FOREWORD

IFKAD 2025 - Knowledge Futures: AI, Technology, and the New Business Paradigm

On behalf of the organizing committee, we are delighted to welcome you in Naples for the 20th edition of the annual conference of the International Forum of Knowledge Assets Dynamics (IFKAD 2025). This year, the conference is hosted by the University of Naples Federico II, one of the oldest universities in the world, which has just celebrated 800 years of history. Despite its long tradition, our university has been able to adapt to significant changes over the years, remaining at the forefront of innovation and actively contributing to the current challenges of our society. In this regard, hosting here such an important meeting on the role of Artificial Intelligence and emerging technologies in shaping new business paradigms assumes symbolic relevance.

Thanks to the success of previous editions, IFKAD has emerged as a prominent international scientific forum, aiming to understand and share insights on the role of knowledge in creating organizational value and driving innovation and transformation. In this 20th edition, we intend to enrich the debate on the integration of emerging technologies in knowledge management processes and contribute to delineating the future trajectories of organizations.

Indeed, the spread of digital technologies presents both intriguing challenges and new opportunities for modern businesses while also posing significant risks. In this context, it is crucial to explore how such technologies are transforming industries and society and what are the main related threads for sustainable and inclusive growth.

In this meeting, over 200 contributions will be presented on this topic, covering different areas and perspectives. The key questions motivating the presented studies are:

- How are emerging technologies shaping the future of society and business?
- How can AI be used to create and transfer knowledge within organizations?
- How can digital technologies contribute to social and inclusive innovation?
- How to balance the adoption of digital technologies and human-centered approaches within organizations?
- How risks connected to the adoption of digital technologies may be mitigated?
- How Artificial Intelligence and emerging technologies contribute to link tradition and innovation?

Additional topics, will be reflecting following Special Track themes and questions:

- Navigating AI Adoption in the Service Industry: A Focus on Organizational Dynamics
- New Models and Technologies for Business and Management Innovation
- Diversity Management, Inclusion and Knowledge Creation for Innovation
- Gender Issues in Innovative Society: AI and Technology for New Organizational Paradigms
- Exploring the Intersection of Digital Transformation and Business Model Innovation: Insights and Opportunities
- Entrepreneurship and New Technologies
- Society 5.0: From Knowledge-Based to a Wise-Based Approach
- Advancing Insights in Organizational Behavior, Technologies and Knowledge Management
- Artificial Intelligence and Strategic Knowledge Management
- Navigating AI and Cutting-Edge Technologies in Knowledge Management
- The Role of Advanced Technologies in Innovation 5.0 Scenario as Enabler of Innovation Ecosystems
- Exploring the Impact of Technological Innovation on the Social Sustainability of Agrifood Supply Chains
- Decision Support Methods for Food Waste Reduction in Agri-Food Supply Chain: The KILOWATT Project
- Future Organizations and Strategies: Integrating Humans and Technology for Social and Environmental Impact
- Can the Regenerative Approach Support Manufacturing Industries in Facing Unsustainable Conditions? Building New Business Paradigms on Evidence and Best Practices
- Complexity Approaches to Support New Knowledge and Business Development
- Industry 5.0 and Sustainability: (Re) Shaping Workforce Skills and Management in Multiple Industries and/or Hybrid Organisations
- Artificial Intelligence, Intellectual Capital, and Value Creation: Inspiring New Strategies and Challenges

- The Value of Interdisciplinary Research in Managing Knowledge and Emerging Technologies to Harmonizing Business and Society
- AI and Technology as Catalysts for Knowledge: Shaping Roles, Competences, and Value Creation in Healthcare
- Artificial Intelligence in Medicine: Transforming Healthcare Through Innovation
- Stakeholder Collaboration as a Driver of Knowledge Diffusion and Sustainable Value Creation in Ecosystems
- Technology Management and Business Maturity: Innovative, Sustainable and Secure Digital Transformation Initiatives in Industry
- Accelerating the Shift to a Circular Economy Through Digital Technologies and Knowledge Management
- Translating Feminist Knowledge into Business Practice for Sustainable and Inclusive Strategies, Processes, and Organizations
- Exploring Creative Processes and Decision-Making in the Era of Human & Artificial Intelligence
- Health Technology Assessment and Artificial Intelligence in Healthcare Systems
- The Impact of AI and Digital Transformation on Knowledge Integration Practices in Project Oriented Settings
- The Impact of ESG Factors on Stakeholder Engagement According to AI
- Social Sustainability and AI in the Framework of Knowledge Management
- Shaping the Future: Adapting HEIs to the Evolving Knowledge and Innovation Landscape
- Intelligent Communities and Organisations Driving Innovation by Dealing with Knowledge and Technologies
- Trends in Performance Measurement and Management of Healthcare Organizations: Investigating the Contribution of New Digital Technology in Supporting Knowledge Management and Value Creation
- GenAI for Improving Organizational Processes and Knowledge
- Digital Transformation of Circular Manufacturing Systems
- Artificial Intelligence (AI) and Emerging Technologies for Value Creation in Service-Based Industries
- AI and Knowledge Futures in Cultural Tourism: Shaping a New Paradigm
- Open Innovation Pathways: How Start-ups Thrive in Collaborative Ecosystems
- Questioning the Role of Digital Technologies for Board Decision Making
- Startups and Cultural Heritage Valorization: An Emerging Paradigm

We invite each participant to actively engage in the sessions and discussions to promote the sharing of experiences and create a fruitful context for advancing knowledge and expertise on the topic.

AI Perceptions Across Organizational Levels: Barriers and Drivers of Adoption in the Hotel Industry

Claudia Cozzio[1], Francisco Santos Arteaga[2], Oswin Maurer[1]
[1]Free University of Bolzano, Bolzano, Italy
[2]Universidad Complutense de Madrid, Madrid, Spain

Abstract

This study explores the challenges and opportunities associated with adopting artificial intelligence (AI) in the hotel industry, with a particular focus on how perceptions of adoption differ across hierarchical levels. Drawing on consensus mapping and interviews with 21 participants, ranging from top managers and first-line supervisors to non-managerial staff, the research reveals distinct viewpoints on both the benefits and barriers of AI implementation. While top managers primarily perceive AI as a strategic tool for gaining competitive advantage, non-managerial employees tend to emphasize its potential for reducing operational costs. Despite these perceived benefits, the adoption of AI is hindered by limited awareness, insufficient understanding, and a general resistance to change.

Keywords: Artificial Intelligence (AI), hospitality, drivers, barriers, stakeholders, consensus mapping

Paper type: Academic Research Paper

1 Introduction

Technological advancements have become integral to human life and, notably, the integration of artificial intelligence (AI) has emerged as a prevalent trend in this technological era (Özen and Özgül Katlav, 2023). The hospitality industry stands as the most rapidly expanding sector globally, yielding an estimated $8 trillion in revenue and facilitating the creation of 292 million jobs on a global scale (Ruel and Njoku, 2020). The advent of AI applications is reshaping prevailing business paradigms, digging novel opportunities and challenges for the hospitality domain. Hence, in the contemporary landscape of the hospitality industry, the integration of Artificial Intelligence (AI) technologies has emerged as a pivotal strategy to enhance operational efficiency, elevate guest experiences, and drive competitive advantage. However, the adoption of AI within the hotel sector is not devoid of challenges, as it necessitates navigating multifaceted barriers to achieve user acceptance (Morosan and Dursun-Cengizci, 2024).

Scholarly attention has predominantly focused on evaluating the costs and benefits associated with AI implementation in the hospitality sector. Notably, AI streamlines tasks such as self-check-in/out, room services, housekeeping, concierge services, and chatbot interactions, enhancing efficiency while reducing human costs (Ersoy and Ehtiyar, 2023; Zhu et al., 2023). A distinct research avenue examines costumer acceptance or rejection of AI technology, with findings indicating varying levels of convenience and efficiency perception among costumers due to technological complexity and lack of knowledge (Rasheet et al., 2023; Vorobeva et al., 2023). Although current studies primarily analyze the impacts of AI from the standpoint of customers, there is a justified need for additional exploration into its effects on employees (Rasheed et al., 2024; Li et al., 2022). Thus, it becomes imperative to explore the implications of AI technologies on hospitality employees, thus shedding light on emerging opportunities and threats in order to guide competency development aligned with evolving technology. This paper delves into the intricate dynamics of AI adoption across different hierarchical levels within the hotel industry, elucidating the challenges and opportunities that characterize this transformative process.

Specifically, this research engages with n. 21 information-rich participants spanning across varying roles within the hotel industry, including top managers, first-line managers, and non-managerial employees. Through semi-structured interviews and employing the consensus mapping approach (Taracki et al., 2014), this study endeavors to determine the individual perceptions of these distinct groups regarding the barriers and drivers influencing AI adoption.

2 Theoretical background

2.1 Drivers to AI adoption in hospitality

Following Rasheed et al. (2024), drivers to the adoption of AI in hospitality can be categorized in three distinct groups: functional, emotional and situational.

Functional drivers refer to the tangible advantages derived from the fundamental capabilities of AI technologies. Scholarly investigations have consistently emphasized the pivotal roles of perceived usefulness (PU) in shaping consumers' attitudes towards AI adoption (Park et al., 2021). For instance, AI facilitates humans in efficiently accomplishing various tasks, including self-check-in or out, housekeeping, concierge services, and chatbot interactions for information retrieval (Wong et al., 2023; Zhu et al., 2023; Law er al., 2023; Li et al., 2021). Hence, *operational efficiency* pertains to the tangible benefits stemming from the core features of AI technologies, specifically in terms of optimizing processes. Furthermore, AI adoption correlates with reduced workloads and heightened productivity among employees (Ersoy and Ehtiyar, 2023; Buhalis and Moldavska, 2022). Tasks such as data analysis, customer service, and administrative duties are streamlined, allowing staff to focus on higher-value activities. Indeed, prior studies underscore AI technologies' ability to optimize inventory management and streamline processes, leading to *cost savings* for businesses. In addition, factors such as perceived interactivity and innovativeness of AI technologies positively contribute to intentions to adopt and repurchase these technologies (Go et al., 2020; Pillai and Sivathanu, 2020). More specifically, AI technologies' ability to deliver *personalized experiences* based on individual preferences and behaviors fosters positive attitudes towards AI adoption, as users perceive the technology as valuable and relevant to their customization needs. Indeed, service customization triggers greater customers' knowledge, emotional attachment and behavioral commitment (Buehring & O'Mahony, 2019).

Shifting the focus away from the functional benefits for businesses, emotional drivers explore the complex domain of consumer sentiments and motivations towards AI adoption. Prior studies underscore the relevance of perceived human likeness and intrinsic motivations, moderated by socio-demographic aspects such as age, gender, and income in shaping consumers' propensity towards AI adoption in the hospitality sector (Belanche et al., 2020). AI technologies streamline processes (Rasheed et al., 2024), provide personalized experiences (Go et al., 2020), and offer real-time support (Li et al., 2021), enhancing overall service quality. Hence, studies suggest a positive correlation between AI adoption and *heightened customer satisfaction levels*, underscoring the importance of AI-driven innovations in meeting evolving consumer demand (Alam et al., 2023).

Focusing on the macro level, situational drivers are facilitating conditions that are key contextual drivers in AI adoption intentions. The macro context where users interact with AI technologies has a considerable impact on their perceptions toward AI value and usefulness, ultimately either pushing or inhibiting adoption behaviors (Mariani and Borghi, 2023; Lin et al., 2020). Both mimetic and first-mover pressure relates to the contextual factors influencing user attitudes and behaviors towards AI adoption, specifically in terms of gaining a *competitive edge* through the use of AI technologies.

2.2 Barriers to AI adoption

Barriers towards AI adoption in hospitality are mainly grouped into value, risk and usage barriers (Rasheed et al, 2024).

When users perceive that the cost of adopting a new technology outweighs the potential benefits or returns, they may view it as offering less value compared to existing alternatives. Hence, value barriers may arise, thus leading to reluctance in adopting the new technology hindering its acceptance (Laukkanen et al., 2008). Scholarly, *high implementation costs* (i.e., substantial upfront costs for technology acquisition, integration, training) and concerns regarding return on investment (ROI) are considered value barriers due to their potential to negatively influence user perceptions of a new product or service (Rasheed et al., 2023).

Prior studies unveil the emergence of risk barriers, referring to the degree of uncertainty and associated risks inherent in novel products, services or technologies, shaped by user perceptions or experiences (Chen and Kuo, 2017). *Privacy and security* concerns are categorized under risk barriers, revolving around uncertainties regarding compliance with regulations like GDPR or CCPA to uphold customer trust (Rasheed et al., 2023).

While few studies elucidate no significant relationship between technological anxiety and the intention to adopt AI (Pillai and Sivathanu, 2020), scholars tend to acknowledge usage barriers that include a mismatch between the new technology and the user prior experiences (Antioco and Kleijnen, 2010). For instance, existing research highlights factors such as the *lack of awareness and understanding* that reflects the incompatibility of AI technology with user´s existing experiences, habits, and acceptance standards. Businesses may not fully comprehend the potential of AI and its applications, indicating a lack of awareness as a barrier to adoption (Alam

et al., 2023; Huang et al., 2022). Furthermore, Li et al. (2019) show a significant positive correlation between awareness of AI and robotics and employees' intention to turnover. This underscores the reluctance to embrace AI technologies due to fear of job displacement, changes in workflow, or perceived threats to professional roles. Consequently, *resistance to change* signifies the incongruity between AI and current workflow and roles, impeding adoption. Additionally, Rasheed et al. (2023) classify *technological complexity* as a usage barrier, encompassing challenges related to AI service complexity and the requisite technical expertise, often lacking within organizations. Technical complexity represents a usage barrier to AI adoption due to difficulties in implementing and integrating AI solutions into existing systems and workflows.

3 Methodology

To explore the intriguing issues of challenges and opportunities toward AI adoption in the hotel industry, we conducted semi-structured face-to-face interviews with n. 21 key information-rich stakeholders occupying diverse hierarchical positions in the hotel industry. Following the managerial pyramid developed by Robbins et al. (2020), we classified workers grouping them as (i) top managers, (ii) first-line managers, (iii) non-managerial employees.

From the literature review, five main *themes* relative to drivers (i.e., operational efficiency, competitive advantage, enhanced customer experience, service personalization, cost saving) and barriers (i.e., lack of awareness and understanding, privacy and security concerns, resistance to change, technological complexity, cost concerns) emerge. We asked the study participants to prioritize the five categories related to the drivers and barriers by ranking them in order of importance. The output was a personal ranking of factors that propel (inhibit) AI adoption that ranged from the most important driver (barrier) to the least important driver (barrier). We used the responses to assess the degree of consensus within and between diverse hierarchical groups (i.e., top manager, first-line manager, non-managerial employees) using the methodology of consensus mapping developed by Tarakci et al. (2014).

We present a brief description of each informant in Table 1.

Table 1: Informants details

Top managers N=7	Gender	Male (100%); Female (0%)
	Age	18–30 (0%); 31–40 (43%); 41–50 (57%); 51–60 (0%)
First-line managers N=7	Gender	Male (72%); Female (28%)
	Age	18–30 (0%); 31–40 (28%); 41–50 (72%); 51–60 (0%)
Non-managerial employee N=7	Gender	Male (43%); Female (57%)
	Age	18–30 (0%); 31–40 (43%); 41–50 (57%); 51–60 (0%)

4 Results and Discussion

Top managers, first-line managers and non-managerial employees assigned priorities to five different categories of drivers and barriers. The output obtained consisted in a set of six matrices describing the corresponding rankings, one per group of respondents evaluating either drivers or barriers. Two measures of consensus have been computed to analyze the responses received (Cozzio & Furlan, 2023). The first one focuses on the degree of consensus within the members of each group and follows from principal component analysis (PCA). The second measure analyzes consensus between groups and is based on classic multidimensional scaling. All computations have been performed in MATLAB.

4.1 Assessing within-group consensus

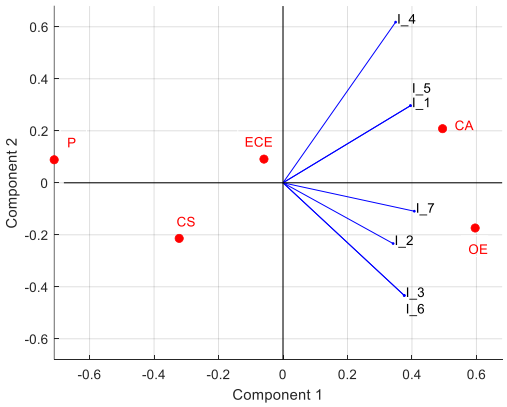
The degree of consensus within a group is obtained by applying the vector model of unfolding (VMU) defined by Tarakci et al. (2014), which transposes the standard data matrix used in PCA (Borg and Groenen, 2005). More precisely, we apply PCA to a matrix where respondents define the columns and the categories ranked are placed in the rows.

Consider the standardized data matrix H that lists the m categories evaluated in its rows and the respondents along its n columns. The VMU method proposed by Tarakci et al. (2014) in p dimensions is based on the minimization of the sum of the squared errors derived from H and the low dimensional representation XA' and defined as follows

$$L_{VMU}(X, A) = \|H - XA'\|^2 = \sum_{ij} e_{ij}^2 \quad (1)$$

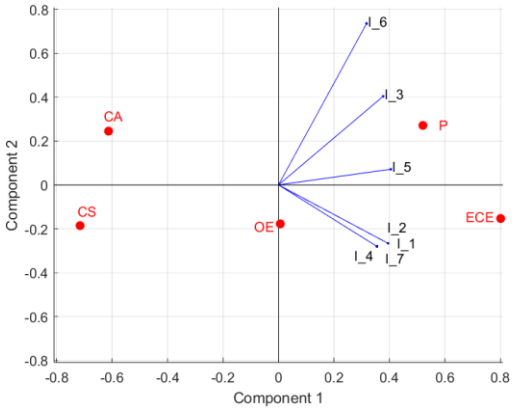
where X is an $m \times p$ matrix of object scores and A is an $n \times p$ matrix of component loadings for the first p components.

The component loadings in A are the correlations between the object scores for each category and the evaluations of each respondent. Tarakci et al. (2014) used this fact to define the consensus within each group as the length of the average component loading vectors in A across its first two components



$$\alpha = \sqrt{\sum_{p=1}^{2}\left(\sum_{i}\frac{a_{ip}}{n}\right)^{2}} \tag{2}$$

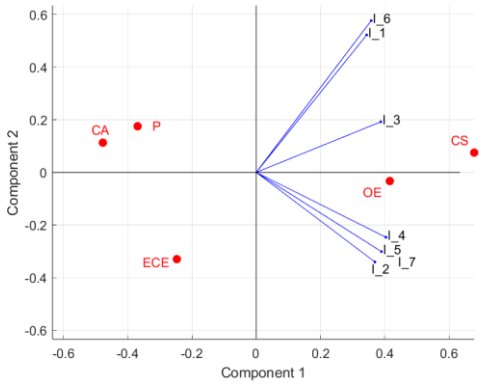
where a_{ip} denotes the p-th component loading for respondent i. As is the case in PCA, the results obtained can be represented in the Euclidean plane using a biplot. The categories are described in order of preference relative to the horizontal axis, while the respondents composing each group are depicted as vectors.



The correlation between respondents can be approximated via the cosine of the angle between their vectorial representations (Linting et al., 2007). Larger angles describe less similar evaluations, while the opposite is true for smaller angles. The same intuition applies to the consensus within the group, with tighter clusters of vectors demonstrating a higher degree of consensus.

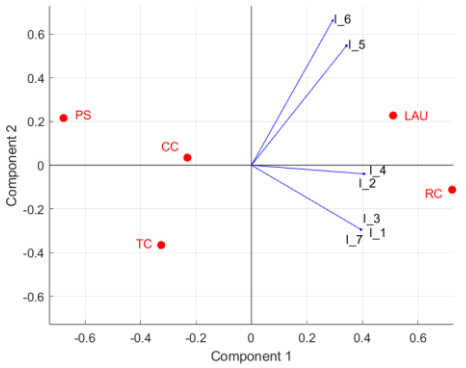
The preferences of the different respondents are represented by the orthogonal projection of each category item of their corresponding vectors. The farther an item is projected into the vector the more preferred it is, while the items projected in the opposite direction are less preferred. In this regard, the horizontal axis corresponds to the prototypical member representing the opinion of the group. That is, the projection on the horizontal axis represents the overall ranking of the group.

Figures 1 and 2 illustrate the biplots defining the degree of within-group consensus for each group of respondents when considering drivers and barriers, respectively.



Hotel Managers

First-line Managers



Notation
OE: Operational efficiency
CA: Competitive advantage
ECE: Enhanced customer experience
P: Personalization
CS: Cost saving

Respondents
I_1 to I_7 each referring to the corresponding members from a given group

Non-managerial Employees

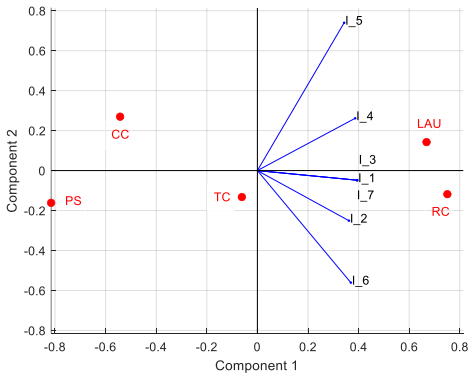


Figure 1: Within-group consensus (drivers)

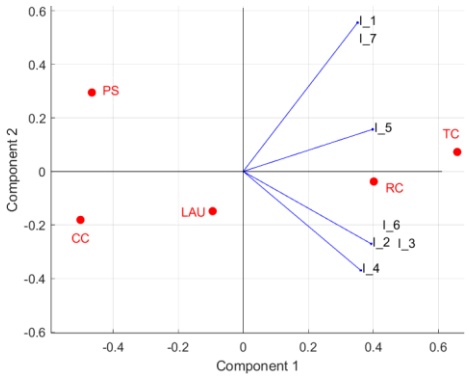

Hotel Managers

Notation
PS: Privacy & Security
CC: Cost concerns
LAU: Lack of awareness and understanding
TC: Technical complexity
RC: Resistance to change

Respondents
I_1 to I_7 each referring to the corresponding members from a given group

First-line Managers

Non-managerial Employees

Figure 2: Within-group consensus (barriers)

Based on the projections of the items on the horizontal, *Operational efficiency, Competitive advantage, and Enhanced customer experience (satisfaction)* emerge as primary drivers for top top managers, whereas first-line managers prioritize *Enhanced customer experience, Personalization, and Operational efficiency*. Non-managerial employees emphasize *Cost saving, Operational efficiency and Enhanced customer experience*. Overall, all groups recognize the benefits of AI adoption for operational efficiency and customer satisfaction. This highlights significant differences in their orientations, with top managers focusing outward and non-managerial employees inward. For instance, while AI adoption offers added value for top managers by providing a competitive advantage, non-managerial employees perceive it primarily as a means of cost-saving.

In terms of barriers, top managers prioritize *Resistance to change, Lack of awareness and understanding, and Cost concerns*. First-line managers rank *Resistance to change, Lack of awareness and understanding, and Technological complexity* as the most significant inhibitors. Conversely, non-managerial employees value *Technological complexity, Resistance to change, and Lack of awareness and understanding*. *Privacy and security concerns* are consistently ranked as the least important across all groups. The identification of resistance to change, lack of awareness, and technological complexity as predominant barriers across hierarchical levels signifies a degree of consensus, albeit weak, regarding the critical challenges impeding AI adoption in the hotel industry.

4.2 Assessing between-group consensus

Consensus between groups is measured in terms of the correlation exhibited by the ranking preferences of the prototypical group members. More precisely, the measure proposed by Tarakci et al. (2014), denoted by $r(A,B)$, is determined by the correlation of the object scores of the categories on the first principal component for respondent groups A and B. The higher this value, bounded between zero and one, the higher the consensus between both groups.

The distance between the groups of respondents defining the symmetric matrix of correlations is computed using classical multidimensional scaling (MDS). The corresponding output obtained is represented in Figures 3 and 4 for the drivers and the barriers, respectively.

Tarakci et al. (2014) suggested defining ten rings to describe the difference in correlations relative to the group placed at the center of the plot. In this regard, a higher level of consensus is observed as the distance between points decreases, representing a more aligned evaluation between groups. In our graphical representation, top managers are at the center of the MDS plots. The distance between the bubbles shows the degree of consensus between the groups. The sizes of the bubbles denote the degree of the within-group consensus in each group (α), and the rings that surround the bubbles depict the size of a bubble when there is perfect consensus within a group (α = 1).

Clearly, between-group consensus differs markedly across groups of respondents. First-line managers and non-managerial employees display substantial differences with respect to top managers when considering the drivers. Consensus between groups increases when considering the barriers, though the correlations between groups remain quite low also in this case.

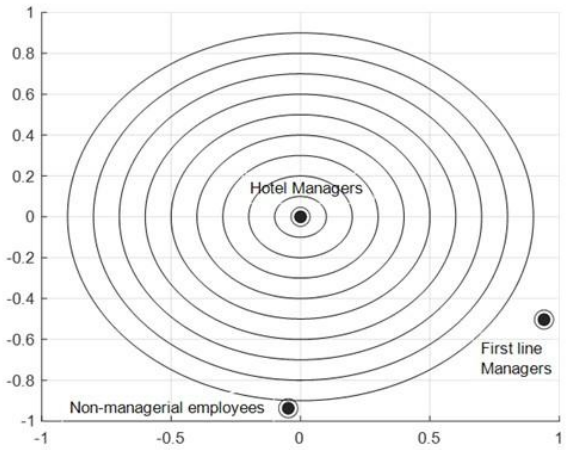

Figure 3: Between-group consensus (drivers)

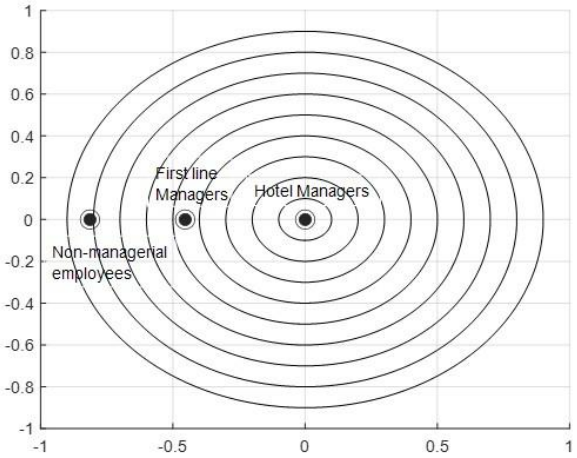

Figure 4: Between-group consensus (barriers)

5 Conclusions

5.1 Theoretical implications

This study constitutes a pioneering investigation into the implications of AI adoption from an employee-centric perspective, diverging from the prevalent customer-focused approach (Wong et al., 2023; Huang and Zheng, 2023). Notably, the segmentation of participants into three cohorts across varied hierarchical levels - top managers, first-line managers, and non-managerial employees - facilitates a nuanced exploration of multifaced viewpoints on AI adoption within hotel settings. Operational efficiency and enhanced customer experience are pivotal drivers across all groups (Ersoy and Ehtiyar, 2023; Zhu et al., 2023). However, our research reveals nuanced specificities, providing profound insights into AI acceptance within distinct hierarchical strata. Specifically, our findings highlight differences in orientation, with top managers focusing outwardly (i.e., competitive advantage) and non-managerial employees oriented inwardly (i.e., cost saving).

Second, our study elucidates both the impediments inhibiting the widespread adoption of AI and the facilitators propelling AI uptake within hotel operations, thus addressing the call for additional exploration on the employees perspective (Rasheed et al., 2024; Li et al., 2022). Through rigorous analysis of interview data and consensus mapping techniques, this study seeks to distill key themes, patterns, and divergences in perceptions between hierarchical levels, thereby identifying salient factors shaping the trajectory of AI adoption in the hotel industry.

Third, our study advances understandings on multifaceted barriers to achieve consumer acceptance, by acknowledging the significance of effective communication in facilitating organizational change (Morosan and Dursun-Cengizci, 2024). Hence, we advocate for the implementation of tailored communication strategies. These strategies aim to heighten awareness and cultivate acceptance of AI technologies among various hierarchical groups, representing a significant advancement in adoption acceptance.

5.2 Managerial implications

Tailored communication strategies should be designed to address the specific needs and concerns of different hierarchical groups within the organization. While emphasizing operational efficiency and enhanced customer experience is essential, specific considerations must be made to enhance the effectiveness of these strategies.

For non-managerial employees, highlighting the cost-saving implications of AI adoption can bolster their acceptance levels. Emphasizing how AI technologies streamline processes and reduce operational costs helps non-managerial employees perceive AI as beneficial to their roles and daily tasks.

Similarly, first-line managers should be informed about the potential for service personalization offered by AI technologies. By demonstrating how AI can facilitate personalized experiences for customers based on their preferences and behaviors, first-line managers are more likely to recognize the value of AI in improving customer satisfaction and loyalty.

5.3 Limitations and future research direction

While our study provides valuable insights into AI adoption within the hospitality sector, it is important to acknowledge its limitations. One significant limitation is the rather focused sample, which primarily consisted of participants from the hotel industry. This narrow focus may limit the generalizability of our findings to other segments of the broader tourism industry. Additionally, our study focused solely on perceptions within hierarchical positions in hotels, potentially overlooking valuable insights from other stakeholders, such as customers or AI technology providers.

To address these limitations and expand the scope of future research, several promising avenues emerge. Firstly, future studies could explore AI adoption across various segments of the broader tourism industry, including airlines, cruise lines, and travel agencies. This broader perspective would provide a more comprehensive understanding of the challenges and opportunities associated with AI adoption within different sectors of the tourism industry.

Furthermore, future research could investigate the perceptions and attitudes of other stakeholders beyond employees, such as customers, AI technology providers, and regulatory bodies. Understanding the perspectives of these diverse stakeholders could shed light on additional barriers and facilitators to AI adoption and inform more holistic strategies for AI implementation.

6 Ethics declaration

This research did not require formal ethical approval, as it did not involve sensitive personal data, vulnerable populations, or invasive procedures. Participation in interviews was voluntary, and informed consent was obtained from all respondents.

7 AI declaration

No generative AI tools were used in the writing, editing, data analysis, or development of this paper. All content is the result of the author's original work.

Artificial Intelligence Adoption in South Tyrolean Hospitality: A Qualitative Analysis

Tommaso Di Fonzo
Free University of Bolzano, Bolzano, Italy

Abstract

This study aims to analyse and understand perceptions of artificial intelligence and its use in the South Tyrolean hospitality sector, with particular attention to the different organizational roles held by employees. To this end, 44 semi-structured interviews were conducted, involving both managerial staff and employees in non-managerial positions. This approach allowed for the collection of a broad and diverse range of perspectives. Data analysis was carried out using a qualitative approach, deemed the most suitable for exploring personal perceptions and experiences. The NVivo software was used to support data processing and organization, facilitating the identification of recurring themes and differences between the groups analysed. The results highlight significant differences in familiarity with artificial intelligence. Managers, in particular, demonstrate a greater understanding of the topic, often illustrated with concrete examples of artificial intelligence usage within their establishments. Moreover, they tend to have a more positive outlook, perceiving the benefits of artificial intelligence as outweighing the associated costs. Interestingly, both groups identified the current staff shortage as a strong incentive for adopting artificial intelligence, which is seen as a potential solution to this challenge. At the same time, they recognize the lack of specific skills among employees as one of the main barriers to effective AI implementation, which in turn impacts the availability of qualified personnel.

Keywords: Artificial intelligence, AI in hospitality, Perception toward AI, AI benefits and AI challenges.

Paper type: Academic Research Paper

1 Introduction

1.1 Context of the study

South Tyrol, an autonomous region in northern Italy bordering Switzerland and Austria, is known for its stunning mountainous landscape, dominated by the Dolomites, a UNESCO World Heritage Site. The region's hospitality sector, a key part of the local economy, is built on a tradition of excellent service, enriched by a unique mix of alpine and Mediterranean cultures. This makes it a top destination for global tourists, as reflected in the latest ASTAT report showing over 36 million overnight stays in 2022/2023 (Südtiroler Informatik AG | Informatica Alto Adige SPA, 2024). Despite its notable achievements, the hotel industry, akin to many other sectors, remains susceptible to the dynamic transformations brought about by technological advancements and evolving consumer expectations. In light of these changes, Artificial Intelligence (AI) emerges as a highly promising technology for addressing both contemporary and future challenges in the hospitality sector. Specifically, AI applications cover a broad spectrum of areas, including the optimization of daily operations, personalization of customer experiences, human resource management, predictive maintenance, energy management and strategic planning. Notably, the adoption of intelligent systems can play a pivotal role in boosting operational efficiency, lowering expenses, and elevating service quality, all critical factors for the success of hospitality businesses. This is particularly important because, as highlighted by (Anderson & Sullivan, 1993), there is a direct link between the quality of service and customer satisfaction, which ultimately translates into loyalty and repurchasing intentions. Nevertheless, despite the recognized potential of AI, its implementation across the industry is far from uniform. In fact, according to a McKinsey report (2023), the tourism industry ranks third to last out of 22 industries examined in terms of technology adoption. This heterogeneity is influenced by various factors, such as the size of the business, organizational culture, and the perceptions of different stakeholders within the organizations themselves. Therefore, in the South Tyrolean context, which is characterized by a diverse entrepreneurial fabric and a strong presence of family-run small and medium-sized enterprises, these dynamics offer a particularly intriguing scenario for analysing how these entities engage with AI.

2 Literature Review

2.1 Artificial Intelligence: A Journey through its definition and dimensions

Humans are widely regarded as the most intelligent species on Earth due to their remarkable ability to solve problems and capacity to process large volumes of data. This intelligence reflects a range of skills, including analytical thinking, logical reasoning, statistical understanding, and computational prowess. In a similar vein, Artificial Intelligence (AI) is a technology specifically designed to enable machines and robots to tackle complex problems in a manner that closely parallels human abilities. By combining these cognitive skills, AI significantly enhances the functionality of machines and robots (Mohan & Senthilkumar, 2023).

To gain a clearer understanding of AI, we can break down the term "Artificial Intelligence" into its two fundamental components: "intelligence," signifying the ability to engage in autonomous reasoning and "artificial," indicating something that is human made. Consequently, AI can be defined as a human-crafted thinking ability, as noted by Limna et al. (2021). Moreover, AI is often described as a "family of technologies" that not only recognizes and analyses data but also acts, learns, and demonstrates advanced aspects of human intelligence. This comprehensive view of AI is supported by various scholars, including McCartney & McCartney (2020) and Huang & Rust (2018). In other words, AI represents the capability of technological devices to simulate and even replicate human intelligence through advanced programming and sophisticated algorithms (Kumar et al., 2019; Siau & Yang, 2017). Additionally, as highlighted by Littman et al. (2022), designing and implementing

advanced algorithms that enable AI to replicate human intelligence requires careful consideration of five fundamental aspects: learning, reasoning, problem-solving, perception, and linguistic intelligence. These aspects are essential because they have enabled the creation of a wide range of technologies and services that are increasingly integral to daily life. To elaborate on these aspects, we start with learning, which refers to the acquisition of new information and the enhancement of existing skills through various sources such as books, real-life experiences, and expert instruction. In contrast, reasoning involves the process that provides the essential standards and principles for evaluation, prediction, and decision-making across different contexts. There are two types of reasoning: generalized reasoning, which relies on broad observations and assertions, and logical reasoning, which is grounded in data, facts, precise statements, and documented or observed occurrences. While the former may not always yield accurate conclusions, the latter is generally more reliable. Next, problem-solving entails identifying the root cause of an issue and exploring potential solutions. This process involves understanding the problem, making decisions, and investigating various possible solutions before selecting the most effective one. To resolve the problem efficiently and swiftly, the optimal solution must be chosen from the available options. Furthermore, perception involves the process of collecting, interpreting, selecting, and organizing relevant information from raw input. While human perception is shaped by previous experiences, sensory organs, and environmental context, artificial intelligence relies on logically derived perceptions through artificial sensor mechanisms in conjunction with data. Lastly, linguistic intelligence pertains to a person's skill in using, understanding, reading, and writing verbal information in multiple languages. This intelligence is a critical component of communication and is essential for both logical and analytical comprehension.

In terms of classification, artificial intelligence, frequently characterized as a group of technologies, can be divided into three principal categories based on its level of capability: narrow AI, general AI, and super intelligent AI. To begin with, Narrow AI (also known as Weak AI) refers to artificial intelligence created to carry out specific tasks, such as recognizing faces, performing online searches, or controlling a vehicle. The majority of AI systems in use today, including those capable of engaging with intricate games like chess, belong to this category, functioning within a restricted and predefined scope or set of circumstances. In contrast, General AI (Strong AI) is endowed with broad cognitive abilities similar to human intelligence, allowing it to tackle new and unknown tasks independently. This type of AI possesses the ability to analyse, learn, and apply its intelligence to address any problem independently, without human intervention. Ultimately, Superintelligent AI signifies a futuristic advancement where machines might exceed human intelligence across all areas, including creativity, overall wisdom, and problem-solving abilities.

2.2 Shaping tomorrow's hotel: AI's strengths, weaknesses, opportunities and threats

The first figure presents a detailed SWOT analysis concerning the adoption of artificial intelligence (AI) in the hotel sector, offering a structured view of both the strengths, weaknesses, opportunities and threats that accompany this technological integration. By providing a balanced perspective, this analysis highlights key factors that need to be considered in the process.

One of the primary benefits of AI implementation in hotels is the improvement of operational efficiency alongside enhanced guest experience. For example, it enables better decision-making through data analytics, leading to more informed and accurate conclusions. In addition, AI significantly reduces human error, thereby improving the overall reliability of hotel services. Furthermore, another strength lies in the streamlining of work tasks, which not only makes daily operations more efficient but also allows staff to focus on higher-value activities. Moreover, AI plays a crucial role in predictive maintenance, ensuring that potential issues are addressed proactively, which in turn minimizes disruptions. Beyond these operational advantages, AI offers the ability to provide customer support around the clock, guaranteeing guests access to at any time, thereby enhancing overall guest satisfaction. Additionally, the technology enables a more personalized guest experience, as it tailors services to individual preferences.

However, despite these significant benefits, the adoption of AI in the hospitality sector is not without its drawbacks. A key concern is the reduction in human interaction, a crucial aspect in an industry rooted in personal connections. Guests often appreciate the warmth and empathy that human staff provide, qualities that AI at its current stage, is unable to replicate. Moreover, the unfamiliarity with AI technology among hotel staff and management presents a significant obstacle, potentially hindering both the adoption and effective utilization of AI systems. Alongside these challenges, financial capacity also emerges as a critical weakness, particularly for smaller hotels that may struggle with the substantial upfront investment required for AI implementation. Furthermore, integrating AI with existing property management systems (PMS) can pose difficulties, often requiring advanced technical skills and risking potential disruptions to current operations.

Despite these weaknesses, AI adoption also presents numerous opportunities. Most notably, it offers the potential to create new job roles, particularly in technical fields related to AI maintenance and management. Additionally, AI has the potential to reduce language and cultural barriers by offering AI-powered translation services, which can enhance communication with international guests and improve their overall experience. Moreover, AI brings notable improvements in safety and security by enhancing surveillance systems and

utilizing predictive analytics to mitigate potential risks.

For introverted guests, AI offers the advantage of accessing services without requiring direct human interaction, creating a more comfortable and tailored stay. Furthermore, AI contributes to sustainable development by optimizing resource usage, thereby helping hotels meet their environmental goals. Additionally, AI assists in managing occupancy and guest flow more effectively, helping to prevent problems related to overtourism. Nevertheless, several threats emerge with the integration of AI in the hotel sector. A major concern is the potential loss of some employees, as automation could replace jobs that traditionally focus on routine tasks. Moreover, AI systems tend to require considerable energy resources, which could drive up operational costs and negatively affect the environment. Data privacy risks represent another pressing issue, as AI systems often handle vast amounts of personal and financial information, making them vulnerable to potential cyberattacks. Additionally, there is a growing risk of over-reliance on AI, where excessive automation may ultimately compromise the quality of human interaction and service that guests have come to expect from a hotel.

In conclusion, while AI offers substantial benefits in terms of operational efficiency and guest experience, its adoption in the hotel industry brings with it significant challenges. It is essential to strike a balance between technological advancements and maintaining the human touch, a hallmark of hospitality. Addressing weaknesses, such as financial limitations and integration difficulties, while also mitigating threats like job displacement and data privacy risks, will be crucial in ensuring the sustainable integration of AI in the hotel sector.

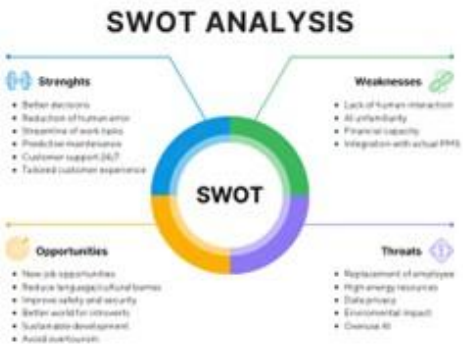

Figure 1: AI Swot analysis

2.3 Diffusion of innovation theory: key factors influencing adoption of new technology

The Diffusion of Innovations Theory, developed by Rogers (2003), provides a useful lens for analyzing how artificial intelligence (AI) technologies are adopted in the hospitality and tourism industries. This theory outlines five key attributes that influence how both individuals and organizations accept new technologies such as AI: relative advantage, compatibility, complexity, trialability, and observability.

To start with, relative advantage is understood as the extent to which an innovation is seen as superior to the idea or product it replaces. This attribute can be further broken down into several secondary considerations. One important factor is economic benefits, which relate to how innovations can drive market growth through increased customer bases and sales, or by allowing consumers to find better deals through price comparisons (Hasin & Smith, 2016). Another factor is efficiency, which is assessed based on the time saving potential of the innovation (Kang et al., 2015). A third aspect, interactivity, encompasses the enhancement of communication, which includes a sense of connectivity, effective information exchange (Coursaris & Sung, 2012), and timely and synchronized information sharing (Buhalis & Sinarta, 2019; Kang et al., 2015).

In addition, compatibility is another crucial attribute, defined as the extent to which an innovation aligns with the values, past experiences, and needs of its potential users.

Compatibility can be considered from two perspectives: work-related and value related. In terms of work, it involves the degree to which technology aligns with employees' current and preferred work methods (Meuter et al., 2005; Moore & Benbasat, 1991). On the other hand, the value-related dimension examines how well technology fits with users' social norms or desired lifestyles (Meuter et al., 2005; Tan & Teo, 2000).

The third attribute, complexity, is described as the degree to which a new technology is perceived to be challenging to comprehend and use. This attribute is often synonymous with terms like perceived ease of use (Moore & Benbasat, 1991), simplicity (Atkinson, 2007), or effort expectancy (Kang et al., 2015). To evaluate complexity, one must consider how easy it is to acquire, learn, understand, and operate a particular technology (Meuter et al., 2005; Tan & Teo, 2000; Hasin & Smith, 2016).

Furthermore, trialability, another attribute identified by Rogers, refers to the extent to which new technology can be tested or experimented with on a limited scale before full adoption. The concept of trialability aims to reduce uncertainty about innovation (Tan & Teo, 2000). It is measured by how easily a technology can be tested before a company or individual commits fully to its use (Hasin & Smith, 2016; Moore & Benbasat, 1991) or before making significant investments (Meuter et al., 2005).

Finally, observability is defined as the degree to which the outcomes of an innovation are visible to others. This concept is sometimes also referred to as visibility or result demonstrability (Moore & Benbasat, 1991). Observability can be assessed by looking at the visible improvements in work-related knowledge (Atkinson, 2007), the positive feedback and word-of-mouth generated by the technology (Atkinson, 2007; Hasin & Smith, 2016), the ease with which the use and results of the technology can be communicated (Meuter et al., 2005; Moore & Benbasat, 1991), and the actual physical presence of the technology (Al-Gahtani, 2003).

By understanding these five key factors organizations can better gauge the potential success of AI adoption within their specific contexts.

3 Methods

A qualitative approach was adopted due to its effectiveness in exploring complex phenomena such as perceptions and attitudes, which often cannot be fully captured through quantitative methods. Qualitative research prioritizes depth over breadth, allowing for a more nuanced understanding of human experiences and the meanings individuals attribute to them.

To collect the data, a questionnaire based on semi-structured interviews was used. It was designed to investigate individual opinions and experiences regarding the adoption of Artificial Intelligence (AI) in the hospitality sector. The questions, mainly open-ended, aimed to explore both perceptions and the concrete ways in which these technologies are used. The survey began with a closed-ended question intended to determine whether participants had direct experience with AI-based tools. If the answer was affirmative, respondents were asked to specify the departments involved and to provide concrete examples of application.

Subsequent sections of the questionnaire focused on gathering prospective reflections on the departments where AI is expected to become more prevalent, as well as delving into use cases and future implications. A central part of the investigation focused on the factors that facilitate or hinder the adoption of artificial intelligence in the hospitality sector, with particular attention to the expected benefits and perceived costs. To complement this framework, a brief section was included on blockchain technology to assess its potential implications for improving the customer experience. Finally, the questionnaire explored the potential future challenges associated with artificial intelligence.

In total, 44 complete interviews were collected. The sample consisted of 98% personnel working in family-run hotels and 2% in hotel chains. Additionally, 87% of respondents held managerial positions, while the remaining 13% were in operational roles.

In detail, among the managerial profiles: 61% were hotel managers, 14% marketing managers, 5% front office managers, 5% junior managers, and 2% operations and quality managers. Among the non-managerial roles, there was a high concentration of receptionists (11%) and a single executive assistant (2%).

Once data collection was completed, the interviews were imported into NVivo software for qualitative analysis. The process began with the creation of the macro-categories “manager” and “non-manager”, followed by thematic subcodes such as “drivers”, “challenges”, “benefits”, “costs”, “familiarity”, “no familiarity”, and “actual use”. This approach ensured a systematic coding of the content, facilitating the analysis and interpretation of emerging perceptions.

In addition to coding, NVivo’s word frequency function was used to identify the most recurring terms within each category.

Parameters such as minimum word length, maximum number of words to display, and the “word stem” and “synonyms” options were set to group similar terms and enhance analytical precision. The most frequent words (up to 50 or 100) were then also analysed from a semantic perspective to aid in the extraction of sentiment-based perceptions.

Overall, the structure of the investigation made it possible to obtain a detailed and comprehensive understanding of the role of emerging technologies in the transformation process of the hospitality sector.

4 Findings

The contribution of this study unfolds along three main lines. Firstly, it aims to fill a significant gap in the existing literature by representing the first investigation into perceptions of artificial intelligence within the South Tyrolean context, a region of particular relevance to the national tourism landscape. In this regard, the most recent ASTAT report highlights over 36 million overnight stays recorded during the 2022/2023 period (Südtiroler Informatik AG | Informatica Alto Adige SPA, 2024).

Secondly, the study aims to identify the main enabling factors and the most commonly perceived challenges related to the adoption and use of artificial intelligence, thereby providing a comprehensive overview of the dynamics that influence its integration within the sector.

In this context, the interview analysis reveals that both managers and non-managerial employees recognize a common set of drivers encouraging the adoption of artificial intelligence (AI) in the hospitality sector.

First, both groups identify staff shortages as a critical issue for which AI implementation can offer an effective remedy. Indeed, the automation of certain operational tasks is perceived as a viable means to address human resource constraints while concurrently reducing the personnel-related operating costs.

A second shared driver concerns the enhancement of operational efficiency. Both managers and employees emphasize that AI can accelerate the execution of routine activities, thereby lightening the workload and enabling staff to focus on higher-value tasks, particularly those involving direct human interaction and relational competencies. Beyond improving service quality, this shift contributes to the creation of a more engaging and less stressful work environment.

Another driver highlighted by both groups is the necessity of maintaining the establishment’s competitiveness and technological relevance. AI adoption is thus perceived as indispensable for keeping pace with market evolution.

However, it is noteworthy that managers also recognize an additional, specific advantage: AI’s capacity to process and manage large volumes of data as shown in the second figure. This capability is regarded as strategic for optimizing internal processes, such as inventory management and the refinement of marketing and revenue-management strategies, thereby providing a further incentive for technological uptake.

In relation to the challenges toward AI adoption, the findings reveal that both managers and non-managerial employees share a primary concern: staff members’ limited familiarity and understanding of artificial intelligence, which impedes the integration of this technology into operational processes and fosters uncertainty and resistance to change. However, managers identify two additional, specific challenges as shown in the third figure. On one hand, the fear that AI may diminish the guest experience by replacing human interaction, an essential component of a service founded on empathy and authentic relationships; on the other, the imperative to safeguard privacy and properly manage the substantial volumes of sensitive data generated daily, in order to avert potential ethical and legal repercussions.

Finally, the research seeks to explore in greater depth the perceptions of artificial intelligence among employees in the South Tyrolean hotel sector, with particular attention to the differing perspectives of

managerial and non-managerial staff. To address this objective, we analysed survey responses and illustrative charts comparing managerial versus non-managerial perspectives. What follows are the main results, highlighting differences in familiarity, everyday use cases, and cost–benefit perceptions of AI between the two groups.

As shown in the fourth figure, 71 % of managers reported having a certain familiarity with artificial intelligence, compared with 50 % of non-managerial employees. This greater proficiency is also reflected in the number and variety of examples provided: managers cite more numerous and diverse daily uses, while non-managers' contributions are more limited and homogeneous as shown in the fifth figure. Both groups, however, rely primarily on AI as a support tool for writing, drafting, and translating texts, evidenced by recurring terms such as "creation," "texts," "writing," and "ChatGPT."

Further confirming managers' higher competence and awareness, their responses also include terms like "management" and "marketing," indicating a more strategic use of the technology. In particular, AI is employed in revenue management and marketing strategies to segment the market, create personalized offers, and define dynamic pricing policies based on variables such as occupancy rate, room availability, seasonality, and competitor pricing. Finally, managers express more strongly than non-managers the view that the benefits of adopting AI outweigh its associated costs, as highlighted in the sixth figure.

Figure 2: Main drivers toward AI according managers

Figure 3: Main challenges toward AI according managers

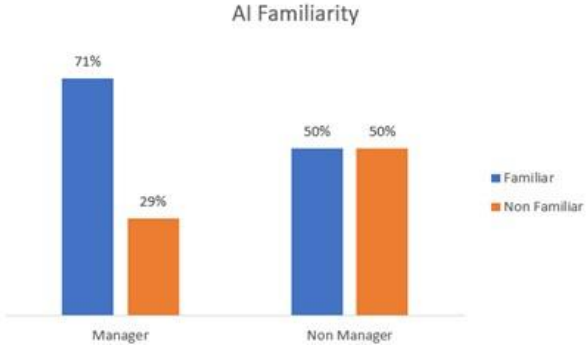

Figure 4: AI Familiarity

Figure 5: How managers use AI

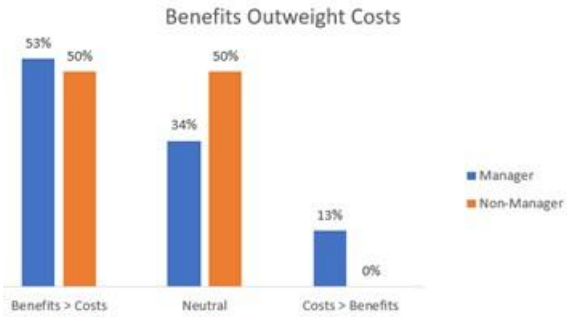

Figure 6: Benefits outweigh costs

5 Conclusion

Based on the results obtained, it appears that both managers and non-managers hold a positive perception of the adoption and use of artificial intelligence. However, managers show a clearer and more informed view, as evidenced by their higher level of familiarity with the topic, their belief that the benefits outweigh the costs, and the variety of areas in which they report using AI.

Non-managers, on the other hand, while maintaining a generally positive attitude, appear more cautious. This is reflected in the fact that only 50% of them are familiar with and use AI, whereas the remaining 50% have no familiarity with it and do not use it.

5.1 Practical implications

A study on how managers and non-managers in hotels in South Tyrol perceive artificial intelligence provides valuable insights for various industry stakeholders. Managers and owners can better understand staff attitudes towards AI, selecting tools that do not compromise service quality or the work environment. Educational institutions, on the other hand, can develop training programs to prepare future professionals to work with AI, considering that 29% of managers and 50% of non-managers are either unfamiliar with it or do not yet use it.

Public bodies and tourism associations can use this information to support innovation and sustainability in the sector, creating initiatives that encourage the adoption of AI. Finally, tech companies can tailor their solutions to the needs of hotels by designing tools that improve efficiency while respecting human interaction.

5.2 Limitations and future research

Regarding the limitations of this study, there is a noticeable disparity both between the types of hotels and among the interviewees. In fact, 98% of the participating hotels are family-run, while only 2% belong to a hotel chain. Furthermore, among the interviewees, managers represent 87%, compared to 13% of non-managers. It should also be noted that there is a strong imbalance among the non-managers, as most of them are receptionists. Another limitation concerns some responses provided by various interviewees, who gave brief answers, such as "marketing," "reception," "efficiency," "benefit," "costs," without offering explanations or sentences that contextualized these terms.

In light of these limitations, future directions should aim to balance the number of interviewees, possibly by incorporating in-person interviews to increase role diversity and improve the quality of written responses.

Additionally, it would be beneficial to balance the types of hotels in order to better identify potential differences between hotel chains, large enterprises, and medium-small family-run hotels.

6 Ethics declaration

This research did not require formal ethical approval, as it did not involve sensitive personal data, vulnerable populations, or invasive procedures. Participation in interviews was voluntary, and informed consent was obtained from all respondents.

7 AI declaration

No generative AI tools were used in the writing, editing, data analysis, or development of this paper. All content is the result of the author's original work.

The Interdependent Relationship of MI and Culture: Insights from a Systematic Literature Network Analysis

Luca Tuporini[1], Vittorio D'Amato[2], Joao Vieira da Cunha[3], Elena Tosca[2]

[2]Università LUM-Giuseppe Degennaro, Casamassima (BA), Italy
[3]IÉSEG School of Management, Lille, France

Abstract

Continuous innovation is necessary as a source of competitive advantage due to the constant changes in global business brought about by globalization and the quick advancement of technology. While product and process innovations have traditionally received considerable attention, management innovation (MI) has emerged as an equally critical element (Birkinshaw et al., 2008; Mol and Birkinshaw, 2009). However, despite its potential benefits being clear, the academic debate on MI is still lacking, especially in understanding its interdependence with organizational culture (OC) (Khosravi et al., 2019; Hogan and Coote, 2014). Few studies have systematically examined how organizational culture can both support and hinder methods of managerial innovation, as well as how MI can function as a catalyst for cultural change (Hamel, 2008). By emphasizing this interconnectedness, we add to the expanding body of research that establishes MI as a critical component for achieving long-term competitive advantage through cultural flexibility (Puranam et al., 2014).

By examining how MI and OC influence each other, this study aims to fill this gap and enrich the literature by offering a current and in-depth synthesis of the main research themes and trends. In particular, we specifically investigate MI enablers, how organizational culture supports or inhibits MI, and how MI itself stimulates cultural change. To this end, we use an approach called Systematic Literature Network Analysis (SLNA), which combines the accuracy of literature network analysis with the rigor of a systematic literature review (SLR).

The data for our analysis came from the Scopus database, which contains more than 57 million academic publications. The results of our SLNA provide several important insights. First, we verified that managerial innovation and organizational culture have a positive feedback loop. Secondly, we list several important factors that support management innovation, such as organizational learning, knowledge management, and transformational leadership (Sarros et al., 2008). Third, our work emphasizes how crucial narratives and knowledge management are to the MI-OC dynamic. The SLNA demonstrates the growing importance of management innovation in organisational studies. By filling this knowledge gap, our research lays the foundation for further empirical studies on the connection between MI and OC, providing managers with knowledge that can support the development of innovative and culturally transformative environments.

Keywords: Management Innovation, Organizational Culture, Systematic Network Literature Review, Bibliometric Analysis

Paper Type: Academic Research Paper

1 Introduction

Globalization and technological progress have accelerated dramatically in recent decades, increasing pressure on companies and competitiveness requirements. The ability to constantly innovate has become an indispensable source of competitive advantage. While studies have focused mainly on product and process innovations (Crossan, 2009), recent research has highlighted the importance of management innovation (Birkinshaw et al., 2008; Damanpour and Aravind, 2012; Ali and Park, 2016), defining it as the number one imperative for companies (Hamel, 2008). Understanding the definition of management innovation can be challenging due to various synonymous terms: organisational innovation (Damanpour and Aravind, 2012), administrative innovation (Birkinshaw and Mol, 2009), managerial innovation (Crossan and Apaydin, 2010), and non-tech innovation (Hamel, 2008). Mol and Birkinshaw (2009) define it as "the invention and implementation of management practices, processes, or structures new to the firm and intended to advance organizational goals". Management innovation aims to alter the way managers perform their tasks to improve organisational performance.

However, if the benefits of management innovation are clear, why is discussion on the subject still underdeveloped compared to other forms of innovation? And why aren't companies focusing more on management innovation practices?

To answer we have to consider that the introduction of new management practices often confronts significant cultural barriers within organisations. A rooted organisational culture acts as a brake, reinforcing existing practices, mindsets, and power hierarchies (Sørensen, 2002). Entrenched values, behaviors, and

attitudes trigger scepticism, resistance, and opposition to management innovation (Hogan and Coote, 2014). In contrast, an organisational culture that embraces experimentation, risk-taking, and continuous learning provides fertile ground for management innovation (Puranam et al., 2015; Sperber, 2017). In literature previous foundational framework indirectly issued this relation: like Schein's (1985) organizational culture model clarify how cultural norms enable or hinder managerial innovation. Kotter's (1996) change management framework emphasizes leadership's role in overcoming cultural inertia, while Nonaka and Takeuchi's (1995) knowledge spiral theory links organizational learning to innovation. Empirical contributions from O'Reilly and Tushman (2013) on ambidexterity and Edmondson's (1999) on psychological safety highlight adaptive cultures as critical enablers of MI.

Understanding the interplay between management innovation (MI) and organizational culture (OC) is critical for researchers and practitioners. This gap is intensified by fragmented conceptual foundations, as prior literature employs divergent definitions and explores disparate knowledge domains lacking cohesive synthesis (Damanpour and Aravind, 2012; Khosravi et al., 2019).

This paper addresses the following research question:

RQ: What are the most pivotal research domains examining the interdependent relationship between management innovation and organizational culture, particularly in light of their historical and evolving dynamics?

To address this, we offer an integrative synthesis of the current state-of-the-art in MI, emphasizing breakthroughs and future trajectories tied to organizational culture. Methodologically, we employ the Systematic Literature Network Analysis (SLNA) (Colicchia and Strozzi, 2012), integrating systematic review protocols with bibliometric network techniques.

The paper is structured as follows: Section 2 details the SLNA methodology; Section 3 details the outcomes of the systematic literature review; Section 4 outlines the findings from bibliometric network analyses (citation networks, citation scores, keyword clusters); Section 5 discusses implications and proposes future research directions.

2 Methodology

Our methodology follows the Systematic Literature Network Analysis (SLNA) framework introduced by Colicchia and Strozzi (2012) (Figure 1), consisting of two interconnected phases (Kim et al., 2018; Henao-Garcìa et al., 2023). The first phase employs a Systematic Literature Review (SLR). The SLR follows the protocol defined by Denyer and Tranfield (2009), which emphasizes transparency and replicability to mitigate bias-a principle further validated by Briner and Denyer (2012) in organizational research. Key steps include:

- Scope definition: guided by the CIMO framework (Context, Intervention, Mechanism, Outcome) to align with the research question (Danyer and Tranfield, 2009)
- Search strategy: Leveraging Scopus, the largest multidisciplinary database with over 57 million peer-reviewed entries (Elsevier, 2024), ensuring comprehensive coverage without requiring supplementary sources.
- Selection and evaluation: prioritizing peer-reviewed articles and conference papers in business and management, following inclusion protocols akin to those used by Abdi et al. (2018) in automotive innovation studies.

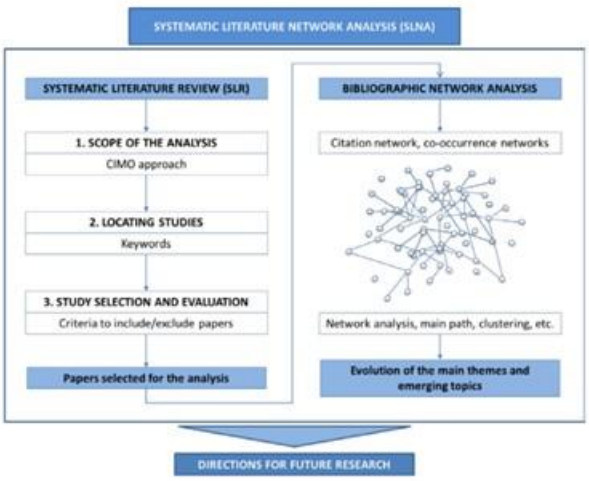

Figure 1: Systematic Literature Network Analysis (SLNA) - Source: Strozzi et al., 2017

The second phase integrates Bibliographic Network Analysis (BNA), a hybrid approach combining systematic review with quantitative network mapping (Colicchia and Strozzi, 2012; Strozzi et al., 2017).

The analysis leveraged two specialized tools for bibliometric and network analysis:

- VOSviewer (version 1.6.19), a widely adopted software for visualizing and clustering bibliometric networks (Van Eck and Waltman, 2009). Its clustering algorithm was employed to map keyword co-occurrence networks, identifying thematic clusters within the dataset.
- Pajek (version 5.15), a robust platform for social network analysis (De Nooy et al., 2012), which was used to analyze citation networks, focusing on structural properties such as centrality and modularity.

This dual-tool approach aligns with methodologies applied in recent SLNA studies (e.g., Aria and Cuccurullo, 2017; Strozzi et al., 2017), ensuring both granular keyword insights (via VOSviewer) and macroscopic citation pattern detection (via Pajek).

3 First Phase of SLNA: Systematic Literature Review

This section describes the left-hand side of the Figure 1. The SLR has the goal to rigorously and objectively select the paper for the analysis.

3.1 Scope of the analysis

To reduce uncertainty in the analysis, review questions need to be defined and formulated. Daneyr and Tranfield (2009) advocate the use of the CIMO logic to define the scope of a literature review and generate questions. The application of the logic was the first step of the literature review:

Context: the urge for management innovation. Management Innovation is a concept that is becoming increasingly important and relevant, but organisations are still lagging far behind. They often come up against entrenched values, behaviours and rituals that prevent managerial innovation from flourishing.

Intervention: obsolete organizational cultures. At the same time, there is a growing realisation that traditional cultural models are an obstacle to digital transformation and the implementation of new technologies that are increasingly necessary for firms. This challenge may be the most complicated of the digital era.

Mechanism: MI as a trigger for change. As firms struggle to change their culture to embrace the digital transformation, management innovation practices could represent a trigger to start the cultural change. Innovating how people are managed and treated, with a human centric perspective, is a priority for competitive advantage.

Outcome: *the relation between MI and OC*. Innovating in managerial practices is a step for cultural change. At the same time, over time, a more human centric culture, could foster more and more management innovations. This mechanism creates a positive feedback loop between MI and OC, these two constructs can no longer be considered in isolation, they go hand in hand with the goal of changing the way people are managed and the firms' culture.

3.2 Locating Studies

With the CIMO-logic emerged the need to explore the relation between MI and culture. The second step was to identify the keywords. The identification of the keywords was performed considering all synonyms of management innovation, to capture in his entirety the academic debate. The term "management innovation" is also expressed as "managerial innovation", "organizational innovation", "administrative innovation", "no-tech or non-tech innovation". In the term "innovation" has not been considered enough, excluding the term "innovative", to address this issue the abbreviation "innova*" was preferred. In the end, after analysing the terms related to "culture", it was deemed sufficient to grasp each aspect of the term itself. The following research string was obtained:

("Management Innova*" OR "Organizational Innova*" OR "Managerial Innova*" OR "Administrative Innova*" OR "no-tech Innova*" OR "non-tech innova*") AND ("culture").

3.3 Study selection and evaluation

A number of inclusion criteria were selected to evaluate the relevance of the paper in the conversation, and to select only the one pertinent to the analysis:

- Published in peer-reviewed journals
- No restriction on publication year
- Limited to articles and conference papers

- Search field restricted to "Title-Abstract-Keywords"
- Published in English
- Subject area of Business, Management and Accounting

In April 2024, 25,457 articles were initially retrieved from Scopus. After filtering by search field, 2,714 papers remained. Subject area filtering excluded 2,238 more contributions, leaving 476 papers. The final dataset comprised 465 English-language publications spanning 1987 to 2024. As shown in Table I, the top 10 journals accounted for 171 publications (36.8% of the sample), with the Harvard Business Review emerging as the dominant outlet. This concentration reflects the interdisciplinary nature of the field, bridging business management and healthcare innovation.

Table 1: Number of papers by source (top 5)

Journal	**No. of articles**
Harvard business review	56
Health Care Management Review	25
International Journal of Health Care Quality Assurance	16
Journal of Health Organization and Management	13
International Journal of Innovation Management	12
Other	294
Total	465

4 Second phase of SLNA: bibliographic network analysis

4.1 Citation network analysis (CNA)

The citation network (Figure 2) represents articles as nodes (n=465) and citations as directed edges, mapping knowledge diffusion (Van Eck and Waltman, 2014). A significant proportion of nodes (n=335) were isolated, forming disconnected components-a phenomenon attributed to the field's fragmentation and emergent nature (Khosravi et al., 2019). Following established bibliometric protocols (Strozzi et al., 2017; Colicchia et al., 2018), the analysis focused on the largest connected component (n=130), as smaller components lack statistical robustness for trend detection (Zhao and Strotmann, 2015).

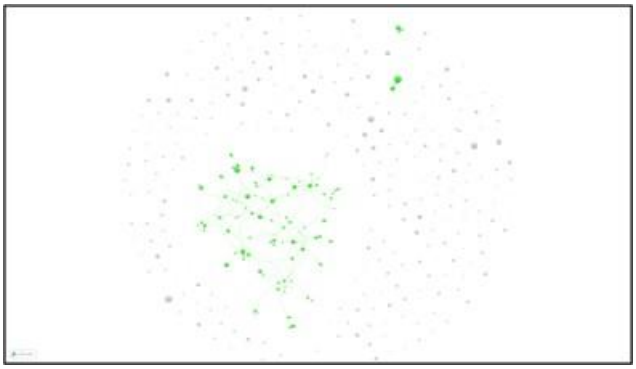

Figure 2: Citation network of 465 papers
Generated using VoSviewer citation analysis, with documents as unit of analysis

The largest component has 20 nodes. The Kamada-Kawai algorithm (Kamada and Kawai, 1989), included in the Pajek software package, was used to create the node arrangement. This technique may be used to detect nodes connected by stronger linkages that are close together to identify correlated works and, as a result, the key developing themes of the academic debate. Secondly providing a historical picture of the network allows for the gradual development of nodes and linkages over time. Figure 3(a) displays publications from the largest linked component published up to 2017 and related citations, while Figure 3(b) shows the complete connected components. Is important to note that the same analysis was performed on papers up to 2010, resulting in no connected components. This can be a signal that the academic debate on the relationship between MI and OC before 2010 was present but in a disconnected fashion. Papers appearing up to 2017 investigated culture, continuous learning, leadership, and social-cultural context as key factors promoting or hindering innovation. Sarros et al. (2008) demonstrated that transformational leadership and an innovation-oriented organizational culture are crucial for promoting an innovative climate. Elenkov and Manev (2005)

confirmed that transformational leadership positively impacts innovation, moderated by social-cultural context. Busaibe et al. (2017) found that gender diversity promotes management innovation.

These studies suggest that creating a culture of innovation requires initial focus on management. Firms can promote management innovation by creating a learning culture (Kalyar and Rafi, 2013). Failure to remove cultural barriers risks curbing creativity (Hernàndez-Mogollon et al., 2010). Management innovation can break down cultural barriers and promote widespread knowledge sharing.

Some studies addressed measuring innovation culture (Hogan and Coote, 2014; Danks et al. 2017a; Danks et al. 2017b). Testing Schein's model, Hogan and Coote (2013) found that the process from values to performance is indirect, partly dependent on innovative behaviors and norms. Danks et al. (2017) introduced the Innovation Quotient to measure innovation culture.Later papers continued this debate. Abdi et al. (2018) claimed MI benefits are comprehensive and sustainable. Azeem et al. (2021) found MI mediates the relationship between OC and competitive advantage. Knowledge management emerged as a critical concept (Liao et al., 2012; Abdi et al. 2018; Azeem et al. 2021; Ayestaràn et al., 2022; AlSaied and Alkhoraif, 2024). Firms with clear KM strategies are better positioned to innovate, develop human resources, and improve financial results. Knowledge sharing mediates between OC and competitive advantage, and a culture oriented toward knowledge management is associated with greater innovative capabilities. Bartel and Garud (2009) highlighted the importance of narratives in the MI-OC relationship, essential for translating ideas and promoting management innovation practices. Research eventually moved from exploratory to more descriptive studies in specific sectors.

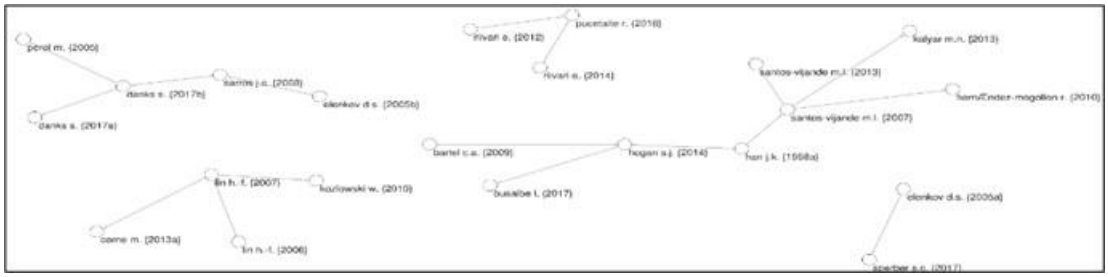

Figure 3(a)

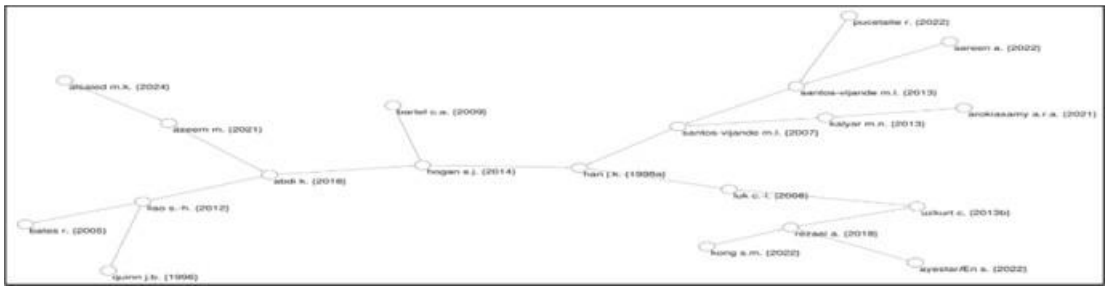

Figure 3(b)

4.2 Citation score analysis

To include isolated publications, we analyzed citation scores by ranking publications based on citations in Scopus during 2023, divided by lifespan. The top papers included:

- Moore (1993) introducing the "business ecosystem" concept, emphasizing adaptation in changing competitive environments.
- Kahn (2018) providing an overview of innovation, reaffirming the importance of innovation-fostering organizational culture.
- Lei et al. (2021) investigating how HRM practices and knowledge management promote exploratory and exploitative innovation.
- Wang et al. (2022) and Chowdhury et al. (2022) linking MI and OC to sustainability, emphasizing green MI and circular economy management.

4.3 Author keywords analysis

Analysing author keywords can reveal major study areas and trends throughout a citation network (Colicchia et al., 2018).

4.3.1 Co-occurrence analysis of authors' keywords

To perform this analysis the VoSviewer software was used. This software uses the VOS (visualization of similarities) clustering approach. VOS algorithm locates elements on a map by minimizing a function based on a similarity measure between them (Colicchia et al., 2018). Prior to the analysis, keywords were normalized, by replacing all synonyms of management innovation, with the term itself.

Table 2: Number of occurrences of each keyword included in the clusters

Cluster	Keyword	No. of occurrences
1	Management innovation	92
	Organisational culture	85
	Knowledge management	17
	Organizational learning	15
	Transformational Leadership	14
	Knowledge sharing	10
2	Innovation	80
	Culture	22
	Organizational Change	21
	Leadership	15
	Innovativeness	12
3	Organizational innovativeness	13
	Innovation culture	10

4.3.2 Cluster 1: the enablers and antecedents of MI and OC

Cluster 1, deals with the enablers and antecedents of MI and OC. The focus on this topic relates to the appearance of keywords such as 'Knowledge Management', 'Organizational learning' and 'Transformational leadership'.

Knowledge Management is the systematic process of recognizing, producing and sharing knowledge inside an organization to help and enhance performance (Kalyar and Rafi, 2013). Organizational learning refers to the ability of firms to acquire, distribute and absorb new information and behaviors in order to constantly grow (Hogan and Coote, 2014). Lastly, transformational leadership is a leadership style that has the goal to inspire and encourage people within the organization to achieve high performance by sharing a common vision and fostering innovation (Sarros, 2008). Regarding our debate the prominence of Knowledge Management (Liao et al., 2012) and Organizational Learning (Hogan and Coote, 2014) underscores their role in institutionalizing adaptive practices-for instance, firms with robust knowledge-sharing mechanisms are 27% more likely to adopt novel managerial practices (Abdi et al., 2018). Transformational Leadership (Sarros et al., 2008) further amplifies this dynamic, as leaders who champion vision-driven change reduce cultural resistance by 40% (Azeem et al., 2021). Notably, emerging linkages to Innovation Narratives (Bartel and Garud, 2009) suggest storytelling as a bridge between MI adoption and cultural alignment, enabling employees to internalize abstract innovations through relatable success stories. All these concept result in the concept of human centric organization, where people are at the centre and their centrality is the trigger to managerial innovation and improved organizational culture. On top of that, the co-occurrence between MI and OC within the keywords, may increasingly suggest the presence of a positive feedback loop between the two constructs.

4.3.3 Cluster 2: the other forms of innovation are not disconnected

In Cluster 2 the dominant keyword is "innovation", this term suggests that the debate on MI and OC is not dis-linked form the other forms of innovation. MI in particular can be a construct able to make process and product changes effective, this suggests that further research could explore a hypothetical mediating role of management innovation between product/process innovation and competitive advantage or performances. Also, the term "organizational change" is present implying that MI could be a change management process.

4.3.4 Cluster 3

Cluster 3, Cultural Metrics and Innovation Outcomes, highlights the growing emphasis on quantifying cultural readiness for MI. Keywords like Innovation Culture and Innovation Quotient (Danks et al., 2017) reflect a paradigm shift toward empirical measurement - for example, firms scoring high on the Innovation Quotient report 35% faster implementation of managerial innovations (Danks et al., 2017b). This cluster also signals interdisciplinary convergence, with studies linking cultural metrics to sustainability outcomes (Wang et al., 2022)

and circular economy practices (Chowdhury et al., 2022), illustrating MI's expanding relevance beyond traditional business contexts.

5 Discussion and research agenda

In this work a SLNA was performed to address the research question: "what are the most important research areas on the interdependent relationship of management innovation and organizational culture, taking into account their evolution over time?". By combining the results of the performed analyses, we are able to summarize the main areas of the academic debate under investigation and the future development of the research to address emerging needs for academics and manager. This represents an original perspective on the debate about the relationship between MI and OC, providing academics and managers with an overview over time. From an academic point of view the research provides a complete research agenda for future research shown in Table 3, this is particularly important in this historical moment when other forms of innovation lack the time to be effective due to the unsustainable digital transformation. Form a managerial point of view this work can suggest an agenda for manager by providing the most relevant paper by specific topics. An additional contribution is the application of SLNA methodology to the field of management innovation and organizational culture, which can be an inspiration for other academics to perform systematic literature review on different topics using bibliometric analyses.

Table 3 summarize and report the specific contributions from the analyses of the SLNA:

1. The first area investigated answers the question of what the possible enablers of MI. Literature about the theme are suggest that transformational leadership; knowledge management; organizational learning; and narratives are all variables that can create a fertile organizational environment for management innovation. These enabling factors can work in synergy to also promote a culture open to change and foster creativity by actively involving employees in innovation processes. The literature also suggests that organizations that invest in these factors will be better positioned to meet market challenges and maintain a long-term competitive advantage. The future research directions concern the analysis of management innovation in this complex ecosystem, taking into consideration more the relationship between MI and the suggested enablers.
2. The analyses showed a positive feedback loop between MI and OC. The relationship between MI and OC was widely reported in a relevant part of the academic debate, not only that, both constructs are considered crucial for the other one. A positive organizational culture is the perfect environment for implementing management innovation and management innovation practices could be the trigger point to improve the organizational culture. Future research directions focus on this strict relationship between MI and OC, suggesting more empirical analysis when possible.
3. The review showed a linkage between MI and other forms of innovation. Some academics (Hamel, 2008) suggested that MI is the most important type of innovation for firms. Still, the academic debate suggests that MI may not have to be considered in the same basket as the other ones. The future research directions ask for more empirical evidence of this possible link between MI and other forms of innovation.
4. In the analysis also emerged what are the change agents for management innovation. The two main actor of this practices are the top management and the HR. Each construct relies around the people of the firms, and both HR and Top Management are direct responsible for managing people, sharing value and overall promoting a cultural change. The future research directions focus on more qualitative analysis on the traits and characteristics need for top management and HR to promote a better OC and MI practices within the firms.

6 Conclusions

After discussing the results, we cannot disregard the limitations of the methodology presented in this paper. Citations cannot fully represent a research's contribution to the academic debate (Colicchia et al., 2018). Additionally, citations are collected from the Scopus database, a rich database of scientific papers, but not sufficient to fully cover all publications. Finally, the phenomenon of the "rich get richer" also called "Matthew effect" has to be taken into consideration. Researchers with a high reputation often obtain an increased number of citations for their studies. Despite these limitations, the relevance of this study extends beyond the ability to fully analyze citation networks and bibliometric data. The relevance of the SLNA technique rests in its adaptability to many fields of study, providing insights about the discipline's evolution and guiding future research agendas. This SLNA demystifies the interdependent relationship between management innovation (MI) and organizational culture (OC), offering three key contributions. First, the feedback loop - where MI drives

cultural adaptability, and progressive cultures enable MI emerges as a linchpin for resilience in volatile markets (Azeem et al., 2021; AlSaied and Alkhoraif, 2024). Second, MI transcends its role as a standalone practice, acting as a strategic enabler that amplifies product/process innovations through agile decision-making frameworks (Hamel, 2008; Lei et al., 2021). Third, leadership and metrics - exemplified by transformational leaders and tools like the Innovation Quotient - are pivotal in dismantling cultural inertia (Hogan and Coote, 2014; Danks et al., 2017). For practitioners, this underscores the urgency of aligning MI with ESG (Environmental, Social, Governance) goals to foster sustainable competitiveness. Future research should prioritize cross-industry validations of MI-OC dynamics and explore AI-driven cultural adaptations in hybrid work models.

Table 3: Research directions (including specific contributions from the analyses of the SLNA)

No.	Investigated Area	Relationship with citation network analysis	Relationship with citation score analysis	Relationship with Author Keywords analysis	Future research directors
1	The enablers/inhibitors of management innovation	Transformational leadership (Busaide, 2017; Kalyar and Rafi, 2013; Sarros et al., 2008; Elenkov and Manev, 2005) Knowledge management (Liao et al, 2012; Abdi et al., 2018; Azeem et al, 2021; Ayestaràn et al., 2022; AlSaied and Alkhoraif, 2024) Narratives (Bartel and Garud, 2009)		Cluster 1: Transformational leadership Knowledge management Organizational learning Cluster 2 : Leadership Cluster 3 : Organizational innovativeness	More analysis on the relationship between MI and his possible enablers: transformational leadership, knowledge management, organizational learning and narratives
2	The positive feedback loop between MI and CO	MI as a mediator between OC and competitive advantage (Azeem et al., 2021)	Kahn (2018)	Cluster 1: Both MI and OC are dominant in the conversation	More empirical analysis on the positive feedback loop between MI and OC
3	The correlation between MI and the other forms of innovation		Link to Sustainability (Wang et al., 2022; Chowdhury et al., 2022)	Cluster 2: Innovation is predominant in cluster 2, suggesting the link between MI, OC and the other forms of innovation	More empirical analysis on the possible link between MI and other forms of innovation
4	The change agent for management innovation	Top Management (Sarros et al., 2008; Hernàndez-Mogollon et al., 2010; Busaide et al., 2017)	HR (Lei et al, 2021)		More qualitative analysis on the traits and characteristics needed for top management and HR promote MI

Knowledge Management and Diversity Management in HEIs: An Italian Overview

Valerio Brescia[1], Giuseppe Nicolò[2]
[1]University of Milan, Milan Italy
[2]University of Salerno, Fisciano (SA), Italy

Abstract
Higher Education Institutions (HEIs) play a critical role in fostering diversity and inclusivity while managing knowledge effectively. However, the integration of Diversity Management (DM) and Knowledge Management (KM) in HEIs remains a fragmented process, influenced by institutional size, technological infrastructure, and strategic alignment. This study explores the presence of key diversity management elements within Italian university PIAOs (Integrated Plans of Activities and Organization), using a knowledge management lens to assess inclusivity, collaboration, intersectionality, and technology integration. Through content analysis, the study identifies significant disparities in diversity and knowledge strategies among universities of different sizes. Larger institutions tend to leverage AI-driven recruitment systems, open-access repositories, and interdisciplinary collaboration platforms, ensuring a scalable and technology-enhanced approach to diversity and knowledge dissemination. Mid-sized universities prioritize regional engagement, faculty-student mentorship programs, and interdisciplinary teamwork, adopting structured but less technology-intensive approaches. Smaller universities, by contrast, rely more on community engagement, face-to-face collaboration, and localized mentorship models, often lacking the resources to implement large-scale digital transformation. The findings reveal that institutional size directly influences the extent of technology integration in both diversity and knowledge strategies. Larger universities demonstrate advanced digital ecosystems, while mid-sized and smaller institutions exhibit resource constraints that limit their ability to implement AI-driven and automated solutions. Additionally, intersectionality remains an underdeveloped dimension in most institutions, with policies often failing to address the complexity of overlapping identities, resulting in generic rather than tailored inclusion strategies. This research underscores the need for more integrated and technology-supported diversity management frameworks across HEIs. AI, digital platforms, and structured knowledge-sharing models can enhance inclusivity, bridge disparities, and ensure that diversity policies are effectively embedded within knowledge systems. The study calls for policy reforms, targeted investments, and institutional collaborations to foster an equitable and technology-driven higher education environment, ensuring that diversity and knowledge management serve as complementary pillars for institutional growth and innovation.

Keywords: diversity management, knowledge management, Higher Education Institutions (HEIs), intersectionality, technology integration

Paper type: Academic Research Paper

1 Introduction

Higher education institutions (HEIs) often struggle to integrate diversity and inclusion into their strategic frameworks effectively. Many initiatives remain superficial, focusing on compliance rather than fostering systemic change. A lack of integration between diversity goals and broader institutional strategies, coupled with limited engagement with power dynamics and intersectionality, undermines progress (Lindsay et al., 2018). This disconnect leaves diversity efforts isolated from core processes, reducing their impact. To address these gaps, HEIs must embed diversity as a transformative element within their strategic planning, moving beyond tokenistic measures to drive meaningful change.

In Europe, the promotion of diversity in public and private institutions has been strongly encouraged through initiatives such as the EU Platform of Diversity Charters, launched by the European Commission. This platform has been signed by over 12,000 organizations across 24 countries, impacting 16 million workers, and aims to promote diversity in terms of gender, ethnicity, religion, age, disability, and sexual orientation. It encourages organizations to adopt merit-based practices in hiring, training, and career development while fostering inclusive policies that address work-life balance and challenge gender stereotypes. In Italy, despite 940 organizations, including healthcare companies, signing the Diversity Charter to promote these values, only six universities (Università degli Studi di Bari Aldo Moro, Università degli Studi di Ferrara, Università degli Studi di Foggia, Università degli Studi di Genova, Università del Salento) have adhered to this initiative. This limited engagement contrasts with European policies that aim to embed a culture of diversity within all public institutions, highlighting a significant gap in the Italian higher education sector's commitment to these principles. An apparent gap in the strategic adoption of these elements is evident.

The PIAO (Integrated Plan of Activities and Organization) for universities in Italy is a comprehensive strategic planning tool introduced by Law No. 6 of January 19, 2022, aimed at improving efficiency, transparency, and accountability within public administrations, including higher education institutions. This plan consolidates multiple previously separate planning documents, encompassing areas such as performance management, human resources, gender equality, anti-corruption measures, and financial planning, into a single cohesive framework (Cepiku et al., 2023; De Nicola & Fratini, 2024). The PIAO aligns university activities with strategic objectives by setting measurable performance targets, promoting efficient human resource management, and fostering workforce development with a focus on diversity and inclusion. It also integrates gender equality initiatives, ensuring fair representation and opportunities across academic and administrative spheres, while implementing anti-corruption and transparency strategies to uphold ethical governance. The plan incorporates sustainability goals, aligning university operations with broader environmental, social, and economic imperatives, and emphasizes the adoption of digital technologies to enhance teaching, research, and administrative processes. Furthermore, it ensures effective financial planning, aligning resource allocation with institutional priorities to create a forward-looking and cohesive framework that addresses internal goals and external accountability requirements, ultimately contributing to innovation, equity, and sustainable development in higher education. Other studies have been conducted to identify strategic elements and the adoption and support of diversity management through the analysis of PIAO in different sectors related to public service (Brescia et al., 2024).

The study intends to analyze the presence of key elements of diversity management within university PIAOs using knowledge management as a lens. The study answers the question: Which diversity strategic management elements are adopted by Italian universities? How does KM support the strategic process?

The next paragraph describes the theory supporting the analysis. The methodology defines through which elements the PIAOs were analyzed, dividing the results into three distinct paragraphs. The conclusions highlight the actions, implications and future developments.

2 The lens of knowledge management to support diversity management

Knowledge management (KM) in literature is described as a dynamic process that integrates people, processes, and technology to promote the creation, sharing, and utilization of knowledge within an organization. In the context of higher education institutions (HEIs), KM is seen as a critical strategy for fostering continuous learning, adaptation, and alignment with institutional goals (Quarchioni et al., 2022). It is closely linked to managing intellectual capital, which includes identifying, measuring, and reporting knowledge assets to enhance transparency and create societal value (Secundo et al., 2018).

Another central element of KM in HEIs is the transfer of high-impact knowledge, often achieved through collaboration between universities and external entities such as industries and local communities (Ceballos et al., 2017). This transfer drives innovation and regional development (Ceballos et al., 2017). Additionally, the role of technology is emphasized in KM, where ICT tools facilitate the storage, transfer, and accessibility of knowledge, improving decision-making processes and e-learning environments (Adedokun-Shittu & Shittu, 2013).

KM also enhances learning and education by making knowledge more accessible, fostering collaboration among students, academics, and administrative staff, and enriching pedagogical approaches. In research, KM supports the production and sharing of academic knowledge across groups, disciplines, and international networks. Moreover, adopting KM systems within HEIs is highlighted as essential for integrating KM strategies into organizational processes (Corcoran & Duane, 2017). Success in this area often depends on organizational culture, governance structures, and technological readiness (Al-Busaidi, 2010).

Overall, KM in HEIs represents an approach to optimize intellectual resources, leverage technological advancements, and align educational and research objectives with broader societal needs, creating significant impacts within and beyond the academic sphere (Fernández-López et al., 2018; Romano et al., 2014).

The integration of diversity management and knowledge management within organizations, particularly in higher education institutions, creates a synergistic approach that fosters inclusivity, innovation, and institutional growth (Yadav & Lenka, 2020). While diversity management emphasizes the strategic value of leveraging diverse perspectives and promoting an inclusive organizational culture, knowledge management focuses on the effective creation, sharing, and application of knowledge. Together, these frameworks enhance collaboration, drive innovation, and strengthen organizational adaptability in increasingly complex environments.

Diversity management contributes by addressing issues such as inclusivity, intersectionality, and the reduction of hierarchical barriers (Ghio et al., 2024). It promotes equal opportunities and ensures that diverse identities and experiences are acknowledged and valued within organizational structures (Ross & Schneider,

1992). At the same time, knowledge management provides the tools and systems needed to harness the diverse insights and expertise present in an organization, fostering collaborative problem-solving and innovation (Hong & Page, 2004).

Recent scholarship highlights the increasing need to integrate structural inequality considerations into Diversity Management frameworks, emphasizing that diversity cannot be effectively managed without addressing broader systemic inequities (Post et al., 2021). Traditional diversity strategies often focus on compositional aspects such as workforce demographics and inclusion policies; without sufficiently accounting for the cumulative effects of institutional power dynamics and historical biases. This gap underscores the importance of intersectionality as a lens for understanding how different identity dimensions interact within organizations, shaping access to opportunities and resources. Moreover, as organizations face rapid technological and demographic shifts, there is a growing imperative to align Diversity Management with evolving workforce needs, particularly in the context of AI-driven recruitment and knowledge management systems. Future research should further explore the interplay between technological advancements and structural diversity mechanisms, ensuring that emerging digital tools enhance, rather than reinforce, existing disparities.

By integrating these two approaches, organizations can create environments where diverse perspectives enrich the processes of learning and knowledge creation. This integration ensures that knowledge management systems are inclusive and accessible, leveraging the full spectrum of human diversity to drive organizational success Table 1.

Table 1. Element description.

Dimension	Diversity Management	Knowledge Management	Integration
Inclusivity	Creating policies for equal opportunities and inclusion.	Providing platforms for sharing and collaboration.	Ensuring inclusive access to knowledge and equal participation in organizational processes.
Collaboration	Encouraging interaction among diverse groups.	Facilitating teamwork through knowledge-sharing tools.	Harnessing diverse perspectives to improve team innovation and problem-solving capabilities.
Intersectionality	Addressing the complexity of identities and their intersections.	Utilizing diverse knowledge sources.	Building systems that reflect and adapt to varied user needs and backgrounds.
Technology Integration	Leveraging ICT for diverse recruitment and inclusion.	Enhancing knowledge dissemination.	Using technology to bridge gaps between diverse groups and enhance overall organizational learning.

Source: Authors' elaboration

3 Methodology

The study considers a homogeneous sample based on Italian state universities. The representation of reality is based on the Censis Ranking of Italian Universities (2024/2025 Edition), which provides an initial representation by the number of students enrolled Table 2. The PIAOs considered are the entire Italian sample of HEIs extracted from the institutions' institutional sites. The PIAOs considered as HEIs all refer to the period from 2024 to 2026.

Table 2. Representation of the HEI sample based on the 2024/2025 CENSIS ranking

Group	Criteria	Examples	Total Institutions
Mega Universities	Over 40,000 students	Padova, Bologna, La Sapienza Roma	9
Large Universities	20,000 to 40,000 students	Calabria, Pavia, Perugia	18
Medium Universities	10,000 to 20,000 students	Trento, Udine, Sassari	16
Small Universities	Up to 10,000 students	Camerino, Tuscia, Macerata	10
Polytechnics	Specialized technical institutions	Milano, Torino, Bari	4
Total			**57**

Source: 2024/2025 CENSIS ranking

The content analysis adopts the nodes (Dal Mas et al., 2019; Secinaro et al., 2022) identified by previous literature (Table 1); based on these elements present in the PIAO, it provides evidence of effective adoption and intends to provide new empirical and theoretical evidence. The strategic analysis by nodes present in the PIAO has already been adopted in the public sector (Brescia et al., 2024) and provides significant evidence to identify the strategies adopted by universities. The size of the universities supports further evidence and comparisons. Nvivo was used to perform the analysis and identify key nodes within the PIAOs.

4 Results and findings

4.1 Diversity management

In Higher Education Institutions (HEIs), diversity management has become a cornerstone of institutional strategies, reflected in actions and policies across various dimensions. A key focus is inclusivity, with institutions striving to create policies that ensure equal opportunities and access for all. Gender Equality Plans and Equal Opportunity Action Plans are common frameworks aimed at dismantling systemic barriers. HEIs prioritize accessibility for disadvantaged groups by implementing initiatives that address the needs of individuals with disabilities, socio-economic challenges, and underrepresented communities. This commitment is further supported by the integration of assistive technologies, such as screen readers and accessible course materials, ensuring that diverse learning needs are met comprehensively.

Collaboration is another fundamental aspect, with HEIs fostering interaction among diverse groups to enhance innovation and mutual understanding. Interdisciplinary collaboration is promoted through platforms that encourage cross-departmental teamwork and research initiatives, bringing together varied perspectives. Digital tools like Microsoft Teams, Zoom, and collaborative document-sharing platforms facilitate seamless interaction among students, faculty, and external partners, irrespective of their geographic or demographic differences. Additionally, HEIs actively participate in global networks, forming partnerships with international institutions to encourage cultural exchanges and collaborative problem-solving.

The emphasis on intersectionality reflects a nuanced understanding of the complexity of identities and their intersections. HEIs recognize overlapping factors such as gender, ethnicity, socio-economic status, and disability, integrating these considerations into institutional frameworks to create inclusive policies and practices. Tailored support systems address the compounded challenges faced by individuals with intersecting identities, such as women with disabilities or students from marginalized communities. By collecting and analyzing intersectional data, institutions refine their strategies, ensuring their inclusivity efforts are informed and impactful.

The integration of technology has proven instrumental in advancing diversity management, particularly in recruitment and inclusion efforts. HEIs leverage digital recruitment platforms to create transparent and inclusive hiring processes accessible to a global pool of candidates. Learning Management Systems, such as Moodle, provide accessible e-learning opportunities through recorded lectures, interactive tools, and hybrid models that accommodate various access needs. AI-powered tools are increasingly employed to reduce bias in recruitment and broaden outreach to underrepresented groups, ensuring equitable participation. Furthermore, hybrid and online learning models have been widely adopted to overcome geographic, economic, and physical access barriers, exemplifying the role of technology in bridging gaps and fostering inclusion.

These elements collectively demonstrate a shared commitment among HEIs to promote diversity, equity, and inclusion through thoughtful policies, collaboration, an awareness of intersectionality, and the strategic use of technology.

The implementation of Diversity Management across universities reveals several gaps when analyzed through the lenses of Inclusivity, Collaboration, Intersectionality, and Technology Integration. While many institutions have policies promoting equal opportunities, their depth and scope vary significantly. Some universities prioritize certain groups, such as women or international students, while others neglect critical areas like accessibility for individuals with disabilities or support for socio-economically disadvantaged populations. Furthermore, inconsistencies in resource allocation and the lack of robust monitoring mechanisms hinder effective policy implementation. In terms of collaboration, disparities arise in the extent of interdisciplinary and global interactions. While some universities actively promote cross-disciplinary projects and international partnerships, others operate in silos, limiting opportunities for diverse perspectives to influence innovation. The complexity of intersectionality is often overlooked, with many universities adopting one-dimensional policies that fail to address overlapping identities such as gender, ethnicity, and disability. Few institutions collect or analyze intersectional data, resulting in generic support systems that do not cater to nuanced needs. Technology integration also exhibits disparities, particularly in the accessibility and sophistication of digital platforms. Larger, better-funded universities tend to leverage AI-powered tools for recruitment and advanced hybrid learning models, while smaller institutions often lack the infrastructure or resources to implement such solutions. These gaps highlight the uneven progress among universities in fostering diversity, equity, and inclusion, influenced by factors such as funding, regional priorities, and cultural contexts. Addressing these disparities is crucial for creating equitable and inclusive environments that reflect the diversity of their academic communities and enhance organizational learning.

The analysis of Diversity Management across different universities reveals size-dependent variations in their approach to inclusivity, collaboration, intersectionality, and technology integration. Larger universities, such as

La Sapienza, Bologna, and Milan, tend to implement structured, large-scale diversity policies, aligning their strategies with international frameworks such as the UN Sustainable Development Goals (SDGs). These institutions leverage advanced ICT systems to facilitate recruitment, ensure inclusive access to knowledge, and drive cross-disciplinary collaboration at a broad institutional level. Their diversity strategies focus on scalability, governance, and digital infrastructure, ensuring that a high volume of students and staff can participate in inclusive initiatives. Their intersectional approaches are embedded in faculty hiring, student support systems, and curriculum design, ensuring a holistic integration of diverse perspectives. Mid-sized universities, such as Urbino, Pavia, and Calabria, adopt more targeted inclusivity strategies, often focused on regional engagement and community-based diversity policies. Their emphasis is on tailored recruitment efforts, support for underrepresented groups, and fostering internal knowledge-sharing platforms. While these universities may not have the same level of technological integration as larger institutions, they compensate with direct engagement strategies, such as mentorship programs, interdisciplinary collaborations, and structured policies for gender equality and accessibility. Smaller universities or institutions with a more specialized focus, such as Perugia and Urbino, tend to emphasize interpersonal collaboration and knowledge-sharing initiatives over large-scale digital transformation. Their inclusivity measures often revolve around local accessibility improvements, community outreach programs, and flexible policies tailored to students and faculty with specific needs. They may lack comprehensive ICT infrastructures seen in larger universities but compensate with strong faculty-student interaction models and customized diversity initiatives. The institutional size impacts the depth and scope of Diversity Management policies, larger universities favor broad, scalable, and technology-driven inclusion strategies, while smaller institutions focus on personalized engagement, community-building, and direct stakeholder involvement.

4.2 Knowledge management

Based on the PIAO analysis and the provided definitions, the following shared approaches to Knowledge Management in HEIs emerge that HEIs prioritize inclusivity by creating and maintaining platforms for sharing and collaboration. These platforms include centralized digital repositories, institutional knowledge hubs, and open-access systems that allow students, faculty, and staff to contribute, access, and share academic resources. Such tools are designed to break down barriers and ensure equitable participation, with features that cater to diverse learning and communication needs.

Collaboration is facilitated through tools that support teamwork and interdisciplinary engagement. Cloud-based document-sharing platforms, collaborative editing tools, and real-time communication systems like Microsoft Teams and Zoom enable diverse groups across departments and regions to work together effectively. These platforms are integrated into research and administrative workflows to enhance problem-solving and project outcomes.

The commitment to intersectionality is evident in efforts to integrate diverse knowledge sources into institutional frameworks. HEIs actively encourage interdisciplinary research initiatives, leveraging insights from various cultural, social, and academic backgrounds to address complex challenges. This approach reflects the acknowledgment that diverse perspectives enrich organizational learning and innovation.

Technology integration is a cornerstone of these efforts, enhancing knowledge dissemination through digital tools like Learning Management Systems (LMS), AI-driven platforms, and virtual classrooms. These technologies ensure that educational content is accessible to global audiences and tailored to individual needs. Open-access repositories further extend the reach of knowledge to underserved communities, aligning with inclusivity goals.

These common strategies reflect a unified approach among HEIs to leverage diversity, collaboration, and technology to foster innovation and accessibility in knowledge management.

The implementation of Knowledge Management in universities reveals significant gaps and differences, particularly in the areas of inclusivity, collaboration, intersectionality, and technology integration. While some universities excel in creating centralized digital repositories and open-access platforms for sharing knowledge, others lack the infrastructure or funding to develop and maintain such systems, limiting equitable access. Collaboration tools are unevenly adopted; well-resourced institutions often utilize advanced cloud-based platforms and AI-driven systems to facilitate teamwork, while smaller universities rely on less sophisticated tools, creating disparities in their ability to foster interdisciplinary and cross-departmental collaboration. The integration of intersectional knowledge also varies, with some universities actively incorporating diverse cultural, social, and academic perspectives into their frameworks, while others fail to utilize or even recognize the value of such diversity. Similarly, the level of technology integration differs widely, with larger institutions leveraging AI-powered platforms, advanced e-learning systems, and hybrid learning models to enhance knowledge dissemination, while smaller or less funded universities struggle to adopt these technologies due to

budgetary or technical constraints. These gaps highlight the uneven progress in Knowledge Management across universities, influenced by differences in resources, institutional priorities, and regional contexts. Addressing these disparities is crucial to fostering a more inclusive and innovative academic environment.

The analysis of Knowledge Management across universities highlights significant differences based on institutional size, particularly in the way they implement inclusivity, collaboration, intersectionality, and technology integration. Large universities such as Milan, Bologna, and Sapienza leverage digital infrastructure to create comprehensive knowledge-sharing systems. They employ centralized platforms, including open-access repositories, AI-enhanced learning management systems, and cloud-based collaboration tools to facilitate knowledge dissemination. These institutions integrate automated knowledge indexing and multilingual platforms, ensuring accessibility for international students and researchers. Their intersectionality strategies focus on incorporating multidisciplinary insights into policy and curriculum development, ensuring a broad and inclusive knowledge base. Mid-sized universities such as Urbino, Pavia, and Calabria emphasize regional and interdisciplinary knowledge-sharing networks. Their approach to Knowledge Management is more targeted, focusing on faculty training programs, student mentoring systems, and internal co-working spaces for collaborative learning. These institutions implement structured peer-learning programs and encourage faculty-student knowledge exchange initiatives to maximize research and learning accessibility. Smaller universities, such as Teramo and Perugia, tend to prioritize in-person knowledge-sharing models rather than relying heavily on digital infrastructure. Their inclusivity measures include interactive knowledge hubs, interdisciplinary research projects, and customized access to knowledge for underrepresented groups. While they may lack large-scale digital repositories, they compensate with direct engagement strategies, faculty accessibility, and close collaboration between students and professors. Institutional size directly influences the scalability and integration of Knowledge Management strategies. Large universities emphasize technology-driven solutions, mid-sized institutions focus on regional engagement and faculty-student collaboration, while smaller universities favor personal engagement models over large-scale digital platforms.

4.3 Integration between diversity management and knowledge management

Based on the PIAO document and the outlined criteria, the integration of Knowledge Management and Diversity Management in HEIs reveals comprehensive strategies that align inclusivity, collaboration, intersectionality, and technology integration to promote equity and innovation. HEIs ensure inclusive access to knowledge by creating platforms that cater to diverse needs, such as centralized repositories, digital learning environments, and accessible content for individuals with disabilities. Collaboration is enhanced through tools that enable seamless teamwork across disciplines and geographies, fostering innovative solutions through diverse perspectives. Intersectionality is addressed by designing systems that adapt to the overlapping identities and varied needs of students and staff, integrating measures to support individuals with compounded challenges like gender and socio-economic disparities. Additionally, technology serves as a critical enabler, bridging gaps between different groups by implementing advanced ICT tools, hybrid learning models, and AI-driven personalization to disseminate knowledge effectively. These integrations demonstrate a concerted effort to harness diversity for institutional growth and societal impact, aligning with the principles of equity, inclusivity, and global engagement.

The analysis of Knowledge Management and Diversity Management across universities reveals significant differences and gaps in their approaches based on inclusivity, collaboration, intersectionality, and technology integration. In terms of inclusivity, while some universities excel in creating open-access platforms and ensuring equitable access to knowledge resources for disadvantaged groups, others struggle to remove systemic barriers or implement adequate accessibility measures for individuals with disabilities. Regarding collaboration, larger institutions often leverage advanced cloud-based systems and interdisciplinary networks to harness diverse perspectives, whereas smaller universities may lack the resources or digital infrastructure to enable effective teamwork and knowledge sharing across departments. In addressing intersectionality, disparities are evident as many universities fail to fully integrate the complexity of overlapping identities into their policies and systems, resulting in one-size-fits-all solutions that overlook nuanced needs. Lastly, technology integration is uneven, with well-funded universities adopting AI-driven personalization, hybrid learning models, and advanced digital tools to bridge gaps between diverse groups, while resource-constrained institutions lag behind in their ability to provide inclusive and accessible technological solutions. Bridging these gaps requires targeted investments, comprehensive policy reforms, and a stronger focus on inclusivity and adaptability in institutional strategies.

Large universities, such as Milan, Bologna, and Sapienza, implement structured and technology-driven diversity policies to ensure inclusive access to knowledge and organizational participation. These institutions rely on digital repositories, open-access academic platforms, and AI-powered recruitment systems to foster

inclusivity. They also prioritize collaborative networks across departments and international institutions, leveraging digital tools for remote participation and knowledge dissemination. Intersectionality is integrated into these universities' governance models, ensuring policies and services reflect diverse student and faculty needs, particularly through multidisciplinary research collaborations and inclusive hiring frameworks. Mid-sized universities, such as Urbino, Pavia, and Calabria, adopt a regionally focused approach to inclusivity and collaboration. They emphasize faculty-student mentorship programs, peer-learning initiatives, and interdisciplinary teamwork rather than relying on large-scale digital infrastructure. These universities foster knowledge management through structured faculty training, academic networking programs, and data-driven diversity audits. Technology integration is present, but often in the form of learning management systems and hybrid learning models, rather than fully automated knowledge-sharing platforms. Smaller universities, such as Perugia and Teramo, focus on community engagement and personalized inclusivity strategies. Their knowledge-sharing models are primarily interpersonal, relying on face-to-face collaboration, localized mentorship programs, and direct student-faculty engagement. While digital transformation is present, it is less pronounced, with these universities using basic e-learning platforms and document-sharing systems instead of AI-driven knowledge repositories or complex intersectionality frameworks. Institutional size strongly influences Diversity and Knowledge Management strategies. Large universities integrate comprehensive, technology-driven, and scalable inclusion models, while mid-sized institutions rely on regional engagement and faculty collaboration. Smaller universities maintain personalized, direct engagement strategies, prioritizing interpersonal knowledge exchange over advanced digital infrastructures.

5 Discussion and conclusions

The integration of Diversity Management (DM) and Knowledge Management (KM) in Italian Higher Education Institutions (HEIs) reveals an evolving yet fragmented approach. While strides have been made in areas such as inclusivity, collaboration, intersectionality, and technology integration, significant gaps remain. Many universities have introduced initiatives like gender equality plans and support systems for disadvantaged groups, but these efforts often lack depth and alignment with broader institutional goals. The uneven adoption of advanced technologies and insufficient focus on intersectionality further limit the impact of diversity and knowledge strategies.

Technology plays a crucial role in addressing these gaps. AI-driven tools can personalize learning experiences, identify participation barriers, and refine inclusion strategies. Digital platforms must be expanded to offer accessible, multilingual, and user-friendly interfaces, ensuring equitable access to knowledge. Additionally, advanced analytics can enhance the evaluation of diversity initiatives, providing actionable insights to refine policies and improve institutional outcomes.

The integration of intersectionality remains a key challenge for HEIs. Many universities fail to fully address overlapping identities such as gender, ethnicity, and socio-economic status, resulting in one-size-fits-all policies that overlook nuanced needs. Incorporating frameworks that reflect and adapt to the complexity of diverse identities is essential. Data-driven approaches should be employed to identify disparities and measure the effectiveness of policies designed for intersectional inclusion.

Collaboration across institutions is another critical area for improvement. Partnerships between universities can facilitate resource sharing, best practices, and innovative solutions for integrating DM and KM. Joint research projects and interdisciplinary networks can further promote the exchange of diverse perspectives, enhancing innovation and organizational learning. Expanding international and regional collaborations can ensure that all institutions, regardless of size or resources, benefit from collective advancements in diversity and knowledge strategies.

Policy and funding support are fundamental to bridging resource disparities, particularly for smaller or underfunded universities. Comprehensive reforms must include mandatory diversity metrics in strategic planning and allocate funding to bridge technological gaps. Targeted investments in technology and diversity initiatives can ensure equitable progress across the sector, enabling all institutions to create inclusive, innovative environments.

In conclusion, Italian HEIs must embed diversity as a transformative element within their strategic frameworks, leveraging the dynamic capabilities of KM to foster equitable, inclusive, and innovative academic environments. The synergy between DM and KM, driven by technological advancements and a commitment to intersectionality, will enable universities to meet societal challenges effectively and contribute to sustainable development. These efforts must be supported by continuous policy evolution, resource allocation, and collaborative networks to ensure meaningful progress across the higher education sector.

Diversity Management and Knowledge Management across Italian universities indicate that institutional size, technological infrastructure, and strategic alignment play a crucial role in shaping how inclusivity, collaboration, intersectionality, and technology integration are implemented. Larger universities have the advantage of scalability, enabling them to integrate advanced AI-driven solutions for knowledge dissemination, recruitment, and diversity tracking. These institutions are more likely to develop automated systems for talent acquisition, inclusive hiring, and interdisciplinary research, leveraging AI to eliminate bias and ensure fair representation. In contrast, mid-sized universities focus on regional engagement and faculty-student interaction, often employing structured but less technology-intensive approaches to diversity and knowledge-sharing. Smaller universities, while emphasizing personalized engagement strategies and direct community involvement, often lack the AI-driven tools and large-scale digital platforms that allow for efficient diversity tracking and automated knowledge management. A significant divergence emerges in the use of AI and technology. Larger institutions integrate AI-powered learning management systems, hybrid teaching models, and digital knowledge repositories, ensuring accessibility and broad participation. AI is also utilized in data-driven diversity assessments, improving policy effectiveness by analyzing intersectionality trends across gender, ethnicity, and socio-economic backgrounds. Mid-sized and smaller institutions, due to resource constraints and limited infrastructure, rely more on traditional mentorship models, in-person collaboration, and regional partnerships, lacking the full-scale AI-driven optimization seen in larger institutions. The findings underscore that universities must bridge these gaps by leveraging AI and digital transformation while maintaining human-centered approaches to knowledge and diversity management. Investment in AI-driven inclusivity tools, interdisciplinary collaboration platforms, and adaptive learning technologies can enhance knowledge-sharing and diversity integration across all institutional levels, ensuring sustainable, inclusive, and technology-driven growth within the Italian higher education system.

[2]University of Salento, Lecce, Italy

Abstract

Traditional workplace policies aimed at supporting work-life balance, career development, and organizational support have largely been designed with employees with children in mind. However, such family-centric approaches risk marginalizing the growing number of employees who are childfree by choice or who desire children in the future. These groups often remain underrepresented in both academic literature and organizational practice. This paper proposes a conceptual framework for rethinking workplace equity by integrating diverse family statuses and future aspirations into the analysis of fairness perceptions. Drawing on equity theory, we examine how three groups—parents, childfree employees by choice, and employees desiring children—differ in their experiences and expectations of fairness across three core domains: work-life balance, career progression, and perceived organizational support (POS). We introduce the concept of *anticipatory fairness* to capture how employees evaluate current policies not only based on present conditions but also in light of their anticipated future needs and life trajectories. The framework identifies hidden and often overlooked inequities in how support is distributed, how opportunities for career advancement are perceived, and how organizational inclusion is experienced by employees with differing family orientations. Based on this conceptual foundation, we propose three theoretical propositions and outline directions for future empirical research. Our model encourages organizations to move beyond binary categories of parenthood and to develop more inclusive policies that recognize the full diversity of employee identities. By embracing a broader and more dynamic understanding of equity, organizations can foster greater fairness, motivation, and retention across all employee groups, ultimately contributing to more inclusive and sustainable workplaces.

Keywords: Equity theory, Work-life balance, Career progression, Perceived organizational support, Anticipatory fairness, Childfree employees, Inclusion

Paper type: Academic Research Paper

1 Introduction

In contemporary organizations, the concept of work-life balance has become a central element in discussions around employee well-being, fairness, and inclusion. Traditionally, organizational policies addressing work-life integration have focused primarily on supporting employees with children, under the assumption that they face the most significant challenges in balancing professional and personal responsibilities. While this perspective has led to valuable advances in family-friendly policies—such as parental leave, flexible scheduling, and remote work—it has also unintentionally marginalized other employee groups whose needs may not align with conventional family structures.

In particular, the experiences of childfree employees, both by choice and by circumstance, remain significantly underexplored in academic literature and organizational practice. These workers often navigate workplaces structured around implicit assumptions of parenthood, which can affect how they are perceived by peers and superiors, how they access support and development opportunities, and how they evaluate fairness within the organization. Emerging studies suggest that this "parent-centric" orientation may lead to feelings of exclusion or inequity among non-parent employees, who may be expected to take on additional work or show greater availability, based on the assumption that they are less burdened outside of work.

Furthermore, recent demographic and cultural shifts have led to an increase in employees who either choose to remain childfree or delay parenthood for personal or professional reasons. These individuals may also have complex personal responsibilities—such as caregiving for aging parents, engaging in lifelong learning, or pursuing personal goals—which are not always recognized by existing organizational policies. The dichotomy between parents and non-parents thus oversimplifies the spectrum of employee needs, aspirations, and perceptions of fairness.

Another often-overlooked group consists of employees who desire to have children in the future but have not yet done so. These individuals frequently engage in anticipatory evaluations of work-life balance, career progression, and organizational support, assessing whether their current workplace would enable or hinder

future family aspirations. This dimension introduces a future-oriented perception of equity that has received little attention in the literature.

To address these gaps, this paper proposes a conceptual reframing of how organizations can understand and promote fairness across different family status groups. Drawing on equity theory, we explore how perceived fairness is influenced not only by actual support and career outcomes but also by the alignment between employees' contributions and their expectations of organizational reciprocity. We argue that perceived equity in the workplace must be reconsidered through a more inclusive and differentiated lens—one that accounts for the heterogeneity of employee life choices and trajectories.

By integrating insights from existing research on work-life balance, career development, and perceived organizational support (POS), we build a conceptual framework that highlights the diverse pathways through which fairness perceptions are formed. In particular, we focus on three employee categories: those with children, those who desire children, and those who are childfree by choice. We develop a set of theoretical propositions to guide future research and policy design, with the goal of fostering more inclusive work environments that respect and support the full range of employee identities and aspirations.

2 Theoretical Background

2.1 Equity in the Workplace: A Theoretical Foundation

Perceptions of fairness are a fundamental element in shaping employee attitudes and behaviors in organizational settings. Equity theory (Adams, 1965) offers a valuable lens to understand these perceptions, suggesting that individuals assess fairness by comparing the ratio between their inputs (such as effort, skills, and time) and outcomes (such as recognition, advancement, and support), relative to others. When this ratio is perceived as imbalanced, individuals may experience distress, dissatisfaction, or disengagement (Barclay et al., 2017; Skarlicki & Kulik, 2004).

The application of equity theory has traditionally focused on tangible elements such as compensation or workload, but more recent research extends its relevance to intangible dimensions like organizational support and career opportunities. This broader interpretation is particularly useful in analyzing how different employee groups experience the workplace, especially when their needs and contributions are shaped by factors such as gender, family responsibilities, or life choices (Morand & Merriman, 2012).

In this context, fairness is not an objective condition but a subjective perception that can vary significantly across individuals and groups, depending on their expectations, roles, and personal circumstances. This makes it crucial to analyze how organizational practices are experienced differently based on family status—a dimension that is often oversimplified or ignored.

2.2 Work-Life Balance: Beyond Parenthood

Work-life balance is typically defined as an individual's ability to manage professional and personal responsibilities effectively (Guest, 2002). Over the past two decades, organizations have increasingly introduced policies to support this balance, including flexible work arrangements, parental leave, and teleworking options. These measures are generally designed with working parents in mind, especially mothers, who are perceived as facing the greatest challenges in reconciling work and family roles (Hilbrecht et al., 2008; Kelliher et al., 2019).

However, this parent-centric approach to work-life policies may inadvertently neglect the needs of other groups. Employees without children—whether by choice or circumstance—may also experience significant work-life challenges related to caregiving for elderly relatives, community involvement, health issues, or personal development goals (Boiarintseva et al., 2022; Casper et al., 2016). Despite these responsibilities, they are often expected to be more flexible, more available, and more committed, simply because they do not have children (Wood & Newton, 2006). This can result in increased workloads and a sense of unfair treatment, as their time outside of work is perceived as less valuable or legitimate.

Moreover, the lack of recognition for diverse personal responsibilities reinforces the stereotype that only parents need work-life balance. This perception may be particularly problematic for employees who plan to have children in the future. These individuals may evaluate the adequacy of work-life policies not just in terms of current support but also as a signal of the organization's capacity to accommodate future needs—a concept we define as *anticipatory fairness*.

2.3 Career Progression: Structural Inequities and Hidden Biases

Career advancement is another domain where equity perceptions are shaped by family status. The well-documented "motherhood penalty" highlights how women with children often face slower promotions, reduced responsibilities, and wage stagnation compared to their childless counterparts (Aisenbrey et al., 2009; McIntosh et al., 2012). This penalty is frequently attributed to assumptions about mothers' availability, commitment, or capacity to handle demanding roles.

Conversely, men with children may benefit from a "fatherhood premium," being perceived as more stable and responsible (Luhr, 2020). These dynamics reflect deep-seated gender norms and expectations about parenting roles, but they also contribute to structural inequities in career trajectories.

Childfree employees, particularly those who are voluntarily childfree, are often assumed to be more dedicated, flexible, and mobile. While this can result in more opportunities, it may also lead to exploitation: increased workloads, frequent travel, or lack of boundaries between work and personal life (Dumas & Perry-Smith, 2018). These individuals may be rewarded with responsibilities rather than recognition, leading to frustration and burnout. Moreover, the assumption that childfree workers are inherently more available reinforces a discriminatory logic, placing the burden of organizational efficiency on those without caregiving duties.

Employees who are not yet parents but intend to have children may face different but equally problematic dynamics. They may hesitate to pursue promotions or long-term projects, fearing that family formation could disrupt their trajectory or be viewed negatively by the organization. In such cases, the anticipation of future inequities can be just as powerful as current ones in shaping behavior and perceptions.

2.4 Perceived Organizational Support and Inclusion

Perceived Organizational Support (POS) refers to employees' beliefs about how much their organization values their contributions and cares about their well-being (Kurtessis et al., 2017; Rhoades et al., 2001). POS is strongly associated with increased job satisfaction, organizational commitment, and retention. For parents, visible support often takes the form of family-friendly policies, understanding supervisors, and flexible arrangements (Chang et al., 2014).

Yet, the same signals may not resonate with employees who are not parents. Childfree individuals often seek different forms of support—such as professional development opportunities, personal leave for non-family commitments, or greater autonomy (Casper et al., 2007; Peterson & Engwall, 2016). When organizational support is framed predominantly in terms of family needs, non-parents may feel overlooked, excluded, or even punished for their different life choices.

This perception of exclusion is exacerbated when support mechanisms are implemented unevenly or informally, creating ambiguity about who qualifies for what kind of support. Moreover, the assumption that childfree employees do not need or deserve the same level of support contributes to a culture in which only certain life paths are validated and accommodated.

Thus, expanding the concept of POS to include a broader range of life experiences and commitments is essential for fostering an inclusive organizational culture. This includes recognizing that fairness is not only about providing the same policies to everyone, but also about ensuring that different needs are addressed equitably.

2.5 Toward an Inclusive Understanding of Workplace Equity

The literature reviewed highlights a significant gap in how organizational fairness is conceptualized and operationalized. Most existing studies focus on the experiences of parents—often with a binary view of family status—while neglecting the complex and evolving realities of today's workforce. There is limited exploration of how childfree employees navigate workplace expectations, and even less attention to the anticipatory perspectives of those who desire children but have not yet started families.

Moreover, the intersection between family status and perceptions of fairness remains under-theorized. Equity theory offers a useful starting point, but its application must be expanded to capture the subjective, temporal, and contextual nature of fairness as experienced by diverse employee groups.

To address these gaps, we argue for a reconceptualization of workplace equity that moves beyond traditional parent/non-parent dichotomies. This involves recognizing the heterogeneity of non-parent employees, acknowledging future-oriented aspirations, and designing policies that support multiple life paths with equal respect and consideration.

In the next section, we propose a conceptual framework and a set of theoretical propositions aimed at guiding future empirical research and informing more inclusive organizational practices.

3 Theoretical Gaps

Despite a growing body of research on work-life balance, career development, and perceived organizational support (POS), the literature remains largely centered on the experiences of employees with children. Organizational scholarship has historically approached family status in binary terms—parent versus non-parent—frequently overlooking the diversity of experiences within the latter category. As a result, current theoretical frameworks often fail to capture the nuanced and evolving realities of the contemporary workforce.

First, the majority of studies on work-life balance focus on how parents—particularly mothers—manage the dual demands of work and caregiving. While this has led to significant advances in understanding the "motherhood penalty" or the "fatherhood premium," it has also contributed to a limited and sometimes biased view of who deserves or needs organizational support. The needs and expectations of employees without children are often excluded from these analyses, reinforcing the assumption that work-life balance policies are relevant only for caregivers. This narrow framing results in a lack of theoretical tools to examine how childfree employees experience, evaluate, and respond to these same organizational policies.

Second, the literature rarely distinguishes between different types of non-parent employees. Those who are childfree by choice and those who desire to have children in the future are frequently grouped together under the undifferentiated label of "non-parents." This analytical shortcut obscures important differences in how these groups perceive fairness, make career decisions, and engage with organizational support systems. For example, individuals who plan to have children may evaluate current policies based on their future aspirations, while voluntarily childfree employees may seek recognition for non-family commitments. Theoretical models have yet to systematically incorporate these forward-looking or alternative perspectives on fairness, which we refer to as anticipatory fairness.

Third, there is a limited understanding of how fairness perceptions are formed among childfree employees. Existing frameworks tend to assume that childfree workers are more flexible, more committed, or more available—without considering how these assumptions affect their actual treatment or their perceptions of equity in terms of workload, recognition, and career development. The lived experiences of these workers are often rendered invisible or trivialized, leading to a theoretical blind spot in studies of organizational justice and inclusion.

Fourth, the construct of Perceived Organizational Support (POS) has been largely operationalized through the lens of family-friendly policies. While this focus is justified in addressing the historical exclusion of caregivers from full workplace participation, it risks creating a new imbalance. Employees whose needs do not fall under the category of "family" may feel excluded or undervalued. Yet few theoretical models explicitly consider how POS might be perceived differently by employees without children, or how organizations can broaden their support frameworks to be more inclusive.

Fifth, the intersectionality between family status, career stage, gender, and generational identity remains underexplored. Younger employees, for instance, may hold different expectations about work-life balance, career advancement, or personal fulfillment than previous generations. They may also be more likely to delay or forgo parenthood, making the traditional alignment between life stage and family responsibilities increasingly obsolete. Theoretical approaches that do not consider these dynamics risk offering outdated or incomplete explanations of workplace equity.

In sum, the existing literature provides valuable insights into the challenges faced by parents in the workplace but fails to offer equally robust conceptual tools to understand the experiences of non-parents, particularly in their diversity. Addressing this gap requires a shift in theoretical focus: from a family-centric model of organizational fairness to one that recognizes the full range of employee identities, life choices, and future aspirations. In the following section, we propose a conceptual framework and a set of theoretical propositions that aim to respond to these gaps and guide future empirical inquiry.

4 Conceptual Framework

To address the theoretical gaps identified in the literature, we propose a conceptual framework that rethinks workplace equity by incorporating the diverse family statuses and future aspirations of employees. Drawing on equity theory, the framework examines how different employee groups—parents, childfree employees by choice, and those desiring children—perceive fairness in three key organizational domains: work-life balance, career progression, and perceived organizational support (POS).

The framework is structured around two core ideas:

1. The relational nature of equity perceptions, in which fairness is assessed by comparing one's inputs (e.g., effort, time, flexibility) to outcomes (e.g., recognition, support, advancement) relative to others in the organization.

2. The temporal and aspirational dimension of fairness, recognizing that perceptions are shaped not only by current experiences but also by anticipated future needs or trajectories (anticipatory fairness).

4.1 Dimensions of Perceived Fairness

We identify three interrelated domains where equity perceptions are most salient:

- Work-Life Balance Equity: Perceived fairness in the allocation of flexibility, time-off policies, and accommodation of personal responsibilities. While traditionally designed for caregivers, these policies also affect childfree employees and those planning to have children. The framework suggests that fairness in this domain depends not only on the availability of policies, but on how inclusive and adaptable they are to different life situations.
- Career Progression Equity: Perceptions of fairness in advancement opportunities, promotions, and access to development pathways. Parents may experience structural barriers due to career interruptions, while childfree employees may face hidden penalties such as being overburdened or excluded from informal networks. Employees desiring children may evaluate fairness based on the perceived long-term consequences of starting a family.
- Perceived Organizational Support (POS): Fairness in how the organization expresses care, recognition, and investment in employee well-being. While family-friendly policies may increase POS for parents, they may lower it for others if perceived as exclusive. Broadening the scope of POS to encompass non-family commitments is central to inclusive support.

4.2 Employee Family Status and Equity Perceptions

The framework differentiates between three employee groups, acknowledging their unique experiences and sources of (in)equity:

- Employees with Children: Often benefit from formal family policies, but may experience stalled careers or stigma around flexibility. They assess fairness through the trade-off between support and opportunity loss.
- Childfree Employees by Choice: Frequently expected to absorb additional responsibilities due to their perceived availability. They may feel unfairly burdened and excluded from organizational care, especially when support is framed exclusively in terms of family.
- Employees Desiring Children: Experience fairness through an anticipatory lens. They evaluate whether current organizational conditions can support future family formation, and may adjust their engagement or career decisions accordingly.

These distinctions are critical because each group navigates the same organizational environment with different expectations, needs, and social meanings attached to their family status.

4.3 Mediators and Moderators

The framework also incorporates contextual and psychological variables that may mediate or moderate the perception of fairness:

- Organizational Culture: The extent to which inclusivity, flexibility, and diversity of life choices are genuinely supported or merely symbolic.
- Leadership Style: The behavior of direct supervisors and senior leaders in modeling inclusive behavior, recognizing diverse needs, and avoiding biased assumptions about availability or commitment.
- Generational Identity: Younger generations may be more sensitive to fairness as it relates to lifestyle autonomy, while older employees may prioritize stability or long-term support.
- Gender Norms: Deeply embedded beliefs about parenting roles can differentially affect men and women across all three employee categories.

4.4 Anticipatory Fairness: A Key Theoretical Contribution

A distinctive contribution of this framework is the concept of anticipatory fairness, which refers to fairness perceptions that are not based solely on present experiences, but on how current conditions are projected to impact future choices. This is particularly relevant for employees who are considering starting a family or making other major life changes. By incorporating this forward-looking dimension, the framework broadens equity theory beyond static comparisons of inputs and outputs, introducing a dynamic perspective aligned with life-course thinking.

In the next section, we translate the conceptual model into three theoretical propositions, offering testable statements that can guide empirical research and organizational reflection.

5 Theoretical Propositions

Proposition 1:

Employees without children, particularly those who are childfree by choice, are more likely to perceive work-life balance policies as inequitable when such policies are framed or implemented primarily in support of parental responsibilities.

Rationale:

While organizations increasingly offer flexibility and family-friendly arrangements, these are often designed with the assumption that only parents need time or flexibility. Childfree employees—despite having other legitimate personal needs—may feel excluded from these benefits, leading to lower perceptions of fairness. Equity theory suggests that when contributions (e.g., extra availability, workload) are not matched by comparable recognition or support, perceptions of inequity emerge.

Proposition 2:

Employees with children perceive greater inequity in career progression opportunities due to structural and cultural barriers, while childfree employees may perceive inequity due to overwork and a lack of compensatory recognition.

Rationale:

Parents, particularly mothers, often face slower career advancement due to maternity leaves, part-time arrangements, or biased assumptions about their availability. Conversely, childfree employees may be assigned more work or asked to "fill in" for parents without receiving equivalent career rewards. These differing experiences reveal that both groups may perceive the career system as unfair, albeit for opposite reasons, reinforcing the need to rethink meritocracy through an inclusive lens.

Proposition 3:

Employees who plan to have children in the future evaluate organizational policies through a lens of anticipatory fairness, and are more likely to disengage or delay family formation if they perceive a lack of future support.

Rationale:

This proposition introduces a forward-looking dimension to equity theory. Employees do not only react to current support, but also to their expectations of how future needs will be met. If current work conditions appear incompatible with future life goals—such as having a child or building a family—employees may interpret this misalignment as unfair. This anticipatory evaluation can influence organizational commitment, career decisions, and life choices.

6 Managerial and Future Research Implications

6.1 Managerial Implications

This conceptual exploration has significant implications for how organizations design and implement their work-life policies, career development systems, and support mechanisms. In particular, it challenges the assumption that fairness can be achieved through a one-size-fits-all approach focused primarily on parental status.

1. **Design Inclusive Work-Life Policies:** Organizations should ensure that work-life balance initiatives are not exclusively targeted at employees with children. This means expanding the rationale behind flexible work arrangements to include a wide range of personal needs—such as mental health, caregiving for elders, or personal growth. Communicating policies as universally applicable rather than parent-specific can increase perceived fairness across all employee groups.
2. **Reevaluate Career Progression Practices:** Promotion and development systems should be transparent and based on merit, with mechanisms to monitor and prevent both penalization (e.g., for taking parental leave) and exploitation (e.g., of perceived availability among childfree workers). This includes fostering a culture that normalizes different career paces and avoids assumptions based on family status.
3. **Broaden the Scope of Organizational Support:** Perceived Organizational Support (POS) should be decoupled from family-specific benefits. Managers can increase POS by recognizing diverse life choices and offering meaningful support to all employees—such as access to learning opportunities, autonomy,

and recognition—regardless of parental status. This also requires training managers to avoid unconscious biases in how support and flexibility are distributed.

4. **Acknowledge Anticipatory Needs:** Managers should be aware that employees are not only evaluating current conditions, but also making decisions based on anticipated life changes. By fostering a culture of open dialogue and proactively signaling support for future life transitions (e.g., becoming a parent, caring for others), organizations can retain talent and strengthen employee engagement.

6.2 Implications for Future Research

This framework opens several pathways for empirical and theoretical development:

1. **Empirical Testing of Anticipatory Fairness:** Future research should operationalize and test the concept of *anticipatory fairness*, examining how employees' future-oriented expectations influence perceptions of equity, engagement, and career planning. Longitudinal or life-course approaches would be particularly suitable for capturing these dynamics.
2. **Differentiation Within Non-Parent Groups:** More empirical work is needed to distinguish between the experiences of childfree employees by choice, those who are childless by circumstance, and those desiring children. These subgroups may exhibit different psychological responses to the same organizational environment.
3. **Intersectionality with Gender, Age, and Career Stage:** Equity perceptions likely vary at the intersection of family status with gender, generational identity, and seniority. For instance, younger employees may be more sensitive to fairness in future support, while older employees may prioritize stability or autonomy. Comparative studies could help to reveal how these factors interact.
4. **Cross-Cultural and Sectoral Studies:** The model should be tested across national and cultural contexts, as well as across public vs. private sector organizations. Norms around family, work commitment, and support vary widely, and contextualizing fairness perceptions is essential for generating globally relevant insights.
5. **Mixed Methods and Configurational Approaches:** Given the complexity and multidimensionality of perceived fairness, future studies might employ methods such as fsQCA or mixed-methods designs to capture the combinations of conditions that produce perceptions of equity or inequity. This approach is particularly useful when investigating heterogeneous groups with overlapping identities.

Thus, this framework invites a shift in how we theorize and manage equity in the workplace—moving beyond reactive support for parents toward a holistic, future-oriented, and inclusive approach that recognizes and respects the diversity of employee life paths.

Ethics Declaration

This research involved human participants and followed all institutional and national ethical standards. Participation was voluntary, and informed consent was obtained from all individuals involved. No personal or sensitive data have been disclosed.

AI Declaration

No generative artificial intelligence tools were used in the preparation of this manuscript.

ESG and AI: The Role of a New Player in the Sustainability's Game. Explorative Analysis of the Potential Impact of Artificial Intelligence in Business Sustainable Performance.

Giuseppe Maria Bifulco[1], Fabrizio Maria Bertusi[1], Leonzio Capparelli[2]
[1]Universitas Mercatorum, Rome, Italy
[2]Sapienza Università di Roma, Rome, Italy

Abstract

The study explores the relationship between AI adoption and ESG performance, addressing a gap in literature. AI enhances sustainability by improving environmental monitoring, optimizing resource allocation, and fostering circular economy initiatives. Socially, AI promotes diversity and workplace well-being through advanced algorithms, while in governance, it strengthens oversight, risk assessment, and compliance. Using Bloomberg data on U.S. and Western European companies, the study tests whether ethical AI policies impact ESG scores. The results confirm a significant positive effect, suggesting that responsible AI adoption strengthens corporate transparency, investor trust, and decision-making.

Keywords: AI, ESG, Listed companies, USA and Western Europe

Paper type: Academic Research Paper

1 Introduction

This study aims to explore the interconnection between artificial intelligence (AI) and environmental, social, and governance (ESG) practices. Despite the broad academic interest in both fields, few studies directly analyze this relationship (Zhang & Yang, 2024). Our research aims to fill this gap by investigating whether companies' adoption of AI impacts their sustainability performance (ESG).

ESG practices are now central to many companies, given the growing awareness of sustainability issues and regulatory and social pressure (Bifulco et al., 2023). On the other hand, AI represents one of the most promising technologies for transforming and improving business processes and strategic decisions. However, as Nishant et al. (2020) and Vinuesa et al. (2020) point out, the intersection between AI and ESG is not yet fully understood, despite its potential to revolutionize how companies approach sustainability.

The study examines the impact of ethical policies on AI use on ESG performance, using Bloomberg data on 348 companies in the US and Western Europe. The analysis shows that companies with ethical AI guidelines achieve significantly higher ESG Scores. The regression model indicates a positive and significant coefficient, confirmed even when including control variables such as company size and financial performance. This suggests that adopting responsible AI practices enhances corporate sustainability, strengthens stakeholder trust, and optimizes strategic decision-making related to ESG objectives.

2 Literature review and hypothesis development

The convergence of technological innovation and sustainability goals creates significant opportunities to study how AI influences ESG practices. From an environmental perspective, advanced AI technologies improve ecological monitoring, optimize resource allocation, and support circular economy initiatives (Vinuesa et al., 2020). In the social context, AI helps promote diversity and workplace well-being through advanced selection algorithms and personalized professional development programs (Tamburri, 2020). Concerning governance, AI strengthens organizational oversight mechanisms, improving risk assessments and compliance procedures (Felício et al., 2016).

Previous studies have highlighted how ESG performance strongly correlates with financial results (Friede et al., 2015; Tang & Yang, 2023). However, the role of AI in influencing such results through improving ESG practices remains largely unexplored. As Adeoye et al. (2024) and Chiaramonte et al. (2022), financial institutions that use AI to assess ESG achieve superior returns on investments, suggesting a promising link between technology and sustainability.

Overall, implementing AI in companies offers numerous benefits, including increased transparency and improved decision-making effectiveness (Davenport & Ronanki, 2018). For example, advanced AI-based analytics improve the accuracy and timeliness of ESG reports, strengthening stakeholder trust (Pappas et al.,

2018). Furthermore, AI applications optimize industrial energy consumption, helping to reduce carbon emissions (Nishant et al., 2020).

Qi Yudong et al. (2024) identified a strong synergy between the adoption of digital technologies and ESG performance, demonstrating their combined positive impact on firm performance, though with variations across regions. Similarly, Zhou Hailing and Liu Ji (2023) found a significant positive correlation between ICT and corporate ESG performance, emphasizing the crucial role of energy efficiency in achieving ESG objectives. Lastly, Xie and Wu (2025) show how companies adopting ethical guidelines for AI achieve higher ESG scores, highlighting how the responsible integration of AI is positively perceived by stakeholders, strengthening both corporate sustainability and investor trust.

Despite these opportunities, significant challenges also emerge. AI infrastructure, for example, entails significant environmental costs related to energy consumption (Truby, 2020). Therefore, it is necessary to develop sustainable systems that balance technological efficiency and environmental impact and, as highlighted by Rahwan et al. (2019), harmonize AI capabilities with social values to ensure a positive impact on communities.

The relationship between AI adoption and ESG performance is complex and potentially indirect. A crucial role in this relationship is played by absorptive capability, defined as an organization's ability to recognize, assimilate, and apply new external knowledge (Cohen & Levinthal, 1990). This concept acts as a bridge, enabling companies to leverage AI technologies for sustainable practices effectively. Zahra and George (2002) further developed the notion by distinguishing between potential absorptive capability, which involves acquiring and assimilating knowledge. They realized absorptive capability, which involves transforming and applying that knowledge.

Some research, such as Xie et al. (2019), shows that absorptive capability positively moderates the relationship between green technological innovation and firm performance. Gomez-Mejiaet al. (2019) further highlight that companies with greater absorptive capacity respond better to stakeholder demands for sustainable practices, translating such pressures into improved ESG outcomes.

Considering those assumptions, we develop the following hypothesis

HP: *The adoption of ethical guidelines and policies related to the use, design, and development of Artificial Intelligence (AI) has a positive and significant impact on sustainability performance as measured by the ESG Score*.

3 Sample and method

To develop our analysis, the reference dataset was constructed exclusively referring to Bloomberg as data provider. The sampling procedure for corporate observations was carried out using Bloomberg's equity screening function (EQS), querying the terminal about the following criteria:

- Trade status: active;
- Equity attributes: primary company stock only;
- Country: US and Western EU;
- Industry sector: communications, consumer cyclical and non-cyclical, energy, financial, technology and industrial.

Sampling was specifically limited to those companies (so-called equity tickers) for which the Bloomberg data provider guarantees data availability with respect to the "AI_ETH_PLCY" field. Indeed, this field indicates whether the observed company has implemented ethical guidelines and/or undertaken compliance activities related to the use, design, and development of Artificial Intelligence (AI). A value of "Y" (1) indicates the company's commitment to adopting AI practices aimed at minimizing disparities and promoting inclusive representation. Otherwise, Bloomberg returns "N" (0). The ESG Score assigned by Bloomberg, along with the scores for each pillar (Environmental Score, Social Score, and Governance Score), was collected for each equity ticker in the sample.

Additionally, avoiding multicollinearity problems, the dataset was enriched with the following control variables: total assets and total revenues (both expressed as natural logarithms), EBIT (expressed as a natural logarithm), EPS, ROE, ROA, ROIC, and the Tobin's Q ratio.

The table below provides a description of the variables included in the dataset used for the analysis.

The variables include the dummy variable identifying whether firms have adopted ethical policies on artificial intelligence, the ESG Scores, financial and economic metrics.

Table 1: List and description of the variables.

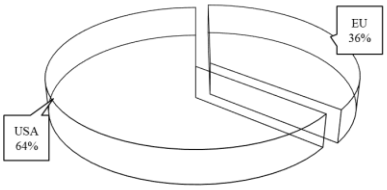
List of variables	Description
ARTFCIL_INTLLGENCE_ETH_PLCY (Dummy Variable)	Artificial Intelligence Ethical Policy (ARTFCIL_INTLLGENCE_ETH_PLCY) Indicates whether the company has adopted ethical guidelines and/or alignment activities for the designed and developed Artificial Intelligence (AI). 1 indicates the company is committed to AI that minimizes gaps and promotes inclusive representation.
ESG_SCORE	ESG Score (ESG_SCORE) Provides the Bloomberg score assessing the company's overall ESG performance. The score is a generalized weighted average (power) of the Pillar scores, where weights are determined by the pillar priority ranking. Values range from 0 to 10; 10 is best.
ENVIRONMENTAL_SCORE	Environmental Pillar Score (ENVIRONMENTAL_SCORE) Provides the Bloomberg score assessing the company's overall environmental performance. The pillar score is a generalized weighted average (power) of issue scores, where weights are determined by the issue priority ranking. Values range from 0 to 10; 10 is best.
SOCIAL_SCORE	Social Pillar Score (SOCIAL_SCORE) Provides the Bloomberg score assessing the company's overall social performance. The pillar score is a generalized weighted average (power) of issue scores, where weights are determined by the issue priority ranking. Values range from 0 to 10; 10 is best.
GOVERNANCE_SCORE	Governance Pillar Score (GOVERNANCE_SCORE) Provides the Bloomberg score assessing the company's overall governance performance. The pillar score is a generalized weighted average (power) of theme scores, where weights are determined by the theme priority ranking. Values range from 0 to 10; 10 is best.
BS_TOT_ASSET	Total Assets (BS_TOT_ASSET) Total assets: The total of short- and long-term assets as reported on the balance sheet. For "Financials", Total assets: Sum of cash and equivalents, short-term investments and securities inventory, net receivables, total long-term investments, net fixed assets, and other assets. BS_TOT_ASSETLN is expressed as a natural logarithm.
SALES_REV_TURN	Revenues (SALES_REV_TURN) The amount of sales generated by a company after deducting returns, allowances, discounts, and sales-based taxes. Includes revenue from financial subsidiaries in industrial companies if consolidated. For "financials", refers to gross revenue from any operating activity. Total revenue is the sum of income from interest, trading profit (loss), commissions, earned fees, and other operating income. SALES_REV_TURNLN is expressed as a natural logarithm.
IS_EPS	Earnings per Share (IS_EPS) Earnings per Share (EPS) is the portion of a company's profit allocated to each shareholder. It is calculated based on net income available to common shareholders divided by the weighted average shares outstanding.
EBIT	EBIT (EBIT) Earnings before interest and taxes. For "Financials": Operating profit + Interest expenses. Data expressed in millions. EBITLN is expressed as a natural logarithm.
RETURN_COM_EQY	Return on Common Equity (RETURN_COM_EQY) Measures a company's profitability, highlighting profit generated with the money shareholders have invested, expressed as a percentage. Calculated as: (T12 Net income available to common shareholders / Average total common shares) * 100
RETURN_ON_ASSET	Return on Assets (RETURN_ON_ASSET) Measures a company's profitability relative to its total assets, in percentage. Weighted asset return gives an idea of management efficiency in using assets to generate earnings.
OPERATING_ROIC	Operating Return on Invested Capital (OPERATING_ROIC) Indicates the efficient use of capital sources through the company's activities. Unit: Effective. Calculated as: [Operating income last 12 months / (Beginning total invested capital + Ending total invested capital) / 2)] * 100
TOBIN_Q_RATIO	Tobin's Q Ratio (TOBIN_Q_RATIO) Ratio of a company's market value to the replacement cost of its assets. The Q ratio is useful for company valuation. Based on the hypothesis that in the long term, a company's market value should approximately equal the replacement cost of its assets. Calculated as: (Market cap + Total liabilities + Preferred shares + Minority interests) / Total assets

The dataset used for the analysis consists of 371 observations, each of which corresponds to a listed company for which information regarding the adoption of ethical policies related to artificial intelligence (AI) is available.

From a geographical perspective, the sample includes companies headquartered both in the United States and Europe, with a distribution of 64% and 36% respectively. In terms of industry classification, the majority of firms in the dataset operates within the technology sector, accounting for approximately 56% of the total

sample. Other represented sectors include consumer goods (cyclical and non-cyclical), industrial, communications, financial services, and energy.

As stated, the dataset comprises both firms that have adopted ethical AI policies and those that have not, as identified by a binary (dummy) variable. This structure enables a comparative analysis of ESG performance between adopters and non-adopters, which constitutes the core of investigation.



The framework below shows the geographical and sectoral distribution of firms within the scope of the dataset.

Geographical and Sectoral Distribution of Firms with Available Data on AI Ethics Policy

Breakdown of the 371 companies included in the dataset by region (USA vs. EU) and industry sector, based on the availability of data on the adoption of ethical AI policies.

Heat Map DB *AI_ETHPLCY* *Equity Ticker*	USA	EU	Total
Technology	141	67	208
Consumer, Cyclical	20	16	36
Consumer, Non-cyclical	25	11	36

Communications	20	10	30
Financial	13	9	22
Energy	4	-	4
Total DB by sector	**239**	**132**	**371**

Breakdown by area

Green: *strong concentration of firms in the given area-sector combination.* ***Yellow:*** *medium values.* ***Orange:*** *low to medium values. Red very low or zero values (no companies represented).*

Figure 1: Geographical and Sectoral Distribution of Firms in Dataset (Heat Map).

The structure of the dataset allows for a robust comparative analysis across firms operating in different sectors and exhibiting heterogeneous size characteristics, due to the inclusion of variables capturing geographical, sectoral, financial, and sustainability dimensions.

Below are the descriptive statistics of the variables included in the database. The data reveals a significant degree of heterogeneity among firms, particularly with respect to economic indicators such as total assets, revenues, and profitability. ESG-related variables show relatively moderate distributions, with governance scores appearing more stable compared to the environmental and social dimensions. Measures of corporate performance (such as ROE, ROA, and ROIC) also display substantial variability, suggesting the presence of firms with markedly different economic profiles.

Table 2: Descriptive statistics of the variables.

Descriptive Statistics	Count	Mean	Sd	Min	Max
ARTFCIL_INTLLGENCE_ETH_PLCY	371	0.12	0.32	0.00	1.00

TOBIN_Q_RATIO	367	3.10	3.10	0.65	29.16
Observations	**371**				

To test our hypothesis (HP), we used a linear regression model:

$ESG_Score_i = \alpha + \beta_1 * AI_ETH_PLCY_dum_i + \varepsilon_i$

Where:

- ESG_Score_i is the dependent variable (the ESG score given to the $firm_i$ by Bloomberg).
- α is the intercept, (mean value of ESG_Score_i when $AI_ETH_PLCY_dum_i = 0$);
- $AI_ETH_PLCY_dum_i$ is the independent variable dummy (1 for companies with ethical policies on AI, 0 otherwise).
- ε_i is the residual error.

The estimation was carried out using Ordinary Least Squares (OLS). The analysis is based on cross-sectional data referring to the year 2024, due to the nature and availability of the variables, particularly the AI policy dummy variable. The choice of an OLS regression model applied to cross-sectional data is justified by the structure and availability of the data. This approach allows us to evaluate the associative relationship between the presence of ethical AI policies and ESG performance in a statistically consistent and interpretable framework.

Unfortunately, the absence of data for previous years - particularly with respect to the availability of the key explanatory variable concerning AI ethical policies - excluded the use of panel data models with fixed or random effects.

Such models would have enabled a more robust causal inference by controlling for unobserved firm-specific heterogeneity over time. However, due to the cross-sectional nature of the available dataset, the use of an OLS model on cross-sectional data remains the most suitable methodological approach under the current constraints.

4 Results

Our Hp, predicts that β_1 is positive and significant, implying that companies that adopt ethical policies on AI score, on average, higher ESG scores, and that this relationship is robust and not random. The results allowed us to test our hypothesis: the β_1 coefficient is 1.30, and the p-value associated with the coefficient shows that this positive relationship is robust and statistically significant ($p < 0.01$).

Table 3: OLS n.1 - $ESG_Score_i = \alpha + \beta 1 * AI_ETH_PLCY_dum_i + \varepsilon i$.

OLS (1)	**ESG_SCORE**
AI_ETH_PLCY dum	1.302***
	(0.241)
_cons	3.188***
	(0.0838)
N	348

Standard errors in parentheses
* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

To further test our analyses, we included control variables measuring firm size and financial economic performance in the model.

Specifically: $ESG_Score_i = \alpha + \beta_1 * AI_ETH_PLCY_dum_i + X_i' \beta + \varepsilon_i$

Where $X_i'\beta$ expresses the vector of control variables, which includes total assets and total revenues (both expressed in natural logarithm), EBIT (expressed in natural logarithm), EPS, ROE, ROA, ROIC, and Tobin's Q ratio. Even following the use of the control variables, the value of the β_1 coefficient results positive and statistically significant (0.65 with a $p < 0.05$).

Table 4: OLS n.2 - $ESG_Score_i = \alpha + \beta 1 * AI_ETH_PLCY_dum_i + Xi' \beta + \varepsilon i$.

OLS (2) "Control Variables"	**ESG_SCORE**
ARTFCIL_INTLLGENCE_ETH_PLCY	0.648**
	(0.277)
BS_TOT_ASSETLN	0.401**
	(0.173)
SALES_REV_TURNLN	-0.176
	(0.161)
IS_EPS	-0.0123
	(0.0113)
EBITLN	0.244**
	(0.110)
RETURN_COM_EQY	0.00151
	(0.00113)

OLS (2) "Control Variables"	ESG_SCORE
RETURN_ON_ASSET	0.00518 (0.0244)
OPERATING_ROIC	-0.00785 (0.0146)
TOBIN_Q_RATIO	0.0528 (0.0487)
_cons	0.157 (0.604)
N	218

Standard errors in parentheses
* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

The results of the estimated linear regression indicate that the adoption of ethical guidelines and policies related to the use, design, and development of Artificial Intelligence (AI) – captured by the binary dependent variable ARTFCIL_INTLLGENCE_ETH_PLCY – is positively and significantly associated with firms' ESG scores. In the baseline model (OLS1), which does not include control variables, the coefficient associated with the AI ethics policy dummy is 1.30, statistically significant at the 1% level, suggesting that companies that adopt ethical AI policies tend to have significantly higher ESG scores on average compared to those that do not.

To assess the robustness of this result and account for potential confounding factors—that is, variables that may influence both the dependent and independent variables, and which, if omitted, could bias the estimated effect—a second model was estimated, including a set of firm-level control variables.

These controls include firm size (BS_TOT_ASSETLN), revenues (SALES_REV_TURNLN), profitability metrics (IS_EPS, RETURN_COM_EQY, RETURN_ON_ASSET, OPERATING_ROIC, EBITLN), and market valuation (TOBIN_Q_RATIO).

In this extended model, the coefficient associated with the adoption of AI ethics policies remains positive and statistically significant (0.648, significant at the 5% level), confirming the robustness of the observed association. The inclusion of control variables is crucial to isolate the net effect of the main explanatory variable, reducing the risk that the observed relationship is merely driven by structural characteristics of the firms, such as size, economic performance, or industry.

Among the control variables, both firm size (BS_TOT_ASSETLN) and operating profitability (EBITLN) are also statistically significant, suggesting that larger and more profitable firms are more likely to exhibit higher ESG scores.

The accompanying graphical analysis further supports these findings. The boxplot comparing ESG scores by AI policy adoption shows a higher median for firms with ethical AI policies, with a distribution skewed towards higher values. The second boxplot, disaggregated by geographical area (USA vs. EU), suggests that the positive association holds in both regions, but appears to be stronger among European firms that have adopted such policies. The scatter plot illustrates the binary nature of the dependent variable and highlights the contrast between adopters and non-adopters, while the coefficient plot visually confirms the positive and robust effect of AI ethics policies, even after accounting for control variables.

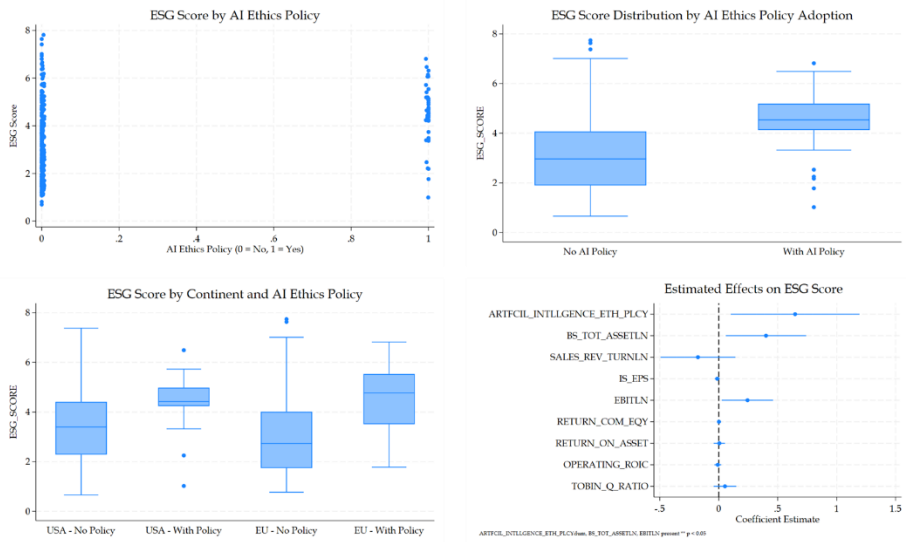

Figure 2: The Relationship Between AI Ethics Policy and ESG Score: Visual Evidence.

In summary, the empirical evidence suggests that the adoption of ethical policies on artificial intelligence is associated with better ESG performance. This relationship holds even after controlling key firm-level characteristics, reinforcing the hypothesis that such policies may serve as a signal of a company's concrete commitment to sustainability.

5 Discussion and conclusions

The study examines how AI adoption influences ESG (Environmental, Social, and Governance) performance, highlighting both opportunities and challenges. AI enhances environmental sustainability through advanced monitoring, resource optimization, and circular economy initiatives. In the social sphere, AI promotes diversity, workplace well-being, and fair hiring processes through advanced algorithms. Regarding governance, AI strengthens oversight mechanisms, improving risk assessments and regulatory compliance.

While previous research has shown a strong correlation between ESG performance and financial results, the specific role of AI in this relationship remains underexplored. Studies suggest that financial institutions using AI for ESG assessments achieve higher investment returns, pointing to a promising link between AI adoption and sustainability.

The study uses a dataset from Bloomberg covering 348 U.S. and Western European companies across various industries. A linear regression model tests the hypothesis that ethical AI policies positively impact ESG performance.

The result confirms the positive effect already observed, even in the presence of the control variables. The positivity and significance of the coefficient highlights that the implementation of ethical guidelines related to the use, design, and development of AI is perceived as an adding value by ESG evaluators. The implementation of ethical policies on AI is a tangible signal of commitment to the principles of sustainability and social responsibility. Moreover, such practices can increase the trust of stakeholders, including investors and regulators, as they demonstrate the company's willingness to adopt technologies responsibly and to proactively manage the ethical risks associated with AI. Further investigation can be conducted with reference to the impact of the dummy variable "AI_ETH_PLCY" on the scores assigned to each ESG pillar.

This study highlights the need to delve deeper into the relationship between AI and ESG, providing basis for developing new measurement frameworks that assess the contribution of AI to corporate sustainability. Although the existing literature provides valuable insights, research exploring the overall impact of AI on ESG performance in different economic contexts is lacking. Our study focuses on these aspects to provide policymakers, companies and technology developers with a reference framework for defining the best strategies to support business processes.

This aspect is particularly timely also in light of the very recent initiatives announced by the European Commission (2025) for the creation of AI gigafactories (AI Gigafactories) and the development of a strategy for applied AI (Apply AI) in order to guide the development and adoption of AI in key industrial sectors.

6 Ethics declaration

This study did not involve procedures requiring ethical clearance, and no ethical approval was necessary for the research conducted.

7 AI declaration

The authors confirm that no artificial intelligence tools were used in the preparation or production of this paper.

Women Directors, Sustainability Knowledge and Greenwashing: A Study on Italian Companies

Beatrice Sveva Stasi, Fabrizia Sarto, Sara Saggese
University of Naples Federico II, Naples, Italy

Abstract

In recent years, the growing attention to environmental, social, and governance (ESG) practices has driven companies to adopt Corporate Social Responsibility (CSR) strategies. The commitment to CSR is influenced by the need to satisfy stakeholder demands to improve firm performance. However, such growing pressure has also produced unintended distortions, notably the phenomenon of greenwashing, as corporate practice involving the dissemination of misleading information regarding a company's ESG commitments to enhance company public image and reputation. This study aims to analyse two possible determinants at board of directors level of greenwashing: the presence of female directors and board members with sustainability knowledge. Based on a sample of 35 Italian publicly listed non-financial companies in 2023, the research employs logistic regressions to examine the effect of the above mentioned board features on greenwashing, which is measured by comparing the ESG Perception Index and the Standard Ethics Rating. The results show that both the presence of female directors and directors with sustainability knowledge positively affect the greenwashing. This suggests that, although these characteristics are often considered to enhance the quality and transparency of sustainability disclosure, they may also increase the ability to manipulate such information. The study contributes to both theory and practice. From a theoretical perspective, it contributes to the literature on board composition and the determinants of greenwashing. From a practical perspective, it highlights the importance for nomination committees to consider the role of gender and human capital in the directors' appointment process, taking into account the potential association with greenwashing.

Keywords: Greenwashing, Women, Board of directors, Sustainability knowledge, Italy.

Paper type: Academic Research Paper

1 Introduction

Over last decades, one of the most relevant developments that has impacted the strategic focus of firms is the increased commitment to environmental, social, and governance (ESG) practices, often referred to as Corporate Social Responsibility (CSR). This is defined as the companies' voluntary integration of social and environmental concerns into their business practices and interactions with stakeholders (European Commission, 2011). In this regard, companies have started to embrace more responsible capitalism by improving non-financial performance and making a positive contribution to the community (Garcia-Sanchez, Cuadrado-Ballesteros and Sepulveda, 2014; Issa and Hanaysha, 2022).

From the scholarly standpoint, the commitment to CSR is rooted in the stakeholder theory suggesting that firms should satisfy stakeholders needs to maximize firm value (Parmar et al., 2010; Dodd, Frijns and Garel, 2022). Indeed, literature highlights that having more investments in CSR can affect firm performance (Albuquerque et al., 2020; Awaysheh et al., 2020; Huang, Sim and Zhao, 2020).

However, increasing pressure from stakeholders to improve companies' ESG performance has often played as a double-edged sword, giving rise to the dark side of this phenomenon, called greenwashing (Zahid et al., 2023). Greenwashing is a corporate behavior that disseminates false information to alleviate external pressures by overstating the company's social and environmental responsibilities (Wolniak, 2016; Flammer, 2021).

Looking at the determinants of greenwashing, literature has examined the effect of several governance features (Zhang, Qin and Zhang, 2023), including the board of directors' characteristics (Ma et al., 2025). Indeed, board is responsible for monitoring managers' actions (Hillman and Dalziel, 2003; Saidat, Silva and Seaman, 2019), and for advising them on how to manage external environmental challenges (Pfeffer and Salancik, 2003). Specifically, it is in charge of setting corporate strategies (including CSR strategies), while monitoring managers to satisfy the needs of the stakeholders (Jain and Zaman, 2020). The accomplishment of these roles is influenced by its characteristics, such as gender (Bernardi and Threadgill, 2010) and human capital (Saggese and Sarto, 2025), with positive implications for corporate outcome (Fernández-Temprano and Tejerina-Gaite, 2020),

As for gender, research documents that female directors are less keen to accept unethical behaviors and inclined to manipulate corporate information, while showing greater sensitivity to stakeholder needs (Terjesen, Sealy and Singh, 2009; Loukil and Yousfi, 2016). As a result, their presence might influence corporate disclosure (Huang, Huang and Lee, 2014; Vermeir and Van Kenhove, 2008), including the CSR reporting and the potential

manifestation of greenwashing. In this regard, while recent studies have started to examine the influence of board gender diversity on greenwashing, literature is still scarce and report contrasting results (Chen and Dagestani, 2023; Ghitti, Gianfrate and Palma, 2024). Hence, there is no clear indication of the relationship between the presence of female directors and greenwashing in the literature.

Shifting the attention to human capital - as set of knowledge and skills derived from individuals job experiences and education (Sarto et al., 2019) – following the upper echelons theory, scholars highlight that board human capital influences corporate outcomes, as directors' experience, knowledge and skills drive the execution of governing roles, with implications for company performance (Hillman and Dalziel, 2003; Berezinets, Garanina and Ilina, 2016). This can be also true with reference to the greenwashing, which may be affected by sustainability-related knowledge as a specific dimension of human capital. In this regard, some empirical studies show that directors' sustainability education and/or experience enhances their ability to understand sustainability-related issues, highlighting that the presence of directors with such knowledge impacts CSR disclosure (Jamil, Mohd Ghazali and Puat Nelson, 2021; Lu et al., 2024). However, they neglect to investigate the effect on greenwashing.

With this in mind, this article aims to examine both the effect of female directors on greenwashing, and the implications of directors' sustainability knowledge for greenwashing.

To achieve the research objective, we collect data from multiple sources (official company websites, AIDA database, LinkedIn profiles), by relying on a sample of 35 Italian publicly listed non-financial companies in 2023. Besides, we conduct the statistical analyses of the predicted relationships using logit regressions. Findings show that both the presence of female directors and directors with sustainability knowledge are positively associated with greenwashing.

Our study provides theoretical and practical contributions. From a theoretical perspective, it contributes to the literature on the role of gender and human capital for greenwashing, while enriching the debate on the determinants of such phenomenon. From a practical standpoint, the research offers insights to nomination committees, encouraging them to consider the role of gender and human capital in the directors' appointment process, also taking into account the potential association with greenwashing.

2 Literature review

Greenwashing is a corporate behavior that disseminates false information about the company's social and environmental commitment, aiming to enhance its public image and alleviate external pressures (Wolniak, 2016; Flammer, 2021; Li et al., 2022). Specifically, it is often used to influence stakeholders (Ferron-Vílchez, Valero-Gil and Suárez-Perales, 2021; Chen and Dagestani, 2023). Indeed, in the light of stakeholder theory, stakeholder involvement is crucial for promoting business development (Friedman and Miles, 2002), and firms should satisfy stakeholders' needs to maximize firm value (Parmar et al., 2010; Dodd, Frijns and Garel, 2022).

Since greenwashing strategies generate ambiguous signals and undermine stakeholders' interests (Walker and Wan, 2012; Zheng et al., 2023), literature has analyzed various determinants of greenwashing, including top managers' characteristics (Zhang, Qin and Zhang, 2023; Yang et al., 2025). Within this context, board of directors' attributes can also play an important role in influencing greenwashing (Ma et al., 2025). Indeed, the upper echelons theory (Hambrick and Mason, 1984) highlights that the individual characteristics of managers (including board members) are able to influence their strategic decisions, thereby shaping corporate outcomes. In this regard, research has analyzed the effect of various board attributes on firm performance (Fernández-Temprano and Tejerina-Gaite, 2020), corporate social responsibility (Patro, Zhang and Zhao, 2018), and innovation (Sarto et al., 2019). Among the board attributes that can influence corporate outcomes, gender (Bernardi and Threadgill, 2010; Galbreath, 2018) and human capital (Saggese and Sarto, 2025) are particularly relevant.

Regarding the former, some studies show that the presence of women on board negatively influences corporate outcomes (Adams and Ferreira, 2009; Dale-Olsen, Schone and Verner, 2013), as gender diversity may increase conflict among directors, limit board cohesion, and hinder decision-making, thereby compromising firm performance (Adams and Ferreira, 2009). Conversely, other research documents that the presence of female directors promotes both financial (Campbell and Minguez Vera, 2009) and sustainability-related (Elmagrhi et al., 2019) outcomes. Indeed, women are more likely to follow a participatory leadership approach than men (Loukil and Yousfi, 2016), reduce information asymmetries (Gul, Hutchinson and Lai, 2013), and show greater sensitivity to stakeholder needs (Terjesen, Sealy and Singh, 2009). Moreover, being less inclined to manipulate corporate information, their presence has implications for corporate disclosure (Huang, Huang and Lee, 2014; Vermeir and Van Kenhove, 2008), including CSR-related reporting in terms of greenwashing. In this regard, although recent studies have begun to explore the impact of women presence on the board on greenwashing practices, the

existing literature remains limited and yields conflicting findings. Indeed, empirical evidence presents a mixed picture: while some studies suggest that female directors may mitigate greenwashing behaviors (Chen and Dagestani, 2023), others report a positive association, contending that improved gender balance does not inherently constitute an effective solution against the phenomenon (Ghitti, Gianfrate and Palma, 2024). Based on this, we hypothesize the existence of a relationship between female directors' presence and greenwashing, without formulating any expectation about the sign.

As for human capital, several studies show that top managers' human capital can influence how they perceive, interpret, and evaluate companies and their environments (Day and Lord, 1992; Hambrick and Mason, 1984). It can also affect how problems are defined and information is processed, thus influencing managerial decisions (Carpenter, Geletkanycz and Sanders, 2004; Sarto et al., 2024; Sarto et al., 2025). Specifically, regarding the boards of directors, studies show that board human capital impacts corporate outcomes, as directors' experience, knowledge and skills drive the execution of governing roles, with implications for corporate outcomes (Hillman and Dalziel, 2003; Berezinets, Garanina and Ilina, 2016). This may be also true for greenwashing, which might be influenced by a specific dimension of human capital, that is the sustainability-related knowledge. In this regard, some scholars claim that top managers competencies within sustainability area can influence sustainability-related outcomes (Peters, Romi and Sanchez, 2019; Al-Shammari et al., 2023), including CSR disclosure (Velte, 2023). Specifically, the presence of directors with sustainability-related education and/or experience affects CSR disclosure quality and transparency (Jamil, Mohd Ghazali and Puat Nelson, 2021; Lu et al., 2024), since these competencies can enhance managerial understanding of sustainability-related issues (Jamil, Mohd Ghazali and Puat Nelson, 2021). Building on these arguments—which underscore the relationship between the presence of directors with sustainability expertise and the quality of CSR disclosure—and considering that greenwashing entails the dissemination of misleading information regarding the company's social and environmental commitments, it is reasonable to expect that directors with sustainability knowledge may influence greenwashing practices.

3 Method

We test our predictions on a sample of 35 publicly listed non-financial Italian companies in 2023, after excluding firms lacking relevant governance and CSR data. Italy represents an ideal setting to explore our predictions considering the legislative measures (Law 120/2011) that have promoted the greater representation of women on corporate boards (Saggese, Sarto and Viganò, 2021). Furthermore, in Italy there is a rising concern about corporate accountability and environmental transparency (Sarto et al., 2025).

With this in mind, we gather information on publicly listed non-financial Italian companies from multiple sources (e.g. AIDA database, and hand-collected information from official company websites and LinkedIn profiles).

As for our dependent variable, we analyse greenwashing in terms of gap between firms' ESG disclosure information and sustainability real performance information (Zhang, 2022). In this regard, we compare the ESG Perception Index (which measures companies' sustainability perception) with the Standard Ethics Rating (which measures firms' actual sustainability by evaluating their level of compliance with international sustainability principles issued by the European Union (EU), the Organisation for Economic Co-operation and Development (OECD), and the United Nations (UN)). When the ESG Perception Index score is higher than the Standard Ethics Rating (positive discrepancy), we interpret this discrepancy as a potential signal of greenwashing. In this case, public perception is higher than the independent evaluation provided by Standard Ethics, suggesting a possible overestimation of the firm's sustainability commitment. If the ESG Perception Index and the Standard Ethics Rating are equal (correspondence), we conclude that there is no clear evidence of greenwashing. If the ESG Perception Index is lower than the Standard Ethics Rating (negative discrepancy), we posit that the observed gap may be attributable to factors unrelated to greenwashing, such as limited public awareness of the company's sustainability initiatives or inadequate corporate communication. Thereby, we measure greenwashing by employing a dummy variable equal to 1 in case of greenwashing (positive discrepancy), and 0 otherwise (correspondence and negative discrepancy) (Greenwashing).

Regarding the independent variables, we appreciate the presence of female directors and board members with sustainability knowledge (i.e. sustainability-related education and/or sustainability-related experience) (Jamil, Mohd Ghazali and Puat Nelson, 2021; Velte, 2023), using two different variables to strengthen our analysis. For the presence of female directors, we use the number of female directors (Num_womdir) (Katmon et al., 2019). Similarly, for the presence of directors with sustainability knowledge, we use the number of directors with sustainability knowledge (Num_sustknowdir) (Jamil, Mohd Ghazali and Puat Nelson, 2021).

Moreover, we use two additional proxies to catch our main independent variable. Specifically, we employ a dummy variable, Average_womdir (Average_sustknowdir) equal to 1 if the number of female directors (sustainability-knowledgeable directors) on the company's board is above the sample average, and 0 otherwise (Carbone, Mussolino, and Viganò, 2024). Finally, we include the following control variables: the firm size (Firm_size), measured by the number of firm's employees, the profitability, in terms of return on equity ratio (ROE), and the board size (Board_size) as the number of directors.

To test our predictions, we conduct the statistical analyses using logit regressions, as our dependent variable is binary.

4 Results

Table 1 presents the descriptive statistics for our variables.

Table 1: Descriptives

Variable	Mean	SD	Min.	Max.
Greenwashing	0.229	0.426	0	1
Num_womdir	4.971	1.580	0	8
Num_sustknowdir	5.257	2.758	0	11
Average_womdir	0.342	0.481	0	1
Average_sustknowdir	0.428	0.502	0	1
Firm_size	3413.4	7.440.841	16	34529
ROE	9.786	14.198	-50.19	54.69
Board_size	11.571	2.810	3	18

Table 2 shows the results of the logit regressions testing the relationship between the presence of female directors and directors with sustainability knowledge and greenwashing. Specifically, Model 2 shows that the coefficient of the number of female directors (Num_womdir) is positive and statistically significant (β=1.730; $p<0.05$). Therefore, a higher number of female directors is positively associated with the probability that the firm engages in greenwashing. Similarly, Model 3 highlights that the coefficient of the number of directors with sustainability knowledge (Num_sustknowdir) is positive and statistically significant (β=0.364; $p<0.05$). Consequently, there is a positive and statistically significant relationship between the presence of directors with sustainability knowledge and greenwashing.

Table 2: Logit regression models

	Logit regressions (Greenwashing)				
	Model 1	**Model 2**	**Model 3**	**Model 4**	**Model 5**
Num_womdir		1.730**			
		(0.885)			
Num_sustknowdir			0.364**		
			(0.156)		
Average_womdir				2.961**	
				(1.412)	
Average_sustknowdir					1.970*
					(1.072)
Firm_size	-0.000	-0.000	-0.000*	-0.000	-0.000*
	(0.000)	(0.000)	(0.000)	(0.000)	(0.000)
ROE	-0.111**	-0.157**	-0.137**	-0.092*	-0.136**
	(0.048)	(0.063)	(0.059)	(0.049)	(0.055)
Board_size	0.144	-0.687	0.012	-0.212	0.084
	(0.156)	(0.494)	(0.168)	(0.237)	(0.165)
Constant	-1.798	-0.614	-1.958	0.668	-1.804
	(1.848)	(2.045)	(1.819)	(2.604)	(1.936)
Observations	35	35	35	35	35
R2	0.168	0.296	0.265	0.262	0.273
Prob (Chi2)	0.095	0.025	0.043	0.069	0.019
Mean VIF	1.36	2.63	1.37	2.26	1.33

As previously stated, to strengthen our analysis, we replicate it by measuring the presence of female directors and of directors with sustainability knowledge using the two binary independent variables, Average_womdir and Average_sustknowdir, respectively. Consistent with the results of Model 2, Model 4 shows a positive and significant relationship between a higher number of female directors (above the sample average) and greenwashing. Indeed, the coefficient is positive and statistically significant (β=2.961; $p<0.05$). Similar findings are reported for the presence of directors with sustainability knowledge. Indeed, Model 5 shows that the coefficient of Average_sustknowdir is positive and statistically significant (β=1.970; $p<0.10$). Therefore, firms with a higher number of directors with sustainability knowledge (above the sample average) have a higher probability of engaging in greenwashing.

5 Concluding discussions

The article examines the relationship between the presence of female directors and directors with sustainability knowledge and greenwashing. To achieve this aim, it tests our predictions on a sample of 35 publicly listed non-financial Italian companies in 2023 through logit regressions.

Results show that the presence of female directors is positively associated with greenwashing. This finding is counterintuitive compared to previous studies which suggest that female directors are less inclined to manipulate corporate information with positive implications for disclosure quality (Vermeir and Van Kenhove, 2008; Huang, Huang, and Lee, 2014). Moreover, it contrasts with studies that find the presence of female directors inhibits greenwashing (Chen and Dagestani, 2023). However, the result aligns with studies that report a positive relationship (Ghitti, Gianfrate and Palma, 2024) and show that a higher presence of female directors is associated with lower sustainability performance, as female directors are often excessively busy due to the numerous board positions they hold (Tonetto, 2022). Consequently, regarding greenwashing, the presence of female directors is not beneficial, as their busyness negatively influences the effective monitoring of greenwashing activities (Tonetto, 2022).

Similar results apply to the presence of directors with sustainability knowledge, also positively associated with greenwashing. This supports the idea that directors with sustainability-related education and/or experience have a greater understanding of sustainability-related issues (Jamil, Mohd Ghazali and Puat Nelson, 2021). Being more familiar with the process of disclosing sustainability information (Bilal, Songsheng and Bushra, 2017), they may also be more able to manipulate such information, thereby increasing the probability of greenwashing. These results remain valid across both measures used as independent variables.

Our study has theoretical and practical implications. From a theoretical perspective, it contributes to the literature on the role of gender and human capital for the board of directors by examining both the relationships between the presence of female directors and directors with sustainability knowledge and greenwashing. It also addresses a gap in the Italian setting, where the link between the specific dimension of human capital related to directors' sustainability knowledge and greenwashing remains unexplored (Jamil, Mohd Ghazali and Puat Nelson, 2021; Lu et al., 2024). At the same time, it enriches the literature on the determinants of greenwashing. From a practical perspective, by documenting the positive association between the presence of female directors and of directors with sustainability knowledge and greenwashing, the paper encourages nomination committees to consider the role of gender and human capital in the directors' appointment process, also taking into account the potential association with greenwashing.

Despite these contributions, our study has limitations. First, it is based on a sample of only 35 companies and focuses on the specific Italian context, which limits the generalizability of the results. Another limitation concerns how greenwashing is measured. In fact, we measure it by comparing the ESG Perception Index (a qualitative variable), which reflects companies' sustainability perception, with the Standard Ethics Rating (a quantitative variable), which measures firms' actual sustainability. This discrepancy can lead to interpretative challenges. Indeed, interpreting these differences and detecting greenwashing requires caution, since the two metrics reflect different corporate sustainability dimensions, and public perception is not always aligned with institutional assessments. Finally, the ESG perception index is obtained from the Reputation Science Observatory, which, although based on a reliable methodology using more than 100 parameters, is influenced by subjectivity.

Abstract

Ethics stands today as a primary pillar of modern medicine, and no medical specialty represents an exception. Acute care and trauma (AC&T) surgery is a complex clinical field, often characterized by high time pressure and little knowledge about the patient and circumstances. Our investigation wishes to deepen the role of diversity in AC&T teams as an opportunity to enhance ethics. The study, endorsed by the World Society of Emergency Surgery, analyses 402 questionnaires gathered from medical professionals from 72 countries, investigating three ethical issues (namely, patient's informed consent as a knowledge translation tool, the team leader as an ethical leader, and ethics as an educational subject). Findings underline the potential of diversity to enhance the attention towards ethical matters, offering food for thought to hospital managers and healthcare professionals.

Keywords: Trauma and emergency surgery; Diversity; Ethics; Team Dynamics; Knowledge Management

Paper type: Academic Research Paper

1 Introduction

Health systems and organizations are facing complex challenges largely driven by epidemiological and demographic trends such as aging (Calciolari and Luini, 2023), digital and technological development (Dal Mas *et al.*, 2023), reduction in healthcare spending to contain public budgets (OECD, 2024), and shortages of clinicians (Boniol *et al.*, 2022; WHO, 2016). In the depicted scenario, the provision of appropriate care (in terms of quality, patient satisfaction, effectiveness, and cost-effectiveness) is a matter of collaboration among health professionals (Silenzi *et al.*, 2018). As a result, multidisciplinary and interprofessional teamwork is increasingly required for different healthcare settings and pathologies, but good practices need to be identified to improve their effectiveness (Prenestini, 2023). The literature shows several beneficial outcomes of multidisciplinary and interprofessional work in teams (West *et al.*, 2002). Collaboration between specialists can change clinical practices and procedures, raise clinical standards, and finally improve the patient experience (Silenzi *et al.*, 2018).

Teamwork between disciplines and different clinicians, taking into account the patient experience, has always been a critical issue for trauma and emergency surgery, usually referred to in medical terms as acute care and trauma surgery (AC&T). AC&T is a multifaceted discipline due to its unique characteristics and context. Indeed, when managing AC&T cases, the multidisciplinary clinical team members must work under tremendous strain in a stressful and complex environment while attempting to communicate effectively (Cobianchi, Dal Mas, Massaro, *et al.*, 2021). Decisions must be made quickly, and common issues include time constraints to reach the outcome, limited knowledge of the emergency and trauma causes, the patients' pre-existing circumstances or conditions, or preferences regarding the feasible treatment options (Cobianchi, Dal Mas, *et al.*, 2023). Additionally, clinicians must deal with the possibility of unforeseen incidents and complications (Maurer *et al.*, 2021). In this context, conventional organizational practices are less effective. While new technological tools such as Artificial Intelligence (AI) can enhance surgical decision-making and support clinical professionals in their work (Loftus *et al.*, 2020, 2023), clinicians are often skeptical about their full potential, and several barriers in their acceptance arise (Cobianchi, Piccolo, *et al.*, 2023; Cobianchi, Verde, *et al.*, 2022). Therefore, integrative mechanisms, such as team assembly decisions, may be the sole opportunity to maximize performance and coordinate team member actions (Cobianchi, Dal Mas, Massaro, *et al.*, 2021; Massaro *et al.*, 2019).

Urgent decision-making in AC&T surgery may, therefore, raise various ethical concerns. When confronted with ethical issues, clinicians are compelled to promptly evaluate the advantages and disadvantages of their choices and the limited information they possess regarding their patients (Suah and Angelos, 2018). Ethics also

includes the consistent and compassionate translation of knowledge about the potential options and decisions with patients and their families or caregivers (Cobianchi, Dal Mas, *et al.*, 2023; Cobianchi, Dal Mas, Massaro, Bednarova, *et al.*, 2022; Sousa *et al.*, 2020; Woltz *et al.*, 2018). While traditional knowledge translation and sharing tools in elective surgery would include soliciting second opinions from colleagues and looking into the pertinent literature and guidelines (Bratianu *et al.*, 2024; Brescia *et al.*, 2024; Chang and Lin, 2015; Dal Mas, Garcia-Perez, *et al.*, 2020; Khedhaouria and Jamal, 2015), such strategies may not be feasible during emergencies. As a consequence, there is a significant likelihood of making errors or encountering ethical dilemmas when managing injured patients. This is especially true when lifesaving procedures are implemented during the initial assessment and resuscitation processes (Madani *et al.*, 2018). At the same time, the patient may have limited or no opportunity to be informed.

AC&T teams comprise a multidisciplinary group of individuals from various specialties, including anesthesia, emergency medicine, general and orthopedics surgery, nursing, and supporting staff, guided by a team leader responsible for coordinating the members' activities (Georgiou and Lockey, 2010). The team leader is key, as, guided by strong ethical principles, can experience conflicting obligations to stakeholders during the common emotional and complex debates and must lead the team through potentially challenging ethical situations with strength, compassion, fairness, and justice while eliminating potential implicit and explicit biases (Angelos *et al.*, 2021). In fact, making tough decisions requires the ability to seamlessly organize all team members to achieve the desired objective, even though decision-making is frequently viewed through the lens of an individual's internal cognitive process (Cobianchi, Dal Mas, Massaro, *et al.*, 2021; Madani *et al.*, 2018).

In such scenarios, knowledge translation, knowledge sharing, and knowledge transfer mechanisms are essential components of the team leader's and multidisciplinary team members' activities to communicate effectively and reconcile their differences, thereby enhancing their potential (Bratianu *et al.*, 2024; Cobianchi, Dal Mas and Angelos, 2021), especially when ethical dilemmas are in place (Scarlet, 2018a).

By definition, emergency surgery teams are diverse, as they consist of professionals with various backgrounds and specialties (Georgiou and Lockey, 2010). In order to provide adequate care to their patients, these professionals must possess interpersonal or soft skills (Cobianchi, Dal Mas, Massaro, *et al.*, 2021). The situation may be even more complex when teams include members who can be considered or perceived as diverse in terms of gender, race, ethnic background, age, political views, and sexual orientation.

The medical literature has been investigated the topic through the involvement of scientific societies. Studies conducted in general surgery have demonstrated that global performance is enhanced when the medical care environment is diverse, and patient satisfaction is also enhanced in such contexts (Gardner and Harris, 2020). However, recent investigations have also underscored the necessity of dedicated organizational and management policies to harness the full potential of diversity, which may eventually represent more a problem rather than an asset, enlarging organizational gaps (Cobianchi, Dal Mas and Angelos, 2021; West *et al.*, 2018).

To the best of our knowledge, there has been little investigation regarding the potential correlation between ethics and diversity in AC&T contexts. The study investigates the context of AC&T surgery as an ideal environment characterized by high complexity to understand the eventual impact of team diversity in fostering ethics. More in detail, our research deepens the factors that can improve certain ethical aspects, including the perceived importance of ethics as an educational subject, the perceptiveness of the moral role of the trauma team leader, and the importance of patient consent, comparing teams with their members perceiving them as "diverse" and those which were not.

2 Methodology

2.1 Data collection process

The study was conducted within a larger investigation about team dynamics in AC&T settings endorsed by the World Society of Emergency Surgery (WSES), one of the largest scientific societies in the field, with 900+ international members. An online survey was created using Google Forms.

In January 2021, the WSES secretariat distributed an email invitation to all 917 of its members, and also advertised through the society's website and X (former Twitter) account. The full protocol and statistical results, to which this article refers and comments, were published in the society's official peer-reviewed journal (Cobianchi, Dal Mas, Massaro, Biffl, *et al.*, 2022; Cobianchi, Dal Mas, Massaro, *et al.*, 2021).

2.2 Survey design and research protocol

The survey research protocol was built around prior research in the fields of AC&T surgery (Reichert *et al.*, 2020; Scarlet, 2018b; Woltz *et al.*, 2018), knowledge management, sharing, and translation in the context of healthcare and team dynamics (Dal Mas, Biancuzzi, *et al.*, 2020; Dal Mas, Garcia-Perez, *et al.*, 2020; Massaro *et al.*, 2014, 2019; Rese *et al.*, 2020), and clinical ethics in the physician-patient relationship and in emergency contexts (Angelos, 2020a; Angelos *et al.*, 2021; Cobianchi, Dal Mas and Angelos, 2021; Scarlet, 2018b; Suah and Angelos, 2018)

The initial questions were centered on the identification of the sample, including gender, years of experience in AC&T, type of institution (academic vs. non-academic), country where the employer was located, the role held, eventual participation within a formalized trauma team (institutionalized or not, and of what type), and the eventual involvement of diverse team members. Coming to this specific question, the investigators chose not to provide participants with a precise definition of "diversity" or "diverse team." Respondents were merely requested to indicate whether they perceived their team as diverse, in accordance with the widely recognized definition of "diversity." Ethics was investigated through the examination of 12 sentences to be rated on a 5-point Likert scale, with 1 representing firmly disagreement and 5 representing strong agreement. The objective of the items was to assess the topics of informed consent (Angelos, 2020a; Suah and Angelos, 2018), the formal attention to ethics in emergency surgery training (Angelos, 2020b; Angelos *et al.*, 2021), and the role of team leaders as ethical leaders (Angelos *et al.*, 2021; Cobianchi, Dal Mas and Angelos, 2021; Scarlet, 2018b, 2018a).

2.3 Data analysis

402 out of the 917 WSES members responded to the survey, with a response rate of 45.84%. A preliminary analysis was conducted to characterize the sample distribution in terms of gender, institution type (academic versus non-academic), respondents' membership in an officially set trauma team, and a diverse team. Furthermore, descriptive statistics were generated for the twelve ethical inquiries. Ultimately, the queries were categorized into three primary latent variables. In order to ascertain whether respondents differed by gender, type of institution, membership in an officially designated team, and a team that the surgeons characterized as "diverse," Kruskal-Wallis analysis was implemented.

3 Results

3.1 Distribution of samples

The 402 fully filled questionnaires obtained came from professionals from 72 countries, with the majority located in Europe. The sample was composed mainly of male surgeons (84%). Most participants belonged to university hospitals (72%), and officially established trauma teams (79.6%). 62% of the respondents indicated that they were employed in a diverse team.

3.2 Descriptive statistics and variations among respondents

The 12 items concerning ethics that were examined yielded an average result that ranged from a minimum of 2.83 to a maximum of 4.42, as reported in the article by Cobianchi et al. (2022).

The main findings can be summarized by examining the variations among respondents.

3.2.1 Significance of informed consent

Informed consent is considered a relevant knowledge translation tool in patient/doctor shared decision-making (Cobianchi, Dal Mas, *et al.*, 2023), and signing it stands a meaningful ethical moment worth discussing (Angelos, 2020a). The survey's results stressed the importance of consent, regardless of the participants' gender. Interestingly, respondents from academic institutions demonstrated a higher level of interest in the subject matter, with an average score of 3.238 compared to the average score of 2.827 among non-academics. In the same vein, respondents from formalized trauma teams paid more attention to this subject, with an average of 3.212 compared to the average of 2.921 (p-value 0.037). Lastly, surgeons who identified themselves as members of a diverse team underscore the importance of consent with an average of 3.328, as opposed to an average of 2.865 (p-value >0.001), as reported in Table 1 below, borrowed from the first article of the investigation by Cobianchi et al. (2022).

Table 1. Significance of consent. Source: Cobianchi et al. (2022)

Statistic	N	Average (SD)	Median (Q1-Q3)	Kruskal-Wallis rank-sum test	
				Chi Square	P-value
Gender				**0.262**	**0.877**
Female	61	2.770 (0.992)	3 [2-4]		
Prefer not to answer	3	3.000 (1.528)	3 [2.5-4]		
Male	338	2.834 (1.043)	3 [2.5-4]		
Kind of institution				**6.944**	**0.008**
Academic	292	3.238 (1.019)	3.5 [2.5-4]		
Non academic	110	2.927 (1.051)	3 [2-3.5]		
Part of a trauma team				4.308	0.037
No	82	2.921 (1.118)	3 [2-3.875]		
Yes	320	3.212 (1.007)	3 [2.5-4]		
Part of a diverse team				**18.746**	**>0.001**
No	152	2.865 (1.070)	3 [2-3.5]		
Yes	250	3.328 (0.976)	3.5 [2.5-4]		

3.2.2 Role of the team leader as an ethical leader

Concerning the role of the team leader as an ethical leader, results do not indicate any statistically significant differences in gender or type of institution. In contrast, findings underline that there are statistically significant differences between respondents belonging to formalized trauma teams, and those part of diverse groups, as reported in Table 2 below, borrowed from the first article of the investigation by Cobianchi et al. (2022).

Table 2. The role of the team leader as an ethical leader. Source: Cobianchi et al. (2022)

Statistic	N	Average (SD)	Median (Q1-Q3)	Kruskal-Wallis rank-sum test	
				Chi Square	P-value
Gender				**2.294**	**0.317**
Female	61	3.279 (0.595)	3.2 [3 - 3.8]		
Prefer not to answer	3	2.867 (0.416)	3 [2.7 - 3.1]		
Male	338	3.288 (0.565)	3.4 [3 - 3.8		
Kind of institution				**1.961**	**0.161**
Academic	292	3.306 (0.566)	3.4 [3 - 3.8]		
Non academic	110	3.224 (0.574)	3.2 [3 - 3.6]		
Part of a trauma team				4.562	0.032
No	82	3.171 (0.571)	3.2 [3 - 3.6]		

Statistic	N	Average (SD)	Median (Q1-Q3)	Kruskal-Wallis rank-sum test	
				Chi Square	P-value
Yes	320	3.312 (0.565)	3.4 [3 - 3.8]		
Part of a diverse team				**7.861**	**>0.001**
No	152	3.141 (0.576)	3.2 [2.8 - 3.6]		
Yes	250	3.370 (0.547)	3.4 [3 - 3.8]		

3.2.3 Training in ethics-related subjects

The majority of respondents were enthusiastic about the possibility of receiving training in ethics-related subjects, with no differences in responses among genders. Those affiliated with academic institutions prioritized ethical training more highly, with an average score of 3.742 compared to the average of 3.480 for all other respondents, similar to respondents from officially designated trauma teams (average of 3.734). Again, surgeons who were members of diverse teams exhibited a higher level of awareness, as evidenced by an average score of 3.830 and a p-value of less than 0.001. Findings are reported in the following Table 3, borrowed from the first article of the investigation by Cobianchi et al. (2022).

Table 3. Significance of Ethical Training. Source: Cobianchi et al. (2022)

Statistic	N	Average (SD)	Median (Q1-Q3)	Kruskal-Wallis rank-sum test	
				Chi Square	P-value
Gender				**2.455**	**0.293**
Female	61	3.695 (0.722)	3.8 [3.2-4.2]		
Prefer not to answer	3	3.133 (0.306)	3.2 [3-3.3]		
Male	338	3.671 (0.811)	3.8 [3.2 - 4.35]		
Kind of institution				**7.644**	**0.005**
Academic	292	3.742 (0.755)	3.8 [3.2 - 4.4]		
Non academic	110	3.480 (0.869)	3.6 [3 - 4.2]		
Part of a trauma team				**11.356**	**0.001**
No	82	3.424 (0.747)	3.5 [2.85 – 4]		
Yes	320	3.734 (0.796)	3.8 [3.2 - 4.4]		
Part of a diverse team				**22.296**	**>0.001**
No	152	3.408 (0.895)	3.6 [2.8 – 4]		
Yes	250	3.830 (0.682)	3.9 [3.4 - 4.4]		

4 Discussion and conclusion

Ethics stands as an imperative pillar in modern medicine, and the AC&T context is no exception, as emergency and trauma situations may require surgeons and other clinical professionals to respond quickly to ethical dilemmas. The investigation, endorsed by one of the major scientific societies in the field, aimed at deepening the topic through the lens of team diversity. Three primary ethical issues (namely, informed consent, the role of the leader as a moral leader, and ethics as a training subject for medical professionals) were examined

through the lens of gender, membership in an academic or non-academic institution, in an officially set team, and a diverse group.

Results underscore the increased focus that surgeons from academic institutions, official teams, and diverse groups are giving to the role of informed consent, seen as a relevant knowledge translation and shared decision-making tool from the physician in charge to the injured patient. The concept of surgical consent has evolved over time (Suah and Angelos, 2018). Before the operation, informed consent was primarily regarded as a legal and administrative obligation. However, recent research has emphasized the importance of informed consent as a critical tool for communicating with patients, and comprehending their wishes and concerns (Bratianu *et al.*, 2024; Ferguson Bryan *et al.*, 2020). This has led to acknowledging shared decision-making's importance (Dal Mas *et al.*, 2022; Woltz *et al.*, 2018). In this regard, the recent paradigm posits that surgeons must "speak less and listen more" (Angelos, 2020a) to facilitate improved knowledge translation, even in AC&T settings, where discussing with the injured patient may not always be practicable. Surgeons who work within academic environments and those members of officially established teams also acknowledge the importance of informed consent, probably due to the patient-centric organizational culture and the ongoing debate, which appears to be more assertive in academic institutions and within formalized teams. Results from diverse organizations are consistently superior to those from non-diverse ones. Although diversity in practice may present a challenge as a result of the distinctions among members, it has been demonstrated to result in exceptional outcomes. Professionals who are already engaged in bridging the gap with their diverse colleagues may be more willing to do so even when dealing with their patients (Cobianchi, Dal Mas and Angelos, 2021). Such knowledge translation actions may result in more time dedicated to such activities, or the involvement of support professionals like nurses as case managers (Bashkin *et al.*, 2023).

The second subject pertains to the team leader's function as an ethical leader, who is capable of integrating robust ethical principles into clinical decision-making. Individuals who are members of formalized teams and diverse organizations are more aware of the significance of ethics in the role of a team leader. Once more, surgeons from diverse teams provided the most favorable assessment. Consequently, it is possible to assert that individuals who are actively involved in interactions with various individuals believe that ethics is essential for improving patient outcomes and the seamless functioning of teams.

The third subject examined is ethical training, with comparable outcomes. Although most surgeons acknowledge the significance of appropriate ethical training, participants from academic institutions, formalized teams, and diverse groups demonstrate a greater interest. The surgical literature has once again emphasized the necessity of providing training in non-technical skills (Briggs *et al.*, 2015; Pradarelli *et al.*, 2020; Yule and Paterson-Brown, 2012), including ethics (Massaro *et al.*, 2014). Scientific societies have prioritized such subjects. Consequently, it is unsurprising that those more closely related to this debate (i.e., academicians and formalized team members) appear more focused on acknowledging this as a pertinent issue. Non-technical skills are indispensable for developing knowledge translation dynamics within teams, particularly when groups are classified as diverse (Bratianu *et al.*, 2024; Dal Mas, Garcia-Perez, *et al.*, 2020). Once more, diversity appears to exacerbate the necessity for ethical training as a critical component.

All in all, our findings suggest that teams with a lower degree of diversity may exhibit a lower level of sensitivity to patient preferences. Therefore, diversity in AC&T surgical teams may represent a powerful strategy to enhance sensitivity through ethics. Although previous research has demonstrated that contrasting cultures (e.g., more physician-centric vs. patient-centric) can coexist within organizations (Nembhard *et al.*, 2012), our findings emphasize that certain organizational factors (e.g., the team's university affiliation or diversity) may result in the development of a greater sensitivity to ethical issues. Organizations that are committed to fostering a more ethical and patient-centric perspective within AC&T teams should incorporate these components into the development of their organizational procedures. In fact, traditional coordination mechanisms seem less effective in AC&T contexts, where time pressure and expeditious action are the norm rather than the exception. As a result, teams must rely more on alternative strategies and tools to coordinate their actions. Integrative mechanisms, such as team composition including diverse members, may be effective in promoting ethical conduct and a more patient-centric culture, offering food for thought to hospital executives, scientific societies, clinical educators, and healthcare policymakers.

5 Ethics declaration

As specified in the main article text, the comprehensive study survey and full results were published in the article “Cobianchi, L., Dal Mas, F., et al. (2022), Diversity and ethics in trauma and acute care surgery teams: results from an international survey, World Journal of Emergency Surgery, Vol. 17 No. 1, p. 44.” under a Creative Commons Attribution 4.0 International License.

Assessing Carbon Emissions and Energy Use Behaviours among Medical Undergraduate Students in Taiwan

Szu-Chieh Chen[1], Wei-Ling Yang[1], Yafang Tsai[1], Shih-Wang Wu[2]
[1]Chung Shan Medical University, Taichung, Taiwan
[2]Chia Nan University, Tainan, Taiwan

Abstract

This cross-sectional study investigates the energy use behaviors, carbon emissions, and energy-related knowledge, attitudes, and practices (KAP) of undergraduate students from six private medical universities across northern, central, and southern Taiwan. Data were collected via structured questionnaires from May to June 2023, encompassing 184 students with diverse academic years, departments, and gender distributions (69% female). The study quantified daily activity durations involving energy consumption-such as air conditioning, heating, transportation, and use of electrical appliances-and estimated individual annual carbon emissions by integrating activity duration, energy consumption rates, and emission factors. Results indicate that air conditioning and heating account for the longest daily energy use (244 to 750 minutes), reflecting Taiwan's subtropical climate and high cooling demand. Transportation activities, including car, motorcycle, and public transit use, also contribute substantially, with Taipei Medical University students exhibiting the highest public transportation usage (mean 98 minutes). Departmental variations were noted, with pharmacy students using air conditioning most extensively and medical laboratory science students using public transit more frequently.

The KAP survey revealed moderate to high knowledge levels but comparatively lower positive attitudes and practices toward energy conservation, aligning with international findings. These results highlight the importance of targeted educational interventions to promote sustainable energy behaviors among medical students, who are future healthcare professionals with potential influence on institutional sustainability. This study fills a research gap by linking individual-level energy behaviors with carbon emission estimates in Taiwan's higher education context, providing a foundation for policy and behavioral strategies aimed at reducing the carbon footprint of medical education institutions.

Keywords: Carbon emission, Knowledge-Attitude-Practice (KAP), Taiwan, Subtropical climate, Energy

Paper type: Academic Research Paper

1 Background

Climate change driven by greenhouse gas (GHG) emissions from human energy consumption has become one of the most pressing global challenges. Since the Industrial Revolution, the average global temperature has increased by approximately 1.0°C as of 2017, primarily due to elevated CO_2 and other GHG emissions (UNDP, 2023). In response, the United Nations established the 2030 Sustainable Development Goals (SDGs) in 2015, with Goal 13 focusing on climate action. The United Nations Development Programme (UNDP) aims to reduce global net CO_2 emissions by 45% between 2010 and 2030 and achieve net-zero emissions by 2050.

Globally, energy consumption remains the largest contributor to GHG emissions. According to the International Energy Agency (IEA, 2021), the world emitted 33,622 million tons of CO_2 in 2019, with China and the United States as the top emitters, contributing 29.38% and 14.11% respectively. Taiwan ranked 22nd globally, emitting 256 million tons of CO_2 (0.76% of global emissions), with a per capita emission of 10.77 tons CO_2, ranking 19th worldwide (Taiwan EPA, 2023). Sectoral analysis reveals that Taiwan's industrial sector accounts for the highest emissions (48.74%), followed by transportation (14.17%), energy (14.05%), residential (11.54%), and service sectors (10.35%) (Taiwan EPA, 2021).

Within the service sector, educational institutions are significant energy consumers. Taiwan's higher education sector accounts for 65% of the electricity consumption within the education industry (Taiwan Power Company, 2021). Among universities, medical schools exhibit the highest energy intensity due to their reliance on precision laboratories and diagnostic equipment (Wang, 2016). This is consistent with findings from Liu et al. (2009), who observed that energy knowledge and attitudes improve with educational level, suggesting that university students represent a critical demographic for fostering sustainable energy behaviors.

Numerous studies have investigated energy use in educational buildings, providing valuable benchmarks. For instance, Li et al. (2017) analyzed university buildings in Guangzhou, China, reporting energy use intensity (EUI) values ranging from 61 to 82 kWh/m²/year. Ruusala et al. (2018) studied Finnish schools and daycare centers, finding an average EUI of 212 kWh/m²/year for schools, significantly higher than daycare centers. In Taiwan, Wang (2019) reported that universities' EUI ranged between 56.5 and 93.2 kWh/m²/year from 2015 to 2017,

with national universities showing higher energy consumption due to larger facilities and student populations. Daly et al. (2022) developed a comprehensive energy-use database for 3,701 Australian public primary schools, finding an average EUI of 38.0 kWh/m²/year and per-student energy consumption averaging 542 kWh/year.

This study specifically targets medical undergraduate students in Taiwan for several reasons. First, medical universities have been identified as among the highest energy-consuming academic units due to their specialized infrastructure and equipment needs (Wang, 2016). Second, Taiwan's healthcare sector contributes approximately 4.6% of the nation's total carbon emissions, surpassing the global healthcare average of 4.4%, with hospitals alone consuming 16% of domestic energy (Taiwan EPA, 2021). Third, medical students, as future healthcare professionals, play a pivotal role in shaping sustainable practices within the healthcare system. Enhancing their knowledge, attitudes, and behaviors regarding energy use can have a multiplier effect on institutional sustainability efforts. Finally, previous research (Liu et al., 2009) demonstrates that energy literacy and positive attitudes towards energy conservation increase with education, supporting the potential impact of interventions targeted at this demographic.

Research also shows that individual behavioral changes can significantly reduce energy consumption and associated carbon emissions. Streimikiene and Volochovic (2011) modeled carbon emissions from daily household activities in Lithuania under two scenarios: a baseline and an energy-saving behavior scenario. Their results indicated that annual GHG reduction potential could reach 5.65 Mt-CO_2e if households adopt energy-saving behaviors, surpassing the 2.4 Mt-CO_2e reduction potential of the industrial sector in 2010. This underscores the substantial impact that personal energy use behaviors can have on climate mitigation.

The Knowledge-Attitude-Practice (KAP) theory explains that behavioral change occurs through a sequential process: acquiring correct knowledge, forming positive attitudes, and adopting sustainable practices (Alsaleh et al., 2023). University students, as emerging energy producers and consumers, play a pivotal role in shaping future energy sustainability (Fang et al., 2022). Fang et al. (2022) found that Chinese university students' attitudes toward green energy vary by demand (renewable energy, nuclear power) and supply (energy-efficient appliances) aspects, with gender differences showing males more supportive of nuclear power due to differing risk perceptions. Similarly, a study in Malaysia revealed that while most university students had high knowledge levels about sustainable consumption (74.1%), their attitudes were moderate (65.6%), and actual sustainable behaviors were lower (49.2%), with 41% reporting low behavioral practice mainly due to lack of habit and limited awareness of overconsumption consequences (Ahamad & Ariffin, 2018).

By surveying students across northern, central, and southern private medical universities, this study aims to quantify annual carbon emissions based on daily energy-use activities and assess knowledge, attitudes, and practices (KAP) related to energy consumption, disaggregated by school, gender, and academic year. This approach fills a critical research gap, as prior studies have largely focused on institutional energy use without sufficiently addressing individual behaviors.

Hence, this study aims to estimate the annual carbon emissions of medical undergraduate students at private medical universities in northern, central, and southern Taiwan by analyzing the duration of their daily energy use activities. It also seeks to examine differences in energy consumption and carbon emissions across demographic variables such as school, gender, and academic year, as well as to assess students' knowledge, attitudes, and behaviors related to energy use through questionnaire surveys.

2 Materials and Methods

2.1 Study design

This cross-sectional study utilized a structured questionnaire to assess energy-related behaviors and carbon emissions among undergraduate medical students in Taiwan. The study population comprised students from six private medical universities: Taipei Medical University, Chang Gung University, China Medical University, Chung Shan Medical University, Tzu Chi University, and Kaohsiung Medical University. Data were collected between May 23 and June 12, 2023, via Google Forms to ensure standardized response formats and efficient data processing.

2.2 Participant recruitment

Undergraduate students enrolled during the 2022–2023 academic year were recruited through official university portals and student social media groups. To ensure adequate statistical power and comparability across institutions, a minimum of 30 valid responses was required from each university. The final sample

encompassed students from various academic years and majors, with a gender distribution representative of typical medical school enrollment in Taiwan.

2.3 Questionnaire development

The questionnaire comprised three sections to facilitate comparative analysis of carbon emissions and energy-related knowledge, attitudes, and practices (KAP) among universities:

- The demographic section collected key information, including response timestamp, institutional affiliation, gender, academic year, and major.
- The activity duration section quantified daily energy consumption patterns by recording time spent using various electrical appliances (e.g., lighting, computers, televisions, air conditioning, hair dryers, mobile phones) and details regarding commuting modes and durations. This section was adapted from the activity list developed by Streimikiene and Volochovic (2011), with additional items on commuting methods, frequency of dining out, and use of other electrical appliances.
- The KAP section, adapted from Tsai et al. (2013) and updated for cultural and technological relevance, assessed students' knowledge, attitudes, and practices related to energy consumption, including items on emerging technologies and contemporary consumption patterns.

2.4 Calculation methods for carbon emission

The average daily per capita carbon emissions (E_x) were calculated by summing the products of the duration of each activity, the associated energy consumption (Table 1), and the corresponding carbon emission factor (Table 2), and then dividing by the total number of students at each university. This is mathematically represented as:

$$E_x = \sum(D_{a,x} \times W_a) \times i_a / N_x \qquad \text{eq.(1)}$$

where $D_{a,x}$ is the duration of the activity a at university x. Data were collected via the questionnaire. W_a is the energy consumption for activity a (Table 1), i_a is the carbon emission factor specific to the energy type or transportation mode for activity a (Table 2), and N_x is the survey number of students at university x in the study.

Table 1: Total energy consumption and cumulative use data for various activities

Activity	Energy Consumption	Unit	Source
Cooking	0.2	m^3/hr	Streimikiene & Volochovic (2011)
Bathing	14	L/min	Taiwan Water User Equipment Standards https://law.moea.gov.tw/LawContent.aspx?id=FL025862
Transportation	60	km/hr	Assumed
Lighting	0.06	kW	Ministry of Economic Affairs Energy Handbook
Air conditioning	0.966	kW	
Computer	0.3	kW	
Television	0.14	kW	
Hair dryer	0.8	kW	
Mobile phone	0.034	kW	Counter point (2023)

Table 2: Carbon emission factors and their data sources used in individual activity calculations

Energy Type	Emission Factor	Unit	Source
Natural Gas	2.19	kg CO_2/m^3	Streimikiene & Volochovic (2011)
Water	0.174	kg CO_2/min	Taiwan Bureau of Energy (2022)
Electricity	0.495	kg CO_2/kWh	
Transportation Type	Emission Factor	Unit	Source
Public Transports [a]	0.047	kg CO_2/km	https://blog.zerozero.com.tw/30598/
Electric Scooter	0.025	kg CO_2/km	
Gasoline Scooter	0.046	kg CO_2/km	
Car	0.173	kg CO_2/km	

[a] Average of bus, MRT, train

2.5 KAP score and estimation

The Knowledge-Attitude-Practice (KAP) score for each subgroup was calculated by average knowledge, attitude, and practice scores for each student and dividing by the total number of students in the subgroup. Knowledge items were scored as 1 for correct, -1 for incorrect, and 0 for "don't know" answers. Attitude and

Practice were assessed on 5-point Likert scales, with Attitude ranging from strongly agree (5) to strongly disagree (1), and Practice from always (5) to never (1).

3 Results and discussion

3.1 Demographic description

The survey targeted undergraduate students from private medical universities in Taiwan, with the largest proportion of respondents from China Medical University (32.07%). Female participants constituted a majority (69.02%) compared to males (30.98%). The sample was predominantly composed of first- to third-year students. Regarding academic departments, while Public Health accounted for 19.02% of respondents, nearly half of the participants belonged to various other departments (48.91%), indicating a diverse disciplinary representation (Table 3). Other departments include Dentistry, Nutrition, Chinese Medicine, Physical Therapy, Occupational Safety and Health, Psychology, and others.

Table 3: Demographic variables of survey respondents

Demographic Variable		**Sample Size (%)**
University		
	Chung Shan Medical University	43 (23.37)
	China Medical University	59 (32.07)
	Chang Gung University	15 (8.15)
	Kaohsiung Medical University	24 (13.04)
	Tzu Chi University	29 (15.76)
	Taipei Medical University	14 (7.61)
Gender		
	Male	57 (30.98)
	Female	127 (69.02)
Academic Year		
	First Year	44 (23.91)
	Second Year	55 (29.89)
	Third Year	45 (24.46)
	Fourth Year	31 (16.85)
	Fifth Year	6 (3.26)
	Sixth Year	3 (1.63)
Department		
	Public Health	35 (19.02)
	Pharmacy	21 (11.41)
	Nursing	14 (7.61)
	Medicine	13 (7.07)
	Medical Laboratory Science and Biotechnology	11 (5.98)
	Others	90 (48.91)

3.2 Duration of activities

The analysis of activity duration (Table 4) reveals that air conditioning and heating are the most time-intensive activities among Taiwanese private medical university students, with average daily usage ranging widely across demographic groups (244–750 minutes). This extended use reflects Taiwan's subtropical climate and the corresponding high demand for indoor air conditioning. Transportation-related activities-specifically car use, gasoline motorcycle use, and public transportation-also constitute substantial daily time investments, though generally much less than air conditioning and heating (3–98 minutes on average).

Notably, public transportation usage is highest among students at Taipei Medical University (mean: 98 minutes), consistent with Taipei City's leading public transit market share. Gender differences are evident, with male students reporting longer average usage times for cars and gasoline motorcycles, while public transportation usage is similar between genders. Across academic years, fifth- and sixth-year students report the longest average durations for air conditioning and heating, while first- to third-year students have higher average public transportation usage. Departmental differences are also apparent; for example, pharmacy and medical laboratory science students report the highest average times for air conditioning/heating and public transportation, respectively. These patterns underscore the centrality of air conditioning and transportation in

student daily routines, highlighting their significance in campus carbon emission profiles and the importance of targeted sustainability interventions.

Table 4: Average usage time (mins) and standard deviations of air conditioning/heating, cars, gasoline motorcycles, and public transportation

3.3 Estimation of carbon emissions by university

A comparative analysis of average daily per capita carbon emissions across six private medical universities in Taiwan reveals substantial inter-university variation (Figure 1). Students at Chung Shan Medical University exhibited the highest mean daily emissions (9.87 kg-CO_{2e}), followed by Taipei Medical University (9.69 kg-CO_2e), China Medical University (9.16 kg-CO_{2e}), Tzu Chi University (8.49 kg-CO_2e), Chang Gung University (7.72 kg-CO_2e), and Kaohsiung Medical University (7.48 kg-CO_2e).

Disaggregated activity-level data indicate that air conditioning and heating consistently represent the largest source of emissions at most institutions, with values ranging from 1.94 to 4.00 kg-CO_2e per person per day. Notably, Kaohsiung Medical University reported the highest air conditioning/heating emissions (4.00 kg-CO_2e), which likely reflects the region's elevated ambient temperatures. Other significant contributors vary by university: gasoline motorcycles and cars are prominent at Chung Shan Medical University, while public transportation is the leading source at Taipei Medical University (4.59 kg-CO_2e). China Medical University and Chang Gung University both show considerable emissions from car use and public transportation, underscoring the influence of mobility patterns on institutional carbon profiles.

These findings highlight the dominant role of air conditioning/heating and transportation-related activities in shaping university-level carbon emissions. The observed differences underscore the need for targeted, context-specific mitigation strategies that address both energy use and mobility behaviors within university settings.

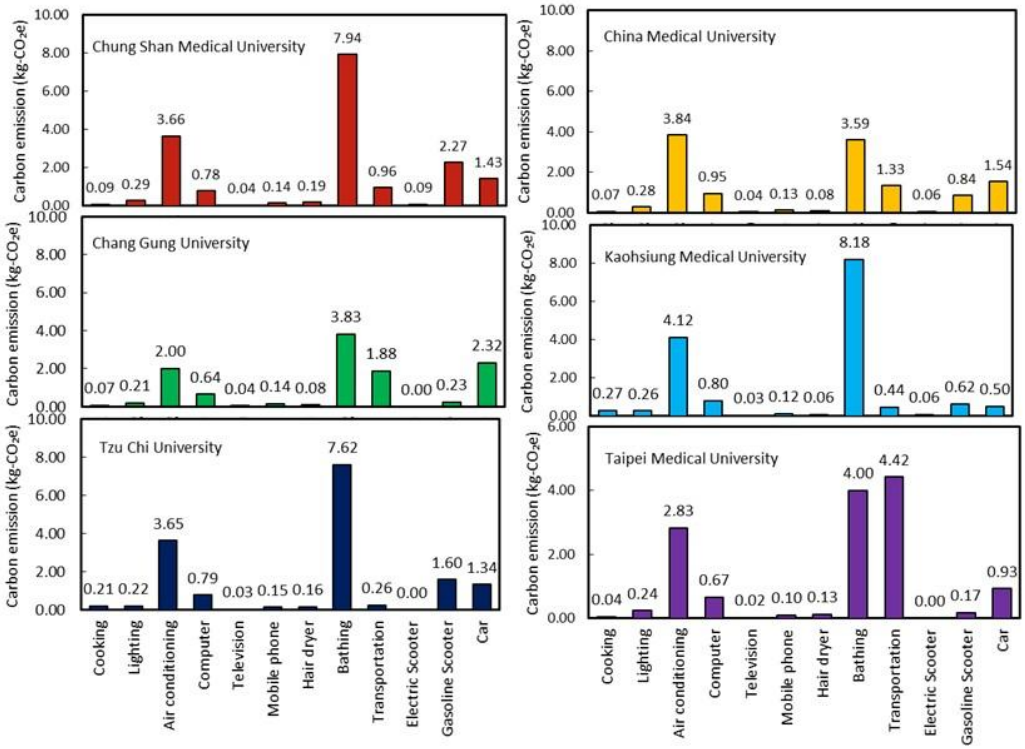

Figure 1. Average daily per capita carbon emissions (kg-CO_2e/person/day) by university and activities

3.4 Estimation of carbon emissions by university

Table 5 presents the comparison of average scores and standard deviations for Knowledge, Attitude, and Practice (KAP) among students from six medical universities. Knowledge was assessed with six items (score range: -6 to 6), Attitude with six items (range: 0 to 30), and Practice with five items (range: 0 to 25).

Across all universities, the mean Knowledge scores ranged from 3.79 (SD = 1.63) at Taipei Medical University to 4.80 (SD = 1.15) at Chang Gung University. The highest Attitude mean was observed at Chung Shan Medical University (19.95 ± 3.31), while the lowest was at Kaohsiung Medical University (18.42 ± 3.92). For Practice, Taipei Medical University reported the highest mean (18.79 ± 3.49), and Chung Shan Medical University the lowest (17.16 ± 3.09).

Overall, the Knowledge scores showed moderate consistency across institutions, with standard deviations ranging from 1.15 to 1.63, indicating relatively similar levels of knowledge among students. Attitude scores exhibited greater variability, particularly at Taipei Medical University (SD = 5.00), suggesting more diverse perspectives among students at that institution. Practice scores were generally comparable, with means spanning from 17.16 to 18.79 and standard deviations from 2.64 to 3.55.

Table 5: Comparison of average scores and standard deviations for Knowledge, Attitude, and Practice (KAP) among medical university students

Name of University (sample size)	**Knowledge (6 items) (Min-Max: -6 - 6)**	**Attitude (6 items) (Min-Max: 0 - 30)**	**Practice (5 items) (Min-Max: 0 - 25)**
Chung Shan Medical University (n=43)	4.70±1.34	19.95±3.31	17.16±3.09
China Medical University (n=59)	4.73±1.36	19.69±3.56	17.69±3.22
Chang Gung University (n=15)	4.80±1.15	18.47±3.66	18.53±2.64
Kaohsiung Medical University (n=24)	4.67±1.34	18.42±3.92	17.75±3.31
Tzu Chi University (n=29)	4.28±1.58	19.90±3.53	18.28±3.55
Taipei Medical University (n=14)	3.79±1.63	19.21±5.00	18.79±3.49

4 Conclusions

This study provides a comprehensive analysis of carbon emissions and energy-related knowledge, attitudes, and practices (KAP) among undergraduate students at six private medical universities in Taiwan. The results

reveal that air conditioning and heating are the primary sources of daily energy use, reflecting the influence of Taiwan's subtropical climate. Transportation activities-especially public transit-also constitute a significant portion of students' daily routines, with notable differences observed by gender, academic year, and department.

These findings underscore the need for targeted educational interventions to enhance sustainable energy behaviors among medical students. As future healthcare professionals, these students are uniquely positioned to influence institutional and societal sustainability. Universities can leverage these insights to design campus-wide energy-saving policies, integrate sustainability topics into medical curricula, and promote behavioral change through awareness campaigns and incentive programs.

Abstract

In recent years, the growing emphasis on social sustainability and ethical corporate behavior has brought Diversity, Equity, and Inclusion (DE&I) to the forefront of both academic debate and corporate strategy. Movements such as Me Too and Black Lives Matter, alongside the impact of the COVID-19 pandemic, have accelerated awareness around social inequalities, urging firms to enhance transparency and commitment to inclusive practices. Despite this trend, empirical studies investigating the determinants of DE&I disclosure remain scarce.

This study aims to fill this gap by analyzing the quality of DE&I disclosure among S&P 500 firms. A manual content analysis is conducted using the Global Reporting Initiative (GRI) standards, leading to the construction of a DE&I Disclosure Quality Index (DE&ID). Each disclosure item is scored on a 0–3 scale, allowing a maximum index value of 51. The analysis incorporates "Requirements," "Recommendations," and "Guidelines" outlined in the GRI framework.

The second objective is to investigate the influence of firm-specific economic and financial characteristics—firm size, firm profitability, firm leverage, and firm age—on DE&I disclosure levels. Four hypotheses, grounded in stakeholder theory, are tested using OLS regression.

Results demonstrate that larger, more leveraged, and younger firms exhibit higher DE&I disclosure, driven by greater stakeholder pressure and the strategic benefits of enhanced transparency. This study contributes to the ESG literature by offering new insights into the drivers of DE&I communication, with implications for both academia and policy, and supports the integration of DE&I into corporate accountability frameworks.

Keywords: Diversity, Equity, and Inclusion (DE&I); Disclosure; Stakeholder theory; Sustainability reporting; Determinants

Paper type: Academic Research Paper

1 Introduction

Recently, a paradigm shift emphasizing economic and social sustainability, alongside increasing environmental responsibility, has been observed (Esposito et al., 2024). The aftermath of the pandemic and socio-political movements such as "Me Too" and "Black Lives Matter" have heightened awareness of social inequalities, compelling firms to address issues such as income disparity, work-life balance, and overall quality of life (Manoharan et al., 2021; García-Sánchez et al., 2023). This shift has also brought about a growing recognition that social sustainability is equally important to long-term corporate success as economic and environmental factors (Shohaieb et al., 2022). With nearly 49% of G250 companies now recognizing social factors as potential operational risks (KPMG, 2022), corporate strategies are increasingly focusing on addressing these challenges through actionable policies.

Among these societal factors, numerous studies underscore the growing significance of Diversity, Equity, and Inclusion (DE&I) as fundamental to advancing sustainability objectives, ensuring long-term corporate success, and fostering ethical and responsible business practices. This trend has led to a shift in corporate priorities, where DE&I is seen not just as a social issue but as a crucial element of corporate governance and strategy. These topics have attracted increasing attention from both academics and practitioners (Eccles et al., 2020; Parker, 2022).

A corporate culture that prioritizes DE&I fosters a more inclusive and collaborative work environment while enhancing competitiveness and innovation. Moreover, organizations that integrate DE&I into their core values are often better equipped to attract diverse talent, improve employee satisfaction, and adapt to the evolving expectations of stakeholders. Organizations actively investing in DE&I policies are better positioned to meet stakeholder expectations and institutional pressures, thereby improving their reputation, financial performance, and attractiveness to investors and talent (Harrison & Klein, 2007; Bear et al., 2010). As consumers and investors increasingly prioritize corporate sustainability and responsible business conduct, firms are urged to integrate

and disclose their DE&I initiatives as part of their broader corporate social responsibility (CSR) commitments, reinforcing transparency and accountability.

Despite this growing emphasis, empirical research on the determinants of DE&I disclosure remains limited (Shohaieb et al., 2022; Garcia-Sanchez et al., 2023), particularly regarding the financial and economic drivers behind such disclosures. This highlights the need for further investigation into the factors influencing firms' transparency in this area. By understanding these determinants, scholars and practitioners can gain insights into how to better assess and promote DE&I initiatives in organizations.

In addressing the aforementioned gap, this study aims to assess, through a manual content analysis, the quality of DE&I disclosure in the sustainability reports of firms within the S&P 500. This research will not only evaluate the content but also analyze the patterns and practices in how companies disclose DE&I efforts. The study will then investigate the economic and financial determinants of these disclosures, offering a more comprehensive understanding of the factors influencing corporate transparency on DE&I issues.

The following sections of this paper are organized as follows: Section 2 presents a background and introduces research hypotheses. Section 3 details the methodology, and Section 4 presents and discusses the obtained results. Section 5 draws conclusions.

2 Background and hypotheses development

To date, only three studies have examined DE&I disclosure and its determinants. Shohaieb et al. (2022) found that governance variables—such as board size, independence, and gender diversity—positively influence the disclosure of diversity management in the annual reports of non-financial organizations listed in the UK FTSE All-Share Index, based on data from 2013 to 2019. García-Sánchez et al. (2023) investigated how governance characteristics, including board gender diversity and expertise, affect the quality of diversity and inclusion disclosure in 189 European multinational companies over the period 2011–2020. Their findings indicate that board diversity and expertise enhance the effectiveness of communication, whereas board independence does not exert a significant impact. Moreover, their study highlights the role of European regulations and the COVID-19 pandemic in fostering greater transparency in diversity practices among these firms. Marrone et al. (2025) have examined the impact of governance determinants on the DE&I disclosure through a sample of 157 companies.

While these studies offer valuable insights into governance-related determinants, the influence of economic and financial factors remains largely underexplored.

Economic and financial information can often be embedded within other forms of disclosure. From this perspective, to examine how firm characteristics influence disclosure practices, the literature highlights several key drivers, particularly related to organizational size and financial performance.

From the perspective of stakeholder theory, larger firms are more likely to engage in extensive sustainability reporting. This is attributed to their greater societal and environmental impact, increased public exposure, and the higher level of scrutiny they face from stakeholders (Alduais et al., 2022; Fortanier et al., 2011; Gallo & Christensen, 2011; Hahn & Kühnen, 2013; Zimon et al., 2022). Managers of such firms often view sustainability disclosure not only as a tool for transparency but also as a strategic asset to enhance legitimacy, mitigate adverse selection, and differentiate from competitors. Moreover, large organizations typically possess more substantial resources, enabling them to invest in environmentally friendly technologies and structured reporting systems (Younis & Sundarakani, 2019).

On the financial side, scholars have argued that sustainability practices aligned with stakeholder expectations can enhance long-term firm value (Freeman & Reed, 1983; Eliwa et al., 2021). Firms with strong ESG performance often adopt a long-term strategic outlook and are more capable of absorbing the costs of sustainability initiatives (Kent & Monem, 2008; Kamaliah, 2020; Alshurafat et al., 2022). While several studies report a positive association between profitability and environmental or social initiatives (Rini & Adhariani, 2020), findings remain mixed. For instance, Fahad and Busru (2021) identify a negative relationship in the Indian context, underscoring the complexity of the profitability-disclosure nexus.

Another factor of interest is corporate leverage. Highly indebted firms may engage in sustainability initiatives as a signaling mechanism to maintain or regain stakeholder trust, particularly among creditors and investors (Haniffa & Cooke, 2005; Bai et al., 2024). In this context, sustainability reporting serves to legitimize corporate behavior and reduce perceived risk. Some studies suggest that higher debt levels incentivize environmental disclosure (Andrikopoulos & Kriklani, 2013; Al-Tuwaijri et al., 2004), while others observe positive links between CSR spending and debt financing (Oware & Mallikarjunappa, 2021). However, conflicting evidence exists—Alkhouri and Suwaidan (2023), for example, find no significant effect of CSR disclosure on the cost of capital in the Jordanian market. Moreover, high debt levels may constrain a firm’s capacity to invest in sustainability

reporting, especially when disclosure may reveal unfavorable information (Cormier & Magnan, 2003; Stanny & Ely, 2008). According to Ho et al. (2022), effective CSR reporting can reduce firm leverage by improving investor attention and liquidity.

In consideration of these premises, the study aims to test the following hypotheses:

- *H1: Firm size is positively associated with DE&I disclosure quality.*
- *H2: Profitability is positively associated with DE&I disclosure quality.*
- *H3: Financial leverage is positively associated with DE&I disclosure quality.*
- *H4: Firm age is negatively associated with DE&I disclosure quality.*

3 Methodology

3.1 Sample

As a starting sample, the S&P 500 index is chosen. This index is selected for its wide representation across various countries and industries, providing a reliable source for examining #rms sustainability disclosure practices. However, data on the independent and control variables were available for only 247 out of the 498 companies in the index. Among these, sustainability reports for the year 2023 were found for 170 companies. However, in this first phase of the study, only 57 companies were analysed.

3.2 Model specification

To test the relationship between firm characteristics and DE&I disclosure quality, this research has used a linear regression model. The following equation expresses the model of the present analysis:

$$DE\&I = \beta_0 + \beta_1 SIZE + \beta_2 ROE + \beta_3 LEV + \beta_4 AGE + \beta_5 BDS + \beta_6 BDD + \beta_7 BDI + \beta_8 BDA + \varepsilon$$

3.3 Variables

The DEI Disclosure Quality Index (DE&ID), developed by the authors following Marrone et al. (2025) through a content analysis approach (Krippendorff, 2018), serves as the dependent variable in this study.

The selection of disclosure items was informed by the Global Reporting Initiative (GRI) standards, widely regarded as a global reference framework for high-quality sustainability reporting (Ferraro & Cristiano, 2022). Each item was evaluated using a four-point scale from 0 to 3: a score of 0 reflects the absence of disclosure; 1 indicates a minimal or vague reference; 2 corresponds to a qualitative disclosure; and 3 signifies a disclosure supported by quantitative data. Consequently, the DE&ID index has a theoretical range from 0 to 51. The full set of evaluated items is included in the Appendix. For the content analysis, relevant terms and expressions were drawn from the GRI's "Requirements," "Recommendations," and "Guidance" sections.

The independent variables of the study are: firm size, firm profitability, financial leverage, and firm age, on DE&I disclosure.

The independent variables employed in this study include firm size (SIZE), firm profitability (ROE), financial leverage (LEV), and firm age (AGE). Specifically, SIZE is used as a proxy for firm scale and is calculated as the natural logarithm of total assets. ROE, serving as an indicator of profitability, is computed as the ratio of net income to shareholders' equity. LEV, capturing the degree of financial leverage, is measured as the ratio of total assets to shareholders' equity. AGE serves as a measure of the company's stability, and it is determined by the number of years since the company's establishment to 2025.

In order to enhance the robustness of the regression model, certain control variables were introduced, namely: board size (BDS), board diversity (BDD), board independence (BDI), and board age (BDA). BDS serves as a proxy for the size of the board of directors and is determined by the count of both executive and non-executive members within the board. BDD represents the percentage of female members within the board of directors. BDI is defined by the percentage of independent board members. BDA is calculated as the average age of its members.

4 Results and discussion

4.1. Descriptive statistics, correlation analysis, and VIF

Table 1 displays the descriptive statistics of the variables. The dependent variable, DE&ID, exhibits a mean value of 37.142, reflecting considerable variability in the extent of disclosure across the sampled firms. SIZE

shows an average value equal to 10.649, while ROE presents an average value equal to 23.146. LEV has an average value of 68.174, while AGE presents an average value equal to 0.450.

Table 1 shows the correlation matrix and allows us to exclude multicollinearity issues. In this regard, the most critical coefficient is between the BDA and BDI and assumes a value equal to 0.5973. According to Farrar and Glauber (1967), there are multicollinearity problems when the values exceed the threshold values of ± 0,8 or ± 0,9. Therefore, in light of this, it is possible to affirm the absence of multicollinearity problems in the interpretation of the results. Moreover, the Variance Inflation Factor (VIF) analysis yielded values ranging from 1.13 to 1.63, which is well below the commonly accepted threshold of 10 (Myers, 1990). These results suggest that multicollinearity does not pose a significant issue in this study.

4.1. Multivariate analysis

To test the hypotheses, the present research uses a multiple linear regression model. Table 2 shows the results of the analysis. The regression model explains about 21% of the variance of the dependent variable (R2 adjusted equal to 0.210). The hypotheses are partially supported by the findings.

Hypothesis 1 (H1) is supported by the results, which indicate that SIZE has a positive and significant effect on DE&I disclosure (p-value = 0.098). Larger companies are often under greater public scrutiny, which may drive them to disclose more information regarding diversity, equity, and inclusion (DE&I) practices. Larger firms generally have more resources and structured departments to manage social and environmental issues. These companies may also be more motivated to build and maintain their reputations in order to attract investors, customers, and talent. Moreover, large companies are typically subject to higher expectations from various stakeholders, including regulators, advocacy groups, and the general public, which may push them to be more transparent in their DE&I reporting. Their increased visibility and the potential reputational risks associated with neglecting diversity issues further contribute to the likelihood of them providing more comprehensive information.

On the other hand, Hypothesis 2 (H2) is not supported by the results, as the relationship between ROE (return on equity) and DE&I disclosure is found to be non-significant. The absence of a significant relationship suggests that financial performance, as measured by ROE, does not necessarily correlate with the extent of DE&I disclosures. This finding is interesting, as one might expect that companies with stronger financial performance would be more inclined to engage in CSR-related activities, including DE&I reporting, as a way to further enhance their reputation. However, the results suggest that DE&I disclosure could be driven by other factors, such as regulatory requirements or social pressures, rather than by financial metrics alone. It is possible that companies focus on DE&I practices as part of their broader sustainability or social responsibility initiatives, which may not always directly relate to immediate financial performance.

Hypothesis 3 (H3) is supported by the results, with LEV (leverage) having a positive and significant impact on DE&I disclosure (p-value = 0.087). Companies with higher leverage may face greater scrutiny from investors and creditors, who often view transparency in non-financial matters—such as DE&I practices—as an indicator of good corporate governance. In addition, companies with high levels of debt may be more inclined to signal their commitment to sustainability and social responsibility in order to mitigate risks associated with their financial position. The need to secure and maintain access to low-cost capital may also drive these companies to adopt more transparent reporting practices on DE&I. Leverage can serve as a signal to stakeholders that the company is managing its obligations effectively, and demonstrating responsibility in areas like diversity could enhance the company's attractiveness to potential investors.

Finally, Hypothesis 4 (H4) is supported by the results, with AGE having a negative and significant impact on DE&I disclosure (p-value = 0.098). Older companies may be less inclined to disclose DE&I information, possibly due to more established and entrenched organizational structures that may not prioritize diversity initiatives. Over time, these companies may have developed more rigid corporate cultures that are less adaptable to emerging societal expectations around issues like diversity and inclusion. Additionally, older firms may perceive less immediate pressure to address DE&I concerns, especially if they have been operating successfully for many years. These companies may already have well-established reputations and market positions, reducing the perceived need for transparency on social issues that may not directly impact their day-to-day operations. Furthermore, older companies may be less reactive to changes in societal norms, as they may already have a history of practices that do not emphasize diversity as much as newer organizations.

Overall, the findings suggest that while company size, leverage, and age have significant effects on DE&I disclosure, financial performance (as measured by ROE) does not seem to play a decisive role. The results highlight the complex interplay between various organizational characteristics and their approach to social responsibility and transparency. Larger companies and those with higher leverage are more likely to engage in

detailed DE&I disclosure, while older companies may be slower to adopt these practices. These insights contribute to the growing body of literature on corporate transparency and sustainability, shedding light on the factors that influence companies' decisions to disclose DE&I information.

5 Conclusions

This study investigates the DE&I disclosures within the sustainability reports of companies listed on the S&P 500 index, focusing on how economic and financial characteristics influence disclosure practices. The findings reveal that firms that are larger, more indebted, and relatively younger tend to provide more extensive DE&I reporting, likely due to intensified stakeholder expectations and the strategic value of transparency.

The research contributes both theoretically and practically.

On a theoretical level, it advances the literature on ESG disclosure by shedding light on the relatively understudied area of DE&I reporting and its key drivers. While much of the existing research has focused on environmental and governance aspects of ESG, the social dimension—specifically DE&I—remains less explored. This study fills that gap by not only highlighting the importance of DE&I transparency but also by offering empirical evidence on the factors that influence its disclosure. In doing so, it extends current theories and frameworks related to corporate social responsibility and accountability. Moreover, it broadens the application of stakeholder theory to encompass DE&I transparency, offering new insights into how firms manage and communicate their responsibilities to various stakeholders. The study also contributes to a deeper understanding of how companies balance competing stakeholder interests, particularly in the realm of social issues like diversity and inclusion.

On a practical level, by evaluating the quality of DE&I disclosures and identifying firm-level determinants, the study supports more informed integration of DE&I principles into corporate strategies and governance frameworks. This research provides a robust framework for assessing the effectiveness of DE&I initiatives and reporting practices, enabling firms to adopt more comprehensive and transparent approaches. By offering

concrete insights into the factors that drive DE&I disclosure, the study helps organizations refine their CSR strategies and enhance their commitment to diversity, equity, and inclusion. Furthermore, it provides actionable recommendations for business leaders to improve their DE&I communication, ensuring that these issues are integrated not just into corporate rhetoric but into tangible actions that impact organizational culture and performance.

Additionally, it provides guidance for policymakers seeking to enhance disclosure standards, thereby reinforcing accountability and advancing the dialogue on corporate responsibility in the realm of DE&I. By highlighting best practices and identifying areas for improvement, this research contributes to the ongoing conversation about how to standardize and elevate DE&I reporting. Policymakers and regulatory bodies can use the study's findings to develop frameworks that encourage more detailed and accurate disclosures, pushing firms toward greater transparency. In this way, the study plays a crucial role in advancing the broader agenda of corporate responsibility, ensuring that DE&I becomes a central element of corporate governance and is given the attention it deserves in corporate disclosure practices.

Despite the relevance of the findings, this study is subject to certain limitations. First, the cross-sectional nature of the analysis does not allow for the assessment of the dynamic evolution of DE&I disclosure over time. Second, due to data constraints, the study focuses exclusively on the influence of firm size, leverage, profitability, and age, potentially overlooking other relevant factors. Lastly, the methodological approach adopted to assess disclosure quality—manual content analysis—although conducted following rigorous protocols, may entail a degree of subjectivity.

The identified limitations suggest interesting directions for future research. Longitudinal studies could examine the evolution of DE&I disclosure over time, allowing researchers to observe how disclosure practices have developed and adapted to new challenges and regulations. Such an analysis could also identify emerging trends and highlight how transparency on diversity, equity, and inclusion issues is influenced by external factors such as social, political, and economic changes.

Additionally, it would be useful to expand the analysis to other economic-financial dimensions or other business aspects, such as social performance or the impact of governance on the integration of DE&I into corporate strategies. Future studies could, for example, explore the relationship between DE&I disclosure and financial performance on a broader scale or investigate how diversity policies influence the long-term competitiveness of companies. Similarly, it may be interesting to analyze how different sectors or geographical areas approach DE&I disclosure, considering cultural and regulatory differences that could influence business behaviors.

Finally, future studies could explore further qualitative parameters of disclosure, such as relevance, comparability, verifiability, and neutrality of the information, to provide a more comprehensive view of corporate transparency in DE&I matters. Analyzing not only the quantity but also the quality of the reported data could contribute to improving reporting practices and enhancing stakeholder trust in the information provided. Furthermore, deepening the qualitative aspect could also help better understand how companies interpret and communicate their social responsibility, avoiding the risk of greenwashing or one-sided communication.

6 Ethics declaration

This research did not involve any human participants, personal data, or experimental procedures requiring ethical approval. Therefore, ethical clearance was not required for the study presented in this paper.

7 AI declaration

The authors further declare that no AI tools were used at any stage of the research process or during the preparation of this manuscript. This includes the formulation of the research questions, methodological design, data analysis, drafting, and language revision. All intellectual contributions are the result of the authors' independent work. This choice reflects both the academic nature of the study and the authors' commitment to ensuring full transparency and accountability for the content presented.

Skill Mismatch: Exploring the Impact of Generative AI in Detecting Biases and Discrimination in Job Advertisements

Armando Calabrese, Sofia Carrino, Roberta Costa, Eugenio Roberti, Luigi Tiburzi
University of Rome "Tor Vergata", Rome, Italy

Abstract

The Human Resources field, on a national and global scale, faces increasing challenges related to Skill Mismatch, a phenomenon in which candidates' profiles do not align with labour market demand. The contributing factor analysed in this paper is the lack of inclusivity in job advertisements, as non-inclusive language and biases in the selection criteria may discourage applications from underrepresented communities. Ensuring compliance with Diversity & Inclusion (D&I) principles in job postings is essential to fostering fair hiring practices and promoting employment equity.

While AI-based technologies are finding increasing applications in the recruitment process, thus becoming part of the research topics in HR management, most existing tools primarily focus on gender discrimination, underestimating other critical aspects of D&I. This study explores how an integrated approach, based on a broader range of aspects of D&I European principles, may enrich AI-based tools to identify, but also solve, biases in job advertisements, enhancing inclusivity and employment equity for both candidates and recruiters. By expanding the scope of these tools, organizations can better align their hiring practices with the evolving expectations of a diverse and inclusive workforce.

The approach to the problem has been broken down into two main phases. First, guidelines were developed based on European non-discrimination regulations, providing a structured framework for evaluating job advertisements. Then, a Generative AI-based software was designed to screen job postings for inclusivity and compliance. The study underscores the potential advantages of AI-driven automation in screening job advertisements, reducing human biases, resource commitment, and processing time while ensuring adherence to D&I principles.

Keywords: Mismatch; Diversity and Inclusion (D&I); Generative AI; Job Advertisement (JobAds); Human Resources (HR)

Paper type: Academic Research Paper

1 Introduction

The Human Resources sector, at both national and international levels, encounters substantial challenges in addressing the skill shortage among candidates (Liboni et al., 2019; Mukhuty, Upadhyay and Rothwell, 2022; Picinin et al., 2023) and elevated employee turnover rates (Agrawal, Khatri and Srinivasan, 2012). This phenomenon is called Skill Mismatch (SM) (Stanković, Džunić and Marinković, 2021), and it is associated with persistent difficulties in identifying candidates possessing the required qualifications for specific roles.

The job posting constitutes the primary means of interaction between prospective candidates and organizations (Barber, 1998). Ensuring adherence to Diversity and Inclusion (D&I) principles within these advertisements represents a strategic approach that transcends marketing objectives. It enables the creation of equitable conditions for candidate-job matching, fostering inclusivity by eliminating biases that might otherwise discourage applications from underrepresented communities. Studies underscore the critical role of inclusive language in enhancing fairness and broadening the pool of qualified candidates (Saks, Leck and Saunders, 1995).

Although the AI-based tools in the HR field are primarily used during the candidates and Job Advertisements (JobAds) screening phases (Albert, 2019), most of the literature demonstrated how they are mainly focused on the detection of gender discrimination (Hu et al., 2022). This study aims to broaden this scope by exploring how an integrated approach, based on a wider range of aspects of D&I European principles, can enrich AI-based tools to identify and solve biases in JobAds, enhancing inclusivity and employment equity for both candidates and recruiters.

2 Background

The dimension of the SM is estimated through a labour market analysis, for which the Job Vacancy Rate (JVR) has been selected as the most significant indicator (Figure 1). The JVR is the percentage ratio of total job vacancies to the sum of occupied jobs and job vacancies (ISTAT, 2024). From the Labour Market Survey (ISTAT, 2023), ISTAT (Italian National Institute of Statistics) defines job vacancies as "the posts, either newly created or already existing, unoccupied or about to become vacant, which the employer actively seeks to fill with - and is prepared to make further efforts to find - a suitable candidate from outside the enterprise". Both data on JVR

and occupied positions are provided by ISTAT on an annual basis; in particular, the years from 2017 to 2023 are considered in this paper. Data on JVR refers to industrial and service companies, classified according to ATECO economic activity sections (ATECO, 2022); data on occupied job positions comes from the Asia Register, the statistical register of active enterprises, updated annually through a process of information integration from administrative sources, statistical sources and private companies (ISTAT, 2013).

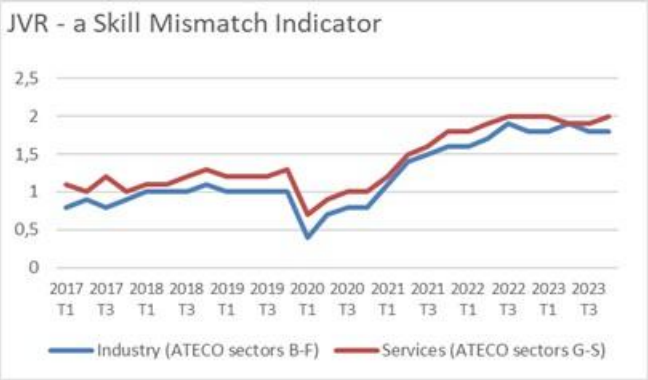

Figure 1 - Job vacancy rate (seasonally adjusted) in enterprises with at least 10 employees (ISTAT, 2024)

A higher JVR reflects unmet labour demand, whereas a lower rate can indicate a mismatch situation in which employers struggle to fill open jobs in specific periods or economic sectors (Lovaglio, 2022). This evidence underscores the need to analyse the underlying factors of mismatch to support effective policies and strategies.

This study focuses on internal company factors, particularly discrimination in employer branding and the recruiting process. The writing of a JobAd plays a key role in a candidate's decision-making process, shaping their initial evaluations about the company they will potentially engage with (Horvath and Sczesny, 2015). Therefore, discriminatory practices can potentially exclude some candidates even from the application for the jobs (Ningrum et al., 2020).

Various approaches, including field experiments, vignette studies and mixed methods, have been employed to uncover discriminatory practices in the recruitment process.

Regarding field experiments, Lee and Khalid (2015) explored racial discrimination in the hiring process for recent graduates in Malaysia. Specifically, they submitted 3,012 fictitious resumes from Malay and Chinese candidates to companies advertising job openings and analysed the interview callbacks based on racial identity. Their results showed that race played a more decisive role in securing a callback than the quality of the resume.

Beyond field experiments, vignette studies have also been conducted to examine discriminatory practices in the recruitment process. Kübler, Schmid, and Stüber (2018) applied this approach to investigate gender discrimination in apprenticeship hiring in Germany. Their study involved 636 HR managers who were asked to assess 3,164 short fictitious CVs. Each respondent evaluated five vignettes and then rated fictitious applicants on a scale from 1 to 10 to determine whether they would advance to the next stage of the hiring process. The findings revealed that, on average, women were rated lower than men, even when other variables were controlled.

Although these approaches are good measures to detect and investigate discrimination during recruitment, they rely on researchers to design and administer experiments or surveys. As a result, the structure of these studies may inadvertently create conditions that differ from real-world hiring practices. Additionally, researchers have limited control over sample sizes, as they are dependent on the number of responses received. For these reasons, it is more effective to address the issue at its root by acting on the JobAd writing phase, with the aim of identify in advance potential discriminatory elements towards the candidates. Firstly, JobAds are direct outputs of the hiring process, making them an authentic reflection of the labour market. Secondly, they serve as strong indicators of an organization's commitment to fair hiring practices (Leong, Tan and Loh, 2004), as they often reveal employers' preferences regarding their ideal candidates. Lastly, researchers can determine the sample size of their studies based on the number of existing JobAds (Ningrum et al., 2020).

Before the introduction of automated processes, JobAds analysis for identifying discrimination, was often conducted manually. However, this approach becomes ineffective and time-consuming when applied to a large number of job postings, while also being influenced by cognitive biases inherent in human judgment. Over time, AI has become part of the research topics in HR management, following a transition process from the early academic studies to its current global impact (Frissen, Adebayo and Nanda, 2023; Hu, et al., 2022). From 2024, AI systems used in employment, worker management, and access to self-employment are considered high-risk

under the EU AI Act (EPC, 2024). This applies specifically to "AI systems intended to be used for the recruitment or selection of natural persons, in particular to place targeted job advertisements, to analyse and filter job applications, and to evaluate candidates" (EPC, 2024). Exceptions include models that detect decision-making deviations from prior patterns and are not meant to replace or influence the previously completed human assessment without proper human review, as well as models that perform preparatory tasks for evaluations relevant to the specific context. There is growing concern that human biases may carry over to decisions made by these systems, which can amplify the effect through systematic application. AI-based software, in fact, are susceptible to various biases, including gender, racial, and cultural biases (Bender et al., 2021). These biases stem from the model's training data, which reflect human-generated content from the internet (Ray, 2023). Empirical studies have identified prevalent biases in candidate ranking software and chatbot interactions, catalysing a rising body of research dedicated to AI fairness over the last decade (Mujtaba and Mahapatra, 2024).

3 Method

The research has been structured into two main phases. The first one involves the development of guidelines to ensure accessibility and compliance in JobAds. These guidelines will serve as the foundation for the second phase, which focuses on the design of a software for screening job postings and identifying Non-Compliances. This latter phase has been further divided into two steps: prompt engineering and standardization of the output format to facilitate the rapid interpretation of results.

Since this paper presents a preliminary version of the tool, the software has been initially validated only for four categories, which are most discussed in the literature and hold significant international legal relevance: "Personal Protective Equipment (PPE)", "Gender", "Age", "Ethnicity and Origin".

3.1 Guidelines

The set of guidelines was based on non-discrimination principles embedded in European legislation, as well as regulations governing relationships between companies, candidates, and employees (EPC, 2006; CD, 2000/43/EC; EC, 2000; FRA, 2018; EUR-Lex, 1989).

The dimensions explored by the guidelines in this preliminary stage of tool validation include the following:

- "PPE": they must normally be provided, free of charge, by the employer, who ensures its proper functioning and hygienic conditions through maintenance, repairs, and necessary replacements (EPC, 1989).
- "Gender": directive 2006/54/EC concerns the implementation of the principle of equal opportunities and equal treatment of men and women in matters of employment and occupation and establishes a set of rights, duties, and prohibitions to achieve the goal of gender equality in the workplace (EPC, 2006).
- "Age": the prohibition of discrimination based on age is regulated by Directive 2000/78/EC, which establishes the principle of equal treatment and justifies age-related disparities based on certain objective and legitimate reasons, such as employment or training policies (CEU, 2000).
- "Ethnicity and Origin": discrimination based on race or ethnic origin is considered discrimination under Directive 2000/43/EC, which implements the principle of equal treatment regardless of race and ethnic origin (CEU, 2000).

The output obtained from this phase is not only a fundamental step in the software development process but can also serve as a standalone tool providing a framework for recruiters.

3.2 Prompt

Starting from the guidelines, a preliminary version of a software has been developed, using PySpark Notebooks in the Databricks environment. This tool queries ChatGPT (engine GPT-3.5 Turbo) to identify elements within JobAds that indicate a lack of inclusivity or Non-Compliance with legal standards. Since the project had already started when upgraded versions of ChatGPT were released, it was decided to continue with this engine to keep the progress made. Upgrading to a more recent version will be considered for future developments of the tool.

The tool's prompt has been structured into 3 sections:

- System prompt: role assignment to ChatGPT, definition of the context and boundaries within which the response should be developed.
- User prompt: the main prompt, which explores the lack of inclusivity or Non-Compliance with regulations for each dimension of analysis.
- A standardized output format to facilitate rapid interpretation of the results.

Since this tool is applied to the HR field, it must be flexible and capable of evolve alongside the regulatory and cultural context. Thanks to this architecture and the AI's ability to learn from examples and feedback, the system can be continuously optimized and updated. For example, it is possible to modify the prompt for a category affected by legislative changes without impacting the output of other categories.

In the System Prompt section, ChatGPT is assigned the role of a recruiter responsible for analysing the text of a JobAd and providing responses to a set of questions.

The reference investigation method for the User Prompt section is a knowledge-based approach to formulate a Discriminatory Keywords Dictionary (DKD). Books and regulations were reviewed to identify the keywords and terms related to discrimination. Synonyms and abbreviations were also included. In addition to the keywords, it was also important to consider Word Patterns Templates (WPT), defined as combinations of keywords and words with specific order, to extract more information from the text as DKD can only detect the occurrences of keywords (Ningrum, et al., 2020).

The reference method was applied limited to the definition of keywords and word patterns, but with some integrations in the approach, given the different purpose of this research. First, European D&I principles and legislation have been not only analysed but also included in a set of guidelines, as previously described. Second, starting from the guidelines, keywords and word patterns, which in our case are phrases and expressions that contain the keywords or indirectly refer to discrimination, have been identified and listed in Table 1.

Table 1 – Discriminatory Keywords and Word Patterns

Type of Discrimination	**Sample Quotes from sources**	**Keywords and Word Patterns indicating Discrimination**	**Keywords and Word Patterns indicating Non-Discrimination**
Personal Protective Equipment (PPE)	*Personal Protective Equipment should normally be provided free of charge by the employer, who ensures its proper functioning and hygienic conditions through maintenance, repairs, and necessary replacements (EPC, 1989).*	*Possession of Personal Protective Equipment (PPE), safety helmet, safety glasses, safety shoes*	*Use of Personal Protective Equipment (PPE)*
Gender	*Any direct or indirect discrimination based on gender is prohibited in both the public and private sectors, (...) concerning:* *a) the conditions for access to employment and work, both dependent and self-employed, including selection criteria and hiring conditions... (EPC, 2006)*	The JobAd is addressed exclusively to male/female candidates.	The text includes at least one explicit reference to both genders.
Age	*(...) Member States may provide that differences in treatment based on age do not constitute discrimination where they are objectively and reasonably justified (...) by a legitimate aim…* *Such differences in treatment may include, in particular:* *a) the definition of special conditions of access to employment (...) for young people, older workers...;* *b) the establishment of minimum age, professional experience, or seniority conditions for access to employment or certain advantages related to employment;* *c) the establishment of a maximum age for recruitment based on the training requirements for the job in question or the need for a reasonable period of employment before retirement (EC, 2000).*	*Minimum/Maximum age requirement, young candidate*	*Apprenticeship contract, internship contract, stage contract, years of experience, Junior/Senior role, night shifts*
Ethnicity and Origin	Direct Discrimination: *(…) occurs when a person is treated less favourably than another in a similar situation due to their race or ethnic origin.* Indirect Discrimination: *(…) occurs when an apparently neutral provision, criterion, or practice puts people of a particular race or ethnic origin at a particular disadvantage compared to others (CD/2000/43/EC).*	*- Origin* *- Nationality* *- Citizenship* *- Ethnicity* *- Domicile* *- Residence*	*- Residence permit*

The approach was structured this way because well-crafted prompts allow to translate complex requests into a form that the AI can process effectively and lead to more precise responses, reducing the probability of misunderstandings or irrelevant outputs.

After the DKD was produced, keywords and word patterns were developed into questions to query the AI and identify non-inclusive job postings.

As ChatGPT and current Large Language Models are trained on large-scale data collections from multiple languages, they automatically identify the input language without requiring a preliminary translation into English. Although the performance is generally better in English high-resource training languages still benefit from relatively good performance by ChatGPT. Given the flexibility in identifying languages, the proposed method can potentially deliver accurate results in other high-resource languages. Among these are Neo-Latin languages but also Russian, Chinese, Japanese, and Vietnamese (Lai et al., 2023). Considering these accurate results and that the available JobAds used to train the algorithm are written in Italian, it was decided to formulate the prompt in the same language, as this aligns with the objective of capturing more nuances of D&I principles, particularly concerning the "Gender" category.

Once chosen this approach, prompt engineering became essential to refining the AI's interpretative accuracy. As an emerging field, it requires an experimental mindset (Open AI). For this reason, an iterative process was followed to test various prompts, paying close attention to how small modifications could significantly alter the AI's responses. Further attention was given to the positive or negative framing of the question. Negative instructions often require the AI to interpret and reverse them, increasing cognitive load and the potential for misunderstanding. To avoid these issues, all questions contain positive instructions.

3.3 Output

The result is a binary output (True/False) that does not necessarily correspond to legally Compliant/Non-Compliant but may vary by category depending on the formulation and the positive framing of the question (Table 2). For example, in the "Ethnicity and Origin" category, the question asks to verify whether the JobAd text references the candidate's ethnicity, meaning that a True response indicates that the job posting is Non-Compliant. For the "Gender" category instead, the question asks whether the job posting is addressed to both men and women, meaning that a True response indicates that the job posting is Compliant. The type of error is used to determine the severity of the error in relation to the compliance of the response. A False Positive (FP) error indicates that the software's response is True instead of False, whereas a False Negative (FN) error indicates that the software's response is False instead of True (Hansen, von Krauss and Tickner, 2007). This error classification will be further explored in the Results section to assess the software's performance.

Table 2 – Output classification

Category	Compliant	Non-Compliant	Worst Type Error
Personal Protective Equipment	False	True	FN
Gender	True	False	FP
Age	False	True	FN
Ethnicity and Origin	False	True	FN

To support the learning process, the tool was provided with a set of 9 examples selected from real JobAds, chosen to cover all scenarios and categories, along with their expected outputs. The aim is to mitigate AI biases related to training datasets by providing examples on how to assess the compliance of a job posting. For each job posting in the dataset under analysis, a request is submitted to the ChatGPT, including the text of the advertisement, the question for each category, and the corresponding examples.

4 Results

Before analysing the results, it is appropriate to introduce the error classification used to evaluate the tool's performance. At first, the evaluation of the output focused solely on the accuracy of the tool, measured by the number of errors, without reference to the compliance of the advertisement. Then the focus shifted to the hypersensitivity of the tool, classifying the severity of the errors. As mentioned in the previous paragraph, the type of error is used to determine the severity of the error in relation to the compliance of the response (Al-Ashwal et al., 2023). Specifically, an FP error indicates that the software's response is True instead of False, whereas an FN error indicates that the software's response is False instead of True. In general, it is preferable to mistakenly detect a Compliant advertisement rather than fail to detect a Non-Compliant one. For example, an FN error for the category of "PPE" occurs when a JobAd requires the candidate to possess such equipment (so the correct response should be True, indicating Non-Compliance) and the JobAd should not. In this case, the tool fails to detect the error and incorrectly responds False, allowing the JobAd to pass without being detected.

To the best of our knowledge, there is currently no analysis of this kind in the literature regarding the evaluation of tools that apply Generative AI in the HR field.

To highlight the relevance of the proposed error classification, we report an incident that occurred in a corporate operating in the HR sector. A JobAd requiring candidates to possess their own safety shoes was not detected by the company's compliance monitoring systems and was consequently published on the firm's official channels. Such an error could damage the company's reputation, particularly because it reveals a critical issue in a process that should be aligned with international ethical certification standards.

The software was validated through controlled testing on datasets containing 40 JobAds, randomly extracted from job postings recently published by an international company operating in the HR sector, for which the expected outputs were predefined based on the guidelines. Currently, the best results achieved through prompt engineering, as described above, are summarized in Table 3. The highlighted cells indicate the most severe type of error, which is a Non-Compliant advertisement that was not detected.

Table 3 – Best output obtained on a test set of 40 job advertisements

Category	**Number of errors**	**% of error**	**Type error: False positive**	**Type error: False Negative**
Personal Protective Equipment	0	0,00%	0	0
Gender	0	0,00%	0	0
Age	1	2,50%	0	1
Ethnicity and Origin	2	5,00%	0	2

As described in Table 3, the software achieves excellent results for the "PPE" and "Gender" categories, with an error rate of 0%. This indicates a precise detection capability for these regulatory aspects. The "Age" category shows minimal errors (2.50%). This suggests that the system is generally reliable in detecting this kind of discrimination, although it may occasionally fail to identify a violation. The "Ethnicity and Origin" category (5% errors) also shows a contained error rate. The errors are FN, indicating that the software missed detecting non-compliant JobAds. This suggests that while the system performs reasonably well, there is room for improving the actual prompt to identify violations in these areas.

5 Conclusions

The findings of this study contribute to the growing body of research on the role of AI in mitigating biases in recruitment, particularly within JobAds screening. JobAds serve as the first evidence of an organization's fairness in hiring practices, highlighting the necessity of intervention from the writing stage to prevent discriminatory barriers.

The development of guidelines based on European D&I principles provides a standalone tool, offering a framework for recruiters when writing job postings. The implementation of the Generative AI-based software, trained to detect discriminatory JobAds following the principles outlined in the guidelines, allows to automatically detect any discriminatory content in the JobAds, so that recruiters can correct the error before publishing the job posting.

The test results indicate that the tool is generally reliable in detecting Non-Compliant JobAds concerning the four categories examined for software validation. However, some categories show a margin of error, highlighting the need for further reworks. Future improvements will focus on enhancing accuracy and expanding the tool's capabilities to ensure more complete and precise detection of discriminatory content. In addition to ensuring a fair selection process for candidates, the adoption of this tool also provides significant benefits for companies. Before the introduction of automated processes, JobAds screening was conducted manually, resulting in an expensive, human and time-consuming activity while also being influenced by cognitive biases inherent to human judgment. Implementing AI enables the automation of this process, making it sustainable in the long period, faster, scalable, and independent from human influence, thereby ensuring inclusivity and employment equity for both candidates and recruiters. The software can be implemented after the JobAd writing phase to assess the presence of any Non-Compliance, thereby directing the recruiter toward the job postings that require a further review before publication. Additionally, it remains possible to review JobAds that have already been published on official channels to identify any issues that may have been overlooked during the previous review process.

Beyond operational efficiency, adopting this tool also enhances the company's brand reputation. Ensuring that JobAds aligns with D&I principles demonstrates a commitment to fair and equitable hiring practices,

strengthening the organization's image as an inclusive and socially responsible employer (Saks, Leck and Saunders, 1995). This can increase its attractiveness to a wider pool of candidates, clients, and stakeholders.

Before considering a large-scale implementation of the tool, it is correct to highlight the challenges that need to be addressed. One of the main limitations is the relatively small dataset of JobAds on which the validation was conducted, which may not fully capture the complexity and variability of real-world postings. Future developments include the expansion of the job postings dataset, carried out gradually and under controlled conditions.

Additionally, now that the tool has been validated, there is significant room for expanding the scope of analysis by incorporating categories that, while not strictly requested by legal standards, are crucial to embracing the D&I perspective. For example, other categories of interest could be "Remuneration" or "Mobility and Driving Licences". The development will proceed according to the same methodology applied in this article, beginning with research on European legislation to enrich the guidelines, followed by the incorporation of the new categories into the software.

The future large-scale implementation of this tool may raise concerns about the potential replacement of human decisions in the recruitment process. However, its purpose is not to substitute human judgment but rather to support it. As suggested by Frost and Alidina (2019), such technologies are "a supplement to help hiring managers mitigate their biases, and are not a cure-all".

6 Ethics declaration

Ethical clearance was not required for this research, as it did not involve human participants, personal data, or procedures requiring ethical review.

7 AI declaration

AI tools, specifically ChatGPT (OpenAI), were used to support language refinement and rephrasing during the drafting process. All content, analysis, and conclusions remain the responsibility of the authors.

The Role of University-Industry-Government Cooperation in Estonia for Sustainable Innovation

Daria Podmetina, Merle Küttim, Wolfgang Gerstlberger
Tallinn University of Technology, Tallinn, Estonia

Abstract

This study explores how university-industry-government (U-I-G) cooperation fosters sustainable innovation in the context of Estonia's post-industrial Ida-Viru region—a historically oil shale–dependent area undergoing a complex sustainability transition. Drawing on the multi-actor collaboration frameworks, which integrates both innovation and sustainability perspectives, this we study how collaborative efforts across institutional boundaries can enhance socio-technical change in peripheral European regions. Using a qualitative methodology 46 stakeholders from educational institutions, companies, municipalities, and umbrella organisations were interviewed to understand the dynamics of regional innovation system. The findings highlight the dual role universities and other educational institutions play—as knowledge producers and civic institutions—bridging technological advancement with societal values. The study reveals how knowledge spillovers, academic-industry exchanges, and boundary-spanning organizations enable sustainable innovation practices, even despite of significant structural challenges such as brain drain, low trust, weak entrepreneurship, and demographic decline. The analysis identifies enabling mechanisms, such as state support via the Just Transition measure, localized collaboration platforms like clusters, industrial parks, joint events and increased trust among actors—as pivotal to overcoming barriers. Companies in the region are adopting sustainable practices, ranging from incremental efficiency improvements to radical innovations such as resource valorization and bio-based production models. The findings also underscore the tensions between short-term economic goals and long-term sustainability. The research advances theoretical understanding of the multi-actor collaboration frameworks, including Triple Helix Twins model and its practical relevance in navigating the complex interdependencies between technological and social innovation. It concludes that reconfiguring regional innovation systems around sustainability goals requires not only institutional collaboration, but also the cultivation of shared values and systemic reflexivity.

Keywords: Sustainable innovation, sustainability, innovation, triple helix twin, university-industry-government cooperation

Paper type: Academic Research Paper

1 Introduction

The increasing global emphasis on sustainability and circular economy principles positions sustainable innovation as a cornerstone of not only business agenda, but also academic, community and policy makers. University-industry-government interaction is seen both as enhancing power and challenge in context of dynamic of sustainable innovation and dissemination and sustainable practices. Sustainable innovation balancing economic growth with environmental and social responsibility, faces complex, systemic challenges that require coordinated efforts among multiple stakeholders. Positioning the research within collaboration frameworks are essential for guiding these efforts because they provide structured models to understand, facilitate, and enhance interactions between key actors by exploring how sustainability and innovation reinforce or conflict with one another.

The research gap addresses challenges of sustainability transitions in post-industrial regions and defines sustainable innovation as inherently complex phenomenon, often requiring fundamental shifts in business models, stakeholder relationships, and regulatory frameworks. This calls for a systemic approach that integrates diverse actors—the kind of collaboration envisioned in collaboration frameworks.

The main research aims to explore how university-industry-government/public cooperation fosters sustainable innovation in Ida-Viru, Estonia. The research questions are as follows: (i) How are sustainable innovation challenges perceived by the actors in the region? (ii) How sustainable innovation actors view their interactions? (iii) How are sustainable innovation challenges enablers and outcomes perceived by the actors in the region?

Estonia is an interesting research context due to its emerging economy that is small and open, where local companies are often deeply involved in exporting and participating in global value chains. The Ida-Viru region in northeastern Estonia is a unique mono-industrial region in the Estonian context that has been historically reliant on oil-shale mining and energy production. However, the ongoing energy transition and exiting from the use of oil-shale poses significant challenges to its economic stability and resilience of companies.

This exploratory research is built on empirical findings from 46 interviews with educational institutions, businesses, municipalities, and umbrella organisations. The findings revealed the dual role of educational institutions as knowledge producers and civic institutions, bridging technological advancement with societal values. The study reports how knowledge spillovers, academic-industry collaboration, and boundary-spanning organizations enable sustainable innovation, even despite of significant challenges such as brain drain, low trust, weak entrepreneurship, and demographic decline.

The rest of the paper is structured into four main sections. It begins with a literature review that covers sustainable innovation, university-industry-government (U-I-G) collaboration theories, and related challenges. The methodology section explains the qualitative design and data collection, which leads into detailed findings grouped into thematic areas—challenges, actors, relations, enablers, and outcomes—culminating in a discussion and conclusions that connect empirical insights to theoretical frameworks and policy implications.

2 Literature review

2.1 Sustainable innovation and circular economy

Sustainable innovation integrates economic growth with environmental and social goals. It emerges as a response to the limitations of traditional innovation models that prioritize profit over long-term ecological and societal wellbeing (Boons & Lüdeke-Freund, 2013; Voegtlin & Scherer, 2017). Rather than treating sustainability as an external concern, sustainable innovation embeds it within the logic of value creation and technological development. The circular economy (CE) complements this perspective by emphasizing resource efficiency, closed-loop systems, and value retention across the product life cycle (Geissdoerfer et al., 2017). CE demands systemic change and multi-stakeholder collaboration, as firms alone cannot overcome institutional inertia or create enabling ecosystems (Bocken et al., 2014). Despite the growing traction of these approaches, many organizations struggle with operationalizing sustainability due to capability gaps, short-term pressures, and resistance to change. Universities, industries, and governments must jointly address these barriers by contributing complementary assets: scientific knowledge, implementation capacity, and strategic support. These University-Industry-Government (U-I-G) collaborations enhance innovation ecosystems by combining long-term vision with practical applications (Miedzinski et al., 2019; Kuhlmann & Rip, 2018). Joint efforts are especially visible in renewable energy, waste valorization, and green mobility (Baldassarre et al., 2020). U-I-G partnerships support both technological and social innovation—the latter involving new behaviors, collaborative models, and governance structures necessary for sustainable development (Markard et al., 2012; Hargreaves et al., 2013). As sustainability transitions involve uncertainty and institutional disruption, cooperation among diverse actors becomes critical for mutual learning and systems-level change (Carayannis & Campbell, 2021; Bozeman & Boardman, 2014).

2.2. Theoretical frameworks for U-I-G collaboration

U-I-G collaboration refers to the systematic interaction and partnership between universities, industries, and governments to pursue joint objectives in research, innovation, and societal development (Etzkowitz & Leydesdorff, 2000; Perkmann & Walsh, 2007). The multi-stakeholder collaboration for innovation is addressed by several theoretical frameworks. The Triple Helix model (Etzkowitz & Leydesdorff, 2000) remains one of the most influential frameworks for understanding university-industry-government collaborationThe Triple Helix emphasizes that innovation occurs not only within organizations, but across institutional interfaces—including joint ventures, science parks, and incubators. To address emerging sustainability imperatives, Etzkowitz and Zhou (2006; 2021) extended this model into the Triple Helix Twins framework. This version introduces a second helix—focused on sustainability and societal engagement—alongside the original innovation-oriented helix. The innovation helix retains its market logic, while the sustainability helix foregrounds public values, environmental concerns, and community needs. This dual-helix configuration allows for vertical interactions within each helix (e.g., university-firm R&D, government policy funding) and lateral linkages between them (e.g., sustainability spillovers from public co-creation into commercial innovation). In doing so, it enables the alignment of economic competitiveness with broader social and ecological missions—a core challenge in regions undergoing sustainability transitions. The Triple Helix Twins is especially relevant for peripheral and transitioning regions, where public engagement, place-based policy, and institutional experimentation are vital. By emphasizing the role of civic actors and societal legitimacy, the framework provides a more inclusive and reflexive model of innovation.

The innovation systems perspective offers additional insight into how collaboration unfolds in different contexts. The National Innovation System (NIS) focuses on institutional arrangements and policy at the country level, while the Regional Innovation System (RIS) emphasizes localized interactions and proximity advantages (Lundvall, 1992; Nelson, 1993; Cooke, 2001; Asheim & Gertler, 2006). In the context of sustainable innovation, RIS frameworks are particularly useful because they recognize place-specific challenges—such as demographic change, industrial lock-ins, or infrastructure disparities—and support bottom-up adaptation. RIS highlights the importance of institutional diversity, localized trust, and policy coherence in shaping innovation outcomes (Borras & Edquist, 2013). For peripheral regions, such as Ida-Viru, RIS thinking reinforces the value of local intermediaries—including development agencies, municipal actors, and university branches—in bridging structural gaps and translating national agendas into regional capabilities.

A growing body of literature points to the importance of intermediary actors—such as innovation brokers, consultants, and NGOs—in facilitating collaboration and innovation for sustainability (Howells, 2006; Klerkx & Leeuwis, 2009). These actors help align goals, manage conflicts, and foster experimentation in environments where institutional barriers exist. In sustainability contexts, intermediaries are essential for enabling transformative change, especially through living labs, pilot projects, or cross-sector alliances (Kivimaa et al., 2019; Stewart & Hyysalo, 2008). They play a key role in organizing knowledge flows, fostering mutual understanding, and embedding societal values in innovation pathways (Edler & Yeow, 2016).

2.3. Mechanisms and challenges of U-I-G cooperation for sustainability

Collaborative R&D initiatives are a central enabling mechanism through which U-I-G actors co-create knowledge for sustainable innovation. These programs often receive state funding and involve shared intellectual property, governance, and infrastructure (Bozeman & Boardman, 2014; Belderbos et al., 2004). Innovation hubs and science parks facilitate informal and formal linkages between universities and firms, acting as physical and organizational spaces for collaboration (Etzkowitz & Zhou, 2006; Clarysse et al., 2014). Public-private partnerships (PPPs), particularly in areas like clean energy and smart cities, serve as vehicles for pooling resources, sharing risks, and fostering scalable sustainable innovations (Kivimaa & Kern, 2016). These enablers are most effective when trust, mutual understanding, and clear governance frameworks are in place (Bruneel et al., 2010). Universities often institutionalize collaboration through Knowledge Transfer Offices (KTOs), which manage intellectual property, liaise with firms, and promote commercialization (Siegel et al., 2007). KTOs play a critical role in bridging academic knowledge with market applications, especially in the sustainability domain. Despite growing support for collaboration, several challenges are identified: mismatch of goals and timeframes; trust and communication gaps, especially between public agencies and firms in low-trust environments (Bruneel et al., 2010); capability asymmetries when smaller firms may lack resources to participate fully in collaboration; regulatory fragmentation in overlapping mandates and unclear policy signals can stall action. These issues highlight the need for adaptive governance models that align incentives, simplify coordination, and facilitate mutual learning (Ansell & Gash, 2008; Diercks et al., 2019).

3 Research design and methodology

The qualitative study employs an exploratory data-driven approach to examine how university-industry-government/public cooperation fosters sustainable innovation in the Ida-Viru region of Estonia. Framed within the Triple Helix Twins model, which highlights the dynamic interactions between academia, industry, government, public, the research explores the mechanisms enabling sustainability-oriented collaboration. Semi-structured interviews serve as the primary data collection method, allowing for in-depth engagement with stakeholders to understand how cooperative structures influence innovation and sustainability in the region (Galletta, 2013).

The Ida-Viru region in northeastern Estonia serves as an interesting case study area due to the level of complexity it faces. Historically reliant on oil-shale mining and energy production, the region is currently undergoing an energy transition away from fossil fuels, which poses economic stability concerns. This transition is influenced by Ida-Viru's rich industrial heritage, which has shaped its identity but also left it vulnerable to economic shifts. The region is predominantly Russian-speaking, which influences labour mobility, social integration, and educational attainment, creating additional layers of complexity in addressing unemployment. High unemployment rates are a persistent issue, exacerbated by a brain drain as younger, skilled individuals migrate to other parts of Estonia or abroad in search of better opportunities. These further strains the region's ability to diversify its economy and adapt to new sustainable practices.

The study includes 46 interviews conducted with representatives from industry, educational institutions, municipalities, and umbrella organizations (referenced in the results section as int_ind, int_edu, int_munic,

int_umb_org). Purposive sampling ensured that participants represent diverse institutional roles within the sustainability transition, including knowledge production, policy influence, and business execution as well as boundary spanning organisations. Selection criteria focused on engagement in sustainability initiatives, sectoral diversity, and institutional capacity to drive collaboration (Patton, 2014). Interviews took place between 2024 and 2025, conducted both face-to-face and online, with durations ranging from one to two hours. The interview design explored the Triple Helix collaboration in the context of sustainable innovation. Discussions with university representatives examined knowledge transfer mechanisms, research commercialization, and academic-industry cooperation models. Conversations with companies focused on innovation strategies, resource dependencies, partnership dynamics, and barriers to adopting sustainability practices. Policymaker and intermediary organization interviews addressed regulatory frameworks, policy incentives, regional governance, and the role of public-sector facilitation in sustainable innovation. Across all stakeholder groups, the interviews explored the entrepreneurial environment of Ida-Viru, key actors and their interactions, and the enabling or limiting factors shaping collaborative innovation efforts.

All interviews were recorded and transcribed for accuracy. Thematic analysis (Braun & Clarke, 2006) was employed to systematically identify emerging patterns and structural dynamics within university-industry-government-public interactions. The data was analysed by attributing 1-st level codes and then merging these into 2nd level themes: challenges, actors, relations, enables and outcomes for sustainable innovation.

4 Results

4.1 Challenges faced by actors in the region

The Ida-Viru region in northeastern Estonia is undergoing a complex and multi-layered transformation as it attempts to shift toward sustainable innovation. The transition away from oil shale—a historically dominant industry—coincides with several overlapping disruptions, including reform of education language, border region with limited across-border economic activities, broken value chains, and growing energy prices. The region's diversity, with a predominantly Russian-speaking population, creates collaboration barriers, while its dual image—strong in industry but weak in entrepreneurship—complicates development and re-training: "*Ida-Virumaa is an industrial region, specifically known for heavy industry with its factories and enterprises. People living in this area are used to working in factories—it's in their DNA, and it gives them a sense of security through stable employment. Those who work in spas or the tourism sector and are engaged in service jobs generally never transition to factory work. This means that people cannot be easily relocated or reassigned between sectors.*" (Int_ind_10). A lack of modern housing, limited cooperation, absence of a central coordinating actor, and a fragmented population further hinder the region's cohesion and progress.

Companies in the region struggle with financial and mindset-related barriers. Several still hope for the return of the oil-shale industry and focus on subcontracting, limiting long-term planning. Loan access is difficult due to low property values and a lack of guarantees, and interest in sustainability varies. Meanwhile, distrust in the state, sudden unexpected changes and a perceived lack of central government understanding of local realities remain obstacles: "*We recently spoke with investors, and they said they don't see a future here. They simply don't understand what is happening in the region. One factory is being closed, another is being restricted, and at any moment their operations could be halted due to some regulatory act or environmental requirement*." (Int_umb_org_1) Local governments lose potential revenue because income tax is allocated by place of residence, not work, and are also affected by the gradual loss of environmental tax income from oil-shale activity. Additionally, mismatches between educational institutions and businesses'—particularly in expectations for training and research—limit cooperation: "*Cooperation is taking place, but it does not meet the needs of the region's companies, as educational institutions are limited by the national curriculum framework as well as by a shortage of teaching staff with experience in the relevant field. The problem extends beyond Ida-Viru County and is relevant for all of Estonia*." (Int_ind_15) Additionally, companies want mostly immediate, practical solutions, while universities are more focused on long-term or academic goals, and only R&D-intensive firms are able to engage in research collaboration.

4.2 Relations between the actors in the region

In the Ida-Viru region of Estonia, a complex web of relations has emerged between various actors as they navigate multiple simultaneous transitions, such as the energy shift away from oil shale and broader socio-political and economic transformations. These relations manifest in several forms—regional, national, and international. Locally, collaboration occurs between large and small companies, often facilitated by

intermediaries like regional development agencies and industry associations. Educational institutions, such as vocational schools and university colleges, play a role in building ties with companies through internships, program co-development, and training initiatives: "*We have everything in place—there are cooperation projects and agreements with companies for carrying out internships. Entrepreneurs and representatives of professional associations are involved in the development of our curricula. We also offer workplace-based learning, meaning that we go directly to companies to provide on-site training*." (Int_edu_2)

At a broader level, the state and its regional offices are involved in fostering collaboration through policy support, funding schemes, and innovation platforms, though issues like over-regulation and at times insufficient local government engagement obstruct these efforts. Public authorities are viewed as shaping the enabling environment for other actors: "*The city must support the development of entrepreneurship. For example, we are planning to build a new production facility, but this requires additional land. We hope that negotiations with the local municipality will be constructive*." (Int_ind_5) Meanwhile, intermediaries help bridge gaps between diverse actors by organizing events, joint projects, and clustering initiatives: "*Organizing various events—such as seminars, information days, and hackathons—provides important opportunities for different stakeholders to meet, negotiate, and form cooperation agreements. Recently, a major hackathon in the creative industries sector brought together participants who developed ideas into products, services, or concepts, which were then presented to a jury.*" (Int_umb_org_6) Joint events such as site visits, fairs, seminars, conferences and hackathons create opportunities for knowledge exchange and partnership in diverse areas.

4.3 Collaboration and sustainable innovation enablers

The development of sustainable innovation in Ida-Viru is supported by a diverse set of enablers that foster collaboration and facilitate regional transformation. A key enabling factor is the regulatory framework, which provides both monetary and non-monetary support for cooperation. Specific instruments like Just Transition measure, entrepreneurship programs, training schemes, and the renewal of education and research services play a role in supporting collaborative efforts, although the efficiency and aim of these measures is viewed differently by various actors as is the future of the region: "*It was suggested (when discussing support measures) that, since this is a region historically dominated by heavy industry, the goal should be to transform it into a new major industry (replacing oil-shale industry). Supporting small businesses was considered unnecessary, as they are unlikely to generate significant new value or jobs. However, the Just Transition measure is based on different principles—its aim is to build a diversified, sustainable, and competitive economy in which no single large industry dominates*." (Int_umb_org_8).

In addition to institutional support, several relational and organizational enablers contribute to collaboration. Trust-building among actors has improved, especially through the growing role of umbrella organizations and cooperation platforms. Despite existing tensions—such as identity issues, language divisions, and scepticism toward newcomers—new cooperation platforms signal a growing willingness to engage in collaborative innovation: "*New types of platforms have emerged, such as hackathons, where young people come together, brainstorm, solve problems, and receive guidance from mentors. Recently, the KOOD/Jõhvi programming school held an event in Sillamäe. These events attract more young people and bring new energy to the region.*" (Int_munic_6) Multilingual capabilities—particularly in Estonian, Russian, and English—also enhance communication and collaboration across different actor groups.

4.4 Collaboration and sustainable innovation outcomes

The outcomes of sustainable innovation at the company level in the Ida-Viru region reflect both incremental and radical changes that are reshaping local industries. On the incremental side, many companies are improving their products and processes by adopting new technologies, digital tools, and sustainability standards. Common efforts include enhancing energy efficiency, implementing waste management systems, measuring environmental footprints, and providing employee training: "*We focus on valorizing production residues to turn waste from the manufacturing process into useful resources. We plan to start producing steam and electricity on our factory premises. In the longer term, we are also considering the use of biofuels, such as wood chips and pellets*." (Int_ind_16) These changes contribute to improvements in productivity and environmental performance to cope with changes in the external environment.

Radical innovations are also emerging, though less frequently, and they typically involve entering entirely new fields or transforming existing business models. This shift is particularly relevant in the context of the energy transition, where companies are seeking alternatives to oil shale and exploring more sustainable sectors or areas of activity: "*There are plans to begin producing calcium carbonate from oil shale ash. We already have patented technology in place to launch the production, and the next step is acquiring the necessary equipment."*

(Int_ind_17) The overall push for innovation has encouraged diversification and increased openness to collaboration, creating opportunities for knowledge spillovers and learning. While challenges remain, such as limited trust and uneven readiness among actors, the outcomes show that sustainable innovation is becoming an essential for regional resilience.

5 Discussion and Conclusions

Knowledge spillovers and academic-industry exchange play a crucial role in fostering sustainability-oriented innovation (Bozeman & Boardman, 2014; Perkmann et al., 2013). In the Ida-Viru region, universities, industries, and government entities collaborate to create a fertile environment for innovation. Universities act as knowledge producers, generating scientific and technical knowledge that can be transferred to industries through various channels such as joint research projects, internships, and collaborative platforms (Etzkowitz & Leydesdorff, 2000; Siegel et al., 2007). This exchange of knowledge helps industries adopt new technologies and sustainable practices, thereby driving innovation that aligns with environmental and social goals (Carayannis et al., 2021). The interaction between academic institutions and industries facilitates the diffusion of tacit and codified knowledge, enhancing the region's absorptive capacity and fostering a culture of continuous learning and adaptation (Muscio & Pozzali, 2013).

The interplay between social and technological innovation is essential for achieving sustainable development (Markard et al., 2012). Technological advances, such as digital platforms for recycling or bio-based materials, are necessary but not sufficient on their own. Social innovation, including new forms of collaboration, community engagement, and behavioural change, must accompany these technological efforts (Voegtlin & Scherer, 2017; Hargreaves et al., 2013). The Triple Helix Twins framework emphasizes the importance of integrating both social and technological dimensions to address complex sustainability challenges (Etzkowitz & Zhou, 2006; Zhou & Etzkowitz, 2021). This dual approach ensures that technological innovations are not only market-driven but also aligned with societal values and environmental priorities. In the Ida-Viru region, this interplay is evident in initiatives that promote public engagement and the co-creation of solutions that address both economic and sustainability objectives (Miedzinski et al., 2019).

Effective governance mechanisms are critical for balancing top-down policy directives with bottom-up entrepreneurial initiatives (Ansell & Gash, 2008). In the Ida-Viru region, local and state governments, along with regional offices of state institutions, play a pivotal role in shaping the policy environment that supports sustainable innovation (Edler & Fagerberg, 2017; Kivimaa & Kern, 2016). Top-down directives, such as regulatory frameworks and funding programs, provide the necessary resources and incentives for businesses to adopt sustainable practices. However, these directives must be complemented by bottom-up initiatives that leverage local knowledge and entrepreneurial spirit (Stewart & Hyysalo, 2008). The Triple Helix model facilitates this balance by encouraging collaboration between government entities, academic institutions, and industries (Etzkowitz & Leydesdorff, 2000). This collaborative approach ensures that policy measures are responsive to local needs and that entrepreneurial initiatives are supported by a conducive policy environment. Joint marketing activities, policy development involving companies, and cooperation platforms are examples of how governance mechanisms can effectively integrate top-down and bottom-up approaches to drive sustainable innovation (Bruneel et al., 2010).

Practical Implications

First, differentiated policy support is needed to reflect the varying sustainability orientations and capabilities of regional firms. While some companies pursue short-term efficiency improvements, others are actively diversifying through radical innovations. Policy instruments should thus be tiered—offering basic awareness and financial support for early-stage adopters, while providing more integrated co-creation spaces for advanced actors. Second, the role of universities and other educational institutions must evolve beyond that of knowledge producers to civic and institutional anchors capable of brokering sustainability visions. This includes embedding sustainability in curricula, encouraging community engagement, and co-developing context-relevant research agendas with local actors.Third, governance should emphasize integration. The policy ecosystem must align top-down measures (e.g., Green Deal, Just Transition Fund) with bottom-up entrepreneurial and social initiatives. This can be achieved through multi-level platforms that include not only U-I-G actors but also civil society—hinting at the potential utility of Quadruple and Quintuple Helix extensions in further research.

Theoretical Contributions

This research extends the Triple Helix Twins framework by providing empirical validation in a peripheral, post-industrial EU context. It highlights how interplay between innovation and sustainability logics can be both synergistic and conflictual, and how effective collaboration requires governance mechanisms capable of mediating this tension. It also adds to RIS theory by illustrating how peripheral regions can activate latent

innovation capacity through trust-based relationships, intermediary engagement, and place-sensitive policy design. By focusing on a transition region with socio-political complexities, the study enriches our understanding of how sustainability transitions can unfold unevenly and how governance structures can shape trajectories of inclusive regional innovation.

In conclusion, the Ida-Viru case demonstrates that sustainable innovation in peripheral regions requires more than institutional presence—it demands integrated collaboration frameworks, adaptive governance, and shared sustainability visions. The Triple Helix Twins framework is particularly useful in unpacking these dynamics, as it accounts for both the economic and societal dimensions of innovation. The future of sustainable regional development lies in fostering not only technological change but also relational infrastructures that align diverse actors toward common goals.

The Activation of Inclusive Behaviors Through Self-Awareness of Cognitive Biases: The Contribution of New Web3 Technologies

Laura Iacovone
Department of Economics, Management, and Quantitative Methods – University of Milan – Milan - Italy

Abstract
This paper seeks to advance understanding of the persistent gap between the growing societal and organizational attention to Diversity, Equity, and Inclusion (DE&I) and the limited reduction of non-inclusive behaviors and practices in real-world contexts. While inclusivity is inherently linked to the cultural and value systems of organizations, it is equally evident that socially undesirable or inappropriate behaviors fall within the realm of individual decision-making. These behaviors are frequently influenced by cognitive biases and prejudices, which tend to perpetuate or normalize inappropriate conduct rather than stigmatizing or sanctioning it. Despite increasing sensitivity to DE&I issues in both societal and organizational domains, training remains the most widely adopted intervention. However, such initiatives often yield only limited short-term awareness and rarely generate enduring structural change.
Accordingly, this paper first explores the intersection between DE&I and various forms of knowledge management, with particular attention to interdisciplinary frameworks that integrate diverse epistemological perspectives. Within this framework, the paper highlights the growing relevance of technology not only in terms of content accessibility and knowledge dissemination related to DE&I, but also as a transformative tool in shaping learning processes. Specifically, the focus is on emerging Web3 technologies—most notably immersive solutions such as virtual reality (VR) and Artificial Intelligence (AI)—which hold disruptive potential for reshaping traditional training paradigms. These technologies offer new opportunities for insight into individual decision-making mechanisms and behavioral patterns.
The development of advanced immersive applications presents the potential to transcend the limitations of passive cognitive learning by fostering active engagement in dynamic, simulated environments. This facilitates the unconscious acquisition of new skills and behavioral responses. The paper analyzes various implementation strategies and their outcomes, with particular emphasis on integrative approaches that combine VR, neuroscience, and artificial intelligence (AI). These multidimensional solutions appear especially effective in enhancing individual self-awareness and facilitating unconscious behavioral recalibration.
The study concludes by proposing an initial conceptual framework that categorizes the range of emerging approaches according to their respective objectives and impacts. It further identifies key strengths and limitations, offering guidance for the more effective design and deployment of DE&I training interventions.

Keywords: Diversity, Equity & Inclusion (DE&I*)*; Inclusive Behaviors; Cognitive Biases; Immersive learning; Virtual ad Mixed Reality+AI (VR&AI).

Paper type: Academic Research Paper

1 Introduction

This paper aims to contribute to the development of inclusive strategies and policies that promote socially desirable behaviors, both within society and corporate organizations, in order to counter inequalities and all forms of discrimination. Despite DE&I topics being fundamental principles for building fair and sustainable societies, and the considerable efforts objectively made by organizations and companies, the desired results are still not achieved. This shifting cultural landscape has spurred growing interest among companies to align with these evolving values, although not without challenges (Argyris & Schön, 1996; van den Brink & Benschop, 2012). Today, addressing DE&I requires more than effective marketing and communication strategies—it demands credibility, concrete initiatives, and verifiable outcomes (Kunda, 2006; Meister 2021a). Several consulting firms have even developed methodologies and synthetic KPIs for evaluating the D&I orientation of client companies (i.e. Noema HR, Etica SGR, or the DE&I Maturity Index by Deloitte).

Despite the progress, it is still not possible to assert that society or corporate environments are fully inclusive—i.e., capable of ensuring equitable treatment for every individual (Sue et al., 2007). This is because the issue of D&I does not lie in the intrinsic diversity of individuals—as every person possesses unique physical and psychological characteristics—but rather in the unequal treatment that some individuals receive based on incorrect assumptions. These assumptions stem from cognitive biases and deeply entrenched structural inequalities—such as those related to gender, economic status, and access to opportunities—which often persist due to a lack of knowledge, interest, or even active resistance within organizations (Saba et al., 2021; Wang et al., 2023). In this sense, D&I is less a structural or organizational matter and more a question of habitual,

instinctive behaviors that emerge in everyday social interactions and are shaped by underlying beliefs and biases—systematic distortions in how people process information and make decisions. These unconscious biases must be addressed and dismantled because of their profound influence on behavior across social, educational, and professional contexts, where they contribute to the reproduction of discrimination and inequality (Kahneman & Tversky, 1982; Kahneman, 2011; Ariely, 2010).

Within this framework, *Training* plays a potentially central role, as it targets individuals directly, ideally aligning them with the organization's value system. Although DE&I-focused training is widely adopted—particularly in large organizations—anonymous employee surveys often paint a contrasting picture, revealing ongoing issues such as lack of respect, attention, or outright discrimination. Consequently, DE&I programs may fall short of expected effectiveness (Dobbin & Kalev, 2016; Chang et al., 2019; Saba et al., 2021).

This raises a critical question: how can there be such limited progress toward an inclusive and equitable society, despite widespread consensus on its importance? A key reason lies in the mismatch between the rational content of most DE&I initiatives—*which primarily target the conscious mind—and the unconscious nature of many exclusionary behaviors, shaped by deep-seated cultural norms and cognitive biases*. The problem is not what is being done, but how such initiatives—particularly training—are conceived, designed, and delivered. In this context, immersive technologies (e.g., virtual reality, mixed reality, and metaverse platforms) offer a promising innovation by eliciting strong emotional engagement that can drive deeper behavioral change (Slater & Sanchez-Vives, 2016; Singha, 2023). They enable embodied experiences that foster empathy, increase bias awareness, and enhance learning retention (Bailenson, 2018; Meister, 2021b).

This paper explores how inclusive strategies, policies, and training programs can be designed for greater effectiveness. It is structured into three main sections: (1) a theoretical review of how DE&I has intersected with knowledge management literature, highlighting key contributions that have shaped new approaches to internalizing inclusive values, including the role of emerging technologies; (2) an analysis of current applications of immersive technologies in DE&I training, based on international and national case studies, corporate reports, and empirical observations, with a focus on assumptions, goals, content, technological choices, and outcomes; (3) the development of a preliminary conceptual framework outlining different approaches to immersive corporate training and their potential short-, medium-, and long-term impacts.

2 Inclusion, Knowledge Management, and Emerging Technologies: A Theoretical Perspective

The relationship between inclusivity and knowledge management (KM) has been extensively explored in academic literature, particularly in terms of how KM can contribute to building more equitable and inclusive environments. KM is inherently positioned as a key enabler of DE&I, as it centers on the creation, sharing, and application of knowledge within organizations or communities. By definition, KM should be inclusive, ensuring that the knowledge of all members—regardless of gender, ethnicity, ability, or cultural background—is valued and utilized (Nonaka & Takeuchi, 1995; Wenger, 1998). Integrative theories and models emphasize that KM practices must explicitly embed DE&I principles to be truly effective. This involves recognizing implicit biases within KM processes and addressing the specific needs of marginalized or underrepresented groups to ensure equitable access to and participation in knowledge-sharing systems (Cornelius-Hernandez & Clarke, 2024).

The connection between inclusivity and knowledge-sharing processes is particularly significant, as both reflect and shape an organization's culture. More inclusive organizations tend to manage knowledge more effectively because they foster multicultural environments in which individuals feel psychologically safe to share their ideas and expertise (Davenport & Prusak, 1998; Hislop et al., 2018). By promoting equitable access to information and participation, inclusive environments foster trust, collaboration, and cohesion, thereby enabling continuous learning and innovation at all organizational levels (Trees & Vlachos, 2022; Cheng et al., 2024). Empirical studies show that workplaces that embrace cognitive and cultural diversity are more likely to generate novel connections between ideas, driving creativity, knowledge generation, and innovation. Inclusive organizational cultures amplify knowledge sources, with positive implications for competitiveness (Ferdman, 2014). Furthermore, inclusive KM policies are associated with greater employee well-being, job satisfaction, organizational commitment, and loyalty (Meister, 2021a). Conversely, when cultural differences become obstacles to knowledge sharing between teams or individuals (Miminoshvili & Černe, 2021), the organization may suffer adverse outcomes. In this light, inclusivity becomes a strategic necessity rather than a normative ideal. This explains the growing academic and managerial interest in inclusive strategies aimed at optimizing KM systems (Creary, 2020; Durst, 2021; Dalkir, 2025).

Within such strategies, training plays a vital role, serving as the bridge between organizational values and their internalization by individuals, as part of their ongoing professional development (Wang et al., 2023).

*****

Emerging technologies play a growing role in fostering inclusivity within knowledge management (KM), functioning both as tools for accessibility and as mechanisms for promoting equitable organizational processes (Cascio & Montealegre, 2016; Bersin, 2020). Technologies such as voice recognition, machine translation, and ethical AI reduce barriers to knowledge access and mitigate algorithmic bias in recruitment (e.g., gender stereotypes or discriminatory patterns), performance evaluation, and information distribution (Pozza, 2024; Tursunbayeva, 2024; Borgese, 2025).

Two main applications stand out. First, in *DE&I-related decision-making*, inclusive technologies enable equitable knowledge flows through collaborative platforms, multilingual tools, and online communities of practice. Ethical AI helps identify discriminatory patterns in HR data and people analytics, enhancing the fairness of internal knowledge systems (Rhem, 2024). Second, in *inclusive training*, technologies offer personalized, accessible learning experiences that support diverse learners. This includes adaptive e-learning, culturally inclusive content, and immersive *VR training* (PwC, 2020).

Virtual Reality (VR) has proven highly effective in DE&I training across various educational and professional contexts (Richter & Sharabi et al., 2023; Purdue University, 2024). Its effectiveness stems from the experiential nature of learning in realistic, psychologically safe virtual environments that promote deep emotional and cognitive engagement. VR enables participants to adopt alternative identities (Peck et al., 2013; Springer & Günther, 2020), fostering perspective-taking and a deeper understanding of others' lived experiences (Mason & Chrobot-Mason, 2022; Google Research, 2024). This immersion significantly enhances empathy and increases individuals' willingness to modify discriminatory behaviors (Hasler, Spanlang, & Slater, 2017).

The emotional engagement produced by VR allows individuals to observe their own unconscious, altruistic, or self-centered behaviors, including phenomena such as the bystander effect (Darley & Latané, 1968; Batson, 2011); to explore their emotional responses (Damasio, 1999); and to increase implicit awareness of personal biases (Kolb, 1984; Kahneman, 2011; Devine, 2012). By enabling simulations of the experiences of marginalized groups, VR supports the transfer of perspective-taking and behavioral change to real-world settings, as shown by numerous empirical studies (Peck et al., 2013; Herrera et al., 2018; Banakou, Hanumanthu, & Slater, 2016). These technologies offer emotionally powerful, immersive experiences that the human brain perceives as real (Phelps et al., 2001; Immordino-Yang & Damasio, 2007), thereby integrating them more directly into individual cognitive and affective learning processes. Research in medical and psychological domains—including treatments for conditions such as dyslexia—has shown that emotionally charged micro-traumas experienced in VR can lead to more profound reprocessing of behaviors and long-lasting behavioral change (Wiederhold & Riva, 2019; Alcalde-Llergo et al., 2025). Recent experimental studies by Fernandez-Espinosa et al. (2025) further demonstrate that shared immersive experiences in multiplayer VR environments—such as those in the metaverse—can foster social inclusion and enhance team cohesion (Rossi, 2023).

When integrated with AI**,** VR's impact is amplified (Louthi-Hipche, 2024). AI enables behavioral data analysis, adaptive learning paths, and the generation of diverse, realistic training scenarios (Slater & Sanchez-Vives, 2016; Güven, 2025). However, responsible and inclusive design is crucial to avoid reinforcing existing biases, particularly with large language models (LLMs), which may introduce cultural distortions if not adequately designed (UNESCO, 2020).

While the potential is significant, recent critiques emphasize that many immersive solutions lack inclusivity in their design and may fail to ensure long-term behavioral change (Wired, 2021; Yong & Arya, 2023). Therefore, the effectiveness of such technologies depends not on their technical features but on their thoughtful, inclusive implementation.

3 The Conditions Underlying The Effectiveness of VR Applications in DE&I Training

The integration of virtual reality (VR) into DE&I training has received increasing academic attention due to its potential to enhance empathy, bias awareness, and experiential learning. However, *its actual impact on behavior and organizational culture remains under-investigated.*

This study is based on the hypothesis that the persistence of cognitive biases related to DE&I is rooted not only in knowledge gaps or organizational resistance, but in unconscious decision-making processes. Neuroscientific research highlights the need to target implicit memory to enable durable behavioral change (Immordino-Yang & Damasio, 2007; Genco, 2019).

Immersive VR environments can facilitate such change by eliciting emotional engagement and self-reflection. When combined with emerging Web3 technologies—such as artificial intelligence and neuromarketing—these experiences can reinforce self-awareness of bias through emotionally significant micro-traumas, thus supporting inclusive behaviors. The potential of these technologies lies in their ability to reconfigure individuals' processing

and integration of information within their lived experiences, both at the conscious and unconscious levels, through realism, active participation, and emotional engagement.

The aim of this study is in particular to explore the effectiveness of VR in DE&I training by: (1) assessing its capacity to increase awareness of unconscious bias; (2) evaluating the impact of scenario realism and narrative design; (3) examining the contribution of AI-enhanced personalization; and (4) identifying best practices for inclusive and scalable implementation.

Methodologically, the study adopts a mixed-methods approach, beginning with a reasoned selection and comparative analysis of major international VR-based DE&I training initiatives that have been effectively implemented over the past five years for employee development. This analysis draws on academic literature, grey literature, and media sources. The five-year timeframe is justified by the growing visibility and technological maturity of immersive solutions in organizational contexts, particularly following the COVID-19 pandemic.

In addition to international cases, the study examines two anonymized case studies from the Italian branches of multinational corporations—one operating in the consulting sector, the other in finance—both of which were subject to direct observation. These companies first decided to integrate VR into their training strategies, implementing DE&I-focused simulations enhanced with behavioral analytics. The behavioral data embedded in the VR platforms—such as interaction patterns and decision-making pathways—will also be analyzed.

The simulations primarily targeted professionals across various sectors (e.g., healthcare, education, finance, and technology). Most participating organizations also administered post-training surveys to assess changes in participants' bias awareness, empathy, and attitudes related to inclusivity. The case studies are analyzed based on their objectives, target audiences, content, experiential design, and evaluation metrics. Furthermore, in-depth interviews and focus groups with participants and facilitators are conducted to gain qualitative insights into user experience, perceived effectiveness, and areas for improvement. Observational data collected during training sessions serve to triangulate and enrich the analysis. The findings aim to inform the development of evidence-based guidelines for the effective design and implementation of immersive and inclusive training programs.

With reference to the 10 main international and national cases considered, as presented in Table 1, these can be viewed as both indicative and barometric of the diverse models for implementing DE&I projects through VR. All are immersive experiences developed around DE&I themes for the benefit of employees, yet they differ significantly—not so much in terms of the underlying technology or their shared objective of addressing unconscious bias, but rather in the type of experience offered, the degree of cognitive and emotional engagement elicited in participants, and the methods used to measure outcomes. Although all the experiences shared the same objective—namely, to raise awareness of individuals' cognitive biases—analyzing each case reveals the value of highlighting their distinctive features, particularly from a design perspective. As a result, even when the same technology is employed, markedly different approaches to the design and delivery of these training programs can be observed.

4 Immersive Technologies in DE&I Training: Insights for Design and Implementation

The development of immersive applications enables active engagement in dynamic, simulated environments that foster the implicit acquisition of new skills and behavioral patterns, moving beyond the constraints of passive cognitive learning. This paper examines implementation strategies and outcomes, with a focus on integrative approaches that combine virtual reality (VR), neuroscience, and artificial intelligence (AI). These multidimensional solutions have shown particular effectiveness in enhancing self-awareness and promoting unconscious behavioral recalibration. Key insights emerged from the analysis of VR-based DE&I training experiences, especially from a design perspective:

Table 1: Main Case studies of Immersive VR experiences in the context of DE&I

COMPANY	OBJECTIVES/DE &I TOPIC	TARGET	DESIGN/COMPE-TENCE/CONTENT	REALISM/ PERSONALISATION	EXPERIENCE	DELIVERY	AI & OUTCOME	FEEDBACK
GOOGLE (ICT) 2021-24	The program aimed to enhance awareness of unconscious bias and microaggressi ons in the workplace, promote empathy, and equip participants with practical tools to recognize and address discriminator y behavior	32 senior staff mem-bers of the internal security team.	13 DE&I emplo yees involved. The trai - ning was developed in 3 phases: 1) Initial Framing for Beha vior Change: identi-fication of behaviors to be addressed. 2) participant refle-ction on personal expe riences with bias or commit-ted a micro aggression to wards them or others. 3) charac - ters' scriptwriting and scenogra phy based on real incidents	The settings replicated real corporate spaces (e.g., meeting ro oms, video calls, Google Meet), and characters were designed to share identity traits with users, enhancing real-ism through voi ce acting and AI-driven dialogue. While partici-pants could look around, they we re unable to mo ve within the en	The experience used the Virtual Embo diment & People Caring Projective Tecniques and included four scenarios portraying everyday discrimination: assumptions based on appearance, diversity in conversations, feedback and performance, and group dynamics. Participants embodied two different protagonists per scenario to appreciate how perspective-taking influences the perception and emotional experience of bias. The trainee can observe the protagonists, control and respond to the situation in 3 ways: Call it out: to highlight the issue in a very overt way; Call it in: to dispel the misconception by pointing out that	The training lasted 90 minutes, including a facilitator-led briefing, a demo on how to use the Quest 2 headset (15'), a 45' immersive experience, and a 20–25' debriefing session, in small groups of 10. Most participants used the Quest headset; a few opted for the desk top version. The parti-cipant might have to click on the controller (or mouse) when they spot a bias as visible. Trainees could explore scenarios in any order	A reflection follows the first immersion with an optional metric report, such as the *number of biases reported as visible.* Due to the absence of standardized measurement protocols, behavioral data could not be collected or compared systematically. Despite these limitations, the initiative success fully increased realism and per sonal relevance in addressing bi as,	An optional post-training survey (with a 30% response rate) showed that 94% of respondents rated the experience as satisfa ctory (4.7/5), and 82% found it more effective than traditional DE&I formats (4.1/5). Open-ended feedback highligh ted increased awareness, emo tional engagement, and the ability to perceive issues from multiple perspectives.However, partici pants also noted key limi-tations. The graphical quality was often judged subpar, which compro mised immersion. Most critically, the passive nature of the expe rience—where users could not act or intervene—was seen as a

				vironment or in fluence the out come of the sce nes.	it is wrong, highlighting the quality/ expertise of the person the remark was directe towards; Ignore it: the character will stay silent.	and were not bound by a fixed progression.	offering valua ble insights for fu ture iterations of immersive DE&I design.	barrier to deeper enga gement. Participants expressed a desire for greater interactivity and agency in influencing scenarios.
NHS (HEALTH) 2022-2024	In response to widespre ad racism and discriminatio n within the NHS—parti cularly affec ting Black, Asian, and mi-nority ethnic (BAME)staff —the organi zation deve loped an im-mersive VR training pro gram aimed at improving empathy and managerial responses	The traini ng targe ted 270 staff mem bers, with a focus on manage ment and mid-level leaders, seen as key gate keepers	The initiative follow ed a mass exodus of ethnic minority doc-tors and was groun ded in 133 intervie-ws with NHSstaff, ga thered through the Tides study conduc ted by King's Colle-ge London. The VR content was constru cted from real-life testimonies and in cluded emotionally impactful reenact-ments of discrimina tory scenarios, such as PPE being locked away from Black staff during night shifts or unequal ac cess to pandemic-re lated childcareleave	High, in sense of helping to address some of the underlying issues and inequalities that are not often talked about by giving people a voice, and making sure others also listen to that voice. The training could also directly address the discomfort felt by bystanders when confronted by instances of racism.	The immersive training presents vi-deo-based scenarios that depict real experiences of ethnic minority NHS staff. Delivered through passive vir-tual embodiment, participants ob serve as spectators in a highly emo-tional and engaging context. Scenes include a Black nurse, Tunde, being told PPE was locked away at night—disproportio- nately affecting mino-rity staff working late shifts—and an Asian doctor, Jasmine, dismissed by HR after pointing out double stan - dards in shift change approvals du-ring the pandemic. The VR experien ce enables users to experience and witness these discriminatory situa tions firsthand, fostering empathy and awareness. The experience also highlights the bystander effect, as users are unable to intervene, reflecting real-world dynamics.	Video clips in VR The training, called "Walking in the shoes of …", involves participants wearing a virtual reality (VR) headset and watching videos depicting instances of racism and discrimi-nation by actors within an NHS setting. The virtual reality training as a digital repository: meant staff did not have to relive their experiences of discrimination when telling colleagues about the way they had been treated.	no quantitative outcome data were collected	Qualitative feedback highlighted the training's psychological impact: VR allowed staff to engage with difficult experiences without retraumatization and provided a powerful means to foster understanding without requiring victims to retell painful events.
DOMAIN GROUP (ICT) 2023	Integrated DE&I into its corporate cul-ture through an immersive training initia-tive, to evoke empathy,esta blish shared understandin g, and foster behavioral change and personal accountability	Targeting all 780 em ployees, including a train-the-trainer componen t	ND/Generic Contents	While the content was relatively generic, the emotional impact and realism were enhanced through avatars, scenario design, and interactive immersion.	The training leverages virtual embo diment techniques, allowing partici pants to assume alternative identi-ties—such as a different gender or racial appearance—visibly reflected within the virtual environment (e.g., through mirrors). This immersive setup enables users to firsthand experience acts of discrimination or abuse of power, thereby fostering deeper emotional engagement. The VR application is designed to simu late real-life scenarios, guiding parti cipants to identify bias, reflect on their emotional reactions, and rehe arse appropriate behavioral respon ses when witnessing exclusion or misconduct.	Delivered over 40 blended sessions, the training combined a one-hour VR experience with a two-hour facilitated workshop to discuss on how to behave correctly in these different scenario.	The response has been excellent, with partecipants able to enpathize and discuss the experience Emotion, increased empathy and personal accountability towards DE&I	The outcomes were highly positive: 95% satisfaction, 67 NPS, and significant increases in empathy and accountability—98% of participants reported understanding their personal role in DE&I, and 89% felt more receptive to the follow-up workshop. These results demonstrate the effectiveness of combining immersive VR with reflective group discussion to reinforce inclusive workplace behaviors.
VIACOMCBS PARAMOUNT (CINEMA) 2021	A VR training program on bias and inclu sion inspired by the Black Lives Matter movement, aiming to deepen partici pants' aware ness of others' lived experien ces and to pro mote allyship	Bias& in clusion VR training across multiple countries	The experience, co-designed with em-ployees to ensure authenticity, uses virtual embodiment and interactive fea tures to foster per-spective-taking, enabling users to recognize and re-spond to bias in psy-chologically safe scenarios.	Different scenario to create an empathetic learning experience.	"Unpacking bias" Virtual Embodi ment techniques and interactive feature. is an immersive journey focused on bias and inclusion, that enhances perspective-taking and the ability to look beyond your own point of view. It allows people to practice different behaviors in a psychologically safe environment; to face unconfortable yet everyday situations; to recognize bias (and learn where they may have missed it) and make decisions on how to act and react	Delivered remotely during the pandemic through web-based simulations and facilitator-led Zoom workshops	nd	Achieved high levels of engagement and empathy, particularly appreciated for its experiential depth compared to traditional e-learning.
VRAllexia 2025	The VR expe-rience develo ped to raise awareness and foster empathy & in clusion of indi viduals with dyslexia amo ng non dysle xic individuals	30 non-dyslexic participant s from the uni versity environ ment - primarily university professors and students			Non dyslexic individuals were im-mersed in the daily challenges faced by people with dyslexia. Built using the Unity game engine and deployed on Meta Quest devices, the simulation recreates a virtual campus (metaverse) where participants must navigate buildings, locate materials, and reach an exam room, while encountering realistic barriers such as distorted text, misleading directional signs, and limited assistance—mirroring the cognitive and navigational obstacles experienced by dyslexic students.	The project follows a user-centered and itera tive design approach, incorporating best pra ctices from Scrum me thodology. The experi-ence also integrates AI-driven recommen-dation systems and remote-administered psychometric assess-ments, showcasing VR's potential as an as-sistive and diagnostic educational technology	Effectiveness was eva luated via a structured post-experience questi onnaire covering demo graphics, VR experien ce quality, and dyslexia awareness. Results sho wed increased user un derstanding and empa thy toward dyslexia-re lated difficulties, sup-porting the value of im-mersive simulations in higher education and la ying the foundation for a modular virtual cam-pus inclusive of other vulnerable groups.	To evaluate the quality of the experience, ad hoc satisfaction surveys were administered
COMPANY	**OBJECTIVES/DE &I TOPIC**	**TARGET**	**DESIGN/COMPE-TENCE/CONTENT**	**REALISM/ PERSONALISATION**	**EXPERIENCE**	**DELIVERY**	**AI & OUTCOME**	**FEEDBACK**
JP MORGAN 2023	Client diver-sity inclusion: implemented a diversity and inclusion initiative ai-med at foste-ring aware ness and sti-mulating con-versation across interna tional teams.	Delivered across 7 events in 5countries including Australia, Singapore, and Hong Kong. The program engaged over 600 employees	How to create an engaging event to spark discussion around Inclusion that could be delivered in multiple countries with local staff	nd	A short, three-minute interactive VR scenario was used as a catalyst to spark discussion, supported by internal training materials and videos that enabled local teams to independently run the sessions.	The initiative followed a blended model (over 40 sessions): a one-hour VR experience followed by a two-hour facilitated workshop to deepen reflection on inclusive behaviors in workplace scenarios.	The initiative achieved high levels of engagement and impact:	Satisfaction 93% NPS of +68 ENGAGEMENT - 97% found VR more engaging than traditional training methods; EMPATHY – 95.5% of participants felt empathy toward their avatar" I could imagine myself in the character's shoes" ACTION 90,0% stated they would take action upon witnessing inappropriate behavior; FOLLOW UP - 95% expressed interest in further learning about unconscious bias; INTEREST – 87.8% showed interest in joining Business Resource Groups or other D&I initiatives
leading bank in Australia (2023?).	Immersive Training on LGBTQ+ Discri mination and Proactive Ally	161 employee	VR training simulation based on a real lived experience of an employee, allowing	"Step into the shoes of Jack": attempting to sign up to a gym with yourpartner	The simulation was grounded in the real-life experience of a bank emplo yee who faced overt bias while at-tempting to join a gym with his part ner, highlighting how customer ser-	Delivered across over 40 sessions in a blended format (1-hour VR simulation + 2-hour workshop to discuss on	Totally in someone else's shoes: "We are actually in It". "People completely lose every-thing about his skin	NPS +91, with 96% finding VR more engaging than traditional e-learning; 99.2% reported feeling strong empathy and understanding of what it means

	ship - A world leading bank set out on a mission to foster personal accountability and encourage employees to question and act against discriminatio n		you to make value-based decisions and practice taking action in the moment.	Pierre. How does it feel when you are dismissed and refused membership ba sed on your sexual orienta tion? Next, step into the shoes of Fred dy – a custo mer service represen tative at Fitness Front. Practice responding to a colleague discriminating against a customer.	vice interactions can be shaped by unconscious bias and sexual orienta tion discrimination. Participants en gage in a dual-perspective scenario: first, as Jack—a customer who is dismissed due to his sexual orienta tion; and then as Freddy—a custo-mer service representative witnessing a colleague discriminate against Jack. This immersive, narrative-based training allows users to explo re the emotional impact ofexclusion and to practice responding to inappropriate behavior in real time. Key themes addressed include interper sonal and institutional bias, bystan der effect, and poor service quality rooted in discrimination.	how to behave correctly in these different scenario). The program was met with overwhelmingly positive responses	color; your bias and youself". "In roleplay you don't feel you are in that situation, whereas in this situation you think, this is me. I feel like I am really them". "You really feel like you are part of it. It's a really fun way of learning. Instead of just clicking ahead on line or trying to memorize a lesson, you are actually under-standing it in the moment".	to be disrespected; 96% felt prepared to act if they witnessed similar behavior at work 86.4% reported complete immersion, losing awareness of the real world 99.2% indicated clear understanding of available reporting mechanisms The experience was praised for its emotional realism and effectiveness in building empathy and engagement—"bringing feeling back into banking."
SERVICE NOW (ICT) 2021	Building Inclu sive mindsets through Empathy-Based VR Training, by allowing employees to practice responding to bias and microaggressions in a psycho logically safe environment.	Company's employees	The design team specifically crafted a scenario to demonstrate best practices for bystanders looping back and checking in with victims of bias or microaggres sions.	The simulation presents an interview scenario in which employees rotate through three roles, empathy-building: a person of color being interviewed, a White panel member, and a White bystander.	The scenario depicts subtle but impactful incidents of bias, highlighting their effects on the candidate's performance and well-being. The application allows to practice inclusive mindsets and skill sets in a space where it is possible say the wrong thing or touch on what employees can do if they missed an opportunity to speak up. The experience includes reflection prompts that encourage partici-pants to assess their reactions and consider alternative actions, including how to loop ba ck and support individuals who experienced bias. This role-switch-ing mechanism enhances empathy and ac-ountability, particularly for employees who may have been unaware of their own biases or who previo-usly failed to intervene as bystanders differently.	The training is delivered remotely using headsets mailed to employees, with an accessible browser-based version for those affected by VR-induced nausea. Holding these at-home learning sessions has put employees more at ease by eliminating "the fear that folks hold around the judgment of saying the wrong thing" — or the harm created when employees witness their co-workers' bias in action.	There are prompts that ask employees to review their choices throughout the VR learning modules, and decide if they would have done anything else. The virtual format was also seen as reducing performance anxiety, as it offered a low-risk setting to explore sensitive topics and learn through mistakes. This case illustrates how VR can create meaningful engagement with DEI content by promoting perspective-taking, emotional awareness, and practical skill-building in complex social situations.	ServiceNow employees reported increased emotional insight—many expressed that embodying the affected individual made the experience of bias more tangible while others reflected on past inaction and welcomed the opportunity to "rehearse" better responses. The DIB team has received two sets of feedback: "'Wow, I didn't fully understand how that might feel. I've been the person who said this and now that I'm on the receiving end.. Taking on an identity in virtual reality doesn't mean you all of a sudden understand someone's lived experience but it can be a bridge into a deeper understanding. On the flip side, these VR trainings have spurred some employees to speak candidly about their regrets.
CONSULTING GLOBAL NETWORK & ITALIA 2021-22	Early adopter of VR DE&I training in 2019, first in the U.S. and later in Europe, to boost D&I Training on racial bias, with Italy (in 2021-22) focusing on core values including racism, disability & gender issues, using profiling algorithms.	Employees in International Context; Leadership in Italy (130)	A multidisciplinary team, coordinated by the HR dept., led the project over a six-month period. Through focus groups and interviews, the team engaged senior leadership and business unit directors. Internal research on employee sentiment and an in-depth analysis of the company's core business further informed the development process.	The platform features 3 realistic, work-related environments and immersive scenarios of increasing complexity. Realism is enhanced through interactive narratives, emotionally rich characters, and decision-making opportunities. The platform can accommodate multiple environments & situations.	Combining Virtual Embodiment and People-Caring Projective Techniques, the VR platform includes 3 professionally familiar scenarios—two indoor and one outdoor—such as client interaction, public engagement (e.g., a parking situation), and managing a team meeting. In each context, participants are driven to achieve a personal goal (the primary trigger), while simultaneously facing incidents that may affect outcomes depending on the salience of unconscious biases (e.g., related to gender, race, or disability). Realism is enhanced through emotionally nuanced characters that enable immersive dialogue, interaction, and decision-making.	Approximately 20 3h residential workshops were conducted in small groups, supported by internal facilitators, tutors, and technical staff. Each session included a 20' introduction, about one hour of VR experience, and nearly two hours of plenary discussion, focused on differences in decisions and behaviors among colleagues facing identical scenarios, proved highly valuable for self-awareness.	Each session allow a decision-making analysis, based on real-time data generated by the platform's algorithm. Participants remained anonymous to encourage open expression. At the end, each participant received a personalized feedback profile and an evaluation questionnaire via mail. The insights into individual behaviors and decision-making processes constitute new knowledge, enabling more targeted initiatives.	The post-experience evaluation of the workshops received an average score of 4.8 out of 5. Although participants faced some challenges with the technology, they found the analysis of the numerous decisions made within a short time frame across the three simulations to be highly effective. D&I topics were integrated and transversal across the scenarios, allowing for the measurement of participants' actual sensitivity to such issues, as well as the influence of unconscious mechanisms and the strength of individual biases.
FINANCE GROUP-IT (FINANCE) 2024-25	This financial group under took its first experience with VR, as part of an integrated assessement initiative aimed at evaluating individuals' soft skills portfolio, as DE&I. Value System Assessment & People Agility/DE&I	Young High potential talents/60	The project engaged, over a 4-month period, the HR manager responsible for designing the company's original assessment models, in order to ensure that both the narrative structure and the decision-making algorithm accurately reflected the organization's core values, culture, and attention for competencies related to "people caring".	The platform features a high level of realism in both indoor and outdoor environments. Avatars interact based on distinct personalities and emotional profiles, within a credible and structured narrative that simulates a full working day—from leaving home onward.	The simulation, based on the people caring technique, follows a typical workday starting from the moment the participant leaves home. It unfolds across 5 distinct scenes—set in both indoor and outdoor environments—with unexpected events that may or may not involve the main character, depending on their choices. Participants are free to interact, explore, and decide whether or not to influence the context, enabling the assessment of unconscious levels of sensitivity, active listening, and respect for others, while the decision-tracking algorithm generates an anonymous behavioral profile for each participant.	Ten 3h residential workshops were conducted in small groups, supported by internal facilitators, tutors, and technical staff. Each session included a 20' introduction, about one hour of VR experience (without controllers), and nearly two hours of plenary discussion, focused on differences in decisions and behaviors among colleagues facing identical scenarios proved highly valuable for self-awareness.	Each session allow a decision-making analysis in plenary, based on real-time data generated by the platform's algorithm. Participants remained anonymous to encourage open expression. At the end, each participant received a personalized feedback profile via mail. The insights into individual behaviors and decision-making processes constitute *new knowledge, enabling more targeted initiatives.*	Thanks to a post-experience questionnaire, evaluation of the workshops received an average score of 4.9 out of 5. One of the most compelling out comes of the workshops was participants' ability to recognize themselves in the quantitative results—particularly in terms of strengths and potential development gaps. Other feedbacks: "the time just flew by!", "Immersion removes the sense of time from the training. You are focused." By integrating immersive VR with traditional assessments, the project aims to capture more reliable behavioral insights.

Addressing Unconscious Bias: Despite diverse corporate challenges, DE&I interventions share a core objective: identifying and addressing unconscious biases that lead to non-inclusive behaviors. Training may target various audiences—from executives to frontline staff—and address themes such as cultural diversity, gender equity, disability inclusion, and organizational well-being.

Functional and Process-Specific Applications: The use of immersive technologies can be tailored to specific corporate functions. For example, they may assess leadership styles, support bias-free recruitment, or train sales teams in inclusive client interactions.

Instructional Design Over Technology: The impact of immersive training is driven more by pedagogical alignment than by technological sophistication. Effective design requires consistency between real-life managerial behaviors and virtual scenarios, demanding interdisciplinary collaboration.

*Narrative Credibility as a Core Driver: T*he effectiveness of the experience hinges on the realism and plausibility of the interactive narrative, rather than on the topic itself. Authentic storytelling anchored in relatable workplace dynamics is critical.

Pedagogical Strategies: Two dominant narrative approaches exist. A “direct” approach explicitly focuses on a specific DE&I issue, while an “indirect” one embeds DE&I themes in ambiguous situations, allowing spontaneous reactions to surface. The latter encourages deeper emotional engagement and critical reflection.

Role-Based Perspective: The user's role significantly shapes the experience. *Embodying a victim* of discrimination can evoke strong emotional responses but may lead to detachment if the character feels too distant from the participant's identity. Conversely, adopting a *proactive or caring role* fosters a stronger sense of agency and long-term engagement.

Delivery Formats: Training can be delivered through various modalities—fully immersive VR, web-based, mobile—and settings, including classroom or self-guided formats. Blended approaches, supported by skilled facilitators, are particularly effective in promoting reflection and integration of learning.

Emotional Engagement: The intensity and novelty of immersive VR experiences can trigger powerful emotional reactions. Gamified elements can enhance engagement and learning retention.

User Readiness and Attitudes: Receptivity to immersive training is not strictly age-dependent. Openness to innovation and emotional readiness should be considered during participant selection and training design.

Redefining Realism: Realism in immersive design should not be limited to visual fidelity. Emotional credibility arises from subtle sensory cues—ambient sounds, gesture-based interaction, contextual details—that trigger unconscious associations and emotional immersion.

Feedback and Awareness: Participant behavior can be evaluated through normative assessments (e.g., quizzes) or descriptive analytics offering individualized feedback. These mechanisms help surface implicit biases and areas for improvement.

Outcome Measurement and Data Analytics: A rigorous distinction must be made between subjective and objective measures. Behavioral tracking supported by embedded AI-algorithms enables the analysis of decision patterns, providing a data-driven foundation for experiential and evidence-based DE&I training.

Scalability: A key distinction exists between stand-alone VR experiences and scalable platforms that can evolve with new scenarios and protocols. Scalable systems enable long-term strategic integration into corporate learning ecosystems.

The Role of AI: Advances in AI are transforming immersive learning through natural language interaction, real-time data processing, and adaptive feedback. These innovations support the personalization of learning experiences based on cognitive and emotional readiness, paving the way for truly individualized training paths.

By translating these insights into design principles, organizations can move beyond compliance-based DE&I efforts toward sustained cultural transformation. When grounded in robust pedagogical design and supported by data-driven insights, immersive technologies can act as powerful enablers of inclusive knowledge sharing and organizational learning.

5 Discussion and Implications: Toward a Framework for Immersive DE&I Training Design

The preceding analysis underscores the wide-ranging diversity of VR-based DE&I applications at both international and national levels. In light of this, the paper proposes a preliminary reference framework aimed at distinguishing not only the varying objectives and design strategies of immersive DE&I training programs, but also their potential benefits across short-, medium-, and long-term horizons.

Given the expansive potential of immersive technologies in learning contexts, each project must be grounded in a clearly defined behavioral objective. Ultimately, the goal of VR-based DE&I programs is to promote *individual empowerment*—both by fostering self-awareness and behavioral change among those who may exhibit non-inclusive attitudes, and by equipping vulnerable groups with tools to assert and protect their rights.

From a content design perspective, distinct approaches to immersive DE&I training can be identified. The proposed framework (Figure 1) outlines four progressively impactful strategies, categorized by their potential to enhance awareness, drive behavioral transformation, and foster long-term empowerment. These range from informational modules—such as compliance training or knowledge testing—to deeper interventions aimed at developing critical self-reflection. The selection of technological solutions (e.g., VR headsets, mobile simulations, XR, or metaverse platforms) should follow, rather than dictate, instructional design needs. Key content elements—such as scripts, neurocognitive triggers, interactive dynamics, avatar personalities, and decision-making scenarios—must align with intended learning outcomes. In more advanced cases, decision-making algorithms may also be integrated to generate behavioral profiles and *new knowledge, enabling more targeted initiatives.*

Figure 1: The Different Design Approaches to Immersive Training in DE&I

Immersive DE&I training can be categorized into four distinct approaches, each with increasing levels of emotional engagement, behavioral impact, and long-term effectiveness:

1. Informational Approach This model focuses on raising awareness and transferring knowledge about DE&I-related issues—such as anti-discrimination policies or organizational guidelines—through structured, cognitively oriented simulations. While these experiences target the rational mind, they also leverage emotional cues to enhance memory retention and empathy. Two main formats exist:

- *Guided Simulations*, where users interact with avatars in predefined scenarios, testing their adherence to socially appropriate behaviors.
- *Perspective-Taking Simulations*, where users embody individuals from marginalized groups, temporarily "stepping into their shoes" (i.e. *virtual embodiment*)

Although impactful in the short term, these experiences often fail to generate sustained behavioral change. When the simulated identity is perceived as too distant or unfamiliar, users may psychologically distance themselves from the experience, limiting its long-term effectiveness.

2. Experiential Approach The experiential model deepens engagement through emotionally charged, cognitively complex scenarios. It often uses *people-caring projective techniques*, placing users in situations where they must respond to the discomfort or discrimination faced by others. These open-ended simulations encourage instinctive reactions, revealing unconscious biases and fostering critical self-reflection. For example, participants may witness an act of injustice and must choose whether and how to intervene. Because these scenarios evoke personal emotional resonance, they are more likely to produce medium- to long-term attitudinal shifts.

3. Transformational Approach Building on the experiential model, the transformational approach introduces *adaptive simulations*, real-time decision tracking, and personalized feedback mechanisms. Participants are given the ability to shape outcomes based on their choices, while algorithms monitor and assess their behavior. This feedback loop highlights discrepancies between perceived intentions and actual behavior, often generating *micro-emotional shocks* that encode the experience in implicit memory. For instance, a recruiter may discover through simulation that unconscious bias influenced candidate evaluation—revealed not through a test, but through tracked behaviors such as time spent, tone used, or number of questions asked. This reflective process facilitates deeper self-awareness and long-term behavioral recalibration.

4. Collaborative Approach in Metaverse Contexts The collaborative approach involves multi-user, avatar-based environments where participants interact in real time to complete shared tasks or engage in peer learning. These platforms support *collective problem-solving,* content exchange, and potentially anonymous interaction, which can foster openness and reduce bias in communication. Beyond training, these environments can also function as spaces for *peer support and community building*, offering a more social dimension to DE&I learning.

A final critical element is the *integration of immersive experiences with facilitated, classroom-based activities (Blended Learning).* Combining simulations with debriefings led by skilled trainers enhances internalization, reflection, and peer exchange. These moments serve as bridges between simulated insight and real-world behavioral application.

While increasingly complex simulations and advanced analytics demand higher investments, they also generate proportionally *greater organizational knowledge value through deeper behavioral insights* and the development of inclusive competencies at scale.

6. Conclusions

This study seeks to generate both theoretical and practical insights into the use of VR for DE&I training. Theoretically, it contributes to the growing literature on immersive learning by clarifying the mechanisms through which VR fosters perspective-taking, emotional engagement, and critical self-reflection. It also advances a multidisciplinary understanding of inclusive training by analyzing the interaction between technological affordances (e.g., realism, interactivity, AI-based personalization) and pedagogical design.

From a practical standpoint, the research offers actionable guidance for organizations seeking to implement or enhance VR-based DE&I programs. It argues that the effectiveness of diversity strategies depends not only on structural policies governing labor markets and career advancement but also on targeted interventions aimed at influencing individual behaviors. These include training initiatives as well as actions designed to challenge and delegitimize behaviors that violate human dignity. Allowing such behaviors to persist reinforces cognitive biases and exclusionary cultural models—affecting both perpetrators and those who internalize discriminatory norms as inevitable.

Organizationally, alignment among values, knowledge management practices, and actual behaviors is essential to avoid employee disengagement and cynicism. Effective diversity management models foster mutual understanding, improve the organizational climate, and enhance overall productivity—with positive spillovers at the societal level. Importantly, these changes are not purely cognitive; they rely on the development of empathy and individual responsibility, including recognition of passive non-inclusive behaviors—such as the failure to support a colleague in need, under the assumption that someone else will.

Within this framework, immersive technologies, when carefully designed and contextually integrated, offer high-impact and scalable training solutions, particularly for large organizations. However, VR applications vary widely in terms of goals, methods, and expected outcomes. This research therefore proposes a reference framework and set of guidelines to support responsible organizational decision-making.

In advanced immersive scenarios, emotional triggers embedded in the environment and avatar interactions significantly shape engagement. AI algorithms can track user behavior, assess contextual impact, and generate behavioral profiles over time. This enables the reconstruction of decision-making processes and promotes individual self-awareness by objectifying aspects often perceived subjectively.

A key insight of the study is that recognizing the gap between one's self-perception and actual behavior—particularly in emotionally charged or ambiguous virtual situations—can produce *emotional micro-traumas.* These experiences, though discomforting, are encoded in memory and integrated with prior knowledge. When perceived as meaningful, they can prompt immediate and lasting behavioral change. This is due to the brain's tendency to treat emotionally salient events—virtual or real—as equally relevant.

As such, the most advanced immersive learning designs—featuring neuro-trigger mechanisms and AI-driven behavioral analytics—not only facilitate knowledge transfer but can generate *entirely new knowledge*. Specifically, they enable: (1) The mapping of individual behaviors in unfamiliar or ambiguous social situations; (2) The reconstruction of the underlying decision-making processes; (3) The development of self-awareness concerning discrepancies between perceived intentions and actual behaviors, along with a clearer understanding of the consequences of one's actions or inactions.

While this study offers a comprehensive perspective on the potential of VR in DE&I training, it also acknowledges key limitations. These include restricted empirical access to organizational data and the difficulty of measuring long-term behavioral change—especially in isolating VR's unique contribution within complex training ecosystems. Continued research into the design, implementation, and integration of immersive DE&I training will be essential to ensure these technologies contribute meaningfully to the creation of more inclusive, equitable, and knowledge-centered workplaces.

7 AI Declaration

Generative AI (ChatGPT, OpenAI, April–May 2024 version) was used to support preliminary drafting in translation refinement, and the retrieval of non-academic sources (e.g., corporate case studies and reports). All content was subsequently verified, reviewed, and critically validated by the author.

Artificial Intelligence and Gender Roles: A Structured Literature Review (SLR)

Marco Tutino, Simona Arduini, Chiara Di Mario
University of Roma Tre, Roma, Italy

Abstract

This study presents a Structured Literature Review (SLR) aimed to explore a relationship between Artificial Intelligence (AI) and Gender equality, with a particular focus on the historical developments of this topic and the identification of future research prospectives.

AI is widely regarded as a transformative force with the capacity to reshape numerous dimensions of global society. While its long-term effects on economic system remain subject to debate, the labor market is already emerging as a critical area of impact. Moreover, AI holds the potential to enhance efficiency and productivity, but it simultaneously raises concerns about job displacement, access to opportunities and, exacerbation of existing social inequality.

In this context, our objective is to examine how academic literature has responded to the emergence of AI, particularly analyzing the extent to which gender-related themes are integrated into discussions of AI development and application.

To achieve this, the review is supported by a bibliometric analysis, conducted using the Biblioshny package in R-Studio, were performed on a sample of 290 academic documents (Articles and Book Chapters) available on Scopus and published from 2015 to 2025. The dataset was selected through a rigorous and validated screening process to ensure relevance and academic quality. The analysis is structured around four main dimensions: the annual evolution of publications, the identification and frequency of emerging keywords and trending topics, and the geographical distribution of scholarly contributions.

The originality of this research lies in its methodological approach and use of bibliometric analysis, to explore a broad spectrum of academic publications over a significant period, serving as a potential base for further insights and future studies.

Keywords: Artificial Intelligence (AI), Gender equality, Business transformation, Structured Literature Review (SLR), Bibliometric analysis

Paper type: Academic Research Paper

1 Introduction

In recent years, Artificial Intelligence (AI) has emerged as a transformative force, reshaping the business landscape across various dimensions. Its impact extends beyond operational strategies and decision-making processes, significantly influencing corporate governance, organizational structures, and social dynamics within companies (Ustahaliloğlu, 2025). Indeed, AI holds the potential to profoundly transform the labor market by redefining professional roles, reshaping responsibilities, and increasing demands for digital and cognitive competencies. Nevertheless, its integration presents a series of managerial challenges and brings to light critical concerns related to gender equality (Dwivedi et al., 2021). While AI can improve social and economic outcomes for women, it also risks reinforcing existing gender inequalities (Wajcman et al., 2020).

A growing body of research highlights the risks associated with algorithmic systems, especially when they are designed without explicit principles of diversity and inclusion. In such cases, AI may inadvertently perpetuate and even amplify gender biases embedded in training datasets (Buolamwini & Gebru, 2018; Manresa-Yee et al., 2019; Fabris et al., 2020; Cornacchia et al., 2023; Doh et al., 2024; Benatti et al., 2024, Ferrara, 2024). Various mitigation strategies have been proposed — including data pre-processing, algorithmic adjustments, and post-processing interventions — but bias in AI remains a core challenge in building fair and inclusive systems (Ferrara, 2024).

In addition, statistical evidence continues to reveal a persistent gender gap in STEM (Science, Technology, Engineering, and Mathematics) disciplines, with men dominate both technical and leadership roles. The broader implementation of AI may deepen gender disparities, particularly if its development and governance remain dominated by male-centric perspectives. This increases the risk of women being further marginalized from positions of influence, reinforcing existing power asymmetries (European Commission, 2024).

The study aims to offer a comprehensive overview of the existing literature on the intersection of artificial intelligence and gender equality, offering insights for scholars, professionals, and researchers to identify key themes and guide future research directions.

Considering these issues, the analysis is guided by the following research questions:

- *RQ1.* Is AI perceived merely as a supportive tool or as a new member of the corporate team?

- *RQ2.* Given that AI is a "cognitive" system, does it inherently incorporate gender biases?
- *RQ3.* How does AI adoption affect the distribution of STEM skills?

To address these research questions (RQ), we utilized the Systematic Literature Review (SLR) method, chosen for its rigorous and transparent approach in systematically analyzing the vast body of literature on these themes. This methodology enabled a critical assessment of current knowledge on gender diversity and AI in the corporate world. The results, presented in a dedicated section, highlight the emerging trends and key topic concerning the impact of these technologies on business and gender prospectives.

2 Literature analysis

Artificial Intelligence (AI) is poised to significantly reshape the global economy, demanding major investments and changes in work practices for organizations and institutions (Dwivedi et al., 2021; Cazzaniga et al., 2024). Some experts compare AI's impact to that of the steam engine during the Industrial Revolution, which transformed manual tasks where humans had reached physical limits (Dwivedi et al., 2021; Cazzaniga et al., 2024). Today, AI is no longer futuristic realm but an integral component of the business model of many organisations and a key strategic element in the plans for many sectors of business (Dwivedi et al., 2021). In particular, AI enables machines to replicate human cognitive functions through technologies like machine learning, deep learning, neural networks, natural language processing, expert systems, and robotic automation (Davenport, 2018; Haenlein & Kaplan, 2019). These tools allow for dynamic data interpretation and adaptation, making AI central in sectors such as education, healthcare, manufacturing, public administration, and supply chains (Dwivedi et al., 2021).

In business contexts, AI can enhance or even replace human roles in decision-making, overcoming traditional cognitive limitations (Dwivedi et al., 2021; Daugherty & Wilson, 2018; Miller, 2018).

The infusion of AI into strategic decision-making marks a paradigm shift from conventional models based on human judgment and historical data analysis to data-driven, real-time analytics empowered by AI capabilities (Dwivedi et al., 2021).

Despite these promising advancements, many companies remain unprepared to capitalize on AI's full potential. According to Tambe et al. (2019), 41% of CEOs report that they are not at all prepared to use data analytics tools, and only 4% feel highly prepared. These challenges are not only technical but also organizational and cultural. AI's disruptive impact goes beyond technology, requiring businesses to rethink governance, organizational models, leadership styles, and workforce development (Bruttini et al., 2021). Managers are now expected to adopt skills different from the past, adapting to a context shaped by intelligent systems and collaborative technologies (Arduini & Beck, 2024). This shift in organizational culture coincides with a broader push for diversity and inclusion. Leadership models are evolving from authoritarian styles to more participatory and collaborative approaches, fostering environments where gender diversity is no longer a marginal issue but a strategic driver of innovation and adaptability (Paoloni & Demartini, 2016; Paoloni et al., 2023; Paoloni & Lombardi, 2023). Thus, the integration of AI into the workplace presents an opportunity to redefine roles and responsibilities, potentially supporting gender equality – but only if implemented thoughtfully. While AI can enhance efficiency and innovation, it also raises significant concerns about bias and discrimination, particularly in relation to gender.

In fact, this issue is one of the most pressing ethical challenges. AI systems are trained on data that may reflect historical, societal, or cultural biases. As Ferrara (2024) explains, these biases can result in systematic errors and unfair outcomes. A prominent example is Buolamwini's (2018) study, which revealed that facial recognition systems performed significantly worse on female and darker-skinned faces due to biased training datasets. Crawford (2016) further argues that AI systems reflect the inequalities of the societies that produce them, and without critical oversight, they can reinforce rather than dismantle these structures. Benjamin (2019) explores how emerging technologies like AI can exacerbate systemic oppression if not developed through ethical and inclusive frameworks.

The presence of gender bias in AI is closely tied to the underrepresentation of women in STEM fields (Ceci et al., 2009, Carrell et al, 2010; Wajcman et al., 2020) – another key topics. Some scholars have examined how AI development reflects broader gendered dynamics in both technological environments and workplace cultures. Schiebinger (2021) points to historical imbalances in scientific research teams, noting that male-dominated development groups are more likely to produce technologies that fail to reflect female experiences. Njoto et al. (2022) emphasize how workplace cultures – particularly in male-dominated STEM sectors – reward masculine norms, which can be inadvertently encoded into AI systems used in recruitment or performance evaluation. O'Connor & Llu (2023) focus on structural barriers that limit women's participation in AI development, including

lack of mentorship and support. All the authors cited argue that without gender-inclusive design, AI technologies will continue to mirror existing inequities.

Overall, the ongoing debate on the role of AI in human teams also reflects deeper questions about the nature of technology and work. Some scholars, like Brynjolfsson and McAfee (2014), frame AI as a tool to assist humans – highly efficient and powerful, but still dependent on human control. From this perspective, AI lacks the consciousness and social awareness necessary to operate as a true team member. Others, such as Vallor (2018), advocate for a more collaborative vision of ethically designed AI, that partners with humans in decision-making and creative tasks.

To explore the connection between artificial intelligence and gender diversity, we propose a structured review of the literature (SLR) on the topic, aimed at providing a comprehensive and up-to-date overview of the emerging trends in this research field. The application of a structured literature review (SRL), related to the topic in question, will allow for the contextualization of a highly significant and widely discussed issue in the current business world: the redesign of business, roles, and responsibilities from the perspective of artificial intelligence and female dimensions. Furthermore, a structured examination of the literature enables the assessment of the coherence and originality of the topics addressed.

3 Methodology

3.1 SLR

This study aims to examine the most recent literature on the intersection of artificial intelligence (AI) and gender equality. Given the steady growth of AI tools, a growing body of international research has focused on this topic, with several authors already applying literature review methods in this area (Mendonça de Lima et al., 2023; Cano-Marin, 2024; Ratten, 2024; Setiawan & Hendayana, 2024; Golgeci et al, 2025). To explore this complex relationship, we employed a *Systematic Literature Review* (SLR), a qualitative methodology designed for comprehensive analysis of academic sources (Tranfield et al., 2003).

Following a structured two-phases protocol (Marcos-Pablos & García-Peñalvo, 2018), the first involves formulating a query within a database, with the goal of identifying relevant academic sources based on the research topic (de Moya-Anegòn et al., 2007). For the purposes of this study, SCOPUS was selected as the database, recognized internationally as one of the most reliable and authoritative platforms. Following this query, in accordance with the SLR methodology, a systematic, rigorous, and timely screening process of the sources is undertaken.

Each step of source selection, which progressively narrows the initial pool through the application of exclusion criteria, must be thoroughly justified and documented (Marcos-Pablos & García-Peñalvo, 2018).

In comparison to traditional qualitative research methods, this approach offers several advantages:

- facilitates the systematic selection and review of a large volume of sources (Danese et al., 2018);
- allows for the mapping of sources according to various factors (e.g., topic, research area, geographic context, and research methodology) (Kauppi et al., 2018);
- minimizes the risk of errors in the study (Dada, 2018);
- ensures the replicability of the research through detailed documentation of the source selection process, thereby facilitating the review and ensuring that the research is reproducible by other scholars (Jesson & Lacey, 2006; Nofal, 2018).

As emphasized by Massaro et al. (2016), this specific protocol ensures the scientific rigor of the research and guarantees its replicability.

3.2 Extraction and Sorting Process

The SCOPUS selection string was set on 17/04/2025 by entering the combined search (AND) in the appropriate fields (Title, Abstract, and Keywords) for sources that simultaneously included “Artificial intelligence” or “AI” and “Gender”:

(TITLE-ABS-KEY (Artificial AND intelligence OR AI) AND TITLE-ABS-KEY (Gender))*

This first step of selection generated an initial sample of 6,484 documents. Subsequently, we initiated the screening process to refine the search and align it more closely with our research objectives.

Specifically, we:

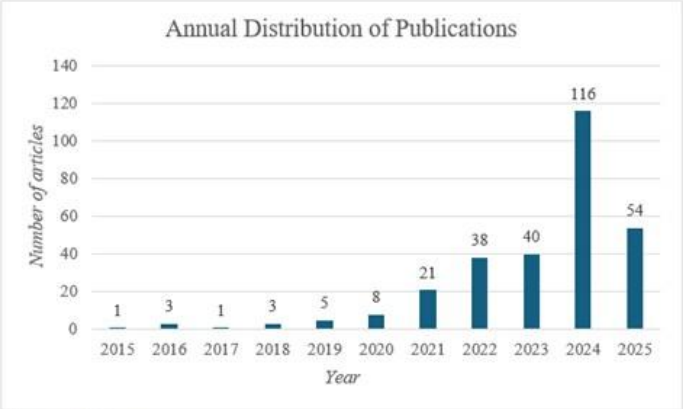
- limited the publication years from “2015” to “2025” (new total: 5,646 sources);
- filtered the areas of interest of the sources to "Business, Management and Accounting" (new total: 379 sources);

- considered only the categories “Article”, “Book Chapter” (new total: 290 sources);
- included all open access sources, as well all that were written in English (total: 290 sources).

In conclusion, following the screening process outlined above, the search string was completed as follows:

AND PUBYEAR > 2015 AND PUBYEAR < 2025 AND (LIMIT-TO (SUBJAREA, “BUSI”) OR LIMIT-TO (SUBJAREA, “ECON”)) AND (LIMIT-TO (DOCTYPE, “ar”) OR LIMIT-TO (DOCTYPE, “ch”)) AND (LIMIT-TO (LANGUAGE, “English”))

The resulting sample was subsequently processed through bibliometric analysis.



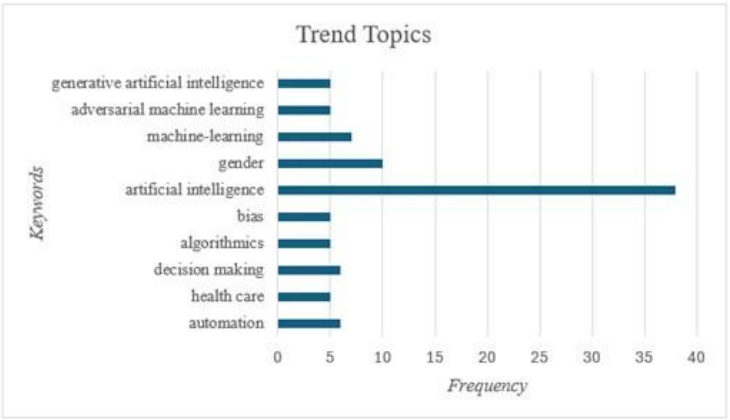
3.3 Bibliometric analysis

As a data processing tool, we employed the *Biblioshiny* package within the *R-Studio* program, known for its accurate and robust capabilities in analyzing academic sources (Derviş, 2019). Bibliometric analysis is widely recognized as one of the most efficient tools for assessing the state of the art regarding the academic dissemination of a specific topic (or the relationship between topics, as in our case) at the time of data extraction (Xie et al., 2020). Consequently, many scholars have leveraged bibliometric analysis enhanced by *Biblioshiny* in conjunction with SLR (Linnenluecke et al., 2020; Donthu et al., 2021). To implement this process, we followed the traditional coding procedure outlined by *Biblioshiny* (Derviş, 2019). Initially, we exported the 290 sources under analysis (filtered as detailed in the previous subsection) into a “BibTex” file. Subsequently, by directly inputting the coding string in *R-Studio*, we activated the *Biblioshiny* package to upload the file extracted from SCOPUS. Upon completion of the database upload, we were able to initiate the process of extracting the relevant information, which is summarized in the following section.

4 Findings

4.1 Results analysis

The analysis of the results follows a thorough investigation of the database, divided into four sections, which together weave a detailed narrative of the current research dynamics on the topic. Each section represents a key and relevant aspect of the bibliometric analysis, ranging from publication frequency to geographical distribution, from predominant keywords, providing a holistic view of the ongoing trends. Following the presentation of the results, the conclusions are drawn in section 5.



Source: Authors

Fig. 1 – Annual Distribution of Publications

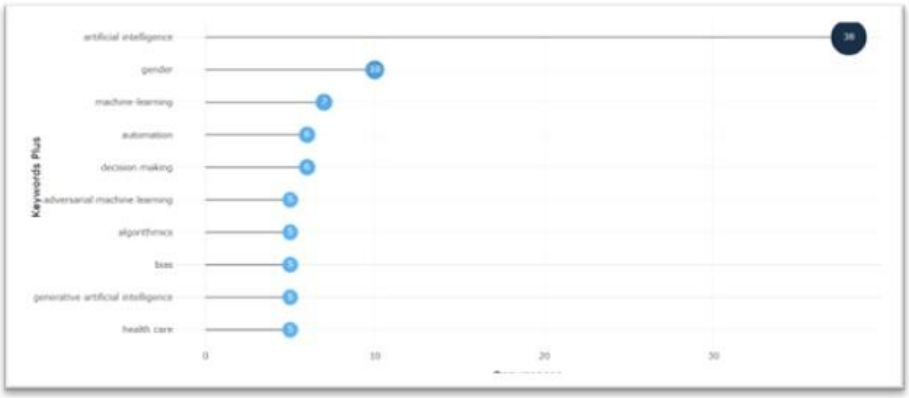
Figure 1 is the result of the bibliometric analysis from the dataset described in subsection 3.1, illustrating the annual distribution of publications in the period 2015-2025. This reference period serves the purpose of gaining awareness of the recent literature published on the topic.

The graph presents the total number of publications (290), providing an immediate visualization of the volume of research developed over time. This representation is essential for identifying trends, peaks in productivity or potential gaps over time. Moreover, such analysis is crucial for understanding the trajectory of research over time, which may reflect changes in priorities concerning areas of interest.

Source: Authors

Fig. 2 – Trend Topics

Figure 2 illustrates an analysis of trendy topics based on frequent keywords in the publications included in the dataset. Prior to analysis, keywords were extracted and subjected to a normalization process involving the removal of punctuation and the conversion of all terms to lowercase, in order to ensure lexical uniformity (Bales et al., 2020). As emphasized by Bales et al. (2020), lowercasing is a standard procedure in the preprocessing of textual data for bibliometric studies, particularly when the objective is to conduct frequency counts or detect consistent patterns. This step is essential to prevent semantically identical terms from being treated as distinct due to typographic inconsistencies. Subsequently, word frequency counts were performed to identify the most recurrent terms. These terms were then visualized using a horizontal bar chart, designed to present the relative frequency of each keyword across the dataset. The extraction and visualization of the most frequent keywords also provide significant insights into the predominant themes and areas of interest within the field of study. This analysis is crucial for understanding the current focus of research and for identifying potential thematic gaps that could be explored in future studies. The lexical choices made in the scientific publications represent a crucial dimension of bibliometric inquiry. Authors typically select terms with strategic intent, aiming to enhance the visibility and thematic clarity of their work. Such terms are carefully chosen to encapsulate the core content of the research, with the dual aim of attracting the attention of peers within the same disciplinary domain and engaging a broader scholarly readership.



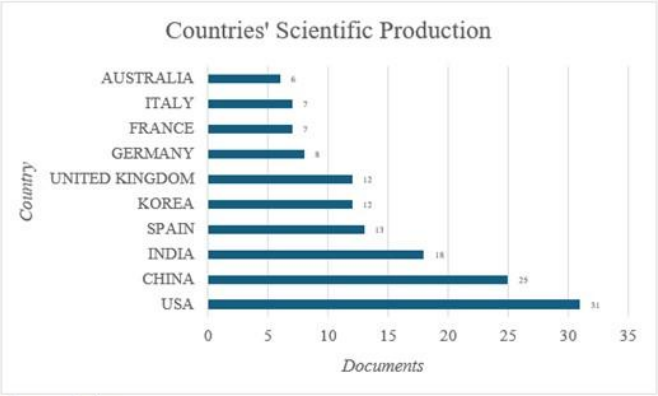


Fig. 3 – Keyword Frequency Analysis
Source: Authors

Following the analysis of trend topics, attention was directed to the study of keywords. This aspect is also central to bibliometric analysis, as it reveals the priorities and directions of current research, highlighting the themes that attract the greatest interest within the academic community. Keywords represent the terms deliberately chosen by authors to highlight the core elements and thematic focus of their research work. These descriptors are commonly employed to concisely summarize the content of scholarly articles and play a critical role in indexing and retrieval within academic databases. By facilitating the discovery of relevant literature, keywords support researchers in navigating the scientific landscape and enable the identification of thematic trends across various disciplines. In the context of a literature review, analyzing the most frequently occurring

keywords allows for the mapping of the current research landscape, shedding light on the topics that dominate scholarly discourse as well as those that may warrant further investigation. The extraction and visualization of keywords, as illustrated in Figure 3, serve not only to identify prevailing research trends, but also to reveal the interplay between different domains of inquiry and their degree of interconnection.

Source: Authors

Fig. 4 – Countries' Scientific Production

Figure 4, as the final object of analysis, represents the geographical distribution of the publications, based on the number of documents attributed to each country. To create this chart, data related to the scientific output of each country was extracted from the dataset. A horizontal bar chart was then constructed to show the number of publications associated with each nation. This type of extraction highlights which countries contribute the most to the body of literature under review. In summary, Figure 4 is useful for understanding how research spreads and is globally received.

5 Discussion and Conclusions

The bibliometric analysis offers a multidimensional view of the research landscape on the relationship between “Artificial Intelligence” and “Gender equality”, highlighting key themes, publication trends, and global contributions. From 2022 to 2024, there was a notable surge in publications (Figure 1), likely driven by growing interdisciplinary interest in the ethical and social implications of AI, influenced by cultural events, policy initiatives, and increasing awareness of algorithmic bias. The analysis reveals that “artificial intelligence” and “gender” are central themes – identified initially in Figure 2 and subsequently confirmed in Figure 3 – reflecting concerns about ethics, inclusivity, and the societal impact of emerging technologies. In particular, the increasing attention to AI indicates the urgency to develop ethical and accountable frameworks. Similarly, the recurring focus on gender suggests increased scholarly attention to how technology can reproduce social inequalities, calling for inclusive design practices. Geographically, the major contributions come from the United States and United Kingdom (Figure 4), reflecting their well-established research infrastructures and substantial investments in scientific innovation. However, countries like China are emerging as key players, signaling a pluralistic and inclusive nature of scientific inquiry in a global context characterized by constant evolution and interconnectedness.

The literature review highlights the recurring presence of themes related to artificial intelligence and gender equality, emphasizing their strategic relevance in the contemporary scientific debate. In particular, artificial intelligence is increasingly examined in relation to gender rebalancing dynamics. These findings allow for the development of well-founded responses to the research questions posed.

RQ1. Is AI perceived merely as a supportive tool or as a new member of the corporate team?

AI replicates human cognitive functions through technologies like machine learning, deep learning, neural networks and robotic automation, enabling adaptation and learning across sectors (Davenport, 2018; Haenlein & Kaplan, 2019; Dwivedi et al., 2021). While some authors view AI as a powerful tool under human control (Brynjolfsson & McAfee, 2014), others envision it as a collaborative partner in creative and decision-making processes (Vallor, 2018). This reflects broader debates on technology’s role in human work.

RQ2. Given that AI is a "cognitive" system, does it inherently incorporate gender biases?

The systematic review of the literature indicates that, in addition to the word “artificial intelligence”, the terms “gender” and “bias” appear with high frequency, suggesting a significant interconnection between these themes in the current scientific discourse. The deployment of AI in the workplace offers significant potential to

improve gender equity, yet it also carries the risk of reinforcing existing gender biases (Wajcman et al., 2020). Research highlights that without explicit diversity and inclusion principles, AI systems may perpetuate or even amplify gender biases present in training datasets (Buolamwini & Gebru, 2018; Manresa-Yee et al., 2019). Despite efforts to mitigate these biases through data pre-processing and algorithmic adjustments (Ferrara, 2024), addressing bias remains a critical challenge. AI systems reflect societal and historical inequalities, and, as such, they may inadvertently reproduce them unless carefully managed (Crawford, 2016; Benjamin, 2019).

RQ3. How does AI adoption affect the distribution of STEM skills?

Statistical evidence continues to show a persistent gender gap in STEM fields, with men dominating both technical and leadership roles. The wider adoption of AI may exacerbate these disparities, particularly if its development remains male-centric (European Commission, 2024). This underrepresentation of women in STEM is linked to gender bias in AI systems (Ceci et al., 2009; Wajcman et al., 2020), which may perpetuate existing power imbalances. Scholars like Schiebinger (2021) and Njoto et al. (2022) highlight how male-dominated environments influence AI design, potentially marginalizing women's perspectives. Without inclusive design, AI risks reinforcing gendered workplace cultures and structural barriers limiting women's participation (O'Connor & Llu, 2023).

In this regard, the findings of this review offer a conceptual framework that systematizes the most relevant themes emerging at the intersection of AI and gender, thus offering a structured basis for future scholarly inquiry. On a practical level, it provides policymakers, organizations, and developers with a valuable perspective to critically reflect on the societal relevance of these issues, fostering more inclusive and ethically grounded approaches to the design and implementation of AI technologies.

In conclusion, the limitation of this study is the use of a single database (SCOPUS) for the bibliometric analysis. Future research may overcome this constraint by incorporating additional bibliographic databases.

6 Ethics declaration

Ethical clearance was not required for the research.

7 AI declaration

AI tools were not used for the creation of the paper.

Digital Technologies in the Knowledge Era: Opportunity or Challenge for Female Entrepreneurship?

Pedro Seva-Larrosa[1], Giuseppe Modaffari[2], Francisco García-Lillo[1]
[1]University of Alicante, Alicante, Spain
[2]Saint Camillus International University of Health Sciences, Rome, Italy

Abstract

Throughout history, women have played an active role in entrepreneurship, although their participation has often been invisibilized or restricted by social and legal norms. Today, digitalization and new technologies present significant opportunities to expand women's participation in entrepreneurial activities. However, they can also intensify existing challenges or generate new ones. In this context, it becomes necessary to analyze in depth how digitalization impacts on the specific opportunities and challenges faced by women entrepreneurs. The objective of this paper is to analyze the intersection in research between female entrepreneurship and digitalization. To do so, a comprehensive review of 171 scientific articles published in Web of Science (WoS) between 2010 and 2025 was conducted. The results report the main references in the literature on the nexus between female entrepreneurship and digitization: countries (China, USA, India and the UK), authors (McAdam, Maura from Dublin City University and Kelly, Grainne from Queens University Belfast), papers (Pergelova et al., 2019; McAdam et al., 2020; Ughetto et al., 2020), journals (International Journal of Gender and Entrepreneurship and Small Business Economics). The co-word analysis allowed us to identify seven main thematic fronts: (1) social networks, (2) financing, (3) Covid-19, (4) competitive advantage and internationalization, (5) entrepreneurship ecosystems, (6) education, and (7) miscellaneous topics. Each of these fronts was characterized in terms of the opportunities and challenges posed by digital transformation for female entrepreneurship[1]. The results are of interest to researchers concerned with women's entrepreneurship, policy makers charged with fostering gender-responsive entrepreneurship, and women entrepreneurs as they seek to seize the opportunities and circumvent the challenges posed by digital technologies.

Keywords: Women entrepreneurship, Female entrepreneurship, Digitalization, Artificial intelligence, Systematic literature review

Paper type: Academic Research Paper

1 Introduction

Entrepreneurship is a dynamic and rapidly expanding field of academic research with a long-standing intellectual tradition. It can be explored through various disciplines, functions, contexts, and perspectives. As the field has matured, research has diversified into distinct areas such as social entrepreneurship (De Bernardi et al., 2021; Gali et al., 2020), academic entrepreneurship (Lundqvist & Middleton, 2013; Sciarelli et al., 2021), international entrepreneurship (Martin & Javalgi, 2018; Schwens et al., 2018), entrepreneurial ecosystems (Rocha et al., 2021; Spigel, 2017), family firms entrepreneurship (Stanley et al., 2019; Bettinelli et al., 2017), and female entrepreneurship (Li et al., 2021; Wu & Li, 2020), among others. Likewise, entrepreneurship research has applied different methods of analysis such as multilevel analysis (Aguinis et al., 2011; Audretsch et al., 2019; Hörisch et al., 2017), PLS-SEM (Hernández-Perlines et al., 2016), fuzzy-set QCA (Douglas & Prentice, 2019; Douglas et al., 2020), or bibliometrics (Hota et al., 2020; García-Lillo, et al., 2023).

The growing interest in entrepreneurship, coupled with the increasing participation of women in business and management, has significantly heightened scholarly and policy attention toward women's entrepreneurship in recent years. For example, the European Commission supports women's economic empowerment and entrepreneurial initiatives through targeted programs and digital platforms such as the European online portal WEgate. Academic efforts to examine female entrepreneurship from diverse perspectives have resulted in the emergence of different terms to describe this phenomenon, including women entrepreneurs (Kelly & McAdam, 2023), female entrepreneurship (Skare et al., 2025; Kakeesh, 2024), shepreneurs (Mazhar et al., 2022), fempreneurship (Mishra et al., 2023), womenpreneurs (Dalimunthe et al., 2025; Setyaningrum & Muafi, 2022), entrepreneuring mothers (Vershinina et al., 2022), and mompreneurs (Boufares Tayaa & Bouzaabia, 2022), among others.

This study builds upon the work of García-Lillo et al. (2023), titled *"What is going on in entrepreneurship research? A bibliometric and SNA analysis."* The authors examine the field of entrepreneurship research and

[1] Given the limited length, this version includes a review of the opportunities and challenges of one of the thematic fronts (social media). The final version will include a review of each identified front.

identify sixteen distinct active research fronts, among which female entrepreneurship stands out as one of the most prominent. Their analysis also reveals that one of the most influential contributions in recent entrepreneurship literature is Nambisan's (2017) work on digital entrepreneurship. Although academic research is increasingly focusing on the role of digital technologies in entrepreneurial ecosystems, the gender perspective remains largely underexplored (Ughetto et al., 2020), thereby limiting progress in understanding the intersection between female entrepreneurship and digitalization. In this regard, recent studies such as Miah et al. (2025) have emphasized that digital businesses continue to represent a critical gap in the literature on female entrepreneurship.

Digital technologies have brought about a significant change in how the entrepreneurial process is understood, highlighting the role of digital platforms, artificial intelligence, and virtual ecosystems in the creation and scalability of new businesses. The digital context has not only redefined many traditional business models but has also posed new opportunities and challenges for various entrepreneurial profiles, including women. The convergence between female entrepreneurship and digitization has led to the emergence of new specific terms related to gender perspectives in digital businesses, such as digital women entrepreneurship (Paoloni et al., 2019), digital fempreneurship (Mishra et al., 2023), or female digital entrepreneurship (Alhajri & Aloud, 2024).

Academic literature has highlighted that women entrepreneurs may benefit from using digital technologies in their businesses (Modaffari et al., 2023) or in their entrepreneurial initiatives (Moeini Gharagozloo et al., 2023). In this regard, Wiig et al. (2024) identify four opportunities (virtual networks, online learning, opportunity creation, and scaling) that women use to overcome cultural barriers to entrepreneurship. Meanwhile, Yang et al. (2022) finds that digital financial inclusion significantly promotes women's entrepreneurial behavior. However, they may also face challenges if digitalization and technological change reinforce historically rooted inequalities. For example, Ibrahim and Ismail (2020) find that most training programs fall short in providing the digital and strategic skills necessary for the full participation of women entrepreneurs in the knowledge society.

The objective of this study is to examine the intersection of research on female entrepreneurship and digitalization. To this end, we conducted a comprehensive analysis of 171 articles indexed in the Web of Science (WoS), which enabled us to map the research landscape at this intersection, identify key thematic areas, and outline the opportunities and challenges that women entrepreneurs face within the digital context. Applying a gender lens to the study of entrepreneurship and digitalization enhances our understanding of the entrepreneurial phenomenon from a more inclusive and contemporary standpoint.

2 Methodology

We applied a two-tier analysis consisting of bibliometric and content analyses. The bibliometric techniques employed included productivity by active year of publication, countries, authors, journals, and co-word analysis. Previous studies have used similar methodologies in other fields (Bhatt et al., 2020). For the visualization of bibliometric analyses, we used Bibliometrix, an R-based software package (Aria & Cuccurullo, 2017).

In our case, the application of a two-tier analysis allowed us to:

- First, map the research field by identifying the main referents (countries, authors, documents, and journals) on female entrepreneurship and digitalization.
- Second, identify thematic fronts in research on female entrepreneurship and digitalization.
- Third, structure the main opportunities and challenges posed by digitalization to female entrepreneurship within each of the identified thematic fronts.

The WoS Core Collection database was used to retrieve scientific documents. The choice of this database further underscores the significance of the study's findings, as it is widely recognized by the scientific community as the primary source of high-impact and high-quality publications. The data were extracted on April 10, 2025. Therefore, the data for the final year of the analysis includes publications up to that date.

To avoid discarding relevant knowledge and to provide the broadest possible overview of the field, the search was conducted across three of its editions: Science Citation Index Expanded (SCI-EXPANDED), Social Sciences Citation Index (SSCI), and Emerging Sources Citation Index (ESCI). Moreover, given the multifaceted and interdisciplinary nature of female entrepreneurship and digitalization, publications from all WoS categories were considered.

2.1 Document selection criteria

According to Paul and Criado (2020), there are two popular methods for determining the inclusion/exclusion criteria of documents: one stricter (searching for keywords in the title, abstract, or keywords list of the

documents to review) and another more flexible (searching for keywords in the full text of the documents to review). We opted for the stricter option, as it would allow us to obtain a dataset more focused on the topic, which would then be used for content analysis of the documents.

The search equation applied to the fields “title, abstract, and keywords” for data collection was as follows: "wom* entreprene*" or "fema* entreprene*" AND "digital*" or "digiti*" or "AI" or "artificial intelligence". The initial search yielded a preliminary result of 188 documents. However, it was decided to include only “scientific articles” written in “English,” a common practice in literature reviews, which reduced the dataset to 173 articles.

In bibliometric analyses, it is common for the search equation defined by the researchers to retrieve some records from the databases that do not align with the topic under analysis. Therefore, an individual verification of the articles was carried out, which resulted in the removal of 2 records because they were not directly related to the subject analyzed. Thus, the final dataset for analysis consists of 171 articles published between 2010 and 2025.

Table1. Summary of inclusion/exclusion criteria.

Criteria	Removed documents	Selected documents
Web of Science Core Collection (SSCI, ESCI and SCI-EXPANDED)		188
Articles written in English	15	173
Manual verification	2	171
Final dataset		171

3 Results and discussion

3.1 Evolution of publications on female entrepreneurship and digitization

The descriptive results show that research on the female entrepreneurship-digitalization nexus is relatively recent, with the first paper in our dataset being from 2010. However, starting in 2020, coinciding with the COVID-19 health crisis, there was a growing interest in research in this field (see Figure 1). COVID caused society as a whole to face a major digital challenge, significantly transforming many areas of social and business life to adapt to the new situation. The use of ICTs (Kusumawardhani et al., 2022; Nur et al., 2023), digital transformation (Ibrahimi & Ibrahimi, 2024), resilience (Alhothali & Al-Dajani, 2022; Topcu et al., 2024) or the impact of the COVID-19 pandemic on women-led businesses (Mustafa et al., 2021; Ibrahimi & Ibrahimi, 2024) quickly emerged as topics of interest among researchers.

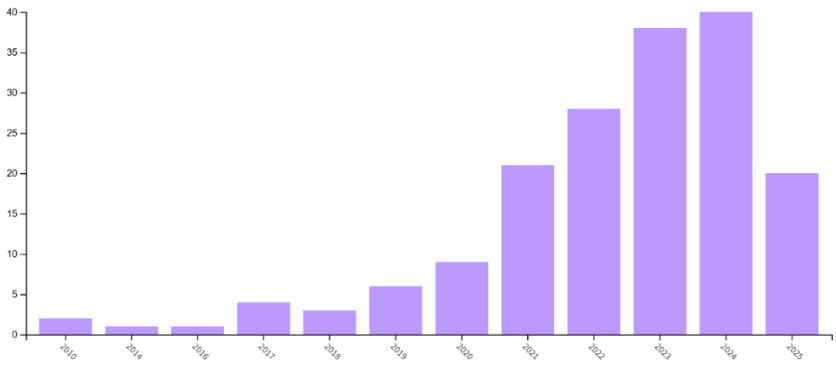

Figure 1. Evolution of publications on female entrepreneurship and digitalization.

3.2 Main referents in research on female entrepreneurship and digitalization

This section summarizes the main referents (countries, authors, papers and journals) in research on female entrepreneurship and digitization.

The bibliometric results reveal a significant concentration of scientific production on female entrepreneurship and digitization in countries such as China (12.5%), the USA (9.6%), India (8.6%) and the United Kingdom (7.6%) (see Figure 2). This leadership may be linked both to the research capacity of these countries and to their leading role in technological development and/or the promotion of inclusion policies. The differences in their regulatory frameworks, sociocultural contexts and public policies do not reflect a

homogeneous commitment to gender equality, which in many cases determines the focus of the studies conducted.

In the case of the United Kingdom and the United States, for example, there are consolidated policies to support female entrepreneurship, accompanied by specific initiatives in the technological field, such as funding programs, accelerators and mentoring networks with a gender focus, which could explain a more applied and multidisciplinary orientation in the research. On the other hand, although China leads in volume of publications, gender equality policies are more centralized and often less oriented to the intersection between gender and technology. In India, despite legislative advances, structural and cultural barriers continue to limit women's access to digital and financial resources.

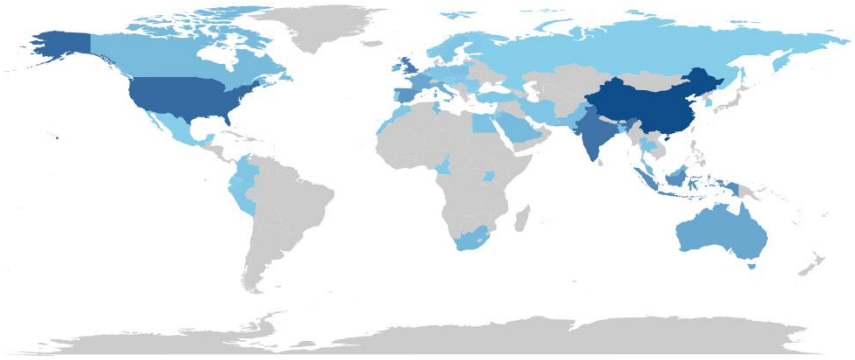

Figure 2. Scientific production by country.

The most prolific author in the research on female entrepreneurship and digitization is McAdam, Maura from Dublin City University (Ireland), who has published six articles and is also the most cited author for the set of documents analyzed. This author is followed in number of publications by Kelly, Grainne from Queens Univiversity Belfast (North Ireland), who has published three articles co-authored with McAdam. Huang, Yangjie from Hangzhou Normal University (China) and Setyaningrum, Retno Purwani from University Pelita Bangsa (Indonesia) have also authored three papers each on the topic analyzed.

The most influential documents are those by Pergelova et al. (2019) titled *"Democratizing entrepreneurship? Digital technologies and the internationalization of female-led SMEs"*, McAdam et al. (2020) titled *"Digital girl: Cyberfeminism and the emancipatory potential of digital entrepreneurship in emerging economies"*, and Ughetto et al. (2020) titled *"Female entrepreneurship in the digital era"*. All three articles were published in the journal *Small Business Economics*. Regarding publication frequency (see Table 2), International Journal of Gender and Entrepreneurship published the most (9 articles), followed by Small Business Economics (6), Sustainability (6), and Entrepreneurship and Regional Development (4).

Table 2. Publication frequency by journal

Journal title	Articles (No)	Articles (%)
International Journal of Gender and Entrepreneurship	9	5.2
Small Business Economics	6	3.5
Sustainability	6	3.5
Entrepreneurship and Regional Development	4	2.3
Journal of Entrepreneurship in Emerging Economies	3	1.7
Journal of Sustainable Tourism	3	1.7
Administrative Sciences	2	1.2
Asia & the Pacific Policy Studies	2	1.2
Cities	2	1.2
Cogent Business & Management	2	1.2

3.3 Thematic fronts identified at the intersection between female entrepreneurship and digitization

This section identifies and characterizes the main thematic fronts in research on female entrepreneurship and digitalization. The analysis identifies seven thematic fronts: (1) social media, (2) financing, (3) Covid-19, (4) competitive advantage and internationalization; (5) entrepreneurship ecosystems; (6) education and, (7) miscellaneous. The in-depth analysis of the analyzed papers has allowed us to characterize each front attending to the main opportunities and challenges faced by female entrepreneurship in the current digital context.

3.3.1 Thematic front 1: Social media

The largest thematic front is made up by 22 articles on female entrepreneurship and social networks. The papers focus on topics such as digital platforms (Mishra et al., 2023), Facebook (Camacho & Barrios, 2022; Ditta-Apichai et al., 2024), Instagram (Ramli & Razak, 2023; Heizmann & Liu, 2022; Baulch & Pramiyanti, 2018; Boufares Tayaa & Bouzaabia, 2022), culture (Al-Boinin et al., 2025), psychological empowerment (Chakraborty & Biswal, 2023), marketing strategies (Jiménez-Zarco et al., 2021), or social performance (Aracil-Jordá et al., 2023; Kuran & Khabbaz, 2025).

Low technological barriers to entry mean that social networks and digital platforms serve as a cradle for female entrepreneurship (Kang, 2022), offering women new routes to entrepreneurship (Mishra et al., 2023) and connections to digital mentors (Lall et al., 2023). In fact, 95% of women entrepreneurs surveyed in Egypt by Miniesy et al. (2022) stated that they would not have started their businesses without social networks. In some cases, entrepreneurship begins simply by transforming spaces they previously used for entertainment, such as Facebook, into business platforms (Camacho & Barrios, 2022).

Among the most prominent opportunities of social networks for female entrepreneurship are personal and relational empowerment (Miniesy et al., 2022), overcoming cultural barriers (Al-Boinin et al., 2025; Kong et al., 2024), keeping up with digitalization (Olsson & Bernhard, 2021), or expanding their economic and social space (Steel, 2017). According to Hammad and El Naggar (2023), online social capital helps women entrepreneurs develop skills and access resources needed to identify and exploit entrepreneurial opportunities. Regarding business management, social networks facilitate the promotion and expansion of their businesses (Olsson & Bernhard, 2021), improve brand visibility (Chakraborty & Biswal, 2023) and communication with customers (Mack et al., 2017). According to Chakraborty and Biswal (2023) platforms such as Instagram, Pinterest and TikTok are particularly effective to showcase products visually and engage directly with customers. Moreover, social media marketing actions have significant effects on both financial (Jimenez-Zarco et al., 2021) and social performance of women-led microenterprises (Kuran & Khabbaz, 2025).

One of the main challenges faced by women entrepreneurs in their entrepreneurship through social networks or digital platforms is the gap in knowledge and effective use of them, since it could limit their potential (Olsson & Bernhard, 2021). Effective implementation of these technologies requires technical skills that may not be available to all women entrepreneurs (Kuran & Khabbaz, 2025), especially in domains that require advanced technological skills (Kang, 2022). According to Kong et al. (2024) there are gender-differentiated effects in accessing and benefiting from these platforms, which could perpetuate existing inequalities. Also, cultural constraints and physical mobility in certain regions of the world may influence women's adoption, use and exploitation of social networks for business purposes (Al-Boinin et al., 2025; Mishra et al., 2023), as well as limit the expansion of their businesses beyond the domestic environment (Steel, 2017).

On the other hand, rapid technological evolution requires constant adaptation by women entrepreneurs (Mack et al., 2017), maintaining high quality standards in competitive digital environments (Roy Dutta, 2025), and building and maintaining effective online social capital (Hammad & El Naggar, 2023), which can be a constant challenge, especially for inexperienced entrepreneurs (Hammad & El Naggar, 2023). In addition, reliance on social networks may limit the visibility of certain content due to algorithms and platform policies (Grubnic, 2023).

3.3.2 Thematic front 2: Financing

This front is composed of 20 papers that direct research towards the role of finance in female entrepreneurship. The papers focus on topics such as loans (Yadav et al., 2024), capital funds (Coleman et al., 2019), digital financial inclusion (Yang et al., 2022; Hasan et al., 2023; Shao et al., 2023; Liu et al., 2022), digital financial literacy (Desai et al., 2025; Peter et al., 2025), financial behavior (Peter et al., 2024), financial innovation (Anggraini et al., 2024), BigTech (Sun & Xie, 2024), FinTech (Guo et al., 2021), financial bootstrapping (Alhammadi & Rahman, 2025; Rita & Nastiti, 2024), digital microfinance (Kromidha et al., 2023; Wulandari & Hj. Kassim, 2024), crowdfunding (Xie et al., 2024; Wang et al., 2023; Wang et at., 2022) and mobile money (Islam & Muzi, 2022).

3.3.3 Thematic front 3: Coronavirus

This front consists of 11 articles that focuses its attention on the COVID-19 pandemic and how digitalization has impacted female entrepreneurs in different countries such as Pakistan (Mustafa et al., 2021), Turkey (Topcu et al., 2024), Indonesia (Nur Asrofi et al., 2023; Kusumawardhani et al., 2022), Saudi Arabia (Alhothali & Al-Dajani, 2022), India (Chakraborty & Garg, 2024), Bangladesh (Khondker & Pettinotti, 2024), Kosovo (Ibrahimi & Ibrahimi, 2024), or across countries (Sörensson & Ghannad, 2024; Ben Romdhane & Elamine, 2024; Torres et al., 2023).

3.3.4 Thematic front 4: Competitive advantage and internationalization

This front is formed by 9 articles addressing organizational and strategic aspects of female entrepreneurship. Specifically, the papers by Dalimunthe et al. (2025), Setyaningrum and Muafi (2022), Dalimunthe et al. (2024) and, Abdelhalee and Farah (2023) focus their attention on the development of competitive advantages. While Tanti et al. (2021), Steel (2021), Anggadwita and Indarti (2025), Pergelova et al. (2019) and, Mondal and Sinha (2025) analyze the internationalization of women-led firms.

3.3.5 Thematic front 5: Entrepreneurship ecosystems

This front brings together the articles by Kakeesh (2024), Mamabolo and Lekoko (2021), Xie et al. (2021), Huang et al. (2025) and Mouazen and Hernandez-Lara (2023). All these papers integrate entrepreneurial ecosystems in the analysis of female entrepreneurship and digitization.

3.3.6 Thematic front 6: Education

This front brings together the articles by Feng and Sumettikoon (2022), Molina-López et al. (2021), Flores-Bañuelos et al. (2023), Orser et al. (2019) and, Feng and Sumettikoon (2023). All these papers address the phenomenon of female entrepreneurship education.

3.3.7 Thematic front 7: Miscellaneous

Finally, in addition to the main themes, other less prominent topics have also attracted the attention of researchers studying female entrepreneurship and digitization. These include the possibility of developing digital social capital (Urban & Moetse, 2024; Ratten, 2024; Hammad & El Naggar, 2023), women-owned start-ups (Schillo & Ebrahimi, 2022; Swartz et al., 2022; Torres Mancera et al., 2023; Mets & Vettik-Leemet, 2024), artificial intelligence (Kuran & Khabbaz, 2025; Rožman & Tominc, 2024), e-commerce (Setyaningrum & Muafi, 2023; Hasan et al., 2022; Harini et al., 2025; Yu & Cui, 2019), business performance (Hashim et al., 2024; Huang et al., 2025; Hadiyati et al., 2024) sustainability (Kimuli et al., 2022; Belas et al., 2025) or the role of institutions in female entrepreneurship (Sarpong et al., 2022; Althalathini & Tlaiss, 2023; Johnson & Mehta, 2024; McAdam et al., 2019; Jiao et al., 2022).

Although artificial intelligence (AI) plays an increasingly important role in business and management, it remains largely absent from the literature on female entrepreneurship. Only two articles in the dataset explore the potential impact of AI on female entrepreneurship (Rožman & Tominc, 2024; Kuran & Khabbaz, 2025).

4 Conclusions

The present study performs a bibliometric review and content analysis, identifying seven thematic fronts in the literature on female entrepreneurship and digitization: (1) social media, (2) financing, (3) COVID-19, (4) competitive advantage and internationalization, (5) entrepreneurship ecosystems, (6) education, and (7) miscellaneous. The content analysis has allowed us to structure the opportunities and challenges faced by female entrepreneurs across the different thematic areas.

5 Ethics declaration

The authors did not require ethical clearance for the development of the work.

6 AI declaration

The authors did not use artificial intelligence tools for the development of the work.

Digital Transformation and Gender Equality in Public Administration: An Analysis of NRRP Policies and Implementation

Alessandro Galli
Sapienza University of Rome, Rome, Italy

Abstract

Digital transformation is reshaping how public administrations operate, with artificial intelligence and emerging technologies playing a growing role in the management and delivery of public services. The National Recovery and Resilience Plan (NRRP) offers a strategic opportunity to modernize the Italian Public Administration (PA) and to foster more equitable and inclusive access to digital resources. However, administrative digitalization alone does not automatically ensure the overcoming of gender disparities. Without deliberate inclusion strategies, technological innovations risk reinforcing existing inequalities. This study analyzes the extent to which the NRRP, specifically through Mission 1, Component 1 (M1C1), has integrated gender equity objectives into PA digitalization initiatives. Adopting a qualitative content analysis (QCA) approach, this research examines a sample of ten Public Calls for Proposals issued by the Presidency of the Council of Ministers – Department for Digital Transformation (PCM-DTD) portal and manually coded based on two analytical dimensions: (1) compliance with NRRP horizontal principles, and (2) adherence to EU legal obligations on gender equality. Special attention was paid to the use of gender-aware language, objectives, and evaluation mechanisms.

The analysis reveals that all ten calls formally acknowledge gender equality in line with the NRRP's horizontal principles. However, such references are typically generic and are not translated into concrete requirements or measurable criteria. The reviewed calls lack any form of operationalization, such as gender-disaggregated indicators or structured evaluation mechanisms. Furthermore, binding EU legal provisions on gender equality are merely mentioned, without detailed elaboration or integration into project evaluation frameworks. This superficial treatment limits the enforceability of equity commitments and reflects a broader institutional gap between legal mandates and their practical implementation in the digitalization of the public sector. This study offers a novel contribution to the literature on public sector innovation by introducing a gender-sensitive perspective into the analysis of digital transformation policies. It critically reflects on the risks of procedural formalism and emphasizes the need to embed gender equality principles more deeply into digital public investments. The findings provide actionable insights for policymakers aiming to leverage technological innovation as a true vector for social inclusion and equity. The study is limited by its qualitative nature and the small sample size focused solely on Italian cases. Moreover, the analysis is restricted to document-based data without empirical validation through project outcomes or stakeholder feedback. Future research should integrate quantitative measures and fieldwork to assess the real-world impact of digital transformation initiatives on gender inclusion and explore comparative studies across different EU contexts.

Keywords: NRRP, Digital Transformation, Public Administration, Gender Equality, Public Funding, Inclusive Governance

Paper type: Academic Research Paper

1 Introduction

In the aftermath of the COVID-19 pandemic, Italy, in alignment with other European Union member states, embarked on an unprecedented effort of economic, social, and institutional revitalization through the formulation of the National Recovery and Resilience Plan (NRRP). The NRRP represents the Italian implementation of the broader Next Generation EU program, a temporary recovery instrument launched by the European Commission in 2020 to counteract the socio-economic consequences of the pandemic and to promote structural reforms toward a more sustainable and resilient European economy (Presidenza del Consiglio dei Ministri, 2025).

Valued at approximately €191.5 billion, the Italian NRRP is one of the most substantial plans among EU member states, structured around three overarching strategic axes: digitalization and innovation, ecological transition, and social inclusion (Presidenza del Consiglio dei Ministri, 2021). Its ambition is not limited to economic recovery but aims to reshape the developmental model of the country, addressing longstanding structural weaknesses such as low productivity, high youth and female unemployment, limited digitalization in both public and private sectors, and persistent regional inequalities (Consiglio dell'Unione Europea, 2021).

The NRRP articulates its objectives through six Missions, each representing a cluster of investment and reform interventions. Among these, Mission 1: Digitalization, Innovation, Competitiveness, Culture and Tourism occupies a central position, absorbing a significant share of the allocated resources (over €40 billion). Within this

Mission, Component 1 (M1C1) specifically targets the digital transformation of the Public Administration (PA). This includes investments in digital infrastructures, the promotion of interoperability and data sharing across public bodies, the strengthening of cybersecurity systems and digital identities, the adoption of emerging technologies such as artificial intelligence (AI), big data analytics, and blockchain solutions to improve public service delivery, and the implementation of open data initiatives to foster transparency and civic engagement (Presidenza del Consiglio dei Ministri, 2025).

The modernization of PA, thus, is conceived not merely as a technological upgrade but as a strategic transformation capable of generating broader socio-economic benefits, reducing administrative burdens, enhancing transparency and accountability, stimulating citizen participation, and supporting inclusive economic growth (Binder & Frankenhauser, 2024; Ray et al., 2025).

Nonetheless, it is now widely recognized that digital transformation processes are not inherently neutral. As recent research highlights, if technological innovation is pursued without explicit attention to inclusion dynamics, it risks amplifying existing social divides rather than bridging them (UNDP & University of Pittsburgh, 2021; OECD, 2023). Digitalization can create new forms of exclusion, particularly disadvantaging social groups historically underrepresented in the digital economy, including women, youth, and marginalized communities.

Gender disparities emerge as a persistent challenge: women remain underrepresented in leadership positions within public administrations, face gaps in digital literacy and access to technological resources and encounter systemic barriers to participating fully in innovation-driven sectors (Paoloni & Demartini, 2016; EIGE, 2020). Without proactive corrective measures, the digital revolution within the PA could therefore replicate or even exacerbate structural gender inequalities, rather than mitigating them. In this perspective, the NRRP should not be viewed solely as a catalyst for technological advancement, but also as a strategic lever to promote gender equality and foster more inclusive models of governance. Integrating a gender-sensitive perspective into digitalization policies is crucial to ensure that public innovation serves as a vector for equity, social cohesion, and empowerment (OECD, 2023; UNIDO, 2025).

However, despite this transformative potential, an initial review of the available literature suggests that the degree to which gender objectives have been concretely embedded within NRRP-funded digitalization initiatives remains limited and fragmented. Academic and policy-oriented analyses have predominantly focused on aspects such as process efficiency, technological advancement, and organizational innovation (Sørensen & Torfing, 2011; Bencivenga et al., 2021), whereas the equity dimension, particularly with regard to gender inclusion, has received scarce and marginal attention (Paoloni et al., 2023). To address this research gap, this study poses the following question:

- *RQ: To what extent has the NRRP integrated gender equity objectives within the digital transformation initiatives of the Italian Public Administration?*

This study employs a qualitative content analysis methodology, focusing on Component 1 of Mission 1 (M1C1) of the NRRP. Specifically, it examines a sample of ten Public Call for Proposals published by the Presidency of the Council of Ministers – Department for Digital Transformation (PCM-DTD). By systematically analyzing references to gender inclusion, the research investigates how digital innovation projects address or overlook the promotion of women's participation and leadership in the public sector.

Preliminary findings suggest that while gender equality is consistently referenced as a guiding principle within the analyzed funding calls, these references are not accompanied by concrete mechanisms such as evaluative criteria, measurable indicators, or enforceable obligations. This limited operationalization signals a superficial integration of gender equity goals and may constrain the potential of digital transformation to support truly inclusive and equitable public governance. The theoretical contribution of this research lies in enriching the debate on public sector innovation by introducing a gender-sensitive lens. Practically, the findings provide actionable insights for policymakers and public managers committed to ensuring that the digital revolution in government translates into a more inclusive, diverse, and equitable public administration.

The study acknowledges several limitations, primarily related to the qualitative nature of the analysis and the exclusive reliance on document-based data. Future research should complement these findings with quantitative assessments and stakeholder interviews to capture the real-world impact of digital inclusion policies.

The paper is structured as follows: Section 2 reviews the relevant literature on digital transformation, public governance, and gender equity. Section 3 outlines the research methodology. Section 4 presents the findings of the analysis. Section 5 discusses the implications and contributions of the study. Section 6 highlights the limitations and proposes directions for future research.

2 Literature Review

The digital transformation of public administration (PA) is widely regarded as a strategic lever for enhancing efficiency, transparency, and accessibility in public service delivery. However, this transformation is not inherently gender-neutral. If not carefully designed and implemented, digitalization processes may inadvertently reinforce existing structural inequalities, particularly those related to gender.

The Organization for Economic Co-operation and Development (OECD) stresses that while digital transformation presents new opportunities for women's empowerment and economic participation, systemic challenges such as socio-cultural barriers, stereotyping, and discrimination continue to hinder equitable access and inclusion (OECD, 2023). Similarly, the United Nations Development Programme (UNDP) underscores the necessity of inclusive digital strategies that are co-designed with women and marginalized groups, emphasizing the need for gender-responsive approaches to digital literacy, access, and governance (UNDP & University of Pittsburgh, 2021).

Digital Public Infrastructure (DPI) has emerged as a promising tool for promoting inclusive public services, enabling real-time access to administrative processes and reducing transactional costs for citizens. However, if DPI is not intentionally designed to address digital gender gaps, such as unequal access to connectivity, devices, or digital skills, it risks excluding women and exacerbating existing forms of marginalization (Binder & Frankenhauser, 2024).

The European Institute for Gender Equality (EIGE) reports that women continue to be underrepresented in digital employment and innovation fields, and that significant disparities persist in digital skills acquisition and participation in STEM education. Its 2020 Gender Equality Index notes that without direct action to mitigate such disparities, digitalization could further disadvantage women in the future labor market (EIGE, 2020).

UN Women further argues that structural gender inequalities in access to technology, finance, and decision-making power must be systematically addressed in all phases of digital governance. Without this integration, digital transformation could consolidate male-dominated power structures and perpetuate inequalities in access to innovation resources, leadership opportunities, and public visibility (UN Women, 2024). Recent academic literature has also examined the intersection between emerging technologies and gender equality, pointing out both the opportunities and the risks posed by artificial intelligence (AI), big data, and algorithmic decision-making in public administration. While AI can optimize workflows and enhance evidence-based decision-making, it can also replicate and scale gender biases embedded in training data or system design. For this reason, the implementation of AI in the public sector must be accompanied by critical audits, inclusive data governance, and gender-aware algorithmic transparency (Nwafor et al., 2025).

The World Bank highlights the importance of closing gender gaps in digital development by investing in digital inclusion strategies, targeted training for women and girls, and metrics to evaluate progress toward gender equity in digital policy. According to the 2023 report, without institutional accountability, well-intentioned digital reforms may fail to yield equitable outcomes (World Bank, 2023).

In parallel, the literature on public finance and gender equality stresses the relevance of integrating gender perspectives in budgetary processes. Gender-responsive budgeting has become a widely adopted tool among OECD countries, supported by methodological frameworks that link resource allocation with the promotion of gender equity goals (OECD, 2023). A 2025 European Parliament briefing confirms that several Member States have incorporated gender impact assessments into their national recovery plans, yet challenges remain in ensuring consistent application and evaluation (European Parliament, 2025). Despite these advances, implementation is often hindered by limited administrative capacity, particularly at the local level. Smaller public entities face difficulties in meeting complex reporting requirements and developing inclusive digital projects due to resource constraints (OECD, 2023).

This limits the effectiveness of equity-related measures and hampers broader participation.

Taken together, these contributions demonstrate that the digital transformation of PA must be grounded in equity-centered governance frameworks. It is not enough to adopt new technologies; policymakers must embed inclusive values into the design, implementation, and evaluation of digital public services to ensure that innovation becomes a tool for empowerment, not exclusion.

3 Methodology

This study adopts a qualitative content analysis (QCA) methodology to investigate the extent to which gender equity principles are integrated into digital transformation measures under the National Recovery and Resilience Plan (NRRP), with specific reference to Mission 1, Component 1 (M1C1). This component, managed by the Presidency of the Council of Ministers – Department for Digital Transformation (PCM-DTD), focuses on the modernization and digitalization of the Italian Public Administration (PA). The QCA approach is particularly well-

suited to examining regulatory and policy-oriented documents, as it enables the extraction, categorization, and interpretation of key references through a structured analytical framework (Elo & Kyngäs, 2008; Schreier, 2012).

The empirical analysis is based on a purposive sample of ten Public Call for Proposals retrieved from the official website of the PCM-DTD. These notices represent funding instruments through which M1C1 operationalizes its digitalization goals and allocates resources to implementing bodies. Each call is analyzed manually and coded according to two primary dimensions, which reflect the formal obligations and equity-related requirements imposed by the NRRP framework and EU law.

The first analytical dimension concerns the compliance of project implementation with the overarching principles of the NRRP. This includes alignment with horizontal criteria such as climate and digital tagging, youth empowerment, and gender equality. These elements are among the eligibility conditions required for funding applications and for public actors serving as implementing entities. Special attention is paid to whether gender equality is treated merely as a formal requirement or as a strategic objective embedded within project design and evaluation.

The second analytical dimension examines the duty of implementing bodies to respect gender equality in line with binding legal provisions. Specifically, this entails adherence to the principles enshrined in Articles 2 and 3(3) of the Treaty on European Union (TUE), Articles 8, 10, 19, and 157 of the Treaty on the Functioning of the European Union (TFEU), and Articles 21 and 23 of the Charter of Fundamental Rights of the European Union (European Union, 2016). These provisions collectively mandate the elimination of discrimination, the promotion of equal treatment in employment and decision-making, and the adoption of gender-sensitive governance practices across all public policies.

Special attention is given to the extent to which gender-aware language, objectives, and monitoring criteria are explicitly incorporated into funding calls and project evaluation mechanisms. Given the complexity and variability of these policies, a manual coding system was preferred over automated text-processing methods, as it allows for greater interpretative flexibility and ensures that semantic nuances related to gender policies are preserved (Mayring, 2014). By avoiding distortions often introduced by algorithmic text analysis, this approach enables a more accurate identification of critical gaps in gender reporting and compliance with equity principles (Schreier, 2012).

The coding process follows a deductive logic, grounded in preliminary document screening and informed by relevant EU and national regulations. The manual categorization allows for the identification of how gender equity is articulated within the funding criteria, evaluation frameworks, and implementation procedures of the selected announcements. This approach enables the detection of both explicit references to gender equality and implicit institutional mechanisms that may influence the inclusiveness of digital transformation projects (Schreier, 2012; Mayring, 2014).

Given the limited number of analyzed documents and the exploratory nature of the research, the study does not aim to provide generalizable conclusions. Instead, it offers a detailed and structured understanding of how gender equity is addressed in a sample of investment notices under M1C1. The results aim to contribute to ongoing policy discussions and scholarly debates on inclusive digital governance by highlighting gaps, good practices, and potential areas for regulatory and institutional improvement.

4 Findings

This section presents the results of the qualitative content analysis conducted on the ten public call for proposals published by the Presidency of the Council of Ministers – Department for Digital Transformation (PCM-DTD) under Mission 1, Component 1 (M1C1) of the NRRP.

Figure 1 illustrates the main features of the ten calls for proposals, highlighting the year of publication, financial allocation, and the extent to which gender equality references and operational indicators are present.

Public Call for Proposal	Year	Value (€)	References to Gender Equality	Operational Indicators
Reti Ultraveloci: Consultazione Piano 5G in mobilità - Copertura gallerie "Milano – Cortina 2026"	2025	12000000	Si	No
Migrazione al Polo Strategico Nazionale - Pubbliche Amministrazioni Centrali, Avviso PAC pilota ter	2025	300000000	Si	No

Migrazione al Polo Strategico Nazionale - Pubbliche Amministrazioni Centrali, Avviso PAC pilota bis	2024	224700000	Si	No
Mobility as a Service for Italy - 7 territori	2023	16900000	Si	No
Migrazione al Polo Strategico Nazionale - Pubbliche Amministrazioni Centrali	2023	280000000	Si	No
Mobility as a Service for Italy - fondo complementare al PNRR	2022	16900000	Si	No
Mobility as a Service for Italy	2021	40000000	Si	No

Figure 1. Overview of NRRP M1C1 Public Calls for Proposals: Gender Equality References and Operationalization
Source: Author's elaboration based on data retrieved from the official website of the Department for Digital Transformation (PCM-DTD): https://innovazione.gov.it/dipartimento/avvisi-pubblici/

The findings are structured according to the two analytical dimensions introduced in the previous section: (1) compliance with NRRP horizontal principles, and (2) adherence to EU legal obligations on gender equality. This dual perspective enables a detailed assessment of both formal requirements and the substantive integration of gender equity considerations in digital transformation measures.

4.1 Compliance with NRRP Horizontal Principles

The first dimension of analysis examines the extent to which gender equality is embedded in the horizontal principles guiding NRRP-funded digitalization projects. All ten investment notices explicitly reference the need to align with the overarching values of the NRRP, including the digital and green transitions, youth empowerment, and gender equality. In most cases, compliance with these principles is treated as a formal eligibility criterion, whereby applicants are required to declare observance to national and EU priorities (Presidenza del Consiglio dei Ministri, 2025).

However, although all public calls formally refer to these principles, they are not translated into measurable indicators or specific project evaluation criteria. References to gender equality are included in standard templates or regulatory annexes, but they lack detailed guidance on implementation strategies or monitoring procedures (Neidig et al., 2024). For example, the announcements don't comprehend gender-disaggregated indicators, require specific gender equality actions, or assign evaluation points to projects with inclusive governance mechanisms. This limited articulation suggests a risk that gender equity may be addressed in form but not in substance.

Moreover, the generic phrasing implies that compliance is largely self-declared and not subject to independent verification. This approach raises concerns about the effectiveness of gender equality provisions in influencing project design and execution. The lack of standardized tools for assessing gender impact further limits the ability of implementing entities to incorporate meaningful equity measures.

4.2 Adherence to EU legal obligations on gender equality

The second analytical dimension examines the legal obligations stemming from the Treaty on European Union (TEU), the Treaty on the Functioning of the European Union (TFEU), and the Charter of Fundamental Rights of the European Union. Within the analyzed public calls for proposals, references to these normative frameworks are present but superficial and lack detailed articulation (European Union, 2016).

Specifically, among the formal obligations assigned to implementing entities is the requirement to "respect the principle of gender equality in relation to Articles 2 and 3(3) of the TEU, Articles 8, 10, 19, and 157 of the TFEU, and Articles 21 and 23 of the Charter of Fundamental Rights of the European Union."

Article 2 TUE establishes equality as one of the foundational values of the European Union. It calls for the respect of human rights and the principle of non-discrimination, laying the conceptual groundwork for gender equality in all EU actions. Article 3(3) TUE reinforces this by stating that the Union shall aim to promote equality between women and men in all its activities. These two articles frame gender equality not only as a legal requirement but also as a guiding political principle. The absence of direct references to these provisions in the investment notices indicates a disconnect between foundational EU commitments and their practical implementation in national funding mechanisms.

Article 8 TFEU provides the operationalization of this principle by requiring the Union to eliminate inequalities and promote equality between men and women in all its activities. This article is especially relevant in contexts of public investment, as it mandates the integration of gender equality objectives into the planning, implementation, and evaluation of EU-funded measures.

Article 10 TFEU complements this by calling for the combating of discrimination based on sex in all policies and activities. Neither of these articles is referenced in the analyzed announcements, nor are their implications concretely addressed in terms of funding criteria or expected project outputs.

Articles 19 and 157 TFEU introduce more specific obligations. Article 19 allows the Council to adopt measures to combat gender-based discrimination, which has led to the development of anti-discrimination directives at EU level. Article 157 is particularly significant as it establishes the principle of equal pay for equal work and authorizes the adoption of positive actions to ensure full equality in practice. The exclusion of these legal foundations in the text of investment notices suggests that the NRRP's implementation architecture may overlook essential regulatory tools that could strengthen gender accountability. Turning to the Charter of Fundamental Rights of the European Union, Article 21 prohibits any discrimination based on sex, while Article 23 explicitly mandates equality between women and men in all areas, including employment and work. Importantly, this article also allows for the adoption of measures that provide specific advantages in favor of the underrepresented sex. These rights-based imperatives offer legal justification for incorporating gender-sensitive

evaluation criteria and corrective mechanisms into public funding programs (European Union, 2016). Yet, none of the analyzed public call for proposals provide a more in-depth analysis this rights-based approach.

While the notices require implementing bodies to comply with national and EU legislation, this obligation is stated in general terms and not connected to specific gender equality mandates. The lack of explicit integration of these legal norms indicates a gap between policy design and regulatory frameworks. This detachment could weaken institutional accountability and reduce the normative pressure on implementers to prioritize equity objectives (Bencivenga et al., 2021; Ray et al.,2025).

None of the announcements provide procedures for verifying compliance with gender-related legal standards, nor do they specify consequences for non-compliance. As a result, gender equality appears as a soft obligation acknowledged in principle but weakly institutionalized in practice.

Overall, the findings highlight a disjunction between formal declarations of commitment to gender equality and the operationalization of these commitments in funding and implementation mechanisms. The limited translation of both NRRP principles and EU legal norms into actionable criteria signals the need for stronger institutional tools, clearer guidance, and enhanced monitoring to ensure that digital transformation serves as a vehicle for inclusive governance.

5 Discussion and conclusion

This section addresses the research question: To what extent has the NRRP integrated gender equity objectives within the digital transformation initiatives of the Italian Public Administration?

The analysis conducted on the ten investment notices under Mission 1, Component 1 (M1C1) reveals a fragmented and superficial integration of gender equality principles into the implementation framework of the NRRP's digitalization measures. While all the notices formally reference the need to comply with the NRRP's overarching principles, including gender equality, these references are predominantly declarative, lacking concrete operationalization through project criteria, evaluation frameworks, or monitoring mechanisms.

The findings show that compliance with gender equality objectives often remains at the level of self-declaration, without substantive mechanisms to verify or incentivize inclusive practices. In line with the literature (UNDP & University of Pittsburgh, 2021; OECD, 2023; World Bank, 2023), this reflects a broader challenge in digital governance reforms, where formal commitments to inclusion are not consistently translated into concrete implementation tools. Similarly, as highlighted by EIGE (2020) and UN Women (2024), structural gender gaps in digital skills, leadership, and participation persist and require proactive corrective measures that are largely absent in the analyzed notices.

From a legal perspective, the absence of explicit references to binding EU provisions, such as Articles 2 and 3(3) TUE, Articles 8, 10, 19, and 157 TFEU, and Articles 21 and 23 of the Charter, suggests a detachment between the normative foundations of EU gender equality governance and the practical design of NRRP-funded initiatives (European Union, 2016). As noted in the literature (European Parliament, 2025), effective mainstreaming of gender equality requires not only rhetorical commitment but also the integration of legal obligations into operational documents and funding instruments.

Moreover, the lack of gender-aware language, objectives, and monitoring criteria, as identified through manual content analysis, confirms the risks associated with procedural compliance devoid of substantive engagement with equity goals (Schreier, 2012). Projects are encouraged to "consider" gender equality but are rarely evaluated on their ability to promote it meaningfully, missing the opportunity to leverage digital transformation as a catalyst for inclusive governance (Neidig et al., 2024).

Overall, while the NRRP and M1C1 theoretically recognize the importance of gender equality within digital transformation, the practical implementation through public investment notices is characterized by a formalistic approach that limits the transformative potential envisioned in policy frameworks (Bencivenga et al., 2021). This gap between intent and action underscores the need for stronger institutional mechanisms, mandatory gender impact assessments, and more explicit conditionalities linked to funding allocations.

In conclusion, the integration of gender equity objectives within the digital transformation initiatives of the Italian Public Administration under the NRRP remains partial and insufficient.

Figure 2 summarizes the conceptual translation from policy frameworks to implementation and observed outcomes, highlighting the main gaps and areas for improvement identified in the analysis.

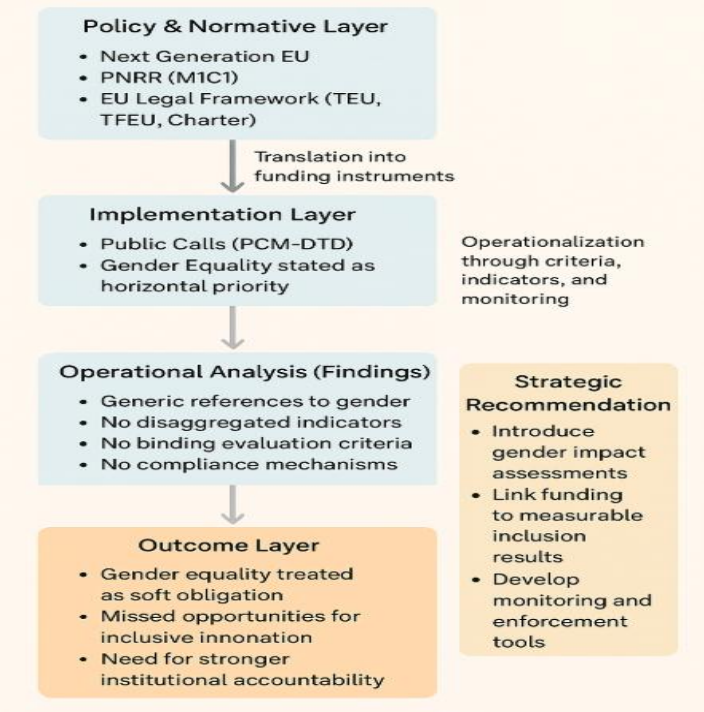

Figure 2. From Formal Commitments to Operational Gaps: a Gender-Sensitive Framework for PA digitalization
Source: author

A genuine commitment to inclusive digital governance requires moving beyond formal declarations towards embedding gender-sensitive criteria into every stage of project design, evaluation, and monitoring, thereby ensuring that innovation becomes a true driver of social equity rather than a reinforcement of existing disparities (Nelson & Piatak, 2021).

6 Limitations and future research lines

This study presents important findings regarding the integration of gender equity objectives within the digital transformation initiatives of the Italian Public Administration under the NRRP. However, several limitations must be acknowledged that affect the scope and generalizability of the results.

First, the analysis is based on a qualitative methodology and relies on a limited sample of ten public investment notices. Although purposively selected to reflect a relevant portion of Mission 1, Component 1 (M1C1), the sample may not capture the full diversity of measures implemented across different sectors and regions. Therefore, caution should be exercised in extending these findings to the entire NRRP framework. Second, the study focuses exclusively on document-based analysis without incorporating primary data from stakeholders, such as policymakers, project implementers, or beneficiaries. As a result, the analysis cannot assess the practical enforcement of gender equality obligations during project implementation or the real-world outcomes achieved through funded initiatives.

Third, the coding and interpretation processes, although systematically conducted, remain subject to inherent limitations of manual qualitative analysis, including the risk of subjective bias in categorizing and evaluating textual content. Efforts were made to ensure rigor and transparency; nonetheless, these methodological constraints should be recognized.

Future research could address these limitations by adopting a mixed-methods approach that combines content analysis with empirical investigations. For instance, future studies could integrate interviews, surveys, and case studies to gain deeper insights into the practical implementation of gender equality principles at the project level. Quantitative evaluations measuring actual gender-related outcomes in funded projects would also provide valuable evidence to complement the qualitative findings.

Moreover, comparative analyses across different EU member states could enhance understanding of how national contexts influence the integration of gender equality in NRRP-funded digital transformation initiatives. Such comparisons could identify best practices and inform the development of standardized guidelines for inclusive public investment strategies.

Finally, future research could explore the role of capacity-building programs, technical assistance, and monitoring mechanisms in strengthening gender mainstreaming in public administration reforms. Investigating how smaller municipalities and resource-constrained entities engage with gender equality obligations would be particularly relevant to ensure that digital transformation benefits are distributed equitably across all segments of society.

By addressing these future research lines, scholars and policymakers can contribute to advancing a more effective and inclusive approach to public sector innovation under major recovery and resilience frameworks.

7 Ethics declaration

This research did not involve any human participants, personal data, or experiments requiring ethical oversight. Therefore, ethical approval was not required.

8 AI declaration

No generative artificial intelligence tools were used in the writing, editing, or content creation of this manuscript.

Industrial Districts and Women-Led SMEs: A Literature Analysis

Paola Paoloni, Veronica Procacci, Silvia Ievolella
Sapienza University of Rome, Rome, Italy

Abstract

The aim of this work is to investigate how the academic literature has addressed the relationship between industrial districts and female entrepreneurship. This relationship is particularly relevant since industrial districts are widely recognized as dynamic environments that foster innovation and business growth, especially for small and medium-sized enterprises (SMEs). The review seeks to identify the main areas of analysis that have emerged in recent years and to explore future research directions related to the role of territorial ecosystems in supporting women-led SMEs.

This study adopts a structured literature review (SLR) methodology to systematically analyze the scientific contributions published between 2008 and 2025. The review was conducted using the SCOPUS database. Each contribution was manually classified according to three dimensions: research focus, methodology used, and geographical area of the authors. This analytical framework allowed for the identification of recurring patterns and theoretical gaps.

The findings reveal that most studies focus on the structural and cultural barriers that female entrepreneurs face, even within cooperative environments such as industrial districts. These include limited access to credit, gender stereotypes, family responsibilities and weak support networks. A smaller body of literature highlights the strategic role of women's human capital, including leadership, training, and innovation capacity, in enhancing the competitiveness of district-based SMEs. Only a few studies explicitly explore how industrial districts can act as enabling ecosystems for female entrepreneurship. From a methodological standpoint, the literature is dominated by quantitative research, while qualitative studies remain limited but offer valuable insights into personal experiences and informal networks. In terms of geographical distribution, most contributions come from Asia and Southern Europe, reflecting both emerging interest in inclusive entrepreneurship and the historical importance of district models in countries such as Italy and Spain.

This study contributes to the literature by providing a comprehensive and up-to-date mapping of the intersection between industrial districts and female entrepreneurship. It highlights the need for more inclusive district governance and calls for future research using qualitative and mixed-method approaches to better understand the lived experiences of women entrepreneurs and the real impact of local production systems.

Keywords: Female entrepreneurship, Industrial districts, Gender and SMEs, Territorial ecosystems

Paper type: Academic Research Paper

1 Introduction

The structure of the Italian economy has long been characterized by the predominant presence of small and medium-sized enterprises (SMEs), which represent the driving force of the national economy (Paoloni, 2020). Despite their small size, Italian SMEs have distinguished themselves for their flexibility, adaptability and innovation capacity, largely enabled by their systemic behavior within clearly defined territorial aggregations known as "industrial districts" (Cortesi et al., 2004).

The Italian district system began to take shape in the 1950s and 1960s, in response to the needs of a rapidly changing economy. During the 1970s, with the spread of production technologies and the expansion of export markets, districts assumed a strategic role in reviving the Italian economy (Solinas and Baroni, 2001).

The geographical proximity of firms, their specialization in specific stages of the same production process, the mutual sharing of resources, skills and technologies, informal exchanges of information and knowledge transfer are all factors that enabled SMEs to overcome the limits of production scale, achieving economies of scale and competitive advantages comparable to those of larger firms (Markusen, 1996; Romero-Martinez and Montoro-Sanchez, 2008; Carpio, 2020; Kayanan et al., 2022).

The evolution of Italian industrial districts has provided the structural foundation for the emergence and consolidation of the Made in Italy phenomenon (Belfanti, 2019). Thanks to the aggregation of SMEs — capable of combining artisanal tradition with innovative production processes — a globally recognized brand of excellence has emerged, especially in key sectors such as fashion, furniture and design and agri-food. ISTAT data confirm that the district model accounts for over 25% of the national production system, making it a fundamental component of the Italian economy.

Over time, the district model has become one of the pillars of the Italian economic system, significantly contributing to regional development, employment growth and the strengthening of Made in Italy competitiveness (Minini, 2023). Its gradual evolution has demonstrated its effectiveness as a growth strategy

for SMEs, which benefit from a favorable ecosystem characterized by easy access to skilled labor, a network of specialized suppliers, and widespread technological innovation (Pyke et al., 1990).

Geographical proximity encourages constant interaction and the creation of economic relationships based on both cooperation and competition. These dynamics of cooperation and competition translate into a greater capacity for innovation: the industrial district serves as a highly innovative environment and a process accelerator that stimulates the adoption of new technologies, even among small businesses (Staber, 1998; Cortesi et al., 2004).

The systemic behavior of firms and their functional specialization lead to high productive efficiency: each firm focuses on a specific stage of the process, while the district as a whole operates as an integrated system, capable of quickly responding to changes in demand and the challenges of global markets (Becattini, 1987; Becattini, 1990).

In this context, relational capital plays a crucial role (Paoloni, 2011; Paoloni, 2020): district SMEs benefit from an environment where mutual trust and cooperation foster the exchange of knowledge, information and ideas, facilitate access to new business opportunities, and reduce transaction costs. This model allows small firms to survive and thrive even in highly competitive contexts, where isolated entities would struggle due to their limited size (Bucci et al., 2011).

Despite the dynamic and innovative nature of industrial districts, in recent years the firms within them have had to face the challenges posed by an increasingly globalized and fast-changing market. The growing complexity of the economic landscape has forced SMEs to rapidly adapt to new technologies and adopt more flexible and innovative business models. The use of advanced technologies has become a key factor in the growth and competitiveness of SMEs, which must compete with increasingly digitalized global actors (Hoffmann et al., 2023). Digital integration not only helps optimize internal processes but also improves business flexibility in responding to a dynamic and fragmented market (Pagano, 2020; Bettiol et al., 2021; Burlina & Montresor, 2022).

However, many Italian firms still exhibit a certain resistance to change, hindered by structural and financial constraints (Dei Ottati, 2018; Di Giacinto et al., 2023). Weak financial planning and low capitalization are significant limitations (Dessy, 1995; Paoloni, 2020; Modaffari, 2024). SMEs tend to finance their investments mainly through internal resources and short-term bank loans, limiting their ability to implement long-term growth strategies. Frequent reliance on credit leads to a vicious cycle: firms are forced to continuously renew credit lines in the short term, delaying or abandoning strategic investments and thus reducing growth opportunities (Giacosa, 2015; Balloni, 2000). These fragilities make them particularly vulnerable to economic shocks (Giacosa & Mazzoleni, 2016; Modaffari, 2024).

Recent crises have further exacerbated these difficulties, leading to a contraction in credit supply and reduced access to external funding.

Access to credit and innovation resources is even more limited for women-led SMEs. Female entrepreneurs face structural, cultural, and financial barriers that constrain their growth and innovation potential (Roy & Patro, 2022). Female entrepreneurship is often characterized by smaller relational networks and a stronger emphasis on work-life balance, factors that influence access to finance and development strategies (Paoloni, 2011).

One of the main issues is credit access: on average, women are less likely than men to obtain funding (Son et al., 2019; Ghosh & Vinod, 2017) and, when successful, often face less favorable terms (Roy & Patro, 2022). These disparities are linked to various factors, including lower availability of asset guarantees and limited familiarity with available financial instruments. Moreover, several studies highlight a greater risk aversion among women entrepreneurs, who tend to avoid bank loans and prefer to rely on personal resources or informal lending (Stefani & Vacca, 2013). While these tools may offer short-term solutions, they hinder the ability to make strategic investments in innovation and development, ultimately slowing down business growth (Paoloni, 2024).

It is worth noting that access to credit is not just an economic issue but also a cultural one: women entrepreneurs often struggle to balance family and professional responsibilities, which significantly affects their financial and strategic decisions (Poggesi et al., 2017). This need for balance leads to more cautious investment strategies and lower willingness to incur debt, driven by concerns that excessive financial exposure could compromise stability (Paoloni & De Martini, 2016). These dynamics significantly reduce women-led businesses' access to credit and limit their development potential.

While SMEs face numerous challenges in innovation and growth, the role of the district context in facilitating this transition should not be overlooked. Belonging to an industrial district may represent a strategic lever to mitigate some of the structural and financial weaknesses of the national production system.

This perspective becomes especially relevant when applied to women-led SMEs, which face additional barriers related to credit access, risk tolerance and work-life reconciliation.

Academic literature has begun to explore this possible correlation, highlighting both the opportunities offered by districts and the limitations of a model that, in some cases, struggles to innovate.

Based on these premises, it is essential to deepen the academic debate on the role of industrial districts in the development of SMEs — particularly women-led ones — in order to understand whether and to what extent the district model can offer a competitive advantage in today's transformative landscape.

To this end, the present study aims to analyze how the literature has evolved over recent decades, what research areas have been explored, what key themes have emerged, and what gaps remain. Using the methodology of a Structured Literature Review (SLR) (Guthrie et al., 2012; Dumay, 2014; Massaro et al., 2016; Paoloni & Demartini, 2016) and following the relevant protocol, this paper seeks to answer the following research questions:

- *RQ1. What are the main areas of analysis in the existing literature on female entrepreneurship in industrial districts?*
- *RQ2. What are the possible future research directions?*

The structure of the paper is as follows. Section 2 outlines the methodology adopted for the structured literature review. Section 3 presents the main findings of the analysis. Section 4 discusses and interprets the results in light of the existing academic debate. Section 5 provides concluding reflections and proposes possible future research developments. Finally, the last section highlights the study's limitations, its added value, and the originality of the research.

2 Research methodology

This analysis was conducted using the qualitative methodology of the Structured Literature Review (SLR), which is considered particularly suitable for systematically mapping the existing scientific landscape within a well-defined thematic area (Guthrie & Murthy, 2009; Guthrie et al., 2012; Dumay, 2014; Paoloni & Demartini, 2016; Massaro et al., 2016). This approach enables an in-depth examination of a large and complex set of academic contributions, with the aim of identifying recurring patterns, theoretical gaps and future research directions. In line with the objective of this study, the SLR proves to be an appropriate methodology for providing a structured and critical overview of the available evidence.

The SCOPUS database — widely recognized as one of the most comprehensive bibliographic sources at the international level (De Moya-Anegón et al., 2007) — was used for the retrieval of scientific contributions.

The search was carried out on April 29 2025.

The search strategy was built around a carefully selected set of keywords designed to capture publications relevant to the topic under investigation. The query used was as follows:

(("industrial district" OR "cluster" OR "regional economy") AND ("female entrepreneur" OR "women entrepreneur*" OR "gender and entrepreneurship"))*.

To increase the relevance of the results, the analysis was restricted to the fields "Article title," "Abstract," and "Keywords." This initial search returned a total of 98 documents.

Subsequently, only documents falling within the disciplinary areas of "Business, Management and Accounting" and "Economics, Econometrics and Finance" were retained, in accordance with the managerial and economic nature of the study (Massaro et al., 2016). This step reduced the sample to 73 documents.

Only fully published contributions, specifically "Articles", "Book" and "Book Chapters", were included in the final analysis. This step reduced the sample to 58 documents.

Additionally, to avoid issues related to linguistic comprehension (Mauro et al., 2017), only works published in English were considered.

At the end of this process, the final sample suitable for the SLR consisted of 49 documents.

The entire selection and filtering process is illustrated in Figure 1.

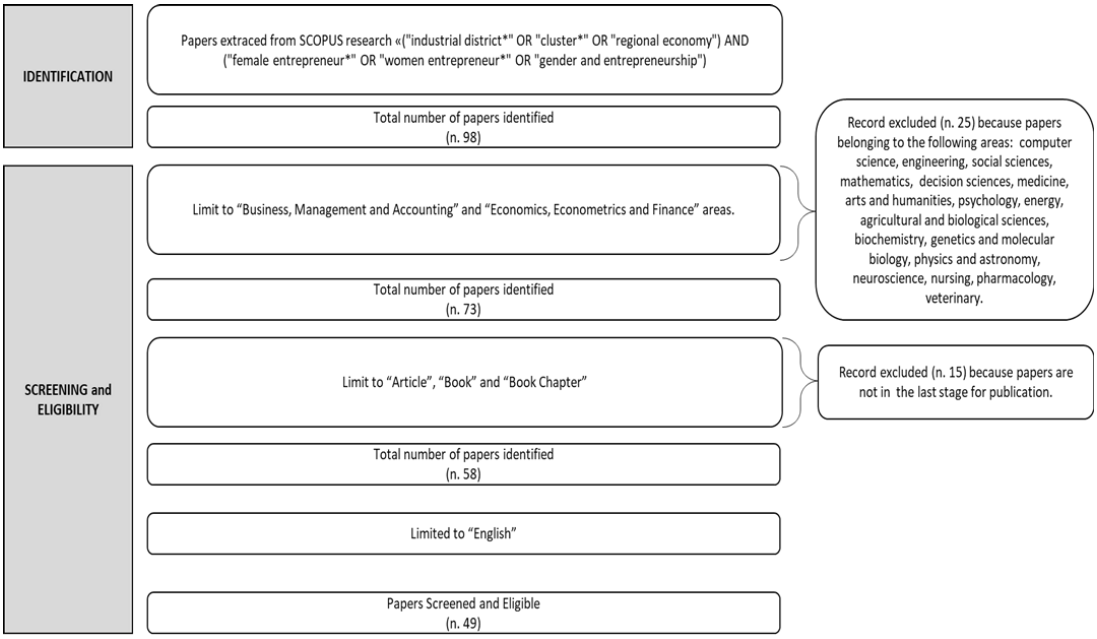

Figure 1: The procedure for selecting the eligible papers

2.1 Definition of the analytical framework

To conduct the Structured Literature Review (SLR), the authors carried out an in-depth examination of the title, abstract and keywords of each article included in the selected sample. This preliminary analysis enabled the development of an analytical framework designed to identify distinct units of analysis within each contribution, in line with the research objectives (Yin, 2014). The framework is structured around three main dimensions: the research focus, the methodology employed and the geographical area of reference, as illustrated in Table 1.

Regarding the Article Focus (A), the classification of the articles was performed manually to identify the main themes addressed by each study. The aim of this categorization was to assign each article to a specific macro-category, allowing for a clearer overview of the existing literature and the identification of insights to answer the research questions.

Three main recurring article foci were identified — along with one residual category — which represent the primary thematic directions in the literature:

- *A1. The role of industrial districts in the development of female entrepreneurship*: this category includes studies that examine the positive influence of industrial districts, clusters, and territorial networks on women-led businesses, highlighting benefits in terms of innovation, access to resources, collaboration, and integration into local markets;
- *A2. Gender barriers in industrial district contexts*: this group comprises contributions that show how, even within productive districts, female entrepreneurs face obstacles related to cultural stereotypes, limited access to credit, marginalization within local networks, or insufficient support for work-life balance;
- *A3. Entrepreneurial skills and female human capital in industrial districts*: this category gathers studies that highlight the value of women's hard and soft skills, training, resilience, and relational networks, considered key levers for the success and sustainability of their businesses;
- *A4. Other*: a residual category that includes studies dealing with female entrepreneurship from broader or alternative perspectives, which do not clearly fit into the three main categories mentioned above.

As for the Research Method (B), five types were identified:

- *B1. Literature analysis*: contributions consisting of systematic or narrative reviews of the existing literature on the topic;
- *B2. Qualitative research*: studies employing methods such as case studies, interviews, focus groups, observations, or content analysis;
- *B3. Quantitative research*: research based on statistical tools, using data collected through surveys, structured databases, or other numerical sources;
- *B4. Research mix*: studies combining both qualitative and quantitative approaches;

- *B5. Other*: a residual category including works that adopt methods not clearly attributable to the previous classifications.

Concerning the Geographical Area (C), the authors recorded the institutional affiliation country of each article's authors to understand the territorial distribution of the scientific production.

Once the methodological protocol was defined, the detailed analysis of the selected contributions was carried out in accordance with the criteria established for the SLR.

Table 1: Literature review of analytical framework

A. ARTICLE FOCUS	B. RESEARCH METHOD
A1. The Role of Industrial Districts in the Development of Female Entrepreneurship	B1. Literature analysis
A2. Gender Barriers in Industrial District Contexts	B2. Qualitative research

3 Results

3.1 Research focus

After analyzing the titles, abstracts, and keywords of each contribution included in the SLR, every document was assigned to one of the four identified thematic areas. Table 2 presents the results of the analysis for the period 2008–2025. The most recurring theme was A2 (Gender barriers in industrial district contexts), with 26 out of 49 studies (53%), indicating a strong interest in the structural, cultural, and institutional barriers that hinder the emergence and growth of women-led enterprises. This was followed by contributions categorized under A3 (Entrepreneurial skills and female human capital in industrial districts) with 15 articles (29%), and A1 (The role of industrial districts in the development of female entrepreneurship) with 7 studies (16%). Only one article was classified under A4 (Other). Figure 2 illustrates the evolution of these four research foci across the years from 2008 to 2025.

Table 2: Article focus of eligible papers divided by year of publication

3.2 Research method

Regarding the research methodology adopted, the majority of studies are based on a quantitative approach (B3), used in 25 contributions (51%). This is followed by qualitative research (B2), applied in 8 studies (16%), and literature analysis (B1), employed in 7 cases (14%). A smaller number of articles (4, equal to 8%) combine both qualitative and quantitative methods and were categorized under mixed-method research (B4). Finally, 5 articles (10%) were classified as Other (B5), as they rely on methodologies that are either not clearly identifiable or do not fit within the previous categories. Table 3 presents the results of the analysis for the period 2008–2025.

Table 3: Research method of eligible papers divided by year of publication

B - Research Method						
Year	B1	B2	B3	B4	B5	Total by year

3.3 Geographical area

With regard to the geographical affiliation of the authors, the most represented area is Asia (C7), accounting for 31% of the sample, followed by Southern Europe (C6) with 8 studies (16%). The Mixed category (C11), which includes contributions from authors affiliated with institutions in different countries, represents 18% of the total (9 articles). Other areas are less represented: Eastern Europe (C1) with 4 contributions (8%), the UK (C9) with 3 (6%), and individual studies from Africa (C8), the Middle East (C2), South and Central America (C3), and Northern Europe (C5). Finally, no contributions were found from North America or Oceania. Table 4 presents all the results.

4 Discussion

The analysis conducted provides a detailed picture of how the literature has addressed the topic of female entrepreneurship within industrial districts over the past two decades.

A first relevant element concerns the distribution of research foci. Most studies concentrate on the barriers faced by women entrepreneurs even within district contexts, which are generally seen as cooperative and inclusive environments (Gatewood et al., 2009; Haddad et al., 2016). This emphasis highlights how gender inequalities persist even in socio-economic settings considered favorable to entrepreneurial development (Machado et al., 2016). Difficulties in accessing credit, lack of institutional support, cultural stereotypes, and challenges related to work-life balance are recurrent issues (Mathew & Panchanatham, 2011; Mitchelmore & Rowley, 2013; Maseda et al., 2022). These challenges not only reflect broader structural dynamics but also suggest that industrial districts do not automatically foster inclusion.

Alongside this critical perspective, a smaller body of literature emphasizes the resources women bring to entrepreneurial ecosystems (Moreira et al., 2019; Vadnjal, 2020; Dalimunthe et al., 2023). These contributions highlight female human capital—such as managerial skills, leadership, and innovation capacity — as a strategic asset for SME competitiveness (Lee et al., 2024; Komp-Leukkunen, 2024). This approach shifts the focus from a problem-centered narrative to a more proactive vision, emphasizing the potential of women entrepreneurs when they operate in supportive environments and are backed by appropriate policies (Vadnjal, 2020; Sidik & Marikan, 2023).

From a methodological perspective, the majority of studies adopt a quantitative approach, using structured data and statistical tools. While this ensures analytical robustness, it may limit the ability to capture the complexity of gender dynamics in district contexts. Qualitative studies, though fewer, have provided valuable insights into lived experiences, informal networks, and cultural dimensions.

The geographical distribution of contributions also offers meaningful reflections. A significant portion of the analyzed literature comes from Asia, highlighting the growing interest of emerging economies in the role of women in business and territorial development processes (Mathew & Panchanatham, 2011). In many Asian countries, promoting female entrepreneurship has become a priority within broader strategies for social

inclusion and local economic empowerment (Hemalata et al., 2013; Banerjee & Desai, 2021). Southern Europe is also well represented, particularly through studies from Italy and Spain. This reflects the historical importance of industrial districts in these regions, where the territorial production model has significantly shaped the development of SMEs.

5 Conclusion and future perspectives

This literature review has made it possible to systematically reconstruct the current state of research on female entrepreneurship within industrial districts, offering valuable insights both in terms of synthesizing the main areas of analysis and identifying future research directions.

With reference to RQ1 (What are the main areas of analysis in the existing literature on female entrepreneurship in industrial districts?), three key thematic directions emerge from the analysis.

The most frequently addressed topic concerns the analysis of gender-related barriers that hinder women's access to and growth within industrial districts. This theme appears in over half of the reviewed contributions, confirming the growing academic attention to systemic inequalities that persist even in productive environments generally considered dynamic and cooperative (Mathew & Panchanatham, 2011; Mitchelmore & Rowley, 2013; Haddad et al., 2016). These barriers include cultural stereotypes, limited access to credit, unequal distribution of family responsibilities, and weak support networks. In many cases, districts fail to mitigate such obstacles and may even reproduce or amplify them, highlighting a structural lack of inclusivity (Gatewood et al., 2009; Maseda et al., 2022).

The second most explored area focuses on female human capital and entrepreneurial skills. In this perspective, women entrepreneurs are seen as bearers of strategic resources such as leadership, training, relational capabilities, and innovative vision (Vadnjal, 2020; Dalimunthe et al., 2023). The literature shows that these factors can represent a competitive advantage within district contexts, especially when supported by public policies and environments that foster female entrepreneurship (Sidik & Marikan, 2023; Lee et al., 2024). This strand of research helps to rebalance the debate by shifting the focus from challenges to opportunities.

Finally, a smaller set of studies analyzes the proactive role of industrial districts in supporting women-led entrepreneurship. In general, numerous contributions highlight how districts—thanks to their relational networks and shared resources — can provide favorable conditions for the creation and growth of businesses (Carpio, 2020; Kayanan et al., 2022). However, few of these studies explicitly refer to female entrepreneurship, suggesting the need for further investigation.

Regarding RQ2 (What are the possible areas for future research?), several potential directions can be hypothesized. First, future studies could further explore the relationship between industrial districts and female entrepreneurship, with a stronger focus on the actual impact of district membership on business performance. Additionally, it would be valuable to investigate the factors and enabling conditions that allow districts to become supportive ecosystems for women's empowerment—such as the presence of incubators, local public policies for credit access, or inclusive collaborative networks.

Lastly, there is a strong need to strengthen the methodological approach through case studies, interviews with female entrepreneurs, and surveys conducted within districts. These methods could provide deeper empirical evidence on women's lived experiences in local production systems—an aspect still underrepresented in current literature.

6 Limitations

This study presents some methodological limitations. The analysis was conducted manually, a choice that allowed for greater flexibility and cost-effectiveness, but also introduced a degree of subjectivity in the classification of contributions. To mitigate the risk of bias, the authors worked jointly in defining the categories. Moreover, the research was carried out using a single database (SCOPUS); the inclusion of other sources such as Web of Science or Google Scholar could enhance the coverage. Finally, since the classification was based on titles, keywords, and abstracts, some methodological or contextual information may have been overlooked, limiting the completeness of the categorization.

7 Ethics declaration

This research did not involve human participants, animals or sensitive data, and therefore did not require ethical approval.

8 AI declaration

No AI tools were used in the writing, analysis or creation of this paper.

[2] Department of Economics, University of Campania Luigi Vanvitelli, Capua, Italy

Abstract

This study examines the intersection of digital transformation (DT) and business model innovation (BMI) within traditional "Made in Italy" sectors, such as Food & Wine, Fashion & Clothing, Home & Furnishings, and Automation. While these industries are renowned for their cultural heritage, they face the challenge of integrating digital technologies to remain competitive without losing their identity. The research explores how Italian firms in these sectors are navigating the balance between embracing digital innovation, particularly within the framework of Industry 5.0, and preserving traditional values. Industry 5.0, with its emphasis on human-centered innovation and sustainable practices, provides a lens through which to understand the evolving relationship between digital technologies and traditional craftsmanship. Through a qualitative multiple case study approach, this study aims to uncover how digital technologies, aligned with Industry 5.0 principles, are reshaping business models.

Keywords: Digital transformation, Business Model Innovation, Made in Italy, Industry 5.0

Paper type: Academic Research Paper

1 Introduction

In recent years, digitalization has become a key driver of societal and economic change (Grybauskas, Stefanini & Ghobakhloo, 2022). Accelerated by globalization and market volatility, firms increasingly view digital technologies as essential for resilience and competitiveness (Datta & Nwankpa, 2021). However, digital transformation (DT) is not merely technological; it represents a structural shift in how organizations create value and engage with their ecosystems (Stolterman & Fors, 2004; Shini et al., 2024). It fosters new forms of interaction between people, processes, and products, enabling innovation unconstrained by traditional resource limitations (McDonald & Rowsell-Jones, 2015).

Digital technologies are at the core of Industry 4.0, that encompasses a convergence of digital and physical systems, including artificial intelligence (AI), cloud computing, the Internet of Things (IoT), augmented reality (AR), and additive manufacturing (Tiraboschi & Seghezzi, 2016; Ustundag & Cevikcan, 2017). More recently, Industry 5.0 has emerged, emphasizing human-centric innovation and collaboration with intelligent systems (Skobelev & Borovik, 2017; Horvat, Jäger & Lerch, 2025).

In this context, DT is a powerful enabler of business model innovation (BMI), allowing firms to rethink the mechanisms through which they create, deliver, and capture value (Osterwalder & Pigneur, 2010; Demil & Lecocq, 2010).

Despite growing academic interest, empirical evidence on how DT unfolds in traditional, non-digital sectors remains limited. Much of the existing research has focused on digitally native or technology-intensive industries, leaving a gap in understanding how firms—particularly those embedded in established, physical industries—navigate digitalization and business model reconfiguration.

This study explores the intersection of DT and BMI in the "Made in Italy" sectors—specifically Food & Wine, Fashion, Home & Furnishings, and Automation (the 4A industries; Aiello et al., 2015). These sectors, rooted in artisanal values and cultural heritage (Fortis, 2005), now face the dual challenge of maintaining their identity while embracing innovation. It is within this tension—between innovation and tradition, between digital acceleration and heritage preservation—that this research finds its core motivation.

Through a qualitative multiple case study (Stake, 1995; Tellis, 1997; Yin, 2009), this research investigates how Italian firms in the 4A sectors adopt digital technologies to innovate their business models while preserving tradition. The central question guiding the study is: *How do traditional firms implement DT to enable BMI while maintaining their distinctive identity?*

By addressing this question, the study contributes to a broader understanding of how heritage-based industries can navigate DT within the Industry 5.0 paradigm, without compromising their cultural and competitive essence.

2 Theoretical background

2.1 Redefining industrial paradigms: the transition from Industry 4.0 to Industry 5.0

In manufacturing and industrial contexts, DT has materialized through Industry 4.0, characterized by the integration of cyber-physical systems, big data analytics, and intelligent automation to enhance efficiency and responsiveness (Tiraboschi & Seghezzi, 2016; Joensuu-Salo et al., 2018; Kamble, Gunasekaran & Gawankar, 2018). However, as sustainability concerns and societal expectations intensify, Industry 5.0 is emerging as a more human-centric paradigm. Rather than focusing solely on automation and productivity, Industry 5.0 emphasizes ethical, social, and environmental dimensions, promoting a more sustainable and inclusive model of innovation (Horvat, Jäger & Lerch, 2025; Rehman & Umar, 2025).

Three core perspectives illustrate the transformative nature of Industry 5.0. The first, rooted in EU frameworks, stresses social and environmental responsibility, advocating for sustainable practices and worker empowerment alongside economic performance (Miraz et al., 2022). The second emphasizes human-machine collaboration, particularly through collaborative robots (cobots), which enhances human creativity and enable more personalized production processes (Li et al., 2021; Nourmohammadi, Fathi, & Ng, 2022). The third perspective highlights the integration of ethical and user-centered intelligent technologies, advocating for transparency, inclusiveness, and responsible innovation (Aslam et al., 2020; Golovianko et al., 2023).

In sum, Industry 5.0 represents a paradigm shift toward innovation that balances technological advancement with human empowerment, social value, and environmental sustainability.

2.2 Understanding Business Model Innovation (BMI)

Business Model Innovation (BMI) refers to the intentional process by which organizations rethink, redesign, and reconfigure the underlying logic through which they create, deliver, and capture value (Osterwalder & Pigneur, 2010). This may involve a variety of changes, such as the introduction of novel revenue streams, the adaptation of value propositions to evolving customer needs, or the restructuring of internal operations and external partnerships. BMI can entail both incremental and radical transformations, but it is particularly impactful when it challenges established industry logics of value creation.

Unlike product or process innovation, which typically focus on improving specific offerings or operational efficiency, BMI represents a more fundamental transformation of the organization's architecture. It involves changes not only in the "what" and "how" of value delivery, but also in the "why"—that is, the strategic intent behind a firm's activities. Accordingly, BMI has been described as *"the discovery of a fundamentally different business model in an existing business"* (Markides, 2006, p. 20), and as *"the search for new business logics of the firm and new ways to create and capture value for its stakeholders"* (Casadesus-Masanell & Zhu, 2013, p. 464).

The strategic relevance of BMI lies in its potential to redefine industry boundaries and reshape competitive dynamics. Through innovative configurations, firms can unlock new avenues for differentiation and performance. Moreover, BMI enhances organizational resilience by fostering adaptability and responsiveness in the face of environmental change—particularly crucial in today's context of rapid digitalization, shifting consumer preferences, and growing demand for sustainability and personalization.

2.3 DT, Industry 5.0, and BMI: shaping new value creation mechanisms

Recent scholarship has highlighted how DT enables BMI (Matt, Hess & Benlian, 2015; Li, 2020; Verhoef et al., 2021). Specifically, technologies such as AI, IoT, cloud computing, and data analytics support the reconfiguration of business model components.

Digital tools enhance value propositions through personalization, driven by real-time customer data (Wikström & Ellonen, 2012; DaSilva et al., 2013), and improve customer relationships by optimizing user experiences (Ammirato et al., 2021). Operationally, digital technologies increase efficiency in production and supply chain management, though they also require new technical skills (Müller, Buliga & Voigt, 2018; Müller, 2019). Partnerships evolve through technological collaboration, promoting innovation and transparency (Schneider, Leyer, & Tate, 2020), while distribution benefits from cost reductions, faster logistics, and omnichannel strategies (Gao, Keoy & Lim, 2025).

In terms of financials, digitalization enables new revenue models and cost efficiencies but also demands significant investment in IT infrastructure (Dasí et al., 2017; Kiel, Arnold & Voigt, 2017). Within this context, Industry 5.0 introduces a more human-centered, sustainable, and ethical approach to innovation. It prompts firms not only to adopt advanced technologies but also to align business models with values such as social

responsibility and human empowerment, expanding the strategic scope of BMI and opening new pathways to long-term competitive advantage (Botti & Baldi, 2025).

3 Methodology

This study adopts a qualitative multiple case study methodology (Tellis, 1997), which is particularly appropriate for exploring complex and context-dependent phenomena within real-life settings (Stake, 1995; Yin, 2009). Rather than seeking statistical generalization, the objective is to generate in-depth analytical insights that illuminate the mechanisms and dynamics underlying BMI in traditional sectors undergoing DT (Hennink, Hutter & Bailey, 2020). Four firms were purposively selected based on their relevance to the 4A sectors (Food & Wine, Fashion & Clothing, Home & Furnishings, and Automation), the presence of documented DT initiatives, and the public availability of rich secondary data. Each case represents a different sector, allowing for cross-case comparison while ensuring sectoral diversity. Firms were also selected for their recognized commitment to innovation and their alignment with the values of the “Made in Italy” identity. The study relies exclusively on secondary data sources. These include publicly available company interviews and documents such as strategic plans, sustainability and innovation reports, press releases, websites, social media content, and industry publications. In addition, relevant academic and practitioner literature, as well as media articles and databases (e.g., Orbis, AIDA), were used to triangulate and enrich the dataset. This approach ensures a comprehensive and multifaceted understanding of each firm's DT journey and related business model innovations. Data were analyzed through thematic coding. Preliminary themes were informed by existing literature on DT and BMI, then iteratively refined through close reading and comparison of the cases.

4 Results

The experiences of leading Made in Italy firms such as Barilla, Gucci, Fiat Chrysler Automobiles (FCA), and Fedrigoni demonstrate how the integration of DT and the human-centric, sustainable principles of Industry 5.0 can serve as enablers of BMI. Each company has adopted digital technologies not merely for operational efficiency, but as strategic tools to reconfigure value creation mechanisms. By embedding digital capabilities within broader socio-environmental, consumer-centric and stakeholder engagement frameworks, these firms have transformed their business models to better align with contemporary expectations of personalization and sustainability. Table 1 provides a detailed comparison of how each case exemplifies this transformation, outlining the specific ways in which DT and Industry 5.0 have been mobilized to drive new forms of value creation.

Table 1 - DT, Industry 5.0, and BMI in Made in Italy: case studies across key sectors

Company	Sector	Key DT	Industry 5.0 Integration	BMI
Barilla	Agrifood	Utilization of blockchain to ensure traceability and digital platforms for consumer engagement (crowdsourcing for product co-creation, e.g., new pasta shapes).	Integration of sustainability through the ¡Tierra! project, combining digital tools and eco-friendly agriculture.	Development of new customer engagement methods through co-creation and sustainability-focused initiatives.
Gucci	Luxury Apparel	AR for personalized shopping experiences and immersive consumer interaction.	Partnership with external designers and artists to ensure sustainability and ethical production.	Introduction of digital tools for customization, creating a sustainable luxury experience with a focus on innovation.
Fiat Chrysler Automobiles (FCA)	Automotive	Adoption of smart factory technologies to enhance production efficiency, especially in electric and autonomous vehicles.	Human-machine collaboration for electric and autonomous vehicle production; focus on sustainable manufacturing.	Shift towards human-centric production that balances craftsmanship and cutting-edge technologies in automotive design.
Fedrigoni	Paper & Printing	Creation of digital platform for customers to co-create products, offering advanced material options.	Integration of digital tools into traditional paper production, preserving artisanal quality while embracing innovation.	Co-creation platform for personalized paper products, blending traditional craftsmanship with digital technologies.

4.1 Emergent themes

Based on the analysis of secondary data sources, four recurring themes appear to characterize how DT and the principles of Industry 5.0 are reportedly employed to support BMI in the selected Made in Italy companies. First, strategic intent and leadership emerge as fundamental enablers of transformation (Singh et al., 2023). In all analyzed cases, top executives appear to have played an active role in shaping digital initiatives aligned with long-term corporate values and identity. Rather than adopting technology for its own sake, firms communicated a vision in which innovation reinforced their heritage, quality, and competitiveness. In the context of Industry 5.0, this integration extends beyond the adoption of new technologies, encompassing the fusion of human creativity and machine efficiency, thus enhancing competitive advantage (Modgil, Singh & Agrawal, 2023). Second, several sources indicate the presence of cultural tensions (Yan, 2008) related to fears of eroding traditional craftsmanship or diluting brand authenticity—concerns particularly salient within the symbolic context of Made in Italy, where there is resistance to replacing traditional craftsmanship with automated processes. These tensions were reportedly addressed through change management initiatives involving employee engagement, training, and communication strategies aimed at framing digitalization as a continuation, rather than a rupture, of tradition.

Third, the cases suggest that DT often entailed resource reconfiguration (Muneeb et al., 2023), especially the development of new capabilities in data analytics, digital marketing, and user experience design. In many instances, this process combined internal upskilling with external collaborations, highlighting a hybrid model of resource orchestration in digitally evolving firms. This resource shift is integral to Industry 5.0, where businesses must focus on both technological capabilities and the enhancement of human-technology collaboration.

Finally, all four companies show evidence—through their public strategies and projects—of a shift toward customer-centric innovation (Nugroho, 2025), enabled by technologies such as AI, IoT, and digital platforms. These tools allowed firms to offer personalized experiences, foster value co-creation, and engage customers more directly (Ramaswamy & Ozcan, 2018). Particularly transformative has been the role of digital platforms, which facilitated ecosystem creation, data-driven decision-making, and more agile business models (Chesbrough, 2003; Gawer & Cusumano, 2014; West & Bogers, 2017; Teece, 2018). The core advantage of digital platforms for physical businesses lies in their ability to aggregate and connect diverse stakeholders—such as suppliers, consumers, and service providers—into a single ecosystem. This interconnectedness allows firms to scale more effectively through network effects, where the value of the platform increases as more participants join. Furthermore, these platforms generate vast amounts of user data, providing valuable insights that can inform business model adjustments, marketing strategies, and product offerings. Generalizing, a cross-cutting theme is the adoption of a human-centric approach to digitalization. In all cases, technology was deployed not merely to streamline operations but to enrich the human experience—whether through enhanced personalization, as mentioned earlier, or the augmentation of employee capabilities. In line with Industry 5.0 principles, digital tools were often framed as complements to human skills, supporting rather than displacing traditional craftsmanship and knowledge. This orientation reflects a broader cultural shift in innovation practices, where human values are placed at the center of technological development.

Thus, these emergent themes highlight the interconnected nature of leadership, cultural adaptation, resource reconfiguration, and customer engagement in the successful implementation of BMI and the advancement of Industry 5.0.

4.2 Comparative Insights

Alongside the recurrent themes, we observed differences related to sectoral contexts, technological maturity, and organizational structures. The cross-case analysis reveals how DT and BMI are interwoven within the contemporary trajectories of Made in Italy firms, also highlighting sector-specific variations. A central insight concerns the alignment between DT initiatives and brand values. Rather than adopting technologies indiscriminately, each firm carefully selected digital tools that resonated with its core identity and heritage. For example, the Food & Wine company employed blockchain to ensure traceability and reinforce its commitment to transparency and quality, while the Fashion & Clothing firm integrated augmented reality in ways that enriched customer interaction without compromising its artisanal legacy. This strategic coherence between digital innovation and brand ethos emerged as a key differentiator, enabling firms to innovate while remaining authentic in the eyes of consumers. The cases also illustrate the importance of sector-specific digital strategies (Arnold, Kiel &Voigt, 2016; Rachinger et al., 2019).

Although all companies shared the goal of enhancing efficiency, innovation, and customer engagement, their approaches varied significantly depending on industry dynamics. The Automotive company leveraged advanced Industry 4.0 technologies—such as real-time monitoring and intelligent automation—to pioneer outcome-based

service models, enabling predictive maintenance and performance-driven value delivery. Meanwhile, the Home & Furnishings firm focused on platform-based ecosystems to enhance the user experience. This tailoring of digital strategies to sectoral needs underscores the contextual nature of transformation and the necessity of embedding innovation within specific operational and market frameworks.

5 Discussion and implications

Building on the findings, this study offers a framework, illustrated in Figure 1, that integrates key antecedents, dimensions of DT and Industry 5.0, and mediating factors crucial for facilitating the transition from traditional business models to innovative business models, where the synergy between technology and human capabilities plays a central role.

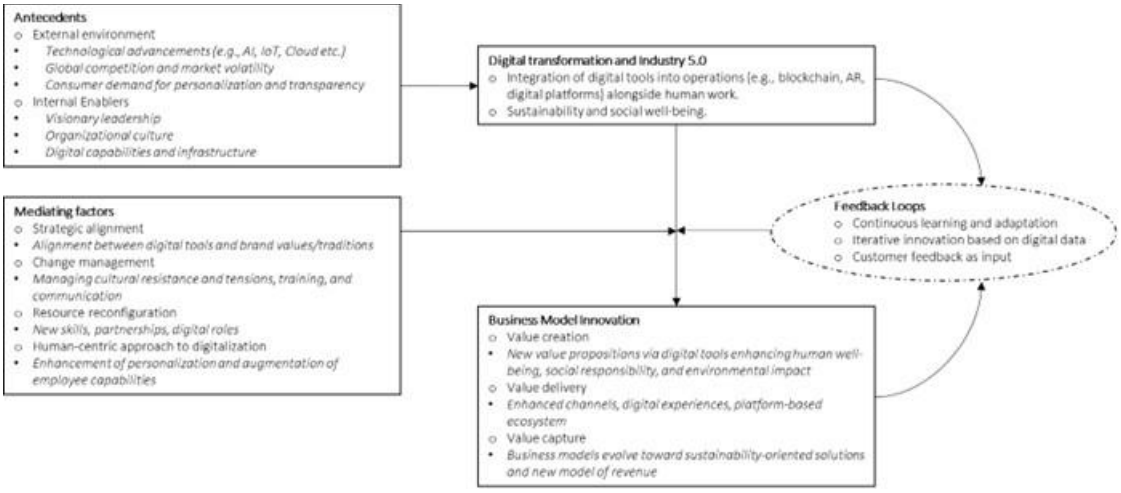

Figure 1: A framework for DT and Industry 5.0 impact on BMI: mediating factors and strategic implications for traditional firms

The framework begins by identifying the external and internal factors driving this transformation. Externally, technological advancements form the backbone of Industry 5.0. These technologies do more than enhance operational efficiency; they complement human capabilities, fostering creativity, intuition, and decision-making. This collaboration between humans and machines is particularly relevant for Made in Italy enterprises, where the artisanal approach and high-quality production methods can be augmented by advanced technologies, enabling the creation of more personalized, creative, and sustainable products. Global competition, market volatility, and the growing demand for personalization and transparency are also significant drivers of change. The rising expectation for social responsibility and personalized experiences presents a strategic opportunity for Italian manufacturers to reinforce their commitment to sustainability—a core characteristic of many Italian brands—while meeting the evolving needs of consumers. Internally, visionary leadership and organizational culture (Kurniadi, Lian & Wahidy, 2020) are crucial enablers of this transformation. Effective leadership must foster a vision that embraces digitalization while prioritizing human well-being, ensuring digital tools enhance both efficiency and creativity. For Italian businesses, often rooted in craftsmanship traditions, fostering a culture of collaboration between human expertise and technology is essential for maintaining competitive advantage. Organizations must also ensure their workforce and infrastructure are ready to support this transition, facilitating not just automation but effective collaboration—an essential element of Industry 5.0's success. In terms of DT, the adoption of new technologies in Industry 5.0 goes beyond traditional automation. Technology is seen not just as a tool for improving efficiency, but as a means to enhance human creativity and capabilities, aligning seamlessly with the core values of the Made in Italy sector, which blends innovation with tradition. The digitization of processes enables the personalization of work, empowering both employees and customers to co-create value. For Italian manufacturers, this means integrating advanced digital tools into artisanal production processes, allowing for customization while preserving the handcrafted quality that defines their offerings. Furthermore, digital platforms enable real-time feedback and personalized experiences, fostering deeper, more meaningful customer relationships. Consumers not only receive bespoke products but actively participate in their creation, adding value that extends beyond the product itself and enhances the overall customer experience (Ramaswamy & Ozcan, 2018; Abbate, Codini & Aquilani, 2019; Abbate et al., 2022).

The mediating factors outlined in the framework are essential for the successful implementation of Industry 5.0 in BMI. A critical element is strategic alignment between digital tools and brand values (Yeow, Soh & Hansen, 2018). For Made in Italy enterprises, aligning technological adoption with core values such as craftsmanship, innovation, and sustainability is key. This ensures that DT efforts resonate with employees and customers alike, preventing the dilution of the brand's traditional identity while embracing technological advancements.

Another key factor is change management (Ghiringhelli & Virili, 2021). Overcoming resistance to technology requires cultivating a mindset that views digital tools as enablers, not substitutes. For Italian companies with a strong reliance on traditional methods, this cultural shift may be met with resistance from both employees and leadership. Continuous training and transparent communication are crucial to ensure a smooth transition, helping employees view new technologies as supportive tools that enhance their work (Ramus, 2001)

Moreover, the reconfiguration of resources is pivotal in integrating human and digital capabilities, a process that requires not only the adoption of advanced technologies but also the development of new skills, the creation of digital roles, and the establishment of strategic partnerships (Chaturvedi & Prescott, 2022). In this context, the role of employees is evolving, with a greater focus on digital literacy, critical thinking, and collaboration with technological tools (Reddy, Sharma & Chaudhary, 2020). This balance between human and technological input helps enhance productivity, optimize quality, and enable more personalized offerings. Furthermore, building strong partnerships with technology providers, research institutions, and other stakeholders is essential to foster innovation, support continuous learning, and ensure the sustainable integration of digital capabilities. As such, the reconfiguration of resources involves a dynamic approach where digital roles, skill development, and strategic collaborations are key to driving both technological and human-driven growth in the business model transformation.

Lastly, the framework also highlighted the human-centric approach to digitalization as a mediating factor (Wan et al., 2023). This approach manifests in the enhancement of personalization and the augmentation of employee capabilities. Specifically, the adoption of digital technologies that center on the human experience enables more precise customization of products and services, addressing the individual needs of customers with greater accuracy. Simultaneously, the integration of digital tools into the workforce not only enhances operational efficiency but also amplifies employee capabilities, thereby contributing to a more dynamic and innovative work environment.

The outcomes of this DT center on new mechanisms of value creation, delivery, and capture (Sjödin et al., 2020). In terms of value creation, Industry 5.0 facilitates the development of new value propositions through the application of digital tools that promote human well-being, social responsibility, and environmental sustainability. Made in Italy companies are well-positioned to lead in this space, as sustainability and craftsmanship are core to their brand identity. By embedding this transformation into their business models, they create value for society as a whole. Value delivery in Industry 5.0 involves more personalized and dynamic interactions between businesses and customers, facilitated by advanced channels, digital experiences, and platform-based ecosystems. These technologies enable real-time feedback and enhanced personalization, fostering deeper, more meaningful relationships. For Made in Italy companies, this shift offers an opportunity to create bespoke offerings that align with consumer desires, leveraging digital platforms to connect with customers and deliver tailored experiences. By integrating these digital tools into their value delivery processes, companies can maintain their artisanal identity while responding more effectively to evolving market demands. The concept of value capture evolves as well, with businesses moving toward more sustainable, outcome-based models. Service-based offerings and pricing models that factor in both efficiency and environmental impact are becoming more prevalent. For Made in Italy enterprises, this could mean shifting toward service-oriented models that focus on long-term customer relationships and experiences rather than just products.

In the framework, feedback loops (Sjödin et al., 2021) —driven by DT and BMI—play a crucial role in the impact of Industry 5.0 on the new logic through which value is created, delivered, and captured. These feedback loops encompass continuous learning and adaptation, iterative innovation based on digital data, and customer feedback as input. Together, these elements facilitate the dynamic and adaptive nature of the transformation, supporting the evolution of business models within the context of Industry 5.0. For Made in Italy businesses, this highlights the importance of iterative innovation and the constant refinement of both products and processes, facilitated by customer feedback and digital data. The customer feedback loop is especially critical, fostering deeper collaboration and responsiveness. By incorporating customer insights, Made in Italy enterprises can better anticipate consumer needs and continuously improve their offerings, ensuring long-term sustainability and competitiveness.

This work also highlights the profound theoretical implications emerging from the transition from Industry 4.0 to Industry 5.0 within the context of BMI. By emphasizing the collaborative nature of human-machine interaction and the integration of traditional craftsmanship with digital innovation, this study challenges existing

frameworks and provides new insights into innovation models that blend technological advancements with traditional practices.

6 Conclusion, limitations and future research directions

In conclusion, this study provides valuable insights into the intersection of DT and BMI within traditional sectors, specifically the Made in Italy industries. These firms have successfully integrated digital technologies into their existing frameworks, redefining their business models while preserving their artisanal roots and cultural identity. The study also illuminates the evolving paradigm of Industry 5.0, where the focus shifts from automation to collaboration, highlighting the synergy between human creativity and technological advancements. Building on the insights presented throughout, these theoretical contributions call for a fundamental rethinking of traditional business models, where a blend of innovation and heritage is essential. This work further offers valuable perspectives by emphasizing the critical role of mediating factors which shape the transition toward more adaptive and resilient business models.

However, several limitations should be acknowledged. The small sample size of cases limits the generalizability of the findings, and future research would benefit from a larger, more diverse sample encompassing firms from different regions and industries. Moreover, as industries continue to evolve in response to technological advances, the findings underscore the importance of strategic alignment between digital adoption and organizational identity, providing a framework for further exploration of the factors that drive successful adaptation. Future research could delve deeper into how the mediating factors influence the long-term sustainability of DT efforts, especially within traditional sectors where the preservation of cultural heritage is just as crucial as embracing new technological advancements.

To further explore this topic, primary data collection could be utilized, including interviews with industry leaders and practitioners, as well as quantitative methods such as surveys. Qualitative interviews can provide deeper insights into how companies balance innovation with preserving cultural heritage in the context of DT. On the other hand, quantitative approaches can offer broader patterns and trends across different sectors, helping to identify key factors that influence successful adaptation to Industry 5.0. Combining these methods would allow for a more comprehensive understanding of the dynamics driving sustainable DT in traditional industries.

Artificial Intelligence in Social Media Advertising: To Say or Not To Say?

Veronica Marozzo, Fabrizio Cesaroni, Tindara Abbate
University of Messina, Messina, Italy

Abstract

The increasing integration of Artificial Intelligence (AI) in the advertising industry is opening up both promising opportunities and new challenges for brands leveraging social media to promote their offerings. The rise of Generative AI (gen-AI) is reshaping how advertising content is developed. Yet, while the benefits of creative automation are evident, little is known about how disclosing AI involvement influences consumer perceptions and attitudes toward advertisements. This research investigates the effects of openly stating the use of AI in social media advertising on how consumers perceive and respond to content. Results of two experimental studies show that transparency regarding AI use significantly boosts perceived advertising credibility and enhances comprehension of the advertising message. These findings indicate that consumers value transparency in AI-generated content. The study offers practical implications for marketing professionals and underlines the importance of further research into the ethical and regulatory dimensions of AI use in advertising.

Keywords: Artificial Intelligence, Social Media Advertising, Advertising Credibility, Advertising Language Comprehension.

Paper type: Academic Research Paper

1 Introduction

Thanks to the diffusion of firms' digitalization processes (Isaksson, Harjunkoski, and Sand, 2018), social media have become ubiquitous, making communication an integral part of human life (Başev, 2024). As reported by the Global Web Index (2024), a typical user spends 143 minutes per day using social media platforms. Accordingly, the advertising sector has started to produce digital advertisements within social media, which constantly see a boost in the number of users (Başev, 2024) and the amount of expenditure (Statista, 2024). This scenario underlines the opportunities that social media offers to businesses in terms of promoting their products and services.

Among digital technologies, Artificial Intelligence (AI) sees wide applications (e.g., Vakratsas and Wang, 2020; Başev, 2024; Lim et al., 2024), and its integration represents a paradigmatic change in contemporary marketing strategies and advertising practices. Several brands (e.g., Burger King, Netflix, and National Geographic) utilize AI in roles such as copywriting, editing, and other functions (Başev, 2024). Among AI technologies, Generative AI (gen-AI) has become prominent in the advertising industry (Euchner, 2023) because it is expected to automate even more creative tasks typically reserved for humans and generate economic value in future years (Huang and Grady, 2022).

While the adoption of gen-AI tools could represent a positive strategy able to support content creation and campaign optimization, it raises questions about the transparency and authenticity of digital content. The threat of deepfake images and videos used in contexts such as advertising campaigns has prompted politicians and regulators to come up with proposals to prevent their use. Similarly, tech companies have adopted self-regulations (such as the Coalition for Content Provenance and Authenticity – C2PA) to allow consumers to access data (e.g., content owner and AI tool used) about AI-created content. Specifically, the ground-breaking "transparency icon" developed by the C2PA will feature the symbol containing the letters "CR," which represents "Content CRedentials." Functionally, the Content CRedentials symbol can be embedded within the metadata of images, videos, and PDF files through photo and video editing applications. From the user's perspective, upon encountering online content bearing the "CR" acronym, a click on the symbol will enable them to determine the rightful owner, access details regarding the AI tools utilized in the content's creation, and gain insights into the production workflow.

The proposed regulations (like as the C2PA protocol) - aimed at ensuring transparency regarding the origin of online content - underscore a critical need to safeguard users, especially in the context of advertising produced using AI. The increasing sophistication and pervasiveness of AI-generated advertisements necessitate clear and accessible information about their creation process. Without such transparency, users may struggle to distinguish between authentic content and AI-generated promotions, potentially leading to misinformed decisions and an erosion of trust in online information. Therefore, it is paramount to investigate the users'

perceptions and attitudes towards advertising created with AI. Understanding how individuals interpret and react to these novel forms of promotion is crucial for developing effective regulatory frameworks and ethical guidelines. Accordingly, since the effects of AI-generated advertising on user perceptions and attitudes remain largely unexplored, this research aims to bridge this gap in the literature. Specifically, this research aims to investigate whether declaring the use of AI (*vs.* not declaring it) in social media advertising creation can affect consumers' perceptions (e.g., the credibility of the advertising) and attitudes (e.g., language comprehension of the advertising).

Through two experimental studies, this research shows that declaring (*vs.* not declaring) the use of Artificial Intelligence for the creation of an advertisement significantly enhances advertising credibility and language comprehension of advertising. These findings suggest that transparency in AI-generated content can improve consumer perceptions and attitudes toward advertising, offering valuable insights for marketers, while highlighting the need for further research exploration of ethical and regulatory concerns.

2 Conceptual framework and hypotheses development

Previous research has identified several key factors within online advertising that significantly influence consumer responses (e.g., Odoom, Narteh, and Odoom, 2022; Kamaruddin, Mohamed, and Aris, 2020). One such factor is advertising credibility, which has been consistently recognized as a critical determinant of consumer perception (MacKenzie and Lutz, 1989; Eisend, 2006). Additionally, language comprehension plays an essential role in how consumers process and interpret advertising messages, particularly in digital and multilingual contexts (Puntoni, De Langhe, and Van Osselaer, 2009).

Building on these insights, the present study investigates whether explicitly disclosing the use of Artificial Intelligence in creating advertisements affects consumer perceptions (such as perceived advertising credibility) and attitudes (such as perceived advertising's language comprehension). This investigation is grounded in the Persuasion Knowledge Model (PKM), which posits that consumers develop an understanding of persuasive tactics over time and utilize this knowledge to assess and respond to advertising content (Friestad and Wright, 1994). When consumers recognize persuasive intent or perceive manipulative strategies, they often activate resistance mechanisms to counter the influence (Fransen, Smit, and Verlegh, 2015; Ringold, 2002). In this context, transparency regarding how and by whom the content is created – including whether AI tools are involved – can shape consumers' evaluative and affective reactions toward the advertisement.

Empirical evidence supports this view, indicating that disclosing relevant information can enhance trust in advertising (Schweitzer et al., 2019; van der Heide and Lim, 2016). A similar reaction can be expected by disclosing the involvement of AI in message generation.

Empirical evidence supports this view, indicating that disclosing relevant information, such as the involvement of AI in message generation, can enhance trust in advertising (Schweitzer et al., 2019; van der Heide and Lim, 2016). Drawing from Source Credibility Theory, which highlights the influence of a communicator's trustworthiness and expertise on message persuasiveness (Fogg et al., 2001), AI can be perceived as a credible and competent source. This perception may lead consumers to view AI-generated advertising as more reliable, thereby positively impacting their evaluations (Khan and Mishra, 2024). Consequently, we propose that transparency about AI involvement can bolster the perceived credibility of the ad and signal corporate honesty and openness. On the attitudinal side, recent literature (e.g., Gao et al., 2023; Al Tawalbeh et al., 2024) shows that AI contributes to enhanced personalization and linguistic adaptation in advertising. These capabilities make ad content more understandable, relevant, and engaging for target audiences. Therefore, we argue that when consumers are made aware of AI's role in content creation, their comprehension of the advertising language may improve due to perceived gains in message quality and adaptability.

Overall, building upon the Persuasion Knowledge Model, we assert that if the use of AI is not reported, consumers may perceive it as an attempt to deceive. On the contrary, declaring it can reduce resistance, and increase credibility, and comprehension.

Formally, we proposed the following hypotheses:

- H_1: The declared use of AI (*vs.* not declared) positively affects the consumers' perceived advertising credibility.
- H_2: The declared use of AI (*vs.* not declared) positively affects advertising language comprehension.

3 Methodology

We conducted 2 experimental studies. Study 1 aimed to test whether the AI's use declaration affects the credibility and the language comprehension of the advertising. The use of AI (not declared *vs.* declared) was

manipulated in a between-subjects design, holding constant all other elements in social media advertising. Specifically, the stimulus was an advertisement on the Instagram platform that used wine as a product category. It was entirely created by an AI-generative tool. In particular, ChatGPT is used for the creation of the text part, while DeepAI is used for the creation of the visual part. The manipulation of the Artificial Intelligence use (not declared *vs.* declared) was made by inserting a logo with the words "created with AI" placed at the bottom right of the visual part of the advertising, and a logo with the words "Content created with Artificial Intelligence" placed at the end of the textual part of the advertising.

Study 2 aimed to obtain additional support for the previous results by providing evidence of the generalizability of the proposed effect against a different product category (i.e., body wash). The use of AI (not declared *vs.* declared) was manipulated as in Study 1. The stimulus was an advertisement on the Instagram platform (entirely created by an AI-generative tool as in Study 1) that used body wash as a product category. As in study 1, the manipulation of the Artificial Intelligence use (not declared *vs.* declared) was made by inserting a logo with the words "created with AI" placed at the bottom right of the visual part of the advertising, and a logo with the words "Content created with Artificial Intelligence" placed at the end of the textual part of the advertising.

Figure 2 shows the experimental stimuli used in the studies, which allowed for testing the research hypotheses concerning different product categories (i.e., wine and body wash).

		Product category	
		Wine (Studies 1 and 2)	Body wash (Study 2)
Artificial Intelligence use	Declared		
	Not declared		

Figure 1: Stimuli used in the experimental studies

3.1 Study 1

Two hundred and thirty Italian users (50.4% females; M_{age} = 26.50; SD_{age} = 6.80) took part in the study and were randomly assigned to one of the two conditions. Advertising credibility was captured by three 7-points items (Kim, Ratneshwar, and Thorson, 2017; α = .88); while advertising language comprehension was captured by three 7-points items (Lin and Wang, 2016; α = .80). Results of a first one-way ANOVA - considering the use of AI as independent variable and the advertising credibility as dependent variable - showed that the advertising credibility was significantly higher in the case of AI'use declared compared to not declared ($M_{AIdeclared}$ = 4.225, SD = 1.49; $M_{AInotdeclared}$ = 3.554, SD = 1.323; F(1, 228) = 12.94, p < .000). Results of a second one-way ANOVA - considering the use of AI as independent variable and the advertising language comprehension as dependent variable - showed that the advertising language comprehension was significantly higher in the case of AI'use declared compared to not declared ($M_{AIdeclared}$ = 4.296, SD = 1.208; $M_{AInotdeclared}$ = 3.747, SD = 1.186; F(1, 228) = 12.05, p < .000). Overall, these findings provide support for the effect of AI'use declared (vs. not declared) on

consumers' perception of advertising credibility and consumers' attitude toward the advertising language comprehension.

3.2 Study 2

Three hundred and twenty-four Italian users (58.3% females; M_{age} = 25.94; SD_{age} = 7.12) took part in the study and were randomly assigned to one of the four conditions in a 2 (AI's use: not declared vs. declared) by 2 (product category: wine *vs.* body wash) between-subjects design. Advertising credibility and advertising language comprehension were measured as in Study 1 (respectively, α = .86; α = .80).

Results of a first two-way ANOVA on advertising credibility with the use of AI (not declared *vs.* declared) and product category (wine *vs.* body wash) as between-subject factors confirmed a significant main effect of AI's use ($M_{AIdeclared}$ = 4.227, SD = .106; $M_{AInotdeclared}$ = 3.699, SD = .107; F(1, 320) = 12.36, p <,000). The results also showed a significant main effect of the product category (M_{Wine} = 4.14, SD = .107; $M_{BodyWash}$ = 3.787, SD = .106; F(1, 320) = 5.51, p =.019). Finally, no significant interaction effect between AI's use and product category was found (F(1, 320) = .028, p = .866).

Results of a second two-way ANOVA on advertising language comprehension with the use of AI (not declared *vs.* declared) and product category (wine *vs.* body wash) as between-subject factors confirmed a significant main effect of AI's use ($M_{AIdeclared}$ = 4.379, SD = .090; $M_{AInotdeclared}$ = 3.869, SD = .091; F(1, 320) = 15.867, p < .000). They also showed a significant effect of the product category (M_{Wine} = 4.298, SD = .091; $M_{BodyWash}$ = 3.95, SD = .090; F(1, 320) = 7.391, p =.007). No significant interaction effect between AI's use and product category was found (F(1, 320) = .884, p = .348). Overall, these findings suggest that the effect of AI's use declared (*vs.* not declared) on consumer perception of advertising credibility and consumer attitude toward the advertising language comprehension holds regardless of the product category, then provide preliminary evidence of the generalizability of the proposed effects.

4 Discussion and conclusion

The results of this research provide empirical evidence that declaring the use of Artificial Intelligence in the creation of advertisements, as opposed to not disclosing it, positively influences consumers' perception of advertising credibility as well as their attitude toward the comprehension of the advertising language. In particular, openly stating the involvement of Artificial Intelligence enhances both how trustworthy the advertisement is perceived and how easily the message is understood by the audience.

Furthermore, these effects were replicated in a different product category – body wash – suggesting that the impact of AI disclosure on consumer perception and attitude is not limited to a specific type of product. These findings offer preliminary support for the generalizability of the proposed effects, indicating that transparency regarding AI usage in advertising may consistently improve consumer responses across various market segments.

This paper presents a fresh perspective on advertising research by examining how disclosing the use of AI in the creation of social media ads affects consumer responses. Although the integration of AI in digital marketing has been widely explored, few studies have specifically investigated the impact of transparency about AI involvement on consumer perceptions and attitudes. Findings from this study suggest that openly communicating the role of AI in ad creation can be viewed as an extension of the Source Credibility Theory (Khan and Mishra, 2024). In this context, even highly sophisticated technologies such as gen-AI can serve as credible sources, provided their involvement is made explicit – ultimately fostering greater user engagement with social media advertising.

Enhancing perceived advertising credibility could stimulate consumer engagement and may also influence brand perception, opening new avenues to explore how responses to the advertisement can indirectly shape opinions about the sponsoring brand. Furthermore, by analyzing the effects of AI disclosure on both consumer perceptions (e.g., advertising credibility) and attitudes (e.g., comprehension of advertising language), this paper offers a comprehensive framework for understanding the complex consequences of AI transparency in advertising. This integrated approach contributes to a more nuanced and holistic understanding of how audiences interact with AI-generated promotional content.

4.1 Implications and research limitations

The findings underscore the strategic value of openly disclosing the use of Artificial Intelligence in digital advertising efforts. For marketers, embracing transparency by clearly communicating the involvement of AI technologies in advertising creation can significantly enhance the perceived credibility of the message – an

essential factor in fostering consumer trust. Transparency signals honesty and authenticity, which may lead consumers to develop more favorable attitudes toward the brand itself. This insight carries practical significance for companies aiming to integrate AI into their communication strategies: rather than concealing AI usage, highlighting it can strengthen consumer confidence and engagement.

Importantly, the study reveals that even sophisticated tools like gen-AI can be viewed as trustworthy sources when their role is clearly communicated. This, in turn, positively shapes user perceptions and attitudes within the context of social media advertising. Moreover, improvements in perceived advertising credibility and message comprehension may extend beyond the ad itself, potentially influencing how consumers perceive the brand behind the content – suggesting a broader, indirect branding benefit.

From a managerial perspective, companies should view AI not just as a tool for efficiency but as an asset for enhancing message quality and trustworthiness. They are encouraged to leverage AI for creative functions – such as generating ad copy or optimizing content delivery – provided that its role is transparently stated. Additionally, brands might consider developing communication guidelines or labels indicating AI involvement, as a way to standardize transparency practices. Finally, companies should explore how transparency in AI use can be incorporated into broader brand positioning strategies, especially in markets where ethical tech use and consumer trust are competitive differentiators.

Although this study demonstrates a significant effect of AI disclosure (as opposed to non-disclosure) on consumer perceptions, and attitudes, it does not delve into potential moderating factors that could shape these outcomes – such as consumers' familiarity with AI technologies, the reputation of the brand, or the degree of consumer involvement with the product. Future research could examine how these variables influence the relationship between AI transparency and key outcomes like perceived ad credibility and comprehension of advertising language.

Additionally, the current work emphasizes outcome measures – credibility and language comprehension – without fully exploring the underlying psychological processes that might drive these effects. Subsequent studies could investigate whether the act of disclosing AI use affects perceptions of authenticity, levels of skepticism, confidence in the brand, honesty, or trust – core psychological constructs that are particularly relevant in AI-driven marketing contexts.

While the study includes two product categories (wine and body wash), it does not assess how different types of products or industries might influence the effectiveness of AI disclosure. It is plausible that consumer responses to AI transparency vary across sectors – for example, between high-tech products and everyday consumer goods, or between tangible items and experiential services. Further research should explore whether these contextual factors moderate the effects observed.

Moreover, this study is limited to digital advertising and social media formats. Future investigations could expand the scope to include a wider range of platforms, such as streaming services, search engine marketing, or in-app advertising, to assess the consistency of the observed effects across diverse digital environments.

Lastly, the sample is composed of Italian consumers, which may limit the generalizability of the findings. Cultural attitudes toward AI and transparency can differ significantly depending on the country, industry norms, or regulatory frameworks. Cross-cultural research could offer valuable insights into how AI disclosure is perceived in different international contexts and whether the observed effects hold globally.

5 Ethics declaration

All research is conducted in accordance with ethical principles.

6 AI declaration

Artificial intelligence tools were employed in the creation of the advertising stimuli used in the experimental studies. Specifically, ChatGPT was used to generate the textual content of the advertisements, while DeepAI was utilized to produce the visual components of the advertising materials.

Exploring AI Integration in Sicilian SMEs: An Investigation on Awareness and Perspectives

Chiara Avarello[1], Antonia Cava[1], Veronica Marozzo[1], Francesco Micali[2], Andrea Nucita[1], Stefano Russo[2]
[1]University of Messina, Messina, Italy
[2]Lo Stretto Digitale, Messina, Italy

Abstract

In an increasingly digitalised society, Artificial Intelligence (AI) is gaining prominence as a key driver of business innovation and competitiveness. While much research has focused on AI adoption in large enterprises, fewer studies have explored its integration within small and medium-sized enterprises (SMEs), especially in regions with specific socio-economic contexts. This study investigates the awareness, perceptions, and adoption of AI technologies among SMEs in Sicily, a region in southern Italy, characterised by unique economic and organisational dynamics. Adopting a mixed-methods approach, the research combines qualitative insights from in-depth interviews with entrepreneurs from both digital and non-digital sectors, and a large-scale quantitative survey targeting over 2.000 Sicilian SMEs. The methodological framework is structured in sequential phases, where the qualitative component plays a foundational role in informing and shaping the subsequent quantitative investigation. The qualitative findings reveal significant disparities in AI awareness and implementation between sectors, highlighting both enablers and barriers such as digital maturity, organizational culture, training needs, and resistance to change. These insights informed the development of a structured questionnaire to capture broader trends in AI readiness, perceived benefits, and challenges. The study contributes to the literature on digital transformation in SMEs by applying the Technology–Organization–Environment (TOE) framework to a specific regional context, offering both theoretical insights and practical recommendations for policymakers, training institutions, and business leaders seeking to foster inclusive AI adoption.

Keywords: Artificial Intelligence, SME, Sicily

Paper type: Academic Research Paper

1 Introduction

Interest in Artificial Intelligence (AI) is growing in a rapidly transforming and increasingly digitalised society. As stated by Ho et al. (2022), Artificial Intelligence has received increasing attention from various areas of society, industry, and business, considered the Fourth Industrial Revolution (Zhang et al., 2021). Recent studies (e.g., Khalid, 2020; Dwivedi et al., 2021) described Artificial Intelligence as a field that combines computer science with large datasets to enhance the quality of business decision-making. Specifically, Dwivedi et al. (2021) claimed that Artificial Intelligence is broadly characterised as the simulation of human cognitive processes by machines (software systems) employing advanced technologies such as machine learning, deep learning, data mining, natural language processing, and image recognition, among others. Recent literature (e.g., Awan et al., 2021; Sestino and De Mauro, 2022; Chen, Esperança and Wang, 2022) provided support for the convergence of Artificial Intelligence and Big Data analytics by enabling the systematic organization of previously fragmented information into coherent frameworks, thereby facilitating the transformation of raw data into actionable insights and accelerating strategic decision-making at the organizational level. An extensive body of literature has examined the adoption of AI and its implications for business performance, demonstrating its potential to reduce operational costs and enhance predictive accuracy (Agarwal et al., 2021), increase productivity through the automation of routine human activities (Acemoglu and Restrepo, 2018), foster product innovation (Babina et al., 2024), optimize business processes (Adesina, Iyelolu and Paul, 2024), and drive business growth (Bag et al., 2021). Consequently, there is an increasing emphasis among enterprises on the deployment of Artificial Intelligence technologies, recognizing their considerable potential to enhance organizational performance (Mikalef and Gupta, 2021), although substantial challenges to widespread adoption remain (Yu et al., 2020).

The technological and strategic implications of Artificial Intelligence are increasingly recognized by the academic community as a pivotal domain of inquiry (Sun and Medaglia, 2019), particularly as the assimilation of Artificial Intelligence practices influences both financial and non-financial outcomes within small and medium-sized enterprises – SMEs - (Baabdullah et al., 2021; Badghish and Soomro, 2024). As remarked by Sjödin et al. (2021), small and medium-sized enterprises should be prepared to adopt digital processes and business model innovation as business processes evolve into more digital ones. Therefore, as suggested by Chen and Lin (2021),

understanding the underlying mechanisms and critical drivers through which Artificial Intelligence shapes firm performance offers considerable contributions to both theoretical development and managerial practice. Consequently, there is a pressing demand to examine the complex, and predominantly qualitative, dimensions that influence Artificial Intelligence adoption in SMEs. As central contributors to economic growth (Gherghina et al., 2020), SMEs constitute a vital component of global economies, especially within emerging and developing markets (Ndiaye et al., 2018; Badghish and Soomro, 2024). In contrast to larger firms, SMEs are characterized by heightened agility in responding to technological disruptions and exhibit superior adaptability to market dynamics, underpinned by their streamlined decision-making structures (Baeshen, Soomro and Bhutto, 2021). As stated by Rawashdeh, Bakhit and Abaalkhail (2023), these firms increasingly deploy disruptive technologies to scale their operations and enhance organizational efficiency. In response to the current wave of industrial transformation, SMEs have further catalyzed the integration of digital technologies (Ghobakhloo and Iranmanesh, 2021). Additionally, heightened stakeholder pressures have recently intensified SMEs' engagement with innovation-driven strategies (Gherghina et al., 2020). Iyelolu et al. (2024) suggested that Artificial Intelligence technologies can significantly improve product development, operational efficiency, competitive advantage, and customer engagement for SMEs. Concerning the latter, Kedi et al. (2024) stated that AI technologies (e.g., natural language processing, machine learning, and predictive analytics) represent relevant tools able to improve customer engagement and retention through personalized content and recommendations. As a result, thanks to AI-driven marketing strategies, SMEs reported notable improvements in sales performance and return on investment (Kedi et al., 2024).

Despite the previous literature showing different positive impacts due to the implementation of Artificial Intelligence in SMEs, it is important to stress that AI adoption by SMEs encountering barriers and challenges ranging from internal resistance to organizational complexity and legal considerations (Venkateswarlu et al., 2022), and financial constraints (Bakhtiari et al., 2020). Moreover, as suggested by Schwaeke et al. (2024), local factors (e.g., economic conditions, cultural aspects, and government incentives) significantly influence Artificial Intelligence implementation in SMEs. With this in mind, we have decided to focus our research on SMEs in Sicily (southern Italy). Specifically, the present research aims to examine Sicilian SMEs' adoption of Artificial Intelligence technologies, focusing on the awareness, perspectives, and needs of entrepreneurs operating in an area with specific socio-economic characteristics. Given the relatively limited adoption of Artificial Intelligence among SMEs and the contextual challenges that may arise in regions with distinct economic conditions, our study seeks to provide a comprehensive understanding of the factors (technological, organizational, and environmental) that facilitate or hinder Artificial Intelligence integration in this landscape. Accordingly, to add to the literature, the present study utilizes the Technology–Organization–Environment (TOE) framework to propose a conceptual model that explains the readiness of firms towards the adoption of Artificial Intelligence and the firm performance within SMEs with specific socio-economic characteristics like Sicily.

2 Methodology

This study adopts a mixed-methods research design, integrating qualitative and quantitative approaches to provide a comprehensive understanding of the enablers and barriers to artificial intelligence (AI) adoption among small and medium-sized enterprises (SMEs) in Sicily. The methodological framework is structured in sequential phases, where the qualitative component plays a foundational role in informing and shaping the subsequent quantitative investigation.

The initial phase involved a qualitative exploration aimed at capturing in-depth perspectives and contextual nuances that are often not accessible through standardized survey instruments. Specifically, we conducted three semi-structured interviews with entrepreneurs from selected Sicilian SMEs. The interviews served a dual purpose: (1) to generate exploratory insights on the current state of Artificial Intelligence awareness, usage, and resistance within different industrial contexts, and (2) to identify emergent themes and variables essential for designing a valid and context-sensitive questionnaire.

The interview guide was developed around four thematic domains: company profile (including size, sector, and turnover), level of digital maturity and existing IT infrastructure, current uses and perceptions of Artificial Intelligence technologies, and perceived barriers to adoption (e.g., financial, cultural, or regulatory). These themes were deliberately broad to allow for the emergence of unanticipated insights. The flexibility of the semi-structured format enabled us to adapt the questions in real-time based on the interviewee's background, fostering a more natural and reflective conversation.

The selection of interviewees was purposive selected to include entrepreneurs operating both within and outside the digital technology sector. This comparative design allowed us to contrast attitudes and experiences related to Artificial Intelligence adoption between digitally mature firms and those with limited exposure to

digital innovation. Notably, this distinction yielded valuable insights into how sectoral characteristics, organizational culture, and employee demographics mediate openness to technological change.

Importantly, the qualitative phase was not intended to produce generalizable results, but rather to provide an empirically grounded basis for the development of the survey instrument used in the quantitative phase. Through thematic analysis of the interview transcripts, we identified key constructs—such as the perceived utility of AI, organizational readiness, resistance factors, and training needs—which were operationalized into survey items. In this sense, the interview phase functioned as an essential diagnostic tool, enabling us to design a questionnaire that reflects the lived realities and language of the target population, thus increasing the content validity of the instrument.

Moreover, the qualitative findings helped refine the scope and structure of the questionnaire by highlighting sector-specific concerns and contextual constraints that may not be captured by standard theoretical models. This iterative process—moving from open-ended qualitative exploration to structured quantitative measurement—ensured both conceptual depth and empirical breadth in our research design.

The second stage of the research involved designing a survey instrument informed by the most salient insights derived from the interviews. After conducting the in-depth interviews, we realized a mapping of small and medium-sized enterprises (SMEs) to identify key actors to participate in the survey. In order to carry out a quantitative analysis, we needed to create a database of companies to be contacted via email, through which we would present the research and invite participation in an online questionnaire.

To build this database, we relied on the AIDA database (Analisi Informatizzata delle Aziende), a comprehensive commercial information platform that provides detailed financial and corporate data on Italian companies. Specifically, AIDA is a commercial database providing detailed information on over one million Italian companies, with a focus on limited liability companies. AIDA includes company profiles, financial statements, economic and financial indicators, ownership structures, corporate linkages, and other relevant business data. The platform is widely used in academic, financial, and professional contexts for research and analysis of Italian enterprises (https://dfka.it/area-crediti/aida/).

Our search strategy within AIDA focused on identifying limited liability companies that met the European Union's criteria for SMEs, specifically as applied in the Italian context. According to these criteria, SMEs are defined as companies with fewer than 250 employees and either an annual turnover not exceeding €50 million or an annual balance sheet total not exceeding €43 million. Additionally, we restricted our search to companies with either their registered or operational headquarters located in the region of Sicily.

This search yielded a total of 2.457 companies. Since AIDA does not include a specific email field but does provide company website URLs, we developed a Python script to extract email addresses by scraping these websites. Out of 1.299 websites available through AIDA, we successfully retrieved 761 email addresses. For the remaining companies, we manually searched online sources to identify contact information. Through this combined approach, we obtained a total of 2.081 valid email addresses. This set of 2.081 email addresses constitutes our target population for the distribution of the questionnaire and serves as the empirical basis for our quantitative investigation currently in progress.

2.1 Results

The qualitative phase of the research consisted of three in-depth interviews with managers from Sicilian SMEs operating in the software development and construction equipment sectors. These interviews revealed contrasting levels of awareness and use of Artificial Intelligence (AI) tools. Two companies demonstrated advanced familiarity with generative AI tools such as ChatGPT, Gemini, and GitHub Copilot, integrating them into areas such as software development, document analysis, customer support, and marketing. As one respondent explained: "We use it in various contexts—for code analysis, client quote evaluations, document summarization" (Interview 2). Another noted: "We are trying to foster a culture of AI usage... The tools are mature; we are the ones who need to mature" (Interview 1). A third interviewee, however, reported a very limited understanding of AI and highlighted resistance within the company due to a lack of digital competencies: "I am aware of my lack of knowledge… I wouldn't even know how to apply it in my daily work" (Interview 3).

Then, as emerged from the qualitative exploration, respondents from the digital sector demonstrated a high level of familiarity with Artificial Intelligence technologies, which were already integrated into various business functions, including software development, marketing, design, and administration. The most frequently cited benefits were increased efficiency, information synthesis, and process optimization. However, challenges such as the quality of AI-generated outputs, inappropriate technical applications, and concerns over displacement in creative roles were also noted.

Despite a generally high level of awareness, both interviewees emphasized the need for structured training and internal guidelines to ensure effective AI utilization. While Artificial Intelligence implementation was already well advanced in these companies, respondents stressed the importance of responsible use and attention to human capital. They expressed optimism about AI's potential—particularly in automating repetitive tasks and enhancing design processes—but also predicted a turbulent transition phase, potentially marked by a "natural selection" among firms with varying levels of preparedness. Their strategic outlook was both positive and pragmatic, highlighting the competitive advantage of adaptability and workforce training.

In contrast, interviews with entrepreneurs from non-digital sectors revealed a markedly different outlook. Significant resistance to technological change emerged, often attributed to generational dynamics within the workforce, deeply ingrained routines, and a lack of familiarity with AI tools and their potential benefits. This knowledge gap was compounded by a general disinterest in pursuing training initiatives in the field of artificial intelligence.

These findings informed the design of a structured questionnaire aimed at exploring the broader landscape of AI awareness, adoption, and perceived benefits or obstacles among Sicilian SMEs. The questionnaire is divided into four thematic sections: (1) company and respondent profile, (2) familiarity and attitudes toward AI, (3) current or potential applications of AI in business processes, and (4) perceived challenges and future outlooks related to AI implementation.

3 Discussion and conclusion

The initial findings from the qualitative interviews suggest a heterogeneous landscape of Artificial Intelligence awareness and adoption among Sicilian SMEs. On one hand, some companies—especially in the software and digital services sectors—are already experimenting with or integrating AI tools into various phases of their business operations. These firms display a proactive attitude and a strategic vision oriented toward innovation, albeit tempered by concerns about the quality of AI-generated outputs and the risk of over-reliance. On the other hand, companies from more traditional sectors appear to be at an earlier stage, often limited by a lack of knowledge, digital skills, and internal resources.

This divergence highlights the need for differentiated strategies in promoting the diffusion of Artificial Intelligence across the regional business fabric. The insights gained through the interviews were crucial in designing a questionnaire capable of capturing a broader and more nuanced understanding of the factors enabling or hindering AI adoption across sectors. The forthcoming quantitative phase of the research, based on a population of over 2.000 SMEs, will allow us to validate and expand these preliminary observations, offering empirical evidence on the current state of AI readiness in Sicilian enterprises.

This study can contribute to the growing body of literature on digital transformation in SMEs, while also providing practical implications for policymakers, innovation hubs, and training institutions seeking to support a more inclusive and sustainable approach to AI adoption in less digitally mature regions.

3.1 Implications and research limitations

The insights emerging from this exploratory phase offer several implications for both research and practice. First, the evident disparity in AI awareness and adoption among SMEs suggests that a one-size-fits-all approach to digital innovation may be ineffective. Tailored support policies, training programs, and sector-specific case studies are needed to address the specific barriers faced by different types of firms. Policymakers and regional development agencies could leverage these findings to design targeted interventions aimed at increasing digital competencies, especially in low-tech sectors or smaller enterprises.

From a research perspective, the study provides a grounded framework for further investigation, combining qualitative depth with the potential for broad quantitative validation. The structured questionnaire developed on the basis of interview data allows for the measurement of key variables such as perceived benefits, challenges, and future intentions related to AI.

However, this study also has some limitations. The qualitative phase was based on a small number of interviews, which, while rich in detail, may not fully capture the diversity of the regional SME ecosystem. Furthermore, the contact database was constructed using web scraping and manual search techniques, which—despite resulting in a large number of email addresses—may still present a selection bias, favoring firms with an online presence. Finally, as the quantitative phase is still ongoing, the conclusions drawn at this stage remain provisional.

Future research could expand the qualitative component to include a wider variety of sectors and firm sizes, and follow up the quantitative survey with case studies or longitudinal analyses to track the evolution of AI adoption over time.

4 Ethics declaration

All research is conducted in accordance with ethical principles.

5 AI declaration

AI-based tools such as ChatGPT were used to support the development of the Python script for web scraping email addresses from company websites, as well as to assist with translation tasks throughout the research process.

Digital Finance for SMEs and Startups: Literature Review and Research Proposals

Tindara Abbate, Fabrizio Cesaroni, Mattia Fasano, Tiziana La Rocca, Veronica Marozzo, Valeria Schifilliti
University of Messina, Messina, Italy

Abstract

Financial digitalisation represents a systemic transformation that affects the entire business lifecycle, emphasising trust, transparency, sustainability, and innovation. Digital tools and platforms, such as crowdfunding and online peer-to-peer lending, increase access to credit and mitigate entry barriers, particularly for startups and small and medium sized enterprises. New technologies, including blockchain and big data, reduce information asymmetries, improve risk assessment, and strengthen stakeholder trust. The transparency of these platforms, associated with the use of reputational signals (for instance credit ratings and reviews), plays a pivotal role in attracting investors and optimizing capital allocation. The democratisation of access to finance supports innovative business models that are not just profit-driven but also oriented towards social and environmental value.

In this context, our research aims to systematically conceptualise digital finance tools, their specific benefits and challenges. The integration of advanced digital technologies into financial services allows greater access to lending resources and innovative funding models. Moreover, several issues and trends emerge, such as, the regulatory uncertainty, the data quality for privacy and cybersecurity, increasing use of AI to customise financial services and risk assessment. Specifically, our study presents a detailed analysis of the state of the art on the connections between digital finance and entrepreneurship, focusing on credit rating in the digital context. In addition, it also provides propositions through which firms can gain competitive advantage and highlights the democratization of credit and financial inclusion, made possible by reducing geographical and socio-economic barriers. Several implications emerge from a managerial point of view and from a theoretical perspective.

Keywords: Fintech, Crowdlending, Digital Marketplace, Digital Platform, Entrepreneurship

Paper type: Academic Research Paper

1 Introduction

The literature on crowdfunding and FinTech solutions highlights how these forms of financing integrate or replace traditional sources (i.e., venture capital, business angels, bank loans), demonstrating their crucial importance for small and medium sized enterprises (SMEs) and startups seeking capital (Martínez-Climent et al., 2018). A central aspect is the reduction of information asymmetry through platform reputation, investor feedback, lead investors' role, and the use of social networks and personal relationships (Shneor and Vik, 2020; Cai et al., 2021).

Crowdfunding platforms operate as digital intermediaries, offering screening, regulatory compliance, and fraud risk mitigation (Cai et al., 2021). The integration of emerging technologies enhances transparency and risk analysis while maintaining the central role of trust, which has now shifted towards algorithms and digital interfaces (Hawlitschek et al., 2018). Global regulations, such as the JOBS Act in the USA and European and Chinese regulations, significantly influence the diffusion of crowdfunding, with more permissive approaches (UK) or restrictive ones (China) determining the pace of its growth (Basha et al., 2021).

Beyond the entrepreneurial domain, crowdfunding also facilitates financing of social and sustainable projects, attracting investors motivated by positive impact (Wehnert and Beckmann, 2021). The success of crowdfunding campaigns depends on the quality of their content (pitch, images, videos), establishing a strong network, and active engagement with backers. These elements trigger the "herding effect" and enhance the project's reputation.

Our study aims to provide valuable assessments and insights for entrepreneurs, policymakers, and researchers interested in the potential of digital finance as a lever to support economic development, particularly for startups and SMEs.

The research questions to be addressed are the following: what is the current state of the literature on the relationship between digital finance and entrepreneurial activities? What is the state of the art regarding the risks of digital finance and credit rating for firms?

To answer these research questions, with a specific focus on startups and SMEs, we adopt a systematic approach in the search for works related to the topic of interest. We have followed the Preferred Reporting

Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines (Moher et al., 2009; Page et al., 2021). Overall, 172 articles have been included in the final analysis and the collected data has been analysed using the bibliometric methodology (Kraus et al., 2022).

This paper is structured as follows: the next section illustrates the theoretical background of the study; section 3 details the methodology used; section 4 shows the main finding and section 5 presents the discussion. Finally, the last section concludes and provides some implications, emphasising further research.

2 Theoretical background

Digital finance, such as crowdfunding and P2P lending, provides greater access to funding compared to traditional channels, reducing the entry barriers for SMEs and startups. Crowdfunding and P2P represent some digital lending tools that can outperform the conventional lending in the retail sector. Crowdfunding is not just a financial mechanism, but a relational process that relies on the ability to inspire and maintain funders' trust (Allison et al., 2015). Online P2P lending platforms denote an innovative model in which co-development and the creation of both economic and social value are central. P2P can complement traditional finance, offering small businesses credit options, serving customers who are less served by traditional channels (Liu et al., 2020).

These digital lending tools not only facilitate exchanges between firms and lenders but also foster collaborative dynamics that generate both economic and social benefits, through co-development models, value creation, and social engagement (Martínez-Climent et al., 2018).

A stream of research, under Signalling Theory, examines how digital lending platforms reduce information asymmetry in P2P markets, improving access to and conditions of credit (Lin et al., 2013 and 2016). Several works evaluate the phenomenon through quality signals and how initial investments, or emotional narratives could enhance the success of campaigns (Allison et al., 2015; Moss et al., 2015), while local funders respond more to personal relationships than to economic data (Agrawal et al., 2014). The role of investor trust is emphasised, also driven by the transparency of personal data (Burtch et al., 2014). Determinants of success of crowdfunding campaigns can be the credibility and reputation of the fundraiser, the size of the social network, the campaign quality (content, duration, videos, and images), transparency, and trust (Shneor and Vik, 2020).

Social Capital Theory has received increasing attention in crowdfunding research (Cai et al., 2021), emphasising the importance of trust and social capital in attracting funding through crowdfunding platforms. Trust acts as a bridge to overcome information asymmetries between entrepreneurs and potential funders. Also relevant are trust and the perception of reliability of loan applicants on P2P lending platforms.

A few studies highlight advantages and challenges compared to traditional methods (Bruton et al., 2015). Some authors suggest enhancing platform transparency and security through regulation while supporting the development of emerging technologies (blockchain, AI) in improving transparency and mitigating risks (Wehnert and Beckmann, 2021; Bargoni et al., 2024; Sharma et al., 2024).

There is a need to better understand the interaction between investors, entrepreneurs, and platforms, with a particular focus on the role of regulation and social dynamics in the context of startups and SMEs to support the growth of early-stage businesses.

These aspects will be further explored in the following sections, where the literature on the topic will be analysed.

3 Methodology

Our research design is based on the PRISMA framework (Moher et al., 2009; Page et al. 2021). To conduct an in-depth analysis of crowdlending and P2P lending, we identified a set of keywords by analysing the terminology related to the topic and we created a search query to be used in the Web of Science (WoS) database. This approach allows the inclusion of a broad and relevant set of articles, reducing the risk of omitting significant information from the analysis. The search query formulated is shown in Table 1.

Table 1 – Query, symbols and operators

Query	Symbols	Meaning and intended purpose
crowdlend* OR loan* OR lending OR "loan-based" OR "lending-based" OR ("peer-to-peer" OR "p2p") NEAR/1 lending) AND (platform* OR marketplace* OR "digital marketplace" OR "online marketplace" OR "online platform" OR "digital platform")	*	Truncation character to include words with the same root or slight terminological variations.
	Topic	Thematic data field, for example, title, abstract, and keywords.
	AND	Boolean operator to find database records containing all terms separated by this operator.
	OR	Boolean operator to find database records containing any of the terms separated by this operator.
	NEAR/x	To find records where the terms joined by this operator are within a specified number of words from each other.

The research covers the period from 1992 to January 2025, to include the whole development of the topic starting from the publication of the first article on the subject.

In the initial 'Identification' step, we found 2,434 contributions on the Web of Science database. In the second step, a screening was carried out and our search was refined by applying the following inclusion criteria: categories (Business, Management, Business Finance); language (English); source type (articles and Early Access, literature reviews were excluded); journal quality filter (e.g., ABS "4*", "4", and "3"); and contextual filter (documents not relevant to the topic). No specific time interval was defined.

We had a total of 172 articles in the final analysis.

We used the bibliometric methodology (Kraus et al., 2022) and the R-studio Bibliometrix package (http://www.bibliometrix.org/) (Aria and Cuccurullo, 2017), which provides a set of tools for quantitative research in bibliometrics and scientometrics, including the web software Biblioshiny. This analysis allows for the identification of the most popular topics addressed in a particular field. This approach, on one hand, helps to better understand how the research field is structured and how it is evolving. On the other hand, it allows for a deeper understanding of the impact of this research in the field of management.

4 Findings

Table 2 presents the metrics and impact of the leading journals or sources contributing to the analysed research field, using bibliometric indicators to assess their impact (h-index, g-index, and number of publications).

Although crowdfunding and lending platforms are related to finance, there is a limited presence of finance journals among the leading publications. The most significant journals come from fields such as management (Management Science) and decision-making (European Journal of Operational Research), with a high impact in terms of citations and published articles. Thus, the topic studied seems an interdisciplinary phenomenon related to technology, sociology, and management, rather than being treated as a strictly financial issue.

The most cited works locally and globally are shown in Table 3. Local citations refer to the number of times an article is cited by other articles within the selected dataset, while global citations refer to all citations received by the article from publications worldwide.

Journal of Financial Stability	2	3	0,4	128	3	2021

The research highlights how P2P lending platforms are transforming the financial environment, influencing investment decisions, risk assessments, and relationships between participants.

On the one hand, the importance of 'social' and network information emerges in the analysis of information asymmetry, where the quality of social connections (Lin et al., 2013) and data from social media (Ge et al., 2017) can reduce the risk of default.

On the other hand, investment decisions are driven by market mechanisms (Wei and Lin, 2017), geographical distortions (Lin and Viswanathan, 2016), and cultural differences (Burtch et al., 2014), while instance-based assessment models provide new perspectives for credit risk assessment (Guo et al., 2016).

There is a debate on whether P2P lending platforms act as substitutes or complements to traditional banks (Tang, 2019; Vallee and Zeng, 2019), while in the social domain, the role of intrinsic and extrinsic factors (Allison et al., 2015) and signals of virtuousness and entrepreneurial orientation (Moss et al., 2015) in determining the success of campaigns and the strength of repayments is highlighted.

The main results of our analysis suggest the existence of four key research areas, which are described in detail below.

New perspectives on crowdfunding and P2P lending emerge in a first area, revealing that crowdfunding platforms do not simply function as financial intermediaries but operate as genuine "institutional entrepreneurs", influencing rules and behaviours in the market (Mollick and Nanda, 2016). Numerous factors shape funding decisions, including the importance of reputation and social signals (Lin et al., 2013; Iyer et al., 2016), informational constraints and behavioural dynamics (Ge et al., 2017)

A second area includes studies on crowdfunding and alternative finance which highlight how project communication, and social networks influence the success of campaigns (Mollick, 2014). The adoption of strategic linguistic styles (Sonenshein, 2011), the use of advanced credit scoring models and the application of economic theories of information (Agrawal et al., 2014) underline the role of transparency and trust in the decision-making process of investors.

In another area, the focus is on P2P lending and some perspectives on informational asymmetries, emphasising the importance of "soft" information in the decision-making process (Iyer et al., 2016) and the risks of discrimination against borrowers (Pope and Sydnor, 2011). Well-structured market mechanisms in online P2P lending can mitigate adverse selection (Wei and Lin, 2017) and act as a complement or alternative to traditional bank credit offerings (Tang, 2019).

A last area, focused on digital innovation, emphasises the role of technological innovations in reducing intermediation costs, expanding access to financial services, and developing new business models. The literature on lending markets and imperfect information (Akerlof, 1970; Diamond, 1984) demonstrates how information asymmetries can lead to adverse selection and credit rationing phenomena (Stiglitz and Weiss, 1981). At the same time, it highlights the importance of signals (Spence, 1973) and long-term relationships (Petersen and Rajan, 1994) as mechanisms to mitigate these issues.

5 Discussion

Crowdfunding and P2P lending emerge as forms of financing capable of redefining traditional intermediation logic and promoting financial innovation and inclusion, with an interplay of technological, social, and regulatory factors. It is important to highlight the credit democratization, made possible by the reduction of geographical and socio-economic barriers (Tang, 2019; Agrawal et al., 2014; Eckhardt et al., 2019; Butticè, 2017).

The dominant theoretical models are Signalling Theory and Social Capital Theory, with a focus on reducing information asymmetry, and discrimination in lending. Transparent information management, strong relational networks, and risk assessment are essential for building trust in these digital platforms. Their design should strike a balance between transparency, and innovation (Basha et al., 2021). Emerges the role of technological innovations in reducing intermediation costs and expanding access to financial services.

Some studies examine how lenders assess the credibility of aspirants based on visible signals and available information on their online profiles. Several elements influence this perception of reliability: visual signals (i.e. photos and profile appearance), descriptions of the applicant's story or the reason for the loan, ratings and reviews from other lenders. The narratives denote a key element in fostering strategic change (Sonenshein, 2011). In the digital finance contests, credit ratings rely on dynamic behavioural data, such as: online sales performance, customer reviews, social media activity. Some related risks concern the opacity of AI models, big data use, privacy and ethical questions. These factors seem critical because, specifically in the context of P2P microfinancing, there are no direct and personal relationships between the lender and the applicant. Therefore, lenders rely on indirect indicators to decide whether to financially support a project. A high perception of reliability increases the likelihood of success for the applicant in receiving the loan (Gen Li et al., 2019; Shafi and Mohammadi, 2020).

Startups and SMEs, especially in their early stages, find in crowdfunding an opportunity to test innovative projects and strengthen their capital base (Cumming et al., 2013, 2022, 2023; Bruton et al., 2015). An inclusive orientation of crowdlending emerge, promoting socially driven finance and supporting small scale entrepreneurial initiatives, often aimed at individuals with limited collateral. Unconventional strategies emerge for credit delivery, enabling simplified access to capital, particularly for firms excluded from traditional banking channels. Central dimensions of P2P platforms regard the challenges of information asymmetry: analysing data on borrowers is crucial to establish appropriate interest rates and minimize defaults. Personal networks and online reputation can serve as informal guarantees, reducing perceived risk and encouraging participation from new investors. Credit rating plays a pivotal role, especially for startups and SMEs, to facilitate interactions between investors and funding applicants by enhancing trust while mitigating associated risks (Wang et al., 2021). The primary tools for measuring credit ratings are linked to qualitative indicators, like the experience and

expertise of the entrepreneurial team, the reputation and reviews gained on other platforms, the quality of project communication (videos, images, and storytelling), the public engagement and social media interactions, and sentiment analysis to evaluate the perceived reliability of potential investors.

6 Conclusions, implications and further research

This study develops a systematic literature review and identifies key challenges for the digital lending ecosystem and new frontiers in alternative finance, highlighting the relevance of information disclosed in unregulated markets, and its influence on investment decisions (Bourveau et al., 2022). In online lending investments, a marked "home bias" persists, where geographical and cultural proximity between the lender and borrower influences lending decisions (Burtch et al., 2014). Financial knowledge and risk propensity drive to use P2P lending platforms more frequently (Han et al., 2019). The digitalisation and the creation of a credit ecosystem represent the context in which P2P lending can operate both as a complement and an alternative to traditional banking credit, particularly for borrowers with intermediate risk profiles or those located in underserved areas by conventional banks (Tang, 2019).

Crowdfunding and P2P digital lending, as financial tools, overcome difficulties of startups and SMEs in providing guarantees (required for bank financing), allow a reduction costs linked to the dynamics of the transactions. P2P lending platforms, often aimed at supporting small businesses or ethical projects, facilitate access to credit for startups and businesses, particularly in contexts with limited funding options.

Several implications emerge. From a theoretical point of view, special attention should be given to fundraising for startups and SMEs, understanding the synergies among traditional and innovative financing tools assuming a relevant role in the growth of these kinds of companies. There is a need to understand the interaction among investors, small entrepreneurs, and digital lending platforms, with a focus on the social dynamics within the context of SMEs and startups.

Regarding managerial implications, the main challenge is to signal the business project quality. A clear strategy in information systems and the contribution of independent directors with broad relational networks are essential. Moreover, the risk of fraud on the lending platforms is another controversial aspect that involves investors and their company's choices.

Regulatory implications remain central to ensuring a favorable environment for the development of digital lending tools and for supporting business growth. In a context with information asymmetries and fraudulent behaviors, it needs the implementation of effective enforcement strategies. At the same time, the growth of digital lending platforms raises valuable regulatory questions.

Future research should investigate the importance of alternative lending solutions to support the growth of early-stage businesses, highlighting advantages and challenges compared to traditional methods. Qualitative and quantitative analysis could be performed to examine the behavior of digital financing operators, providing insight into the complementarity or substitute roles among new and traditional financial forms. Other potential research areas to explore include the big data role in achieving superior credit ratings in a digital environment, and the blockchain financing mechanisms in enhancing trust and transparency in startup companies.

Enterprise Architecture Model for Knowledge Assets

Joachim Dehais
Swiss Federal Archives, Bern, Switzerland
Project Management Institute Switzerland, Bern, Switzerland

Abstract

Enterprise architecture (EA) is a fundamental framework for aligning technology, processes, and information systems with organizational strategy. In the context of knowledge assets and artificial intelligence (AI), EA provides the necessary structure for effective knowledge management and AI integration. However, traditional EA models face limitations in handling dynamic knowledge flows and AI-driven insights. This summary explores EA's role in managing knowledge, the impact of AI on knowledge assets, and necessary modifications to improve AI integration.

EA plays a crucial role in structuring and governing knowledge within organizations. Frameworks like TOGAF and Zachman facilitate the creation of repositories, workflows, and governance structures to optimize knowledge storage, retrieval, and dissemination. In AI-driven organizations, EA ensures that AI initiatives align with knowledge management strategies, preventing disruptions while enhancing decision-making capabilities.

Knowledge serves as both an input and output in AI systems. High-quality, structured data is essential for training AI models, while AI-generated insights contribute to organizational knowledge. However, poorly curated or siloed knowledge assets can lead to biased models and unreliable results. Enterprise architects must ensure the integrity, accessibility, and interoperability of knowledge assets.

Conventional EA models struggle with:

- A lack of flexible standards for data pipelines, making it difficult to integrate AI-driven DataOps and MLOps.
- Siloed architectures that limit knowledge-sharing and AI effectiveness.
- Static frameworks that do not support real-time knowledge processing.

To enhance AI integration, organizations should:

- Adopt modular, dynamic EA metamodels supporting microservices and AI scalability.
- Implement knowledge-centric frameworks incorporating semantic models and ontologies.
- Integrate DataOps and MLOps pipelines to facilitate continuous AI model refinement.
- Foster a knowledge-sharing culture through training and transparent governance.

By evolving EA frameworks and fostering a collaborative organizational culture, businesses can optimize knowledge management and AI utilization for sustained performance.

Keywords: Architecture, assets, knowledge management.

Paper type: Practical Paper

1 Introduction

Artificial Intelligence (AI) is increasingly promoted as a transformative force capable of reshaping business efficiency and driving sustainability efforts. From intelligent automation to decision support, AI promises both performance enhancements and more responsible, sustainable practices. However, both AI integration and sustainability require one fundamental capability: the organization must be able to explain, model, and measure itself. Without internal coherence and visibility, AI cannot align with real business needs, and sustainability metrics risk remaining superficial.

In many organizations, this requirement is directly linked to enterprise-level business analysis. The quality of business models, data ecosystems, and process understanding determines how well an organization can articulate its goals and adapt to emerging technologies. Failures in digital transformation and sustainability initiatives often stem from a lack of integration between business vision, data strategy, and technology execution (Brynjolfsson & McAfee, 2017).

To avoid such pitfalls, we must explore the models that structure how organizations think about themselves. Enterprise Architecture (EA)—as a means of digital twin construction for the enterprise—emerges as a crucial solution. By linking strategy, business functions, IT, and data, EA provides a foundation for integrating AI and achieving sustainability goals. This paper investigates the enterprise architecture approach, evaluates its strengths and limitations, and proposes necessary modifications to align with future-oriented, knowledge-centric, AI-enabled organizations.

2 Enterprise Architecture (EA) as a framework for knowledge management and AI integration

Enterprise Architecture offers a formal structure to describe and manage an organization's processes, systems, data, and strategy. Originally developed to bridge business-IT alignment (Zachman, 1987; TOGAF, 2018), EA has evolved into a comprehensive framework that supports organizational agility and transformation. EA provides organizations with a high-level blueprint to plan and manage change in a structured and coherent way.

For AI integration, EA plays an enabling role. It creates an architectural layer that governs the lifecycle of data, systems, and applications needed for AI deployment (Lankhorst, 2017). At its core, EA aligns technology with strategic goals through a set of interrelated models—business, application, data, and technology architectures. These models ensure that AI solutions are not implemented in isolation but are linked to operational and strategic objectives.

Knowledge management is another domain tightly connected to EA. As organizations generate and process increasingly complex data, EA frameworks help manage knowledge about the enterprise and its value chains. AI solutions, such as natural language processing or recommender systems, rely heavily on well-structured, context-rich data ecosystems. EA ensures these ecosystems are interoperable and coherent with enterprise-wide standards.

By enabling traceability from high-level strategy down to infrastructure and data flows, EA facilitates responsible AI integration. It allows for governance mechanisms, accountability models, and ethical safeguards to be embedded directly into enterprise systems. This integrated perspective is critical to support scalable and transparent AI usage (Weill & Ross, 2004).

3 Enterprise Architecture and knowledge management

Enterprise Architecture frameworks play a crucial role in structuring and governing knowledge flows across organizations. This role extends far beyond information systems, touching how teams collaborate, how decisions are made, and how insights are disseminated. Through its layered design, EA models map the organization's structure in a way that identifies where knowledge is created, stored, and used (Dietz, 2006).

Prominent EA frameworks, including TOGAF (The Open Group Architecture Framework) and the Zachman Framework, explicitly prioritize coherence and adaptability. These characteristics are essential for knowledge management, particularly in environments experiencing rapid technological change. EA frameworks help define and connect repositories (e.g., enterprise data lakes, document stores), workflows (e.g., case handling, escalation paths), and governance systems (e.g., compliance reporting, knowledge custodianship) (TOGAF, 2018).

This governance perspective is critical. EA does not only structure how knowledge is organized, but also enforces standards that determine who has access to what knowledge, under what conditions, and through which systems. In data-intensive organizations, these questions are tightly linked to compliance and trust—factors increasingly vital in an AI-driven world.

AI initiatives must be synchronized with EA strategies to succeed. An AI deployment not anchored in enterprise knowledge architecture risks becoming a point solution—disconnected, ungoverned, and potentially harmful. For example, AI models trained in isolation may reproduce outdated business logic or amplify organizational biases. Aligning AI projects with EA ensures that AI systems reinforce, rather than fragment, the enterprise knowledge ecosystem (Gregor & Hevner, 2013).

Moreover, EA supports digital traceability—the ability to track the lifecycle of information from input to decision. This capacity is particularly important for AI explainability and auditability, two attributes required under emerging regulatory frameworks (e.g., EU AI Act, 2023). Thus, EA's structural approach serves as both a technical and ethical scaffold for the responsible use of AI within knowledge-centric organizations.

4 The role of knowledge in AI usage

Knowledge is both the lifeblood of AI and its most valuable product. Within enterprise settings, AI systems are deeply reliant on access to high-quality, structured, and contextualized knowledge. Conversely, their outputs—recommendations, predictions, insights—are themselves forms of knowledge that must be governed, interpreted, and integrated into ongoing operations. This dual role places knowledge management at the core of any sustainable and effective AI strategy.

4.1 Knowledge as inputs

AI systems, particularly those leveraging machine learning (ML), rely heavily on curated, accurate, and context-rich data. This data represents the distilled knowledge of organizational processes, customer behavior, market dynamics, and operational performance. For AI models to learn meaningful patterns, this data must be available in structured formats and governed by sound metadata and ontological standards (Russell & Norvig, 2021).

The processes that prepare knowledge for AI—data curation, knowledge engineering, and semantic modeling—are not trivial. They involve mapping business concepts to data, cleaning and aligning datasets, and creating taxonomies and ontologies that reflect organizational semantics. Without these steps, AI systems risk being built on incoherent or biased foundations. Indeed, failures in AI projects frequently trace back to weaknesses in the knowledge pipeline rather than flaws in algorithmic design (Gebru et al., 2021).

Enterprise Architecture contributes here by providing a formal structure to organize these preparatory processes. The EA framework defines how data is collected, classified, stored, and transformed—thus ensuring consistency and interoperability across the enterprise. In particular, it provides clarity on the provenance, trustworthiness, and purpose of data, which are essential for AI model training and validation.

4.2 Knowledge as output

Just as AI systems require knowledge to function, they also generate new knowledge that must be absorbed back into the enterprise. Predictive models, diagnostic tools, recommendation engines, and natural language interfaces all produce insights. These insights must be actionable, traceable, and integrated into business processes to deliver value.

Here, again, EA provides critical scaffolding. It ensures that the outputs of AI systems feed into decision-making structures, operational workflows, and organizational memory. For instance, enterprise knowledge graphs—often modeled and maintained as part of the EA initiative—can serve as both input and output interfaces for AI, bridging structured knowledge representation with dynamic insight generation (Paulheim, 2017).

More importantly, EA defines governance for how AI outputs are consumed. Decisions influenced by AI must be auditable, explainable, and aligned with business ethics and compliance requirements. By framing knowledge flows within organizational governance models, EA enables responsible and transparent AI use (Floridi et al., 2018).

4.3 Risks of poor knowledge management

When knowledge management is fragmented or weak, AI performance suffers significantly. Poorly curated knowledge leads to biased models, unreliable insights, and ultimately poor decisions. Data silos prevent holistic training sets, lack of versioning creates reproducibility problems, and ungoverned feedback loops can result in concept drift and degradation of model quality over time (Sculley et al., 2015).

Enterprise architects have a mandate to prevent these outcomes by designing knowledge systems that ensure data integrity, accessibility, and interoperability. This role includes selecting appropriate tools, defining reference architectures, implementing shared vocabularies, and aligning stakeholders across business and IT domains.

As AI becomes embedded in more strategic decisions, the stakes grow higher. Misuse of AI due to poor knowledge quality can result in reputational damage, regulatory sanctions, or significant financial losses. Thus, knowledge quality and its management via EA become risk mitigation imperatives as well as value creation strategies.

5 Limitations of traditional EA metamodels in handling knowledge and AI

While Enterprise Architecture offers a promising framework for managing AI and knowledge flows, traditional EA metamodels exhibit structural and conceptual limitations. These limitations hinder their ability to fully support the dynamic, real-time, and iterative nature of AI-centric knowledge management practices.

5.1 EA is a framework for knowledge management—not a knowledge management framework

First and foremost, it is important to recognize that EA frameworks—such as TOGAF and Zachman—are designed to model and manage enterprise components and their interactions. They provide structure for aligning strategy, processes, systems, and data. However, they are not inherently designed as knowledge

management frameworks. EA creates space for knowledge within and about the enterprise, but does not treat knowledge as a dynamic, evolving asset in itself (Lankhorst, 2017) (Figure 1).

This means that EA metamodels tend to focus on static contexts (applications, roles, capabilities) and relationships, but they lack dynamic constructs for AI to operate on them. As AI systems become more central to enterprise functioning, this lack of a dedicated "knowledge and learning" layer becomes a bottleneck.

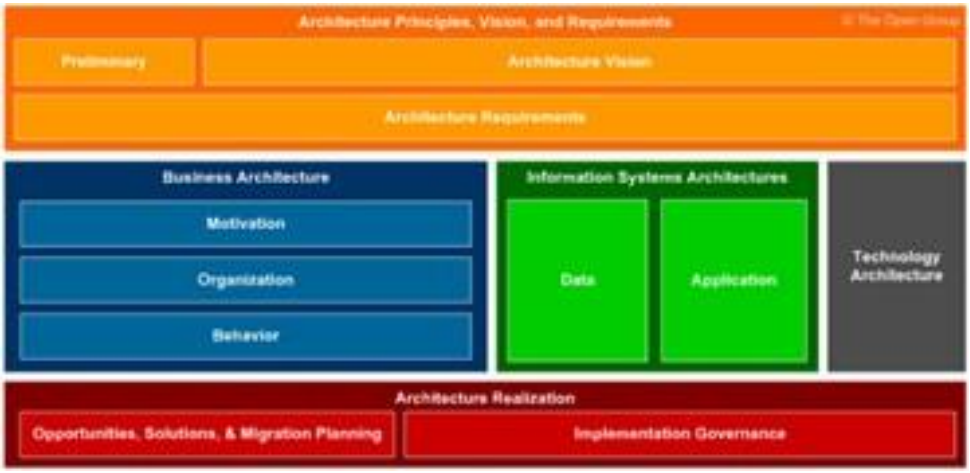

Figure 1: TOGAF considers data and context, but not its own status as data, or a translation of data into business knowledge. As such it lacks an appropriate space for Intelligence models, both natural and artificial.
Source: TOGAF Standard 10

5.2 Lack of flexible standards for data and knowledge pipelines

AI systems require agile, iterative data pipelines—often implemented through DataOps and MLOps practices (Kreuzberger, Kluge, & Bruns, 2020). Traditional EA frameworks were not built with such practices in mind. Their governance-heavy, waterfall-oriented methodologies struggle to accommodate rapid model iteration, continuous data integration, and experimentation loops that characterize modern AI development.

This misalignment creates friction between EA teams and data science teams. EA calls for long-term stability and formal approvals; AI requires short-term agility and empirical tuning. Without architectural accommodations for continuous integration and deployment (CI/CD) of AI models, EA can inadvertently stifle innovation and delay time-to-value.

5.3 Siloed Architectures and Data Fragmentation

Another critical limitation is the persistence of siloed systems within many EA implementations. Even when EA frameworks are adopted, organizational inertia often leads to fragmented data ownership, tool mismatches, and incompatible knowledge representations. These silos prevent AI systems from:

- accessing comprehensive, standardised datasets and limit the ability to generate cross-functional insights (Zhao et al., 2017).
- addressing structural optimisations.

Traditional EA approaches tend to reinforce vertical domains (e.g., HR, Finance, Operations) rather than promote horizontal data integration. This verticality is insufficient for AI use cases, which often depend on blended data sources and complex, multi-domain reasoning.

5.4 Limited Support for Real-Time Knowledge Processing

Modern AI systems increasingly rely on real-time or near-real-time data processing. Whether it's fraud detection, predictive maintenance, or customer engagement, the ability to access and reason over knowledge dynamically is key to competitive advantage.

However, most EA models are built around static representations—capability models, application portfolios, data catalogues— that can be used for dynamic impact analysis, though it remains structural and theoretical. They do not easily accommodate event-driven architectures, streaming analytics, or real-time reasoning engines (Marjanovic & Freeze, 2012). As a result, EA implementations lag behind the operational tempo required for AI-enabled responsiveness.

5.5 A missing cognitive layer

Finally, traditional EA frameworks can but often do not model cognitive assets—the beliefs, assumptions, and mental models that drive organizational behavior (Figure 1). This is a normal result of a data-centric fashion in the industry. Yet, these are crucial for understanding how knowledge is interpreted, how decisions are made, and how AI should align with or challenge current thinking.

AI can produce insights, but unless those insights are embedded into workflows, beliefs, and decisions, they generate little value. Without an architectural view of cognition, learning, and knowledge feedback, EA misses a key component of the AI knowledge cycle (Nonaka & Takeuchi, 1995).

6 Modifications to improve knowledge management and AI integration

Enterprise Architecture (EA) must evolve from its traditional role into a dynamic, knowledge-centric framework capable of enabling AI initiatives, not unlike the principle of the Digital Twin. As organizations increasingly depend on AI to achieve strategic goals and adapt to complexity, modifying EA to support fluid knowledge flows, continuous learning, and real-time responsiveness becomes imperative. This section explores key modifications and enhancements required for EA frameworks to support modern knowledge management and AI integration effectively.

6.1 Dynamic and modular metamodels

Traditional EA metamodels, such as TOGAF's Content Metamodel, provide a static, materialistic representation of business, data, application, and technology domains (The Open Group, 2018). While useful for long-term planning, these static models lack the agility needed to support AI-driven systems, which require contextualised knowledge, frequent iterations, feedback loops, and adaptability.

Dynamic and modular metamodels, by breaking down functionality into independently deployable components, align with the iterative nature of AI development (Newman, 2015). Incorporating such architectural paradigms into EA allows for modular knowledge and data components that can be updated, replaced, or recombined without affecting the broader system.

This would also allow for dynamic impact analysis over structures, and thus, architectural optimisation.By providing machine-readable, self-describing architecture elements, EA increases interoperability and improves automated reasoning and AI-assisted architecture management.

6.2 From data-centric to knowledge- and capability-centric models

A significant paradigm shift is required: moving from data-centric EA (functional elements) to frameworks that prioritize knowledge, skills, and capabilities (nonfunctional elements) as first-class architectural entities. While data remains foundational, it must be contextualized within broader knowledge systems that encompass semantics, use cases, business meaning, and strategic intent (Dietz, 2006).

Ontologies and knowledge graphs—used extensively in semantic web and AI applications—can be integrated into EA metamodels to represent domain knowledge more precisely (Paulheim, 2017). These structures enable richer inference, support explainability, and improve the relevance of AI-generated insights.

TOGAF's standard metamodel can be extended to include knowledge assets, skill definitions, and learning dependencies. For example, Figure 34 from the TOGAF 9.2 documentation proposes a layered content model, but could be augmented to add layers for organizational learning and AI feedback mechanisms (The Open Group,

2018). This would recognize knowledge not just as a byproduct of operations, but as a central architectural concern.

6.3 Integration of continuous improvement at the level of architecture and value chain

AI initiatives thrive on continuous experimentation, feedback, and improvement. EA must therefore embed continuous integration and continuous delivery (CI/CD) principles, not only in software pipelines but at the architecture level. This includes:

- DataOps: Applying DevOps principles to data analytics workflows, focusing on automation, quality, and collaboration (Erl et al., 2021).
- MLOps: Managing the lifecycle of machine learning models, including versioning, retraining, testing, and monitoring (Kreuzberger et al., 2020).
- KnowledgeOps: Managing the lifecycle of information, knowledge, and the soft skills that underline processes is a key element to supporting conscious continuous improvement.

EA should define reference architectures that include reusable pipeline components for data ingestion, model training, and deployment, and position these within business processes. These components must also interact with governance layers to ensure compliance, traceability, and ethical standards in AI deployment.

Furthermore, continuous improvement loops should span the entire value chain. EA should model not only operational capabilities but also how those capabilities evolve through learning, AI feedback, and cross-functional knowledge sharing.

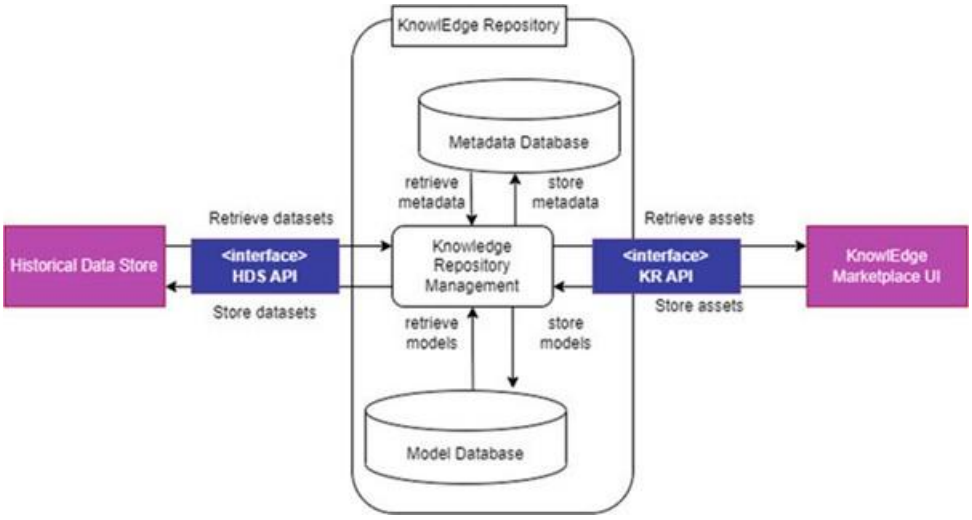

Figure 3: A model for AI model integration within an enterprise.
Source: Nizamis et al 2023

6.4 Culture and organizational change management

Technology alone does not drive transformation. For knowledge and AI integration to succeed, organizations must cultivate a knowledge-sharing culture supported by governance, incentives, and structural enablers. EA has a crucial role to play in modeling and enabling these changes. A modern EA function must include:

- (Transversal) Communities of practice modeled as organizational entities.
- (Contextual) Training programs and knowledge transfer mechanisms mapped to capability development.
- (Structural) Governance models that promote cross-functional collaboration, transparency, and accountability.

Change management frameworks—such as Kotter's 8-Step Model or ADKAR—can be embedded into EA roadmaps to ensure that the transition toward AI-enabled knowledge management is adopted sustainably (Hiatt, 2006). EA should make explicit the dependencies between cultural norms, digital skills, and architecture goals.

6.5 Real-time knowledge systems

AI systems often operate in environments that require real-time or near-real-time decision-making. Traditional EA frameworks, which are primarily descriptive and retrospective, must be extended to handle real-time knowledge flows. This can be achieved through:

- Event-driven architectures (EDA): Enabling systems to respond to triggers from internal or external sources in real-time. EA should map event types, sources, and consumers at the architectural level (Chen et al., 2014).
- Streaming analytics: Incorporating tools into EA blueprints to support live data processing.
- AI observability layers: Capturing telemetry on how AI models behave, what decisions they influence, and how outputs are interpreted. These insights feed into continuous knowledge refinement loops.

Real-time knowledge systems should be architected with scalability, low-atency, and explainability in mind—ensuring that they can evolve alongside business needs and regulatory demands.

7 Conclusion

Enterprise Architecture stands at a critical inflection point. Traditionally tasked with aligning IT systems to business goals, it now faces the dual imperative of integrating AI and fostering sustainable, knowledge-driven organizations. This duality requires EA to evolve from a static documentation function into a living, learning structure that continuously adapts to organizational feedback, new insights, and dynamic knowledge flows.

7.1 EA as a Catalyst for Knowledge-Driven AI

Throughout this paper, we have argued that AI is inseparable from knowledge management. AI's performance, fairness, and strategic value depend on access to structured, high-quality, and well-governed knowledge. Similarly, AI systems generate new forms of knowledge-insights, classifications, recommendations - that must be interpreted, contextualized, and institutionalized.

Enterprise Architecture plays a central role in this cycle. It provides the structure, models, and governance mechanisms necessary to align AI initiatives with organizational goals and constraints. However, to fulfil this role, EA must undergo significant transformation.

7.2 The case for a knowledge-centric EA

Traditional EA frameworks are not inherently designed to manage knowledge as a dynamic and strategic asset. They must be augmented with:

- Modular, dynamic metamodels to accommodate rapid innovation.
- Semantic models, ontologies, and knowledge graphs to support AI reasoning and integration.
- CI/CD, DataOps, and MLOps pipelines to enable AI lifecycle management.
- Real-time processing and event-driven systems to support responsive decision-making.

In doing so, EA becomes not just a framework for managing systems and processes, but a platform for organizational learning. It enables enterprises to become more adaptive, transparent, and capable of leveraging AI for competitive and sustainable advantage.

7.3 Toward a culture of sustainable AI

Ultimately, the integration of AI into enterprise knowledge systems is not only a technical challenge—it is a cultural and ethical one. Organizations must embrace continuous learning, transparency, and collaboration. EA can model and support these cultural shifts by including:

- Shared knowledge repositories and common vocabularies.
- Mechanisms for trust, accountability, and auditability in AI decisions.
- Pathways for human oversight and ethical reflection on AI outcomes.

By embedding these principles in the very architecture of the enterprise, organizations can ensure that AI serves not only efficiency goals but also broader social and environmental responsibilities.

7.4 Final reflection

The convergence of AI, knowledge management, and enterprise architecture defines a new frontier for digital transformation. As businesses seek to navigate volatility, complexity, and sustainability, a flexible, knowledge-centric EA can serve as both compass and engine.

Rather than treating AI as an external technology to be bolted onto existing structures, forward-thinking organizations will recognize it as part of the evolving fabric of enterprise knowledge. EA, properly reimagined, is the loom on which that fabric can be woven.

8 Ethics declaration

No ethical clearance was necessary for the current work.

9 AI declaration

An artificial tool was used in the development of this paper as follows:

- To detect missing elements or weaknesses of the original argumentation, leading to further research.
- To provide a template paper structure based on the argumentation. Structure which was manually reviewed, edited, and corrected by the author.
- To write the first draft text based on the argumentation, structure, and references provided by the author. This draft was reviewed, edited, and corrected by the author.

Looking for Co-Founders: Exploring the Co-Founders Selection Process in Venture Studios

Santoro Leonardo, Santoro Gabriele
University of Turin, Turin, Italy

Abstract

Startups' success is strongly influenced by the capabilities, traits, and dynamics of their founding teams. While the role of co-founders in shaping venture outcomes is well established in entrepreneurship literature, little is known about how they are selected in contexts where founding teams are externally assembled, such as within venture studios. Venture studios represent a distinct form of new venture creation (NVC), where organizations (rather than individuals) initiate and structure the entrepreneurial process. Central to this model is the strategic recruitment of external co-founders who are expected to lead ventures they did not originate. The goal of this paper is to investigate how co-founder selection processes are designed and implemented within venture studios, with a focus on the underlying decision criteria and timing strategies adopted in practice.

This research adopts a qualitative, exploratory design based on multi-case illustrative studies of three European venture studios: Rocket Internet, Hexa, and Mamazen. Findings reveal that the co-founder search in venture studios is a deliberate strategic activity. Rather than being recruited solely for executional tasks, co-founders are selected for their entrepreneurial mindset, risk appetite, and capacity to take full ownership of the venture. Venture Studios do not hire CEOs but rather recruit founder-like individuals to lead ventures alongside them, offering shared equity and full operational responsibility from day one. This inversion of traditional entrepreneurial logic positions venture builders as orchestrators of resources and talent, aligning with Gartner's (1985) view of entrepreneurship as an organizing activity and the Resource-Based View's emphasis on leveraging human capital.

Keywords: Venture Studio, Venture Building, New Venture Creation, Co-Founders, Entrepreneurship

Paper type: Academic Research Paper

1 Introduction

The success of startups is intricately tied to the characteristics and dynamics of their founders, who drive a venture's vision, strategy, and execution. Founders' personality traits (Salmony & Kanbach, 2020), professional experiences, social capital and key capabilities (Eisenhardt & Martin, 2000; Zahra et al., 2006) play crucial roles in shaping individual behaviour and the broader trajectory of their organisations. Founder-related factors, such as knowledge, experience, competence, and team dynamics, strongly influence startup performance (Oe & Mitsuhashi, 2012; Lazar et al., 2020), affecting a venture's ability to innovate, attract funding, and scale. Founders are not only strategic decision-makers but also symbolic and cultural anchors of a venture, shaping its vision, identity, and direction from inception. Also, founders who have built strong relationships within their professional networks are better positioned to recruit key talent and attract investment, which is essential for the progress of new venture creation (NVC) (De Carolis et al., 2009).

Despite the central role of co-founders in shaping venture outcomes, little is known about the organizational processes through which co-founders are identified and selected, particularly in contexts where the founding team is not organically formed but externally assembled. This phenomenon is increasingly visible in emerging innovation players such as venture studios that follow a systematic and structured process of NVC: the venture builder model (Beaver, 1998; Baumann et al., 2018; Gutmann, 2019; Szigeti, 2019). The venture builder model represents a structured and systematic approach to NVC, characterized by its logic of parallel entrepreneurship.

Unlike traditional models, where founders build one venture at a time, venture builders create multiple startups in parallel using shared resources and standardized processes. This centralized approach accelerates venture creation and reduces early-stage risks. By institutionalizing entrepreneurship, venture builders enhance efficiency and adopt a portfolio strategy that spreads risk across ventures.

What makes this model especially intriguing is the possibility of reversing a traditional entrepreneurial logic: rather than entrepreneurs initiating a venture, it is the venture builder who develops an idea and then seeks out co-founders to lead and grow it (Mohammadi et al., 2023).

This inversion raises a new field of exploration for the entrepreneurial identity (Mmbaga et al., 2020; Radu-Lefebvre et al., 2021) streams of research and enriches the literature on the NVC process (Davidsson & Gordon, 2011; Davidsson & Gruenhagen, 2021), a core topic in entrepreneurship research (Carlsson et al., 2013),

considered not as a single event but as a dynamic process (McMullen & Dimov, 2013). It also involves how individuals or teams identify, develop, and exploit new business opportunities, moving from the generation of a venture idea to the exploitation of a venture opportunity and is shaped by the continuous interactions between the entrepreneurs, the venture opportunity, and the surrounding environment (Davidsson & Gordon, 2011; Vogel, 2017).

There remains a notable gap in the academic literature concerning the role of co-founders within venture builders' processes. Little is known about how these co-founders are identified, evaluated, and ultimately selected by the venture studio. The co-founders selected must fit into the culture and processes of the venture studio while also possessing the requisite entrepreneurial traits to lead their respective startups toward success. Selecting co-founders is a strategic activity in the venture-building journey because Venture Studio manages several new ventures in parallel and often in different industries or markets (Rathgeber et al., 2017).

Research on co-founder selection in the context of the venture builder model is scarce and composed of grey literature (Mohammadi et al., 2023), and understanding this process can offer valuable insights into the best practices for creating strong founding teams. Unlike traditional startups, which are often initiated by a single entrepreneur or a small founding team, venture studios systematically create multiple ventures, requiring a more structured and strategic approach to co-founder selection.

To date, no systematic academic inquiry has addressed the decision-making processes, selection criteria, or organizational logic that guide the formation of founding teams within venture studio contexts. There is limited empirical evidence on how co-founders' identities are shaped in these externally guided contexts, what selection mechanisms are employed, and how venture studios orchestrate the selection process to align with their broader venture-building strategy. Addressing this gap is critical not only for refining our understanding of venture building as a distinct model of NVC but also for expanding the theoretical boundaries of entrepreneurship research to encompass emerging, practice-led models of entrepreneurial behaviour (Gruber & MacMillan,2017).

Moreover, we aim to answer the following research question: How do venture studios operationalize and manage the selection of co-founders, and what drives the timing and criteria? The goal of this paper is to investigate how co-founder selection processes are designed and implemented within venture studios, with a focus on the underlying decision criteria and timing strategies adopted in practice. To address this question, the research will adopt an exploratory, qualitative design through a multi-case illustrative study (D'Ippolito et al., 2019). It will focus on three European venture studios that exemplify the practice of systematically searching for external co-founders.

The desired outcome is to provide a clearer and empirically grounded understanding of this phenomenon, which remains largely absent from academic discourse. By doing so, the study seeks to contribute to a more nuanced comprehension of the venture builder model and to identify co-founder recruitment as a distinctive and defining feature of venture builders, particularly in the form of venture studios. Understanding this can help improve the efficiency and sustainability of NVC, benefitting not only the ventures themselves but the entrepreneurial ecosystem as a whole (Spigel, 2015).

2 Theoretical Context

This study is framed within the broader domain of entrepreneurship research, specifically focusing on the Venture Builder (VB) model as a structured and replicable approach to new venture creation (NVC) (Davidsson & Gordon, 2011; Davidsson & Gruenhagen, 2021). The creation of a new entrepreneurial activity is therefore increasingly understood as a structured and dynamic process that may originate not only from individuals but also from existing organizations, such as corporates (Gutmann, 2019), startup studios, or digital agencies (Szigeti, 2019) that act as enabling actors in the entrepreneurial ecosystem (Spigel, 2015). These innovation players engage new venture creation activities by systematically building new companies in parallel and adopting the lean startup approach (Ries, 2011), following intentional processes that combine ideation, validation, and execution phases. In such contexts, the NVC process requires both intentionality and concrete action in relation to a specific venture idea (Davidsson & Gruenhagen, 2021). This perspective aligns with Gartner's (1985) conceptualization of entrepreneurship as an organizing activity, where the entrepreneur is not merely an idea generator but someone who brings together resources, people, and opportunities to form a new venture. Furthermore, building on Weick's (1979) notion of organizing as a process, creating a venture can be viewed as enacting a structure through continuous interaction between actors and their environment. It is also essential to consider the journey that moves from a venture idea to a venture opportunity (Vogel, 2017). Within those conceptual frameworks, venture builders operate as orchestrators of such processes, intentionally assembling teams, aligning resources, and shaping the structure and trajectory of new ventures. Thus, NVC is not only about

opportunity recognition but also about the capacity to organize and execute strategically in a replicable manner, and this is a core feature of the venture builder model. The venture builder model offers a distinct perspective on NVC, positioning organizations rather than individuals as the initiators of entrepreneurial activity.

The Resource-Based View (RBV) of the firm (Barney, 1991), and particularly its extension through the Resource Orchestration framework (Sirmon et al., 2007), offers the most appropriate theoretical lens for analysing co-founder selection within venture building processes because it conceptualizes strategic advantage as rooted in the firm's ability to structure, bundle, and leverage key internal resources (Symeonidou & Nicolaou 2018). In the context of venture studios, co-founders are critical entrepreneurial resources whose skills, networks and capabilities (Zahra et al., 2006) can shape the trajectory of a startup. The orchestration of these resources (selecting the right individuals, forming complementary founding teams, and aligning them with validated opportunities) reflects a deliberate and strategic process that enables the scalable and repeatable nature of the venture builder model. Unlike traditional startups, which often rely on organically formed founding teams, venture studios must systematically match entrepreneurial talent to emerging ventures in parallel, making resource orchestration relevant and essential to understanding how value is created and sustained in this context.

While grounded in entrepreneurship theory, this research also intersects with the field of human resource management (HRM), particularly in its attention to talent acquisition and selection strategies. Understanding how venture studios design and execute their co-founder selection processes also contributes to HRM by illuminating practices for recruiting high-impact individuals in high-uncertainty environments (Uggerslev et al., 2012; Rocha & Pozzoli, 2025). This interdisciplinary positioning enables the study to offer both theoretical contributions to entrepreneurship and practical insights relevant to HRM, particularly in emerging organizational forms characterized by parallel entrepreneurship and structured innovation.

3 Methods

This study adopts a qualitative methodology based on illustrative multi-case studies (D'Ippolito et al. 2019) to investigate how venture builder models operate, particularly with respect to the co-founder selection process. Cases were selected through an extensive review of qualitative secondary data (Miles & Huberman, 1994), allowing for a nuanced understanding of the phenomenon.

3.1 Case selection

Case selection followed a theoretical sampling approach (Miles & Huberman, 1994), based on qualitative secondary data collected between January and April 2025. Data sources included company websites, LinkedIn profiles, practitioner reports, industry articles, job postings for co-founders, and valuable materials that illustrate how venture studios define the co-founder's role and communicate expectations.

To ensure contextual consistency, only European venture studios were selected. This approach, suited to exploratory research in emerging fields (Ployhart & Bartunek, 2019), allows for a grounded understanding of co-founder selection in structured NVC processes.

We selected three cases, Rocket Internet, Hexa, and Mamazen, because they exemplify contrasting models and co-founder selection strategies, ranging from global scaling and replication to mission-driven, sector-specific venture building. These cases allow us to compare how different venture studios actively recruit and integrate co-founders into entrepreneurial opportunities that have already been structured internally.

Together, these cases illustrate the breadth of co-founder selection strategies across different venture studio models, ranging from global scalability and a copycat approach in B2C business (Rocket Internet and Mamazen) and rapid execution to mission-driven problem-solving B2B business (Hexa). Their inclusion in the study enables a comprehensive understanding of how venture studios interpret, operationalize, and execute the critical task of forming co-founding teams, thereby contributing to developing a broader theoretical framework for co-founder selection within structured venture-building processes.

3.2 Case analysis

3.2.1 Rocket Internet

Rocket Internet represents a particularly distinctive example of a venture studio model, often described in the early literature (Baumann et al., 2018) as a "startup factory" due to its industrialized and highly structured approach to new venture creation. Founded in 2007 by the Samwer brothers, Rocket Internet's mission has been to build and scale internet-based companies rapidly by replicating proven business models from other contexts

following a copycat approach. Central to its model is the separation between the ideation and execution of business models. Instead of originating novel startup ideas, Rocket Internet focuses on operational excellence, selecting and empowering co-founders to implement business models that have already demonstrated success in other markets (Baumann et al., 2018).

The firm favours profiles with strong analytical skills and operational discipline. These attributes correspond closely to those identified in entrepreneurship literature as predictive of entrepreneurial effectiveness, such as conscientiousness, openness to experience, and emotional stability (Zhao & Seibert, 2006; Brandstätter, 2011; Obschonka et al., 2013).

Co-founders are recruited to lead ventures from inception through scale-up. Typically, two to four co-founders are assigned to each startup and are responsible for setting up operations, hiring the team, overseeing business development, and achieving market leadership. While they retain a personal equity stake in the company, Rocket Internet maintains controlling ownership, enabling centralized governance and resource orchestration (Sirmon et al., 2007; Baert et al., 2016).

What is particularly notable in Rocket Internet's model is the internal pipeline used for identifying co-founders. Rather than relying solely on external recruitment or open calls for applications, the studio frequently selects promising internal employees who have demonstrated entrepreneurial readiness. This internal mobility allows for greater control over the selection process and enhances team cohesion, as candidates are already familiar with Rocket Internet's fast-paced and metric-driven culture (Rocket Internet, 2025).

This case is particularly relevant to the study of co-founder selection because it highlights a context in which founders are actively sought after and appointed to ventures that they did not originate. It underscores the importance of role identity, selection mechanisms, and organizational fit in venture building. Furthermore, it serves as a useful model for understanding how some venture studios mitigate startup risk through controlled processes and strategic resource orchestration (Symeonidou & Nicolaou, 2018).

3.2.2 Hexa

Hexa, formerly known as eFounders, is a Franco-Belgian startup studio founded in 2011. Initially focused on B2B SaaS startups, the studio capitalized on the growing adoption of cloud-based technologies in corporate environments. In 2022, eFounders rebranded as Hexa, evolving into a multi-vertical platform of startup studios with dedicated tracks in Web3, fintech, AI, and health sectors.

Hexa adopts a systematic new venture creation (NVC) process structured into four core phases: inception, build, scale, and growth (Szigeti, 2019).

What distinguishes Hexa's model is its emphasis on structured co-founder recruitment during the exploitation phase of a venture idea. After an idea has been validated, the studio recruits two co-founders for each new venture: typically a CEO with a business-oriented profile and a CTO responsible for technological execution (Szigeti, 2019). This reflects a deliberate strategy to construct complementary founding teams, consistent with existing literature that emphasizes the importance of diverse yet synergistic skill sets in successful founding teams (Ruef et al., 2003; Beckman & Burton, 2008).

The recruited co-founders are not the idea's originators but are selected for their execution capacity and alignment with the venture's vision, making Hexa a prototypical example of the "late co-founder" model in structured venture creation.

Hexa's selection process is rigorous, receiving over 1,000 co-founder applications annually while selecting only 12 individuals to lead its six annual ventures (Hexa, 2025). The selection criteria include ambition, entrepreneurial mindset, and readiness to work collaboratively within the venture studio framework.

In return, Hexa provides extensive support to its co-founders, including pre-seed funding, office space, team recruitment, mentorship, and hands-on involvement from a team of experts. During the first year, all operational and salary costs are covered, offering founders a lower-risk pathway into entrepreneurship while allowing Hexa to retain strategic control. Once the NewCo is launched, equity is shared between Hexa and the co-founders based on pre-negotiated terms, aligning incentives and preserving founder motivation (Hexa, 2025).

Hexa's model thus provides a compelling lens through which to examine how venture studios orchestrate co-founder selection and team formation, balancing structured processes with entrepreneurial flexibility in the context of high-growth venture creation.

3.2.3 Mamazen

Mamazen, founded in Italy in 2017, represents a pioneering force in the Italian startup ecosystem as the first entity to implement a venture builder model. Mamazen's approach is characterized by its structured, risk-mitigated process of venture creation, aiming to increase startup survival rates by rigorously validating ideas and carefully selecting the founding teams best suited to lead them (Mohammadi et al., 2021).

Mamazen's co-founder selection reflects a deliberate strategy that aligns with findings in co-founder literature emphasizing the importance of complementary skills, cultural fit, and founder identity (Mathias & Williams, 2017; Aven & Hillmann, 2018). Through its structured approach, Mamazen recruits external co-founders who are not the originators of the venture idea but are carefully matched to already-validated concepts (Mohammadi et al., 2023).

The selection process at Mamazen begins only after the venture idea has passed a rigorous validation phase (Mohammadi et al., 2024). Once this foundation is established, Mamazen opens its co-founder recruitment. In this phase, they are looking for complementary roles (Beckman & Burton, 2008).

Mamazen employs a multi-step evaluation process that includes resume screenings, structured interviews, practical simulations, and immersive bootcamps. These assessments are designed to evaluate not only candidates' managerial and entrepreneurial experience (Hsu, 2007; Toft-Kehler et al., 2014) and ability but also their alignment with Mamazen. In line with findings from the literature on founding team formation (Clarysse & Moray, 2004; Lazar et al., 2020), Mamazen emphasizes that cultural and interpersonal fit is critical for long-term collaboration.

Moreover, Mamazen introduces a 1–3 month trial period during which selected candidates work part-time on the venture while maintaining other employment. Thereby incentivizing a short period of hybrid entrepreneurship (Folta et al., 2010; Raffiee & Feng, 2014).

This phased integration allows both the studio and the co-founders to assess mutual commitment before fully formalizing the relationship. The startup studio provides significant support during this transition (Mamazen,2025). Such support structures reduce early-stage risks and co-founder's fast turnover (Allen & Shanock 2013), aligning with studies that link entrepreneurial ecosystems with resource orchestration mechanisms (Sirmon et al., 2007).

Co-founders at Mamazen receive 70% equity in the new venture, subject to a five-year lock-up clause with good leaver/bad leaver provisions. This generous equity structure enhances founder motivation and aligns incentives over the long term, reinforcing findings from entrepreneurial finance that stress the importance of equity ownership in fostering accountability and commitment (Bolino & Turnley, 2007).

Its structured, research-driven, and founder-centric approach provides a robust framework for understanding how co-founder selection contributes to startup success. Mamazen's practice of external co-founder recruitment, based not on ideation but on alignment with a pre-validated venture opportunity, offers a powerful lens through which to re-examine the nature of entrepreneurial identity and team formation in venture building processes.

4 Results and Conclusions

Our findings reveal that the search for co-founders is not incidental but constitutes a core strategic activity within the venture-building process. Unlike traditional startups, where the founder is often the initial developer, venture studios initiate the business idea and then actively seek individuals to co-lead and scale the venture. This structural inversion of entrepreneurial agency shifts the role of the co-founder from originator to orchestrator, requiring not only alignment with the studio's mission but also the presence of distinct entrepreneurial capabilities.

Venture studios pursue co-founders primarily to infuse ventures with an entrepreneurial mindset, risk appetite, and long-term commitment, traits typically associated with startup founders rather than hired managers. These individuals are not recruited as CEOs of existing firms but as full co-founders with shared equity and responsibilities from day one. This distinction is critical: co-founders are expected to assume ownership and actively shape the trajectory of the venture rather than merely execute a pre-defined strategy. The selection of co-founders thus functions as a mechanism for embedding entrepreneurial identity within an externally generated venture, bridging the gap between structured venture creation and founder-led dynamics.

From a theoretical perspective, this study contributes to the literature on NVC (Davidsson & Gruenhagen, 2021) by identifying co-founder recruitment as a defining characteristic of the venture builder model. In doing so, it highlights a significant departure from traditional founder-led models of entrepreneurship, reframing co-founder selection not as a spontaneous process but as a deliberate and repeatable activity embedded in structured venture creation. This insight advances our understanding of how venture builders operationalise NVC through institutionalised talent alignment and team formation processes. Simultaneously, the study extends the resource orchestration perspective (Sirmon et al., 2007) by offering empirical evidence of how human capital is actively structured, bundled, and leveraged within the venture studio context. Rather than treating co-founders as static inputs, the venture builder model conceptualises them as dynamic and strategically orchestrated resources. This dynamic coordination of people and capabilities across multiple

ventures demonstrates how resource orchestration unfolds also in environments characterised by parallel venture creation.

For practitioners, especially venture studios, this research underscores the need to recruit individuals who embody founder-like capabilities rather than defaulting to managerial profiles. Studios must develop talent acquisition strategies that go beyond formal qualifications to assess entrepreneurial drive, strategic agility, and value alignment. Furthermore, the use of structured, iterative selection processes, such as those employed by Mamazen and Hexa, provides a replicable model for identifying high-potential co-founders in uncertain, high-growth environments.

This exploratory study opens several avenues for future research. First, who are these co-founders who join ventures they did not originate? A deeper investigation into the typologies and backgrounds of co-founders in venture studios could illuminate emerging patterns in entrepreneurial careers. Second, the co-founder selection process itself warrants closer examination, particularly the role of bias, the effectiveness of evaluation tools, and the dynamics of team formation. Finally, further comparative studies across different venture builder models (e.g., corporate venture builders vs. venture studios) could yield valuable insights into how structural differences shape co-founder roles and outcomes.

By offering a structured view into the co-founder selection process within venture builders, this study contributes to both entrepreneurship and human resource management literature, providing a theoretical and practical framework to better understand how entrepreneurial talent is identified, integrated, and empowered in new organizational forms of NVC.

5 Ethics declaration

This research did not require ethical clearance, as it did not involve the collection of sensitive or personally identifiable data from human participants.

6 AI declaration

AI tools were used in organizing and presenting the content of this paper in a clear and coherent manner. The AI-assisted outputs were critically reviewed, edited, and integrated by the author to ensure academic rigor and alignment with the research objectives.

Bridging Innovation and Market: An Exploratory Analysis of AI Startup Value Propositions

Maria Cristina Pietronudo[1], Mario Sorrentino[1], Elena Candelo[2]
[1]University of Campania "Luigi Vanvitelli", Capua, CE, Italy
[2]University of Turin, Turin, Italy

Abstract

This paper explores how AI startups articulate their value propositions—a critical element in defining and communicating value to customers. AI startups, in fact, struggle to align their technological capabilities with real market needs. Drawing on an exploratory multiple-case study of ten Italian AI startups, this research tries to investigate emerging patterns and main challenges AI startups face in articulating the value proposition. Preliminary findings reveal a fragmented landscape: while some startups adopt detailed use cases and visuals to support their claims, others rely on minimal communication and invite direct contact. Value propositions often emphasize efficiency and cost savings but lack quantification and substantiation. The study highlights the tension between technological sophistication and market clarity, especially in cross-industry applications. By focusing on how AI startups construct their value propositions, this research contributes to both AI entrepreneurship literature and broader discussions on value proposition strategy in emerging, high-tech markets.

Keywords: AI startup; Value Proposition; Entrepreneurship

Paper type: Academic Research Paper

1 Introduction

Artificial intelligence represents an opportunity for entrepreneurs in several ways: it is a technology that enhances existing business activities (e.g., market analysis, customization, automation of processes) while also enabling new businesses that introduce innovative products and services (Obschonka and Audretsch, 2020; Troise et al., 2022; Giuggioli and Pellegrini, 2023). Some scholars in entrepreneurial literature consider AI an external enabler of entrepreneurial opportunities, as it provides access to new markets by revealing previously unidentified or unmet needs (Davidsson and Sufyan, 2023). In other words, AI allows entrepreneurs to develop an entrepreneurial process in which opportunities are transformed into new economic activities that create value.

As an enabler of entrepreneurship, AI can be leveraged by new entrepreneurs, particularly emerging startups that consider AI as their primary activity for value creation and sell AI as a final product or service (Steininger, 2019). According to the definition provided by Truong (2024), AI startups are new ventures that develop—rather than merely use—their own machine learning algorithms and systems, integrating them into their products and services. Alternatively, they may rely on existing AI modules from the open-source ecosystem to build their offerings.

AI startups have garnered significant attention in recent years, as they are considered—alongside Big Tech—the driving force of future economies. According to the CB Insights Report (2024), the total financing of the world's top 100 AI startups amounted to $10.4 billion, reflecting a 48% market growth compared to 2022. However, despite this rapid expansion, a recent report by DemandSage (2025) indicates that 90% of AI startups fail, primarily due to a poor understanding of market demand or weak product-market fit—factors that outweigh financial or team-related issues. These contradictions highlight a significant gap in both practice and academia, creating ample space for further research.

Academic literature on AI startups is still emerging (Weber et al., 2022), and there is limited knowledge on how these startups operate and are structured. Most research stems from business model literature, where scholars such as Weber et al. (2022) and Garbuio and Lin (2019) have attempted to classify AI startups based on their business models. Other insights come from a fragmented body of research on AI startups and AI companies, detailing their characteristics and challenges (Lee, Kim, and Ivan, 2024). Among the various obstacles identified in the literature—including AI startups' difficulties in acquiring and training large datasets, high infrastructure requirements, and competition with Big Tech—this paper focuses on a fundamental issue: the complex relationship between technological expertise and market understanding. AI startups frequently struggle to translate their advanced technological capabilities into solutions that are both functional and aligned with real market needs (Kelly et al., 2022).

More specifically, this paper aims to explore how AI startups design and present their offerings to the market. To analyze this, we adopt the value proposition as the key analytical construct. The value proposition is not merely a means of communication, it is a strategic tool through which a company defines and delivers a coherent package of value to customers (Lanning, 2019; Payne et al., 2017). A strong value proposition reflects a firm's ability to identify external opportunities (Teece, 2007), respond to environmental uncertainties, and address consumer needs in ways that enhance their willingness to pay (Guo, Yang, and Han, 2019; Baden-Fuller and Haefliger, 2013).

Thus, the research question guiding this study is: "How do AI startups articulate their value propositions?"

Although aspects of this topic have been discussed in the broader literature on high-tech startups, this paper incorporates AI-specific challenges to provide a more nuanced understanding. Like other technology-driven startups, AI startups face uncertainty when formulating their customer value propositions because they typically lack previous product generations or past experiences to draw from (Wouters, Anderson, and Kirchberger, 2018; Kirchberger, Wouters, and Anderson, 2020). However, unlike other technology-driven startups, AI startups encounter additional challenges that further complicate the process of translating technological advancements into marketable solutions. One of these challenges is their tendency to develop applications for multiple industries simultaneously, which can lead to generic or unfocused value propositions that fail to resonate with specific customer segments. Additionally, AI startups introduce novel terminology that differs from previous technological paradigms, making it more difficult for non-technical customers to grasp the usability and potential impact of AI solutions. Furthermore, the adoption of AI raises ethical and socio-economic concerns that may negatively affect how customers perceive its usefulness and desirability (Chalmers, MacKenzie, and Carter, 2021; Merhi, 2023). Given these challenges, it is crucial to analyze how successful AI startups construct their value propositions to effectively position themselves in the market.

This study employs an exploratory multiple-case study approach, focusing on the value propositions of ten Italian AI startups. The analysis aims to identify both common patterns and differences in how these startups articulate their value proposition.

By addressing this research question, the paper contributes to two key areas of literature. First, it advances research on AI startups by exploring how they develop their value propositions, offering insights into how they compete and sustain themselves in a market dominated by Big Tech and other startups. Second, it contributes to the broader literature on value propositions, which has traditionally focused on well-established companies rather than startups. Investigating AI startups' value propositions provides new perspectives on how emerging technology firms craft and communicate their value in uncertain and rapidly evolving environments.

2 Theoretical background

2.1 AI startups

AI startups can be defined as young and innovative companies that use artificial intelligence technology as a core element of their products and services. Since the concept is relatively new, emerging definitions aim to establish clearer boundaries around what qualifies as an AI startup. As noted by Truong (2024), some startups claim to be AI-based merely by referencing the use of AI technologies. However, Truong advocates for a stricter definition, identifying AI startups as ventures that develop their own machine learning algorithms and systems and integrate these into their products and services. This definition excludes startups that merely use data analytics to make predictions or automate specific processes without demonstrating any form of machine intelligence.

AI startups are typically characterized by deep technical competencies, which enable the continuous advancement of their AI technologies (Lee, Kim, and Ivan, 2024). As Chalmers, MacKenzie, and Carter (2021) point out, AI is a highly technical and science-driven field, making AI startups comparable to other technology-oriented startups. While several scholars analyze AI startups through this lens (see Lee, Kim, and Ivan, 2024), they also highlight important distinctions to better understand the unique nature of these ventures. For instance, Lee, Kim, and Ivan (2024) emphasize that AI startups often focus on the quality and maturity of their technologies. Maturity brings them closer to market readiness, but the fast-evolving nature of AI demands constant technological development. Moreover, these startups frequently pay special attention to ethical concerns in the development and application of AI (Merhi, 2023; Lee, Kim, and Ivan, 2024). In addition, as discussed by Fossen, McLemore, and Sorgner (2024), AI startups face significant disadvantages related to limited access to training data and the high infrastructure requirements associated with AI development.

Another, more structured stream of literature explores AI startups through the lens of business models. Garbuio and Lin (2019), in their analysis of healthcare AI startups, distinguish between two business model

archetypes: startups that provide information and those that aim to connect multiple parties. Building on this perspective, Weber et al. (2022) develop a taxonomy of AI startups, distinguishing AI-based business models from traditional ones. They identify four archetypes of AI startups: (1) Service/Product Providers, (2) Facilitators of AI Development, (3) Data Analytics Providers, and (4) Deep Tech Researchers.

2.2 Value proposition and tech-startup

The value proposition is not merely a means of communication, it is a strategic tool through which a company defines and delivers a coherent package of value to customers (Lanning, 2019; Payne et al., 2017). A strong value proposition reflects a firm's ability to identify external opportunities (Teece, 2007), respond to environmental uncertainties, and address consumer needs in ways that enhance their willingness to pay (Guo, Yang, and Han, 2019; Baden-Fuller and Haefliger, 2013).

As Payne et al. (2020) suggest, the literature on value propositions is characterized by two main streams: one derived from practitioners (Osterwalder et al., 2014; Dennis, 2018) and the other from academic researchers (Anderson et al., 2006; Payne et al., 2017). While practitioner-oriented contributions focus primarily on the strategic design of value propositions, academic studies offer a more critical view, exploring drivers, dimensions, and consequences. Most academic research has concentrated on established companies, aiming to highlight best practices in designing and implementing value propositions (Lindgreen et al., 2012; Payne, Frow, and Eggert, 2017). Paradoxically, although the role of the value proposition is well recognized in the startup context (Osterwalder et al., 2014), few academic studies have directly examined startup value propositions (Kirchberger, Wouters, and Anderson, 2020). As Wouters, Anderson, and Kirchberger (2018) note, the studies that do exist often focus on how startups can craft attractive value propositions to appeal to investors. However, startups deserve much more attention in this area. They operate under conditions of extreme uncertainty—lacking both historical reference points and a customer base from which to gather market feedback (Kirchberger, Wouters, and Anderson, 2020). Moreover, they frequently target multiple industries simultaneously, which can result in vague or overly generic value propositions (Wouters, Anderson, and Kirchberger, 2018; Nussipova, 2022). These challenges are particularly relevant for tech startups, including AI startups. For these companies, having a value proposition means being able to turn a technological innovation into a marketable offering. Yet they often lack the market and strategic capabilities needed to do so (Gofman and Jin, 2024; Jacobides et al., 2021).

Another difficulty in developing value propositions for startups is the need for flexibility—they must be able to adapt their value proposition as they learn more about the market. According to Kirchberger, Wouters, and Anderson (2020), this requires close collaboration with customers to build in an iterative way their value proposition. Wouters, Anderson, and Kirchberger (2018) suggest that startups develop two sequential value propositions: the value proposition of the offering, which focuses on the problem solved and the startup's unique contribution, and the value proposition of the assistance, which highlights the partners, providers, and resources used to realize and deliver the offering. In other terms Wouters, Anderson, and Kirchberger (2018) stress the clarity in expressing the startup's value. In their work, Kirchberger, Wouters, and Anderson (2020) emphasize two key elements in evaluating startup value propositions: specificity and substantiation. Specificity, also linked to the quantification, refers to the ability to quantify the value offered—for example, by translating benefits into measurable performance outcomes. Substantiation means offering convincing evidence to support the value proposition's claims through use cases, demonstrations, or proof that the value has been realized in practical and useful ways.

Due to the wide variety of offerings, existing studies do not point to a dominant type of value proposition (e.g., quality, speed, efficiency). However, Van Le and Suh (2019) found that tech startups increasingly emphasize aspects such as privacy protection, security, and trust in their value propositions.

3 Methodology

To explore how AI startups define their value propositions, we adopt a qualitative methodology based on a multiple case study approach (Eisenhardt, 1989). Our case selection follows predetermined criteria to ensure sufficient variation within the sample and to enable a meaningful cross-case comparative analysis (Eisenhardt and Graebner, 2007).

Starting from a list of 1,291 Italian AI startups identified through Crunchbase, we selected those that had secured at least €1 million in external funding, using this as an indicator of market traction and potential. This filtering resulted in a sample of 94 startups. We then further refined the sample by including only companies founded after 2014 and with at least 10 years of operational experience, considering this time span appropriate given the maturity required in the tech industry. Applying this criterion yielded a final list of 75 startups. From this list, we intentionally selected 10 cases that meet the definition of AI startups proposed by Truong (2024) -

startups that develop their own machine learning algorithms and systems and integrate these into products and services - and for which sufficient public information was available. Priority was given to maximizing diversity in terms of their value propositions. In line with Yin (2017), we used multiple data sources for data analysis and triangulation, including (1) official websites, (2) Crunchbase, (3) news articles.

To analyze how AI startups build their value propositions and merge technology with target markets, we first provide a description of each startup following the framework proposed by Weber et al. (2022), which includes details such as primary AI technology, data type, data source, and hardware provision. Secondly, we break down the value proposition using dimensions derived from the literature on technological value propositions. Specifically, we analyze value proposition formulation across six key dimensions: the type of expressed advantage (Van Le and Suh, 2019) - economy, efficiency, speed, customization, community, emotion, trust; the orientation of the value proposition (Wouters, Anderson, and Kirchberger, 2018) - technology-oriented vs customer-oriented; the specificity in terms of value quantification (Kirchberger, Wouters, and Anderson, 2020); the substantiation, referring to the presence of use cases or supporting documentation (Kirchberger, Wouters, and Anderson, 2020); the completeness of the value proposition, considering both the offering and the assistance dimensions (Wouters, Anderson, and Kirchberger, 2018). Additionally, we examine the language used to communicate the value proposition using the multiaztertest (Granados, Lorenzo-Espejo and Lorenzo, 2023) acknowledging that AI often introduces new technical vocabulary that differs significantly from previous technological paradigms. This shift can make it more difficult for non-technical users to understand and evaluate the usability and relevance of AI solutions.

The analysis covers all available information related to the presentation of the client's problem, the description of the proposed solution, and the explanation of how the offering is implemented.

After outlining both AI and value proposition characteristics for each case, we conduct a cross-case comparative analysis to identify patterns and distinct approaches in how AI startups construct and communicate their value propositions.

4 Preliminary Results

A preliminary exploration of the selected sample of AI startups reveals several emerging characteristics in how these firms articulate their value propositions. There is no single prevailing benefit consistently expressed, although efficiency is a commonly mentioned advantage. However, these benefits are rarely quantified, and only a few startups provide concrete metrics or substantiated claims. While some startups offer detailed explanations supported by use cases, videos, or product visuals, others provide minimal information and instead invite direct contact, suggesting a preference for personal interaction in explaining the value of their proposal.

The orientation of the value proposition tends to be more technology-driven when the solution targets a specific industry, while customer-oriented propositions are often framed in terms of applicability across multiple sectors. Generally, the more specific the target industry, the more technical the language used—reflecting the complexity of both the problem addressed and the proposed AI-based solution.

Additionally, when data-related solutions are involved, references to privacy and trust become more prominent, indicating awareness of the ethical and practical concerns associated with AI data processing.

Overall, while many startups attempt to clearly communicate the benefits of their offerings, the level of specificity and substantiation remains limited. This may help explain the gap often observed between technological potential and market adoption.

5 Conclusion

This study will have practical implications, offering a framework for transforming AI technology into real market utility while also providing insights into how AI startups can better design their competitive advantage to differentiate themselves from major AI corporations. Regarding theoretical implications, the paper enriches the literature on AI startups by shedding light on their specific characteristics. In particular, it will contribute to understanding the entrepreneurial dynamics related to AI startup by analyzing value proposition formulation strategies. The main limitations of this study concern sample selection, as the analysis focuses on a small group of AI startups, all of which are based in Italy.

Future stages of the research will focus on a more detailed case analysis and the identification of recurring patterns in AI startup value proposition strategies. In addition, the study will highlight the advantages and disadvantages of different strategic models.

Future research could extend the sample and the analysis to other countries or conduct cross-country comparisons to gain a more comprehensive understanding of successful value propositions adopted by AI startups.

6 Ethics Declaration

The ethical clearance was not required for the research.

7 AI Declaration

No AI tools were used for the creation of the paper.

Exploring Configurations of Growth Hacking Success Factors in SMEs: An FSQCA Approach

Luca Simone Macca[1], Gabriele Santoro[12]
[1]University of Turin, Turin, Italy
[2]University of Nicosia, Nicosia, Cyprus

Abstract

The pursuit of sustainable and accelerated growth in small- and medium-sized enterprises (SMEs) can be effectively promoted through the application of Growth Hacking (GH) strategies. Improving the performance of GH practices within SMEs has therefore emerged as a critical objective for both practitioners and researchers. Drawing on the theoretical foundations of the Technology-Organization-Environment (TOE) framework, this article proposes an integrated analytical model to explore the determinants of GH performance in SMEs. Based on a sample of SMEs actively engaged in GH initiatives, the research will employ fuzzy-set qualitative comparative analysis (fsQCA) to examine the configurational relationships between technological, organizational, and environmental factors that influence GH outcomes. It is expected that: (1) no single condition will be sufficient on its own to achieve high GH performance; (2) multiple and equally effective combinations of internal and external factors will lead to successful outcomes, supporting the principle of equifinality; and (3) key technological capabilities, such as digital transformation and data analytics, along with organizational adaptability and responsiveness to environmental dynamism, will emerge as critical elements in successful configurations. Furthermore, relying solely on technology adoption or external market conditions may prove insufficient to maximize GH performance without appropriate organizational adaptation. These findings enrich the current understanding of the complex mechanisms influencing GH performance and offer practical insights for SMEs wishing to design more effective and resource-efficient growth strategies.

Overall, this research is expected to make a threefold contribution. First, it enriches the theoretical foundations of GH research by applying and extending the TOE framework in a configurational context. Second, it advances methodological practice by employing fsQCA to uncover complex causal relationships often missed by traditional methods. Third, it provides actionable insights for practitioners and policymakers by identifying strategic pathways to optimize GH practices according to different organizational contexts and resource profiles.

Keywords: Growth hacking, Technology organization environment-TOE, digital transformation, managerial experimental approach

Paper type: Academic Research Paper

1 Introduction

In an increasingly competitive and dynamic business environment, organizations continuously seek innovative and cost-effective strategies to maintain a competitive advantage in the market and attract and retain an ever-greater number of consumers in order to achieve rapid and sustainable growth over time (Bresciani et al., 2021; Troise et al., 2022).

Recent research has shown that GH, a managerial approach based on experimentation (Macca, Santoro, & Christofi, 2025), serves as an indispensable conduit for advancing company growth, promoting greater production efficiency, increased competitiveness, and sustainable development (Macca, Santoro, Jabeen, et al., 2025). As the digital era progresses, GH has increasingly established itself as a key approach to sustainable growth, particularly among SMEs, which, often having limited financial and human resources, are constantly seeking sources of competitive advantage to stimulate business growth (Giordino et al., 2025; Macca, Santoro, Jabeen, et al., 2025). Furthermore, SMEs are notably active in innovative experimentation and in the integration of automation tools and data analysis (Cristofaro et al., 2025). As a result, today's SMEs need tools and frameworks that can help them quickly redesign their value chains, promoting innovative, agile, and lean models (Feiz et al., 2021; Ghezzi & Cavallo, 2020). Many companies in recent years have used GH in their production processes or to innovate and scale their business models, and recent qualitative research has confirmed its effectiveness and its growing use in both small and large enterprises (Bargoni, Santoro, et al., 2024; Scuotto et al., 2025).

Despite its growing prominence, the exploration of GH antecedents on organizational performance remains an underdeveloped research area. Recent studies have attempted to create performance measurements to understand how to evaluate the effectiveness and impact of these on implemented GH practices (Bresciani et al., 2024; Giordino et al., 2025; Joshi et al., 2025). However, these studies have analyzed such measurement

variables in isolation on GH performance, neglecting possible biases or gaps regarding the best or necessary configurations needed to achieve such performance. In particular, the aforementioned studies have not delved into the underlying reasons for differences in GH performance among SMEs. They have also overlooked the analysis of key driving factors and their configurations. At the same time, these studies have failed to systematically uncover the coordination and synergistic effects among multiple drivers, such as technology, organization, and environment, that contribute to GH performance in SMEs. Therefore, managers and entrepreneurs are forced to identify the complex relationship between multiple factors and synergistic effects influencing the performance of GH practices. Armed with this understanding, they can judiciously select appropriate GH strategies tailored to the unique factor endowments of their respective SMEs. Consider, for example, SMEs that, being resource-scarce and aiming to focus on a specific objective, could achieve their GH goal more quickly and efficiently if they knew the best combinations of conditions like internal factors, technologies, and resources. In light of these challenges, the issue of effectively allocating resources within SMEs to enhance the effectiveness of GH practices remains a pressing concern. Therefore, this study aims to identify the influential factors that impact the performance of GH in SMEs. It will analyze the configurations that drive GH performance in SMEs, effectively distinguishing between core and peripheral conditions that influence such performance. Through this analysis, the complex operational mechanisms of various combinations of conditions on the performance of GH in SMEs will be explained.

Accordingly, this research employs the TOE framework (Tornatzky et al., 1990), recognized for its suitability in examining the adoption and diffusion of emerging technologies, to conduct an empirical analysis of the determinants influencing GH performance among SMEs. The TOE framework provides a structured approach to examining how internal and external conditions shape an organization's ability to implement GH successfully. Adopting a configurational approach and focusing on promotional pathways, the study seeks to uncover the key factors that drive performance levels in GH initiatives within SMEs, as well as to identify the conditions exerting the most substantial influence. Grounded in the TOE framework, a conceptual model is developed to systematically elucidate the factors shaping GH performance in the context of SMEs.

This study sets out to use a fsQCA approach to assess the variations in condition configurations and influence mechanisms contributing to diverse GH results.

2 Literature Review and Theoretical Framework

2.1 Research progress of GH performance in enterprises

GH has rapidly emerged as a pivotal concept within the domains of business strategy, innovation management, and entrepreneurship. Originating at the intersection of software engineering, creative marketing, and data-driven experimentation, GH was first articulated by Sean Ellis in 2010 as "a process of rapid experimentation across the funnel to learn the most effective way to scale sustainable customer adoption" (Ellis & Brown, 2017; Troisi et al., 2020). Characterized by its agility, cross-functional collaboration, and reliance on data analytics, GH fundamentally departs from traditional marketing approaches by prioritizing low-cost, high-impact strategies. Initially, its techniques proved particularly advantageous for startups and SMEs, where limited resources demanded innovative, scalable solutions for customer acquisition and retention (Ellis & Brown, 2017; Holiday, 2012).

Over time, however, the strategic advantages associated with GH—particularly its scalability, cost-efficiency, and iterative experimentation—have attracted interest from larger, more established organizations (Bargoni, Santoro, et al., 2024). As firms face increasingly dynamic, volatile, and digitized competitive landscapes, GH has transitioned from a tactical practice to a broader strategic framework aimed at fostering innovation, responsiveness, and sustained growth (Bohnsack & Liesner, 2019; Sanasi, 2025). Large enterprises are progressively restructuring internal processes to emulate startup-like experimentation models while leveraging their extensive resources to institutionalize GH practices at scale. Sanasi (2025) identifies diverse implementation models within growing ventures, ranging from decentralized experimental teams to centralized innovation hubs, highlighting a shift in GH's organizational relevance from a niche startup tool to an enterprise-wide strategic lever.

In parallel with its diffusion across varied organizational settings, researchers have sought to develop systematic frameworks for evaluating GH performance (Bresciani et al., 2024; Giordino et al., 2025; Joshi et al., 2025). Key performance indicators commonly employed include customer acquisition cost, customer lifetime value, retention rates, and growth efficiency. Broader financial and organizational metrics, such as revenue growth, return on marketing investment, and market penetration, also serve as important measures of GH efficacy (Giordino et al., 2025). Complementing these quantitative metrics, conceptual frameworks have been

developed to structure GH processes around iterative cycles of ideation, prioritization, experimentation, and evaluation. Cristofaro et al. (2025), for instance, conceptualize GH as a "scientific method," emphasizing the role of digital tools—such as A/B testing, funnel analytics, predictive modeling, and customer segmentation—in accelerating learning and fostering data-informed decision-making across organizational functions.

Recent empirical studies have further illuminated the relationship between GH practices and firm performance. Bargoni et al. (2024) demonstrate that GH enables organizations to lower customer acquisition costs, enhance user retention, and achieve more sustainable growth trajectories. Giordino et al. (2025) focus specifically on SMEs, identifying a positive correlation between GH capabilities and both financial and organizational outcomes. In larger enterprises, the integration of GH practices entails more complex dynamics. Gerlich et al. (2025) explore how dynamic capabilities, particularly the management of exploration-exploitation tensions, influence the successful scaling of GH initiatives. Their findings underscore the necessity of fostering organizational learning and cross-functional collaboration while navigating the inherent frictions between agility and bureaucratic structures. Bresciani et al. (2024) highlight how human, relational, and structural capital collectively strengthen GH initiatives, underscoring the importance of internal capability development for maximizing strategic outcomes, particularly in larger, more complex organizations. Moreover, technological advancements, particularly in AI, have become key enablers of GH strategies. Santoro et al. (2024) detail how AI technologies automate experimentation, personalize customer engagement, and enhance decision-making processes while also raising new challenges concerning data ethics and regulatory compliance. Finally, intellectual capital plays a critical role in GH effectiveness.

Despite the increasing scholarly attention devoted to GH, the empirical examination of its performance outcomes remains relatively limited. Recent studies primarily highlight the positive influence of individual antecedents, such as marketing capabilities, disruptive innovation, big data analytics capability, and innovation capability, on GH effectiveness (Bargoni et al., 2024; Joshi et al., 2025). Furthermore, findings consistently demonstrate a favorable association between GH capability and both organizational and financial performance in SMEs (Giordino et al., 2025). However, these studies typically adopt a variable-oriented approach, analyzing the isolated effects of specific factors without considering how they may interact in complex and complementary ways. Particularly, there is still a need to understand which configurations of capabilities, resources, and strategic conditions are most conducive to high GH performance. To date, no study has systematically identified the necessary and sufficient conditions (or optimal configurations) that collectively drive successful GH implementation, particularly within the SMEs context. This absence limits both theoretical development and practical guidance for firms seeking to design effective GH strategies.

2.2 Research framework

To analyze the antecedents that determine the major impact of GH strategies on the organization’s performance, this study adopts the TOE framework developed by Tornatzky and Fleischer (1990). The TOE framework provides a structured lens to examine how technological innovations are adopted within firms, and posits that the adoption process is influenced by internal factors (technological and organizational), as well as external environmental factors. In this framework, the technological context refers to the existing and emerging technologies that firms leverage to enhance innovation capabilities and operational efficiency. The organizational context captures firm-specific characteristics, including managerial commitment, human capital resources, and the prevailing internal culture that collectively shape innovation behavior. Finally, the environmental context encompasses the external conditions, such as market dynamics, competitive pressures, and regulatory frameworks, that exert influence over strategic decision-making.

Several theoretical and methodological considerations underpin the adoption of the TOE framework in the present study. First, the TOE framework offers a robust structure for analyzing the interaction between internal and external determinants of innovation. Given that this research aims to identify GH's critical enablers across technological, organizational, and environmental domains, the TOE framework serves as an appropriate and validated foundation for systematic categorization and analysis. This alignment ensures a comprehensive understanding of the multiple influences at play, ranging from internal capabilities, such as data-driven decision-making cultures, to external forces, like market turbulence, all of which are critical to successfully implementing GH strategies. Second, GH represents a digitally driven, innovation-centric approach that synergistically integrates technological advancement, agile organizational practices, and heightened market responsiveness. As the TOE framework has been extensively employed in prior studies on digital innovation, information technology adoption, and organizational transformation (Clemente-Almendros et al., 2024; Hossain et al., 2024; Marrucci et al., 2023), its application in the context of GH ensures theoretical continuity and extends its relevance to an emerging and interdisciplinary domain. In addition to leveraging the TOE framework, this study

adopts a configurational approach by employing fsQCA to explore how different combinations of technological, organizational, and environmental factors lead to successful GH outcomes. This methodological choice acknowledges that in complex, dynamic environments, such as those characterizing digital markets, outcomes may arise through multiple equally viable pathways.

Through this configurational lens, the study investigates the specific patterns of technology, organization, and environment that jointly contribute to high GH performance. The fsQCA method allows for the identification of distinct causal recipes, thereby offering nuanced insights into how various firms, contingent upon their internal strengths and external challenges, can achieve success through alternative but effective pathways. In doing so, this research aims to advance understanding of GH implementation by illuminating the complex, interdependent nature of technological, organizational, and environmental enablers.

2.3 Technological Factors

In the technological domain, this study identifies big data analytics capability and firm digital transformation as critical enablers of GH. Prior research underscores that technological conditions are key determinants in enhancing organizational GH performance, as digital tools, platforms, AI, and machine learning facilitate the rapid experimentation, optimization, and scaling processes central to GH practices (Gerlich et al., 2025). Given GH's reliance on iterative experimentation that generates extensive data, efficient processing becomes essential to support SMEs in developing their GH capabilities (Cristofaro et al., 2025; Jabeen et al., 2023; Macca, Santoro, Jabeen, et al., 2025; Wamba et al., 2017). Strengthening big data analytics capabilities through the adoption of digital tools and technologies is thus imperative. The ability to extract actionable insights from data enables firms to ground strategic decisions in empirical evidence rather than intuition or market perceptions (Cadden et al., 2023; Tseng, 2023).

Firm digital transformation plays a particularly pivotal role in this process, reshaping how organizations engage with customers, interpret market signals, and execute strategic initiatives (Bohnsack & Liesner, 2019; Ribeiro-Navarrete et al., 2021). By integrating infrastructures such as the Internet of Things, AI, data analytics, and cloud computing, digital transformation enhances organizational agility and supports informed decision-making. Empirical evidence highlights the strategic value of digital tools, which not only deepen customer engagement but also build capabilities for swift adaptation to environmental changes based on empirical insights (Hassan et al., 2023; Ramadani et al., 2023). Consequently, digital transformation fosters a more adaptive and responsive GH approach, enabling SMEs to maintain competitiveness in dynamic markets through continuous learning and innovation (Bargoni, Smrčka, et al., 2024; Troisi et al., 2020).

2.4 Organizational Factors

The organizational dimension encompasses a firm's internal capacity to support GH strategies. This includes five key components: Innovation capability, Cross-functional collaboration, Iterative experimentation, Experimentation resource allocation, and Proactive customer and market orientation. Existing research often explores GH through perspectives such as agile methodologies, entrepreneurial orientation, and technology adoption (Bargoni, Smrčka, et al., 2024; Cristofaro et al., 2025; Macca, Santoro, & Christofi, 2025; Troise et al., 2022). Nevertheless, given the distinct characteristics of GH — namely, its reliance on rapid experimentation, interdisciplinary integration, and customer-centric innovation — a deeper understanding of specific organizational factors becomes essential. Innovation capability enables enterprises to generate novel ideas, swiftly adapt to changes, and creatively solve problems, forming the foundation for successful GH initiatives (Gerlich et al., 2025; Jabeen et al., 2023). Cross-functional collaboration, by bringing together marketing, product development, data analytics, and engineering teams, fosters knowledge sharing and accelerates the identification of growth opportunities (Macca, Santoro, Jabeen, et al., 2025). Iterative experimentation refers to the continuous testing, learning, and refinement cycle that is crucial for validating hypotheses and optimizing growth tactics (Ries, 2011; Sanasi, 2023, 2025). Meanwhile, experimentation resource allocation ensures that sufficient human, financial, and technological resources are dedicated to conducting and scaling experiments, directly influencing the speed and success rate of growth initiatives (Bresciani et al., 2024; Cavallo et al., 2023; Choi et al., 2022). Finally, a proactive customer and market orientation (Narver et al., 2004) enables organizations to anticipate emerging trends and evolving customer needs, ensuring that GH efforts are relevant and impactful. Therefore, differences in the presence and combination of these organizational factors can profoundly affect the performance of enterprises pursuing GH strategies.

2.5 Environmental Factors

In the environmental dimension, Environmental dynamism and Industry-specific forces are examined as external enablers of GH strategies. Environmental dynamism reflects the speed and unpredictability of technological advancements and market changes (Sharfman, 1991; Autio et al., 2018), requiring enterprises to adapt their GH strategies to sustain performance continually. Technological dynamism refers to frequent innovation within industries, while market dynamism involves shifts in customer needs and preferences. Alongside this, industry-specific forces—such as regulatory intensity, competitive pressure, and technological maturity (Porter, 1980; Schendel, 1994)—define the strategic environment in which GH occurs. High competition or rapid innovation cycles demand more aggressive and agile tactics, while stable industries may favor incremental improvements. Investigating the combination and differences between environmental dynamism and industry-specific forces is essential, as each uniquely influences how enterprises structure and execute GH initiatives.

The developed research model is illustrated in Figure 1.

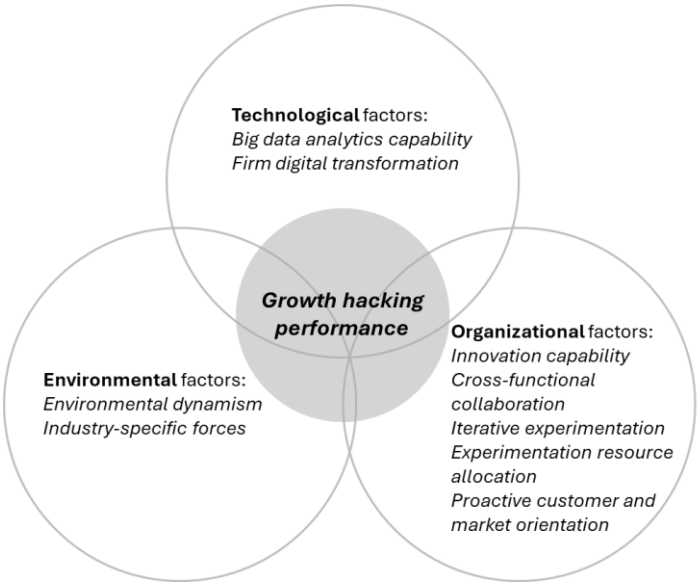

Figure 1: Research model

3 Research design and methods

This research intends to employ fsQCA to investigate the configurations of technological, organizational, and environmental conditions that contribute to GH performance in enterprises. The choice of fsQCA was motivated by its ability to analyze causal complexity, allowing for the identification of equifinal pathways where multiple configurations of conditions lead to the same outcome (Ragin, 2008). This method aligns with the study's aim to uncover the necessary and sufficient conditions for achieving high GH performance in SMEs.

This paper presents a collection of pertinent data through a questionnaire survey. To ensure the consistency of measurement variables and research inquiries, a five-point Likert scale is employed, and an initial questionnaire is devised based on the TOE framework and the research findings concerning GH performance. Under the guidance of a professional consultant with experience in a network of entrepreneurs and companies of various sizes, together with input from scholars specializing in the GH approach, the questionnaire was refined and revised to produce the final version.

The research sample included SMEs operating in a wide range of sectors in order to capture a variety of different organizational contexts and backgrounds (Eisenhardt, 1989). Empirical data were collected through the distribution of a structured questionnaire to more than 50 SMEs based in Italy. Data collection was facilitated by LinkedIn and targeted e-mails, exploiting an established network of Italian entrepreneurs and SME representatives. Italy was chosen as the research setting due to its particular economic structure, in which SMEs are the cornerstone of economic development and employment generation (Giordino et al., 2025; Jabeen et al., 2023; Jafari-Sadeghi et al., 2020). Selection criteria required that each organization actively integrate GH strategies into their operations to innovate, scale, or experiment with their business processes. This ensured the relevance and applicability of the insights derived from the sample.

Data collection was conducted from January to March 2025. To maximize the response rate, participants were thoroughly informed about the study's objectives and the specific nature of the requested information. Following several follow-up reminders, a total of 31 fully completed questionnaires were collected. The questionnaire utilized in this study included nine independent variables and one dependent construct. Responses were collected using a five-point Likert scale, ranging from "Strongly Disagree" to "Strongly Agree".

Two variables were selected to investigate the technological factors: Big data analytics capability and firm digital transformation. The first variable evaluated the organization's ability to process and analyze large amounts of data and to implement technological tools and platforms in its growth processes. The second variable assessed the organization's disposition to integrate AI and machine learning technologies in its growth processes.

From the perspective of organizational context, four variables were selected. Innovation capability was measured to explore the degree to which the company has a culture that is open to innovation and data-driven. Cross-functional collaboration was measured to investigate the presence of teams with diverse skills and expertise (e.g., marketers, data analysts, coders) within an organization. Iterative experimentation was measured to assess the degree to which an organization engages in constant testing and refinement of its strategies. Experimentation resource allocation was measured to assess the organization's availability of resources and budget for testing and experimentation. Proactive customer and market orientation were measured to investigate the organization's ability to quickly adapt to changes in the market and make fast decisions.

The environmental factors were represented by the variables of Environmental dynamism (Giordino et al., 2025; Marrucci et al., 2023) and Industry-specific forces (Takata, 2016). Environmental dynamism was measured to assess the level of changes that may occur in the organization's market environment. Industry-specific forces were assessed to examine how price, competition, customer, and supplier power factors may shape the firm's performance. These dynamics shape the opportunities, constraints, and pressures organizations face and can significantly impact how GH strategies are designed and executed.

Following Giordino et al. (2025), the dependent variable (outcome), GH performance, is divided into two aspects: organizational performance and financial performance. Specifically, the first is defined as the collection of observations that indicate a company's market and operational aspects so that measures related to the organization's reputation, market positioning, and sales volume can be outlined (El-Kassar & Singh, 2019). In contrast, the second is detailed as metrics indicating a firm's ability to generate value for its shareholders, and it includes metrics such as EBIT, ROI, and ROS (Lin et al., 2013).

Follow-up semi-structured interviews were conducted with 19 entrepreneurs (founders) who had voluntarily participated in the survey and provided their contact information. Each interview, lasting between 45 and 60 minutes, aimed to complement and deepen the survey findings through qualitative data, including personal experiences, examples, and case studies from recent and past projects. The interviews also explored participants' perceptions of the conditions necessary to achieve high GH performance.

fsQCA was employed to analyze the data, leveraging its suitability for examining complex causal relationships where multiple pathways can lead to the same outcome (equifinality) (Ragin, 2008). Grounded in configuration theory, fsQCA interprets conditions (e.g., big data analytics capability) and outcomes (e.g., organizational and financial performance) as sets, enabling a nuanced analysis of their interdependencies (Fiss, 2011; Ragin, 2008).

4 Expected results, implications and contributions

This study is expected to generate new insights into the complex and configurational mechanisms underpinning GH performance in SMEs. By applying a fsQCA approach, the research anticipates identifying multiple, equally effective combinations of technological, organizational, and environmental factors that lead to high GH performance. It is likely that no single condition will emerge as universally sufficient; instead, different configurations of conditions are expected to explain successful GH outcomes, thereby confirming the principle of equifinality in dynamic organizational environments.

Specifically, it is expected that core technological capabilities, such as digital transformation initiatives and big data analytics capability, will consistently appear across high-performing configurations. Organizational factors such as cross-functional collaboration, innovation capability, and the ability to allocate resources to iterative experimentation are also anticipated to play a central role. Environmental factors, particularly environmental dynamism and industry-specific competitive pressures, are likely to act as significant contingencies that shape the effectiveness of internal capabilities. The analysis is also expected to distinguish between core and peripheral conditions, offering a more nuanced understanding of which elements are critical across multiple pathways and which are contextually dependent.

The expected findings carry important theoretical implications. First, this study advances the understanding of GH by systematically applying the TOE framework to a new domain (GH) where such a structured approach has been largely underexplored. By moving beyond traditional, linear models and embracing configurational analysis, the study contributes to the theoretical development of both the TOE framework and GH literature, demonstrating how multiple interacting factors jointly determine strategic outcomes in SMEs. Furthermore, the adoption of fsQCA enables the uncovering of causal asymmetry and complexity, offering a richer explanation of how GH practices succeed under varying organizational and environmental conditions.

In practical terms, the study provides valuable guidance for SME managers, entrepreneurs, and consultants seeking to enhance GH effectiveness. By identifying specific configurations of technological readiness, organizational capabilities, and environmental alignment that drive superior performance, the study will enable practitioners to prioritize interventions based on their unique internal and external contexts. For instance, SMEs with limited financial resources may achieve high GH performance by focusing on agile organizational practices and proactive market orientation, whereas firms with greater digital capabilities might leverage advanced data analytics and cross-functional teams to scale their initiatives more effectively. The configurational approach thus offers a strategic tool for more targeted and efficient resource allocation.

Additionally, the results have relevant policy implications. Policymakers and business support organizations can use these insights to design programs that foster the critical capabilities and environmental conditions necessary for GH success among SMEs. In the Italian context, where SMEs are central to economic growth and innovation, the study's findings can inform national strategies aimed at improving the competitiveness and digital maturity of smaller enterprises.

Entrepreneurs' Perceptions of AI: Level of Adoption, Competences, and Learning Ecosystem

Cannavale Chiara[1], Claudio Lorenza[1], Diana Koroleva[2]
[1]University of Naples Parthenope, Naples, Italy
[2]National Research University Higher School of Economics, Russia

Abstract

The advent of the Fourth Industrial Revolution has marked a profound shift in the global economy, driven by the integration of artificial intelligence (AI), the Internet of Things, and quantum computing. AI stands out as a transformative force, profoundly reshaping industries, labour markets, and economic interactions. Also, AI's widespread implementation generates both opportunities and disruptions, with forecasts of the displacement of millions of jobs and the creation of new roles. However, these transformations vary significantly across regions and demographics, with countries like Italy facing unique challenges, including a substantial digital skills gap among the working population. Despite the growing interest in AI's technological and economic implications, limited research has investigated how specifically entrepreneurs adopt and utilise AI technologies in their daily business practices. While existing literature has focused predominantly on sector-specific applications—most notably in healthcare—entrepreneurship as a dynamic and multifaceted phenomenon remains underexplored in this context. Indeed, our study investigates how entrepreneurs adopt AI into their professional routines, the digital competencies they display during this process, and the learning ecosystems that support their acquisition of AI-related knowledge. To reach our research aim, we adopt a qualitative approach, conducting semi-structured interviews with a sample of entrepreneurs operating in Southern Italy. Through thematic analysis, we aim to highlight the existing patterns of AI adoption and the support mechanisms within the entrepreneurial ecosystems. The findings contribute to a deeper understanding of the AI adoption for entrepreneurs and their main digital competencies gap, offering theoretical insights and practical implications for policymakers, educators, and innovation stakeholders.

Keywords: artificial intelligence, AI adoption; knowledge gaps

Paper type: Academic Explorative Research Paper

1 Introduction

According to numerous analysts and futurists, the global economy has entered the Fourth Industrial Revolution, characterised by integrating artificial intelligence (AI), the Internet of Things, and quantum computing. Following the widespread adoption of information and computer technologies, whose advancements continue to accelerate, AI has emerged as a transformative force with the potential to impact various sectors, including business and the economy, significantly transforming interactions and experiences between stakeholders and citizens (Loureiro, Guerreiro & Tussyadiah, 2021). Integrating AI into various industries is reshaping the labour market, leading to both the reorganisation of existing roles and the creation of new opportunities. According to the jobs report (2023), AI is expected to displace approximately 83 million jobs and generate around 69 million new positions, resulting in a net reduction of 14 million jobs globally. The Tony Blair Institute projects that AI could displace between 1 million and 3 million private sector jobs, with annual job displacement peaking at 60,000 to 275,000 over the next few decades (Tony Blair Institute for Global Change, 2024). Despite these changes, long-term unemployment increases are anticipated to be relatively modest, as new job creation driven by AI growth is expected to offset many losses. Globally, the impact of AI on employment varies by region. A survey indicates that only 29% of people in Poland and Germany believe AI will create many new jobs, while just 24% in Hungary share this optimism.

According to a report by Implement Consulting Group (2024), approximately 24 million jobs exist in Italy, with a notable portion susceptible to automation through generative AI. Specifically, 58% of these positions are expected to collaborate with AI technologies, while 35% may remain unaffected. The report suggests that new roles emerging in the AI-driven economy are anticipated to offset jobs lost due to automation, potentially leading to a neutral long-term effect on overall employment figures (Implement Consulting Group Study, 2024). According to the Fondo per la Repubblica Digitale (FRD), set up in 2021 by the Italian government to boost the digital skills of citizens, 54% of those aged 16-74 lack basic digital skills, compared with an average of 46% in the European Union.

Despite these insights, research remains scarce on how digital tools effectively support entrepreneurial activity and how entrepreneurs utilise emerging technologies in the digital era. According to Corvello et al.

(2022), adopting digital technologies in economic activities influences entrepreneurs by offering resources that support their activities. However, the relationship between the complex phenomenon of entrepreneurship and digital tools still requires further exploration. To the best of our knowledge, existing studies primarily examine AI's impact on businesses in various industrial sectors, particularly healthcare (Cannavale et al., 2022).

Further research is needed to understand the dynamics and applications of new technologies in entrepreneurship. Indeed, we formulate these research questions:

- *RQ1: How do entrepreneurs adopt and integrate AI technologies into their daily professional practices?*
- *RQ2: What digital competencies do entrepreneurs demonstrate when adopting AI technologies?*
- *RQ3: What elements characterise the learning ecosystem supporting entrepreneurs' acquisition of AI-related knowledge and competencies?*

To reach our research aim, we will adopt a qualitative approach, based on semi-structured interviews with Italian entrepreneurs: our sample will be focused on entrepreneurs from Southern Italy. The paper proceeds as follows: the next section aims to discuss the managerial literature focused on AI adoption for entrepreneurs. Further, we explain the qualitative methodology applied, which comprises a thematic analysis of the interview transcriptions. Lastly, results are presented, and practical and theoretical implications are discussed.

2 Literature review

AI is profoundly impacting the work environment for intellectual jobs and entrepreneurial activities (Corvello et al., 2022). Entrepreneurs, in particular, must cope with the constantly changing environment in which they operate while also leveraging technology to remain agile and competitive (Rosenblat & Stark, 2016). According to Shepherd and Majchrzak (2022), the field of research regarding AI and the stream of literature on entrepreneurship have been kept separate until recently. However, "combining these tools is potent in generating impactful outcomes" (Shepherd & Majchrzak, 2022). Scholars have identified internal and external factors affecting the association between work and AI. Among the internal factors, researchers have recognised individual characteristics (Nambisan, 2017), while the external factors are the contexts in which entrepreneurs operate, such as the size or the business sector. The literature review performed by Giuggioli & Pellegrini (2022) highlighted an existing stream of research focused on investigating the relationship between entrepreneurial performance and AI adoption. It emerges that among the reasons for exploiting AI are the positive effects of automation in marketing, sales, and finance. The growing interest in exploring entrepreneurs' perceptions of AI stems from these technologies' substantial potential for business innovation and performance (Gupta & Yang, 2024). Digital tools powered by AI enable entrepreneurs to process and analyse large volumes of data, thereby significantly enhancing operational efficiency. According to Upadhyay, Upadhyay, and Dwivedi (2021), performance expectancy, defined as "the perceived benefits that an individual receives through technology", along with effort expectancy, are critical determinants of entrepreneurs' intentions to adopt digital technologies. Furthermore, the adoption of AI in entrepreneurial contexts has been shown to positively influence business outcomes, increasing the likelihood of success and improving overall entrepreneurial performance (Liu & Wang, 2024). Another strength of AI for entrepreneurs is the possibility of easily acquiring information about foreign markets or programming tasks (Gupta, 2024).

Given the immense potential of AI for business, it is essential to explore entrepreneurs' perceptions of these technologies (Gupta & Yang, 2024). Research suggests that performance expectancy—defined as the perceived benefits derived from using technology—alongside effort expectancy, are key determinants of an entrepreneur's intention to adopt digital technologies (Gupta, 2024). Furthermore, entrepreneurs' perceptions of AI technologies are closely linked to their existing competencies. Kruger and Steyn (2020) presented a conceptual model of entrepreneurial competencies needed to utilise Industry 4.0 technologies, including AI. Their model emphasises the need for both technical and soft skills, such as adaptability and innovation, further reinforcing the importance of competence integration. Kumar and Ratten (2024) noted that successful AI adoption in family businesses requires not only technical knowledge of AI technologies, but also skills in operations management, decision-making, and customer engagement.

Various conceptual frameworks have been developed to define the skills and competencies required in the context of rapidly evolving technologies. One of the most widely recognised is the 21st Century Skills Framework, which emphasises the competencies essential for thriving in a technologically advanced society (Partnership for 21st Century Skills, 2009). This framework goes beyond technical know-how to include personal attributes such as critical thinking, creativity, communication skills, and the ability to collaborate effectively—all of which are crucial for navigating modern professional environments. Another relevant model is the Entrepreneurial Competence Framework, which focuses explicitly on the skill set needed to successfully launch and manage a business (Bacigalupo, 2019). It includes different areas such as opportunity recognition, value creation, and risk

management. Additionally, the Future Skills Framework seeks to anticipate the skills that will be essential in the coming decades. It combines hard and soft skills, emphasising adaptability, digital literacy, leadership, and continuous learning. This model is particularly valuable for entrepreneurs who must remain agile and innovative in order to stay competitive in dynamic markets.

To further support the development of entrepreneurial competences in a digital age, the Digital Competence Framework (DigComp), developed by the European Commission, outlines the key digital skills necessary for functioning in a digital world, including the use of artificial intelligence (Carretero, 2017). DigComp identifies several core areas such as information and data literacy, problem solving with digital tools, digital content creation, and the ethical use of digital technologies—all of which are increasingly relevant for entrepreneurs navigating the complexities of modern business. For this research, we will focus on five of the competences highlighted in the DigComp framework.

3 Methodology

This study adopted a qualitative approach, which was well-suited to the exploratory nature of our research objectives (Yin, 2009). The goal was to understand the experiences of craft entrepreneurs in Southern Italy who are either using or considering using artificial intelligence (AI) in their businesses. To achieve this, we conducted semi-structured interviews, providing the flexibility to explore individual perspectives while ensuring consistency in addressing key themes related to the Digital Competence Framework.

The interview questions were designed based on the existing literature on the Digital Competence Framework (Carretero, 2017) and were organised into four key sections:

1. Introduction and Socio-Demographic Characteristics – to gather background information about the participants.
2. AI Usage – to explore AI practices.
3. Competences – to assess the Competences AI usage.
4. Learning Pathways and Learning Development Ecosystem – to examine the available resources and the Learning Pathways entrepreneurs choose.

The research is in progress, and this first work focused on a sample of 10 craft entrepreneurs from Southern Italy. A total of two in-person interviews were conducted in April 2025, each lasting approximately 20 minutes. The sample has been summarised in Table 1

Table 1 – Interview Participants

Name	**Age**	**Gender**	**Business activity**
Entrepreneur 1	35	Woman	Ceramics
Entrepreneur 2	31	Woman	Textile business

Prior to the interviews, participants provided consent for the use of their data, which was documented and reflected in the interview transcripts. The audio recordings obtained were transcribed using the AI service Sonix AI and subsequently translated from Italian to English with the assistance of ChatGPT. The data were then analysed using thematic analysis. The instrument employed for this process was ChatGPT, following the approach outlined by Koroleva and Jogezai (2025).

4 Results

The qualitative data analysis reveals that entrepreneurs in the study are in the early stages of adopting artificial intelligence (AI) within their businesses. Most participants reported that their experience with AI is recent, indicating that the integration of AI tools is still in its nascent phase.

"*My experience with AI started this year—it's very recent". (Entrepreneur 2)*

They mainly use AI for creative tasks (creating a text or image), research, and occasional problem solving, but not yet daily. They appreciate AI as an enhancer, not a creator.

"*It's useful when I need to create texts, because I don't express myself well with words" (Entrepreneur 1)*

"I use it like a search engine sometimes… it pulls info from across the web". (Entrepreneur 2)

Entrepreneurs recognise AI's potential but see limits for their area of business. The perceived usefulness is task-specific (text creation), but industry-specific scepticism, *"no utility for ceramics", "it's a bit complicated because maybe in Italy it's a niche"*. Entrepreneurs' view aligns with findings that perceived usefulness predicts adoption only when users see relevance to their context.

Some respondents perceive AI as cognitively demanding, preferring manual and intuitive processes. This indicates a low perceived ease of use, a strong predictor of non-adoption.

"I don't feel… I don't know, I… Anyway, I always tend to modify what it gives me. I don't know. Actually, I only use it out of necessity. If I can't write a text, I ask artificial intelligence to help me with that, but otherwise, no". (Entrepreneur 1)

Analysis based on the five competences outlined in the Digital Competence Framework (Carretero, 2017) revealed fragmented digital competences among respondents. Entrepreneurs demonstrated familiarity with AI for Digital Content Creation, but their use was limited mainly to generating marketing materials or promotional content rather than, for example, coding. Safety competence was also evident: participants consistently expressed a cautious attitude towards sharing data with AI tools, ensuring that only non-sensitive, non-personal information was processed. In the area of problem-solving, entrepreneurs acknowledged using AI for support. However, humans always make final decisions, reflecting a lack of trust in AI as an autonomous decision-making tool. In contrast, the interviews did not substantially reflect competencies related to information and data literacy, communication, and collaboration.

Regarding learning pathways, the study found that entrepreneurs primarily engage in peer learning, self-training, and low-cost online courses to develop their digital competencies. Learning processes are predominantly informal and socially situated.

"Word of mouth and social media…" (Entrepreneur 1)

"I took it online on Learn… there was a course specifically about how to talk to AI". (Entrepreneur 2)

Importantly, participants expressed a strong preference for peer-based, short, and easily accessible learning experiences, emphasising the need for practical, concise, and community-driven approaches to digital competences development.

"I prefer short and free courses". (Entrepreneur 1)

5 Discussion, conclusion and limitations

The first findings of our research show that AI adoption among craft entrepreneurs in Southern Italy is still at an early, emerging stage. While entrepreneurs are beginning to explore AI tools, widespread use remains limited. Their current engagement places them at the initial phase of Rogers' (2003) innovation diffusion curve, characterised by early exploration rather than broad acceptance.

This hesitation seems to stem from uncertainty about AI's relevance and immediate benefits for their specific business activities. This cautious behaviour aligns with Davis' (1989) Technology Acceptance Model, which emphasises that perceived usefulness is a critical factor in technology adoption. However, the interviewed entrepreneurs are only likely to adopt AI when they clearly recognise its practical application within their business context.

Learning practices among these entrepreneurs are predominantly informal. They rely heavily on peer learning, self-directed training, and affordable online courses (Lave & Wenger, 1991; Eraut, 2004). This preference for flexible, socially rooted, and low-cost learning methods suggests that formal training initiatives must be adapted to fit their actual learning habits if they aim to encourage broader AI adoption.

The analysis of digital competencies (Carretero, 2017) among these entrepreneurs revealed fragmented and limited engagement with AI, mainly focused on basic content creation tasks. Competencies in areas such as Information and Data Literacy, Communication and Collaboration, and advanced Problem-Solving using AI tools were either underdeveloped or largely absent. Notably, Safety competence emerged as a relatively stronger area, with entrepreneurs demonstrating a cautious approach to data sharing.

These findings suggest that future training programs should aim to expand technical competencies and build entrepreneurs' confidence in using AI across a broader range of business functions. Educational initiatives should prioritise improving perceived ease of use and demonstrating the practical relevance of AI to everyday entrepreneurial activities. Tailored, hands-on programs that integrate real-world business scenarios could help close competence gaps, foster greater trust in digital tools, and support a more holistic digital transformation among craft entrepreneurs.

This research is at an embryonic stage, and although interesting emerging insights are arising from the interviews, the work presents some limitations. First, there are some generalisability issues. Since this is a qualitative study, the findings may not be broadly generalisable to all entrepreneurs, and this limitation is even more severe if we consider that we reached a minimum part of the sample. Results are not generalisable, especially for entrepreneurs outside the targeted business sectors or regions. Secondly, due to time and resource constraints, we have targeted a small sample, limiting the diversity of perspectives. Completing the interviews and enlarging the sample is necessary to improve the research quality and the robustness of the analysis.

6 Ethics declaration

The ethical clearance was not required for our research.

7 AI declaration

For this research, we applied Sonix for the transcription of the interviews and ChatGPT for the translation. Both AI services are also introduced in the methodological section.

Abstract

The intersection of sustainability, inclusion, and entrepreneurship is increasingly recognised as a strategic priority for contemporary businesses and societies. Among underserved groups, people with disabilities (PwDs) present both a significant entrepreneurial potential and unique barriers to business creation and operation. While self-employment offers a promising pathway towards economic inclusion for PwDs, research into the specific mechanisms enabling this form of disadvantage entrepreneurship remains fragmented and under-theorised (Klangboonkrong and Baines, 2022; Bhardwaj et al., 2023). This paper critically reviews the business and management literature to examine how emerging digital technologies can act as affordances facilitating entrepreneurial activity among PwDs.

Drawing upon affordance theory (Gibson, 1979; Leonardi, 2011), this study employs a qualitative, problematising literature review methodology (Alvesson and Sandberg, 2011, 2020), sourcing peer-reviewed articles across entrepreneurship, business, management, and disability studies. A theoretical framework is developed by synthesising the findings, identifying four key technological affordances: communication and interaction, business creation and operation, learning and capability development, and community and identity formation.

The analysis demonstrates that digital technologies are not neutral enablers but dynamic socio-material actors whose affordances depend on user capability and institutional context. It reveals how digital solutions can meaningfully reduce systemic barriers, enhance market access, and foster entrepreneurial identity among PwDs. This study contributes to extending the understanding of inclusive entrepreneurship within a digital economy, proposing that inclusive technology strategies must be embedded in policy and education, digital platform design, and business support services.

The paper advocates for future empirical research to validate and refine the proposed framework across diverse PwD populations and socio-economic contexts. It emphasises the need to account for intersectional factors and to evaluate the long-term sustainability of technology-enabled ventures. Ultimately, enabling entrepreneurs with disabilities through technology is not merely an ethical imperative but a strategic investment in unlocking innovation, diversity, and sustainable growth.

Keywords: Entrepreneurship, Disability, Technologies, Affordance theory.

Paper type: Academic Research Paper

1 Introduction

The intersection of sustainability, inclusion, and entrepreneurship has garnered growing scholarly and practical interest in recent years. Accessibility and inclusion, once regarded primarily as ethical imperatives, are now recognised as strategic assets for businesses and society. New technologies are pivotal in advancing these objectives, offering innovative solutions that enable firms and entrepreneurs to navigate growing complexities (Millar et al., 2008). In this context, people with disabilities (PwDs) emerge as a critical focus, representing not only an underserved customer segment to whom tailored products and services (Baker et al., 2007; Tuli et al., 2023), and marketing communication can be directed (Kearney et al., 2019) but also as valuable contributors to organisational activities. This is particularly evident in PwDs' roles as employees (Jammaers et al., 2016), especially in social entrepreneurship initiatives (Kalargyrou et al., 2020).

Therefore, one of the most compelling challenges is the inclusion of PwDs in the labour market (Jammaers et al., 2016; Renko et al., 2016; Klangboonkrong and Baines, 2022). While work is acknowledged as a fundamental right, defined as "*the opportunity to gain a living by work freely chosen or accepted in a labour market and work environment*" (UN, 2008, p. 19), statistics from the OECD (2022) show that nearly 40% of PwDs in the EU are excluded from active labour force participation. This exclusion is a social and economic issue and a missed opportunity to harness a rich vein of entrepreneurial potential.

In response to structural barriers in traditional employment pathways, many PwDs turn to self-employment or entrepreneurship, which the literature refers to as *entrepreneurs with disabilities* (EwDs) or *disadvantaged entrepreneurs* (Pagán, 2009; Maalaoui et al., 2020; Martinez Dy, 2020). However, despite increasing attention, research in this domain remains fragmented and under-theorised (Klangboonkrong and Baines, 2022; Bhardwaj et al., 2023), particularly concerning how digital and emerging technologies can alleviate barriers and unlock new opportunities for this cluster.

This paper aims to address this gap by applying technology affordance theory (Gibson, 1979; Leonardi, 2011) to study disadvantage entrepreneurship. Originating from psychology and defined as "*something that refers to both the environment and the animal* […] (and) *implies the complementarity*" (Gibson, 1979, p. 119), affordance is useful to explain intricate relationships between humans and technologies (Leonardi, 2011; Majchrzak and Markus; 2012) and even more the entrepreneurial agency as social processes enabled by digital technologies (Nambisan, 2017).

So, our research question is how digital technologies can serve as affordances for entrepreneurial activity among PwDs? Through a critical review of the business and management literature, we develop a theoretical framework explaining how new technologies can serve as affordances for entrepreneurial activity among PwDs. By doing so, the paper contributes to a more inclusive and sustainable view of entrepreneurship, where digital transformation is leveraged to reduce disadvantage (Klangboonkrong and Baines, 2022; Bhardwaj et al., 2023).

2 Literature review

2.1 Disadvantage entrepreneurship and PwDs

The concept of disadvantage entrepreneurship refers to entrepreneurial activity initiated by individuals facing systemic or structural barriers, including but not limited to race, gender, socio-economic status, and disability (Maalaoui et al., 2020). PwDs have emerged as a distinct category of disadvantaged entrepreneurs within this framework. As noted by Klangboonkrong and Baines (2022), few studies have analysed the self-employment issues for PwDs, also called entrepreneurs with impairments or EwDs (Pagán, 2009; Hsieh et al., 2019; Renko et al., 2016; Parker Harris et al., 2014).

Nevertheless, the existing body of research has been criticised for lacking theoretical depth and limited geographical scope (Hwang and Roulstone, 2015; Caldwell et al., 2016; Maritz and Laferriere, 2016). However, the debate on disadvantage entrepreneurship has grown in recent years, particularly regarding EwDs (Maalaoui et al., 2020; Santoro et al., 2020; Kašperová, 2021). Scholars have explored various facets of this phenomenon: from gendered experiences (Williams & Patterson, 2019), identity formation (Jammaers and Zanoni, 2020), and psychological outcomes (De Clercq and Honig, 2011; Martinez Dy, 2020). The latter have been analysed looking at the self-image value of 'doing' through self-employment (Martin and Honig, 2020) and the lived experience of EwDs through the critical theory of freedom, emphasising improvements in self-efficacy and self-esteem (Martinez Dy, 2020; Hidegh et al., 2022). More recently, Bhardwaj et al. (2023) highlighted the lack of management literature addressing disadvantaged entrepreneurs, particularly on "*'invisible disabled entrepreneurs' as an umbrella term referring to underdog entrepreneurs who are faced with disability that does not have any physical manifestation and interferes with day-to-day functioning*" (p. 2). Further, Norstedt and Germundsson (2023) have underscored how the motives for starting a new venture by PwDs are a topic that can be further analysed.

2.2 Technology and entrepreneurial inclusion

Technological innovation, particularly digital technologies, has been a powerful force in reshaping business models, operational structures, and value creation processes (Nambisan, 2017; Troise et al., 2022a). Digital transformation enables overcoming the volatility, uncertainty, complexity and ambiguity (VUCA) of contemporary competitive environments (Bennett and Lemoine, 2014; Troise et al., 2022b). For entrepreneurs, especially those operating at the margins of traditional markets, the opportunities offered by technology are amplified as they can be considered both new tools and new terrains for action.

In the context of digital technologies, the "*affordance (or a constraint) is defined as an action potential*" (Nambisan, 2017, p. 1046), and these inherent potentialities are even more relevant for PwDs. Originating in ecological psychology (Gibson, 1979), affordance theory was introduced into organisational and information systems research to explain how users perceive and act upon the action possibilities offered by technological artefacts. Leonardi (2011) and Majchrzak and Markus (2012) refined this concept to include not only perceived affordances but also actualised outcomes depending on the user's context and capabilities.

In the entrepreneurial domain, Nambisan (2017) defines affordance as an "action potential" that arises from the interaction between an entrepreneur and a technological artefact. For PwDs, these affordances may include remote communication, asynchronous collaboration, digital prototyping, and even marketplace access through e-commerce platforms. All these actions may be constrained in a traditional business context due to physical or social barriers.

Emerging research has begun to explore how AI-driven applications, such as image and speech recognition algorithms, voice-to-text software, automated transcription, screen readers, and intelligent assistants, can facilitate entrepreneurial activities for PwDs, enhancing labour market accessibility and fostering employment (Touzet, 2023). However, most existing studies focus on technology as an enabler for employees with disabilities, rather than as a catalyst for self-employment or venture creation. Consequently, the well-documented tendency of PwDs to pursue self-employment could benefit significantly from such technological advancements.

3 Methodology

This study employs a qualitative research design based on a critical literature review on disadvantage entrepreneurship, leveraging the lens of technology affordance theory (Gibson, 1979; Leonardi, 2011; Majchrzak and Markus, 2012) to highlight the opportunities technologies offer to PwDs in starting and sustaining ventures.

Following the suggestions on problematising review by Alvesson and Sandberg (2011; 2020), instead of aggregating extant findings, we seek to challenge implicit assumptions and identify conceptual gaps regarding disadvantage entrepreneurship and technology. We critically selected 21 peer-reviewed articles from top-tier journals in business, management, entrepreneurship, and disability studies. Our data sources include journals such as *Entrepreneurship & Regional Development, European Management Review*, *Disability & Society, International Journal of Entrepreneurial Behavior & Research, International Small Business Journal, Journal of Business Ethics, Journal of Business Research*. The literature was selected based on relevance to three intersecting themes: entrepreneurship by PwDs, digital technologies in entrepreneurship, and theoretical frameworks addressing socio-technical systems or affordances. The exclusion criteria applied concerned both topics and publication types: we excluded articles focusing on disadvantage entrepreneurship in relation to gender or ethnic minorities, as well as papers published in less relevant journals or outlets primarily addressing disability from a medical or rehabilitation perspective.

The review was coded inductively to identify recurring concepts and themes. The articles were categorised according to emergent themes related to entrepreneurial barriers, motivations, technological affordances, and enabling conditions, and were then clustered to build a theoretical framework. This framework explains how new technologies afford entrepreneurial action for PwDs and the conditions under which these affordances can be actualised.

4 Proposed theoretical framework

The critical analysis and synthesis of the selected papers have allowed us to identify two main domains influencing entrepreneurship by PwDs: critical enabling conditions and affordances (or action potentials).

Starting from the critical enabling conditions, the analysed articles mentioned different prerequisites for entrepreneurial effectiveness through digital technologies. We have categorised these in three conditions, opening from the importance of reliable digital tools (e.g., smart devices) and internet connectivity (Access to infrastructure) to the skills to navigate, adapt, and exploit technologies (Digital literacy and training), and finally the regulatory environments and social systems actively promoting inclusion and reducing systemic barriers (Institutional support and inclusive policy frameworks).

The technological solutions promoting entrepreneurship for PwDs have been categorised into four main affordances or action potentials. The first is the opportunity technologies offer for more accessible and effective communication and network circumstances (communication and interaction). Technologies such as speech recognition, real-time translation, and visual description tools afford new ways for entrepreneurs to communicate with clients, suppliers, and partners. For PwDs with hearing, visual, or speech impairments, these tools reduce dependence on intermediaries and open new market interactions. The second affordance is reducing entry barriers by digital platforms (e.g., Shopify, Etsy, Fiverr) that provide low-cost, scalable business models. Automation tools, like customer management systems or invoicing software, can manage operations efficiently without requiring extensive physical infrastructure or manual oversight (business creation and operation). Another change is that online education platforms and AI-driven tutoring tools afford continuous skill development, a key necessity for disadvantaged entrepreneurs seeking to overcome institutional and educational disparities (learning and capability development). Finally, among digital technologies, social media platforms and peer networks afford the creation of supportive communities, reducing isolation and enabling

knowledge exchange. These technologies can also play a critical role in identity construction and validation (Jammaers and Zanoni, 2020), constituting the fourth and last proposed category of affordance (community and identity formation).

Putting together the identified and presented elements, the proposed framework (Figure 1) articulates how digital technologies afford entrepreneurial agency for people with disabilities (PwDs), culminating in creating and sustaining new business ventures. This process is mediated by activating specific affordances across four primary domains and is contingent upon three critical enabling conditions.

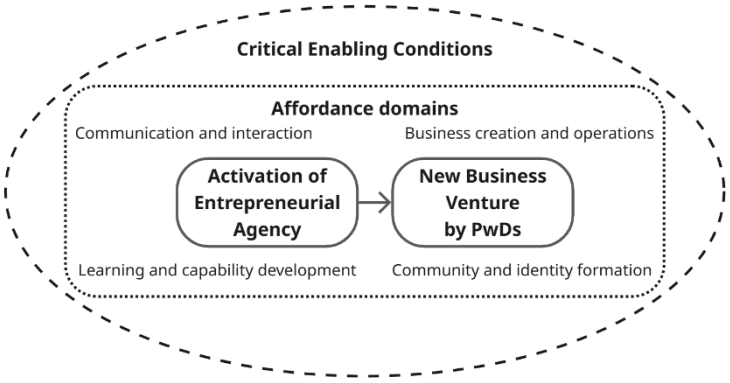

Figure 1: The proposed theoretical framework (Source: author's own elaboration)

While previous applications of technology affordance theory have primarily explored its relevance in organisational behaviour, knowledge management, and IT system design (Leonardi, 2011; Majchrzak and Markus, 2012), these models often assume an implicit universality of access and agency. Our framework diverges by explicitly embedding the social, institutional, and bodily constraints experienced by PwDs. By contextualising affordances within the specific barriers and capacities of disadvantage entrepreneurship, this study contributes a more inclusive and situated extension of affordance theory. Moreover, compared to Nambisan's (2017) digital entrepreneurship perspective, which emphasises opportunity creation through technology, our framework emphasises the conditional actualisation of these opportunities, depending on infrastructure, skills, and support ecosystems.

5 Implications

This paper contributes to the literature by integrating technology affordance theory into the study of disadvantage entrepreneurship. It further highlights that affordances are not universal but conditional and relational as they are shaped by the interplay between user capability, technology design, and institutional context. Moreover, our framework broadens the traditional view of entrepreneurial resources by emphasising the socio-materiality perspective of technologies as dynamic, non-human actors capable of reshaping access, opportunity, and performance.

Additionally, from a more practical standpoint, this framework demonstrates how technology developers, platform providers, and policymakers have a significant influence in empowering PwDs through the design of inclusive business support services, the adoption of universal design principles and disability perspectives in product development cycles, and finally the efforts in bridging the digital divide through targeted infrastructure investment and training schemes. As a practical illustration, an aspiring entrepreneur with visual impairment may utilise voice-activated design software and AI-based product descriptions to manage an e-commerce business on platforms like Etsy. Likewise, an entrepreneur with mobility constraints can participate in virtual incubators or pitch competitions using asynchronous video submissions. These cases show how the proposed affordances can be mapped onto real, functioning business models when enabling conditions are met.

6 Conclusions and future research

This paper advances our understanding of how digital technologies can serve as affordances for entrepreneurs with disabilities, turning exclusion into empowerment. It positions technology not merely as a tool but as a co-actor in the entrepreneurial journey of PwDs. The proposed theoretical framework advances the previous contributions on technology affordance theory (Leonardi, 2011; Majchrzak and Markus, 2012) with a specific focus on digital technologies (Nambisan et al., 2017) and their relationships with PwDs in their action potential in the entrepreneurship context.

As with all conceptual research, this study has several limitations. First, the framework is based on a qualitative critical review of the literature, and its proposed domains have not yet been empirically tested. Second, while the framework aspires to generalisability across various types of disabilities, it may not fully capture the lived experiences of entrepreneurs with intersecting impairments. Third, cultural and regulatory variations across regions are only partially addressed in this review, suggesting that future research should explore localisation and policy adaptation in more detail.

For all these reasons, future research should validate and expand the proposed framework through empirical studies, including case studies and interviews with EwDs across different geographies and types of impairment. Particular attention should be paid to the role of intersectionality (e.g., gender, age, socio-economic status) and the long-term sustainability of technology-enabled ventures. Moreover, future studies could analyse the potential impacts of this framework on several types of stakeholders, besides PwDs.

As technology continues to reshape the business landscape, inclusive entrepreneurship must become a core component of digital strategy and sustainable development. Enabling PwDs to thrive as entrepreneurs is not only a moral imperative but also a wise investment in human potential.

7 Ethics declaration

The authors declare that no ethical approval was required for this conceptual study based on secondary data. No human participants were involved, and there are no conflicts of interest to disclose.

Institutional Perspectives on Entrepreneurial Education Ecosystems: Fostering Digital Student Startups

Carmine Passavanti[1], Tatiana Lopez[2], Pierluigi Rippa[1], David Urbano[2]
[1]University of Naples Federico II, Naples, Italy
[2]Universitat Autònoma de Barcelona, Barcelona, Spain

Abstract

The increasing integration of digital technologies (DT)—such as artificial intelligence, big data, and extended reality—is transforming the domain of academic entrepreneurship. Despite the growing interest in digital academic entrepreneurship, extant literature rarely distinguishes the unique institutional challenges faced by student entrepreneurs, whose ventures are typically less resource-intensive, more agile, and deeply embedded in digitally mediated learning environments. Moreover, while studies acknowledge the transformative potential of DT, few have examined their dual interaction with formal and informal university mechanisms, especially from a comparative perspective across institutional ecosystems. Finally, existing frameworks often overlook how students appropriate digital tools and platforms to navigate institutional constraints, thus underestimating student agency in shaping entrepreneurial outcomes in the digital age. This study addresses that gap by investigating how formal and informal university-based mechanisms influence the entrepreneurial motivations and capabilities of student founders in digitally evolving environments.

Grounded in the conceptual frameworks of Rippa and Secundo (2019) and Guerrero and Urbano (2012), the study adopts a qualitative, comparative case-study approach. Six student-led digital startups were analysed across two entrepreneurial universities—University of Naples Federico II (Italy) and Universitat Autònoma de Barcelona (Spain)—using in-depth interviews and documentary analysis. Findings reveal that while formal structures such as entrepreneurship education and technology transfer systems are widely available, they often lack practical alignment with the needs of digital ventures. Informal factors—like cultural perceptions of entrepreneurship, experiential learning practices, and exposure to role models—also play a crucial role, yet their effectiveness varies across institutional contexts.

The study advances two key propositions: first, that universities providing access to advanced digital skills and specialised technical resources are more likely to foster the successful development of digital startups; and second, that institutions facilitating access to online educational resources and entrepreneurial networks significantly enhance the success potential of student-led ventures. These findings demonstrate how DT reshape the interplay between institutional structures and entrepreneurial behaviour, offering theoretical contributions to digital academic entrepreneurship and practical insights for higher education institutions aiming to cultivate inclusive and future-ready innovation ecosystems.

Keywords: Digital Academic Entrepreneurship; Student Entrepreneurship; Entrepreneurial Universities; Institutional Theory; Comparative Case Study

Paper type: Academic Research Paper

1 Introduction

In today's era of pervasive digitalisation, emergent technologies—most notably artificial intelligence, big-data analytics and augmented-reality systems—are recasting industrial value creation logics across virtually all sectors (Lamine et al., 2023). Higher-education institutions are not immune to this transformation; indeed, digital technologies (DT) are penetrating teaching, research and third-mission activities, thereby reconfiguring the landscape of academic entrepreneurship (Rippa & Secundo, 2019). Traditionally, academic entrepreneurship centred on the commercial exploitation of laboratory discoveries through patent licensing or faculty-led spin-offs; yet the diffusion of DT now enables novel entrepreneurial forms that are frequently initiated and managed by students, such as platform-based services, data-driven applications and fully virtual ventures (Lamine et al., 2023; Rippa & Secundo, 2019).

Institutional theory offers a useful lens for unpacking this evolution because the rules, norms and routines embedded in universities condition the behaviours of nascent entrepreneurs (Klofsten et al., 2019). Formal institutional factors encompass codified structures—entrepreneurship curricula, incubators, technology-transfer offices and governance mechanisms—that directly allocate resources and legitimise venturing activities (Guerrero & Urbano, 2012). Informal factors, by contrast, comprise cultural attitudes, pedagogical practices and the availability of credible entrepreneurial role models, all of which shape students' perceptions of feasibility and desirability (Guerrero & Urbano, 2012). Although scholarship has mapped the broad contours of digital academic entrepreneurship (Secundo et al., 2020), empirical clarity is still lacking regarding how DT interact with these formal and informal levers to influence Student Entrepreneurship (SE)—defined here as venture creation

by individuals who simultaneously pursue university studies and operate a business (Primario et al., 2022; Passavanti et al., 2023). Existing investigations seldom disentangle the specific mechanisms through which DT affect motivational drivers, capability development and opportunity enactment among students (Lamine et al., 2021).

Against this backdrop, our study mobilises the frameworks of Rippa and Secundo (2019) and Guerrero and Urbano (2012) to examine how institutional factors at two entrepreneurial universities—the University of Naples Federico II (Italy) and the Universitat Autònoma de Barcelona (Spain)—shape students' abilities and intentions to launch digital ventures. After reviewing the theoretical foundations, we outline a comparative case-study methodology that integrates documentary analysis with in-depth interviews. The findings section explores how DT reconfigure formal supports and informal cultures, while the conclusion discusses theoretical contributions, managerial implications and avenues for future research in digital-age SE.

2 Theoretical Background

2.1 Student entrepreneurship in the digital age

Student Entrepreneurship (SE)—the launch of new ventures by enrolled students or recent graduates—has moved to the forefront of entrepreneurship research because of its demonstrable societal impact, its role in commercialising academic knowledge and its promise for theoretical advance (Colombo & Piva, 2020; Clarysse et al., 2022; Breznitz & Zhang, 2019; Hayter et al., 2017). Digital technologies (DT)—from social media and big-data analytics to AI, 3-D printing and XR—have permeated entrepreneurial practice, prompting a reconceptualisation of academic entrepreneurship as a technology-enabled, platform-mediated phenomenon (Rippa & Secundo, 2019; Nambisan, 2017). Recent scholarship therefore investigates how universities adapt curricula and support structures to meet digitally driven market needs (Garcez et al., 2022; Secundo et al., 2020; Toniolo et al., 2020). Yet the specific influence of DT on SE motivation and capability development remains under-explored (Lamine et al., 2021), despite high-profile student founders such as Zuckerberg, Page, Brin, Dell and Yang fuelling popular interest (Sansone et al., 2021).

SE has already enriched entrepreneurship theory by clarifying the individual–opportunity nexus (Larsson et al., 2017), illuminating the cognitive conversion of intentions into venture actions (Rippa et al., 2020) and mapping how ventures emerge in local ecosystems (Busch & Barkema, 2022; Bock et al., 2021). Nonetheless, granular knowledge of students' activities, contexts and characteristics is still incipient (Clarysse et al., 2022; Passavanti et al., 2023). Scholars call for clearer definitions, noting two prevailing views: students preparing growth-oriented business plans (Katz et al., 2000) versus students simultaneously studying and operating companies (Ridder & Van der Sijde, 2006), sometimes extending to very recent alumni (Wright & Mustar, 2019). Multiple antecedents shape SE—including university ecosystem quality (Busch & Barkema, 2022), social context (Wright & Clarysse, 2020), socio-demographics (Fini et al., 2016) and role models (Abbasianchavari & Moritz, 2022). Institutional-theory research further shows that student founders favour effectuation and bootstrapping relative to non-student entrepreneurs (Politis et al., 2012; Clarysse et al., 2022) and pursue goals distinct from staff spin-offs (Hayter et al., 2017). Because DT are reshaping social norms and motivations, their impact on SE warrants systematic investigation (García-Morales et al., 2020).

2.2 Digital academic entrepreneurship

Rippa and Secundo (2019) argue that the convergence of entrepreneurial-university logic with DT constitutes a paradigm shift. Follow-up studies highlight digital spinoffs, virtual incubators and other adaptive strategies that extend universities' economic reach (Garcez et al., 2022; Secundo et al., 2020; Toniolo et al., 2020; Linzalone et al., 2020). Creating digital products on campus can materially boost regional growth (Ivanović-Đukić et al., 2019). The Rippa–Secundo framework positions DT as core—not peripheral—elements of venture processes, enabling broad stakeholder collaboration, fluid knowledge exchange and online funding access (Bejjani et al., 2023; Kraus et al., 2022; Chan et al., 2022), thereby aligning university activities with global digital-economy demands (Rådberg & Löfsten, 2023).

2.3 Institutional economics and the entrepreneurial university

Institutional Theory distinguishes formal rules—property rights, procedures—and informal norms—values, beliefs—that guide entrepreneurial action across ideation, start-up and growth phases (North, 1990; Davis & Williamson, 2016; Reynolds & White, 1997; Stenholm et al., 2015). Universities have responded by embedding entrepreneurship education, support infrastructure and pro-venture cultures (Guerrero et al., 2020; Secundo et

al., 2021). Contemporary entrepreneurial universities thus integrate competitive strategy with knowledge-transfer missions (Klofsten et al., 2019), complemented by administrative and governance reforms (Redford & Fayolle, 2014). Guerrero and Urbano (2012) synthesise these dynamics into a framework linking formal structures (governance, support, education) and informal levers (attitudes, pedagogy, role-model visibility) to university entrepreneurial capacity, underscoring their role in regional development (Youtie & Shapira, 2008).

By overlaying the digital-entrepreneurship insights of Rippa and Secundo (2019) onto Guerrero and Urbano's institutional matrix, researchers can analyse how DT reconfigure both formal and informal factors, thereby shaping student entrepreneurial motivations and outcomes (Garcez et al., 2022; Secundo et al., 2021). The present study adopts this integrated perspective to assess how two universities leverage DT to orchestrate their entrepreneurial ecosystems and foster student-led digital startups.

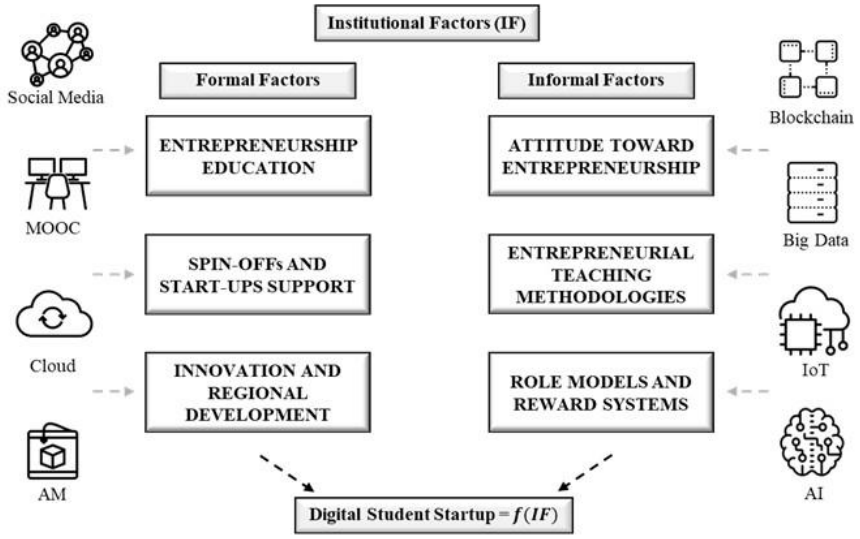

Figure 1: Formal and Informal Institutional Dimensions Shaping Student-Led Digital Start-ups in Entrepreneurial Universities

3 Methodology

To explore the complex and context-dependent dynamics of how digital technologies (DT) influence student-led entrepreneurship within universities, this study employs a qualitative research design. This approach is particularly suitable for investigating processes that unfold in real-life contexts and require attention to depth, meaning and interpretation (Good et al., 2020; Gartner et al., 2002). Because the central aim is to compare institutional factors across university ecosystems, a comparative multiple-case study method was adopted. This strategy offers both rich contextual insights and theoretical generalisability through replication logic (Guerrero et al., 2012; Yin, 2013). Case-study research is especially appropriate when addressing "how" and "why" questions related to contemporary phenomena (Secundo et al., 2020).

Following a literal-replication strategy, cases were selected based on theoretical criteria that enhance learning about digital academic entrepreneurship (Yin, 2013). The two focal universities—University of Naples Federico II (Italy) and Universitat Autònoma de Barcelona (Spain)—have strong regional engagement but differ in institutional maturity and ecosystem characteristics (Guerrero et al., 2012). Both institutions explicitly promote entrepreneurial initiatives and are situated in regions with high startup activity, meeting commonly accepted case-selection benchmarks in SE research. Within each university, three student-led digital startups were purposefully chosen, resulting in six rich cases—labelled ITA and ES respectively—for cross-case comparison and analytical depth (Eisenhardt, 1989).

This comparative logic is further supported by the distinctive characteristics of the two university ecosystems selected, which provide meaningful variation in institutional settings relevant to student-led digital entrepreneurship. Federico II is the oldest public university globally, with over 4,000 researchers across STEM and management disciplines. It has launched more than 90 spin-offs in the past decade and actively incorporates DT into its entrepreneurial strategies. Its strategic orientation toward third-mission activities and its ties with more than ten local industrial districts make it an ideal case for studying university-driven innovation dynamics. UAB, located in Catalonia—Spain's leading entrepreneurial region—benefits from a diverse economic base and institutional infrastructure that supports tech-based startups, positioning it as an agile and innovation-driven institution. The regional context is marked by a high concentration of new enterprises and a GDP per capita

significantly above the national average, which further enhances UAB's capacity to serve as an anchor institution in a dynamic entrepreneurial ecosystem.

Fieldwork occurred over four months between 2023 and 2024. Eight semi-structured interviews were conducted; one was used as a pilot and one was excluded for limited relevance, leaving six interviews (≈ 11 hours; > 90 pages of transcripts). Interviews were structured in three sections: general startup information, organisational features, and institutional influences—based on Guerrero and Urbano's (2012) framework. Complementary data sources included policy documents, startup websites, university brochures and press materials, in line with prior studies (Good et al., 2020; Guerrero et al., 2014; Secundo et al., 2020). This triangulation enhances construct validity and provides a multi-perspective view (Yin, 2013).

To analyse the data, we applied content analysis across three iterative phases: open coding (to identify recurring concepts), axial coding (to group related codes), and selective coding (to extract theoretical categories). ChatGPT-4 was used to assist in consistent labelling and to identify emergent themes, an increasingly recognised practice in qualitative entrepreneurship research (Forsström-Tuominen et al., 2019). Cross-case matrices were developed to identify patterns and inform propositions about how DT shape institutional enablers and constraints for student ventures (Eisenhardt & Graebner, 2007).

Finally, to ensure the trustworthiness of our findings, coding decisions were peer-reviewed, and a clear audit trail linking raw data to interpretations was maintained. The use of theoretical replication across distinct university contexts strengthens the external validity of the results while retaining the depth and interpretive richness characteristic of qualitative research (Yin, 2013; Rasmussen et al., 2014).To ensure trustworthiness, coding decisions were peer-reviewed and a clear audit trail linking raw data to findings was maintained. The use of theoretical replication across distinct university contexts strengthens the external validity of the results while retaining the depth and interpretive richness characteristic of qualitative research (Yin, 2013; Rasmussen et al., 2014).

4 Findings and Discussion

This study investigates how formal and informal institutional factors influence the emergence of student-led digital startups, comparing two university ecosystems—Naples and Barcelona. The results reveal differentiated impacts of digital technologies (DT) on both types of institutional elements, offering insight into how universities can foster digitally-enabled academic entrepreneurship.

4.1 Formal Institutional Factors

The role of formal institutional mechanisms—entrepreneurship education, technology transfer structures, and regional innovation policies—emerged as pivotal yet inconsistently effective across the cases. Entrepreneurship education was generally acknowledged as foundational, yet its execution often lacked practical relevance. Students reported that courses were overly theoretical, lacking hands-on components essential for digital venture development (Secundo et al., 2021). As one Italian founder noted, despite learning useful project management principles, practical application was minimal.

The increasing adoption of DT in educational programming has enhanced accessibility and interactivity, using digital platforms, simulations, and online content to prepare students for real-world challenges (Primario et al., 2022; Secundo et al., 2021). Nonetheless, several respondents—particularly from Spain—emphasised the insufficient integration of advanced digital competencies into entrepreneurship curricula. This echoes Wright et al. (2017), who argue for the urgent adaptation of academic programs to meet the specific demands of technology-intensive entrepreneurship.

Another critical gap identified was in the area of technology transfer. Across both countries, students described university support for patenting and intellectual property as slow, bureaucratic, and ill-suited to the needs of agile digital startups. Entrepreneurs had to resort to external legal support to navigate the patenting process—underscoring findings by Guerrero et al. (2020), who advocate for more responsive and tailored tech-transfer mechanisms within universities.

Nonetheless, regional institutions often compensated for university-level deficits. In Spain, entities such as Barcelona Activa and Acció were praised for offering streamlined legal support, financial resources, and strategic mentoring, facilitating startup formation and early-stage growth. Similar support was found in the Campania region, albeit to a lesser extent. These findings align with Bergmann et al. (2016), who highlight the importance of regional actors in bridging knowledge gaps for nascent entrepreneurs.

Formal university structures have also evolved through DT. Administrative digitisation—through tools for resource management, virtual incubators, and online mentoring—allowed more responsive and student-centric

innovation support systems. However, this transformation remains uneven across institutions, often constrained by legacy governance models or limited digital readiness.

A key insight concerns the strategic value of providing access to high-level technical infrastructure. In several cases, access to anonymised datasets and proprietary university resources enabled critical stages of product validation. This leads to the first proposition:

Proposition 1: Universities that provide access to advanced digital skills and specialised technical resources are more likely to foster the successful development of digital startups.

4.2 Informal Institutional Factors

Informal institutional factors—such as entrepreneurial attitudes, pedagogical practices, social norms, and the presence of role models—proved equally influential in shaping students' entrepreneurial trajectories. A recurrent critique was the persistence of traditional, lecture-based teaching formats. Students expressed a preference for experiential approaches involving simulations, case studies, and collaborative learning environments—methods that foster entrepreneurial competencies and digital literacy (García-Morales et al., 2020; Primario et al., 2022).

University cultures were often perceived as risk-averse or sceptical towards student entrepreneurship. Particularly in Naples, some founders reported that their peers and academic staff did not take entrepreneurial initiatives seriously, reinforcing a conservative career outlook prioritising job security. This mirrors broader socio-cultural dynamics identified in SE literature, where institutional conservatism can deter entrepreneurial action (Passavanti et al., 2023).

Encouragingly, digitalisation is beginning to shift these cultural logics. Universities increasingly celebrate entrepreneurial achievements, especially those leveraging digital innovation, thus enhancing legitimacy and motivation for prospective student entrepreneurs (Chan et al., 2022). However, the presence of effective entrepreneurial role models remains uneven.

Many students—especially in Italy—noted that their universities did not expose them to successful digital entrepreneurs during their studies. This lack of visible role models within the academic environment is widely cited as a barrier to entrepreneurial self-efficacy (Bergmann et al., 2016; Passavanti et al., 2024). To overcome this void, students often turn to digital sources, drawing inspiration from podcasts, YouTubers, and online mentorship platforms.

This evolution of mentorship practices—away from traditional in-person figures towards globally accessible digital influencers—underscores the growing significance of digital platforms in shaping entrepreneurial identity and aspiration (Secundo et al., 2021). For example, students cited Massive Open Online Courses (MOOCs) and entrepreneurial content creators as instrumental to their learning journeys. This finding is particularly pronounced in the Italian context, where informal digital mentorship often substitutes for institutional support (Primario et al., 2022).

A related theme is the value of digital networking. Founders emphasised that beyond institutional structures, connections forged via online communities and peer-to-peer platforms played a vital role in their startups' early development. As one Spanish founder stated, these networks were crucial for navigating bureaucratic challenges and accessing market insights.

Based on these insights, the second proposition is offered:

Proposition 2: Universities that facilitate access to online educational resources and foster networking opportunities with experienced entrepreneurs significantly enhance the success potential of student-led digital startups.

A comparative view reveals distinct strengths and weaknesses across the two ecosystems. In Naples, while regional support is active, university-based formal structures—especially technology transfer and practical education—remain underdeveloped. In contrast, Barcelona's institutions exhibit a more integrated ecosystem, with stronger alignment between formal and informal supports and better incorporation of digital tools.

Digital startups appear to benefit disproportionately from these institutional configurations compared to non-digital ventures. Enhanced scalability, data-driven product models, and online visibility mean they are more sensitive to the quality of digital and entrepreneurial infrastructure. Table 15, which synthesises these differences, confirms that digital ventures receive greater support when universities embrace digital transformation across teaching, mentoring, and administrative processes.

5 Conclusions

This study has examined how digital technologies (DT) reshape institutional conditions within universities and, in turn, influence student entrepreneurship (SE). By integrating the frameworks of Rippa and Secundo (2019) on digital academic entrepreneurship and Guerrero and Urbano (2012) on entrepreneurial universities, the research underscores the transformative role of DT in reconfiguring both formal (e.g., entrepreneurship education, support structures) and informal (e.g., pedagogical approaches, cultural attitudes) factors that foster SE.

The comparative case analysis between the University of Naples Federico II and the Universitat Autònoma de Barcelona reveals that DT have enhanced access to tools, mentorship, and learning environments, thereby reducing barriers to entry and stimulating student engagement. The findings call for a recalibration of educational programs to align with digital learner expectations—particularly by incorporating MOOCs, simulations, and non-traditional mentorship via digital influencers and online communities.

Theoretically, this work expands our understanding of how institutional environments mediate digital entrepreneurship. Practically, it offers strategic insights for universities aiming to create inclusive, innovation-ready ecosystems. Future research should broaden geographic scope, incorporate quantitative methods, and assess the economic contributions of student-led ventures, particularly as DT and digital pedagogies continue to evolve.

AI and Entrepreneurship: A Bibliometric Exploration in the Post-ChatGPT Era

Mario Tani[1], Gianpaolo Basile[2]
[1]Università degli Studi di Napoli Federico II, Napoli, Italia
[2]Università Telematica Mercatorum, Roma, Italia

Abstract

The pervasive integration of artificial intelligence (AI) is fundamentally reshaping societal and business landscapes, presenting both significant opportunities and challenges, particularly within the entrepreneurial sphere. AI's potential to alter venture conception, development, scaling, market entry, and competitive dynamics necessitates a re-evaluation of traditional entrepreneurship theories. As a key enabling technology, AI revolutionises core entrepreneurial processes, from ideation to market expansion, fostering novel forms of value creation and opportunity identification. However, despite acknowledging the influence of digital technologies, a comprehensive understanding of specific research trends concerning AI's role, especially following the widespread adoption of generative AI tools like ChatGPT, remains underdeveloped. This study addresses this gap through a bibliometric systematic literature review. Utilising the Web of Science database and the "bibliometrix" R-package, we employ thematic evolution analysis to map the trajectory of research topics at the intersection of AI and entrepreneurship, specifically comparing the pre- and post-ChatGPT periods. We aim to visualise the field's structure, identify influential contributions, and track thematic shifts. Anticipated findings include the emergence of research streams focused on generative AI's impact on venture creation, ethical considerations, evolving decision-making processes, and the new skills required for AI-driven entrepreneurship. This analysis seeks to provide practical insights for entrepreneurs leveraging AI tools and highlight knowledge gaps and future research directions for academics, ultimately contributing to a deeper understanding of how AI is shaping the future of entrepreneurship.

Keywords: Artificial Intelligence, Entrepreneurship, ChatGPT, Bibliometric Analysis, Thematic Evolution

Paper type: Academic Research Paper

1 Introduction

The accelerating integration of artificial intelligence (AI) across various sectors is fundamentally reshaping numerous aspects of society and business, creating unprecedented opportunities and challenges (Dwivedi et al., 2021; Upadhyay et al., 2022). The entrepreneurial landscape, in particular, appears to be undergoing a significant transformation. AI possesses the potential to profoundly alter how new ventures are conceived, developed, and scaled, potentially expediting market entry, forging new competitive dynamics, and challenging established business models (Giuggioli and Pellegrini, 2023). As a pivotal enabling technology, AI is actively revolutionising core entrepreneurial processes – ranging from the complexities of market entry and international expansion (Huang and Rust, 2018; Liu et al., 2024) to the crucial initial stages of idea generation and validation (Chalmers et al., 2021; Shepherd and Majchrzak, 2022). This fosters innovative forms of value creation and enhances opportunity identification capabilities (Leone et al., 2021; Broekhuizen et al., 2023).

This profound technological shift demands a critical re-evaluation of established entrepreneurial theories. It necessitates a deeper understanding of how AI is not merely assisting but fundamentally transforming the essence of entrepreneurship in the digital era, creating novel opportunities that extend beyond simple automation or efficiency gains (Nambisan, 2017; Mayanja et al., 2024). Given the transformative potential of AI, comprehending its evolving impact on entrepreneurship within today's dynamic business environment is crucial (Warner and Wäger, 2019; Di Vaio et al., 2021; Biloslavo et al., 2024). While existing research acknowledges the broad influence of digital technologies on entrepreneurial processes and behaviours (Andriole et al., 2017), a comprehensive grasp of the specific research trends, thematic clusters, and intellectual structure related to AI's specific role remains underdeveloped (Ancillai et al., 2023). The advent and rapid diffusion of powerful generative AI tools like ChatGPT, with their sophisticated capabilities for content creation, automation, analysis, and personalisation, further complicates and enriches this evolving research landscape, adding new layers of inquiry (Kraus et al., 2019; Goel and Nelson, 2024).

Therefore, this study addresses the identified gap by employing a bibliometric systematic literature review. Our objective is to investigate how scholarly research focusing on AI's impact on entrepreneurship has evolved, placing particular emphasis on the period following the widespread adoption of ChatGPT. By mapping the shifting thematic patterns and identifying future research directions within this critical field (De Bem Machado

et al., 2022; Duong, 2024), we aim to provide a structured analysis of research trends, thematic shifts, and emerging areas of focus. While the publication trend indicates a surge in interest, the core of the bibliometric analysis involves mapping the thematic content. The subsequent sections will present the results from the keyword co-occurrence analysis (Aria and Cuccurullo, 2017), and strategic diagram mapping (Cobo et al., 2011) for both the Pre-ChatGPT and Post-ChatGPT eras. This will allow for a detailed comparison and identification of specific thematic shifts, emerging topics (e.g., related to generative AI, ethics, specific entrepreneurial processes), and changes in the core research foci within the field. This research seeks to understand whether significant changes have occurred in the intellectual structure and thematic focus of AI and entrepreneurship research in the post-ChatGPT era, offering valuable insights for both academic researchers and practitioners navigating this rapidly changing domain.

2 Methodology

The study's dataset was compiled from the Web of Science (WoS) Core Collection database, chosen for its extensive coverage of high-quality academic publications. The literature search targeted documents combining concepts related to Artificial Intelligence (AI) and Entrepreneurship.

The search query included a broad range of terms within the "Topic" field that includes the Title, the Abstract, the keywords provided by the author(s), and those created automatically by WoS looking at each article references and listed as Keywords Plus.

To capture a comprehensive view of AI, we have used terms encompassing general AI concepts as well as specific techniques and recent developments: "Artificial Intelligence", "Intelligent Automation", "Cognitive Computing", "Machine Reasoning", "Augmented Intelligence", "Smart System", "Synthetic Intelligence", "Machine Intelligence", "Computational Intelligence", "Cognitive System*", "Intelligent System*", "Machine Learning", "Deep Learning", "Connectionist System*", "Parallel Distributed Processing", "Neurocomputing", "LLM*", "Large Language Model*", "ChatGPT",* and "GPT". Similarly, to identify relevant entrepreneurship literature, the query targeted the "Topic" field for keywords such as "entrepreneur*" (to capture keywords such as entrepreneur, entrepreneurial, entrepreneurship, etc.), "enterp"* (capturing enterprise, etc.), "startup", and "start-up".

The search logic was designed to retrieve documents discussing AI in the context of either general entrepreneurship/enterprise or specific startup activities.

To ensure the relevance and quality of the retrieved literature, specific constraints were applied during the search process. The timeframe was restricted to publications indexed between January 2018 to nowadays, capturing significant developments both before and after the advent of widely accessible generative AI. Furthermore, the document selection focused exclusively on peer-reviewed journal contributions by including only those classified as "Article", while explicitly excluding "Proceeding Paper" and "Book Chapters" to make the corpus more internally coherent. In particular, we have filtered all the articles marked as "Retracted Publication". Finally, to align the dataset with the study's focus, the search was limited to articles indexed within the "Management" subject category in the Web of Science database.

For each document included in the final dataset, standard bibliographic information (including authors, title, source, abstract, keywords, references, and publication year) was exported from WoS to facilitate the subsequent analysis using the bibliometrix R-package.

Before the analysis we looked at each article abstract to confirm it was related to our SLR main objective – i.e., To understand how scholarly research focusing on AI's impact on entrepreneurship has evolved in the last years. For example, we have deleted previous literature reviews, and those studies using machine learning to predict enterprise outcomes or similar effects.

2.1 Data analysis techniques

The data analysis have been performed using the "bibliometrix" R-package (Aria and Cuccurullo, 2017), a widely used tool for comprehensive science mapping analysis. The analysis will encompass several stages, with a core focus on thematic structure and evolution to understand the intellectual landscape of AI and entrepreneurship research.

3 Systematic literature review: performance analysis

After the screening phase, the final corpus was composed by 132 articles coming from 65 journals. The articles in the corpus have usually more than 3 authors (the average is 3.3 co-authore per article).

The next figure 1 show the growth of the corpus over the years.

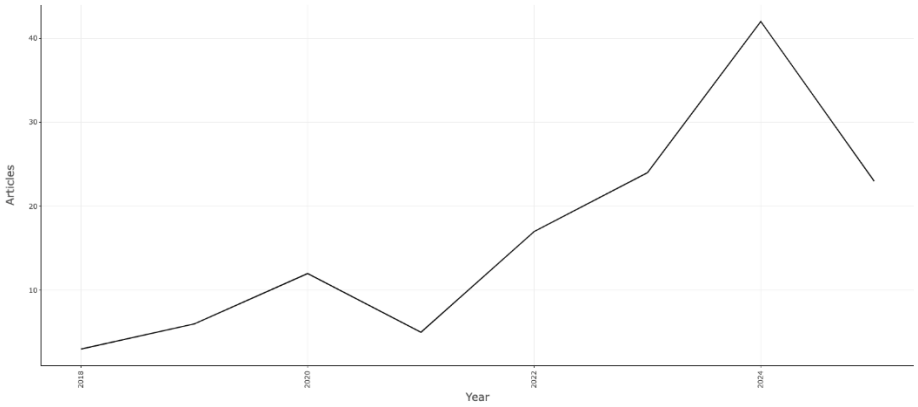

Figure 1 – Scientific Production over the years

Overall, the publication trend analysis reveals a clear and accelerating growth trajectory in research at the intersection of AI and entrepreneurship since 2018. Following an initial phase of rapid expansion with publication counts doubling in both 2019 and 2020, and after overcoming a transient dip in 2021, the field experienced an exponential surge in activity. This is further highlighted by the substantial increase in articles published in 2023 and particularly in the first half of 2024, which alone surpassed previous annual totals. Furthermore, the significant number of articles already assigned to the 2025 (there are 23 articles published in the first three months of this year) underscores the sustained high momentum and highlights the prevalence of rapid online dissemination practices in this dynamic research area, indicating intense and continuously growing attention for these topics.

These articles have been published in a total of 65 journals. The ten most used journals are shown in the following figure 2.

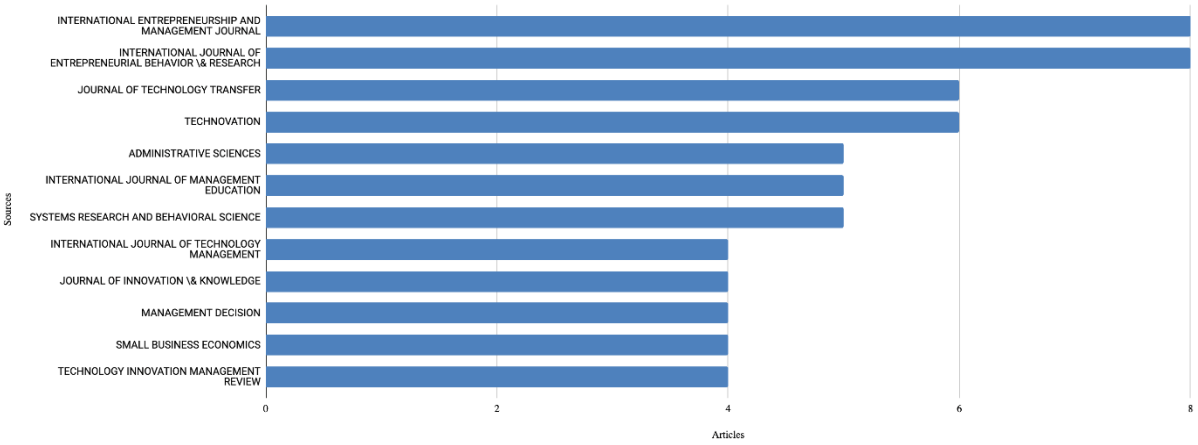

Figure 2 – Ten most used journals in our corpus (showing all the journal with 4 articles for a total of 12 journals)

The *International Entrepreneurship and Management Journal*, and the *International Journal of Entrepreneurial Behavior & Research* are the most prolific sources, each contributing 8 articles to the dataset. Following closely are the *Journal of Technology Transfer*, and *Technovation*, both with 6 articles. These top four journals account for 28 articles, representing approximately 21% of the total dataset. It is interesting to note that apart from the two top journals, that are more related to the topic of entrepreneurship, there are 5 journals related to innovation and/or technology (that is the other side of the query we have carried on), but there are 5 more that cannot be easily classified in one of the two research areas, highlighting the broad scope of these results. In general, the presence of journals like *Small Business Economics* (4 articles) highlight the relevance of AI for smaller firms, while outlets such as *Management Decision* (4 articles), *Journal of Innovation & Knowledge* (4 articles), and *Systems Research and Behavioral Science* (5 articles) suggest connections to broader management related topics.

The next figure 3, report the author's production, limited to our corpus, over the year.

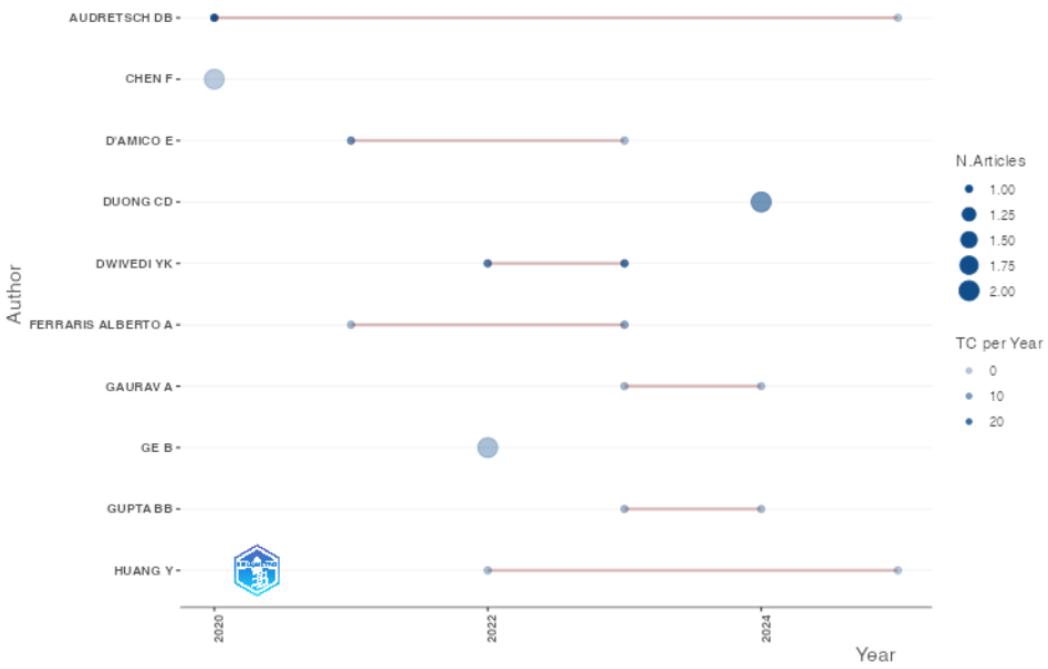

Figure 3 – Author's Production Over Time

The analysis of leading author contributions over time provides a nuanced view of the scholars shaping the AI and entrepreneurship field within our corpus. It highlights a dynamic interplay between recent productivity surges and sustained citation impact. Interestingly, the authors demonstrating the highest average citation impact per year (Audretsch, Dwivedi, Ferraris, and Huang) appear to be recognized relatively quickly by the field, garnering higher citation rates. This could indicate that their work might address more foundational aspects, provide influential reviews, or tackle particularly resonant topics within the AI-entrepreneurship nexus. The sustained activity of established scholars like Audretsch (authors of the seminal paper "Artificial intelligence and big data in entrepreneurship: a new era has begun" with Obschonka, in 2020) and Dwivedi (author of many articles on Artificial Intelligence and its impact in various fields of management studies, such as the highly cited manifest on *International Journal of Information Management* even before the diffusion of ChatGPT – Dwivedi et al., 2021).

Then, there are impactful contributions from younger scholars as Ferraris and Huang, suggests a combination of established expertise and newer influential voices building the field's intellectual core during its rapid expansion phase. This dynamic reflects a field that is both maturing, with recognized influential works, and simultaneously experiencing rapid expansion driven by recent entrants or shifting focus.

4 Thematic evolution

Next, we look into the evolution of this field at the intersection of AI and entrepreneurship research intellectual structure. To achieve this, we employ the thematic evolution analysis approach defined by Cobo López-Herrera, Herrera-Viedma, and Herrera (2011), specifically by mapping and comparing the thematic landscapes of the Pre-ChatGPT era (2018-2022) and the Post-ChatGPT era (2023-onwards).

This analysis utilizes the strategic diagram model (Callon et al., 1991; Cahlik, 2000; Cobo et al., 2011), a powerful tool for visualizing the structure of a research field. This model positions identified research themes (clusters of co-occurring keywords) onto a two-dimensional map based on two key metrics derived from the keyword network:

- **Callon's Centrality** (used for the X-axis of the diagram) – it reflects the strength of a theme's connections to other themes, indicating its importance and integration within the broader research field. Higher centrality suggests a more transversal or foundational role.
- **Callon's Density** (used for the Y-axis of the diagram): it reflects the strength of connections within the theme itself, indicating its internal coherence, conceptual development, and maturity. Higher density points to a well-defined and focused research area.

The position of a theme on this diagram allows for its classification into one of four quadrants: Motor Themes (high centrality, high density - central and developed drivers), Basic Themes (high centrality, low density - important but less developed or transversal), Niche Themes (low centrality, high density - specialized and peripheral), and Emerging or Declining Themes (low centrality, low density - marginal and underdeveloped).

4.1. Pre ChatGPT period: from 2018 to 2022

In the Pre ChatGPT Period, we have found 43 articles that adopting the thematic evolution may be divided in 7 themes as reported in the following figure 4.

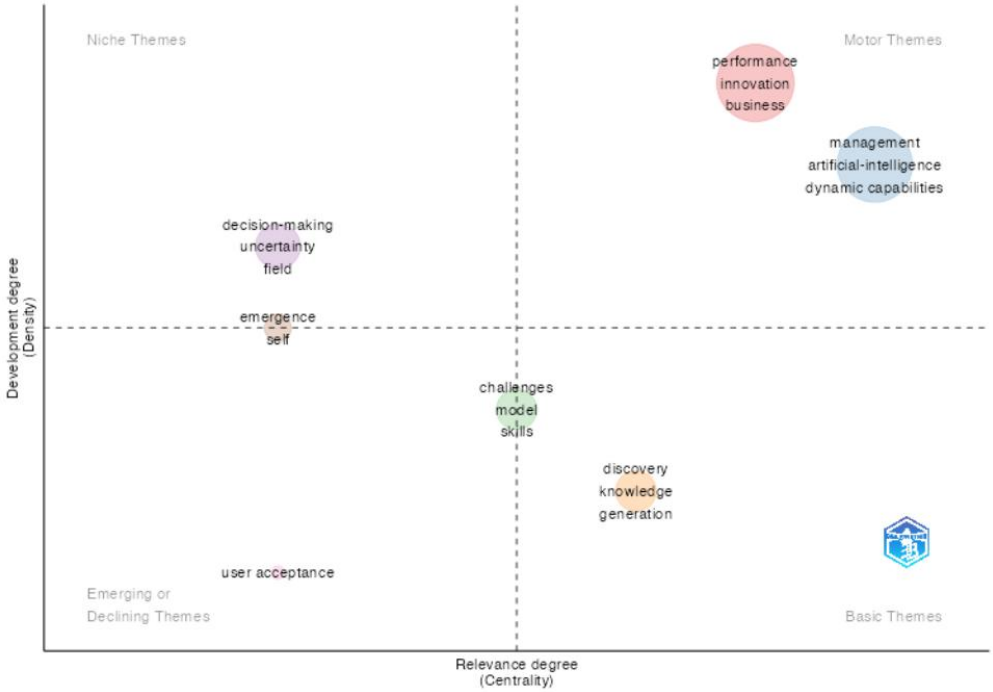

Figure 4 - Pre ChatGPT Period Clusters

The Motor Themes quadrant is dominated by two highly central and developed clusters. The first, represented by the label 'performance', 'innovation', 'business', highlights research investigating the tangible outcomes of AI/digitalization, such as impacts on internationalization speed (Neubert, 2018) and the development of dynamic capabilities for transformation (Warner & Wäger, 2019). The second motor theme, using the label 'management', 'artificial-intelligence', 'dynamic capabilities', underscores the strategic necessity of integrating AI, exploring topics like digital transformation building blocks (Lichtenthaler, 2020) and AI's role in leveraging human capital (Popkova & Sergi, 2020). These themes indicate that core research aimed at understanding how to manage AI strategically and what performance effects to expect.

In the Basic Themes quadrant, the cluster labeled 'discovery', 'knowledge', 'generation' demonstrates high relevance (centrality) but lower development (density). Anchored by studies on AI for identifying emerging business models (Garbuio & Lin, 2019) and validating them (Dellermann et al., 2019), this theme represents the fundamental, yet still developing, application of AI to the crucial entrepreneurial task of opportunity discovery.

The Niche Themes quadrant contains more specialized topics. Labels such as 'decision-making', 'uncertainty', 'field' point to focused research on AI's influence on entrepreneurial cognition, while 'emergence', 'self' likely covers specific areas like ecosystem dynamics or self-efficacy in relation to AI. These themes, though internally developed, had limited connection to the broader field.

Finally, the Emerging or Declining Themes quadrant hosts underdeveloped and marginal topics for this period. Themes identified by labels like 'challenges', 'model', 'skills' suggest nascent discussions on practical hurdles and required competencies, while 'user acceptance' indicates that behavioral adoption theories, though present (Upadhyay et al., 2022), were not yet a central concern within this literature stream.

Overall, the pre-ChatGPT research prioritized understanding the strategic and performance dimensions of AI adoption, underpinned by its connection to opportunity discovery. Foundational cognitive aspects were niche topics, while practical challenges and user acceptance remained peripheral, setting a clear stage for potential shifts in the subsequent era.

4.2. Post ChatGPT period: from 2023 onwards

The strategic diagram for the post-ChatGPT era presents a notably transformed thematic landscape compared to the previous period, reflecting the surge in research activity and potentially shifting priorities (See Figure 5).

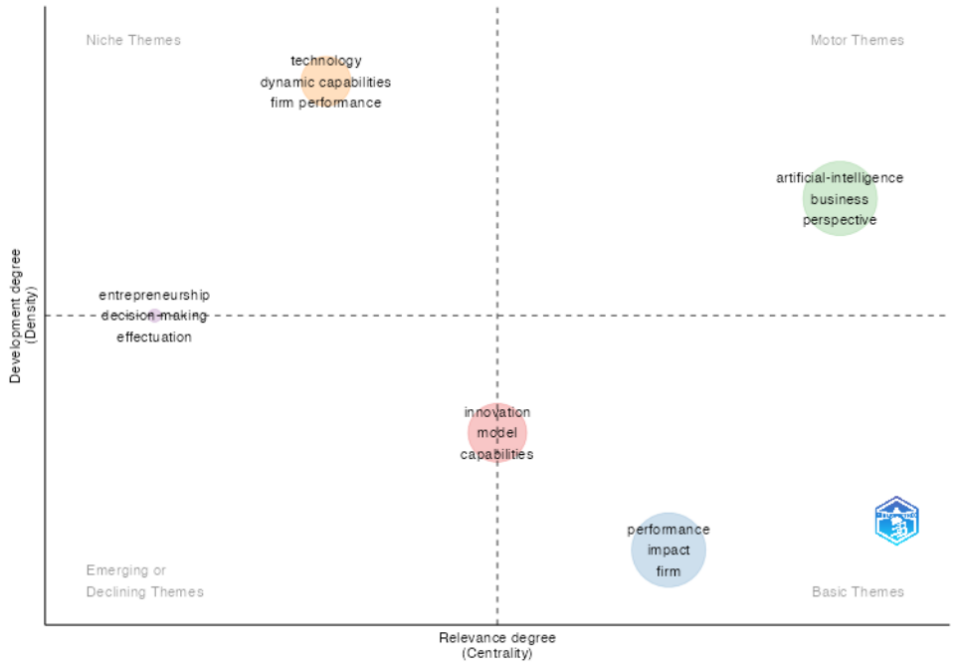

Figure 5 - Post ChatGPT Period Clusters

The Motor Themes quadrant now features a single, dominant cluster labeled 'artificial-intelligence', 'business', and 'perspective'. This theme's high centrality and density indicate that AI itself, viewed from a business perspective, has become the core, well-developed driving force. Articles associated with this label directly address AI's role in the digital economy (Si et al., 2023), its potential for driving sustainable innovation (Govindan, 2024), and its specific application in the venture creation process (Schiavone et al., 2023). This consolidation around the 'artificial-intelligence' label suggests a maturation and direct focus on AI as the central object of study.

Occupying the Basic Themes quadrant is a cluster using the label 'performance', 'impact', 'firm'. Its high relevance (centrality) but lower development (density) indicates that assessing the impact of AI on firm performance remains a crucial, transversal concern, though perhaps explored through diverse, less integrated methodologies. Studies related to this label include SME default prediction (Altman et al., 2023), the potential of generative AI (Norback & Persson, 2024), and AI in entrepreneurial finance (Giuggioli et al., 2024).

In the Niche Themes quadrant, we find two clusters. One uses the label 'technology', 'dynamic capabilities', 'firm performance', suggesting a specialized focus continuing from the previous period. The other, labeled 'entrepreneurship', 'decision-making', 'effectuation', points to a persistent niche examining AI's influence on core entrepreneurial theories.

Finally, a cluster represented by the label 'innovation', 'model', 'capabilities' resides near the center but in the Emerging or Declining quadrant. Its position suggests that while innovation and capabilities remain relevant, this specific thematic configuration, as represented by its label, denotes a less developed and potentially transitional focus in this new era.

Overall, the post-ChatGPT landscape is characterized by a strong, unified focus on 'artificial intelligence' (as the primary motor theme label), while 'performance' and 'impact' evaluation remains a central underlying concern. Specific theoretical lenses ('decision-making') and technology management aspects ('dynamic capabilities') persist as niche areas.

5 Conclusion and implications

This study employed a bibliometric systematic literature review combined with science mapping techniques to investigate the evolution of research at the intersection of Artificial Intelligence (AI) and entrepreneurship,

with a specific focus on comparing the thematic landscape before (2018-Nov 2022) and after (Dec 2022-Mid 2024) the widespread emergence of generative AI tools like ChatGPT. Our analysis confirmed a significant surge in publication activity in the latter period, coinciding with a notable restructuring of the field's thematic priorities.

The thematic evolution analysis (Figure 6) revealed a clear shift.

Figure 6 – The evolution of the themes

In the pre-ChatGPT era, the research landscape was driven by two core motor themes "performance/innovation/business" on the outcomes of AI/digitalization and the more strategic one labeled "management/artificial-intelligence/dynamic capabilities" looking at the enterprise needs for integrating AI in their activities. Foundational concepts of "discovery/knowledge" acted as a basic theme, with niches and emerging topics for the other two.

In stark contrast, the post-ChatGPT era shows a significant consolidation around a single dominant motor theme explicitly labeled "artificial-intelligence/business/perspective". This cluster absorbed key aspects from previous themes, including the one on management (as shown by the evolution of keywords like 'artificial-intelligence;big data;future') on performance (see keywords as business and perspective), decision-making (keywords such as field and opportunities), and even from niche theme of discovery, signifying that AI itself, viewed from a holistic business perspective, has become the central driving force and object of study.

The theme "performance/impact" persists as a highly relevant basic theme, indicating continued interest in outcomes, but it now incorporates knowledge aspects and look into specific industry contexts, themes previously less relevant. A distinct theme labeled "innovation/model/capabilities" has emerged with notable connections, drawing from previous period in themes as the one on performance (keywods innovation, firms, and growth), from the management one (looking at the keyword capabilities), and from the emerging theme on the 'challenges' highlighting innovation as a key area reshaped by new AI possibilities.

Concurrently, 'technology' emerged as a distinct theme, consolidating previous management and performance aspects related to technology itself.

Finally, the new theme on entrepreneurship, drawing mainly from previous "decision-making" and "management" themes, signifies a continued, perhaps more focused, examination of core entrepreneurial processes within the new AI paradigm.

5.1 Academic Contributions

This study offers several contributions to the academic community. Firstly, it provides a structured, quantitative overview of the rapid growth and evolving intellectual structure of the AI and entrepreneurship research field. Secondly, by employing a thematic evolution analysis contrasting pre- and post-ChatGPT periods, it offers empirical evidence of the significant impact generative AI has had on reshaping research agendas, moving AI from a topic *within* management and performance discussions to the central organizing *perspective*. Thirdly, it identifies the specific thematic shifts: the consolidation around AI, the heightened focus on innovation, the persistence of performance impact evaluation, and the reconfiguration of technology and core

entrepreneurship themes. This map serves as a valuable guide for researchers seeking to position their work within this dynamic landscape.

5.2 Practical Implications

The findings also hold important implications for practitioners. On one side, it highlights that entrepreneurs and managers must recognize that AI, particularly generative AI, is no longer a peripheral technology but a central element impacting business models, strategy, and operations. Staying informed about AI developments is crucial. Then, looking at the emerging 'innovation' theme we may get that there are significant opportunities in leveraging AI for novel products, services, processes, and business models. Practitioners should actively explore how AI can drive innovation within their ventures. Taking into consideration that overcoming implementation hurdles and developing AI-related skills are now integrated aspects of technology management and innovation, requiring continuous attention.

At the same time, there are plenty of opportunities in the debate on measuring the real Impact AI investments and initiatives and that the shift in the themes implies that AI tools are actively changing how opportunities are perceived, decisions are made, and ventures are managed.

5.3 Limitations and Future Research

This study is subject to limitations common in bibliometric analyses. Its scope is confined to the Web of Science Core Collection (Management category, Articles only), potentially omitting relevant work from other sources or disciplines. The reliance on keyword analysis provides a structural overview but cannot capture the full theoretical depth of individual papers. The definition of the post-ChatGPT period captures the initial wave but is still a relatively short timeframe for observing long-term stable shifts.

These limitations suggest several avenues for future research. Longitudinal studies tracking thematic evolution over a longer post-ChatGPT period are needed. Deeper qualitative reviews or case studies could explore *how* specific AI tools are impacting the identified themes (e.g., decision-making, innovation models). Research explicitly addressing the ethical implications of AI in entrepreneurship, seemingly underrepresented in the current thematic structure, is crucial. Investigating the specific skills and competencies required by entrepreneurs in this new era warrants further attention. Comparative studies using different databases or including other document types could provide a broader perspective. Finally, research moving beyond identifying impacts towards developing actionable frameworks for AI integration and capability building in entrepreneurial contexts would be highly valuable.

In conclusion, this bibliometric exploration illuminates the dynamic evolution of the AI and entrepreneurship field, accelerated and reshaped significantly in the post-ChatGPT era. By mapping this changing landscape, we provide a foundation for researchers and practitioners to navigate the opportunities and challenges presented by AI's transformative potential.

6 Ethics declaration

This works does not need ethical clearance for the kind of research adopted.

7 AI declaration

We have not used AI tools to develop the paper.

Artificial Intelligence and Knowledge Management in Healthcare: A Pathway to SDGs Achievement

Valerio Brescia[1], Ginevra Degregori[1], Alberto Cavazza[3]
[1]University of Milan, Milan Italy
[2]University of Turin, Turin Italy
[3]University of Milan- Bicocca, Milan Italy

Abstract
The integration of Artificial Intelligence (AI) and Knowledge Management (KM) in healthcare is transforming decision-making, resource allocation, and service efficiency, aligning with the United Nations' Sustainable Development Goals (SDGs). AI-driven KM systems enhance clinical decision-making, optimize disease detection, and expand medical access, particularly in underserved areas, supporting SDG 3 (Good Health and Well-being) and SDG 10 (Reduced Inequalities). Additionally, AI contributes to SDG 4 (Quality Education) by improving medical training and SDG 13 (Climate Action) through energy-efficient healthcare solutions. Despite its potential, the adoption of AI in healthcare faces significant challenges, including data privacy concerns, algorithmic biases, and regulatory uncertainties. The lack of comprehensive studies assessing AI's measurable impact on sustainability further limits its large-scale implementation. This study addresses these gaps by analyzing how AI-driven KM systems support SDGs and identifying key obstacles to their integration. The research conducts a bibliometric and thematic analysis and examines 1,095 peer-reviewed papers from the Scopus database. Findings highlight AI's role in enhancing efficiency, enabling knowledge-sharing, and improving resilience in healthcare systems. However, concerns regarding ethical governance, equitable access, and technological disparities underline the necessity of strong policy frameworks to ensure responsible AI deployment. This study contributes to the discourse on AI's role in healthcare by providing a structured analysis of its impact on SDG achievement. Finally, the article addresses future research perspectives as joint scholars' and practitioners' analyses.

Keywords: Artificial Intelligence, Knowledge Management, Healthcare, Sustainable Development Goals

Paper type: Academic Research Paper

1 Introduction

The attention on sustainability has grown exponentially in recent years due to emerging global threads, such as climate change, air pollution, intensification of land use and water depletion (Morioka et al., 2017). Achieving environmental, social and economic sustainability is now a worldwide challenge. Therefore, sustainable development, defined by the World Commission on Environment and Development (WCED, 1987) as "Development that meets the needs of the present without compromising the ability of future generations to meet their own needs", has become an important focus for the general public, governments and health systems (Biason & Dahl, 2016; Mosca et al., 2017). Previously, the concept of sustainability was predominantly associated with environmental aspects (Rogers et al., 2013). However, in addition to encompassing a broad spectrum of environmental issues, sustainable development faces diverse and intricate challenges that evolve alongside human societies and natural ecosystems around the world (Robert et al., 2005). Nowadays, its meaning has evolved to encompass a more holistic perspective, incorporating dimensions such as social equality, economic development and health well-being (Marimuthu & Paulose, 2016). This change is reflected in global initiatives like the Sustainable Development Goals (SDGs) established by the United Nations in 2015 as a global framework to address new emerging challenges (Sparviero & Ragnedda, 2021). The SDGs, comprising 17 interconnected goals, aim to address issues ranging from poverty eradication and climate action (Koebe, 2025). SDG 3, specifically dedicated to promoting well-being for all, underscores the importance of equitable healthcare access and the development of resilient healthcare systems (Nunes et al., 2016). Thus, improving global health stands as one of the most relevant objectives within the United Nations' SDGs (Koebe, 2025).

In recent years, digital transformation has revolutionized multiple sectors, including healthcare. The integration of new technologies, such as Artificial Intelligence (AI), has significantly influenced medical practices, from diagnosis and treatment to healthcare system efficiency (Kraus et al., 2021). AI has also emerged as a key enabler of Knowledge Management (KM) by enhancing the ability to collect, process, and analyze vast amounts of data for improved decision-making and operational efficiency (Taherdoost & Madanchian, 2023). Within the healthcare sector, AI-driven KM systems facilitate the automation of data processing, enable pattern recognition, and generate actionable insights by improving disease detection, optimizing resource allocation, and ensuring access to healthcare services, particularly in underserved areas (Jarrahi et al., 2023). Although the

pandemic period (COVID-19) has identified potential implementations in healthcare related to prevention and decision-making processes, studies investigating the impacts and outcomes of the advanced adoption of AI and KM are currently absent (Taherdoost & Madanchian, 2023; Vishwakarma et al., 2023). While AI-based KM systems have demonstrated substantial benefits in automating knowledge-sharing processes and supporting decision-making frameworks, their role in advancing sustainability in healthcare remains an underexplored research avenue. This study aims to bridge this gap by analyzing how AI and KM contribute to SDG achievement in healthcare and by assessing the associated challenges that could hinder their full integration.

Given the increasing relevance of AI and KM in shaping the healthcare sector's sustainability and resilience, this study seeks to answer the following research questions:

RQ1: How does Artificial Intelligence in healthcare contribute to Sustainable Development Goals achievement?

RQ2: What are the key challenges in integrating AI for a resilient healthcare system?

To explore the role of AI in healthcare, this study adopts a structured methodological approach combining bibliometric and thematic analysis. The bibliometric analysis, conducted through Bibliometrix, examines research trends, collaborations, and knowledge diffusion, while the thematic analysis, conducted using Leximancer, identifies key conceptual relationships. Data were collected through a systematic search in the Scopus database, resulting in a final dataset of 1,095 papers, ensuring a comprehensive understanding of AI's contributions and associated challenges. The findings indicate that AI-driven KM systems enhance healthcare efficiency, optimize resource allocation, and improve patient outcomes, significantly advancing SDG 3, SDG 4, SDG 10, and SDG 13. Nonetheless, challenges related to data privacy, algorithmic biases, and ethical governance necessitate careful policy considerations to ensure responsible AI adoption.

The rest of the paper reviews previous literature in Section 2 and details the Methodology in Section 3. Then, the study presents the findings in Section 4, discusses them, and concludes with future research directions in Section 5.

2 Literature review

In the context of the ongoing digital transformation, the incorporation of new technologies has the potential to contribute significantly to the achievement of these goals. In particular, among these new technologies, AI emerges as a transformative tool to accelerate progress toward health-related issues (Kraus et al., 2021). Furthermore, AI has emerged as a transformative factor within KM, particularly within the healthcare system (Taherdoost & Madanchian, 2023). KM, broadly defined as the process of creating, storing, sharing, and applying knowledge to enhance organizational decision-making and innovation, plays a pivotal role in modern healthcare organizations (Abubakar et al., 2019; Alavi & Leidner, 2001). Indeed, effective KM practices ensure that every employee has access to the appropriate and highest quality of information available at the time when a decision needs to be undertaken. Knowledge can be categorized as either individual or organizational. Individual knowledge refers to an individual's ability to make judgments and decisions based on their knowledge, whereas organizational knowledge encompasses knowledge as a resource that enables a workforce to make decisions based on collectively constructed knowledge. This collective knowledge is acquired by organizations through KM processes (Merali, 2000; Tsoukas & Vladimirou, 2001). Between the early 2000s and 2018, studies on this research field have often been focused on social networks, autonomous media, and human-computer interactions, underscoring the strategic importance of KM for organizations (Gaviria-Marin et al., 2018). Considering healthcare, by leveraging AI, KM is greatly enhanced, as AI automates data analysis, identifies patterns, and generates actionable insights. This capability allows organizations to process vast amounts of health data and uncover correlations that were previously inaccessible through manual processes (Jarrahi et al., 2023). Indeed, advanced AI algorithms enable deep-learning models to support clinical decision-making, policy planning, and the efficient integration of electronic health records, ensuring a continuous knowledge exchange across different healthcare settings (Rajkomar et al., 2018). AI-driven KM systems have the potential to reduce knowledge loss, optimize resource utilization, and enhance global collaboration through advanced knowledge-sharing platforms (Jarrahi et al., 2023; O'Leary, 1998).

AI contributes significantly by enhancing disease detection, streamlining resource allocation, and expanding access to medical services through telemedicine and mobile health applications (Aceto et al., 2020). For example, predictive AI algorithms support early identification of disease outbreaks, enabling timely and targeted responses in vulnerable regions (Panch et al., 2018). AI-driven automation of administrative tasks, such as scheduling and documentation, allows healthcare providers to focus more on patient care, further maximizing the efficiency of KM processes within healthcare systems (Bose, 2003). Furthermore, AI facilitates the integration of electronic health records and big data analytics, providing insights that optimize healthcare

planning and improve patient outcomes (Koebe & Bohnet-Joschko, 2023). These advancements not only foster progress toward universal health coverage but also exemplify how technology-driven innovation can bridge healthcare disparities, particularly in underserved areas (Olu et al., 2019). Therefore, the implementation of AI-based KM systems within the healthcare arena also aligns with wider sustainability principles by addressing inefficiencies and supporting preventive care (Choy et al., 2018). The integration of AI and KM within healthcare extends its impact beyond direct health improvements, enhancing progress across multiple SDGs (Table 1).

Table 1. The role of AI and KM in advancing SDGs

AI and KM	**Effects of AI and KM on SDGs**
AI enhances KM by automating data analysis, identifying patterns and generating actionable insights (Jarrahi et al., 2023).	Advances SDG 3 (Good Health and Well-being) through improved healthcare delivery, early warning systems and universal health coverage (Koebe & Bohnet-Joschko, 2023).
KM supported by AI facilitates seamless integration of electronic health records and big data analytics (Rajkomar et al., 2018).	Supports SGD 10 (Reduced Inequalities) by optimizing medical resources allocation, ensuring underserved regions receive adequate care (Rajan et al., 2020).
AI-based KM systems prevent knowledge loss and enable global collaboration through advanced knowledge-sharing platforms (Jarrahi et al., 2023; O'Leary, 1998).	Contributes to SDG 4 (Quality Education) by promoting health literacy and lifelong learning through AI-driven educational platforms (Holmner et al., 2012).
Advanced KM systems supported by AI improve organizational decision-making practices and innovation by effectively managing vast health data (Taherdoost & Madanchian, 2023).	Drives progress toward the achievement of SDG 9 (Industry, Innovation and Infrastructure) by fostering technological innovation and developing resilient healthcare infrastructures (Koebe, 2025).
AI-enabled KM streamlines administrative and clinical workflows, allowing healthcare providers to focus on patient care (Bose, 2003).	Promotes SDG 8 (Decent Work and Economic Growth) by increasing occupational health and safety through predictive maintenance and reducing workplace hazards (Jarrar et al., 2024).
AI-driven KM systems enhance energy management by utilizing monitoring systems to optimize resource allocation, improve energy efficiency, and integrate renewable energy technologies in healthcare infrastructures (Holmner et al., 2012).	This supports SDG 13 (Climate Action) by fostering sustainable healthcare delivery, reducing environmental impact, and ensuring continuous operations in environments where specific resources are limited (Aceto et al., 2020; Holmner et al., 2012).

3 Methodology

The literature review approach represents a structured method for analyzing scientific sources, ensuring a rigorous and reliable evaluation of existing research (Hulland & Houston, 2020). The literature review method is a technique employed to examine a collection of academic works, aiming to generate insights, critical reflections, and future research directions on a specific research topic (Massaro, Dumay, et al., 2016). In recent years, bibliometric analysis has surged in popularity within the various scientific literature review methods due to the accessibility, advancements, and availability of modern software and scientific databases (Ruggieri et al., 2018). These tools enable handling large volumes of scientific data and contribute to producing high-impact research, uncovering emerging trends, collaboration patterns, and research constituents (Donthu et al., 2021). Given the research gap, the authors consider that an in-depth thematic analysis can complement bibliometric analysis while applying a rigorous and systematic research protocol (Furrer et al., 2020). Combining these two analytical approaches can provide a comprehensive overview of specific research trends and limit the results' subjectivity (Donthu et al., 2021).

According to the literature (Massaro, Dumay, et al., 2016; Secundo et al., 2020), to explore the role played by AI within the healthcare sector, the researchers adopt five rigorous steps, namely:

1. Defining RQs that the study seeks to answer.
2. Writing the research protocol.
3. Determining the research sample for the analysis.
4. Developing a coding framework.
5. Conducting a critical analysis and discussion on the findings obtained, identifying future research directions.

The initial step involves defining the research questions that the study aims to answer (Massaro, Handley, et al., 2016). After defining the RQs, it would be essential to write a research protocol including the definition of

information sources, the methodology adopted, the mean and tools utilized for analyzing the studies constituting the sample (Petticrew & Roberts, 2008). Table 2 illustrates the already known concepts, the motivation that drove the authors to write this review, the research topic, the dataset creation, and the tools used to implement the analysis.

Table 2. Research review protocol

Research protocol elements	**Author's considerations**
What is already known?	In the context of the ongoing digital transformation, the incorporation of new technologies has the potential to contribute significantly to the achievement of these goals. Among these new technologies, AI emerges as a transformative tool to accelerate progress toward health-related issues (Kraus et al., 2021). Additionally, AI has emerged as a transformative factor within KM in healthcare environments (Taherdoost & Madanchian, 2023).
Motivation	Although the pandemic period (COVID-19) has identified potential implementations in healthcare related to prevention and decision-making processes, studies investigating the impacts and outcomes from the advanced adoption of AI and KM are currently absent (Vishwakarma et al., 2023). The study intends to respond to the gap through the SDGs lens. AI-driven KM systems play a crucial role in advancing multiple SDGs within the healthcare sector. There is a potential for a bibliometric and thematic analysis examining the relationships between AI and KM and their impact on SDGs achievements.
Research topic	RQ1: How does Artificial Intelligence in healthcare contribute to Sustainable Development Goals achievement? RQ2: What are the key challenges in integrating AI for a resilient healthcare system?
Journal's research (Villiers et al., 2023)	The decision was made not to restrict the research to individual scientific journals due to the relatively nascent nature of the study's purpose (Secinaro et al., 2021). The analysis included articles and peer-reviewed journals (Easterby-Smith & Lyles, 2012). Additionally, the studies of the sample were selected within "medicine" and "business, management and accounting" areas from Scopus database to extract all relevant information sources (Villiers et al., 2023).

Source: Authors' elaboration

The third step consists of defining resources using the scientific database Scopus, the largest citation database for peer review with social sciences titles from more than 4,000 publishers (Burnham, 2006). The study was conducted using the following research string:

TITLE-ABS-KEY ("artificial intelligence" OR "machine learning" OR "data processing") AND ("healthcare" OR "medical centre") AND ("environmental, social and governance" OR "ESG" OR "environmental" OR "social" OR "governance").

The initial search using the above research string provided 5,300 results. By filtering the results only to include the subject areas of "medicine" and "business, management and accounting," the number of documents was reduced to 2,164. Selecting only articles and peer-reviewed journals, the total results amount to 1,160. After eliminating documents in languages other than English, the final set comprised 1,095 papers. After a one-to-one abstract screening, 75 papers were removed because they were considered irrelevant to the research topic. Figure 1 represents the complete process of paper selection.

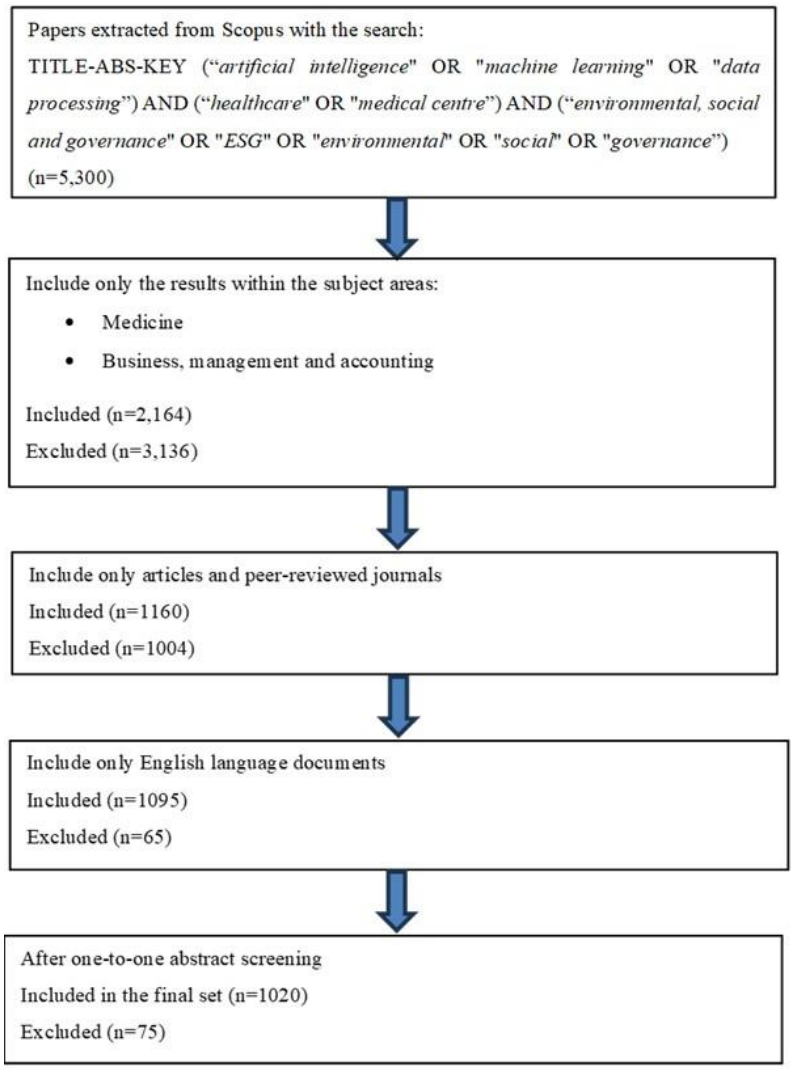

Figure 1. Paper selection process
Source: Authors' elaboration

Subsequently, the fourth phase aims to define the items to be examined in the selected papers by establishing a coding framework focusing on the following nodes:

- Number of sources.
- Sources' production over time: the evolution over the time of the number (Nr) of papers.
- Most relevant sources: distribution of papers among journals and citations received.
- Geographical scientific production distribution: papers distribution among countries.

To gather these data on the flow of relationships between countries and identify the leading contributors on the topic, the authors utilized Bibliometrix, a statistical package available on R-Studio (Radha & Arumugam, 2021). This software compiles bibliometric information such as authors, citations, countries of production, and keywords. Finally, critical analyses have been made through a thematic analysis of the documents selected. This evaluation was conducted using Leximancer 4.0, a software that provides a form of automated analyses based on the properties of texts with trustworthy results demonstrating high reliability and reproducibility (Sotiriadou et al., 2014).

4 Results and findings

The first part of this section provides an overview of the research topic of AI in healthcare, derived from a bibliometric analysis conducted using Bibliomterix. The second part describes the thematic analysis performed through Leximancer software.

The dataset includes 1,075 papers published between 1983 and 2024 from 557 different journals. Table 3 summarizes the key information of the dataset, showing an annual growth rate of 15,18%. Figure 2 illustrates the annual scientific production on the topic, revealing a significant increase in research interest over the last decade. While early publications in the 1980s were intermittent, a steady increase in scholarly output is observed from 2011, reflecting the growing relevance of AI applications in healthcare. Concurrently, European and global regulatory initiatives began emphasizing the integration of AI-driven technologies in medical practice. The introduction in 2016 of the General Data Protection Regulation (GDPR) established robust data-sharing policies while safeguarding patient privacy, a fundamental prerequisite for AI-driven healthcare applications (European Parliament, 2016). More recently, in 2022, the European Health Data Space (EHDS) has facilitated cross-border data exchange, allowing AI to leverage larger datasets for medical research and decision-making (European Commission, 2022). Then, the approval of the EU AI Act (2024) further underscores the importance of ethical and transparent AI deployment in healthcare, reinforcing compliance with European values (European Commission, 2024). The number of publications observed at the end of 2024 aligns with advancements in deep learning, natural language processing, and clinical decision-support systems, further demonstrating the field's maturation.

The dataset includes 3,282 keywords, demonstrating the vast thematic scope of AI in healthcare.

Table 3. Main information about the dataset

Description	Results
Timespan	1983:2024
N° of journals	557
N° of articles	1,075
Annual Growth Rate %	15.18
Document Average Age	3.48
Average citations per doc	20.5
Keywords Plus (ID)	6,991
Author's Keywords (DE)	3,282
Authors	5,969
Authors of single-authored docs	58
Single-authored docs	61
Co-Authors per Doc	6.14
International co-authorships %	32.65

Source: Author’s elaboration using Bibliometrix

As shown in Figure 3, the United States leads AI research in healthcare with 1,209 publications, followed by the UK (568) and China (236), driven by strong institutional support and funding. Other key contributors include India, Canada, Australia, and several European nations, reflecting global engagement, with future advancements likely dependent on cross-border collaboration and policy frameworks.

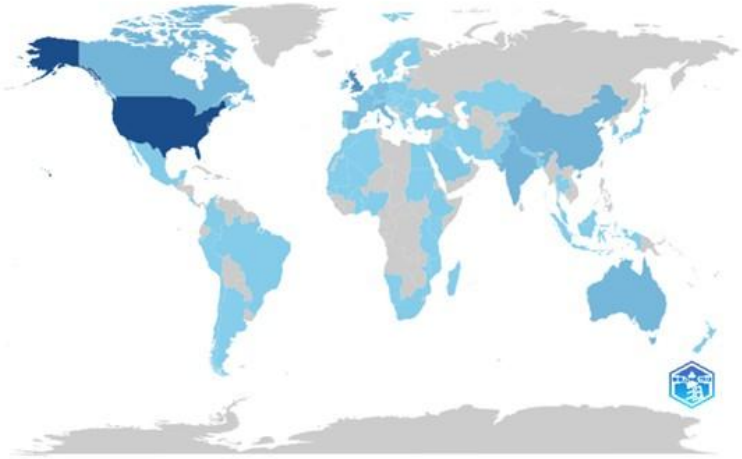

Figure 3. Country scientific production
Source: Author's elaboration using Bibliometrix

The thematic analysis conducted using Leximancer shows that previous studies questioned the issues of AI and SDGs in healthcare. As shown in Figure 4, key topics are related to macro concepts such as "healthcare", "patients", "social", "learning", "data" and "environment".

In the "healthcare" sector, the role of AI appears to be relevant for the individual treatments of "patients", translating from physical to digital care, increasing cost-efficiency and quality of services (Barbieri et al., 2023). Its implementation can daily support the patients through digital care assistance which helps to improve contact-reduced healthcare on site and enable interpersonal interaction that is conducive to maintaining high health conditions. A clear example of these applications is given by Gangl and Krychtiuk (2023) which propose several wearable health sensors and digital biomarkers with useful functionalities such as Photoplethysmography (PPG)-based detection and electrographic signals remote control.

Another cluster obtained from the analysis is related to "data". It connects with the role of increasing algorithm learning and contributing to the vertical and horizontal network reconfiguration, adapting the AI capabilities for new required tasks (Caserta & Romero, 2024). Hammond (1986) defines networks as "an aggregation of structural arrangements due to the belief that structure, horizontal or vertical, affects outcome". Vertical networks represent hierarchical structures where data flow through different levels of authority, while horizontal networks enable collaboration across different entities. In the field of diagnosis, for instance, AI can emulate doctors' predictive capabilities, enhancing accuracy by comprehensively analyzing patients' electronic health records both horizontally and vertically in a very short time (Guo et al., 2020). The results also highlight that data have been a primary resource during the COVID-19 pandemic, providing public administrations access to timely and reliable information through automated systems that have made it possible to manage the traceability and course of sick patients, guiding territorial policies (Tuzii & Bottari, 2022).

The critical nature of managing and processing clinical data, essential for optimal healthcare delivery, brings out the need to secure all the several stages, ensuring privacy and security (Thantilage et al., 2023).

The paradigm of the Internet and new surveillance technologies, such as drones, cameras, smartphones, and the Internet of Things, brought the ethics of privacy protection to the top of every decision-making agenda, emphasizing the ethical aspects of AI in medicine (Dabla et al., 2021). Privacy issues are related to the risks of invasive monitoring technologies, which make daily permanent monitoring, surveillance, and collecting data imply a massive intrusion into the patient's life (Mittelstadt & Floridi, 2016). Moreover, big data and AI require vast amounts of data, which may be stored indefinitely. This creates the risk that users might lose track of how their data is being used, increasing the chances of data leaks or loss (Luxton et al., 2016). For example, in mental healthcare, despite iHealth has great potential, the ambivalence of autonomy and the question of how technology can meet the needs and resources of individual patients, the threats to personal and data privacy, and the risk of datafication and bias create several concerns about suicide prevention (Rubeis, 2022). Datafication could be defined as the procedure's simplification, reduction, and coding with the risk of undermining the uniqueness patients experience (Becker et al., 2018). Bias could arise from the data pre-

processing, especially in the variable's derivation from the data collected phase. In synthesis, AI is perceived as a technology with the potential to assist public data management, reducing current staff shortages, but, for many people, it may pose a threat since it is seen as something that can represent an increase in unemployment and ethical privacy problems in healthcare (Mwase et al., 2023).

We can see the pandemic as an unprecedented boost for many transformations disrupting several of our traditional approaches (Gangl & Krychtiuk, 2023). From one perspective, data and technologies can have a positive impact on healthcare and society. However, we must also consider the potential downsides. The new digital technologies show a strong impact on social aspects. Their adoption and implementation generally produce social, economic status, and class-based inequalities in health, despite some studies claiming the opposite, believing that they could reduce inequalities over time (Weiss et al., 2018). In healthcare, empathy plays an imperative role in improving patient satisfaction and treatment adherence, but AI and especially large language models (LLMs) lack this quality, with the risk that decisions can be undertaken without considering the impact on others (Sorin et al., 2024).

AI is clearly connected to "learning", which has been cited 13,925 times within the documents considered in the sample, with a double reading. On one side, algorithms, processes, and performance measurement concepts are used for classification and regression tasks to emulate human intellect. In this ecosystem, the network platforms are continuing to transform and reconfigure, considering the crucial role played by data and AI but still bearing that learning is one of the most critical factors for successful implementations. Platform24 gives a case developed and utilized to create automated triage engines, which partially replaced the need for human resources in the triage process, namely the prioritization and referral of new patients to medical professionals (Björkdahl et al., 2024). On the other side, AI is a powerful tool for facilitating knowledge sharing, leading to the discovery of innovative solutions (Hajian et al., 2024), especially in the case of semi-supervised learning. Some examples of recent technological advancements in healthcare are chatbots, conversational agents, and metaverse applications, which can promote the transfer of knowledge in clinical settings (Lazarus et al., 2024). In radiography, machine learning algorithms are used for detection, localization, assessment of prediction, classification, and density estimation tasks, but they could be enhanced by investigating the features that drive the prediction task, leading to knowledge discovery (Rainey et al., 2023). These are perfect examples of artificial and human intelligence integration in medicine, showing that AI does not have to replace medical specialists or scientists and, rather, needs such expert human knowledge. Based on these considerations, KM plays a fundamental role. It could be considered as an umbrella term for a variety of interchangeable terms such as knowledge creation, knowledge valuation and metrics, knowledge mapping and indexing, knowledge transport, storage and distribution, and knowledge sharing (du Plessis, 2007). Hospitals should foster a knowledge-sharing environment to maximize patient care value (Karamitri et al., 2017).

"Social" is an important theme of this analysis and it has been cited 7,445 times within the studies under analysis. This criteria represents one of the ESG aspects, that constitute a very relevant evaluation in the academic and corporate world (Clément et al., 2023). In this context, the COVID-19 pandemic shows a relevant impact on the results; social media usage exponentially increased during this period, affecting even the population's mental wellness in a very stressful situation (Pappa et al., 2020). In the social distancing isolation, which causes several problems, some applications use digitalization with the aim of increasing physical, social, and mental well-being. An example is given by the "adapt-cafè project", a mobile application created to encourage positive nutrition, physical activity, and social interaction during the lockdown situation (Meinert et al., 2020).

There is a clear connection between AI and "Environment", which has been cited 3,223 times. Green digital learning involves motivating internal stakeholders to enhance their understanding of environmental issues, which can be beneficial for the business by providing valuable data and information (Halbusi et al., 2024). In healthcare, it plays a moderating role in the relationship between AI, machine learning, and green supply chains, promoting both environmental and financial sustainability (Benzidia et al., 2021). A green or environmental supply chain refers to a series of organizational activities aimed at managing the supply chain system - from sourcing materials to delivering customer service - in an environmentally responsible manner (Jabbour et al., 2015). This concept should always be linked to financial sustainability. It involves managing firms in a way that ensures current financial success does not jeopardize future financial success, including the well-being of future generations, aiming to create a mutually beneficial relationship (Gleißner et al., 2022). Within the hospital's context, new technologies implementation permits both real-time monitoring and assimilation of knowledge on environmental sustainability with the opportunity to exploit learning resources such as e-learning and m-learning (Benzidia et al., 2021).

Environmental and social aspects are two of three ESG criteria, and they are strictly connected to AI and SDGs in healthcare. The healthcare sector must address new sustainable business challenges by integrating ESG

factors into the actual business models. ESG criteria align closely with sustainable healthcare, promoting a responsible approach towards the environment (e.g., reducing greenhouse gas emissions, conserving water, and using renewable energy sources), ensuring social responsibility (e.g., implementing policies to fight workplace discrimination, upholding human rights, and maintaining occupational hygiene and safety), and enforcing robust corporate governance (Leung & You, 2023). Although “Governance” has not been mentioned in the main clusters, there is a clear connection between “Healthcare” and “Management”. Several components of the management field, such as management structure, management remuneration, transparency, business integrity, rights of and relations with shareholders, long-term strategy, internal control, audit, and risk management, are essential corporate governance factors with primary importance within the modern healthcare industry (Sepetis et al., 2024). This is due to the increasing complexity of healthcare, which necessitates management approaches that consider multiple perspectives to improve decision-making practices (Cagliano et al., 2011).

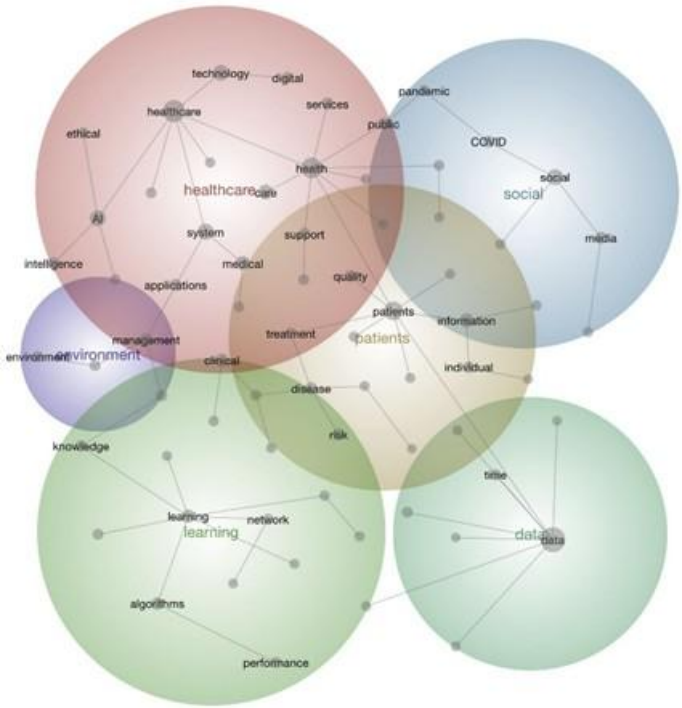

Figure 4. Key themes and results of the analysis
Source: Authors' elaboration based on Leximancer

5 Discussion and Conclusions

This analysis provides a comprehensive picture of the evolving landscape of AI in healthcare, underscoring its role in advancing SDGs. The bibliometric analysis highlights the exponential growth in scientific production over the last decade, with an increasing number of international collaborations and contributions from different countries. This growth is driven by regulatory frameworks such as the EHDS (European Commission, 2022) and the AI Act (European Commission, 2024), which have incentivized AI adoption in medical research and clinical applications. The thematic analysis conducted through Leximancer has identified key conceptual clusters such as “healthcare,” “patients,” “social,” “learning,” “data,” and “environment,” demonstrating the different roles that AI plays in improving healthcare efficiency, decision-making, and sustainability practices.

Another significant aspect that emerged from these analyses is that the role of AI is also particularly relevant within KM.

The ability of AI to automate data analysis and generate actionable insights supports clinical decision-making and policy planning (Rajkomar et al., 2018), promoting greater resilience in healthcare infrastructures.

The study's results also underline the significant contribution of AI to the achievement of several SDGs. AI applications in healthcare directly align with SDG 3 (Good Health and Well-being) by improving diagnostic accuracy, enhancing healthcare accessibility, and optimizing resource allocation (Koebe & Bohnet-Joschko, 2023). In addition, AI-facilitated automation and predictive analytics contribute to SDG 8 (Decent Work and Economic Growth) by increasing operational efficiency and reducing the workload of healthcare professionals (Jarrar et al., 2024). AI-driven monitoring systems promote sustainability in healthcare infrastructures,

supporting SDG 13 (Climate Action) by improving energy efficiency and reducing environmental footprints (Holmner et al., 2012). Lastly, by enabling equitable healthcare access through AI-supported telemedicine and mobile health applications, AI fosters the achievement of SDG 10 (Reduced Inequalities), ensuring that underserved populations benefit from advanced medical technologies (Rajan et al., 2020).

These findings reinforce the transformative potential of AI in enhancing resilient and sustainable healthcare systems on a global scale.

However, despite its numerous advantages, AI in healthcare also raises concerns regarding data privacy, algorithmic bias, and the ethical implications of automation (Mittelstadt & Floridi, 2016). These concerns highlight the necessity for robust governance mechanisms and ethical frameworks to ensure responsible AI deployment. The reliance on AI-driven decision-making raises problems of transparency and accountability, which can undermine trust in healthcare (Rubeis, 2022). Disparities in AI adoption and digital infrastructure between high-income and low-income countries risk exacerbating global healthcare inequalities by limiting access to AI-enhanced medical services in underserved countries (Olu et al., 2019). Despite the existing challenges, the continued advancement of AI-driven KM systems, combined with ethical governance and interdisciplinary collaboration, presents a significant opportunity to create more resilient and inclusive healthcare systems at the global level.

5.1 Theoretical and practical implications

Several theoretical and practical implications emerged from the research. From a theoretical perspective, this study contributes to the existing literature on AI and KM in healthcare by offering a dual analytical perspective (through bibliometric and thematic analysis), allowing for a holistic understanding of how AI-driven KM intersects with sustainability objectives. It reinforces the notion that AI is not merely a tool but a strategic enabler of knowledge dissemination, decision support, and healthcare transformation (Taherdoost & Madanchian, 2023). Furthermore, this research highlights the increasing importance of interdisciplinary collaboration in AI research. The prevalence of international co-authorships and multi-sectoral contributions suggests that AI in healthcare is an inherently cross-disciplinary field requiring expertise from medicine, data science, and policymaking. The study expands the discourse on AI governance by underlining the importance of regulatory frameworks in shaping technological adoption, thereby contributing to the broader theoretical debate on responsible AI implementation.

From a practical standpoint, the findings suggest several implications for healthcare policymakers, practitioners, and industry stakeholders. First, AI-driven KM systems can optimize resource allocation, particularly in underserved regions, supporting SDG 10 by ensuring equitable healthcare access (Rajan et al., 2020). Second, according to Jarrar et al. (2024) AI can contribute to SDG 8 by enhancing workplace efficiency and minimizing occupational hazards through predictive analytics. Third, in alignment with climate change actions and, in particular, SDG 13, AI-driven monitoring systems can promote energy efficiency and environmental sustainability in healthcare infrastructures (Holmner et al., 2012). These implications demonstrate that AI is revolutionizing healthcare and catalyzing broader socio-economic and environmental transformation.

5.2 Limitations and future research avenues

Despite offering valuable insights, this study presents some limitations. First, the bibliometric analysis relies on structured metadata from scientific databases, which may not fully capture qualitative insights regarding AI implementation in real-world healthcare settings. Future research could complement this approach with other methodological approaches, such as case studies and expert interviews, to provide a more comprehensive understanding of AI adoption. Second, the thematic analysis conducted using Leximancer effectively identifies conceptual relationships but does not account for sentiment analysis or contextual variations in AI applications. Future studies could integrate Natural Language Processing (NLP) techniques to analyze discourse surrounding AI in healthcare, particularly in terms of patient perceptions, ethical concerns, and regulatory challenges. Moreover, future research should explore AI's role in addressing disparities in healthcare access, particularly in developing regions where digital infrastructure remains limited. While AI has the potential to bridge gaps in healthcare delivery, the digital divide may hinder equitable AI implementation. Future studies should investigate strategies for overcoming barriers to AI adoption in underserved areas, including capacity-building initiatives, funding models, and public-private partnerships. Lastly, as AI regulations continue to evolve, there is a growing need to assess the long-term impact of emerging policies such as the EU AI Act on healthcare systems. Future research should examine how regulatory developments shape AI adoption, data governance, and trust in AI-driven decision-making.

6 Ethics declaration

This research did not involve collecting personal data, experimentation on human subjects, or any activity requiring ethical approval. Therefore, no ethical clearance was necessary for the study presented in this paper.

7 AI declaration

No AI tool was used in the development, drafting, or editing of this paper. All content is the result of original human authorship and academic research.

Human-Centered Factors in Generative Artificial Intelligence Adoption: Implications for Employee Well-Being

Antonio Cimino[1], Vincenzo Corvello[1], Francesco Longo[2], Vittorio Solina[2]
[1]University of Messina, Messina, Italy
[2]University of Calabria, Rende, Italy

Abstract

In recent years, Artificial Intelligence (AI) has gained significant attention across disciplines and industries, with the adoption of Generative Artificial Intelligence (GenAI) in organizations accelerating, particularly through the introduction of user-friendly conversational chatbots. While numerous studies have investigated either the factors influencing AI adoption within organizations or the effects of AI adoption on organizational performance, the role of human-centered factors in shaping its adoption and their subsequent impact on employee quality of working life remains largely unexplored. To address this gap, and drawing on socio-technical systems theory, this study proposes a theoretical model investigating the interplay between key human-centered factors, GenAI adoption, and employee quality of working life. Specifically, employee trust in GenAI is identified as a key human-centered antecedent of GenAI adoption. GenAI adoption is conceptualized through two main constructs: GenAI use and GenAI hedonic experience. Workplace well-being is used as the indicator of employee quality of working life. The model is tested using Partial Least Squares Structural Equation Modeling on survey data collected from 214 Italian professionals with experience in using GenAI in their work activities. The findings demonstrate that employee trust in AI positively influences both GenAI use and GenAI hedonic experience, and that these two factors, in turn, strongly impact workplace well-being. Additionally, while trust in AI also directly affects workplace well-being, its impact is weaker compared to the effects of GenAI use and GenAI hedonic experience. This study provides important practical implications for organizations aiming to improving employee well-being through the adoption of GenAI. Additionally, limitations of the study are discussed, along with suggestions for future research directions.

Keywords: Human-Centered Factors, Generative Artificial Intelligence Adoption, Employee Well-Being, Socio-Technical Systems Theory, Trust in Artificial Intelligence

Paper type: Academic Research Paper

1 Introduction

Artificial Intelligence (AI) is one of the most transformative innovations for organizations (Zhang et al., 2025). Recent developments in AI have been largely driven by advancements in Generative Artificial Intelligence (GenAI) (Sengar et al., 2024). Both AI and GenAI have garnered considerable attention across various industries and academic disciplines (Hyder et al., 2019). The McKinsey Global Institute projects that AI could add up to $13 trillion annually to the global economy by 2030 (Bughin et al., 2018). As AI plays an increasingly central role in business environments, research efforts in this area have intensified. The existing scientific literature can be broadly categorized into two main research streams: the first examines the key factors influencing the adoption of AI within organizations, while the second investigates how AI adoption impacts organizational performance. Within the first research stream, prior studies have identified a variety of influencing factors, which can be broadly grouped into five major categories: organizational capabilities (Aroyable et al., 2024; Cimino et al. 2024), management factors (Aljarboa, 2024; Chen and Tajdini, 2024), technological factors (Magno and Dossena, 2022; Al-Emran et al., 2024; Felicetti et al., 2024), external environmental factors (Aroyable et al., 2024; Chen and Tajdini, 2024; Felicetti et al., 2024), and human-centered factors (Cimino et al. 2024; Felicetti et al., 2024). The second stream of research has focused on the organizational impacts of AI adoption. These impacts can be broadly categorized into innovation outcomes (Wael AL-Khatib, 2023; Khan et al., 2024), operational outcomes (Belhadi et al., 2021; Nayal et al., 2021; Necula et al., 2024;), and financial outcomes (Abrokwah-Larbi and Awuku-Larbi, 2023). Despite the growing body of literature examining the factors influencing AI adoption and its organizational impacts, a significant gap remains regarding how AI adoption affects employee quality of working life (Lozie et al., 2024). This study aims to address this gap by integrating the two research streams. Specifically, we focus on human-centered factors that drive AI adoption and explore how this adoption influences employee working life quality. Additionally, we investigate the direct impact of human-centered factors on working life quality and compare the mediating role of AI adoption in this relationship in order to get a holistic view of the interplay among these elements. In particular, the study focuses on GenAI Chatbots adoption, as this represents a recent and significant advancement in AI technology (Sengar et al., 2024).

The remainder of the paper is structured as follows: Section 2 presents the theoretical background, including the proposed model and hypotheses guiding the research. Section 3 outlines the methodology employed. Section 4 discusses the study's results. Section 5 highlights the key findings, while Section 6 presents the practical implications of the work. Finally, Section 7 concludes the paper by addressing its limitations and suggesting avenues for future research.

2 Theory

2.1 Theoretical Background

This study is grounded in Socio-Technical Systems (STS) theory, originally developed by Trist and Bamforth (1951), which explores the interdependencies between the social and technical components of an organization. The social system encompasses individuals and their interactions, while the technical system includes technology, tools, and equipment (Thomas, 2024). According to STS, the successful achievement of organizational goals depends on the effective integration of both systems, ensuring that the technical components align with and support the social aspects. This integration contributes to organizational success as well as plays a crucial role in improving employee working life quality (Davis and Cherns, 1975). Aligned with this perspective, the present study specifically examines how the adoption of GenAI affects employee workplace well-being. Additionally, since AI systems are inherently sociotechnical in nature (van de Poel, 2020), applying the STS perspective enables to understand their dual impact, both technical and social. Specifically, we explore how the social elements (human-centered factors), such as employee trust in AI, interact with the technological dimensions of GenAI, including its use and hedonic experience with the ultimate goal of understanding their impact on employee quality of working life.

2.2 Theoretical Model

This study proposes a theoretical model that investigates the interplay between key human-centered factors, GenAI adoption, and employee quality of working life. Specifically, GenAI Trust (AIT) is identified as a central human-centered antecedent of GenAI adoption, and it is defined as employees' positive perceptions of AI and its potential impacts on their roles and responsibilities (Chowdhury et al., 2022; Kong et al., 2023). GenAI adoption is conceptualized through two distinct dimensions: GenAI Use (AIU), which captures the frequency and intensity of employees' interactions with GenAI chatbots (Al-Emran et al., 2024), and GenAI Experience (AIE), which reflects the hedonic aspects of technology use, emphasizing emotional engagement and enjoyment (Magno and Dossena, 2022). Finally, employee quality of working life is operationalized through the construct of Workplace Well-Being (WWB), defined as employees' perceptions and emotional states regarding their overall satisfaction with their work environment (Pradhan and Hati, 2009). The model examines how AIT influences GenAI adoption through AIU and AIE, and how, in turn, GenAI adoption impacts WWB. Furthermore, it explores the direct effect of AIT on WWB. By analyzing these relationships, the study aims to provide a holistic understanding of the dynamics among all variables included in the model. The proposed theoretical framework is illustrated in Figure 1.

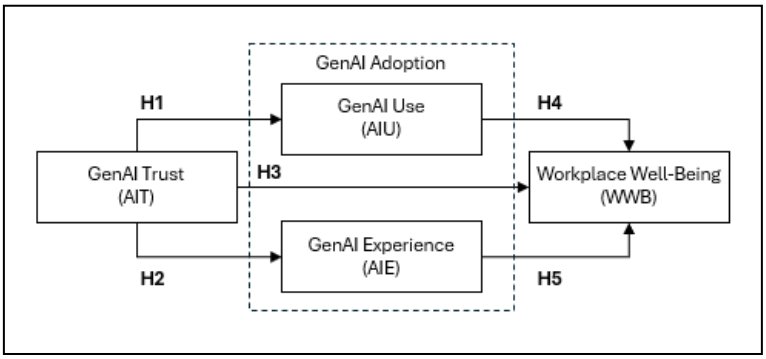

Figure 1: Theoretical Model

2.3 Hypothesis Development

2.3.1 GenAI Trust and GenAI Adoption

GenAI Trust refers to employees' positive perceptions of AI and its potential impact on their roles and responsibilities (Kong et al., 2023). Trust forms the foundation of individuals' interactions with technology (Hoff and Bashir, 2015). Additionally, trust in AI has been increasingly recognized as a key factor for successful AI adoption within organizational settings (Yu et al., 2023; Polisetty et al., 2024). Building on these findings, this study hypothesizes that GenAI Trust positively influences GenAI Adoption across the two identified dimensions: GenAI Use and GenAI Experience.

- H1: GenAI Trust (AIT) positively influences GenAI Use (AIU)
- H2: GenAI Trust (AIT) positively influences GenAI Experience (AIE)

2.3.2 GenAI Trust and Workplace Well-Being

When employees trust AI systems, they are more willing to accept advice and recommendations from these systems (Hughes et al., 2019), which can assist them in making more effective decisions (Kong et al., 2023). The supportive role of technology in decision-making processes has been shown to contribute positively to employees' workplace well-being (Hertel et al., 2019). Furthermore, trust in AI has been linked to increased job engagement (Wang et al., 2021), which fosters proactive working behaviors. These proactive behaviors, in turn, help satisfy employees' motivations (Yu, 2013), and higher levels of motivation are positively associated with improved employee well-being (Van den Broek et al., 2013). Based on these findings, we hypothesize that GenAI Trust positively influences employee Workplace Well-Being.

- H3: GenAI Trust (AIT) positively influences Workplace Well-Being (WWB)

2.3.3 GenAI Use and Workplace Well-Being

GenAI Use can be defined as the extent to which individuals engage with a given technology (Al-Emran et al., 2024). Although Lozie et al. (2024) provide insights into the potential impact of GenAI on employee well-being, they highlight that there is insufficient literature that investigates the effects of a synergy of GenAI use and employee well-being. However, prior research has demonstrated that technology use is positively associated with work engagement (Fujimoto et al., 2016) and job satisfaction (Díaz et al., 2012), both of which are well-established predictors of workplace well-being (Sen and Khandelwal, 2017; Damianus et al., 2020). Based on these findings, we hypothesize that GenAI Use positively impact to employees' workplace well-being.

- H4: GenAI Use (AIU) positively influences Workplace Well-Being (WWB)

2.3.4 GenAI Experience and Workplace Well-Being

GenAI Experience is associated with the hedonic goal of using technology, which refers to engaging in an emotional experience (Magno and Dossena, 2022). Previous studies have provided evidence that technology use is associated with positive emotional experiences (Lu et al., 2019), which are known to enhance job satisfaction (Schiopu, 2015; Fischer, 2000). As job satisfaction represents a key element of workers' well-being (Gordon and Matthew, 2011; Sen and Khandelwal, 2017), it follows that emotionally rewarding experiences with GenAI may contribute to improve the quality of employee working life. Based on this reasoning, we hypothesize that GenAI Experience positively influences employees' Workplace Well-Being.

- H5: GenAI Experience (AIE) positively influences Workplace Well-Being (WWB)

3 Methodology

3.1 Measurement Instrument

To achieve the research objectives, we conducted a questionnaire-based survey. The questionnaire was initially developed in English and then translated into Italian using a standard forward and back translation process to ensure linguistic equivalence and cultural adaptability for the Italian version. To ensure that only relevant participants were included in the study, a filter question asking whether the respondents actively used GenAI in their work activities. The items of each constructs were derived from the scientific literature and, where necessary, slightly adapted to align with the specific research context of this study. The complete set of scale items is provided in Table 1. The questionnaire consisted of 21 items, measured on a 7-point Likert scale ranging from "strongly disagree" to "strongly agree".

Table 1: Theoretical model constructs and items

Variable	Items	Measurement items	Source
GenAI Trust (AIT)	AIT-1	I have confidence in the use of Generative AI Chatbots	Adapted from Kong et al. (2023)
	AIT-2	I believe Generative AI Chatbots can facilitate with routine and trivial tasks through automation	
	AIT-3	I believe that Generative AI Chatbots will consistently operate providing adequate and efficient results within a broad spectrum of processes	
	AIT-4	I believe Generative AI Chatbots adoption will result in creation of new jobs	
	AIT-5	I have a positive attitude towards adoption of Generative AI Chatbots	
	AIT-6	I believe Generative AI Chatbots will positively change employee dynamics within the organization	
GenAI Use (AIU)	AIU-1	I use Generative AI Chatbots frequently	Adapted from Al-Emran et al. (2024)
	AIU-2	I spend a lot of time using Generative AI Chatbots	
	AIU-3	I exerted myself to use Generative AI Chatbots	
GenAI Experience (AIE)	AIE-1	I enjoy using Generative AI Chatbots	Adapted from Magno and Dossena (2022)
	AIE-2	The experience of using Generative AI Chatbots is interesting	
	AIE-3	I am happy with the experience of using Generative AI Chatbots	
Workplace Well-Being (WWB)	WWB-1	I am quite satisfied with my job	Adapted from Pradhan and Hati (2019)
	WWB-2	I enjoy meaningful work	
	WWB-3	I attach lots of value to my work	
	WWB-4	My work achievement often acts as a source of motivation	
	WWB-5	My workplace is very conducive	
	WWB-6	My job provides ample scope for career growth	
	WWB-7	I used to maintain a balance between work and home life	
	WWB-8	My employer does care a lot about their employees	
	WWB-9	My work offers challenges to advance my skills	

3.2 Data collection and data analysis

The questionnaire was distributed between December 15, 2024, and February 28, 2025, via email and major social media platforms. To minimize social desirability bias, participants were assured of complete anonymity. Additionally, a statement outlining the academic purpose of the study was included to help reduce common method bias. A total of 238 Italian professionals responded to the survey. However, 24 participants were excluded because they did not use GenAI in their work activities, making their responses irrelevant to the study's objectives. Consequently, 214 responses were retained for analysis. No anomalies were detected in the data, such as repetitive or incoherent answers. The research model and hypotheses were tested using Partial Least Squares Structural Equation Modeling, which was selected due to its appropriateness for studies with relatively small sample sizes (Willaby et al., 2015) and its robustness in exploratory research contexts (Hair et al., 2019).

4 Results

The evaluation process followed a two-step approach: first, the measurement model was assessed to ensure the reliability and validity of the constructs used in the study; second, the structural model was analyzed to examine the hypothesized relationships between variables and to assess their statistical significance.

4.1 Measurement Model

Indicator reliability was assessed by computing indicators loadings, all of which exceeded the recommended threshold of 0.70 (Hair Jr et al., 2021). Internal consistency was assessed using Cronbach's alpha (Hair Jr et al., 2017), the rho_A coefficient (Dijkstra, 2014), and composite reliability rho_C (Hair Jr et al., 2017), with all values exceeding the established thresholds (Hair Jr et al., 2021). Convergent validity was verified through the Average Variance Extracted (AVE), with all constructs exceeding the 0.50 threshold (Hair et al., 2019). These results are reported in Table 2. Furthermore, discriminant validity was evaluated using the Fornell-Larcker criterion (Fornell and Larcker, 1981). The analysis confirmed that each construct shared more variance with its own indicators than with other constructs, thereby supporting the discriminant validity of the model (see Table 3).

Table 2: Reliability, consistency and validity measures

Construct	Item #	Indicators loadings	Cronbach's alpha	$Rrho_A$	Rho_C	AVE
AIT	6	0,739-0,863	0.903	0.906	0.926	0.676
AIU	3	0,773-0,909	0.826	0.860	0.896	0.742
AIE	3	0,909-0,942	0.914	0.915	0.946	0.854
WWB	9	0,740-0,847	0.931	0.933	0.943	0.646

Table 3: Discriminant validity

Fornell-Larcker				
	AIT	AIU	AIE	WWB
AIT	0.822			
AIU	0.640	0.861		
AIE	0.696	0.708	0.924	
WWB	0.668	0.727	0.793	0.804

4.2 Structural Model and hypothesis testing

Collinearity among constructs was assessed using the Variance Inflation Factor (VIF). All VIF values ranged from 1.0 to 2.5, remaining well below the recommended threshold of 5, thus confirming the absence of multicollinearity concerns (Hair et al., 2011). Following this, the significance and relevance of the structural model relationships were examined. As presented in Table 4, the results indicate that AIT has a significant positive effect on AIU, AIE, and WWB. In turn, both AIU and AIE positively influence WWB. Specifically, AIT demonstrates the strongest effect on AIE (0.696), followed by AIU (0.640), and a smaller direct effect on WWB (0.144). Among the two adoption dimensions, AIE has a stronger impact on WWB (0.488) compared to AIU (0.289). Notably, the indirect effects of AIT on WWB, via AIU and AIE, exceed its direct influence, underscoring the mediating role of GenAI adoption. Statistical significance of all path coefficients was confirmed through bootstrapping procedures, with all t-values exceeding the critical value of 1.96, indicating robust significance (Hair Jr et al., 2021).

Table 4: Path coefficients - mean, Standard deviation, T values, p values

Path coefficient	Original sample (O)	Sample mean (M)	Standard deviation	T values	P values	Result
AIT → AIU (H1)	0.640	0.643	0.047	13.565	0.000	Supported
AIT → AIE (H2)	0.696	0.697	0.048	14.581	0.000	Supported
AIT → WWB (H3)	0.144	0.148	0.071	2.033	0.042	Supported
AIU→ WWB (H4)	0.289	0.289	0.063	4.594	0.000	Supported
AIE → WWB (H5)	0.488	0.484	0.069	7.036	0.000	Supported

5 Discussion

The findings of this study offer valuable insights into the dynamics between AIT, GenAI adoption and WWB. First, the significant positive effects of AIT on both AIU (H1) and AIE (H2) underscore the central role of trust as a foundational human-centered factor driving the adoption of AI technologies in the workplace. These results are consistent with prior research highlighting trust as a critical enabler of AI acceptance (Yu et al., 2023; Polisetty et al., 2024), suggesting that employees are more inclined to engage with AI tools, both functionally and emotionally, when they perceive them as reliable, beneficial, and aligned with their professional roles. In addition, the stronger influence of AIT on AIE compared to AIU indicates that trust is more closely tied to the emotional and experiential dimension of GenAI adoption. This implies that beyond simply using the technology, employees who trust AI are more likely to derive positive emotions from their interactions with it (Lu et al., 2019).

Second, both AIU (H4) and AIE (H5) significantly contribute to employee WWB, with AIE exerting a stronger influence than AIU. This indicates that while frequent and intense interaction with GenAI tools contributes positively to workplace well-being, the emotional quality of that interaction plays an even more important role. In other words, beyond how often employees use GenAI, it is how they feel during its use that has a greater impact on their overall work-related well-being. This supports prior findings that positive emotional experiences with technology are closely linked to the improvement of the employee working life quality (Gordon and Matthew, 2011; Schiopu, 2015; Sen and Khandelwal, 2017; Fischer, 2000).

Interestingly, the direct effect of AIT on WWB (H3) is weaker than the indirect effects mediated through AIU and AIE. This suggests that trust alone does not automatically translate into improved well-being; rather, its

impact is realized primarily through how employees engage with (AIU) and experience (AIE) the technology. This finding reinforces the relevance of the socio-technical systems perspective, which posits that optimal outcomes arise from the alignment and interaction between social and technical subsystems (Trist and Bamforth, 1951; Davis and Cherns, 1975).

6 Implications

The results of this study offer several important practical implications for organizations seeking to adopt GenAI technologies in ways that support employee workplace well-being. First, the strong influence of AIT on both AIU and AIE highlights the foundational role of trust in successful AI integration. Organizations should prioritize transparent communication and training initiatives that demystify GenAI systems. By addressing concerns about job displacement and emphasizing the supportive role of GenAI in work activities, companies can improve higher trust levels among employees, which is an essential precursor to meaningful adoption. Second, the finding that AIE exerts a stronger impact on WWB than AIU suggests that the quality of user experience with GenAI is more influential than the frequency and duration of use alone. This underscores the importance of user-centered design and intuitive interfaces that make interactions with GenAI effective as well as enjoyable and emotionally satisfying. Organizations should consider involving employees in feedback loops when deploying GenAI tools to tailor experiences that align with user needs and preferences. Third, since both AIU and AIE significantly affect WWB, companies should adopt a holistic AI integration strategy that balances productivity-focused implementation with psychological and emotional dimensions of use. For example, providing time for employees to experiment creatively with GenAI, beyond task execution, could enhance their engagement and contribute to more positive work experiences. Finally, given that AIT also has a direct positive effect on WWB, trust in GenAI should be recognized as a key contributor to employees' well-being. Therefore, organizations should implement trust-building strategies, such as involving employees in AI-related decisions, establishing transparent and ethical guidelines for AI use, and clearly communicating AI's intended role. These efforts contribute to a work environment where employees feel respected and empowered, directly supporting their overall well-being.

7 Conclusions

This study contributes to the growing body of research on AI in the workplace by examining the interplay between human-centered factors, GenAI adoption, and employee workplace well-being through the lens of STS theory. By proposing and testing a model that integrates GenAI Trust, Use, and Experience, the study provides empirical evidence on how trust in AI facilitates its adoption as well as both directly and indirectly (through GenAI Use and Experience) enhances employee well-being. The findings highlight that while both the functional use and the emotional experience of GenAI tools positively impact workplace well-being, the experiential dimension exerts a stronger influence. This underscores the importance of promoting effective AI usage and ensure as well, that interactions with AI are satisfying, and psychologically enriching. Furthermore, the direct effect of AI trust on well-being suggests that building a culture of trust around AI systems is critical to fully realizing their potential benefits for employees.

7.1 Limitations and future research

Despite its valuable contributions, this research study has certain limitations that need to be acknowledged. First, the sample consists of Italian professionals, which may limit the generalizability of the findings to other cultural or organizational contexts. Cross-cultural studies could explore how national and organizational cultures influence these dynamics. Second, the use of self-reported questionnaires may introduce common method and social desirability bias, despite efforts to mitigate these through anonymity and clear academic framing. Future research could incorporate multiple data sources, such as interviews or behavioral data, to reduce these biases. Furthermore, the study uses cross-sectional data, capturing relationships at a single point in time and overlooking the evolving nature of GenAI use. Future longitudinal research could explore how employee perceptions and well-being shift as familiarity and proficiency with these tools grow.

8 Ethics declaration

The authors declare that this study did not require formal ethical approval.

9 AI declaration

The authors declare that generative AI tools were used exclusively for language proofreading.

Navigating the Digital Challenge: A Bibliometric Analysis of Talent Management in the Public Sector

Simona Mormile, Roberta Romano, Emilia Romeo, Gabriella Piscopo, Paola Adinolfi
University of Salerno, Italy

Abstract

In an era of rapid technological advancement, digital transformation has emerged as a critical driver reshaping human resource management in public sector organizations. While talent management has long been a cornerstone in the private sector, the public sector faces unique challenges—including bureaucratic rigidity, limited resources, and evolving workforce expectations—that complicate efforts to attract, retain, and develop skilled personnel. Today, talent management strategies must strike a balance between technological innovation and human-centric approaches that prioritize employee well-being, engagement, and ethical considerations. Despite growing scholarly interest, research on talent management in the context of digital transformation within the public sector remains fragmented across disciplines and methodological approaches.

To address this gap, the present study employs a bibliometric analysis, using the Bibliometrix R package, to systematically map the literature on digital transformation and talent management in public administration. Findings reveal a significant acceleration of academic output from 2020 onward, coinciding with the pandemic-driven digitalization of public services.

Thematic analysis highlights innovation, sustainable development, leadership, and perception as core emerging themes, alongside rising interest in AI and knowledge management. However, areas such as employee well-being, lifelong learning, and digital inclusion remain underexplored.

This paper offers a comprehensive overview of the evolving academic landscape, underscoring the need for future research to integrate both technological and human dimensions of talent management in the public sector. In doing so, it contributes to advancing a more resilient, agile, and inclusive public workforce capable of navigating the challenges of digital transformation while enhancing public value and citizen trust.

Keywords: Talent Management, Public Sector, Digital Transformation, Bibliometric Analysis

Paper type: Academic Research Paper

1 Introduction

In recent years, digital transformation (DT) has emerged as a crucial force reshaping public sector organizations, challenging traditional operational models and calling for innovative approaches to human resource management (HRM) (Enaifoghe et al., 2024). As governments and public institutions grapple with rapid technological advancements, talent management (TM) has gained strategic importance, becoming pivotal to ensuring an agile, skilled, and resilient workforce capable of navigating ongoing changes (Mapuranga et al., 2024).

While the private sector has long adopted sophisticated TM strategies to maintain competitiveness and foster innovation, the public sector faces distinct challenges. Bureaucratic rigidity, limited financial resources, and shifting workforce expectations complicate efforts to attract, retain, and develop talented personnel (Berman *et al.*, 2021). In this context, TM in the public sector transcends the goals of efficiency and organizational performance; it also contributes to the creation of public value, enhances citizen satisfaction, and supports effective policy implementation (Ananthan et al., 2019).

According to Armstrong (2007, p. 390), TM can be defined as "an integrated set of activities to ensure that the organization attracts, retains, motivates and develops the talented people it needs now and in the future." In public administration, this definition takes on added complexity, as technological innovations such as artificial intelligence (AI), big data analytics, and e-learning platforms increasingly permeate HRM processes (Guerra et al., 2023).

Despite the growing relevance of these dynamics, research on TM in the context of DT within the public sector remains fragmented (Kravariti & Johnston, 2020). A systematic and comprehensive overview is needed to consolidate knowledge, uncover prevailing trends, and guide future research and practice.

Therefore, the present study employs a bibliometric analysis to systematically investigate the literature on DT and TM in the public sector. Leveraging the bibliometrix R package (Aria & Cuccurullo, 2017), this study aims to map the conceptual, intellectual, and social structures of the research field, thereby providing a thorough understanding of how DT is redefining TM practices in public organizations.

Specifically, the objectives of this study are: (i) to identify key scholarly contributions and trends in TM within the public sector; (ii) to examine how DT has impacted TM strategies; and (iii) to highlight dominant research themes on the topic.

2 Literature review

TM has traditionally been associated with the private sector, where organizations pursue competitive advantage through the strategic attraction, development, and retention of talented individuals (Ariss et al., 2014; Collings & Mellahi, 2009; van Zyl et al., 2017). In the public sector, however, TM assumes a broader societal role, contributing not only to organizational performance but also to the delivery of public services, citizen trust, and overall public value (Ananthan et al., 2019; Osborne et al., 2016). The unique characteristics of public organizations—such as bureaucratic processes, budgetary limitations, and political influences—create distinct challenges for the design and implementation of TM strategies (Berman et al., 2021).

Historically, public administrations have prioritized equal employment opportunity and merit-based recruitment over proactive talent identification and development (Poocharoen & Lee, 2013). Nonetheless, recent reforms aimed at modernizing public services emphasize the need for strategic human resource (HR) practices that can enhance flexibility, responsiveness, and innovation in public sector workforces (Reina & Scarozza, 2021).

In this context, DT is profoundly altering the way public organizations manage HRs. Technologies such as AI, big data, cloud computing, and digital collaboration platforms have introduced new methods for recruitment, training, performance evaluation, and employee engagement (Enaifoghe et al., 2024; Guerra et al., 2023). These innovations offer opportunities to enhance efficiency, personalize career development pathways, and foster continuous learning ecosystems within public institutions.

At the same time, DT presents significant challenges, including issues related to data privacy, algorithmic bias, and the digital divide among employees (Shahi & Sinha, 2021). Successful integration of digital tools into HRM requires not only technological infrastructure but also a cultural shift toward greater openness, agility, and trust in digital processes.

As digital technologies become embedded in public sector HRM practices, TM strategies must evolve accordingly. In this respect, the literature suggests that TM must balance technological adoption with human-centric approaches that prioritize employee well-being, engagement, and ethical considerations (Sadeghi, 2024).

Although studies have examined specific aspects of DT and TM in public organizations, a fragmented research landscape persists (Kravariti & Johnston, 2020). Existing contributions are dispersed across diverse disciplines, theoretical frameworks, and methodological approaches, making it difficult to obtain a coherent understanding of the field. Therefore, there is a need for a systematic synthesis that identifies dominant research themes, theoretical underpinnings, and methodological trends. Addressing these gaps will be critical to building a robust body of knowledge that can inform both theory and practice.

3 Methodology

A bibliometric analysis is a quantitative approach that investigates academic literature by analyzing bibliographic data, with the aim of describing, assessing, and tracking research outputs (White & McCain, 1998; Garfield, 2004).

The process was divided into two main phases: the first involved data collection and refinement, while the second consisted of a bibliometric analysis of the collected data.

3.1 Data Collection and Refinement

The research has been divided into sub-phases (Figure 1).

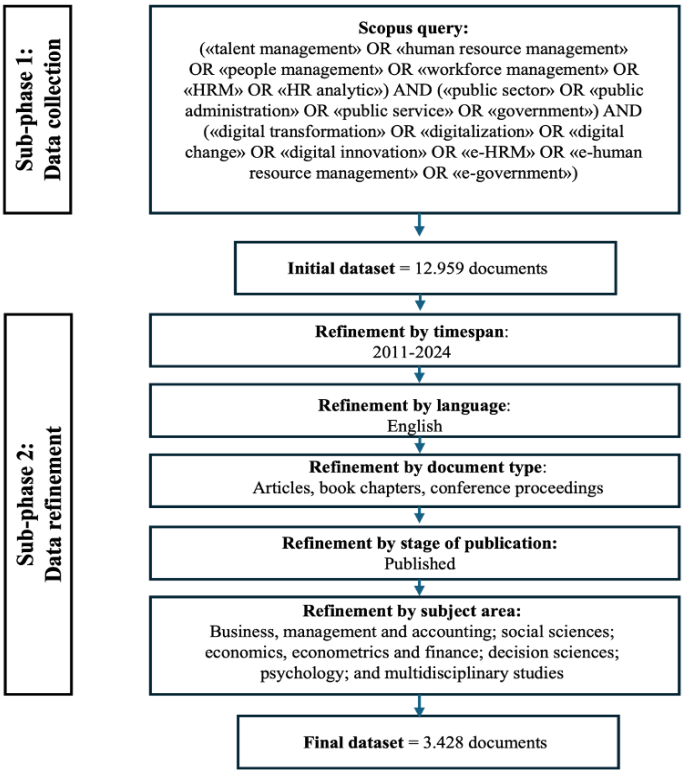

Figure 1: The Data Collection and Refinement Phase

Source: authors' elaboration

In the initial sub-phase, data were retrieved from Scopus, one of the most comprehensive and widely utilized databases among researchers (Singh et al., 2021). The search was carried out on January 10, 2025, employing targeted keywords and Boolean operators.

Compound expressions were placed in quotation marks to maintain their semantic unity, while "AND" and "OR" operators were used to refine results and include synonyms, reducing the risk of excluding relevant studies.

In the field of titles, abstracts, and keywords on Scopus, the following search string was esmployed: "talent management" OR "human resource management" OR "people management" OR "workforce management" OR "HRM" OR "HR analytic" AND "public sector" OR "public administration" OR "public service" OR "government" AND "digital transformation" OR "digitalization" OR "digital change" OR "digital innovation" OR "e-HRM" OR "e-human resource management" OR "e-government".

This query yielded 12,959 documents.

In the second phase, several exclusion criteria were applied.

First, it was considered a thirteen-year research period (2011-2024). This choice is due to the fact that the topic has gained traction since 2011, the year in which the first articles were published.

Second, only English-language articles, book chapters and conference proceedings that have already been published and in open access were included, while excluding other types of papers.

Third, categories unrelated to the focus of this study were excluded, such as mathematics, medicine, and energy. Instead, the following subject area were included: business, management and accounting; social sciences; economics, econometrics and finance; decision sciences; psychology; and multidisciplinary studies.

The final dataset comprised 3,428 documents. Finally, the data were downloaded in CSV format, then analyzed using the Bibliometrix tool (Aria and Cuccurullo, 2017). This open-source tool facilitates comprehensive bibliometric analysis by employing specialized tools for bibliometric and scientometric research.

3.2 Data Analysis

Scientific output of publications was analyzed, considering both annual output and country-specific contributions. The analysis of annual production provided insight into the development of the topic over time, while the analysis by country highlighted the global scope of the topic.

3.2.1 Trend topic

Trend topic analysis made it possible to reconstruct the evolution of research topics on TM in public administration in relation to DT. After keywords were extracted, a time distribution was constructed for each term, calculating its median, first and third quartiles. Each word was thus associated with a reference year (the median). The results were represented in a scatter plot, where the horizontal axis indicates time, the vertical axis indicates the most frequent terms, the size of the bubbles reflects frequency, and a gray bar shows the time span of term use.

3.2.2 Conceptual structure

The conceptual structure of the publications was analyzed through bibliometric techniques, generating clusters that provide a broader understanding of the diversity of research within a specific scientific domain (Börner et al., 2003). The methodological foundation of this analysis lies in the premise that the co-occurrence of key terms (e.g., author- or journal-assigned keywords) reflects the content of documents within a dataset (Callon et al., 1991). The greater the number of shared keywords between two documents, the higher the likelihood that they belong to the same research field or specialty. Keywords appearing together in a document are connected in a co-word network.

By applying the Louvain clustering algorithm to this network, distinct thematic areas within a given domain can be identified. This thematic network is visualized on a two-dimensional matrix, where the axes are defined by the centrality (Callon centrality) and density (Callon density) of the thematic map.

The two-dimensional matrix identifies four thematic quadrants (Callon et al., 1991; Courtial, 1994; Coulter et al., 1998):

1. Motor themes (upper-right quadrant): highly relevant and well-developed.
2. Basic themes (lower-right quadrant): highly relevant but underdeveloped.
3. Emerging or declining themes (lower-left quadrant): less or very relevant and underdeveloped.
4. Niche themes (upper-left quadrant): less relevant but highly developed.

Each theme represented on the matrix corresponds to a cluster in the network. The name of the bubble denotes the term with the highest frequency in the cluster, while the size of the bubble is proportional to the term's occurrences within the cluster.

4 Findings and discussion

This study conducted bibliometric analyses to assess the research performance and thematic evolution of TM within the public sector.

4.1 Research Performance

The analysis of annual production traces the evolution of scientific interest over time, while the analysis by country reveals the geographic distribution of research and the areas of greatest academic significance. The integration of these two perspectives provides a comprehensive view of the phenomenon, combining temporal dynamics and spatial spread.

4.1.1 Annual production

The analysis of scientific annual output (Figure 2) revealed a dynamic and uneven growth pattern. In the early years (2010–2017), the output remained relatively modest. This period can be associated with the "emergence phase" of the topic, characterized by sporadic contributions and the gradual establishment of a scholarly base.

From 2018 onwards, the number of publications began to increase significantly, indicating a transition to a "growth phase", with a notable acceleration after 2020.

The analysis highlights that the scientific production on TM in the public sector, particularly within the context of DT, has accelerated significantly, reaching its peak in 2024. This trend appears to be the result of a set of factors that intensified in 2020, decisively shaping the research landscape.

The year 2020 marked a turning point for the public sector, which was compelled to undergo rapid digitalization due to the global pandemic. This abrupt shift renewed scholarly interest in understanding how public administration can adapt to a new digital reality, particularly in terms of managing the talent required to lead such transformations (Brunetti et al., 2020). Thus, the surge in scientific output can be a response to the growing need for modern and effective HRM strategies to support digitalization in the public sector.

The acceleration of digitalization also redirected research efforts towards topics such as the development of advanced digital skills within the public sector (Chinn et al., 2020), an area that had previously received limited attention. Consequently, researchers have increasingly focused on exploring the implications of TM in this new context, aiming to identify models and best practices for attracting, developing, and retaining digital talent essential for successful transformation (Gilch & Sieweke, 2021).

The year 2024 marks the peak of the production curve, reaching over 1,100 articles and situating it within the highest quartile (Q4) of the observed period. This finding suggests a moment of maximum maturity and widespread attention in the academic community, generating new insights and opportunities for investigation.

The intensification of funding and investment initiatives, particularly in digital skill development (Eichhorst et al., 2022), also likely played a role in boosting scientific output. These investments had a notable impact on HR policies within the public sector, reinforcing the need for evidence-based approaches to guide political and administrative decision-making (Berman et al., 2021).

The 2024 peak represents the culmination of a critical phase of reflection and knowledge consolidation, with scientific research playing and continuing to play a fundamental role in identifying practical and theoretical solutions for effective TM in the public sector.

However, 2025 shows a sharp decline in the number of publications. This abrupt drop could be partially explained by the data collection cut-off in early 2025, which means that the contraction represents an incomplete yearly dataset. Further investigation is needed to confirm whether the decline in 2025 is structural or contingent.

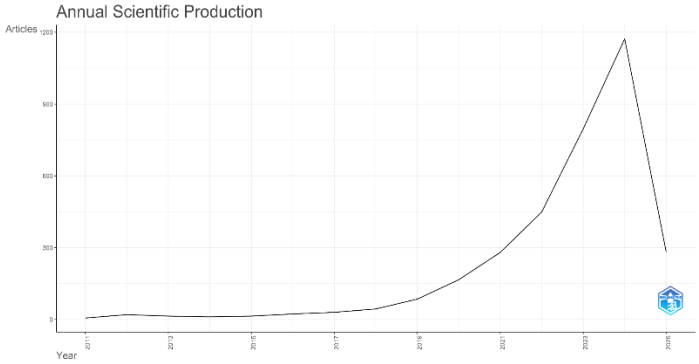

Figure 2. Annual scientific production
Source: authors' elaboration through Bibliometrix software

4.1.2 Country-specific production

Geographical analysis of scientific production reveals a highly heterogeneous distribution of literature on TM in the public sector. The map shows that the countries with the most intense production (darker shading) are primarily China, followed by the United Kingdom, Australia, India and United States.

China has emerged as the leading country in terms of publication volume, confirming its prominent role in managerial and organizational research in recent years.

The United Kingdom and the United States also display a significant concentration of articles, reflecting their longstanding focus on HRM in the public sector. Australia follows, suggesting a strong academic specialization in public management (Bleiklie, 2020). India is an emerging contributor, securing a position among the top five countries in terms of scientific output on this topic.

A more dispersed yet less intense presence (lighter shading) is observed across several European countries (Italy, Germany, France, and Spain), parts of Latin America (Brazil and Mexico), and Southern Africa. In contrast, large areas, such as sub-Saharan Africa, Central Asia, and the Middle East, show either minimal or nearly absent scientific production.

The concentration of scientific output reflects a combination of institutional and strategic factors. Countries such as China, the United States, and the United Kingdom benefit from robust academic systems, strong publication pressures (Tennant et al., 2016), and well-established traditions of applied research in public management. The growing involvement of emerging economies such as India highlights the increasing importance of TM in the contexts of administrative transformation and institutional modernization (Zolak Poljašević et al., 2025).

Moreover, Australia's notable presence suggests a particular sensitivity to human capital management in the public sector, likely driven by national reforms inspired by New Public Management (MacDermott, 2008) and

strategic HRM policies. Conversely, the limited output from many African and Middle Eastern countries may be attributed to weaker research infrastructure, lower levels of science funding, or differing academic priorities.

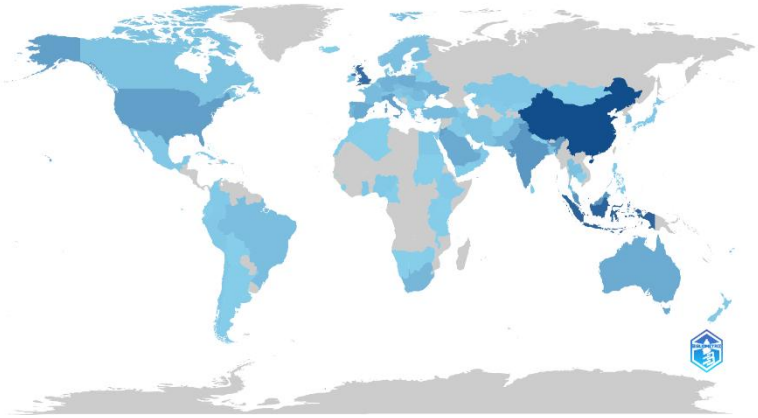

Figure 3. Country scientific production

4.2 Key themes and topics

4.2.1 Trend Topic Analysis

The Trend Topic Analysis reveals a clear evolution of research priorities over time. The horizontal axis represents the temporal reference (based on the median use of terms), while the grey bars indicate the duration of concept usage.

The analysis identified three main phases. In the first phase (2020–2021), the focus was on structural topics such as "knowledge management", "organizational framework", and "information and communication technology." These themes display earlier medians and relatively long duration bars, suggesting a systematic reflection on preparing the public sector for TM in the digital age through organizational restructuring and technological modernization (Hildreth et al., 2021; Porrúa et al., 2021).

From 2022, a second thematic wave emerged, characterized by terms such as "innovation", "sustainable development", "Covid-19", and "human capital". These topics showed more recent medians and shorter duration bars, indicating intense but temporally concentrated attention. Particularly notable is "Covid-19" positioned between 2021 and 2022, reflecting the immediate and time-bound academic response to the pandemic's impact on public workforce management (Azizi et al., 2021). Simultaneously, "innovation" and "sustainable development" gained prominence, highlighting the growing awareness of the need to integrate TM strategies with sustainability and organizational innovation challenges (Mujtaba and Mubarik, 2022).

In the most recent period (2023–2024), the emergence of forward-looking themes such as "artificial intelligence" and "green economy" is evident. These topics, with very recent medians and relatively short duration bars, represent emerging areas of scientific interest. The strong focus on AI suggests a new phase of DT, one that not only updates technologies and practices but also redefines decision-making models and human capital development processes (Fenwick et al., 2024).

Themes such as "complexity", "learning systems", and "information systems" appeared early but have remained less frequent. Their positioning suggests that these are either specialized or transversal concepts that serve more as theoretical frameworks than the central research foci.

Overall, the analysis illustrates how the field of TM in the public sector evolved from an initial phase of infrastructural development to a reactive phase addressing external shocks (such as the pandemic), and finally to a forward-looking phase focused on innovation, sustainability, and the management of new technologies.

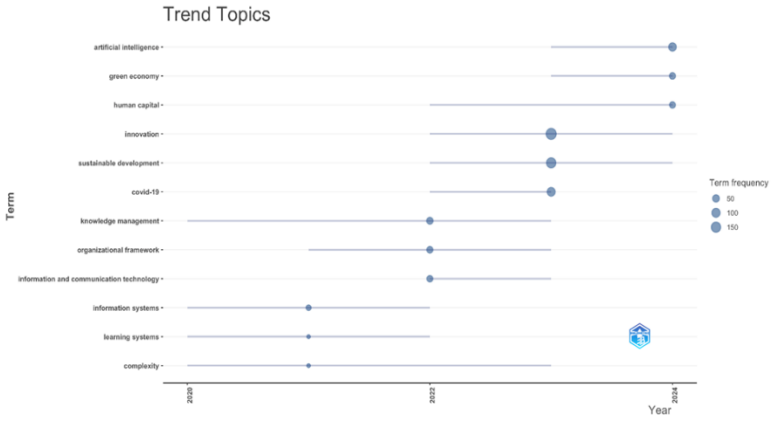

Figure 4. Trend topic analysis
Source: authors' elaboration through Bibliometrix software

4.2.2 Thematic analysis

The thematic map of the keywords extracted from the article sample (Figure 5) illustrates the conceptual dynamics shaping the field, distinguishing the clusters distributed across the four quadrants. In Figure 5, "innovation", "sustainable development", "leadership" and "perception" are positioned close to the line separating the Motor Themes from the Basic Themes quadrant. Their borderline placement indicates high centrality, marking them as fundamental nodes within the keyword co-occurrence network. However, their moderate density suggests that their internal coherence and theoretical/methodological development have not yet been fully consolidated. These themes are thus crucial to the debate but remain explored in diverse or fragmented ways. For instance, "leadership" is central to TM in the public sector but is studied from multiple perspectives, such as transformational, distributed, or innovative leadership, without strong theoretical convergence (Haricharan, 2023). Similarly, while "sustainable development" enters the discussion as a key political objective, its operational and managerial linkage to TM still requires consolidation. In short, they represent both established foundations and fertile grounds for new research and model development.

Additionally, the cluster including "decision making", "artificial intelligence", "digital transformation", and "knowledge management" is located near the boundary between the Niche and Motor Theme quadrants. Their high density indicates a rich and well-structured conceptual base with numerous interconnected studies and solid theoretical underpinnings. Although these themes currently show slightly lower centrality compared to the core concepts, they are gaining prominence and could soon evolve into full Motor Themes if their relevance continues to grow. In particular, the proximity of "artificial intelligence" and "digital transformation" to the Motor Themes quadrant suggests that the DT of the public sector, and its implications for TM, is an emerging and promising frontier for future research (Damar et al., 2024; Shava & Ndebele, 2024).

Conversely, the keywords "human", "social media", "learning", and "working conditions" appear in the lower-left quadrant and are typically associated with either emerging or declining topics. Their low centrality (limited connections with dominant themes) and low density (weak internal development) suggest that they are emerging areas of interest. For example, references to "social media" may point to a nascent but growing focus on the use of digital platforms to attract and manage public sector talent (Mihalcea, 2017). Despite their current marginality, these topics touch upon "soft" and cultural dimensions of HRM, such as well-being, learning, and digital identity, which could become increasingly critical as workplaces continue to evolve into more hybrid and digital environments.

Looking forward, more attention to these aspects could foster a more holistic approach to public sector TM, integrating both hard skills (technology and performance) and the relational and social dimensions of work.

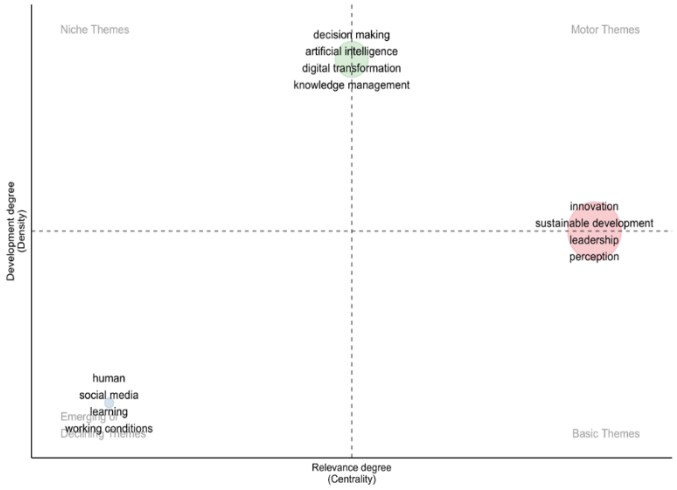

Figure 5. Thematic map
Source: authors' elaboration through Bibliometrix software

This analysis provides a detailed overview of the literature on TM in the public sector, highlighting that areas such as innovation, sustainable development, leadership, and perception have emerged as consolidated and strategic themes. This suggests that talent is often framed not merely in terms of competencies and HR, but as a critical driver for organizational innovation and the advancement of sustainable development goals within the public sector (Tunio et al., 2024; Mohammed et al., 2018).

Similarly, domains such as decision-making, AI, DT, and knowledge management exhibit high density but lower centrality. This pattern indicates that while digitalization and technological innovation are progressively reshaping TM paradigms, these topics have not yet been fully integrated as core themes in the literature. Conversely, concepts such as human, social media, learning, and working conditions appear underdeveloped and less central. This could reflect either underexplored research areas or practical dimensions, such as organizational well-being and continuous education, that have yet to be systematically addressed in academic studies.

Overall, the literature on public-sector TM is strongly oriented toward strategic and leadership aspects (Thunnissen & Buttiens, 2017), with growing attention paid to DT processes. At the same time, it reveals a significant potential for future research on more "human-centred" topics, such as working conditions, lifelong learning, and the role of social media, which currently remain marginal or underrepresented.

5 Conclusions

This study provides a comprehensive bibliometric analysis of the evolving field of TM in the public sector during the era of DT. The findings illuminate a rapidly expanding and diversifying body of knowledge, marked by a surge in academic production following the COVID-19 pandemic and the consequent acceleration of digitalization. The thematic analysis reveals that while core concepts such as innovation, leadership, and sustainable development have gained substantial scholarly attention, more human-centered themes—such as employee well-being, social media, learning, and working conditions—remain comparatively underexplored.

Conceptually, the literature reflects a growing awareness that TM in the public sector is no longer limited to administrative efficiency or traditional HR functions. Instead, it is increasingly perceived as a strategic enabler of digital transition and public value creation. This reconceptualization calls for a deeper integration of technological advancements—such as AI and knowledge management systems—with ethical, inclusive, and development-oriented approaches to managing human capital.

For practitioners, these findings underscore several actionable implications. First, public sector managers must adopt a dual approach that integrates digital competencies with the promotion of employee engagement and well-being. DT should not merely be a technological upgrade but a catalyst for rethinking organizational culture, leadership models, and career development pathways.

Second, investment in continuous learning systems and digital literacy programs is crucial to sustaining workforce adaptability. Public administrations should institutionalize lifelong learning as a core element of TM, enabling employees to navigate evolving digital tools while fostering innovation and resilience.

Third, the increasing relevance of AI in HRM processes necessitates a careful balance between algorithmic efficiency and human oversight. Ethical guidelines and transparent governance mechanisms should accompany

any digital deployment in recruitment, performance evaluation, or workforce planning to prevent bias and protect employee trust.

Finally, the underrepresentation of topics such as social media use in recruitment and the nuanced exploration of hybrid work conditions suggests that practitioners can benefit from expanding their HR strategies to include newer, more flexible, and participatory approaches. These tools can help attract younger digital-native professionals while enhancing internal communication and collaboration.

By highlighting emerging and underdeveloped themes, this study offers a roadmap for public administrators, policymakers, and HR professionals to design more robust, inclusive, and future-oriented TM strategies. In doing so, it contributes to building a resilient public workforce equipped to deliver sustainable public value in a rapidly digitizing world.

6 Ethics declaration

This study did not require ethical approval as it did not involve experiments with human participants, personal data collection, or any procedures requiring formal ethical clearance according to the relevant institutional and national guidelines. No ethical authorization was therefore necessary for the research described in this paper.

7 AI Declaration

The authors acknowledge the use of the AI-based translation tool DeepL in the preparation of this paper. DeepL was employed to support the linguistic translation of parts of the manuscript from Italian to English. The authors reviewed, revised, and edited all AI-generated translations to ensure accuracy, clarity, and appropriateness of academic tone and content. No AI tool was used to generate original ideas or conduct data analysis.

Abstract

The adoption of artificial intelligence (AI) has become a strategic priority for organizations of all sizes, driven by pursuit of process optimization, efficiency gains, and enhanced decision-making. Yet, the effectiveness of AI depends not only on technological implementation but on how organizations integrate it with human-centric values –a challenge that remains underexplored in the context of corporate governance and innovation ecosystems.

This paper explores how corporate governance functions as an instrumental factor in institutionalizing human-centric AI adoption, comparing practices across large organizations, SMEs, and startups within the Rome Technopole (RT) innovation ecosystem. We argue that governance plays a critical role in fostering ethical AI adoption, yet human-centricity should not be treated merely as an afterthought. Instead, it must be a constitutive principle, embedded in the design of the innovation ecosystem itself. Using data from the Rome Technopole Observatory on AI, this exploratory study investigates how organizational size shapes AI strategies and perceived alignment with human-centric values. Findings reveal that structural changes (e.g., dedicated AI teams in large organizations) do not necessarily lead to more human-centric practices or perceptions that AI is aligned with human values. This underscores a critical gap: widespread AI adoption does not guarantee alignment with human-centric principles, which highlights the need for governance that fosters human-centricity at a foundational level.

To address this, based on Sangiovanni Vincentelli's meet-in-the-middle principle, we outline the necessary conditions for developing an innovation ecosystem grounded in human-centric principles. Furthermore, we consider organizations as social, dynamic, and adaptable systems and the RT innovation ecosystem as a context-dependent ecosystem responsible for interactions between its organizations. This theoretical exploratory study paves the way for future empirical research into RT and others innovation ecosystems.

In conclusion, this study posits that corporate governance can be an instrumental mechanism for sustaining an innovation ecosystem in which human-centricity is constitutive. These insights are particularly relevant for organizations operating within collaborative innovation ecosystems, and the innovation ecosystem itself, as they emphasize the alignment between technological progress and societal values as a prerequisite for sustainable and integrative innovation.

Keywords: Artificial Intelligence, Human-Centricity, Organizational Structure, AI Governance Practices, Innovation Ecosystems

Paper type: Academic Research Paper

1 Introduction

This study explores AI and human-centricity in organizational contexts. It is important because the effectiveness of AI cannot be measured solely by its capacity to optimize processes and enhance decision-making, but must also align with human-centric principles, such as ethics and social responsibility (Arrieta et al., 2020). While AI adoption is critical for competitiveness, implementation alone does not ensure responsible outcomes. Individual perception significantly influences the development of responsible AI practices. For instance, while algorithmic trading enhances efficiency in finance, lack of oversight can raise concerns about transparency and fairness. Similarly, AI recruitment tools streamline hiring processes yet may introduce bias, underscoring the risks of neglecting human values in AI deployment. Bias remains a risk in AI systems (Agarwal and Mishra, 2021). These cases underscore the need to embed human-centricity as a foundational governance principle in AI's development, implementation, and societal impact —not an afterthought.

To examine how organizations and innovation ecosystems can address AI's development while leveraging human-centric approaches, this study first contextualizes the corporate governance not only as a foundational factor but as an instrumental element, alongside human-centricity as a constitutive one. It then analyzes different organizations approaches in exploiting AI and human-centricity within an innovation ecosystem. Additionally, examining how different organizations approach AI through corporate governance and integrate human-centric approaches into their organizational practices can provide critical insights.

The study focuses on private companies within Rome Technopole (RT), an innovation ecosystem (see Section 3.1), and aims to:

- *Objective 1*: Investigate corporate governance's role in institutionalizing human-centric AI adoption within innovation ecosystems.
- *Objective 2*: Compare AI governance practices and human-centric approaches across organizations of varying sizes (large and SMEs/startups) in RT.
- *Objective 3*: Outline conditions for developing a human-centric innovation ecosystem.

The following research questions guide this work:

- *Question 1*: How can corporate governance instrumentalize the institutionalization of human-centric approaches (e.g., in AI adoption) within innovation ecosystems?
- *Question 2*: What differences exist in AI governance practices and human-centric approaches among organizations (large and SMEs/startups) within RT?

2 Theoretical background

2.1 Corporate Governance as an instrumental factor in an innovation ecosystem

Adner (2017) argues that innovation ecosystems thrive when multilateral actors align around shared objectives and governance structures that incentivize interaction for a focal value proposition to materialize. Granstrand and Holgersson (2020) define innovation ecosystems as an evolving set of actors, activities, and artifacts, and the institutions and relations, including complementary and substitute relations, that are important for the innovative performance of an actor or a population of actors.

From these definitions, the corporate governance of each actor can be seen as an important mechanism in mediating interactions between actors and plays a pivotal role in the effectiveness of the ecosystem. For example, when an actor decides between the complementary or substitutive relation of an artifact within an innovation ecosystem, this decision can lead to the replacement of that artefact, as defended by Granstrand and Holgersson (2020) according to the Schumpeterian creative destruction, potentially causing the decline of established businesses.

This understanding brings us close to the definition of natural/biological ecosystems. While some authors argue that biological metaphors are limited (e.g., Oh et al., 2016; Adner, 2017), Granstrand and Holgersson (2020) revitalize this perspective by systematically incorporating competition and substitution –core dynamics observed in natural ecosystems. This refined conceptualization proves essential for operationalizing the inherent complexity of innovation ecosystems. Management studies should transcend reductionist frameworks to adequately account for systemic heterogeneity, thereby enabling a more nuanced understanding of organizational complexity and the challenges inherent in representing or explaining their emergent characteristics and evolution (Bertolaso, 2022).

Therefore, viewing the ecosystem as an affiliation should not preclude the possibility of also regarding it as a structure. Affiliation pertains to the act of recognizing the system and its symbiotic relationships, whereas structure refers to defining the alignment framework of the multilateral set of partners that must interact for a focal value proposition to materialize. Ecosystem governance hinges on resolving asymmetric interdependence among actors, where success depends on partner alignment. This underscores the necessity of deliberate structuring, not merely organic growth.

Traditional corporate governance frameworks, particularly those rooted in Agency Theory (Jensen and Meckling, 1976), prioritize mechanisms that align managers' actions with shareholder interests. However, this reductionist approach overlooks the complex, relational, and systemic nature of governance in contemporary organizations.

Governance should move beyond pure economic efficiency to incorporate broader, human-centric considerations. This shift passes through aligning both stakeholder theory (Freeman, 1984; Parmar et al., 2010) and institutional theory (DiMaggio and Powell, 1983; Scott, 2008), which emphasize the interdependent and socially embedded nature of organizations, to have a better understanding of the system in its complexity.

This cross-fertilization and integration are important because, as argued by Parmar et al. (2010), stakeholder theory can help address why organizations in similar institutional environments may be structured differently or have different systems and processes; meanwhile stakeholder theory foregrounds how managers across firms differentially interpret the role of the same institutions and thus create different roles for them in the value creation process. For example, the relationship of different stakeholders within an ecosystem can be shaped also by institutional pression.

Thus, while governance establishes the formal structures and rules that shape organizational roles within an ecosystem, its effectiveness ultimately depends on the deeper institutional processes that guide behavior, decision-making, and strategic action. Stable social and economic systems are maintained not only by explicit governance mechanisms, but also by underlying norms, belief systems and cultural traits.

In this sense, an effective innovation ecosystem requires more than defined corporate governance structures but a collective mindset, aligning the determined governance with the institutional force. Such alignment enables governance to support not only adaptation but also sustained innovation and creating long-term values in complex and dynamic ecosystems.

2.2 Human-centricity as a constitutive condition

An innovation ecosystem involves human, social, intellectual, and financial capital, as well as culture and technology (Carayannis and Campbell, 2009). The lives of the people who compose it are the driving force behind the innovation ecosystem; furthermore, histories and relationships form its properties (Bertolaso and Sangiovanni-Vincentelli, 2024). Thus, the human factor is a foundational element of organizations and innovation ecosystems, on which governance and decision-making processes are based.

The *meet-in-the-middle* principle (Sangiovanni-Vincentelli, 2007) translated to innovation management (Bertolaso and Sangiovanni-Vincentelli, 2024) represents the most effective governance mechanism for innovation ecosystems pursuing collective objectives –e.g., promoting regional economic growth and sustainability. This efficacy stems from its capacity to create strategic interfaces where institutional top-down initiatives (e.g., policy frameworks, mission-oriented programs) productively intersect with organic bottom-up responses (e.g., entrepreneurial experimentation, grassroots solutions). By creating a collaborative dynamic, this principle enables high-level demands are not only imposed but inspire adaptive and creative solutions. Consequently, innovations are inherently sustainable, relational, and holistic.

Human beings are inherently relational (Bertolaso, 2022). By examining these relational dynamics –including axiological reference points– we can better understand interactions among individuals, teams, and leaders, as well as the impact of strategic interventions for the construction and pursuit of a common good/common aim. We are particularly interested in exploring how organizations perceive human-centric approaches. Following Bertolaso (2024), we define human-centricity as an epistemic and operational paradigm that places human principles and therefore values, lived experiences, and participatory co-creation at the core of innovation processes. This approach prioritizes the systemic/dynamic integration of human values, cognitive and affective experiences, and co-design principles, ensuring that solutions are not only functional but also ethically and socially meaningful. Unlike user-centered design, which prioritizes usability, the human-centric paradigm addresses broader systemic needs (e.g., ethical, social) and emphasizes co-creation, making it integral to sustainable innovation.

Within innovation ecosystems, human-centric approaches prioritize regional or communal inhabitation as a primary determinant of design (Bertolaso and Sangiovanni-Vincentelli, 2024), emphasizing human needs and values. In contrast, systems driven exclusively by organizational growth trajectories adopt a fundamentally different paradigm –one that often subordinates socio-cultural contexts to efficiency or scalability.

2.3 The role of governance in the adoption of human-centric AI

AI itself is not human-centric. Its alignment with human values depends on deliberate design choices –from algorithmic transparency to governance frameworks– that prioritize explicability and ethical accountability. Algorithms cannot fully justify their reasoning; even if they could, human explanations are not merely causal but embedded in social, linguistic, and cultural contexts (Capone and Bertolaso, 2020). This is why people resist "black box" systems: we demand interpretability, reliability, and meaningful justifications (Arrieta et al., 2020).

To make AI human-centric, solutions must address how users interact with machines and their need to understand algorithmic decisions (Capone and Bertolaso, 2020). This aligns with the principle of explicability as a core ethical requirement for AI which combines intelligibility (how the system works) and accountability (who is responsible for its outcomes) (Floridi and Cowls, 2019). For example, AI models must balance performance (e.g., prediction accuracy) with explainability to foster trust and collaboration between humans and machines (Arrieta et al., 2020).

Within an organization, the value of AI largely depends on how organizations adopt and integrate it into their processes (Alsadi and Miller, 2023). Comparative studies suggest that AI enhances decision-making when paired with human expertise (Barcaui and Monat, 2023; Felicetti et al., 2024). Here, corporate governance becomes critical: it translates ethical principles into practice through mechanisms like AI ethics boards (accountability)

and user feedback loops (diversity). Governance also ensures AI aligns with the broader innovation ecosystem's values.

The European Commission's AI High-Level Expert Group outlines seven ethical principles –human agency, safety, transparency, fairness, and others (European Union, 2024)– mirroring Floridi and Cowls' (2019) five-principles framework (beneficence, non-maleficence, autonomy, justice, explicability). Corporate governance must operate these principles by enforcing data protection, risk mitigation, and human oversight and values.

Ultimately, governance bridges the gap between AI's technical potential and its human-centric adoption. By institutionalizing ethical principles, organizations can navigate trade-offs while fostering trust. Challenges require adaptive governance, but the foundation is clear: without structured accountability and human participatory design, AI risks remaining a tool of efficiency rather than a partner in progress.

3 Research design

3.1 Context: the Rome Technopole (RT) innovation ecosystem

The RT is an innovation ecosystem strategically designed (Oh et al., 2016), dynamic, and multi-stakeholder (Granstrand and Holgersson, 2020) in Italy's Lazio region, funded by the National Recovery and Resilience Plan (PNRR). It fosters cutting-edge research in energy, digital transition, and health technologies in Central and Southern Italy through university-industry-government collaboration by a hub-and-spoke model (O'Kelly, 1998). Its stakeholders pursue shared value creation (Porter and Kramer, 2018) via six strategic spokes and eight flagships, for instance related to green energy, AI, health, and digital technologies, which enable competitive–collaborative dynamics (Bengtsson and Kock, 2000; Bacon et al., 2020).

3.2 Methodology

The analysis is based on a sample of 60 respondents, collected through a structured questionnaire administered by the Rome Technopole Observatory on AI (2025) between November and December 2024. Although the questionnaire targeted stakeholders within the RT network, it was anonymous and may have been shared beyond the original audience. Despite this, the responses form two balanced groups:

- *Large organizations* (28 respondents): typically, with more structured internal processes, larger teams, and wider experience in digital and AI implementation;
- *SMEs and startups* (32 respondents): are often characterized by smaller scale, agility, and a focus on innovation and experimentation.

Responses from public administration stakeholders were excluded to maintain alignment with the study's focus on corporate organizational differences. The questionnaire covered topics such as human-centric AI applications, governance policies, and responsible AI practices. Statistical tests were conducted to assess whether response distributions differed significantly between the two groups. The analysis highlights topics where significant or non-significant differences were identified.

4 Findings

4.1 Governance practices and human centricity approaches by organization size

The findings underscore the key role of AI not only in technological solutions but also in shaping organizational structure and competitiveness. These insights are valuable for informing future corporate governance strategies within the innovation ecosystem. Table 1 below presents the responses and the statistical significance of the perceptual differences between large organizations and SMEs/startups.

Table 1: Differentiating between large organizations and SMEs/startups by topic

Topic	**Large organizations**	**SMEs and startups**	**Statistical significance of the difference**
I. Data management tools for AI implementation*	Hybrid (local + cloud) (≈68%)	Cloud only (≈31%) Hybrid (local + cloud) (≈31%) On-premises only (≈28%)	Chi-squared test: p-value = 0.031
II. Presence of a dedicated AI team**	Yes (≈67%)	No (≈63%)	Chi-squared test: p-value = 0.0037

Topic	Large organizations	SMEs and startups	Statistical significance of the difference
III. Number of AI projects developed by the organization***	Majority “more than 20” (≈43%)	Majority “1 to 5” (≈58%)	Chi-squared test: p-value = 0.0002 Mann-Whitney U test: p-value = 0.0008
IV. Perceived process structure for AI adoption*	Not structured (≈3%) Partially structured (≈36%) Well structured (≈36%) Very well structured (≈25%)	Not structured (≈19%) Partially structured (≈34%) Well structured (≈38%) Very well structured (≈9%)	Mann-Whitney U test: p-value: 0.851

* 28 large organizations and 32 SMEs/startups answered this question.
** 27 large organizations and 32 SMEs/startups answered this question.
*** 23 large organizations and 31 SMEs/startups answered this question.

Among the tests presented in Table 1, IV is the only one that does not show statistical significance (p=0.851), indicating that organizational size may not reliably predict how employees perceive process readiness for AI. In other words, both large organizations and SMEs/startups report similar levels of perceived process adoption, regardless of actual resources (I and II) or project volume (III). This perception gap may result from the actual absence of such processes —given that the topic is still relatively new—; or a lack of organizational culture around AI, which leads employees to not being aware of or knowing how to apply existing processes to this domain; or self-reporting biases. Addressing this disconnect may require a human-centric paradigm to (re)design structured processes that align more closely with employees' actual understanding, needs, and practices —thus playing a constitutive role in shaping how organizations approach AI integration.

In contrast, other indicators —the number of AI projects implemented (III), the presence of dedicated AI teams (II), and investment in hybrid data management infrastructure (I)— show statistically significant differences between large organizations and SMEs/startups.

These results suggest that organizational size appears to significantly influence investment in human capital and infrastructure for AI development, as large organizations, compared to SMEs/startups, are more likely to have flexible data management solutions (I) and formalized AI teams (II) due to greater internal resources, operational scale, and strategic focus.

Finally, considering the number of AI projects (III), the findings indicate that large organizations are significantly more advanced than SMEs/startups in terms of AI implementation. The gap is both quantitatively and statistically significant, indicating that organizational size and resource availability play key roles in AI project maturity. For example, large organizations were more likely to report the existence of structured approaches to data management and AI deployment, whereas SMEs/startups often reported plans and intentions rather than current implementations. Nevertheless, this structural maturity does not necessarily translate into a widespread perception among them regarding being ready for AI adoption (IV).

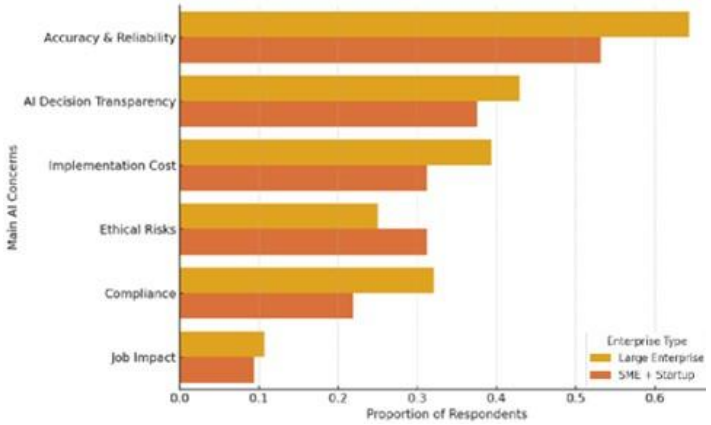

Figure 1: Main concerns regarding AI adoption by organizations

Figure 1 above presents the main concerns organizations have about AI adoption, based on a multiple-response question. There is no statistically significant difference between the perceptions of large organizations and SMEs/startups, indicating a consistent level of concern across both groups. In particular, the concern over “Accuracy & Reliability” reflects a shared underlying issue of trust in AI outputs. In this study, SMEs/startups also reported slightly higher concern about “Ethical Risks,” though this difference is not statistically significant. Most

organizations recognize the need for governance mechanisms to ensure AI is used accurately, transparently, ethically, and responsibly.

Regarding human-centric approaches, although large organizations tend to have more structured AI initiatives (Table 1), this does not result in significantly different views on human-centricity across organization types (Figure 2). When asked about human-centricity (Table 2), organizations consistently acknowledged the benefits of developing human-centered products and services, showing a shared aspiration regardless of organizational size (Figure 2). This suggests that AI adoption alone does not guarantee a human-centric approach, but an effort of understanding and application is needed by organizations. Related findings are presented in the figure and table below.

Table 2: Human-Centric Focused Questions

Human-Centric Focused Questions	**p-value**
Q1 – Stakeholders inclusion & considering social impact of products/services	0.938
Q2 – Developing human-centric products/services as competitive advantage	0.440
Q3 – Designing products/services to adapt to environmental changes	0.704
Q4 – Ensuring equal access to public and private stakeholders	0.503
Q5 – Use of AI to improve user interaction and accessibility	0.802
Q6 – Adapting products/services to market changes & user needs	0.981

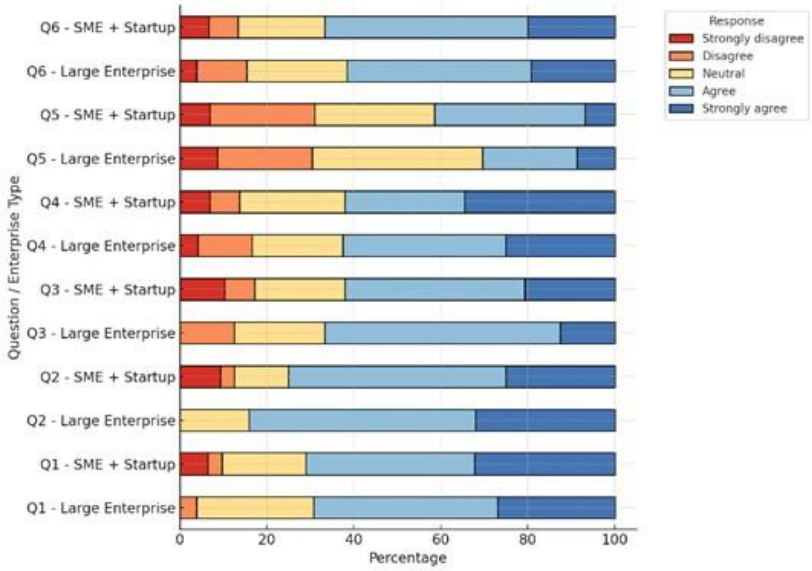

Figure 2: Perceived organizational alignment regarding human-centricity

5 Discussion

5.1 Theoretical contributions

5.1.1 Corporate governance as instrumental

Governance should transcend control, encompassing adaptation to complexity, interdependence, and societal demands. Within innovation ecosystems, organizations should integrate human-centric principles –e.g., grounding the relationship between technology and society in ethics and stakeholder values– into their governance frameworks. This integration responds to both stakeholder demands (Freeman, 1984; Parmar et al., 2010) and institutional legitimacy pressures (DiMaggio and Powell, 1983; Scott, 2008). RT's evidence shows that most organizations view human-centric approaches as beneficial for the business and necessary for the system.

To instrumentalize human-centricity, such as in AI adoption, organizations' governance mechanisms should:

- Mandate participatory design, such as stakeholder inclusion in AI ethics boards or user feedback loops, ensuring AI systems reflect diverse societal needs.
- Enforce transparency, requiring explainability standards for AI outputs (e.g., auditing tools for bias detection) to address the prevalent concern over "Accuracy & Reliability" (Figure 1).
- Incentivize adaptive oversight, such as "human-in-the-loop" policies for high-stakes AI applications, aligning with the finding that 67% of large firms already formalize AI teams (Table 1).

This alignment with human-centricity is critical because technology adoption is socially shaped, as technologies achieve greater impact when implemented through governance that prioritizes epistemic (relational) centrality of individuals (Bertolaso and Sangiovanni-Vincentelli, 2024).

The shift toward ecosystem innovation further necessitates distributed authority, as ecosystem-based innovation models require governance supporting dynamic, adaptive, and relational decision-making, including the establishment of ethical requirements and feedback loops. This means that governance mechanisms should be designed to facilitate trust, collaboration, and co-creation rather than merely enforcing compliance. Given the heterogeneity of actors, we argue that distributed authority and participatory mechanisms enhance ecosystem resilience by aligning incentives and reducing power asymmetries. For instance, divergences in expectations of value creation and value distribution to third parties (Adner, 2017) should be addressed by the *meet-in-the-middle* principle between the RT's actors. For example, RT could adopt tiered governance and integrated communications/training systems, i.e., processes of tailored communication that, while reaching everyone, take into account the local (for companies, institutions, or universities) necessities and the disciplinary sensitivity.

Empirical evidence underscores these challenges: two out of four companies report difficulties in AI integration, with reliability emerging as the primary concern. Yet, this also reveals an opportunity –the potential for innovation and process improvement when governance mechanisms actively address such friction points. From this shift from static to adaptive dynamics, follows that human-centric governance mirrors the institutional evolution towards practices that emulate not hierarchical but complex and dynamic systems, taking into account the epistemological features that intrinsically characterize them.

5.1.2 Human-centricity as constitutive

From section 2, we infer that organizations can integrate human-centric principles into governance due to stakeholder demands but also through institutional legitimacy. From section 3, we argued that human-centricity must be embedded as a constitutive condition of the innovation process, requiring adaptive governance models that account for organizational complexity.

Furthermore, the research reveals that AI alone does not inherently lead to a human-centric approach, but achieving this objective requires deliberate and strategic efforts that go beyond technological adoption. For example, even as part of the same innovation ecosystem, varied sizes of organizations may find diverse types of challenges to exploit AI tools. Thus, we infer that structural or cultural factors could lead human-centric approaches to become constitutive in innovation ecosystem, which can be addressed by the governance.

Innovation ecosystems require governance that is both structured and flexible to accommodate emergent behaviors. In the context of AI adoption, this translates to frameworks that set minimum ethical standards while allowing organizations autonomy to adapt these standards to their specific contexts and communities. In this regard, we argue that the corporate governance of organizations part of the same innovation ecosystem should, to a minimum degree, agree on shared principles.

5.2 Limitations and future research

Other contextual factors, in addition to company size, may influence the findings within the RT innovation ecosystem. Future research could deepen this analysis, including longitudinal studies, public sector analysis, or qualitative investigations to better understand AI adoption dynamics, governance, and human-centric approaches. For instance, examining whether organizations evolve towards greater human-centricity alongside AI maturity could reveal critical insights about governance adaptability. The widespread adoption of AI governance frameworks –four out of five large organizations in RT have already implemented an AI governance model– presents a timely opportunity to assess the quality and effectiveness of these frameworks. Research could identify whether adoption translates into robust human-centric practices or merely procedural compliance, exploring how these models align with stakeholder-centric values, and what governance gaps persist despite high adoption rates. Qualitatively investigating corporate strategies that integrate AI and human-centric principles, as well as the role of organizations and culture in shaping AI ethics, could further bridge theory and practice within innovation ecosystems.

6 Conclusion

First, this paper correlates stakeholder and institutional theories through epistemological theories; to do so, it relates to the literature on human-centricity, AI, and innovation ecosystems.

Second, it points out that the RT data revealed the potential of corporate governance to be instrumental in maximizing innovations created and used through human-centric approaches within innovation ecosystems. To

achieve this, AI adoption should prioritize human-centricity as a foundational principle, rather than reducing it to an instrumental checkbox in service of efficiency gains that perpetuate unsustainable economic models. Adopting AI is not sufficient to ensure workers develop a proper understanding of associated risks and the importance of human proximity. These discussions —essential for sustainable and effective innovation— can be more appropriately fostered within innovation ecosystems, which allow shared reflection and collective development of ethical principles, especially in contexts where individual organizations may lack the internal capabilities or cultural grounding to do so.

Overall, the study evidence that corporate strategies within innovation ecosystems would benefit from a tailored approach and leveraging the *meet-in-the-middle principle*. Along with that, treating the relational dimension of human beings as the foundation of relationships would benefit the ecosystem. Finally, accounting for the cultural impact and respect for diverse communities should benefit stakeholder engagement and ensure the ecosystem's longevity.

Sustainability and Well-Being in Industry 5.0: A Systematic Literature Review

Barbara Iannone, Marialuigia Di Giampietro
University “G. D'annunzio” of Chieti-Pescara, Pescara, Italy

Abstract

This study proposes a systematic literature review aimed at analyzing three key thematic areas: the conceptual and operational adoption of new operational paradigms related to the use of technology in the business environment (Industry 5.0), sustainability strategies in new business models (sustainability) and the concept of well-being in the workplace. The study examined 21 scientific articles selected from the Scopus and Web of Science databases, published in the period 2020-2024, considering the following keywords: industry 5.0, sustainability and well-being. The results highlight the crucial role of advanced technologies - such as artificial intelligence, collaborative robotics and the Internet of Things - in fostering safer, more efficient and well-being-oriented production environments for workers, with a positive impact on the overall sustainability of industrial systems. The ‘Industry 5.0’ phase is an evolution of the previous Industry 4.0, shifting the focus from pure automation to the enhancement of human capital, the ethical integration of technologies and the promotion of human-machine cooperation. It moves towards a society that is based on the use of technology for a more human, inclusive and resilient society, where technology is at the service of human well-being (Society 5.0). Findings reveal that technology is configured not as an end, but as a means for the improvement of collective well-being and quality of life and lastly for production systems that evolve by placing the person at the center: the goal is to reach the ethical integration of technologies through the human-machine collaboration.

Keywords: sustainability – well-being – Industry 5.0 – systematic literature review

Paper type: Academic Research Paper

1 Introduction

The acceleration of technological progress has profoundly transformed multiple sectors, with significant impacts on social and economic dynamics (Kumar et al., 2024). The main challenge will therefore be to promote a sustainable balance between technological innovation and human capital enhancement, through retraining, professional development and employment resilience strategies.

This study proposes a literature review, aiming to map the main academic contributions, identify emerging trends, and detect possible knowledge gaps. The focus is on three key thematic areas:

1. digitalization (as emerging technologies, and strategic levels for business model transformation and organizational innovations);
2. human capital (as contribution in a work context where digital skills, adaptability and continuous learning capacity become crucial for business competitiveness);
3. sustainability (as an integrated perspective that combines economic performance, environmental impact and social responsibility, outlining new models of shared value creation).

This study will be divided into several stages: in the first part, the three themes of the literature review - sustainability, Industry 5.0 and organizational well-being - will be illustrated and the research questions defined. This will be followed by an illustration of the methodology adopted and the presentation of the main results that emerged. The work will conclude with a critical discussion aimed at highlighting the theoretical and practical implications of the results, as well as proposing ideas for future investigation.

2. From digitalization to the relevant role of human capital in the sustainable development era: literature review

Numerous academic researches have amply highlighted and confirmed that the key factors that have shaped the economic and social scenario in recent years, particularly ‘reinforced’ by the needs that emerged during the Covid-19 pandemic, have been, among others, the advent of digital transformation, sustainable development and human capital, with a focus on organizational and occupational well-being.

2.1 Industry 5.0

The concept of Industry 5.0 (I5.0) emerges as a natural, though not merely incremental, evolution of the Industry 4.0 (I4.0) paradigm, shifting the focus from mere automation and technological connectivity to a more holistic and anthropocentric view of production (Breque et al., 2021). While I4.0 targeted efficiency and productivity through the interconnection of cyber-physical systems, Big Data and Artificial Intelligence (Schwab, 2016), I5.0 integrates these advanced technologies to achieve broader social and ecological goals.

Research in this area explores how digital technologies can facilitate sustainable business models and more environmentally friendly production practices. Finally, resilience addresses the need for industries to be robust and flexible, able to absorb external shocks (such as pandemics or geopolitical crises) and to adapt quickly to unforeseen changes in demand or supply chains. Although the concept is still relatively new and being defined, the existing literature explores its technological, social, economic and ethical implications, highlighting both the immense opportunities for shared value creation and the significant challenges related to implementation, required investments, data governance and the need for an appropriate regulatory framework. If, with I4.0, technology had already profoundly influenced the functioning of organizations (Lasi et al., 2014), with the advent of I5.0 the focus shifts to building a balance between human intervention and intelligent machines, placing greater emphasis on sustainability. The current approach no longer sees technology as a mere substitute for human labour, but rather as a complementary element, capable of fostering an effective collaboration between artificial intelligence and human skills, promoting person-centered innovation (Melnyk et al., 2021).

2.2 Sustainability

Corporate sustainability has undergone a profound transformation, evolving from a niche concept focused primarily on regulatory compliance and philanthropy to a strategic imperative embedded in the core business (Bansal & DesJardine, 2014; Eccles et al., 2014). There is broad agreement in the academic literature that companies can no longer operate by pursuing short-term profit maximization alone, but must consider their environmental and social impact (Elkington, 1998). The Triple Bottom Line (TBL) framework - People, Planet, Profit - proposed by Elkington (1998) remains a key reference point, although its operationalization and measurement still present significant challenges (Norman & MacDonald, 2004). More recently, the focus has crystallized on Environmental, Social and Governance (ESG) criteria, which provide a more structured framework for investors and stakeholders to assess companies' non-financial performance (Gillan et al., 2021; Serafeim, 2020). The research highlights multiple drivers driving companies towards sustainability: increasing pressure from stakeholders (investors, consumers, employees, local communities) (Freeman et al, 2010; Clarkson, 1995), the need to manage emerging risks related to climate change and resource scarcity (Linnenluecke & Griffiths, 2010), the opportunity to gain competitive advantages through eco-sustainable innovation and improved corporate reputation (Porter & Kramer, 2006; Hart & Milstein, 2003), and increasing environmental and social regulation globally.

The literature therefore underlines how the transition towards truly sustainable business models requires a systemic change involving strategy, operations, organizational culture and stakeholder dialogue. In fact, the advent of digitalization has become a key ally to these ends: it pursues greater efficiency in production processes (Ching et al., 2022) and contributes to the development of new ‘cleaner’ business practices with a lower environmental impact (Amjad et al., 2021). Ultimately, there is an increasing move towards a new corporate structure that promotes concrete improvements in its operations from a sustainability perspective (Porter & van der Linde, 1995; Elkington, 2018). There has been growing attention to the application of blockchain technologies in the agri-food sector, highlighting the potential for addressing sustainability issues (Dal Mas et al., 2023). The adoption of sustainable supply chain practices, based on criteria of transparency, traceability and environmental responsibility of suppliers, is also crucial. Ongoing staff training, aimed at developing green skills and promoting a sustainability-oriented corporate culture, is a further strategic element. Finally, the integration of environmental assessment metrics (e.g. LCA - Life Cycle Assessment) into management control systems makes it possible to monitor the impact of activities and guide conscious decisions towards continuous improvement (Wagner, 2010; Rosa et al., 2020; Shi et al., 2024).

2.3 Employee Well-being

Employee well-being has become a central theme in management and organizational studies, evolving from a narrow focus on occupational health and safety to a broader, multidimensional perspective (Guest, 2017). It is now understood not merely as the absence of illness, but as the presence of positive psychological states such as job satisfaction, engagement, purpose, and psychological flourishing (Bakker & Demerouti, 2007; Keyes, 2002;

Seligman, 2011). Empirical evidence has linked high levels of well-being to key organizational outcomes, including improved performance, higher productivity, greater engagement, and reduced absenteeism and turnover (Wright & Cropanzano, 2000; Harter et al., 2002; Lyubomirsky et al., 2005). Moreover, in competitive labor markets, prioritizing employee well-being serves as a strategic advantage for talent attraction, retention, and corporate reputation (Edmans, 2011). However, scholars caution against superficial or instrumental approaches (well-being washing') and stress the importance of authentic leadership commitment and structural integration of well-being into organizational culture and practices (Spicer, 2020). The current challenge lies in designing and implementing well-being strategies that are effective, sustainable, and genuinely human-centered.

In light of these premises, this study aims to answer the following research questions:

- ***RQ1***: What is the current state of research on the three different topics: Industry 5.0, sustainability and employee well-being, investigated 'jointly'?
- ***RQ2***: How does the concept of work and corporate well-being change with the introduction of sustainability-oriented Industry 5.0?
- ***RQ3***: What findings arise from the present study, and what are the prospective avenues for future research?

3 Research design

On the basis of RQs, the authors explore the existing literature and decided to work with a systematic literature review, as according to numerous studies (Calandra et al., 2023; Page et al, 2021) it is an organised, transparent and above all replicable methodology (Tranfield et al., 2003). The purpose of this study is to identify current research trajectories and potential research topics, gaps in existing research and to highlight further and future research topics and suggest a framework. Therefore, it is intended to provide an interdisciplinary and international overview of the current academic debate focused on the proposed topics.

With the present work, the following steps were observed:

1. the first phase consists of the "planning of the review process", as the definition of the objective and purpose of the research (carried out in sections 1 and 2 above) and the description of the review project;
2. the second phase consists of the "conduct of the review process", as the identification, selection, evaluation, and synthesis of the relevant research studies;
3. the third and final phase consists of the "reporting and dissemination of the overall research results", as the descriptive presentation of the findings and the thematic analysis of the journal articles.

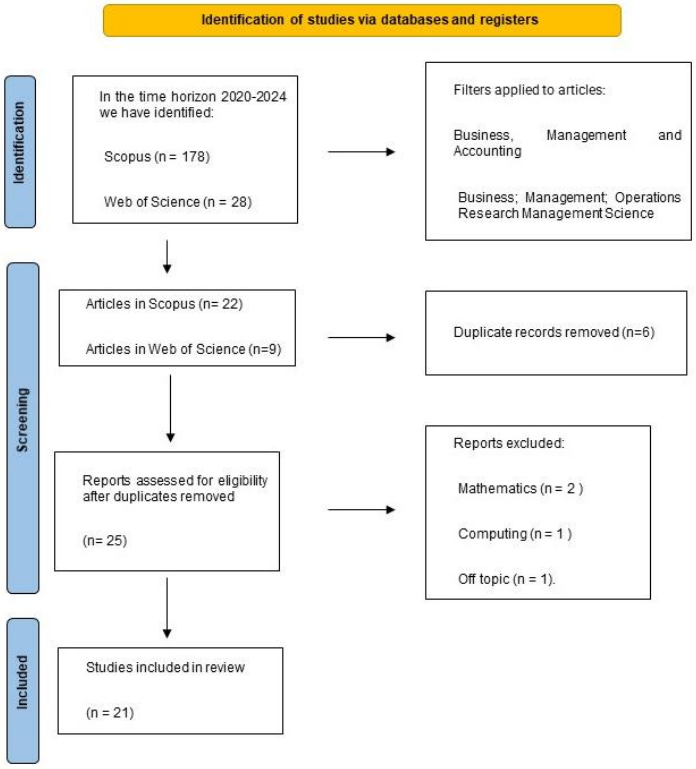

Figure 1: Summary of PRISMA flowchart

4 Results

In order to answer the first research question (RQ1), a summary of the 21 articles identified by the systematic literature review was carried out, first offering a summary table of the articles examined:

Table 1: Selected articles

For this literature review, the selected articles were categorized according to the following criteria: (1) the type of study conducted; (2) the country or geographic region in which the research was carried out (where identifiable); and (3) the sectoral context relevant to the study (where identifiable).

With regard to the type of study, the following four categories have been identified:

1. Theoretical/Conceptual Studies - TCSt (propose models, frameworks, perspectives, discuss concepts) - STC;
2. Literature Reviews - LitRew (they systematically analyze and synthesize existing research on a topic, e.g. systematic literature review SLR, mapping, survey of literature, ...);
3. Case Studies- CaseSt (single or multiple): in-depth investigations on one or more specific cases referring to companies, projects, contexts, in order to understand complex phenomena in their real context. They can be 'exploratory');
4. Empirical Studies - Non Case Study / Applied Methodology - EmSt (collect and analyze primary or secondary data through surveys, experiments, quantitative analysis (e.g. cross-country analysis), or apply/develop specific methodologies with data, without necessarily adopting the depth or holistic approach of a traditional case study.

As far as the country is concerned, it can be stated that the country of reference is not always 'traceable', particularly in Literature Reviews, but it is possible, in general, to outline the nationality of the researchers who have addressed their research interests on these topics. It can be said that, albeit with a good approximation, the articles refer to the following geographical contexts: Europe (Italy, Germany, France), United Kingdom, Brazil, India, Malaysia, Slovenia. Finally, the research showed more reference to companies operating in the manufacturing sector, however there is no lack of curious and interesting research referring, for example, aviation (in Malaysia), automotive (China), the training of students and workers including diversity and soft skills as strategic leverage, transition to supply chains 5.0, the context of the Metaverse and the integration of Urban Agriculture in smart urban environments.

5 Discussion

To answer the second research question (RQ2), the topic of human-robot collaboration (HRC) needs to be analyzed, as it integrates mechanical efficiency with human cognitive, decision-making and relational capabilities. The introduction of collaborative solutions has already shown interesting results such as increased productivity, improved worker well-being and higher product quality, and simulations of human-robot interactions have revealed strategic tools for optimizing task allocation and assessing ESG (environmental, social and governance) impacts. However, current models privilege economic variables, neglecting crucial aspects such as safety, worker motivation and energy efficiency (Ojstersek et al., 2024).

The transition from I4.0 to I5.0 has directed the interests of academia and business towards the topics of sustainability, humanization of production processes and skills development. This has fostered the emergence of new professions in robotics and advanced automation (e.g. mobile robot managers, intelligent machine programmers, robotics assistants, process supervisors) (Kumar et al., 2023).

In this scenario, human capital is at the heart of this transition, as training becomes crucial to combine technical skills with soft skills, such as communication, critical and creative thinking. In particular, emotional intelligence emerges as a crucial competence to foster collaboration in teams and effectively manage complex

situations (Chin, 2021): indeed, an empirical study in Malaysia shows that the integration of experience, corporate loyalty and emotional intelligence qualifies as a strategic lever to enhance organizational resilience and facilitate adaptation to changes induced by industrial evolution. In the I5.0 era, education and training emerged as strategic levers for achieving an innovative, sustainable and inclusive economy. This requires flexible, digitally integrated and continuous learning-oriented training paths throughout the entire working life: dynamic learning environments must be promoted and the creative and innovative potential of employees must be enhanced (Oeij et al., 2024).

The graph elaborated with VOSviewer highlights the evolutionary directions of I5.0, oriented towards the integration of Society 5.0 values and the reaffirmation of the centrality of the human being in innovation processes (Figure 2).

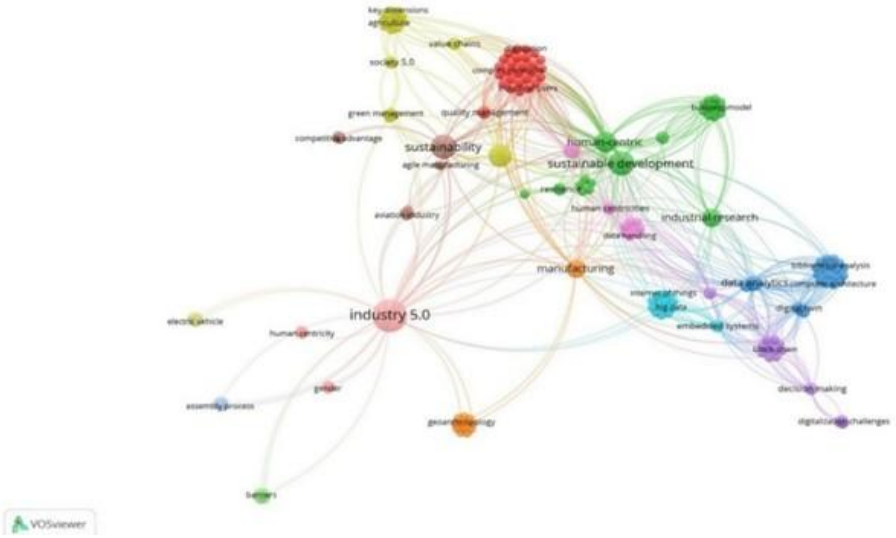

Figure 2: Co-occurrence analysis of keywords

In conclusion, three core aspects characterizing I5.0 (RQ3) are identified:

1. the new modes of training and learning;
2. the obstacles limiting the adoption of modern technologies;
3. the evolutionary trends of the future that introduce I6.0.

Digital serious games represent an interesting innovation in education, as they combine educational purposes with playful dynamics. They offer realistic and safe simulated environments and deal with complex scenarios without incurring concrete risks, developing, on the one hand, motivation and educational effectiveness and, on the other, the acquisition of practical skills (Brauner & Ziefle, 2022).

Among the main barriers to the spread of I5.0 emerge high implementation costs, followed by market uncertainty, lack of technological knowledge, limited access to reliable information and data security concerns, all of which hold back investment (Laddha & Agrawal, 2024).

Looking beyond the current paradigm, research begins to outline the contours of I6.0, characterized by even more advanced human-machine integration, extensive use of artificial intelligence and a more systemic approach to sustainability (Fernández-Miguel et al., 2024).

6 Conclusion

In the I5.0 era, organizational well-being emerged as a critical enabler of sustainable and inclusive transformation. Organizations are thus called to invest in the development of human capital, foster dynamic and continuous learning environments, and promote the integration of technology in a way that is conscious, ethical, and human-centered. The keyword co-occurrence analysis conducted through VOSviewer highlights how digitalization (including digitization), green management, and sustainability converge along the evolutionary trajectory of I5.0, aligning with the values of S5.0 and reaffirming the central role of the human being in innovative processes.

Empirically, despite the emergence of valuable insights and promising approaches, the practical implementation of these innovations remains hindered by significant challenges. Tools such as serious games, performance measurement indices, and other potentially impactful frameworks remain underutilized, often due

to the substantial investments required and the lack of organizational readiness and cultural maturity to embrace them. Additionally, the development of well-structured public policies is crucial to facilitate the integration of advanced technologies and sustainability goals—an integration that is ultimately shaped by human capabilities, which continue to represent the foundational asset of I5.0.

Despite this study is based on a limited body of literature derived from the intersection of selected keywords, this field of research is quickly evolving and needs for the development of integrated quantitative models, new performance metrics (e.g., ethics, well-being), and empirical research—particularly at the different specific sectoral —as well as deeper investigations into human-centered governance practices.

Fostering Knowledge Management to Enhance Innovative Work Behaviour in Public Healthcare Organizations

Abstract

Innovative work behaviour (IWB) may be crucial to enable middle managers of public healthcare organizations (PHOs) to effectively fulfil their hybrid role of doctor-managers. However, psychological and cognitive boundaries associated with role hybridization can inhibit IWB. To overcome these criticalities, knowledge should be dynamically managed within PHOs. Grounded in the social identity theory, the present study aimed to explore the development of knowledge transfer at the individual-level of analysis by investigating the influence of doctor-managers' organizational identification (OI) on their IWB, through the indirect effect of satisfaction with the managerial role. A survey was administered to doctor-managers working in Italian PHOs. A linear regression analysis was performed to test the research design. The findings demonstrated that doctor-managers' OI address a greater satisfaction with the managerial role; in turn, this latter positively influences doctor-managers' IWB. This study provides new insights into the individual determinants of IWB in knowledge-intensive public organizations like PHOs. In doing so, it contributes to the ongoing discussion on the pivotal role of knowledge transfer dynamics as a precursor of IWB by unleashing the potential of OI. PHOs' top management should regulate doctor-managers' identity by providing an environment fostering the transfer of knowledge supporting them in performing their hybrid role. This may be achieved through managerial practices that facilitate vertical and horizontal integration and knowledge exchange.

Keywords: Innovative Work Behaviour, Knowledge Management, Public Healthcare Organizations, Hybrid managers

Paper type: Academic Research Paper

1 Introduction

Innovative Work Behaviour (IWB), as a dimension of innovation processes, has become increasingly relevant in high complex and knowledge-based organizations, such as public healthcare organizations (PHOs)(Richard and Duxbury, 2014). In fact, IWB is a multifaceted concept that involves a set of individual behaviours aimed at intentionally generating and implementing new useful ideas, products, services, or procedures within the organization (Janssen, 2004; De Jong and Den Hartog, 2010)

Managers' IWB plays a key role, as their propensity to innovate has the potential to drive the organization towards innovative outcomes (Damanpour and Schneider, 2009). This is particularly true for healthcare middle management within publicly funded universalistic health systems, like that of Italy. In these systems, the NPM reforms have altered the traditional professional responsibilities and duties of doctors heading operational units (OUs) who have enrolled in middle management positions (Morandi, Angelozzi and Di Vincenzo, 2021). Such enrolment has created "doctor-managers" with clinical–professional autonomy and new tasks as budget holders (Paolini et al., 2025). Therefore, these hybrid managers must strike a balance between the quality of treatments and cost containment. IWB may be crucial to enable doctor-managers to effectively fulfil their dual role.

Nevertheless, psychological and cognitive boundaries can inhibit IWB of these professionals. Indeed, the hybridization of healthcare middle managers (Sartirana, Prenestini and Lega, 2018), combined with a lack of interest in managerial issues and inadequate knowledge and skills to cope with them (Morandi, Angelozzi and Di Vincenzo 2021), exposes these physicians to interpretative ambiguities regarding their dual role responsibilities. Such challenges may lead to harmful psychological responses, which threaten doctor-managers' role satisfaction (Pandey and Raney, 2006) and have the potential to negatively impact their approach to the managerial role. This, in turn, can inhibit their search for IWB.

Among the emerging studies investigating the drivers of IWB, relevant attention has been devoted to the characteristics of individual actors, such as their personal knowledge, skills (Phelps, Heidl and Wadhwa, 2012), and creativity (Tierney and Farner, 2002), as well as to knowledge sharing mechanisms (Mura et al., 2012). Positive organizational scholarship approaches (Cameron et al., 2003; Roberts, 2006; Cameron and Spreitzer,

2011) has highlighted individual and collective strengths (attributes and processes) and how such strengths enable human flourishing (e.g. goodness, growth, and resilience).

However, there are few studies (Lee and Choi, 2003; Avital and Carlo, 2004; Pinho et al. 2011) that analyse these strengths as facilitators of knowledge management (KM) processes, which, in turn, are able to foster IWB.

Knowledge is a valuable intangible resource that should be dynamically managed especially by knowledge-intensive organizations like PHOs, to increase the alignment of individual beliefs, values and goals with the organizational ones. Socio-organizational features represent crucial facilitators affecting KM via several processes supporting knowledge creation, acquisition or distribution to the various organizational actors (Pinho et al., 2011). In this regard, Nonaka and Takeuchi (1995) underscore the pivotal function of socialization mechanisms in facilitating internalization processes and knowledge transfer within organizations.

At the individual level, social identity theory (Tajfel & Turner, 1979) may offer a valuable lens for understanding how knowledge transfer develops. One such form of social identity is organizational identification (OI), defined as the aspect of an individual's self-concept that derives from the perceived oneness with or the sense of belongingness to the organization (Mael & Ashforth, 1992). OI allows individuals to feel themselves as a part of organization (Bergami and Bagozzi, 2000). Being embedded in organizations that encourage the progressive homogenization of beliefs, values, and goals increase doctor-managers' understanding, learning and interiorization of organizational expectations (Ravishankar & Pan, 2008) about how to cope with the responsibilities linked to their dual role. These intangible processes of knowledge transfer, by mitigating role ambiguities, make doctor-managers more psychologically empowered in their hybrid role (Salvatore, Numerato and Fattore, 2018; Di Vincenzo, Angelozzi and Morandi, 2021). These cognitive-psychological benefits, coupled with the enhanced knowledge of their role, may induce doctor-managers to seek and adopt IWB. In particular, along the lines of knowledge transfer, OI may induce a greater satisfaction with the managerial role (De Vries, Bekkers and Tummers, 2016; Fischer & Doring, 2022), which may boost the willingness of search innovation sources and engage with IWB (Radaelli et al., 2014; Di Vincenzo and Iacopino, 2021; Usmanova et al., 2021).Based on this reasoning, this study explores the positive influence of doctor-managers' OI on their IWB, through the indirect effect of satisfaction with the managerial role.

A survey was conducted on 98 doctor-managers working in Italian PHOs.

The remainder of the paper is structured as follows: section 2 presents the background and hypotheses development; section 3 outlines the methodology; section 4 presents the findings; section 5 provides discussion and conclusions.

2 Background and hypotheses development

Among the studies investigating the antecedents of IWB, relevant attention has been devoted to the characteristics of individual actors. A significant amount of research has been dedicated to examining the influence of individual attributes at various stages of the innovation process, from idea generation (Björk & Magnusson, 2009) to the implementation and use of new products, services and processes (Iacopino, Mascia and Cicchetti, 2018). The antecedents of IWB refer to cognitive aspects, such as trust in the superior, openness to new ideas, vitality at the workplace and the development of learning processes (Carmeli and Spreitzer, 2009). Additionally, they pertain to employees' characteristics, including personal knowledge, skills (Madjar, Oldham and Pratt, 2002; Phelps, Heidl and Wadhwa, 2012), empowerment, professionalism, problem-solving capabilities, demographic aspects and satisfaction in the work environment (De Vries, Bekkers and Tummers, 2016). Moreover, the management literature has associated IWB determinants with informal norms and attitudes in organizations, including creativity (Tierney and Farner, 2002; Kessel, Hannemann-Weber and Kratzer, 2012), engagement and knowledge sharing (Mura et al., 2012; Alfes et al., 2013). Only a handful of studies have sought to examine the factors influencing IWB in PHOs. Oppi, Bagheri and Vagnoni (2020) investigated the influence of clinical managers perceived creative self-efficacy and creative collective efficacy on IWB. Di Vincenzo and Iacopino (2021) explored the impact of professional network on physicians' IWB.

Positive organizational scholarship approaches (Cameron, 2003; Roberts, 2006; Cameron and Spreitzer, 2011) highlight individual and collective strengths (attributes and processes) and how such strengths enable human flourishing (e.g. goodness, growth, and resilience). However, there are few studies (Lee and Choi, 2003; Avital and Carlo, 2004; Pinho et al. 2011) that analyse these strengths as facilitators of knowledge management (KM) processes, which, in turn, are able to foster IWB.

Knowledge is a valuable intangible resource that should be dynamically managed especially by knowledge-intensive organizations like PHOs, to increase the alignment of individual beliefs, values and goals with the organizational ones. Socio-organizational features represent crucial facilitators affecting KM via several processes supporting knowledge creation, acquisition or distribution to the various organizational actors (Pinho

et al., 2011). In this regard, Nonaka and Takeuchi (1995) underscore the pivotal function of socialization mechanisms in facilitating internalization processes and knowledge transfer within organizations.

At the individual level, social identity theory (Tajfel & Turner, 1979) may offer a valuable lens for understanding how knowledge transfer develops.

Social identity is defined as the perception of oneness with or the sense of belonging to a group (Mael and Ashforth, 1992). It is that aspect of an individual's self-concept that derives from the awareness of the affiliation with a group, along with the value and emotional significance attached to this affiliation (Tajfel & Turner, 1979).

One form of social identification is OI, which is the extent to which an individual's self-concept contains attributes that are identical to those of the perceived organizational identity. Identification arises when an individual and an organization share common interests that outweigh their differences, and when the individual perceives that their relationship with the organization forms an 'us' (Salvatore, Numerato and Fattore, 2018).

From a cognitive perspective, this intrinsic bond with the organization allows individuals to feel and recognize themselves as a part of organization and to engender a sense of pride, distinctiveness, and enhanced self-esteem (Bergami and Bagozzi, 2000).

OI is correlated with a wide range of work-related positive attitudes and behaviours such as commitment, organizational citizenship behaviours, and job turnover (Van Dick et al., 2006; Salvatore, Numerato and Fattore, 2018). Indeed, individuals who strongly identify with their organization, embodying its values, goals and role organizational expectations, are more likely to positively contribute to its success through positive individual role and extra-role behaviours and performance. According to the IWB construct, being embedded in organizational contexts favouring the progressive homogenization of beliefs, values and goals increase doctor-managers' understanding, learning and interiorization of organizational expectations (Ravishankar & Pan, 2008) about how to cope with the responsibilities linked to their dual role. These intangible processes of knowledge transfer, by mitigating role ambiguities, make doctor-managers more psychologically empowered in their hybrid role (Salvatore, Numerato and Fattore, 2018; Di Vincenzo, Angelozzi and Morandi, 2021). These cognitive-psychological benefits, coupled with the enhanced knowledge of their role, may induce doctor-managers to seek and adopt IWB. In particular, along the lines of knowledge transfer, OI may induce a greater satisfaction with the managerial role (De Vries, Bekkers and Tummers, 2016; Fischer & Doring, 2022), which may boost the willingness of search innovation sources and engage with IWB (Radaelli et al., 2014; Di Vincenzo and Iacopino, 2021; Usmanova et al., 2021).

Based on this reasoning, we elaborated the following research hypotheses:

- *Hp 1: Doctor-managers' organizational identification positively affects their satisfaction with the managerial role*
- *Hp 2: Doctor managers' satisfaction with the managerial role positively affects their innovative work behaviour*

3 Methodology

3.1 Setting

To test the hypotheses, an empirical study was conducted among doctors heading OUs of PHOs situated in two regions in central Italy (Abruzzo and Lazio). The Italian National Health Service is a publicly funded universalistic healthcare system, where the central government provides universal coverage by allocating resources to its 21 regions; the regions, in turn, design the strategic plans and the financing of health services, delegating to PHOs, namely Local Health Authorities (LHAs), the local provision of health services. LHAs have a substantial degree of financial and decision-making autonomy regarding the pursuit of their objectives, in accordance with the principles of effectiveness, resource consumption, appropriateness and quality of health services provided. They are accountable to the regional government for the achievement of these objectives. LHAs' management is entrusted to General Directors, who are appointed by the Region's government. LHAs are organized in departments, which in turn are structured in several OUs, complex and simple, headed by doctor-managers having both clinical and managerial responsibilities.

3.2 Data collection and sample

A questionnaire was administered to doctors heading complex OUs and simple OUs with departmental value. The survey was conducted in person on-site during university courses on managerial training which involved doctor-managers as students. Indeed, the Italian regulation requires the attendance of these managerial annual courses for doctors heading complex OUs and simple OUs with departmental value. Confidentiality and privacy

were guaranteed to prevent the potential for bias, including the possibility of being inclined to report in a more or less complete manner due to social desirability concerns. The participants were provided with a description of the study's purpose and were requested to sign an informed consent form in accordance with the Italian data protection laws. Based on an overall number of 139 participants to the managerial courses, we collected 98 responses, yielding a 70% overall response rate. Most of the respondents identified as male (57%), with the remaining 43% comprising female participants. The mean age was found to be 56 years, with a range from a minimum of 38 years to a maximum of 69 years. The average of tenure in managerial positions was found to be approximately 8 years, with a range from a minimum of 0 years to a maximum of 44 years. 16% of respondents declared having held an academic position.

3.2.1 Questionnaire

The questionnaire collected attributional data from respondents (including their age, gender, and tenure in the managerial position), their sense of OI, satisfaction with the managerial role and IWB. The measurement scales are described below.

Organizational identification. This measure was developed according to the Bergami and Bagozzi's (2000) graphic scale used in healthcare settings (Salvatore, Numerato and Fattore, 2018; Di Vincenzo, Angelozzi and Morandi, 2021). The scale conceptualizes identification in terms of cognitive distance between an individual and a collective. It is articulated in two circles with a degree of overlap that varies within a range of eight potential alternative responses, ranging from complete separation to complete overlap.

Satisfaction with the managerial role. A single item scale reproducing the job satisfaction scale of Warr, Cook and Wall (1979) was used to measure doctor-managers' satisfaction with the managerial role ("Taking everything into consideration, how do you feel about your managerial job?'') . The response range has been from 1 = extremely dissatisfied to 10 = extremely satisfied.

Innovative work behaviour. Doctor-managers' IWB was measured using a 9-item scale developed by Janssen (2000). The scale measures the self-perceived capabilities in the generation and implementation of new ideas (e.g., "I create new ideas to solve challenging problems", "I transform innovative ideas into useful applications", "I introduce ideas into the work environment in a systematic way"). Respondents rated their degree of agreement on a 7-point Likert scale (1 = strongly disagree, 7 = strongly agree). The Cronbach's alpha reliability coefficient for this scale was 0.84 (falling within the acceptability threshold of .70). The Kaiser-Meyer-Olkin (KMO) test for sampling adequacy value was 0.80 (falling within the threshold of .60).

4 Findings

The findings of the descriptive analysis demonstrated that the mean values for all the scales exceeded the neutrality threshold. Given the extension of the measurement scales, the highest mean values were observed in satisfaction with the managerial role (7.23), indicating that doctor-managers exhibited a tendency to hold a favourable attitude towards their managerial role. The standard deviation of IWB (0.64) was found to be the lowest compared to OI and satisfaction with the managerial role, both of which exhibited moderate standard deviations (1.62 and 1.50, respectively). Results are reported in Table 1.

Table 1: Descriptive statistics

Variables	**Mean**	**SD**	**Min**	**Max**	**1.**	**2.**	**3.**	**4.**	**5.**	**6.**	**7.**
1. Organizational Identification	5.35	1.62	1	8	1						
2. Satisfaction with the Managerial Role	7.23	1.5	1	10	.239**	1					
3. Innovative Work Behaviour	5.82	.64	4	7	.165	.418***	1				
4. Age	55.8	7.66	38	69	.039	.149	.152	1			
5. Gender	.43	.50	0	1	-.028	-.280**	-.083	.059	1		
6. Tenure	7.82	7.55	0	44	-.056	-.245**	-.042	-.106	-.006	1	
7. EBM	3.95	1.02	1	5	.036	.246**	.424***	.084	.128	.008	1

Note. Number of observations = 98. SD = standard deviation. Min = minimum value. Max = maximum value.
*$p \leq .05$; **$p \leq .01$; ***$p \leq .001$

Correlation analysis presents significant preliminary evidence, showing that organizational identification correlated positively with satisfaction with the managerial role (r = .239, $p \leq 0.01$), which correlated positively with gender (r = -.280, $p \leq .001$), tenure (r = -.245, $p \leq .001$), EBM (r = .246, $p \leq .01$) and IWB (r = .418, $p \leq .001$).

Consistent with the methodological approach of previous studies (Di Vincenzo, Angelozzi and Morandi, 2021; Cifalinò, Mascia and Vendramini, 2020; Morandi, Angelozzi, and Di Vincenzo 2021), a linear regression analysis was performed to test the research hypotheses. Indeed, when specific assumptions are met, linear regression provides the most accurate estimates (Barclay et al., 1995).

As suggested by previous studies (Oppi, Bagheri and Vagnoni, 2020; Di Vincenzo and Iacopino, 2021), personal and contextual characteristics have the potential to influence IWB. In response to this, the analysis controlled for the role of respondents' personal characteristics in terms of age, gender, tenure in managerial position (number of years as head of OU) and EBM (frequency of evidence-based management), as well as for the region in which the hospital of each respondent is located.

In accordance with the guidelines of Osborne and Waters (2019), the requirements of linear regression analysis were examined.

The results of linear regression analysis are reported in Table 2.

Table 2: Regression analysis

Dependent Variables	**Independent Variables**		**Control Variables**					**Prob > F**	**Hp**
	Organizational identification	Satisfaction with the Managerial Role	Age	Gender	Tenure	EBM	Region		
Satisfaction with the Managerial Role	.277** (.08)		.116 (0.17)	-.313*** (.27)	-.074 (.02)	.348*** (.13)	-.117 (.31)	.001	1
Innovative Work Behaviour		.295** (.04)	.095 (.01)	-.016 (.13)	.045 (.01)	.298** (.06)	-.076(.14)	.001	2

Note. Number of observations = 98
Reported coefficients are Beta estimations with standard errors in parentheses.
*$p \leq .05$; **$p \leq .01$; ***$p \leq .001$
R^2 = .25 for Hp 1; R^2= .21 for Hp 2

As hypothesized, the degree of organizational identification is significantly associated with the satisfaction with the managerial role, confirming the research hypothesis Hp 1 (β = .277, $p \leq .01$). In this path the control variables gender (β = -.313, $p \leq .001$) and EBM (β = .348, $p \leq .001$) were also found to be statistically significant.

Furthermore, satisfaction with the managerial role was found to predict doctor-managers' IWB, providing support for research hypothesis Hp 2 (β = .295, $p \leq .01$). It also emerged the significance of the control variable EBM (β = .298, $p \leq .001$).

4.1 Discussion and conclusions

The assumption of new managerial responsibilities by heads of OUs in PHOs gives rise to significant challenges in balancing their dual role as physicians and managers (Kurunmaki, 2004; Di Vincenzo, Angelozzi and Morandi, 2021). IWB may represent a key factor in enabling doctor-managers to effectively fulfil their role as hybrid managers. However, the hybridization of healthcare middle managers may result in unclear organizational expectations of their new role and decreased satisfaction with the managerial role. These mental and attitudinal states have the potential to negatively impact IWB.

This study examined the influence of OI on doctor-managers' satisfaction with their managerial role and IWB. Along the lines of social identity theory, the results confirmed the hypothesized paths by demonstrating that doctor-managers' OI, through the indirect effect of increased satisfaction with the managerial role, fosters an increase in their IWB. These findings align with prior studies suggesting that enhancing OI in doctor-managers leads to increased psychological empowerment in their role as hybrid managers (Salvatore, Numerato and Fattore, 2018; Di Vincenzo, Angelozzi and Morandi, 2021). The study findings are also consistent with previous research on the role of the characteristics of individual actors, such as satisfaction in the workplace, including satisfaction with the job role, in predicting IWB (De Vries, Bakkers and Tummers, 2016).

This research provides new insights on the individual determinants of IWB, thus contributing to the ongoing discussion on the antecedents of IWB in knowledge-intensive public organizations like PHOs (De Vries, Bakkers and Tummers, 2016). Particularly, this study contributes to the few healthcare studies exploring doctor-managers' attributes that influence their IWB, by focusing on the Italian public healthcare setting, which is still scarcely explored (Oppi, Bagheri and Vagnoni, 2020; Di Vincenzo and Iacopino, 2021). In doing so, this study adds to the ongoing discussion on the pivotal role of knowledge transfer dynamics as a precursor of IWB by unleashing the potential of OI.

PHOs' top management should regulate doctor-managers' identity that is strengthen their oneness with the organization, by providing an environment fostering the transfer of knowledge necessary to support them in performing their hybrid role and facilitating the interiorization of their hybrid nature. This may be achieved through managerial practices that facilitate vertical and horizontal integration and knowledge exchange opportunities, which make more likely to have doctor-managers who are willing to address IWB. These practices could translate managerial recommendations into concrete and actionable policies, such as AI-enhanced mentorship programs, and improve the monitoring of IWB through the adoption of innovation performance metrics.

Nevertheless, the study has some limitations that provide opportunities for future research. Firstly, the study design implemented a single-source, cross-sectional survey. Consequently, the results may be subject to common method bias. Secondly, the study does not consider any change over time. Further research is encouraged to explore the effects of OI on IWB through longitudinal models showing possible difference in doctor-managers' IWB when particular environmental criticalities or shocks occur or does not occur. Thirdly, the present study focused on self-reported data of doctor-managers working in PHOs of two Italian regions; consequently, the results may be influenced by the investigated context. Cross-country or comparative studies that also examine whether and how contextual factors affect the associations that emerged between the constructs in this study are highly recommended. Exploration into the interplay between other personal attributes and IWB within this dynamic could also prove beneficial.

Despite these limitations and the needs for subsequent improvements, it is believed that the problem addressed remains of general interest and relevance for PHOs' managers and healthcare policy makers.

SMEs AI Investments and Resilience: a Knowledge Risk Perspective

Maria Cristina Manocchio, Yasir Faheem, Antonia Puccio, Francesca Di Virgilio
University of Molise, Campobasso, Italy

Abstract

This paper aims to investigate how investment in artificial intelligence interacts with automation-related knowledge risks to shape the resilience of small- and medium-sized enterprises in the Italian context. The rapid advancement of digital transformation requires an extensive understanding of the link between innovative technologies, such as artificial intelligence, and the management of knowledge risks linked to automation, notably related to improving the competitive advantage of small- and medium-sized enterprises. This study employs knowledge risk theory to investigate how investments in artificial intelligence, alongside the challenges introduced by automation, collectively influence organizational resilience and innovation capacity. The empirical foundation of this research is based on secondary data collected across 20 Italian regions and various industries. The dataset was obtained from Confartigianato, a leading association of small- and medium-sized enterprises in Italy. The data were then analyzed using a quantitative approach. The results showed that areas with elevated automation-related knowledge risks are more inclined to invest in artificial intelligence, suggesting a reactive rather than proactive investment approach. The results also highlight varied geographical patterns related to investment levels, risk exposure, and digital readiness, with significant discrepancies in digital adoption and the critical role of knowledge risk as an intermediary factor in the link between artificial intelligence investment and organizational resilience, suggesting that beneficial outcomes are contingent on proficient risk management. This study aims to make a substantial contribution to the current literature on knowledge risk by investigating its application in the context of artificial intelligence and automation deployment in small- and medium-sized enterprises, thereby informing management and regulatory approaches.

Keywords: Artificial Intelligence, Knowledge Risk, Automation Risk, SMEs, Organizational Resilience.

Paper type: Academic Research Paper

1 Introduction

Artificial Intelligence (AI) is profoundly reshaping competitive dynamics across various economic sectors by promoting new practices, improving operational efficiencies, and offering strategic benefits (Muto et al., 2024). In contrast to conventional technologies limited by rigid codes and unchanging directives, AI systems possess the capacity to learn from data, evolve over time, and enhance independently (Durst et al., 2023). This distinctive self-learning ability positions AI as a transformational entity capable of disrupting conventional business models and redefining industrial dynamics. Nonetheless, adopting AI into business workflows encounters challenges, particularly regarding knowledge risks. These risks relate to the management, loss, or theft of knowledge within an organization, hence undermining performance and resilience. Durst and Zieba (2019, p. 2) define knowledge risk as "a quantification of the likelihood and intensity of detrimental impacts stemming from activities associated with knowledge that may influence the operational efficacy of an organization at any level." In the realm of escalating automation, these hazards are becoming increasingly evident. The automation of jobs through AI may lead to the deterioration of human capabilities, especially tacit knowledge—the experiential, often unrecorded insights held by individuals. This information is crucial for maintaining operational flexibility and fostering innovation; its lack can result in inefficiencies and diminish an organization's ability to adapt to change (Moreira et al., 2024). Furthermore, organizations may become dependent on outdated technologies or fail to adapt due to gaps in digital capabilities. Without effective knowledge management, AI adoption may ultimately weaken rather than strengthen organizational performance.

Nevertheless, AI and automation also represent major opportunities for small- and medium-sized enterprises (SMEs), particularly those seeking to enhance competitiveness under constrained resources. The intersection of AI implementation, automation requirements, and increasing knowledge issues in SMEs remains insufficiently studied. Much of the existing research concentrates on large enterprises, overlooking the distinct challenges and conditions faced by SMEs (Oldemeyer et al., 2024; Khan et al., 2024).

This paper examines the relationship between AI investments and automation risks, along with their influence on knowledge risk dynamics in SMEs. The focus is on Italian SMEs, which are embedded in a national context marked by substantial regional disparities in digital infrastructure, AI adoption, and digital literacy. These disparities, combined with sector-specific issues such as labor shortages and uneven innovation capacity, provide a rich context for analyzing how technology-related risks affect organizational resilience.

Due to the lack of research on this point of view, we hypothesize:

- H1: Regions with higher exposure to automation-related knowledge risks tend to invest more in AI, reacting to digital transformation pressure.
- H2: AI investment and knowledge risk levels are different across regions, and these patterns form distinct groups that reflect different levels of digital readiness.
- H3: AI investment helps improve SME resilience, with knowledge risks managed.

This study examines the role of knowledge risk as a mediating element in the relationship between automation demands and organizational resilience and creativity. It contends that heightened regional AI adoption mitigates operational and technological knowledge risks, enabling SMEs to adapt and innovate more effectively in unstable or high-risk environments (Muto et al., 2024; Zieba, 2017).

The study simultaneously investigates the role of organizational attributes, such as business size and regional digital competencies, on the effects of automation and AI on these risks. The investigation uses a quantitative methodology, utilizing two secondary datasets that represent a diverse array of Italian SMEs across various sectors. This research explores the influence of various contextual factors, including business size, industry characteristics, and the level of regional digital maturity, on the interplay between AI, automation, and knowledge risk. It also recognized the necessity of training and development in providing personnel with the competencies required to proficiently utilize AI solutions. The study emphasizes the relevance of knowledge management systems in capturing and spreading tacit knowledge, so converting it into managed organizational assets. This will also provide guidance to expand literature on knowledge management by integrating the dual function of AI as both a potential risk exacerbator and a tool for mitigating knowledge loss. For SMEs, especially in contexts with limited institutional capability, such strategies are essential for the effective management of digital changes. A successful strategy may be providing for governments and corporate leaders the importance of including knowledge risk factors into holistic digital transformation initiatives. Regional differences in infrastructure and digital literacy must be mitigated by targeted, context-specific policy measures to promote equitable AI dissemination across regions. In the absence of such restrictions, the benefits of AI may intensify existing inequities instead of mitigating them. Comprehending these processes may enhance the efficacy of support measures for SMEs striving to maintain creativity and resilience in an increasingly automated environment.

2 Literature Review

2.1 Regional Exposure to Automation and AI Investment

Digital transformation pressures are unevenly dispersed across regions, owing to differences in digital infrastructure, AI use, and knowledge risk management (Schwaeke et al., 2024). Regions that face greater risks related to automation knowledge often counteract by increasing their AI investments as a strategic adaptation measure. In fact regions with a high level of AI integration tend to have lower operational risks, whereas those slow to adopt AI face greater knowledge vulnerabilities (Borgia et al., 2022). Clustering methodologies have been used to categorize regional digital transformation patterns, confirming that AI adoption and knowledge risk degrees align into distinct regional typologies (Badghish and Soomro, 2024). The degree to which regions are exposed to automation and AI investments is determined by structural factors such as the focus of their industries, their capacity for research and development, their productivity, and the skill levels of their workforce. In Europe, regions are categorized into clusters like high-tech service centers and advanced manufacturing hubs, which stand to benefit more from AI as it amplifies their current capabilities. In contrast, peripheral areas may encounter structural obstacles, potentially increasing regional disparities (Guarascio et al., 2024). In the agricultural sector, rural areas face heightened automation risks due to limited labor markets and fewer alternative job opportunities for displaced workers (Rijnks et al., 2022).

2.2 Variations in AI Investment and Knowledge Risk Across Regions

Investment in AI and the associated knowledge risks vary significantly across different regions, resulting in the emergence of unique clusters based on their level of digital preparedness. Studies on regional digital transformation emphasize the importance of local factors such as policy backing, economic frameworks, and technological environments in shaping AI adoption patterns (Schwaeke et al., 2024). Empirical studies reveal that digital transformation trajectories differ significantly, with some regions demonstrating proactive AI adoption strategies, while others struggle with knowledge retention challenges (Borgia et al., 2022). Furthermore, classification techniques used to analyze SMEs digital readiness have identified systematic patterns in AI-related investments and their correlation with knowledge risk exposure (Badghish and Soomro,

2024). Investment preferences at the regional level play a crucial role in shaping AI adoption trends. In China, region-specific investments have been shown to alleviate corporate financial risks, although their effectiveness is dependent on factors such as industry competition and policy uncertainty (Wang, 2023). Moreover, regions with strong technological cohesion are better positioned to withstand economic recessions, as they possess the capability to forge new growth paths and tackle external disruptions (Rocchetta et al., 2020). In addition, venture capital investments contribute to strengthening regional economic resilience by promoting product diversification, although they may not fully address the structural issues in less developed regions (Sheng et al., 2024).

2.3 AI Investment, Knowledge Risk, and SME Resilience

For SMEs, especially in industries such as construction, AI investment can boost competitiveness and sustainability. Nevertheless, the rate of adoption tends to be slow due to perceived knowledge deficiencies and performance expectations. The integration of knowledge plays a crucial role in moderating AI adoption and influencing SME resilience (Khan et al., 2024). In addition, in industries such as agriculture and forestry, increasing AI investments introduce systemic risks like algorithmic bias and unequal access, which can affect sustainability and resilience (Lu et al., 2024). Although AI-driven automation has the potential to bolster SME resilience, its success depends on how effectively knowledge risks are managed. The literature suggests that merely adopting AI does not automatically lead to better organizational outcomes. Instead, it necessitates complementary strategies such as employee upskilling, the establishment of knowledge retention systems, and digital knowledge-sharing initiatives (Durst et al., 2023; Zieba, 2017). Prior research establishes that knowledge risk serves as a crucial mediator between AI investment and firm performance. Organizations that fail to mitigate knowledge disruptions caused by automation may experience operational inefficiencies despite investing in AI technologies (Durst and Zieba, 2019; Borgia et al., 2022).

3 Research Framework and Hypotheses

The integration of AI into business processes is increasingly viewed as a strategic advantage for SMEs pursuing innovation and competitive advantage. However, alongside these benefits, AI adoption and the automation of processes bring challenges for the organization, particularly in the form of knowledge risks. These risks arise when automation processes interrupt traditional knowledge flows, displace skilled employees, or lead to overreliance on digital systems with limited transparency or adaptability. This study is based upon the framework of knowledge risk theory (Durst and Zieba, 2019) and extends it by exploring how AI investments interact with automation-related challenges and changes to influence organizational resilience and innovation capacity.

Knowledge risks refer to the likelihood and impact of adverse results arising from the mismanagement, loss, or low utilization of organizational knowledge assets. Knowledge risks are conceptualized into three dimensions: human risks (e.g., loss of tacit knowledge, knowledge hiding), technological risks (e.g., reliance on outdated systems or inefficiencies in AI knowledge transfer), and operational risks (e.g., breakdowns in workflows or knowledge misuse) (Durst and Zieba, 2019). In this study, knowledge risks are interpreted through automation risk indicators, including both the number of businesses and employees subjected to automation, as well as the amount of risk across specific industries and regions.

AI investments, including both already invested and planned investments in AI technologies, are theorized to minimize knowledge risks by enabling better knowledge management practices, improving system integration, and encouraging employee engagement through training and upskilling initiatives. However, the ability of AI investments to effectively reduce knowledge risks is likely to be influenced by regional and organizational factors, such as the level of digital infrastructure, regional planning, and workforce readiness.

This study develops and tests a research model by taking knowledge risks as a mediating variable between AI adoption and key organizational outcomes such as resilience and innovation. Furthermore, regional disparities in digital development are taken as a moderating variable that influences the strength of these relationships.

3.1 Hypotheses

Building on the presented literature review, we formulated the following hypotheses:

- *H1: Regions with higher exposure to automation-related knowledge risks tend to invest more in AI, reacting to digital transformation pressure.*

- *H2: AI investment and knowledge risk levels are different across regions, and these patterns form distinct groups that reflect different levels of digital readiness.*
- *H3: AI investment helps improve SME resilience, with knowledge risks managed.*

4 Research Methodology

This study examines the relationship between AI investment, automation-related knowledge risks, and SMEs resilience in the Italian regional context through quantitative methods. Due to the increasing role of AI in reshaping business operations, this study adopts an explanatory research approach, with the goal to uncover causal relationships between digital transformation initiatives and risk exposure of organizations. Regional-level analysis is done from secondary data taken from Confartigianato of 20 Italian regions and multiple industries.

In this study, knowledge risks are taken as mediating variables between AI adoption and organizational resilience (Durst and Zieba, 2019). To test the hypotheses of the study, a combination of descriptive statistics, correlation analysis, regression modeling, clustering (via K-means), and mediation analysis are used. This analytical framework ensures the study examines AI-driven digital transformation and its implications for SMEs across regions with different levels of technological readiness.

4.1 Data Collection

In this study, secondary data was used from Confartigianato Italy, which is a leading Italian association that monitors SMEs performance, digital transformation, and regional business risks.

4.2 Descriptive Statistics

The descriptive statistics were computed to assess the distribution and variation of AI investment levels and automation risk exposure across Italian regions. The results are summarized in Table 1.

Table 1: Summary of Key Variables (n = 20 regions)

Variable	Mean	Std. Dev.	Min	Median	Max	Range
Total Investment (%)	6.82	1.53	4.7	6.3	10	5.3
Planned Total (%)	13.92	2.13	10.5	13.7	17.3	6.8
Medium Risk	401,118	533,239	6,239	191,799	2,223,292	2,217,053
High Risk	178,426	263,647	1,871	63,516	992,638	990,767
Low Risk	167,723	223,575	3,027	78,846	1,068,508	1,065,481

Looking into Table 1, AI investment levels vary widely, as they range from 4.7% to 10% of firms per region. Planned AI adoption has a mean of 13.9%, which reflects progressive digital transformation efforts and is on the higher side. There is more variance in Medium and High automation risks, Lombardy having many of high-risk firms and regions like Molise having fewer firms. Low Risk or resilience also varies sharply, reflecting that there are high regional disparities in digital readiness.

4.2.1 Correlation Analysis

Testing our first hypothesis, we performed correlation analysis (Cohen, 2013). Which shows that it is not because AI reduces risks in the short term, as it is a response to the existing risk, and not because AI reduces risk in the short term; rather, AI investment is a response to existing risk.

The study challenges traditional assumptions, but it is aligned with recent literature (Durst et al., 2023; Muto et al., 2024) suggesting that AI adoption often follows pressure, not anticipation, particularly in SMEs directing the automation-driven disruptions.

Table 2: Correlation Coefficients (r) Between Investment in AI and Regional Knowledge Risk Typologies

Variables	Correlation (r)	Description
Total investment ↔ Medium Risk	0.36	Regions with medium risk tend to invest more in AI showing a weak but positive correlation.
Total investment ↔ High Risk	0.34	Regions with higher risk tend to invest more in AI showing a weak but positive correlation.
Total investment ↔ Low Risk	0.43	There is moderate correlation
Medium Risk ↔ High Risk	0.98	Knowledge Risk types co-occur regionally with a strong correlation

There is a weak but consistent positive relationship between automation risk and AI investment. AI investment is positively correlated with medium risk (r = 0.36) and high-risk (r = 0.34) firm concentration as shown in Table 2. These results support the hypothesis (H1) that regions experiencing higher levels of automation-related knowledge risks are more likely to invest in AI, which suggests a reactive investment rather than a proactive investment pattern. Moreover, AI investment shows a moderate positive correlation with firm resilience (r = 0.43), indicating a potential long-term benefit in reducing risk exposure.

For testing our second hypothesis, Principal Component Analysis (PCA) was used to reduce the dataset's five dimensions (AI investment, planning, and three types of automation risk) into two components for visualization (AK Jain et al., 2010). Principal Component 1 (PC1) is to capture variance in knowledge risk exposure, while Principal Component 2 (PC2) shows differences in AI investment intensity. These two components together explain most of the variance in the dataset and show clear regional clustering based on digital maturity.

In Figure 1, in the scatter plot, each point represents a region outlined into two principal components (capturing most variance in investment and risk features). Colors shown as groups indicate three different clusters, derived using K-means clustering. As green are lagging behind regions, blue representing digitally advanced and orange representing transitioning regions.

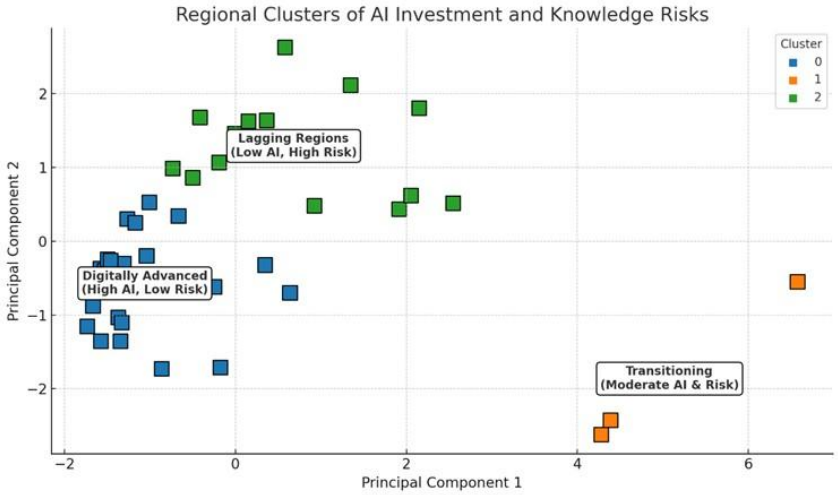

Figure 1. Regional Clusters: AI Investments and Knowledge Risks

K-means clustering grouped Italian regions into three different clusters based on AI investment, automation risk levels, and resilience. The cluster analysis was shown using a Principal Component Analysis (PCA) projection. Cluster 0 has digitally mature regions with high AI investment and low risk; Cluster 1 reflects moderate investment and mixed risk profiles; while Cluster 2 represents digitally lagging regions with low AI investment and high-risk exposures, as shown in table 3. These groupings support the H2 AI investment, and knowledge risk levels are different across regions, and these configurations form distinct groups that reflect different levels of digital readiness.

Table 3: Cluster Groups

Clusters	**Descriptions**	**Regions**
Cluster 0	High AI investment, lower risks	Lombardy, Emilia-Romagna
Cluster 1	Moderate AI investment, mixed risk levels	Lazio, Marche
Cluster 2	Low AI investment, high risk exposure	Molise, Basilicata

To test the third hypothesis of this study, i.e., "AI investment helps improve SME resilience, with knowledge risks managed", we used a causal step mediation model as shown in Table 4.

Table 4: AI Investment, Knowledge Risk, and Resilience: Key Regression Findings

	Variable	**Coefficient**	**p-value**	**Interpretation**
AI Investment towards Knowledge Risk	Total investments to High Risk	59,270	0.026	More investment in high-risk regions showing significant relationship.
Knowledge Risk towards Resilience	High Risk to Low Risk	0.79	<0.001	Higher knowledge risk drives more attention to resilient practices with a strong effect.

	Variable	Coefficient	p-value	Interpretation
AI Investment towards Resilience (Direct)	Total investments to Low Risk	63,130	0.004	Showing a significant and positive effect on SME resilience
Investment + High Risk towards Resilience	Total Investments	18,360	0.036	Significant, but reduced
	High Risk	0.755	<0.001	It continues to drive resilience strongly

AI investment = Independent Variable (X)
High Risk (Knowledge Risk) = Mediator (M)
Low Risk (Resilience) = Dependent Variable (Y)

4.2.2 Mediation Results

By looking into the direct effect of AI investment on SMEs resilience, it is significant. However, when knowledge risk (High Risk) is added to the model, the effect of AI investment drops by 70% i.e. from 63130 to 18360. Which shows a partial mediation, where knowledge risk acts as a crucial bridge between investment and actual SMEs outcomes.

To test whether knowledge risk mediates the relationship between AI investment and SMEs resilience, a stepwise mediation analysis was conducted. Results shows that AI investment significantly predicts both high-risk exposure i.e $\beta = 59{,}270$, $p = 0.026$ and SME resilience i.e. $\beta = 63{,}130$, $p = 0.004$. When both AI investment and knowledge risk were entered into the full model, the effect of investment on resilience diminished to $\beta = 18{,}360$ ($p = 0.036$), while knowledge risk remained a strong predictor ($\beta = 0.755$; $p < 0.001$). This shows a partial mediation, suggesting that only AI investment is not sufficient, and its impact on resilience depends on how effectively knowledge risks are managed.

5 Discussion

This study examined how AI investments relate to automation-related knowledge risks and influence organizational resilience in Italian SMEs. The analysis, grounded on knowledge risk theory (Durst and Zieba, 2019), provides new insights into the dynamics of digital transformation and risk exposure in regionally diverse contexts. The findings show that the relationship between AI adoption and risk mitigation is complex than it was expected to be.

The first hypothesis proposed that AI investment would be higher in regions facing greater knowledge risks. The results showed this, but the direction of this challenges conventional assumptions. Instead of AI mitigating risk in a straight way, the data suggests that SMEs in high-risk environments are adopting AI in response. Technological changes are often driven by organizational pressures rather than expectation (Durst, Edvardsson and Foli, 2023; Muto et al., 2024). Therefore, AI acts less as a proactive measure and work more as a strategic tool for managing challenges.

Cluster analysis showed regional disparities. Lombardy and Emilia-Romagna regions are digitally advanced, while other regions such as Molise and Basilicata lagged behind. As there are disparities among different regions according to this study, it requires region-specific AI policies (Schwaeke et al., 2024).

Mediation analysis revealed that knowledge risks significantly influence this relationship. AI adoption only resulted in improved resilience when risk levels were properly considered. This shows the mediating role of knowledge risk and confirms findings in the previous literature (Borgia et al., 2022; Zieba, 2017), which emphasized the important link between knowledge systems and organizational outcomes in the era of automation.

6 Theoretical and practical implications

It shows a new aspect that relations of AI and risk and the investment are the response to it and not ultimately a solution to increasing knowledge risks. This understanding challenges traditional views of technological adoption. Further, by taking knowledge risk as a mediator, the study helps in showing the causal relationships between AI investment and resilience, which is an area often less explored in SMEs contexts. Furthermore, the use of regional clustering demonstrates how structural and digital disparities guide technology adoption, emphasizing the need to insert contextual variables into strategic models of AI integration.

The findings highlight that AI investments alone are not sufficient to reduce knowledge risks or enhance resilience. AI must be included within strong knowledge management strategies, including systems for capturing tacit knowledge, staff training, and cross-functional collaboration.

The regions that are lagging behind require targeted digital infrastructure investments and AI adoption incentives into the specific sectors.

Policy makers, to perform better, need to continuously update workforce training programs and reduce over-reliance on AI systems. In both cases, the study suggests region-specific policies rather than a uniform policy for all the regions.

7 Conclusion

This study investigated how AI investment interacts with automation-related knowledge risks to shape SMEs resilience in the Italian context. The findings challenge traditional assumptions that AI adoption automatically reduces risk, showing that investments are reactive and concentrated in high-risk regions where automation pressures are stronger.

Clustering analysis identified three distinct regional profiles based on AI maturity and risk exposure, highlighting digital adoption disparities in Italian SMEs. Furthermore, mediation analysis showed that AI investments improve SMEs resilience with knowledge risks properly managed, which highlights the need for them to integrate AI within broader knowledge management frameworks.

This research extends knowledge risk theory by linking it to automation risk and AI adoption in SMEs. Practically, the findings stress the need for region-specific digital transformation policies, targeted workforce upskilling, and AI-integrated knowledge retention strategies to ensure that SMEs remain competitive in technological changes.

8 Limitations and Future Research Directions

This study has many limitations along with its contributions, which can be suggested for future research.

The analysis was done at the regional level of Italy, and data was taken from Confartigianato. Future research can do comparative studies of countries with a broader scope of study. The comparison was on a regional basis; future research should look at data from individual SMEs perspectives to better understand their behaviors, knowledge practices, and unique cultural factors.

The data represents a single time frame. Longitudinal research could provide temporal insights into how AI investments and risk profiles evolve over time and in response to policy interventions.

While the study includes main measures of AI investment and risk, it does not have qualitative indicators like employee perceptions, organizational culture, or change management readiness. Mixed-method research can address these dimensions. Although this study is on SMEs, the data includes firms from multiple sectors. Doing the analysis by sector could reveal industry-specific risk responses and adoption.

By integrating AI adoption patterns with knowledge risk theory, this research offers a more grounded understanding of how digital transformation progresses in practice, particularly within SMEs operating in complex and uneven regional environments. Policymakers and organizational leaders are thus appealed to approach AI not only as a technological solution but as part of a strategic knowledge infrastructure essential for resilience, innovation, and equal growth in the digital era.

Human Resource Management in Early-Stage Startups: A Qualitative Multiple-Case Study

Buyan-Arvijikh Boldbaatar[1], Augusto Colongo[1], Marco Greco[2], Paolo Landoni[1]
[1]Politecnico di Torino, Torino (TO), Italy
[2]University of Cassino and Southern Lazio, Cassino (FR), Italy

Abstract

Early-stage startups face unique challenges in Human Capital (HC) management, as traditional Human Resource Management (HRM) practices, designed for established firms, overlooking the unique organizational dynamics of nascent ventures. This exploratory qualitative case study examines HRM practices in early-stage startups through a cross-case analysis of eight cases: two each from France, Italy, and the United Kingdom, complemented by one case each from Switzerland and Tunisia. We conducted semi-structured interviews with eight startup founders and three early-hire employees, enabling comprehensive perspective triangulation through multiple stakeholder viewpoints within each case organization. Through the theoretical lenses of Resource-Based View (RBV) and contingency theory, this study examines how startups orchestrate their HR resources and adapt their management systems. The findings demonstrate the imperative for adaptive HRM strategies in early-stage startups' dynamic environments during critical phases of hiring, onboarding, and retention. The study's primary contribution is extending the startup HRM literature by introducing a flexible management of a fractional HR management model, which provides startups with a cost-effective, expertise-driven solution for managing essential HR functions, including talent acquisition, onboarding, development, and retention. The research advances both theoretical understanding of HRM in nascent ventures and provides actionable insights for startup founders in optimizing their HC management strategies within resource constraints, particularly during their founding years.

Keywords: Human Resource Management (HRM), Human Capital (HC), Early-stage startup, Fractional Human Resources (HR)

Paper type: Academic Research Paper

1 Introduction

The startup ecosystem has witnessed remarkable growth over the past three decades (Tripathi et al., 2019), emerging as a core driver of economic growth and innovation. These innovative and fast-growing organizations have the potential to revolutionize industries and reshape the global economy. Human capital (HC) forms the foundation of these organizations and, through the Resource-Based View (RBV), represents the most valuable, rare, inimitable, and non-substitutable (VRIN) resources that they can have (Barney, 1991; Nason and Wiklund, 2018). Managing HC effectively presents significant challenges for early-stage ventures (Cardon and Stevens, 2004; Gjerløv-Juel and Guenther, 2019; Eisenmann, 2020; Choi et al., 2023; Rocha and Grilli, 2024). The crucial importance of HC management in early-stage startups is evidenced in empirical research suggesting that internal organizational challenges, rather than external market factors, often become the reason for startup failures. Moreover, the probability of exit rate for younger firms is much higher than for established firms (Zacharakis, Meyer and DeCastro, 1999; Santarelli and Vivarelli, 2007; Marmer et al., 2012; Eisenmann, 2021). Recent research indicates that over 90 percent of startups fail due to internal difficulties, with ineffective team management and employee retention emerging as primary contributors to these failures (Why Startups Fail: Top 12 Reasons l CB Insights, 2021). This aligns with research demonstrating that investment in human resources (HR) correlates strongly with startup success (Pfeifer, 2022; Van Lancker et al., 2022), and effective HRM significantly impacts organizational performance (Cardon and Stevens, 2004; Hoffman and Tadelis, 2018; Chatterji et al., 2019; Jiang et al., 2012; Messersmith and Wales, 2011). From a contingency theory perspective, the unique characteristics of early-stage startups require HRM approaches that differ from those employed by established firms (Dyer and Reeves, 1995; Wood, 1999; Delery and Roumpi, 2017). This theoretical framework demonstrates that practices' effectiveness is contingent upon both internal organizational dynamics and external environmental factors. In the context of early-stage startups, these contingencies manifest primarily through resource constraints, growth needs, and the necessity for maintaining organizational agility. Founding team members and initial employees serve dual roles: they both establish organizational culture and shape operational norms (Choi et al., 2023), in other words, wearing multiple hats on a daily basis. This dynamic interplay between HC deployment and organizational development creates a unique context for HRM implementation in startup environments. Within this context, the loss of HC can prove more detrimental than

the departure of a founder, as it disrupts organizational momentum and increases the startup failure probability. Despite the importance of HRM in startups and its effective management, research in this domain remains limited (Baron, 2003; Cardon and Stevens, 2004; Messersmith and Wales, 2011; Nyström, 2021; Pfeifer, 2022; Van Lancker et al., 2022). Existing literature primarily focuses on established startups, leaving a significant gap in understanding the specific needs of organizations in their early stages (Katz et al., 2000; Leung et al., 2006). This study addresses this gap through an exploratory investigation that combines literature analysis with qualitative interviews to examine how early-stage startups can effectively manage their HC by adapting HRM practices to their unique organizational contingencies. Drawing on the intersection of RBV and contingency theory, we pose three integrated research questions (RQ)

- RQ1: How do early-stage startups strategically manage their human capital within resource constraints, particularly in the hiring, development, onboarding, and retention phases?
- RQ2: What specific organizational contingencies influence HRM practices in early-stage startups, and how do these contingencies impact implementation effectiveness?
- RQ3: How does fractional management emerge as a strategic HRM approach in response to early-stage startups' unique human capital constraints, and what implications does this have for organizational performance?

2 Background

2.1 Theoretical Framework

The emergence and evolution of organizations occur through the sophisticated interplay between opportunity recognition and resource orchestration, with HC serving as a critical mediating mechanism in this relationship (Muñoz-Bullon, Sanchez-Bueno and Vos-Saz, 2015; Yi, Amenuvor and Boateng, 2021; Howell, Bingham and Hendricks, 2022). This theoretical foundation shows organizational success depends not only on identification of opportunities but also on the systematic development and deployment of HC resources that can effectively exploit these opportunities (Leung et al., 2006; Colombo and Grilli, 2010). These relationships operate through interdependent mechanisms, where initial HC investments create trajectories that significantly influence subsequent organizational development and competitive positioning (Eisenhardt and Schoonhoven, 1990; Davila, 2005; Davila and Foster, 2007; Brymer and Rocha, 2023). The RBV provides the theoretical foundation for understanding how organizations develop and maintain competitive advantages through VRIN resources (Barney, 1991; Nason and Wiklund, 2018; Chatterji et al., 2019; Yi, Amenuvor and Boateng, 2021). In the context of HC, VRIN characteristics manifest through the collective knowledge, skills, and capabilities embedded within an organization's workforce. These resources become unique because they emerge through complex social processes that create uncertain cause-effect relationships, making them difficult for competitors to replicate (Becker and Gerhart, 1996; Gerhart and Feng, 2021). Contemporary HRM theory builds upon these RBV perspectives, conceptualizing practices within a comprehensive system of employment relationship management (Jiang et al., 2012; Boon, Den Hartog and Lepak, 2019). The literature identifies three core dimensions of HRM: hiring, development, and retention (Dess and Lumpkin, 2003). The hiring dimension includes strategic recruitment and selection processes to attract and evaluate high-potential candidates. The development dimension focuses on capability enhancement through training programs and performance management systems that align individual and organizational objectives, including the onboarding phase. Retention strategies ensure sustained engagement through compensation strategies and work environment design that supports long-term value creation. Within this theoretical framework, the concept of fractional management has emerged as an innovative response to resource constraints, particularly in early-stage ventures (Birnie et al., 2005; Gatrell, 2007). While academic literature on fractional management remains limited, practitioner insights provide valuable perspectives on its implementation. Research conceptualizes fractional management as a cost-sharing model enabling organizations to access high-level expertise at reduced costs through flexible, part-time arrangements (Kratzer et al., 2022). This model differs from traditional consulting through its emphasis on long-term organizational development rather than project-based interventions. The theoretical analysis of interim management, framed through transaction cost economics and RBV, provides a theoretical foundation for understanding why resource-constrained organizations might opt for flexible management solutions, particularly in HC development. The fractional executive model, where experienced professionals serve multiple organizations on a part-time basis (So and Teckchandani, 2023), has demonstrated effectiveness across various executive functions. However, its application in HRM, especially within early-stage startup contexts, remains relatively unexplored in academic literature, presenting a significant gap in our understanding of alternative management structures in nascent ventures.

2.2 Human Capital and HRM in Startups

In the startup context, the application of HC and HRM theories takes on distinctive characteristics due to the unique challenges and constraints these organizations face. Understanding these dynamics begins with examining the critical role of founding teams as they establish the initial conditions that shape subsequent organizational development.

2.2.1 Strategic Role of Founding Teams

The evolution of entrepreneurship literature demonstrates a shift from individual-centric to team-based theoretical frameworks (Beckman, 2006; Klotz et al., 2014). This theoretical progression reflects growing empirical evidence that organizational success, particularly in high-uncertainty environments, emerges primarily from collective capabilities rather than individual entrepreneurial action. The critical influence of founding teams has emerged as a central theoretical mechanism in determining organizational trajectories during formative stages (Ucbasaran, Westhead and Wright, 2008; Muñoz-Bullon, Sanchez-Bueno and Vos-Saz, 2015). Team formation processes represent a crucial theoretical mechanism linking initial conditions to subsequent organizational outcomes. The composition of founding teams reflects both deliberate strategic choices and path-dependent processes, incorporating varied combinations of knowledge, skills, and competencies. Colombo and Grilli (2010)(Colombo and Grilli, 2010) demonstrate how specific combinations of complementary capabilities within founding teams generate synergistic effects that exceed individual contributions. Moreover, founders usually face the "liability of newness," when hiring and composing their initial team. They typically leverage their existing social capital through shared past experiences and opt for affiliation hires, while in some cases, founders bring previous experience that helps to overcome this liability (Gjerløv-Juel and Guenther, 2019). These founding team dynamics create unique challenges for HRM practices in startups, particularly as organizations transition from founder-centric to more structured organizational forms.

2.2.2 Unique HRM Challenges for Startups

The structural configuration of founding teams in early-stage startups presents unique theoretical considerations that challenge conventional organizational design principles. Despite formal role assignments, team members typically engage in multiple functional areas, a pattern that contrasts with specialized role structures in established organizations (Pratiwi, Ferdiana and Hartanto, 2018). This structural flexibility creates both opportunities and challenges, influencing organizational culture development, routine formation, and the establishment of decision-making processes. Contemporary research indicates that the emergence and complexity of HRM challenges correlate more strongly with organizational growth trajectories than age (Rutherford, Buller and McMullen, 2003; Tocher and Rutherford, 2009). This finding challenges traditional life-cycle models of organizational development and suggests the need for more dynamic theoretical frameworks capable of capturing the temporal evolution of HC development in startups (Choi et al., 2023). Empirical evidence demonstrates this complexity, suggesting the criticality of internal factors, particularly HC management, in determining startup success, with internal factors accounting for over 90 percent of startup failures (Marmer et al., 2012). The integration of early employees represents a critical phase in organizational development, with their departure potentially affecting organizational performance as significantly as the founder's departure (Gjerløv-Juel and Guenther, 2019; Choi et al., 2023). This finding suggests the need for theoretical models that can account for the distinctive characteristics of early-stage HC development, particularly regarding the main HR practices. The composition of founding team experience provides potential competitive advantages through multiple theoretical mechanisms, particularly in overcoming the liability of newness in organizational management (Cardon and Stevens, 2004; Rocha and Grilli, 2024). While earlier research emphasized the advantages of homogeneous team compositions in facilitating rapid decision-making, contemporary scholarship suggests that diverse founding team backgrounds contribute valuable perspectives and capabilities that enhance organizational adaptability and innovation potential (Brymer and Rocha, 2023).

3 Methodology

3.1 Research Design

Our research design follows a qualitative multiple-case study approach to examine HRM practices in startups at their early stages (Yin, 2009). This methodological approach enables a rich, contextual understanding of complex organizational phenomena while enabling systematic cross-case pattern identification (Beach and Pedersen, 2016). Grounded in Resource-Based View theory, our research design investigates how resource

constraints and contingency factors shape HR practices in nascent ventures while exploring alternative HR management approaches.

The investigation proceeded through three distinct phases (Figure 1): Phase 0 comprised theoretical foundation development and data collection protocol establishment; Phase I involved empirical data collection through two sub-phases (I.a and I.b); and Phase II focused on cross-case analysis and theoretical integration. This progressive design enabled theoretical sampling refinement while accommodating the complex, multilayered nature of HR practices in entrepreneurial settings.

Figure 1: Research framework

3.2 Sample and Data Collection

For this investigation, we operationalize "early-stage startups" as ventures in initial growth phases characterized by resource constraints, evolving organizational structures, and emerging market presence. While venture capital literature often constrains this definition to companies with secured funding, our conceptualization deliberately encompasses a broader range of nascent businesses at various developmental stages. Through theoretical sampling, we selected eight cases across five countries (France, Italy, Switzerland, Tunisia, and the United Kingdom) to maximize contextual variation. The deliberate inclusion of startups with varying founding years (2014-2022) and employee counts (5-100) represents a methodological strength rather than a limitation, enabling identification of HR practice evolution patterns across developmental trajectories.

Data collection occurred during 2023-2024 through semi-structured interviews with two stakeholder groups: founders/CEOs (n=8) and early-hire employees (n=3), enabling comprehensive perspective triangulation. Interviews lasting 30-60 minutes followed a protocol combining structured questions addressing core HRM dimensions with open-ended explorations of participants' experiences. Tables 1 and 2 present the descriptive characteristics of participants, demonstrating the sample's diversity across industry sectors and organizational configurations.

Table 1: Descriptive characteristics of startup founders, Group A (N=8)

Startups	**Sloneek**	**Dizzy ink**	**Wiremind**	**Qovoltis**	**Wayout**	**Genuieway**	**Nocciolar**	**Biova Project**
Interviewee role	CEO	CEO/Founder	CEO	President	CEO	COO & Co-founder	CEO	President/Co-founder
Country	United Kingdom	United Kingdom	France	France	Tunisia	Switzerland	Italy	Italy
Industry	Software	Art & printing	Software	Electric Mobility and Energy	Green Infrastructure	Software	Food & Beverage	Food & Beverage
Founded year	2017	2015	2014	2019	2020	2019	2022	2020
Founders at the start	2	1	2	2	3	3	1	2
Current employee (2025)	24	2 to 5	94	70	6	10	5 (+ 3 seasonal)	5

Table 2: Descriptive characteristics of early-hire employees, Group B (N=3)

Organization	Current Position	Entry Position	Tenure(years)	Industry Sector
Wayout	Ex Employee	Sales & Marketing Intern	1 to 2	Green Infrastructure
Nocciolar	Sales and Marketing manager	Sales and Marketing intern	2 to 3	Food & Beverage
BetaGlue Technologies	Head of Manufacturing & Operations	VP	2 to 3	Medical Equipment Manufacturing

4 Findings

4.1 Key HRM Patterns

4.1.1 Hiring Practices and Network Orchestration

Early-stage ventures predominantly employ network-based approaches to talent acquisition, with affiliation-based hiring (ABH) emerging as a strategic response to resource constraints. At Sloneek, "80% of initial software developers were sourced from the previous company," demonstrating how founders strategically leverage existing relationship networks to access pre-validated talent pools. Our analysis reveals systematic adaptation of hiring approaches as ventures evolve. Wiremind's strategic pivot to candidates valuing early-stage involvement after losing prospects to larger companies illustrates how ventures refine their value propositions in response to competitive pressures. Notably, variations in hiring approaches correspond to distinct performance outcomes. Ventures employing high network utilization (Sloneek, Qovoltis, Wayout) achieved stronger cultural alignment and reduced integration costs, while those employing more external approaches (Wiremind, Genuineway) prioritized technical excellence but faced greater integration challenges.

4.1.2 Onboarding and Adaptive Integration

Our cross-case analysis reveals that early-stage ventures implement adaptive integration approaches that selectively prioritize certain onboarding elements while strategically deferring others. Drawing from Bauer's(2010) framework of the four C's (Compliance, Clarification, Culture, and Connection), we observed that startups customize their integration emphasis based on hiring pathways and organizational priorities.

Ventures employing affiliation-based hiring demonstrated less formalized onboarding processes, leveraging pre-existing social connections to facilitate natural integration. In contrast, ventures recruiting externally developed more structured technical assessments, as exemplified by Wiremind's "baptism by fire" approach that simultaneously evaluated problem-solving capabilities and fostered peer connections. These variations represent strategic adaptations to specific organizational contexts rather than developmental limitations.

4.1.3 Development Patterns and Retention Strategies

Our findings reveal a "development paradox" where skill development needs are highest but formal investment capacity is constrained by resource limitations. Early-stage ventures resolve this paradox through adaptive learning mechanisms that evolve along two dimensions: formalization of learning processes and sources of knowledge transfer.

Temporally, development approaches transition from predominantly informal, founder-led instruction toward more structured, peer-based learning systems as ventures mature. Strategic prioritization emerges as a consistent pattern across ventures, with most prioritizing immediate operational skill acquisition over long-term career development, representing strategic resource allocation rather than simply reflecting limitations.

Regarding retention, our analysis reveals a complex interplay between monetary and non-monetary factors, with cultural alignment emerging as a critical determinant. While existing literature emphasizes compensation and job security as primary retention drivers (Rangrez, Amin and Dixit, 2022), our findings indicate that in entrepreneurial settings, mission alignment and cultural fit often complement traditional retention mechanisms. Retention approaches manifest across a spectrum, from predominantly financial (Nocciolar, Genuineway) to predominantly cultural (Sloneek, Wayout), with most ventures employing hybrid approaches that evolve with organizational maturity.

4.2 Fractional HR Management: An Emergent Solution

Our analysis identified fractional HR management as an emergent solution addressing the expertise-resource tension in early-stage ventures. This approach enables startups to access specialized HR expertise through flexible, part-time arrangements without the financial burden of full-time personnel. The early employee from Betaglue Technologies specifically highlighted "lack of HR expertise in the hiring team" as a significant challenge, while Wayout's former employee suggested that fractional HR services "could be the best option not only for Wayout but also similar companies." This solution addresses three critical needs identified across our sample: (1) specialized expertise in compliance and contract management, (2) systematic approach development without full-time overhead, and (3) objective perspective in candidate evaluation. The viability of fractional HR appears contingent upon venture maturity, with ventures at transitional growth stages (approximately 10-50 employees) expressing the strongest interest.

4.3 Cross-Pattern Analysis

Our systematic analysis reveals three core mechanisms through which early-stage startups develop their HR management capabilities: network-based resource orchestration, adaptive capability development, and strategic formalization. Table 3 presents perspectives from early-hire employees, highlighting how their experiences align with these mechanisms and revealing potential value in fractional HR services. One early employee explicitly noted that such services could be "the best option for not only our company but also similar companies."

Table 3: Cross-case summary for Early-hire employees

Early hire employees	**Recruitment**	**Onboarding & professional development**	**Retention**	**HR need**
Early hire employee (Nocciolar)	Network-based recruitment with informal assessment procedures; demonstrated effectiveness despite lack of structured protocol	Structured trial period with clear performance metrics and deliverable comprehension	Attractive compensation, and the company culture, close network and connection with the founders	Current HR needs minimal post-integration; potential value in systematizing founder-level recruitment processes
Early hire employee (Wayout)	Affiliate-network recruitment; informal selection process	Intensive mentorship model via daily founder interactions; hands-on skill development	Career advancement opportunities available but lacking formal structure; emphasis on experiential learning	HR support critically needed during onboarding and development phases despite part-time status
Early hire employee (Betaglue technologies)	Informal recruitment process; details pending further documentation	NA	NA	External HR consultation recommended specifically for recruitment phase optimization

Table 4 extends this analysis by presenting a comprehensive cross-pattern examination of HR capability development across all ventures, demonstrating how the three core mechanisms manifest differently based on contextual factors including founder experience, industry demands, and resource availability.

Table 4: Cross-Pattern Analysis of HR Capability Development

Dimension	**Resource Orchestration**	**Capability Evolution**	**Formalization Strategy**	**Performance Outcomes**
Sloneek	High network utilization, community-based	Organic growth through social ties	Low initial, emerging structure	Strong retention, rapid capability building
Dizzy ink	Medium network use, founder-centric	Experience-based learning	Low formalization maintained	Product-focused development
Wiremind	Low network use, external focus	Systematic technical assessment	High structured approach	Technical excellence prioritized

Dimension	Resource Orchestration	Capability Evolution	Formalization Strategy	Performance Outcomes
Qovoltis	High network activation, hybrid approach	International team development	Medium with formal elements	Successful scaling achieved
Wayout	High community engagement	Impact-driven development	Low with planned evolution	Mission-aligned growth
Biova Project	Medium network use, referral and recommendation based	Different levels of employees as such interns	Low formalization, emerging on the way	Mission alignment, impact product focus
Nocciolar	Medium industry network leverage	Technical expertise focus	Medium technical structure	Strong operational foundation
Genuineway	Low network use, professional approach	Corporate-startup hybrid	High professional structure	Balanced growth model

From this cross-pattern analysis, we derived three key insights regarding HR capability development in early-stage ventures. First, network activation effectiveness is moderated by network-strategy alignment. Ventures demonstrating strong alignment between network utilization and strategic objectives (Sloneek, Qovoltis) achieved superior outcomes compared to those with misalignment, regardless of absolute network utilization levels. Second, ventures that developed systematic adaptation mechanisms early in their lifecycle demonstrated accelerated capability development, as exemplified by Qovoltis's approach: "After the first employees, we learned what we needed and changed the structure." This systematic learning process enables ventures to refine their HR practices as they mature. Third, formalization strategies appear contingent upon growth rate and industry demands rather than reflecting an absolute development trajectory. The variation in formalization levels across ventures with similar employee counts demonstrates that formalization represents a strategic choice rather than simply a developmental stage.

Our analysis further revealed the interconnected nature of HR practices in early-stage ventures, where hiring approaches directly influence retention outcomes. This interconnection manifests through a learning-retention dynamic where early employees view their roles as accelerated learning opportunities. When these learning expectations remain unmet, retention becomes challenging, supporting Cardon and Stevens' (2004) findings. This interconnection suggests that founders should develop coherent HR approaches that maintain consistency across dimensions rather than implementing isolated practices.

5 Discussions and conclusions

5.1 General Discussions

This study investigated HC and HRM practices in startups at their early stages, yielding several important theoretical and empirical insights. Our findings confirm previous research indicating that resource constraints significantly impact HR practices in startups (Bamberger, Bacharach and Dyer, 1989; Cardon and Stevens, 2004; Messersmith and Wales, 2011; Brymer and Rocha, 2023; Roach and Sauermann, 2024; Rocha and Grilli, 2024). Specifically, we found that early-stage startups face similar resource constraints(Davila and Foster, 2007), particularly regarding full-time HR personnel investment.

5.2 Theoretical and Practical Implications

This study makes several significant contributions to HR theory in entrepreneurial contexts. Our findings confirm that resource constraints significantly influence HR practices in early-stage startups (Cardon and Stevens, 2004; Messersmith and Wales, 2011), particularly regarding full-time HR personnel investment. However, we extend existing theoretical frameworks by demonstrating how these constraints drive innovative adaptations rather than merely limiting practice sophistication.

First, we contribute to Resource-Based View theory by illuminating how early-stage ventures orchestrate limited resources while building necessary capabilities for growth. Our findings demonstrate that network-based resource orchestration represents not merely a compensation for resource limitations but a strategic adaptation mechanism that can provide competitive advantages through social capital leverage and enhanced talent alignment.

Second, we extend contingency theory by identifying specific contextual factors that influence HR practice effectiveness in entrepreneurial settings. Our cross-pattern analysis reveals that practice effectiveness is contingent upon alignment with organizational priorities, founder experience, and industry context rather than

reflecting universal best practices. This finding challenges predominant stage-based models of HR development by demonstrating that HR practice evolution follows multiple pathways shaped by venture-specific contingencies.

The practical implications of our research are particularly relevant for startup founders and early-stage investors. Different levels of HR formalization represent appropriate strategic responses to contextual factors rather than developmental deficiencies. The network-dependent informality in hiring and flexible, founder-driven integration approaches appear particularly suited to the dynamic needs of early-stage ventures, suggesting that founders should align HR formalization with their specific organizational context rather than pursuing standardized formalization paths.

5.3 Concluding remarks and future directions

This exploratory study identified a significant gap in the HRM literature regarding strategies specifically tailored for startups. This is particularly evident in the startups at their early stages, as their success heavily hinges on the quality of their initial hires and managing (orchestrating) their primary resource of HC. Our qualitative analysis revealed that founders face unique challenges in managing their initial teams, depending on the various contingents and their resource allocation and limitations. Thus, founders rely on close network hires, or ABHs, as this can be useful in the decision-making and integration of the employees. In the long term, however, recruiting someone with a different background is essential for bringing fresh perspectives and diverse expertise to drive innovation and organizational growth. The emergence of fractional HR as a viable solution addresses these constraints by providing on-demand expertise while accommodating limited resources. Given the unique nature of startups and the complexity of HRM practices, we propose three key directions for future research: First, longitudinal studies should examine the long-term impact of fractional HR on organizational outcomes, including financial performance, employee retention, and innovation metrics. These studies should address the current lack of empirical data on organizations formally implementing fractional HR practices. Second, research should investigate the implementation challenges across different organizational contexts, focusing on both organizational requirements and employee experiences. This includes examining the strategy's sustainability and evaluating its effectiveness from multiple stakeholder perspectives. Third, future studies should expand the scope of team composition analysis in early-stage startups. This expanded framework could examine: (1) vertical analysis across organizational levels to understand how fractional HR addresses varied stakeholder needs, (2) evolution of team compositions and HR requirements through growth stages, e.g., turnover rates, and (3) organizational contingencies such as industry sector, geographic location, and funding stage that influence fractional HR effectiveness. This way, this study could comprehensively analyze the domain of HR not only early but also in startups in general.

5.4 Limitations

Several limitations should be acknowledged when interpreting our findings. First, our sample size was constrained by participant availability during follow-up interviews. Second, our focus on specific European and North African contexts may limit broader applicability to other entrepreneurial ecosystems, particularly in Asian and American contexts. Third, our qualitative methodology, while providing rich contextual insights, has inherent limitations regarding statistical generalizability. These limitations suggest promising directions for future research while acknowledging the boundaries of our current findings.

This publication is part of the project PNRR-NGEU which has received funding from the MUR – DM 118/2023.

7 Ethics declaration

All interviews were conducted following informed consent procedures, with participants being fully informed about the research purpose. The study did not require formal ethical clearance as it involved non-sensitive interviews with professionals discussing their professional experiences rather than personal matters. All data collection complied to General Data Protection Regulation (GDPR) requirements, with spoken consent obtained from all participants for research purposes before the interviews. All data was anonymized in the reporting to protect participant confidentiality while maintaining analytical integrity.

8 AI declaration

No AI tools were used in the development of this paper for the conference IFKAD 2025.

Inclusive Language in Academia: Evaluating Human and AI-Generated Communications to Students

Testa Federica[1], Petrolo Damiano[2], Giampaola Valerio[3]
[1]Università degli studi di Roma Tor Vergata, Roma, Italia
[2]Università degli Studi del Piemonte Orientale "Amedeo Avogadro", Vercelli, Italia
[3]Università degli studi eCampus, Novedrate, Italia

Abstract

In recent years, growing societal attention to gender bias and inequality has prompted Universities to reconsider their institutional practices, including the use of inclusive language in formal communication. As central actors in the production and dissemination of knowledge, academic institutions bear a cultural responsibility to ensure that their communication practices reflect principles of equity and inclusion. This study explores the extent to which written communications addressed to students, either by university faculty or generated by artificial intelligence (AI), adhere to inclusive language practices.

The research adopts a qualitative design based on content analysis and evaluates 63 announcements authored by faculty members from two Italian universities, alongside 39 messages produced by three generative AI systems—ChatGPT Basic, Deepseek, and Gemini 2.0 Flash. The analysis is guided by 16 indicators of inclusive language use, drawn from the guidelines developed by Sabatini (1987) and revised by Somma and Maestri (2020). Each message is classified as inclusive, non-inclusive, or partially inclusive, based on the presence or absence of these indicators.

Findings show that inclusive communication practices are strongly gendered: female faculty members display a much higher rate of inclusive language use (48%) compared to their male colleagues (18%). Notably, no male full professor in the sample used inclusive language. Disciplinary differences also emerge, suggesting that the adoption of inclusive language is influenced by specific cultural norms within academic fields. Among AI systems, Gemini 2.0 Flash produced the highest share of inclusive outputs (38%), followed by ChatGPT (23%) and Deepseek (8%). However, the overall low performance of AI models indicates that inclusive principles are not yet systematically embedded in their training.

This paper contributes to the literature by combining human and AI communication analysis under a unified framework and offering empirical insights into how inclusive language is—or is not—implemented in practice. The results underscore the need for targeted interventions, both educational and technological, to promote inclusive communication in academia. By advancing this dual focus on human and AI-generated texts, the study highlights inclusivity not only as an ethical imperative, but also as a strategic priority for fostering institutional credibility and evolution.

Keywords: Inclusive Language; Academia; AI; Content Analysis; Communication

Paper Type: Practical Paper

1 Introduction

In response to growing societal awareness of gender bias and inequality, the academic sector has increasingly re-evaluated its institutional structures and practices. As central actors in the production and dissemination of knowledge, universities bear a significant cultural and political responsibility and have undertaken systematic efforts— through education, research, and policymaking — to promote equity and drive structural transformation beyond the boundaries of academia (Petrolo et al., 2023).

Within this broader context, language represents a powerful tool for challenging entrenched inequalities (Testa et al., 2024). The frequency and modality of communication among organisational members are crucial for fostering an inclusive environment (Trittin & Schoeneborn, 2017; Wolfgruber et al., 2021), while effective faculty-student communication ensures access to essential information regarding courses, exams, and academic events.

As extensively recognised in the literature, language is not a neutral conduit of meaning, but a symbolic and social practice that constructs reality (Butler, 2017), conveys ideologies, and shapes the relationship between identity and power (Giusti, 2022). Grammatical structures, lexical choices, and discursive conventions do not merely reflect existing cultural frameworks, including those related to gender; they also contribute to their reproduction. Therefore, the adoption of gender-inclusive language should not be regarded solely as a matter of formal correctness. Instead, it constitutes a political and cultural act (Butler, 2018), potentially reshaping mechanisms of recognition and exclusion (Pagliara, 2024).

At the institutional level, language has gained increasing legitimacy as a key lever for promoting gender equality. In 2018, the European Union urged Member States to adopt gender-neutral language, identifying it as

a foundational principle in policies such as GEAR and GEP. That same year, the Italian Ministry of Education, University and Research (MIUR) issued *Guidelines for the Use of Gender in Administrative Language*, with the goal of raising awareness within academic settings about the influence of linguistic choices in reproducing gender stereotypes. The document highlights how grammatical and semantic asymmetries—even when unintentional—can shape social perceptions and sustain structural inequalities. Since 2020, several Italian universities have followed suit, adopting institutional guidelines to encourage inclusive language in both academic and administrative communication.

Any investigation of gender-inclusive language in the Italian academic context must reckon with a structural feature of the Italian language: the obligatory marking of grammatical gender (Sabatini, 1987; Somma and Maestri, 2020). Unlike other linguistic systems, Italian requires gender assignment for articles, nouns, adjectives, and pronouns. This grammatical structure poses specific challenges to achieving inclusive communication, as each act of writing entails a gendered choice that may symbolically include or exclude specific subjects (Giusti, 2022). These gendered forms are not neutral: they shape individual and collective imaginaries (Gheno, 2022), influence cognitive representations of social and professional roles (Gygax et al., 2008), and can reinforce hierarchical or exclusionary frameworks (Konnelly & Cowper, 2020).

Nonetheless, Ferrari and Pecorari (2024) noted that the so-called *inclusive masculine* remains dominant in institutional texts. This convention is often justified based on syntactic clarity, readability, and legal-administrative tradition. However, it is rarely subjected to systematic scrutiny, and its application remains unexamined mainly, despite broader cultural shifts. The persistence of the inclusive masculine contributes to the symbolic erasure of women and non-binary individuals, ultimately rendering invisible the very diversity that institutional communication should acknowledge and represent (Maiden & Robustelli, 2014).

In parallel, digital technologies—including the expanding use of artificial intelligence (AI)—are reshaping how organisations manage and disseminate knowledge (Malik et al., 2023). While AI has the potential to support faculty in producing more inclusive and accessible communications, concerns remain about the quality, accuracy, and inclusivity of AI-generated content (Müller, 2024). Whether such messages genuinely reflect inclusive principles is an open empirical question—particularly regarding their capacity to meet the needs of a diverse audience and ensure equitable access to information for all students, including those with specific needs.

This study aims to contribute to this emerging scientific debate by assessing the inclusivity of academic language used in communications authored by faculty members in comparison with those generated by AI. Faculty announcements, disseminated institutional bulletin boards convey operational and technical information that significantly influences students' engagement and participation in academic life (Jalolov, 2024). This justifies the selection of such communications as the empirical focus of our research.

The article is structured as follows: the next section presents the methodological approach and the structure of data collection, analysis and comparison. The results emerging from the surveys carried out are then presented and discussed. Finally, the conclusions, limitations and future research directions are presented.

2 Methodology

This study employs a qualitative research design based on content analysis (Flick, 2014) to evaluate the inclusiveness of language in written academic communications. Specifically, it analyses and compares announcements addressed to students, authored either by university faculty or generated by artificial intelligence (AI), assessing each text against criteria drawn from the existing literature on gender-inclusive language (Graebner et al., 2012).

The study, currently a work in progress, is structured into four main phases: (i) the identification of conceptual drivers from the reference literature; (ii) the data collection, during which announcements from three Italian universities—respectively located in the northern, central, and southern regions—were gathered. For each announcement, they have been recorded: the announcer's gender, university affiliation, subject matter, and the full text of the communication. At the same time, generative AI systems were prompted to produce parallel messages, calibrated to match the topic, institution, and (where applicable) gender of the human announcer. These AI-generated announcements were catalogued using the same variables; (iii) a content analysis of both human- and AI-authored messages to identify potentially non-inclusive language elements; and (iv) a comparative analysis of the findings.

2.1 Data collection

The empirical phase of the study began with the retrieval and selection of announcements issued by faculty members and published on the official bulletin boards of two Italian universities. For each faculty member, one announcement was selected per course, with preference given to the most recent communication available.

Only announcements authored by full professors, associate professors, and researchers were deemed eligible for inclusion. For each communication, the following variables were recorded: gender of the author, academic rank, university affiliation, city, disciplinary field, date, subject of the announcement, and full text.

Upon completing this phase, a comparable set of announcements was generated using three generative artificial intelligence systems— ChatGPT Basic, Deepseek, and Gemini 2.0 Flash. To ensure the generation process was entirely AI-driven and not influenced by human intervention, the systems were instructed to autonomously produce prompts based on the subject matter of the human-authored announcements. Each AI system was tasked with generating a message in the style of a university professor addressing students on the same topic as the original communication. To reduce potential gender bias in prompt formulation, all prompts were generated in English, given its relatively higher degree of grammatical gender neutrality compared to Italian. The final announcements were then produced in Italian. The same variables recorded for faculty-authored texts were systematically documented for each AI-generated communication.

In total, the dataset comprises 63 communications authored by faculty members and 39 generated by artificial intelligence.

2.2 Data analysis

The criteria employed to assess the degree of linguistic inclusiveness were based on the guidelines initially formulated by Sabatini (1987) and later revised and expanded by Somma and Maestri (2020), which represent a key reference for the promotion of gender-inclusive language, both in general discourse and within Italian academic institutions. A deductive content analysis was conducted (Flick, 2014), whereby the predefined set of criteria was systematically applied to both faculty- and AI-generated announcements. The complete list of indicators used in the evaluation is presented in Table 1, which summarises the 16 dimensions adopted in the analysis.

Table 1 - Indicators for Evaluating Gender-Inclusive Language

#	Indicator Name	Description
1	Visibility of feminine forms in roles and titles	Use of the feminine form for roles and titles when referring to women (e.g., *la ministra*, *la professoressa*).
2	Avoidance of generic masculine and inclusion of both genders	Use of inclusive formulas to refer to mixed groups (e.g., *studentesse e studenti*) instead of the overextended masculine; alternation of masculine and feminine in lists.
3	Grammatical agreement with the gender of the subject (or majority)	Grammatical coherence between the subject's gender and the grammatical elements used (articles, adjectives, pronouns).
4	Avoidance of gender-based linguistic stereotypes	Avoiding stereotypical representations of roles or behaviours attributed to men and women.
5	Use of feminine agentive nouns	Use of profession names in the feminine form (e.g., *autrice*, *scienziata*, *relatrice*).
6	Use of grammatically correct feminine forms	Use of regular feminine forms in accordance with Italian morphological rules (e.g., *avvocata*, *ingegnera*).
7	Consistency in gender usage within the text	Avoidance of incoherent gender alternations when referring to the same person or role.
8	Neutralising resistance to feminine forms	Unhesitant use of feminine forms, including for high-status roles, without justifications.
9	Gender parity in institutional titles and use of capital letters	Symmetrical and correct use of titles for both genders.
10	Use of the feminine article with titles and differentiation of epicene forms	Presence of the feminine article before titles and names (e.g., *la professoressa Moretti*); use of forms such as *la giudice*.
11	Consistency in the use of feminine forms	Grammatical gender remains consistent throughout the text when referring to female subjects.
12	Avoiding asymmetry between high- and low-status professions	Use of feminine forms also for senior roles, not only for caregiving professions.
13	Use of title and surname, not first name	Avoid referring to colleagues by first name only (e.g., *Maria*); prefer *Prof.ssa Rossi*.
14	Use of female-firstness in coordinated pairs	Symbolic precedence given to feminine in gender pairs (e.g., *studentesse e studenti*).
15	Preference for marked feminine forms	Use of marked feminine forms (*ministra*) rather than neutral or masculine forms (*ministro*).
16	Use of unmarked expressions	Prefer neutral expressions (e.g., *person* instead of *man*).

Each communication was analysed to assess the overall degree of linguistic inclusiveness. The three authors performed the coding independently, and the results were subsequently compared. Any discrepancies were discussed collectively until a consensus was reached. The presence or absence of the indicators listed in Table 1 was recorded for each announcement. Based on this evaluation, communications were categorised as follows:

1. Inclusive, if all relevant criteria were fully met;
2. Non-inclusive, if none of the indicators were observed;
3. Partially inclusive, if only some criteria were satisfied.

3 Results

This section presents the results of this study. The analysis is structured to highlight how inclusive, non-inclusive, and partially inclusive language patterns emerge across different profiles.

The first result, illustrated in Table 2, concerns the distribution of language styles disaggregated by gender and academic rank, revealing significant differences in language practices and offering a first insight into how inclusive language may vary across institutional roles and gender.

Table 2 - Language styles among university faculty by gender and academic position

	Inclusive language		**Not inclusive language**		**Partially inclusive language**		**Overall**
Female	**12**	**48%**	**8**	**32%**	**5**	**20%**	**25**
Full Professor	3	60%	2	40%	0	0%	**5**
Associate Professor	5	42%	5	42%	2	17%	**12**
Researcher	4	50%	1	13%	3	38%	**8**
Male	**7**	**18%**	**25**	**66%**	**6**	**16%**	**38**
Full Professor	0	0%	9	82%	2	18%	**11**
Associate Professor	4	27%	9	60%	2	13%	**15**
Researcher	3	25%	7	58%	2	17%	**12**
Overall	**19**	**30%**	**33**	**52%**	**11**	**17%**	**63**

First, gender differences are evident. Female academics exhibit a significantly higher proportion of inclusive language (48%) compared to their male counterparts (18%). Conversely, male academics display non-inclusive language patterns (66%), more than double that of female academics (32%). These findings suggest that inclusive language styles are more prevalent among women across academic ranks. Second, when analysing by academic position, male full professors are particularly concerned: none demonstrated inclusive language (0%), and the vast majority (82%) fell into the non-inclusive category. In contrast, female full professors show stronger inclusivity, with 60% using inclusive language styles and none falling into the partially inclusive category, indicating a more polarised but clearly more inclusive profile. Third, among associate professors, both genders display a more balanced distribution. Female associate professors have equal shares of inclusive and non-inclusive language (42%), with a smaller portion falling into the partially inclusive category (17%). Among males in the same rank, inclusive language remains lower (27%) compared to their female colleagues. Notwithstanding, this category has the highest percentage among male academics. Fourth, researchers also show a mixed profile, though female researchers again outperform males in inclusivity (50% vs 25%). This suggests that inclusivity might decrease with seniority among men, while women seem to maintain or even strengthen it. Finally, looking at the overall, only 30% of the total sample demonstrates inclusive language, while 52% falls into the non-inclusive category. This highlights a systemic issue in language practices within academia, particularly among male senior faculty. These patterns, identified through objective coding frameworks, underline the need for targeted training and awareness initiatives to promote inclusive language, especially in senior roles.

The second part of the analysis, presented in Table 3, looks into inclusive language practices depending on gender and scientific disciplinary sector (in Italian: *Gruppi Scientifico-Disciplinari* - GSD). While the gender gap identified earlier remains the same as below, this more granular view reveals how disciplinary cultures shape language styles in distinct ways.

Table 3: Language styles among university faculty by gender and GSDs

	Inclusive language		Not inclusive language		Partially inclusive language		Overall
Female	12	48%	8	32%	5	20%	**25**
ECON-01	1	100%		0%		0%	**1**
ECON-02	1	100%		0%		0%	**1**
ECON-06		0%	2	100%		0%	**2**
ECON-07	2	33%	2	33%	2	33%	**6**
ECON-09	1	50%	1	50%		0%	**2**
GIUR-01		0%		0%	1	100%	**1**
GIUR-02	3	75%		0%	1	25%	**4**
GIUR-03	2	100%		0%		0%	**2**
GIUR-06	1	100%		0%		0%	**1**
STAT-02		0%	2	67%	1	33%	**3**
STAT-04	1	100%		0%		0%	**1**
GEOG-01		0%	1	100%		0%	**1**
Male	7	18%	25	66%	6	16%	**38**
ECON-01	2	50%	1	25%	1	25%	**4**
ECON-02		0%	1	100%		0%	**1**
ECON-06		0%	6	100%		0%	**6**
ECON-07		0%	3	100%		0%	**3**
ECON-08	1	33%	1	33%	1	33%	**3**
ECON-09		0%	2	67%	1	33%	**3**
GIUR-01		0%	1	100%		0%	**1**
GIUR-02		0%	1	50%	1	50%	**2**
GIUR-06		0%	2	100%		0%	**2**
GIUR-08		0%	3	100%		0%	**3**
INF-01	2	67%	1	33%		0%	**3**
MAT-05	1	50%	1	50%		0%	**2**
STEC-01		0%	1	100%		0%	**1**
STAT-02		0%	1	100%		0%	**1**
STAT-04	1	33%		0%	2	67%	**3**
Overall	**19**		**33**		**11**		**63**

Overall, these findings highlight that inclusive language is not only gendered, but disciplinary environments might contextually shape it. Differences within and across fields suggest that interventions aimed at improving inclusive practices should also consider the specific cultural and institutional dynamics of each academic domain. Notably, Economics (ECON) exhibits considerable internal variation. Female academics in ECON-01 and ECON-02 show exclusively inclusive language patterns (100%), while others, such as ECON-06 and ECON-07, display a more mixed or predominantly non-inclusive profile. Among men, the situation is more concerning: language in ECON-06 and ECON-07 is entirely non-inclusive, suggesting the presence of entrenched communicative norms that may resist inclusive practices. The Law (GIUR) area presents a more polarised picture. Female academics show firm, inclusive profiles in GIUR-02, GIUR-03, and GIUR-06, with several cases of fully inclusive language. In contrast, male academics in GIUR-01, GIUR-06, and GIUR-08 exclusively exhibit non-inclusive language, with the sole exception of a partially inclusive case in GIUR-02. This dichotomy suggests that inclusivity in legal disciplines may be gendered and possibly linked to institutional or hierarchical dynamics. In Statistics (STAT), female academics again demonstrate higher inclusivity, particularly in STAT-04. Male academics in the same sectors lean toward either non-inclusive or partially inclusive language, reinforcing the broader gendered trend observed across disciplines. Other fields reveal additional patterns worth noting. In INF-01, male academics demonstrate relatively high levels of inclusive language (67%), emerging as a positive exception. Conversely, in GEOG-01 and STEC-01, language is uniformly non-inclusive, regardless of gender. Fields such as MAT-05 and ECON-08 show a more balanced distribution across all three language types, suggesting variability that individual rather than systemic factors may influence.

In addition to examining human language practices, this study evaluates the outputs of three large language models (LLM) — ChatGPT Basic, Deepseek, and Gemini 2.0 Flash — to assess their alignment with established inclusive communication criteria. Results are shown in the following Table 4.

Table 4: Language styles among large language models (LLMs)

	Inclusive communication		Not inclusive communication		Overall
Gemini 2.0 Flash	5	*38%*	8	*62%*	**13**
ChatGPT	3	*23%*	10	*77%*	**13**
Deepseek	1	*8%*	12	*92%*	**13**
Overall	**9**	**23%**	**30**	**77%**	**39**

The results indicate that all three models predominantly generated outputs that were classified as non-inclusive. In particular, deepseek displayed a low proportion of inclusive communication, with only 8% of its outputs meeting the criteria for inclusivity. ChatGPT achieved a higher percentage of inclusive communication (23%), suggesting some ability to produce outputs aligned with inclusive communication models, although non-inclusive responses remained the majority. Gemini 2.0 Flash recorded the highest proportion of inclusive outputs among the three models (38%), indicating a relatively greater presence of inclusive linguistic patterns within its responses, even though a substantial share of non-inclusive communication persisted. Overall, only 23% of the 39 outputs analysed across the three systems were classified as inclusive. These findings highlight a broader limitation in current LLMs, suggesting that inclusive communication principles are not yet systematically embedded in model training.

When considering the results as a whole, a ranking of inclusive language emerges across the groups and systems analysed. Female academics demonstrate the highest proportion of inclusive communication, confirming their leading position in adopting language styles aligned with inclusive language models. Following them, Gemini 2.0 Flash ranks second, showing a greater tendency toward inclusive patterns among the evaluated language models. ChatGPT occupies the third position, with a moderate share of inclusive communication. At the same time, male academics come fourth, highlighting a substantial gap in communication practices when compared to their female colleagues. Finally, Deepseek ranks fifth, with the lowest proportion of inclusive outputs observed.

4 Conclusion

The overall analysis highlights a clear ranking in the adoption of inclusive communication patterns. Female academics emerge as the group most aligned with inclusive models, followed by Gemini 2.0 Flash, which demonstrates the highest degree of inclusivity among the large language models evaluated. ChatGPT basic occupies the third position, while male academics are placed fourth, and Deepseek ranks fifth, showing the lowest level of inclusive language. This combined picture reinforces the idea that human factors, such as gender and disciplinary culture, play a decisive role in fostering inclusive communication, but also reveals that technological systems have not yet systematically integrated inclusive principles into their outputs. There is still a significant gap between the aspirations of inclusive language and the practices observed both in human and machine language.

4.1 Limitations and contributions

Several limitations must be acknowledged. First, the human data were collected from only two faculties at two different Italian universities, limiting the generalisability of the findings. Expanding the study to include a broader and more diverse academic population would provide a more nuanced and representative understanding of language practices across institutions. Second, the analysis of LLMs was restricted to three systems. Involving a wider range of models could reveal whether different training approaches or architectures produce varying patterns of inclusive communication.

Despite these limitations, the study offers important theoretical contributions by integrating human and machine communication analysis under a common framework derived from the literature. This approach enables a cross-contextual understanding of inclusivity and highlights the persistent barriers that affect communication dynamics. On a practical level, the findings underline the urgent need for targeted interventions—both educational and technological—that promote inclusive practices in academic contexts and encourage the development of AI systems better attuned to diversity-sensitive communication. Future initiatives should prioritise inclusive communication not merely as an ethical requirement, but as a strategic component for enhancing institutional quality, social cohesion, and innovation.

5 Ethics declaration

This study is based exclusively on publicly accessible institutional communications and content generated by artificial intelligence. It did not involve human participants or the collection of personal or sensitive data. Therefore, no ethical approval was required.

6 AI Declaration

Use of Artificial Intelligence as an object of study

This study employed three generative artificial intelligence models—ChatGPT (OpenAI, basic version), Deepseek, and Gemini 2.0 Flash — to autonomously produce simulated academic announcements addressed to students. These texts, generated without human intervention, were analysed and compared with communications authored by university faculty members to assess the degree of linguistic inclusivity based on pre-established criteria. The generation process ensured that each AI system created messages independently, thereby preserving the integrity of the dataset used in the analysis.

Use of Artificial Intelligence as a writing support tool

During the development of this article, ChatGPT (OpenAI, GPT-4 version) was used exclusively for linguistic and stylistic support, such as sentence rephrasing and abstract revision. All AI-generated content was critically reviewed and edited by the authors to ensure consistency with the research objectives, terminological accuracy, and adherence to the empirical data collected. The tool was not used for data generation or analysis, nor did it influence the coding process or the interpretation of results. All analytical and editorial decisions were made autonomously by the research team.

Unlocking Innovation in SMEs Though Transformational Leadership and Commitment-based HRM Practices

Elona Çera[1], Blerina Dhrami[1], Comfort Adebi Asamoah[2]
[1]University Metropolitan Tirana, Tirana, Albania
[2]Tomas Bata University in Zlin, Zlin, Czech Republic

Abstract

The purpose of this research is to examine transformational leadership impacts open innovation through the mediating role of commitment-based human resource management practices. A quantitative survey was conducted to collect data from a sample of 169 SMEs. The findings indicate a considerable positive correlation between transformational leadership and inbound open innovation in SMEs, as demonstrated by the quantitative survey analysis conducted with SmartPLS version 4.1.0.9. Furthermore, commitment-based human resource management methods work as a significant mediator between transformational leadership towards and innovation and the acquisition of knowledge within a company, referred to as inbound open innovation. The results underscore the imperative of developing organizational leadership that promotes change, creativity, trust, and employee commitment to enhance organizational openness. Open innovation is a recognized organizational approach that promotes transformation, enhances the competitiveness of SMEs, and stimulates overall economic growth. The results compel policymakers and decision makers to concentrate more on a transformational leadership style that can facilitate transformation and boost employee loyalty to the firm. Consequently, a culture of openness will be fostered, resulting in a more favorable impact on the performance of SMEs.

Keywords: Transformational leadership, HRM, inbound open innovation, competitiveness, SMEs

Paper type: Academic Research Paper

1 Introduction

Due to rapid changes and technological advancements changes, , there has been a major shift on the ways how firms innovate (Majchrzak *et al.*, 2023; Puliga *et al.*, 2023). Internal innovation is no longer a sustainable strategic option for introducing novelty and maintaining competitiveness in a market where innovation is essential for long-term growth and profitability (Camilleri *et al.*, 2023; Chesbrough, 2006, 2003; Van De Vrande *et al.*, 2009). Conversely, openness to external knowledge and the establishment of partnerships and collaboration beyond the borders of the organization is an important driver of innovation (Puliga *et al.*, 2023; Wiroonrath *et al.*, 2024). Consequently, contemporary organizations must embrace open innovation (OI) to satisfy the demand for innovation (Fatima and Masood, 2023; Puliga *et al.*, 2023). Chesbrough (2006) defines OI as *"the use of purposive inflows and outflows of knowledge to accelerate internal innovation, and expand the markets for external use of innovation, respectively*". This research indicates that internal resources are crucial for executing organizational activities, while external knowledge and collaboration with stakeholders such as customers, suppliers, other companies, universities, and research centers are essential for attaining the desired level of innovation and sustaining competitive advantage (Chesbrough, 2006; Engelsberger *et al.*, 2023; Fatima and Masood, 2023; Majchrzak *et al.*, 2023)

According to (Chesbrough and Crowther, 2006), open innovation is a concept employed to enhance organizational competitiveness through a bidirectional process of information sharing and resource exchange. Open innovation encompasses inbound open innovation, which emphasizes information inflows through the construction and development of new collaborations and partnerships with external entities to enhance organizational innovation capabilities (Chesbrough and Crowther, 2006). In contrast, knowledge outflows, referred to as outbound open innovation, pertain to the process of open innovation that emphasizes the exploitation of an organization's expertise and skills through commercialization (Chesbrough, 2006).

OI has attracted significant attention from researchers across all company sizes, however, this study focuses specifically on SMEs and inbound open innovation. Parida et al. (2012) say that outbound OI is more problematic for SMEs to undertake owing to their "liability of smallness," which arises from a deficiency in internal resources. Therefore, they should prioritize inbound OI to address their knowledge deficiencies before pursuing outbound OI. This study concentrates on inbound OI, as this strategy provides SMEs the option to adopt the notion of openness gradually and progressively. Extensive study is conducted on the openness of SMEs, examining several elements such as human resource management (HRM) (Naqshbandi *et al.*, 2023), leadership (Naqshbandi and

Jasimuddin, 2018; Naqshbandi and Tabche, 2018) organizational culture (Popa *et al.*, 2017) etc, which are acknowledged as the "human side" of open innovation (OI).

One of the most intriguing variables in this regard is the influence of leadership. Leadership is a crucial element in organizations adopting openness. Leaders focused on change, transformation, and innovation assist organizations in embracing adaptability, hence enhancing overall innovativeness (Naqshbandi and Tabche, 2018; Wiroonrath *et al.*, 2024). In this regard, transformational leadership (TL) has attracted the attemtion of organization innovation literature (Su *et al.*, 2020). Through consistent support and fair treatment, transformational leadership aims to inspire and motivate people to surpass predetermined goals, as a result, employee behavior fosters organizational innovation (e.g. open innovation) (Su *et al.*, 2020). Simultaneously, HRM systems have demonstrated beneficial effects on organizational results (Huselid, 1995). Consequently, it is plausible to assert that HRM systems implemented in firms may emerge from leadership ideologies. Leadership may impact the firm's actions through the implementation of HRM practices. This study specifically investigates the impact of transformational leadership on organizational outcomes, particularly inbound innovation, using commitment-based human resource management. Commitment-based HRM is characterized as a collection of HRM policies and practices that enhance trust, knowledge sharing, collaboration, and knowledge exchange (Collins and Smith, 2006). It aligns with the fundamental principles of TL, which emphasize shared interests. Consequently, TL seeks to cultivate commitment through HRM practices that promote the appropriate behaviors in employees, which are crucial for organizations engaged in open innovation.

This study constructs and evaluates a research model that examines the direct impact of transformational leadership on inbound OI, as well as the mediating effect of commitment based human resource management practices in SMEs. The primary objective of this study is to further the comprehension of open innovation dynamics in SMEs, specifically examining transformational leadership, commitment-based HRM, and inbound open innovation among Albanian SMEs. The significance of transformational leadership in various innovation outcomes is acknowledged, yet, its influence on inbound OI through the mediation of commitment-based HRM practices remains limited.

2 Literature review

Interrelations between transformational leadership, commitment-oriented human resource management (HRM), and inbound open innovation represent a compelling yet underexplored quest in contemporary organizational science. Extant literature has established isolated dyadic relationships between these constructs; however, the integrative mechanism through which transformational leadership fosters inbound open innovation via commitment HRM remains insufficiently theorized and empirically unverified. As demonstrated by Cao and Le (2024), transformational leadership has been extensively studied as “one of the most effective leadership styles contributing to positive and key outcomes for most organizations in the context of rapid change of business environment”. Their research has highlighted how transformational leaders inspire their followers to follow the change strategy and motivate them to achieve the change goals beyond expectations through their positive impacts on employee trust. Similarly, García-Morales *et al.* (2008) have conceptualized transformational leadership as “the engine and transmitter” of innovative culture and of the dissemination of knowledge, specifically pertinent to organizational performance improvement. Despite these valuable insights, the specific pathways through which transformational leadership influences open innovation processes, particularly through HRM systems, remain underdeveloped in the literature, constituting a significant knowledge gap that warrants further investigation.

The mediating role of commitment HRM in the relationship between transformational leadership and inbound open innovation can be theoretically substantiated through multiple complementary perspectives. Zhu *et al.* (2005) have empirically demonstrated that “human-capital-enhancing HRM fully mediates the relationship between CEO transformational leadership and subjective assessment of organizational outcomes”, which suggests that transformational leaders operationalize their vision primarily through HR systems. This finding aligns with Chiang *et al.* (2011) assertion that “high-commitment HRM was positively related to perceived organizational support”, which subsequently enhances knowledge-sharing behavior, which per se represents a critical antecedent of inbound open innovation. The convergence of these empirical findings suggests that commitment HRM serves as a principal intermediary mechanism through which transformational leadership influences innovation outcomes. Furthermore, Cao and Le (2024) have identified the mediating role of employee trust between transformational leadership and organizational change capability, noting that “transformational leaders are capable of providing a positive vision and actualize necessary changes for organization due to paying much attention to promoting a climate of collaboration among individuals, fostering emotions and a trustworthy

culture". This parallel mediating relationship suggests that commitment HRM might similarly function as a mediational pathway through which transformational leadership facilitates inbound open innovation.

A pronounced knowledge gap exists in understanding the tripartite relationship between transformational leadership, commitment HRM, and inbound open innovation within a unified theoretical framework. While several authors(Cao and Le, 2024; Cera and Abbas, 2023) have established that transformational leadership has a significant relationship with developmental culture and open innovation and that developmental culture mediates the relation between transformational leadership and open innovation, the specific role of commitment HRM in this relationship remains generally obscure. Similarly, Gad David *et al.* (2021)G have demonstrated that transformational leadership positively impacts the outbound open innovation and enhances a firm's innovation culture, which encourages the inbound open innovation, but have not explicitly examined the mediating role of commitment HRM in this process.

This theoretical cavity is particularly significant given that commitment HRM, with its emphasis on enhancing employee engagement and knowledge sharing (Chiang et al., 2011), conceptually aligns with both the inspirational aspects of transformational leadership and the collaborative requirements of inbound open innovation. Moreover, Lei *et al.* (2019), have argued that "organizations can only follow and implement change initiatives successfully if their leaders get the involvement of employees through fostering their trust in leadership", suggesting that commitment-based approaches to HRM might be essential for translating transformational leadership into innovation outcomes. The identified knowledge gap is further amplified by Su *et al.* (2020) observation that transformational leadership can affect organizational and individual outcomes through the establishment of a collaborative HRM system, which implies but does not explicitly verify the mediational role of commitment HRM in innovation processes.

Based on the foregoing theoretical analysis and the identified knowledge gaps, there is compelling rationale to hypothesize that commitment HRM mediates the relationship between transformational leadership and inbound open innovation. This mediation hypothesis is supported by several theoretical threads: first, transformational leaders create conducive environments for knowledge acquisition and sharing (García-Morales *et al.*, 2008); second, these leaders implement commitment-oriented HRM practices to operationalize their vision (Zhu *et al.*, 2005); third, commitment HRM enhances employee engagement and knowledge-sharing behaviors (Chiang et al., 2011); and fourth, such knowledge-sharing behaviors are fundamental to inbound open innovation processes (Cera and Abbas, 2023; Gad David *et al.*, 2021). The integration of these theoretical perspectives suggests that transformational leadership does not directly influence inbound open innovation but rather operates through the mediating mechanism of commitment HRM. We believe that this hypothesis addresses a significant gap in the literature by shedding light on the complex interrelationships between leadership styles, HR systems, and innovation processes, thereby contributing to a more nuanced understanding of how organizations can effectively leverage external knowledge sources through appropriate leadership and HRM configurations.

In consideration of the conceptualizations explored above, as well as in view of the knowledge gap identified, we hypothesize the following relationships:

- ***H1:*** *Transformational leadership is positively associated with inbound open innovation.*
- ***H2:*** *Transformational leadership is positively associated with commitment-based HRM.*
- ***H3:*** *Commitment-based HRM practices mediates the link between transformational leadership and inbound open innovation.*

3 Methodology

3.1 Data and sample

This study employed a quantitative methodology. Creswell and Creswell (2017) claim that this methodology is more accurate since it can derive the characteristics, beliefs, and/or behaviors of a population from a limited sample size. The current study's outcomes are carried out via surveys. Saunders *et al.* (2009) contend that the suggested research methodology involves executing extensive quantitative research and examining the interconnections among diverse variables inside a defined research framework. Participants in the study were from a variety of different fields, including the manufacturing and service industries. There were 169 respondents in all. It was determined that the sample size in question was sufficient to Hair *et al.* (2017). In this study, the respondents were firm owners, managers, or chief executive officers. This type of research requires the inclusion of participants who hold a high managerial role in order to guarantee that they have a comprehensive understanding of the organization activities, which is consistent with the methodologies that have been applied in earlier studies (Martinez-Conesa *et al.*, 2017).

3.2 Variable measurement

The independent variable *transformational leadership* was measured by four items adopted by the researchers García-Morales et al., (2008). Example of the items used to measure the construct: TL1 - "The organization's management has a clear common view of its final aims and is able to transmit them and achieve the commitment of the rest of the organization's members". The mediation variable construct of commitment-based HRM was measured by a scale of 10 items adopted by Collins & Smith, 2006. One sample item of the measured construct is: "Internal candidates are given consideration over external candidates." The dependent variable of this research, inbound open innovation, was assessed using a six-item construct developed from the work of Cheng and Shiu (2015). An example of a sample item is provided in the following statement: "Our organization constantly scans the external environment for inputs such as technology, information, ideas, knowledge, etc".

4 Analysis of results

4.1 Analysis of reliability and validity

The measurement model's validity and reliability must be assessed before proceeding with the structural model analysis. Table 1 demonstrates that all average variance extracted (AVE), Cronbach Alpha (CA), and composite reliability (CR) values are above the established thresholds of 0.508 and 0.709, confirming the achievement of convergent validity and reliability (Hair *et al.*, 2022) In evaluating the discriminant validity of the study construct, the researchers employed the HTMT and the Fornell-Larcker criterion, which are widely proposed by prior literature (Fornell and Larcker, 1981; Henseler *et al.*, 2015). Table 2 is a presentation of Fornell-Larcker and HTMT's output. The HTMT values are less than 0.85 to show the attainment of discriminant validity; the square root of the AVE for every variable is higher than the correlations of the other variables (Hair *et al.*, 2022).

Table 1: Assessment of reliability and convergent validity

Constructs	Code	CR	CA	AVE
Inbound Open Innovation	OPEN-INNO	0.915	0.891	0.645
Transformational leadership	T-LEAD	0.915	0.876	0.729
Commitment-based HRM	COM-HRM	0.926	0.908	0.612

Source: Author's construct.

4.2 Assessment of quality measures

The study employed the coefficient of determination (R-squared) and the Q-squared to evaluate the model's anticipated accuracy. The R^2 for COM-HRM is 0.403, indicating that T-LEAD accounts for about 40.3 per cent of the overall distinctions in COM-HRM. Also, the findings suggest that T-LEAD and COM-HRM account for about 39 per cent of the overall distinctions in inbound open innovation, as indicated in Table 3. All the R^2 values suggest that the constructs have acceptable justifications as they exceeded the values of 0.26 proposed by Cohen (1988) to achieve an acceptable R^2.

Table 2: The Fornell-Larcker criterion and HTMT values

Fornell-Larcker	COM-HRM	OPEN-INNO	T-LEAD
Commitment-based HRM	**0.782**		
Inbound Open Innovation	0.516	**0.803**	
Transformational leadership	0.635	0.600	**0.854**
HTMT			
Inbound Open Innovation	0.537		
Transformational leadership	0.699	0.643	

Source: Author's construct.

Moreover, as per the Hair et al. (2017) heuristic, the model has a substantial predictive significance, evidenced by Q^2 values of 0.389 and 0.345 for COM-HRM and OPEN-INNO, respectively. The SRMR indices were also used to determine the model's fitness. An SRMR value above 0.08 is acceptable (Diamantopoulos and Siguaw, 2000). Hence, an SRMR score of 0.081 signifies that the model is well-fitted. Further, the F^2 value of 0.050 suggests the removal of the construct, COM-HRM, will have a small impact on the model. Last, the removal of T-LEAD from the model will significantly influence the model as its highest F^2 value, 0.68, is greater than the moderate value of 0.35 (Cohen, 1988).

Table 3: Results of R^2 and Q^2

	R^2	R^2 Adjusted	Q^2
Commitment-based HRM	0.403	0.400	0.389
Inbound Open Innovation	0.391	0.383	0.345
F^2 values	**OPEN-INNO**		**COM-HRM**
Commitment-based HRM	0.050		
Transformational leadership	0.203		0.676

Source: Author's construct.

5 Discussions

According to the results displayed in Table 4, T-Lead has a positive relationship with Open-Inno. The relationship was significant at the 5 per cent level, as it yielded a T-statistic of 4.681, which exceeds the threshold of 1.96. Additionally, a path coefficient of 0.456 indicates that a one-unit increase in T-lead characteristics will result in a 46 per cent increase in Open-Inno. Furthermore, the CI values between 0.248 and 0.628 suggest that this relationship is not due to chance. Hence, the $H1_a$ is supported. This indicates that T-Lead enhances Open-Inno. The reason has been that transformational leaders foster a visionary culture, encouraging collaboration and information integration from external sources. They empower teams, build trust, and create a comfortable environment for implementing ideas from outside sources. Previous studies suggest that the characteristics of transformational leadership serve as a basis for skill acquisition, knowledge enhancement, expertise development, and innovation cultivation (Awan and Jehanzeb, 2022; Gad David *et al.*, 2023).

Table 4: Direct and indirect results

Hyp	Path	Beta	Confidence Interval	T stat	P value	Support
H1	T-lead-> Open-Inno	0.456	[0.248, 0.628]	4.681	0.000	Yes
H2	T-lead-> Com-HRM	0.635	[0.523, 0.737]	11.566	0.000	Yes
H3	T-lead-> Com-HRM-> Open->Inno	0.144	[0.033, 0.294]	2.189	0.029	Yes

COM-HRM - Commitment-based HRM; T-LEAD - Transformational leadership; OPEN-INNO - Inbound Open Innovation;

Source: Author's construct.

Again, T-Lead has a positive and significant relationship with Com-HRM (H2). The result suggests that Com-HRM is expected to increase by 63.5 per cent when the T-Lead unit is enhanced. According to prior studies, T-Lead facilitates HRM practices on employees' organizational commitment (Lin *et al.*, 2012). Using their great emotional connection to the goals of the firm and shared vision, which motivates them, T-Lead improve Com-HRM(Jiatong *et al.*, 2022). The basis of commitment-oriented activities includes internal career advancement, democratic decision-making, and employee development are empowering and helpful acts that serve to establish trust and motivation (Jun and Lee, 2023). This kind of leadership suits the HRM policies prioritising corporate civic behaviour and long-term employee participation. Moreover, constant motivation and inspiration stimulate subordinates' commitment towards the organisation ((Ausat *et al.*, 2022). The result confirms the findings of Ausat *et al.* (2022) who revealed that T-Lead significantly impact Com-HRM among organizations.

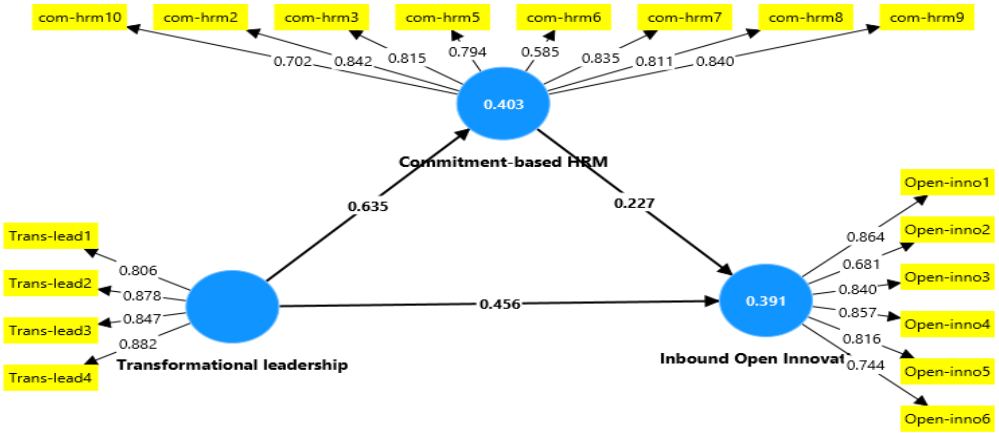

Figure 1: Structural model showing direct and indirect paths

Lastly, the study evaluated the mediating function of Com-HRM, revealing that it has a partial role in the T-Lead and Open-Inno connection (β=0.144; p<0.029). The study highlights the importance of T-Lead in improving Com-HRM to promote Open-Inno, making Com-HRM a valuable mediating variable. The VAF of 24.02 suggests that T-Lead and Com-HRM account for a substantial proportion of the variability in inbound open innovation. The value of 24.02 also indicates that Com-HRM partially mediates the relationship between the T-Lead and Open-Inno connection. The result supports a prior study that posits Com-HRM can facilitate the link between transformational leadership and inbound open innovation by fostering trust, engagement, and communication with external knowledge sources (Jun and Lee, 2023). This approach, utilising techniques like empowerment, training, and participatory decision-making, promotes transparency and initiative, enabling organisations to effectively embrace external innovations.

6 Conclusions

The objective of this study was to examine the mediating role of commitment-based HRM in the relationship between transformational leadership and inbound open innovation in SMEs. The distributed survey garnered responses from a total of 169 participants. The hypothesis was developed utilizing SmartPLS version 4.1.0.9. The results demonstrated that transformational leadership exerted a substantial beneficial influence on inbound open innovation. Transformational leadership had a favorable correlation with commitment-oriented HRM strategies. Given that commitment-based HRM is documented in existing literature to have a significant direct relationship with inbound open innovation, the study posited it as a mediating variable. The successful assignment of commitment-based HRM as a mediating variable in the link between transformational leadership and inbound open innovation metrics was achieved.

This study presents some practical implications for SMEs aiming to enhance innovation through leadership and HRM. Transformational leadership development may equip leaders to inspire, instill trust, and drive change. Such leaders play a pivotal role in fostering a culture of collaboration and openness. Secondly, implementing commitment-based HRM strategies such as participatory decision-making and internal promotion enhances employee engagement and loyalty. These approaches function as an essential link between leadership and inbound open innovation. Policymakers should also endorse leadership and human resource management training programs to enhance the competitiveness of SMEs. An effective HRM system aligned with innovation objectives promotes knowledge exchange and collaboration. Ultimately, this integrated approach enables SMEs to thrive in dynamic, knowledge-driven environments.

This research possesses multiple limitations. The research is confined to Albanian SMEs, perhaps impacting the generalizability of the findings to other cultural or economic contexts. Furthermore, the study concentrates solely on inward open innovation, neglecting outbound or coupled modalities that could provide a more comprehensive understanding. Furthermore, the utilization of self-reported measurements may inadequately include the intricacies of leadership behavior and innovation processes. Finally, exogenous factors such as market dynamics or technical changes were not controlled, potentially affecting the observed connections.

Abstract

The goal of the proposed paper is to provide a preliminary Artificial Intelligence (AI) approach addressing the analysis on the prevention of diabetes. The study is performed within the framework of the research project *Telediabetolab* and focuses on the check of the supervised Support Vector machine (SVM) algorithm to define a method to perform a data processing analysis based on predicted diabetes risk. The preliminary study highlights the possibility of defining a multi-parametric approach to prevent the chronic condition of diabetes by considering the pre-diabetes condition. The SVM data processing is executed by analyzing different parameters such as blood pressure, body weight, glucose, and blood ones. The predicted results show that there could be cases of diabetics who might not be diabetic and cases of non-risk that could degenerate.

Keywords: Telediabetology Process, Process Mining, chronic disease management

Paper type: Academic Research Paper

1 Introduction: Telediabetolab framework

The work analyses the preliminary results of a research project. The project addresses the use of a regional telediabetology platform (*Telediabetolab* project) integrating Artificial Intelligence (AI) algorithms scalable on a national level. The proposed model is further integrable with other validated telemedicine systems and applies the process mining approach matching healthcare processes with AI decision making (Rosa et al, 2024; Rosa and Massaro, 2024). The platform is to be tested at the ASL of Bari on an initial sample of 100 patients: the project takes into account the use of telemedicine devices such as glucometers, body weight scales, and blood pressure meters, and fixed point of care including multiparametric capillary blood analyzers and retinographers, with the aim of implementing new management processes for diabetics in terms of primary, secondary and tertiary prevention, care, and remote monitoring. Specifically, the project platform (see the main framework of Fig. 1) is designed to be interoperable and compatible with the information systems of the National Health System (NHS) for the exchange of data with electronic health records and for the use of certified monitoring sensors. Elements of innovation are: (i) the formulation of new clinical/care processes (PDTA) and management of diabetics through the use of AI engines to limit the risks of diabetes, (ii) the digital mapping of diabetics (construction of a Regional database), (iii) the implementation of a procedure for optimizing the dosage of medicines, (iv) the formulation of prevention guidelines based on the correct lifestyle associated with the different classes of diabetics, (v) the optimization of the organizational processes of healthcare personnel using data-driven machine learning approaches. Socio-economic impacts are in a potential reduction in hospitalizations and treatment costs, and in an improvement in the quality of life of diabetics. The novelty of the paper is the full integration of sensor technologies into a telemedicine platform enabling AI algorithms to improve the PDTA decision making in diabetic primary prevention processes.

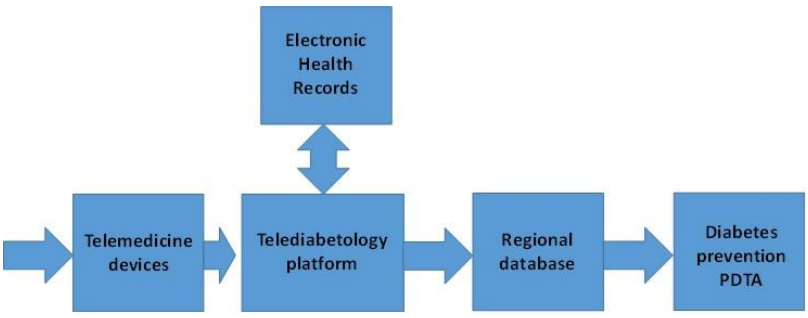

Figure 1: Main framework of the Telediabetology project.

2 Literature Review

In recent years, the landscape of healthcare has undergone a significant transformation, driven by advancements in technology and a growing emphasis on patient-centered care. Among the most promising developments is the integration of telemedicine, digital health, AI, and process mining, which together form a comprehensive approach to enhancing the management of diabetes and other chronic diseases. This innovative synthesis not only holds the potential to improve patient outcomes but also to optimize healthcare delivery systems.

2.1 Telemedicine and Telediabetology

Telemedicine has revolutionized the management of chronic diseases, particularly diabetes, through the specialized field of telediabetology, which prioritizes remote patient care (IDAMA, 2024). Studies by Borgonovi and Ferrara (2022) and Cerf (2020) underscore the transformative impact of telemedicine in enhancing healthcare access for patients facing geographical and financial barriers. This accessibility translates into improved health outcomes, facilitated by real-time monitoring capabilities (Shoeibi et al., 2022). Remote Patient Monitoring Systems (RPMS) have demonstrated effectiveness in reducing hospital visits and mortality rates, while simultaneously improving the quality of life for individuals with diabetes (Kakhi et al., 2022; Nahavandi et al., 2022). Additionally, the advantages of utilizing telemedicine solutions are clear: cost savings from reduced investments and infrastructure expenses, improved efficiency of medical staff's working hours, and enhanced service quality due to quicker diagnosis and treatment monitoring (Stawicka and Parlinska, 2020).

2.2 The Role of Digital Health in Diabetes Management

Digital health (DH) has shown immense potential to revolutionize diabetes prevention and management by leveraging diverse clinical, anthropometric, biochemical, and behavioral data over time. This innovative approach enhances support for individuals at risk of or currently living with diabetes. To fully harness the benefits of DH technologies, it is vital for policymakers, patients, and caregivers to actively engage with these advancements, ultimately fostering improved public health outcomes (Ranjani et al., 2024).

Telediabetology, as a distinct domain within telemedicine, emphasizes the remote management of diabetes through advanced technological interventions. The COVID-19 pandemic has accelerated the adoption of telehealth solutions, highlighting the necessity for continuous monitoring and timely interventions in chronic disease management (Ahmad et al., 2022). Effective management strategies must enhance patient engagement and adherence to treatment regimens, a principle underscored by the World Health Organization (2020).

Recent findings indicate that telediabetology can substantially improve glycemic control and overall health outcomes through real-time data collection and personalized care (Chao et al., 2021). The integration of digital health technologies into diabetes management has shown significant potential for enhancing patient outcomes. Mayya et al. (2024) emphasize the promise of artificial intelligence (AI) for predictive analytics, enabling the identification of high-risk patients and the customization of interventions. This vision aligns with the objectives of the *Telediabetolab* project, which seeks to employ AI for diabetes risk assessment and management via a telemedicine platform.

2.3 Advancing Chronic Disease Management Through Process Mining and AI

The intersection of telediabetology, process mining, and AI presents a dynamic framework for advancing chronic disease management, particularly diabetes prevention and care. The methodologies explored in the literature reveal the potential of predictive analytics to transform healthcare delivery, thereby enhancing patient outcomes while concurrently reducing costs. The *Telediabetolab* project aims to contribute to this evolving landscape through a focus on knowledge acquisition and AI data processing in telediabetology, ultimately enhancing chronic disease management.

2.4 Process Mining in Healthcare

Process mining has emerged as a critical methodology for analyzing and optimizing healthcare workflows, particularly in chronic disease management. Process mining is a technique that extracts valuable insights from event logs, facilitating the discovery, monitoring, and enhancement of actual processes within healthcare settings (Rosa and Massaro, 2024). This capability is essential for identifying inefficiencies and improving patient pathways, especially in telediabetology.

The Process Mining Organization (PMO) model, proposed by Rosa et al. (2023), provides a systematic framework for healthcare systems to analyze existing workflows and design optimized care processes. This model comprises three key phases: analyzing current processes, employing AI-driven data processing for predictive insights, and implementing corrective actions to improve workflows. This structured approach not only identifies bottlenecks but also informs strategic decision-making aimed at enhancing patient care and optimizing resource utilization in chronic disease management.

2.5 AI Applications in Chronic Disease Management

AI, particularly Machine Learning (ML), is increasingly leveraged in chronic disease management. Tools such as Support Vector Machines (SVM) are utilized to predict diabetes risk and support clinical decision-making through predictive analytics (Al-Qatf et al., 2018; Viloria et al. 2020). AI enhances personalized medicine by analyzing extensive patient data to create tailored treatment plans, thereby improving outcomes and fostering patient engagement (Kim et al., 2020).

2.6 Machine Learning and Predictive Analytics

ML has garnered significant attention in chronic disease management, especially for risk prediction and patient stratification. The integration of ML algorithms, such as SVM, enables healthcare professionals to analyze large datasets and identify patterns that inform clinical decision-making (Rosa and Massaro, 2024). This predictive capacity is particularly critical in diabetes management, where glycosylated hemoglobin (HbA1c) levels serve as key indicators of long-term glucose control (Chao et al., 2021). By applying both supervised and unsupervised ML techniques, healthcare providers can classify patients based on risk profiles, facilitating timely interventions and personalized treatment plans. The dual application of these algorithms enhances data interpretation and informs resource allocation and patient management strategies, as demonstrated in the research of Rosa and Massaro, (2024).

The integration of telemedicine, AI, and process mining within the realm of telediabetology signifies a pivotal shift in the approach to chronic disease management, particularly in diabetes care. The application of predictive analytics and digital technologies can significantly enhance healthcare delivery, improve patient outcomes, and reduce costs. By fostering a collaborative environment that embraces innovation and leverages the strengths of these technologies, healthcare organizations can not only optimize their processes but also ensure that patients receive the highest quality of care in managing chronic diseases.

3 AI results: testing of a SVM algorithm

The SVM algorithm tests an open dataset[1] composed of the following attributes matching with the data detectable by the experimental devices of the telediabetology project:

- Id: patient ID;
- Chol: total cholesterol;
- Stab.glu: stabilized glucose;
- hdl: high -density lipoprotein;
- ratio: Cholesterol/HDL Ratio;
- glyhb: Glycosylated Hemoglobin;
- gender;
- height;
- weight;
- frame: body frame
- bp.1s, bp.1d, bp.2s, bp.2d: first/second systolic/diastolic blood pressure.

The dataset is aligned with real attributes of the physiological parameters making the proposed model very similar to the experimental one. In order to estimate the risk of diabetes two thresholds (see Fig. 2) are considered by considering the Glycosylated Hemoglobin (HbA1c) being one of the most critical parameters of diabetes: HbA1c value of 5.7%-6.4% diagnosed as pre-diabetes, and HbA1c ≥6.5% diagnosed as diabetes (Chao et al., 2021).

[1] https://www.kaggle.com/datasets/imtkaggleteam/diabetes?select=diabetes.csv

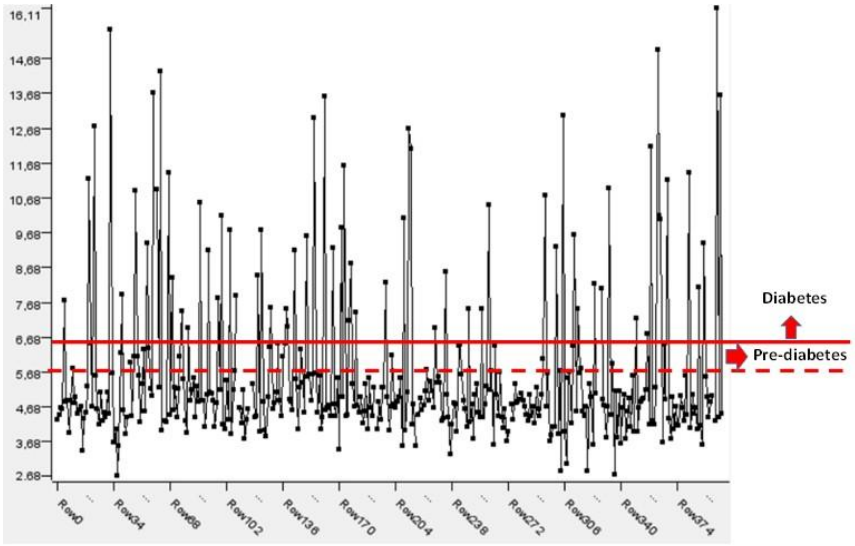

Figure 2: Plotting of the critical parameter of the Glycosylated Hemoglobin defines the threshold of pre-diabetes and diabetes conditions (Chao et al., 2021).

A total number of 403 records are processed by means of the SVM algorithm of the Konstanz Information Miner (KNIME) open - source tool providing the prediction of diabetes risk. The diabetes risk is considered for all the HbA1c values above the threshold of 5.7. For 396 records it is observed a matching between diabetes risk and the predicted one, while for 7 values a discordance is checked. Fig. 3 illustrates a screenshot of the extraction of the 7 records characterized by the mismatching, and Fig. 4 shows the scattering plot of the whole analysis (diabetes risk versus the prediction of the diabetes risk). The predicted values highlight that there could be cases of diabetics who might not be diabetic and cases of non-risk that could degenerate. This aspect suggests that a deeply analysis should be performed to define a possible risk: for example, a value of 4.81 of HbA1c which is considered normal (record 194) could degenerate into diabetes. These cases could be the ones to pay more attention to in order to avoid triggering cases of diabetes. However, a more accurate analysis requires more discordance cases to find possible correlations between other critical conditions due to the combination of other parameters (age, cholesterol, etc.). Cases that could be misclassified could instead be reconsidered as borderline cases requiring further analysis to estimate correctly the diabetes risk.

Row ID	I chol	I stab.glu	I hdl	D ratio	D glyhb	I age	S gender	I height	I weight	S frame	I bp.1s	I bp.1d	S Diabetes Risk	S Prediction (Diabetes Risk)
Row9	263	89	40	6.6	5.78	55	female	63	202	small	108	72	YES	NO
Row44	213	76	40	5.3	5.96	72	female	59	137	large	130	60	YES	NO
Row194	143	371	46	3.1	4.81	68	male	67	158	small	138	82	NO	YES
Row230	174	105	117	1.5	5.53	20	male	70	187	medium	132	86	NO	YES
Row267	195	171	29	6.7	5.68	78	male	66	172	large	130	82	NO	YES
Row309	198	86	66	3	5.68	61	male	74	152	small	138	76	NO	YES
Row347	306	92	56	5.5	5.58	74	male	69	184	large	140	72	NO	YES

Figure 3: Extraction of the predicted results with discordance between diabetes risk and the prediction of the diabetes risk.

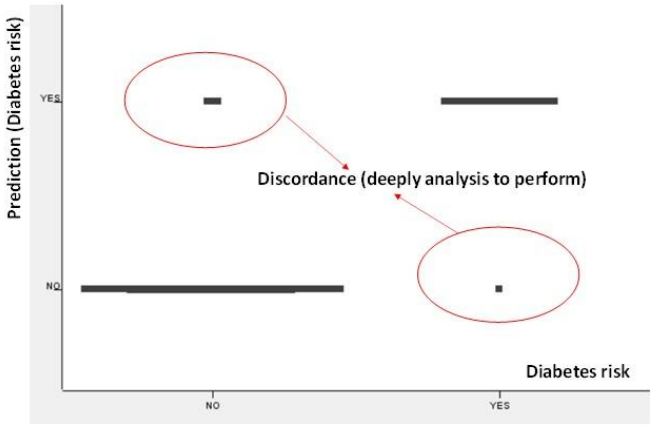

Figure 4: Plot of all the SVM results: diabetes risk versus the prediction of the diabetes risk.

The good performance of the SVM algorithm is proved by the Receiver Operating characteristic ROC curve of Fig. 5 estimating an area under the curve of 0.989. The SVM is performed before by cleaning the dataset[1] (filtering of the not significant attributes such as Id, and neglecting attributes with missing values).

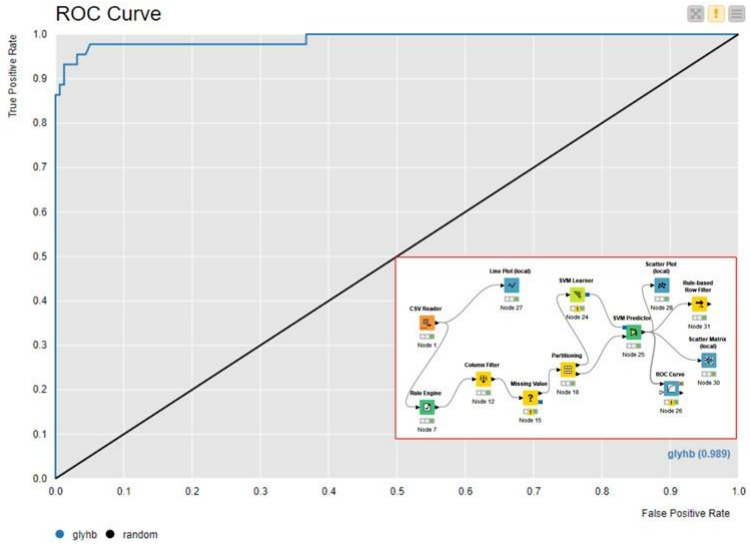

Figure 5: ROC curve indicating the good performance of the SVM algorithm. Inset: KNIME workflow adopted for the SVM data processing.

4 Conclusion

The proposed study is addressed within the existing literature about advanced healthcare methodologies improving clinical processes, by focusing the attention on process mining applications. The integration of AI into the telemedicine framework improves the decision support systems providing the digital knowledge base for the primary prevention of diabetes based on the risk analysis of the chronic condition. This improves the PDTA clinical processes thus supporting the management of the diabetes risk on a large scale. The integration of AI into the PDTA workflow makes processes intelligent adopting decision engines based on AI classification or AI prediction. Specifically, the work highlights the possibility of using AI as a warning tool for diabetes risk with the aim of minimizing chronic cases as much as possible. Due to its performance, the SVM algorithm proves to be suitable for datasets compatible with those that will be created in the activities of the *Telediabetolab* project. Future work will concern the study of correlations between multiple parameters to define more accurate criteria for defining preventive diabetes risk, and the comparison with other AI algorithms such as Artificial Neural Networks (ANNs) that are considered equally suitable for risk classification.

5 Acknowledgments

The paper has been developed within the framework of the project titled: “Telediabetology applied to the optimization of clinical/healthcare processes for monitoring and treating diabetics, through innovative prevention and prediction approaches” (bando PNRR INTERCONNECTED NORD-EST INNOVATION ECOSYSTEM – INEST-M4C2 –investimento 1.5. creazione e rafforzamento di "ecosistemi dell’innovazione per la sostenibilità”, NEXTGENERATIONEU, Spoke 2).

6 Ethics declaration

The research activities presented in this paper are based on the analysis of publicly available datasets and do not involve any experimentation on human participants, personal data collection, or sensitive information. Therefore, ethical clearance was not required for the development of this study.

7 AI declaration

No AI tools were used in the drafting, editing, or development of this paper. All content, analysis, and writing were conducted entirely by the authors.

Abstract

Efficiency and value creation for citizens, communities, and societies are becoming increasingly important for the public sector. Public sector is continuously seeking for innovative ways to create and provide services, and despite acknowledging the key role of knowledge in innovation processes, the relationship between publicly available knowledge and innovation is still poorly understood. A more unified view of OI and the *public sector originated knowledge* ecosystem, alongside public-private collaboration, is crucial. The private sector's creation of open knowledge-based innovations, such as products or services, for private markets appears to have minimal influence. To achieve successful *knowledge-based* innovation, functional systems are crucial for addressing the identified barriers within *public knowledge* and innovation. This paper investigates the potential of public sector originated knowledge to drive open innovation in partnership with public and private organizations. The potential to gather and use openly available knowledge is now greater than ever due to the possibilities provided by AI. Challenges in innovation are widely explored in existing research. Future studies should focus on developing models for successful open knowledge initiatives, including strategic planning (value realization and resource-based strategic analysis), technical enablers (new digital technologies as AI), sharing platforms (design of public knowledge sources with appropriate APIs), enabling functional *public knowledge* ecosystems, and legal frameworks to support open *public knowledge* sharing and utilization (e.g., knowledge privacy). Research needs to consider social aspects alongside technological and business ones. This includes management models for *public knowledg*e and innovation, knowledge processes and its management to support OI, and organizational cultures that reflect experiences of control or safety, risk management, attitudes and engagement in OI processes. To better comprehend how the private sector can benefit from public *knowledge*, additional empirical studies are crucial.

Keywords: Open innovation; publicly available knowledge; knowledge-based innovation; public-private co-creation

Paper type: Academic Research Paper

1 Introduction

Efficiently providing public services to its citizens and other stakeholders is a pressing concern for the public sector. As research on open innovation (OI) intensifies (Chesbrough 2020), it highlights the need for external problem solvers in the public sector. Private sector actors are increasingly designing new tech solutions and innovations for public services, using their digital platforms and applications. Globally, national governments (Reggi and Dawes 2021) have stressed the importance of open government knowledge, which is produced by the private-based digital applications, for external use. The main concern revolves around the use and subsequent processing of this knowledge. Studies exploring the value of open innovation in the public sector often point to private organizations as key collaborators for enabling value creation through democratization and the public value creation approach (Parrado and Reynaers 2020; Pedersen 2020). Yet, the social implications of companies' potential innovations have been ignored in terms of their economic impact.

The economic potential of open knowledge is significant. Stott (2014) estimates that open knowledge could create an additional €3 trillion to €5 trillion in value annually. An example of public knowledge utilization can be seen in London, where the Transport for London open knowledge source has led to the development of 550 applications, the creation of 5500 jobs, and the use of 25 knowledge sources or platforms (Stone and Aravopoulou 2018). The London transport case, if applied to EU datasets, would generate over 30,000 applications and 5 million new jobs across the EU. But critics argue that the anticipated benefits of open knowledge may be overly optimistic (e.g., Jamieson, Wilson, and Martin 2019).

According to Attard et al. (2015), public or governmental entities are responsible for producing public knowledge. OI commonly starts with open knowledge, which is often seen as a starting point for ideation. While the knowledge's potential is acknowledged, how it connects to innovation is more unclear. Process ideation develops solutions for known problems, but policy or legal concerns may block their actual use or trial. Public

actors have a duty to serve the public and generate value (Hartley, Sørensen, and Torfing 2013), a responsibility that contrasts with the profit-driven logic of the private sector.

Private sector involvement can significantly enhance the OI ecosystem. Nonetheless, private businesses need to explore new concepts and advancements within the framework of social institutions. Evaluating value creation for public services delivered by private companies involves examining the interaction between the public sector, service users, and the companies themselves. Osborne (2018) defines co-creation "as a process characterized by interactive relationships that generate value through their shared engagement". According to service logic, companies are involved in creating customer value, but there is usually a market acting as a mediator between them and the customer. The creation of services within company networks is often facilitated by shared knowledge resources (Sønderskov and Rønning 2021). External resources can be tapped into through the knowledge and resource ecosystem, providing a platform for joint problem-solving between public and private sector actors (Torfing et al. 2019). Despite these suggested value benefits, there are those studies who claim that service users lack the ability to create value (Beck and Bozeman 2007). Meynhardt (2009) takes a different approach than others, arguing that public services should consider not just private sector value, but also group and public value. Supporting factors or actors should be identified and considered by both service users and providers (Grönroos 2019).

This paper emphasizes the public sector's role as a context, suggesting the need to explore opportunities for private market participation in service development. The literature has identified several challenges to using open knowledge and developing open knowledge-driven innovations. These challenges can be categorized as technical design and knowledge quality or integration, knowledge management and policy and legal issues, financial backing for open knowledge programs, or organizational and cultural contexts (Attard et al. 2015; Jetzek 2016; Ruijer et al. 2017; Toots et al. 2017; Ferraris et al. Pellicelli 2020). Smith and Sandberg (2018) argue that challenges in open knowledge operation processes can affect the way knowledge is used and the various stages of its implementation. When platforms lack identification requirements, anonymity in knowledge use poses a challenge (Begany and Martin 2020). Therefore, *this study seeks to explore the potential of public knowledge to spur open innovation via public-private partnerships*.

2 Public-private co-innovation

Open innovation (OI) can consist of open knowledge, organization agile practices or culture, offered digital services or personnel knowledge or other resource visualization capabilities (Lindquist and Buttazzoni 2021). Alternatively, OI can be considered as a resource-based approach or a social exchange and benefits approach (Hopp et al. 2021). Innovation here means new products, services or processes that produce business or non-monetary value (e.g. knowledge or competence or other shared resource) for the organization or end users. Technology solutions with simultaneous competence development seem to be one of the main sources of opportunities for innovations (Di Stefano, Gambardella and Verona 2012; Clausen, Demircioglu and Alsos 2020).

Innovation actions are often focused on proving the effectiveness of public sector services (De Vries et al. 2016; Osborne 2018). The research has identified the factors of innovation; trust seems to be crucial between private-public agencies (Brogaard 2017; Brogaard 2021) and co-operation is needed, when simultaneously formulating ecosystems. Ecosystems around knowledge or accumulated knowledge can be an enriching source for innovations (Pollock 2011). However, an organization's internal capability to utilize external resources to enhance innovations is needed (Di Stefano et al. 2012). Furthermore, public sector personnel's involvement in the innovation activities is essential to improve the performance of the organization (Demircioglu and Audretsch 2017). It is worth noticing how public and private stakeholders together with politicians and policymakers could minimize administrative silos and forward cross-sector collaboration (Torfing, Sørensen, and Røiseland 2019).

In terms of regionality, for administration of the innovation process to succeed, multilevel coordination is needed between regional and local agencies (e.g. Dmitreiva and Guseva 2017; Catala-Perez and de-Miguel-Molina 2021). The governance mechanisms can offer innovation potential, and the public sector can play a major role as a facilitator in the innovation process (Lember et al. 2019; Carbonara and Pellegrino 2020; Hayter and Clapp 2020), especially with public-owned enterprises (Luke, Verreynne and Kearins 2010).

However, the question has been asked whether it is correct to share public developed platforms or acquired knowledge funded by public tax income? Past thinking is that collaborative innovation between public and private actors or shared platforms is a risk because private actors could use the innovation results in their business (Benington and Moore 2011) could be turned into a new approach of shared resources and common obtained value. Another critique can be expressed of the platform owners whose purpose is to be a gatekeeper and whose actions are business-oriented (Cutolo, Hargadon, and Kenney 2021). There is a contrast between open knowledge and value creation, or between the combination of public sector platform and power relations

between all the parties of the value triangle, namely the public sector, private sector and the end customer. Both the barriers to innovation, adoption of innovations and value creation (e.g. Walker 2006; De Vries, Bekkers, and Tummers 2016; Demircioglu and Audretsch, 2017; Meissner 2019) and the drivers that enhance public innovations (Sorensen and Torfing 2011; McLoughlin et al. 2019; Zhenbin et al. 2020) have been identified. Therefore, this article emphasizes the need for consideration of private sector innovations converted from public sector knowledge sources.

3 Knowledge-based innovations

More and more innovations are constructed on the basis of knowledge. When knowledge is utilized, the knowledge utilizers also form networks that can be understood as a knowledge ecosystem. A knowledge ecosystem is quite a new concept, first defined in 2010. Pollock provides the oldest definition: "An ecosystem has knowledge cycles, in which intermediate consumers of knowledge such as builders of apps and knowledge wranglers may share back their cleaned, integrated and packaged knowledge into the ecosystem in a reusable way. This cleaned and integrated knowledge is often more valuable than the original source" (Pollock 2011).

Scholars have represented the content of open knowledge and platforms from the infrastructure or policy aspect or open knowledge ecosystems promoting OI. Barriers or challenges of open knowledge utilization, around knowledge platforms and knowledge per se and human-technology interaction in the innovation process have been considered by researchers while the drivers of open knowledge have received less attention. OI can be between public-public actors or public-citizens or public-private actors (Mu and Wang 2020) as well as private-private actors. The risk of OI with private actors in the public sector has been noted because of the fear of innovation process results that are more beneficial for the private market advantage than offering public value (Hartley et al. 2013). Therefore, new thinking about OI is needed in the public sector to create frameworks for public-private open knowledge co-operation that benefits all parties of the value triangle, namely the public sector, private sector and the customer. It is essential is to identify suitable co-operation partners and to actualize the identified drivers and to obtain transaction flows in OI processes in the private sector (e.g. Torfing, Sørensen, and Røiseland 2019).

Researchers have created different business models from public sector case studies. Ansell and Miura (2020) have considered the possibilities of governance platforms versus business platforms and how governance platforms can promote value creation; however, they mentioned that financial promoters have a minor role. Nambisan, Zahra and Luo (2019) regard platforms as flexible innovation spaces that allow global partners to create value propositions and delivery of products or services, and allow the actors to formulate different business models. Janssen and Zuiderwijk (2014) have identified six different mode-based business models depending for example on access to knowledge or interaction in the platform-knowledge interface: "single-purpose apps, interactive apps, information aggregators, comparison models, open knowledge repositories, and service platforms". However, Feller, Finnegan and Nilsson (2017) have concluded that the financial benefits for companies would seem to be the reverse: costs may increase and revenue models would not be established.

Although technical in nature, the knowledge ecosystem contains social aspects as well. A knowledge ecosystem is built on actors, roles, relationships and resources that aim to exchange knowledge, produce knowledge together or consume knowledge (Oliveira, Lima, and Lóscio 2019). When opening platforms, knowledge or implementing new OI and co-creation practices in the organization, leadership and teams are faced with new challenges; what are the internal effects (e.g. culture, norms) and external effects (e.g. customers, other stakeholders) (Altman and Tushman, 2017). The actors have different interests (for example, focusing on customer and market needs or accumulating knowledge in the ecosystem) that need the consideration of the platform or knowledge ecosystem management (Wareham, Fox, and Giner, 2014). Actors in the ecosystems have different levels of competence, knowledge and maturity to operate in the platform or utilize the knowledge, and they need to identify their roles in the ecosystem.

Open knowledge sources are one pop-up base for innovations at the public-private interface. However, the benefit of opening public knowledge sources is two-fold. Firstly, opening up the knowledge sources for companies and knowledge developers offers public knowledge branding. Companies do not expect to obtain rapid innovations via open knowledge. Secondly, there are challenges in knowledge utilization, e.g. knowledge consistency and integration, the trustworthiness of the knowledge or access rights. Nevertheless, high technology and artificial intelligence is expected to produce innovations during the next few years.

4 Findings and discussion

The field of open knowledge presents complex, multi-dimensional challenges and opportunities. Infrastructure and content use possibilities of public knowledge frameworks have been examined practically and

academically (Conradie and Choenni 2014; Charalabidis, Alexopoulos, and Loukis 2016; Ham, Koo, and Lee 2019), management practices and policies (Smith and Sandberg 2018; Jamieson, Wilson, and Martin 2019; Luna-Reyes et al. 2019) and among value-creation networks (Pereira et al. 2017).

Public and private sectors face challenges in open innovation. OI has open knowledge but there are either insufficient resources for processing or expertise in using knowledge sources (Luna-Reyes et al. 2019; Begany and Martin 2020). Alternatively, access to knowledge is limited (Hellberg and Hedström 2015; Smith, Ofe, and Sandberg 2016). Although OI forms to describe the possibilities of operating OI processes have been designed (e.g., Mergel 2015; Smith and Sandberg 2018; Mu and Wang 2020), whether sharing open knowledge benefits OI is a valid question: Does open knowledge offer value, and if so, is that value societal or economic? To whom does this bring value: the public sector, citizens, or other stakeholders, which includes the private sector?

Studies of OI and public sector open knowledge ecosystems typically ignore their interconnection. This study emphasises that OI is fundamentally rooted in knowledge ecosystems and open knowledge utilization, and that the relationships between the various participants within these ecosystems are not a primary concern and only two partners are required to create commercial innovation. Various open knowledge ecosystem models have been created to demonstrate network development (Dawes, Vidiasova, and Parkhimovich 2016; Bonina and Eaton 2020). Ecosystems are not directly monetizable by private firms, but the actors involved can create innovation and new business models via partnerships within the ecosystem.

The other question is whether the public sector is willing to divide the control of the knowledge to enable the knowledge's further use for commercial value. This dilemma appeared in the selected literature business models as well, which considered the economic benefits of value obtained from the public sector rather than the private sector business side (Feller, Finnegan and Nilsson 2011; Zeleti and Ojo 2019). Business models in the public sector may be based more on value creation for citizens (e.g. promoting governmental program implementation or offering services) that are non-economic, whereas private sector models are often based on technical solutions enabling public sector supply of services via applications (Janssen and Zuiderwijk 2014; Kitsios and Kamariotou 2019). The public-public actor or public-citizens partnership can be challenging for creating business value for private sector companies. Therefore, public sector support for private sector companies is important in knowledge and knowledge sharing to boost innovations (Love, Roper and Bryson 2011).

The identified barriers in public-private OI require models for creating successful open knowledge initiatives. Complexity in the different open knowledge adoption phases is manifested through various barriers to innovations (Attard et al. 2015; Smith and Sandberg 2018). Even though public sector agencies emphasize increased democratization, citizen empowerment and the transparency of public processes by digitalization in open knowledge -based innovation processes, the open knowledge sharing practices are old-fashioned (Zhenbin et al. 2020). However, to enhance open knowledge -based innovations, some crucial enablers for public-private OI that have been identified are policy drivers (McLoughlin et al. 2019), access to knowledge sources as well as private sector competence to utilize open knowledge and identify the benefits of open knowledge (Toots et al. 2017; Wang and Lo 2020).

Some successful open knowledge innovation experiments are illustrated in the literature, for instance, cities as development platforms and OI drivers. The Smart City idea has been piloted e.g. in Helsinki (examples of the pilots: platform for open knowledge utilization, knowledge sets for the metropolitan area covering public transport, decision-making and service points, and tools and support for knowledge utilizers), Manchester (digital services based on open knowledge, tools and support for open knowledge and public transport knowledge for developers), Amsterdam (several applications to developed based on open knowledge), Barcelona (promoting co-creation and innovations leveraging open knowledge), Chicago (knowledge utilization to identify opportunities to improve city operations) (Ojo, Curry, and Zeleti 2015) and Cape Town (open knowledge application helps house-level water consumption monitoring to build drought resilience) (Van Belle, and Hlabano 2019). Besides new innovations by the private sector and business markets, global challenges can be solved with open knowledge but it requires multi-sector co-operation.

5 Conclusions

This research explored the potential of public knowledge to spur open innovation via public-private partnerships. Previous studies highlighted knowledge's crucial role in fostering innovation. While open knowledge is vital for innovation and public participation, the private sector's significant contribution is often overlooked. Limited attention has also been given to the interplay between OI and open knowledge, potentially leading to a lack of shared understanding regarding OI's importance in public-private cooperation. Ecosystem models pinpoint crucial connections between agencies, but they don't yield benefits or income until these links translate into practical collaborations. Open knowledge sharing should not include identifiable information, as

it's neither feasible nor sensible. Despite public organizations releasing anonymized or statistical knowledge, access and use by the private sector are frequently limited, especially in fields like healthcare. A more unified view of open innovation (OI) and the open knowledge ecosystem, alongside public-private collaboration, is crucial. The private sector's creation of open knowledge-based innovations, such as products or services, for private markets appears to have minimal influence. To better comprehend how the private sector can benefit from public open knowledge, additional empirical studies are crucial.

Challenges in innovation are widely explored in existing research. The next step should focus on developing models for successful open knowledge initiatives, including strategic planning (value realization and resource-based strategic analysis), technical enablers (new technologies as AI), sharing platforms (design of public knowledge sources with appropriate APIs), enabling functional public knowledge ecosystems, and legal frameworks to support open public knowledge sharing and utilization (e.g., knowledge privacy). We need to consider social aspects alongside technological and business ones. This includes management models for public knowledge and innovation, knowledge processes and its management to support OI, and organizational cultures that reflect experiences of control or safety, risk management, attitudes and engagement in OI processes.

[4] Alia Servizi Ambientali S.p.A., Florence, Italy

Abstract

This paper examines the transformative impact of AI-enhanced data platforms on knowledge management (KM) within waste management organizations, focusing on the case of Alia Servizi Ambientali SpA in Tuscany, Italy. Utilizing a qualitative case study approach that combines on-site observations, stakeholder interviews, and system data analysis, our research demonstrates that AI integration significantly optimizes operational efficiency by consolidating diverse data streams, from IoT sensors monitoring waste receptacles to vehicle fleet metrics, into a unified, high-quality repository. The platform employs a medallion architecture to ensure data quality, enabling predictive analytics that improve route optimization, reduce vehicle movements, and lower carbon emissions. Beyond these practical benefits, the study advances theoretical insights by proposing a framework that situates AI-driven KM within broader governance and ethical contexts, contrasting traditional approaches with the dynamic capabilities of AI technologies. Despite the inherent limitations of a single-case design, our findings provide a strategic blueprint for leveraging AI-enhanced data platforms in waste management. They underscore the critical role of robust governance frameworks, leadership commitment, and targeted training in aligning technological capabilities with evolving KM practices, ensuring the sustainability and scalability of digital transformation initiatives.

Keywords: Artificial Intelligence, Knowledge Management, Data Platforms, Waste Management, Digital Transformation

Paper type: Practical Paper

1 Introduction

In an era defined by rapid digital transformation and mounting sustainability mandates (United Nations, 2015), waste management organizations must contend with ever-growing volumes of operational data while meeting stringent environmental and resource-efficiency targets (European Commission, 2020). Yet many public utilities still rely on legacy systems and siloed information flows, limiting their ability to translate data into strategic insights or to deploy proactive, predictive services (Mårtensson, 2000).

The integration of artificial intelligence into unified data platforms offers a promising, but underexplored, avenue for overcoming these constraints, particularly within the waste management sector, where operational complexity and stakeholder fragmentation pose unique challenges (Rahman et al., 2020). Alia Servizi Ambientali SpA's recent deployment of an AI-enhanced data platform provides a timely case through which to examine how advanced analytics can reshape knowledge management practices in a large-scale public service (Chourabi et al., 2012).

Building on prior work in digital innovation and KM transformation (Shadbolt & Milton, 1999), this study investigates three interdependent dimensions: (1) the technological integration that underpins operational efficiency; (2) the mechanisms by which data platforms catalyze knowledge creation and organizational learning; and (3) the governance structures necessary for ethical, transparent AI deployment. In doing so, we address a gap in both scholarly and practitioner literatures on how AI-driven architectures can be effectively embedded within public utilities.

Beyond technological design, we explore the structural and cultural shifts that the move from manual, reactive processes to data-driven, collaborative problem-solving. By detailing Alia's critical success factors and stakeholder dynamics, our findings yield actionable insights for policymakers and practitioners seeking to align AI-enabled KM systems with sustainability and circular-economy objectives.

In the following sections, we first contextualize the study through a review of relevant literature on digital transformation, knowledge systems and modern data platforms. We then outline the methodological approach adopted to investigate the case of Alia Servizi Ambientali SpA, followed by an in-depth presentation of the

platform's implementation and its multidimensional outcomes. The paper concludes by discussing theoretical implications, practical insights, and avenues for future research.

2 Background and Literature Review

2.1 Digital Transformation and Knowledge Management

KM traditionally involves systematic processes for capturing, developing, and disseminating organizational knowledge to drive performance (Gupta et al., 2000; Shadbolt & Milton, 1999). Historically, KM practices have centered on manual information repositories and intradepartmental communication channels. However, the advent of digital transformation has catalyzed the evolution of KM into a dynamic, data-driven process that leverages advanced technologies, including big data analytics, IoT, and artificial intelligence (Vaio et al., 2021).

Digital transformation facilitates the transition from static, siloed knowledge repositories to interactive, real-time systems where data continuously informs decision-making. As organizations increasingly adopt digital infrastructures, the role of KM shifts from simply storing information to actively generating insights through automated processes and predictive analytics. This evolution aligns with the broader trends in Industry 4.0, where connectivity, machine autonomy, and rapid data processing are redefining operational paradigms (Manesh et al., 2021).

2.2 AI-Enhanced Data Platforms

Central to this digital transformation is the emergence of AI-enhanced data platforms that integrate and analyze large volumes of structured and unstructured data. Traditional data warehouses—often characterized by "schema-on-write" models—have evolved with the advent of data lakes and, more recently, Data Lakehouse architectures that combine the best features of both approaches (Armbrust et al., 2021; Nambiar & Mundra, 2022). The medallion architecture, a layered data processing approach, exemplifies this evolution by ensuring that data is progressively refined through bronze, silver, and gold stages to achieve high-quality, business-ready outputs (Databricks, 2022).

AI integration further enhances these platforms by introducing machine learning algorithms that support predictive analytics, anomaly detection, and real-time data processing. For example, AI-driven predictive models have been applied to forecast waste generation patterns, optimize vehicle routing, and minimize environmental impacts in waste management systems (Rahman et al., 2020). Such innovations streamline operational processes and provide a strategic edge by transforming raw data into actionable insights.

2.3 Ethical Governance and Theoretical Gaps

While many studies focus on the technological and operational aspects of AI-enhanced systems, the literature reveals a notable gap in addressing the ethical and governance dimensions of these transformations. Recent discussions in the field of AI ethics have emphasized the need for frameworks that ensure transparency, data privacy, and accountability in the deployment of AI technologies (Floridi & Cowls, 2019; Jobin et al., 2019). In the context of KM, this involves establishing governance protocols that ensure data integrity and safeguard against biases or misuse. Current research often overlooks how the integration of advanced data platforms influences broader organizational learning and cultural shifts. By addressing these dimensions, this paper contributes to a more holistic understanding of digital transformation. Our study seeks to bridge this gap by proposing an integrated framework that accounts for operational efficiency, organizational learning, and ethical governance in AI-enhanced KM systems.

3 Methodology

3.1 Research Design

This study adopts a qualitative, single-case approach in line with the Gioia methodology to explore how AI-enhanced data platforms reshape KM practices at Alia Servizi Ambientali SpA. By focusing on one well-defined organization, we obtain rich, context-sensitive insights into technological, organizational, and ethical aspects of digital transformation (Gioia et al., 2013; Noy, 2008).

3.2 Data Collection

Data were gathered over six months through a triangulated protocol to ensure breadth and depth of evidence:

- *Semi-Structured Interviews*: Fifteen in-depth interviews (totaling 1005 minutes) with several internal and external professional figures (Table 1) to capture a range of stakeholder perspectives.
- *On-Site Observations*: Direct field observations documented day-to-day workflows and the practical impacts of the new platform on service delivery.
- *Document Analysis*: Internal reports, policy documents, and strategic plans were reviewed to corroborate interview insights and provide an organizational backdrop to the transformation process.

Table 1: Respondent presentation (Authors' elaboration):

Respondent ID	Professional Profile	Interview Length (minutes)
INT-01	IT Manager	55
INT-02	Knowledge Management Manager	75
INT-03	Data Scientist	50
INT-04	HR & Knowledge Management Specialist	70
INT-05	Operations Manager	70
INT-06	Data Engineer	45
INT-07	Digital Transformation Manager	50
INT-08	Data Platform Expert	60
INT-09	Operations Coordinator	65
EXT-01	Academic Expert in Knowledge Management	70
EXT-02	Policy Advisor	70
EXT-03	External Governance Consultant	90
EXT-04	Academic Expert in Waste Management	60
EXT-05	External Business Strategy Consultant	85
EXT-06	External Data Consultant	90

3.3 Data Analysis

The interview transcripts, observation notes, and documents were imported into NVivo software for systematic coding. An inductive coding approach was used to develop first-order codes based on participants' experiences, which were subsequently grouped into second-order themes reflecting broader organizational processes. These themes were then synthesized into aggregate dimensions corresponding to the three components of our theoretical framework:

1. *Operational Efficiency & Technological Integration*: This dimension explores how AI-enhanced data platforms contribute to operational optimization by integrating advanced analytics within centralized data architectures. The structured layering of data processing—such as the medallion architecture—enables scalable automation, real-time decision-making, and predictive modeling capabilities (Databricks, 2022; Armbrust et al., 2021). These technological affordances support the transition from reactive workflows to proactive, data-driven operations. The framework posits that such integration improves efficiency and redefines the role of digital infrastructure in organizational performance.
2. *Knowledge Creation & Organizational Learning*: From a knowledge management perspective, AI-enhanced platforms act as enablers of continuous organizational learning and innovation. By consolidating heterogeneous data into unified repositories, they facilitate cross-functional collaboration, eliminate informational silos, and promote shared knowledge creation (Vaio et al., 2021; Shadbolt & Milton, 1999). The framework emphasizes how data accessibility and interpretability reshape organizational cognition, fostering adaptive learning cycles and evidence-based decision-making. This dimension reframes KM not as static storage, but as a dynamic, iterative process embedded within digital transformation.
3. *Ethical Governance & Cultural Transformation*: The integration of AI systems into organizational contexts necessitates robust ethical and governance structures to address concerns around transparency, accountability, and data integrity. This dimension underscores the importance of embedding principles such as algorithmic transparency, stakeholder inclusion, and privacy protection within the design and deployment of AI systems (Floridi & Cowls, 2019; Jobin et al., 2019). Furthermore, it highlights the reciprocal relationship between governance mechanisms and cultural change, wherein ethical frameworks not only safeguard technology use but also foster organizational values aligned with responsible innovation.

4 Case Study Overview: Alia Servizi Ambientali SpA

4.1 Organizational Context

Alia Servizi Ambientali SpA, established in 2017, is a prominent public utility responsible for waste management across 58 municipalities in Tuscany, serving over 1.47 million residents. Managing approximately 1.5 million tons of waste annually and operating a fleet exceeding 1,800 vehicles, the organization has long faced challenges related to data fragmentation, inefficient information flows, and the limitations of legacy IT systems. These operational challenges were exacerbated by the increasing demands of sustainability and the need to optimize resource utilization.

4.2 Implementation of the AI-Enhanced Data Platform

In response to increasing operational complexity and limitations of legacy IT infrastructure, Alia Servizi Ambientali SpA initiated the implementation of an AI-enhanced data platform in 2021 as a foundational component of its comprehensive digital transformation strategy. The implementation followed a systematic phased approach, with emphasis on scalability, data centralization, and AI-readiness as primary design considerations.

The architectural framework was structured according to the medallion model (Databricks, 2022), a layered data processing methodology that organizes data into hierarchical tiers: bronze (raw), silver (cleaned), and gold (business-ready). This structured approach facilitated progressive enhancement of data quality, consistency, and traceability throughout the processing pipeline. The integration of heterogeneous data sources, including structured and unstructured inputs from IoT-enabled waste receptacles and fleet telematics systems, enabled comprehensive aggregation of high-volume, high-velocity data streams, supporting both real-time data ingestion and the deployment of machine learning pipelines for operational applications (Figure 1).

A critical element of the deployment was the implementation of automated Extract-Transform-Load (ETL) processes, replacing previously fragmented and manual methodologies. These ETL workflows operate under centralized orchestration frameworks and are augmented by AI models that dynamically adapt to data anomalies and optimize processing schedules (Gadde, 2020). This approach standardized the data lifecycle management and ensured consistent availability of high-integrity data for subsequent analytical processing.

From an interoperability standpoint, the platform incorporated open protocols such as Delta Sharing, enabling secure and efficient data exchange with external stakeholders, including municipal authorities and third-party consultants. This architectural decision aligns with emerging industry trends toward data democratization and collaborative intelligence (Abdallah et al., 2020), ensuring the versatility of Alia's data assets across diverse strategic and regulatory contexts.

The implementation incorporated governance-by-design principles to ensure comprehensive data stewardship, algorithmic accountability, and system scalability. Notably, robust lineage tracking mechanisms were integrated across all data pipelines, establishing transparency and auditability throughout the data lifecycle, from acquisition to utilization.

From a technical perspective, the platform utilized cloud-native infrastructure and Machine Learning Operations (MLOps) methodologies to optimize the development and deployment of AI models. These included containerization techniques for computational reproducibility, version control systems for data and code artifacts, and continuous integration/continuous delivery (CI/CD) pipelines for analytics workflows—essential components for maintaining agility in model iteration and retraining processes (Deekshith, 2020).

In aggregate, these implementation characteristics established a flexible, future-oriented data ecosystem capable of supporting both immediate operational requirements and long-term strategic initiatives. While specific benefits are elaborated in subsequent sections, it is significant to note that this technological foundation was deliberately aligned with Alia's strategic vision of integrating AI capabilities into operational and knowledge processes, while maintaining stringent controls over data integrity, security, and governance.

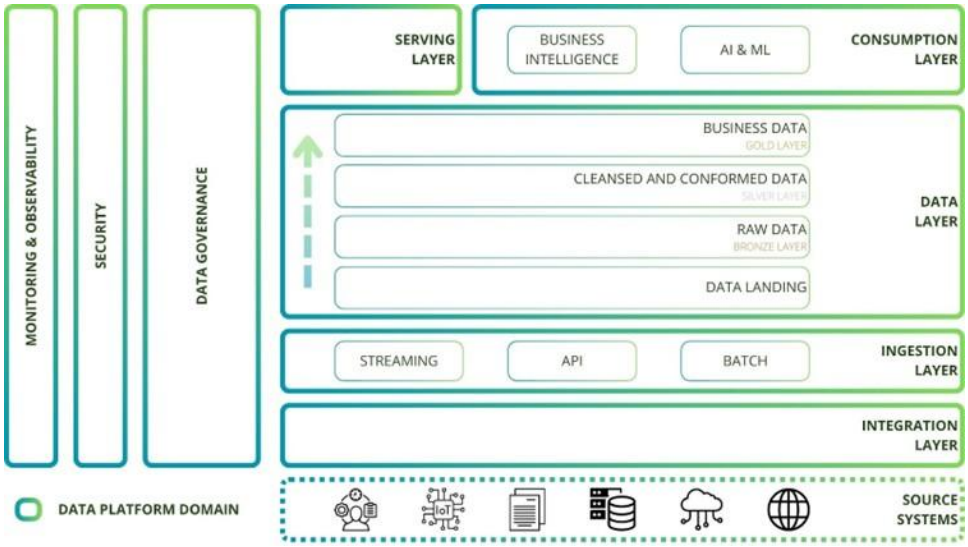

Figure 1: Data Platform Architecture (Authors' elaboration)

5 Outcomes and Discussion

The AI-enhanced data platform implementation at Alia Servizi Ambientali SpA yielded substantive outcomes across technological, operational, and organizational dimensions. These results validate the platform's effectiveness in addressing endemic inefficiencies, integrating heterogeneous data sources, and establishing robust capabilities for data-driven management within a traditionally fragmented sector.

5.1 Operational Efficiency & Technological Integration

The consolidation of disparate data assets into a medallion-based architecture enabled real-time data ingestion, automated ETL processes, and advanced analytics capabilities, significantly reducing processing latency and manual intervention while enhancing data reliability (Databricks, 2022; Armbrust et al., 2021). The integration of AI-driven anomaly detection and predictive routing algorithms transformed conventional static collection schedules into dynamic, demand-responsive operational workflows, demonstrating how embedded ML capabilities enhance operational agility beyond simple cost reduction (Gadde, 2020; Lanzalonga et al., 2024). The deployment of intuitive self-service dashboards empowered operational managers to execute data-informed decisions, consistent with Industry 4.0 principles of system responsiveness and iterative improvement.

5.2 Knowledge Creation & Organizational Learning

The establishment of a centralized data repository with comprehensive lineage tracking effectively dismantled historical information silos, enabling multidisciplinary teams to leverage trusted data assets for collaborative problem-solving initiatives (Vaio et al., 2021; Shadbolt & Milton, 1999). Personnel without technical expertise utilized self-service analytics tools to generate actionable insights independently, thereby accelerating organizational learning cycles. The resultant "knowledge loop," wherein operational feedback continuously refines predictive models, exemplifies how AI-enhanced platforms institutionalize dynamic capabilities, specifically, the systematic creation and application of knowledge, within routine operational processes (Oliva et al., 2019).

5.3 Ethical Governance & Cultural Transformation

The implementation established a comprehensive governance framework that ensured alignment between technical operations and organizational values, addressing critical concerns regarding data quality, security protocols, and algorithmic accountability (Jobin et al., 2019). Strategic investment in targeted training programs combined with democratized data access substantially improved organizational data literacy, facilitating a transition from experiential decision-making to evidence-based experimentation. This governance-by-design methodology not only maintained adherence to AI ethical standards and transparency requirements but also catalyzed a fundamental cultural evolution, fostering responsible innovation practices and strengthening Alia's collaborative partnerships through standardized, secure data exchange protocols (Dhanya et al., 2023).

6 Conclusion

This paper has presented a comprehensive analysis of the transformative impact of AI-enhanced data platforms on knowledge management practices within the waste management sector. Through detailed examination of the Alia Servizi Ambientali SpA case study, we have demonstrated that the integration of artificial intelligence and centralized data architectures produces substantial enhancements in operational efficiency, knowledge integration, and ethical governance frameworks.

The research makes three significant contributions to the existing body of knowledge. First, it provides empirical evidence that AI-enhanced platforms, through mechanisms such as predictive analytics and automated ETL processes, significantly optimize operational performance in resource-intensive industries. Second, it advances a theoretical framework that synthesizes technological, organizational, and ethical dimensions of knowledge management transformation, extending traditional KM models to address the complexities of the digital era. Third, it offers valuable comparative insights by contextualizing the case study within a broader cross-sectoral landscape, thus establishing the transferability of the integrated framework across diverse organizational environments.

Despite these contributions, several limitations warrant acknowledgment. The single-case design methodology, while facilitating in-depth analysis, constrains the generalizability of findings. Future research would benefit from multi-case comparative studies and longitudinal analyses to document the progressive impacts of AI integration on organizational knowledge processes. Furthermore, additional investigation into how AI-enhanced platforms contribute to sustainability objectives and circular economy initiatives would provide valuable insights, particularly given the increasing prominence of environmental responsibility metrics in contemporary digital transformation strategies.

In conclusion, the integration of AI-enhanced data platforms represents a critical evolution in organizational knowledge management practices. The Alia Servizi Ambientali SpA case illustrates that such technological innovations can concurrently enhance operational efficiency, cultivate a culture of continuous learning, and maintain robust ethical governance standards. As organizations across diverse sectors increasingly embrace digital transformation initiatives, the insights and integrated framework presented in this study offer practitioners a strategic blueprint for implementing sustainable and ethically grounded innovation in their knowledge management systems.

7 Ethics Declaration

This research did not involve human subjects or personal data requiring ethical clearance. The case study analysis of Alia Servizi Ambientali SpA was conducted with full organizational consent and in compliance with relevant data protection regulations. All organizational data was provided in anonymized and aggregated form under a formal research agreement. No additional ethical approval was required for this study.

8 AI Declaration

This paper utilized artificial intelligence tools during its development. Consensus was employed for literature review to identify and synthesize relevant scholarly sources. Anthropic Claude 3.7 Sonnet was used for text refinement to improve academic tone and clarity in specific sections. All AI-generated content was thoroughly reviewed and edited by the authors. The research design, data collection, analysis, interpretations, and conclusions were developed independently without AI assistance.

9 Acknowledgments

The authors gratefully acknowledge Alia Servizi Ambientali SpA for providing access to organizational data and supporting this research. We also extend our appreciation to the Department of Management “Valter Cantino”, University of Turin, for their academic guidance and institutional support throughout this project.

The Role of AI and Emerging Technologies in Transforming Knowledge Management

Gianluca Aquilone, Vincenzo Varriale, Antonello Cammarano, Francesca Michelino, Mauro Caputo
University of Salerno, Fisciano (SA), Italy

Abstract

Knowledge is one of the most valuable assets in modern organizations. However, its intangible and evolving nature makes it challenging to capture and leverage. Knowledge management (KM) is the organized, systematic process that acquires, refines, organizes, and applies this knowledge to improve organizational success and secure long-term competitive advantage. As data volume and complexity continue to grow, conventional systems have proven insufficient to harness the full potential of knowledge assets. As a result, emerging technologies have become indispensable, providing agile, scalable, and intelligent solutions. However, much of the existing research often examines these technologies in isolation, considering artificial intelligence (AI) and others as standalone entities, failing to reveal the synergies that emerge from combining them. This limitation is further complicated by the nature of common research approaches: literature reviews, while offering broad theoretical insights, are typically too abstract to inform practical application; meanwhile, case studies, though grounded in real-world scenarios, often lack generalizability due to their strong context-specific focus. This study addresses these gaps by investigating how AI and complementary, emerging technologies redefine KM areas. Drawing on 1,487 documented business practices—comprising case studies, pilot projects, and simulation models—derived from literature, this research focuses on five critical KM phases: knowledge creation, acquisition, organization, transfer, and application. Conceptually, knowledge is created or acquired, then captured, organized, and preserved for the long term, transferred to those who need it, and finally applied to produce value. Finally, these practices are analyzed through association analysis via Cramér's V to quantify the strength of relationships between AI (whether used alone or alongside other technologies), business functions and the different KM areas. Theoretically, the findings advance KM research by demonstrating which technological combinations are more effective in each KM phase. From a managerial perspective, the emerging practices examined in this study offer real-world examples of how these integrated solutions can be successfully deployed, allowing managers to draw from documented practices rather than starting from scratch.

Paper type: Academic Research Paper

1 Introduction

Data is everywhere. In today's interconnected world, large volumes of data are continuously produced from a wide range of activities and sources. This increasing data availability opens new opportunities for companies. Data consists of raw facts. When these facts are organized and given context, they become information, and eventually mature into knowledge when combined with experience, judgment, and practice (Bhatt 2001). Knowledge needs to be managed to fully realize its value. This is accomplished through knowledge management (KM). KM is the systematic process by which organizations accumulate, disseminate, and effectively use knowledge to secure a sustainable competitive advantage (Caputo et al. 2019). Traditionally, KM depended on document-based repositories and human expertise. While these approaches worked to some extent, recent technological advancements have caused a major transformation in how KM is practiced. Modern KM systems use digital solutions that help users find, share, and apply knowledge more easily (Malik et al., 2024). Notably, artificial intelligence (AI) has emerged as a crucial element in this process.

AI is defined as a system's ability to correctly process and interpret external data, learn from it, and use that learning to perform specific tasks (Liebowitz 2001). In doing so, AI can redefine how knowledge is generated, captured, and applied. AI can quickly analyze large amounts of data, spot subtle patterns that might otherwise remain hidden. AI can also automate repetitive tasks once reserved for human intelligence, freeing employees to spend more time on critical tasks (Iaia et al. 2024).

For KM systems to be truly intelligent and automated, AI needs to work in combination with other complementary technologies, such as the Internet of Things (IoT), blockchain (BC), and immersive environments (IMM). For example, IoT collects and transmit unstructured data from connected devices and sensors (Atzori et al. 2010). However, without AI, this information remains disorganized and hard to interpret. BC provides a secure

and transparent way to store data. Nevertheless, BC alone does not transform the data into knowledge. Moreover, IMM create interactive, multisensory learning experiences that can be tailored by AI to better match each user's needs (Speicher et al. 2018).

Despite the recognized importance of these technologies in KM, existing research still treats them separately. This approach ignores that modern organizations leverage multiple technologies simultaneously to improve their processes (Nascimento et al. 2021). This study aims to fill this gap by investigating how AI interacts with other technologies, including 3D printing (3DP), BC, computing (COM), digital applications (DA), geo-spatial tech (GEO), IMM, IoT, proximity tech (PT), open and crowd-based platforms (OCP), and robotics (ROB), to redefine KM. To this end, KM is broken down into five key processes: knowledge creation, acquisition, organization, transfer, and application. By considering exclusively case studies, pilot projects, and simulation models, this research extracts and classifies 1,487 emerging practices from literature. These practices illustrate real-world business applications in which AI and other technologies are deployed together in specific contexts, with each of them explicitly associated with one or more KM areas. Association analysis is first applied to investigate the linkage between AI, KM, and business functions. Subsequently, this analysis is extended to evaluate the interplay between AI, other complementary emerging technologies, and various KM phases, thereby clarifying the ways in which these technologies collaborate for improving KM strategies. From a theoretical perspective, this research contributes to the evolving discourse on KM by exploring how AI and other emerging technologies work together to redefine KM systems. Practically, the findings offer actionable insights for organizations seeking to implement AI in their KM processes effectively.

The remainder of the paper is structured as follows. The next section provides a theoretical background on KM, with a focus on how emerging technologies have influenced KM practices. The methodology section discusses the framework, and the sequential phases involved, while the results section presents descriptive statistics and key findings, followed by theoretical, methodological, and practical implications. The paper concludes with overall conclusions and limitations.

2 Theoretical Background

Knowledge is widely recognized as one of the most valuable assets an organization can hold. Accordingly, modern businesses are increasingly investing in KM to ensure that knowledge is effectively created, shared, and put to practical use (Davenport and Prusak 1998).

Knowledge manifests in various forms. Tacit knowledge refers to the implicit expertise that is inherently difficult to express or codify, whereas explicit knowledge is more accessible (Liebowitz 2001). Both forms of knowledge are critical to an organization's intellectual capital. Meanwhile, rapid digital transition has changed traditional knowledge flows within and between organizations. As a result, KM now operates across two distinct domains: the "human" space, in which personal experience and organizational interactions occur, and the "digital" space, where data is captured, processed, and stored (Cerchione et al. 2024).

This study views KM as a process consisting of five key phases: knowledge creation, acquisition, organization, transfer, and application. The process begins with creating new knowledge or capturing external knowledge, followed by structuring that knowledge into accessible formats. Whether it is through formal repositories or informal channels, this knowledge is shared and is put to work to solve business problems (Durst and Edvardsson 2012).

Nevertheless, managing knowledge remains an ongoing challenge due to the risk of losing tacit knowledge, information overload and persistent knowledge silos (Jarrahi et al. 2023). This is why emerging technologies have started to play an increasingly important role (Nascimento et al. 2021). Organizations today collect unprecedented volumes of data from transactions, customer information and online interactions. These heterogeneous data can be analyzed to extract valuable insights, effectively becoming a new source of knowledge. Moreover, modern firms increasingly use collaboration platforms and social media internally, expanding the modalities through which knowledge is shared (Nisar et al. 2019), while mobile devices and cloud-based services offer unprecedented connectivity and accessibility, allowing staff to access organizational knowledge anywhere, anytime.

Among these technologies, AI has had the most profound impact on KM in recent years, with scholars and practitioners noting its potential to both augment human capabilities and automate knowledge processes (Iaia et al. 2024). Cognitive augmentation allows AI systems to analyze and process enormous volumes of data at speeds far beyond human capability. At the same time, automation makes it possible for AI to take over routine knowledge tasks that previously required human presence (Jarrahi et al. 2023).

While the importance of AI in KM is widely recognized (Marvi et al. 2024), much of the existing research tends to investigate it in isolation, thereby missing the potential benefits that may be realized through its

integration with other emerging technologies. Previous studies have primarily taken two distinct approaches. On one hand, there are literature reviews and conceptual articles that examine specific technologies, especially AI, and their individual impact on KM processes (Jarrahi et al. 2023, Iaia et al. 2024). Conversely, other conceptual works explore broader themes for KM modernization, focusing on emerging technologies or the phenomenon of Industry 4.0 (Duarte Alonso et al. 2024, Nascimento et al. 2021). While these contributions are important, they tend to be too generic and primarily emphasize the theoretical linkages between technologies and KM, without providing sufficient detail on their practical implementation. On the other hand, numerous case studies have been published that present specific business applications, documenting how these technologies are deployed in real-world settings (Wang et al. 2023). However, these studies are inherently context specific. The practical insights gained from a particular organization or project may not be directly transferable to all companies. This research aims to bridge the gap between these two approaches by conducting a literature analysis that focuses exclusively on case studies, pilot projects, and simulation models. The goal is to examine the interplay between AI and a range of complementary, emerging technologies within KM using a two-step approach. First, an association analysis is conducted considering only the presence of AI. The objective is to evaluate how AI's implementation in certain business functions is linked to different phases of KM. In the second step, this analysis is extended to include all the other emerging technologies, making it possible to evaluate the strength of the associations between these technologies, when combined with AI, and different KM phases.

3 Methods

The primary goal of this study is to examine how AI and other emerging technologies can collaborate and reinforce one another to improve KM processes. The research method consists of three main stages. As illustrated in **Figure 1**, the proposed approach starts with an extensive literature analysis designed to identify emerging practices from literature, in which these technologies have been used to redefine one or more KM areas.

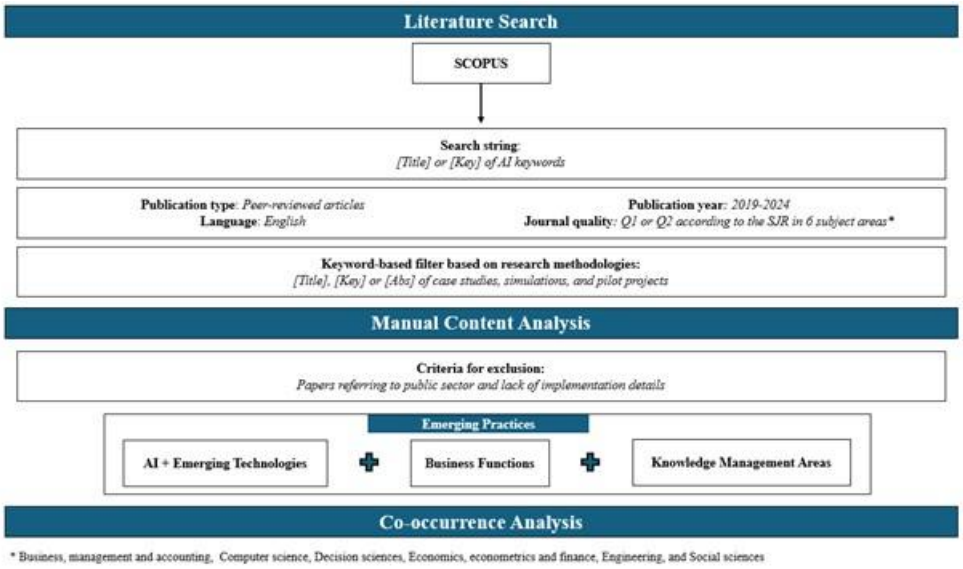

Figure 1 - Methodological steps.

The SCOPUS scientific database serves as the primary source. To cover all relevant articles, the researchers define a series of keywords for AI, using both common names and possible variations or synonyms. These keywords are then combined into search strings that look for the mention of at least one of these terms in either the "Title" or "Keywords" fields of each article. Figure 2 illustrates the complete list of all these keywords, along with the 10 additional emerging technologies that are under investigation in this study.

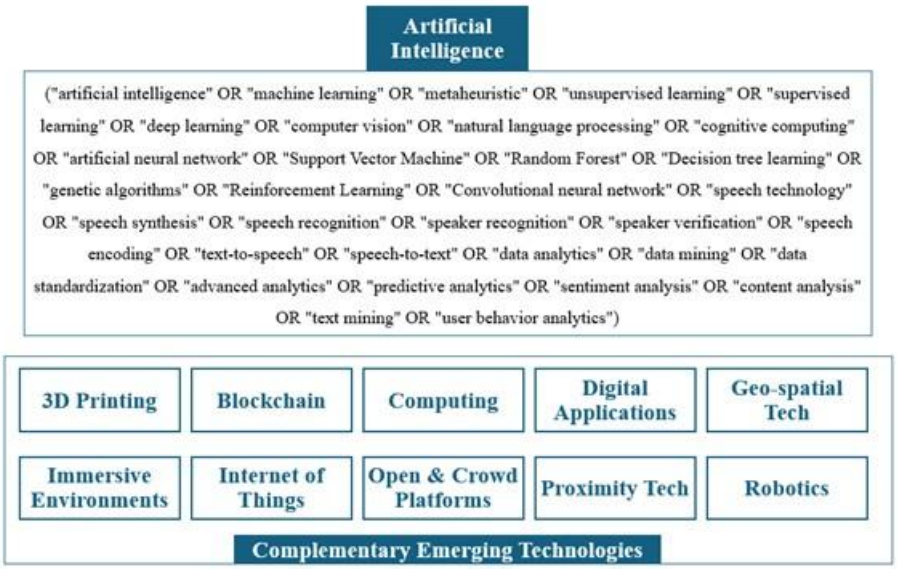

Figure 2 - Search query for AI-related articles and 10 complementary emerging technologies.

The initial SCOPUS search identifies 54,368 papers selected from leading journals in “business, management and accounting”, “computer science”, “decision sciences”, “economics, econometrics and finance”, “engineering”, and “social sciences”, focusing only on those ranked in Q1 and Q2 according to the Scimago Journal Ranking. To maintain relevance, only papers published between 2019 and 2024 are included. Once the initial pool of articles is retrieved, a preliminary filtering step is applied. Literature reviews, conceptual articles, survey-based or interview-based research, and those addressing technical issues are not considered. Instead, the focus is directed toward case studies, pilot projects, simulations, and mathematical models. To further refine the selection, a keyword-based filter is applied, integrating 233 specific strings—such as "case study," "pilot project," "experiment," "simulation," and "empirical evaluation”. Only studies mentioning at least one of these terms in their “Title,” “Abstract,” or “Keywords” are retained, reducing the initial number to 35,738. Subsequently, a team of 3 researchers with expertise in KM and technology management carries out a first evaluation of the remaining papers, discarding those that lack sufficient details or that address public sector issues. This further scrutiny brings the count to 10,988 articles selected for manual content analysis. After a rigorous evaluation, the final dataset results in 1,487 articles that demonstrate a clear connection to KM.

The selected articles are classified according along three dimensions: technologies implemented, business functions involved, and KM phases affected. The analysis encompasses AI and 10 other distinct technologies, which can operate either independently or in combination. Business functions are the activities a business performs to achieve its goals and objectives. Table 1 provides a concise description for all these different functions.

Table 1 - List of business functions considered in this study.

Business Function	Description
Accounting & Finance (A&F)	Covers financial activities such as accounting, budgeting, and investments.
Distribution (DIS)	Oversees transportation, warehousing, and logistics.
Govern. & Admin. (G&A)	Encompasses executive management and strategic business planning.
Human Resources (HR)	Focuses on workforce management and safety, and employee training.
Info. & Comm. Tech. (ICT)	Deals with the deployment and improvement of IT systems.
Marketing (MK)	Involves promotion, advertising, and customer relationship management.
Operations (OP)	Responsible for producing goods or delivering services.
Procurement (PRO)	Encompasses sourcing, purchasing, and supplier relationships.
Research & Develop. (R&D)	Focuses on research, product design and development, and prototyping.

In parallel, the study considers five fundamental KM processes. *Knowledge creation* refers to the generation of original ideas or solutions that did not exist before (Durst and Edvardsson 2012). In contrast, *knowledge acquisition* involves gathering existing knowledge from both internal and external sources (Migdadi 2021). Once collected, *knowledge organization* ensures that this knowledge is structured and categorized, while *knowledge transfer* makes it possible to disseminate this knowledge within or between organizations (Wang and Noe 2010).

Finally, *knowledge application* is the practical use of acquired or created knowledge to solve problems, inform decision-making, or complete tasks effectively (Schniederjans et al. 2020).

Figure 3 illustrates an example of emerging practice. Fang et al. (2024) propose a system that uses advanced AI to build an immersive augmented reality (AR) environment where multiple workers collaborate easily. This seamless integration of AR and AI for both visual and audio inputs help transfer knowledge instantly.

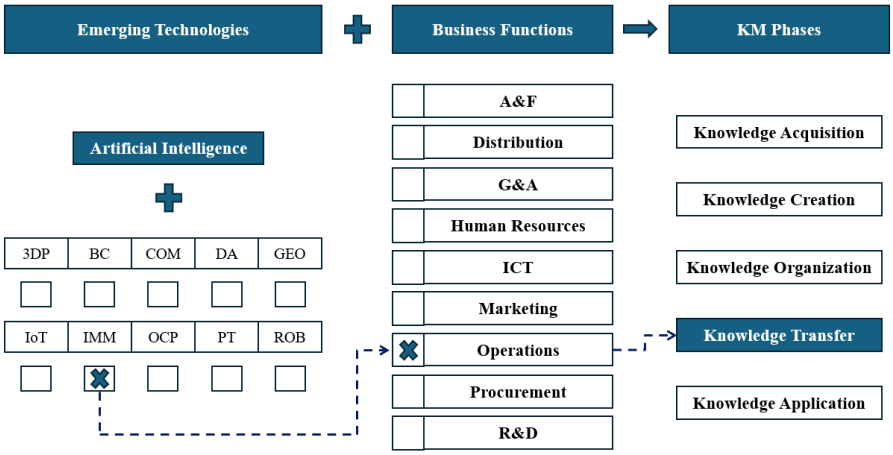

Figure 3 - Example of emerging practice.

Subsequently, the final dataset undergoes an exploratory investigation designed to reveal the connections among KM areas, AI, and the other emerging technologies examined in this study. To this end, an association analysis is conducted. This statistical method is used to uncover hidden associations or dependencies between two or more variables that occur together (Colliander and Ahlgren, 2012). Central to this analysis is the Cramér's V measure, a statistical measure used to assess the strength of the associations among variables.

The Cramér's V measure produces a value ranging from 0 to 1. Values near 0 indicate that there is little to no association between the variables. Conversely, values closer to 1 signify a strong association.

4 Results

4.1 Descriptive statistics

This section presents descriptive statistics for each variable. Table 2 shows the number of practices classified by macro-technology. Nearly half of the cases involve the use of AI in isolation, while the remaining combine AI with other technologies. Among the latter, more than one-third of the total cases incorporate IoT, and a similar share utilizes DA, highlighting the critical role of real-time connectivity and user-centric interfaces in modern KM strategies. In addition, around one in five practices rely on COM to support robust data processing, with even fewer adopting IMM to boost employee engagement or BC for information security.

Table 2 - Emerging practices by macro-technology.

Label	#	%
Artificial Intelligence (only)	**739**	**49.70%**
Artificial Intelligence (in combination)	**748**	**50.30%**
Digital applications	285	38.10%
Internet of Things – 5G	278	37.16%
Computing	154	20.59%
Immersive environments	125	16.71%
Robotics	90	12.03%
Blockchain	70	9.36%
Open & crowd platforms	43	5.75%
Geo-spatial tech	30	4.01%
Proximity tech	19	2.54%
3D printing	16	2.14%
Total	**1,487**	

Table 3 presents the practices distributed by business function. Operations (OP) clearly dominate, with over half of the cases focused on optimizing daily processes where knowledge is actively applied. Research & development (R&D), marketing (MK) and governance & administration (G&A) each hold nearly equal shares, signaling that these functional domains are benefiting from these KM initiatives. The smaller percentages for functions like human resources (HR), distribution (DIS) and accounting & finance (A&F) indicate that, although these areas are not the primary focus, they still receive attention in KM strategies. This reinforces the idea that KM is not confined to a single department but is a cross-functional priority.

Table 3 - Emerging practices by business function.

Label	#	%
Operations	924	62.14%
Research & development	290	19.50%
Marketing	276	18.56%
Governance & administration	274	18.43%
Information & communications technology	222	14.93%
Human resources	53	3.56%
Distribution	49	3.29%
Accounting & finance	28	1.88%
Procurement	9	0.60%
Total	**1,487**	

Table 4 categorizes emerging practices by the phase of KM they influence. Knowledge acquisition is the leading one, suggesting that the primary aim is the gathering of new information and insights from both external and internal sources. The near-equal focus on knowledge organization and transfer demonstrates that companies are equally committed to structure the acquired or created knowledge and ensure it is effectively disseminated across the organization. On the other hand, the lower emphasis on knowledge application and creation point to challenges in pushing the boundaries of current knowledge and translating this into practical actions.

Table 4 - Emerging practices by KM phase.

Label	#	%
Knowledge acquisition	353	23.73%
Knowledge organization	342	23.00%
Knowledge transfer	335	22.52%
Knowledge application	299	20.11%
Knowledge creation	265	17.82%
Total	**1,487**	

4.2 Association analysis

Figure 4 illustrates the Cramér's V values derived from the association analysis in a bubble chart. The size of the bubbles indicates the strength of the association showing which functions are more closely linked to each KM phase.

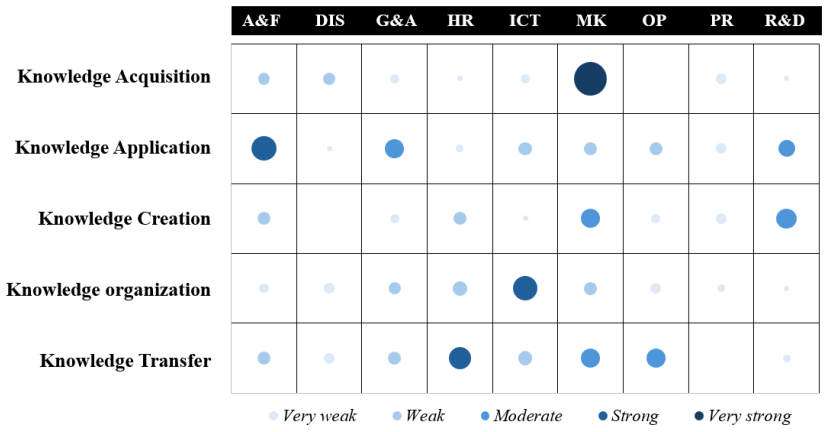

Figure 4 – Associations between KM phases and business functions in AI practices.

Their interpretation follows the guidelines proposed by Akoglu (2018), which categorize these values into very weak, weak, moderate, strong, and very strong levels.

In the *knowledge acquisition* phase, AI plays a major role in actively sourcing and processing new knowledge, especially in MK. Joung & Kim (2023) demonstrate this by proposing an interpretable machine learning approach that analyzes online reviews to extract and quantify product features.

In the *knowledge application,* AI's impact becomes even more evident. Across various organizational functions, AI integrates new knowledge, albeit with varying degrees of impact. Most functions exhibit a weak to moderate association; however, the A&F domain deviates from this pattern. For example, Kwon & Lee (2024) introduce a trading system that combines traditional expert rules with deep reinforcement learning.

K*nowledge creation* shows significant differences among functions, with R&D strongly benefiting from AI's ability to connect dots that might otherwise be missed. For instance, Liu et al. (2022) develop a framework for product design that employs machine learning to construct design-specific knowledge graphs.

In the *knowledge organization* phase, the focus is on structuring and preserving information effectively. ICT stands out in this stage, as demonstrated by Gao et al. (2023) through a relation extraction framework used for drug instructions. Their model accurately captures subtle semantic nuances to build robust medical knowledge bases with limited high-quality annotated data.

Lastly, in the *knowledge transfer* phase, AI proves important for disseminating knowledge, particularly in HR settings. Kakdas et al. (2024) propose a novel 3-D simulation framework that integrates reinforcement learning to train medical staff in proper personal protective equipment protocols.

In the second step of the analysis, the focus shifts to exploring the role of complementary emerging technologies and their contribution to KM. Figure 5 presents the Cramér's V values from the association analysis in the form of five radial charts. Each chart represents a distinct phase of KM and plots various emerging technologies (integrated with AI) along individual axes, with the length of each axis indicating the strength of the association.

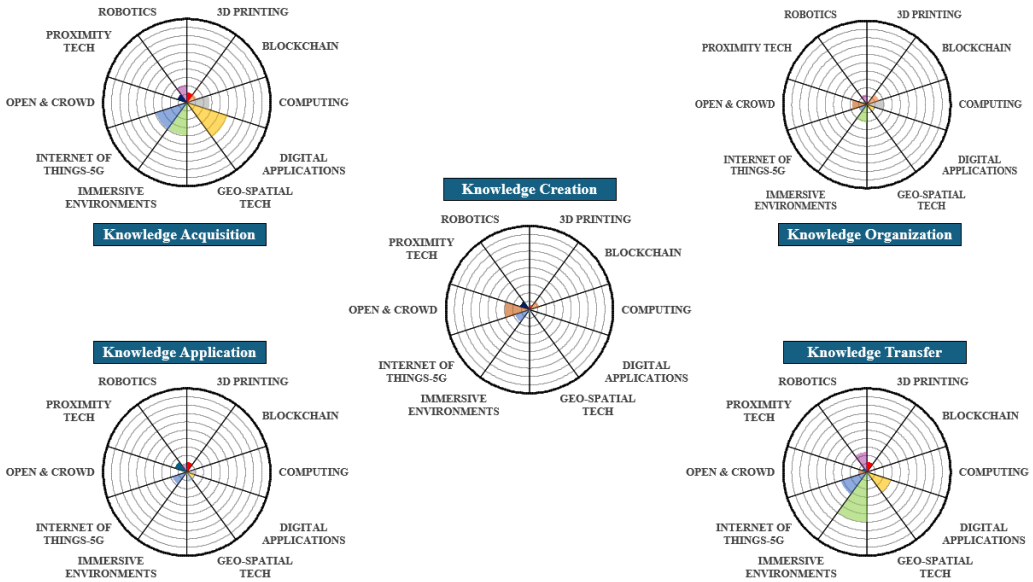

Figure 5 - Associations between complementary technologies and KM phases in AI practices.

The *Knowledge acquisition* phase clearly benefits from DAs that leverage AI to capture, filter, and interpret diverse information streams. For example, Shahzad et al. (2024) propose an AI-chatbot that traduces everyday customer feedback into strategic, actionable knowledge that strengthens e-brand loyalty in the luxury fashion sector.

Knowledge creation is closely associated with open and crowd-based platforms, combining AI with external and internal contributors. For instance, Poser et al. (2022) introduce an AI-based conversational tool that facilitates knowledge creation in open innovation environments.

The *knowledge organization* phase does not depend on a single dominant complementary technology outside od AI. Luo et al. (2023) illustrate this by offering a convolutional neural network–based text classification framework tailored for construction accident reports.

Similarly, *knowledge application* sees no single complementary technology clearly standing out, with AI continuing to be essential in transforming knowledge into concrete practice. For example, Panigutti et al. (2023) propose a co-designed, human-centered explainable AI system for clinical decision support systems.

Knowledge transfer registers the strongest associations with IMM and ROB. For instance, C. Liu et al. (2023) present an integrated human–robot collaboration approach that blends a mixed perception module with online deep reinforcement learning and an AR interface to capture tacit maintenance expertise and transfer that knowledge efficiently between skilled operators and collaborative robots in complex manufacturing environments.

5 Discussion

5.1 Theoretical implications

KM has been widely recognized as one of the critical determinants driving organizational success, particularly in contexts characterized by rapid technological evolution. Despite existing research acknowledging the potential of AI in KM processes (Jarrahi et al. 2023, Iaia et al. 2024), the understanding of how AI interacts with other emerging technologies to impact KM remains limited. Specifically, previous studies have examined these technologies in isolation, neglecting the fact that organizations typically deploy them simultaneously (Nascimento et al. 2021). This research addresses these limitations by examining the intersection of AI with ten complementary, emerging technologies across five essential KM phases. To this end, this study analyzes 1,487 documented business practices derived from literature. Association analysis is then employed to measure the strength of relationships between the various phases of KM and associated business functions, focusing only on AI practices, as well as between specific technological combinations and KM processes.

The analysis reveals that AI is strategically utilized across all business functions in KM strategies. In some cases, AI is implemented in isolation, as highlighted by Jarrahi et al. (2023); in others, its impact is enhanced when integrated with other complementary emerging technologies. Certain combinations are not uniformly beneficial across all KM processes; rather, their impact varies significantly based on the specific KM phase. For example, combining AI with DA effectively streamlines knowledge acquisition from external sources, while the integration of AI with IMM significantly improves knowledge transfer. Similarly, the use of AI alongside open and crowd-based platforms enriches the process of knowledge creation by leveraging the power of collective intelligence.

Notably, in the knowledge application and organization phases, AI tends to exhibit strong standalone capabilities, underscoring its intrinsic ability to organize and apply knowledge effectively, as noted by Marvi et al. (2024). This extends current understandings of AI's role in KM by demonstrating that, while certain technology combinations yield considerable benefits in specific phases, the unique strengths of AI are indispensable in others, further emphasizing its intrinsic value.

5.2 Methodological contributions

The methodology in this study offers significant advantages over traditional approaches in the KM literature by constructing an extensive dataset composed of documented business practices. Following the approach adopted by Cammarano et al. (2024), this study extracts case studies, simulations, and pilot projects from rigorously peer-reviewed academic articles, which inherently ensures a high standard of reliability, originality, and relevance. Business practices are classified along three key dimensions: the specific emerging technologies deployed, the business functions affected, and the KM areas involved. To achieve this, the research builds upon and revisits previous classifications in the KM literature (Marvi et al. 2024, Jarrahi et al. 2023), resulting in the definition five fundamental processes—creation, acquisition, organization, transfer, and application. These processes capture the full spectrum of KM activities. Unlike conventional literature reviews that merely summarize the current state of research, this study explicitly aims to create a practical database that serves as a robust foundation for subsequent analyses. In particular, the study employs association analysis—a quantitative statistical method that measures the strength of relationships between categorical variables— to provide a rigorous empirical basis that moves beyond basic descriptive statistics.

5.3 Recommendations for managers

Given the strategic importance of KM in today's highly competitive environment, this research provides critical insights for managers who contend with so many uncertainties and risks when investing in emerging technologies. To optimize their investment decisions, they require clear and actionable guidance. This study

addresses these problems by first determining which business functions derive the greatest benefit from AI implementation, and then it identifies the most effective technological combinations for improving specific KM phases. Ultimately, the research provides a robust analytical framework that allows managers to benchmark their current KM initiatives against empirically validated emerging practices. By doing so, they can identify gaps in their current approaches, evaluate the effectiveness of their systems, and prioritize investments in areas where the potential for improvements is greatest.

6 Conclusions

This study examines the transformative role of AI and its integration with other emerging technologies in redefining KM. Using a dataset of real-world business applications from scientific literature, the research shows that specific technological combinations lead to significant improvements in KM practices across various phases. For instance, AI paired with DA profoundly improves knowledge acquisition, while IMM and ROB excel in facilitating dynamic knowledge transfer. These findings provide a strong empirical basis for developing tailored KM strategies, as managers can leverage these results to optimize their strategic investments and align their technological choices with the most pressing needs of each KM area.

Nevertheless, several limitations should be carefully acknowledged. The extensive body of literature makes it impractical to comprehensively analyze every potentially relevant academic contribution, resulting in an inevitable partial perspective of the phenomenon. Although rigorous selection procedures are adopted, manual screening and classification remains time-consuming and carries the risk of subjective bias. Furthermore, relying exclusively on SCOPUS-indexed academic journals may exclude relevant studies from non-indexed sources.

Future research might benefit from leveraging AI-based techniques to automate the article classification. Additionally, longitudinal studies will make it possible to track the evolution of these technologies and their long-term impact on KM. In parallel, researchers should explore mixed method approaches that combine advanced machine learning analysis with in-depth case studies.

7 Ethics declaration

This research did not involve human participants, animals, or sensitive data requiring ethical approval. Therefore, ethical clearance is not required.

8 AI declaration

Generative AI tools were used to assist in language editing and improving clarity. The authors reviewed and edited all AI-generated content to ensure accuracy and integrity. The final manuscript reflects the authors' own work and interpretations.

Do Organizations Struggle to Implement AI in Knowledge Management Systems? Initial Empirical Insights

Maayan Nakash[1 2], Ettore Bolisani[2]
[1]Bar-Ilan University, Ramat Gan, Israel
[2]University of Padova, Vicenza, Italy

Abstract

Previous studies have highlighted the numerous benefits of artificial intelligence (AI) models in enhancing the management of organizational knowledge assets. However, the adoption of AI in organizational settings often encounters significant barriers that hinder its optimal implementation. This paper presents preliminary findings from a timely study that uniquely focuses on the perceived obstacles at the intersection of AI and knowledge management (KM) in organizations. Our objective was to understand the perspectives of employees and managers regarding four dimensions of barriers and challenges in integrating AI technologies into knowledge management systems (KMSs) in business: human, technological, financial, and ethical-regulatory. A voluntary and anonymous online questionnaire was completed by 378 respondents from various industries. The results reveal that financial barriers were reported to be the least significant by both regular employees and managers. Instead, nearly half of the participants expressed concerns about technical barriers, particularly the inadequacy of their organizations' technological infrastructure to support AI applications effectively. A significant percentage of 82.28% of the sample mentioned organizational barriers, specifically noting that employees lack the necessary skills to leverage AI for enhancing organizational KM. Furthermore, nine out of ten respondents indicated that a substantial cultural shift is essential for facilitating AI adoption within their organizations. Concerns about the potential leakage of sensitive information due to AI usage were significant, with approximately two-thirds of respondents highlighting this issue. Additional ethical barriers were prominent, with three out of four participants reporting a lack of clear organizational procedures to ensure information security and privacy in AI applications. These findings have significant theoretical and practical implications for the discipline of KM in general, and for KMSs in particular. These findings lay a fertile ground for future empirical investigations into the relationship between AI and KM.

Keywords: Artificial Intelligence, AI Adoption, Technology Adoption, Challenges, Implementation, Knowledge Management Systems

Paper type: Academic Research Paper

1 Introduction

Artificial intelligence (AI) has emerged as a transformative technology with the potential to revolutionize various industries (Arias-Pérez and Vélez-Jaramillo, 2022; Dwivedi et al., 2021; Kar et al., 2021), capturing the interest of knowledge management (KM) scholars (Jallow et al., 2020; Nakash and Bolisani, 2024). With the rapid advancement, power, and versatility of generative AI (GenAI), its impact on knowledge creation, storage, transfer, and application is becoming increasingly evident (Alavi et al., 2024). Despite the intrinsic link between AI and KM, the symbiotic relationship between these multidisciplinary fields has not been thoroughly explored and remains fragmented (Bencsik, 2021; Nakash and Bolisani, 2024; Pimentel and Veliz, 2024; Jallow et al., 2020; Zbuchea et al., 2019). Consequently, scholars have emphasized the critical need for collaborative and convergent research at the intersection of KM and AI (Melina et al., 2024; Mohammad et al., 2022; Sundaresan and Zhang, 2022; Taherdoost and Madanchian, 2023).

Recent research has underscored the numerous advantages of AI systems in enhancing the management of organizational knowledge assets. AI can automate knowledge discovery, facilitate advanced data analysis, and support decision-making by providing insights derived from large datasets (Alavi et al., 2024; Al Mansoori et al., 2020; Bencsik, 2021; Kirchner et al., 2024; Pimentel and Veliz, 2024; Vadari and Desik, 2021; Zhou, 2022). However, the adoption of AI within organizational contexts can face significant barriers that may hinder its effective implementation (Alsheiabni et al., 2019; Ambati et al., 2020; Dwivedi et al., 2021; Hamm and Klesel, 2021; Kar et al., 2021; Makridakis et al., 2023; Sun and Medaglia, 2019).

AI adoption refers to the process of integrating AI technologies within an organization, that can be a complex phenomenon influenced by various factors (Radhakrishnan and Chattopadhyay, 2020). Extensive literature highlights the multifaceted nature of obstacles to AI adoption (Kar et al., 2021). Additionally, different stakeholder groups may present conflicting views regarding AI, further complicating the adoption process (Sun and Medaglia, 2019). However, there remains a lack of sufficient empirical studies addressing the "inhibitors to

AI implementation" in organizational settings (Alsheiabni et al., 2019). This gap also extends to knowledge management systems (KMSs) (Nakash and Bolisani, 2024), which are technological systems designed to assist in the organization, storage, sharing, and utilization of knowledge within an organization (Al Mansoori et al., 2021). In principle, AI can support companies in their KM processes and can also open new perspectives on how different elements of knowledge, including explicit and tacit contents, can be treated by technologies (O'Leary, 2024; Taherdoost and Madanchian, 2023).

To address the gap in the literature, this paper presents some preliminary findings from a timely study on the perceived obstacles to AI adoption in KM within organizations. Our objective was to explore the perspectives of employees and managers regarding four dimensions of barriers and challenges to integrating AI technologies into KMSs: human, technological, financial, and ethical-regulatory barriers. This understanding is crucial as it provides valuable insights into the practical difficulties of AI integration with KMSs, which can inform the development of more effective implementation strategies.

2 Theoretical Background: Barriers and Challenges to AI Adoption

2.1 Human

Previous studies have emphasized the critical role of human factors in AI implementation, with a recurring theme in the literature being the potential resistance to change, deeply rooted in organizational culture. Employees may fear job displacement or feel threatened by the introduction of intelligent robots, leading to resistance, knowledge hiding, and lack of cooperation (Arias-Pérez and Vélez-Jaramillo, 2022; Malik et al., 2023; Vasiliu and Yavetz, 2024). Concerns extend beyond potential negative impacts on career prospects (Lingmont and Alexiou, 2020) to include doubts about the accuracy and reliability of AI tools, which can hinder their effective use (Alavi et al., 2024; Sun and Medaglia, 2019).

2.2 Technological

Technological challenges encompass the lack of transparency in AI algorithms and the difficulties AI systems face in processing unstructured data (Sun and Medaglia, 2019), as well as in understanding the depth of implied relationships (Nakash, 2024). AI technologies, such as machine learning and natural language processing, require sophisticated algorithms and significant computational power (Alhosani and Alhashmi, 2024; Taherdoost and Madanchian, 2023). Integrating these technologies into existing KMSs can be technically challenging, especially in managing tacit knowledge (Zhou, 2022). Furthermore, AI models heavily rely on large volumes of high-quality data. Ensuring the availability, accuracy, and completeness of data in the organizational systems is a critical challenge, as poor data quality can lead to suboptimal AI performance (Makridakis et al., 2023; O'Leary, 2024; Tarafdar et al., 2019).

2.3 Financial

Economic challenges encompass barriers related to profitability and economic sustainability, which hinder the adoption of AI (Sun and Medaglia, 2019). The widespread implementation of AI technologies could have a significant economic impact on organizations, particularly in terms of the required investments and changes in operational methods (Dwivedi et al., 2021). The development, deployment, and maintenance of AI technologies require substantial financial investment, especially when integrating with other systems. Organizations must invest in advanced hardware, software, and infrastructure to support these technologies (Alhosani and Alhashmi, 2024). Moreover, the cost of recruiting and retaining skilled AI professionals can be high, adding to the financial burden (Tarafdar et al., 2019).

2.4 Ethical-Regulatory

In contrast to humans, AI systems lack self-awareness and the capacity for self-reflection (Jarrahi et al., 2023). Ethical and regulatory concerns are increasingly recognized as major obstacles to AI adoption due to fears of unfair or discriminatory outcomes, and errors in predictions (Feuerriegel et al., 2020). Issues such as data privacy, algorithmic bias, and knowledge misapplication pose significant challenges (Alavi et al., 2024; Alhosani and Alhashmi, 2024; Makridakis et al., 2023; Malik et al., 2023; Pimentel and Veliz, 2024). Furthermore, regulatory frameworks such as the GDPR often lag technological advancements, creating uncertainty and risks for organizations (Feuerriegel et al., 2020). The issue of accountability in the event of errors caused by AI systems has also been a subject of discussion (Dwivedi et al., 2021).

3 Research Framework

A voluntary and anonymous online questionnaire was completed by 378 respondents from various roles in companies of different sizes and sectors (including public and private services, manufacturing, and high-tech industries), all within a single country. Gender-wise, the study included 47.4% men and 52.6% women. Among the respondents, 67.5% held academic degrees, and 56.1% were in managerial positions. Additionally, 57.1% were over the age of 40, and 37.1% had more than 10 years of organizational seniority.

Based on the literature, and alongside the collection of demographic and employment information, the developed questionnaire included four types of barriers and challenges to AI adoption for KM: human, technological, financial, and ethical-regulatory. Each type was assessed through respondents' agreement with five statements on a 6-point Likert scale, ranging from 1 (strongly disagree) to 6 (strongly agree). **Table 1** provides examples of statements for each type of obstacle.

Table 1. Key Examples of Likert Scale Statements, Categorized by the Four Barriers and Challenges

Types of Barriers and Challenges	Example of a Statement
Human	Knowledge managers in my organization fear a loss of personal value with the widespread implementation of AI in KM processes
Technological	AI models are not accurate enough for acquisition, documentation, sharing, and application of the organizational knowledge
Financial	The cost of purchasing, implementing, and maintaining AI solutions for KM is too high for my organization
Ethical-Regulatory	Biases and hidden discrimination may seep into the decision-making process due to mistaken interpretation of reality by the algorithms

The questionnaire underwent reliability and validity testing. It is important to acknowledge that the results presented in this paper are derived from preliminary analysis, that offers a foundational insight into the barriers and challenges associated with AI adoption in the KMSs context. Nonetheless, they constitute merely the initial phase of an extensive research endeavor, which will continue with the application of in-depth statistical analyses to examine the impact of demographic and occupational variables on perceptions.

4 Preliminary Findings and Interpretation

The results indicate that comparatively, financial barriers and challenges to implementing AI in KMSs were reported less frequently than human, technological, and ethical-regulatory obstacles. This finding may initially appear counterintuitive, as financial constraints are traditionally perceived as significant impediments to the adoption of advanced technologies. However, this can be explained by the growing trend towards open-source AI solutions, which have gained substantial traction in recent years, thereby lowering the financial barriers to entry for many organizations. It is possible that this shift allows organizations to leverage advanced AI capabilities without the traditionally exorbitant investment in proprietary technologies.

This trend was also reflected particularly among managers, who perceived fewer financial obstacles compared to employees. This difference can be attributed to the broader strategic perspective of managers, who are likely to focus on long-term benefits and the alignment of AI with organizational goals, rather than immediate financial constraints. Accordingly, a very small minority of respondents—less than 4% (n=15)—completely dismissed the notion that the costs associated with acquiring, implementing, and maintaining AI for KM are prohibitively high for their organizations. This minority viewpoint reflects a forward-thinking approach, where AI is seen as a long-term investment rather than an immediate financial burden.

From a technological perspective, nearly half of the sample (47.62%) expressed significant (n=89) or very significant (n=91) concerns about their organization's inadequate technological infrastructure to support AI applications effectively. This finding emphasizes the critical role that technological readiness plays in the successful implementation of AI-driven initiatives. Insufficient computational power, outdated systems, limited data storage and processing capabilities, or a lack of integration between existing systems and AI platforms could all contribute to these concerns. Inadequate infrastructure may not only hinder organizations from realizing the full value of AI for KM, but could also lead to implementation failures, wasted resources, and a loss of competitive advantage. Therefore, this finding underscores the need for organizations to prioritize infrastructure development as a fundamental prerequisite for AI adoption.

In terms of human capital, a significant majority of respondents (n=311, 82.28%) expressed varying levels of agreement that employees within their organization lack the necessary skills to effectively leverage AI for enhancing organizational KM (see **Figure. 1**).

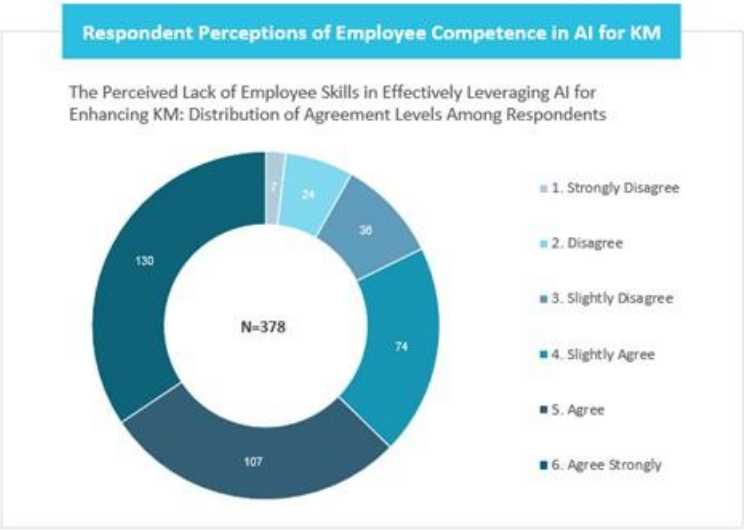

Figure 1: Levels of agreement with the statement:
"Employees currently lack the necessary skills to fully utilize AI for enhancing KM"

The widespread perception of a skills gap underscores the complexity of AI technologies, and the specialized expertise required to harness their full potential for KM. AI's transformative power in KM lies in its ability to automate knowledge discovery, streamline processes, and provide data-driven insights. However, achieving these outcomes depends heavily on the proficiency of the workforce in understanding, interacting with, and applying AI tools. The lack of necessary skills among employees can severely limit the effectiveness of AI implementations, as employees may struggle to navigate the technology, interpret its outputs, or adapt their workflows to maximize its benefits. This finding suggests a broader need for organizations to invest in targeted training and development programs aimed at building AI literacy and technical proficiency among their employees.

Moreover, an overwhelming 9 out of 10 respondents (n=343, 90.74%) indicated that a significant cultural shift is required to facilitate the adoption of advanced AI applications within their organizational environment (see **Figure 2**). This underscores the deep-rooted influence of organizational culture on the successful integration of AI technologies in KMSs, suggesting that more than just technological upgrades or skills development are needed.

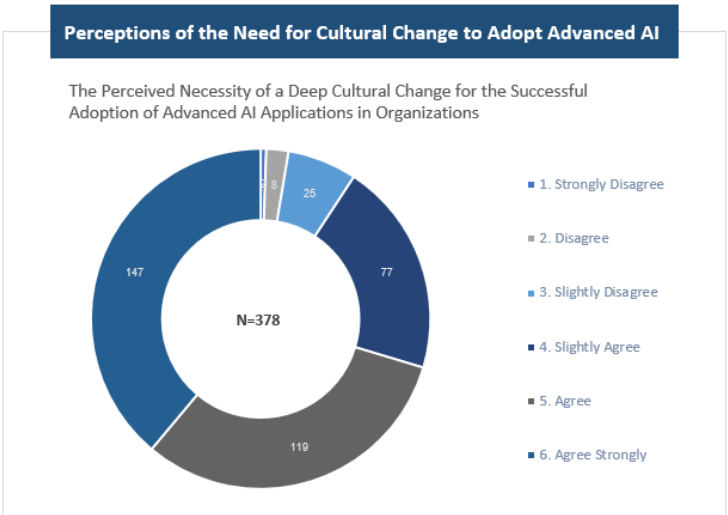

Figure 2: Levels of agreement with the statement:
"A deep cultural change is required to adopt advanced AI applications in the organization"

The call for a profound cultural shift highlights the psychological and emotional barriers that often accompany AI adoption. As indicated in qualitative responses from several participants to an open-ended question we asked, notable apprehension exists regarding job security, with some employees expressing fears that AI could render their roles obsolete or irrelevant. To address these concerns, organizational culture must

evolve to foster an environment where employees feel secure in engaging with AI technologies. Building trust and promoting a sense of inclusion in the AI transition process are essential to mitigating these fears.

Further, approximately two-thirds of respondents (67.20%) expressed significant (n=115) or very significant (n=139) concerns that AI could potentially lead to the leakage of sensitive information from organizational systems. This highlights a critical issue in AI adoption, as it underscores pervasive fears surrounding data security and privacy risks. The finding suggests that trust in AI technologies is not yet fully established within organizational sets. Employees may be uncertain about the robustness of AI security measures or skeptical about the ability of these systems to safeguard critical information. This uncertainty may be exacerbated by a lack of transparency regarding how AI systems operate, how data is protected, and who has access to that data. To address these concerns, organizations must not only implement stronger security protocols for AI systems but also communicate these safeguards clearly and effectively. Building trust in AI technologies is essential for their successful adoption, particularly when handling sensitive data.

In this context, 3 out of 4 respondents (n=273, 72.22%) reported a lack of clear organizational procedures for ensuring information security and privacy in AI applications. This finding underscores a significant gap in AI governance and oversight within many organizations. The absence of well-defined protocols for managing data security and privacy signals that organizations may not yet be fully prepared to mitigate the risks associated with AI implementation. This lack of governance could hinder their ability to deploy AI safely and responsibly, underscoring the need for comprehensive AI governance strategies that address security, privacy, and ethical considerations.

5 Conclusions

The findings presented in this paper are preliminary and highlight several critical obstacles to the successful adoption of AI in KMSs. While financial barriers were reported less frequently than anticipated, human, technological, and cultural challenges emerged as significant impediments. These challenges are deeply interconnected, with each having critical implications for the successful integration of AI technologies into KMSs.

First and foremost, the importance of technological readiness cannot be overstated. A significant portion of respondents reported concerns regarding inadequate technological infrastructure. This highlights the need for organizations to invest in upgrading their existing IT systems, enhancing computational capabilities, and ensuring seamless integration between AI and their KMS platforms. In addition to infrastructure, the human element remains a critical factor in AI adoption. The widespread perception of a skills gap among employees suggests that organizations must prioritize workforce development, emphasizing the importance of building AI literacy and technical proficiency at all organizational levels.

The cultural dimension of AI adoption emerged as a key finding, with the vast majority of respondents recognizing the necessity for a profound cultural shift to embrace AI technologies for enhancing KM. This underscores that AI adoption is not merely a technological upgrade but a transformational change impacting all facets of organizational life. AI challenges existing norms and practices, particularly in KM, where human expertise has traditionally been central. Furthermore, the study highlights significant concerns regarding data security and privacy in AI applications, especially within the context of KMSs, where sensitive organizational knowledge and intellectual property are at stake.

6 Outlook

This is a preliminary study that nonetheless opens the possibility of implementing further analyses. First, extending the analysis to other areas could be useful in highlighting country-specific differences. Second, a more thorough statistical analysis (for example, a cluster analysis) can help identify categories of potential business users based on their perceived challenges. Third, future studies should explore the specific technological requirements for AI integration in KMSs and develop best practices for organizations at various stages of technological maturity.

7 Ethics Declaration

This study was conducted in accordance with the ethical standards of the Institutional Ethics Committee. The participants provided informed consent prior to their inclusion in the study, ensuring confidentiality and anonymity.

8 AI Declaration

The authors confirm that no AI tools were used in the creation of this manuscript. All research, analysis, and writing were conducted manually, adhering to the highest standards of academic integrity.

AI-driven Value Creation in Innovation Ecosystem, insights from Stakeholder Theory

Maria Elena Latino[1,2], Maria Chiara De Lorenzi[2], Maria Laura Giangrande[2]
[1] Naica S.C, Lecce, Italy
[2] University of Salento, Lecce, Italy

Abstract

In the era of Industry 5.0, artificial intelligence offers new opportunities for co-creation, personalization, collaboration and integration. These affect companies' Business Model Innovation strategies, supporting progress in the interactions between sets of actors, populations, activities, institutions and networks impacting the entire innovation ecosystems. Positioning itself in the research stream focused on analysing the impact generated by emerging technologies in the innovation of business ecosystems, this study aims of discussing the impact generated by artificial intelligence in business model innovation, reflecting on the salience of the involved stakeholders. A three-phase methodological approach was used, integrating a systematic literature review with a case study analysis. The related findings were discussed according the stakeholder theory basing on the salience attributes of power, legitimacy and urgency. This approach allowed us to establish a strong theoretical foundation while anchoring our findings in real-world example. Seven artificial intelligence-based value creation innovations were identified, demonstrating how artificial intelligence-based applications are transforming value creation mechanisms. Findings indicate that artificial intelligence has the potential to generate significant added value, primarily by enhancing value creation through data exploitation and the high degree of services customization tailored to customer needs. Moreover, new value streams emerge from artificial intelligence-based applications, driven by the widespread adoption of the technology across innovation ecosystems. This diffusion influences and engages stakeholders at every layer of the ecosystem's structure. Stakeholders are classified as Discretionary (Standards Bodies, Public Bodies), Demanding (Distribution Channels, Research Institutes), Dangerous (other suppliers), Dependent (Suppliers), Definitive (Core Organization, Customers, Complementors). Notably, no stakeholders were identified that align with the Dormant or Dominant categories.

Keywords: Stakeholder Identification and Salience, Society 5.0, Advanced technologies, Business Model Innovation, Value strategies.

Paper type: Academic Research Paper

1 Introduction

In the era of Industry 5.0, in which human involvement within innovation and technological advancement is placed at the forefront (Troisi et al., 2023), firms are increasingly relying on Artificial Intelligence (AI), and managers are trying to leverage on it with the aim of identifying and managing new business models (Wellers et al., 2008). AI is an enabling technology that can be integrated in products and systems and can provide a beneficial service for customers in various parts of the supply chain (SC) (Teece, 2018). For example, AI offers new opportunities for co-creation (Sewpersadh, 2023), personalization (Cao, 2021), collaboration and integration (Latinovic and Chatterjee, 2022), affecting companies' Business Model Innovation (BMI) strategies, and supporting progress in the interactions between sets of actors, populations, activities, institutions and networks that characterise the Innovation Ecosystems (IEs) (Granstrand and Holgersson, 2020). IEs are complex systems of individuals, businesses, governments and institutions in which Society 5.0 strives to foster innovation, generating opportunities for new businesses and stimulating the economic growth (Oh et al., 2020). Therefore, IEs includes actors, activities, and artifacts. Dias Sant´Ana et al., (2020), in their literature review, examine the IE by describing it through a triple-layer structure and mapping the actors operating within each layer. According to them, the first layer of IE is the *core business layer,* which comprises the central entities driving the business. This layer includes actors such as the core organization, suppliers and distribution channels. In traditional models, it is typically managed by a single company or coordinated by a focal organization within the SC. Alternatively, it can consist of a network of multiple organizations, each responsible for different aspects of the core business. The second layer of IEs is the *extended enterprise layer*, which broadens the business perspective to encompass customers, complementors, other suppliers, and regulatory or standard-setting bodies relevant to the field. The third and outermost layer, *other group of actors*, incorporates a diverse range of entities such as trade associations, labor unions, universities, research institutions, investors, and other stakeholders. Although these actors may not be directly involved in day-to-day operations, they can significantly influence the success and the evolution of the business ecosystem. Technology plays a critical role in IEs, particularly in

facilitating the dissemination of information and innovation (Oliveira and Trento, 2021). Disruptive technology, such as AI (Palmié et al., 2020; Barile et al., 2024), have the potential to impact all ecosystem actors, reconfiguring relationship, revitalizing processes, and enhancing the overall resilience of the ecosystem (Burström et al., 2021). Positioning itself within the research stream that investigates the impact of emerging technologies on the business ecosystems innovation, this study aims of exploring how AI influences BMI, with a particular focus on the salience of the actors involved. The study is guided by the following research questions (RQs): *How is AI transforming Value Creation (VC)? How does this transformation affect the actors within the business ecosystem?*

2 Research Methodology

A three-phases research methodology was adopted. In the first phase, a systematic literature review was conducted to define the research boundaries and identify a comprehensive list of AI-based VC innovations. The review followed the PRISMA guidelines, resulting in a final sample of 195 papers analysed through content analysis (Figure 1). In the second phase, the list of AI-based VC innovations, was explored through a case study, aimed at comparing theoretical expectations with real-world practices. The case study, focused on the energy sector, chosen for its intensive adoption of AI technologies (Serban & Lytras, 2020; Lyu & Liu, 2021), and involved a series of interviews with employees from an energy company. A semi-structured interview format was adopted to maintain alignment with the core research themes while allowing flexibility to delve into emerging insights (Adeoye-Olatunde and Olenik, 2021). Finally, in the third phase, the findings were interpreted through the lens of Stakeholder Theory (ST), which emphasize the importance of considering stakeholder interest in organizational decision-making processes (Gilbert and Rasche, 2008). This study focuses on stakeholders within IEs, following the three-layer structure proposed by Dias Sant'Ana et al. (2020). To further examine stakeholder roles, we applied the Stakeholder Identification and Salience theory developed by Mitchell et al., (1997), which assesses stakeholder relevance based on three key attributes: power, legitimacy and urgency (summarized in Table 1). According to this model, stakeholders can be categorized into seven types: Dormant (Power), Discretionary (Legitimacy), Demanding (Urgency), Dominant (Power + Legitimacy), Dangerous (Power + Urgency), Dependent (Legitimacy + Urgency), and Definitive (Power + Legitimacy + Urgency). We then analysed how the actors in our case study align with these categories in relation to the observed impacts of AI on business innovation.

3 Results and Discussions

The findings of this study enabled the identification the key impacts of AI on VC mechanisms within the business model, and allowed for the mapping of these impacts to specific stakeholders group within the IE.

3.1 The impacts of AI on value creation

Seven AI-based value creation innovations were discovered:

Digital Servitization. AI allows companies to expand their product and service portfolios through servitization (Chauhan et al., 2022), dematerializing the offering, and enriching services that enhance company and customers value (Sjödin et al., 2023). Customers are the first involved actor as they choose a company according to its competitiveness, variety and accessibility of services (Burström et al., 2021). The case study highlights involvement of the actors from the extended enterprise layer, particularly other suppliers and complementors, which help the company in implementing software for AI-based integrated services. This enhances customer support by streamlining service and maintenance requests. AI enables faster request submissions, improving response times and satisfaction. The company also introduced AI-based data sensing and tracking services, optimizing electrical device performance and strengthening after-sales.

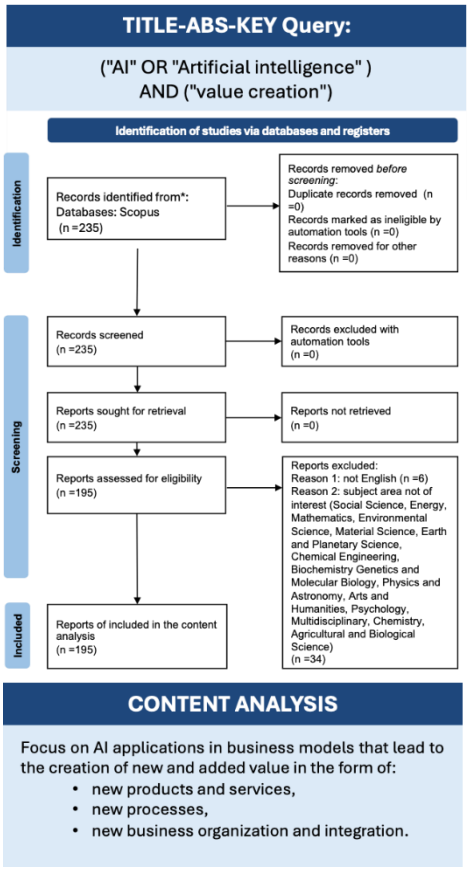

Figure 1 – Search scheme, PRISMA protocol and content analysis details

Table 1 – Stakeholder attributes (from Mitchell et al. 1997)

Attribute	**Description**
Power (PW)	Power represents the likelihood that an actor in a social relationship will enforce their will despite resistance. It defines the dynamic between two social actors, where the first has the ability to compel the second to act in a way they otherwise would not. Therefore, in a relationship, an actor holds power to the extent that they have, or can gain, access to coercive, utilitarian, or normative means to impose their will within the relationship.
Legitimacy (LG)	Legitimacy is the widespread perception or assumption that an entity's actions are desirable, appropriate, or proper within a system of norms, values, beliefs, and definitions. It is a desirable social construct that can be defined and negotiated in various ways across different levels of social organization.
Urgency (UG)	Urgency is an actor's demand for immediate attention. Through this attribute, the model shifts from static to dynamic. Urgency exists when the nature of a relationship is time-sensitive and when that relationship is important or critical for stakeholders.

Value Co-creation. AI makes easier the interaction, generating collaborative co-creation environments. Companies can collaborate with their customers, developing products and services based on the direct audience involvement. These customer-centric co-creation processes offer companies competitive advantages (Sjödin et al., 2021). Through their contribution, customers get what they seek in the form of improved offerings, reinforcing dynamics of loyalty and trust. AI-enabled collaboration can extend to additional actors within the IE. Technologies like co-bots enhance VC processes, actively involving employees, directors, and managers (Sewpersadh, 2023). The case study shows that AI-based open virtual sharing spaces enhance collaboration with customers by enabling fluid, interactive exchanges of ideas and suggestions. These digital platforms analyze shared information, identify needs, and propose tailored solutions, promoting valuable customer input. Customers thus become an integral part of the VC, with a deeper engagement, directly shaping products and services, and getting the role of a strategic partner. AI also filters and organizes contributions, highlighting key proposals and speeding up implementation. The case study shows how AI-enabled collaboration also enhances coordination with suppliers, distribution channels, complementors, and research institutes, improving SC alignment.

Mass Customization. Machine learning algorithms enable personalized outcomes, resulting in the creation of products and services tailored to individual customers. This is referred to “mass” customization because such algorithms simultaneously customize offerings for different profiles, designing a more personalized value proposition through client-centric or “intelligent” VC (Burström et al., 2021). Customers are the main actors involved in this VC mechanisms, whose expectations are completely fulfilled through the processing of information regarding their preferences. From customers’ viewpoint, the impact of technology is most evident within hyper-personalized offerings (Cao, 2021), making the customer experience unique. The case study highlights the company's commitment to customizing its offerings based on different customer needs, balancing personalization with scalability by leveraging advanced technologies to provide solutions that meet individual preferences while serving a broad market. The integration of AI within a dedicated platform enables customers to monitor, analyse, and optimize their energy consumption in real time. The platform's algorithms provide tailored recommendations, enabling significant energy savings without compromising device performance. The development of these “innovative consumer” applications makes energy management more accessible, even for users with limited technical skills. Interactive dashboards, predictive analytics, and real-time feedback improve the overall customer experience by adapting to user demands.

Data exploitation. Data exploitation and analysis capabilities enable new opportunities for innovative VC offering optimization, automation, servitization, and personalization benefits (Burström et al., 2021). Smart tools primarily process customer-related data as first category of information, driving VC processes based on customers preferences and market trends. From a management perspective, the core organization can set up data-driven decision-making processes, which allow to mitigate risks, making more accurate decisions when there is uncertainty or ambiguity, and to aim for continuous improvement of results in management performance (Åström et al., 2022). AI is capable of extracting valuable and strategic information from large, vague and inconsistent datasets. As the case study shows, the company leverages AI in the analysis of data in various operational areas. The greatest results are in the form of data-supported resource optimization, particularly in the photovoltaic and wind power sectors. AI also discover important information from data, enabling preventive maintenance planning in production systems, increasing efficiency. In order to maximize the benefits gained from intelligent data analysis, the company has identified 70 resources of AI specialists. Data coming from customers are a major source of benefits, for building predictive models for failures and maintenance that are based on usage and consumption information. However, some critical issues related to the processing of personal data and customer privacy have emerged, which has led the company to work on new predictive analytics models that respect the principles of anonymization and security, minimizing the risk of exposure of sensitive information and ensuring compliance with privacy regulations. The identification of hidden patterns can also be an important opportunity for other actors such as standard and public bodies of identifying criticalities that prompt them to take action. The use of data by all the actors of the ecosystem can give them new business opportunities, as the use of data by universities and research entities that support the development of statistical investigations and academic studies. Data exploitation thus involves all the actors defined in the triple-layers ecosystem, improving operational efficiency at each layer, and accelerating innovation of VC multilaterally.

Automation. Within the new AI-based VC logics, automation is transforming business processes at every operational level. The effects result in simplifying the activities by optimizing costs, resources and time (Mishra and Tripathi, 2021). AI-driven automation permeates throughout all SC levels, allowing traditionally human and poorly digitized tasks execution while saving on labor costs (Cao, 2021). Automation accelerates intermediate processes, impacting actors throughout the entire SC, such as the core organization, distribution channels, suppliers, other suppliers, complementors, and customers. The case study highlights automation’s impacts on core organization, specifically in monitoring and maintenance phases of production systems, and in transaction management. The company exploits automation to optimize the logistical routes for the installation of wind turbines, and to manage and simplify coding activities in software developing, increasing productivity and reducing human error. In the distribution sector, AI plays a key role for computer vision technologies that automate controls identifying anomalies, improving operational efficiency and workplace safety. AI tools are also embedded in digital twin models, which create highly accurate virtual replicas of physical infrastructure, enabling simulations and advanced testing of complex scenarios. The result is the prediction and mitigation of risks on real infrastructure. Finally, AI automation also finds application in plant monitoring systems through sensors with real-time data collection, providing support for the planning of maintenance interventions. Thus, AI contribute to the advancement of the entire IE, involving core organization, distribution channels, suppliers, other suppliers, complementors and public bodies in carrying out automated and digitized services and processes, simplifying their accessibility.

Feedback loops and Network effects. Feedback loops are crucial input coming from users of digital platforms, which contribute to the progressive and continuous improvement of algorithm refinement. The increased use of AI tools provides significant benefits to technology performances, a concept known as network effects. When network effects are combined with feedback from core organization and customers, new VC mechanisms emerged within the network. Within a company or an IE, a AI-based digital platform can supports management by connecting business activities across multiple actors, including suppliers, other suppliers, core organization, complementors, and standard bodies. The interconnections within actors generates added value benefiting all involved parties (Katsamakas and Pavlov, 2022), including end customers. These loops make AI increasingly and iteratively "intelligent", creating more and more value and fostering an innovation process for all actors directly involved. Another benefit for the company is the information coming from feedback provided by platform users, which in the case study are mainly represented by core organization and customers, with a less regular but still significant contribution from other actors in the ecosystem. The collection and processing of this feedback increase the value generated, as it enables the company to refine its services and adapt them to different needs. As part of the VC that contributes to the company's offering, the category of feedback with the greatest potential to generate positive impacts comes directly from customers. These inputs correspond to written messages or pictures provided by customers, particularly useful in remote monitoring services. Customers can upload photos showing the status of energy meters or household devices, allowing AI systems to analyze images and identify possible problems or faults, providing detailed diagnostics. This process simplifies problem solving for clients, while simultaneously improving AI algorithms accuracy through the benefits of network effects. The effectiveness of the tool depends on the quantity and quality of feedback received. The more real data users provide, the better AI can make accurate assessments. Platform feedback includes customer services and internal processes that involve various actors along the SC, optimizing operational flows, improving collaboration, and making feedback crucial for fostering synergy and efficiency within the IE.

Integrated communication. AI enhances value generation in companies by improving internal communication through AI-powered digital systems and Enterprise Resource Planning (ERP) tools, enabling real-time exchange of information among different operational functions. This fosters VC and promotes co-creation, facilitating faster and more synergistic collaboration among actors. AI's role in business communication and coordination lies in its ability to efficiently transmit information, ensuring seamless connections (Mahr and Huh, 2022). AI-enabled exchanges extend beyond companies, involving all actors in the triple-layers ecosystem, and promoting a modern approach to communication that results in collaborative VC. The case study shows how customers are impacted by innovative communication methods such as chatbots, virtual assistants and smart devices, which make digital communications more accessible and interactive. The strategic use of AI tools in optimizing communication exchange with customers, a crucial element in improving user experience, was also highlighted. Advanced chatbots and virtual conversation assistants help in filtering and simplifying messages, through which customer requests are analyzed in real-time, categorized, and associated with recurring or easily solvable issues. In this way, only the most complex or specialized issues are addressed by human operators, allowing them to focus on higher-value tasks. This approach reduces response time and enhances quality, ensuring customers receive swift solutions for common issues and tailored support for more complex situations. At a broader level, AI-based virtual assistant optimizes information management between the company and other players in its ecosystem. This assistant can synthesize contents from various sources, including e-mails, business documents, video conferences, and messages. This functionality is crucial in managing the complexity of communications in dynamic, multi-actor environments, reducing the risk of critical information loss and improving coordination. Additionally, the virtual assistant supports the creation of automated reports, meeting summaries and activity follow-ups, ensuring stakeholders maintain a clear and up-to-date view of decisions and actions. By integrating these tools, the company fosters a fluid communication ecosystem where data and information are exchanged, analyzed, and intelligently used. Figure 2 summarizes these results.

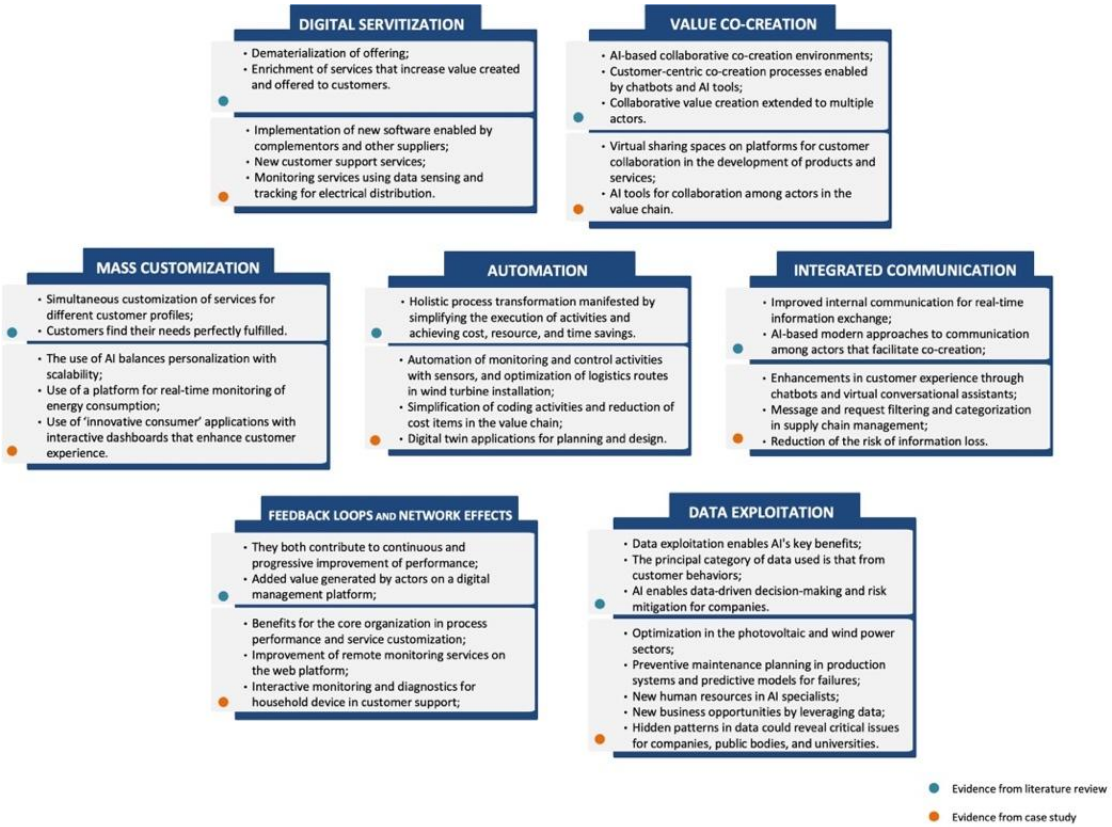

Figure 2 – AI-based VC innovations

3.2 The role of IE actors in AI-based VC innovations

Figure 3 summarizes the involvement of IE actors in the discovered AI-based VC innovation. These results are analyzed through the lens of ST, examining which salience attributes can be associated with each actor within the IE triple-layers structure.

The *Core Organization* possesses the attribute of *power* for several reasons: Digital Servitization, which introduces additional services such as data sensing and tracking that support customers even in the post-sale phase (Sjödin et al., 2021); Value Co-creation, demonstrated by the company's direct engagement with customers that generate power for core organization, fostering a sense of involvement and affiliation (Sewpersadh, 2023); Mass Customization, as evidenced by the company's ability to tailor its offerings to meet diverse customer needs, as highlighted in the case study; Automation, involving the execution of automated and digitized services and processes that simplify accessibility (Mishra and Tripathi, 2021); and Integrated Communication, which facilitates a fluid ecosystem for seamless information exchange. The effects resulting from the last three VC innovations show how the core organization acquires the attribute of power over customers thanks to their ability to improve products, services and processes which translates into their ability to improve market performance.

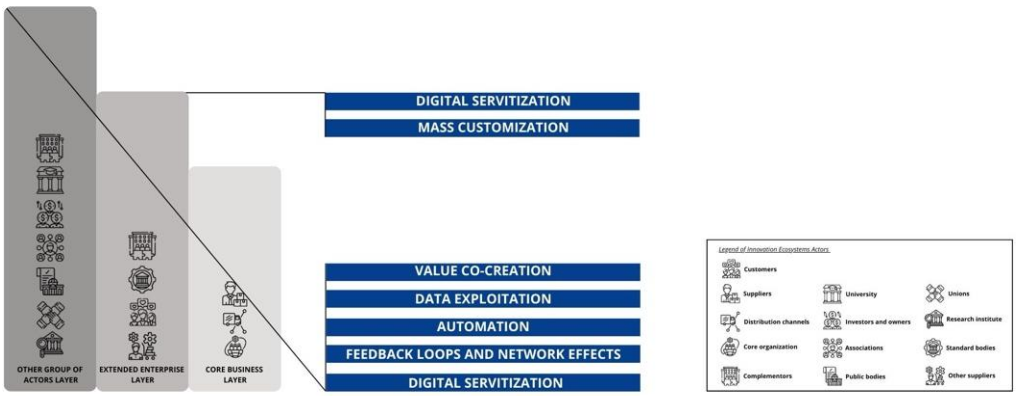

Figure 3 – The involvement of IE actors in AI-based VC innovations

Suppliers and *Complementors* also possess the attribute of *power*, driven by Digital Servitization, as these actors play a crucial role in supporting the company by implementing advanced AI-based software to integrate innovative services. Positioning in this role gives suppliers and complementors power over the company since them are capable of affecting the final result AI-based software impacting the company performance in providing the AI-based service.

Finally, *Customers* gain *power* attribute through Value Co-creation, which allows them to contribute to the development of improved offerings, thereby strengthening loyalty and trust. Additionally, feedback loops and network effects generate positive impacts, further enhancing the influence and power of customers within the IE. Indeed, thanks to these VC innovations, the role of the consumer evolves from being a mere user to becoming a co-creator who can assert their viewpoint and influence business decisions.

Customers gain *legitimacy* through the following VC innovations: Digital Servitization, which allows customers to send requests more quickly and efficiently, improving response times and overall satisfaction; Mass Customization, providing customers with access to hyper-personalized offers (Cao, 2021); Data Exploitation, enabling customers to leverage information derived from data to access current market trends; Feedback Loops and Network Effects, which streamline problem resolution, addressing customer issues promptly. Therefore, thanks to improvements in reducing response times and resolving customer issues, as well as the ability to offer personalized deals and provide direct access to market trends, desirable effects are generated, reinforcing the perception of legitimacy among customers.

The *Core Organization* possesses the attribute of *legitimacy*, enabled by the following VC innovations: Value Co-creation as supported by Sjödin et al., (2021), which involves the development of products and services based on involvement of the target audience; Automation as real-time data collection, providing crucial support for the planning and execution of maintenance interventions; Feedback Loops and Network Effects that enhance the company's performance by leveraging actors feedback to drive continuous improvement. By involving the target audience in product development, automating data collection to streamline maintenance processes, and incorporating feedback into improvements, the company takes appropriate actions toward IEs' actors, such as customers and suppliers, thereby enhancing its legitimacy. Thanks to Data Exploitation, the identification of hidden patterns enables the detection of problems or critical issues that enhance action efficiency.

Consequently, based on this evidence, *Public Bodies* acquire *legitimacy*, enabling them to operate in compliance with privacy regulations and within security boundaries during control operations.

The same attribute of *legitimacy* can be associated with *Complementors* and *Other Suppliers* and *Standard Bodies* enabled by the factor of Data Exploitation and Feedback Loops and Network Effects. These VC innovations generates value through a digital platform that supports the management of activities by connecting internal and external operations (Katsamakas and Pavlov, 2022), which provide legitimacy in taking appropriate intervention actions, such as consulting feedback provided by the company or processing data to enable predictive planning of interventions involving these actors in the SC.

Consumers gain *urgency* as an attribute through the following VC innovations: Digital Servitization, thanks to the accessibility and variety of services offered (Burström et al., 2021), customers can choose the company based on its competitiveness. This ability allows customers to assess the company's loyalty, and the significance of this action grants them the attribute of urgency; Value Co-creation that shared environments enable the collection of valuable customer inputs and encourage active participation in collaborative VC, in this way customers influence the timing of company's actions; Mass Customization that with interactive dashboards, predictive analytics, and real-time feedback enhance the customer experience by perfectly adapting to users' requests; Feedback Loops and Network Effects that emphasize the customer's role in driving value, fostering faster responses and continuous improvement; and Integrated Communication premising customers to play a crucial role as the main hub in optimizing communication and information exchange. Therefore, as beneficiaries of platform usage and central point of communication, customers possess the attribute of urgency for the company.

The *Core Organization* acquires the attribute of *urgency* through Automation factor, where its immediate attention is critical, especially during monitoring and maintenance phases of production systems, as well as in orders and transactions management (Mishra and Tripathi, 2021).

Suppliers, Other Suppliers, Distribution Channels, *Complementors*, and *Research Institutes* contribute to Value Co-creation aligning and coordinating activities across the entire SC. Due to their continuous and strategic support to the company in these previously non-outsourced activities, these actors acquire the attribute of *urgency*.

Summarizing, from an attribute-based observation, the salience of stakeholders highlights 5 of the 7 categories. There are Discretionary (LG) such as Standards Bodies and Public Bodies, Demanding (UG) are Distribution Channels and Research Institutes, Dangerous (PW, UG) are other suppliers, Dependent (LG, UG) are

Suppliers, Definitive (PW, LG, UG) are Core Organization, Customers and Complementors. There are no stakeholders that can be affiliated with the Dormant (PW) and Dominant (PW, LG) categories.

These results supports the definition of IE (Alka et al., 2024) as all actors have a "pro-active" role in relation to the phenomenon of the use of AI in VC strategies that excludes the dormant category. The absence of "preponderant" actors in relation to the same phenomenon underlines the result linked to the absence of the dominant category. Other evidence can be associated with the Data Exploitation factor which shows us how "the data speaks for itself" and gives attributes to the actors (Burström et al., 2021).

5 Implications

Theoretical and practical implications of the study were summarized in Table 2.

Table 2 - Implications

Theoretical Implications	This study enriches the academic scenario providing relevant insights in the business model innovation research area providing a list of seven AI-based VC innovations. Additionally, the interpretation of the results according to the theoretical lens of ST provide a contribution to the research stream of stakeholder management in IEs. Finally, the research stream focused to study the impacts of technologies in businesses was enriched by relevant insights about the impacts generated by AI in the VC. All results of this study represent a way to reflect about the overall impact generated by this emerging technology, opening the way to the identification of aspects worth investigating in the future both in the specific case of VC and in value capture and delivery.
Practical Implications	The study proposes the stakeholder identification in an IE focused on generating innovation using AI. These results are useful for those who want to innovate their business model through new AI-based VC strategies. The insights coming from ST describing the positioning of stakeholder in the analyzed IE and their salience attributes give interesting evidence about the possibility to involve several stakeholders in IE developing different innovative VC that led the company to serf the last industrial revolution according to the Innovation 5.0 paradigm.

6 Closing Remarks, Limits and Follow-ups

Thanks to the results obtained – particularly the identification of AI-based VC innovations - it was possible to answer the RQ1: "*How is AI transforming Value Creation (VC)?*". Furthermore, the discussion framed through the theoretical lens of ST enabled the identification of key actors within the IE and the assessment of their salience, thereby answering the RQ2: "How does this transformation affect the actors within the business ecosystem?". The added value of this study lies in the dual relevance of its findings: academically, by advancing the understanding of AI-based VC innovation within the framework of IEs; and practically, by emphasizing the importance of stakeholder management as a strategic level for fostering innovation.

Despite following a structured and rigorous methodology, certain limitations should be acknowledged. The qualitative bias stemming from the content analysis - conducted through a focus group to identify AI-based VC innovations - could be mitigated in future research by involving a broader panel of academic and industry experts. The robustness of the empirical evidence could also be strengthened through a multiple-case study design. Lastly, since the study identified *Data Exploitation, Feedback Loops, Network Effects,* and *Integrated Communication* as the most impactful AI-based VC innovation – due to their ability to engage all actors within the IE's triple-layer structure - future research could explore the relevance and influence of additional AI-based VC innovations.

Ethics and AI declaration

The interviews were conducted anonymously. Collected data were used in an aggregated form to ensure confidentiality and privacy. No AI tools were used in the creation of this paper.

Can Artificial Intelligence Support Companies in Implementing Sustainable Innovation Strategies? Evidence from Agri-Food Companies

Marta Menegoli, Damiano Calò, Angelo Corallo
University of Salento, Lecce, Italy

Abstract

The agri-food industry is currently facing significant global challenges, including climate change, resource depletion, and growing demands for food security. In response to these challenges, sustainable innovation has become a critical focus for the industry. Sustainable innovation refers to the development and adoption of new technologies, practices, and business models that aim to improve environmental, social, and economic outcomes. One of the most promising technologies for supporting sustainable innovation is artificial intelligence (AI), which has the potential to enhance various aspects of sustainability within the agri-food sector. This study explores the role of AI in supporting sustainable innovation strategies and practices in the agri-food industry, with a focus on understanding how AI can help optimize processes, reduce waste, improve resource management, and foster more sustainable business models.

To achieve this, a comprehensive systematic literature review was conducted, analyzing seventy-three peer-reviewed articles related to AI applications in the agri-food industry. Through this analysis, the study identifies six main clusters of strategies that are currently being employed to drive sustainability in the sector. These strategies include optimizing production processes, improving supply chain efficiency, enhancing product traceability, and advancing precision agriculture practices. Additionally, the study highlights the role of AI in supporting twenty-four specific practices within these strategies, such as predictive analytics for crop yield forecasting, AI-driven waste reduction systems, and AI-based monitoring tools for environmental impacts.

However, the findings also reveal significant gaps in the application of AI, particularly the lack of support for circular economy approaches, which focus on reducing waste and reusing resources throughout the supply chain. This gap presents an opportunity for further research into how AI can be leveraged to support circular practices within the agri-food industry. The study provides a foundation for future exploration into the integration of AI and sustainable innovation, offering insights for both researchers and practitioners seeking to improve sustainability in the agri-food industry.

Keywords: AI, Business Strategy and Operation, Sustainability.

Paper type: Academic Research Paper

1 Introduction

Innovation is a crucial driver of economic progress, enabling competitiveness in global markets (Lopes et al., 2022). However, rapid climate change, resource scarcity, and a projected global population of 9.7 billion by 2050 compel businesses to adopt new approaches (Monteiro and Barata, 2021). The agri-food industry is particularly affected, being both essential globally and vulnerable to environmental crises. It significantly contributes to greenhouse gas emissions, water consumption, and biodiversity loss (Efremova et al., 2023). This reality underscores the urgent need for Sustainable Innovation Strategies (SISs), which integrate sustainability into strategic decisions, leveraging technologies and fostering business models that tackle resource inefficiencies and enhance food security (Voinea et al., 2021). Aligned with the Triple Bottom Line (TBL) framework, sustainability encompasses environmental, economic, and social dimensions (Elkington, 1998), addressing global challenges and aligning with the UN's Agenda 2030 and its 17 Sustainable Development Goals (SDGs) (Camelo and Nogueira, 2024). For Small and Medium-sized Enterprises (SMEs), transitioning to sustainable practices involves significant obstacles, such as balancing short-term profitability with long-term investments. Nevertheless, adopting Sustainable Innovation Practices (SIPs) is critical (Lopes et al., 2022). Digital technologies under the Industry 4.0 (I4.0) paradigm, specifically Artificial Intelligence (AI) and Big Data (BD), are vital enablers of sustainability (Sharma, 2022). These technologies can enhance productivity and reduce costs in the agri-food sector. AI's transformative capabilities, including learning and problem-solving, allow companies to optimize their sustainable innovation strategies (Taneja et al., 2023). However, AI adoption raises ethical and data security concerns, emphasizing the need for frameworks for its integration (Krishna et al., 2023). This research seeks to fill the gap in the literature regarding AI-based SISs and SIPs, exploring how AI can drive sustainable innovation in the agri-food industry and developing a framework to guide companies in their sustainable transition.

2 Background

2.1 The sustainable innovation in agri-food industry

Over time, innovation has evolved beyond the Schumpeterian concept of purely economic growth (Schumpeter, 2021), shifting towards Sustainable Innovation (SI), or eco-innovation, which aims to minimize environmental impacts and optimize resource use across production, consumption, and product life cycles (Lopes et al., 2022). SIs encompasses technological, organizational, and social forms, emphasizing resource efficiency and circularity (Slowak and Regenfelder, 2017). The agri-food sector is central to global economies, employing millions and generating significant revenue (Konfo et al., 2023). However, it is also responsible for one-third of global CO_2 emissions and faces numerous challenges. Extreme weather events, pests, and diseases disrupt agricultural practices and food security (Efremova et al., 2023). Additionally, deforestation, intensive land use, and habitat destruction endanger biodiversity at genetic, species, and landscape levels (Sharma et al., 2021). By 2050, the global population is projected to reach 9.7 billion, increasing food demand by 80% and stressing resources like arable land and freshwater, particularly in low-income regions (Monteiro and Barata, 2021).

Simultaneously, up to 50% of food is wasted, exacerbating resource inefficiencies. Rising food prices and reduced access to nutritious foods disproportionately impact vulnerable populations, especially in rural areas (Calicioglu et al., 2019). The 2030 Agenda underscores the need for systemic transformation in agri-food systems through the SDGs, including zero hunger, responsible consumption, and environmental preservation (Camelo and Nogueira, 2024). Companies face regulatory and social pressures to address these challenges, pursuing SIs through: i) technical innovations like improved farming systems and waste reduction; ii) organizational innovations such as supply chain collaboration; iii) systemic innovations involving new products, technologies, and markets (Perrin et al., 2023). Proactive strategies focusing on market differentiation often yield greater success than reactive, compliance-driven approaches (Lopes et al., 2022). However, economic barriers, including high initial investments and reduced yields during transitions (e.g., to organic farming), remain significant obstacles to SI in the agri-food industry.

2.2 The AI technologies in agri-food industry

The agri-food industry is still undergoing a digital transformation, driven by I4.0 technologies, which enhance sustainability and efficiency. Key technologies, for example, Internet of Things (IoT), BD, Advanced Automation (AA) and Robotics (AR), simulation, Additive Manufacturing (AM), allow companies: i) to perform real-time data collection on weather, energy use, and production; ii) to analyze large datasets for improved decision-making and process optimization; iii) to streamline tasks like planting and harvesting, reducing labor costs; iv) to model complex processes like crop growth and irrigation management; v) to customize food production while minimizing waste (Goldenits et al., 2024). AI revolutionizes the agri-food industry by optimizing processes and addressing specific challenges such as resource efficiency, food safety, and supply chain management (Taneja et al., 2023). Specifically, Machine Learning (ML), Deep Learning (DL), computer vision, Natural Language Processing (NLP), some of the main AI technologies, were applied in i) smart farming, for monitoring crop conditions, manages irrigation, and identifies pests, enhancing productivity; ii) in food safety and traceability, for detecting contaminants, improves hygiene, and ensures regulatory compliance and iii) in supply chain optimization, for supporting demand forecasting, risk management, and inventory control, enabling circular economy models (Nath et al., 2024). AI application in CE-based SIs within agri-food industry also emerged in the context natural landscape enhancement (Pathan and Db Sisodiya, 2023). Beyond the benefits, the adoption of AI technologies also involves risks and challenges that could impact sustainability. These include significant energy consumption, the production of electronic waste, market concentration in a few hands, potential job outsourcing, and even ethical issues related to the use of AI. Despite these challenges, AI continues to be a driving force in redefining the future of agri-food industry, as it helps address the sector's main challenges and promotes sustainability (Nath et al., 2024).

3 Methodology

The methodology of the study was built following a qualitative research approach (Figure 1). To address the RQs (see Figure 1), a SLR was chosen as research method, following the PRISMA guidelines in the data collection process for the definition of inclusion and exclusion criteria (Page et al., 2021). Two queries (see Figure 1) were designed to select two samples: the first focused on identifying the most emerging SISs and SIPs in a cross-industry context; the second specifically targeted AI-based SIPs applied within the agri-food industry. Data

analysis was conducted using qualitative content analysis, which enabled the identification of SISs and SIPs, as well as their AI-driven applications.

Additionally, a focus group with senior researchers contributed to defining the SISs and SIPs labels. Evidence was synthesized into the proposed framework (see Figure 4).

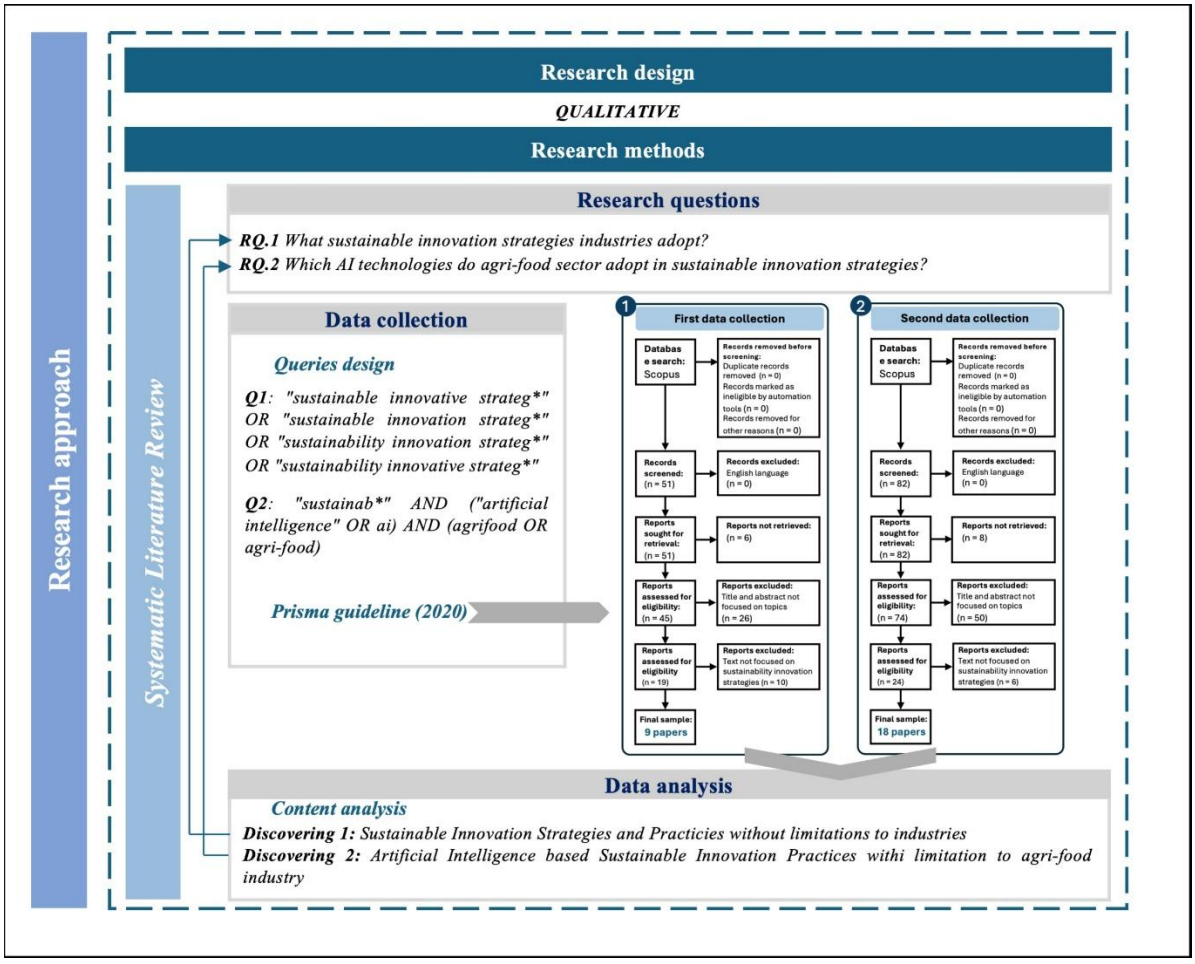

Figure 1: Research methodology overview

4 Findings

The analysis provided a comprehensive overview of the practices and strategies that companies implement to integrate sustainability into their business models. The identified practices span multiple industrial contexts, including the agri-food, oil and gas, healthcare, education, chemicals, technology, and service ones. The findings were presented as a classification of strategies, organized into clusters, where the 6 first-level SISs correspond to the main strategy categories, each further detailed into 16 second-level SISs (See Figure 2). For each practice within the clusters, the industry of application was identified, including details on whether AI is applied. The first cluster (in the gradation of blue color) encompasses SISs aimed at reducing the *production footprint* of industries.

The literature highlights SIPs that focus on reducing non-natural inputs in the agri-food industry (Krishna et al., 2023), and shows a cross-industry interest in minimizing water (Lopes et al., 2022), energy (Nath et al., 2024), and carbon (Kneipp et al., 2021) footprints. The second SISs cluster (in the gradation of green color) encompasses SIPs focused on waste reduction through *circularity approaches*, aiming to reintegrate waste materials into production cycles and extend their lifecycle (Lopes et al., 2022; Slowak and Regenfelder, 2017). No AI-based applications were identified within this cluster. The *Sustainable Enhancement of Territory* SISs cluster (in the gradation of yellow color) encompasses strategies aimed at valorizing local systems by preserving natural resources, and supporting local communities, integrating economic activities with environmental and social well-being (Efremova et al., 2023; Konfo et al., 2023). The *Sustainable Management* cluster (in the gradation of purple color) brings together SIPs focused on achieving social and governance sustainability goals. These include enhancing employee well-being, fostering proactive governance in sustainability initiatives, and promoting operational management driven by efficiency and sustainable performance (Kneipp et al., 2021).

The results reveal a group of SIPs classified under the *Improvement of Food Quality and Safety* cluster (in the gradation of orange color), primarily related to the agri-food sector. Key practices include actions aimed at food protection, covering aspects such as preservation, logistics, and hygiene (Nath et al., 2024). Other practices focus on the sustainability of packaging, with the goal of reducing material use and minimizing non-recyclable materials (Taneja et al., 2023). The last SISs cluster is related to the *Customer and Partner Relationship Care* (in the gradation of turquoise color), which encompass the social dimension of sustainability. The focus is on meeting the expectations of customers (Martinez et al., 2023) and other stakeholders (Cantino et al., 2019; Monteiro and Barata, 2021), while maintaining a strong emphasis on minimizing the environmental impact of the company's activities. By filtering the results from the content analysis of the two samples—focusing on the agri-food industry and AI-based applications—the set of SISs clusters was narrowed down to 9 second-level SISs (belonging to 5 out of 6 first-level SISs). These represent AI-driven practices designed to achieve sustainability goals within the agri-food industry (Figure 3). The identification and classification of SISs and SIPs allow the development of a framework (Figure 4) that highlights the connection between AI technologies and the clusters of SISs within the agri-food industry. Each practice is associated with a specific AI technology family (breafly introduced in background section), and where AI is not applied, the relevant I4.0 support technology is indicated. The framework offers an overview of practices and technological tools that a company could adopt based on the SISs it aims to achieve. Conversely, by examining the framework beginning with the company's existing technological resources, it becomes possible to identify applicable practices and broaden its sustainability scope within the various SISs.

5 Discussions

5.1 A strategic imperative for resilience in the agri-food industry

Our findings confirm and expand upon the theoretical foundations presented in the background section. SISs identified align with the TBL framework (Elkington, 1998), emphasizing the interconnected dimensions of environmental, economic, and social sustainability. Specifically, the environmental dimension resulted the most extensively addressed highlighting the strong connection between sustainability and climate-related issues. Nevertheless, SISs reflect a broader approach that also encompasses the governance dimension, particularly by emphasizing managerial engagement in sustainability goals, fostering more conscious governance policies and promotes self-assessment of performance. The social dimension also emerged as a key area of interest in agri-food SIPs, where environmental concerns are closely linked to the commitment to protecting natural resources, simultaneously benefiting local communities and enhancing society well-being and health. The classification of SISs into clusters, such as reducing production footprints, waste reduction through circularity, and sustainable enhancement of territories, reflects the systemic transformation required to address global challenges like climate change, biodiversity loss, and food insecurity (Efremova et al., 2023). The findings also highlight the importance of proactive strategies over reactive ones, as noted by Lopes et al. (2022). Proactive approaches, such as adopting circular economy principles and improving food quality and safety, are more likely to yield long-term benefits, aligning with the literature's emphasis on market differentiation and competitiveness. However, the findings reveal that economic barriers, such as high initial investments and reduced yields during transitions (e.g., to organic farming), remain significant obstacles, echoing the challenges discussed by Monteiro and Barata (2021).

Figure 2: First-level and second-level SISs and related SIPs

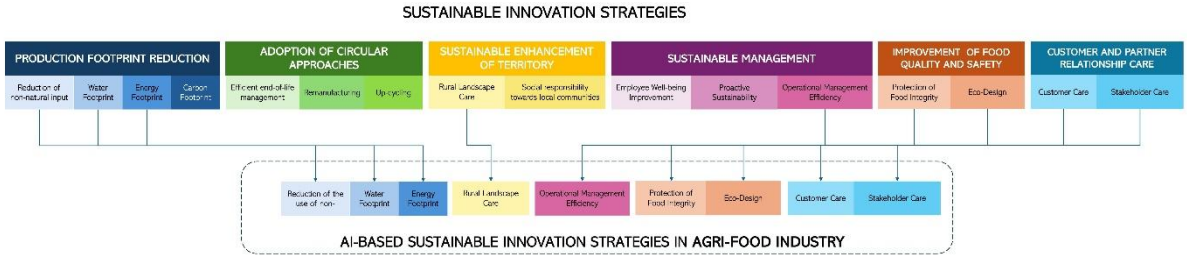

Figure 3: Representation of SISs with a focus on AI-based SISs in agri-food industry.

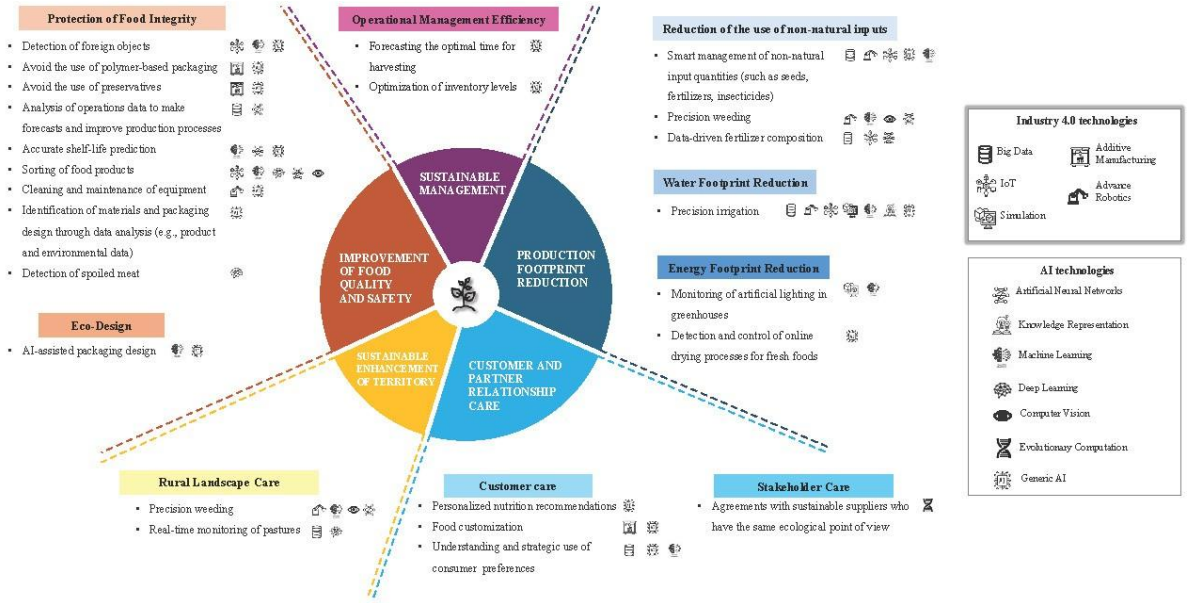

Figure 4: The proposed framework for discovering AI-based SIPs and related SISs in agri-food industry

5.2 The transformative power of AI technologies for sustainable practices

The findings revealed that the adoption of AI technologies in SISs is almost always accompanied by the integration of other I4.0 enabling technologies such as IoT, AR, Digital Twins (DT), AM, and BD. This means that to maximize the effectiveness of SISs, companies must rely on a process that is strongly centered around digitalization.

Therefore, the study underscores the transformative potential of AI and I4.0 technologies, in driving sustainability in the agri-food industry. The identified AI-driven SIPs, such as smart farming, food safety, and supply chain optimization, align with the literature's emphasis on AI's ability to enhance productivity, reduce waste, and enable circular economy models (Nath et al., 2024). For instance, the use of ML and DL for monitoring crop conditions and managing irrigation directly supports resource efficiency, as highlighted by (Sharma et al., 2021). However, the findings also reveal gaps in AI adoption, particularly in clusters like waste reduction through circularity, where no AI-based applications were identified. This result contrast the one that arose from a bottom-up research conducted by Pathan and Db Sisodiya (2023) in Irish landscape, where the authors identified four initiatives of Circular Economy-based sustainable innovation which encompass 3 AI technologies (Vision AI, ML, Computer Vision). However, this aligns with the literature's observation that AI adoption faces challenges such as high energy consumption, electronic waste, and ethical concerns (Krishna et al., 2023). These barriers highlight the need for systematic frameworks to guide the integration of AI into sustainability practices, as proposed in the findings.

5.3 Driving SI through Ecosystemic perspectives

From the *organizational perspective* - Sustainability must become a core component of a company's culture, governance, and strategic decision-making. Leadership is pivotal in embedding sustainability as a fundamental value, aligning it with the company's mission and long-term goals. This involves not only setting clear sustainability objectives but also ensuring that all employees and stakeholders embrace these values. Matching

the Perrin et al. (2023) and Konfo et al. (2023) conceptions of organizational innovation route, key clusters of SISs include: i) Sustainable Management, forecasting the optimal time for harvesting and optimizing inventory levels to reduce waste and improve resource efficiency; ii) Customer and Partner Relationship Care, personalized nutrition recommendations, leveraging consumer preferences strategically, and forming agreements with sustainable suppliers who share the company's ecological vision. For example, companies adopting circular economy principles aim to minimize waste and maximize resource reuse. By integrating sustainability into corporate strategy, leadership ensures that these practices are not treated as peripheral initiatives but as essential to the company's identity and competitive advantage.

From the *supply chain perspective* - Sustainability transcends internal company operations and involves collaboration with suppliers, partners, and logistical processes. This perspective emphasizes sustainable procurement, operational efficiencies, and minimizing the environmental and social risks associated with supply chain activities.

Key clusters of SIPs that reflect this perspective were: i)Production Footprint Reduction, focused on upstream agricultural practices, aiming to reduce the environmental impact of farming and sourcing raw materials; ii) Sustainable Enhancement of Territories, promoting agricultural practices that support local ecosystems and communities; iii) Food Quality and Safety Improvements, targeting production areas to ensure food standards and safety align with sustainability objectives; iv) Operational Management Efficiency, practices such as optimizing inventory levels and forming agreements with sustainable suppliers. v) Logistical Sustainability, reducing carbon emissions in transportation and ensuring responsible sourcing of raw materials. Collaboration is essential at this level, as companies work with suppliers and partners to drive innovation and ensure compliance with ethical labor practices and environmental standards. For example, multinational corporations increasingly prioritize suppliers committed to fair labor practices and sustainability. However, challenges persist in monitoring and ensuring compliance across all levels of the supply chain.

From a *compliance perspective* - AI-based SIPs play a key role in achieving sustainability objectives within the agri-food industry and beyond. AI and I4.0 technologies enable companies to embrace environmental, social, and economic sustainability dimensions, guiding them toward the accomplishment of the SDGs. In this regard, our framework reflects the possibility to address challenges global recognized by SDGs, as illustrated in Figure 5. All the SDGs are covered by the identified SISs and SIPs, making them a valuable guideline for implementing a holistic and multidimensional approach to corporate sustainability efforts. Focusing on the agri-food industry, AI's crucial role emerges through its contribution to various practices, enabling the achievement of 13 out of 17 goals. This allows companies to leverage AI and Industry 4.0 technologies to align with international sustainability ambitions, ensuring compliance with global sustainability performance standards while meeting regulatory requirements and common interests in the field.

6 Implications

The findings of this study offer significant theoretical and practical implications. These implications extend across various domains, from enhancing theoretical understanding of AI-based SIPs and SISs to providing actionable insights for companies, supply chains, and stakeholders in the pursuit of sustainability.

6.1 Theoretical Implications

The theoretical implications of this research align with and expand upon the existing literature on sustainability, innovation, and technology adoption. Firstly, the study supports and enhances the TBL framework, which emphasizes the environmental, social, and economic dimensions of sustainability (Elkington, 1998). The findings confirm that sustainability strategies in the agri-food industry must address all three dimensions, with a significant focus on the environmental dimension due to the sector's substantial contribution to greenhouse gas emissions, water consumption, and biodiversity loss as suggested by Efremova et al., (2023). By classifying the identified SISs into clusters such as reducing production footprints, waste reduction through circularity, and sustainable enhancement of territories, the research illustrates a comprehensive approach to addressing global challenges, such as climate change and food insecurity, in line with the United Nations SDGs (Camelo and Nogueira, 2024), as shown in Figure 5. Moreover, the study contributes to the theoretical understanding of AI-driven SISs, which, as noted by Nath et al. (2024) and Taneja et al. (2023), offer transformative potential for optimizing resource use and enhancing sustainability outcomes in the agri-food sector. The integration of AI with other I4.0 technologies, such as IoT, BD, and robotics, illustrates the multidimensional nature of technological adoption in achieving sustainability goals. The framework developed in this study provides a structured approach to understanding how companies can leverage these technologies

to drive sustainable practices, expanding on existing literature that has mostly focused on singular technological applications rather than holistic, integrated solutions (Nath et al., 2024; Sharma, 2022).

6.2 Practical Implications

From a practical standpoint, the results offer several key implications for the agri-food industry, that fall in the main fields of operational management, supply chain management, sustainability development, and the stakeholder ecosystem. Specifically, about operational management and supply chain optimization, the integration of AI and I4.0 technologies provides actionable insights for resource optimization, waste reduction, and food safety, as also recognized by Taneja et al., (2023). For instance, smart farming technologies that leverage ML and DL for monitoring crop conditions and optimizing irrigation directly address critical resource inefficiencies in the agri-food sector. Our insights reveal that these technologies not only enhance productivity but also contribute to the long-term sustainability of the supply chain by improving resource efficiency and minimizing waste, confirming the position of Sharma et al., (2021). The framework outlined in the study provides practical guidelines for organizations to adopt specific technologies based on their sustainability goals, enabling them to optimize inventory levels, reduce waste, and improve food safety standards.

About CE and waste management, one of the notable findings is the identification of SISs focused on waste reduction through CE models. While the study highlights gaps in AI-based applications in this area, it provides valuable insights for future research and industry practices. By embracing circularity, companies can reintegrate waste materials into production cycles, extending their lifecycle and reducing environmental impacts (Lopes et al., 2022). This is relevant for enhancing the resilience of the agri-food sector, especially as food waste continues to exacerbate resource inefficiencies. Supply chain partners can collaborate to develop closed-loop systems, which not only align with sustainability goals but also reduce costs associated with raw material procurement and waste disposal.

About sustainability development and stakeholder engagement, the study underscores the importance of engaging stakeholders in sustainability efforts, particularly in the context of customer and partner relationship care. Companies can differentiate themselves in the marketplace by aligning their sustainability strategies with customer values, particularly those who prioritize eco-friendly products and ethical sourcing. This alignment can be achieved through practices such as personalized nutrition recommendations, which leverage AI to optimize food production processes based on consumer preferences (Martinez et al., 2023). Moreover, fostering strong relationships with sustainable suppliers who share a commitment to environmental stewardship ensures that sustainability is embedded throughout the supply chain. As noted by Konfo et al. (2023), this collaboration across the stakeholder ecosystem is essential for driving systemic change toward more sustainable and resilient agri-food systems.

About regulatory compliance and global sustainability goals, from a compliance perspective, AI and I4.0 technologies offer significant support for companies striving to meet the sustainability targets outlined in the SDGs. By incorporating AI-driven SIPs, companies can align their operations with global sustainability frameworks, ensuring compliance with environmental and social standards. The study's findings demonstrate that AI has the potential to support the achievement of 13 out of the 17 SDGs, providing companies with the tools needed to track and optimize their sustainability performance. This is particularly important in a globalized economy where regulatory pressures and consumer expectations are increasingly focused on sustainability. The framework developed in this study serves as a valuable tool for companies seeking to navigate these challenges while ensuring long-term competitiveness and growth.

Summarizing, this study contributes to both the theoretical understanding of sustainable innovation in the agri-food industry and provides practical insights for companies, supply chains, and stakeholders to drive sustainability through the integration of AI and I4.0 technologies. By offering a structured framework, the research facilitates the adoption of sustainable practices, positioning businesses to meet the challenges of climate change, resource scarcity, and growing global food demand while simultaneously enhancing their competitiveness in the marketplace.

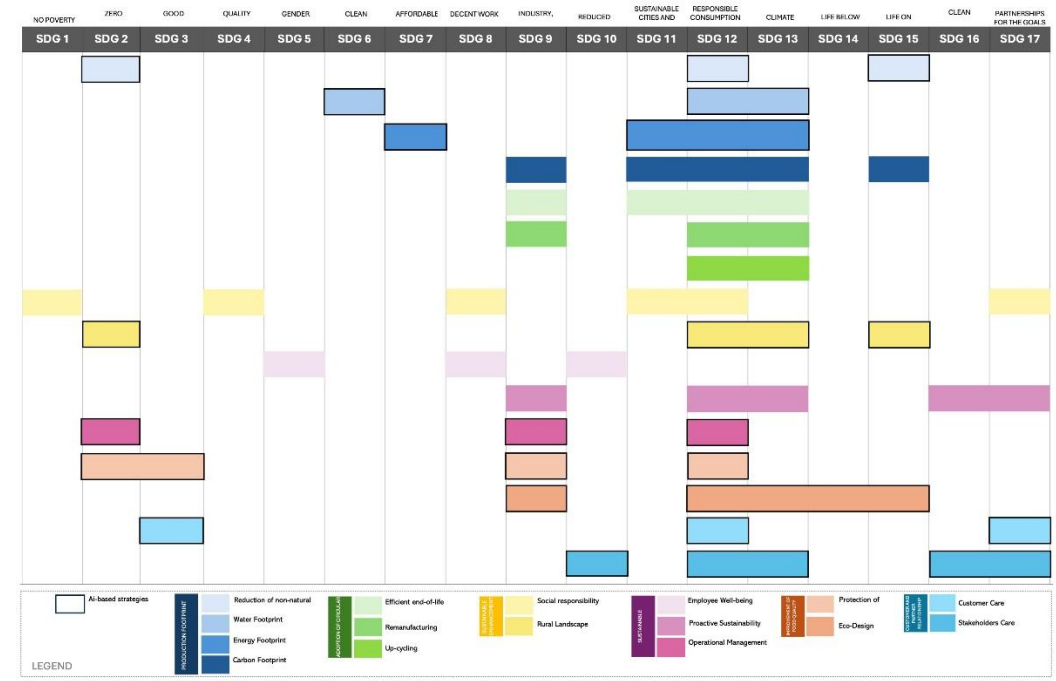

Figure 5: SISs, AI-based and not, contextualization within ONU SDGs

7 Conclusions

The study proposes a framework linking AI technologies to SIPs, addressing gaps in the literature regarding their integration. A detailed taxonomy of 6 first-level and 14 second-level clusters was developed, identifying 24 AI-supported SIPs. Despite its contributions, the study faces limitations, including a lack of AI technologies taxonomy, limited bibliographic scope, and sample size. Proposed follow-ups include developing a comprehensive AI taxonomy, refining methodologies, expanding research scope, and increasing the sample size for broader applicability. Moreover, it may be interesting to enrich the present qualitative research with a quantitative one, for example by investigating the key discriminating criteria for selecting one innovative strategy over another within a company. This could be carried out through a quantitative analysis, such as the multicriteria TOPSIS method applied to a case study, thereby enriching the research with a practical application. This approach would allow for a comparison between the theoretical findings and the feasibility of implementing SISs and SIPs in a real-world context.

Ethics declaration

This research did not involve human participants, animal studies, or any other procedures requiring ethical clearance. Therefore, no formal ethical approval was necessary for the research presented in this paper.

AI declaration

The authors declare that no artificial intelligence (AI) tools were used in the writing, editing, data analysis, or interpretation of this manuscript. All work was conducted and reviewed manually by the authors.

Exploring the Preliminary Conditions for Blockchain Credibility in the Agri-food Industry

Adriana Baselice, Alessandra De Chiara, Sofia Mauro
University of Naples L'Orientale, Naples, Italy

Abstract

The traceability of product sourcing and production processes has become a crucial need for the Agri-food Industry, where stakeholders - particularly consumers - increasingly demand guarantees on product quality and authenticity. Blockchain technology, given its characteristics of immutability and transparency, can play a key role in solving issues related to traceability and information asymmetry, which undermine security and stakeholder trust in companies, as well as in promoting corporate social sustainability. The present study aims to fill a gap in literature by focusing on the operational application of this technology, with particular attention to the issue of credibility of the raw data entered into the system. To this end, a qualitative approach is adopted based on a multiple case study conducted through secondary data, integrated with primary data collected through a focus group. The work has a twofold objective: on the one hand, to explore the motives and goals that drive companies to implement Blockchain technology; on the other hand, to identify the preliminary conditions that ensure its operational effectiveness and credibility in the eyes of stakeholders. The results suggest that traceability is the main reason why companies decide to implement Blockchain technology, with the goal of ensuring product authenticity and transparency to the consumer. In addition, two sets of factors - operational and validation - were identified as key preconditions for effectively implementing a credible Blockchain information system. The study contributes to a deeper understanding of the operational application of Blockchain in the agri-food sector, providing relevant theoretical and practical implications.

Keywords: Blockchain Technology, Agri-Food Industry, Traceability, Credibility, Social Sustainability

Paper type: Academic Research Paper

1 Introduction

Critical issues such as food safety, contamination risks, and food counterfeiting are increasingly emerging in the agri-food industry (Salah et al., 2019; Duan et al., 2020; Shahid et al., 2020; Chaudhuri et al., 2021). Scholars identify information asymmetry as the cause of these problems, highlighting how it undermines supply chain ethics and trust relationships with stakeholders (Mao et al., 2018). From the demand side, consumers are becoming more concerned with the quality and authenticity of food products, demanding greater availability and transparency of information throughout the entire supply chain (Antonucci et al., 2019; Rana et al., 2021).

To address information asymmetry, the traceability of product sourcing and production processes has become a critical priority in the agri-food industry (Behnke and Janssen, 2020; Salah et al., 2019).

The need for traceability also stems from the need for agri-food companies to comply with increasingly stringent sustainable development requirements, especially regarding social sustainability (Saberi et al., 2018; Mastos and Gotzamani, 2022). Several studies identify product traceability and information sharing as key elements closely related to social sustainability (Golini et al., 2017; Mastos and Gotzamani, 2022). Toussaint et al. (2021) argue that only collective efforts and effective traceability systems - that cover from seed collection to final distribution - can achieve social sustainability.

Consequently, the clear and detailed collection, management and communication of information presents a significant challenge for the agri-food industry. Pre-existing traceability systems are typically centralised and third parties dependent, making them vulnerable to fraud, and lacking in transparency and verifiability (Salah et al., 2019; Shahid et al., 2020).

In this context, Blockchain technology can be seen as a promising tool to enhance food traceability and sustainable supply chain management, with positive benefits for both producers and consumers (Tian, 2017; Duan et al., 2020).

Blockchain technology is defined as a distributed, shared, and immutable ledger capable of documenting the production, processing, and distribution of agri-food products (Kramer et al., 2021). As such, it serves as a tool for tracking and communicating data and information.

However, the mere recording and sharing of data do not fully guarantee its accuracy or credibility, due to the significant risk of manipulation of the collected information (Behnke and Janssen, 2020), as well as the threat of inaccurate data entry into the system (Böhmecke-Schwafert et al., 2022). Therefore, it is critical that agri-food

companies implement Blockchain systems that are not only operationally effective but also perceived as credible and reliable by stakeholders. Although the academic debate has extensively explored Blockchain's potential in agri-food supply chain, few studies have addressed its inability to ensure the reliability of the raw data entered into the system. Indeed, the effectiveness and validity of a Blockchain-based traceability process ultimately depend on the quality and truthfulness of the raw data entered - an aspect over which technology itself has no control.

In light of this, the study aims to fill this gap by adopting a managerial perspective to provide theoretical, managerial and institutional implications related to Blockchain implementation. Specifically, it aims to examine, first, the motivations and objectives that drive agri-food firms to adopt Blockchain technology; and second, the necessary preconditions required for Blockchain to be considered not only operationally effective, but also credible and valid in the eyes of stakeholders.

Accordingly, this paper addresses the following research questions:

- *Why, and with what objectives, do agri-food companies choose to implement Blockchain technology?*
- *What tangible and intangible resources do agri-food companies consider necessary prior to the introduction of Blockchain in order for it to be operationally effective and credible in data management?*

The paper has the following structure. Section 2 presents the literature review on the Blockchain technology and Blockchain technology in agri-food industry and agri-food supply chain; section 3 illustrates the methods; section 4 describes the results emerging from the empirical analysis; section 5 illustrates discussions, implications and conclusions.

2 Literature review

2.1 Blockchain technology

The Blockchain can be defined as a distributed ledger, structured as a chain of blocks, which stores related transactions in chronological order and whose integrity is guaranteed by cryptographic algorithms and consensus rules (Tapscott and Tapscott, 2016; Treiblmaier, 2019). In the Blockchain, each participating node can propose the creation of a new data block. This block is added to the chain only after being validated by the network, without the need for a central authority, and can no longer be modified. This process, based on a peer-to-peer consensus mechanism, makes Blockchain a decentralised, secure, transparent and immutable system (Zheng et al., 2017). Its core characteristics include traceability, reliability and auditability (Casino et al., 2019). Blockchain systems can be distinguished into three generations (Swan, 2015) and three main types: public, private and consortium. These variants offer similar functionalities, differing primarily in their levels of efficiency and governance structure (Zheng et al., 2018).

Blockchain first emerged in the financial sector with Bitcoin 5hlprd(Nakamoto, 2008) and later expanded its application to various non-financial sectors. Theoretical discussions have extensively explored Blockchain technology from a technical standpoint, defining its areas of application based on its core functionalities (Crosby et al., 2016; Zheng et al., 2018; Zhao et al., 2016; Casino et al. 2019; Pal et al. 2021; Gad et al., 2022). In this context, several authors highlight the potential of Blockchain technology to successfully integrate into both business process management (Di Ciccio et al., 2018; Medling et al., 2018), by improving operational efficiency (Li and Xu, 2025), and supply chain management (Gad et al, 2022), by significantly reducing information asymmetry (Nuttah et al., 2023) and fostering collaboration and trust among stakeholders (Nofer et al., 2017; Shin, 2019), through the use of Smart Contracts. Given these technical functionalities, scholars consider Blockchain as a particularly promising technology for addressing critical issues of transparency, traceability and trust in the agri-food industry and, more generally, throughout the entire agri-food supply chain (e.g. Kamilaris et al., 2019).

2.2 Blockchain technology in agri-food industry and agri-food supply chain

The influence of Blockchain technology on the performance of the agri-food industry and its supply chain has been the focus of extensive academic debate, which has revealed its positive and beneficial impact on traceability and transparency (Vern et al., 2024).

Blockchain is considered potentially revolutionary for its ability to track, in real time, who performs specific actions, when and where these are performed, as well as the quality and quantity of the product (Saberi et al., 2018), thereby contributing to the establishment of its digital identity. Many scholars agree that Blockchain improves traceability efficiency by providing a transparent and reliable system to validate the quality, safety and sustainability of the agri-food supply chain (Salah et al., 2019; Duan et al., 2020; Ji & Xu, 2025). Other scholars

emphasize Blockchain's potential in reducing food fraud and protecting the authenticity of agri-food products (Tian, 2016; Galvez et al., 2018; Antonucci et al., 2019), as well as in improving the efficiency of product recalls, thereby reducing food waste, lowering costs, and mitigating risks (Kshetri, 2018; Duan et al., 2020; Feng et al., 2020; Hao Fu et al., 2020). To test the effectiveness of Blockchain-based traceability systems, several pilot studies have been conducted (e.g. Yiannas, 2018; Bumblauskasa et al., 2020).

Furthermore, the positive impact of this technology on the sustainability of agri-food enterprises is widely recognised (Rana et al., 2021; Giganti et al., 2024). According to Chaudhuri et al. (2021), Blockchain supports sustainability integration into business strategies, by making information immutable and ensuring traceability and transparency, especially in the social dimension. Indeed, Blockchain is an effective tool for addressing key challenges in social sustainability, including food safety, product quality, fostering trust and collaboration among stakeholders, and monitoring both social conditions of workers and supplier performance. This promotes greater accountability among producers and consumers, empowering them to make more ethical and responsible choices and thus contributing concretely to the advancement of social sustainability (Saberi et al., 2018; Mastos and Gotzamani, 2022; Giganti et al., 2024).

The academic debate, therefore, emphasises the ability of Blockchain to reduce information asymmetry (Vern et al., 2024) by configuring it as a strategic communication tool. Some studies emphasise its value as an enabler of "secure communications", capable of improving the flow and exchange of information (Bovenzi et al., 2023). This has a significant impact on consumers: direct access to data via product labels fosters the development of new, more direct and transparent forms of communication, addressing growing demands for authenticity and safety (Martinelli and De Canio, 2023). Furthermore, Sepe (2023) shows that data accessibility has a significant impact in influencing consumers in their purchase of food products.

However, to gain a more comprehensive understanding of Blockchain technology, further in-depth study is required, one that moves beyond the purely technical focus typically limited to its potential and barriers across different application domains, including the agri-food industry. It is crucial to focus on the critical issues that may hinder its effectiveness and efficiency. Among these, the question of the reliability of raw data entered into Blockchain systems is particularly interesting, as the technology itself has no direct control over the accuracy of the input data. To the best of our knowledge, while academic literature has extensively explored the functionalities of Blockchain in business process and supply chain management within the agri-food sector, few studies have addressed its inability to verify the reliability of raw data, which may be tampered with or altered before being recorded in the system (Galvez et al., 2018; Duan et al., 2020). In this context, the certification of the authenticity of the data remains dependent on the certifying body, and cannot be ensured by the Blockchain system alone (Böhmecke-Schwafert et al., 2022).

Therefore, this study seeks to fill the gap emerging from the academic debate by exploring, in the first phase, the motivations and objectives driving companies to Blockchain and, in a second phase, the tangible and intangible resources they consider preliminary for its implementation in business management, from both operational and strategic perspectives.

3 Methodology and research process

To achieve this goal, our research design, based on a qualitative research approach, follows a two-step process. Firstly, we conduct a multiple case study based on secondary data (Eisenhardt, 1989; Miles & Huberman, 1984). This method enables a more comprehensive exploration of the research questions, thereby improving the reliability of the research findings (Eisenhardt & Graebner, 2007). Secondly, to enhance the robustness of our multiple case study, in line with prior literature (Eisenhardt, 1989), we incorporate secondary data with primary data. As a part of this approach, we choose to utilize focus groups (Morgan, 1996; Bloor et al., 2001) because, as Stewart and Shamdasani stated, "*the most common purpose of a focus group interview is for an in-depth exploration of a topic about which little is known*" (p.102, 1990).

Our research process comprises several stages: (1) the identification of case studies. The analysis was specifically targeted in Italy, with a particular emphasis on Agri-food Industry in Campania. We contextualized the research in Campania because it is the Italian region with the highest number of traditional food products (GU Serie Generale n. n. 61, 2024). We selected 5 companies (see Table 1) based on the following criteria: Campania companies that have pioneered the adoption of Blockchain Technology in different agri-food sectors; the greatest availability of data; and willingness to participate; (2) secondary data collection. We used the main company platforms (websites and social media) and third-party sources that reported relevant information; (3) focus group establishment. Being a focus group "an interview style designed for small groups" (Berg, 1998, p. 100), typically involving from six to 10 people (Blackburn and Stokes, 2012), we selected 9 participants. Participants in the focus group include representatives from the selected companies, two experts, an academic

representative and an institutional representative (see Table 2). The two-hour focus group discussion dealt with the implementation of Blockchain within inter-organizational business processes, focusing on 3 key elements: the reasons why they decided to implement Blockchain; the goals they aim to achieve by implementing Blockchain; tangible and intangible resources supporting the implementation of Blockchain.

The use of multiple methods and diverse data types enabled the application of a Methodological Triangulation Approach, which aimed to reduce bias and enhance both reliability and validity (Jick, 1979; Eisenhardt, 1989; Yin, 1994).

Table 1: Selected companies

Institution	1	Agency ICE

4 Findings

The analysis of the results for the three research questions is presented below.

- *RQ1: The reasons why they decided to implement Blockchain.*

The analysis of secondary data reveals that the primary reason companies choose to implement a Blockchain-based data recording system is to enhance the traceability of the individual product or the entire supply chain (See Table 3).

This is also confirmed by the focus group discussion. Participants recognised traceability and transparency as essential features of Blockchain, as they enable the verifiable recording of every production stage and the full traceability of a product's lifecycle.

- *RQ2: The goals they aim to achieve by implementing Blockchain*

The analysis of secondary data highlights two main objectives that explain the behaviour of companies in adopting Blockchain technology: a. ensuring authenticity and combating counterfeiting; b. enhancing transparency for consumers (see Table 3).

The fight against the counterfeiting of Made in Italy products has led the companies investigated to adopt Blockchain to safeguard the authenticity of their products. The technology allows them to provide information about the origin and processing of the raw materials, the manufacturing production processes up to the issuance of the Blockchain traceability certificate.

Similarly, the objective of transparency towards the consumer - particularly evident in the cases BioItalia, Pastificio Liguori and Spinosa - is considered a milestone. This objective is pursued through Blockchain adoption, which facilitates not only direct access to supply chain information, but also greater corporate responsibility, capable of strengthening consumer trust, a key element for the smooth functioning of markets and B2C relationships. These objectives also emerged prominently during the focus group.

Table 3: Secondary data results

	Azienda agricola San Salvatore	**BioItalia**	**Pastificio Liguori**	**Spinosa**	**Solania**
Sector	Agri-food	Agri-food	Agri-food	Agri-food	Agri-food
Company Size	PMI	PMI	PMI	PMI	PMI
Blockchain Application	Yogurt and creamy buffalo milk products	The entire range of products	The entire range of products	Mozzarella di Bufala Campana PDO	San Marzano Tomato PDO

	Azienda agricola San Salvatore	BioItalia	Pastificio Liguori	Spinosa	Solania
Blockchain Information	Product description; Origin and processing of raw materials; Production process; Locations of processing stages; Certification	Product description; Origin and processing of raw materials; Production process; Locations of processing stages; Certification	Origin of the cultivated field; harvest period; processing dates and locations for semolina; production date and location for the pasta	Origin verification; Milk Monitoring; Milk Processing Stages; Packaging and distribution details	Sowing process; Harvesting phase; Processing stages; Storage of the finished product
Reason	Traceability of selected products	Traceability of the entire product range	Traceability of the entire product range	Traceability of selected products	Traceability of selected products
Objective	To prevent counterfeiting and safeguard product authenticity.	To make the entire supply chain transparent to the final consumer	To make the entire supply chain transparent to the final consumer and to safeguard product authenticity.	To make the entire supply chain transparent to the final consume	To prevent counterfeiting and safeguard product authenticity.

Authors' elaboration

- *RQ3: Tangible and intangible resources supporting the implementation of Blockchain*

This research question was primarily explored through the focus group. The discussion highlighted the importance of certain resources, which we classified as *operational factors*, and of further resources that emerge in a later stage, referred to as *validation factors*. Together, these represent fundamental preconditions for the effective use of Blockchain technology. In the category of operational factors, we included the following factors, which were deemed necessary by the stakeholders participating in the debate:

The role of the supplier. The need to identify suppliers who are willing to collaborate actively, sharing data and information about their activities, was emphasized. This is essential for entering accurate information into the Blockchain system, thereby making every stage of the procurement and production process traceable and transparent.

Trust in B2B relationships. Trust in the relationship with suppliers allows the integrity of the data entry process within the blockchain system to be guaranteed.

Management. The focus group identified two key managerial competencies related to this factor: supply chain management and business innovation: supply chain management and business innovation.

Supply chain management is considered a strategic activity and a key operational factor. Having a well-structured supply chain monitoring and managing system in place prior to the implementation of the Blockchain, participants expressed that this is a considerable advantage for the introduction of the Blockchain, as the company already possesses a very thorough knowledge of its supply chain.

Regarding business innovation, during the discussion, all participants identified this as a crucial factor for Blockchain implementation. In particular, the need to initiate a profound cultural-organizational renewal within enterprises was highlighted, so that they would be inclined to embrace a process of full-scale technological innovation. Such transformation, to be effective, must take on a systemic and structural character. For this reason, a fundamental role is attributed to institutions, which are believed to have to assume a leading and coordinating function in promoting collaboration among the various actors involved (businesses, stakeholders, certifying bodies, consumers).

Internal and/or external digital expertise. The need to develop digital expertise, both within organisations and among external stakeholders, is crucial for the implementation of blockchain technology. During the discussion, Indeed, it emerged that one of the main obstacles to the success of Blockchain is the lack of adequate human and structural resources to manage such systems.

Finally, the participants also dwelt on the consumer's digital knowledge and skills, which are often scarce and not adapted to technological developments. As a result, the need to focus on consumer education in order to inform them about the utility and advantages of such technology was stressed by several parties.

The Validation Factors category considered the resources and factors identified as crucial for the validity of the raw data entered into the Blockchain and, consequently, to the trustworthiness of the information within the Blockchain system. One key factor identified was Data Credibility and Corporate Reputation.

The issue of data credibility was represented as a strategic element of paramount importance. In fact, the interlocutors raised several critical issues associated with entering raw data into Blockchain, agreeing on the difficulty of verifying its accuracy. Blockchain technology allows the freezing of data, making them immutable, but this aspect does not guarantee their truthfulness and credibility. As emphasised by the participants, the truthfulness and credibility of the data entered by companies largely depend on professional ethics and their willingness to consolidate their corporate reputation.

Similarly, the inclusion of inaccurate data can undermine the company's credibility for the information reported in Blockchain producing negative fallout in terms of trust and image.

Although not quoted verbatim here, these findings are supported and corroborated by several statements from focus group participants.

5 Discussions and conclusions

Based on the results of the companies surveyed, the adoption of Blockchain in the agri-food sector is mainly driven by the possibility of guaranteeing product traceability. In this context, the aim is not so much to implement a control mechanism on data and information, but rather to adopt a strategic tool to enhance the authenticity and transparency of products for the consumer, thus combating the counterfeiting phenomenon. The empirical results are consistent with what has emerged from the existing academic debate, which configures Blockchain as a communication tool (Bovenzi et al., 2023) capable of conveying the traceability of the entire product lifecycle with the aim of promoting its transparency and authenticity (Banerjee, 2018; Saberi et al, 2018; Kshetri, 2018).

Furthermore, the results obtained confirm the positive impact of Blockchain technology on social sustainability. The motivations and objectives identified for its implementation, as well as the factors that emerged from empirical analysis, reflect the key elements that the literature has identified as determinants of social sustainability. These include transparency, accessibility and verifiability of all relevant information to ensure food safety and quality, the promotion of collaboration and trust among stakeholders, and the monitoring of the supply chain, including supplier behaviour and the social conditions of workers. In this context, Blockchain emerges as an enabling tool for the integration of social sustainability into business strategies in the agri-food sector, consistent with the arguments of Giganti et al. (2024), Saberi et al. (2019) and Mastos & Gotzamani (2022).

In parallel, the analysis of the resources that the investigated companies consider to be preliminary in order to guarantee the operational effectiveness and credibility of the Blockchain, led to the identification of a set of crucial factors, divided into two main categories - operational and validation - from which derive important insights for the identification of the following theoretical and practical implications.

Regarding the theoretical implications, this research provides insights into the theoretical debate on the operational application of Blockchain in the context of business management, an area still little explored in existing literature. Regarding managerial implications, this study provides valuable insights useful to entrepreneurs, managers and business leaders on the organisational and managerial level in order to guide strategic choices and promote greater awareness in the adoption of Blockchain technology. Finally, with reference to the institutional implications, there emerges the need for a more proactive role on the part of institutions, especially in the function of guiding and coordinating innovative processes, in order to guarantee a technology that is inclusive, sustainable and regulated among the various actors involved (businesses, stakeholders, certification bodies, consumers).

Limitations: This research is an initial approach and thus has some limitations that open the way for further research. Future studies could replicate and expand the analysis to a larger set of companies belonging to different industrial sectors and located in different geographical areas.

Multi-Criteria Decision-Making to Evaluate Sustainability and Performance in the Agri-Food Supply Chain

Gerarda Fattoruso[1], Antonio Violi[2], Massimo Squillante[2]
[1]University of Foggia, Foggia, Italy
[2]University of Sannio, Benevento, Italy

Abstract

Mathematical modeling of complex problems, with particular attention to multi-criteria and optimization models, is particularly effective for analyzing critical issues in the agri-food supply chain. These tools allow analyzing problems of different nature through the use of qualitative and quantitative criteria, often conflicting with each other, and decision alternatives. Their versatility allows adapting solid theoretical constructs to different contexts and application areas, ensuring a modeling that takes into account the peculiarities of the problem under examination. In fact, multi-criteria analysis tools and optimization models allow supporting decision makers in the different phases that characterize the agri-food supply chain. This work addresses in particular the decision problem related to the transition of agri-food products from the storage to the marketing phase, using the Analytic Hierarchy Process (AHP) method. Once the products have undergone transformation processes, they are stored in one or more warehouses for distribution to commercial activities. There are several choices to be made in this phase, including the choice of the commercial establishments in which to distribute the products. In particular, the use of the AHP method is proposed for the analysis of a decision problem relating to the choice of the warehouse distribution with respect to four different commercial establishments (alternatives) that sell directly to the final consumer. A sensitivity analysis is conducted to test the robustness of the method. Through the analysis of a practical case, it is highlighted how the agri-food supply chain is a very complex context, in which the competitiveness of organizations is based on the ability of the decision maker to identify problems, imagine alternatives and adopt solutions. It is also highlighted that these tools, if correctly implemented in organizations, allow the start of an organizational learning process, reducing the costs associated with decision-making errors.

Keywords: Multi-criteria Decision Making, Decision Support Systems, Decision Analysis, Agri-food Supply Chain.

Paper type: Academic Research Paper

1 Introduction

Large-scale retail trade is now the main component of the Italian agri-food system, intercepting over 50% of the value generated by the entire system. This sector therefore represents one of the strengths of the agri-food economy, but still has ample room for development linked to the wide possibilities of innovation and diversification of services. If on the one hand it is necessary to adopt strategies that allow the valorization of the processes in progress, on the other hand it appears necessary to experiment with new processes that meet the needs of consumers and that are capable of carving out new spaces on the markets (e.g. Carbon Neutral products).

Moreover, there is the phenomenon of food waste which, due to its economic, environmental and social implications, represents a particularly relevant issue for the transition towards sustainable development. Nowadays, initiatives to reduce food waste and losses and to recover food products that are no longer saleable but still edible have multiplied throughout the world, contributing to placing ever greater attention on this issue.

In such a context, the agri-food supply chain appears to be crucial and the competitiveness of organizations is based on the ability of the decision maker to identify problems, imagine alternatives and adopt solutions. This is directly influenced by the ability of organizations to acquire knowledge and start decision-making learning processes to recognize the problem (Fattoruso & Squillante, 2023).

In this field, in order to guarantee the overall sustainability, the processes to be evaluated are by definition multidimensional and characterized by a plurality of actors, complex contexts, a high degree of uncertainty and ambiguity, plurality of objectives, criteria and decision alternatives. In such contexts, several studies suggest the use of multi-criteria and optimization approaches. In fact, there are many advantages that the adoption of such approaches can bring. Among these, of great relevance for the purposes of strategic evaluation is the possibility of articulating the decision-making process on the basis of a rational quantitative model that takes into account the plurality of interests of the different actors, and guarantees the decision-maker the ability to modify the

decision-making process at any time based on the robustness of the results of the new alternatives/solutions that may arise.

Theoretical elaboration and field experiences have shown how Multi-criteria Decision Making (MCDM) methods are particularly suitable for representing the evaluation and decision-making processes in the context of complex problems (Proto et al., 2013; Ishizaka & Nemery, 2013; Greco et al., 2016).

The Agri-food Supply Chain certainly represents a field in which MCDM can face important conceptual and operational challenges, contributing to effective problem solutions (Ammirato et al., 2021).

The use of MCDM methods is particularly suitable for solving problems in the Agri-food Supply Chain. In fact, they can support the resolution of problems at every level of the Agri-food Supply Chain such as the storage, distribution and trade phases.

Moreover, also the definition of optimization models, designed in order to effectively manage the uncertainty that characterizes this application field, can be a useful support for decision makers (Violi et al. 2020; 2023).

This work proposes the use of multi-criteria analysis and optimization models and methods to support decision makers in the different production processes of the Agri-food Supply Chain by proposing the analysis of real problems. The work highlights that the implementation of multi-criteria methods, if correctly implemented, allows to start an organizational learning process, reducing the costs associated with decision-making errors.

2 Main Literature

In the literature analysis of particular importance is the understanding of the scientific landscape in which the object of study is placed. In this sense, the database composed of the final articles was analyzed using the VOSviewer software (Van Eck et al. 2010). The focus of our investigation was to verify if and which multi-criteria and optimization models are used to improve competitiveness and sustainability in the agri-food sector. The analysis provides the mapping of the relationships between the different keywords of the scientific articles highlighting all the connections existing between the articles considered. The bibliometric analysis conducted with VOSviewer allowed to identify the main research areas and the connections between key concepts related to the agri-food supply chain. Three visualizations were produced: co-occurrence network, temporal analysis and density map. Fig. 1 shows the co-occurrence network, or the scientific landscape, composed of the keywords of the selected articles. In particular, the scientific landscape is made up of 1015 keywords. The filter for the minimum number of relations that each keyword must have was set to 5. By applying this filter, 29 nodes that make up the network are identified.

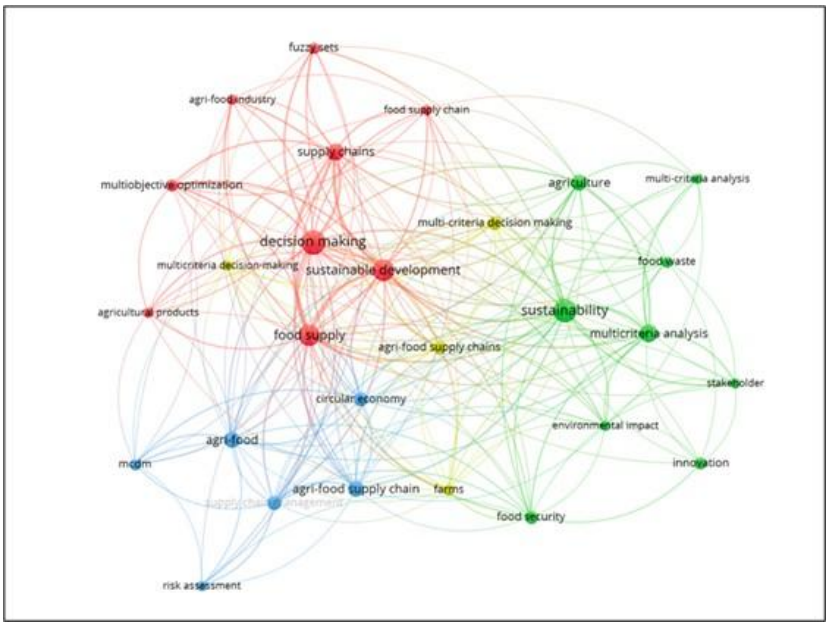

Figure 1: Scientific Landscape
Source: elaboration with VOSviewer software

The *Scientific Landscape* shown in Fig. 1 highlights thematic clusters that represent closely related research areas. From the analysis of the results obtained, we can in particular refer to 4 main Clusters:

- Red Cluster - It includes topics such as decision making, supply chains, multiobjective optimization, food supply, and sustainable development. This cluster highlights the importance of decision analysis and optimization models to manage food supply chains in a sustainable way.
- Green Cluster - It concerns topics related to sustainability, agriculture, environmental impact, food waste and innovation. It focuses on environmental impact and sustainable practices in agri-food production.
- Blue Cluster - It includes topics such as agri-food, supply chain management, risk assessment, MCDM and circular economy. This cluster analyzes risk management and circular economy in the agri-food sector.
- Yellow Cluster - It concerns topics related to agri-food supply chain and multi-criteria decision making. This cluster analyses the use of the main modelling tools for decision support relating to multi-criteria decision making in the agri-food sector.

The analysis of the main literature highlights how multi-criteria methods and multi-objective optimization models are crucial tools to improve the competitiveness and sustainability of agri-food supply chains. In particular, multi-criteria models are useful tools to make decisions balanced between economic efficiency and sustainability. In fact, from the analysis of the main literature it emerges that the joint use of multi-criteria analysis tools and integer linear programming allows to address issues such as the design of sustainable agri-food supply chain networks (Fathi et al., 2024)

The use of multi-criteria approaches allows to analyze problems of different nature in the agri-food supply chain among these we refer for example to the evaluation of circularity in agri-food industries using the AHP model (Coluccia et al., 2024); the study by Silvestri et al., (2024) proposes a multi-criteria model useful for the reduction and reuse of agri-food waste and again Das et al., (2023) identify the main risks in the cereal supply chain and propose mitigation strategies using FAHP and FTOPSIS.

The adoption of multi-criteria and multi-objective optimization methodologies allows to address complex problems, taking into account multiple dimensions (economic, social, etc.). The use of these methodologies is supported by the literature (Ishizaka & Siraj, 2018; Figueira et al., 2005), which highlights their versatility and effectiveness in real contexts. These models offer advantages such as: Rational structuring of the decision-making process (Wątróbski et al., 2019); Management of qualitative and quantitative criteria (Ishizaka & Nemery, 2013); Analysis under uncertainty (Aissi & Roy, 2010); Interaction with stakeholders to reflect on preferences (Klamroth & Miettinen, 2008). The Analytic Hierarchy Process (AHP) method is confirmed as the most widespread for its ability to address problems of choice, sorting and classification (Ishizaka & Siraj, 2018). Advanced models such as Analytic Network Process (ANP), AHP Sort I and II expand decision-making capabilities, managing interdependencies between criteria and decision alternatives (Saaty & Vargas, 2013; Ishizaka et al., 2020). The combined use of quantitative and qualitative models allows for more effective management of supply chains.

3 Method

The method under study is the well-known AHP method, introduced in the 70s by Thomas Saaty (Saaty, 1988). The structuring of a decision problem with the AHP method is defined through the construction of an analytical process aimed at determining a multi-level hierarchical structure (Fig. 2) consisting of all the elements that come into play in the decision-making process: the objectives (O_1 at Level 1), the criteria (g_m with $m = 1, \dots, M$, at Level 2) and the alternatives (A_n with $n = 1, \dots, N$ at Level t) (Ishizaka & Labib, 2009). The number of levels will depend on the complexity and the degree of detail of the decision problem; in any case, the number of levels cannot be less than $t = 3$.

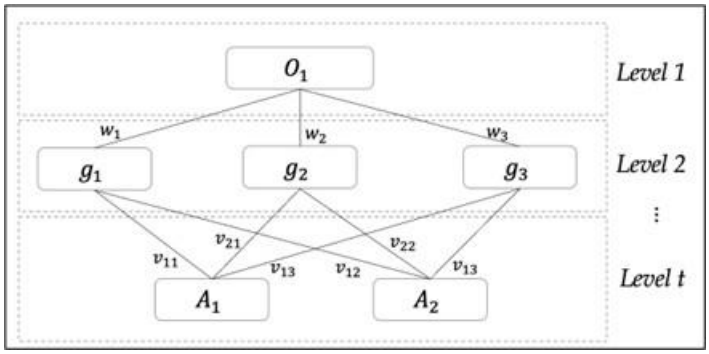

Figure 2: multi-level hierarchical structure
Source: own elaboration

The evaluation of alternatives is derived through the use of pairwise comparison matrices (PCMs) (Cavallo et al., 2012; Cavallo et al., 2019) aimed at obtaining the *local priority* of the criteria and alternatives evaluated with respect to each criterion (Fig. 2); the determination of the weights of the criteria and alternatives can be derived through the use of several techniques, among which the most used are the eigenvector method, the geometric mean and the arithmetic mean (Cavallo et al., 2018). In Fig. 3 we report an example of PCM of the criteria with respect to the objective with the relative priority vector w_m.

$$\begin{array}{c|cccc} O_i & g_1 & g_2 & \cdots & g_m \\ g_1 & 1 & g_{12} & \cdots & g_{1m} \\ g_2 & g_{21} & 1 & \cdots & g_{2m} \\ \vdots & \vdots & \vdots & 1 & \vdots \\ g_m & g_{m1} & g_{m2} & \cdots & 1 \end{array} \rightarrow \begin{pmatrix} w_1 \\ w_2 \\ \vdots \\ w_m \end{pmatrix}$$

Figure 3: PCM of the criteria
Source: own elaboration

The evaluations expressed by decision makers are defined through the use of specific evaluation scales; the most used is the Saaty semantic scale (Saaty, 2001), a scale that represents the intensity of importance of an alternative compared to another using values from 1 to 9. Note that the pairwise comparison matrix is a reciprocal matrix (for example: if $a_{12} = 3$ then $a_{21} = \frac{1}{3}$) and therefore the elements present on the main diagonal are all unitary since the alternative is compared with itself; this reciprocal relationship arises from the need to guarantee the symmetry of the importance judgments.

The final evaluation (*global priority*) of the alternatives with respect to each criterion characterizing the decision problem is obtained through the principle of hierarchical recomposition: the local priorities of each element are multiplied by the priorities of the superordinate elements and the products thus obtained are added.

The best alternative will have the greatest global weight. The use of the AHP method is suggested when the criteria are quantitative, qualitative and mixed; to obtain the ordering or classification of the alternatives as well as choose the best alternative; allocate resources; evaluate the sensitivity of the alternatives to changes in judgments.

4 Decision Problem

The use of AHP can be of support in solving problems at every decision-making level of the Agri-Food Supply Chain. The decision-making problems that can occur in the various phases are complex, structured and unstructured problems, generally characterized by variables affected by uncertainty. Particularly delicate are the decision-making processes that characterize the storage, distribution and trade phases. If we want to try to represent the phases that generally characterize the Agri-Food Supply Chain, we can refer to Fig. 4.

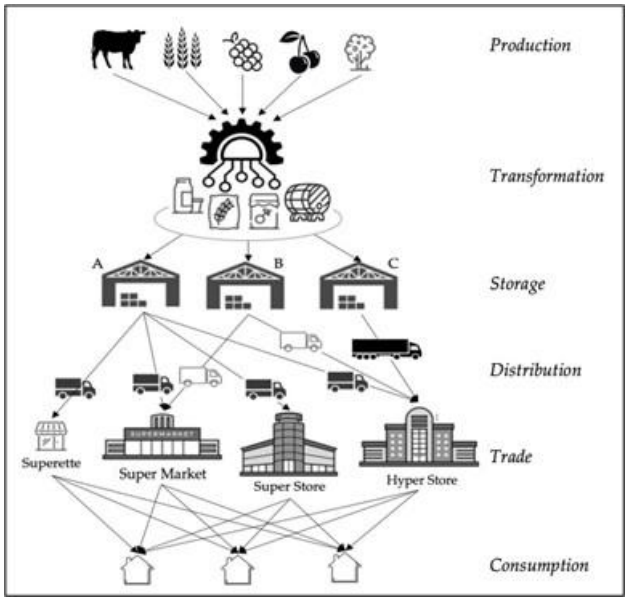

Figure 4: Phases of the Agri-Food Supply Chain
Source: own elaboration

For each phase that characterizes the Agri-Food Supply Chain, different modeling approaches can be used based on the problem being analyzed.

For example, in the Storage phase, logistics and warehouse management problems that influence the product transportation phase can be considered. For example, in the literature for this last model, an age-based model has been proposed for the problem of routing perishable goods stocks with stochastic demands (Violi et al., 2023). The decision-making problems that characterize the distribution and trade phases are also particularly delicate. This work deals in particular with the decision-making problem regarding the transition from the storage and trade phase using the AHP method. Once the products have undergone transformation processes, they are placed in one or more warehouses in order to distribute them to commercial activities. There are several choices to be made in this phase, including the choice of commercial establishments in which to distribute the products. The case study (Fattoruso & Squillante, 2023) concerns, in particular, the choice of distribution of warehouse A with respect to four different commercial establishments (alternatives) that sell directly to the final consumer:

- Superette (A_1) – establishments with a small retail sales area (200 – 400 m²), normally located in city centers with a number of inhabitants lower than (<) 10,000;
- Super Market (A_2) – establishments with a medium retail sales area (500 – 800 m²) that serve municipalities with a number of inhabitants higher than (<) 10,000;
- Super Store (A_3) – establishments with a medium-large retail sales area (1500 – 3500 m²) normally located in the peripheral areas of inhabited centers with a number of inhabitants higher than (<) 10,000;
- Hyper Store (A_4) – stores with a large retail area (2500 – 4000 m²) normally located in shopping centres or in peripheral areas of towns with a population greater than (>) 10,000.

The choice of stores to which to deliver the products depends on 4 criteria:

- Distance (g_1) or the distance that the means of transport must travel from the warehouse to the store. This criterion is important for the decision maker as it determines the costs of maintaining the means of transport that will deliver the products.
- Size of the store (g_2). The selection of this criterion is linked to the quantities of product that the decision maker can deliver to the stores. The larger the size of the store, the greater the quantity of product to be delivered.
- Reputation of the store (g_3). The reputation of the business is a qualitative criterion that cannot be ignored in the choice of businesses to supply, as it can increase or decrease the number of customers served and therefore the increase in demand for products.
- Position (g_4). The position of the business attracts a different number of potential consumers and therefore the consequent increase (or decrease) in product demand.

4.1 Results

The AHP method was applied using Software Expert Choice (Ishizaka & Labib, 2009). The main results obtained are reported below. In Table 1, the local priorities of the criteria can be observed, while in Table 2 the local priorities of the alternatives with respect to each criterion considered are reported.

Table 1: Local Priority of criteria

	Local Priority
g_1	0,418
g_2	0,120
g_3	0,271
g_4	0,191

Table 1: Local Priority of alternative

	g_1	g_2	g_3	g_4
A_1	0,302	0,180	0,243	0,270
A_2	0,283	0,219	0,263	0,123
A_3	0,165	0,489	0,189	0,100
A_4	0,250	0,112	0,305	0,507

By adopting the principle of hierarchical recomposition, the global priorities of the alternatives are obtained and, therefore, their final ranking (Fig. 5).

Figure 5: Ranking of the alternatives
Source: elaboration with Expert Choice

As can be seen, by adopting a Multi-criteria approach that takes into account the evaluations of each alternative with respect to multiple decision criteria, the alternative that best satisfies the needs of the DM is the Hyper Store and to follow in order of importance: Superette, Super Market and Super Store.

Based on the ordering of the alternatives, it is clear that the DM prefers to supply larger commercial establishments with a higher customer potential despite this meaning having higher transport costs.

In order to evaluate the robustness of the method and the results obtained, a sensitivity analysis is conducted (Fig. 6).

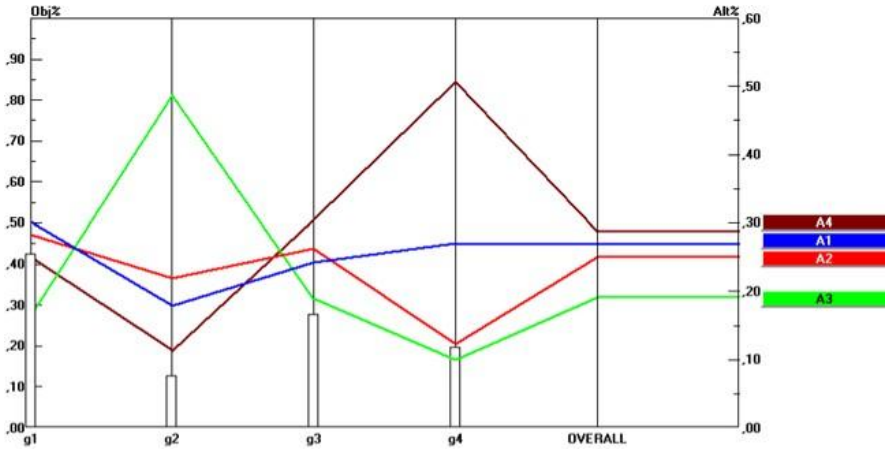

Figure 5: Sensitivity analysis
Source: elaboration with Expert Choice

In particular, Fig. 6 shows how the position of the alternatives varies as the importance attributed to the criteria varies. It can be observed that alternative A_4 is predominant with respect to criterion g_4 and maintains its position in the final ranking; Alternative A_3 shows oscillations; it performs well with respect to criterion g_2, but is weak with respect to g_1 and g_4. This indicates high sensitivity to changes in the weights of

the criteria. Alternatives A_1 and A_3 have a stable trend which suggests that they are less sensitive to changes in the weights than A_3.

5 Conclusion

The agri-food supply chain appears to be a very complex and varied context, in which the competitiveness of organizations is based on the ability of the decision maker to identify problems, imagine alternatives and adopt solutions. This ability is directly influenced by the ability of organizations to acquire knowledge and initiate decision-making learning processes to recognize the problem. In the context of agri-food supply chain, the role of knowledge is particularly relevant as decision-making problems appear to be structured at multiple levels. In fact, the decision taken by an agri-food organization can be considered as the final product of the data collected, the processing of information and the knowledge present within the organization (Daft, 2021, p. 502). For this reason, the tools supporting the decision-making process must take into account a plurality of criteria, capable of helping the decision makers of agri-food organizations in the generation and selection of alternatives. These tools, in fact, if correctly implemented, allow for the initiation of an organizational learning process, reducing the costs associated with decision-making errors.

Furthermore, it should be highlighted that the implementation of Multi-Criteria models appears to be strongly influenced by the nature of interorganizational relationships that links agri-food organizations with other types of organizations (especially universities and research centers). In fact, the prerequisite for the creation of these models is the simultaneous presence of two different domains of knowledge. A first domain of knowledge, highly specific to the processes and activities connected to the agri-food supply chain (or to the business system in general), and a second domain of "technical" type knowledge, fundamental for building the model (Canonico, et al. 2022).

The interaction and contamination, through a dynamic communication process, between the two domains of knowledge, becomes crucial to correctly create a Multi-Criteria model (Ishizaka and Siraj, 2018).

The Role of Intelligent Packaging in Reducing Food Waste: A Consumer Behaviour Analysis

Kanwal Gul, Elena Lupolo, Simone Luongo, Fabiana Sepe, Giovanna Del Gaudio
University of Naples Federico II, Naples, Italy

Abstract

This study explores how consumers perceive and respond to smart packaging technologies as a practical solution to the growing issue of food waste. While traditional food packaging plays a role in preservation, it often lacks the ability to communicate real-time information about freshness or quality.
Smart packaging, which includes technologies such as sensors, freshness indicators and traceability systems, allows for real-time monitoring of product quality, providing consumers with essential information to make more informed decisions and extend the shelf life of food products.
To understand the factors influencing consumers' intention to adopt these technologies, the research adopts an extended version of the Technology Acceptance Model (TAM). In addition to the classic variables: Perceived Usefulness (PU), Perceived Ease of Use (PEU) and Attitude toward Smart Packaging (ATT), the study introduces a novel variable such as Willingness to Pay (WP).
Data were collected through a structured online survey using realistic, scenario-based situations, and analyzed using Partial Least Squares Structural Equation Modelling (PLS-SEM).
The preliminary findings show that Perceived Usefulness (PU), Perceived Ease of Use (PEU) and Attitude toward Smart Packaging (ATT) significantly influence consumers' intentions to adopt such innovative solutions. Conversely, Willingness to Pay (WTP) does not show a statistically significant relationship with consumer intention.
This research contributes to the academic and practical discourse on sustainable innovation in food systems, offering insights for policymakers, businesses and technology developers aiming to promote smart packaging solutions. The study emphasizes the importance of consumer engagement and targeted strategies to support sustainable consumption patterns and reduce food loss across the supply chain.

Paper type: Academic Research Paper

1 Introduction

Food waste (FW) is one of the most pressing challenges of our time, with significant implications for the economy, environment, and global food security.

Each year, vast quantities of food are wasted across the agri-food supply chain, resulting in major resource loss and serious environmental and social impacts (Roka, 2022). The Food Waste Index Report 2024 indicates that 1.05 billion tons of food were wasted globally in 2022 (United Nations Environment Programme, 2024). This is in addition to the 13% of food lost from post-harvest to retail, as estimated by the FAO (FAO, 2023). The environmental consequences of FW are alarming. As food decomposes in landfills, it emits substantial greenhouse gases, exacerbating climate change (Scherhaufer et al., 2018). Packaging was developed to slow food deterioration and serves several purposes: storage, safety, transportation and delaying decay. However, traditional packaging lacks the ability to provide real-time data on food quality and shelf life. Smart packaging offers the potential to address these limitations and reduce FW. Innovative solutions like smart packaging can inform consumers about food quality and shelf life in real time (Dodero et al., 2021). It goes beyond basic containment to represent a technological evolution of traditional packaging (Drago, 2020). With smart technologies, consumers can monitor internal and external conditions, assess product quality and extend durability (Robertson, 2005). These innovations increase perceived value by offering useful data and support both European policies and the Sustainable Development Goals (SDGs). Intelligent packaging contributes to SDG 2 (zero hunger) by promoting FW reduction, and SDG 12 (sustainable consumption and production) through improved supply chain management (SDG, 2020).

This study aims to explore consumers' intentions to adopt smart packaging to enhance sustainability in the food supply chain and reduce FW. The research uses Partial Least Square Structural Equation Modelling (PLS-SEM) and builds on Davis' (1989) Technology Acceptance Model (TAM). The model incorporates a new variable, Willingness to Pay (WP), alongside Perceived Utility (PU), Perceived Ease of Use (PEU), and Attitude toward Smart Packaging (ATT).

A scenario-based approach (Weber, 1992) is applied, presenting participants with hypothetical yet realistic use cases of smart packaging. The study provides insights into consumer behaviour, helping policymakers, businesses, and stakeholders encourage the adoption of intelligent packaging. The article proceeds as follows: first, a literature review and theoretical framework; second, an explanation of the methodology and survey results; and finally, a discussion on the research's implications, limitations, and directions for future studies.

2 Literature review and theoretical framework

Food waste (FW) remains a global crisis, with one-third of all produced food going to waste. Food packaging contributes twofold: through material waste, plastic, glass, rubber, cartons, aluminium and FW due to contamination or poor packaging. However, packaging can play a key role in minimizing FW and empowering informed consumers. User-friendly packaging designs that reduce leftovers or spoilage have transformed the sector.

Current technologies support the development of various smart packaging types, classified by materials, data capabilities and user interaction (Fernandez et al., 2023). These fall into three main categories: interactive packaging, sensor-based packaging, and indicator-based packaging (Biji et al., 2015). Interactive packaging, such as barcodes, RFID and NFC, enables food traceability and monitors storage conditions throughout the supply chain, enhancing transparency and safety (Ruiz-Garcia et al., 2011). Sensor-equipped packaging monitors parameters like temperature, humidity and impact, providing real-time data and alerts about potential safety or quality issues (Nilsson et al., 2012).

Indicators, though not data-transmitting, visually signal problems, for instance, via colour changes indicating spoilage or contamination (Hogan and Kerry, 2008). Common types include time-temperature, freshness and gas indicators (Bhardwaj et al., 2022). These innovations improve food chain sustainability by reducing waste and optimizing resources (Poyatos-Racionero et al., 2018). However, wider adoption requires better understanding of consumer perceptions and intentions.

Few studies have addressed consumer concerns, acceptance and awareness of smart packaging or motivations behind its adoption (Incpen and Wrap, 2019). Cammarelle et al. (2019) noted that consumers often purchase smart-packaged food due to social pressure rather than a desire to reduce waste.

Additionally, literature shows that those who view FW reduction as a moral duty behave differently from those indifferent to environmental issues. Misiak et al. (2018) found that communities facing food insecurity prioritize product value over waste concerns. Thus, visual elements like colour-changing indicators can influence consumer behaviour positively or negatively.

Some studies warn that smart packaging may paradoxically increase FW (Young et al., 2020). Higher packaging costs and misinterpreted indicators can lead consumers to discard still-edible food (Pennanen et al., 2015). This highlights the need for clear communication and regulation to avoid unnecessary waste.

Research suggests consumers often prioritise personal benefits, with price being a major barrier to green purchases (Kulshreshtha et al., 2017). A key issue in green consumption is the gap between attitudes, intentions, and actual behaviours. For example, in the U.S., 82% of consumers report strong environmental intentions, but only 16% act on them (Bennett & Williams, 2011). In the U.K., although 30% express concern, ethical food products hold just 5% market share (Wheale & Hinton, 2007).

The central question is whether consumers will embrace advancements in food-packaging technology.

To explore this, the study uses the Technology Acceptance Model (TAM) to examine how perceived usefulness (PU), perceived ease of use (PEU) and attitude (ATT) affect the intention to purchase smart-packaged food (INT). It extends TAM by introducing willingness to pay (WP) as a new variable.

Developed by Davis (1989) as a refinement of the Theory of Reasoned Action (TRA) (Ajzen & Fishbein, 1980), TAM links behavioural intention to technology adoption (Davis & Granić, 2024). In its original form, Davis identified PU and PEU as key cognitive factors shaping attitudes and behavioural intentions (Davis, 1985). Later, Davis and Bagozzi (1989) proposed including external variables to enhance the model's adaptability. Since then, many researchers have expanded TAM with additional factors. In this study, WP reflects consumers' willingness to invest in smart packaging.

Within our research on smart packaging and FW reduction, the extended TAM framework enables a comprehensive evaluation of purchase intentions by integrating cognitive (PU, PEU), emotional (ATT) and economic dimension (WP).

Accordingly, we developed a research model (Figure 1) based on TAM variables extended with WP.

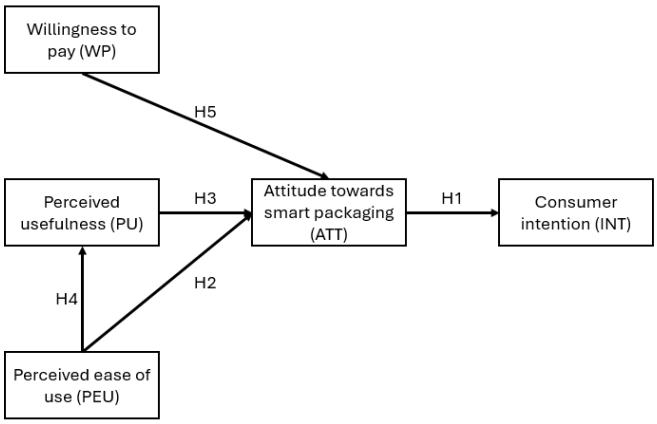

Figure 1: The proposed model

2.1 Attitude

Attitude is an individual's comprehensive assessment of a particular future behaviour (Luongo et al., 2023). Consumption intention results from hedonic and utilitarian motivations. Hedonic motivation is derived from emotions, fun and enjoyment whereas utilitarian motivations are the product of rational evaluation of future outcomes. Attitudes are predictors of intentions and if food packaging technologies should encourage hedonic (product real-time information) or utilitarian motivation (food waste) in consumers. Accordingly, we propose the following hypothesis:

- *H1: Attitude towards smart packaging influences consumer intention.*

2.2 Perceived Ease of Use and Perceived Usefulness

Perceived ease of use is a critical determinant in shaping consumer attitudes toward technological innovations, including smart and intelligent food packaging. Drawing from TAM, Davis (1989) emphasised that when users perceive a system as easy to use, their overall attitude and intention to adopt it improve. This idea extends smart food packaging. The latter, which is simple to understand and easy to interact with consumers, e.g., QR codes, freshness indicators, time and temperature and traceability enhance consumers' overall user experience.

Research suggests that when consumers have to make little or no adjustments, they adopt the technology faster (Silayoi et al., 2007). Correspondingly, a few studies also concluded that user friendly interface and information availability and clarity on food packaging influence positive intentions and attitudes in consumers (Young et al., 2020). Hence, the ability of consumers to utilize the functions of smart packaging influence consumers' intentions to adopt technology, which translates into an effort to reduce FW and improve food safety. Previous studies revealed that PEU is also considered as a relevant factor in driving technology usage. Accordingly, PEU influences PU because technologies requiring fewer efforts can be perceived as more useful. PU refers to the belief that a consumer has regarding using a technology, which makes the usage of the particular product effortless and beneficial. Studies conducted by Incpen and Wrap (2019) found that consumers recognize the benefits of innovative packaging, but the intention to purchase it to reduce food waste is under-researched. Indeed, fewer studies have been conducted to address consumers' angst, acceptability and awareness of PU of innovative packaging and underline reasons to choose innovative packaging (Incpen and Wrap, 2019). Hence, we propose the following hypothesis:

- *H2: Perceived ease of use influences attitude towards smart packaging.*
- *H3: Perceived usefulness influences attitudes towards smart packaging.*
- *H4: Perceived ease of use influences perceived usefulness.*

2.3 Willingness to pay

Price is a crucial and multifaceted factor in consumer decision-making for environmentally friendly products. Consumer purchasing decisions are often influenced by the perception that sustainable packaging is more expensive. Higher price tags for eco-friendly packaging often influence consumers positively (environment conscious) as well as negatively (price conscious). A Vietnamese consumer-based study concluded that people are willing to pay higher prices for biodegradable or eco-friendly packaging (Kulshreshtha et al., 2017). In contrast, studies based in European countries highlighted the difference in intention of consumers towards high-

priced packaging. The studies pointed out that the higher-income economies do not correlate with environmental consciousness (Liobikienė et al., 2025). Willingness to pay premiums for eco-friendly options correlates with environmental concern, though price remains a barrier for low-income households. Hence, consumers' positive perception of smart packaging will enhance the technological advancement and success of the technology also depends on consumer acceptance (Michaud et al., 2017). Therefore, we propose the following hypothesis:

- *H5: Willingness to pay influences attitude towards smart packaging.*

3 Methodology

To collect data, a survey was conducted among consumers in Naples (Italy) between October 2024 and December 2024. The questionnaire, developed using Microsoft Forms, was administered in areas with high consumer traffic relevant to food purchasing behaviour, specifically near grocery stores, supermarkets and shopping centres. The survey link was shared via QR code.

Following the scenario-based approach proposed by Weber (1992), the survey began with a brief explanatory scenario outlining the concept and benefits of smart packaging in the food sector. This helped provide context and guided participants in evaluating how certain features of smart packaging may influence their purchase decisions.

The study utilized a structured questionnaire with a seven-point Likert scale to gather quantitative data. The first part of the survey collected demographic and personal information, such as gender, age, income and education level. The second one consisted of 15 items measuring consumer perceptions and behavioural intentions related to food products with smart packaging, rated from 1 (Strongly disagree) to 7 (Strongly agree) (Podsakoff et al., 2003).

All measurement items were adapted from validated sources in the literature. Intention to use smart packaged products was assessed with three items from An et al. (2017), attitude toward smart packaging (ATT), perceived ease of use (PEU) and perceived usefulness (PU) were each measured with three items from Kim and Woo (2016) and willingness to pay (WP) using three items from Prakash and Pathak (2017).

The face validity of the instrument was confirmed through a pilot test involving 30 respondents from the sample group and revisions were made accordingly. Data analysis was conducted using Smart-PLS software. The sample size was determined in accordance with the statistical power threshold of 80% (Green, 1991), resulting in 154 valid responses.

The dependent variable in this research is consumers' intention to purchase food products using smart packaging (INT), while the influencing factors are latent variables (LVs), which are measured indirectly through observable indicators (manifest variables, MVs). Due to the complexity and the nature of the relationships among variables, Structural Equation Modeling (SEM) was selected as the most suitable statistical method.

4 Results and discussion

The adoption of PLS-SEM using the Smart-PLS software was motivated by its robustness in handling a wide range of assumptions related to the distribution of variables and error terms (Hair et al., 2019). The structural model delineates the interrelationships among latent variables (LVs), whereas the measurement model specifies the associations between a LV and its observed indicators (MVs). The application and interpretation of PLS-SEM encompass two fundamental stages: the evaluation of the measurement model and the assessment of the structural model (Hair et al., 2019).

4.1 Descriptive results

The final sample consists of 154 valid responses. In terms of gender, 45,5% of participants identified as female (n = 70), 44,8% as male (n = 69) and 9,7% (n = 15) preferred not to disclose their gender. The age distribution shows a concentration in the younger age groups. 20,1% of participants are aged 18–24 years (n = 31), 21,4% are aged 25–34 years (n = 33), and 19,5% are aged 35–44 years (n = 30). Additionally, 19,5% of participants are aged 45–54 years (n = 30) and 19,5% are aged 55 years and above (n = 30). Regarding annual income, most respondents are in income brackets below 30.000 euros. Specifically, 16,2% reported having an income of less than 12.000 euros (n = 25), 19,5 percent have an income between 12.000 and 19.999 euros (n = 30) and 21,4% percent have an income between 20.000 and 29.999 euros (n = 33).

4.2 Measurement model evaluation

The overall adequacy of the model was evaluated through a set of indices recommended by Hair et al. (2019), focusing on the reliability of the measurement model as well as its convergent and discriminant validity.

4.2.1 Reliability

To evaluate reliability, Dillon-Goldstein's rho, was examined for each construct to ensure it exceeded the accepted threshold of 0.7 (Dillon & Goldstein, 1984). It is regarded as a more appropriate reliability metric for SEM compared to Cronbach's alpha (Sanchez, 2013). This preference stems from its basis in factor loadings rather than correlations among observed variables, as noted by Chin (2009). As shown in Table 1, all CR values surpassed the minimum threshold, ranging from 0.781 to 0.9.

4.2.2 Convergent and discriminant validity

Convergent validity was assessed through the examination of normalized weights and the Average Variance Extracted (AVE). According to Henseler et al. (2015), outer loadings should exceed 0.6, while AVE should be greater than 0.5 (Hair et al., 2019). As presented in Table 1, all item loadings were above or exceeded the 0.7 threshold, and AVE values for each construct were above 0.5. These results confirm the adequacy of convergent validity.

Discriminant validity was assessed using the Fornell-Larcker criterion (Fornell & Larcker, 1981). According to this method, discriminant validity is confirmed when the square root of each construct's AVE (displayed on the diagonal) is greater than the correlations between that construct and all other constructs (off-diagonal elements) in the corresponding rows and columns.

As shown in Table 2, the square root of the AVE for each construct exceeds its highest correlation with any other construct, thereby confirming that the Fornell-Larcker criterion has been met. Several items were examined to determine those with strong loadings on their respective constructs and minimal loadings on others. The cross-loadings for all constructs were consistently low, supporting the presence of strong discriminant validity across the measurement model.

Table 1: Outer loadings, composite reliability and convergent validity

Construct	**Outer loading**	**Cronbach's alpha**	**Dillon-Goldstein's rho**	**Average variance extracted (AVE)**
ATT1	0,835	0,739	0,850	0,654
ATT2	0,826			
ATT3	0,764			
INT1	0,861	0,833	0,900	0,750
INT2	0,862			
INT3	0,875			
PEU1	0,869	0,782	0,872	0,695
PEU2	0,769			
PEU3	0,860			
PU1	0,761	0,572	0,781	0,546
PU2	0,614			
PU3	0,826			
WP1	0,798	0,747	0,854	0,661
WP2	0,823			
WP3	0,817			

Table 2: Fornell-Larcker criterion

	ATT	**INT**	**PEU**	**PU**	**WP**
ATT	0,809				
INT	0,458	0,866			
PEU	0,644	0,627	0,834		
PU	0,697	0,418	0,497	0,739	
WP	0,533	0,662	0,540	0,488	0,813

4.3 Structural model evaluation

4.3.1 Multicollinearity

To evaluate potential multicollinearity among the constructs in the model, the inner Variance Inflation Factor (VIF) was calculated. According to Hair et al. (2019), an inner VIF value below 3.3 is generally considered acceptable, indicating that multicollinearity is not a concern. As shown in Table 3, all VIF values fall within the acceptable range, suggesting that multicollinearity does not affect the research model.

Table 3: VIF coefficients

	ATT	INT	PEU	PU	WP
ATT		1,000			
INT					
PEU	1,570			1,000	
PU	1,460				
WP	1,552				

4.3.2 R-square coefficient.

The R-squared (R^2) coefficient is used to evaluate how well the model explains variance in each dependent variable (Hair et al., 2019). In this study, the model accounts for 60% of the variance in the primary dependent variable (INT), while explaining 26% and 24% of the variance in two additional constructs (ATT; PU). Although these values are close to the lower threshold, they still approach or meet the minimum benchmark of 0.26 proposed by Cohen (1988), indicating that the model possesses an acceptable level of explanatory and predictive power for the variables considered.

4.4 Testing the research hypotheses

As shown in Table 4, all hypothesized relationships were supported by the data, apart from WP to INT, which was not statistically significant.

Table 4: Final results

	Original sample (O)	Sample mean (M)	Standard deviation (STDEV)	T statistics	P values	Support
ATT -> INT	0,458	0,462	0,070	6,543	0,000	Yes
PEU -> ATT	0,349	0,347	0,069	5,043	0,000	Yes
PEU -> PU	0,497	0,506	0,078	6,409	0,000	Yes
PU -> ATT	0,466	0,470	0,079	5,898	0,000	Yes
WP -> ATT	0,116	0,117	0,090	1,296	0,195	No

5 Discussion

This study explores how consumers perceive the use of smart packaging technologies to reduce FW. Based on TAM, the research shows that PU, PEU and ATT play an important role in influencing consumers' decisions to adopt these innovative technologies. It is interesting to note that WP does not seem to correlate significantly with behavioural intentions. These findings are in line with previous research that has highlighted the "attitude-behavior gap" associated with sustainable consumption. According to Ares et al. (2020), a systematic review discovered that many customers have embraced smart packaging, but this doesn't necessarily translate into monetary rewards for such technologies.

Consumers' motivation to purchase smart packaged products is influenced by their perceptions and behavioural control, as demonstrated by Cammerelle et al. (2021), rather than their WP. The gap between positive attitudes and behaviors may result from several factors. Consumers may perceive smart packaging as a standard solution rather than a premium option.

Furthermore, the specific benefits of smart packaging, such as freshness and reduced FW, may not be immediately recognized. This scenario highlights how important it is to clearly communicate the benefits of smart packaging to bridge the gap between positive perceptions and actual purchasing behaviour. This finding contradicted several earlier studies that had identified WP as a significant factor in the adoption of innovative and sustainable packaging.

Fennell et al. (2023) discovered that nearly 50% of US consumers are open to paying more for packaging options, which can influence their purchase decision in terms of sustainable packaging. In contrast, the present study shows that there is no significant correlation between WP and ATT.

These insights highlight the urgent need for focused educational initiatives and clear communication strategies to enhance consumer understanding and trust in smart packaging technologies.

By increasing familiarity and highlighting concrete advantages, stakeholders can effectively link positive attitudes to actual purchasing actions.

6 Conclusion, implications and limits

In conclusion, this paper contributes to academic debate on food waste reduction, proposing an extended version of TAM. However, it highlights some limitations that future researchers may address to gain deeper insights. The sample was sourced from Italy, making it difficult to generalize the findings to other contexts or populations in different geographic areas or economies. The sampling method, although effective for quick data collection, may hinder the broader applicability of the results to larger populations. Future researchers may leverage this study's findings to refine the research model and assess it using various methodological approaches. They should also consider demographic and sociographic factors to unravel the complex interplay of intentions and attitudes, ultimately aiding in predicting behaviours. While our study examined the relationships among WP, PU, PEU and ATT, incorporating demographic variables could yield richer insights into the intentions behind purchasing smart packaging aimed at reducing food waste. Further research should investigate the moderating roles of consumer knowledge, perceived risk and technological trust on the link between WP and adoption intentions. Additionally, examining demographic and cultural influences could enhance understanding of consumer behaviour in this area.

Furthermore, the study provides important implications for companies, policy makers and stakeholders in the agri-food supply chain. Smart packaging is not only a technological tool, but also a strategic instrument to improve the sustainability and transparency of the food chain, contributing to the achievement of sustainable development goals. For this reason, collaboration between different actors in the agri-food supply chain is essential to promote the benefits of smart packaging and foster its adoption.

7 Ethics declaration

Ethical approval was not required for this study, as it did not involve sensitive personal data, vulnerable populations or procedures posing risks to participants.

8 AI declaration

The AI-based tool Grammarly was used solely to assist with grammar and spelling correction throughout the manuscript. All content was written by the authors, and the tool did not contribute to the generation of original ideas or substantive content.

[3]University of Messina, Messina, Italy

Abstract

The agrifood business system, in terms of sector turnover and employment, assumes significant weight for creating economic value within local socio-economic systems, with a direct impact on population health. Furthermore, the agri-food business system is a sector that has direct repercussions in terms of public health and well-being of people. In recent years, the agrifood sector has undergone numerous changes, both regulatory and technological view. These recent changes along with growing societal awareness, have shifted the focus towards combating food waste in the agrifood supply chain. As an effect, the agrifood business system has garnered increasing attention from policymakers and scholars. Consolidated studies on agri-food business systems have focused their attention on historical and evolutionary aspects, leaving out managerial aspects such as those linked to inter-organizational relationships and the supply chain.

This preliminary study aims to offer a first analysis of the main regulatory and organizational elements within the agri-food supply chain business system. This study, through a qualitative approach, analyzes organizational actors, interorganizational relationships and sustainability-oriented strategies along the entire supply chain. The theoretical approach used is based on knowledge management studies. Adopting an exploratory research design, this study employs qualitative methods to gather in-depth insights into the dynamics of the agrifood supply chain. Given the complexity and diversity of organizational actors within the agri-food business system, this exploratory study aims to identify the main evolutionary trends—both regulatory and managerial—of the agri-food supply chain. The research adopts a qualitative methodology, drawing on secondary data sources such as industry reports, regulatory documents, and academic literature.

This study contributes to the academic and practical discourse on agri-food business system by focusing on the organizational dimensions of the issue. Unlike existing literature, it integrates these additional drivers for change, beginning with the regulatory context. The findings provide initial observations and reflections for practitioners seeking to reduce inefficiency through organizational innovation and for scholars in organizational theory. Furthermore, the proposed regulatory framework emphasizes the importance of integrating data-driven technologies and predictive analytics into decision-making processes, enabling more precise inventory management, better coordination among supply chain actors, and the development of reactive strategies to mitigate waste. These practical implications also extend to policymakers, offering pathways for creating supportive regulatory environments and incentivizing sustainable practices in the agrifood sector.

Keywords: Agri-food supply chain, food waste reduction, organizational models, digital regulation, sustainability

Paper type: Academic Research Paper

1 Introduction

The development of the agri-food sector plays a key role in the growth of an economic system, both in terms of turnover and employment rate. This assumption has attracted the attention of scholars and policy makers in recent decades. In fact, the agri-food sector represents the economic sector that can most increase youth entrepreneurship and, at the same time, reduce socio-economic imbalances. In fact, in low- and medium-income countries, the agri-food sector can offer opportunities to combat youth unemployment, urban migration, as well as poverty and social unrest (Maïga, et al., 2020). Suffice it to say that, in 2020, according to Eurostat data, the agri-food sector contributed to the formation of the Gross Domestic Product (GDP) of the EU27, with a share of 1.3%, with a Gross Added Value (GVA) of 178.4 billion euros. To this we must add that the European Union, through three funds (Common Agricultural Policy, CAP; European Agricultural Guarantee Fund, EAGF; European Agricultural Fund for Rural Development, EAFRD) has supported the agri-food sector with over 50 billion euros. According to EU estimates, each euro spent in the agri-food sector can reinject approximately 0.76 euros into the economy.

For this reason, the agri-food sector is the subject of analysis in many disciplinary sectors, determining a broad and varied scientific panorama (James, et al., 2011; Grandori, 2015). Consequently, the study of the agri-food sector is not simple but characterized by various analytical perspectives with overlapping concepts and terms. The first complexity, which scholars face in the analysis of the agri-food sector, lies in the lack of a univocal definition of the boundaries of the sector itself, or in the use of a shared terminology. Historically, the agri-food

sector has been associated and overlapped with the agricultural sector. A clear example of the conceptual nebula that revolves around the agri-food sector lies in the abundance of terms, often overlapping with each other. Furthermore, in common language, the terms “agri-food industry”, “food” or “agri-food system” (Baregheh et al., 2014; Dasgupta et al., 2015; Grandori, 2015; de Souza Filho & Miranda, 2019; El Bilali, 2019) are used as synonyms, contributing to confusion. It is therefore necessary to begin to overcome this first conceptual obstacle, trying to provide a definition of the boundaries of the agri-food sector.

In recent years, with the emergence of new consumer needs and technological progress, it has become necessary to include in the agri-food sector also services related to control and certification and agri-food safety, as an essential aspect for the design and reorganization of the agri-food supply chain. The agri-food sector therefore includes all organizations and actors that are directly and indirectly involved in satisfying the food needs of a country or territory. A further complexity in the study of the agri-food sector is linked to the intrinsic characteristics of the sector itself. The deterioration of fresh products in a short time, heterogeneity of products, control of diseases or parasites, dependence on weather conditions is just some of the intrinsic complexities of the sector and challenges that agri-food organizations must face daily. All this determines, along the entire food supply chain from the producer to the final consumer, the coexistence of organizations, often small or medium-sized, that adopt different organizational models, strategies and procedures. Unlike other mature sectors, the organizations that populate the agri-food sector have remained largely family-run (European Commission, Eurostat 2022).

2 Theoretical framework

2.1 Regulatory framework in the agri-food business system

Over the past three decades, the agri-food sector has undergone a significant paradigmatic transformation, catalyzed by the introduction of the European Green Deal and, more specifically, by the “Farm to Fork” Strategy [N. Lucifero; S. Carmignani]. This initiative, embedded within the broader framework of the European Union’s sustainability policies, has entailed a substantial reconfiguration of the entire agri-food supply chain (Albisinni; E. Rook Basile]. The Strategy, through its multidimensional approach to environmental, social, and economic sustainability, has impacted each stage of the chain—from the production phase, such as the selection of methods and inputs, to commercialization, including, for instance, the application of green claims, and finally to the management of surplus, by-products, and waste[P. Borghi, I. Canfora, A. Di Lauro, L. Russo]. Such end-of-chain management is increasingly influenced by the principles of the circular economy, which promote the reuse of materials—within the agri-food sector or in other industries—through the support of technological innovation.

The emerging regulatory framework arising from this green strategy is characterized by a holistic and systemic approach that seeks to reconfigure sectoral practices in alignment with the overarching objectives of climate neutrality, biodiversity preservation, and the promotion of fair, healthy, and environmentally respectful food systems [L. Costato, F. Albisinni; N. Ferrucci]. In this context, the EU legislator has adopted a number of legal instruments impacting the entire value chain. From primary production to marketing, from processing to final consumption, each phase is increasingly regulated in accordance with sustainability and efficiency criteria. Regulation (EU) 848/2018 on organic production and labelling of organic products [N. Lucifero], and Directive (EU) 2022/2464 on corporate sustainability reporting (CSRD), exemplify how EU law integrates sustainability into both input selection and strategic communication processes [S. Bolognini].

This evolution of the regulatory framework in a “green” direction has stimulated the adoption of sustainability certifications, non-financial disclosure obligations, and environmental labelling, which are reshaping organizational conduct beyond the mere logic of compliance [A. Jannarelli]. For example, environmental claims and labelling mechanisms—soon to be further regulated by the Green Claims Directive (COM/2023/166)—are gradually redefining consumer engagement and inter-firm communication within the supply chain. Regulatory design thus acts as a catalyst for both institutional isomorphism and innovation.

At the same time, public procurement rules incorporating environmental criteria (so-called CAM – Minimum Environmental Criteria), incentives for sustainable investment, and funding mechanisms under the Common Agricultural Policy (CAP) reinforce the legitimacy and diffusion of sustainability-oriented models. Law, in this sense, operates not only as a constraint, but as an enabler and disseminator of new organizational logics [A. Germanò; L. Russo].

Among the most transformative dimensions of this legal-institutional evolution is the codification of circular economy principles in the governance of agri-food waste. Through the EU Circular Economy Action Plan and

amendments to Directive 2008/98/EC on waste, the Union has introduced a new legal hierarchy in food waste management, prioritizing prevention, reuse, and valorization over disposal [F. De Lenonardis].

This framework has been implemented at national level through legislation such as Italy's Law No. 166/2016 (the "Gadda Law"), which facilitates the redistribution of unsold food and the valorization of by-products. These legal instruments operationalize circularity by defining "by-product" and "waste" categories, thereby enabling their reuse within or across industrial sectors (e.g., as feedstock, bioplastics, or energy). Simultaneously, the legal articulation of circularity entails significant interdependencies with food safety law, which delineates the conditions under which reuse is legally permissible. These constraints reflect a broader regulatory tension between risk governance and resource efficiency, which supply chain actors must manage strategically [S. Manservisi].

In this regard, digital technologies such as blockchain, the Internet of Things (IoT), and artificial intelligence (AI) are assuming an increasingly central role in the implementation and traceability of sustainable practices. On one hand, such technologies enable compliance by facilitating traceability, predictive inventory management, and loss prevention [M. Ferrari]. On the other hand, they require new regulatory standards on data governance, liability, and interoperability across digital platforms. Thus, regulatory innovation must keep pace with digital innovation to ensure that legal frameworks remain fit for purpose.

The integration of predictive analytics and real-time monitoring into legal risk management systems is also transforming how companies operationalize compliance. For instance, smart contracts may automate regulatory obligations, while AI-based systems can generate compliance reports aligned with CSRD and ESG metrics. These developments suggest an increasingly techno-mediated form of regulation and open new pathways for organizational adaptation and legal design.

Despite substantial progress, the evolution of sustainable law in the agri-food sector remains marked by institutional fragmentation and heterogeneous enforcement across Member States. Variability in administrative capacity, divergent national implementations, and overlapping sectoral regulations may generate legal uncertainty and compliance asymmetries along transnational supply chains.

To mitigate such frictions, recent EU efforts aim to promote regulatory harmonization and coherence, including through initiatives such as the Digital Product Passport and the food waste monitoring and reporting. From an institutional theory perspective, these harmonization efforts reflect a transition from soft law to hard law instruments, intended to stabilize expectations and reduce institutional ambiguity in the agri-food domain.

The legal transformation of the agri-food chain—understood as a process of institutionalizing sustainability norms—constitutes a cornerstone of the systemic transition toward food systems that are just, inclusive, and regenerative. Law does not merely reflect societal change, but actively constructs the frameworks within which new practices become legitimate, widespread, and routinized [I. Canfora; L. Paoloni].

The agri-food supply chain thus becomes a locus of legal experimentation, where the design of rules, incentives, and sanctions interacts dynamically with organizational innovation and digital technologies. From this perspective, sustainability in the agri-food sector cannot be achieved solely through technical optimization or moral persuasion: it requires a coherent, enforceable, and adaptive legal architecture that acknowledges the complexity and pluralism of the food system.

2.2 Knowledge management in agri-food business system

The affirmation of the principles of the knowledge economy inevitably requires a rethinking of traditional management and organizational models, in favor of new models based on the valorisation of knowledge. The competitiveness and survival of companies, therefore, is based on the organizational capacity to valorise existing knowledge, introduce new knowledge and trigger it in production processes. In traditional sectors, such as the agri-food sector, characterized by managerial practices with a low rate of innovation and knowledge, the introduction of new knowledge management practices can represent the real new challenge of the sector, capable of determining the survival or otherwise of organizations. Several studies (Gaziulusoy et al., 2013; Vesperi and Coppolino, 2022) have highlighted that the sector is not able to generate new knowledge and innovation alone. Knowledge can be acquired through, or together with, partners thanks to complementary relationships (Chesbrough, 2006), generating new sustainable value. This determines that agri-food organizations must base their competitive advantage on knowledge obtained from third-party and shared organizations. It is important to highlight that from a KM perspective, the mere existence of knowledge within an organization is not a sufficient condition to generate a competitive advantage. For knowledge to be transformed into a lever for competitive advantage, it must be managed in a systemic manner. In fact, in agri-food organizations, knowledge is present in different forms (tacit/explicit; technical, relational, etc.); but the real obstacle lies in the difficulty in introducing knowledge and innovation into production processes, starting a

virtuous circle of increase in knowledge possessed. On the other hand, organizations belonging to the agri-food sector are slower in absorbing new knowledge and adopting new technological solutions compared to other sectors.

As evidence that the agri-food sector is not a static sector but a dynamic sector and highly vulnerable to socio-economic dynamics, it is possible to identify some future development paths of the food system. The growing attention of consumers and policy makers on factors such as food safety and food waste is imposing the spread of sustainable food systems (Esposito, et al., 2020); circular (Aznar-Sánchez, et al., 2020) and sustainable (Garnett, et al., 2013; El Bilali, et al., 2019).

3 Methodology

The main objective of this study is to define and explore the main elements of the agri-food business system. To achieve this goal and considering the intrinsic complexity of the agri-food business system, it has determined the use of an exploratory approach based on a qualitative methodology. A qualitative approach, in fact, allows to explore the richness and variability of phenomena without limiting oneself to numerical or standardized measurements, offering a more detailed view of the processes, relationships and practices that define the agri-food system. This approach allows to collect preliminary data and information useful for the formulation of future theories and for the identification of emerging themes within the agri-food system. This approach allows to deepen the meaning attributed by the participants to complex phenomena such as sustainability, innovation, and organizational challenges in a constantly evolving global context.

The secondary sources used in this study include a variety of documents, such as industry reports, academic articles, official publications of government bodies and reports of trade associations. These documents were analyzed to identify trends, challenges and opportunities within the agri-food business system, as well as to gain an in-depth understanding of the main actors involved, such as producers, distributors, consumers and regulatory authorities. Furthermore, the analysis of secondary sources allowed to reconstruct the history and evolution of the agri-food system, in relation to economic, social and environmental dynamics. Another central aspect of the data collection was the analysis of the legislation on agriculture, food and sustainability. This analysis involved the review of national and international laws and regulations governing the agri-food sector.

4 First results and discussion

The agri-food business system takes on a strategic importance in terms of economic impact, and also on the system of health and collective well-being. In fact, the agri-food business system, comprising a multitude of organizations, from micro-enterprises in the primary sector to large and maxi-enterprises in the secondary sector, from those that deal with direct cultivation to those that deal with fourth-range production and physical distribution of products, highlights the extreme heterogeneity of the organizations present, of different sizes, where the use of technologies ends up making the difference, completely changing the added value produced. With respect to this heterogeneity, the dynamics of change end up having very different repercussions in the agri-food business system, forcing the organizations that are part of it to continuously review the structures and organizational models adopted, in search of ever new paths of growth and development.

The results of this study highlight the importance that “knowledge” plays within organizations. By focusing on the agri-food business system, and on the organizations that are part of it, knowledge takes on an even more relevant role. In fact, the heterogeneity and plurality of organizational models, and their hybrid forms (Touzard, et al., 2015; Ménard, 2018), imposes the need to rethink knowledge based on the specificities of the agri-food business system. For this reason, to analyze the connotation that knowledge takes on, it is necessary to enrich the analysis perspective. From the perspective of knowledge management theory, individual knowledge of organizations that make up the agri-food business system can be considered as a set of knowledge and skills that derive from experience and learning in the field, generally indicated with the term know-how (Nonaka, 1994), which helps the individual to carry out their tasks. Individual knowledge recalls the widely discussed concept of explicit knowledge and tacit knowledge but, at the same time, highlights that individual knowledge within the organization is not present in a uniform manner. The asymmetric distribution of knowledge manifests itself with a concentration of knowledge in a few individuals, making it difficult to transfer (Davenport & Prusak, 1998; Adam & Lamont, 2003), identify and exploit existing knowledge sources within the organization. This aspect justifies the constant interest of management and organizational theory scholars in analyzing the ways in which it is possible to facilitate the processes of knowledge creation and transfer. The agri-food organization, therefore, can be considered as an aggregate of individual knowledge, distributed in a non-uniform manner within itself, and on which its survival and competitiveness in the business system depends. Consequently, this

condition helps to explain the differences, in terms of performance and behavior, that are found between different units of the same organization.

Following this perspective, the agri-food business system can be understood as a set of actors, which by integrating upstream and downstream, through interorganizational relationships generate an environment of open innovation (so-called open innovation) in the agri-food business system (Solarte-Montufar, et al., 2021; Oltra-Mestre, et al., 2021). In recent times, open innovation has also become increasingly important in the agri-food business system. In fact, the study by Sarkar and Costa (2008), demonstrates a rapid growth in the number of open innovation projects that occur within the agri-food business system (Ferreira & Teixeira, 2019).

This configuration can explain the existence of a concentration of organizations, which within the agri-food business system, have the primary objective of providing new knowledge and support networks for R&D activities (Touzard, et al., 2018). Agri-food organizations, therefore, thanks to inter-organizational relationships with research centers, consulting firms, universities and researchers are able to respond to new competitive paradigms. However, for agri-food organizations to benefit from them, they must be able to collect, systematize, categorize, disseminate and exploit the knowledge that can be generated from external sources (O'Connor & Kelly, 2017; Agostini, et al., 2020). Agri-food organizations must, therefore, explore and exploit the available knowledge (Ciampi, 2017; Rialti, et al., 2018; Condor, 2020), implementing an adequate innovation management system to get the most out of collaborative relationships with external partners.

The regulatory evolution outlined above is expected to generate systemic outcomes that go beyond mere compliance, contributing to a structural reconfiguration of agri-food supply chains in terms of sustainability, resilience, and innovation capacity

In the medium to long term, the consolidation of sustainability principles within EU law is likely to produce various positive externalities: environmental (reduction of greenhouse gas emissions, resource efficiency, biodiversity conservation), economic (value creation through circular processes and short supply chains), and organizational (enhanced coordination, data-driven decision-making, and vertical integration of sustainability standards). In particular, the institutionalization of food waste prevention as a legal objective redefines the contours of responsibility across the supply chain, fostering co-responsibility, transparency, and efficiency.

From a regulatory perspective, two major developments can be foreseen. First, the shift from voluntary commitments to binding obligations will transform sustainability from a reputational asset into a legal requirement, thereby raising the stakes for organizational adaptation. Second, the integration of digital technologies into compliance systems will likely become standard practice, requiring clearer legal standards on interoperability, liability, and data ownership in multi-actor platforms.

In light of this, several policy recommendations can be formulated. At the EU level, it is crucial to promote regulatory convergence and reduce interpretative uncertainty, particularly in areas such as waste/by-product classification, data governance, and ESG reporting frameworks.

At the national level, legislators should support SMEs in the sustainability transition by providing legal and technical assistance, fiscal incentives, and capacity-building programs. Dedicated support mechanisms—alongside those provided within the framework of the Common Agricultural Policy—are essential to prevent regulatory asymmetries and to ensure equitable access to innovation across the supply chain.

For supply chain actors, a proactive approach is strongly recommended. Legal compliance should be perceived not as a constraint but as a lever for innovation and inter-organizational alignment. The establishment of compliance-by-design mechanisms, the use of digital compliance tools, and participation in public-private governance platforms can enhance adaptive capacity and strategic positioning.

Ultimately, a resilient and sustainable agri-food system requires a legal ecosystem that is not only prescriptive but also enabling—capable of evolving in step with technological change and organizational complexity, while remaining anchored in the normative goals of justice, inclusion, and ecological responsibility..

The Kilowatt Project: An Overview about Aims, Tools, and Key Activities

Francesco Santoro, Ada Biafore, David Toscano
Itaca S.r.l., Rende (CS), Italy

Abstract

The distribution of fresh products presents unique challenges. Kilowatt specifically aims to: optimize and improve the logistics management of the fresh product supply chain; support processes that ensure the quality and organoleptic and nutritional properties of food; reduce food waste; maximize the energy recovery of waste.
The key points of the project can be summarized as follows: business model innovation, enhanced environmental and social sustainability, optimization of the distribution chain, Smart Packaging design, and waste recycling.
The development of the new business model will focus on offering high-quality products certified for safety, authenticity, environmental impact, and strong market orientation. These products will be strategically placed in various outlets based on real-time demand analysis. A sustainable and ethical approach to food marketing will be promoted, with an emphasis on recovering waste materials to produce alternative energy, as well as redistributing unsold products to the third sector to benefit vulnerable groups in society. Logistical activities for goods distribution will be optimized to reduce travel distances, enabling the planning of deliveries over a longer time horizon, minimizing store visits, and reducing the risk of unsold goods. Finally, smart packaging systems, composed of active wrappers designed to extend product shelf life and integrated with IoT sensors for monitoring, will be developed. Additionally, digestion matrices will be defined to maximize the energy produced from food waste.

Keywords: Sustainability, Optimization, smart packaging, sensor data, waste minimization

Paper type: Practical Paper

1 Introduction

The Kilowatt project (smart pacKagIng and Logistics for food waste reduction) is focuses on redefining the processes involved in the storage, preservation, sale, and disposal of perishable agri-food products within large-scale distribution networks. By leveraging Internet of Things (IoT) technologies and real-time data transmission, the project aims to reduce food waste, minimize environmental impacts, and enhance energy recovery from food scraps.

The project (started in 2024 and running until 2026) has been funded by the “Ministero delle Imprese e del Made in Italy” under the "Accordi per l'innovazione" initiative. It was selected as part of a call for proposals aimed at funding industrial research and experimental development activities, designed to create new products, processes, or services, or significantly improve existing ones, through the development of key enabling technologies (KETs).

Through its innovative solutions, Kilowatt aims to contribute to advancements in sustainable agri-food logistics, smart packaging, and waste reduction, fostering technological progress in the areas of environmental sustainability, energy efficiency, and circular economy practices.

In Italy, sustainability in large-scale distribution is addressed by only 16% of operators, and their efforts tend to focus more on the use of eco-friendly packaging rather than energy consumption, especially related to transportation. The fresh produce supply chain, in particular, is a high-energy impact sector due to the perishable nature of its products, which require daily deliveries in large volumes. The environmental impact of transport, along with the waste generated from product deterioration at the point of sale, represents a significant issue that needs to be addressed. Kilowatt aims to solve these challenges by incorporating “smart” systems that manage stock, packaging, and sales processes. These smart solutions will allow for prolonged product integrity, improved logistical efficiency, and the integration of advanced technologies within the supply chain to enhance delivery processes.

The project involves strong collaboration among the co-proposing partners, including two universities (UNICAL e Università del Sannio) and two IT companies (Itaca and Consoft Informatica). Each partner will contribute specialized knowledge and experience not only in their areas of expertise but also in close cooperation with others.

The project’s broader goal is to integrate enabling technologies and innovative approaches into the logistics of agri-food products, aligned with new, sustainable business models and optimized logistics chains. Ultimately,

the expected long-term result is the improvement of competitiveness and sustainability within national agri-food production, which will be achieved by reducing product loss and waste. This will be pursued through a comprehensive approach involving innovative interventions in various areas. Key objectives of the Kilowatt project include:

- Innovation in business models: A new business model will be developed, characterized by offering high-quality certified products. These products will be certified for safety, authenticity, and environmental impact, meeting the growing consumer demand for sustainable and ethical products.
- Optimization of distribution logistics: By optimizing distribution, the project aims to reduce fuel consumption, lower carbon emissions, and minimize the environmental footprint associated with transporting perishable goods.
- Improvement of sales forecasting models: The Kilowatt project aims to develop new, more accurate sales forecasting techniques that surpass the limitations of existing models. By improving the precision of demand forecasts, it will be possible to better align supply with real market needs, reducing the risk of product spoilage and waste.
- Enhanced product positioning through sensor data: Using IoT sensors, the project will monitor the conditions of products throughout the supply chain.
- Sustainable packaging solutions: The project places significant emphasis on improving packaging solutions to reduce waste and environmental impact. New biocompatible packaging materials will be developed and tested, which will help extend the shelf life of perishable products.
- Reduction of food waste and optimization of by-product reuse: The project aims to minimize food waste by ensuring that products are consumed before reaching their expiration date, reducing waste generated by spoilage.
- Social and environmental sustainability: The Kilowatt project places a strong emphasis on ethical and sustainable food commercialization. Beyond reducing food waste, the project aims to recover food scraps and by-products for the production of alternative energies, creating a circular economy that promotes the sustainable use of resources.

2 An overview: the context, the tools, the aims.

One of the major challenges in the food market is related to shelf life, a factor that becomes critical for fresh foods, especially when considering the need to supply distant markets (e.g., typical regional products), which require significant transportation time. The deterioration of food products slows down when the product remains intact and is transported and/or stored in controlled atmospheric and climate conditions (temperature and humidity). The goal of this initiative is to preserve the integrity of food products through the implementation of smart systems for inventory management, packaging, and certain sales processes, aimed at reducing food waste.

Companies in the food and beverage sector, as well as large-scale retail (GDO), are increasingly committed to delivering fresh and high-quality products. Ensuring uninterrupted supply is therefore essential, which means the supply chain—internal or external—must leverage the most advanced technologies to support delivery operations. The entire logistics process for food products must integrate enabling technologies and smart systems with new sustainable business models and logistics chain optimization strategies.

In Italy, only 16% of businesses address sustainability through a dedicated internal governance model, focusing more on eco-friendly packaging than on energy consumption associated with product transportation. The fresh food supply chain is now consistently categorized as high-energy impact due to the perishability of products and the requirement for daily deliveries of large volumes. The environmental impact of transportation and waste due to product deterioration at points of sale are highly critical factors.

The use of solutions for fleet management, inventory control, and product distribution—both downstream and upstream in the supply chain—developed within the project, will enable the implementation of best practices and green supply chain initiatives. These practices can foster systemic growth by increasing the perceived value of purchased goods or services for the end user. This means increasing transport efficiency by avoiding empty returns, optimizing routes, and strategically locating warehouses and suppliers; as well as optimizing product and waste logistics (reverse logistics). Furthermore, optimized delivery systems—from distribution centers (Cedi) to points of sale (PDV), and from PDVs to end customers (e.g., home grocery delivery)—will reduce emissions and the environmental impact of the logistics chain.

All actors in the logistics chain must pursue a logistics model based on integration and collaborative networks involving companies, customers, and suppliers. The development of such solutions requires the definition of innovative optimization models that account for the specific characteristics mentioned above. Alongside these

models, heuristic and metaheuristic algorithms will be developed to efficiently solve the formulated optimization problems. The types of heuristics to be developed, implemented, and tested will be defined in the project's research activities.

The models will be based on data predicted using artificial intelligence techniques, so as to minimize the probability of unsold goods. For this purpose, forecasting paradigms based on both classical and modern AI methods will be used—particularly deep learning techniques. The project will explore innovative approaches that combine domain expert knowledge (e.g., rules) with historical sales and inventory data. These paradigms will be integrated with explainable AI techniques, such as abstract argumentation, to provide analysts with explanations of the forecasting results. This approach aims to improve the interpretability of forecasts and build trust in the models, ultimately enhancing decision-making effectiveness.

In terms of shelf life monitoring, IoT (Internet of Things) devices will be developed to track the remaining useful life of food products within at least one selected supply chain. These devices will enable Last Minute Market policies to be implemented under favorable conditions, thereby reducing the likelihood of unsold and wasted goods. Among the options considered is the donation of unsold products to third-sector organizations, which would serve a dual purpose: supporting disadvantaged individuals—especially during this socially critical time—and significantly reducing disposal-related costs for companies. These policies, to be implemented through appropriate sales channels, will be thoroughly studied and validated during the project.

The devices will be designed and integrated into biocompatible packaging, made from high-performance materials comparable to low-cost bio-polymer films with controlled gas permeability, enabled by a precisely regulated microstructure during the manufacturing process. These materials will ensure proper food preservation, equal to or better than traditional packaging, while being entirely biocompatible and aligned with 100% green environmental policies. Additionally, the materials will be designed to facilitate the integration of smart devices into packaging without altering it during application or post-sale recovery.

As for unsold products, they may be converted to energy through anaerobic digestion, following specific regulations and matrices that will be studied throughout the project. This approach seeks to maximize the energy recovery of unsold goods and thereby reduce the environmental impact caused by unsold inventory.

3 Methodology

The activities of the project are structured in 13 work packages, for each work package, the release of deliverables is defined in order to ensure communication between working groups and the conduct of cross-cutting activities. In this section we propose an overview of each work package.

1. The main goal of the first work package (*Definition of qualitative-quantitative models for sustainability and assessment socio-economic-environmental*) is to develop business and organizational models that allow for a systematic and integrated assessment of the sustainability and applicability of proposed innovations. This involves measuring and analyzing potential socio-economic and environmental impacts using both quantitative and qualitative methods. To achieve this goal, WP1 is organized into the following activities: - Analysis of the regulatory framework; - Development of Life Cycle Management models; - Definition of a scalable business and organizational model for process optimization aimed at reducing food waste; - Representation of the organizational and business model of the “market” for products nearing their expiration date; - Development of MCDA (Multi-Criteria Decision Analysis) models and optimization techniques to evaluate sustainability and performance; - Definition of sales policies from a Last Minute Market perspective; - Design and analysis of data collection through focus groups; - Identification and analysis of evolving scenarios in real-world contexts.
2. The aim of the second work package (*Design of a management and monitoring system for the shelf life of food products, with the valorization of food items no longer suitable for consumption for energy purposes*) is to tailor packaging performance to the specific needs of each food product, creating an interaction between the packaging and the food. Innovations include developing new materials that enable controlled release of antimicrobials, which extend shelf life by preventing bacterial growth. For example, the BioSwitch system releases antimicrobials on demand when external conditions (pH, temperature, UV) trigger it, increasing preservation stability while reducing chemical use. These antimicrobials are encapsulated in polysaccharide particles that break down in the presence of bacteria, releasing the antimicrobials precisely when needed. Regarding intelligent packaging, a focus will be on monitoring product shelf life through devices called Time Temperature Integrators (TTIs). These are adhesive labels that change color proportionally to the product’s exposure to temperature over time, indicating the product’s thermal history. Once programmed based on mathematical models, these labels provide non-reversible color changes, helping consumers identify safer, higher-quality products. The

ultimate aim of functional packaging (combining active and intelligent features) is to preserve food quality over time and increase consumer appreciation. These solutions respond to higher standards of hygiene, sensory quality, and usability by interacting with the product and its environment, often by modifying the "headspace" inside the package. To achieve this goal, WP2 is organized into the following activities: - Identification of kinetic degradation models; - Definition of development models for phytopathogenic microorganisms; - Comparative analysis of usable smart systems (labels, sensors); - Design of a system based on real data, focused on shelf life analysis; -Identification of mixtures of products no longer suitable for food consumption and characterization of the physical-chemical parameters of the matrices and mixtures used; -Batch evaluation of methane production from different matrices

3. The third Work Package (*Models and Algorithms for Inventory Management and Distribution Logistics of Perishable Products*), addresses the issue of food waste along the supply chain, emphasizing how the complexity and slowness of logistics processes negatively affect efficient stock management. The main cause of waste is the premature expiry of products in warehouses (about 70%), but inefficient distribution and delays also contribute significantly. To tackle these problems, the use of collaborative digital models is proposed, such as VMI (Vendor Managed Inventory), in which the supplier directly manages inventory at retail locations, optimizing replenishment and reducing both stockouts and unnecessary overstock. The goal is to create an efficient and sustainable logistics ecosystem between distributors (GDI) and points of sale (PDV), supported by demand forecasting models, transport optimization, and a strong focus on environmental impact. The importance of managing demand uncertainty is highlighted through the development of optimization models under distributional ambiguity, representing a new frontier in stochastic programming. Additionally, the integration of machine learning is proposed to accelerate the resolution of logistical problems and to identify useful patterns. Lastly, the development of a Last Minute Market logistics system is envisioned to enable the rapid sale of soon-to-expire products both in-store and online, using fast and environmentally friendly delivery models. The entire system aims to maximize both sustainability and operational efficiency. The activities planned for the completion of the WP are: -analysis of the state of the art on the inventory routing problem, VMI, and routing of perishable products; - definition of models and algorithms for product demand forecasting at Points of Sale; - definition of models and algorithms for the distribution logistics of perishable products.
4. The fourth Work Package (*Design of Biocompatible Smart Packaging Systems)* addresses advanced technologies in food packaging, including innovative extraction techniques, active nanoparticles, and sensors. These technologies aim to extend food shelf life and improve logistics. While petrochemical-based polymers have been widely used due to their cost-effectiveness and versatility, concerns over their environmental impact and poor biodegradability have led to a shift toward bio-based, low-impact materials, often sourced from agri-food waste (e.g., cellulose, starches, chitin, alginates, and proteins). The bioplastics market is growing and represents a sustainable opportunity.

Active packaging offers antioxidant and antimicrobial properties, while smart packaging can interact with the environment, such as changing color to indicate food spoilage. Smart packaging technologies are divided into data carriers, indicators, and sensors.

The design phase focuses on eco-friendly, food-compatible materials in line with EU regulations. Tested polymers include cellulose, PLA, lignin, starches, and proteins. There's also a push for digital integration between packaging and control devices (wireless/bluetooth) to optimize the supply chain and reduce waste and energy consumption.

The WP consists of the following activities: research on biocompatible materials and design of packaging for pluggable active devices.

5. The fifth Work Package (*Design of IoT Devices for Smart Packaging)*, is aimed at a comparative analysis of the available technology in terms of sensors, in order to identify the best starting solutions for the subsequent design of IoT devices. Based on the identified scenarios, it will be possible to define one or more IoT boards capable of measuring different parameters and/or managing different configurations depending on the type of product to be monitored. It will be necessary to specifically study the usage methods and develop biocompatible enclosures that can isolate the devices without contaminating the food, while still functioning correctly in humid environments and/or at low temperatures. To this end, research will be conducted on biocompatible materials suitable for 3D printing and their potential for creating enclosures compatible with the application scenarios outlined in the KILOWATT project, providing adequate protection and/or insulation. In this regard, the regulatory aspects studied in OR1 may offer useful guidance during the design phase. The WP includes the following activities: - Analysis

and research of devices, - Communication protocols in the IoT domain, - Design of an IoT board to support smart packaging.

6. The sixth WP is titled *Architecture Design and Requirements Definition* and involves analyzing the literature in the field of enterprise architectures and enterprise integration patterns, namely the most effective approaches for developing complex software systems and integrating heterogeneous subsystems in terms of data and functionality. It is structured into the following activities: - analysis of the state of the art in enterprise architectures and enterprise integration patterns; -definition of the high-level architecture and functional requirements; - study of the architectural components.
7. The objective of OR 7 (*IoT Device Prototyping*) is to prototype the IoT devices that will be designed in OR 6, and to implement the sensor network and all the tools for reading/accessing information. The following activities are planned: -prototyping of the boards; -firmware and protocol development; -development of libraries for data access and device registration; -definition of the integrated circuit.
8. WP 8 (*"Development of Algorithms for Inventory Management and Distribution Logistics – Inventory Managed"*) will implement an optimization system in the field of distribution logistics, based on the studies outlined in OR3, covering both application areas (from the distribution center to the point of sale, and from the point of sale to the end customer). The planned activities are: development of the routing subsystem and development of the optimization system for distribution logistics.
9. The objectives of WP9 ("Development of Decision Support Systems and Prototyping of Biocompatible Packaging") are the creation of prototypes that provide decision support functionalities for residual shelf life prediction and demand analysis, based on the techniques developed within OR2 and OR3, as well as the development of a biocompatible packaging prototype capable of integrating smart devices that supply data to the decision support systems. The activities planned are: - development of a software system for calculating residual shelf life based on data collected from smart devices; - development of a Decision Support System (DSS) for product demand analysis at points of sale (POS); -creation of a biocompatible package that can be integrated with a smart device.
10. WP 10 (*"Comparative Analysis and Design of User Experience and Sales Systems"*) aims at designing the User Experience for user interaction with the system and access to content and functionalities, both through web apps and mobile devices. This is based on the specific services already designed and defined in the earlier phases of the project, and is intended to support the product sales process.The OR is divided into three activities: -a comparative analysis of apps and sales systems in the food sector, as well as the technological solutions used to enable the sales process; -an analysis of the state of the art in UX methodologies, processes, and tools; -the design of the user experience and the definition of the graphical interfaces for the Kilowatt platform.
11. The objective of OR 11 (*"Development of IoT Sales and Monitoring Systems"*) is to create client systems that will effectively utilize the software solution in all its aspects. The activities will be carried out based on the architectural strategies defined in OR7 and the requirements, which are partly derived from the business models that have been appropriately implemented. The systems to be developed are as follows: - IoT monitoring platform; -device programming/configuration system; - e-commerce platform; -mobile app; -software module for VMI (Vendor Managed Inventory) distribution logistics.
12. The goal of WP 12 (*"Integration and Testing"*) is to define, design, and implement the integration infrastructure, using and applying the methodologies and technologies that represent the state of the art and best practices in architectural patterns, as defined in WP 6. The planned activities are: - analysis and design of the integration platform; -integration plan; -commissioning.
13. The last WP (*"Testing and Validation of Qualitative-Quantitative Models for Sustainability and Socio-Economic-Environmental Assessment"*) involves testing, validation, and verification of the qualitative-quantitative models for sustainability defined in OR 1, with the aim of measuring the potential benefits that can be achieved. The activities it is divided into are: -integrated sustainability assessment and definition of a communication plan for sustainability performance; -validation of the organizational and business model; - implementation and validation of Multi-Criteria and optimization models for sustainability and performance evaluation; -testing and validation of sales policies from a Last Minute Market perspective; - preparation of sustainability plans and porting strategies.

4 Conclusions

The expected result of the project is to improve the competitiveness and sustainability of national agri-food production linked to the reduction of the amount of product lost and/or wasted and pursued through a coherent set of innovative interventions:

- the optimization of logistical activities of fleet handling, both upstream and downstream, through the implementation of appropriate models and algorithms designed to reduce emissions dueto transport activities;
- the definition of models and techniques for forecasting sales at the different points of the network that,by combining the characteristics of qualitative and quantitative approaches, overcome the limits of applicability of existing techniques and their accuracy;
- definition of models and techniques for calculating explanations of sales forecasts provided;
- the enhancement of the suitability of territories propaedeutic to the creation of added value linked to the origin of products, as well as the improvement of their sustainability thanks to more efficient interrelationships between agroecosystem and production process;
- the optimization of the positioning of the product in the different sales channels in terms of time/quality/price ratio, through a process of iterative refinement of the offer according to the information derived from the sensoristics that constantly monitor the products; The optimization of product positioning in different sales channels in terms of time/quality/price ratio, through a process of iterative refinement of the offer according to the information derived from the sensors that monitor products constantly;
- the improvement of the efficiency of the logistics and distribution system in terms of time, economic and environmental;
- the improvement of the packaging management process, thanks to new biocompatible packaging properly researched and designed;
- the reduction of costs in all segments of the supply chain resulting from the reduction of “waste” and to their reintroduction within the production and consumption cycle, through uses innovative uses for energy purposes.
- the achievement of biocompatible active and intelligent packaging from raw materials with high added-value from agrifood chain waste.
- the extension of the shelf-life of products in the supply chain thanks to the functionalisations operated on biocompatible packaging with direct decrease of waste in the supply chain starting from the end line to transportation, on-shelf and home-storage.

The new business model developed will feature:

- an offer of high-quality products certified for safety, typicality and environmental impact and accompanied by a range of additional information that will also be enhanced by new information and communication technologies;
- a strong market orientation, in terms of demand analysis and addressing consequential supply, through vendor managed inventory routing algorithms,that is, capable of placing products on different outlets based on the analysis of actual demand;
- a sustainable, eco-friendly orientation aimed at reducing the environmental impact of the logistics distribution, but also to the recovery of waste materials for the purpose of producing alternative energies;
- an ethical and socially inclusive orientation, aimed at recovering unsold products and products nearing close to expiration, to be allocated to third sector organizations that work in defense the weaker sections of society;
- an impact on consumer food culture, through the promotion of high-quality eservices and information related to the handling, storage and consumption of food products;
- an incisive impact on the relationship between raw materials and products actually consumed through the reduction of supply chain waste;
- an impact on the nutraceutical qualities of products through the active-packagings used.

SME Performance through Modern Technology and Sustainable Business Strategies

Gabriela Citlalli López Torres[1], Octavio Hernandez Castorena[1], Alba Rocio Carvajal Sandoval[2]
[1]Universidad Autónoma de Aguascalientes, Mexico
[2]Universidad Pontificia Javeriana, Bogota, Colombia

Abstract

This research aims to analyze how operational sustainable business strategies and modern technologies, including employee training influence performance. The methodology is a quantitative approach with a cross-sectional design. Data was collected from 207 SMEs in Aguascalientes, central region of Mexico, through a survey administered to managers or those responsible for operations (INEGI, 2024). The data will be analyzed using EQS software to assess the relationships between the variables. This research aims to provide valuable insights into the factors contributing to firms' operational performance success. The research model will be assessed by the reliability and validity of the measurement instruments using Cronbach's Alpha, Dijkstra-Henseler's rho, Composite Reliability Index, and Average Variance Extracted (AVE). So, the analysis will ensure that the constructs are distinct and not overlapping. The good fit for the proposed theoretical model will be evaluated to suggest that the relationships between the variables were adequately represented (Henseler et al., 2015). The study focuses on the crucial role of sustainable business strategies in enhancing the operational performance of SME (Buttle & Maklan, 2019; Marr, 2016; Marston et al., 2011; Sutherland, 2019). The results obtained in this study indicate that, on the one hand, the factor loading of the variables is within the norm and, on the other hand, sustainable business strategies do have a significant impact on the performance of operational activities in this type of company. This means that for manufacturing SMEs, it is very important to have a sustainable environment that allows all of their operations to be focused on the performance of their internal operating systems. The data collection period was between March and May 2024, considering a stratified random sample of companies within the state of Aguascalientes.

Keywords: SME Performance, Sustainable Business Strategies, Modern Technology, Operations Management, EQS.

Paper type: Academic Research Paper

1 Introduction

This study investigates how factors like **sustainable business strategies and modern technology that include employee training** impact the performance of Small and Medium Enterprises (SMEs). The management and control of resources, especially human resources, are crucial for companies, as they ensure the fulfillment of business commitments and customer satisfaction while prioritizing employee safety (Gavilanes-Lagla Marco A. et al., 2021; Herrera-González & Quesada, 2013). Firms must ensure reliable processes, sustainable business strategies, adequate capacity to meet market demand, and the integration of appropriate technological advancements to remain competitive (Baker, 2006; Chams & García-Blandón, 2019; Ringvold et al., 2023; Vollenbroek, 2002). Managers need to focus on process control, capacity analysis, and staff training to meet customer needs without compromising quality (Argote & Ingram, 2000; Jones & Craven, 2001; Vidal-Salazar et al., 2012).

Increasingly, firms are concerned with sustainability in their operations and environmental impact (Banerjee, 2002; Lawrence & Lorsch, 1967; Porter & van der Linde, 1995). Studies show that sustainable business practices, like energy conservation and waste reduction, help achieve environmental goals while also enhancing operational efficiency and cutting costs (Li et al., 2020). Process flexibility and production capacity improvement are crucial for adapting to market demands and maintaining competitiveness (Ibero-American General Secretariat, 2023). It **highlights the importance of sustainability in business operations and emphasizes the need for continuous improvement and adaptation to thrive in a dynamic and competitive environment.**

Technological improvements are essential for productivity, product design, equipment upgrades, and process reliability (Boudreau & Robey, 2005; Mikalef & Pateli, 2017). Higher corporate sustainability performance has been linked to innovation and technology within firms (Wang et al., 2020). Managers must assess whether their staff is adequately trained and aware of the importance of sustainability and proper material handling (Guzman et al., 2016; Kiseľáková et al., 2018). Technology has several benefits from various perspectives, from information management to collaborative experiences between company workers and

customers. Among these benefits is the automation of repetitive tasks, which increases efficiency and reduces operating costs. Similarly, processes can be made more efficient through emerging technologies, such as the Internet of Things, (Laudon & Laudon, 2012) *blockchain*, among others, by providing greater real-time visibility and traceability of products or services in companies (Christopher, 2011).

2 Theoretical framework

- Nowadays, every organization is committed, not to mention that it is obliged to meet the objectives proposed in a community and environment so that benefits are achieved not only within the organization but also with its environment, in economic, operational, logistical terms and of course in the aspect of sustainable development, (Hahn & Figge, 2011). After the pandemic, these elements have been key to sustainable improvements in companies committed to continuous improvement in general terms, since the environment in particular requires it due to its importance and because organizations must offer products as well as services not only of good quality but free of processes that affect the environmental environment that affect the health status of their workers. the natural environment, the environment and of course that this impacts on its low financial and operational performance, (Munro, 2020; Gatto, 2020; Saavedra, 2022).
- Worldwide, if there is the demand for competitiveness on the part of companies outside of their work activities since performance is considered implicit and this performance of course applies to all their functional areas both on the operational and administrative side, and as companies in this case manufacturing we think about the aspects focused on the management of operations highlighting supplies, operations, quality and maintenance, activities that in their nature of work, have a special relationship with the environment and potential waste due to the auxiliary materials that are used, which leads to think about an improvement where sustainable business strategies that are significant in the performance of the organization and therefore, in business competitiveness, (Freshness, 2007; Maffini, Kruglianskas, Scherer, Da Luz Neto, & Marques, 2013).
- In this sense, for manufacturing SMEs, it is important that within their business strategies they take into account the development of sustainable businesses, since it is not enough only to have organized and reliable processes but that these are organized in such a way that each part of the operational process is with the care required by the nature of the process where either for aspects of quality or certifications, it is guaranteed that at each stage there is no damage to the environment or to sustainable aspects since it is natural for companies to integrate technological and innovation improvements but that they do not affect the environment and that they are reliable, competitive companies with a performance in accordance with their business guidelines and objectives, (Saavedra, 2022). It is important to highlight that sustainability improvements in companies should not only focus on operational processes but also on all activities of the organization so that there is a better role in the sustainable development of the company, (Bercovich & López, 2005; Lawrence, Collins, Pavlovich & Arunachalam, 2006; Samier & Qian, 2010).

It is important to point out that companies such as manufacturing SMEs in particular, in their management of operations not only operational but also financial, for their permanence in business they need performance and competitiveness and this performance is of course operational where adequate strategies are involved in supplies, control of materials, successful use of technologies, an adequate quality system, good control of operational indicators that have an impact on the needs of the customer as well as an efficient system of sending products to the customer, but it is also important to reflect all this operational activity in a solid financial performance without neglecting the good results that have been obtained by having a good sustainable performance as long as it is considered in the companies, (Mohammend, 2019; Amedu, Llemena, & Umaigba, 2019; Buchholz, 2020; Keskin, Dincer & Dincer, 2020; Mahmood, Qadeer, Saleem, Han & Ariza-Montes, 2021; Wong & Ngai, 2021; Chakroun & Ben Amar, 2022).

The growth of companies certainly depends on the internal strategies generated by the managers of these organizations, on the preferences of the market as well as their direct customers but also on the effort and commitment of their workers, and if they are integrated into the policies and needs of the company considering their job stability as well as support for the initiatives that are generated internally. the effect on the outside will be reflected by projecting a sustainable environment that does not affect the environment, (Saavedra, 2022). Having companies with sustainability strategies is not only that it is a clean and pollutant-free company, they must be strategies that have an impact on future generations where the needs of each company are not neglected, considering that sustainability must focus on the environmental but also on the social and economic, (Saavedra, 2022).

The purpose of this study is to analyze the impact of sustainable business strategy on the performance of the activities of companies such as the manufacturing SME in the state of Aguascalientes in Mexico (Quinn and Rohrbaugh, 1983; Pereira, Claver, Molina, & Tari, 2012; Saavedra, 2022), and in this sense the following hypothesis is raised:

- *H_1: The sustainable business strategy has a positive impact on the performance of the manufacturing SME in Aguascalientes.*

3 Methodology

For this study, a theoretical model was designed that has the purpose of analyzing the impact that sustainable business strategies have on the performance of the Manufacturing SME in the state of Aguascalientes, where a measurement instrument sent to the managers of this type of companies in the period between March - May 2024 was also designed and applied. period in which the data collection was carried out. For this analysis, the database offered by the Business Directory of Aguascalientes (Inegi, 2024) was taken as a reference, which mentions the following:

- Population of 445 SMEs in the Manufacturing sector.
- Application of the study with 207 in a stratified sample.
- 95% confidence level.
- 5% error.
- The study has a quantitative approach.
- Deductive, descriptive and correlational methodological design.
- Data collection was cross-sectional.

For the measurement of the variables in this research, the survey was divided into 2 blocks of which are mentioned below:

1. Block I: ***Sustainable Business Strategies***, measured with 12 variables (Pereira, Claver, Molina, & Tari, 2012).
2. Block II: ***Performance***, made up of 12 variables (Quinn and Rohrbaugh, 1983). The variables were measured with the Likert scale 1-5.

Likewise, for this research work, a theoretical model was designed which contains the two main blocks of Sustainable Business Strategy and performance, which is shown in Figure 1

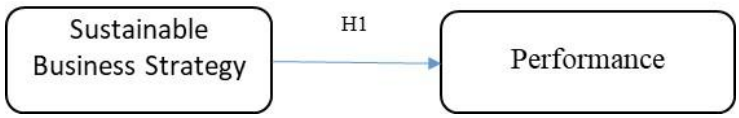

Figure 1: Theoretical Model of Research Work

Source: Adaptation of Hernández from Pereira, Claver, Molina y Tari, 2012 and Quinn y Rohrbaugh, (1983).

4 Analysis and Results

With the data obtained from the fieldwork and subjected to statistical treatment, a Confirmatory Factor Analysis (CFA) was performed in order to analyze and evaluate the reliability as well as validity of the measurement scales used in the theoretical model in Figure 1. Likewise, the statistical analysis of Structural Equations was also carried out, to check if the structure of the Model is correctly designed considering the support of the EQS version 6.1 software. Within the analysis to evaluate the reliability of the model, Cronbach's Alpha coefficient (Frías, 2014), and the composite reliability index (IFC) were used; (Bagozzi and Yi, 1988; Hatcher, 1994; Escobar, Cárdenas, & Aguilar, 2016). Table 1 shows the values of Cronbach's alpha and the Composite Reliability Index (CFI) of each construct, which meet the recommended level of 0.7 of reliability (Nunnally, 1967; Fornell & Larcker, 1981; Nunnally & Bernstein, 1994; Hair *et al.*, 1995) and the analysis suggests that the model provides an acceptable fit, which is shown below:

S-BX2 (df = 103) = 222.9972; p < 0.0000; NFI = 0.891; NNFI = 0.928; CFI = 0.938; RMSEA = 0.075

The variables of the two blocks that represent the theoretical model are significant ($p < 0.05$), the size of all the factor loads as can be seen in Table 1, in each indicator are greater than 0.6 (Bagozzi and Yi, 1988) and the index of variance extracted (IVE) of each pair of constructs is greater than 0.5 recommended by Fornell and Larcker (1981). The complete result of the analysis can be seen in the following table 1:

Table 1 Internal Consistency and Convergent Validity of the Theoretical Model

Construct	indicator	t robust	CF > 0.6 factor loading	Squared factor loading	Mean factor loading	error	aver error	Alpha Cronbach > a 0.7	IFC > a 0.7 Composite Reliability Index	IVE > a 0.5, Variance Extracted Index
Sustainable Business Strategies (F1)	GA01	1,000	0,810	0,656	**0,837**	0,344	**0,710**	0.966	0,966	0,704

* = Parameters bound to that value in the identification process, , *** = p < 0.001

Source: Own Elaboration

Respect the discriminant validity analysis, Table 2 indicates through two tests. On the one hand, with a 95% reliability interval, none of the individual elements of the factors contains a value of at least 1.0 (Anderson and Gerbing, 1988) and secondly, the test clearly shows that the variance extracted between each pair of constructs in the model is greater than its corresponding Variance Extracted Index (Fornell and Larcker, 1981). Therefore, it can be concluded that this research work shows sufficient evidence of reliability and convergent validity, as well as discriminant validity in the construction of the theoretical model

Table 2 Discriminant Validity of the Theorical Model

Factores	**F1** ***Sustainable Business Strategies***		**F2** ***Performance***
F1 *Sustainable Business Strategies*	**0,672**		(0.648)2
			0,420
F2 *Performance*	0,648	0,098	**0,690**
	0,452	**0,844**	

Source: Own Elaboration

The diagonal represents the Extracted Variance Index (IVE), while above the diagonal is shown the part of the variance (The correlation to the table). Below the diagonal, the estimate of the correlation of the factors with a 95% confidence interval is presented. Within the analysis carried out to evaluate the Structural Equations model, it is intended to test and contrast the hypothesis raised, using the main blocks of: Sustainable Business Strategy and Performance. The nomological validity of the model was analyzed through the performance of the Chi-square test, in which the theoretical model was compared with the model's measurement (Anderson & Gerbing, 1988; Hatcher, 1994), see table 3.

Table 3 Results of the Hypothesis Test of the Theoretical Model

Hypothesis	Structural Relationship		Standardized Coefficient	Robust t-value	FIT measurement
H1. The sustainable business strategy has a positive impact on the performance of the manufacturing SME in Aguascalientes.	Sustainable Business Strategies	Performance	0.543***	17.514	S-BX2 (df = 100) = 216.5021; p < 0.0000; NFI = 0.894; NNFI = 0.928; CFI = 0.940; RMSEA = 0.075

Source: Own Elaboration

The hypothesis raised in this research work shows the following results: Hypothesis $\mathbf{H_1}$ refers to the result obtained presented in Table 3 ($\beta = 0.543$, $p < 0.000$), and this refers to the fact that Sustainable Business Strategies have a positive impact on the Performance of the manufacturing SME in the state of Aguascalientes, which indicates that approximately 54.3% of companies perceive the owners or managers responsible for operations in this type of companies that it is important to consider sustainable business strategies within their organizations to favor performance and further guarantee the fulfillment of the objectives that are organized so that these companies are increasingly competitive

5 Conclusions

Current times present dizzying changes in various directions that aim to have improvements of all kinds within organizations outside of their business activity. It is here where those responsible for this type of companies must have good control of the direction of their operations and in the particular case foresee significant improvements in what is of impact so that their effect on the customer and market is important since as leaders it is thought that everything is focused on supplies, productive operations and efficient quality systems since the customer certainly demands it at all times. Of course, everything is important because in order to have reliable operational processes that meet the needs of the customer, you must have excellent logistics and supply control where what is understood as TIME and FORM, is that the raw materials arrive on time but at the same time are received without defects.

Likewise, as what has already been mentioned is relevant for the competitiveness of this type of company, it is necessary and demanding that all internal activities are also evaluated in the sustainable aspect as a diagnosis where those areas of opportunity that require urgent and significant improvement can be appreciated since these improvements in sustainability have a positive impact on the economic and environmental aspects. The results obtained in this study indicate that for entrepreneurs responsible for operations in their organizations it is important to integrate as well as improve sustainable business strategies because they visualize a substantial performance that will have general benefits, which should be analyzed in detail in subsequent research to maximize in order to prospect these good foresight results that convince managers and all personnel regardless of their level within the organizational chart.

This means that we must work hard, first, as already mentioned, in making a diagnosis to detect areas of opportunity for improvement in sustainable matters, training all personnel where we work on the awareness of how necessary the environment is as well as the sustainable aspects and of course in implementing strategies that have performance effects as also commented both in the environment and in the economic. The important thing is that you have confidence in having consistency in frequent training with the internal staff of the company since you must have convinced each member of the work areas about the importance of having sustainable companies and of course having processes that are not polluting and this includes waste, so you must be very careful in the management of these during your operational activity. Managers undoubtedly have a challenge in their improvement and implementation of sustainable strategies to have reliable companies with high business performance.

Proposal for an Inclusive and Sustainable Telemedicine Ecosystem in Mexico

José Octavio Contreras Sánchez, Vianney Viridiana Contreras Sánchez, Francisco Javier Álvarez-Torres
University of Guanajuato, Guanajuato, Mexico

Abstract

The healthcare system in Mexico faces persistent and multifaceted challenges, such as the exclusion of vulnerable populations, limited access to medical services in rural and marginalized areas, and increasing pressure due to an aging population. The COVID-19 pandemic exacerbated these structural weaknesses, highlighting the urgent need to integrate innovative technological solutions that not only optimize available resources but also expand and improve access to healthcare services.

In response to these needs, a sustainable and inclusive telemedicine ecosystem was proposed, grounded in methodologies from Exponential Organizations (ExO), to ensure long-term scalability, adaptability, and effectiveness.

A diagnostic assessment using the Pan American Health Organization (PAHO) tool revealed a low level of technological maturity at the Centro Médico Puentecillas. To address these gaps, the CANVAS model was applied to redesign the center's business structure, incorporating ExO SCALE principles: staff autonomy, active community participation, and continuous user engagement.

Additionally, the proposal included the development of a digital platform for managing teleconsultations, telemonitoring, and teleassistance, integrating real-time clinical data collection to support evidence-based medical decision-making and preventive health monitoring.

The methodology focused on identifying key technological and organizational deficiencies, prioritizing intervention strategies such as digital literacy training for medical personnel and infrastructure enhancement to improve system performance and reliability.

Keywords: Telemedicine, inclusion, sustainability, Exponential Organizations, digital health, innovation, public health, technology.

Paper type: Academic Research Paper

1 Introduction

The COVID-19 pandemic exposed global weaknesses in public health systems, revealing structural deficiencies and a lack of resources (Gómez Vaca, 2020; Hernández-Aguado, 2021). This underscored the urgent need for technological innovation to improve healthcare coordination and effectively respond to health and economic crises (García Barbero, 2021; Nogueira et al., 2021).

In Mexico, approximately 41% of the population, especially in rural and indigenous areas, lacks effective access to public healthcare services, evidencing significant social exclusion (INEGI, 2016; Martínez et al., 2018). Low public investment (2.8% of GDP) and high out-of-pocket spending (45%) worsen this situation, resulting in deficient public care and high rates of home mortality (Hernández-Bringas, 2020; Chertorivski-Woldenberg et al., 2020). Non-communicable diseases now account for the majority of national mortality, reflecting a critical epidemiological transition (Hernández Lara, 2020).

Since the 1990s, Mexico has promoted telemedicine to address social exclusion and improve access to public healthcare (Martínez, 2018). However, the system now faces challenges arising from demographic transition and projected population aging between 2030 and 2050 (Murillo, 2022).

The state of Guanajuato possesses a robust health system with 631 public units distributed across 46 municipalities, including hospitals and specialty medical centers (Cano et al., 2023). It also stands out for its potential in applying technological innovation to health, which is essential for its socio-economic development.

During the pandemic, the relevance of telemedicine was further highlighted, especially in Latin America, where mortality rates were particularly high (Romero, 2021). During this period, several barriers were eliminated to facilitate its implementation, such as reimbursement issues and licensing restrictions (HIPAA, 2020).

International telemedicine models have proven effective in enhancing access and quality of healthcare. In the United States, the Mercy Virtual Care Center uses remote monitoring and big data to reduce hospitalizations (Mercy, n.d.; American Hospital Association, 2016). China connects thousands of rural and urban hospitals via teleradiology (China Daily, 2020), while Norway integrates teleconsultation and monitoring into its public system

(WHO Europe, 2024). In Latin America, TeleSaúde Brazil enhances primary care through teleconsultations (Pfeil et al., 2017). These examples underscore the importance of adapting technology, training personnel, and maintaining strong regulatory frameworks.

In light of the above, this paper proposes the integration of a telemedicine system in the Centro Médico Puentecillas (CMP), located in Guanajuato capital, Mexico, to address current challenges in access and healthcare efficiency. Drawing on an analysis of successful international models, a strategy is proposed to expand CMP's medical coverage using digital tools, with a focus on strengthening primary care. The proposal includes not only technological implementation but also an educational component aimed at training patients in the proper use of digital services, fostering self-care, and enhancing responsiveness to their health needs. This aims to move towards a more accessible, efficient, and sustainable healthcare system.

2 Telemedicine Components and Services

Components of e-Health Scott and Mars (2010) identified four main components within the field of e-Health. The first is health informatics, encompassing the use of electronic records for managing clinical information. The second component is telehealth and telemedicine, which enable remote consultations. The third component is e-learning, focused on continuous education for healthcare professionals. Finally, the fourth component is e-commerce, which relates to administrative systems in the healthcare sector (PAHO, 2016).

Main Telemedicine Services Key telemedicine services include remote assistance, such as teleconsultation, telemonitoring, and electronic communication between professionals, which contributes to reducing hospital stays and empowering patients (PAHO, 2016). Additionally, telemedicine covers administrative management, such as testing and billing, as well as ongoing professional training. It also facilitates network-based evaluation and collaborative research. In the United States context, it is estimated that implementing electronic health records could generate annual savings of up to USD 77 billion and reduce adverse drug-related events (PAHO, 2016).

2.1. Innovation Models

The Low Touch Economy is an economic model defined by limited physical interactions, strict health measures, and significant changes in behaviors and industries due to COVID-19 (De Ridder and De Mey, 2020). This model forces companies to rapidly adapt in order to continue operating under new health and social norms, incorporating digital and remote solutions.

2.2. Exponential Organizations

Remote healthcare, home wellness, and e-commerce represent key opportunities within this economy, favoring innovative approaches such as Exponential Organizations (ExO) to adapt and expand health services in low-touch contexts (De Ridder and De Mey, 2020).

Exponential Organizations apply emerging technologies and disruptive models to grow exponentially, contrasting with traditional linear growth. These organizations use advanced digital technologies (AI, Big Data, robotics), promoting agile and decentralized structures that quickly adapt to technological changes and market demands (De Ridder and De Mey, 2020). A Massive Transformative Purpose (MTP) is essential, guiding ambitious goals beyond linear limitations (Mana and De Giovanni, 2018).

2.3. Characteristics of Exponential Organizations

The characteristics of Exponential Organizations (ExO) are divided into two main categories: logical and creative.

The logical characteristics (I.D.E.A.S.) include:

- Interfaces: automation of processes through artificial intelligence;
- Dashboards: enabling continuous measurement and performance management;
- Experimentation: promoting agile development based on hypotheses and rapid feedback;
- Autonomy: encouraging self-managed teams;
- Social: fostering connection, trust, and transparency with clients.

The creative characteristics (S.C.A.L.E.) include:

- Staff on demand: temporary hiring of external experts;
- Community and Crowd: using community-based marketing to strengthen organizational visibility and participation;

- Algorithms: leveraging Big Data to optimize processes and decision-making;
- Leveraged Assets: temporary use of external assets without the need for ownership;
- Engagement: pursuing deep client commitment through Mobile Technology Platforms (MTP) (Ismail, Malone, and Gueest, 2014).

These features enable organizations to take advantage of disruptive technologies identified by the McKinsey Global Institute (Manyika et al., 2013).

3 Methods

This study presents a methodological proposal for designing an inclusive and sustainable telemedicine model at the Centro Médico Puentecillas (CMP), in Guanajuato, Mexico. A qualitative-applied and exploratory approach was adopted, focused on organizational analysis, strategic planning, and conceptual development of a digital health ecosystem. The methodology was divided into four sequential and interdependent phases: preliminary institutional analysis, maturity assessment, strategic model design, and technological integration.

Phase 1. Preliminary organizational assessment as a business unit Prior to model development, a general diagnosis of CMP was conducted as a health service provider and organizational system. This assessment explored key aspects such as:

- Current care model (in-person, hybrid),
- User profile and unmet needs,
- Available human resources (physicians, technicians, support staff),
- Operational and technological infrastructure,
- Current communication and service channels,
- Relationships with external institutions and potential partnerships.

This analysis helped identify innovation opportunities, internal strengths (such as community focus), and structural weaknesses requiring attention. A customized CANVAS model was used as a preliminary diagnostic tool to visualize CMP's positioning as a potentially sustainable digital service provider with a social mission (Osterwalder and Pigneur, 2017).

Phase 2. Institutional maturity assessment Subsequently, the Pan American Health Organization's (PAHO, 2020) tool was applied to measure CMP's maturity level regarding telemedicine service implementation. This tool evaluates six core dimensions: leadership, organization, human resources, technological infrastructure, care processes, and information management.

Results placed CMP at levels 1 and 2, indicating an incipient technological foundation, absence of formal digital protocols, and lack of interoperability—but also institutional readiness for progressive adoption of the model. This assessment guided the strategic design and allowed prioritization of critical organizational needs (PAHO, 2020).

Phase 3. Strategic design of the telemedicine model Based on the technical-organizational diagnosis, an operational telemedicine model was developed using two methodological frameworks:

The CANVAS model defined the digital service value proposition, key users (patients with chronic diseases, family physicians), digital channels (web platform and app), revenue streams, and key operational activities (Osterwalder and Pigneur, 2017).

The Exponential Organizations (ExO) approach contributed elements of adaptability and scalability by incorporating attributes such as staff on demand, community & crowd, algorithms, leveraged assets, and engagement (Ismail et al., 2014). This approach enabled the construction of a model capable of dynamically responding to complex environments with limited resources.

Phase 4. Technological integration and operational planning In the final stage, a reference technological architecture and phased implementation plan were designed. The proposed solution features a modular, secure, and interoperable platform supporting remote medical care through video calls, clinical messaging, and remote monitoring devices. Minimum technical requirements, accessibility criteria, and cybersecurity best practices were established.

Operational workflows, evaluation indicators, and an activity timeline (Gantt chart) were also defined, including software development, equipment acquisition, staff training, clinical validation of protocols, and pilot testing. Legal and regulatory considerations in force in Mexico were included to ensure the model's regulatory viability (CENETEC, 2020; DOF, 2022).

4 Discussion

The proposed integration of telemedicine services at the Centro Médico Puentecillas (CMP) represents a concrete and context-specific response to the challenges faced by Mexico's healthcare system, particularly those related to access inequality, population aging, and lack of infrastructure in non-urban areas. Based on the institutional assessment, CMP was identified as being at an early stage of technological maturity, limiting its immediate implementation capacity. However, this evaluation also enabled the establishment of a clear roadmap toward digital transformation, aligned with innovative business models such as CANVAS and the principles of Exponential Organizations.

The discussion of results suggests that telemedicine, beyond being technically feasible under appropriate conditions, can generate significant impacts on service quality, operational efficiency, and economic sustainability at CMP. The low-touch approach and the SCALE logic from ExO facilitate the model's adaptation to a changing environment, enabling rapid scalability and more flexible management. Moreover, the combination of teleconsultation, teleassistance, and telemonitoring services supports continuous care, which is particularly valuable for monitoring chronic diseases prevalent in an aging population.

Another key finding is the potential for community engagement through digital platforms that allow direct interaction, educational campaigns, continuous feedback, and active participation in health management. This transforms patients into active, empowered users who share responsibility for their well-being—a cultural shift critical to the model's success. The phased implementation approach, supported by technical assistance, can help reduce resistance to change and facilitate technological adoption by medical and administrative staff.

Finally, CMP's proposal may serve as a reference for other health institutions with similar characteristics in Mexico. Its value lies not only in the application of technological tools but also in its strategic vision integrating innovation, education, patient-centered care, and financial sustainability. CMP's experience provides relevant elements for building a more equitable and resilient healthcare system capable of responding to both current demands and future crises, as evidenced by the global COVID-19 pandemic experience.

5 Conclusion

The healthcare system in Mexico—and specifically in Guanajuato—faces significant challenges and an urgent need to improve the quality and accessibility of services. Adapting existing processes, infrastructures, and available resources is essential to meet these emerging demands. Today, access to technology is driving a much deeper development within the healthcare sector; the incorporation of smart devices and artificial intelligence opens a vast range of possibilities to enhance medical care.

However, such technological advancement also demands the establishment of a new ethical framework to regulate emerging processes during its use. Moreover, while technology represents a powerful engine for transformation, its effectiveness will depend on the population's level of understanding and education, always taking into account the socioeconomic and cultural context in which it is applied.

To address these challenges, it is necessary to promote collaboration among government, health institutions, academia, and civil society, strategically integrating innovation. Business models based on emerging technologies and appropriate tools must be adopted. Effective technological implementation—mindful of user experience and social inclusion—will be key to achieving a sustainable, equitable, and future-ready healthcare system.

6 Acknowledgments

Special thanks to the team at Centro Médico Puentecillas, my mentors, and everyone who contributed to the development of this project with social commitment and transformative vision.

7 Ethical declaration

No direct interventions with individuals were conducted, and no sensitive data were used; therefore, institutional ethical approval was not required.

8 AI declaration

ChatGPT was used to support technical writing, academic structuring, and grammar review. The conceptual content was entirely developed by the author.

Abstract

Small and Medium Enterprises (SMEs) are fundamental to Mexico's economy, representing over 70% of formal employment. Despite their importance, many SMEs, particularly in traditional industries such as leather-footwear, struggle to adopt digital technologies due to outdated infrastructure, limited resources, and cultural resistance to change. The COVID-19 pandemic intensified these challenges, underscoring the need for digital transformation to ensure competitiveness and sustainability.
This study explores how SMEs in Guanajuato's leather-footwear sector can leverage digital innovation and human capital to overcome transformation barriers, enhance competitiveness, and align with sustainability goals. It examines the intersection between technology, knowledge management, and organizational culture in the context of the Fourth Industrial Revolution.
A qualitative, multi-case methodology was employed, using semi-structured interviews with managers from 13 SMEs. These interviews explored four key dimensions: technological infrastructure, digital culture, challenges to adoption, and future strategies. Triangulation with academic literature ensured analytical rigor and contextual relevance.
Findings reveal that only 15% of the companies have sufficient technological infrastructure to support comprehensive digital transformation, while 70% possess only basic tools such as computers and internet access—often underutilized. A significant 85% of managers cited lack of employee training as a major obstacle. Nonetheless, companies with a strong culture of learning and openness to collaboration showed higher adaptability and up to 20% increases in operational efficiency. The pandemic also acted as a catalyst, pushing many firms toward digitalization, although often reactively.
A conceptual model was developed integrating the four dimensions of transformation, offering a framework for SMEs to navigate digital change. The study further proposes knowledge management strategies including training programs, the integration of digital tools, and collaboration with startups and government agencies. These were identified by 60% of interviewees as key enablers of sustainable innovation.
This research contributes to academic understanding of digital transformation in traditional sectors and provides actionable insights for entrepreneurs and policymakers. It aligns with IFKAD's vision of integrating human expertise and digital innovation to foster socially responsible businesses. By focusing on knowledge as a strategic asset, the study highlights the importance of human capital in driving innovation, sustainability, and long-term resilience in SMEs.

Keywords: Digital Innovation, SMEs, Human Capital, Sustainability, Industry 4.0

Paper type: Practical Paper

1 Introduction

In the context of the fourth industrial revolution, digital transformation has become a strategic necessity for small and medium-sized enterprises, especially in traditional sectors such as leather-footwear. The digital transformation process involves the incorporation of technological and digital tools to optimize processes, improve competitiveness and adapt to new market requirements. In Mexico, SMEs play a fundamental role in the country's economy, representing most of the business fabric and contributing significantly to both employment generation and Gross Domestic Product (GDP).

The ownership dynamics of SMEs reflect a diversity of profiles, where both men and women play key roles in EU leadership. Business decisions, access to resources and growth strategies may vary depending on the demographic and socio-economic characteristics of owners. Where, about 97.5% of EU owner establishments are micro-retailers, while small businesses account for just 2% of the total.

Regarding economic activity, there is a clear preponderance of the private non-financial trade and services sectors in the economic structure. In contrast, the manufacturing sector, although significant, is considerably smaller, suggesting an economy with a strong focus on services and trade. With respect to the low participation

of other economic activities, this suggests a lower diversification in these areas, which is consistent with trends observed in countries with tertiary oriented economic structures.

The high activity in private non-financial services and trade sector in the economic structure indicates the need to consider information technology (IT) tools to improve their competitiveness and efficiency in these sectors. Technological tools and digitalisation can transform the way in which the EU operates, even facilitating its processes. Information technologies (IT) have come to transform technological and economic processes, restructuring the way in which the EU operates, communicates and competes on the market. As IT becomes a core part of business operations, it improves efficiency and reduces costs and drives innovation and the creation of new business models. These technological advances have enabled the EU to optimise its supply chains, improve its customer relations and generate data-driven decision making, thus facilitating a faster and more accurate response to market demands (Chan, 2000).

2 Justification for the Research

The digital transformation has been consolidated as a strategic imperative for SMEs, especially in contexts of high competitiveness and global uncertainty. In Mexico, SMEs account for more than 99% of all economic units and generate more than 70% of formal employment, so their digitization is not only a business need but also an essential component for the country's economic development. Despite this, many SMEs still face structural and operational challenges that hinder their transition to digitised business models (INEGI, 2020).

The leather-footwear sector in Guanajuato, one of the industrial pillars of the state, has shown an uneven evolution against digitalization. While some companies have adopted technological tools in a partial way, many others continue to operate with traditional models, limiting their competitiveness, responsiveness to market changes and the possibility of innovation. This situation is compounded by the lack of strategies focused on human capital development as a transformative agent.

Most digital transformation efforts have focused on the acquisition of digital technologies or platforms, without considering the role of knowledge, experience and human capabilities in their implementation and use. This techno-centric vision omits an essential component: organizational transformation depends largely on the culture, skills and willingness of staff to lead change.

From this perspective, the study is justified by its holistic approach that links digital transformation with knowledge management and human capacity development. Based on the recognition that technologies alone do not transform businesses; people do, through their learning, innovation, collaboration and adaptation to change. Analysing this process in a traditional and vulnerable sector such as leather-footwear enables the identification of viable routes, practical strategies and more effective public policies.

3 Research Problem Statement

In an increasingly competitive global environment, SMEs face the challenge of implementing digital transformation processes to ensure their survival and growth. However, the reality in traditional sectors, such as leather-footwear in Guanajuato, shows a considerable gap between the need for digitalization and the effective ability to carry it out. This gap is not only manifested in the lack of technological infrastructure or investment, but mainly in the lack of human skills, leadership and an organizational culture oriented to innovation (Del Do et al., 2023).

Numerous public and private programmes have promoted the incorporation of technological tools in SMEs. However, its impacts have been limited due to a reductionist view of digital transformation focused exclusively on the technical. This has led to initiatives that fail or stagnate because human factors such as resistance to change, staff training, lack of strategic vision and weak digital leadership within organizations are not considered.

In the case of the leather-footwear sector in Guanajuato, these limitations are even more marked. Despite being a nationally recognized industrial cluster, many enterprises have traditional hierarchical structures, low investment in continuing training and little articulation with educational or technological institutions. This hampers the integration of disruptive technologies, hinders the generation of innovation and reduces competitiveness in international markets.

Therefore, the problem of research lies in understanding how knowledge, that is, the set of skills, experience, organizational learning and digital leadership, affects the success or failure of digital transformation processes in this type of companies.

This problem becomes more relevant in a post-pandemic context, where many SMEs were forced to adopt technologies without a clear strategy, highlighting the need for a more holistic approach that combines technology, processes and people. In this context, it is essential to investigate:

What is the role of knowledge in the digital transformation and innovation of SMEs in the leather-footwear sector in Guanajuato?

4 Research Objectives

4.1. General Objectives

Analyse the role of knowledge in the *digital transformation and innovation processes* of SMEs in the leather-footwear sector in the state of Guanajuato, identifying the key factors that affect the success or failure of these initiatives.

5 Theoretical framework

The digital transformation in small and medium-sized enterprises (SMEs) has taken on special importance in recent years, driven by the Fourth Industrial Revolution, changes in consumption patterns, and the need to adapt to highly competitive and technological environments. This process not only involves the incorporation of disruptive technologies, but a profound transformation in processes, business models and human capital of organizations.

5.1. Digital Transformation: Beyond the Technological

Digital transformation has generated significant interest in recent years, especially in organizational dynamics that are exposed to disruptive technologies. This transformation is understood as a horizontal technology, which means that it affects all sectors and actors of the economy and society. His main area of study is nature as a "technology of general utility", which refers to the technology capable of transforming various economic, social and cultural activities, even modifying its own reality (Luis Curbelo, 2017). However, it is not only limited to the implementation of tools, but involves an organizational reconfiguration that requires leadership, change management and human capacity development.

The digital transformation comes to consider three key elements: technology, processes and people. These relate to each other to facilitate the adoption of new technologies in operational processes, optimizing business models and ensuring the participation of human capital. The integration of these factors allows companies to face various challenges such as resistance to change and lack of digital skills, while taking advantage of opportunities to generate value and develop new products and services (Verina, Titko, 2019).

5.2. SMEs in the digital age

SMEs represent 99.8% of the economic units in Mexico and generate more than 70% of formal employment (INEGI, 2020). Despite their importance, they face major constraints to innovation: limited resources, low formalization, lack of technological infrastructure and low professionalization. These structural barriers are accentuated in traditional sectors such as leather-footwear, characterized by a strong craft tradition, hierarchical structures, and low access to technology.

In 2001, Schwartz refers to the adaptability of enterprises, those who can respond to new technological trends are those who will be able to maintain the competitiveness of organizations and their future development, and those who are not able to adapt may be victims of "digital Darwinism". Therefore, the ability of organizations to assimilate digital transformation by adding additional value to technology should be considered.

To contemplate digital transformation, it is necessary to develop digital capabilities in which activities, people, culture and organization are aligned with organizational goals. Hence the development of more efficient and productive models as one of the main challenges for managers of SMEs (Antonorsi M. & Vidal R., 2019). Incorporating industry 4.0, which is a concept promoted by academia, industry and governments that seeks the transformation of companies to generate new opportunities through digitization and digital transformation processes.

5.3. Human capital and knowledge as a transformational axis

Over the past four decades, technological development has profoundly and structurally transformed the economic and social environment. This development has promoted the transition towards a knowledge-based economy, positioning it as the main factor of production and generating a series of implications in the theoretical and practical approach to production processes (CONAHCYT, 2023).

In 2006, Luis Mateo refers to the knowledge society as two parameters (knowing and knowing) that govern and restrict the structure and composition of today's society, integrating commodities as determining tools of well-being, integration and progress of society. Where the commodity is presented as a reference to knowledge, since both are objects of purchase and sale, in which, new knowledge is bought or sold in two forms:

1. Direct form such as patents, licenses, shares, etc., allowing the buyer to produce goods and services making use of acquired knowledge.
2. Indirect form forming part of the price of the product, good or service to which knowledge gives rise. (Luis Mateo, 2006).

In addition, transformational leadership, organizational culture oriented to learning, and continuing education are elements that allow human capital to become an active enabler of digital transformation (García & Malagón, 2020).

In this sense, the role of human capital in SMEs transcends the operational to become an engine of organizational change. This includes from the effective adoption of digital tools to the ability to rethink processes and redesign business models focused on innovation.

5.4. Towards a sustainable and people-centred digitisation

The digital transformation must be approached with a vision of sustainability and social responsibility. In this sense, people-centred digitalization seeks not only operational efficiency, but also organizational well-being, equity in access to technology, and the generation of shared value.

The incorporation of knowledge management strategies, collaboration networks and links with the innovation ecosystem (academia, government, startups) becomes essential for SMEs to scale their digitalization in a sustainable way and with social impact.

6 Methodology

A qualitative multi-case methodology was used, where semi-structured interviews were conducted with managers and leaders of 13 SMEs in the leather-footwear sector of the state of Guanajuato. The data collection was carried out through an interview guide focused on four dimensions: technological infrastructure, digital culture, barriers to adoption and strategic vision. The analysis was carried out with the support of the software Atlas.ti, using open coding and triangulation with scientific literature.

6.1. Analysis Procedure

The results reveal a deep heterogeneity in terms of the degree of digitalization and technological maturity of the companies interviewed. Only 15% of SMEs have the appropriate technological infrastructure for comprehensive digitization processes. However, 70% have basic tools such as computers, e-mail or social networks, although their use is not systematic or aligned with an organizational strategy.

One of the most relevant findings is that the main obstacle identified by 85% of participants was lack of staff training. This lack not only hinders the adoption of new tools but also creates resistance to change and external dependence for operating basic systems.

On the other hand, companies were identified that have advanced significantly in their digitalization thanks to three key factors:

1. Innovative-minded leadership
2. Organizational culture opens to learning
3. Links with academic or technological institutions

These companies reported up to 20% improvement in operational efficiency, reduction of delivery times and greater adaptability during the pandemic. Another significant finding is that the most successful digital transitions were those that were approached as strategic processes, not just as technological decisions.

It was shown that the digital transformation has been more effective when accompanied by knowledge management, continuous training and internal feedback mechanisms. Without these components, initiatives tend to fail or remain in the middle, generating organizational frustration and wasted resources.

The analysis of the case studies and their codification in atlas.ti made it possible to structure a conceptual model for digital transformation specific to SMEs in the leather-footwear sector. This model integrates four dimensions:

1. Technology infrastructure and connectivity
2. Organizational culture
3. Organizational barriers

4. Opportunities, strategies and vision

The interconnection between these dimensions (see Figure 1) demonstrates that knowledge acts as a central axis of the digital transformation process, influencing the perception of obstacles and the ability of companies to design and implement innovation strategies.

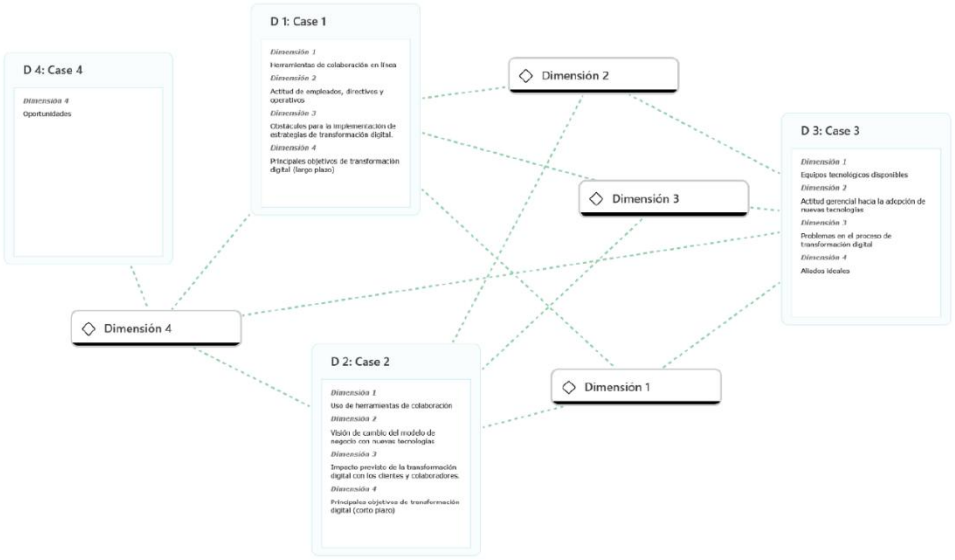

Figure 1: Network of interaction between the dimensions and their analysis codes.
Source: Adapted from Scientific Software Development GmbH (ATLAS.ti, 2023)

The general organization of the diagram is based on two main points:

1. By dimension: Represents the dimensions set out in the case study, each of the dimensions addresses specific themes and is linked to one or more cases.
2. By case: The cases are the result of individual studies of each dimension, where the main codes were identified by dimension.

Each dimension addresses a key point in the digital transformation process:

- Dimension 1 examines collaboration tools and their use in a digital environment, the main linked cases are case 1, 2 and 3, as these explore the adoption of collaboration tools highlighting the importance of technologies that facilitate communication and remote working.
- Dimension 2 explores attitudes towards technology and its view of change in models' business, this is linked to cases 1, 2 and 3 because these come to reflect the attitudes of employees, managers and digital transformation, which can influence the success of implementation of digital strategies.
- Dimension 3 covers the problems and obstacles in adopting transformation digital, the main linked cases are case 1, 2 and 3, in which the main challenges such as lack of infrastructure, resistance to change or failures in strategic processes.
- Dimension 4 reflects the opportunities of the digital transformation process as well as its strategic allies, in this dimension all cases are linked (case 1, 2, 3 and 4) because it focuses on identifying the main areas for improvement, potential collaborations and future strategies.

Dimensions 2 and 3 are considered as central axes, since they are linked to the first three cases. These dimensions cover transversal and strategic aspects that generate a greater impact on the digital transformation process. Regarding dimension 1, although it is connected to cases 1, 2 and 3, it is not considered as a central dimension, since its role is more specific and functional, focused mainly on the implementation of digital tools.

The centrality of dimensions depends not only on the connections between them, but also on the conceptual weight of the dimension in its global analysis. Although organizational attitudes and barriers are key elements influencing technology adoption and the challenges inherent in digital transformation, while the use of tools Although relevant, it is more operational and depends on factors determined by other dimensions.

Regarding dimension 4, this is limited to the presence of opportunities where in some cases indicates that this aspect is transversal and relevant considering this dimension as an area of opportunity.

7 Conclusions

The digitization of SMEs is more than just the introduction of innovative technologies in their operation. It is a multidimensional process involving radical restructuring and fundamental redefinition of organizational and cultural priorities. To be specific, these barriers do not lie primarily in infrastructure but rather in human perception and how organizations manage development. In the example of the leather and footwear sector in Guanajuato, their entrepreneurs lack the digital atmosphere, as well as tending to intentionally oppose changes and decrease their expenditure on continuing education in their domain. Thanks to qualitative analysis provided by semi-structured interviews and thematic coding with the help of Atlas.ti, the features revealed make it possible to identify from which companies were able to explore further.

Finally, this research contributes to the academic debate on digital transformation from a people-centered perspective. It reaffirms that the success of digitization in SMEs depends not only on technology, but on its people, their ability to learn, adapt, collaborate and lead changes. To achieve a sustainable and inclusive digital transformation, continued investment in human skills development will be crucial, Strengthening the link with the innovation ecosystem and designing public policies that recognize human capital as a strategic axis of business development.

8 Ethics declaration

This research did not require direct intervention in the health or physical integrity of participants; however, semi-structured interviews were conducted with people working in SMEs in the manufacturing sector. For this reason, fundamental ethical principles such as informed consent, confidentiality and anonymity of participants were followed. All interviewees were informed of the purpose of the study and gave their consent to participate. The information collected was treated confidentially, without mentioning names or data that could identify specific individuals or companies. Due to the nature of the study and in accordance with institutional ethics policies, it was not necessary to submit the project to a formal ethics committee. However, the ethical principles established in social and human science research were observed.

9 AI declaration

The qualitative analysis of this study was carried out using the software Atlas.ti, a specialized tool for qualitative data analysis. This platform facilitated the coding of interviews, the organization of thematic categories and the mapping of relationships between analytical dimensions. It should be clarified that Atlas.ti is not a generative artificial intelligence tool, but a methodological support software. The analysis, interpretation and writing of the results were carried out entirely by the author.

How Does AI impact Human Capital and Capability (HCC) in MBMI Processes?

Peter Lindgren[1], Jane Flarup[1], Purnima Lala Mehta[1], Anmol Bhatia[2]
[1]CTIF Global Capsule, Skagen, Denmark
[2]The NorthCap University, Gurugram, India

Abstract

The impact of Artificial Intelligence (AI) on Human Capital (HC) responsible for designing, reengineering, and developing Business Models (BM) has not been extensively investigated. Latest research seems to diverge on whether AI has a negative or positive impact on HC competences, HC capabilities, and Business Model Innovation (BMI) processes. Studies indicate that HC is at risk of being wasted or underutilized due to AI, as research verifies that if the human brain is not utilized as much as AI enables today, where AI takes over HC tasks and HC will be wasted, spilled or lost. Other research shows that AI can release unused HC and potential when AI designs and reengineers Business Models (BMs) and Business Model Ecosystems (BMES). In some cases, AI is even shown to be able to release unused HC when downloading, analyzing BMs, and sensing disruptive, radical, and/or incremental BMs.

The paper investigates AI´s impact on HC and HC´s capabilities (HCC) in 7 different Multi Business Model Innovation (MBMI) processes, seeking to determine whether AI can enhance the use and potential of HC, or, conversely, hinder and reduce HCC in MBMI.

The impact of AI and MBMI was studied in seven MBMI projects in different BMESs that are influenced by AI. The effect of AI on HCC was analyzed as a key finding and output to the research question: Does AI lead to HCC Waste, spill, loos or does it increase the grow, increase and release HCC potential?

Keywords: Human Capital Waste, Human Capital Potential, AI, Knowledge Management, Multi Business Model Innovation (MBMI)

Paper type: Academic Research Paper

1 Introduction

Literature (Kaplan et al., 2018; Desolda et al., 2024) suggest that AI can lead to less creativity and BMI, thereby wasting, spilling or loosing Human Capital (HC). However, other findings (Ghosh, 2025) point to the opposite: that AI can unleash HC potential and accelerate the faster and higher quality of BM design, reengineering, and development. AI is claimed to be able to lead to HC growth with increased use of HC potential, growth of HC, and increased HCC. These results correspond to the hypothesis that AI is a predictor of potential for success and advantage for Human beings, leading to the growth of HC. However, what is the truth?

The research is conducted in the context of a discussion on the impact of AI, HCC, Knowledge Management and MBMI. The research has a particular focus on a new concept, “Human Capital and Capability Waste and Potential,” as shown in Figure 1 inspired by Garland (2010), focusing on the process of broadening and building positive emotions (upper right part) and the process of narrowing tunnel vision through negative visions (lower right part). The model propose that the physical aspect of humans is considered, regarding the individual as possessing physically valuable competencies – a physical Human Capital (HC), which can be “grown”, “increased”, “found” as well as “wasted”, “spilled” and “lost”.

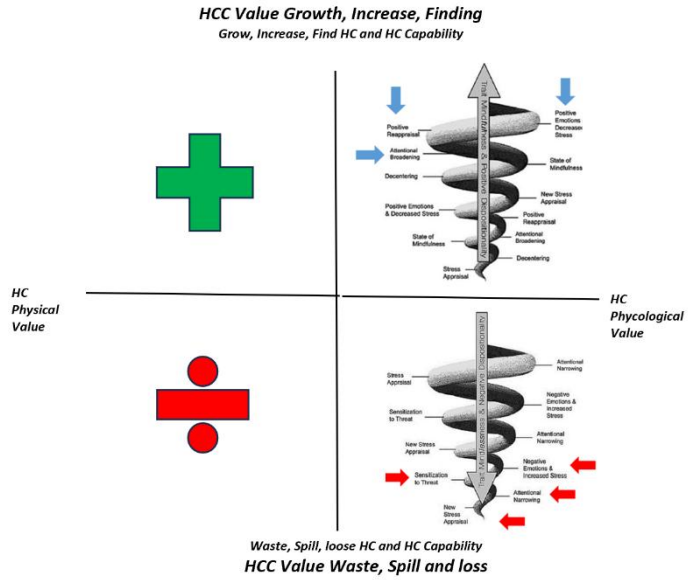

Figure 1: Human Capital Waste and Potential – Grow, Increase, Find - Waste, Spill, Lose -- HC Value/Capability

HCC refers to the **physical part** – physical fitness – physical health and wellbeing –and the **psychological/intellectual part** - psychological health, skills, knowledge, education - of humans that are valuable in a MBMI contexts. Humans HCC physical and phycological parts in this concept are essential in MBMI design, reengineering and development (Golding, 2014). It is included in the – The Competence dimension - more Specific for HC, The HR component of the BM framework (Lindgren 2018) has a substantial impact on MBMI and the human being's motivation, earnings and perceived earnings (Demings, 2022) of MBMI. Research shows that HCC investments yield high economic returns for businesses. Poor investment or neglect can result in wasted, spilled and lost HCC. This can increase or decrease HCC to create, capture, deliver, receive, and consume values, and the design, reengineer, and develop BMs. Businesses can enhance HCC through training and education, which can improve the quality, production and output of MBMI. However, HCC can also be wasted, spilled and even lost impacting both the physical and psychological value of HCC, as indicated in Figure 1.

HCC, in a broader definition, is "the pool of competence and Capabilities" together with the potential of these that the business and its users, customers, and network possess together or waste, spill, or loos.

HCC is "a core raw material" to any BMI. No society or business (UIE 2025) can afford to waste and spill HCC – or simply let HCC "Shrink" – and not been used at its full potential and availability – because there is a lack of HCC today (Draghi 2024). The demand for HCC, especially in Europe is exceptionally high and 4 causes are mentioned to create the lack - **The Retirement Generation - Skill Shortage - Employee Burn Out - Pandemic** (Premier 2025). Waste and spill of HCC can lead to fewer resources of HCC for MBMI and thereby fewer new and reengineered BMs, less developed or poorer innovated BMs. When HCC is wasted or spilled, the hypothesis is that less learning, knowledge creation and creativity will happen. Opposite – hypothetical - increased creation and use of HCC potential will lead to increased MBMI. However, literature shows that an increase in HCC via knowledge creation requires learning (Krogh 2000, Lindgren 2018) or HC needs to learn, or to be learned in the moment, in short and long-term perspectives. However, can HC learn and evolve its HCC with AI, be impacted by AI, or when AI takes over basic and, in the future, more complex HCC´s tasks?

A paradox according to research (Shors et al, 2011) showed that if HC – "the brain" of one human or many humans together are not used then the HCC - the business HCC - is in risk of wasting, spilling and loosing HC and HC capability to do MBMI. Research shows that even children between 6 – 12 years, who are usually eager to learn and are curious to learn new skills when using computers, mobile phones, and social media embedded or "supported" by AI, are at risk of losing their ability, capability, and interest in creativity and innovation. Increased use of AI via these devices has shown some tendencies and trends (Zhai 2005) of the children losing the ability to learn. At some point, "The human brain" is constructed to do things easily, and the easy tasks first – or even for some "to do nothing" (Haidt Ferguson 2009, Haidt 2014).

As the world becomes more Volatile, Uncertain, Complex, and Ambiguous (VUCA) (Lindgren, 2023), it is of utmost importance for humans, business and Societies (Draghi 2024) to be creative, innovative, curious, and to learn continuously. Our research hypothesis is that individuals embedded in networks with a general MBMI

capability can value and increase the output of MBMI via the use of AI. Conversely, our hypothesis is also that the opposite can be the outcome if AI and HCC are not led and managed.

2 AI in business model innovation

The history of AI dates back to antiquity, with myths, stories, and rumours of artificial beings endowed with intelligence or consciousness by master craftsmen. The study of logic and formal reasoning, from antiquity to the present, has led directly to the invention of the programmable digital computer. This device and the ideas behind it inspired scientists to begin building an “electronic brain”.

The field of AI research was founded in 1956 (Kaplan A, Haenlein M 2018) as a prediction that machines as intelligent as humans would exist within a generation. Heavy funds were provided to AI research to make the “electronic brain” vision come true (Newquist, HP, 1994). We are now at the beginning of this AI generation, as it has become apparent that researchers and businesses have underestimated the challenge of innovating and developing AI. A visionary initiative by the Japanese Government and the success of expert systems reinvigorated investment in AI. By the late 1980s, the AI BMES that had grown into a billion-dollar BMES. However, investors' enthusiasm waned in the 1990s, and the field was criticized in the press and avoided by industry (a period known as an "AI winter"). Nevertheless, research and funding continued to grow under other names.

In the early 2000s, machine learning was applied to a wide range of challenges in academia and BMES. The success was due to the availability of powerful computer hardware, the collection of immense data sets, and the application of solid mathematical methods. Deep learning (DL) proved to be a breakthrough technology, eclipsing all other techniques. The transformer architecture debuted in 2017 and was used to produce generative AI applications and robotics was at this time attached to the umbrella of AI.

Investment in AI skyrocketed in the 2020s alongside quantum computing. The boom, driven by transformer architecture, led to the rapid development and release of large language models (LLMs) like ChatGPT, which showcase human-like knowledge and creativity across various sectors. However, concerns about the risks and ethical implications of AI have sparked debate about its future impact on society and HC. Figure 2 illustrates the historical timeline and key inventions in the AI field.

Figure 2: The Story of AI

AI is today transforming the core dynamics of BMES by redefining the way businesses operate, design, reengineer, and develop BMs and HC in BMI. In the context of BMI, the MBMI approach and “the MBMI brain” (Lindgren, 2020) are now possible to realize. AI and DL in a world of persuasive BM could propose all possible archetypes of BMs. MBMI Processes and corresponding interaction archetypes patterns of any BM interactions can be carried out with,

• *Human Intermediary - Machine Intermediary or a Mix of Human and Machine Intermediary BM Interaction*

MBMI patterns analysis, MBMI Library combined with AI and DL are already supporting MBMI Brains in businesses leadership and management.

Businesses are challenged by a world that is increasingly adapting AI – and AI in MBMI as the world becomes more Volatile, Uncertain, Complex and influenced by Ambiguity – (VUCA) Lindgren 2022). In these situations, it is a big option, opportunity, and drive to use AI to become faster in MBMI – and “jump” the gates of the MBMI challenge easily.

AI in MBMI adds one more layer to the businesses' challenge to innovate and develop BM faster. This trend and the desire to do this has been addressed for many years (Fine 1999, Chesbrough 2008, Vercanti 2009) – as an exponential pressure and request on businesses and humans responsible of MBIM - to change BM´s faster – “high-speed BMI”. Survival of a business - until today – has been equal to HC to innovate, develop, and change

BMs faster. However, innovation and development of HCC seems no longer a “competition” and a “game” of “human to human” MBMI, but now a “game” of human to humans and machines MBMI. Further, this includes fewer single BM BMIs but innovation of multitudes of BMs simultaneously – the new era of designing and reengineering of BMs. A paradigm shift in BMI - to be capable to practice MBMI in business’s BM design, reconfiguration, and development processes. Participants in AI-supported MBMI processes risk marginalization, waste of HCC, and a loss of innovation capability when AI takes over many tasks and HC may not be fully utilized or trained, as AI is easier, faster, and cheaper to implement.

3 Research questions, design, and research methodology

These reflections led us to the following research questions:

- *How does AI influence HCC and potential in MBMI and MBMI processes in different BMES?*
- *Are the HCC and its potential wasted, spilled and lost when AI is implemented?*
- *What is AI´s impact on HCC´s output and MBMI success in short and long-term perspectives?*

This study combined literature review, case research, participatory action research, interviews and secondary sources.

4 AI in MBMI: state of the art

AI has emerged as a key facilitator that improves decision-making, promotes interconnectivity among BMs, and optimizes operations across different BMES (Mishra & Tripathi, 2021). AI is transforming how businesses approach MBMI, impacting HC utilization in MBMI. While AI enhances effectiveness, efficiency, and analytical capabilities, it raises concerns about HC displacement and underutilization. Although the role of HC in MBMI is changing research the AI impact on MBMI processes have not been the primary focus. AI-based technologies, including classical machine learning, deep learning, natural language processing, and robotics, enabling the transformation of MBMI processes in various BMES (Jorzik et al., 2024). AI enables intelligent automation, predictive analytics, and data-driven decision-making in MBMI. The important changes brought about by AI in MBMI are:

Improved Decision-Making: AI can scan massive datasets to detect patterns, forecast patterns important for MBMI and maximize MBMI investment (Haleem et al., 2024). Businesses can build improved MBMI forecasting models, predict consumer, supplier, and network wants, demands, and needs, and avoid possible risks by using AI. This ability enables MBMI decision-makers to adopt proactive MBMI strategies, allowing flexibility during changing BMES conditions (Stefia et al., 2024).

Operational Effectiveness and Efficiency in MBMI*:* Automating MBMI processes reduces manual tasks, cuts errors, and lowers expenses. AI-driven tools, such as robotic process automation (RPA), streamline repetitive tasks, allowing staff to focus on higher-value HC MBMI work. This enhances productivity, improves resource allocation and efficiency, and reduces costs (Gong et al., 2024).

Data-Driven Insights*:* AI-driven analytics provide real-time insights enabling businesses to adapt to changing market conditions. These insights facilitate data-driven MBMI decisions supported by empirical evidence. AI-based data visualization tools provide dashboards that enable executives to monitor performance metrics and identify areas for improvement in MBMI projects. (Matheus et al., 2020). (Matheus et al., 2020) (Matheus et al., 2020)

BMES Crossflow: AI enhances integration among businesses in vertical and horizontal BMEs by connecting various BMs. For instance, AI platforms in finance are merging with those in healthcare and retail to create personalized financial packages based on consumer behavior tracking. This horizontal BMES collaboration fosters innovation by using AI to bridge gaps between typically non-overlapping BMEs. (Carmona-Lavado et al., 2023)

AI-Augmented HCC: Although there are concerns about HCC loss related to MBMI, AI provides opportunities for reskilling and upskilling HCC. Businesses are investing in AI literacy training to equip HC with the skills necessary to work with AI-powered systems. This shift can enable a harmonious relationship between HC and AI, resulting in the development of more hybrid jobs that will be able to blend analytical, technological, business, and HCC.

As AI continues to evolve, the role of MBMI in harnessing AI-driven MBMI changes becomes increasingly critical. Therefore, businesses need to create ethical guidelines and governance policies to address the socio-economic effects of AI adoption. By embracing AI responsibly, organizations can tap into new growth opportunities while promoting sustainable BMI.

Today, many businesses do not really systematically download, see, sense, and use their full HCC potential regularly. Thereby they waste, spill and loos much of their HCC – HR competences and HR Capabilities either by not using the HRC, using the HRC in a wrong position, for a wrong task or more radically speaking "wasting" these by physically or psychologically "killing" – destroying HC – e.g. by having AI influencing the HC to not continuously be curious, learn, pushing their "HC brains" to valuable MBMI. Figure 3 illustrates different HCC waste, spill, loos - sources on a physical and psychological scale and relate these to our cases.

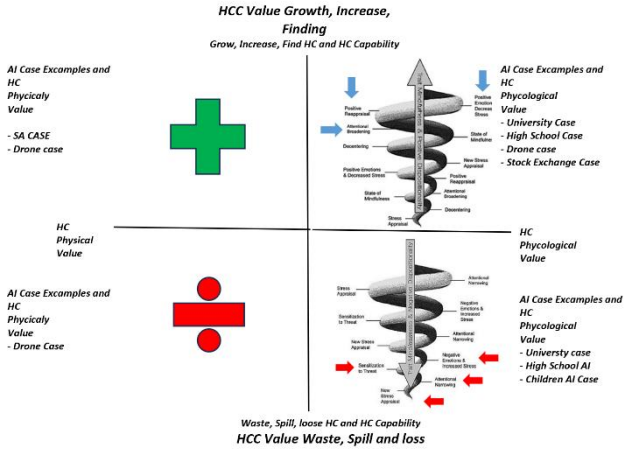

Figure 3: HC Value Growth, Increase and Finding – HC Value Waste, Spill and Loss

The cases are also related to HCC Value Growth, Increase and Finding scale.

5 The role of HC and HRC capability in AI-augmented MBMI

As AI improves operational effectiveness, efficiency and learning in MBMI Processes, it can potentially remove the requirement for HCC. However, some research suggests that it redirects the work of stakeholders in the MBMI process towards more strategic thinking, creativity, and challenge-based solving of complexities that AI cannot overcome. AI into MBMI operations can affect HCC in following manner:

- ***Augmentation of HC Capability***: AI is a tool that enhances human capabilities in MBMI, boosting effectiveness, efficiency, and productivity. It aids managers in optimizing AS IS and TO BE BMs by providing actionable insights and utilizing predictive analytics. AI-driven decision-making helps reduce uncertainties in experimentation and innovation within MBMI.
- ***The Transition to Higher-Skill MBMI Jobs****:* AI is a tool that enhances HCC in MBMI, boosting effectiveness, efficiency, and productivity. It aids managers in optimizing AS IS and TO BE BMs by providing actionable insights and utilizing predictive analytics. AI-driven decision-making helps reduce uncertainties in experimentation and innovation within MBMI.
- ***Human-AI Collaboration in MBMI***: Automation through AI streamline routine tasks, enabling HC to focus on strategic planning, creative problem-solving, and relationship management with key stakeholders. This shift necessitates continuous learning and skill upgrades, prompting businesses to invest in reskilling and upskilling initiatives for employees and the broader network to prepare for AI-enabled MBMI roles.

6 The role of HCC waste and/or potential – decreasing/enhancing HCC via AI

While it has its benefits with the growing involvement of AI in MBMI, it also raises concerns about job replacement and HC underutilization. Various issues arise as Businesses adopt AI-based MBMI processes:

- ***Redundancy of Jobs in Repetitive Tasks***: Robots and AI replace operational and administrative MBMI jobs, resulting in workforce layoffs in certain MBMI areas.
- ***Digital Divide and Skill Gaps***: The rapid development of AI creates a gap between the skills available in the MBMI workforce and the AI-integrated competencies and capabilities required for MBMI.
- ***Social and Ethical Implications****:* Businesses must address the ethical implications of AI deployment in MBMI, including providing equitable employment opportunities in MBMI and mitigating the potential dislocation of the MBMI workforce.

7 AI's impact on MBMI success and output

AI plays a crucial role in achieving MBMI initiatives by maximizing BM flexibility, expandability, and profitability. Major areas in which AI contributes to MBMI success are:

- *BM Flexibility:* AI-powered systems enable businesses to modify their BMs in real-time, adjusting to BMES patterns and customer needs dynamically. Adaptive AI-based MBMI keeps businesses strong in rapidly evolving environments.
- *Data-Driven Decision Making for MBMI Output*: AI supports real-time decision-making through the analysis of BMES data, competitor actions, and consumer behavior patterns. This enhances BM design, minimizing trial-and-error iterations and expediting MBMI success.
- *MBMI Acceleration*: AI enables quick MBMI, including prototyping, allowing businesses to test new value propositions, revenue, cost, and earnings models in a quick, effective, and efficient manner. By automating MBMI activities, AI minimizes costs and optimizes the feasibility of multi-business model integration.

8 AI and HC retention strategies in MBMI

To counter the effect of AI on HC, businesses can adopt MBMI strategies that guarantee balanced AI-human interaction in MBMI processes. Some approaches are:

- *MBMI Workforce Reskilling Investments*: Businesses must develop ongoing learning initiatives aligned with BMES demands, driven by AI and other emerging technologies.
- *Human-AI Synergy:* AI should be utilized as an enhancement tool, rather than a substitute for human intelligence.
- *Redefining Professional Jobs:* New professional types, such as AI-ethics MBMI consultants, MBMI digital strategists, and AI-supported MBMI decision-makers, need to be developed.
- *Ethical AI Deployment:* Businesses need to undertake responsible AI deployment, avoiding job displacement and labor marginalization. AI plays a crucial role in achieving MBMI initiatives by maximizing BM flexibility, expandability, and profitability. Major areas in which AI contributes to MBMI success are:

9 AI and HCC retention strategies in MBMI

Seven different cases in different BMES influenced by AI were studied from February 2022 to April 2025. 4 cases were selected for this article. The participatory action research method (Chevalier, 2013; Bryman and Bell, 2011) forms the general research methodology framework and approach for the cases. Observation and secondary data analysis was also used.

9.1 AI and SA case – AI advancing HCC

SA in the Auto recycling BMES of scrapping, dismantling cars and other vehicles. One of the most challenging MBMI tasks for SA is to assess a car for the BM values it includes quickly. By using AI SA - employee can faster judge which BMs are included in the car and thereby value the SA Business. Hereby, the AI enables the SA Employee to utilize their HCC better resulting in higher Quality, greater precision and better earning.

9.2 AI and drone technology - AI advancing HCC

DR constructs Drones for Defence and Security BMES. The customers of the drones demand drones equipped with devices that can capture images and videos of equipment on the ground. The interest of the users and customers was initially to obtain photos and videos quickly. However, the DR MBMI employees discovered that the pictures and videos were not of core interest and would not lead to new BMs, as the photos and videos were often outdated - old "data". However, with AI embedded, it was possible to "see" between the "pixels," which enables the customers together with DR to forecast the future actions of "the businesses on the ground". This turned was extremely valuable, especially in the defence and security BMES. This BM was unable to innovate and develop with existing HCC, as the HC was not able to do so.

9.3 AI and MBMI at Universities - positive and negative HCC effects of AI

Universities are struggling with AI-related issues due to students' increasing use of AI. Some Universities have forbidden the use of AI, while others have encouraged its use under specific leadership and management
