2023; Reynolds, 2023). The lack of a unified regulatory framework and uncertain liability profiles hinder KM effectiveness, complicating the traceability, attribution, and resolution of decisions. The internal governance of DAOs, based on "fluid" and non-procedural forms of power, makes it difficult to identify clear power hierarchies and, consequently, to establish responsibility regimes (Piselli, 2019). Identifying a legal wrapper for such organizations would provide greater clarity regarding the applicable responsibility regime, which is essential for knowledge management. This ambiguity makes the management of legal knowledge and the adaptation to regulatory requirements complex. (Napieralska and Kepczynski, 2024).

Current laws do not consider DAOs' structural peculiarities. Only the United States, based on a historic judgment, has laid the foundations for a formal recognition of these organizations (Sarcuni v. bZx DAO; Ortolani, 2019).

In addition, the decentralized structure of DAOs, together with the anonymity of their members, contributes to further blurring the boundaries of legal liability, hampering effective organization and transmission of legal knowledge (Napieralska and Kepczynski, 2024). A study by Davier et al. (2023) highlights that the lack of clear legal guidelines complicates the management of legal knowledge and compliance. Legal ambiguity hampers the identification of responsibilities in cases of non-compliance and complicates staff training, as it is difficult to convey precise legal obligations, leading to inefficiencies in knowledge sharing and decision-making processes.

4 Conclusions

From the proposed hypotheses, it emerges that a portion of the literature has focused solely on the relationship between blockchain and knowledge management, highlighting the potential of this technology to enhance knowledge management practices. However, there is limited, if absent, attention to DAOs, despite their representing a direct evolution of blockchain applications in governance and collaboration. Hence, the existing understanding of the relationship between blockchain and knowledge management is a significant body of research, whose contribution can be useful in addressing and overcoming previously identified risks.

This gap can be attributed to the fact that DAOs, while offering new paradigms for the management and distribution of knowledge, are still emerging phenomena, often poorly understood and not yet fully integrated into traditional theoretical frameworks of knowledge management.

In this context, the findings show that while these organisations offer significant advantages in terms of knowledge management, their strengths can also lead to operational and managerial weaknesses. This significant gap limits the further exploration of theoretical hypotheses. This highlights the need to broaden research horizons to fully understand the implications of DAOs on organisational and cognitive processes. These authors suggest developing a conceptual model that synthesizes the main enabling and critical factors of knowledge management in DAO contexts, opening the way to new empirical validations. The model could be articulated in three interrelated dimensions (technological, organisational and socio-cultural), each of which represents a critical axis for understanding how DAOs transform knowledge creation, sharing and protection.

It will be essential to develop interdisciplinary studies combining law, organisational theory and information systems to develop regulatory frameworks supporting effective KM practices. Another promising area of research concerns the exploration of socio-cultural dynamics within DAO communities, as inclusion, trust, and digital literacy, which could offer a more articulated vision of how knowledge is generated, shared and preserved in decentralized ecosystems.

Blockchain Technology and Non-Fungible Tokens (NFTs) in Museums: Legal Considerations

Antoinette Strada, Chiara Vandoni, Guido Perboli
Polytechnic University of Turin, Turin, Italy

Abstract

New technologies, particularly blockchain and non-fungible tokens (NFTs), are profoundly transforming the cultural and artistic sectors. Museums are actively responding to this shift by adopting advanced digital tools that enable more engaging, personalized, and innovative visitor experiences. Through the integration of NFTs and immersive technologies, museums can extend the boundaries of cultural participation beyond the physical space, allowing users to interact remotely or gain access to exclusive content such as private exhibitions, supplementary materials, and virtual events. NFTs also allow museums to offer limited digital editions of artworks to collectors around the world, fostering new communities and business models based on digital ownership and participation.

These emerging opportunities demand a reevaluation of how artworks are protected, enhanced, and enjoyed in digital environments. However, for stakeholders to adopt these tools with confidence, several challenges must be addressed.

This study, grounded in the Italian legal framework, investigates key legal issues including copyright law, image rights of cultural assets, and the role of Online Dispute Resolution (ODR) mechanisms in resolving disputes that may arise in NFT transactions. Additionally, the study examines the fiscal implications linked to the creation and commercial use of NFTs by companies.

In a context marked by regulatory uncertainty and diverging legal theories, our research reviews prevailing interpretations and, pending legislative action, proposes a preliminary legal framework. This framework aims to ensure that the creation and transfer of NFTs via smart contracts can be carried out in a transparent, secure, and legally coherent manner, fostering greater trust in the digital transformation of the cultural heritage sector.

Keywords: Blockchain, Legal Framework, ODR, Smart Contract, Museums

Paper type: Academic Research

1 Introduction

New technologies such as blockchain and Non- Fungible Tokens (NFTs) are revolutionizing the cultural and artistic sectors.

NFTs are an ideal tool in the cultural and artistic sector (Damiani, E., 2022; Dignani, A., 2025) as they determine new ways of protecting, valorising and enjoying cultural heritage.

By selling NFTs with underlying artwork, museums can offer audiences remote and interactive experiences, or to digitally replicate or create virtual collections, and build loyalty. They also allow for automatic royalty payments in the event of resale and create sustained revenue streams.

Although NFTs offer significant potential, their adoption raises questions that produce conflicting legal theses.

Therefore, the objective of this research is to identify a legal framework that enables stakeholders to act with awareness and legal security.

To this end, this study examines, within the Italian legislation, the intersection between NFTs and museums, with attention to copyright and the right to the image of cultural assets. Finally, it considers the possibility of using the digital dispute resolution (ODR) and the fiscal implications associated with the sale of NFTs of a company by itself.

2 Value of smart contract on blockchain

2.1 Definition and structure

Article 8 ter, paragraph 2 of Italian Decreto Legislativo (DL) 135/2018 defines a smart contract as a computer program that operates on technologies based on distributed ledgers and whose execution automatically binds two or more parties based on effects predefined by them. This execution meets the requirement of written form provided that the interested parties are identified through a digital process that complies with the standards set by the “Agenzia per l’Italia Digitale”. Blockchain is one of the Distributed Ledger Technologies (DLT) on which a smart contract can operate.

One of the defining features of the smart contract is that it *self-executes* when predetermined conditions occur (Capone, A., 2023): if a predetermined condition occurs (if), the smart contract executes a certain part of the contract (then).

2.2 Is this a legal (juridical) contract?

Clearly, the smart contract, considered only from an IT perspective (smart contract *code*), is not a contract.

However, when it is used to govern legal relationships between parties, the concept of the smart legal contract emerges, giving rise to contrasting legal theories. In this context, a smart contract serves as a technological tool that verifies, enforces, or replaces traditional contracts using blockchain technology (Bassan, F. and Rabitti, M., 2023).

One theory considers it impossible to qualify the smart legal contract as a *juridical* contract (Rampone, F., 2019): it is a mere IT tool for the performance of a previously created traditional contract.

But there is an opposing theory that considers the smart legal contract a real juridical contract and, consequently, distinguishes it from the simple smart contract code (Finocchiaro, G., 2018): the parties use exclusively a smart contract to regulate their jural relation, applying the contractual legislation.

Between the two opposing theses, there are others with intermediate nuances: For instances, (Tommasini, M., 2022) suggests that a smart contract may serve both as a means of executing a previously agreed-upon legal will (instrumental or executive smart contract) and as the sole expression of the parties' mutual intent (constitutive smart contract).

We believe that the preferable solution is to consider the smart contract as the *form* of the juridical contract: in fact, the juridical contract (externally manifested by the parties through the form / smart legal contract) is that of sale, donation, etc. The contract is in fact, pursuant to art. 1321 of the Italian Civil Code (cc), the *agreement* of two or more parties to establish, regulate or extinguish a patrimonial jural relation between them and is made up of essential elements, including the form (art. 1325 cc). The latter represents the external way in which the agreement of the parties is manifested. The art. 1350 prescribes that certain acts listed therein and other acts specifically indicated by the law must be made (… in writing…), under void penalty, we can certainly deduce that, unless the law provides otherwise, the principle of freedom of form applies (Manente, M., 2019).

Furthermore, considering that contracts stipulated electronically or telematically are valid pursuant to Italian Decreto del Presidente della Repubblica 445/2000 and the Italian Digital Administration Code (CAD), we can deduce that the smart contract can serve as a form for different types of *juridical* contract (Tommasini, M., 2022).

Even in cases where written form is legally required, the smart contract can be considered valid since art. 8 ter paragraph 2 Italian Decreto Legge 135/2018 that provides the smart contract satisfies this requirement if signed on the blockchain through the process established by the Agenzia per l'Italia Digitale and following the guidelines of the Italian Ministry for Technological Innovation, therefore with the identification of the parties through electronic signature (Capone, A., 2023).

Therefore, supported by authoritative legal scholarship (Bomprezzi, C., 2019; Capone, A., 2023; Manente, M., 2019), we conclude that the *smart legal contract* should not be considered a juridical contract in itself, but rather the *form* through which a juridical contract is expressed.

2.2.1 Is its immutability a problem?

At this point, several challenges emerge that require careful analysis: chief among them are the automatic execution of the smart contract (its core feature) and the immutability ensured by the blockchain.

These characteristics may conflict with certain Italian legal concepts, such as *supervening impossibility*, which refers to the occurrence of an unforeseen event that makes it impossible for one party to perform and justifies a request for the equitable modification of contractual obligations. In this context, the rigidity of a smart contract could indeed be seen as a limitation.

However, one legal theory correctly believes that this problem can also be overcome. (Bellomia, V., 2020; Fauceglia, D., 2020; Tommasini, M., 2022) clarify that the outcomes associated with the modification or discharge of a contract can still be achieved through the structure of smart contracts. This is because smart contracts operate using conditional logic (*if...then* statements), enabling parties to embed predefined scenarios and their corresponding consequences at the time of contract formation.

In Italy the condition is contemplated by art. 1353 cc: the parties may subordinate the effectiveness or the discharge of the contract or of an agreement to a future and uncertain event.

It can be inferred that if the parties wish to resort to the smart contract, they must mandatorily (despite the letter of the code speaking of possibility) subordinate the effectiveness or the discharge of the contract or of an agreement to a specific future and uncertain event.

In alignment with our earlier thesis that the smart contract represents the *form* of the juridical contract, this theory reinforces the view that a smart contract must necessarily incorporate conditional elements to remain valid and functional within the Italian legal system. In this way, the much-debated immutability of blockchain technology becomes a benefit, especially when understood through the concept of *notarization*, which ensures tamper-proof and timestamped recording of the contract's content. (Galli, C., 2022).

(Tommasini, M., 2022) also talks about the possibility of introducing a self-destruct kill function.

(Bassan, F. and Rabitti, M., 2024) believes that any problem relating to the unchangeability of the smart contract can be solved by switching to the more recent *on-chain contract* (see next paragraph) by virtue of its greater plasticity.

2.2.2 What language does it use?

Another critical issue relates to the *language* used by smart contracts. Typically written in programming languages, smart contracts are not structured to express complex legal concepts.

Even when explanatory text in natural language is added alongside each line of code, remains the problem that the contracting party cannot be sure if the translation into natural language is correct (Bomprezzi, C., 2019).

To overcome this issue, (Bassan, F. and Rabitti, M., 2024) advocate for a transition from *smart legal contracts* to *on-chain contracts*. These contracts are written simultaneously in both natural and programming languages and executed on a third-generation public blockchain. (Bassan, F. and Rabitti, M., 2024), being able to leverage a more innovative technology, propose the transition from the smart legal contract to the contrat *on chain*, using a public third-generation blockchain technology (which can use natural language) as an infrastructure and a controlled-access logical platform as a superstructure.

They are supported by a logically structured platform with controlled access, ensuring clarity and correctness from both a human and machine perspective (see also D'Arpe, S., 2024). This model creates a user experience analogous to signing a traditional online contract and enables the *negotiation, formation, and performance* of the contract entirely on the blockchain.

However, public blockchains (*permissionless*) present challenges: they allow anonymous and unrestricted access, which conflicts with the legal requirement for proper party identification in contracts. The theory under discussion addresses this concern by using a controlled-access logical platform, which restricts access to authorized cryptographic addresses and requires non-anonymous wallets. This model enables compliance with anti-money laundering regulations while preserving the security advantages typical of private blockchains.

Until third-generation blockchain platforms become widely adopted, even the advocates of on-chain contracts acknowledge that alternative approaches can be used. One such approach involves combining a traditional contract with a smart legal contract and securing a certification of correspondence between the natural language version and the coded one—issued by a third party, such as the logical platform itself.

This certification could then be recorded on the blockchain, thus acquiring probative value under Italian law.

3 NFTs

3.1 Definition and value of NFTs

NFTs (Non-Fungible Tokens) are tokens, i.e. groups of data stored on blockchain, that certify the ownership of digital or physical objects through a unique identification code and the recorded identity of the issuer and owner. They are non-fungible, meaning they are unique, indivisible, and irreproducible.

Can NFTs certify not only ownership, but also the authorship and authenticity of the underlying object? According to (Galli, C., 2022; Damiani, E., 2022) NFTs act as cryptographic codes equivalent to the artist's signature and therefore certify authorship and authenticity. While, according to others the NFTs only attest to the act of registration on the blockchain by the first seller. Consequently, while NFTs may demonstrate provenance, ownership, and subsequent transfers, they do not inherently verify the authorship or authenticity of the original work. The metadata entered during the NFT's minting could be false or misleading (Dignani A., 2025; Tommasini, M., 2023).

To address this problem, it would be possible to upload onto the NFT both the certification of an expert (such as the director of the museum that has custody of the work), and the delegation agreement for the creation of the NFT. In this case, authenticity and authorship would also be proven. A simpler case is when the native digital work has been tokenized directly by the author, identified with certainty (Marchegiani, L., 2023).

It is also worth noting that an NFT, once minted on a blockchain, represents both the *corpus mechanicum* of the work (physical support of the artwork, therefore a tangible thing), and the ownership title of such *corpus mechanicum* : therefore it can be considered both as a property object and as a title of ownership of a thing (Frezza, G. and Virgadamo , P., 2023).

3.2 NFT on artwork and economic exploitation rights

The creation of an artwork is protected under the Italian Civil Code and Law 633/1941. Upon creation, the author acquires both moral rights and economic exploitation rights (Art. 6, Law 633/1941). Unlike moral rights, economic rights may be waived or transferred to third parties

According to Article 109 paragraph 1 of Law 633/1941, the transfer of a copy of a work does not imply the transfer of its economic exploitation rights unless explicitly agreed upon. Moreover, under Article 110, such a transfer must be documented in writing.

A recent legislative proposal (*Disegno di Legge* S. 1146, currently awaiting approval) seeks to extend copyright protection to works created with the support of artificial intelligence, provided that the output reflects the intellectual contribution of the human author (Art. 25, paragraph 1, lett. a).

Applying these rules to NFTs representing artwork, t becomes clear that an NFT cannot be equated with the work itself (Marchegiani, L., 2023): it consists of groups of data, among which there is also a unique identification code of the associated work.

Therefore, unless otherwise explicitly agreed, the purchaser of an NFT acquires only the associated metadata—not the underlying work itself. The economic exploitation rights of the work remain with the author. Furthermore, the author can embed clauses in the smart contract that enforce royalty payments on future resales, thereby preserving a share of proceeds from secondary transactions.

Prior to any transfer, it is also essential to examine the terms of service and contractual conditions stipulated by the platform used for issuing or trading the NFT.

3.3 NFT and image rights of cultural assets

According to the definition of cultural asset given by art. 2 paragraph 2 of Decreto Legislativo 42/2004 - Code of Cultural assets and Landscape (BCP code), a cultural asset is defined as a testimony of civilization with cultural value. This implies that a cultural asset is incorporeal in nature (Tommasini, M. 2023). Although it is embodied in a physical medium, its legal value transcends that physicality (De Angelis, D., 2024; Kurkani, K., 2023; Nardi, S., 2022; Calculli, G., 2024), as it carries a message capable of enduring across generations, much like a historical document (Italian Consiglio di Stato, AP, judgement 5/2023).

The image of cultural asset is legally protected: the judgment of the Corte d'Appello of Bologna 1792/2024 confirms that a right to the image of the cultural asset can certainly be configured since articles 107 and 108 of the BCP code, implementing art. 9 of the Italian Constitution.

For this reason, the protection of the right to the image is perpetual (De Angelis, D., 2024) and complements that of copyright, which has a defined duration in consideration of the different dimension of the two types of protection (Tribunale of Firenze, order 11.04.2022).

Art. 107 BCP code establishes the prohibition of the reproduction of cultural assets, unless this is granted; art. 108 specifies that, for the use of cultural assets, permission fees, reproduction fees and, possibly, a bail are due (not so if there is no business purpose but study, research, etc., paragraphs 3 and 3 *bis*) and art. 106 provides that the permission of individual use of cultural assets can be obtained for purposes compatible with their cultural destination, provided that the transfer guarantees the conservation and public enjoyment of the asset.

Thus, museums must evaluate whether a proposed use of a cultural asset might degrade its symbolic or intangible value (Piperata, G., 2023).

Ministerial Decree 108/2024, issued by the Ministry of Culture, establishes minimum fees and charges for the commercial reproduction of images of cultural assets.

Given the incorporeal nature of a cultural asset's image and the capabilities of technologies such as NFTs and smart contracts on the blockchain, once a museum has authorized the creation of an NFT, the asset can achieve broader dissemination. This fosters new business models, expands cultural access (Dignani, A., 2025), and mitigates risks of physical deterioration.

4 NFTs in the museum sector

If a museum decides to create an NFT of one of its artworks to sell or donate to visitors, the legal considerations discussed above must be taken into account.

Typically, a specialized company is commissioned to mint the NFT. Depending on the contractual arrangement, visitors may:

- Purchase the NFT directly from the company (establishing a legal relationship solely with it),
- Acquire it through a bundled offer from the museum (ticket + NFT),
- Receive it as a complimentary addition to their basic admission ticket.

For example, a museum might contract a company to produce a limited NFT series of an artwork from its permanent collection. The contract will govern the remuneration owed to the company, which could take the form of:

- A one-time fixed payment from the museum (if the museum distributes the NFTs directly),
- A percentage of net proceeds per NFT sold (if the company handles distribution to visitors).

In either scenario, all rights to the original and digital versions of the artwork remain with the museum, particularly if the artwork is part of the national heritage.

A typical user experience might involve the visitor entering the museum with a standard ticket, scanning a QR code displayed beside the artwork, agreeing to terms and conditions on their smartphone, and downloading the NFT to their wallet for personal use.

In another scenario, a museum might commission an NFT based on a work by an external artist featured in a temporary exhibition. In such cases, the artist's prior authorization is mandatory (Marchegiani, L., 2023), including any potential transfer of economic exploitation rights to the museum. The contract should stipulate the respective compensation for both the company and the artist. The visitor would then purchase a bundle and gain personal access to the NFT.

Here is a real-life case: NFT of Doni Tondo minted for the Uffizi Galleries

According to the contractual terms, the company retained the patent for the NFT creation technology, while the Uffizi Galleries retained full rights to both the original painting and its digital reproduction. The Galleries received 50% of the net proceeds from each NFT sale, and a certificate of authenticity signed by the director was issued with each token. An official press release confirmed that no rights were alienated in the transaction.

In all cases, however, the use of a cultural asset’s image is strictly subject to prior authorization from the competent authority, along with payment of the corresponding reproduction or licensing fees (Piperata, G., 2023).

5 The company that issues and directly sells the NFT

When a company negotiates directly with the author of a digitally native artwork, who transfers the economic exploitation rights, it must also consider the associated tax implications.

The sale of an NFT with underlying intellectual work represents an income of the seller: for the company it is business income -point 3 of the Circolare Italian Agenzia delle Entrate 2023/30/E (Circ.)-.

The company may establish royalties: once minted, the NFT can be sold on the primary market (initial sale by the creator) and subsequently on the secondary market (resale). Normally, each resale on the secondary market generates a royalty for the original creator (Circ. point 3.7.1.3).

We believe that the company can set royalty percentages on future resales even by giving away an NFT for free at a promotional level.

Because it is a company (and therefore a person who cannot be considered the author), the sell is subject to IVA, similar to VAT in the UK (therefore point 3.7.1.3 of the Circolare cannot be applied).

Anyone who holds NFTs must pay an annual impost, which may be a stamp duty (Circ. point 3.7.2.) or ad valorem of crypto-assets (Circ. point 3.7.3.), except for amounts lower than those established from time to time by fiscal legislation.

Finally, the estate duty and gift tax are applicable on transfers of assets and rights due to death, by donation or free of charge, also with reference to crypto-assets, the taxable base of which is determined by assuming the market value on the date of the succession or donation, detected by the exchange platform where the crypto-asset was originally purchased or by a similar platform where the same crypto-assets are negotiable (Circ. point 3.7.4).

6 ODR

Alternative Dispute Resolution (ADR) is a method of resolving disputes that is an alternative to the judicial process. It includes various legal institutions such as mediation and arbitration.

ADRs can also be implemented online: in this case they are called Online Dispute Resolution (ODR). They are distinguished into human-based ODR (online ADR), if the technology is only the means that allows the impartial

third party to normally carry out his role, and machine-based ODR (cyber ADR), when technology takes on an active role to enhance or replace man (Peruginelli, G., 2007), for example settling pecuniary disputes through the exchange of blind offers between the parties if they come closer to within a certain percentage.

Based on new blockchain and smart contract technologies, smart ODR has then appeared, which has the innovative feature of being equipped with self-enforcement: regardless of the parties, it ensures the automated execution of the outcome of the procedure after reaching the resolution of the dispute.

Smart ODR systems also allow the mediator to both estimate and increase the probability of reaching an agreement between the parties by indicating the best mediation strategy in reference to the specific case.

All these characteristics, including the consequent standardization of the procedure, distance ODR from the inspiring idea of the original ADR (Mingardo, L., 2020), but we still believe they can find profitable application in some matters, such as disputes regarding NFTs, where standardization could further favor the speed of the procedure and still guarantee a confidential, cost-effective, effective solution and, moreover, without the possibility of subsequent non-compliance.

We therefore believe it is useful to insert a clause in the smart legal contract that provides the smart ODR for any reason of dispute (due for example to the malfunctioning of the system.

7 Conclusions

Stakeholders operating in the NFT and digital artwork sector currently face substantial legal uncertainty due to conflicting theories and gaps in legislation. This study has aimed to clarify the legal status and practical implications of emerging technologies within the Italian legal framework.

In conclusion, we can say that in Italy in our opinion:

- The smart legal contract (even in its most recent version of contract on chain) represents the *form* of a juridical contract (therefore one of its essential elements).
- Parties using a smart legal contract must necessarily enter into a conditional contract.

In the absence of specific regulation, it is advisable to draft a traditional contract in parallel with the smart contract and obtain certification of correspondence (e.g., from the NFT trading platform) between the off-chain signed text and its encoded version.

The ideal solution, where technologically available, is to use third-generation blockchain systems that support natural language contracts.

- When NFTs are created and transferred via blockchain and smart contracts, they can certify provenance and subsequent transfers, but not authorship or authenticity, unless additional certification (e.g., from a museum director) is uploaded to the blockchain.
- The buyer of NFT does not buy the underlying artwork, even if it is digital. Unless explicitly agreed otherwise, the buyer may only make personal use of the NFT. The economic exploitation rights remain with the author or institution, who may embed royalty clauses to ensure compensation upon resale.
- Even when copyright has expired, a company wishing to create an NFT of a cultural asset must obtain official authorization and pay reproduction and permission fees.
- If the company negotiates directly with the author and acquires exploitation rights, it must comply with fiscal regulations outlined in Circolare Agenzia delle Entrate 2023/30/E.
- Regardless of whether a traditional or smart contract is used, it is highly beneficial to include a smart ODR clause to promote efficiency, enforceability, and cost control.

In our opinion, although through evolutionary interpretation it is often possible to apply existing rules to new technologies (Bellomia, V., 2020; Bomprezzi, C., 2019; Galli, C., 2022; Tommasini, M., 2022), legislative intervention is needed in case of gaps and to resolve conflicts between the various legal theories. Only in this way, all stakeholders will be able to act with clarity and confidence in these innovative technologies.

Sarajevo 1992-2025: The Contribution of Art between War and Peace, Analogue and Digital

Elisa Bonacini
University of Bari "Aldo Moro", Bari, Italy

Abstract

To celebrate the anniversary of the Dayton agreements after the Sarajevo war (1992-1995), a phygital exhibition *Sarajevo 1995-2025. From war to peace on the thirtieth anniversary of the Dayton Peace Agreement* is going to be launched between Bari and Sarajevo, inspired by the *Ars Aevi project* and celebrated through words and experiences of many protagonists, from local to Italian authorities, from children of yesterday to the adults of today.

Born as a political and peaceful artistic action in response to the war, conceived and realized by Enver 'Enjo' Hadžiomerspahić, the project started in 1992 from the Michelangelo Pistoletto's donation of his artwork *Porta allo Specchio*. Become one of the greatest contemporary art collections, *Ars Aevi* will find its definitive location in the new Museum of Contemporary Art designed by Renzo Piano in 2005, donated to Sarajevo and just presented according to its executive design. The collection can be known and enjoyed thanks to the website, the online catalogue and a virtual exhibition, a sort of demo preview of the new Sarajevo Museum.

The project of the *Sarajevo 1995-2025* exhibition, realized through the collaboration of the University of Bari "Aldo Moro", many Italian and Bosnian institutions and the partnership of the Ars Aevi Museum, aims to promote intercultural dialogue and peace, through an exhibition combining stories and contents, in a physical, digital, interactive and immersive way, by using different digital tools, such as an interactive 'augmented' catalogue and a VR exhibition on ArtSteps.

Keywords: Digital Art History, VR experiences, Phygital exhibitions, VR exhibitions, Virtual environments.

Paper type: Academic Research Paper

1 The Ars Aevi project as an inspiring ideal and value-based model for contemporary art and peace building processes

Before introducing the *Sarajevo 1995-2025. From war to peace on the thirtieth anniversary of the Dayton Peace Agreement* exhibition, a premise is required, necessary to describe what happened under the bombings, starting from 1992, and in the following decades. In the peacebuilding process, contemporary art was an essential protagonist: the *Sarajevo 1995-2025* exhibition got inspired from the *Ars Aevi project*, as an ideal and value-based source for the project itself which will be inaugurated in Bari in autumn 2025.

The anagram itself of the project, a logo embracing the name of Sarajevo like a *tai*, represents Ars Aevi's ethical-visual identity, in a perpetual and progressive balance between contrasting forces. *Art of an era crossing the limits of time*: this is the meaning of the Latin expression, chosen as a (partial) graphical anagram of Sarajevo, described on the website collecting the history of the collection, born as a political and peaceful act in response to the war (fig. 1).

In 1992, faced with the horrors of war and the siege of Sarajevo, culture and art were used as true instruments of resistance (Caira and Cavigioli 2021). Contemporary art was called to contribute in a peace-message building, in a collective and participatory way, to a visionary and long-term project launched by Enver 'Enjo' Hadžiomerspahić, former director of the Biennale Jugoslovenska Dokumenta in Sarajevo (1987-89), together with other Bosnian intellectuals and artists. Over the last thirty years since the beginning of the Bosnian war, this call to the arts shaped a very rich collection (over 160 works), the Ars Aevi Museum of Contemporary art, which is coming to a definition of its own physical and definitive museum space, after its "nomadic and itinerant dimension" (Azzerboni 2023).

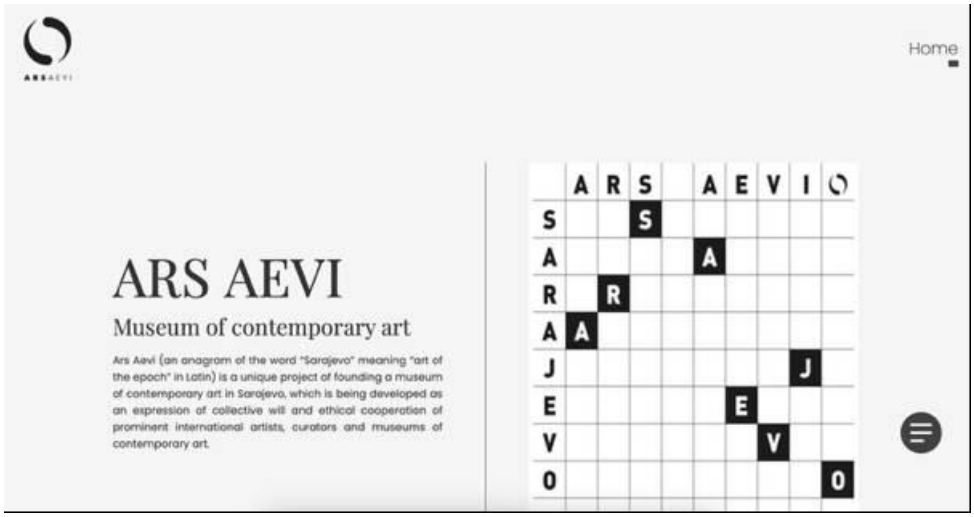

Figure 1: Homepage of the Ars Aevi website.

32 years later, 'Enjo' himself left testimony of his initiative, which he led until 2017 (replaced in 2018 as Ars Aevi Director by Senka Ibrišimbegović, University of Sarajevo, which is partner of our initiative), in a long interview to Franco Giuliano, reporter during the war for the *Gazzetta del Mezzogiorno* newspaper and creator of the *Sarajevo 1995-2025* exhibition. Hundreds of artists from all over the world transformed Sarajevo into a multicultural capital of art and the art collection itself into a universal message of the value of art from a moral and aesthetic point of view, as declared in the manifesto of Ars Aevi Museum on the website: *Art can overcome evil and destruction. Culture is the mother of tolerance. Intercultural dialogue enriches. The universal language of art unites*.

Just at the beginning of the siege of Sarajevo (June 1992), when it was *crazy* thinking about art under bombings, the idea of 'Enjo' was immediately embraced by the city of Sarajevo itself and by the Bosnia-Herzegovina State as a long-term project (under its first name *Sarajevo 2000*), immediately revealed as an innovative model and a unicum for participation and vertical cooperation between artists, museums, centres and foundations of contemporary art from all over the world (MIMEH 1999). The 45th Venice Biennale, in 1993, was the occasion to present its concept to the world. Thanks to Enrico Comi - the artistic director of the Sarajevo 2000 project by founding the "Spazio Umano/Human Space" Contemporary Art Centre in Milan -, Michelangelo Pistoletto's exhibition in 1994 was the first response to that call: his *Porta allo Specchio*, dating 1989 (fig. 2) started the collection (Hadžiomerspahić 2005; *Ars Aevi* 2009; Comi 2015, pp. 19-21; Carolo 2016; Webber 2018; Azzerboni 2023).

Thanks to many Italian institutions, the voice of art soon made itself heard with great power as a manifestation of resilience against that war and every war, as never before in our contemporary times. The answer of the most famous artists - from Kounellis to Kosuth, from Accardi to Abramovich, from Kapoor to Viola, just to name a few - was not long in coming and the curators of the institutions called to select the works became over the years co-founders of the project, which therefore had a unique museogenesis. From 1994 until 2012, the creation of this collection was the focus of specific exhibitions/donations, organized by museums, centres and foundations of contemporary art, such as those of Milan (Spazio Umano, 1994), Prato (Centro Pecci, 1996, to whose curator Bruno Corà we owe the invention of the anagram of the project, called *Ars Aevi 2000*), Ljubljana (Moderna Galerija, 1996-97), Venice (Biennale; Querini Stampalia and Bevilacqua La Masa foundations, 1997), Vienna (Museum moderner Kunst Stiftung Ludwig, 1998), Bolognano (Paradise Museum in the estate of Lucrezia de Domizio Durini, 2003), Istanbul (BM Contemporary Art Centre, 2007) and Podgorica (Centre for Contemporary Art of Montenegro, 2012), thus forming the various *nuclei* of the collection, to which is added the nucleus of Sarajevo itself, formed thanks to a series of personal exhibitions (1994-2006). In 2023, Ars Aevi Nucleus Kyiv have been created as an expression of solidarity with Ukraine, according to its mission in peacebuilding. After an initial exile condition, hosted by different exhibition venues and in turn a widespread instrument of cultural resistance, in 1999 'Enjo' decided to set up an exhibition at the Centar Skenderija in Sarajevo: a historic event for the art world, with the first 105 artworks (installations, paintings, sculptures, photographs). Due to the most innovative moral value in the world, this museological approach since 1999 have been recognized and supported by UNESCO and its Goodwill Ambassador, the architect Renzo Piano.

Since 2019, the collection is temporarily housed at the Viječnica, the seat of the Sarajevo Municipality, one of the symbols of a war (the National and University Library before the siege), deliberately not spared from incendiary bombs, cannon fire, grenades, rebuilt in 1996-2014.

The Ars Aevi collection, presented in an online catalogue on the website (the only place where the entire collection is described so far: http://www.arsaevi.ba), will find its definitive location in the new Museum, presented by Renzo Piano in 2005, updated in 2012, donated to the City of Sarajevo and financed in its executive design by the Italian Agency and by a crowdfunding launched in collaboration with UNESCO. Already in 2002, Renzo Piano donated a new pedestrian bridge, connecting the two banks of the Miljacka river to allow access to the area where the Museum will be built, where the white and blue flags of Daniel Buren's installation, *La Place des drapeaux* still stand. Here, on 20 August 2024, the first stone of the new Museum has been laid, realizing Piano's design idea (fig. 3).

Figure 2: The first artist for the Ars Aevi collection (from the Ars Aevi Picture book).

Figure 3: Rendering of the Museum of Contemporary Art ARS AEVI project by Studio Nonstop (Sarajevo), designed by Renzo Piano Building Workshop (©Studiononstop).

2 The Sarajevo 1995-2025. From war to peace on the thirtieth anniversary of the Dayton Peace Agreement phygital exhibition

The web offers the *Ars Aevi* collection the opportunity to be known and enjoyed in its entirety, thanks to the website, the catalogue with the artworks' descriptions and the virtual exhibition that 3D reproduces the spaces designed by Renzo Piano, a sort of interactive demo of the new Sarajevo Museum (figs. 4-5), surrounded by *La Place des drapeaux* Buren's installation, symbolically marking the Terrain of the Future Museum of Contemporary Art, since 1996.

Figure 4: The Ars Aevi virtual exhibition.

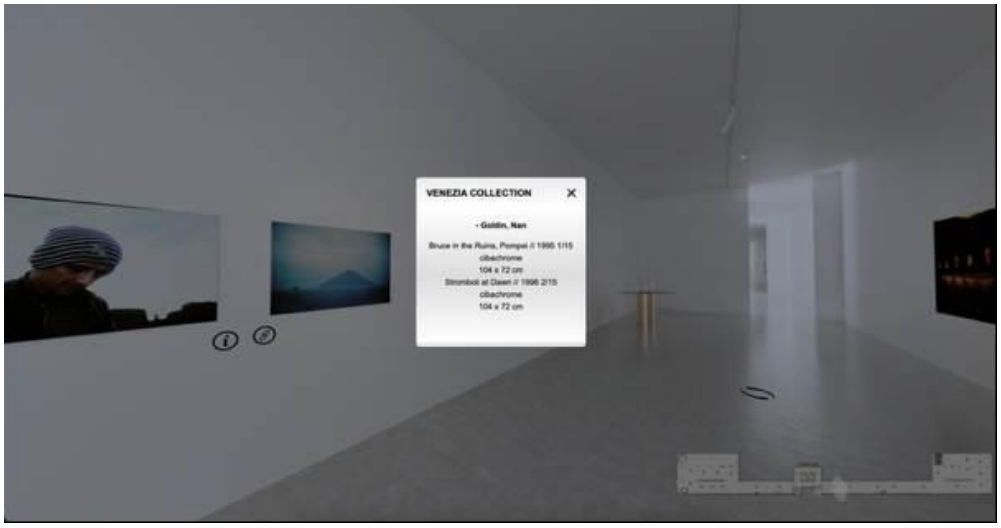

Figure 5: The Ars Aevi virtual exhibition.

To tell the story of the *Sarajevo 1995-2025* exhibition, the University of Bari staff and the DABIMUS digital university lab directed by Nicola Barbuti decided to use different digital tools, expanding the physical exhibition in content and space, such as an interactive augmented catalogue, whose contents are hosted in a special mobile application, EXEBook, developed and owned by DABIMUS (Barbuti and De Bari 2022), and an exhibition on ArtSteps, a free platform for building virtual exhibitions, which will be better described in this paper.

Starting from the images of the devastated urban landscape, from the letters that the children of Sarajevo wrote to their peers in Puglia, from the testimonies of the many protagonists, who populate the virtual rooms of the exhibition, a special place is occupied by the *Ars Aevi* collection immersive story.

The process, which guided the choices regarding the exhibition, led the curator Franco Giuliano and the University of Bari and DABIMUS staff to proceed with the digitization of all the archive and photographic material related to the years in which Giuliano was sent in Bosnia for the *Gazzetta del Mezzogiorno*, during the Balkans war. On that occasion, in addition to recounting that event on the Italian press, Giuliano collected and published on the newspaper dozens of letters written by the children of the Catholic School of Sarajevo, involving prominent Italian and Bosnian personalities of the time. “Sarajevo calls Puglia” was the title of the newspaper’s initiative, inviting readers to send gifts to the Bosnian children.

The concept of the exhibition revolves around the photographic documentation, news and life of the people and the city of Sarajevo, created through those letters/messages that in 1995 students entrusted to Giuliano and were translated and published in *La Gazzetta del Mezzogiorno*, to which many children from Puglia answered by sending gifts that were brought with a special mission. Those testimonies, letters and newspaper pages from Sarajevo, together with other important documents, can now tell, after 30 years, what the War in the Balkans was and what the Balkans are today. Some of those children, now adults, were interviewed and

involved 30 years later to document how much and how the war affected and still affects their lives. The wounds of the soul are then combined with the wounds that the landscape has suffered through the destruction of symbolic monuments of the city. In fact, Sarajevo's cultural heritage was also heavily involved during the war in the former Yugoslavia: cultural and religious sites were destroyed or seriously damaged and the city's urban landscape itself shows holes, cracks and gashes that still recall wounds that seem incurable.

The exhibition, in its physical and virtual version, wants to document these events through photographic augmented panels which refer to digital content of various types: newspaper articles, letters, photographs, video-testimonies, audio content, also linked to the expanded exhibition catalogue, developed by DABIMUS through their specific EXEBook application and AI tools, such as Genially (used both as backend to host mapped resources with original objects and environments, and to build interactive learning and communication materials), and by the writer, to a VR exhibition on ArtSteps, where a selection of the digitized content are displayed.

3 From SecondLife to ArtSteps, Virtual Reality Platforms and the *Sarajevo 1995-2025 VR Exhibition*

The use of virtual environments to foster new forms of connection and engagement with art has entered common practice, thanks to its high educational, interactive and informative potential. Since the end of the 1990s and in the first half of the 2000s, the first entirely virtual museums and full immersion platforms such as Second Life (a MUVE, *on-line multi-user virtual environnement*) revealed their potential for new cultural learning processes in a collective space, in which multiple users interact simultaneously (Bonacini 2011).

Created in 2003 before Facebook and defined as a proto-metaverse system, SL is the true forerunner of the metaverse launched by Meta, an essential starting point for any discussion on the topic of virtual environments (Calveri 2023). On SL, in 2007, the Royal Gallery of Dresden virtually recreated the original disposition of the paintings, as they appeared in the *Gallery of the Old Masters* around 1750. In Italy, in the meantime, we were witnessing the innovative *SLAssisi project*, the digital recreation of the Basilica of St. Francis of Assisi, damaged by the 1997 earthquake, and accessible on the web in an immersive mode through head-up displays, derived from the world of immersive gaming, whose replicability in the cultural sphere was then beginning to be tested (Bonacini 2011). It is no coincidence, therefore, that between 2007 and 2011 SL hosted the *Metaverse Museum* project, which for years displayed digital art exhibitions, created exclusively in this parallel virtual world; then moved to *Craft World Opensim* and, in 2023, opened to artists' creativity until landing on Spatial platform in 2023. The case of the *Metaverse Museum* itself is clear proof of how the creation of artistic spaces in virtual worlds is a practice much further away in time, digitally speaking, than one might think.

Virtuality can therefore be considered one of the answers that modern technology provided regarding the role that communication had to play as an intrinsic function of the work of art, to avoid denying or prejudicing the artistic experience itself, if not in its full authenticity, at least in its potential for articulation and connections (Ragghianti 1974; Pietroni, Pagano and Fanini 2018). Almost given up for dead, SL has seen a relaunch and a total restyling over the last few years; then, favoured by the pandemic for the opportunity of creating virtual educational environments, it still boasts thousands of active virtual scenarios today, including artistic experiences, such as the VR version of the MoMA (fig. 6) and the Vordun Museum and Gallery, a virtual museum created on SL in July 2016 and updated to date with numerous exhibits created through reproductions of works of art in the public domain (fig. 7), equipped with descriptive audio guides and working in immersive mode. Since March 2023, SL has also launched its beta-version for mobile devices on app stores.

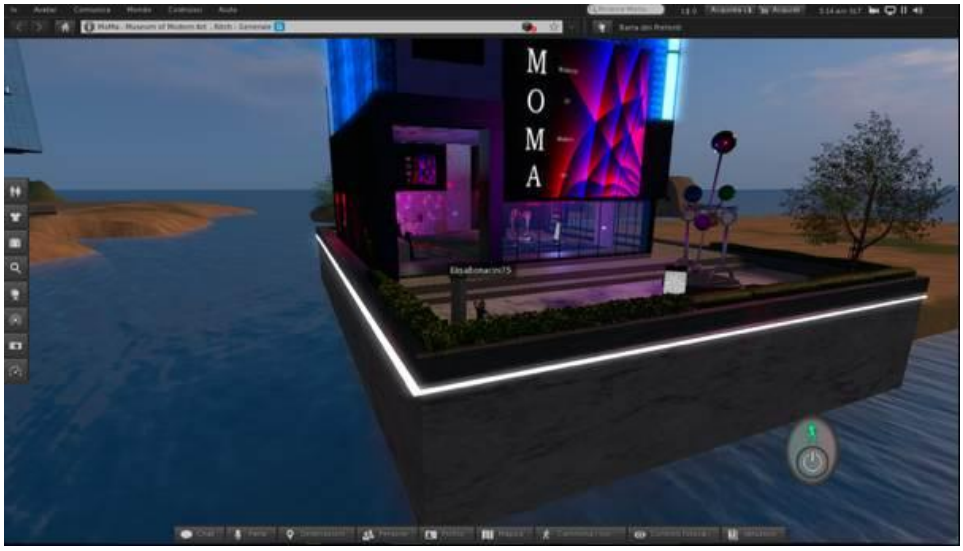

Figure 6: The MoMA virtual gallery on Second Life.

Figure 7: The European Masters gallery in the Vordun Museum and Gallery on Second Life.

After more than twenty years, virtual experiences have confirmed their great potential both in the communication and enjoyment of art, and in engagement with the public, thanks to the implementation of interactive solutions and communication models based on a storytelling approaches (Bonacini 2023). In this panorama, virtual museums are to be considered places where an experience of artistic perception can be recreated, stimulating wonder through the creation of a multimedia and multisensory environment to trigger a creative process useful for directing, internalizing and assimilating the understanding of historical content (De Vincentis 2023).

Among the web platforms available (in addition to Spatial, it is enough to mention Kunstmatrix, CoSpaces, ArtPlacer or Curat10n), ArtSteps is one of the most highly versatile in creating three-dimensional spaces easily and intuitively navigable (Parson 2023; Vital et al. 2023); therefore, especially after the lockdown, it has been used for virtual projects of an educational and informative nature (Fokides and Sfakianou 2017; Cruz and Torres 2022; Dell'Utri 2002; Garbui and Pellizzari 2022; Piva 2023), for virtual exhibitions produced by museums and cultural institutions (Dell'Utri 2022; Leonardi and Bonacini 2024), or for immersive digital art portfolios, created by digital artists or art galleries. In general, tools such as ArtSteps are skilful in transforming art presentation and visualization solutions, even in participatory and collaborative ways, allowing experimental decision-making and creative-thinking activities, in the context of the virtualization of the historical-artistic experience.

In addition, platforms such as ArtSteps allow experimentation with digital and virtual curation solutions. This is certainly one of the most innovative activities that a *digital art historian* can undertake, from a creative and scientific point of view, as it is one of the areas of greatest experimentation that digital revolution introduced into museological and museographic practices.

3.1 The Sarajevo 1995-2025 VR exhibition on ArtSteps

The *Sarajevo 1995-2025 VR exhibition* (https://www.artsteps.com/view/67ead8dca81e5737cc3427c2) is the virtual and immersive version of the story told through the other media, the physical exhibition and the interactive catalogue with its application, in Italian and Bosnian languages.

To create the virtual exhibition, it was decided not to use a pre-existing template, but to design the spaces taking advantage of the full potential of the virtual exhibition surface, available by the ArtSteps system itself, corresponding to approximately 1300 square meters (a maximum of 36 meters per side). From a design point of view, the creative process was therefore developed in a series of intuitive steps, from the creation of the exhibition space to its planning through visual (photos, videos) and narrative (captions, audio descriptions) content. Original photos, videos, newspaper pages were all digitized by DABIMUS staff. In this case, the textual contents of the articles, transcribed in Italian and translated into Bosnian by Maurizio De Bari and the DABIMUS staff were interpreted in Italian by the students of the Digital Valorisation of Museum Collection course at the University of Bari, while those in Bosnian by nuns and students at the Catholic School of Sarajevo. CABOLO® AI-based solution have been used for speech-to-text transcription, translation and subtitling all the video interviews (as a form of sponsorship for the phygital exhibition by the Cedat 85 firm).

The visit route was designed with an introductory environment, in which the entire exhibition is presented (the graphics of which were created as a thesis project by Alessia Cioce, a student of the Digital Heritage specialistic degree course at the University of Bari), and four rooms that lead the virtual visitor on the narrative path.

The first room, *Sarajevo, the war and the Dayton Agreement* in 1995, is dedicated to the visual and documentary framing of the last months of the war until the signing of the agreements that put an end to four years of conflict. Original parts of a video-documentary, realized for the Italian television in December 1995, and the photographic repertoire of war correspondent Franco Giuliano, have been used with photos collected through other witnesses, such as the commander of the Italian contingent in Sarajevo, general Pedone, and the press review, which recounts the turbulent moments that then led to peace.

The second room, entitled *Ars Aevi. Art as Peace Instrument*, is an artistic tribute, thirty years later, to the great project launched by Enver 'Enjo' Hadžiomerspahić in the aftermath of the outbreak of the War (fig. 8). Thanks to the full collaboration of the Ars Aevi Museum, in the persons of its director Senka Ibrišimbegović and her staff, we were able to select the works to be digitally exhibited within the entire digitized collection. In this way, space was left for a real "exhibition within the exhibition", characterized by a specific digital curatorship, which guided the artworks choice. This section is immediately introduced by the *Ars Aevi*'s anagram and two short videos, in Italian subtitled in Bosnian language, in which Enjo recounts the birth and development of his creature, which has become a manifestation of the resilience of global culture against that war and every war. It was decided to highlight 4 or at most 5 works from the same nucleus, starting from the oldest (Milan 1994) and Michelangelo Pistoletto's artwork (fig. 9), ending with the Podgorica collections (2012). Each section is introduced by the name of the collection and an interactive image (accompanied by a short audio description in Italian, with the writer's voiceover, and in Bosnian language, with Senka Ibrišimbegović's voiceover) taken from the *Picture Book*, which briefly indicates the number and name of the artists who participated in that specific exhibition and the name of the curator who was responsible for its selection [starting with Enrico Comi (partner of the *Sarajevo Biennale* and the true driving force behind the project in Italy, who was the artistic director of the *Sarajevo 2000* project and the founder of the "Spazio Umano/Human Space" Contemporary Art Centre in Milan) and by the Centro Pecci in Prato (to whose curator Bruno Corà we owe the invention of the *Ars Aevi 2000*)]. Among the more than 160 digitized images, artworks were deliberately selected, as they would allow users to read linked-themes such as life and death, precariousness, passage, human connections, desires. The stuffed ducklings in the photo by Ingeborg Lüscher (1998) or the brave teddy bear by Dimitri Prigrov (1998) cannot help but recall the small "desiderata" of Bosnian children in their letters. The *Hanged Man* by Juan Muñoz (1988) simultaneously recalls Bill Viola's video installation, *The Passing* (1991), and Nan Golden's photograph, *Bruce in the Ruins, Pompei* (1995). Tony Cragg's installation *Quarry* (1990), in which a crane is surrounded by a series of cement bags, reminds ua a machine gun post, linking on the one hand to Jan Håfström's tragically ironic installation *Holiday Inn, Sarajevo* (1997), with its façade built from jute bags and wood; on the other to Marjetica Potrč's installation *A House With a Room for Possessions* (1999) or Nebojša Šerić's photograph of a soldier in a trench (1998), from the Viennese nucleus. The selection of the three works from the Vienna collection gives us an even more powerful meaning, with Andrés Compagnucci's *Gonzo* offering a bunch of coloured flowers, a sign of peace, the blood-red hammer and sickle by Sándor Pinczehelyi (1973) and, again, the soldier in the trench by Nebojša Šerić (fig. 10).

In the third room, *Sarajevo calls Puglia*, letters and press reviews tell users the great humanitarian event that involved children from both sides of the Adriatic sea, thanks to the initiative promoted by the *Gazzetta del Mezzogiorno*, through its reporter Franco Giuliano. He firstly collected letters from Bosnian childern to send to Italy, and collected reply letters from all Puglia region, involving children and their families. In those weeks, between December 1995 and January 1996, hundreds of letters travelled between the two opposite coasts of the sea. Then, Giuliano arranged the much-desired gifts delivery, thanks to a mission organized by the then Minister of Defense Andreatta. Bosnian and Italian letters have been selected to be exhibited in this virtual route, transcribed into the corresponding languages and translated. The letters' voiceover was made by children from the same schools involved at the time, the Catholic School in Sarajevo and a local school in Bari; the newspaper's voicever by students from the University of Bari.

In the end, the last section, *Testimonies between war and peace*, collects videointerviews of some of the protagonists of those events, in two languages and subtitled in Italian or Bosnian.

4 Conclusions

The *Sarajevo 1995-2025 VR exhibition* is a demonstration of how these virtual spaces are open to creativity and design, a place where Digital art-historians and Digital curators could develop their new digital and virtual skills, by curating virtual exhibition and itineraries, as real curated pathways (De Vincentis 2023). This virtual project, created through the digitalization of analog contents and the use of AI tools, has its true core in the participation in telling stories, in reading newspaper articles and letters, trying to return, in a digital and virtual way, the same collaborative spirit that both the *Ars Aevi* initiative had, for the world of art, and the *Sarajevo calls Puglia* one, from an humanitarian point of view.

5 Acknowledgements

We would like to thank Franco and Enrica Giuliano for their collaboration in identifying the archive and photographic material that could be reused for the physical and virtual exhibition; Nicola Barbuti, Maurizio De Bari and the DABIMUS staff for the digitization of all the material provided, for the transcription and translation of the articles of the *Gazzetta del Mezzogiorno* and the letters of the Bosnian and Italian children; Senka Ibrišimbegović and her staff from the Ars Aevi project, for having accepted the proposal of a virtual collaboration at a distance to give visibility to the contemporary art collection of Sarajevo; PierLuigi Mirizzi and the Media Division Group to let us reuse archival content from Gazzetta del Mezzogiorno; Alessia Cioce for the graphic design of the exhibition; the group of the Department of Audiovisual, music and performance disciplines of the University of Bari (Federico Zecca, Angela Saponari, Francesco Dongiovanni) for their collaboration in editing the video interviews; the nuns and students of the Catholic School of Sarajevo for collaborating in the revision of the translations and the voice-over of the texts in Bosnian; the students of the Digital Valorization of Museum Collections course at the University of Bari.

6 Ethics declaration

The writer has been authorized by the Ars Aevi museum, partner of the project, for the publication of the images on ArtSteps.

7 AI declaration

No AI tool have been used in developing this paper.

The Human in the Loop: Artificial Intelligence as a Co-Pilot in the Creative Process of the Artists. A Critical Analysis in Visual Arts

Maria Antonietta Cipriano, Paola Demartini
Roma Tre University, Rome, Italy

Abstract

The rise of Artificial Intelligence (AI) in the visual arts represents a significant shift in contemporary creative practices, prompting urgent questions about the nature of art, the role of the artist, and the boundaries of human-machine collaboration (Cetinic & She, 2023; Rooij, 2024). This paper investigates how generative AI technologies are reshaping the visual arts, with a particular focus on their influence on the creative process (Miller 2019), the attribution of authorship, and audience perception.

Adopting a thematic literature review methodology within an interdisciplinary framework—spanning art theory, media studies, and cognitive science—the research synthesizes key developments from 1975 to 2024. The literature covers a temporal span from the earliest seminal explorations of computer-aided art (Molnar, 1975) to the most recent advances in generative AI technologies and critical discourse (Chiodo, 2024; Messer, 2024). This diachronic range enables a comprehensive understanding of both the historical evolution and the contemporary debates surrounding AI's role in the visual arts.

This research identifies and analyses three core conceptual themes emerging in the discourse. First, the ontology of AI-generated art interrogates the core concepts that address the definition of art, AI, and the links between them. Following a logical progression, the second theme that emerged presents the critical debates revolving around three central issues: authorship, originality, and intentionality (Floridi, 2021; Hertzmann, 2018; Chiodo, 2024). Finally, the review addresses the issue of audience perception, with particular attention to the cognitive bias that emerges when individuals evaluate artworks produced by AI (de Roji, 2024). This final theme is crucial for understanding not only how AI artworks are judged aesthetically but also how deep-rooted expectations about human creativity influence the reception of machine-generated art.

By drawing a historical parallel to the initial resistance faced by photography in the 19th century (Hertzmann, 2001), the paper contextualizes the current scepticism toward AI art as part of a broader cultural negotiation of new media. The findings suggest that AI is not displacing human creativity but rather expanding its modalities—offering novel pathways for artistic exploration and expression.

This study contributes to the academic debate by moving beyond polarized narratives of celebration or rejection, and instead, provides a nuanced, evidence-based reflection on the evolving dynamics between artists, machines, and audiences.

Keywords: Artificial Intelligence; Visual Arts; Creative Process; Human-Machine Collaboration; Audience Perception

Paper type: Academic Research Paper

1 Introduction

Nowadays, Artificial Intelligence (AI) is embedded in our lives, is set to profoundly influence sectors such as healthcare, education, commerce, finance, security and welfare (Ford, 2021; Lee and Qiufan, 2021). AI can be defined as intelligence performed by machines (McCarthy, 2007) and has received extensive academic attention. With the advent of AI, the field of arts and creativity faces new opportunities and challenges (Vinchon et al., 2023). Recent advancements in Generative AI (GenAI), such as ChatGPT, Midjourney, and DALL-E, have introduced unprecedented opportunities for producing content and ideas (Sestino and De Mauro, 2022).

AI is transforming how artists create, experiment, and interact with artworks. While AI's influence on music composition, design, digital media and creativity process has been widely studied (Carnovalini & Rodà, 2020; Anantrasirichai & Bull, 2022; Guo et al., 2023), scholars have only recently begun to critically examine the implications of AI-generated imagery and its role in visual arts (Cetinic & She, 2023; Rooij, 2024). AI is no longer merely a tool for automation; it is emerging as a co-pilot in the artistic process, engaging with human creators in complex, collaborative, and sometimes unpredictable ways. AI has become an integral part of many visual art practices (Rooij, 2024). AI, which mimics human thinking and behaviour, can give artists new tools and possibilities to create art in innovative ways.

The visual arts are important to society and culture. It spreads beauty and inspires new ideas. It also challenges what is normal. So, when we start using AI in art, we need to take a step back and think about what it means to create art. The research posits that the integration of generative AI in visual art is not merely a

technological advancement but a significant cultural shift, which necessitates a revaluation of our understanding of art and the artist (Garcia, 2024).

This study seeks to explore the intersection between AI and artistic creativity, addressing the following fundamental key research questions:

- How is AI influencing the creative process in visual arts?
- Can AI be considered a co-creator or merely an advanced tool for artists?

Through an interdisciplinary lens, this research aims to investigate how AI-assisted artistic creation challenges traditional notions of authorship, artistic agency (Zembylas & Niederauer, 2018), and creative decision-making (Sternberg, 2003).

This research contributes to the growing discourse on AI and creativity by systematically analysing the role of AI in visual art through an interdisciplinary lens. While literature has two points of analysis: either celebrate AI as a revolutionary creative force or dismiss it as mere automation, this study highlights the interactive and collaborative nature of AI-assisted art.

The paper is structured as follows. Section 2 traces AI's journey in visual arts, from early computational experiments to modern generative tools. It also draws a parallel to the introduction of photography, which initially disrupted traditional artistic methods but later expanded creative possibilities. Section 3 outlines the methodology, detailing the criteria and process for conducting a thematic literature review. Section 4 presents the findings, organised around three central themes: the ontology of AI-generated art, debates around authorship and intentionality, and audience perception of AI-created works. Section 5 discusses the implications of these findings for artistic practices and cultural theory. Finally, Section 6 offers concluding reflections on the future role of AI in the visual arts and its potential to reshape our understanding of creativity.

2 Background: AI's journey in visual arts

The background section unfolds around two main themes: (1) the evolution of AI in visual arts and (2) a historical parallel with the advent of photography. The selection of literature aimed to provide a critical and informed perspective on the impact of AI in contemporary artistic practice, while also situating it within a broader historical and cultural context. Overall, the reviewed literature provides an overview of the current state of AI in visual arts and help to draw connections with past experiences to enlighten the ongoing debate.

2.1 AI in Visual Arts: History and Evolution

The early experiments in AI and visual art are often linked to Harold Cohen, who began developing the drawing system AARON in the late 1960s. Initially, AARON was designed to generate basic abstract shapes, but over time it evolved to make independent artistic decisions (Miller, 2019; du Sautoy, 2019). Visual artists have been integrating digital technology into their creative processes for decades. For example, Vera Molnár (Molnàr, 1975) used geometric plotter drawings, while Sim explored AI-generated animations (Sims, 1991). More recently, the development of advanced AI image generation tools such as Midjourney (2022) and DALL-E 2 (2022) has significantly expanded the role of digital technology in image creation. These advancements have raised important questions and concerns about the role and relevance of visual artists in a rapidly changing technological landscape. This early exploration laid the groundwork for further developments in machine-generated creativity. Decades later, the emergence of Generative Adversarial Networks (GANs) marked a significant turning point (Mazzone & Elgammal, 2019) in the process of creating visual art (Goodfellow et al., 2014). GANs entered the AI conversation in 2014 when researcher Ian Goodfellow published an article theorizing that GANs represented a significant step forward in the capabilities of neural networks. In fact, Goodfellow theorized that unlike earlier AI art tools such as Google DeepDream, which modified pre-existing images in often predictable ways, GANs had the potential to generate original, high-quality images from scratch (Schneider & Rea, 2018). So, basically GANs is divided into two neural networks: one acts like an "artist" and the other like a "critic." The artist network tries to create new images based on patterns that finds in the data, while the critic network evaluates these images by comparing them to real ones (Still & d'Inverno, 2019).

GANs came to the attention of the public in October 2018 when, despite an estimated sale price of between $7,000 to $10,000, a portrait entitled Edmund de Belamy, from La Famille de Belamy, was sold at Christie's in New York for $432.500 (Christie, 2018; Notaro, 2020). The name "Belamy" was a reference to the creator's name of GANs, Ian Goodfellow, that roughly translate to "Bel ami" in French. The authors of the portrait were Obvious, *"a Paris based collective of artists, machine learning researchers and friends interested in AI for Art"* (Obvious 2018). The sale raised criticism from both art critics and AI artists due to several factors: the image's low resolution, the use of a pre-existing GAN model developed by Robbie Barrat in 2014 (with no proper attribution to him). Additionally, the work was presented and signed with a line of algorithmic code, reinforcing a machine-

centred narrative (Notaro, 2020). Adding to the controversy, the promotional material for the sale featured the group's slogan, "creativity isn't just for humans". As Vincent (2018) notes, this motto reflected Obvious deliberate embrace of a narrative that attributed creative agency to the algorithm itself, thereby intensifying debates around authorship and authenticity in AI-generated art.

However, since the boost of AI Art popularity triggered by Christie's auction, the number of artists involved in making AI Art is rising worldwide. The fact that AI Art gained momentum in the last years is reflected in the growing number of online platforms featuring AI Art such as AIArtists.org, as well as exhibitions, conferences, competitions and discussion panels dedicated to AI Art.

Figure 1 shows several examples of contemporary AI artworks.

Figure 1: Examples of AI art. 1) Obvious, Portrait of Belamy; 2) Mario Klingemann, Memories of Passersby; 3) Sofia Crespo, Neural Zoo

In recent years GenAI has become increasingly influential in the field of visual arts. In fact, diverse categories of AI tools are available to artists for producing their works (Braguez, 2023) through text-to-image platforms such as DALL·E, MidJourney, and Runway ML.

The fist, developed by Open AI in 2021 (Kang & Yi, 2023; Leivada et al, 2023), uses text prompts to generate imaginative images, allowing artist to visualize abstract concepts and incorporate AI-generated designs into their work (Jain et al., 2022). On the other hand, MidJourney (Borji, 2022; Hanna, 2023; Huang et al., 2023) released in 2022, enables artists to explore different styles and techniques, offering a dynamic way to apply stylistic transformations to existing or AI-generated images (Johnson et al., 2008). The capabilities of Midjourney have been investigated by other researchers in areas such as graphic design (Mansour, 2023), architecture (Jaruga-Rozdolska, 2022), industrial design (Yin et al., 2023).

The latter, Runway ML (Othman, 2023) was launched in 2018 by Runway AI Inc; this platform forms a variety of applications, but the one that interest us is exploring its capabilities in text-to-image.

These tools use sophisticated machine learning models, often trained on datasets of text-image pairs, to produce original visual content from simple textual prompts (Jain et al., 2022). Their emergence is transforming the role of the artist, the creative process, and the broader cultural understanding of image-making.

Table 1 show some of the different tools available in this moment for visual arts, following the work of Braguez (2023); while figure 2 show a timeline view of the most important technological milestones that led to the current AI Art production based on the research of Cetinic & She (2021).

2.2 The Historical Parallel: The Advent of Photography

When looking to the past for insights into the relationship between AI and art, few inventions offer a more significant parallel than the emergence of photography in the 19th century (Hertzmann, 2001). This parallel has been widely explored in existing literature by Hertzmann (2018) and Aguera y Arcas (2017), so it will be shortly addressed here. The photography initially faced resistance from traditional painters who perceived it as a threat to established artistic practices. However, rather than rendering painting obsolete, photography catalysed new artistic movements, such as Impressionism, which shifted focus from representational accuracy to explorations of light and perception. A promising precedent for AI-generated art lies in the eventual acceptance of photography as a legitimate art form. This acceptance emerged through a dynamic exchange between photography and painting: photographers began adopting the formal and aesthetic sensibilities of painting, such as refined approaches to lighting and composition, while painters responded to photography's unique qualities, including its compositional flatness and the ability to capture movement. This mutual influence created a positive feedback loop, where each medium evolved by engaging with the other. Yet, as Hertzmann (2018) argues that it will be possible that a similar dialogue could develop between AI and traditional forms like painting, prompting artists across both domains to rethink and expand their creative perspectives.

3 Methodology: A thematic Literature review

Several fields of research have explored the ontological value of the artwork as both output and artifact, as discussed by Floridi (2021), while others have examined the artistic process and its moral dimensions (Fioravante & Vaccaro, 2024; Chiodo, 2024) Additional scholars have focused on the innovative processes related to decision-making, often referred to as "design". Traditionally, decisions within innovation processes have been made by humans; however, what happens when machines begin to assume that role? This question lies at the core of recent reflections, such as those by Verganti (2020).

The selection of authors in this literature review is driven by the inherently interdisciplinary nature of the topic. Given that the intersection of AI and art spans multiple research domains, the analysis draws upon scholars from both the humanities and socio-economic fields. Although the debate itself remains relatively niche, it is fundamentally interdisciplinary, involving contributions from diverse array of research backgrounds.

This study seeks to explore the intersection between AI and artistic creativity by addressing the following key research questions:

- How is AI influencing the creative process in visual arts?
- Can AI be considered a co-creator or merely an advanced tool for artists?

3.1 The protocol of the thematic literature review

This research employs a thematic literature review methodology to explore the field of visual arts in relation to AI. Relevant literature was identified using keywords across academic database such as Google Scholar. In fact, Google Scholar was selected for its comprehensive coverage of scholarly publications. This database was also implemented with a search on ResearchGate to discover recent research not yet published.

Selection criteria included highly cited publications in English between 1975 to 2024 that explicitly examine the intersection between visual art and artificial intelligence. The literature covers a temporal span from the earliest seminal explorations of computer-aided art (Molnar, 1975) to the most recent advances in generative

AI technologies and critical discourse (Chiodo, 2024; Messer, 2024). This diachronic range enables a comprehensive understanding of both the historical evolution and the contemporary debates surrounding AI's role in the visual arts. Keywords employed in the literature search are coherent with the paper's RQ such as "AI and visual art", or "AI and creative process of artists".

Sources were selected according to specific inclusion criteria: publications needed to engage directly with the application of AI in visual artistic practices. Works primarily focused on AI applications in unrelated fields- such as education, healthcare or philosophical reasoning- were systematically excluded. This rigorous screening process resulted in a final selection of 32 references directly pertinent to the intersection of AI and visual art.

To this end, a thematic literature analysis was conducted to examine practices combining art and artificial intelligence. This step provides an in-depth understanding of the field and identifies critical aspects requiring further research.

Based on the above-mentioned logic, we identified the principal papers on which our thematic literature review is grounded. Table 2 provides examples of some of these key sources that form the foundation of this review, organized according to four criteria: citation reference, main thematic focus, publication outlet and the academic field to which each work contributes. This organization highlights the multidisciplinary nature of the research landscape, spanning art theory, media studies, machine learning and digital humanities.

In the following sections, based on our protocol of exclusion and inclusion, the review will examine key concepts and current debates, focusing on:

- The ontology of AI Art
- Current Debate on AI-generated art
- The Cognitive Bias Toward AI Art (i.e., audience perception)

The first theme is fundamental for defining the core concepts that address the definition of art, AI, and the links between them. Following a logical progression, the second theme that emerged presents the critical debates revolving around three central issues: authorship, originality, and intentionality. Finally, the review addresses the issue of audience perception, with particular attention to the cognitive bias that emerges when individuals evaluate artworks produced by AI. This final theme is crucial for understanding not only how AI artworks are judged aesthetically but also how deep-rooted expectations about human creativity influence the reception of machine-generated art.

Table 2: Example of Papers Included in Our Thematic Literature Review

Paper References listed on the base of quotations	**Main Themes of the paper**	**Journal name**	**Journal's academic field**
Elgammal et al. (2017) (859 citations)	Creative Adversarial Networks (CAN) and AI art generation	Conference paper published on the eighth International Conference on Computational Creativity (ICCC)	Computational Creativity, Machine Learning
Hertzmann (2018) (291 citations)	Philosophical question: can computers create art?	Arts (MDPI)	Computational Aesthetics
Miller (2019) (363 citations)	Exploration of AI-powered creativity	The MIT Press	Cognitive Science, Creativity Studies
Daniele & Song (2019) (76 citations)	Human-AI collaboration in art creation	*Proceedings of the 2019 AAAI/ACM Conference on AI, Ethics, and Society*	AI Ethics and Creativity
Verganti, R., Vendraminelli, L., and Iansiti, M. (2020) (808 citations)	Innovation and AI-driven design processes	Journal of Product Innovation Management	Innovation Management, Design Studies, AI Integration
Goenaga (2020) (50 citations)	Critique of Edmond de Belamy and AI authorship	*AusArt*	Art Criticism
Floridi, 2021 (216 citations)	Ethics of AI-generated synthetic images (deepfakes, ectypes)	Ethics, Governance, and Policies in AI	Ethics, AI Policy, Philosophy
Cetinic & She (2022) (577 citations)	Review and future of AI art	*Transactions on Multimedia Computing, Communications, and Applications (TOMM)*	Multimedia Systems, AI Art
Sartori, L., and Bocca, G. (2023) (139 citations)	Public perceptions and socio-technical imaginaries of AI	AI & Society	AI Ethics, Sociology of Technology

4 Findings

The thematic literature review conducted in this study revealed three major conceptual areas that critically shape the current discourse on AI and visual arts: the ontology of AI-generated art; issues of authorship, originality, and artistic agency, and audience perception and cognitive biases toward AI-generated artworks.

Each theme is outlined below in detail.

4.1 The Ontology of AI Art: Defining Art, AI and the links between them

A significant body of literature interrogates the fundamental question: *Can AI-generated outputs be considered true art?*

Traditional theories of art, such as those of Plato (1955), Tolstoy (1995), and Croce (1920), emphasize human emotional experience, intentional expression, and cultural transmission as essential to artistic creation.

What is particularly interesting is the definition of Croce (1904), he stated that art is a "is a higher form of intuition, therefore a higher type of knowledge reached through expression"; also, interesting is that of Altieri (1987) which described artistic expressivity as a creative and profound manifestation of human agency. Furthermore, a more pragmatic approach is proposed by Dickie (1969) who poses two conditions for art to exist: 1) to be an artifact; 2) some society or sub-group needs to confer the status of "candidate for appreciation".

Equally important for human evolution is technology. As proposed by Leroi-Gourhan (2012), technical tools are a manifestation of the "milieu interieur", the ensemble of cultural and mental traditions of a group, including art. In this research, we adopt one of the most widely accepted definitions of AI, commonly attributed to Marvin Minsky (Wiggins, 2006): *"The performance of tasks, which, if performed by a human, would be deemed to require intelligence"*. Based on this definition, AI can take many forms, from simple rule-based systems to more advanced models. According to Song and Daniele (2019), there are generally two types of AI:

- AI that tries to replicate human cognition (thinking, learning, decision-making),
- AI that doesn't try to mimic humans but still performs intelligent tasks in other ways.

If an AI system can create art or showing signs of creativity, it belongs to the first group, under the field of Computational Creativity, which studies how machines can simulate or support creative processes like those of humans.

4.2 Authorship, originality, and intentionality of AI-generated art

The current debate on AI-generated art evolves around three key aspects: authorship, originality, and intentionality. Different scholars offer different perspectives on whether AI can create true art or if it is merely a tool that assists artists: Floridi (2021) argues that digital artwork is an *ectype*, a copy based on data models, raising questions about AI art originality; Verganti (2020) argues about innovative processes related to decision-making, which many researchers and professionals refer to as "design". Hertzmann (2018) states that art is a social process, and that AI lacks artistic intentionality. Instead, AI-generated artworks result from mathematical optimizations rather than personal expression (Hertzmann, 2018, p. 3). Chiodo (2024) explores AI art as a cultural phenomenon that challenges traditional definitions of authorship and creativity. By blurring the boundaries between artist, tool, and audience, AI forces a rethinking of what constitutes artistic agency (Chiodo, 2024, p. 6). Rather than focusing on AI's limitations, Chiodo explores how AI expands artistic possibilities, raising questions about whether AI should be seen as a co-creator rather than just a tool.

The perspectives of Floridi, Hertzmann, and Chiodo illustrate the complex and evolving nature of AI in art. Floridi and Hertzmann emphasize AI's dependence on human input and its lack of true creativity, while Chiodo highlights its potential to redefine artistic authorship. This raises fundamental questions:

- Is AI-generated art a new artistic medium or simply a computational tool?
- Does artistic intentionality define art, or is aesthetic value alone sufficient?

These discussions remain central to understanding the future role of AI in the creative process.

4.3 The Cognitive Bias Toward AI Art

How people react and deal with AI outcomes has become an interesting issue in recent years (Peeters et al., 2021; Pelau et al., 2021). A crucial aspect in analysing the impact of AI on visual arts concerns the public's perception and biases toward works generated using this technology. The recent literature suggest that people show both positive and negative bias towards AI (Fietta et al., 2021; Sartori & Bocca, 2022). Experimental studies such as Di Dio et al. (2023) state that when audiences are informed that a visual artwork was creating using AI, this diminishes emotion, appreciation and valuation of the work. This highlight the fact that audience might have

a bias against AI in visual art; in fact, informing audiences that AI was used in art creation can influence their aesthetic experience, independently if the objective qualities of an artwork (de Rooij, 2024).

A recent meta-analysis conducted by de Rooij (2024) highlights a significant trend: audiences tend to perceive AI-generated art as "less authentic" compared to art created by human hands. This finding fits into a broader context that could be described as the "AI Creativity Paradox" (de Rooij, 2024). This paradox is evident in the fact that, although the public may express admiration or interest in artworks produced by AI, they often reject the idea that a machine can be truly creative.

Up until now, artistic creativity has been intended exclusively as a human product and typically assumed to belong of human beings (Sawyer, 2011). However, we are nowadays facing a new era in which AI shows creative abilities (Miller, 2019) in painting visual artworks (Elgammal et al., 2017) sold by international auction houses and exhibited in important museums (Goenaga, 2020). This dichotomy suggests an important distinction in the minds of observers: while AI-generated art can be appreciated for its aesthetic or conceptual qualities, the lack of genuine human "intent" and a creative process like that of humans seems to undermine the perception of its inherent authenticity.

5 Discussions

The thematic analysis reveals that the incorporation of AI into visual arts represents a profound and multifaceted transformation, rather than a mere technological enhancement.

The findings illustrate that the integration of AI into visual arts constitutes a disruptive yet generative force in the evolution of creative practices. The discussion around the ontology of AI-generated art (Floridi, 2021) proves particularly relevant. While works created with AI may possess aesthetic and conceptual value, the question of their originality and their status as ectypes (copies based on data models) remains open.

The issue of cognitive bias towards AI-generated art (de Rooij, 2024; Di Dio et al., 2023) is another crucial aspect. In fact, persistent audience biases suggest that the full cultural acceptance of AI art remains contingent upon broader societal shifts in how creativity itself is conceptualized.

Drawing a historical comparison, the early rejection of photography in the 19th century provides an important precedent for understanding the current debates around AI in art (Hertzmann, 2018). Initially, photography was criticized as a purely mechanical process that lacked artistic value. However, rather than replacing traditional art forms, photography eventually inspired new movements such as Impressionism. In the same way, although AI-generated art is currently viewed with scepticism, it may, over time, gain broader acceptance. However, this shift will require a redefinition of artistic standards and cultural values.

The growing presence of AI-generated artworks in prominent artistic contexts (Elgammal et al., 2017; Goenaga, 2020) suggests an evolution in public perception and a potential overcoming of these initial prejudices.

Rather than replacing human creativity, AI acts as an *amplifier*, offering new aesthetic possibilities while exposing fundamental tensions about intentionality and authenticity. Artists engaging with AI in their creative process could suggest us that AI is not merely a tool, but rather an evolving partner or a co-pilot. Its role varies depending on the artist's approach, artistic goals, and the specific AI technology employed. While in some contexts AI primarily acts as an enhancer of human capabilities, in others it emerges as a form of co-creation, where AI actively contributes to the generation of ideas and the realization of the artwork. This dynamic prompt a reconsideration of our understanding of art, the artist, and the creative process in the age of AI

6 Conclusion

This study critically explored the intersection between AI and the visual arts, emphasizing how AI is reshaping the creative process and challenging established concepts of authorship, originality, and artistic agency. Through a thematic literature review, the paper identified and analysed three key areas of debate: the ontology of AI-generated art, the attribution of authorship and intentionality in AI-assisted creation, and the audience's cognitive responses to AI-produced artworks.

The findings indicate that the integration of AI into artistic practice represents more than a technical innovation—it reflects a broader cultural transformation. While generative AI tools expand the possibilities for artistic production, they also raise fundamental questions about what constitutes art and who—or what—can be considered an artist. AI does not replace human creativity but enhances it, offering artists new tools and opportunities for expression. However, public scepticism remains, largely due to the perception that AI lacks human intention or emotional depth.

This mirrors the initial resistance to photography in the 19th century, highlighting how new technologies, initially perceived as threats to artistic authenticity, can eventually lead to new forms of creative expression and legitimacy within the art world. Similarly, AI-generated art may follow this trajectory as cultural attitudes evolve

and definitions of creativity expand. In response to the research questions, it can be concluded that AI is profoundly influencing the creative process in the visual arts, offering artists new possibilities for experimentation, conceptualization, and production.

In conclusion, AI should not be viewed as a replacement for human creativity but as an evolving partner in the creative process. Its role varies depending on the artist's intentions, the context of use, and the interpretive frameworks of the audience. As generative AI will continue to develop, it becomes increasingly important to examine its implications for artistic practices, cultural institutions, and our broader understanding of creativity in the digital age.

AI for Start-up Decision-Making and Knowledge Management: Evidence from an Innovation Ecosystem

Chiara Bellini, Débora Cristina De Andrade Vicente, Lucia Marchegiani
Roma Tre University, Rome, Italy

Abstract

The increasing integration of artificial intelligence (AI) into decision-making processes represents a fundamental lever for competitive positioning, especially for start-ups operating in innovative ecosystems such as Rome Technopole (RT). This paper analyzes whether and how RT startups adopt AI to support decision-making and knowledge management processes, basing these processes on ethical and human-centric principles.

After the preliminary reconstruction of the conceptual framework, using a qualitative-quantitative approach based on semi-structured interviews and questionnaires aimed at innovative startups and SMEs, the study shows that AI solutions are used for big data analysis, simulation of future scenarios and optimization of business strategies. Technologies, in fact, enhance the effectiveness of decisions through predictive analysis and automation, without ever replacing the critical contribution of the human element, which remains guaranteed through feedback, periodic meetings and mentorship sessions. At the same time, transparent and secure data management is essential to establish a climate of trust with stakeholders.

In addition, the adoption of AI is integrated with economic, social, and environmental sustainability criteria, directing innovation towards ethical and responsible business models, in line with the 17 Sustainable Development Goals and Environmental, Social, and Governance (ESG) standards.

The results indicate that, while still in its infancy, the use of AI in RT startups offers significant opportunities for growth and competitiveness, if the integration between advanced technology and human resources is strengthened.

Keywords: Artificial Intelligence, Knowledge Management, Decision-making process, Innovation Ecosystem, Start-up

Paper type: Academic Research Paper

1 Introduction

The integration of AI into business decision-making has become a critical element for business success, especially in innovative ecosystems (Adner, 2017; Granstrand and Holgersson, 2020) in the era of Industry 5.0 (Carayannis et al., 2024), as well as in the emerging innovative ecosystem (Dedayir et al. 2018) Rome Technopole (RT), the subject of this paper.

Start-ups active in innovation ecosystems can leverage AI to: i) analyze data sets and information, ii) identify market trends and iii) define competitive business strategies (Burström et al. 2021). Given that the early years of startups are often marked by uncertainty, resource constraints and high bankruptcy rates (Cantamessa et al., 2018), AI support is strategic. At the same time failures and constraints provide valuable learning experiences to access and/or develop new skills, abilities and outline innovative strategic orientations (Corvello et al., 2024). However, the integration of AI into decision-making and strategic processes raises concerns about ethical compliance and the need to preserve the central role of human judgment in decision-making processes (Eapen et al., 2023).

This paper aims to analyze whether and how start-ups operating within the RT innovation ecosystem use AI to support decision-making and strategic processes and how these can be grounded in humanistic and ethical principles. In this regard, the Knowledge Management (KM) framework (Edwards et al., 2003; Venkitachalam and Willmott, 2015) plays a fundamental role in ensuring that AI is used not only to improve the efficiency and effectiveness of business processes, but also to support decisions that respect ethical values (Vaccaro, 2022).

The start-ups of the RT innovative ecosystem serve as a paradigmatic example of how the collaboration between AI and human decision-making capabilities can positively influence their strategies and evolutionary paths. It is therefore considered necessary to explore how the KM framework can effectively integrate AI in an ethical way, while ensuring the autonomy of decision-makers.

At this aim, the paper is structured as follows: i) definition of the conceptual framework deriving from the analysis of the main theoretical contributions about Knowledge Management, AI and ethical implications; ii) quali-quantitative analysis of the strategic behavior of RT start-ups through the administration of semi-structured interviews and questionnaire; and finally, iii) comparison of the approaches adopted.

2 Conceptual framework

The integration of AI is a key factor in creating competitive advantages (Krakowski et al. 2023) and supporting the digital transformation of enterprises. In fact, AI supports companies in value creation processes (Porter and Kramer, 2018) especially in B2B markets by promoting virtuous iterative cycles that significantly enhance the ability to co-generate value (Leone et al. 2021). The ways in which AI can create value can be divided into four dimensions (Borges et al. 2021): i) decision support - AI as a tool to support and improve decision-making processes; ii) customer and employee engagement -AI to improve the interaction and experience of both customers and employees; iii) automation -AI to automate processes and increase operational efficiency; and finally, iv) new products and services – AI to enable new product and service offerings.

Figure 1 offers a conceptual representation that highlights how business strategy intersects in a dynamic and integrated way with information technologies, highlighting some key aspects. Business strategy and information technology (IT) no longer operate in isolation (Chari et al. 2025; Gamboa, 2024); on the contrary, they develop in a process of continuous alignment, in which IT strategy is integrated into the planning and pursuit of business strategies (decision making) (De Bem Machado et al. 2022). At the heart of the diagram is the interconnection between IT infrastructures, organizational processes, and human resources. It is highlighted how these elements must work together in a synergistic way to create an effective digital strategy, which is not limited to the implementation of technologies alone but also promotes cultural change and the transformation of business processes. Technological resources, in this perspective, become fundamental levers for innovating the business model and creating new market opportunities. Finally, the dynamic nature of the relationship between IT and strategy emerges, highlighting that alignment requires constant adaptability to market developments and technological innovations.

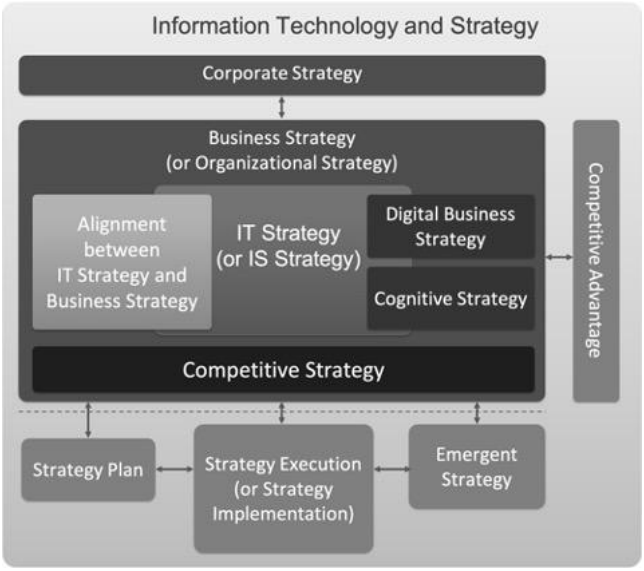

Figure 1. Integration between IT and strategy
Source: Borges et al. 2022

The study conducted by Leoni et al. (2024) highlights how the integration of AI into Knowledge Management (KM) processes improves the quality, timeliness and accuracy of decisions within the organization. The role of AI in KM processes is appreciated in terms of automation and data management, operational functions and generative AI. The latter aspect is particularly important because generative AI tools are revolutionizing KM as they can generate content that facilitates the creation and dissemination of knowledge (Oppioli et al., 2023). The adoption of AI tools within KM processes leads to a significant improvement in decision-making, thanks to more efficient data management and a greater ability to generate insights useful for strategic decisions (Nazeer et al., 2023).

The relationship between AI, KM, and decision-making emphasizes the importance of successful AI integration into KM processes, as it directly influences decision outcomes, and the need to evaluate AI's effectiveness in achieving desired outcomes, as perceptions of its benefits or disadvantages can influence future adoption decisions (figure 2).

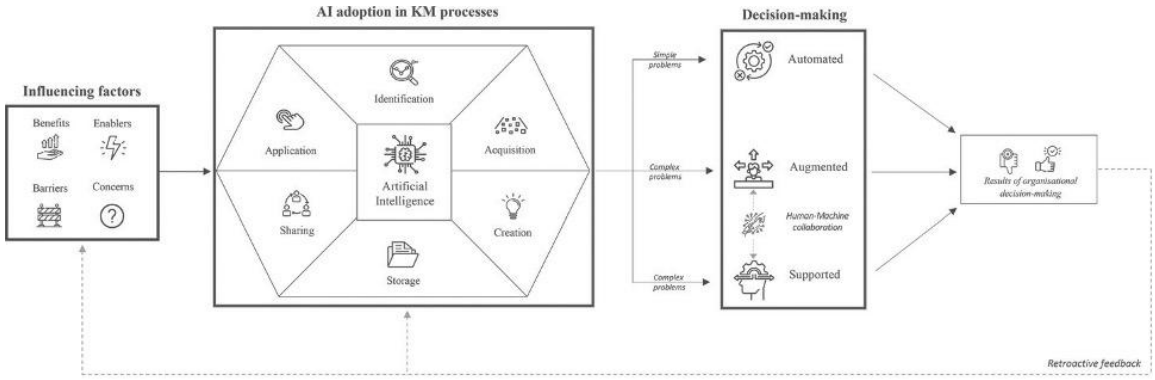

Figure 2. AI, Knowledge Management and decision making
Source: Leoni et al. 2024

Figure 2 shows that KM and decision-making are interconnected and mutually influence, in line with previous contributions that consider firms as complex systems, in which decisions are formed based on the interactions between multiple factors and actors (Parasuraman et al., 2000). In this perspective, interactions are made even more complex by human-AI interaction (Di Vaio et al., 2022). In this perspective, the framework suggests that AI mainly plays a complementary rather than competitive role with humans (Budhwar et al., 2022), identifying three specific types of decision-making (i.e., automated, augmented, and supported) based on the problem that needs to be solved and its complexity.

Adopting AI within KM processes enhances an organization's decision-making capabilities by rendering them more effective, accurate, and flexible (Agrawal et al., 2017a; Duan et al., 2019; Metcalf et al., 2019). It should be emphasized that the implementation of AI technologies alone does not guarantee a positive impact on performance; only the combination with systems that promote knowledge sharing creates an environment in which existing and new information can be adequately valorized, contributing to a sustainable improvement in business performance (Olan et al. 2022).

An interesting evolution is represented by the introduction of the concept of knowledge warehouse which refers to an integrated architecture that is not limited to collecting and processing data, but also aims to capture, codify, organize and share the knowledge (explicit and tacit) present within the company. This approach expands the role of decision support systems (DSS), directing them towards improving the knowledge and mental model of decision-makers, to make decisions more informed and effective (Nemati et al. 2002).

Figure 2 helps to identify factors that influence the adoption of AI in KM processes that can be categorized into: benefits, enablers, and barriers. Adopting AI in KM processes significantly reduces operational time and costs by enhancing real-time data collection and analysis, and spurring creativity and innovation for more informed decisions. Enabling factors include commitment from managers, an agile organization, and a strong customer base. However, cultural resistance to change, fear of replacing humans, shortage of skilled personnel, and high upfront costs are major barriers that can limit the effectiveness and integration of AI tools into KM processes. Added to these are also the lack of trust in automated decision-making processes and an inadequate level of commitment on the part of those in leadership positions in the company (Kar et al. 2021).

The topic of human-AI interaction has drawn the attention of academia to the idea that careful design of decision-making structures that integrate AI and human decisions can improve the quality, efficiency, and fairness of organizational choices. Human-AI interaction, if well designed, makes it possible to exploit the speed and accuracy of AI together with human interpretative capacity and flexibility, ensuring a balance between technological innovation and managerial responsibility (Shrestha et al. 2019). The contribution of Jarrahi et al. (2023) highlights how the partnership between humans and AI represents a turning point in the way companies create, store, share, and apply knowledge. Building on earlier reflections on organizational knowledge dynamics, the integration of AI into decision-making and KM processes recalls the foundational work of Ciborra (2002), who emphasized the importance of situated practice and mindfulness in technology adoption. Rather than viewing AI purely as a rational optimizer, it is essential to consider how human improvisation and organizational culture shape the actual use of digital tools. This perspective aligns with recent developments on human-AI symbiosis and dynamic capability.

The symbiotic approach (humane-AI symbiosis) makes it possible to exploit the speed and efficiency of AI, without losing the critical and contextual element that only humans can provide. In addition, the strategic interaction between humans and AI fosters positive impacts that can be seen in terms of business performance. Effective collaboration between AI and Human Intelligence (HI) contributes to the development of the

company's dynamic capability, i.e. the ability to adapt, be agile and respond effectively to a volatile and ever-changing competitive environment (Chowdhury et al. 2022). If employees trust technology and know exactly how their role integrates with it, the company tends to gain competitive advantages. In turn, skills in using AI positively influence business performance, with effects mediated by dynamic capability: an environment in which companies can quickly reconfigure processes and optimize resources leads to greater efficiency and a faster response to the challenges of the competitive environment.

The integration of AI, while offering significant advantages, raises complex issues, so it should be accompanied, at the same time, by a profound ethical reflection, which considers not only economic efficiency, but above all the protection of the rights and dignity of employees (Rodgers et al. 2023) and which considers the plurality of values and democratic participation. The real challenge for companies lies in balancing the benefits of automation with ethically responsible management, which places the human being at the centre (Varma et al. 2023) by promoting participatory and transparent processes in contemporary society.

The construction of the conceptual framework, albeit synthetic, underlines how adopting an integrated strategy in which AI and human intelligence collaborate synergistically not only facilitates innovation and digital transformation, but also produces concrete benefits in terms of competitiveness, effectiveness, efficiency and value creation.

3 Methodology

The paper adopts an empirical qualitative-quantitative approach based on the collection and analysis of data and information through the administration of a semi-structured interview with the founders and decision-makers of a sample of start-ups selected within the emerging innovation ecosystem RT (table 1). The start-ups were selected among those that participated in the Technè acceleration project of Spoke 2 of the Tecnopolo of Rome (see section 3.1) dedicated to digital startups and spin-offs of the Lazio Region and the Regions of Southern Italy.

Table 1. Sample of interviewed start-ups

Start-up	Sector	Core product or service
1	Health & Bio-pharma	Service for assessing the degree of reliability of research articles.
2	Digital transition	Digital platform for optimizing economic-financial reporting systems.
3	Energetic transition	Service for assessing the degree of sustainability (algorithm), including social and environmental, of tourism companies.
4	Digital transition	Management of coaching services, events, tournaments and E-sports team management.
5	Digital transition	Automation of collaborative projects.
6	Digital transition	Virtual assistance for tourism services.
7	Health & Bio-pharma	Research, development, marketing of phytoderivative products.

Source: own elaboration

Among the start-ups mentioned (table 1), 4 accepted the invitation to participate in the interviews and belong to the digital transition (3) and energy transition (1) sectors.

The semi-structured interview explored in depth the following thematic areas: human-centric and sustainable business models; support and collaboration within the RT; AI-Based platform for the simulation of business models and possible future scenarios.

Before proceeding with the analysis of the results (section 4), it is considered appropriate to illustrate the articulation in terms of actors, relationships and objectives of the emerging innovation ecosystem RT (section 3.1), since it represents the most appropriate strategic and organizational context for the development of the qualitative study.

3.1 Rome Technopole (RT) emergent Innovation Ecosystem

RT is an ambitious strategic project to create an innovation ecosystem (Adner, 2017) in Italy's Lazio region, integrating research, technology transfer, and education to drive regional and national economic transformation. Funded by the National Recovery and Resilience Plan (PNRR) 2021–2027, RT is designed as a strategic system (Oh et al., 2016) where each actor plays a specific role in generating sustainable value (Chandler, 2022). RT generates shared value (Porter & Kramer, 2018) by: i) strengthening Lazio's technological and economic fabric through collaboration among universities, businesses, and local governance; ii) establishing a

hub for cutting-edge research in energy and digital transition and in health and biopharmaceuticals; iii) enhancing STEM education and research capacities in Central and Southern Italy toward international excellence. These dynamic, multi-actor ecosystems are characterized by interdependence, and co-specialization and include actors, activities, and artifacts that shape innovation performance (Granstrand & Holgersson, 2020).

RT currently displays characteristics of an emerging innovative ecosystem (Dedehayir et al., 2018) in a hub-and-spoke configuration. Mapping identified five stakeholder categories (Freeman, 2023): seven public and private universities, four research centers, fourteen private companies, six institutions, and eight associations and start-ups. RT manages relationships, resources, and skills across the system (Valkokari et al., 2016). This arrangement promotes agility and resilience in adapting to emerging technologies and market shifts.

Actors collaborate and compete (Bacon, Williams & Davies, 2020) vertically, horizontally, and cross sectorally, adopting integrated innovation strategies and multiple roles. RT's six strategic spokes are: (1) applied research, (2) technology transfer, (3) advanced education, (4) vocational training, (5) industrial partnerships, and (6) shared research infrastructure and joint laboratories (RIPI). RT leads eight flagship projects addressing green energy, digital transition, AI in aerospace, health technologies, and human-centered AI. These projects aim to drive sectoral innovation and translate research into marketable solutions.

Participants drive four macro strategic activities—research, education, technology transfer, and community involvement—through specific projects. RT's competitive advantage stems from fostering collaboration, innovation, and new market opportunities, manifested through: i) differentiation and resource diversification; ii) facilitated access to innovations; iii) economies of scale and scope; iv) risk reduction; v) continuous innovation and organizational learning; vi) speed to market; and vii) sustainable development. By managing strategic interdependencies among stakeholders, RT fosters continuous co-evolution in response to technology shifts, market demand, and participants' actions aligned with future growth objectives. This continuous co-evolution aligns development with stakeholder's initiatives and strategic growth targets. RT aspires to be a regional, national, and European reference point, supporting long-term economic and social progress.

4 Results

The analysis of the semi-structured interviews highlights a path of integration of AI in the early stages, characterized by a certain heterogeneity in terms of infrastructure and organizational maturity.

The startups analyzed integrate digital tools as strategic levers and not just isolated technologies. First, AI and Machine Learning (ML) act as a decision support engine: a start-up uses predictive and deductive algorithms to guide the entrepreneur in governance choices, preventing e.g. crisis situations, while another start-up implemented AI digital assistants to automate customer relations processes (e.g. acceptance), freeing up Human Resources time for higher value-added activities. Another start-up addresses the issue of sustainability through a scoring algorithm, developed which assigns a score of 0–100 to accommodation facilities. This real-time reporting system supports operational decisions to reduce carbon footprint and improve ESG performance.

The blockchain, used by one of the start-ups interviewed, guarantees immutability and transparency in network agreements, offering a trust layer on which to develop future ethical AI applications. The adoption of smart contracts, the digital rights of stakeholders are protected, and regulatory compliance is promoted.

It emerges, therefore, that each technology does not remain isolated, but becomes an integral part of the business model:

- AI and ML power dashboards and decision-making scenarios;
- scoring algorithms translate sustainability metrics into concrete actions;
- blockchain serves as a secure infrastructure for smart contracts and governance;
- digital interfaces (QR-codes) streamline the provision of services.

In addition, these results are also confirmed by a study conducted by the RT AI Observatory (2025) on a sample of 60 companies, of which 32 are SMEs and start-ups. That study shows a diversified infrastructure adoption within RT: about a third use only cloud solutions, another part operates on hybrid infrastructures (on-premise and cloud), and many remain tied to local systems, while a small group is migrating to more integrated platforms. At the AI level, this mix reflects an experimental phase, with transitions to more modern models. Regarding decision-making processes, many companies have partially or well-structured procedures for AI adoption, but a significant share signals the need to formalize and strengthen these processes. However, organizational gaps remain: only 8 out of 32 companies have a dedicated AI team, 4 plan to hire, and as many as 20 do not have specialized in-house skills, which affects the effectiveness of digital integration. Operational experience is also still limited: the majority have implemented 1–5 AI projects, a large group have not yet started any, and very few companies have more than 6 projects.

In our study, the interviewees are implementing advanced platforms that, through machine learning algorithms, simulate strategic scenarios, evaluate business models, monitor cash flows, and assign sustainability scores (0–100). Some of these algorithms are already protected as intellectual property. Automation facilitates data-driven decision-making and optimizes both operational management and strategic planning.

On the innovation front, a collaborative model is emerging: humanized AI platforms are being developed through mentoring and R&D sessions, integrated with internal expertise, allowing for more flexible and critical decision-making. Digital solutions enhance human input through recurring feedback and discussions, while ensuring secure and transparent data management. The focus on sustainability is reflected in the adoption of the 2030 Agenda and ESG principles as strategic frameworks, promoting fair and inclusive internal policies.In conclusion, although SMEs and start-ups show a strong propensity for innovation and AI exploration, there are areas for improvement, especially in terms of structuring internal processes, creating dedicated teams and consolidating skills, which are key elements for transitioning from an experimental phase to full digital integration.

5 Limitations and future research directions

A limitation of the analysis lies in the small and diverse sample: many of the start-ups examined do not have teams specialized in AI, which compromises the generalizability of the results and limits an objective assessment of the actual impact of AI in decision-making processes.

In addition, despite the presence of numerous conceptual models, many applications of AI in the strategic and governance fields remain in the preliminary or theoretical phase, highlighting the need for further empirical studies to validate the expected benefits and deepen the interaction between AI and knowledge management. In addition, it would be appropriate to extend the validation of the analyses also to innovative start-up SMEs already operating in sustainable businesses at an economic, social, environmental and ethical level to contribute to overcoming the strategic, organizational, cultural and financial barriers that characterize the digital transition.

6 Conclusions

The analysis conducted in this paper highlights how AI-based models can significantly improve business decisions, providing predictive information and optimizing investments in IT infrastructure and business strategies. In fact, AI is configured as a strategic lever that contributes to the creation of competitive advantage thanks to the automation of processes and the extraction of new knowledge from big data.

The transformation of business models emerges as a complex and long process, which can be supported by the development of interactions that are not only competitive, but also collaborative between the players in the innovation ecosystem. In fact, the integration of AI in RT start-ups, despite being in its early phase and characterized by organizational heterogeneity, represents a strategic lever that enhances the interdependencies between advanced technology and human know-how in an ethical and sustainable way, while requiring further investments to consolidate dedicated processes and teams. Belonging to the RT has favored matchmaking with universities and other key stakeholders in the digital transition processes, although no real dedicated partnerships have been born. In this regard, a project of the RT Spoke 2 is engaged in the development of an AI-based platform conceived as a hub for simulations, feedback and networking, a powerful value multiplier for all startups.

The proposed conceptual models offer start-ups a framework to integrate AI into knowledge management processes, thus optimizing decision-making. AI supports the activation of a virtuous circle of learning that underlies decision-making processes and that favors innovation processes, therefore the creation of economic, social, environmental and ethical value of companies. These elements outline a perspective in which technological innovation is not an end in itself but is closely intertwined with values that aim at responsible and sustainable business management. The integration of a human-centric approach, data protection and integrated sustainability creates a business system in which technologies are a strategic ally at the service of informed, ethical and responsible choices.

Therefore, entrepreneurs and managers are invited to invest in the involvement and training of staff, as well as in the adoption of strategic-organizational choices (e.g. re-design of work processes) that allow them to fully exploit the potential of AI by ensuring ethical and sustainable human-AI integration.

Abstract

This study explores how Artificial Intelligence is reshaping managerial competencies in modern organizations. While much of the literature emphasizes technological capabilities, we adopt a human-centric perspective to map the evolving competencies, skills, knowledge, and responsibilities that managers must acquire to navigate the evolving technological landscape. The analysis is grounded in a Systematic Literature Review conducted in accordance with the PRISMA framework. A total of 92 peer-reviewed academic articles were examined using a hybrid methodology that combines Large Language Model-assisted content extraction with structured human coding. The resulting taxonomy groups these competencies into four macro-areas: (1) strategic and decision-making competencies, (2) technical and analytical skills, (3) ethical and legal regulatory knowledge, and (4) leadership and change management. Each category includes specific sub-competencies reflecting the complex, interdisciplinary nature of AI adoption. The findings reveal a predominance of studies focused on tertiary industries and a strong reliance on qualitative research designs. A fit score was applied to assess each contribution's alignment with the review's objectives. By mapping the evolving skillset required for AI readiness, the study offers both theoretical insights and practical orientation for managers, educators, and policymakers seeking to navigate digital transformation responsibly and effectively.

Keywords – Managerial Competencies; Artificial Intelligence; Large Language Models; Systematic Literature Review; Human Resource Management

Paper type - Academic Research Paper

1 Introduction

Artificial Intelligence (AI) is transforming the dynamics of business management by introducing new ways of automating decisions and reshaping work structures. Far from being merely a technical shift, the diffusion of AI represents a socio-organizational transformation that affects the nature of managerial work (Haesevoets et al., 2021; Wilson & Daugherty, 2018). As AI systems become increasingly embedded in operational and strategic processes, managers are expected not only to oversee technological integration but also to exercise judgment in complex hybrid environments where human and machine intelligence coexist and interact (Kolbjørnsrud, 2024).

The concept of competence has been widely debated across educational, psychological, and managerial domains, yet its theoretical foundations remain fragmented. Hoffmann (1999) highlights the distinction between input-based and output-based approaches to competence: the former defines competence as a set of knowledge, skills, and abilities, while the latter emphasizes observable performance and behavior within a specific context. Wong (2020) further stresses that the literature frequently conflates related terms such as skill, ability, and capability, creating conceptual ambiguity. This lack of clarity becomes particularly problematic when attempting to define the competencies needed in dynamic and technologically evolving environments, such as those shaped by AI. Despite such definitional challenges, the managerial literature has produced a range of frameworks aimed at identifying the competencies required for effective leadership. A notable point of agreement across the literature is the centrality of certain competency domains: leadership ability and communication skills repeatedly emerge as critical factors for managers in almost every context; similarly, strategic or analytical thinking competencies are consistently emphasized, reflecting the importance of cognitive skills in managerial roles (Asumeng, 2014; Bolzan De Rezende & Blackwell, 2019; Hawi et al., 2015; Khoshouei et al., 2013). While some models are generic and cross-sectoral, others are tailored to specific industries, highlighting domain-specific competencies such as customer focus or project-based coordination (Bolzan De Rezende & Blackwell, 2019; Hawi et al., 2015). Overall, a widely accepted core set of managerial competencies appears to exist, although often enriched or recontextualized depending on organizational role or environment. However, most of these frameworks were developed before the widespread adoption of AI, and few explicitly incorporate the challenges posed by data-driven and algorithmically mediated decision-making.

The urgency of updating these frameworks has grown in light of the transformations triggered by the increasing diffusion of AI technologies. According to the Future of Jobs Report (2025) by the World Economic Forum, by 2030 only one-third of work-related tasks will be performed exclusively by humans, down from 47% in 2025. Although 92 million jobs are expected to be displaced, approximately 170 million new positions will be created globally, resulting in a net employment gain of 78 million. Simultaneously, 39% of current core competencies are projected to become obsolete or significantly altered. In response, more than half of the global workforce will require reskilling, and 85% of companies plan to invest in workforce development initiatives to close emerging skill gaps (WEF, 2025). Beyond its effect on specific competencies, AI is increasingly recognized as a transformational force that redefines how organizations operate. The concept of AI readiness has emerged to describe an organization's ability to absorb and implement AI in a sustainable manner. It encompasses dimensions such as strategic alignment, resources, knowledge, culture, and data (Jöhnk et al., 2021). This transformation unfolds on multiple levels, influencing organizational processes, group dynamics such as collaboration with algorithms, and individual perceptions including attitudes toward AI, perceived fairness, and concerns over skill obsolescence (Bankins et al., 2024). At the managerial level, this transformation prompts a redefinition of responsibilities and decision-making roles. Rather than being displaced, managers are increasingly positioned as coordinators of hybrid systems where human judgment and algorithmic insight must be integrated. Augmented decision-making models, where AI supports but does not replace human input, are more widely accepted and more effective than full automation (Haesevoets et al., 2021). This view aligns with the emerging concept of collaborative intelligence, whereby new managerial functions are introduced to ensure ethical, strategic, and operational alignment between humans and machines (Wilson & Daugherty, 2018). These insights highlight the growing disconnect between existing models and the evolving managerial reality, reinforcing the need for a structured synthesis of the academic literature to identify and classify AI-related competencies within a coherent and transferable framework.

Recent studies have introduced novel managerial roles such as AI translators, ethical ambassadors, and algorithmic brokers (Lippert & Dresden, 2024), suggesting a shift in the capabilities required by contemporary managers. Yet, the existing research is often fragmented, and theoretical contributions vary in how they define and frame competencies; more specifically, there is a significant lack of systematization regarding the specific managerial competencies required to govern such transformations (Aziz et al., 2024; Bevilacqua et al., 2025). Furthermore, foundational ambiguities persist around key terms such as competence, skill, and ability (Hoffmann, 1999; Wong, 2020), complicating attempts at building a shared taxonomy. This paper seeks to address this gap by conducting a Systematic Literature Review on managerial competencies in the context of AI adoption. Following the PRISMA protocol for article selection and filtering, a curated corpus of peer-reviewed academic contributions was analyzed. Prompt engineering techniques were applied using Large Language Models to extract relevant content related to managerial knowledge, skills, and abilities. Subsequently, a Structured Content Analysis, performed by human judgment, was used to develop a taxonomy of competencies and to group them into coherent conceptual families. The study is guided by three main research questions:

- *RQ1*: Which AI-related competencies are essential for board members and corporate executives in the current technological landscape?
- *RQ2*: How are managerial roles evolving in response to the integration of AI into organizational processes?
- *RQ3*: What ethical and regulatory considerations should shape the competency profile of corporate leadership roles?

The subsequent sections of the article are structured as follows. Section 2 details the methodology employed, highlighting the selection criteria and analytical techniques. Section 3 provides an overview and discussion of the key findings, including the proposed taxonomy along with sectoral and methodological trends. Lastly, Section 4 concludes with reflections and suggestions for future research directions.

2 Methodology

This study employs a Systematic Literature Review as a structured, transparent, and replicable method for synthesizing existing knowledge, minimizing bias through rigorous protocols and standardized procedures (Nightingale, 2009). To ensure methodological transparency, the review process was aligned with the PRISMA framework (Moher et al., 2009), which provides a structured format for article identification, screening, eligibility assessment, and inclusion. The methodology was articulated in three main phases: (i) selection of the article corpus; (ii) AI-assisted extraction of articles' content; and (iii) analysis of managerial competencies through structured content analysis.

2.1 Article Selection Criteria

Regarding scientific literature, the research was conducted using major bibliographic databases, specifically Scopus and Web of Science, with a structured and articulated search strategy. The primary query was constructed by combining terms related to three key dimensions:

(TITLE-ABS("artificial intelligence") OR TITLE-ABS(AI) OR TITLE-ABS("machine learning") OR TITLE-ABS("ML"))
AND
(TITLE-ABS("competenc") OR TITLE-ABS("skill"))
AND
(TITLE-ABS("board of director") OR TITLE-ABS("board member") OR TITLE-ABS(boardroom) OR TITLE-ABS("C-suite") OR TITLE-ABS("C-level") OR TITLE-ABS("chief executive") OR TITLE-ABS(CEO) OR TITLE-ABS(CFO) OR TITLE-ABS(CTO) OR TITLE-ABS("top manage") OR TITLE-ABS("senior manage") OR TITLE-ABS("executive*") OR TITLE-ABS("corporate governance") OR TITLE-ABS("leaders*"))**

The search was further refined by applying filters related to document type (articles and review papers) and language (English), as well as by focusing on specific disciplinary areas (Business, Management, and Social Sciences). To ensure the relevance and quality of the analyzed articles, the following inclusion criteria were applied: (1) peer-reviewed articles and review papers in English; (2) papers focused on managerial skills in the AI era.

Concurrently, the following exclusion criteria were established: (1) purely technical AI studies without a managerial focus; (2) single case studies that are not generalizable; (3) studies focused exclusively on technological aspects without managerial implications; and (4) documents not accessible in full text.

In the first phase, a preliminary screening based on titles and abstracts was conducted to exclude documents clearly unrelated to the research objectives. Each contribution was assessed for its apparent relevance to the core research questions. This process identified 110 relevant documents out of an initial corpus of 189. Due to accessibility issues, only 95 articles were ultimately included in the review.

2.2 AI-assisted extraction through LLMs and prompt engineering
