The categorization of the selected articles was conducted through an AI-assisted extraction process, leveraging the capabilities of the Gemini Flash 2.0 Large Language Model within a human-in-the-loop process. The use of LLMs in literature reviews has become increasingly consolidated, particularly for automating tasks such as article summarization and data synthesis (Antu et al., 2023). In line with recent empirical studies, the model was applied to systematically extract predefined content areas from each article: managerial competencies, sector of application (classified, where possible, according to ISIC codes revision 4), empirical results, managerial and theoretical implications, ethical considerations, best practices, methodological details, theoretical framework, limitations, future research directions and an interpretative fit score ranging from 1 to 5, indicating the degree of alignment between each paper and the objectives of the systematic review.

The effectiveness of this phase hinged on the design and iterative refinement of prompts, a technique widely recognized as critical to the success of LLMs' accuracy (Lin, 2024). Each prompt was structured according to a Role-Task-Expected Features-Example framework, which enabled the model to execute tasks with clarity and internal consistency. This approach aligns with established prompting methodologies, including the PARTS framework (Park & Choo, 2024), which emphasizes role specification, objective definition, and desired structure explanation as essential components to maximize output relevance. To reduce hallucinations, the temperature parameter was fixed at 0, which is in line with recent best practices that suggest low-temperature settings enhance determinism and consistency (Ekin, 2023). Furthermore, the application of negative prompting techniques was crucial: the model was explicitly instructed to return "NOT-DEFINED" when the content extracted from the article did not match the criteria of the specific query. This technique, documented as effective in minimizing speculative outputs (Lin, 2024), proved especially valuable in tasks such as competency identification, where semantic misalignment would compromise the validity of the output. The prompt engineering process followed an iterative refinement strategy, with multiple cycles of adjustment based on output evaluation conducted through human judgement. Where appropriate, few-shot prompting was employed using manually curated examples extracted from a subset of articles. This approach was particularly effective for enhancing model comprehension in extracting complex categories (Chen et al., 2023) such as managerial competencies, empirical findings, and managerial implications.

From a technical standpoint, the prompting system was operationalized through the integration of Langflow v1.2.0 and KNIME Analytics v5.4.0. Langflow enabled the visual design of prompt-response pipelines connected

to Gemini Flash 2.0, while KNIME was used to automate the parsing of article texts, generate input prompts, manage sequential requests, and aggregate the model outputs into a unified dataset. At the end of this stage, 3 out of 95 articles in the corpus were excluded because their text could not be extracted from the source file. Thus, the number of articles effectively analyzed corresponds to 92, as shown in Figure 1.

Following the extraction phase, a Structured Content Analysis was conducted to classify the managerial competencies identified across the reviewed articles. By leveraging a coding approach based on human expertise, all managerial competencies were grouped by the authors into recurring thematic patterns through an iterative categorization process. This method allowed for the construction of a coherent and replicable taxonomy, capturing the strategic, relational, and cognitive dimensions of managerial skills in AI-driven organizational contexts.

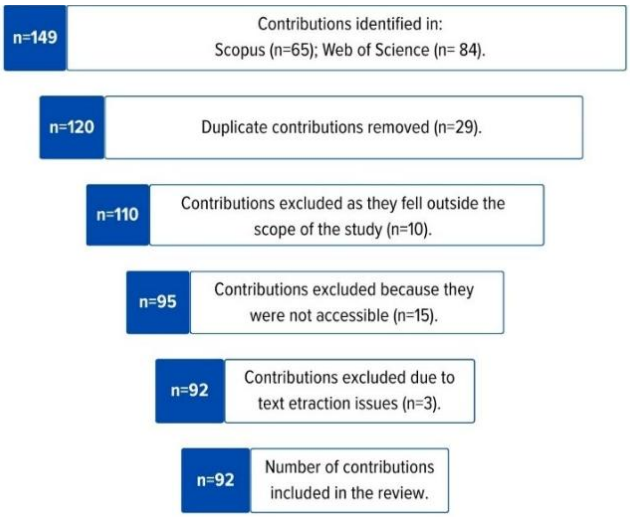

Figure 1: Diagram of the article selection process.

3 Results and discussion

The following sections present the results of this study, organized into two main areas: (i) managerial competencies, and (ii) numerical meta-analysis.

3.1 Managerial competencies

The main results are presented through a structured taxonomy of managerial competencies that emerged from the analysis of the reviewed articles. As shown in Figure 2, the taxonomy adopts a hierarchical structure articulated over two levels: four macro-competency families, each encompassing a set of sub-competencies that reflect distinct managerial competencies in AI-integrated contexts. The following discussion focuses on the four overarching dimensions identified through Structured Content Analysis: strategic and decision-making competencies, technical and analytical skills, ethical and regulatory knowledge, and leadership and change management capabilities.

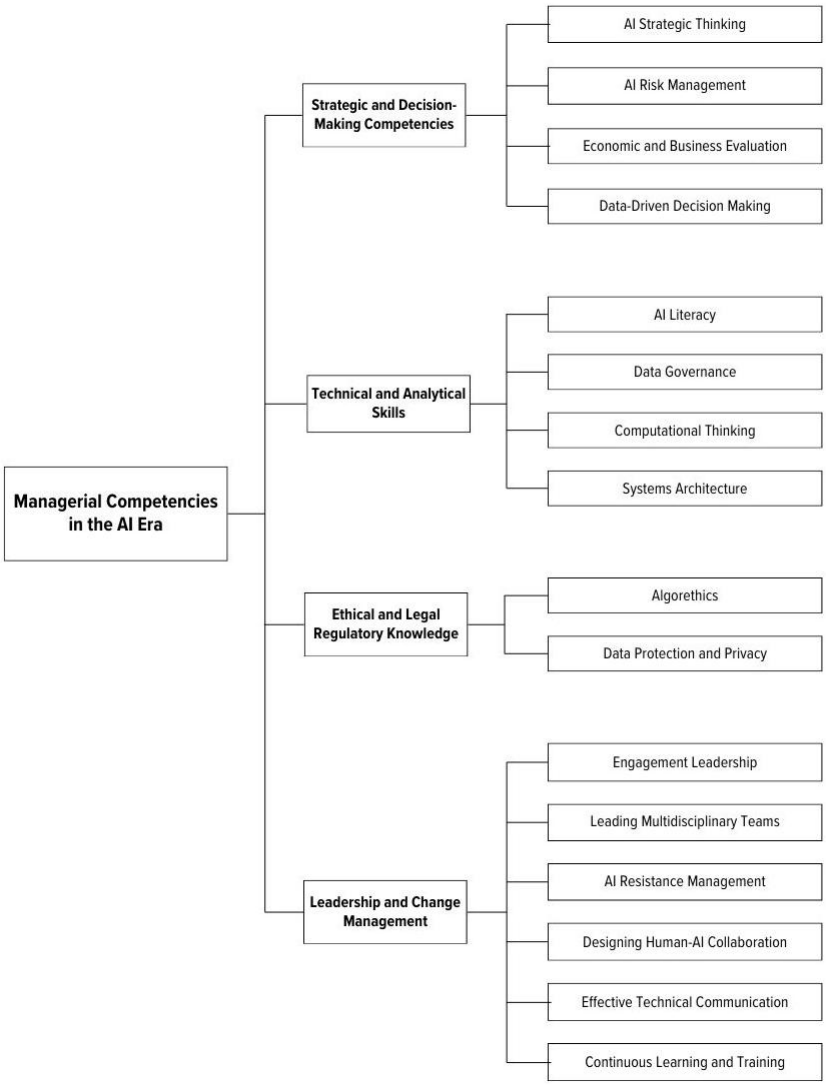

Figure 2: Two-level hierarchy diagram of managerial competencies

3.1.1 Strategic and Decision-making Competencies

The first family concerns strategic and decision-making competencies, which are recognized as paramount for managers operating in AI-driven environments. Strategic leadership capabilities and long-term vision are considered essential, particularly in contexts where shared orientations must be developed and perceptual divergences overcome in AI-based initiatives (Caro, 2008). The evaluation of AI from an economic and business standpoint is also frequently addressed, with a strong emphasis on the need for competencies that allow managers to assess its profitability and organizational impact (Baumgartner et al., 2024). Themes related to critical judgment and the ability to make decisions in complex and uncertain scenarios emerge as well, where a data-driven and experimentation-oriented mindset is often recommended as a managerial requirement (Jorzik et al., 2024). Moreover, a focus on data comprehension and familiarity with AI-supported decision-making processes is emphasized to ensure proper integration of algorithmic insights into managerial routines (Surbakti et al., 2024). Based on these contributions, four areas of competence were identified within this family: “AI Strategic Thinking”, which refers to the awareness of emerging technological trends and the ability to anticipate their impact and integrate AI into broader business goals; “AI Risk Management”, which involves understanding the risks associated with AI technologies and the ability to identify and assess such risks effectively; “Economic and Business Evaluation”, which concerns the ability to evaluate the financial and operational costs and benefits of AI adoption and to estimate the economic value of organizational data; and “Data-Driven Decision Making”, which relates to understanding how AI algorithms function, interpreting their outputs, and effectively integrating such insights into business processes.

3.1.2 Technical and analytical skills

The second family of managerial competencies focuses on technical and analytical AI-related skills, which are widely discussed across the reviewed literature. These competencies include the knowledge of AI applications, organizational data sources, and system interfaces (Baumgartner et al., 2024). AI literacy among top managers is also emphasized as a critical factor for effective AI adoption and business alignment (Pinski et al., 2024). Competencies related to data management play a prominent role, particularly in terms of the ability to handle both structured and unstructured data (Richthofen et al., 2022). Finally, technical skills related to the application of machine learning techniques are highlighted as essential for the operational implementation of AI solutions in organizational settings (Karki & Hadikusumo, 2023). Based on these contributions, four core subcategories were defined under the family of technical and analytical competencies. “AI Literacy” refers to the understanding of basic AI terminology, core functionalities, and the operational logic of AI applications, as well as the ability to evaluate performance metrics such as reliability and generalizability. “Data Governance” involves familiarity with the processes and tools for managing structured and unstructured data, including data quality procedures and metadata documentation practices at the enterprise level. “Computational Thinking” reflects the capacity to frame and solve complex problems using a structured and algorithmic approach. Finally, “Systems Architecture” relates to knowledge of enterprise digital infrastructures and the ability to integrate AI solutions with existing systems and platforms in a coherent and scalable way.

3.1.3 Ethical and regulatory knowledge

The ethical, legal, and governance aspects of AI represent central themes across a substantial portion of the reviewed literature. As AI technologies become increasingly embedded within organizational workflows, ensuring responsible and sustainable use requires structured competencies related to regulatory compliance and ethical decision-making. Organizational principles guiding AI implementation are seen as fundamental in promoting accountability and fostering trust (Fenwick et al., 2024). Ethical awareness is identified as a key managerial competency for AI governance, including the ability to anticipate, recognize, and mitigate ethical risks (Shahzad, 2024). Data protection and privacy also emerge as critical concerns, requiring managers to understand the implications of handling sensitive information in AI-driven systems (Baumgartner et al., 2024). In addition to privacy issues, effective governance must account for systemic vulnerabilities and emerging threats, calling for competencies in the design of robust control mechanisms (Almeida, 2025). Accordingly, two specific areas of competence were defined under this category: “Algorethics” refers to the awareness of the ethical dimensions of AI, the ability to recognize and mitigate algorithmic bias, and the capacity to translate moral values into computable principles. “Legal and Regulatory Knowledge”, on the other hand, concerns familiarity with relevant legal frameworks and policy landscapes, as well as with the principles of compliance, privacy, and data protection, which have become indispensable in contemporary management practices.

3.1.4 Leadership and change management

The successful adoption of AI requires strong leadership capable of managing organizational change and guiding teams through complex transformation processes. One crucial aspect of this competency area is the ability to coordinate interdisciplinary teams while actively involving end users in AI-related transitions to foster smoother integration and broader acceptance (Baumgartner et al., 2024). The concept of AI leadership often coincides with that of an “AI evangelist”, a figure able to inspire and motivate employees while promoting a comprehensive vision of AI implementation (Jorzik et al., 2024). Empathetic, inclusive, and adaptive communication practices are considered critical for ensuring employee alignment and overcoming resistance to AI-related change (Aldighrir, 2024). Considering these contributions, six sub-categories of competencies were identified. “Engagement Leadership” refers to the innovative mindset and openness to technology required to engage and motivate employees throughout AI adoption processes. “Leading Multidisciplinary Teams” concerns the capacity to assemble, coordinate, and manage cross-functional groups in AI projects, fostering collaboration, emotional intelligence, and effective integration between human and algorithmic components. “AI Resistance Management” highlights the ability to address and overcome cultural obstacles to AI adoption, providing both emotional and operational support during transitional phases. “Designing Human-AI Collaboration” relates to the definition of human and machine roles and the design of hybrid workflows. “Effective Technical Communication” involves the ability to translate AI-related concepts for non-technical audiences, ensuring organizational alignment and comprehension. Lastly, “Continuous Learning and Training” reflects the importance of cultivating a continuous learning mindset and of promoting upskilling initiatives among individuals unfamiliar with AI tools and processes.

3.2 Comparative overview

To contextualize the proposed taxonomy, Table 1 compares it with selected pre-AI competency frameworks.

Table 1: Overview of competency areas in existing frameworks and in the present AI-focused taxonomy

Model	Key competencies identified
(Hawi et al., 2015)	Leadership, problem solving, decision making, customer focus, strategic planning.
(Asumeng, 2014)	Intrapersonal skills (i.e., self-control, self-awareness, creativity), interpersonal skills (i.e., team building, networking), leadership, technical/business skills (i.e., business acumen, analytic thinking, decision-making), career skills (i.e., work commitment, work efficacy), mentoring skills (i.e., coaching, empathy, desire to help others).
(Khoshouei et al., 2013)	Value, analysis, decision-making, knowledge, adaptation, performance, leadership, communication.
Proposed taxonomy	AI strategic thinking, AI risk management, economic and business evaluation, data-driven decision making, AI literacy, data governance, computational thinking, systems architecture, algorethics, data protection and privacy, engagement leadership, leading multidisciplinary teams, AI resistance management, designing human-AI collaboration, effective technical communication, continuous learning and training.

3.3 Numerical meta-analysis

Alongside the qualitative taxonomy, a numerical meta-analysis was carried out to quantitatively assess the key characteristics of the reviewed articles. This approach offers complementary insights into the consistency and relevance of the contributions.

3.3.1 Application areas and sectors

Figure 3 illustrates the ranking of studies across ISIC-coded sectors. In cases where no specific application area was mentioned, the label “GENERAL” was applied. This category, together with “P – Education” and “M – Professional, scientific and technical activities”, accounts for the majority of cases.

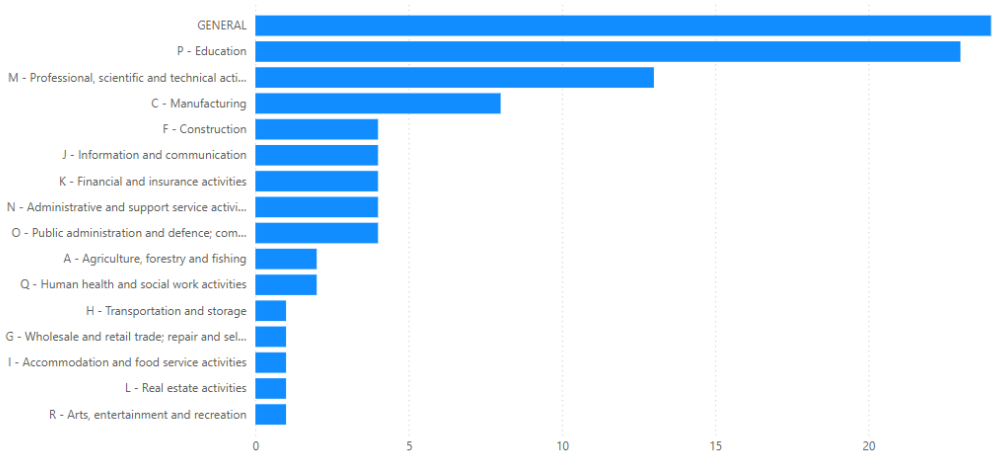

Figure 3: Horizontal bar chart showing the ranking of contributions by application area

These areas were then aggregated into macro-sectors according to ISIC Revision 4 classification. Records labeled as “GENERAL” were excluded. As shown in figure 4, most studies fall within the tertiary sector, with only a few contributions linked to secondary and primary sectors. This corroborates with Kataria & Devershi Mehta (2025), who found that AI adoption is notably higher in tertiary sectors.

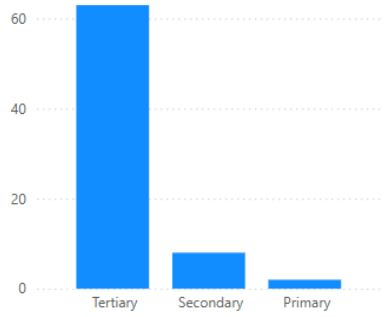

Figure 4: Vertical bar chart showing the ranking of contributions by sector.

3.3.2 Methodologies

As shown in Table 1, qualitative methods are the most represented, with content analysis and case studies as the dominant approaches. Quantitative designs follow, mainly through surveys and statistical analysis. Mixed methods and theoretical or conceptual papers are rare, and experimental designs appear only marginally.

Table 2: Absolute and relative frequencies of methodologies of the contributions

Methodology (Keyword)	Count	Relative Frequencies
QUALITATIVE - CONTENT ANALYSIS	26	28,3%
QUANTITATIVE - SURVEYS	14	15,2%
QUALITATIVE - CASE STUDIES	11	12,0%
QUANTITATIVE - STATISTICAL ANALYSIS	11	12,0%
QUALITATIVE - INTERVIEWS	9	9,8%
QUANTITATIVE - CROSS-SECTIONAL STUDIES	6	6,5%
MIXED - SEQUENTIAL EXPLANATORY DESIGN	3	3,3%
THEORETICAL	3	3,3%
CONCEPTUAL	2	2,2%
EXPERIMENTAL - FIELD EXPERIMENT	2	2,2%
MIXED - CONCURRENT TRIANGULATION DESIGN	2	2,2%
EXPERIMENTAL - QUASI-EXPERIMENTAL RESEARCH	1	1,1%
QUANTITATIVE - EXPERIMENTS	1	1,1%
QUANTITATIVE - LONGITUDINAL STUDIES	1	1,1%
Total	**92**	**100,0%**

3.3.3 Fit scores

The fit score measures how well each article aligns with the review's objectives. As shown in Figure 5, most studies scored between 3 and 5, with no article rated 1.

$$Average\ Fit\ Score = \frac{(2 * 9) + (3 * 28) + (4 * 39) + (5 * 16)}{92} = 3.7$$

The average score is 3.7 out of 5, confirming a generally strong thematic coherence across the contributions.

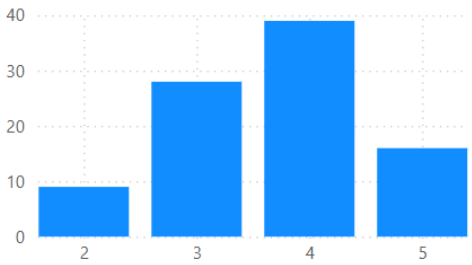

Figure 5: Histogram showing the distribution of fit scores among contributions.

4 Conclusions and future research

The proposed taxonomy offers a structured framework to understand how managerial roles evolve in AI-driven environments, where the integration of strategic, technical, ethical, and leadership competencies becomes increasingly essential. Beyond theoretical relevance, this framework holds practical value for organizations seeking to assess skill gaps, define targeted training initiatives, and align managerial development with technological transformation. In response to RQ1, the study identifies a structured set of AI-related competencies that are essential for corporate executives and managers operating in technologically advanced contexts. Regarding RQ2, the study suggests that the evolution of managerial roles in organizations is increasingly shaped by emerging demands such as the design of effective human–AI collaboration, the ability to govern algorithmic systems, and the capacity to lead interdisciplinary teams. These role transformations are reflected in the competencies required, which encompass strategic, technical, ethical, and change-oriented dimensions. Finally, addressing RQ3, the taxonomy includes a dedicated dimension on ethical and regulatory knowledge, highlighting the growing importance of governance, compliance, and algorithmic responsibility in leadership profiles.

From a theoretical perspective, the study contributes to the growing literature on AI and management by synthesizing fragmented insights into a coherent and operational taxonomy. It provides a useful reference for future empirical research aiming to validate, adapt, or extend the proposed framework in different contexts. However, some limitations must be acknowledged. The review only includes academic publications in English and covers literature published up to early 2025. Additionally, the taxonomy has not yet been tested in applied settings. Although LLM-assisted prompting ensured consistency and scalability, it may have introduced simplifications or overlooked implicit nuances in more interpretive articles. Future research could empirically test the framework across industries and managerial levels, examine the dynamic development of AI-related competencies over time, and explore their interplay with organizational culture, structure, and innovation strategies in real-world implementation scenarios. This framework can also serve as a practical roadmap for upskilling strategies and organizational readiness assessments in an AI-driven economy, offering concrete guidance to companies, training institutions, and policymakers involved in the digital transition.

5 Ethics declaration

No ethical approval was required for this study.

6 AI declaration

Large Language Models were employed to support content extraction and classification during the analysis phase, and to assist with language editing during the writing process. All substantive content, interpretations, and final editorial decisions were made by the authors.

Advancing Holistic Heritage Impact Assessment through Human-Digital Collaboration

Paola Demartini, Michela Marchiori, Rosa Fioravante, Flavia Marucci
Roma Tre University, Roma, Italy

Abstract

This paper explores the development and implementation of a digital knowledge-action platform designed to embed and translate the SoPHIA (Social Platform for Holistic Impact Assessment) method—a multidimensional framework for evaluating cultural heritage initiatives—into an accessible and participatory digital environment. Building on the Horizon 2020-funded SoPHIA project, the SoPHIA for CHANGES initiative, led by Roma Tre University and funded under Italy's Next Generation EU program, sought to address this gap by creating a digital platform grounded in the participatory ethos of the original SoPHIA method. The research employed a Participatory Action Research (PAR) approach, involving iterative cycles of collaboration between academic researchers, digital developers, and cultural heritage stakeholders. This methodology ensured that the platform was not merely a technical artefact but a co-created tool for reflexive learning, action, and knowledge transfer.
The research makes several significant contributions. Firstly, it enhances our understanding of how digital platforms function as socio-technical infrastructures for knowledge creation and dissemination within the cultural sector. It highlights a shift from static information repositories to dynamic, reflexive systems that actively engage and empower users. Secondly, the study introduces a process model for designing a comprehensive heritage impact assessment platform grounded in participatory knowledge management. This model offers valuable guidance for developing future knowledge-action platforms in cultural management and other complex, interdisciplinary domains. Ultimately, this project sheds light on how cultural heritage impact assessment can be disseminated and sustained through digital means without losing the critical reflexivity and human judgment that define meaningful heritage work. It demonstrates that digitalization, when rooted in participatory principles, can enhance—not replace—human creativity, sense-making, and collective action.

Keywords: Digital platform, Cutural Heritage, Impact Assessment, Knowledge Management, SoPHIA method

Paper type: Academic Research Paper

1 Introduction

Over the last two decades, literature on digital technologies and knowledge management has extensively addressed how new tools can reshape creativity, collaboration, and decision-making (Raisch & Krakowski, 2021; Eapen et al., 2023). Within the cultural sector, scholars have emphasized the disruptive and empowering potential of digitalization for heritage preservation (Zhou et al., 2012), cultural engagement (King et al., 2016; Doğan, 2022), art markets (Wang and Wang, 2021), and activities linked to creativity processes in arts (Ghosh and Fossas, 2022).

In particular, in the field of heritage management, there have been significant efforts at both European and country levels in digitizing and archiving historical data, artefacts and artworks to safeguard past knowledge (Macrì and Cristofaro, 2021) and share cultural heritage in a "phygital" (physical and digital) way (Del Vecchio et al., 2023).

However, despite these technological advances, there remains a notable gap in how methods for impact evaluation of cultural initiatives/projects may be operationalized and translated into accessible tools for practitioners, communities, and policymakers.

Addressing this gap, the H2020-funded SoPHIA project (Marchiori et al., 2021) developed a holistic heritage impact assessment framework, grounded in a multidimensional method. Inspired by the Faro Convention's people-centered approach to heritage, SoPHIA emphasized the need to assess the social, cultural, environmental, and economic impacts of cultural initiatives. Yet, while the method and toolkit of SoPHIA produced valuable knowledge on how to assess cultural heritage initiatives, the challenge of making this knowledge ready for use and broadly accessible persisted. In particular, questions remained around how to transfer this knowledge to diverse stakeholders through user-friendly digital means while maintaining the participatory ethos central to the original approach.

Building on this foundation, the Roma Tre University research team initiated the SoPHIA for CHANGES project, developing a digital knowledge-action platform (McIntosh et al., 2023), here defined as a digital tool that seeks to manage and organize knowledge, aiming at embedding and transferring the SoPHIA method within

a wider cultural heritage ecosystem. The project was funded through Italy's Next Generation EU investments under the CHANGES-*Cultural Heritage Active Innovation for Sustainable Society* partnership.

Against this background, this paper seeks to address the following research question: *How can the knowledge of the SoPHIA method be effectively translated and embedded into an interactive digital platform?*

To answer this research question, the project adopted a Participatory Action Research (PAR) methodology (Cornwall & Jewkes, 1995; Cornish et al., 2023). PAR offered a coherent epistemological and methodological framework to support co-creation, collective interpretation, and iterative learning processes during the platform's development. Unlike traditional top-down digitization projects, the platform design was grounded in cycles of problem identification, collaborative knowledge generation, reflection, and action with active involvement from researchers, technology partners, and representatives from the cultural heritage field. This methodology was fully aligned with the participatory nature of the SoPHIA model, ensuring that platform development was not merely a technical exercise, but rather a collective, critical, and creative endeavor. It was grounded in the logic of a boundary object (Leigh Star, 2010) —designed as a tool that is both comprehensible and accessible to academics and professionals across diverse fields of expertise.

The research made several key contributions. First, it advances knowledge on how digital platforms can act as socio-technical infrastructures for knowledge creation and transfer in the cultural sector (Dameri and Demartini, 2023), and moving beyond static information repositories towards dynamic, reflexive environments that empower users. Second, it provides a process model for developing a holistic heritage impact assessment platform based on participatory knowledge management principles, offering insights for future development of knowledge-action platforms in the cultural management field and other complex, interdisciplinary fields.

In practice, the SoPHIA for CHANGES platform represents a pioneering attempt to operationalize a holistic, people-centered impact evaluation framework through digital environments. It offers users a guided, interactive experience to evaluate cultural projects, selecting from sector-specific themes and indicators, learning from best practices, and adapting evaluations to local contexts. The platform integrates both academic and experiential knowledge, emphasizing collective ownership of the assessment process. Furthermore, by embedding mechanisms for continuous feedback and participatory updating, the platform embodies a knowledge ecosystem capable of evolving alongside its user communities.

Ultimately, this project sheds light on how cultural heritage impact assessment can be disseminated and sustained through digital means without losing the critical reflexivity and human judgment that define meaningful heritage work. It demonstrates that digitalization, when rooted in participatory principles, can enhance—not replace—human creativity, sense-making, and collective action.

The remainder of the paper details the background literature, methodology, key phases of the project, and broader implications for knowledge management theory and practice.

2 Background and research themes

In recent years, investments in the protection and enhancement of cultural heritage—both public and private—have grown significantly (Labadi et al., 2021). This trend reflects a broader acknowledgment of cultural heritage's role in driving social, cultural, and economic regeneration in contemporary societies (UNESCO, 2018). Despite an abundance of case studies and best practices (CHCfE, 2015), consensus remains limited regarding the core values and principles that should underpin such investments.Several landmark reports have sought to address this conceptual gap, including *Impact 08*, which evaluated Liverpool's tenure as European Capital of Culture (Garcia et al., 2010); *Cultural Heritage Counts for Europe* (CHCfE Consortium, 2015); and the *European Quality Principles for EU-funded Interventions* (ICOMOS, 2020). Each of these initiatives contributed to developing more structured approaches to assessing the value of cultural heritage projects.

Among the most recent and comprehensive contributions is the SoPHIA project, developed by a multidisciplinary team led by Roma Tre University (Marchiori et al., 2021). Grounded in the Faro Convention (Council of Europe, 2005), the project emphasizes shifting attention from the intrinsic value of heritage to its significance for individuals and communities. In doing so, it proposes a more dynamic and inclusive understanding of cultural heritage.

The SoPHIA Consortium aimed to construct a holistic evaluation framework to assess cultural heritage initiatives. This framework sought not only to identify intended outcomes and benefits but also to capture actual impacts across a range of dimensions (SoPHIA website).

At the core of the SoPHIA method are three analytical drivers:

People: This dimension includes stakeholders involved in decision-making or the use of cultural heritage. Understanding their perceptions and cognitive engagement is crucial to attributing meaning and value to cultural heritage.

Time: A temporal dimension guides investment decisions at different stages—ex-ante, ongoing, and ex-post—in project planning and execution.

Impact Domains: This perspective emphasizes a multidimensional evaluation framework that measures expected or realized impacts/changes from a multidisciplinary perspective. The SoPHIA impact domains emerged from discussions among over 200 European experts and encompasses six main themes of potential impact: social capital and governance; identity of place; quality of life; education, creativity, and innovation; work and prosperity; and protection (Marchiori et al., 2021; Baioni et al., 2021)

The SoPHIA project generated several outputs, including a conceptual method and a practical toolkit for implementation.

Upon completion of the project, the Roma Tre research team focused on two follow-up directions: applying the SoPHIA method to real-world case studies (Marchiori et al., 2024a, 2024b), and developing a digital platform to operationalize the method and facilitate its application through an automated, user-guided process (Demartini et al., 2025).

To this end, the team launched the *SoPHIA for CHANGES* project under the umbrella of the CHANGES partnership. This broader initiative involves 25 universities, research institutions, and businesses and aims to establish a national research infrastructure for the cultural heritage sector (CHANGES website).

The digital platform—conceived as a *knowledge-action* platform (McIntosh et al., 2023; Codagnone et al., 2016; Bonina et al., 2021)—is under development from April 2024 to November 2025. A joint team comprising Roma Tre researchers and a technology partner is collaboratively defining the platform's design, functionalities, and data processing mechanisms.

This effort is guided by a central research question: How can the knowledge developed in the H2020 SoPHIA project be effectively embedded into the digital platform *SoPHIA for CHANGES* and transferred to users?

Two interrelated research themes of knowledge management and practice underpin this research question:

Knowledge creation and transfer within cultural ecosystems:

The cultural sector has limited literature addressing how knowledge flows across academia and practitioners. Existing research suggests that, in a cultural ecosystem (Borin and Donato, 2015), collaboration among diverse yet complementary actors —rather than competition—creates a trust-based environment contributing to knowledge exchange and innovation. Such ecosystems encompass a wide range of stakeholders—including public institutions, private enterprises, artists, researchers, and citizens—whose interactions contribute to the production and consumption of culture. Within these systems, universities act as enablers and connectors, activating relationships and mobilizing talent (Florida, 1999) to generate cultural, economic, and social value (Dameri and Demartini, 2023).

Digital platforms as enablers of knowledge translation:

The study conducted by Baioni et al. (2021) revealed that digital social platforms are increasingly being employed in the cultural sector. Despite their relevance and diffusion, however, the degree of interaction with stakeholders is very low, and these platforms are mostly conceptualised as showcase websites. Building on the SoPHIA approach, this project aimed to go beyond and investigate how a knowledge-action platform can integrate automated processes with human-centered interpretation, opening new possibilities for participatory and reflexive evaluation in the cultural sector.

3 Methodology

To address our research question, it is important to fall back on the research approach that characterized the H2020 Sophia project.

The evaluation of the impacts generated by a cultural initiative, or project, implies the idea of a change — whether cultural, social, environmental, or economic — that can be produced within society (Rogers, 2014). These changes can be of multiple natures and require multidisciplinary knowledge to be identified, captured and evaluated. Moreover, in many cases, such changes can only be assessed by capturing the perceptions of those who, directly or indirectly, are the beneficiaries, recipients, or stakeholders involved in the cultural initiative.

Based on these premises, the SoPHIA research group adopted a Participatory Action Research (PAR) approach.

3.1 The Participatory Action Research

The Participatory Action Research (PAR) is a collaborative research methodological approach that actively involves participants (often community members or stakeholders) in the research process with the dual goal of generating knowledge (Cornwall and Jewkes, 1995; Cornish et al. 2023; Vaughn and Jacquez, 2020) and driving social change (Aguilera et al. 2007).

Unlike traditional research, where subjects are studied from a distance, PAR empowers individuals to become co-researchers—participating in the design, data collection, analysis, and even the implementation of solutions. As it has been defined:

"The key difference between PAR and conventional research lies not in methods, but in who defines problems, who owns the results, and who acts upon them." Cornwall & Jewkes (1995, p. 1669)

PAR is rooted in principles of democracy, equity, and social justice, aiming to address real-world problems through cycles of reflection, planning, action, and evaluation. It is particularly prevalent in fields like education, community development, healthcare, and social work. Its main features can be summarized in the display of a research design based on being: Collaborative: Involves researchers and participants equally. Action-oriented: Focuses on practical solutions. Reflective and iterative: Cycles of planning, acting, observing, and reflecting. Contextual: Rooted in the local, social, or cultural environment. Transformative: Seeks to empower and bring about systemic change. (Reason and Bradbury, 2001; Kindon et al. 2007).

According to Cornwall & Jewkes (1995), Participatory Action Research (PAR) involves a plurality of actors, each contributing distinct knowledge and roles within a shared process of inquiry and change. The actors engage in a dialogical and dialectical relationship. The goal is not extraction of information but co-production of knowledge and transformation (see table 1).

Table 1: PAR Actors

Involved actor(s)	**Role in PAR**
Community of practice / interested community	Central protagonists and co-researchers who identify problems, generate knowledge, and take action. Community of practice experiences and perspectives are the foundation of the research.
Researchers / Facilitators	Not neutral observers but engaged facilitators who support, catalyze, and co-analyze, aiming to reverse conventional power hierarchies. They contribute tools and theoretical frameworks, but relinquish control.
Inclusive perspective (involves all interested groups)	Minority groups are empowered through participation to address issues affecting their lives.
Institutions, NGOs and other intervening actors	Sometimes initiate or support PAR projects, but their agendas must be critically balanced to avoid co-opting community processes.
Change agents	Both internal (community-based) and external (e.g., researchers, NGOs), they help initiate and sustain cycles of reflection and action.

PAR revolves around a cyclical, action-oriented learning process where knowledge is built with and for those it concerns.

Here is how that unfolds:

1. Problem Identification

- Initiated by community members or jointly with facilitators.
- Based on lived experiences and local priorities, not imposed externally.
- Techniques include participatory mapping, storytelling, and visual tools.

2. Knowledge Generation and Interpretation

- Involves multiple epistemologies — blending scientific, experiential, and indigenous knowledge.
- Emphasis is on community-driven interpretation, not researcher-led.
- Researchers act as catalysts and learners, not authority figures.
- The process surfaces invisible structures, power relations, and assumptions.

3. Reflection & Mutual Learning

- Participants and researchers engage in collective reflection.
- This is not linear: learning evolves through the process ("praxis").
- Focus is on critical consciousness — recognizing problems and their structural roots.

Note that steps two and three are actually iterative moments that alternate multiple times

4. Action and knowledge translation/dissemination

- Knowledge leads to action, which provokes further reflection and learning.
- Solutions are driven by a people-centered perspective

3.2 The Participatory Action Research applied to our research project

As shown in the following table 2, the principles that underpin the H2020 SoPHIA project align closely with the PAR approach.

Table 1: SoPHIA core concepts that align with PAR

Sophia Principle	**PAR alignment**
Holistic impact	Community-driven, contextual insights
People-centered perspective	Co-Creation and shared interpretation
Integrated Policy-making	Action stage of PAR feeds into governance
Inclusive stakeholder voice	Central tenant of PAR

4 Findings

In the following, we will focus on the analysis of the processes of knowledge creation and transfer identified on the basis of the PAR approach and followed to design and implement the digital platform. Successive phases, actors involved, outcome and challenges encountered will be described.

4.1 Identification of the problem

The Problem Identification phase was crucial for ensuring the SoPHIA knowledge platform addressed the real needs of the cultural heritage sector.

This process can be summarized in two sub-phases, all grounded in a participatory action research (PAR) approach.

Phase I – Co-design of the SoPHIA method and Toolkit

The H2020 SoPHIA Consortium, together with diverse stakeholders such as local communities, heritage managers, NGOs, and policymakers, collaborated to identify crucial sector needs and define project goals. Among the key challenges were managing the multitude of disciplinary perspectives and ensuring that both the method and the toolkit would function as accessible, flexible tools across various professions and sectors.

Through open dialogue, several participatory workshops with stakeholders and discussions among the researchers, the Sophia method and its Toolkit were developed. These artifacts serve as ‘bridges’ or ‘boundary objects’, (Leigh Star, 2010) facilitating understanding among actors speaking different ‘languages’ within the cultural heritage ecosystem.

Phase II - Platform Concept Development

Within the Roma Tre CHANGES project team, debates were held to conceptualize the knowledge-action platform. This internal co-identification process focused on translating the SoPHIA method principles into a dynamic and participatory digital space capable of connecting research, action, and stakeholders. The objective was to define a platform that goes beyond static content, fostering real engagement and collaborative knowledge building.

Key outputs of this phase concern the identification of main problems. A critical point emerged around the choice between a window-website and a knowledge platform. The goal was to find a solution emphasizing user engagement and active enactment, ensuring the platform would not just inform but also empower stakeholders. Another criticality, researchers encountered, lay in the technological translation of the platform vision: it had to remain faithful to the participatory principle, stimulating active involvement in the evaluation process by the user while offering robust, user-friendly technology.

4.2 Knowledge Generation and Interpretation: from a method-model to a user-driven evaluative and learning process

The second phase, Knowledge Generation and Interpretation, emphasizes plural epistemologies and participatory engagement. Knowledge here is not the sole domain of scientists but emerges from integration of scientific and experiential knowledge.

Along with this approach, community-driven interpretation was central in the SoPHIA method. Instead of imposing external frameworks, knowledge production was collaboratively shaped by local stakeholders — communities, practitioners. Researchers no longer serve as authoritative knowledge-bearers but reposition themselves as catalysts and co-learners. Their role was to facilitate dialogue and create spaces for exchange.

Accordingly, customization of the digital platform was approached as a co-creative effort, aiming to embed in the digital tool sector-specific understandings of impact and brainstorming sessions were held internally within the core team of Roma Tre University.

Researchers collaboratively refined and summarised themes and sub-themes, anchoring them to indicators that were meaningful and recognizable to diverse users, including heritage managers, local communities, and policymakers. Special attention was given to the translation and simplification of SoPHIA guiding indicators for each original dimension, ensuring that these remained faithful to the original method and model, but were reformulated into accessible language and operational categories suited to the platform's diverse user communities.

A central aim during this step was to guarantee a blending of scientific, experiential, and sector-specific knowledge, ensuring that community perspectives guided interpretations rather than being researcher-imposed. To strengthen the relevance and applicability of the platform, case studies were integrated, enriching raw data with real-world examples. This allows users not only to engage with abstract models but also to connect with practical, lived experiences.

The process marked a deliberate transition from a general method-model to a user-driven evaluative and learning process, offering users concrete and actionable tools. By introducing best practices and tips, the platform moved beyond theoretical frameworks, proposing a dynamic, adaptive knowledge space capable of supporting reflexive learning and decision-making. This iterative approach aimed to enable users to recognize and validate their own knowledge systems within the platform environment.

4.3 Reflection and learning. Translating the SoPHIA method in the platform

The third phase, Reflection and Learning, based on shared interpretation and evaluation, was pivotal for translating the Sophia method framework into a practical and operational digital knowledge platform. This phase involved a continuous, participatory process of shared interpretation and evaluation carried out collaboratively by the Roma Tre University team and the technological partner team .

In a series of co-design workshops, wireframes and preliminary versions of the platform interface were collaboratively developed. These sessions included knowledge gathered by and from sector experts in cultural heritage, user experience, design, and data visualization. Together, the participants conceptualized key components such as the structure of the digital interface, navigation pathways, dashboard organization, and visualization tools (e.g., graphs, impact maps, progress trackers). The design process was dynamic, allowing the platform to evolve iteratively based on feedback and insights gathered during the workshops.

A central aim during this step was to ensure that the platform remained user-friendly while preserving the breadth, completeness, and depth of Sophia's rich conceptual framework. This required balancing the complexity of the original method with the need for clarity and accessibility for a wider range of users, including non-specialists in cultural heritage assessment. This translation preserved the theoretical rigor of the original method but made it operable through structured user workflows within the platform, ensuring users could navigate, input, and analyze information intuitively.

Key outputs of the process have been: a preliminary version of the digital platform was developed, aligned with user-centered design principles. A core set of evaluation indicators was established through collaborative refinement processes. Key lessons were integrated regarding how to communicate complex knowledge in a simplified yet rigorous manner. Researchers adopted an approach that combined specialist knowledge with engineering, aiming at user-centered design, through participatory validation, with the goal of making complex Sophia cultural heritage assessment method accessible, operational, and impactful within the platform environment.

4.4 Knowledge Translation and Dissemination: future steps

The fourth phase, Knowledge Translation and Dissemination, is a forward-looking phase, aimed at ensuring the long-term vitality, usability, and evolution of the digital platform developed from the Sophia method. Although still in the design stage, this phase outlines essential processes for operationalizing the platform in real-world contexts, enabling knowledge transfer across user communities, and establishing foreseen mechanisms for ongoing refinement

A critical action involves the deployment of trial versions of the platform among a selected group of pilot users representing the target audiences — including cultural heritage practitioners, policymakers, researchers, and community organizations. The trials aim to:

- Test the usability and intuitiveness of the interface to ensure a user-friendly experience
- Assess the applicability and relevance of the embedded indicators and dashboards
- Gather initial feedback on the user experience, interpretation of knowledge structures, and practical outcomes derived from using the platform

Structured trial protocols will be developed, including observation of user interactions, guided task completion exercises, and post-trial debriefing sessions.

Recognizing that the cultural heritage sector is dynamic and evolves in response to shifting societal, political, and technological contexts, the platform's sustainability depends on establishing continuous feedback mechanisms.

Future actions will include:

- Feedback channels embedded within the platform (e.g., user surveys, feedback forms, quick reporting buttons)
- Periodic focus groups and interviews with representative users
- Longitudinal monitoring of user engagement metrics and patterns
- Co-creation labs held at regular intervals to discuss new needs and adapt the platform accordingly

By institutionalizing a cyclical model of feedback, reflection, and redesign, the platform will remain aligned with emerging needs and retain its relevance over time.

This phase should yield: A set of validated methods for feedback collection and analysis; Guidelines for iterative redesign based on evolving user needs or policy changes; Definition of a sustainability plan ensuring the platform's active life and ongoing relevance; Fostering a vibrant, engaged user community that sees itself as co-owner of the platform's knowledge ecosystem.

Overall, phase 4 recognizes that the process of knowledge translation does not end with the launch of a digital platform and the embedding of Sophia method in the digital ecosystem, rather focusing on users as active participants in sustaining, adapting, and disseminating the embedded knowledge over time. Furthermore, it seeks to involve the community of practice further in continuous assessment and refinement of the platform itself.

To sum up, Figure 1 present a map of the processes followed by the team, which are the focus of reflection in this paper to answer our research question: How can the knowledge of the SoPHIA method be effectively translated and embedded into an interactive digital platform?

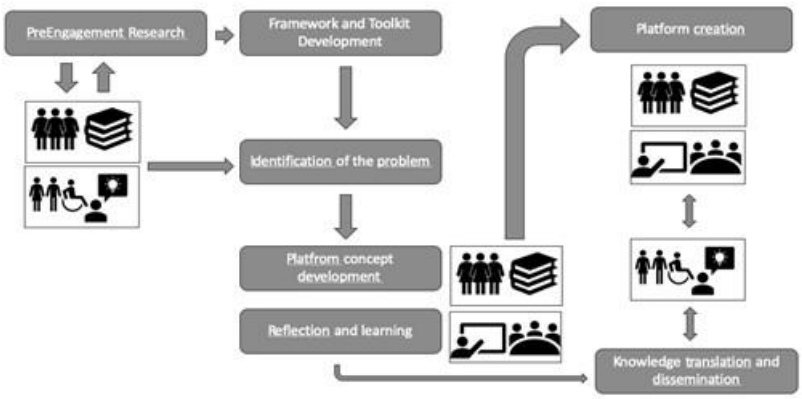

Figure 1: Participatory knowledge processes-SoPHIA digital platform

5 Conclusions

The findings of our research have enabled us to formulate the following main contributions.

Contributions to previous research

- Digital platforms exhibit three fundamental characteristics: technological mediation, task execution, and user interaction (Bonina et al., 2021). The *SoPHIA for CHANGES* platform embodies these traits by facilitating the transfer of knowledge on impact assessment—developed by researchers and experts of the cultural sector —to a wider audience. Through guided phases and interactive steps, users can adapt and apply the method within their specific contexts.
- The platform serves not only as a medium for knowledge transfer but also as a catalyst for new knowledge creation and its practical application. Its interactive design enables continuous updating through user-contributed case studies, fostering learning and inquiry. In this regard, our research contributes to the discourse on how academic research can support knowledge generation and translation in the cultural sector, particularly through the use of tailored digital tools (Dameri & Demartini, 2023).

Practical Contributions

- The platform represents a pioneering effort to archive knowledge and best practices from over 200 experts, serving as a valuable guide for investors, managers, policymakers, entrepreneurs, and citizens seeking evaluation insights in the cultural sector.
- The SoPHIA for CHANGES platform may contribute significantly to the fields of cultural heritage management, impact assessment, and digital technology integration. By offering an innovative and inclusive tool for evaluating cultural projects, the platform addresses critical knowledge gaps and supports stakeholders in making informed decisions. Ultimately, the project demonstrates that digital tools, when grounded in participatory principles, can facilitate the transfer of embedded knowledge through automated processes while preserving the essential roles of human judgment, creativity, and collective engagement.

Future research could further explore the user's perception of the balance between human and digital collaboration in practice and investigate how the platform evolves as new data and case studies are integrated.

The research also acknowledges certain limitations, particularly subjective biases. To enhance reliability, preliminary findings and interpretations were validated by organizational participants not involved in the initial data collection process. This validation provided an additional layer of objectivity and reduced the influence of researcher biases (Yin, 2018).

Digital Healthcare Technologies and the Co-Design of Healthcare Services: A Scoping Review

Elvira Tiziana La Rocca, Raffaella Coppolino
University of Messina, Messina, Italy

Abstract

Healthcare today more than ever is supported by technological innovation that has allowed the improvement of the standards of diagnosis and treatment but also the enhancement of the collection of anamnestic information and monitoring of the treatment path. The new digital health technologies (DHT) and the use of algorithms based on machine learning and artificial intelligence have improved the integration and analysis of data from different sources, becoming a driving force for network collaborations both for research purposes and for healthcare. Moreover, the innovative solutions resulting from the integration between technology and healthcare, aiming at strengthening health services efficiency and patient outcomes, involve the need to integrate complex technologies and specific skills in the design of instruments, devices, specialized health care services. In this context, the theme of co-designing healthcare services comes into play, and it involves a due analysis of the challenges to be faced in implementing co-design architecture.

The aim of the paper is to identify and analyse the coverage of the body of literature on the implication of DHT implementation in the co-design of healthcare services and give a trustworthy indication of the bulk of studies available as well as an overview of the key issues analysed. A scoping review is carried out to map the research done in this field and to identify critical themes and challenges.

The results of this work allow us to outline a cognitive map of the "areas of involvement" and to understand which challenges have already been faced and which are rising. Several interesting theoretical and managerial implications emerge.

Keywords: Digital Health Technologies, healthcare services co-design, scoping review

Paper type: Academic Research Paper

1 Introduction

The integration of digital health technologies (DHT) in healthcare systems has transformed the landscape of medical diagnosis, treatment, and patient care. Developments in machine learning and artificial intelligence have enhanced the capture, analysis, and application of health data from different sources to facilitate enhanced decision-making and coordination in clinical practice and research (Zhang et al., 2025; Rocco et al., 2024). These innovations offer significant potential to improve healthcare efficiency, optimize resource allocation, and enhance patient outcomes. However, the successful implementation of DHT requires a structured approach that comprehends specialized knowledge, technological capability, and insight into healthcare complexities (Kasula, 2024; Adeghe, Okolo and Ojeyinka, 2024).

In this new digital landscape, co-design of healthcare services has emerged as a crucial strategy to ensure that technological innovations align with patient needs, clinical workflows, and organizational goals. Co-design, as an open process involving several stakeholders (including healthcare practioners, technology creators, and patients), aims to create solutions to advance service development and patient experience (Wilson et al., 2024). Despite the potential benefits, there are significant challenges to the use of co-design methods in healthcare, involving the combination of advanced technologies, cross-disciplinary collaboration, and regulatory concerns.

Although research on digital health technologies and co-design in healthcare has progressed, there is a gap in the literature regarding the intersection of these two fields. Studies mostly focus on the technological advancements in healthcare or design processes but rarely explore their combined implications.

This study seeks to fill this gap by investigating how DHT influences the co-design of healthcare services, identifying key themes and challenges, and offering an overall picture of the current literature. Our research questions are: *How do scholars address the topic of DHT in the co-design of health services? Are there emerging key themes and challenges in the use of DHT in the co-design process of health services?*

We explore these aspects via a scoping review based on PRISMA standards and guidelines revised for scoping review (Page et al., 2021; Arksey and O'Malley, 2005; Tricco et al., 2018). By mapping the existing body of literature, our study provides insights on the key themes, concerns, and implications of DHT-driven co-design in healthcare.

This paper is structured as follows. The next section proposes a theoretical background. Section 3 presents the methodology, search strategy, selection criteria and data analysis. Section 4 illustrates our main results. Discussion and conclusions in the last section with some managerial and theoretical implications.

2 Theoretical background

Our analysis of the theoretical background regards two main streams of research: the role of digital health technologies in healthcare, and co-design methods applied to healthcare services. An understanding of both these fields allows to examine their intersection and to assess how digital innovations can enhance healthcare service design.

2.1 Digital Health Technologies in Healthcare

Digital health technologies involve a broad range of innovations, like telemedicine, wearable health monitoring systems, electronic health records, and AI-based diagnostic tools. Such technologies facilitate real-time health monitoring, personalized treatment plans, and data-driven decision-making, thereby improving the overall productivity and effectiveness of healthcare services (Cure et al., 2025; Tian et al., 2025). Machine learning algorithms and AI models have enhanced data processing capabilities, enabling predictive analytics to be used, automated diagnosis, and supporting more accurate patient risk analysis. Their increased adoption underscores their potential in transforming healthcare delivery and improving network collaborations among healthcare institutions.

However, the application of digital health technologies should be guided by ethical considerations. According to Hanjahanja-Phiri et al. (2024), ethical concerns for data privacy, informed consent, and the digital gap should be properly managed to avoid health inequities, to ensure responsible technology rollout, and to facilitate inclusive healthcare service design

2.2 Co-Design in Healthcare Services

Co-design, or participatory design, refers to the active participation of different stakeholders in designing healthcare services and technologies; it ensures that solutions are context specific, user-based, and address the needs of patients and healthcare professionals (Kasula, 2024). Co-design fosters a culture of collaboration in which knowledge sharing and interdisciplinarity enhance the process of developing healthcare innovations. Nonetheless, the integration of co-design and healthcare is not challenge-free, with technical feasibility straddling against user demand, managing stakeholder expectations, and health regulations (Adeghe, Okolo and Ojeyinka, 2024).

The integration of DHT in co-design activities introduces both opportunities and challenges. A good example is the co-design of digital mental health applications to foster youth, as explored in Ezimora et al. (2025), which emphasized the importance to give priority to end-users' lived experiences when designing technology. Similarly, Australian First Nations community research stresses the need for culturally specific co-design approaches that address healthcare access challenges (Khanal, 2025). Stakeholder involvement is relevant for effective and sustainable healthcare innovations development.

Ethical concerns should be integrated into co-design practices (Hanjahanja-Phiri et al., 2024), to ensure equitable and transparent public health surveillance and data-driven healthcare practices. On the one hand, digital tools enable efficient data collection, real-time feedback, adaptability of services and personalization. On the other hand, challenges such as data security concerns, need to be addressed to ensure the successful implementation of DHT-driven co-design frameworks (Wilson et al., 2024).

3 Methodology

As mentioned above, our research questions are: *How do scholars address the topic of DHT in the co-design of health services? Are there emerging key themes and challenges in the use of DHT in the co-design process of health services?*

To address these questions, the present study undertakes a scoping review methodology using the original Arksey and O'Malley framework (2005), further enhanced by Levac, Colquhoun and O'Brien (2010) and Tricco et al. (2018). A scoping review or scoping study is a form of knowledge synthesis that addresses an exploratory research question with the aim of mapping key notions, kinds of evidence, and gaps in research related to a defined area or field by systematically searching, selecting and synthesising existing knowledge (Colquhoun et al., 2014).

3.1 Search strategy and eligibility criteria

We conducted a literature search of relevant articles from Scopus, Web of Science and PubMed databases, with any limitation in the range of years of publication, in the language or the type of publication. This choice was made because the intention was to include all peer reviewed publications that, since the beginning of the implementation of DHT in the healthcare sector, have dealt with the topic, regardless of the use of a lingua franca. No screening was performed also regarding research areas, as health and technology are fields that are enriched also by studies from other disciplines. No exclusions were made based on the type of documents, as each contribution supports the formation of the scientific panorama.

This wide approach is also maintained in the string of search and in including in the selected record also the secondary sources of Scopus database. The database search terms included digital health* technolog* OR “dht” AND “co-design*” and the search strategy was adapted to suit each database.

The search results (as of April 2025) produced: 468 entries on Scopus, plus 5 secondary records; 344 entries on WoS and 327 on PubMed. The results from each database were exported to Zotero and duplicates were removed.

At the end of this first screening, the sample resulted in 621 publications.

3.2 Data charting

In the second step of our work, we used VosViewer (Van Eck and Waltman, 2010, 2017) to visualise the network of authors and co-occurrences. In this step, publications with a maximum of 25 authors were extracted and, among them, the connections between authors were identified. The total number of identified authors is n.3,505. Among them, 295 authors present at least two documents on the topic, and 28 present co-authorship links. This criterion has been used to identify the main themes harbingers of connections and, therefore, synergies between researchers. Figure 1 highlights that the set of publications is formed by a constellation of research groups, with often no connections.

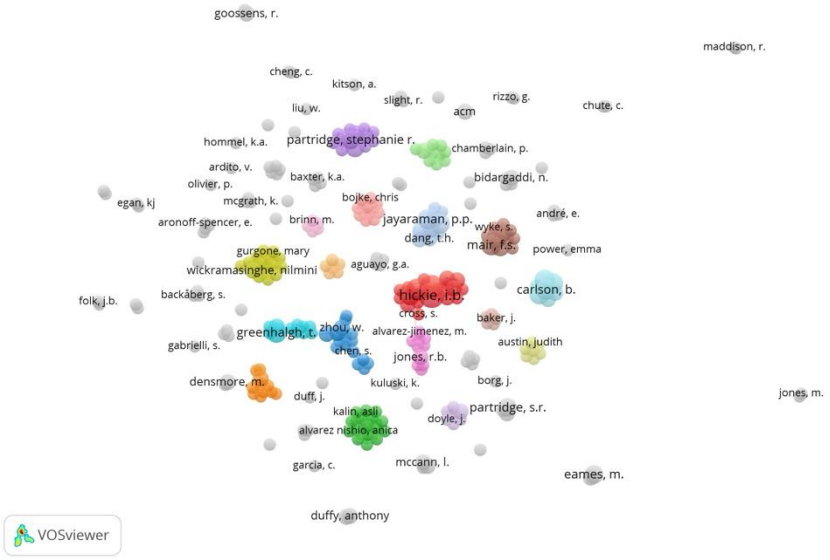

Figure 1 Constellation of authors (items:295; weight: documents; documents per author:2)

Regarding the main themes, an analysis of the co-occurrences in the titles and abstracts was carried out on the same sample. Out of 17,835 terms, those co-occurring at least 10 times were identified, i.e. 664 and, among them, those with greater relevance (60%) were 398. Of these, 46 generic terms were excluded that provide very little information and decrease the usefulness of the map, such as names of some months, and terms such as *journal, research, academic, paper, peer, period* and so on. The result is presented in figure 2, which also highlights in yellow the keywords of the most recent publications.

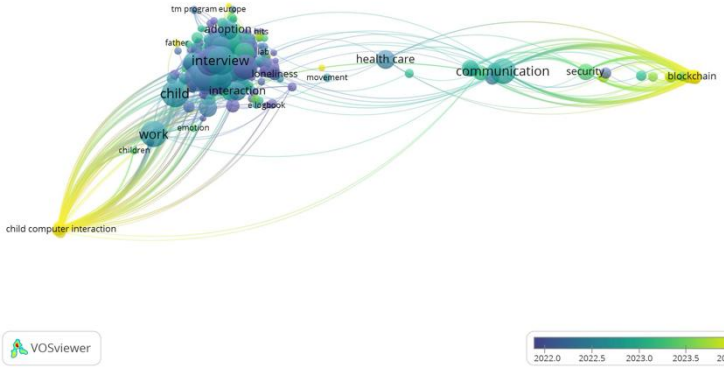

Figure 2 Overlay map of key terms (items:352; score: average publication year)

We can identify two distinct clusters: the first is focused on technological evolution and the related themes of communication and data security (figure 3); the second is focused on child and family health with particular focus on computer interaction (figure 4).

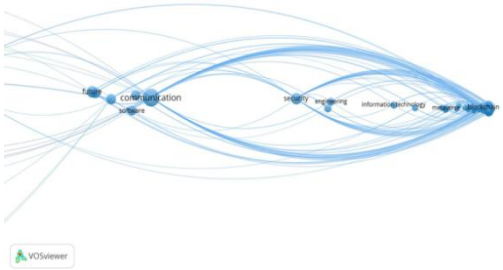

Figure 3: Cluster 1

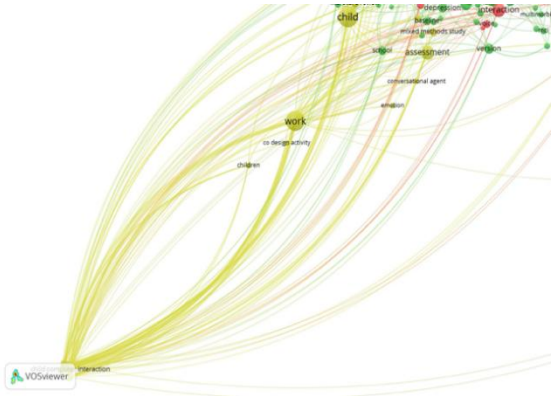

Figure 4: Cluster 2

Two other clusters, however, are strongly connected to each other and concern issues of management of healthcare processes, roles and specific diseases (figure 5)

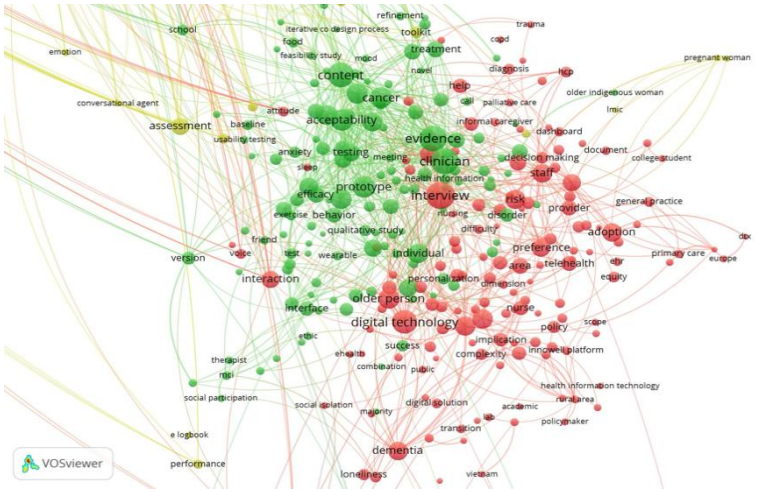

Figure 5 Cluster 3 and 4: The cohesion is based on the proximity of the keywords to each other.

4 Results

The analysis carried out has allowed us to understand how much the analysis of the implementation of DHT in healthcare co-design processes is still at an early stage. The studies that have proliferated in recent years seem strongly connected to the reference context and this is evident both from the presence of not linked constellations of scholars, and from the predominant choice of qualitative analyses (see table 1) which tend to deepen the understanding of behaviours, motivations and reactions, but have the limitation of producing results that are difficult to generalise and therefore not exportable.

Table 1: Used method, occurrence and relevance

Id	term	occurrences	relevance score	Id	term2	occurrences	relevance score2
1	interview	131	0.4227	**21**	preferred reporting item	10	24.643

Regarding the topics explored by the different groups, the following are of great relevance: mental health especially in young people and children (Bevan Jones et al., 2020; Hammond et al., 2021; Jones et al., 2020; Lipson-Smith et al., 2019); the health of an entire community (Henson, Chapman, et al., 2022; Henson et al., 2023a, 2023b, 2024; Henson, Rambaldini, et al., 2022); the care of older people (Bally et al., 2023; Darley and Carroll, 2022); support patients before and after surgery (Robinson et al., 2021, 2022); the support to selfcare and caregivers of cancer patient and people with dementia (Dang et al., 2021, 2023; Dang, Ludlow, et al., 2024; Dang, Wickramasinghe, Forkan, et al., 2024; Dang, Wickramasinghe, Jayaraman, et al., 2024).

Some of these topics represent strong challenges for today's society. Challenges that the correct co-design of interventions and the use of digital technologies can help to face and overcome.

5 Discussion and Conclusion

Our research develops a cognitive map of the "areas of involvement" concerning the role of DHT in healthcare and co-design methods applied to healthcare services. At the same time, some key themes, challenges and implications emerge in this field.

The mapping approach of our study highlights that in this new contest the traditional top-down decision making needs to evolve towards more network-based stakeholder interactions, with a patient-centered model and new forms of stakeholder engagement. Managers need to be flexible and collaborative with stakeholders,

invest in training approaches to develop digital skills for the successful implementation of healthcare policies. Moreover, with the increasing involvement of patients and caregivers, healthcare companies need to develop engagement strategies and implement ethical guidelines to ensure responsible DHT adoption in co-design, avoiding data privacy concerns.

Particularly, “taking a look at home”, this study can be useful for healthcare managers and policy makers to understand and act on the dynamics that are being activated in Italy with the application of the DM 77/22 for the development of proximity healthcare, which requires healthcare managers and policy makers to become increasingly familiar with the use of DHT, AI and machine-based learning in the management of interorganizational relations and partnerships for the co-design, co-management and co-monitoring of healthcare services and procedures.

In summary, the cultural and technological evolution of recent years led to an increasingly active involvement of patients, caregivers but also policy makers and suppliers of tools and devices in the care process.

6 Ethics declaration

The authors state that ethical approval was not required for this research.

7 AI declaration

The authors state that AI was not used in this research.

Abstract

Over time, the evolution of digital technologies has enabled a new perspective on knowledge as a collaborative and dynamic process, shaped through interactions among multiple stakeholders. These technologies facilitate real-time information sharing and support continuous knowledge creation and management in flexible, adaptive ways. Organizations increasingly rely on these digital tools to harness internal and external collective intelligence, fostering innovative knowledge practices. Particularly in project-oriented environments—characterized by complexity and constant change—digital platforms are essential to centralize information, promote collaboration, and enhance knowledge traceability and adaptability.
In this context, emerging platforms such as the metaverse reshape how work and collaboration occur. No longer limited to science fiction, the metaverse now provides immersive, interactive, and collaborative environments enabled by Virtual, Augmented, and Mixed Reality technologies. These digital spaces allow human resources to engage in work, learning, and social interaction in new ways. The metaverse, therefore, offers a promising environment for supporting knowledge management (KM) processes across organizations.
Despite growing interest in virtual environments for learning and communication, the implications of the metaverse for knowledge management remain underexplored. In particular, little attention has been given to how the metaverse affects the various dimensions of knowledge—from tacit to explicit, individual to collective, and from creation to application—especially in project-driven settings. This study addresses this gap by investigating the metaverse as a platform for KM, with a focus on how it facilitates the conversion of knowledge across these dimensions.
Using a qualitative methodology based on multiple case studies, the research examines how immersive virtual environments can enhance knowledge sharing, visualization, and decision-making in complex projects. Findings reveal that the metaverse enables the transition between tacit and explicit knowledge, supports real-time collaboration across distributed teams, and creates value at both individual and organizational levels. Features such as virtual prototyping, scenario planning, and real-time interaction with data and workflows improve communication, alignment, and coordination in project teams.
In conclusion, the metaverse offers a transformative opportunity to address the challenges of knowledge management in dynamic, project-based environments. This study provides insights that could be relevant to both scholars and practitioners in the fields of Human Resource Management and Information Technology.

Keywords: Knowledge Management; Human Resource Management; Digital Technologies; Metaverse; Case study

Paper type: Academic Research Paper

1 Introduction

Over the years, the widespread adoption of digital technologies has fostered a reconceptualization of knowledge as a co-created asset emerging from interactions among diverse stakeholders. Digital tools, by enabling rapid and continuous information exchange, support knowledge creation and management in dynamic and fluid forms. These technologies empower organizations to harness collective intelligence both internally and externally, facilitating novel approaches to knowledge development within organizational ecosystems. In such a context, knowledge must be effectively managed and integrated to ensure mutual understanding and practical relevance, particularly within project-oriented environments characterized by complexity, interconnection, and dynamism (Canonico and Söderlund, 2010). Getting control of multi-project organizations: Combining contingent control mechanisms. International Journal of Project Management, 28(8), 796-806.. The effective use of digital tools becomes essential to centralize information, foster collaboration, guarantee traceability, and mitigate knowledge fragmentation. Among the emerging technological frontiers, the metaverse is gaining recognition as a transformative environment where the dynamics of work and collaboration are evolving (Carter, 2022). Enabled by Virtual Reality (VR), Augmented Reality (AR), and Mixed Reality (XR)—collectively referred to as Web3—the metaverse offers a virtual, interactive, immersive, and collaborative space that can be accessed by Human Resource functions across organizations to perform tasks, engage in social activities, and facilitate

learning. Concrete implementations of metaverse-based practices are already evident in the corporate world. For example, Coty launched a virtual "Coty Campus" to upskill its 11,000 employees in digital competencies using immersive technologies (Vogue Business, 2022). Similarly, Accenture introduced the "Nth Floor," a corporate metaverse used for onboarding 150,000 employees, each equipped with VR headsets (Axios, 2022). Pfizer has also integrated metaverse solutions for internal training and team-building activities (Immersive Learning News, 2024). These examples demonstrate the metaverse's potential to transform knowledge sharing and learning processes within complex organizational settings.

Despite the growing relevance of such applications, the implications of the metaverse for knowledge management (KM) remain underexplored. In particular, a comprehensive understanding of how the metaverse affects various knowledge dimensions—such as the transition from tacit to explicit, the movement from individual to collective knowledge, and the process from creation to application—remains insufficiently addressed, especially in project-oriented contexts.

To investigate this gap, this study adopts a qualitative research design based on the multiple case study methodology (Stake, 1995; Tellis, 1997). This approach is well-suited to examining emerging and complex phenomena, as it facilitates the collection and interpretation of rich, contextual, non-numerical data (Hennink et al., 2020). It also allows researchers to capture subtle organizational dynamics, test new hypotheses, and generate novel research questions—particularly in areas such as digital transformation and the intersection of KM and immersive technologies. Through the analysis of case studies, this research explores how the metaverse facilitates knowledge management processes in project-oriented environments by enhancing collaboration, promoting the flow of information, supporting knowledge conversion, and improving organizational adaptability.

2 Theoretical background: Exploring knowledge management in the metaverse leveraging on project-oriented environments

In recent years, the organizational landscape has been profoundly transformed by the rise and widespread use of digital technologies. This shift has led to a reconceptualization of knowledge, no longer perceived as a static entity but as a dynamic and relational process, resulting from the co-creation among multiple organizational and inter-organizational actors (Piccolo et al., 2022; Iandolo et al., 2021; Schiuma et al., 2022). In this regard, knowledge is increasingly understood as articulating three fundamental dimensions (Ammann, 2009) for understanding and managing knowledge within organizations. It classifies knowledge according to its location (internal, explicit, or external), its kind (such as factual, procedural, or strategic), and its quality (including depth, structure, and modality). This model helps identify how knowledge is stored, expressed, and applied, offering a more nuanced view than traditional binary distinctions like tacit versus explicit. The literature has highlighted how digital technologies support the creation, sharing, and application of knowledge by enabling real-time and large-scale collaboration and communication (Fulk & DeSanctis, 1995; Argyres, 1999). Specifically, the integration of collaborative tools and digital platforms has enabled organizations to better leverage collective intelligence, both internally and within broader ecosystems (Bonabeau, 2009; Armenia & Loia, 2022). These technologies integrate data and knowledge from heterogeneous sources, enhancing organizational responsiveness to environmental complexity and supporting continuous learning (Yang et al., 2023). Nevertheless, KM practices face significant challenges in project-oriented contexts (Canonico et al., 2022), where temporary structures, complex stakeholder interactions, and uncertain outcomes make knowledge sharing and integration particularly difficult (Carlile & Rebentisch, 2003). In these environments, traditional hierarchical models of information management often prove ineffective due to the fragmentation of knowledge flows and the difficulty in ensuring traceability and operational coherence across teams (Waardenburg et al., 2022). Therefore, digital tools that can centralize information, enhance collaboration, ensure transparency, and facilitate adaptive work processes become essential (Muller et al., 2024).

Amid this backdrop, growing interest has emerged around the metaverse—a set of persistent, interactive, and immersive virtual environments enabled by technologies such as Virtual Reality (VR), Augmented Reality (AR), and Mixed Reality (XR), collectively referred to as "Web3" (Carter, 2022). Although originally conceived in science fiction literature, the metaverse is increasingly seen as a relevant space for interaction, learning, and collaboration within organizations (Hirsch, 2022). Several studies have acknowledged the potential of the metaverse to foster immersive and engaging experiences that support experiential learning and the co-construction of knowledge (Duan et al., 2021; Truong et al., 2021; Siyaev & Jo, 2021).

The metaverse can thus be seen as an effective platform to support conversions between different knowledge forms and to encourage individual and collective learning in complex and dynamic contexts (Loia et al., 2025). By leveraging immersive virtual environments, organizations can simulate scenarios, test operational

alternatives, and foster a deeper understanding of project goals. This leads to stronger coherence across organizational levels, reduced communication barriers, and improved alignment on deadlines and objectives (Siyaev & Jo, 2021). Furthermore, the metaverse proves especially useful for KM in processes such as onboarding, continuous training, and performance management, as it allows for the creation of contextualized and experiential learning paths (Duan et al., 2021). Furthermore, the metaverse introduces novel possibilities for developing organizational memory through immersive simulations and virtual archives. By embedding knowledge in interactive digital environments, organizations can preserve critical insights and lessons learned, enhancing long-term knowledge retention and reuse. This is particularly relevant in project-oriented contexts, where the cyclical nature of teams and tasks often hinders continuity (Argyres, 1999; Kirkman et al., 2004). As such, the metaverse can function not only as a space for real-time collaboration but also as a strategic repository of organizational intelligence, facilitating seamless knowledge transfer across projects and generations of employees (Hirsch, 2022; Fjeldstad et al., 2012).

However, the specific implications of the metaverse for KM remain relatively underexplored in academic research. Existing studies often focus on technological or experiential aspects (Loia et al., 2025) without providing a comprehensive analysis of their impact on different dimensions of knowledge and their management within organizational settings. Research is limited on using the metaverse in volatile, multi-stakeholder, project-oriented environments with temporary goals. These settings require tools and models that are highly adaptive while ensuring continuity in knowledge processes and organizational learning (Kirkman et al., 2004).

In conclusion, recent literature suggests that the metaverse represents a promising frontier for KM, particularly in project-oriented contexts. However, further theoretical and empirical work is needed to fully understand its strategic and operational implications. The main challenge lies in integrating technological potential with organizational needs by developing KM models that are flexible, scalable, and sustainable in the long term. Future studies could study integrating the metaverse into organizational processes can generate tangible benefits for KM, particularly by facilitating transitions between tacit and explicit knowledge, and by creating virtual environments where information is easily shared and contextualized (Ammann, 2009).

3 Methodology

We employed a qualitative case study approach (Yin, 1994, 2003) to thoroughly examine the core characteristics of the phenomena under investigation. The objective of this study was to gain a comprehensive understanding of the subject matter and to clarify its complexities. The case study methodology, as defined by Eisenhardt (1989) as a research strategy focused on understanding the dynamics within specific contexts, prioritizes qualitative approaches and ongoing research (action research) to describe, explain, and illuminate the evolving aspects of organizational phenomena. This methodology is particularly well-suited for investigating phenomena that involve multi-dimensional constructs, which are not easily operationalized through quantitative variables and are not fully defined semantically in the existing body of literature. According to Yin (2009) case studies are valuable for explaining, describing, or exploring events or phenomena in their real-life contexts, particularly when exploring causal relationships and pathways, such as those associated with the organizational adoption of new technologies. Unlike other research methodologies, the case study approach is particularly effective for addressing 'how' and 'what' questions, which can, in turn, contribute to theory development or refinement. This is especially pertinent to advancing theoretical insights on the adoption of the metaverse within organizations, an area that has gained growing attention in recent academic discourse.

While the Single Case Study approach is typically employed to observe and analyze unique, specific events, this study adopts a Multiple Case Study design to investigate recurring processes and phenomena through the comparative analysis of several similar cases. The Multiple Case Study approach facilitates a direct comparison of the similarities and differences in implementation practices across various contexts and it allows for more generalizable conclusions (Eisenhardt & Graebner, 2007). Adopting a qualitative and exploratory research approach, this study analyzes three international companies that are actively applying metaverse-based technologies. To maintain confidentiality, the names of the organizations and their CEOs were anonymized. The first CEO interviewed leads a recently established startup whose explicit mission is to support companies and brands in entering the metaverse. This Italian-based metaverse agency specializes in developing immersive experiences, services, and content through Virtual Reality, Augmented Reality, and NFTs. The second CEO represents an American company composed of a team of uniquely skilled professionals with decades of experience in the design, production, and application of immersive virtual reality solutions. With deep expertise in creative design, camera technology, software engineering, and hardware integration, the company delivers high-impact VR content and applications across a wide range of sectors, including advertising, sports, education, tourism, and entertainment. The third CEO leads an Italian metaverse studio based in Northern Italy, focused on developing immersive experiences that connect people, foster learning, and enhance organizational performance. This company offers consulting, tailor-made immersive projects, and a comprehensive training and education program aligned with corporate needs.

The interviews conducted played a crucial role in supporting the analysis of the case studies and enhancing the understanding of the benefits of implementing metaverse approaches. Specifically, within five months (from November 2024 to March 2025), two researchers conducted interviews with the CEOs of selected innovative companies in the metaverse domain, aiming to explore the use of these advanced technologies in the higher education context. The interviews averaged 60 minutes in length and were structured around open-ended questions. During each interview, the primary objectives of the research were introduced and discussed with the key informants. Subsequently, the researchers posed questions relevant to the research topic. While the

interview protocol was followed, experts were encouraged to engage in a conversational exchange. To ensure consistent transcription, interviews were recorded, and notes were taken. The interview transcripts underwent a two-pass verification process. Data coding was initially conducted separately by two researchers, and then the researchers shared and integrated their analyses to ensure the highest level of reliability (Gilmore & Coviello, 1999).

Table 2. Data collection and analysis

Data collection and analysis	Description	Main contribution
Set of semi-structured interviews	Initial data gathering	Preliminary characterization
Archival analysis	Additional information concerning both the technologies and the initiatives are gathered from sources such as reports and external communication	Further characterization and categorization of the metaverse towards the organizational environment
Data analysis, reduction, display and identification of interpretation patterns	Data are put into tables, and also analyzed in light of the theoretical constructs originated from the literature review. The data analysis is conducted through a combination of sessions where each of the authors works individually and then shares his/her result with the other researchers. Interpretation patterns emerged from this process	Key analytical concepts and findings are identified
Iteration with the literature	The review of key literature allows for better grounding the theoretical foundations of our investigation into current scholarly work	Key propositions about the contribution of design-based learning in open innovation

4 Results and discussion: The metaverse as a transformative enabler of knowledge management in project-oriented contexts: a knowledge cube perspective

In analyzing the data collected, certain key aspects related to knowledge management and organizational learning within the metaverse emerged. Specifically, the analysis revealed that the metaverse plays a crucial role in reshaping organizational processes, particularly in project-oriented environments. Emerging as an integrated, immersive ecosystem built on Virtual Reality (VR), Augmented Reality (AR), and Mixed Reality (XR), the metaverse offers a new frontier for knowledge management (KM). In particular, the study found that the metaverse's impact on knowledge integration and adaptation is essential for achieving project goals, especially within environments characterized by complexity, fluidity, and innovation. This analysis utilizes the Knowledge Cube model to examine the metaverse's influence on the type, kind, and quality of knowledge in organizations engaged in complex, temporary, and multi-stakeholder projects. The results highlight how the metaverse facilitates the exchange and application of knowledge, contributing to more effective organizational learning and project success.

4.1 Type or location dimension: integrating internal and external knowledge

The Type dimension distinguishes between internal (organizational, experiential) and external (market, stakeholder) sources of knowledge. In project-oriented contexts, the ability to combine these sources in real time is critical.

In terms of the location dimension, the metaverse enables real-time externalization of internal knowledge by allowing participants to embody avatars and interact in immersive environments, effectively bridging tacit and explicit knowledge through simulations and embodied communication. This supports internalization as well, as individuals can experience knowledge-rich contexts that mirror real project scenarios, promoting deeper personal assimilation. Furthermore, the metaverse provides a collaborative virtual ecosystem that bridges internal expertise and external information. In the three multinational case studies analyzed, CEOs reported that metaverse platforms can contribute to codify tacit knowledge (e.g., expert routines, lessons learned) into visual models and immersive simulations, which could then be augmented with external regulatory data, client inputs, and competitive intelligence. This integration ensures that project teams align their decisions not only with internal goals but also with dynamic environmental requirements.

By enabling a fluid exchange between internal and external knowledge reservoirs, the metaverse supports holistic, up-to-date understanding across project stakeholders—thus enhancing agility and coordination.

4.2 Kind or content dimension: bridging propositional and procedural knowledge

This dimension refers to the differentiation between propositional knowledge ("know-what") and procedural knowledge ("know-how"), both of which are essential in executing complex projects.

Along the content (kind) dimension, thus, the metaverse fosters a convergence of propositional, procedural, and strategic knowledge. Project team members can collaboratively engage with dynamic data, perform virtual tasks, and strategize within shared virtual spaces, blending declarative facts with hands-on practice and high-level planning in a unified context. Moreover, acquaintance-based knowledge is enriched through continuous exposure to simulated project environments that replicate complex, real-world dynamics.

In the three organizations studied, metaverse-based environments were used to transform abstract guidelines into interactive simulations, allowing team members to collaboratively test procedures, rehearse operational tasks, and revise workflows in response to live project needs. These platforms fostered contextualized learning by embedding knowledge into simulated environments where it could be experienced, rather than simply documented.

As a result, knowledge transfer became more experiential, intuitive, and scalable, especially for onboarding, role adaptation, and inter-team coordination. This transformation is particularly valuable in project-oriented settings where team compositions shift frequently and procedural continuity must be maintained.

4.3 Quality dimension: enhancing validity, reliability, and relevance

The Quality dimension evaluates knowledge based on its validity, reliability, and relevance to decision-making and operational success.

The metaverse improves these aspects by enabling real-time testing of hypotheses, simulation of multiple project scenarios, and experiential validation of project strategies. In the cases examined, organizations used immersive tools to validate design assumptions, conduct virtual inspections, and evaluate stakeholder feedback within interactive 3D environments. These practices reduced ambiguity, minimized rework, and accelerated consensus-building.

Thus, regarding the quality dimension, the metaverse enhances the structure and automation of knowledge by integrating multimodal representations—visual, auditory, spatial—within cohesive virtual frameworks. It supports deeper levels of knowledge by enabling layered interactions and feedback, while also increasing generality through scalable, cross-domain applications. Consequently, the metaverse acts as both a container and a catalyst for high-quality knowledge processes, supporting reflective and collaborative practices that are critical in complex project-oriented work.

Furthermore, by logging actions and decisions in persistent virtual spaces, the metaverse allows organizations to build a traceable, auditable organizational memory—essential for learning across projects and institutionalizing best practices.

4.4 Final reflections

Viewed through the lens of the Knowledge Cube, the metaverse emerges as a strategic enabler of advanced KM practices in project-oriented contexts. Its immersive, persistent, and collaborative nature facilitates the integration of internal and external knowledge (Type), enables the transfer of both declarative and procedural knowledge (Kind), and enhances the trustworthiness and applicability of knowledge assets (Quality). As shown through the three multinational case studies, the metaverse is not simply a digital novelty but a socio-technical architecture with the capacity to transform knowledge dynamics, sustain learning, and improve project outcomes in volatile, high-stakes environments.

5 Conclusion, limitations, and future research directions

This study provides a first attempt to stimulate an understanding of how the metaverse can serve as a transformative infrastructure for knowledge management (KM) in project-oriented environments. By analyzing three case studies, the research demonstrates how immersive virtual environments support the integration, codification, and dissemination of knowledge across distributed, cross-functional teams. Interpreting the findings through the lens of the Knowledge Cube model, the metaverse is shown to impact the type, kind, and quality of knowledge by enabling experiential learning, enhancing procedural transfer, and strengthening the validity and relevance of shared knowledge assets. As project contexts become increasingly volatile, dynamic,

and collaborative, the metaverse emerges not only as a technological innovation but as a socio-technical system that reconfigures how knowledge is produced, mobilized, and retained within organizations.

From a theoretical standpoint, this research contributes to the growing body of literature on digital transformation and KM by situating the metaverse within a well-established conceptual framework—the Knowledge Cube. It offers an original perspective on how immersive technologies affect the epistemological dimensions of knowledge creation and transfer in project settings. Moreover, the study extends the discourse on knowledge management in project-based organizations by highlighting how new technologies enable not only storage and retrieval, but also contextualized understanding and tacit-to-explicit conversion. This aligns with and advances theories of socio-technical systems, organizational learning, and dynamic capabilities.

For practitioners, the findings underscore the strategic potential of adopting metaverse technologies to enhance knowledge-intensive processes in project-based work. Managers are encouraged to explore immersive environments as collaborative knowledge spaces that can enhance team alignment, decision-making quality, and project agility. Specifically, the metaverse can facilitate onboarding, cross-functional collaboration, prototyping, and experiential training—activities that are essential for maintaining project momentum and innovation. Investing in these platforms may yield long-term benefits in terms of organizational learning, memory retention, and responsiveness to change, especially in complex, multi-stakeholder project ecosystems.

This research is not without limitations. First, the qualitative, multiple-case study design, while rich in depth, limits the generalizability of the findings across all industries and organizational types. Second, the analysis is based on early adopters of metaverse technologies, which may not reflect the experiences of less technologically mature organizations. Another limitation of this study lies in its exclusive reliance on in-depth interviews with the CEOs of the selected organizations. While these perspectives provide valuable strategic insights, they do not capture the views and experiences of other key professional roles—particularly project managers—whose operational involvement and practical knowledge could offer a more nuanced understanding of how the metaverse impacts project execution and knowledge practices on the ground.

Future research could address this gap by exploring the impact of the metaverse in smaller organizations or in varying organizational contexts, providing a more comprehensive understanding of its potential across a wider range of industries and company sizes. Future research should seek to expand the empirical base by conducting longitudinal and comparative studies across different industries and cultural contexts. Quantitative investigations could also be employed to validate the effects of metaverse-based KM on project performance, innovation rates, and team effectiveness. Additionally, further exploration is needed to examine the ethical, psychological, and organizational challenges associated with immersive technologies—such as user fatigue, data privacy, and virtual behavior norms. Finally, integrating the metaverse with emerging technologies such as artificial intelligence and blockchain presents fertile ground for advancing both theory and practice in digital knowledge ecosystems.

[4]ALTIS Advisory, Milano, italy

Abstract

This paper explores the concept of knowledge ecosystem created by Treedom, a pioneering B-Lab certified startup at the intersection of technology and environmental conservation. This research aims to provide a comprehensive understanding of how organizational dimensions play a role in a knowledge ecosystem settings where multiple logics coexist. In particular, we adopt the experience of a consultancy project carried out by ALTIS Advisory[1], a consultancy spin-off of Università Cattolica del Sacro Cuore devoted to promoting sustainability in established organizations and new entrepreneurial initiatives. This empirical study was based on a qualitative investigation. We carried out the analysis iteratively using a semi-grounded approach, and our data informed the selection of theories. Three data collection techniques were used: documentary analysis, participant observation and semi-structured interviews (one of the authors was part of the consultancy team during the project). The combination of social purpose and commercial strength equips Treedom to sustain, scale, and amplify the benefits generated throughout the ecosystem. Within this ecosystem, knowledge operates as a strategic asset that underpins the shared objectives of Treedom and its stakeholders. The social-impact assessment carried out by ALTIS Advisory thus became a collective learning exercise, enabling every actor to acquire deeper insight into their own capabilities, those of their counterparts, and the project as a whole.

Keywords – Knowledge creation, Hybrid organization, Consultancy project

Paper type: Academic Research Paper

1 Introduction

This paper explores the concept of knowledge ecosystem created by Treedom, a pioneering B-Lab certified startup at the intersection of technology and environmental conservation. This research aims to provide a comprehensive understanding of how organizational dimensions play a role in a knowledge ecosystem settings where multiple logics coexist. In particular, we adopt the experience of a consultancy project carried out by ALTIS Advisory, a consultancy spin-off of Università Cattolica del Sacro Cuore devoted to promoting sustainability in established organizations and new entrepreneurial initiatives.

The main goal of the project was to realize a path aimed at establishing a model for monitoring and measuring the impact of Treedom's agroforestry projects in the world. We decided to analyse this single case study due to its market success and given the replicability of the business model, as well as its adherence to the different environmental and sociocultural contexts of the countries in which Treedom operates. Assessing and measuring impact from a holistic perspective carries several conceptual ad operational consequences (Cerchione et al., 2025). Specifically, for this startup meant changing the mainstream paradigm, thus abandoning the financial performance assessment alone in favour of a more integrated and multidimensional system of evaluating the firms' outcomes (Liute & De Giacomo, 2022). What draws attention is the need to measure how an organization's activities affect the local area and community by quantifying the importance stakeholders assign to the changes they have experienced in their own lives (e.g., Adib et al., 2021; Xie et al., 2024). The context where the consultancy project was carried out is a classical example of hybrid area, where profit and nonprofit organizations cooperate in order to put together public (or common) and private goals. Treedom as B-Corp is a typical example of hybrid organization and the consultancy projects involves different actors that could be considered as part of a hybrid context (ONG, consultancy firm, local communities, etc). Though still in its infancy—and therefore marked by a degree of conceptual fluidity—this emerging field is rapidly gaining traction and holds exceptional promise, positioning hybrid organizations as one compelling arenas for future research (e.g., Cornelissen et al., 2o21; Vakkuri et al., 2021). Our aim is to give an insight from a knowledge ecosystem perspective. The rest of the paper is organized as follows: in the next section we introduce the

[1] *For more information on the consultancy firm, please visit the following website: https://www.altisadvisory.com/home/*

concepts of hybrid context. After a methodological section we present the case study; the last section discusses the main results and conclusions.

2 The hybrid context

The topic of hybrid organisations has been receiving renewed attention and research recently, due to the escalating social, environmental and economic challenges that organisations worldwide are facing (e.g., Stubbs, 2017). Therefore, there are several sources claiming that the number of hybrid organisations is growing (e.g. Haigh et al., 2015; Ratinho & Bruneel, 2024). Hybrid organizations are a compelling subject of study—not only for the distinctive structures they adopt, but also for their capacity to forge relationships and build collaborative networks that underpin their survival and entrepreneurial success (e.g., Cantele et al., 2023; She & Michelon, 2023). They offer an important contribution to society by fostering new models of local development and by nurturing multi-stakeholder organisations that drive territorial transformation through innovative, participatory, and adaptable solutions (e.g., Esposito et al., 2025; Wang et al., 2020). From this point of view, therefore, the boundaries between the profit and non-profit, public and private, work and voluntary dimensions appear increasingly blurred, in the face of the emergence of 'hybrid' actors, in which value is created, retained and shared through new and multiple forms of production by traditional businesses, non-profit organisations and public administrations (Boni et al., 2025). Therefore, the need to bring together the social and entrepreneurial perspectives requires the adoption of a 'hybrid' approach, capable of reconciling two visions that are only apparently different, the social and non-profit and the entrepreneurial and profit-driven business (Riso et al., 2024). The social, environmental and economic challenges open up new spaces of opportunity for the hybrid model (Holt & Littlewood, 2015), whose rise in contemporary society is explained by scholars with reference to an increasing prevalence of pluralistic and complex institutional environments (Pache & Santos, 2010; 2013; Thornton & Ocasio, 2008). A key aspect of this process is the involvement of actors from civil society and the third sector. These actors act as catalysts for new local initiatives and bottom-up experimentation, contributing to the transformation of social protection systems by providing more adaptable and contextualised responses than traditional public policies. Private actors and so-called social entrepreneurs also play an important role, introducing new ideas and investments that can support social innovation initiatives (Ghisellini et al., 2024). B-Corps are a classical example of hybrid organizations, as stated by Boni et al., 2025: 4440): "*…organizations part of the B Corp movement adopt a positioning in the hybrid spectrum that is closer to fully commercial for-profit organizations. B Corps are purely for-profit firms, which adopt a hybrid structure given by their social or environmental mission, having no legal obligation of profit retentions (Cao and Gehman 2021)*".

3 Methodology

This empirical study was based on a qualitative investigation (Yin, 2003). We carried out the analysis iteratively using a semi-grounded approach, and our data informed the selection of theories (Van Maanen et al., 2007). Three data collection techniques were used: documentary analysis, participant observation and semi-structured interviews (one of the authors was part of the consultancy team during the project).

Management scholars have increasingly adopted action research as a methodology to validate various research outcomes (Eden & Huxham, 1996). The capacity of action research to establish connections between theory and practice renders the results of action research potentially pertinent, comprehensible, and compelling to both practitioners and academic audiences (Baskerville, 1997). The methodology of action research is characterized by its dual objective of engaging in action and generating knowledge and theory pertaining to action (Coughlan & Coghlan, 2002; Erro-Garcés & Alfaro-Tanco, 2020). The involvement of the (client) organization in the study enhances the trustworthiness and reliability of the findings due to the collaborative nature of the analysis (Argyris & Schön, 1991).

4 The Treedom case: main findings

Founded in Florence in 2010, Treedom is the first organisation that allows people to plant trees from a distance and follow online the story of the project they will contribute to. Thanks to its business model, Treedom is a Benefit Corporation and has been a member of the Certified B-Corp since 2014. Since its foundation, more than 4,000,000 trees have been planted in Africa, Latin America, Asia and Italy, directly involving local organisations and farmers who, in their daily work on the individual seedlings, virtually connect with businesses and people globally through the 'adoption' system. All trees are planted directly by local farmers and help to produce environmental, social and economic benefits in full adherence to all dimensions of sustainability and fostering the 17 SDGs of the United Nation 2030 Agenda. By planting trees alone, Treedom contributes to the

achievement of 9 of the 17 Sustainable Development Goals. Treedom has chosen to undertake, with the scientific and methodological support of ALTIS Advisory, a path aimed at creating a model for monitoring and measuring the impact of its agroforestry projects in the world. A model that is characterised by its replicability over time and its adherence to the different environmental and socio-cultural contexts of all the countries in which Treedom operates. The results are therefore in line with the positive outcomes demonstrated by similar case studied on hybrid organizations, thus fostering the idea of the improvement of social and environmental impacts through its operations (e.g., Ghisellini et al., 2024; Boni et al., 2025). On top of the substantial impacts, measuring them means changing the financial- performance-led assessment paradigm, in favour of a more holistic system of evaluating firms' managerial practices and outcomes. Emerging evidence suggests that attention is now turning—cautiously—to measuring how an organisation's activities influence its territory and reference community, while also estimating, with due care, the weight each salient stakeholder group places on the changes it perceives in its own daily life (Riso et al., 2024). Measuring impact is tantamount to activating a dialogue: it is a choral work that combines expertise and scientific method with knowledge and experience of the specific context (Adib et al., 2021; Xie et al., 2024).

In line with the principles of Social Value's social impact assessment (Esteves et al., 2012), the methodology adopted mainly refers to the Theory of Change (Rajagopalan & Spreitzer, 1997) and follows a stakeholder-driven approach, with several successive steps. The fundamental characteristic of this methodological process lies in the fact that, through the involvement of relevant stakeholders, it is possible to collect their opinions and experiences regarding the pathways of change, determining the outcome dimensions to be attributed to Treedom's different activities, in an attempt to curb bias and self-referentiality that could arise from questions selected in desk mode. The theoretical framework of the Theory of Change is based on the observation that the construction of impact is realised through causal links and gradual and successive changes over time: thanks to the activities provided, the beneficiary at first expands his or her theoretical knowledge, subsequently increases his or her skills or begins to plan the implementation of previously developed theoretical knowledge and finally implements change through a modification of his or her behaviour (Rajagopalan & Spreitzer, 1997). Consequently, the indicators are defined around these elements of change: in some cases, they seek to assess the theoretical knowledge arising from the satisfaction generated by the intervention; in others, the skills developed within relationships; and in still others, the behavioural shifts and the resulting enhancement of the beneficiary's psychosocial well-being. Selecting the impact stakeholders constitutes the first necessary step in initiating the evaluation process and underscores its collective character, since it involves, from the very outset, the active participation of Treedom's representatives. The representatives were invited to fill out a structured questionnaire with the aim of identifying that specific subgroup of stakeholders on which it is possible to detect and measure the actual change that occurred between before and after the activation of agroforestry projects. The measurement process therefore advances along this dialogic track, blending desk research with the direct engagement of the heads of local organisations in Kenya, Madagascar, and Nepal through open-ended interviews. These meetings sought to explore how Treedom's projects relate to - and affect - each stakeholder group, with the specific aim of identifying:

- distinctive features of Treedom's activities and relationships;
- perception of the effects generated by Treedom's activities;
- possible contribution of parties external to Treedom to the generation of the effects identified above;
- potential risks and negative impacts.

The data that emerged from the survey phase made it possible to outline the impact dimensions, i.e. the areas in which Treedom's activity generates a change in stakeholders, declined in one or more impact indicators/themes.

5 Discussion and conclusions

Treedom's philosophy is to build sustainable ecosystems by directly engaging thousands of farmers worldwide. By covering the upfront costs of tree-planting, it enables them to develop resources that, over time, both safeguard the local environment and create ongoing income streams. The approach goes well beyond a simple financial transfer: it becomes an opportunity to share knowledge, establish production methods and processes, heighten awareness of local resources, and plan medium- to long-term programmes for growth and stewardship. The impact assessment is configured as an essential strategic tool for analysis and planning available to the organisation since it allows to deepen the knowledge of its ecosystem, identify projects related to its mission and business vision and make their management efficient in terms of resources, improve its accountability and structure an effective flow of communication to stakeholders in terms of enhancing the results achieved. The impact assessment conducted with Treedom therefore aims to determine how and to what

extent the agroforestry projects represent, for all stakeholders involved. Treedom finances projects in rural communities in the south of the world and also carries out projects with a strong social value in Italy. The first step is the training and financing of the communities involved in the projects, obtaining extraordinary results in terms of their own empowerment. The trees and their fruits belong to the farmers, allowing them to diversify and supplement their income and in some cases to launch micro-entrepreneurship initiatives. Financing the planting of new trees with Treedom serves to support the trees' care in the first years of their life, when they are not yet productive in terms of fruit.

In this sense, Treedom and all the stakeholders involved could represent a peculiar example of knowledge ecosystem. As stated by Öberg and Lundberg (2022; 293) "The concept of knowledge ecosystems has gained traction in recent research, with such ecosystems focusing on the knowledge-enhancing activities (knowledge sharing, knowledge development) rather than business interactions of a defined number of parties organised around a specified knowledge search or practice." Van der Borgh et al. (2012) describe the traditional knowledge ecosystem as a network of knowledge intensive firms and other interdependent actors whose effectiveness and efficiency rely on being geographically close to one another. More recent work argues that, while proximity can still facilitate knowledge creation, modern digital coordination tools now enable such ecosystems to operate across substantial distances, so co location is no longer indispensable (Still et al., 2014). In fact, Treedom demonstrates that spatial proximity has become largely incidental: its stakeholder constellation spans multiple continents, yet effective coordination and oversight are secured through sophisticated digital platforms, illustrating the expanding strategic reach of technology in sustainability-oriented, tech-enabled enterprises (Leitão et al., 2024). Although knowledge ecosystems were once dominated by universities and public research institutions, recent scholarship recognises that profit-seeking organisations also make substantive contributions to knowledge generation and diffusion (van der Borgh et al., 2012). The present case extends this insight, showing that a distinctive hybrid, for-profit enterprise such as Treedom can assume a central orchestrating function within the ecosystem, mobilising dispersed capabilities and aligning heterogeneous stakeholders around shared innovation trajectories. The ecosystem derives its cohesion from a clearly shared mission and values. One local partner remarked:

"Treedom is our main partner; its goals are identical to ours. Because it is both our principal collaborator and funder, we dedicate roughly 90 percent of our efforts to working with Treedom."

Beyond this strategic alignment, Treedom and its stakeholders explicitly view education as a pivotal lever for enhancing local livelihoods. As a representative of another partner organisation explained:

"What Treedom is a taking care and we talk many times and they also did training to us is first of all the importance of the nursery. The importance of doing the training to the farmers and the importance to do the follow up of the plantation. This is this is what we agree with Treedom".

Although Treedom's social mission remains paramount, its profit orientation is equally instrumental to the initiative's overall success. As a certified B-Corp that operates for profit, Treedom brings both a disciplined, professional approach to project management and the financial capacity that allows local partners to expand. The resulting growth is evident in the figures reported across the network. As one partner observed:

"This year we are increasing the number of trees we plant, reaching many more farmers, and expanding into additional districts."

In short, the combination of social purpose and commercial strength equips Treedom to sustain, scale, and amplify the benefits generated throughout the ecosystem. Within this ecosystem, knowledge operates as a strategic asset that underpins the shared objectives of Treedom and its stakeholders. Among the six overarching goals Treedom articulates—promoting education, cultivating awareness of social and environmental sustainability, disseminating sustainable agronomic practices, and investing in research and development—each is fundamentally knowledge-based. This orientation is reflected in key performance indicators reported in the social report, such as "variety of new cultivation tools and technologies introduced and adopted" and "extent of farmers' understanding of the environmental effects of their agricultural activities." The interviews conducted during the project reinforce this centrality: local partners see themselves as primary conduits for transferring knowledge to their communities, and all of them run tailored training programmes. The social-impact assessment carried out by ALTIS Advisory thus became a collective learning exercise, enabling every actor to acquire deeper insight into their own capabilities, those of their counterparts, and the project as a whole. Ultimately, Treedom's hybrid status - as a profit-making B-Corp with a pronounced social mission - creates the conditions for a robust knowledge ecosystem: commercial resources fund continuous capacity-building, while socio-environmental commitments keep knowledge creation and diffusion squarely focused on community development. Knowledge is a specific dimension of the system, because it is considered a fundamental "asset" to get Treedom and stakeholders' goals.

Abstract

In the management of public sector, digital transformation is supposed to lead to new and better service delivery by increasing efficiency and transparency, and by improving accountability. The complexity of the transformation process increases, in terms of actors involved and effects on working practice and way of interacting and offering services. The pressure is more and more on the response to the changing needs and aspirations of the society, supporting self-governance for local communities to be able to govern themselves with no or little interference from government. This process is still ongoing, requiring a great effort from academics and practitioners to understand different dynamics. This paper copes with a case of organizational change "triggered" by a process of digital transformation. We are specifically engaged in the change management of INPS concerning the potential development of a technological application for managing disputes under the jurisdiction of the Court of Auditors, with the objective of monitoring the recovery of state damages caused by the fraudulent actions of public employees.

In this setting, the focus is on the analysis of the reengineered business process in the effort to analyse jointly the digital transformation project and the organizational change. The paper may be located within emergent digital transformation literature.

Keywords: digital transformation, organizational change, public administration

Paper type: Academic Research Paper

1 Digital transformation in a public context

Digital Transformation (DT) is an expression related to a variety of organizational contexts and perspectives, both private and public, and it often used interchangeably with terms such as digitization, digitalization (Mergel et al, 2019). According to Otia and Bracci (2022), concepts such as digitization and digitalization underline technology, while DT is more concerned with strategy and the overall business model.

A stream of the literature has analysed the opportunity to deploy new technologies to stay competitive, in order to improve the efficiency through standardization (see, for example, Andal-Ancion et. al, 2003). A different stream has defined digital transformation as a way to rebuild business models following the needs of customers, by using new technologies. In this sense, digital transformation is a process of change that concerns innovation, the way in which it is implemented in the organization, and how people involved react to it. According to Luna-Reyes and Gil-Garcia (2014) in the public sector it is possible to identify two different transformations: (1) the transformation of internal processes, and (2) the transformation of the relationships between governments and other social and political actors (institutional transformation).

In the public domain, the concept of digital transformation seems more and more controversial, due to different kind of technological initiatives taken to overall the typical weakness of public administrations. According to Denhardt and Denhardt (2015), the processes of digital transformation in public administration are "complex" phenomena that involve the redesign and management of organizational structures, dynamics, processes, practices, tools and organizational and inter-organizational relations of the stakeholders involved.

Moreover, in the public sector arena, another expression is adopted to represent the digital transformation process. Many scholars refer to digital government or digital governance (Eom and Lee, 2022) as the way governments are trying to find innovative digital solutions to social, economic, political and other pressures, and how they transform themselves in the process (Janowski, 2015:221). What is interesting is the way to look at digital government as a process in action and in continuous evolution. Janowsky (2015:221) identified four different steps: Digitization (Technology in Government), Transformation (Electronic Government), Engagement (Electronic Governance) and Contextualization (Policy-Driven Electronic Governance).

The four-stage model is defined on whether the transformation has an internal or external impact and if transformation is or not related to a specific context in terms of sector or geographical space (country or city).

Moving from a step to another, the complexity of the transformation process increases, in terms of actors involved and effects on working practice and way of interacting and offering services. While in the first step the main focus is on technology, in the fourth step the pressure is on the response to the changing needs and aspirations of the society, supporting self-governance for local communities to be able to govern themselves with no or little interference from government Janowsky (2015:232).

This process is still ongoing, requiring a great effort from academics and practitioners to understand different dynamics.

As stated by Andersson et al. (2022:2) "digital technologies come with a logic of standardisation, rationalisation, efficiency, text-based communication and quantitative judgements (Petrakaki and Kornelakis, 2016); a logic that fits work that is purely calculative rather well. Other types of public sector work, for example social work, comes with a logic of situation specific practices, care, knowledge creation, qualitative judgements, and involves the careful and slow interaction with citizens, that embody and to some extent negotiate, the formal rules of the bureaucracy".

Even if it is not clear at all what digital transformation is and what it is not, the analysis of the allows the understanding that is a process that involves strategical and organizational dimensions and that is characterized by change.

In our perspective, such process is dynamic and context specific, so our approach is not finding the way fails or gets success, but understanding which organizational dynamics take place in a digital transformation experience. As stated by Andersson et al. (2022:2) "*The dynamics of how these changes come about in practice is however not known, and there is thus a need to look more carefully at how the work of public administrators is transformed though the development and implementation of automated technologies*".

Managerial literature, in fact, has mostly focused on understanding what are the critical success factor enabling digital transformation in the public sector (Gideon Mekonnen, 2019), and, except for a few of contributions (Mergel et al., 2019), has not yet investigated the different practices adopted in diverse public administrations following an interpretative perspective. In public administrations, practices are different because take place in specific settings, cultures, and legal frameworks. In this perspective, our work aims to investigate how to implement a digital transformation process in a unique context of public administration.

This article examines a case of an organizational change hypothesis initiated by a digital transformation process. We concentrate on overseeing the initial phase of the transformation launched at Inps, specifically the development of a technology application for managing public accounting loss litigation, which is intended to monitor the recovery of the State's credit.

In this setting, the focus is on the analysis of the reengineered business process in the effort to analyse jointly the digital transformation project and the organizational change. The paper may be located within emergent digital transformation literature.

In the remaining part of the contribution, after an analysis of the concepts of digital transformation, and a brief description of the intervention of digital transformation, we will analyse the methodologies of intervention designed and being implemented for the management of this complex case of organizational change.

2 Research method

This empirical study is grounded in a qualitative research design, employing an iterative and semi-grounded approach to data collection and theory building. Theoretical constructs were progressively developed and refined in the light of the empirical material, following a predominantly inductive logic. The investigation is based on a single-case study, selected purposefully for its relevance in illustrating the complexities of organizational transformation and digital innovation within a public administration setting (Yin, 1994). As Dyer and Wilkins (1991:614) emphasize, the in-depth examination of a single case may serve to uncover novel theoretical relationships and challenge established assumptions.

The selected case involves Italian National Social Security Institute (INPS), Italy's primary public social security institution, which administers a wide range of welfare programs including pensions, unemployment benefits, and income support. With a workforce of over 25,000 employees and a highly decentralized organizational structure, INPS represents one of the largest public institutions in the country and serves as a paradigmatic context to explore public sector digitalization initiatives. The case is situated within a broader organizational change program undertaken by INPS, aiming to modernize its internal processes and service delivery through digital transformation strategies.

This case study examines a specific intervention proposal inside INPS, in which a mid-level public employee recognized significant deficiencies in the ICT dimension of the overall process of overseeing and reclaiming fines related to convictions levied by the Court of Auditors on personnel accountable for administrative offences.

The data were collected through a triangulated methodology incorporating document analysis, participant observation, and semi-structured interviews. The documentary corpus included strategic plans, organizational charts, internal reports, and digital transformation roadmaps. These materials allowed for a comprehensive understanding of the structural and procedural aspects of the change initiative, including timelines and change management tools. Participant observation constituted the principal source of data. It was conducted over a six-month period, with the embedded researcher attending regular project meetings, and intra-departmental coordination sessions, to analyze all administrative, legal, economic, and technical complexities associated with the management and oversight of the phenomenon.

Observations were recorded in the form of detailed field notes, which captured both formal decision-making processes and informal interactions among project stakeholders. In the six months (October 2023 - March 2024) in which the data collection phase was carried out. During the data collection phase, approximately 30 comprehensive interviews were conducted with key informants, including several employees from the Directorate of Information Technology and Innovation (DCTII) and public officials directly engaged in the pilot phases of the digital services redesign.

The analysis of the current situation was essential, involving the mapping of primary and support processes, the identification of the requisite legal framework that must be adhered to and serves as the legal prerequisite for transformation, the recognition of critical issues or areas for improvement, the exploration of solutions, and the subsequent organic redesign of the process utilizing enabling digital technologies. The presence of elevated critical metrics indicated the need and opportunity to enhance the overall effectiveness and efficiency of the operation. The comprehensive effort aimed to discover operational criticalities, thereby determining the essential functionalities of the application and its practical feasibility, particularly regarding interoperability. The endogenous factors (internal context) and exogenous variables (external context) were delineated. The analysis of several variables has facilitated the formulation of an IT strategy conducive to attaining the established objectives. The meetings discussed the technical design intervention, which may encompass both a phase of mere digital transition and a following one of genuine transformation.

The analysis proceeded in multiple iterative stages. Initial memos were produced based on preliminary coding of interview transcripts and observational notes by the proficient regional team, which proposed the investigation and identification of key concerns to formulate the change plan.

The study team deliberated on these documents to develop common interpretative frameworks. The current process was subsequently built using a combination of inductive and deductive coding strategies based on the recommendations generated by the Team, highlighting essential characteristics such as coordination mechanisms, interpretative challenges, and technical affordances.

Triangulation was systematically applied, comparing the insights from interview data with field observations and documentary evidence. Particular attention was paid to the discursive and practical manifestations of knowledge sharing across professional boundaries—e.g., between IT personnel and frontline administrators—emphasizing how new tools and routines were localized, adapted, or resisted. The analytical approach has been informed by theoretical frameworks from organizational change and public sector innovation studies: the proposed digital transformation seeks to enhance the performance of both individual and collective processes, in accordance with the objectives established by the legislator.

In the final phase, the data were synthesized into a narrative that elucidates the unfolding of the transformation process at INPS, highlighting the critical tensions and enabling factors that shaped its trajectory.

3 Case study

3.1 The INPS "Co.Ded" Platform Initiative

In Italian National Social Security Institute (INPS), digital transformation is of paramount importance for achieving organizational efficiency and reinstating citizens' confidence in institutions. Conte and Solari (2023) emphasized that the INPS scenario exemplifies not merely a technology advancement but also a fundamental transformation in organizational structure, propelled by the integration of three strategic pillars: digital innovation, technological modernization, and human capital enhancement. The axes of change are located within wider theoretical frameworks, including the New Public Management paradigm (Pollitt et al., 2007), the digital-era governance model (Dunleavy et al., 2006), and the developing concept of public value creation, which

collectively necessitate a reconfiguration of bureaucratic models towards participatory, adaptive, and user-centric governance forms.

In this context, INPS serves as a distinctive area of study for understanding how digital transformation, combined with a strategic initiative to engage internal stakeholders via viral and distributed change mechanisms (Solari, 2016), can enhance both the operational efficiency of a public institution and its ability to create value within intricate socio-technical systems.

The digital transformation at INPS was not only a technological replacement, but a purposeful and systematic organizational redesign based on participative principles and underpinned by a cohesive change management framework. Understanding that the efficacy of digital tools is influenced by organizational culture and human behaviour, INPS implemented its transformation through four interconnected workstreams: (1) articulating vision and strategic intent, (2) cultivating strategic human capital, (3) systematizing institutional knowledge, and (4) innovating work modalities, including the structural integration of smart working (Solari, 2023).

The comprehensive digital transformation initiative of INPS in our case study primarily centers on the creation of a technological application for overseeing public accounting loss litigation, intended to track the restitution of State damages arising from the fraudulent actions of public employees.

3.2 The assessment of the as-is system

The current process of public accounting loss is characterized by high procedural complexity, low technological support, and a reliance on manual tasks. Activities span multiple organizational levels (territorial, regional, central) and involve several functional domains (disciplinary offices, legal services, accounting units).

The administration of fiscal damage (“danno erariale”) recovery at INPS is fragmented across several dimensions:

- procedural dimension: the process is delineated into distinct phases—reporting misconduct, commencing disciplinary proceedings, escalating legally to the Corte dei Conti, and ultimately enforcing financial recovery—each managed by a separate organizational unit without centralized coordination;
- technological dimension: diverse software environments (e.g., SAP, ARCA, "Recupero Indebiti," S.G.D. platform - document management, RIAF, Reduced and Disjoint Payments, PUNTO FISCO, PDND) operate in isolation, lacking systematic interoperability. Essential data elements, like case status, recovery amounts, and regulatory deadlines, necessitate manual extraction and re-entry across systems, thereby amplifying inefficiencies and heightening the organization's vulnerability to data loss or misreporting.
- geographical dispersion: accountability for implementation is distributed across regional, central, and local offices, each possessing varied competencies and interpretative latitude regarding defined protocols.

The as-is situation reported an organizational misalignment, in which structure, processes, and information systems are not cohesively arranged.

A significant aspect of the status quo is the excessive dependence on human interaction. The complete workflow, encompassing damage assessment and the commencement of recovery operations, is conducted manually by individuals possessing extensive tacit knowledge. The lack of process automation implies that: the precision of data is contingent upon the specific competencies and diligence of personnel; employee turnover, subjective judgment, and knowledge silos compromise process consistency; compliance risk escalates, when legally mandated deadlines (e.g., annual reporting to the Corte dei Conti) may be overlooked due to excessive workload or coordination deficiencies.

The impetus for transformation is not only efficiency-driven but normative: INPS, as a major national welfare institution, operates under increasing scrutiny regarding public value, equity, and digital maturity. The proposed transformation—conceptualized as both a technological intervention and an organizational redesign—therefore becomes essential not only for performance improvement but for institutional accountability and resilience.

3.3 Business process reengineering and digital enablement (to be)

The digital transformation program implemented by INPS was based on the foundation of Business Process Reengineering (BPR) (Hammer and Champy, 1993). The program sought to completely rethink the process for executing and monitoring financial recovery associated with public employee wrongdoing, rather than simply digitizing current procedures. The transition involved a fundamental shift from a disjointed, manual, and human-reliant process to a cohesive, automated, and digitally traceable system.

In the development phase of the digital transformation proposal, the goals and project objectives were delineated, with the latter being more explicit and specific, as they concentrate on the precise final outcomes

to be attained upon project completion. The work under review was assessed for adherence to the S.M.A.R.T. methodology (Specific, Measurable, Achievable, Realistic, and Time-bound).

The Process Card – Critical Process Profile was employed to elucidate the purpose of the process, defined as its final output. This tool facilitated a concise and detailed identification of the service recipients, the expectations to be fulfilled, the functions to be executed, the reference standards, and the contribution to the internal customer.

The subsequent phase involved the hierarchical decomposition of the process, progressing from macro-activities to elementary activities, which represent the optimal level of disaggregation necessary for a comprehensive description of the process activities, following a top-down methodology; the selected instrument for this decomposition was the Work Breakdown Structure (WBS).

The Work Breakdown Structure (WBS) for elementary activities was developed, delineating the precise level 2 activities to which I allocated each process actors, specifying their related roles, responsibilities, and qualities.

The access control model matrix delineates access rights for each role, facilitating access regulation and restricting information knowledge to only what is essential for executing requisite job responsibilities.

This ensures a high level of security and protection for the information and data entered in the INPS application.

The shift from the "as-is" to the "to-be" configuration was formulated within a holistic framework. The newly developed digital infrastructure, termed "*Contenzioso Danno Erariale Dipendenti (Co.Ded*)", aims to replace the existing fragmented and document-centric methodology with a platform that can manage the complete end-to-end procedure. The architectural redesign was guided by principles of modularity, interoperability, data integrity, and role-based access control, along with the core elements of the Italian Codice dell'Amministrazione Digitale and the European Interoperability Framework (2017). The system was conceptualized to act as a centralized, secure, and interoperable application for managing litigation-related procedures at INPS.

The objectives were mainly to enable automatic assignment of recovery procedures based on territorial jurisdiction, ensuring real-time traceability, integrating access controls and role-based functionalities to produce automated reports for both internal governance and external judicial authorities.

The use of a process-oriented methodology will facilitate a distinct delineation of process boundaries, identifying the initiating and concluding events (i.e., receipt of the final ruling by the Corte dei Conti and closure of the recovery file), the principal responsible entities (notably the Disciplinary Proceedings Unit—UPd) and regional teams, and the essential outputs (such as official notifications, structured reports, and procedural updates to oversight bodies). Internal stakeholders anticipated enhanced timeliness, procedural transparency, data accessibility, and the eradication of superfluous manual activities.

The platform architecture was designed in accordance with the concepts of platform thinking, as defined by Gawer and Cusumano (2014). The Co.Ded will serve as a digital nexus that connects with established corporate systems, including SAP for payments, RIAF for preventive enforcement actions, and the S.G.D. document management platform, facilitating semantic and procedural interoperability across functions. This integrative architecture will enable real-time data synchronization, timely state credit recovery efforts, automatic task distribution based on jurisdictional criteria, and a cohesive audit trail that complies with cybersecurity norms and public accountability.

A key characteristic of the Co.Ded platform proposal is its ability for sophisticated automation. The system independently will produce procedural documentation, including official warnings, responsibility assignments, and annual reports for the Corte dei Conti. It will also encompasse a notification engine that detects procedural bottlenecks and dispatches notifications to the accountable units. In subsequent generations, the platform may integrate artificial intelligence modules—such as chatbots for user support or case-based reasoning systems that suggest actions based on past data—thereby evolving into a more intelligent and adaptive process architecture.

The project, upon implementation, should be organized into several phases: initial feasibility assessment, system design and prototype, pilot implementation, nationwide rollout. The allocation of roles among functional units was identified, thus ensuring project governance and reducing role ambiguity—termed "accountability vacuums" by Scott and Davis (2007) in complex bureaucracies.

Importantly, the design of Co.Ded was not solely focused on technical capabilities but sought to augment institutional capability. By integrating decision logic into the system, INPS can institutionalize implicit knowledge, diminish reliance on individual expertise, and enhance resilience against people turnover, regulatory changes, or procedure intricacy.

Moreover, the platform will guarantee complete adherence to legal regulations pertaining to administrative processes, privacy, and public financing. The platform will provide strong safeguards against data loss, unwanted access, and information imbalances that have traditionally affected document-heavy public sector settings.

The Co.Ded platform will signify a technological advancement of the procedural and institutional framework overseeing a vital function inside INPS. It indicates a transition from human-centered coordination to digitally mediated governance, providing an exemplary framework for other public administrations aiming to synchronize digital transformation with organizational efficacy and legal responsibility.

The Co.Ded platform aims to significantly enhance the operational performance of INPS in managing financial damage recovery. Expected benefits include reduced processing times, increased transparency, higher legal compliance, and improved coordination among departments. Moreover, the system's modular structure allows for scalability and potential reuse in other public agencies facing similar challenges.

The platform is designed not only as a technical solution but also as a driver of an olistic organizational change, fostering a culture of digital innovation, interdepartmental collaboration, and data-driven decision-making. Its implementation aligns with broader policy goals of modernization, accountability, and digital sovereignty in the Italian public sector.

4 Discussion and conclusion

The deployment of the Co.Ded platform at INPS signifies not merely a technology enhancement; it embodies a significant shift in organizational culture and the institutional frameworks that dictate public sector operations. Although the platform will enhance efficiency and automates processes, its most profound effects lie in the symbolic and cognitive transformations it initiates within the business. The project serves as a model for how strategically integrated digital technologies can transform the normative frameworks, practices, and identities that define bureaucratic systems.

Historically, public administrations have exhibited a culture of procedural formalism, wherein legitimacy is rooted in rigorous compliance with defined regulations rather than in output-oriented or value-driven reasoning. The implementation of a platform such as Co.Ded, which reconfigures responsibilities, automates compliance functions, and links remote organizational units, breaks this balance and fosters a more procedural, integrated methodology to administrative chores. Employees are now accountable for contributing to a comprehensive process regulated by common metrics, digital traceability, and procedural transparency. The platform will implement a transition from task-oriented to process-oriented thinking, as articulated by McCormack and Johnson (2001). The transition necessitates a significant cognitive restructuring of work processes. Prior to the digital intervention, staff workers were indoctrinated into a segmented perspective of their duties, frequently restricted to the boundaries of their administrative silo. The new system requires them to align their actions with a comprehensive organizational framework, acknowledging the interdependencies that govern the entire damage recovery process.

The digital transition has also engendered new professional jobs and hybrid competencies. With the blurring of lines between legal-administrative functions and digital system management, new roles have evolved, including digital process coordinators, data integrity officers, and compliance analysts possessing digital proficiency. These roles function at the intersection between conventional knowledge and the demands of platform governance, necessitating both technical skill and the ability to manage organizational complexity. The organizational structure progressed towards more horizontal coordination, collaborative decision-making, and distributed responsibility—characteristics linked to the post-bureaucratic organizational paradigm (Heckscher & Donnellon, 1994).

The Co.Ded platform will enhance internal trust and external credibility by rendering processes visible, verifiable, and legally valid, particularly in the eyes of jurisdictional and supervisory entities like the Corte dei Conti. The digital transformation serves as a catalyst for institutional renovation, allowing the organization to align its bureaucratic responsibilities with modern demands for efficiency, transparency, and responsiveness.

Recent contributions to the study of organizational change in the public sector have emphasized the centrality of participation, trust, and symbolic alignment in sustaining digital transformation. Solari (2023), drawing on his experience with INPS, conceptualizes transformation as a participatory process grounded in the co-construction of meaning among internal stakeholders. His account shifts the analytical focus away from purely technical or top-down approaches, suggesting that durable change arises through the legitimization of new practices within the cultural and narrative fabric of the institution. In this view, digital infrastructures—while necessary—do not themselves generate transformation unless embedded within a broader context of relational trust, and adaptive learning.

The INPS and Co.Ded platform case may will provide a useful empirical contribution to the literature on digital transformation in public administration, especially when analysed through strategic and sociotechnical frameworks. Digital transformation, as posited in recent research (Vial, 2019; Verhoef et al., 2021), beyond the mere implementation of new technologies; it constitutes a significant and systemic alteration that redefines an

organization's value proposition, operational capabilities, and institutional logic. The change inside INPS signifies a major transition from technology serving as a supportive tool to technology acting as a catalyst for structural reconfiguration.

The proposal corresponds with the fundamental principles of digital transformation—customer focus, data-informed decision-making, cross-functional integration, and modular platforms—while tailoring them to the specific limitations and responsibilities of a public sector environment. By substituting disjointed, paper-based methods with a digitally connected system, the organization will transform the focus of value creation from isolated administrative tasks to collective, traceable results contained inside a unified technical framework.

This case exemplifies how public organizations can strategically orchestrate digital transformation to resolve structural inefficiencies and enhance public value creation.

By aligning technological interventions with organizational restructuring, regulatory frameworks, and user requirements, the INPS will establish a foundation for a reproducible model of process innovation inside the Italian public administration.

Untangling Proof-of-Concept Projects: A Systematic Literature Review

Adriana Scuotto, Paolo Canonico
University of Naples Federico II, Naples, Italy

Abstract

The past decades have witnessed a surge of research interest in academic engagement, largely focusing on academic entrepreneurship. However, academics also engage through other forms of knowledge application, broadly referred to as academic engagement. Drawing on the domain of academic engagement, in the last years arise an innovative form named Proof-of-concept (PoC) characterized by the interaction between many actors coming from different contexts, as researchers, professionals, managers and entrepreneurs.

This paper aims to review and analyze organizational mechanisms in proof-of-concept projects (PoCP). It develops the theoretical literature on PoC, particularly in the context of university-industry relations in academic engagement. Through a systematic literature review (SLR), the paper examines 85 published articles.

Findings show that literature on PoC is fragmented; various definitions of PoC are used and different typologies of PoC need the adoption of different organizational mechanisms. The research identifies areas that are currently underdeveloped. While the knowledge management framework is lacking in the reviewed literature, our findings highlight a growing interest in this area.

Recent studies reveal a call from the literature to identify knowledge integration issues and mechanisms for successful PoCP in academic engagement field. This paper provides an overview of the current state of research on PoCP and outlines new research opportunities, focusing on underexplored areas within the academic engagement field.

Keywords: Academic Engagement, University-Industry relations, Proof-of-concept, Project, Knowledge integration, Digital transformation

Paper type: Academic Research Paper

1 Introduction

Over the past decades, research into academic engagement increased. Most of this research studied academic entrepreneurship (Agrawal, 2001), which includes patenting, licensing, joint ventures, spin-offs and so forth. However, there are other ways for academics to ensure application of their knowledge. These forms of interaction have been referred to as academic engagement (Perkmann et al., 2013; Perkmann et al., 2021).

Considering this assumption, we will focus on the form of Proof-of-Concept Projects (PoCP) characterized by the interaction between many actors coming from different contexts, as researchers, professionals, managers and entrepreneurs (Maia and Claro, 2013; Hayter and Link, 2015; Battaglia et al., 2021; Tolin and Piccaluga, 2024).

The starting point is that most of the studies in this field have so far concentrated on project inputs – such as funding – and project outputs – such as number of spin off or licensing. However, the key fact that collaboration in PoCP is a practical application of knowledge is early stage. Though research shows that the need of integrate specialized but complementary knowledge is a major topic in project environment (Tell, 2011), moreover in interdisciplinary setting as PoCP.

The paper aims to contribute to the theoretical development in the field PoCP as privileged observation point of university-industry relations in academic engagement.

In this light, we are leaded a systematic literature review (SLR) on this specific topic as part of an ongoing research project targeting *"Open the black box of proof-of-concept projects: challenges and opportunities"*.

Drawing on previous works that offer a theoretical conceptualization of PoCP process (Zaitsava et al., 2024; Tolin and Piccaluga, 2024; Battaglia et al., 2021), we asked *what PoCP is, how PoCP unfolds, and which organizational conditions affect the knowledge integration process in PoCP*. We focused on these research questions because they matched the impressions gained from our initial reading and because they fit with the aspired review scope (Snyder, 2019).

The structure of our paper is as follows. We first briefly describe the current state of the literature on proof-of-concept, to provide central concepts, search terms and definitions. Next, we present our systematic literature review on PoCP and knowledge integration in academic engagement domain. Finally, we discuss the emerging themes and derive conclusions, limitations and suggestions for future research.

2 Background

According to Perkmann and Walsh, academic engagement processes are based on "high relational involvement in situations where individuals and teams from academic and industrial contexts work together on specific projects and produce common outputs" (Perkmann and Walsh, 2007, p. 263).

In order of this, a growing number of universities have recently introduced Proof-of-Concept Project (PoCP) with the goal to bring research-based inventions (RBI) close enough to a commercialization point or raise interest of investor to growth a spin off. PoCPs support the commercialization of emerging technologies enhancing the creation of synergies between university and industry.

2.1 PoC as a U-I research project: characteristics and mechanisms

A Proof of Concept (PoC) is generally understood as a test or a preliminary demonstration aimed at validating the feasibility of an idea or technology during the early stages of development or adoption. More in-depth, particularly when integrated into formal pathways, PoC have an operational nature that compels universities institutions and research groups to transfer knowledge concretely both within and outside organizations.

Therefore, we can refer to PoC as a project, specifically U-I research project.

Projects are comprised of teams consisting of diverse specialists with varying skill sets, brought together to achieve a specific goal or complete a defined task within established constraints of cost and time (Canonico et al., 2013; Canonico et al., 2017). As temporary systems, projects have a transient and multidisciplinary nature, features that fundamentally contribute to shaping the possibilities as well as the obstacles for generating knowledge and accumulation of learning (Sydow et al., 2004).

In light of this, on one side PoCP can act as a platform capable of facilitating collaboration opportunities between academic institutions and the external world, promoting the sharing of knowledge, research partnerships, and mutual enrichment through the exchange of innovative ideas (Battaglia et al., 2021).

On the other, PoCP requires an heterogenous background of specialist expertise that is essential to achieve outcomes but needs to integrate complementary knowledge and often very different approaches to work. This tool tackles these dimensions by integrating knowledge from different scientific disciplines, on the one hand, and from research and practice, on the other hand.

2.2 Knowledge integration processes in U-I research project

Knowledge integration is particularly challenging in context as project where individuals deal with multiple ideas, values, and perceptions (Gugerell et al., 2023).

The theory of knowledge integration emphasizes the economic value of specialization and the effectiveness of integration. In other words, competitiveness depends on the diversity and strategic value of specialized knowledge, as well as an organization's capacity to integrate the knowledge in an effective manner. Therefore, knowledge integration focuses on "combining specialized but complementary knowledge" (Tell, 2011, p.27) with the purpose of taking advantage of actors' differentiated knowledge bases and complementarities.

The different forms of knowledge present within a PoCP represent an important resource for problem-solving. However, this raises the question of how – in spite of or because of these differences – knowledge can be exchanged and ultimately integrated in such a manner as to achieve common goals. This challenge calls for the use of appropriate mechanisms such as innovative and emergent technologies that can facilitate knowledge integration practices.

Understanding how knowledge is integrated across disciplinary boundaries in a PoCP context is a pressing issue within the area of management and organizations (Battaglia et al., 2021; Tolin and Piccaluga, 2024). The process of knowledge integration is key to the added value of PoCP. Therefore, in PoCP context, a focus on understanding the organizational conditions affect the knowledge integration and the strategies and mechanisms to achieve this, also taking in the account the impact of digital transformation, becomes relevant (Canonico et al, 2017).

Starting from this background and from the main contributions of the managerial literature on PoCP (Battaglia et al., 2021; Zaitsava et al., 2024; Tolin and Piccaluga, 2024), our paper aims to highlight a literature research gap and provide valuable insight for scholars for further exploration of undersized topics, such as the knowledge integration process in PoCP.

3 Methodology

As the research background revealed the novelty of the PoCP phenomenon is observed, the methodological solution is to explore the phenomenon adopting a literature review choosing a systematic approach.

Systematic literature review (SLR) begins by (1) establishing the search question and determining the parameters for a literature search, then (2) conduct the search using keyword searches and screening to produce the "content" to be analyzed, then (3) analyse and synthesize the content, and (4) report and discuss the results (Tranfield et al., 2003; Snyder, 2019). To explores the growth of the topic, we performed a search using SCOPUS database that was particularly chosen for its comprehensive coverage across the area of management research (Williams et al., 2021). Systematic reviews improve the quality of the review process and outcome by employing a transparent, reproducible procedure.

We followed the steps outlined in the latest *Preferred Reporting Items for Systematic Reviews and Meta-Analyses* - PRISMA statement, a guideline designed to help authors transparently report why the review is done, what the authors do and what the authors find (Mishra and Mishra, 2024). PRISMA statement are widely accepted guidelines for performing SLR in healthcare research (Cook et al., 1997) but in recent years its wide use in management research is debated among scholars (e.g. Mishra and Mishra, 2023). In recent years some authors agree with the use of a protocol as PRISMA extending it to specific objectives reviews of management literature (e.g., Fan et al., 2021; Crawford and Jabbour, 2023; Graessler et al., 2024).

3.1 Data collection and inclusion criteria

The first step was to identify studies focused specifically on proof-of-concept. To do so, we conducted a search in the SCOPUS database using the keyword "proof-of-concept" and its variations such as "proof of concept" and "proof of concepts". The initial search was conducted without any limitations or restrictions on publications, with the first phase of the database search conducted on data (112.642 items).

The second step involved focusing on the concept of university-industry relations. Selecting search terms proved to be more complex because of the variety of terms used for describing these collaborations.

We initially established a search string with the term "industry", "business", "academic", "university" to capture any variations of the keywords (5908 items).

We then narrowed down the review by using three specific search terms.

The first was "project", a valuable tool for understanding how the university-industry relations happen.

The second term was "program", a precise description of the domain in which these collaborations emerged.

The third term was "process", a term that allow us to identify works describing this iterative dimension of this relations.

In addition, the names of researchers who had published a substantial amount of work in the field and were frequently cited by other authors were also used as keywords in the search (e.g Battaglia D., Zaitsava M., Tolin, G.)

Records (2618 items) were included in our final set if they met four inclusion criteria:

1. Language: only studies published in English were included.
2. Year of publication: we selected records published in the period > 1999 and < 2025
3. Document type: we selected records limited to articles
4. Subject area: we selected records limited to Business, management and accounting and Economics, econometrics and financing areas

After the screening stage, paper abstracts and contents were fully analysed, to exclude any articles that did not consider proof-of-concept from the managerial perspective. This left a total of 139 articles that were selected and coded along predefined themes on university-industry relations in PoCP common themes drawn from literature (Battaglia et al., 2021; Tolin and Piccaluga, 2024).

The literature review identified the scarcity of research on applying knowledge management to the context of PoCP (85 items).

This process is detailed in the Figure 1.

4.2 Insight from the studies

This section aims to discuss the main findings to answer *what PoCP is* and *how PoCP unfolds* analysing frameworks used and definitions of PoC studies.

To conduct this second phase of analysis, we used keywords' co-occurence analysis to identify how articles related to each other through a visual relatedness. The processes of (1) creating keywords network and (2) clustering keywords was supported with the use of the VOSviewer application, developed by the Centre for Science and Technology Studies of the University of Leiden, the Netherlands (Van Eck and Waltman, 2009).

(1) Regard the keywords network, once the file was uploaded to VOSviewer, a threshold was set relating to the minimum number of citations for the keywords equal to 5, identifying 60 keywords reported within the co-occurence map.

Figure 5 shows a network map that visualized both the frequency of keyword occurrence and patterns of co-occurrence.

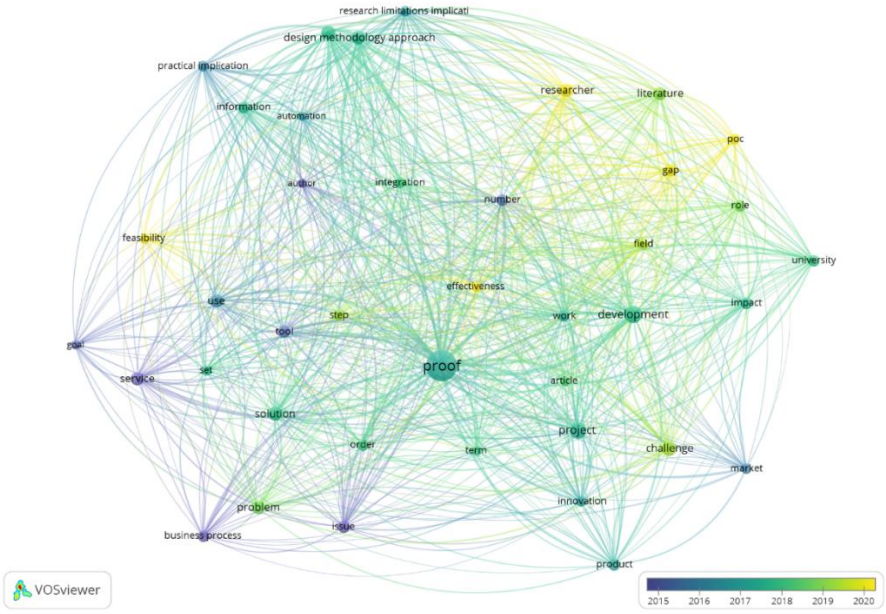

Figure 5 – Emerging themes from network map
Source: own study based on data retrieved from Scopus database as of 20 February 2025
and analysed with the use of VOSviewer

The creation of the map was functional to the analysis of the cluster of documents identified by the search in SCOPUS, which cover a time horizon from 1999 to 2024 but as can be seen from the map the keywords that meet the 5-citation threshold are included in documents between 2012 and 2024.

(2) Regard clustering keywords, as can be seen from the Fig. 6, scientific research in recent years has touched on various themes and topics and it is particularly simple to identify the trend it has followed. The papers comprising the research sample provide 1242 keywords. The co-occurrence should include 59 high-frequency keywords with the minimum number of occurrences equal to 3. However, in the sample there are 59 keywords meeting this threshold. In the map, the size of nodes manifests the frequency of keywords' occurrence, while lines show relationship among keywords.

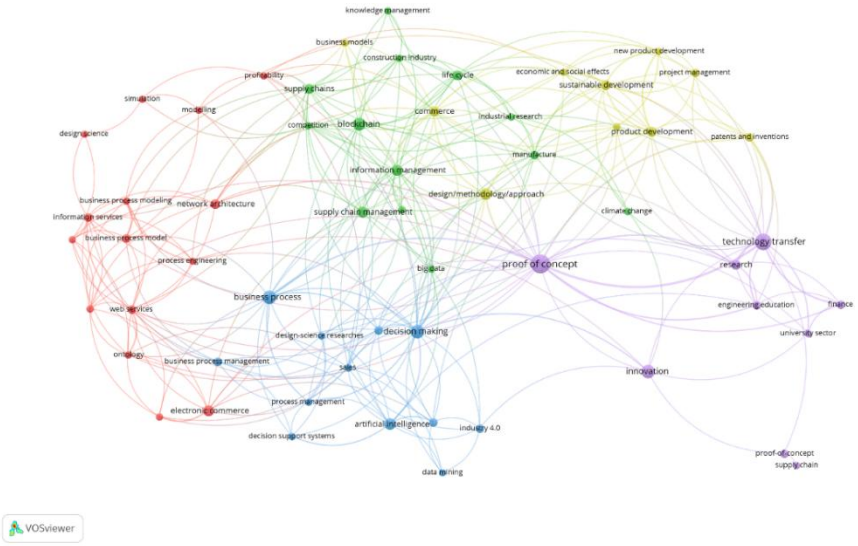

Figure 6 – Co-occurrence of high-frequency keywords
Source: own study based on data retrieved from Scopus database as of 20 February 2025 and analysed with the use of VOSviewer

With the use of this method, identified high-frequency keywords can be categorized into 5 clusters corresponding to the areas of research interest in the field.

Cluster analysis of high-frequency keywords is presented in Table 2.

Table 2 – Clusters of high-frequency keywords related to a PoCP

Cluster	Items	High-frequency keywords	Issue
C1	15	web services (15), information services (12), business process model (10), electronic commerce (10), network architecture (10), ontology (11), user interfaces (11), e-business (9), profitability (9), service-oriented architecture (9), business process modelling (8), process engineering (8), modelling (7), simulation (4), design science (3)	Business process management
C2	13	supply chains (18), manufacture (17), life cycle (16), blockchain (15), information management (14), competition (13), supply chain management (12), construction industry (11), big data (9), industrial research (9), maintenance (9), knowledge management (5), climate change (5)	Knowledge and information management
C3	12	decision making (25), business process (18), automation (16), sales (15), artificial intelligence (13), design-science research (9), machine learning (9), process management (8), business process managing (8), decision support system (6), data mining (5), industry 4.0 (7)	Decision making management
C4	10	business models (6), commerce (16),design/methodology/approach (14), economic and social effect (11), new product development (10), patents and inventions (9), product design (10), product development (15), project management (7), sustainable development (12)	Project management

Source: own study based on data retrieved from Scopus database as of 20 February 2025 and analysed with the use of VOSviewer

The emerging topics within the research field dealing with the issues related to a PoCP were identified also with the use of VOSviewer. The findings from the analysis are presented in Figure 7 that shows the temporal keyword co-occurrence analysis tracking the frequency of occurrence of keywords in conjunction with the publication dates of the documents.

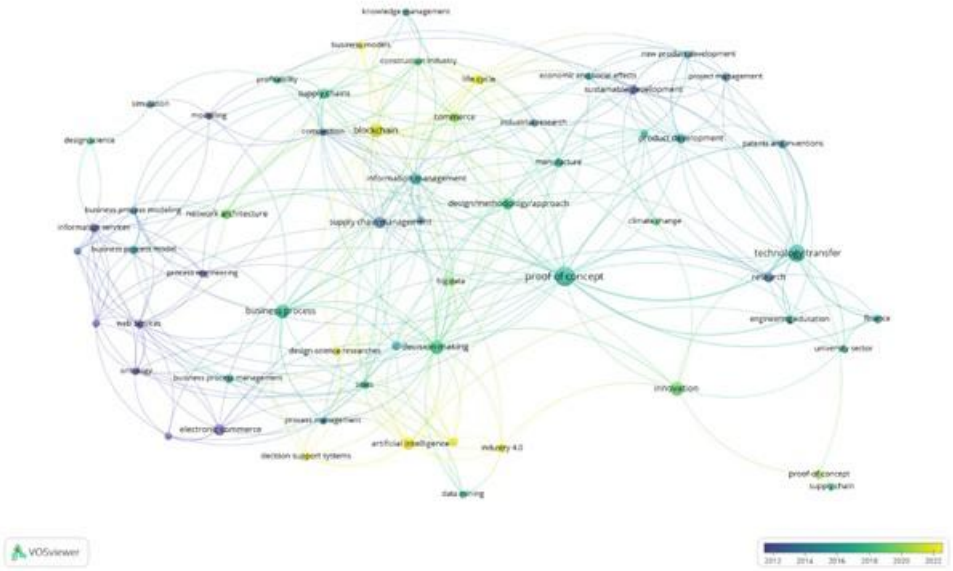

Figure 7 – Emerging keywords (overlay visualization)
Source: own study based on data retrieved from Scopus database as of 20 February 2025
and analysed with the use of VOSviewer

The analysis indicates the keyword on the yellow points and arcs representing hot topics attracting a growing attention of the research community in recent years as the zoom of the overlay visualization show in Figure 8.

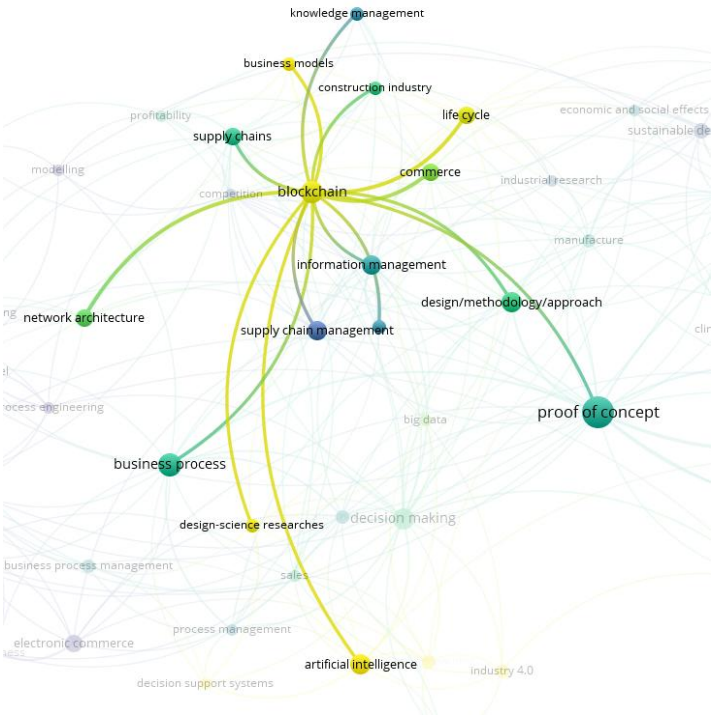

Figure 8 – Emerging keywords in the 2021-2024
Source: own study based on data retrieved from Scopus database as of 20 February 2025
and analysed with the use of VOSviewer

Summing up, the study has identified and discussed five key frameworks associated with the concept of a PoCP: (1) business process management, (2) knowledge and information management, (3) decision making management, (4) project management, (5) innovation management.

Moreover, emerging, three areas attracting a growing attention of the research community in recent years have been enumerated:

1. tool area, as blockchain, artificial intelligence and life cycle of new technologies and innovation product;
2. process/project area, as information management, knowledge management, business process management;
3. method area, as design/approach/methodology and design-science researchers.

This section improves the analysis of the areas of implication of the findings.

5 Discussion

This section aims to discuss the overall findings to answer *which organizational conditions affect the knowledge integration process in PoCP* addressing several implications in the following sub-sections.

5.1 Implication 1: what is PoC? All sets are not equal

According to Battaglia et al. (2021), PoC is described as a "black box", a process that is clearly in terms of input and potential output, without knowledge of its internal mechanisms. In terms of definitions, on one hand, PoC is widely used as tool to test a new concept at early stage of innovation; on the other hand, PoC is also a research and methodological approach used to develop knowledge.

In this sense, a PoC can be identified as a "project", and these perspectives may open many possibilities of future research avenues.

5.2 Implication 2: only some aspects are investigated

The review highlighted that almost all papers are about innovation management. Though the major issue in PoC is the integration of many types of data from many different sources. There are significant technical and cultural obstacles to the practical realisation of data integration which is a prerequisite for collaboration projects as a PoC. They, by definition, bring together multiple university and industry communities, who are most often not familiar with the data handling conventions of their counterparts.

This challenge open to investigate how to train young researchers to address the specific challenges of collaborative projects, including effective communication across disciplines, engagement with non-academic stakeholders, and complex project and knowledge management.

5.3 Implication 3: there is a lack of a common definition of PoCP as a knowledge integration process

The review has revealed a lack of a knowledge management perspective in the framework models of the papers. While most articles touch on topics and variables related to knowledge mechanisms, the recurring frameworks often focus on open innovation and digital transformation.

This gap suggests that exploring knowledge processes in PoC could pave the way for future research opportunities.

5.4 Implication 4: common elements that affect the integration of knowledge in PoCP

The most insightful papers, from a knowledge perspective, highlight that conducting PoCP involves overcoming various barriers inherent in the setting. There are often tensions between disciplines, also terminology differences between sectors are a barrier. Often integration between more related disciplines can be more difficult than between more widely separated disciplines, both because of approaches and expectations and because of institutional barriers.

Moreover, a co-production of knowledge is required, and different actors develop characteristic language, criteria and ways of working that demand integration of project activities.

The Table 3 summarizes the details emerging from the review linked to the focus topics of knowledge literature (e.g. Grant, 1996; Enberg et al., 2006; Foss et al., 2010) to open issues for a future research agenda on PoCP.

Table 3 – PoCP as KI process: focus topics and main variables analysed of the *implication 3* and *4*

PoCP as KI process: focus topics and main variables analysed		
Focus	***Details***	***Quotations***
Interaction to support PoCP	Social interaction to support/influence the knowledge process	Passarelli et al., 2018, 2020
	Governance to support/influence the knowledge process	Rasmussen and Sørheim 2012 Brem and Radziwon, 2017
	Methods and strategies of interaction	McAdam 2006; McAdam 2010 Jones et al., 2023
	Interaction barriers	Passarelli et al., 2018, 2020
Human factors that affect the PoCP	Personal motivation, skills and absorptive capacity, personal knowledge, decision-making capabilities	Battaglia et al., 2021 Posillico and Edwards, 2024
	Individual barriers	Battaglia et al., 2021 Pacheco et al., 2024
Organisational factors that affect the PoCP	Management support	Hoang et al. 2022 Rochon et al., 2010
	Organisational culture	Paget et al., 2024
	Internal resources: financial, technological, rewards	Munari et al. Nicholls-Nixon et al. 2022
	Organisational barriers	Pacheco et al., 2024 Tolin and Piccaluga, 2024
External factors that affect PoCP	Customers, suppliers, competitors	Zaitsava et al. 2024 Swamidass 2013
	Financial programme, coaching, time	McAdam 2010

Source: authors' elaboration

5.5 Implication 5: bridging the gap and identifying tools to support knowledge integration in PoCP

Understanding the processes of knowledge integration can reveal new enablers and techniques. From this perspective, fostering dialogue between academics and practitioners becomes crucial to achieving the most impactful outcomes.

In this regard, it would be important starting empirical research on PoCP members using interviews to conduct an in-depth analysis of many aspects related to knowledge integration

6 Conclusion remarks

The study makes two specific contributions to the existing literature, developing a comprehensive conceptualization of the PoCP process from a knowledge integration perspective and outlining an agenda for future research that can explore this emerging area of research more deeply with empirical evidence.

Our review addressed two central research objectives.

First, given the emerging and fragmented nature of PoCP, we asked what PoCP is and how it can be described in a more uniform way. In this light, we provide a stronger conceptual foundation for scholars and practitioners to build on. The review succeeded in broadening the understanding of PoC in two respects. On the one hand, only a few studies have previously investigated PoC as a project environment; on the other hand, the review served as a starting point for exploratory research hypotheses in future theoretical and empirical work, linking the characteristics of relationships in U-I projects with the development of PoC activity.

Second, we aim to identify the underlying principles and organizational conditions that influence the PoCP process and the existing mutual knowledge barriers that may hinder the achievement of the desired outcomes. This aspect of the findings could be useful both theoretically and practically. Building on previous work by Battaglia et al. (2021), Zaitsava et al. (2024), and Tolin and Piccaluga (2024), we observe that there are important underlying organizational mechanisms that influence the PoCP process. Our review aims to advance the research by opening new lines of research on how these mechanisms operate, with a particular focus on the relationship between university actors and external stakeholders in relation to activity levels, roles, and responsibilities in the PoCP.

Our study also had several limitations.

First, we encountered difficulties in developing an optimal search string. The term “proof of concept” is widely used, with different meanings across different disciplines and fields, making it difficult to narrow down the selection of articles.

Second, our review does not provide a comprehensive overview of all the literature in the context of open innovation or digital transformation. There is a vast literature in related fields. However, our primary goal was to consolidate knowledge in the social sciences, particularly in the management and organizational literature.

Although considerable effort was invested in the development of this study, it is essential to recognize some limitations inherent to SLR method. Our review protocol used a recognized database, Scopus, but we may have overlooked relevant research older than the timeline of our protocol or included it only in other databases, introducing potential publication bias or incomplete coverage. This is despite extensive backward and forward searches. Finally, human judgment was required at various stages of this search, which introduced potential subjectivity. However, this systematic literature review has made several efforts to ensure intersubjective verifiability and replicability, following international standards for transparent and rigorous academic practice.

Beyond these limitations, according to Massaro et al. (2016), a systematic literature review “is not the end of the road, but the beginning of new journeys.” Combining both theoretical insights and practical implications, this research has advanced the understanding of PoC and contributed to enriching organizational studies by opening the “black box” of the PoCP process.

7 Ethic declaration

This research did not required an ethical clearance.

8 AI declaration

This research did not involve use of artificial intelligence tools.

Preliminary Study on the Impact of Artificial Intelligence in ESG Practices: A Multi-Case Approach in the Italian Market

Giovanni Spatola[1], Stefania D'Aprile[1], Maria Zifaro[1], Andrea Presciutti[1], Alessandro Broglia[2]
[1]Mercatorum University, Rome, italy
[2]Up2You Srl SB, Milan, Italy

Abstract

The integration of Environmental, Social, and Governance (ESG) principles into corporate strategy has emerged as a global imperative, catalyzed by regulatory frameworks, investor pressure, and increasing stakeholder expectations. However, the complexity of ESG data collection, analysis, and reporting poses significant challenges for organizations. Recent advances in Artificial Intelligence (AI) have led to the development of AI-enabled platforms, such as PlaNet, CliMax, and Choral, which promise to transform ESG management. This paper presents a comprehensive analysis of the adoption and impact of these platforms across a diverse set of Italian companies, drawing upon more than twenty real-world case studies from sectors including finance, consulting, manufacturing, events, and digital. Through a mixed-methods approach combining document analysis, platform review, and cross-case synthesis, we examine how AI supports ESG data management, stakeholder engagement, decarbonization strategies, and organizational learning. Our findings reveal sector-specific adoption patterns, highlight operational improvements, and document the emergence of new forms of transparency and cultural engagement. The study concludes with actionable recommendations for organizations seeking to leverage AI for sustainable business transformation and outlines avenues for future research on the digitalization of ESG.

Keywords: artificial intelligence, knowledge management, sustainability, ESG, innovation

Paper type: Academic Research Paper

1 Introduction

In recent years, the strategic importance of Environmental, Social, and Governance (ESG) criteria has grown exponentially on a global scale. The combined pressures of regulatory change—such as the European Union's Corporate Sustainability Reporting Directive (CSRD), the United States' Securities and Exchange Commission (SEC) proposals, and the Sustainable Finance Disclosure Regulation (SFDR)—alongside shifting consumer preferences and investor demands, have made ESG integration a business necessity rather than a choice. Across all sectors, organizations are under increasing scrutiny to provide transparent, standardized, and measurable evidence of their sustainability efforts and social responsibility (Davenport & Prusak, 1998; Davenport et al., 2020).

Despite the growing consensus on the importance of ESG, companies face a daunting array of challenges in managing ESG data, metrics, and reporting. The process typically involves multiple actors—ranging from sustainability managers and financial controllers to IT departments and external consultants—and spans diverse information systems, business units, and regulatory environments. Traditional approaches, often reliant on manual data entry and fragmented spreadsheets, have proven inadequate to manage the increasing complexity and volume of ESG-related information. This can lead to inconsistencies, inefficiencies, and even reputational risks due to reporting errors or delays.

The emergence of Artificial Intelligence (AI) as a transformative force in corporate sustainability marks a pivotal shift in how organizations approach ESG challenges. AI-enabled platforms—such as PlaNet, CliMax, and Choral—offer the prospect of automating repetitive tasks, extracting actionable insights from unstructured data, and fundamentally rethinking stakeholder engagement. By leveraging predictive analytics, natural language processing, and machine learning, these technologies promise to increase the efficiency, accuracy, and impact of ESG management, while also fostering a culture of continuous learning and improvement.

This paper seeks to systematically review the application and outcomes of AI for ESG in a broad set of Italian companies. Rather than focusing solely on theoretical potential, we draw upon an empirically rich, multi-case study approach, offering insights that are both contextually grounded and transferable to other markets. Our aim is to provide a robust foundation for understanding the transformative potential of AI in sustainability management, and to inform both practitioners and scholars of best practices and key challenges.

2 Literature Review

2.1 The Evolution of ESG Reporting and Knowledge Management

The field of ESG has evolved rapidly, with the proliferation of reporting frameworks such as the Global Reporting Initiative (GRI), the Sustainability Accounting Standards Board (SASB), the Task Force on Climate-Related Financial Disclosures (TCFD), and, more recently, the European Sustainability Reporting Standards (ESRS). These frameworks provide guidelines for companies to report on a broad range of environmental, social, and governance indicators, but also increase the complexity of compliance.

Knowledge management (KM) systems have long been recognized as critical enablers for effective ESG strategies. As Davenport and Prusak (1998) argue, KM supports the acquisition, organization, and dissemination of data, facilitating both internal learning and external reporting. In the context of ESG, effective KM enables organizations to break down silos, ensure data consistency, and drive continuous improvement. However, traditional KM approaches—centered on manual processes and static repositories—often fall short in addressing the dynamic, multidimensional nature of ESG information.

2.2 Artificial Intelligence in ESG: Opportunities and Barriers

AI technologies, including machine learning, natural language processing, and large language models (LLMs), have demonstrated their value across a wide range of business domains (El-Kassar & Singh, 2019). In the ESG context, AI can:

- Automate data collection and validation, reducing human error and increasing speed;
- Analyze complex datasets, including carbon footprints and decarbonization pathways;
- Generate and personalize sustainability reports in alignment with international standards;
- Engage employees and stakeholders through innovative formats such as gamification, serious games, and interactive learning modules.

Several studies have highlighted the potential of AI to revolutionize ESG management (Smith et al., 2021; World Economic Forum., 2025; Wamba-Taguimdje, S. et al, 2020). However, barriers remain. These include technical challenges (data harmonization, system integration), organizational resistance (digital skills gaps, change management), and hical considerations (data privacy, algorithmic transparency). Empirical research on the real-world implementation of AI in ESG, particularly in multi-sectoral contexts, remains limited.

2.3 The Italian Context and Research Gap

Italy offers a particularly interesting context for studying the digitalization of ESG. The country is home to a diverse industrial base, ranging from large multinational corporations to innovative small and medium-sized enterprises (SMEs). Recent years have seen a surge in ESG reporting and sustainability initiatives, driven both by regulatory compliance and a growing recognition of the business value of sustainability. Yet, as in other markets, companies face significant challenges in scaling up their ESG efforts and ensuring data quality.

This study addresses the research gap by analyzing the adoption and impact of AI-enabled ESG platforms (PlaNet, CliMax, Choral) in a representative sample of Italian companies, spanning banking, finance, consulting, manufacturing, events, and digital sectors.

3 Methodology

3.1 The Italian Context and Research Gap

This research adopts a mixed-methods approach, combining qualitative and quantitative techniques to deliver a comprehensive analysis of AI adoption in ESG practices. The study is structured around three core components:

- Document Analysis: Over twenty case studies, white papers, and official reports are systematically reviewed. These documents, sourced from company disclosures, platform vendors, and academic publications, provide detailed accounts of ESG initiatives, AI-enabled solutions, and organizational outcomes.
- Platform Review: Official documentation and product pages for PlaNet, CliMax, and Choral are analyzed to map technical functionalities, innovation drivers, and sectoral applications. Special attention is paid to features such as data automation, real-time monitoring, user engagement, and compliance alignment.

- Cross-Case Synthesis: A thematic synthesis is conducted across all cases to identify sectoral adoption patterns, functional outcomes, user feedback, and best practices. Where available, quantitative metrics (e.g., time saved, error reduction, engagement rates) are extracted to support qualitative findings.

3.2 Case Selection Criteria

Cases were purposively sampled to maximize diversity in sector, organizational size, ESG maturity, and stage of digital transformation. The sample includes both large corporations and SMEs, with representation from finance, consulting, manufacturing, event management, digital services, and more. Priority was given to companies with documented experience in adopting at least one AI-enabled ESG platform.

3.3 Data Collection and Analysis

Data were collected through a combination of document analysis, review of public disclosures, and where possible, semi-structured interviews with company representatives and platform providers. Thematic analysis was used to code and categorize findings, with cross-validation against public data and third-party audits where available. Analytical rigor was ensured through iterative coding, peer review, and triangulation of multiple sources.

3.4 Research Limitations

While the multi-case approach provides rich insights, several limitations should be noted. First, the sample is limited to Italian companies, which may affect generalizability. Second, access to primary data (e.g., interviews) was limited for some cases, necessitating reliance on secondary sources. Finally, the evolving nature of AI platforms means that findings reflect a specific moment in time and may not capture future developments.

4 Results

4.1 AI-Enabled Platforms: Functional Overview

4.1.1 Planet

PlaNet is Up2You's flagship platform for ESG education and employee engagement. Designed to leverage the motivational power of gamification, PlaNet offers a suite of interactive tools—including quizzes, video lessons ("video pills"), team challenges, leaderboards, and unique rewards—to foster knowledge, engagement, and behavioral change around sustainability. The platform is fully customizable, allowing organizations to tailor content, branding, and learning pathways to their specific needs. PlaNet's scalability and intuitive design have driven its adoption by over 450 companies across finance, consulting, manufacturing, and events. Key features include real-time progress tracking, personalized feedback, and integration with broader ESG strategies.

4.1.2 Climax

CliMax is an AI-powered platform dedicated to carbon management and decarbonization strategy. It centralizes carbon data from multiple organizational sites and products, automates the calculation of Scope 1, 2, and 3 emissions, and provides real-time monitoring of emission trends. The platform supports the design and execution of decarbonization strategies, integrating certified offsetting projects (e.g., Verra, Gold Standard) and producing audit-ready reports validated by third-party certifiers such as RINA. CliMax's data automation features minimize manual entry errors and allow for granular analysis by location, business unit, or product line, making it especially valuable for manufacturing and multi-site organizations.

4.1.3 Choral

Choral is designed to streamline the creation of sustainability reports, ensuring alignment with international standards such as GRI, ESRS, and VSME. The platform uses AI to automate data collection, facilitate real-time collaboration among multiple users, and enhance stakeholder engagement through targeted communications and feedback loops. Choral's customizable branding features enable organizations to produce visually distinctive reports, while its compliance tools facilitate independent assurance by accredited auditors. By reducing reporting time and minimizing errors, Choral has become a preferred solution across finance, consulting, and services.

4.2 Case Study Synthesis

The study analyzed a diverse sample of Italian organizations, including:

- Finance/Asset Management: Azimut, Banco Azzoaglio
- Consulting: BakerMcKenzie, Randstad, Colliers
- Manufacturing: Aeffe, IB Chem, Sodai, Italtel, Talea Group
- Events & Services: TEDXMilano, OIC Group, Caribe Bay, Panino Giusto, Xenia, Team Emirates, Gattinoni, Yocabè
- Digital & Tech: Kotuko, Mimosa Milano, Atlantic, Edison

Table 1- AI Platform Adoption Across Case Studies

Company	**Sector**	**Main Platform(s)**	**Core AI-Enabled ESG Functions**
Azimut	Finance	Choral, CliMax	Carbon emission (Scopes 1/2), data validation, reporting, employee engagement
Banco Azzoaglio	Banking	Choral	GHG data collection (20+ branches), reporting, training, data consistency
BakerMcKenzie	Consulting	Choral	Data collection, multi-site reporting, stakeholder engagement
Randstad	Consulting	Choral	Stakeholder engagement, ESG reporting, data validation
Colliers	Consulting	Choral	Emission tracking, ESG data, reporting
Kotuko	Digital	Choral, PlaNet	Gamified ESG education, data collection, reporting, employee engagement
Aeffe, IB Chem, etc.	Manufacturing	CliMax, Choral	Carbon footprint, decarbonization, data automation, reporting
TEDXMilano, OIC, etc.	Events/Serv.	PlaNet	ESG training, employee engagement, gamification

Many companies employ more than one platform for complementary ESG needs.

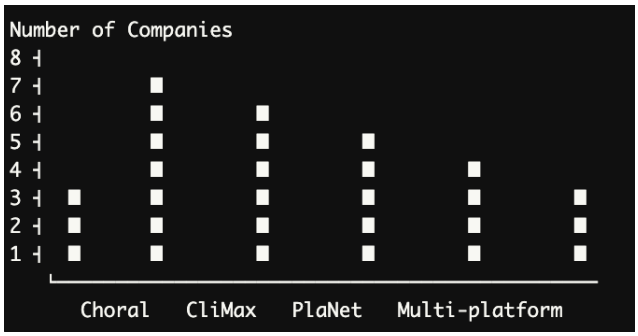

Figure 1 - Adoption of AI-Enabled ESG Platforms by Sector

Legend:

- Choral: most widely adopted for ESG reporting and stakeholder engagement across sectors.
- CliMax: leading for carbon management in manufacturing and finance.
- PlaNet: focused on gamified education, primarily in digital, events, and services.
- Multi-platform: several companies use two or all three for integrated ESG management.

ESG Functionality	**Choral**	**CliMax**	**PlaNet**
Data Collection	✓	✓	✓
Data Consistency Check	✓	✓	
Carbon Footprint		✓	
Reporting Automation	✓	✓	
Stakeholder Engagement	✓		✓
Gamification/Training			✓

Figure 2 - AI Functionalities Adopted Across Case Studies

4.3 Case Highlights

Azimut

Azimut, a major asset management group, implemented Choral for multi-site carbon data collection (Scopes 1 and 2). The adoption enabled automated data validation, streamlined GRI/ESRS-compliant reporting, and generated actionable insights for decarbonization. In parallel, CliMax was leveraged for scenario-based decarbonization strategy and real-time emission monitoring, while PlaNet supported employee ESG training and engagement through gamified modules.

Banco Azzoaglio

Banco Azzoaglio is a regional bank employing Choral for automated and accurate ESG data collection from over 20 branches, verification of data consistency, and management training on sustainability. The implementation led to increased reporting accuracy, a measurable reduction in reporting cycle time, and a more engaged workforce. Feedback from internal stakeholders indicated that the platform's user-friendly interface and automated notifications facilitated cross-departmental collaboration.

Consulting and Services

Firms such as BakerMcKenzie, Randstad, and Colliers adopted Choral for coordinating data collection from multiple offices, automating sustainability reports, and engaging a diverse range of stakeholders. These organizations reported significant reductions in manual workload, improved data reliability, and higher response rates from stakeholders, attributed to Choral's integrated communication tools.

Digital, Events, and Manufacturing

Companies in the digital and event sectors, including Kotuko, TEDXMilano, OIC, and Panino Giusto, utilized PlaNet for ESG education and employee engagement. By integrating gamified content, these organizations fostered a culture of sustainability, as evidenced by increased participation in ESG initiatives and improved knowledge scores in post-training assessments. Manufacturing firms (Aeffe, IB Chem, Sodai, Talea Group, etc.) employed CliMax for systematic carbon footprint calculations (Scopes 1, 2, and 3), real-time emission monitoring, and decarbonization scenario planning, resulting in improved audit outcomes and compliance.

4.4 Cross-Case Findings

- **Sectoral Preferences:** finance and consulting sectors favor Choral for robust reporting and collaboration features. Manufacturing and industry prioritize CliMax for carbon management and emissions tracking. Events, services, and digital companies adopt PlaNet for staff engagement and ESG education.
- **Multi-Platform Integration:** leading organizations often combine platforms—PlaNet for engagement, Choral for reporting, and CliMax for emissions—achieving holistic ESG management.
- **AI Value Drivers:**
    - Time and error reduction in data collection and reporting.
    - Improved data consistency and auditability.
    - Increased stakeholder participation and trust.
    - Enhanced employee ESG culture through interactive learning.
- **Quantitative Outcomes:** across cases, organizations reported reductions in reporting cycle times (up to 40%), increased stakeholder engagement rates (by over 30%), and improved audit scores, demonstrating tangible benefits of AI integration.

5 Discussion

5.1 Relating Findings to Existing Literature

The findings from this multi-case analysis resonate with and extend the current body of literature on AI and ESG. As highlighted by El-Kassar & Singh (2019), the integration of AI into sustainability management is not only a technological upgrade but also a catalyst for organizational transformation. The Italian cases confirm that AI-enabled platforms are crucial for overcoming the limitations of traditional knowledge management (KM) systems, as theorized by Davenport & Prusak (1998). The adoption of tools like Choral, CliMax, and PlaNet has facilitated a shift from siloed, manual processes to integrated, automated ESG management, enabling companies to respond more dynamically to regulatory and stakeholder demands.

Additionally, the sector-specific adoption patterns observed in the Italian context mirror global trends. For example, manufacturing firms' emphasis on carbon management (via CliMax) aligns with international pressures on heavy industry to decarbonize, while finance and consulting's adoption of advanced reporting platforms (like Choral) reflects the growing importance of transparency and compliance in these sectors (*World Economic Forum., 2025*).

5.2 Sectoral Nuances and Organizational Change

The case studies reveal that the effectiveness of AI-enabled ESG platforms depends not only on technological capabilities but also on organizational readiness. In manufacturing, the complexity of Scope 3 emissions and the need for granular, plant-level data make platforms like CliMax indispensable—yet their success hinges on strong internal data governance and sustained training. In banking and consulting, where ESG data is often dispersed across multiple branches or client accounts, Choral's collaborative features and AI-driven consistency checks have been especially valued.

Change management emerges as a critical factor. Companies that invested in comprehensive onboarding, ongoing training, and cross-functional ESG teams reported higher engagement rates and smoother platform adoption. This supports the notion, found in recent research (Wamba-Taguimdje, S. L. et al,

2020), that technology adoption in ESG must be accompanied by parallel investments in people and processes.

5.3 New Opportunities and Emerging Risks

While AI platforms have yielded clear efficiencies—reducing reporting cycle times and improving data quality—they also introduce new challenges. Over-reliance on automated recommendations can lead to "black box" decision-making, where the rationale for certain ESG actions is not fully transparent to users. Some interviewees expressed concerns about data privacy, especially in relation to sensitive HR or supply chain information processed by AI systems.

Moreover, the gamification of ESG education (as seen with PlaNet) has proven highly effective in boosting engagement, but it also requires careful calibration to ensure that learning outcomes are substantive and not merely competitive. Companies must balance the motivational benefits of gamification with the need for rigorous, impactful ESG training.

5.4 Scalability and Internationalization

The platforms studied are designed to be scalable, supporting organizations ranging from SMEs to multinational groups. Their multi-language support and customizable features make them suitable for international rollouts, a point of strategic importance as ESG regulations become increasingly harmonized across the EU and beyond. However, the degree of customization required to align with local regulations and cultural expectations can be significant, underlining the need for vendor support and flexible implementation strategies.

5.5 Limitations and Critical Assessment

Despite the positive outcomes, several limitations should be acknowledged. The reliance on secondary data in some case studies may introduce reporting bias. The pace of technological change means that platform functionalities and user experiences are continually evolving, potentially limiting the long-term generalizability of findings. Furthermore, empirical evidence on the direct impact of AI-enabled ESG platforms on financial performance remains scarce and warrants further investigation.

6 Managerial Implications and Recommendations

6.1 Choosing and Implementing AI-Enabled ESG Platforms

Organizations should carefully assess their ESG maturity, sector-specific needs, and internal capabilities before selecting an AI platform. For instance, manufacturing firms with complex supply chains may prioritize platforms with advanced carbon tracking and scenario analysis, while consulting and financial services may focus on robust reporting and stakeholder engagement features. A phased implementation—starting with pilot projects and progressively scaling up—can help manage risks and optimize learning.

6.2 Integrating Multi-Platform Solutions

The evidence suggests that combining multiple platforms (PlaNet for engagement, Choral for reporting, CliMax for emissions management) yields the most comprehensive results. Integration across platforms should be prioritized to avoid data silos and maximize the value of AI-driven insights. IT departments play a key role in ensuring seamless data flows and maintaining cyber-security standards.

6.3 Fostering an ESG Culture through Engagement

Gamification and interactive learning modules, as offered by PlaNet, can be powerful tools for embedding sustainability values across all levels of the organization. HR departments should collaborate with ESG managers to design engaging, contextually relevant training programs and to recognize and reward ESG-related achievements.

6.4 Ensuring Data Quality and Compliance

Automated data validation and audit trails, as provided by Choral and CliMax, are essential for meeting increasingly stringent regulatory requirements. Companies should establish clear data governance policies and regularly review platform outputs for accuracy and completeness. Third-party assurance and certification can further enhance credibility and stakeholder trust.

6.5 Managing Change and Building Capacity

Successful adoption of AI in ESG requires dedicated change management efforts. This includes clear communication of the benefits and expectations, regular training, and the creation of cross-functional ESG teams. Leadership commitment is crucial: C-suite executives must champion digital transformation and allocate resources for continuous improvement.

6.6 Addressing Risks and Ethical Considerations

Organizations must remain vigilant about potential risks, including data privacy, algorithmic bias, and over-automation. Transparent AI models, regular audits, and clear ethical guidelines should be established to mitigate these risks and ensure that technology supports, rather than undermines, corporate responsibility.

7 Conclusion

This preliminary study demonstrates that AI-enabled platforms are rapidly transforming ESG practices in Italian companies, delivering measurable improvements in efficiency, transparency, and stakeholder engagement. Through the adoption of innovative solutions such as PlaNet, CliMax, and Choral, organizations have not only automated and improved the accuracy of ESG data management but also fostered a culture of sustainability and collaboration. Sectoral nuances reveal that a one-size-fits-all approach is insufficient; instead, organizations benefit most from integrating multiple platforms tailored to their specific needs.

The findings contribute to the growing body of knowledge on the intersection of AI, knowledge management, and ESG, offering both practical guidance for practitioners and a foundation for future academic inquiry. However, the study also highlights emerging challenges—ranging from data privacy concerns to the need for explainable AI—and underscores the importance of human-centered change management.

Future research should expand the analysis to include more industries, longitudinal impact assessments, and cross-country comparisons. Quantitative studies assessing the financial and reputational returns of AI-driven ESG innovation will be particularly valuable. As regulatory expectations and stakeholder demands continue to evolve, the strategic integration of AI into ESG will remain a critical differentiator for organizations seeking to lead in sustainable business.

8 Acknowledgements

This research received no specific grant but acknowledges Up2You for providing access to the ESG platforms analyzed.

9 Ethics declaration

The research presented in this paper did not require the collection of sensitive data, nor the direct involvement of human or animal subjects; therefore, no approval from an ethics committee was necessary. All

data used derive from public sources, corporate documentation, and already available scientific literature. Should the collection of primary data become necessary in the future, the procedure established by current regulations and the affiliated institutions will be followed.

9 AI declaration

During the drafting of this paper, Artificial Intelligence (AI) tools were used exclusively to support language revision and for stylistic suggestions, without any substantial part of the scientific content being automatically generated. All ideas, analyses, and conclusions are the result of the authors' work. The use of AI was therefore limited to editing and spelling/grammar checking functions.

Optimizing ESG Risk Assessment Processes with AI-Driven Process Mining: A Framework for Proactive Sustainability Management

Paola Campana, Riccardo Censi, Fulvio Schettino, Chiara De Pucchio
Sapienza University of Rome, Rome, Italy

Abstract

The growing focus on sustainability and mitigation of environmental risks has made the ESG (Environmental, Social and Governance) framework a central element in the strategic and operational management of modern organizations. In a context marked by increasingly stringent regulatory pressures – such as the Corporate Sustainability Reporting Directive (CSRD) and the recommendations of the Task Force on Climate-related Financial Disclosures (TCFD) – companies are now called upon to integrate ESG metrics into their decision-making processes, in order to address global challenges such as climate change, biodiversity loss and the necessary ecological transition. However, the fragmentation of available data and the lack of adequate predictive tools continue to hinder truly effective and future-oriented ESG management. This study proposes an innovative operating model based on the synergistic integration between Artificial Intelligence (AI) and Process Mining, with the aim of improving monitoring, automation and transparency in ESG processes. AI allows the processing of large volumes of heterogeneous and unstructured data, while Process Mining allows you to map and optimize business flows, detecting inefficiencies and ensuring traceability. The model proves to be particularly effective for financial institutions and companies operating in sectors with high climate exposure, providing concrete answers to the needs of regulatory compliance and strategic sustainability. The adoption of this approach makes it possible not only to anticipate environmental risks, but also to strengthen organizational resilience and support the transition to a "sustainability-first" paradigm. The study highlights the transformative potential of AI-driven Process Mining in ESG management, offering scalable and replicable solutions for sustainable innovation that combines efficiency, responsibility and competitiveness in the long term.

Keywords: Artificial Intelligence, ESG, Process Mining, Environmental Risk Assessment, Climate Change

Paper type: Academic Research Paper

1 Introduction

Climate change represents one of the most complex and pervasive challenges for the global economic and financial system. The incessant expansion of human activities has led to a significant increase in greenhouse gas emissions, aggravating global warming and generating negative consequences such as extreme weather events, sea level rise and destruction of ecosystems (Di Bella, 2020). These phenomena have significant impacts not only on the environment, but also on the stability of firms, on the security of investments and on economic competitiveness (Engel et al., 2015).

At the regulatory level, the United Nations 2030 Agenda and the European Green Deal have strengthened the centrality of climate sustainability in political and industrial agendas. However, despite growing awareness, many companies are still unprepared to identify and manage climate risks (Ai & Gao, 2023). According to Omar et al. (2020), strengthening climate resilience requires companies to develop capacities to assess and absorb risk information, translating this knowledge into strategic actions. In this context, the ESG (Environmental, Social and Governance) framework is established as an essential tool for guiding organizations towards sustainable, transparent and resilient business models. The integration of ESG metrics into risk management is now critical not only for regulatory compliance, but also for long-term value creation (Leoni, 2024). The growing focus on sustainability has prompted supranational institutions and regulators, such as the European Union with the Corporate Sustainability Reporting Directive (CSRD) and the Task Force on Climate-related Financial Disclosures (TCFD), to adopt increasingly stringent and detailed regulations (Brende & Sternfels, 2022; Zhao et al., 2024).

Alongside the regulatory component, a crucial role is played by the ability of companies to integrate digital tools for predictive analysis, reporting automation and proactive sustainability management. Emerging technologies, such as Artificial Intelligence (AI), Process Mining and Natural Language Processing (NLP), offer new possibilities to transform ESG assessment from a manual and reactive process to an intelligent, automated and strategic system (Amiri et al., 2024; Minz & Khattar, 2024). The joint use of AI and Process Mining makes it possible to improve traceability, identify anomalies in ESG flows and support timely decisions (Gerassis et al., 2021).

Despite the growing importance of ESG principles, many organizations struggle to implement them effectively. The difficulties stem from structural factors such as data fragmentation, the absence of standardized

methodologies and the reliance on outdated assessment tools (Kalogiannidis et al., 2024). In the face of these critical issues, this study proposes the integration of two synergistic approaches: on the one hand, a structured methodology for the self-assessment of climate-related and environmental risks, in accordance with the ECB Guidelines (2020) and the expectations of the Bank of Italy; on the other hand, an innovative digital framework based on Artificial Intelligence (AI) and Process Mining, to optimize the analysis and reporting of ESG risks (Amiri et al., 2024; Minz & Khattar, 2024).

The aim is to provide a theoretical and operational basis to support companies in the adoption of intelligent and integrated tools, capable of addressing environmental and regulatory challenges with proactive and data-driven approaches.

2 Theoretical framework

2.1 The strategic role of ESG in corporate governance

The integration of ESG principles into corporate governance models is now recognized as a necessary condition for effective risk management and for strengthening organizational resilience. Environmental risks, particularly those related to climate change, are increasingly being transformed drivers for business models. They impact not only economic aspects, but also social and environmental ones, triggering changes in value chains, operational management and stakeholder relations (Di Bella, 2020; Ai & Gao, 2023). Climate change manifests itself through direct effects, such as extreme weather events and sea level rise, but also through indirect impacts, such as fluctuations in demand, price volatility and rising insurance costs (Engel et al., 2015). Numerous studies underline that companies are not yet fully aware or ready to face these risks. According to Omar et al. (2020), it is crucial for companies to improve their capacity to absorb and transform climate-related information in order to maintain competitiveness and business continuity. Failure to prepare can result in financial losses, reputational damage and reduced access to credit.

To promote a resilient and sustainable economy, companies must adopt a systemic view of ESG risks, capable of integrating technological tools, business strategies and regulatory compliance. A multidimensional approach allows to simultaneously consider physical risks (e.g. floods, droughts, heat waves), transition risks (e.g. new regulations, carbon taxes, technological innovation) and liability risks, such as legal claims arising from environmental damage caused by business activities (FSB, 2015; ECB, 2020). In this context, the ECB Guidelines (2020) and the EBA take on a central role, setting out precise expectations for the banking system in terms of identifying, managing and communicating climate-related and environmental risks. These documents clearly indicate that financial institutions must incorporate ESG risks into their strategic models and risk management mechanisms. In particular, it is required to identify the most exposed sectors and geographical areas, assess the impact on products and services and define climate and environmental risk reduction objectives in business plans (Pasquini, 2020).

ESG risks are reflected in all traditionally monitored risk categories: credit, market, operational, reputational, strategic and liquidity risk. Acute climate change, such as the increase in scorching days, has already been associated with a decline in business performance and increased fragility of supply chains (Pankratz et al., 2023). In addition, the adaptation to a low-carbon economy has impacts on operating margins, demand for goods and asset valuation, triggering an overall reorganisation of business models, especially in emission-intensive sectors. Within this paradigm, the "E" (environmental) component is the one on which the most attention is focused by companies, supervisors and investors (Naeem et al., 2022). Initiatives such as the United Nations 2030 Agenda and the Network for Greening the Financial System (NGFS) have pushed for greater harmonization in the classification and management of environmental risks. The NGFS has introduced a detailed classification table that distinguishes the main components of physical and transition risks, thus providing a useful tool for financial institutions in the risk identification and assessment phase (Pasquini, 2020).

2.2 Regulatory and technological integration in ESG management

The growing awareness of the importance of climate risk management has also led to greater attention to the role of technological innovation, with particular reference to Artificial Intelligence (AI) and Process Mining. The integration of these technologies makes it possible to overcome the inefficiencies of traditional ESG models, which are often manual and not very dynamic, improving the quality and timeliness of the information available. Technologies such as Natural Language Processing (NLP), deep learning and predictive analytics make it possible to analyze large amounts of ESG data from heterogeneous sources (regulatory reports, media, social networks), thus supporting proactive and data-driven risk management (Amiri et al., 2024; Gerassis et al., 2021).

Process Mining allows you to visualize and monitor operational processes in real time, mapping any deviations from ESG standards and identifying inefficiencies or bottlenecks in the reporting chain (Schreiber, 2020). This synergy between AI and Process Mining translates into greater transparency and traceability of corporate ESG flows, facilitating regulatory compliance and improving communication with stakeholders. Empirical evidence shows how the adoption of advanced digital tools can facilitate a shift from a reactive to a proactive logic in risk management. According to Burnaev et al. (2023) and Kim & Lee (2022), the automation of ESG processes not only reduces manual workload, but also allows for hidden patterns in data and predictive scenarios useful for strategic planning. In addition, the application of sentiment analysis techniques makes it possible to detect the external perception of the company in real time, providing an additional tool for reputation management (Kiriu & Nozaki, 2020).

The adoption of a theoretical framework based on the integration of regulatory requirements, digital innovation and a long-term strategic vision is the main way to effectively address the challenges of climate change. Companies that are able to systematically integrate ESG tools into their decision-making models will not only strengthen their resilience, but will gain a competitive advantage in terms of reputation, attractiveness for investors and sustainability in the long term. A central reference point is the ECB Guidelines (2020) and the EBA Recommendations, which outline the obligation for banks to integrate environmental risks into their business models and business strategy. In particular, two main types of climate risk are defined: physical risk, deriving from extreme climatic events or gradual environmental changes, and transition risk, linked to regulatory, technological and reputational adaptation towards a sustainable economy (Pasquini, 2020; Caldecott et al., 2021).

Physical risk can manifest itself in direct damage to structures and assets, disruptions in the supply chain, or reduced productivity, with concrete impacts on revenues, cash flows, and business value (Pankratz et al., 2023). Transition risk, on the other hand, is expressed through costs related to regulatory compliance, market loss for carbon-intensive sectors, and possible legal disputes for environmental liabilities (EBA, 2020). In addition to these, there is a third level of risk that is often less considered: "liability risk", i.e. legal and reputational liability linked to environmental damage caused by corporate activities, as highlighted in the most recent European regulatory consultations (FSB, 2015; EBA, 2020). Alongside the regulatory dimension, contemporary literature emphasizes the role of technological innovation in ESG management. In particular, Artificial Intelligence (AI) and Process Mining are establishing themselves as enabling tools to overcome the limitations of traditional evaluation models. Natural Language Processing (NLP), predictive analytics, and deep neural networks enable meaningful insights to be extracted from large volumes of unstructured data, such as business reports, social media, and regulations (Amiri et al., 2024; Gerassis et al., 2021). In addition, deep learning finds application in areas such as agriculture and natural resource management, making it possible to predict emissions, deforestation, and biodiversity loss more accurately and in a timely manner (Ezenkwu et al., 2024).

2.3 Synergies between AI and Process Mining for ESG Transformation

Process Mining, on the other hand, makes it possible to map and optimize sustainability-related business processes, improving the traceability of ESG flows, detecting inefficiencies and facilitating regulatory compliance in real time (Schreiber, 2020; Minz & Khattar, 2024). This technological integration is particularly relevant in regulated and information-intensive sectors, such as banking, insurance and energy, where transparency and accountability are critical.

The review of the literature (Kim & Lee, 2022; Burnaev et al., 2023) suggests that the AI–Process Mining combination is divided into three main directions:

1. Advanced ESG data analytics: With the support of AI, you can improve the quality and consistency of your data by spotting anomalies and emerging trends.
2. Optimization of ESG processes: Process mining enables continuous tracking of compliance and the identification of bottlenecks.
3. Automation and decision support: thanks to the digitization of reporting processes, errors and time are reduced, improving the timeliness and quality of strategic decisions (Yaseen, 2023; Sokolov & Abramova, 2023).

In addition, several studies underline that the adoption of these digital tools allows not only a faster reaction to emerging risks, but also the construction of moral and reputational capital useful for dealing with future crises (Lins et al., 2017; Deng et al., 2013). This dynamic approach allows companies to adopt a resilience-oriented mindset, capable of integrating sustainability within the corporate culture and core decision-making processes. The evolution of governance models, which increasingly incorporate stakeholder engagement practices and transparency in the disclosure of ESG data, should also be considered. In this context, AI can also support

sentiment analysis on social media and the assessment of public perception, providing real-time feedback on corporate reputation and the effectiveness of environmental and social strategies (Kiriu & Nozaki, 2020). Finally, ESG-based technologies are also showing an increasing impact on sustainable investing. The growing interest from institutional investors in robust and documented ESG practices is driving companies to structure digital and measurable strategies to improve their ESG rating (Naeem et al., 2022; Popescu & Yu, 2024). The traceability offered by Process Mining, combined with the predictive capacity of AI, is a key element in attracting capital and strengthening stakeholder trust. The proposed theoretical framework is based on a twofold innovation: on the one hand, the standardized structuring and classification of ESG risks, in line with current regulations; on the other, the adoption of intelligent technologies that allow predictive and adaptive management of sustainability. This integrated vision represents a game-changer for companies that want to address climate change not only as a threat, but as an opportunity for transformation and sustainable growth.

3 Methodology of approach and proposed solutions

3.1 High-level process

The present work has developed an operating model based on the digitization of business processes and the synergistic use of technologies such as Artificial Intelligence (AI), Robotic Process Automation (RPA) and Machine Learning (ML). The approach adopted resulted in the construction of a Business Process Model and Notation (BPMN) (Mahdi et al, 2024) that describes, in detail, the phases that lead to the definition of risk. This scheme, which represents the skeleton of the theoretical model, has been developed with the aim of identifying for each process area the value-added activities and those that are repetitive or standardizable, in order to optimize the entire path through automation. The mapping of the processes has made it possible to highlight numerous critical areas, often linked to manual or untraceable operations, which slow down the risk analysis and reduce its effectiveness.

In the first phase of the model, the analysis focuses on the definition of operating environments and the identification of internal processes that do not generate value. In this phase, Process Mining (Aalst 2022) was used, an advanced tool that makes it possible to reconstruct the real flows of the organization starting from the information systems, highlighting inefficiencies and redundancies. The output of this analysis provided the basis for a targeted redefinition of processes through the design of RPA solutions (Tripathi et al, 2025), capable of automating recurring and operationally intensive tasks.

Considering the high-level process, the BPMN model (figure 1) has been divided into different operational areas, where the first macro area is dedicated to risk calculation. In this first phase, a questionnaire that can be adapted for each company is used, aimed at defining the reference environments, KPIs, weights associated with each risk category, and assessing the current risk through a scoring system. The second macro area concerns strategic planning, which is responsible for representing the results obtained, organizing them into risk clusters by importance, and illustrating the mitigation plan with the corrective actions to be taken. The third macro area concludes the process with the definition of a managerial action plan, focused on monitoring deviations and continuously updating strategies based on the results of the analysis.

Figure 1. High level BPMN of the process. Our elaboration.

Once the different steps had been defined, a careful analysis was launched aimed at identifying the most suitable algorithms for their automation. The choice fell on the use of multiple and integrated models, which collaborate with each other in a modular way (Wang et al, 2024). This solution has proven to be more efficient than using a single monolithic model, as it allows performance to be optimized with less information usage. In addition, the adoption of intermediate outputs along the various stages of the process allows constant and timely monitoring, improving control and operational transparency (Stern et al, 2023 and Wu et al., 2021).

3.2 Risk Assessment Process

More specifically, in the macro area of Risk assessment, the final goal is to divide customers into clusters to identify a level of gross risk for the company. This action allows for the breakdown according to the risk that they pose to the business. To achieve this, several steps are carried out in the process.

Going into the details of the model, the study of the same has shown the presence of a risk analysis based on static elements and repetitive manual tasks of information exchange. The development opportunity identified in the study proposes the use of machine learning algorithms, the training of which is aimed not only at risk classification, but also at its evaluation with a view to minimizing losses.

In fact, the risk definition process is divided into several steps with different levels of manual skill and analysis.

The first step of the macro area of the Risk assessment involves the use of two separate questionnaires to identify risk categories. The first questionnaire is aimed at identifying the presence of risks generated by customers; the second is aimed at measuring the severity of the risk in individuals identified as suffering from potential criticalities. It was therefore decided to automate the generation of these questionnaires through the use of Robotic Process Automation (RPA), developing a bot capable of producing a standardized checklist. According to the framework developed by Wellmann et al. (2020), repetitive and standardised activities, such as the production of questionnaires, fully fall within the technical feasibility criteria. Introducing RPA in this operational phase helps reduce the risk of human error and ensure consistency in information collection.

Furthermore, the sole limitation to the administration of questionnaires is partially efficient although perfectly manageable by humans. This dimension can be broadened by introducing more in-depth analysis techniques (Kelley-Quon LI., 2018).

Therefore, in parallel with the automation of the generation of checklists for corporate risk assessment through RPA, an additional component based on Web Scraping techniques has been introduced, with the aim of enriching the decision-making process through the automatic and systematic collection of data from both internal sources (company documentation, management reports, digital archives) and external sources (institutional sites, financial indicators, regulatory portals and sectoral databases). This technique allows to automatically aggregate data from multiple sources, structuring them into consistent outputs that can be integrated with internal company systems (Ferrara et al., 2012). In addition, according to Wellmann et al. (2020), to validate all the criteria provided by RPA, it is necessary to use applications to support the model. This activity is part of a broader logic of business intelligence, where the ability to access and analyze distributed and not always structured information is essential to build a dynamic and updated representation of the operating context and potential risks.

This process translates into a double advantage: on the one hand, it improves the ability to identify weak signals or anomalies in the external context, and on the other hand, it allows the internal parameters used in risk assessment models to be kept up to date. Furthermore, thanks to the ability to access structured content in real time, Web Scraping helps to automatically populate risk indicators (KPIs), strengthening the reliability of the analysis model (Ferrara et al., 2012).

The second step relating to the Risk assessment is the definition of the weights for each of the risk categories identified in the first step. In our case, the approach adopted is oriented towards a logic of minimizing losses, focusing on a central concept: the protection and monitoring of a minimum company assets, understood as a critical threshold below which the integrity and operational continuity of the company could be compromised. The deterioration of company assets becomes the metric through which the severity of the risk is measured: the more significant the expected damage, the greater the weight assigned to the detected risk.

In this case, the process involves the search for information and data from authoritative sources such as the European Union or the Italian Government for a qualitative attribution of weights supported as much as possible by objective criteria. However, this system has a subjective component that can affect the comparability and objectivity of the results (Koradecka et al., 2010).

In fact, in this case, a structured analysis of the sources has been provided. Three machine learning techniques have been identified that can make the assignment of weights objective. The three techniques selected are respectively Random Forest, Gradient Boosting Machine and Logistic Regression. These solutions are comparable and can be integrated with each other.

The first model, the Random Forest, proves to be particularly suitable for its robustness and flexibility in business contexts where it is necessary to assign weights to risk variables starting from complex, heterogeneous and sometimes redundant datasets. The main advantage of this algorithm lies in its ability to identify the most relevant variables for risk prediction, through internal selection mechanisms based on measures of importance (Speiser et al., 2019). However, the Random Forest technique is known to be a "black box" model. This reduces

the transparency of decisions, which is crucial for the application of this study as already highlighted. Furthermore, if not properly optimized, the model can involve high processing times, especially in the training phase, in the presence of very large or complex datasets, so its use is recommended in small business contexts.

The second model, the Gradient Boosting Machine (GBM) algorithm, is an ensemble learning technique (combination of multiple predictive models) based on sequential optimization of weak models. This method is able to build highly accurate models through an iterative process that aims to correct, step by step, the errors made by previous predictions. Unlike the Random Forest, which works in parallel on independent trees, the GBM builds the model sequentially, which makes it particularly sensitive to parameter adjustment, but also very powerful from a predictive point of view (Tian et al., 2020). However, this system can be subject to overfitting especially in the presence of large datasets (Tian et al., 2020).

The third model, Logistic Regression, is a well-established technique widely used in risk modeling. Second, Logistic Regression represents an extremely effective tool to analyze binary variables, such as in the case of risk events, while allowing to include multiple explanatory variables in the model and to estimate the probability of occurrence of an event that can also be interpreted in the decision-making field. One of the main strengths of this model is its transparency and simplicity of interpretation, which makes it particularly useful when it is necessary to explain the modeling choices to non-technical stakeholders (Sperandei, 2014).

Therefore, the power of the first two models and the transparency of the results of the third can be combined to provide an accurate weight definition that is understandable to outside observers.

Once the risk categories and the weights associated with them have been defined, the process continues in the mapping of the business processes that are put in the matrix with the risk areas to understand their probability and impact, thus defining the gross risk. This process is totally discretionary and is based on the collection of information carried out up to that moment. The calculation of probability and impact, then, are exclusively linked to a current calculation without considering historical trends. Furthermore, in the specific context of the company in question, the result is extremely influenced by the characteristics of the customers of the process who must be clustered in order to be evaluated. This work is carried out manually through an initial skimming of the riskiest subjects and an in-depth investigation exclusively on them. This approach is effective, although limiting, if carried out by a person. The approach we suggest is a wide-ranging analysis of the basic information of all customers and a model capable of reconstructing the historicity of the subjects to include the forecast within the considerations.

In this context, it was decided to integrate Artificial Intelligence as a tool to support these activities. Flammini et al. (2023) proposes a methodological approach to risk management through AI systems. This model is not limited to data collection or technical automation alone, but aims to generate operational intelligence through the continuous processing of performance and risk indicators. This strengthens the organization's ability to respond promptly to potential critical events. It suggests an AI tool capable of carrying out an in-depth and structured analysis capable of generating a dynamic clustering of customers.

3.3 Strategic definition and creation of the action plan

Once the level of risk has been defined, the process continues with strategic planning in which the most critical areas are identified and priorities are set. This plan defines both the monitoring and implementation times of the measures envisaged, with the aim of arriving at an objective assessment of the degree of mitigation obtained. Finally, the last step of the process involves the construction of an action master plan. In the creation of the latter, targeted interventions are identified and developed through a structured analysis. Given the high interconnection between the second and third macro areas of the model, the decision was made to adopt a single automated approach for both phases.

In the current process we find a definition of priority levels based on brainstorming and analysis approaches with experts to determine priorities together with forecasting future impacts and monitoring actions. Also in this case, discretion plays a decisive role in the result.

To limit the discretionary contribution, the framework of Flammini et al. (2023) was again considered, which with its power of analysis is able to provide objective elements to the decision-making process. Therefore, the final steps of the process can be grouped and simplified by having the tool produce several intermediate outputs that can help decision-makers to have the correct guidelines.

4 Conclusions

In conclusion, the model developed in this work is configured as an integrated ecosystem of intelligent technologies applied to risk management, capable of combining automation, predictive analysis and decision support in a single operational architecture. The adoption of tools such as RPA, AI and Machine Learning,

supported by a solid mapping of processes through BPMN, has made it possible to outline a systemic path oriented towards efficiency, the reduction of human error and the enhancement of company data.

A key aspect of the model is the ability to segment customers based on the risk they bring to the business. Using clustering techniques, customers can be grouped into homogeneous clusters, making it easier to identify high-risk customers and take targeted corrective measures.

The innovative contribution of this model lies in the ability to transform risk management into a modular, adaptive and proactive process, overcoming the traditional static and fragmented approach. The integration of Web Scraping techniques and Business Intelligence tools has also significantly expanded the scope of information available, enriching assessments with dynamic and contextual elements from inside and outside the organization.

These developments have opened the door to higher investigations and considerations. Among the most interesting ones, certainly, is the opportunity to integrate the results of risk assessment into predictive models that convey the same results into mathematical optimization models. This would provide decision-makers with a clear guideline in the field of short- and long-term strategic planning that has never been addressed before. The introduction of machine learning algorithms such as Random Forest, Gradient Boosting Machine and Logistic Regression could open the door to better reliability of forecasts and to refine the definition of weights in risk categories, adapting modeling choices according to the complexity and transparency required in the different operational areas. The synergistic use of these models has proven to be more efficient than monolithic solutions, favoring incremental data processing and constant monitoring of outputs.

Looking ahead, the framework outlined can also be extended to other business decision-making areas, where the complexity of data and the need for rapid responses require the adoption of flexible, intelligent and automated models. At the same time, the approach remains open to subsequent evolutions, including the introduction of emerging technologies, such as Large Language Models or generative AI systems to further enrich risk analysis, forecasting and simulation capabilities.

Ultimately, this work intends to contribute to the development of a new vision of corporate risk management, based on the integration of organizational know-how and technological potential, capable of enabling increasingly timely and sustainable decision-making models.

5 Ethics declaration

The present research did not require the approval of an ethics committee, as it does not involve human subjects, sensitive personal data or experimentation on living beings. All the information used comes from publicly accessible sources and scientific literature.

6 AI declaration

Generative Artificial Intelligence tools have not been used for the drafting or processing of the contents of this document. All sections of the paper were developed independently by the authors, without the aid of generative AI applications.

Exploring the Synergy: AI-Driven Knowledge Management, ESG Performance, and Stakeholder Perceptions in the Energy Sector

Giovanni Spatola, Giuseppe Ambrosio, Marianna Mancino, Maria Zifaro, Andrea Presciutti
Mercatorum University, Rome, Italy

Abstract
The global imperative for sustainable development is compelling industries to reassess operations, emphasizing Environmental, Social, and Governance (ESG) criteria. The energy sector, pivotal yet environmentally impactful, faces intense pressure to innovate sustainably. Artificial Intelligence (AI) offers transformative potential, particularly its application in Knowledge Management (KM) systems to enhance information handling for superior ESG performance. However, a literature gap exists concerning the interplay between AI-driven KM, ESG outcomes, stakeholder perceptions, and corporate competitiveness in this sector. This proposal outlines a study to investigate these dynamics: how AI-driven KM influences ESG outcomes, how stakeholders perceive these innovations, and how such practices might bolster energy companies' competitive advantage. A mixed-methods design is planned (literature review, three Italian energy sector case studies, a survey of ~150 stakeholders). Findings are expected to show a positive AI-KM impact on ESG metrics, multifaceted stakeholder perceptions (more positive externally, varied internally with concerns like job displacement), and enhanced competitiveness through innovation and efficiency. The study aims for theoretical contributions to the AI-KM-ESG nexus and practical insights for energy executives.

Keywords: artificial intelligence, knowledge management, ESG performance, stakeholder perception, energy sector, mixed-methods research, sustainability, digital transformation

Paper type: Academic Research Paper

1 Introduction

The 21st century demands sustainable development, pushing Environmental, Social, and Governance (ESG) criteria to the forefront of corporate strategy (Eccles et al., 2014). The energy sector, vital yet a major environmental contributor (York & Bell, 2019), must transition to cleaner models while ensuring energy security and affordability. Artificial Intelligence (AI) is a key enabler, with its capacity to optimize operations, enhance efficiency, and improve ESG reporting (Duan et al., 2019). A promising AI application is in Knowledge Management (KM), crucial for innovation and achieving ESG targets (Nonaka & Takeuchi, 1995). AI-powered KM can help energy companies understand their ESG footprint and embed sustainability.

Despite interest in AI, KM, and ESG, their intersection in the energy sector is under-researched. Empirical studies are lacking on:

- How specific AI-driven KM practices influence ESG performance indicators.
- How diverse internal and external stakeholders perceive these technological adoptions.
- The mechanisms through which these initiatives affect corporate competitiveness.

Stakeholder perceptions are critical (Freeman, 1984), as AI introduction is a socio-technical shift evoking varied reactions (Brynjolfsson & McAfee, 2014). This research aims to understand the interplay between AI-driven KM, ESG performance, stakeholder perceptions, and competitiveness in the energy sector. Specific objectives are:

- Assess how AI-driven KM influences ESG metrics in selected energy companies.
- Analyze stakeholder perceptions of AI in KM for sustainability.
- Evaluate how AI-driven KM, mediated by ESG performance and stakeholder perceptions, could enhance corporate competitiveness.

A mixed-methods approach (qualitative case studies, quantitative survey) is proposed. Anticipated outcomes include empirically grounded insights for theory and practice, aiding energy sector navigation of digital transformation and sustainability.

2 Theoretical background and research motivation

This research integrates four domains: Knowledge Management (KM), AI's role in KM, ESG frameworks in the energy sector, and Stakeholder Theory.

2.1 Knowledge management (KM):

KM involves managing organizational knowledge for competitive advantage (Drucker, 1993). It distinguishes tacit (personal, hard to codify) and explicit (formal, communicable) knowledge (Polanyi, 1966), with models like SECI (Nonaka & Takeuchi, 1995) explaining their conversion. Effective KM improves decision-making and efficiency (Davenport & Prusak, 1998). In ESG, KM is vital for managing complex data (emissions, compliance) and integrating sustainability (Ling, 2013), though traditional systems struggle with Big Data.

2.2 Artificial intelligence (AI) as an enabler of advanced KM

AI can transform KM by overcoming traditional limitations (Jarrahi, 2018). Key AI technologies include Machine Learning (ML) for pattern identification and prediction (e.g., predictive maintenance), Natural Language Processing (NLP) for analyzing unstructured text (e.g., stakeholder feedback), expert systems, Robotic Process Automation (RPA), and Knowledge Graphs for intuitive knowledge discovery (Hogan et al., 2021). AI enhances all KM stages but faces challenges like data quality, algorithmic opacity, ethics, and employee resistance (Dwivedi et al., 2021). Human-AI synergy is a promising path (Batista et al., 2022).

2.3 Environmental, social, and governance (ESG) in the energy sector

ESG criteria evaluate a company's societal impact (Gillan et al., 2021). Environmental aspects (emissions, resource use) are critical for the energy sector's low-carbon transition (IPCC, 2023). Social factors include health/safety, DEI, and just transition (Heffron et al., 2021). Governance covers leadership, ethics, and risk management (Bebchuk & Tallarita, 2020). ESG reporting standards (GRI, SASB, TCFD) are evolving, with investor pressure driving improvements. AI can automate ESG data collection, monitoring, risk analytics, and reporting.

2.4 Stakeholder theory and perceptions

Stakeholder Theory (Freeman, 1984) emphasizes managing relationships with all affected parties. AI adoption for sustainability impacts diverse stakeholders differently. Internal stakeholders (employees, management) may see benefits but also fear job loss or de-skilling (Autor, 2015). External stakeholders (investors, regulators) might view AI positively for ESG but have concerns about data governance or accountability. Navigating these perceptions requires engagement and ethical AI principles (Rawlins, 2008).

2.5 Synthesis and justification

While literature exists on KM, AI, ESG, and Stakeholder Theory individually, their integrated empirical study in the energy sector is lacking. This research addresses this gap by investigating how AI-KM influences ESG, how stakeholders perceive these changes, and the net effect on competitiveness.

3 Methodology

A mixed-methods sequential explanatory design (QUAL -> quan) is proposed, grounded in a pragmatist paradigm (Morgan, 2014). Qualitative findings will inform the quantitative phase.

3.1 Phase 1: Qualitative case study research

Case Study Selection

Three energy companies in Italy will be purposively selected based on: active AI-driven KM for ESG, explicit ESG focus, varied profile (desirable), and accessibility. Anonymity will be ensured.

Data Collection

- Semi-structured Interviews: ~15-20 per company (45-60 total) with diverse internal (executives, managers, technical staff, employees) and potentially select external stakeholders (investors, regulators). Themes: AI-KM motivations for ESG, tools/processes, perceived impacts, benefits/challenges, effects on KM, perceptions (job roles, ethics), and competitiveness. Interviews (60-90 min) will be recorded and transcribed.
- Document Analysis: Corporate ESG/sustainability reports, strategic plans, AI-KM system documentation, communications, and public ESG data.
- Observational Data: Non-participant observation of AI-KM system use.

3.2 Phase 2: Quantitative survey research

Instrument Development: A structured questionnaire based on qualitative findings and validated scales (adapted for AI-KM for ESG context, e.g., from Davis, 1989 for TAM; Kock et al., 2021 for AI anxiety). Sections: demographics, AI-KM awareness/use for ESG, perceived ESG impact, AI attitudes/concerns (job security, transparency), organizational support, and perceived KM/competitiveness impact. Likert scales will be used. Pilot testing and translation (if needed) will be conducted.

Sampling and Administration: ~150 stakeholders, primarily from the case study companies (stratified sampling considered). Online administration via platforms like Qualtrics. Anonymity guaranteed.

3.3 Data analysis plan

Qualitative: Thematic analysis (Braun & Clarke, 2006, 2019) of interview transcripts and documents using CAQDAS (e.g., NVivo). Within-case then cross-case analysis.

Quantitative: Statistical software (SPSS/R). Descriptive statistics, correlation analysis, comparative analysis (t-tests, ANOVA), and potentially exploratory regression analysis.

Integration: Qualitative findings will explain and contextualize quantitative results.

3.4 Ethical considerations

Strict adherence to ethical principles. IRB/Ethics Committee approval from Mercatorum University will be obtained. Key aspects: informed consent, anonymity/confidentiality, voluntary participation, secure data management, risk/benefit assessment, and potential feedback to companies.

4 Expected results and hypotheses

This study anticipates findings on AI-KM's impact on ESG, stakeholder perceptions, and competitiveness.

4.1 Expected impact on ESG performance

Hypothesis 1a (Environmental): it is hypothesized that the implementation of AI-driven KM systems will be positively correlated with measurable improvements in environmental performance indicators.

Expected Findings: AI applications (predictive maintenance, grid optimization) leading to tangible benefits, supported by KM for data capture and best practice dissemination.

Hypothesis 1b (Social): AI-driven KM initiatives will associate with positive social outcomes (e.g., enhanced OHS, better training) but may reveal nuanced challenges (e.g., employee anxiety).

Expected Findings: KM facilitating safety protocol tracking and stakeholder feedback management.

Hypothesis 1c (Governance): AI-driven KM will enhance governance (transparency, compliance, risk management).

Expected Findings: AI tools improving ESG reporting accuracy and timeliness, AI analytics aiding ESG risk identification.

4.2 Expected stakeholder perceptions

Hypothesis 2a: External stakeholders (investors, regulators) will generally hold more uniformly positive perceptions of AI-driven KM for ESG than internal stakeholders.

Expected Findings: Externals viewing initiatives as signals of innovation and proactive ESG management.

Hypothesis 2b: Internal stakeholders will exhibit more heterogeneous perceptions, with significant concerns (job security, skill gaps, algorithmic transparency, privacy) alongside recognized benefits.

Expected Findings: Survey quantifying these concerns

Hypothesis 2c: Perceived adequacy of organizational change management (communication, training) will significantly moderate internal stakeholders' perceptions and acceptance of AI-driven KM.

Expected Findings: Effective change management correlating with lower concerns and higher acceptance.

4.3 Expected impact on KM processes and corporate competitiveness

Hypothesis 3a: AI-driven KM will lead to demonstrable improvements in KM capabilities (knowledge capture, sharing, application, innovation).

Expected Findings: AI tools enhancing knowledge accessibility and fostering a learning culture.

Hypothesis 3b: Enhanced ESG performance, facilitated by AI-driven KM, will positively associate with perceived/actual improvements in corporate competitiveness (reputation, investor confidence, efficiencies, innovation).

Hypothesis 3c: Positive stakeholder perceptions of AI-driven KM and ESG initiatives will further amplify competitive advantages.

Exemplary Tables of Anticipated Survey Data Constructs

To provide a clearer picture of the quantitative aspect, the tables below illustrate the type of constructs that it is planned to measure via the survey and the general format of the results it is expected to obtain.

Table 1 - Examples of Key Constructs and Planned Measurement Approaches for the Stakeholder Survey

Construct Category	**Example Construct**	**Potential Measurement Approach (Illustrative)**
Perceptions of AI-KM System	Perceived Usefulness of AI-KM for ESG Tasks	5-item scale adapted from Davis (1989) (e.g., "Using the AI-KM system improves my performance in ESG-related tasks.") - Likert 1-7
	Perceived Ease of Use of AI-KM	4-item scale adapted from Davis (1989) (e.g., "Learning to operate the AI-KM system is easy for me.") - Likert 1-7
Impact on ESG Performance	Perceived Contribution of AI-KM to Environmental Perf.	3-item scale developed for study (e.g., "AI-KM has significantly helped our company reduce its carbon footprint.") - Likert 1-7
	Perceived Contribution of AI-KM to Social Perf.	3-item scale (e.g., "AI-KM has improved workplace safety in our company.") - Likert 1-7
Stakeholder Concerns	AI-related Job Insecurity	4-item scale adapted from Kock et al. (2021) (e.g., "I am worried that AI might make my job redundant.") - Likert 1-7
	Algorithmic Transparency Concerns	3-item scale (e.g., "I often don't understand how the AI-KM system arrives at its recommendations.") - Likert 1-7
Organizational Factors	Adequacy of AI-related Training	3-item scale (e.g., "The company has provided sufficient training for using the new AI-KM tools.") - Likert 1-7
	Quality of Communication about AI Changes	3-item scale (e.g., "Management has clearly communicated the reasons for implementing AI-KM systems.") - Likert 1-7
Impact on KM & Competitiveness	Improvement in Knowledge Sharing	3-item scale (e.g., "AI-KM has made it easier to share relevant knowledge with my colleagues.") - Likert 1-7
	Perceived Impact on Company Competitiveness	4-item scale (e.g., "Our company's use of AI for ESG and KM strengthens its competitive position in the market.") - Likert 1-7

Note: This table illustrates examples of constructs and potential measurement approaches planned for the survey. Actual scales will be finalized after the qualitative phase and pilot testing.

Table 2 - Illustrative Format of Expected Aggregate Quantitative Survey Results

Key Indicator Measured	***Expected* General Finding (Illustrative Format)**
Mean Score: Perceived Usefulness of AI-KM for ESG Tasks	Expected: Moderately high to high (e.g., Mean > 5.0 on a 7-point scale), varying by user role.
Percentage of Employees Expressing High Job Insecurity due to AI	Expected: A notable minority (e.g., 20-30%) expressing high levels of concern.
Correlation: Adequacy of Training vs. Perceived Ease of Use of AI-KM	Expected: Strong, positive, and statistically significant correlation.
Difference in Perceptions: Managers vs. Non-Managerial Employees	Expected: Managers to report significantly more positive perceptions of AI-KM benefits and lower concerns compared to non-managerial staff.
Relationship: Perceived ESG Improvement vs. Perceived Competitiveness	Expected: A significant positive association, suggesting that stakeholders link better ESG outcomes (via AI-KM) to stronger competitiveness.

Note: This table illustrates the type of aggregate results and relationships the study aims to uncover through the quantitative survey analysis.

By systematically testing these hypotheses and exploring the expected findings through a mixed-methods approach, this research aims to provide a comprehensive, empirically grounded understanding of the pivotal role AI-driven KM can play in advancing ESG agendas and shaping competitive dynamics in the energy sector, while also highlighting the critical importance of managing stakeholder perceptions effectively.

5 Discussion of potential implications

This research is poised to offer significant theoretical and practical implications.

5.1 Potential Theoretical Implications

The anticipated findings are expected to offer highly relevant and actionable insights for managers, policymakers, and other practitioners:

- Advancing AI-KM-ESG Nexus Understanding: Providing empirical investigation of this tripartite linkage, potentially offering a more granular theoretical model.
- Refining Stakeholder Theory: Demonstrating diverse stakeholder perceptions of AI-driven sustainability, adding nuance for transformative technologies.
- Contributing to Socio-Technical Systems Theory: Reinforcing STS tenets by showing AI success depends on co-adaptation of social and technical elements.
- Informing Competitive Advantage Theories: Suggesting AI-KM for ESG as a potential valuable resource (RBV) or dynamic capability.
- Methodological Contribution: Offering a mixed-methods exemplar for AI and sustainability research.

5.1 Potential Practical Implications

- Guidance for Strategic AI Implementation for ESG: Offering energy executives clearer understanding of impactful AI-KM applications and integration roadmaps.
- Framework for Proactive Stakeholder Engagement: Equipping managers to design effective communication, training, and change management, mitigating resistance.
- Informing Ethical AI Governance: Aiding development of ethical AI frameworks within companies.
- Optimizing KM for Sustainability: Revealing best practices for AI-driven KM to enhance organizational learning in ESG.
- Enhancing ESG Reporting and Investor Relations: Helping companies meet investor demands and improve access to capital.
- Benchmarking and Performance Improvement: Providing a basis for companies to benchmark their AI-KM-ESG efforts.
- Policy Recommendations: Offering insights for policymakers on fostering beneficial AI adoption for sustainability.
- Applicability to Other Sectors: Findings likely relevant for other industries facing similar digital and sustainability transformations.

6 Conclusion

This research proposal outlines an empirical investigation into the AI-KM, ESG performance, and stakeholder perception nexus in the Italian energy sector, addressing a key literature gap. A sequential explanatory mixed-methods design (qualitative case studies followed by a quantitative survey) is proposed.

It is anticipated that AI-driven KM can enhance ESG performance, but stakeholder perceptions will be complex, with internal stakeholders expressing concerns (job security, transparency) alongside benefits. Effective change management is crucial. Improved ESG and positive stakeholder engagement via AI-KM are expected to boost competitiveness.

Potential contributions are significant: theoretically advancing understanding of the AI-KM-ESG linkage and Stakeholder Theory; practically offering actionable insights for executives on AI deployment, stakeholder management, and ethical governance.

Acknowledged limitations include qualitative generalizability, data access, survey cross-sectional nature, potential researcher bias, and causal inference complexity. Mitigation strategies are planned. Future research could include longitudinal studies, cross-cultural comparisons, and deeper dives into specific AI technologies or mitigation strategies.

This research is timely and relevant, aspiring to contribute valuable knowledge for guiding industries towards a technologically advanced, economically competitive, environmentally sound, socially equitable, and ethically governed future.

7 Acknowledgements

The conceptualization of this research proposal has been developed within the framework of the PhD program in Sustainability and ESG at Mercatorum University of Rome. The proposing authors are grateful for the institutional support and intellectual environment that has facilitated this endeavor.

8 Ethics declaration

This research will strictly adhere to ethical principles, with prior IRB/Ethics Committee approval. Informed consent will be obtained, ensuring voluntary participation and the right to withdraw. Confidentiality and anonymity of participants and organizations will be rigorously protected throughout the study. Data will be managed securely, minimizing risks and upholding research integrity.

9 AI declaration

This study investigates AI-driven Knowledge Management as its subject, not developing new AI. Ethical implications of the studied AI systems, including bias, transparency, and job impact, are central to the research. Standard data analysis software (CAQDAS, SPSS/R) is planned; any use of generative AI tools by researchers in manuscript preparation will be transparently acknowledged. The focus is on AI's real-world application and societal impact in the energy sector's ESG efforts.

Artificial Intelligence, Knowledge Management and Reduced Work Time: Rethinking Organizational Competitiveness

Marianna Mancino, Maria Zifaro, Giuseppe Ambrosio, Giovanni Spatola
Mercatorum University, Rome, Italy

Abstract

Business success is no longer defined solely by financial performance or the quality of goods and services provided. It is imperative for companies to embed sustainability into their strategic frameworks, embracing socially and environmentally responsible practices. Businesses must now prioritize aligning profit with ethical and sustainable practices that enhance lives, protect the environment, and foster inclusive communities.

In this new mindset, work focuses on growth as well as output, redefining productivity around well-being and sustainability in a people-centered "productive revolution."

Emerging technologies such as artificial intelligence (AI) offer new ways of organizing work, helping companies use their resources more effectively. It is through intelligent automation that many repetitive, low-value tasks can be eliminated, freeing up time for more strategic and creative activities. This makes it possible to reduce working hours without compromising, and indeed improving, both productivity and competitiveness.

At the same time, AI plays a fundamental role in knowledge management (KM), due to its ability to collect, analyze, and organize large volumes of data, enabling the creation, sharing, and preservation of knowledge within companies.

The reduction of working hours is increasingly central to the debate on the future of work, closely linked to the issue of work-life balance. Improving the balance between private and professional life has become a priority for many companies. What experiences such as the "4 Days Week" have demonstrated in various European countries is that they can bring tangible benefits: greater well-being, motivation, productivity, and improved talent retention.

The present study aims to explore the role of AI in transforming work models, focusing in particular on the effects of reducing working hours on productivity and knowledge management. The analysis will be carried out through a theoretical-documentary research approach, based on an integrated review of scientific literature, institutional reports, and national and international business cases, with particular reference to the themes of artificial intelligence, productivity, and knowledge management.

Keywords: Artificial Intelligence, Productivity, Worktime Reduction, Knowledge Management, Well-being

Paper type: Academic research paper

1 Introduction

In the era of digital transformation and increasing focus on sustainability, companies are facing a crucial challenge: reconciling the adoption of new technologies with employee well-being and organizational competitiveness. In this context, artificial intelligence (AI) is not merely a tool to enhance efficiency—it is a strategic lever for fundamentally rethinking how work is organized and experienced.

AI enables the automation of repetitive and low-value tasks, thereby freeing up time and cognitive resources for activities with greater human significance. This development contributes to a broader redefinition of productivity, one that takes into account not only economic output but also the quality of working life. In this context, Work Time Reduction (WTR), already piloted in several countries, emerges as a tangible strategy for improving work-life balance (WLB), supported in part by AI's transformative potential.

At the same time, the role of Knowledge Management (KM) is gaining strength: intelligent technologies not only facilitate access to and sharing of knowledge, but also enable a more flexible and sustainable reorganization of business processes.

This study explores how AI can transform workplace structures by enhancing efficiency, knowledge management, and employee well-being, positioning knowledge, motivation, and innovation as key pillars of new organizational models.

The central research question is as follows: How can artificial intelligence contribute to a sustainable reduction in working hours without compromising, and indeed, while strengthening, business competitiveness, through more effective knowledge management?

The analysis will focus on the relationship between AI, KM and WTR, identifying the organizational conditions that enable a virtuous transformation of work. Based on a theoretical and documentary review of recent literature, the paper aims to build a conceptual model capable of guiding companies toward a more human, efficient, and sustainable future.

2 Theoretical framework

2.1 Industry 5.0: AI, automation, and productivity

With Industry 5.0, technology is no longer focused just on increasing output, but on creating value for people, society, and the environment. Unlike Industry 4.0, which focused primarily on automation and efficiency, Industry 5.0 places the human being at the center and promotes sustainability, resilience, and well-being at work (Breque, De Nul & Petridis, 2021).

In this context, intelligent technologies can enhance worker well-being, offer greater flexibility, and improve collaboration between humans and machines, promoting a cultural transformation based on participation and shared responsibility (Nirupama et al., 2024). AI thus becomes a strategic ally in building more inclusive, flexible, and human-centered workplaces.

Today, AI is one of the main drivers of productivity transformation. It goes beyond the limits of traditional automation by enabling systems to handle not only mechanical or repetitive tasks but also complex ones (Muro et al., 2019). Industry 5.0 therefore promotes a cultural shift in which technology serves people and society. The aim is to create a more ethical, sustainable, and future-oriented work model.

AI-driven automation, especially generative AI (GenAI), is reshaping operational processes, making them more efficient, accurate, and faster. By automating repetitive tasks, GenAI reduces human error and frees up time for more strategic activities, thereby improving the quality of work (WEF, 2024).

Recent studies (Rožman et al., 2023) highlight that AI can reduce perceived workload, increasing engagement and performance. However, to fully benefit, organizations need proper training and a flexible, tech-integrative culture (WEF, 2024). Productivity gains depend on accessible technology, alignment with human skills, and strong leadership. The most significant advantages currently favor early adopters with an innovation-oriented mindset, adequate resources, and rapid AI integration capabilities (Filippucci et al., 2024).

2.2 Knowledge management, competitiveness, and AI

Knowledge, as a key intangible asset for competitiveness, emerges from a collective, dynamic process involving experience, values, and context. KM plays a strategic role in fostering learning, innovation, and adaptability. Davenport and Prusak (1998) define knowledge as a fluid mix of contextual information, experience, and intuition, embedded not only in systems but also in practices and culture. KM, therefore, must be approached as a holistic system integrating people, technology, and management. The SECI model by Nonaka and Takeuchi (1995) frames knowledge creation as an ongoing cycle, socialization, externalization, combination, and internalization, that drives innovation through the "knowledge spiral".

This dynamic can only function effectively within an enabling environment. The workplace must encourage the sharing, organization, and enhancement of knowledge. Without a culture oriented toward KM, this process risks stagnation, and knowledge may become dispersed. Wiig (1997) argues that business success depends on the ability to manage knowledge in a structured way, through activities such as monitoring, developing appropriate infrastructures, and transforming and enhancing intellectual resources.

The idea of the knowledge-based firm is now well-established in the literature. Grant (1996) emphasizes that competitive advantage stems from the ability to integrate individual knowledge, while Nonaka, Toyama, and Hirata (2008) highlight the importance of continuous circulation and renewal of knowledge within the organization.

Today, knowledge can be managed in a more structured way thanks to systematic processes for collecting, organizing, and enhancing knowledge, processes made more effective by digital technologies, particularly AI (Berryhill et al., 2019; Agostino, Arnaboldi, & Busco, 2021).

Corporate experiences such as those of E80 Group and Pfizer show that AI can transform complex archives into intelligent hubs (E80 Group, 2023; AWS & Pfizer, 2023). These tools support decision-making and improve operational efficiency. Knowledge management becomes faster, more accessible, and user-oriented. Time is freed up for higher-value activities, opening the door to a potential sustainable reduction in working hours.

2.3 Work life balance and work time reduction

Work-Life Balance (WLB) is becoming increasingly important for building sustainable organizations that prioritize employee well-being, with technology playing a key role in helping individuals maintain a healthy balance between professional and personal life (Cookey, 2025).

In response to technological change and evolving employee needs, many companies are rethinking how work is structured. Solutions such as reduced working hours and remote work offer greater flexibility and improve quality of life while maintaining high levels of productivity (Trougakos et al., 2024; Corso et al., 2023).

The "4-Day Week" model, reducing the workweek to four days without salary cuts, has been trialed in various countries with promising results. Empirical evidence highlights benefits for both employees and organizations, including higher job satisfaction, lower burnout rates, improved work-life balance, increased productivity, and reduced turnover (Campbell, 2024).

These outcomes are also supported by theory, particularly Self-Determination Theory (Deci & Ryan, 1985; 2000), which argues that motivation and well-being stem from the fulfillment of three core psychological needs: autonomy, competence, and relatedness. When the work environment supports these needs, employees tend to show higher levels of energy, engagement, creativity, and performance (Van den Broeck et al., 2008; Gagné & Deci, 2005). Conversely, rigid and controlling structures may undermine motivation and increase stress.

From this perspective, what truly makes a difference is not merely the reduction of working hours as a conciliatory measure, but its role as a strategic lever to enhance engagement and improve the quality of professional life. Organizations that embrace such approaches are better positioned to innovate, attract talent, and adapt to change, while promoting a culture based on well-being, trust, and the appreciation of people.

AI is reshaping organizational models, influencing productivity, KM, and employee well-being. However, a key area of inquiry remains: how can artificial intelligence contribute to a sustainable reduction in working hours without compromising, and indeed, while strengthening, business competitiveness, through more effective knowledge management?

To address this issue, the study proposes breaking it down into two more specific research questions, allowing for a clearer and more structured analysis:

- How can the integration of AI into knowledge management contribute to a sustainable reduction in working hours within organizations? This question focuses on the role of AI-enhanced KM as a lever for freeing up time and reorganizing work processes.
- How can a reduction in working hours, enabled by AI, maintain or even enhance business competitiveness? Here, the emphasis is on the impact of work time reduction (WTR) on organizational performance when supported by AI.

While these two questions address different dimensions, they ultimately converge in the development of an integrated model in which AI acts as a driving force for organizational transformation aimed at long-term well-being and competitiveness.

3 Methodology

This study adopts a theoretical-documentary approach aimed at exploring the role of artificial intelligence in transforming organizational models, with particular focus on the reduction of working hours and knowledge management. The methodology is based on an integrated analysis of secondary sources, scientific, institutional, and corporate, selected for their relevance, timeliness, and credibility.

Specifically, the analysis includes: articles published in international peer-reviewed scientific journals; reports and white papers from institutions such as the OECD, European Commission, Aspen Institute, and McKinsey & Company; and documented corporate case studies (e.g., Pfizer, E80 Group, Microsoft Japan, Shopify).

The documentary research was conducted using keywords such as: Artificial Intelligence, Work Time Reduction, Knowledge Management, Productivity, and Work-Life Balance. The selected sources cover the period from 2019 to 2025, with priority given to the most recent publications and empirical evidence related to real-world experiments (e.g., the "4-Day Week").

The analysis was guided by a sequential logic model, AI → Knowledge Management → Work Time Reduction → Competitiveness, which served to interpret the collected data in light of the central research question. Materials were examined from both a comparative and conceptual perspective, identifying recurring patterns, organizational implications, and enabling conditions.

Although no primary data were collected, the chosen methodology makes it possible to outline an integrated conceptual model that can support future empirical research and strategic reflections in the context of digital transformation in the workplace.

4 Discussion and findings

4.1 AI, knowledge management and work time reduction

How can the integration of AI into knowledge management contribute to a sustainable reduction in working hours within organizations?

Integrating AI into knowledge management is a strategic lever for optimizing working time and enabling sustainable work hour reduction (Morandini et al., 2023). AI represents a new form of knowledge investment, enhancing intangible capital and increasing capital deepening—key as much corporate value now stems from knowledge, innovation, and human capital (Filippucci et al., 2024; Corrado et al., 2022). AI streamlines knowledge discovery by analyzing large datasets, identifying patterns, and organizing information efficiently. A notable example is E80 Group S.p.A., where AI transformed unstructured data into a semantic knowledge graph, evolving into a Knowledge Hub that improved access to information, collaboration, and operational continuity (E80 Group, 2023).

In other sectors, such as pharmaceuticals, intelligent systems have shown similar impact. Pfizer, for example, implemented AI-driven solutions to extract, categorize, and recommend relevant scientific content from massive datasets, significantly reducing research time and improving overall efficiency. This accelerated the acquisition and dissemination of scientific knowledge within R&D processes (AWS & Pfizer, 2023). As a result, the time saved could be reinvested in higher-value activities, contributing to a more sustainable use of working time.

In the hospitality industry, the knowledge concierge concept offers another effective application. Here, intelligent virtual assistants accompany guests throughout their stay, automating repetitive tasks such as reservations, check-in/check-out, FAQ responses, and handling of personalized requests.

These systems provide timely, relevant, and updated responses, improving the user experience (McDowell, 2024). At the same time, they allow human staff to focus on tasks requiring empathy, creativity, and problem-solving, easing operational stress and improving shift organization.

AI also enables access to and activation of latent knowledge, such as dark knowledge (Zhang et al., 2025): information not easily codified or immediately identifiable by humans but present within large organizational datasets. This type of knowledge can be critical for solving complex problems, anticipating risks, and improving processes. It also helps reduce uncertainty and response times, further supporting smarter use of working hours.

A notable example is Microsoft Japan's 2019 trial of a four-day workweek, launched under the Work Life Choice Challenge program. The results were significant: a 40% increase in productivity, a 23% drop in energy costs, and a sharp reduction in average meeting duration. Although this initiative was not directly AI-driven, it produced similar effects: streamlined workflows, elimination of non-essential activities, and a redefinition of operational priorities (Microsoft Japan, 2019).

These cases demonstrate that the integration of AI into KM systems can become a powerful lever for achieving a sustainable reduction in working hours. By automating repetitive and low-cognitive tasks, AI improves knowledge access and management, freeing up both time and mental resources.

This enhanced efficiency allows for a more intelligent distribution of working time, with tangible benefits in terms of both productivity and well-being. As emphasized by the IA2 Observatory, the benefits of AI emerge when it is embedded in organizational models that emphasize continuous learning and the development of human capital (Aspen Institute Italia, 2024).

In this context, AI does not replace people, it amplifies their contribution, enabling a more human and dynamic form of knowledge management (Farrell et al., 2023). According to the OECD, this can lead to more sustainable and resilient organizations, where reduced working hours are matched by greater value creation (OECD, 2025).

4.2 AI and work time reduction as a lever for competitiveness

The authors inquire how the reduction in working hours, enabled by the use of AI, can maintain or even enhance business competitiveness.

Work-Life Balance (WLB) has become key to workplace well-being, as more free time improves psychosocial health, focus, and performance. Organizations implementing WLB measures, like flexible schedules or non-monetary benefits, report reduced stress, higher job satisfaction, better performance, and lower absenteeism (Halpern, 2005; Abid & Barech, 2017; Rodríguez-Sánchez et al., 2020).

Beyond individual and organizational benefits, WLB practices make companies more attractive to young talent. This, in turn, helps recruit qualified, motivated individuals, contributing to a more stable work environment (Rodríguez-Sánchez et al., 2020).

Work Time Reduction (WTR) is an increasingly relevant WLB strategy involving fewer weekly hours without cutting pay or raising workload (Trougakos et al., 2024). Unlike part-time work, it restructures schedules across the organization and is seen as a strategic investment in human capital, as shown by international cases (Van Rossum, 2025). WTR builds on the WLB concept, aiming to boost well-being, motivation, productivity, and overall performance.

A large-scale trial in Iceland between 2015 and 2019 showed that reducing the workweek to 35-36 hours maintained or even improved both productivity and service quality. Following its success, 86% of Icelandic workers secured the right to a shorter workweek through collective agreements (Haraldsson & Kellam, 2021).

European pilot programs demonstrate the benefits of a four-day workweek, with UK companies reporting a 35% revenue increase and reductions in stress and turnover (Lewis et al., 2023), Portuguese workers citing improved motivation and WLB (Gomes & Fontinha, 2024), and 73% of German firms continuing trials due to better work quality (Backmann et al., 2024). Though not AI-led, these cases show how technology and process optimization support successful WTR.

AI is widely seen as a tool to improve task allocation and time management (European Commission, 2024), making reduced workweeks more feasible and scalable. A U.S. survey found that 59% of AI users reported higher job satisfaction, 30% saw improved efficiency, and 90% of AI-using companies supported WTR, compared to only 41% among non-users (Tech.co, 2024). This suggests that AI adoption enhances productivity and fosters openness to new work models.

Effective AI integration requires rethinking organizational structures, guided by clear governance separating strategic oversight (often by senior leaders) from functional implementation, typically through hybrid models (McKinsey & Co., 2025). CEO involvement, as in Shopify's AI-first hiring policy (Lütke, 2024), is crucial for aligning innovation with company goals.

Adoption is rising: 73% of organizations recognize AI's value in accelerating tasks and 66% in automating low-value work (European Commission, 2024). Generative AI, now used by 63% of firms, is increasingly embedded in workflows (McKinsey & Co., 2025). Leading companies apply systemic approaches using roadmaps, KPIs, training, and communication to align AI with strategy.

However, realizing WTR through AI also requires cultural change, greater team autonomy and accountability. AI doesn't replace work but redefines it, elevating human skills and fostering well-being-centered, inclusive workplaces (Bankins et al., 2024). Ultimately, AI-driven efficiency supports reduced working hours while enhancing well-being, motivation, and competitiveness, positioning WTR as a strategic path to sustainable innovation.

4.3 Conceptual model proposal

In light of theoretical and practical evidence, a conceptual model of organizational innovation is proposed, summarizing the relationships between Artificial Intelligence (AI), Knowledge Management (KM), Work Time Reduction (WTR), and Business Competitiveness. The model consists of six main components:

Based on both theoretical insights and practical observations, we propose a conceptual model of organizational innovation that highlights the interplay between six key components:

- Artificial Intelligence (AI) as a driver for intelligent automation;
- enhanced Knowledge Management (KM);
- Work Time Reduction (WTR) as an organizational strategy;
- improved Productivity and Well-being;
- renewed Business Competitiveness;
- reinvestment in AI for continuous improvement.

These elements form a circular, self-reinforcing structure, where each component supports and amplifies the others in a virtuous cycle of innovation.

AI is the foundation of the model, enhancing efficiency and work quality by automating low-value tasks and transforming data into structured knowledge, thus enabling a smarter allocation of time to strategic and creative activities.

The second pillar, Knowledge Management (KM), is a dynamic, AI-powered ecosystem that enhances knowledge sharing, supports continuous learning, and improves access to information, enabling better collaboration and reducing repetitive cognitive work.

The synergy between AI and KM enables time optimization, making work time reduction (WTR) both feasible and productive. Through smarter workflows and task redistribution, organizations can reduce working hours while maintaining or even improving performance, fostering a culture of trust, autonomy, and goal-oriented work.

When supported by smart technologies, reducing working hours enhances well-being and work-life balance, lowering stress and boosting motivation. At the same time, clearer goals and streamlined tasks increase productivity, proving that well-being and performance can grow together.

This virtuous cycle leads to a new enterprise model focused not on work intensity, but on balancing technological efficiency, human development, and sustainability—making well-being, team stability, and talent retention central to organizational growth

Ultimately, the model fosters continuous improvement by reinvesting gains in efficiency, well-being, and development into AI solutions, employee training, process innovation, and a stronger organizational culture.

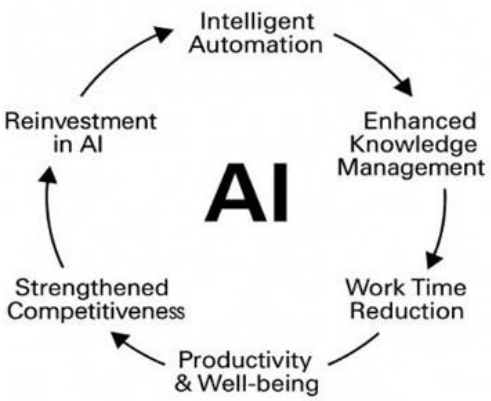

Figure 1. AI, KM and WTR virtuous cycle

In summary, a virtuous path of innovation has been outlined, represented by a circular model (Figure 1) in which each component supports and reinforces the others, giving rise to a continuous and integrated evolutionary dynamic.

The proposed model is based on the idea that the adoption of AI, when integrated into an advanced KM system and accompanied by organizational rethinking, can generate simultaneous benefits in productivity, well-being, and competitive sustainability.

This approach reflects a vision aligned with the principles of Industry 5.0, promoting a cultural and organizational evolution where reduced working hours are not a concession, but a strategic outcome enabled by the intelligent and systemic use of technological innovation.

5 Critical analysis

This article leads to the presentation of a conceptual model that links Artificial Intelligence (AI), Knowledge Management (KM), Work Time Reduction (WTR), and corporate competitiveness. The model offers a perspective on technological change that highlights the transformative potential of AI, not as a threat, but as an opportunity to rethink work patterns and timing in terms of well-being and sustainability. The inclusion of concrete examples enhances accessibility, even for non-specialist audiences, while references to recent sources lend relevance to current dynamics in the world of work and technological innovation.

However, the text presents some limitations that merit further examination. First, the study is based entirely on a theoretical-documentary analysis: it lacks original data, interviews, or field observations. These elements could have strengthened the validity and practical applicability of the arguments.

Moreover, the model overlooks several critical issues related to AI. These include implications for the labor market, psychological impacts, risks resulting from algorithmic biases, and inequalities in access to technology. Additional concerns involve the proper management of data and the protection of privacy.

The optimistic view of the virtuous cycle risks oversimplifying the real challenges of applying AI in productive contexts, as the positive outcomes of shorter workweek trials mainly concern SMEs operating in digital or flexible sectors—quite different from the well-structured, capital- and knowledge-intensive firms that typically succeed in adopting AI (Filippucci et al., 2024; ISTAT, 2024).

Furthermore, the diffusion of AI remains uneven. SMEs are often hindered by a lack of financial resources, technical skills, and adequate infrastructure. These difficulties are even more pronounced in rural or less-developed areas, where infrastructure gaps and a weaker innovation ecosystem are prevalent.

Finally, the real-world implementation of the "4 Day Week" has revealed several challenges, such as increased workload on active days, coordination difficulties, reorganization costs, and the complexity of evaluating productivity outcomes.

To promote AI as a driver for reducing working hours, it's crucial to test the model across different companies to ensure broad, fair, and sustainable adoption. An empirical study should support this by identifying key organizational factors and ethical implications in AI integration.

6 Ethics declaration

This research did not involve human or animal subjects, nor did it collect any sensitive data; therefore, approval from an ethics committee was not required.

7 AI declaration

No Artificial Intelligence (AI) tools were used in the creation or editing of this work. However, online translation tools such as Google Translate were used only to assist with language translation. All ideas, structure, and final content are the original work of the authors, and full responsibility for the accuracy and integrity of the work remains with the authors.

Artificial Intelligence as a Driver for Educational Inclusion: Developing a Generative AI Chatbot to Support Professors and Students

Stefania D'Aprile, Giovanni Spatola
Universitas Mercatorum, Rome, Italy

Abstract

Social sustainability is a fundamental pillar for the balanced and inclusive development of contemporary societies. It embodies the commitment to social equity, inclusion, respect for human rights, and the promotion of collective well-being. Artificial intelligence (AI), with its increasing deployment, is emerging as a key tool for addressing social challenges and promoting sustainability goals, which, to date, also involve education, following the provisions of Sustainable Development Goal 4 (SDGs 4) of the UN 2030 Agenda. The integration of artificial intelligence (AI) technology into education has introduced many possibilities. However, it also raises ethical issues that require careful consideration. This paper aims to highlight the importance of considering AI as a driver for educational inclusion, starting with an analysis of its potential. The study delves into the benefits and challenges of the introduction of a generative AI chatbot by Multiversity Group, Italy's largest group operating in the Digital Education sector and Europe's second largest group, which, driven by its vision of AI-enhanced education, collaborated with strategic consulting firm Bain & Company to build such a generative chatbot, leveraging OpenAI technology, to provide a better learning experience for students by fostering engagement and interaction with professors, and to combine didactic delivery and interactive assistance to learners. This paper aims to explore the emerging contribution of AI in education to promote innovative and inclusive educational delivery to reduce possible educational inequalities, considering the benefits, challenges and ethical implications of implementing the technology. AI can be an enabler for social progress, but it requires attention relative to the risks of discrimination and risks related to privacy and data security. The paper analyzes the high-impact challenges faced in developing the generative AI project to ensure that student data is securely managed in compliance with legal standards, such as GDPR 2016/679, the qualitative value of responses, the need for continuous monitoring, and overcoming any technological limitations.

Keywords - Artificial intelligence, social sustainability, inclusive education, digital education, role of AI in education

Paper Type: Practical Paper

1 Introduction

Artificial intelligence is revolutionizing the educational sector, offering innovative tools for personalized learning and accessibility. Educational inclusion is a central challenge in the modern school and academic system. Emerging technologies, particularly AI, offer innovative tools to foster more accessible and personalized education. Chatbots based on generative AI can provide assistance to students, contributing to the reduction of educational barriers. This paper aims to explore the emerging role of AI to promote innovative and inclusive educational provision, reducing possible educational inequalities, and analyze the benefits, challenges, and ethical implications related to implementing the tool. Inclusive education is a central element of social sustainability, aimed at ensuring equal educational opportunities for all, regardless of economic, geographic, or personal barriers. However, structural inequalities persist that limit access to quality education. *Ad hoc* public policies that promote universal access to AI technologies and educational resources and are aimed at bridging the digital divide between geographic areas and social groups are crucial on this point. AI offers significant opportunities to overcome multiple types of barriers, improving accessibility by implementing online learning systems that can reach remote or disadvantaged communities, providing access to high-quality content, personalizing learning pathways and bridging existing gaps. It is possible, then, to consider AI as a driver for educational inclusion, starting with an analysis of its potential. Driven by the vision of AI-enhanced education, Multiversity Group collaborated with strategy consulting firm Bain & Company to build a generative, 24/7 responsive chatbot, leveraging OpenAI technology, to provide a better learning experience for students by fostering engagement and interaction with professors. The pilot project also included the introduction of a customized tool that would enable faculty to complete administrative tasks 90 percent faster, allowing them to focus more on higher-value teaching activities. The goal of the project was to elevate continuous interactive learning experiences, becoming a benchmark for AI-powered instruction across all of its programs. This innovative new service will complement student lectures and regular tutoring provided by the academic cohort

and university services, providing better understanding of complex concepts, important clarifications, additional insights and reference sources. This assistance tool will also provide students with instant feedback. AI is evolving rapidly, and companies need to identify real-world applications that generate sustainable value in their respective industries to secure a competitive advantage. The launch of this AI assistance tool represents a real game changer for the online experience of students and professors

2 The role of artificial intelligence in education

The introduction of AI education is exponential growth. Many areas of education can benefit greatly from the application of artificial intelligence, which improves administrative management and school learning. Intelligent tutoring systems, adaptive learning platforms, natural language processing, data analytics and virtual bot assistants all fall under the umbrella of new technologies anchored by AI. Indeed, AI is being used in various educational fields, leading to a number of benefits. Firstly, AI algorithms can analyze individual student performance to create tailored study paths and structure so-called "*adaptive learning.*" These tools ensure that each student receives the appropriate support based on his or her own pace and learning style. In addition, AI can detect educational difficulties or gaps early, offering targeted interventions to prevent school or even academic dropout through a process of prior identification of needs. Artificial intelligence systems evaluate huge amounts of data to personalize learning paths based on each student's strengths, weaknesses and detected deficiencies. In fact, technologies related to the use of AI make it possible to assess student data to determine which students are at risk of failing a course or are having difficulty with a particular subject. Data on student achievement and detected behavior can be analyzed by predictive analytics algorithms to help educators and teachers identify possible critical issues. Such a model allows preemptive analysis of specific issues to be carried out, enabling teachers to act promptly to resolve them. Artificial intelligence, therefore, enhances "targeted" learning experiences, motivating and retaining students. AI-based analytics systems enable real-time assessment of student performance and the effectiveness of instructional programs, ensuring progress monitoring and accommodating the individual needs of students with learning difficulties or special needs. The use of such technologies improves accessibility through digital platforms and virtual assistants, such as intelligent tutors, who can provide individualized assistance to students. One of the most innovative tools developed for educational inclusion is the generative AI chatbot. Advanced Natural Language Processing (NLP) algorithms enable chatbots to intelligently understand and respond to students' questions, adapting content to their needs, thus making educational processes more accessible and personalized. Personalized learning for each individual student is one of the main benefits using artificial intelligence in digital education. Artificial intelligence algorithms can personalize instruction by assessing information about students' learning preferences, interests and progress. The OECD-OECD report “The potential impact of Artificial Intelligence on equity and inclusion in education” highlights how artificial intelligence can prevent dropout by identifiyng at risk students early through personalized tools that enhance learning. The World Economic Forum’s “Shaping the Future of Learning: the Role of AI in Education 4.0” report also emphasizes the fact that AI makes personalized teaching sustainable, improves learning 98 percent of the time, overcoming the limitations of large-scale application. Artificial intelligence is a key tool for addressing the major challenges in digital education, overcoming traditional barriers and redefining the educational experience to make it more equitable, inclusive and innovative. The true potential of AI lies in its ability to store and analyze huge amounts of data about students, with the purpose of personalizing instruction for each learner. There is a branch of machine learning called "deep learning," a subset of Machine Learning, based on artificial neural networks with multiple layers. It is used to analyze large amounts of complex data with high accuracy. The world of education is going through a period of radical transition, driven by technological evolution, changes in labor market needs and the intensifying need for continuous learning. The World Economic Forum (WEF), moreover, stressed the importance of synergistic collaboration among educational institutions, businesses and governments in order to build a learning system that is more inclusive, adaptive and aligned with the skills of the future.

Below we present two diagrams illustrating a typical model of AI-based digital learning in academia: (1) a process flow diagram and (2) a layered architectural diagram. Both highlight the key elements of the technology-based Digital Learning Model: student data collection, AI/ML analysis, content personalization, delivery via digital platforms, continuous monitoring/feedback and iterative cycle of improvement.

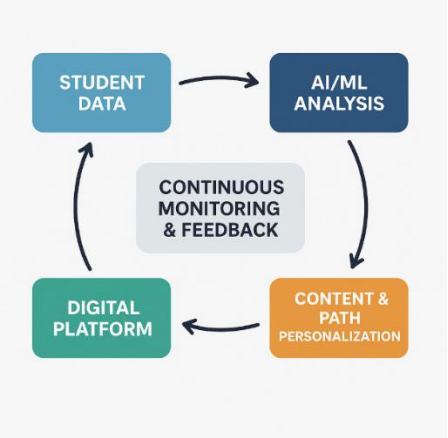

Figure 1: Adaptive model for AI enabled Digital learning

The flowchart shows the sequential steps (in circular form) of the AI-based adaptive learning model. It starts with the acquisition of student data: the system collects information on the performance (e.g., grades, quiz results) and online behaviors (e.g., response times, participation in activities) of each student. This raw data forms the basis on which the AI will operate, providing the informational "fuel" for the model to learn and generate insights. In the AI/ML analysis phase, *machine learning* algorithms and *Natural Language Processing* techniques process the collected information to identify recurring patterns and predict future performance: for example, the strengths and weaknesses of each student are identified, analyzing outcomes and interactions over time. Such analyses produce useful knowledge about the individual learning profile (e.g., specific knowledge gaps, cognitive style, level of engagement). Based on these insights, customization of content and pathways follows: the AI system builds a tailored training pathway, adapting the level of difficulty, the pace of progression, and selecting the most appropriate learning materials for a specific student. Essentially, AI decides what to offer and *how to* offer it, so that each student receives “the right content at the right time" based on his or her progress. The delivery phase takes place through digital platforms: typically a web-accessible Learning Management System (LMS) or mobile app that delivers this personalized content to the student, presenting the learning activities through a user-friendly interactive interface. The digital educational platform then acts as a conduit between the AI and the student, providing the adaptive educational resources while recording new user interactions. During the course execution, continuous monitoring with immediate feedback takes place: the system tracks the student's progress in real time and provides instant automatic feedback on exercises, quizzes, and activities performed. For example, AI can flag errors made in a quiz and offer tailored explanations or suggestions, allowing the student to correct their deficiencies immediately. In parallel, teachers have access to control panels (dashboards) through which they can track student progress, treat it as "human monitoring" and provide additional qualitative feedback or motivational support when needed. Finally, the model incorporates an iterative cycle of improvement: all data collected during activities (results, times, clicks, paths followed) continuously feed the AI system. Through repeated cycles of learning from new data and feedback, the AI progressively refines its algorithms, increasing the accuracy of predictions and the quality of recommendations with each iteration. This closed feedback *loop* ensures that the system gradually becomes "smarter" and more effective as more and more students use it, creating continuous improvement for both student performance and the instructional strategies employed. The model is dynamic and self-regulating. The AI learns from real behaviors, adapts content, observes learning effectiveness, and constantly updates itself, providing a personalized, effective, and constantly evolving learning experience.

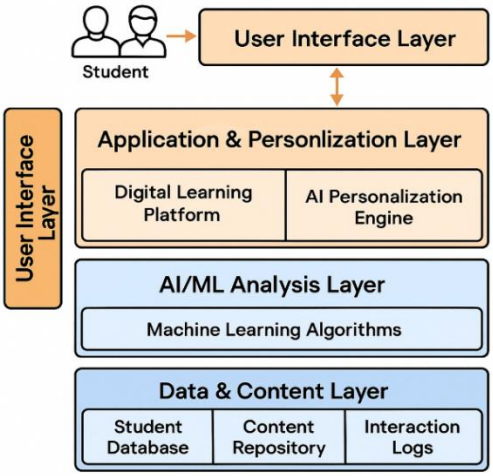

Figure 2 Layered architecture of the adaptive model for artificial intelligence-enhanced digital learning

The architecture of an adaptive model for artificial intelligence (AI)-enhanced digital learning is structured into multiple layers, each with a specific role, which together enable a personalized learning experience for the student. The student is the starting point: he or she interacts with the system through a digital user interface. The second diagram represents the layered architecture (layered architecture) of an AI-based digital learning system, highlighting the main functional components arranged in layers. User Interface Layer: at the top layer are the interfaces through which human actors interact. On one side is the learner, who accesses content and activities through a web or mobile application (the front-end LMS); on the other side is the teacher, who uses a monitoring dashboard to track student progress and intervene as needed. This layer provides user-friendly access to the platform's features, enabling learning anywhere, anytime. Application & Personalization layer: immediately below the user interface resides the actual e-learning platform (LMS backend) along with the business logic and AI modules that orchestrate the personalized experience. This is where the management of courses, learning materials, and adaptivity rules takes place: for example, an AI personalization engine processes requests from the user interface (e.g., "student X has completed unit Y") and, based on learned patterns, determines what content to offer next to the student. This level serves as the "brain" of the application, where AI techniques are applied in real time to adapt the training path. AI/ML Analysis layer: in some architectural models, a layer dedicated to intelligent analysis is distinguished, where Machine Learning algorithms and predictive models trained on educational data reside. This analytical layer processes collected data (student performance, interaction logs, etc.) in the background using methods such as neural networks, data mining algorithms, and NLP in order to extract useful knowledge. The results of the analysis (e.g., the degree of mastery of a certain topic or the prediction of future difficulties) are then passed to the higher application level, which translates them into concrete instructional actions (e.g., proposing a remedial exercise on a topic in which the student has shown deficiencies). Data and Content Layer: at the base of the architecture we find the data layer, which includes the databases and archives that are essential to the functioning of the system. Here reside the student database (containing profiles, results, activity history), the repository of learning content (lessons, exercises, videos, documents available for delivery), and interaction logs (detailed traces of every action taken on the platform). This layer feeds the upper layers by providing the information needed for both AI analysis and content presentation: in other words, the raw data stored in the repositories is what enables AI to make informed decisions. Importantly, a bidirectional flow of information takes place in the architecture: from the low levels upward, data and analysis feed into instructional decisions (data -> AI -> personalization -> user), while from the high levels downward, feedback and newly acquired information flows (e.g., user interactions and teacher-given ratings return to the data layer). Specifically, monitoring results (student performance, automatic AI-generated feedback, and teacher observations) are returned to the database in the form of new data, closing the learning loop of the system. This modular and layered architecture ensures scalability and clarity: each layer plays a distinct but interconnected role, contributing overall to an adaptive and continuously improving learning experience. On the basis of the above, while AI analyzes data to provide personalized recommendations, teachers can focus on high-value-added activities (mentoring, emotional support), leveraging the insights provided by the system. In summary, the presented model combines data collection, intelligent algorithms and human intervention in a virtuous cycle: this enables the university student to be offered a tailor-made educational pathway delivered through modern digital platforms and to continuously improve both teaching

effectiveness and learning success. The ultimate goal is to offer **personalized, adaptive, interactive, data-driven learning** that supports the student on his or her journey in a continuous and dynamic way.

3 Generative AI chatbots for educational support: the case of Multiversity Group

The Multiversity Group, a leader in Digital Education in Italy and second in Europe, in collaboration with strategic consulting firm Bain & Company, has developed a chatbot based on OpenAI technology to support students belonging to the Group's Digital Universities. The collaboration between OpenAI and Multiversity has created an environment of innovation in the educational landscape. Such technological integration is changing the way students and faculty interact. One of the most innovative aspects of the AI chatbot is its ability to interact in real time with learners, who in this way receive support in the study and deepening of complex concepts, getting immediate answers, as if they were interacting with a personal tutor. The more than two hundred thousand students at the group's universities already had the opportunity to take classes flexibly, benefiting from tutoring and university services, but with this innovation they had additional ways to personalize the educational experience and improve exam preparation. In addition, the chatbot, developed and tested with the cooperation of professors and with an accuracy of more than 99 percent, will be useful for the lecturers themselves, refining the interactivity of teaching. The implementation of this AI assistant represents a significant step toward the education of the future. The current version of the chatbot not only provides information, but has the potential to transform into a more advanced assessment system. It itself becomes an analytical tool that identifies areas where students can improve. This ability to personalize not only makes learning more accessible, but also creates an inclusive educational pathway. This approach could, in the long run, revolutionize the way we learn, enabling more and more students to address their gaps and enhance their skills. Multiversity's project represents an ambitious educational vision that integrates technology and learning. The synergy between artificial intelligence and humanity in education is gaining increasing relevance. Potentially, the use of these technologies makes it possible to redefine the role of educators, who will no longer be mere transmitters of information and knowledge, but valuable guides in the learning experience. The world of education is constantly evolving; the inclusion of artificial intelligence tools such as the Multiversity Group's is a significant step in this direction. The implementation of such technologies could not only improve the effectiveness of teaching, but we could see a real process of "democratizing" access to education, opening up new opportunities for students from diverse backgrounds. The future of education looks promising and full of opportunities because of this radical change. The increased demand for flexible and personalized educational solutions necessitates the need to develop tools such as the one implemented by Multiversity, which are critical to meeting the needs of modern students. This technology not only enhances the learning experience, but also prepares students for the challenges of an increasingly digitized and innovative world. The chatbot has helped elevate learning experiences by providing insights and clarification of complex concepts. The goal is to transform digital education, making it more inclusive and effective. The pilot project also included the introduction of a customized tool that would enable teaching staff to complete administrative tasks 90 percent faster, allowing them to focus more on higher-value teaching activities and streamline paperwork. The goal of the project was to aim to elevate continuous interactive learning experiences, becoming a benchmark for artificial intelligence-powered education in all its programs. This innovative new service complements student lectures and regular tutoring provided by the academic cohort and university services, ensuring a better understanding of complex concepts by supplying necessary clarifications, additional insights and reference sources. AI is evolving rapidly, companies need to identify real-world applications that generate sustainable value in their respective industries to secure a competitive advantage. The launch of this AI assistance tool represents a real game changer for the digital learning experience of students and professors.

4 Challenges, ethical implications and future prospects

The integration of artificial intelligence (AI) in education represents a momentous transformation, but it also poses relevant and complex challenges. The introduction of AI into teaching and research practices raises fundamental issues related to algorithmic transparency, protection of personal data, equity of access and prevention of systemic bias. On the ethical side, one of the main risks is algorithmic bias: the use of unrepresentative datasets can generate discriminatory responses or perpetuate pre-existing inequalities. Smart tutors must be trained on diverse data to avoid discrimination. Continuous monitoring is essential in order to ensure the production of accurate and appropriate content. One of the biggest critical elements lies in the fact that AI chatbots can provide false, misleading, harmful, and biased information. It is, therefore, critical that algorithms be designed in a transparent, auditable and equity-oriented manner. Equally important is the need for students to learn to critically examine the production, distribution, ownership, design, and use of these tools

to make informed decisions about their use in their field of study and in their future careers. Another crucial aspect is the issue of privacy: the collection and processing of sensitive student data requires strict security protocols, informed consent, and full compliance with current regulations, think GDPR 2016/679. In addition, there is a need to work hard on continuing education to foster the adoption and use of AI technology by teachers and students. It is important for teachers to develop digital skills by participating in professional development opportunities in order to experiment with innovative teaching methods that can make use of AI-enhanced tools to analyze and address the specific learning needs of each student. Educational and educational institutions must be at the forefront of the use of AI because of its enormous impact on learning and future job requirements. The widespread adoption of AI tools in school and college settings, however, risks exacerbating the digital divide among students with different access to devices, connections and digital skills. Addressing these additional issues related to AI use requires taking a multifaceted approach involving technological innovations, ethical guidelines, legal regulations and educational efforts aimed at promoting the integrity and responsible use of AI. The term "digital ethics" refers to a set of values and principles for the proper use of technology in relationships among individuals, groups and entities. Digital ethics represents a crucial aspect in the implementation of artificial intelligence (AI) in education and academia, requiring critical reflection on how such technologies are developed, adopted and used. There is a need to ensure that AI-based tools respect the principles of inclusiveness, student autonomy, and academic integrity, while preventing automation from compromising educational quality or accentuating pre-existing inequalities. In addition, the responsible integration of AI requires the adoption of shared ethical guidelines and constant monitoring of social and cognitive impacts in order to promote informed and sustainable use of technology within educational and research settings. AI has a significant and disruptive impact on society. Many organizations have launched a wide range of initiatives to establish ethical principles for the adoption of socially useful AI. In the context of artificial intelligence (AI) implementation in educational and academic settings, digital ethics not only imposes standards of transparency, fairness and accountability, but also raises the need to guard against *ethical bluewashing* phenomena. This term describes the practice through which institutions and companies exhibit a formal commitment to ethical principles without such statements being translated into substantive changes in operational practices. In education, the risk of ethical bluewashing is manifested when AI integration is presented as inherently respectful of students' rights or promoting inclusivity, without any real control over the algorithms used, real stakeholder participation, or independent evaluation of impacts. Therefore, critical reflection on digital ethics must necessarily include analysis of the dynamics of bluewashing, so that AI adoption occurs in a genuinely virtuous and collectively welfare-oriented manner. It is incumbent on academic and administrative leaders to reflect on and assess the existence of bluewashing problems in the use and advancement of AI among university students. To manage these critical issues, it will be essential to develop ethical and inclusive public policies, introduce specific regulations, enhance technological infrastructure and promote digital literacy. Indeed, maximizing the positive impact of AI in education requires concrete actions. The future prospects of AI in education are, however, promising: if implemented ethically and responsibly, it can contribute to more personalized teaching, adaptive and continuous learning and a more accessible, equitable, sustainable education system. The adoption of intelligent chatbots that are active 24 hours a day every day, as evidenced by recent experiments in the university context and the case study regarding the Multiversity Group, is a concrete example of how AI can improve the student experience, foster autonomy, and optimize educational resources. The future will see an evolution of chatbots with increasingly advanced capabilities for personalized student support. For an ethical implementation of AI in education, it is essential to ensure transparency in algorithms, equity in access to technology and continuous monitoring of the effectiveness of AI tools. Transparency, accountability and close monitoring are key to mitigating the risks associated with the use of AI in academia. Although AI has the potential to revolutionize education for all economies around the world, its implementation must be guided by the principles of transparency, fairness, equity and responsible use to ensure positive impacts for the benefit of all stakeholders.

5 Conclusions

Generative AI represents a revolutionary opportunity for educational inclusion by improving access to and personalization of learning. The case of Multiversity Group's chatbot demonstrates the potential of these technologies in supporting both students and teachers. However, to ensure ethical and effective implementation, it is critical to address technical, regulatory and educational challenges. Artificial intelligence represents a tremendous resource for promoting social sustainability through inclusive education. In order to fully realize this potential, it is critical to ensure that AI is designed and implemented with a user-centered approach, within guidelines, ethical standards, and regulatory dictate. Through responsible, cross-sectoral

engagement, it will be possible to transform AI into a concrete driver of sustainable social progress for the benefit of the community. To date, structural inequalities persist that limit access to education. A sustainable and effective AI-powered educational landscape requires vigilance, collaboration, and commitment to high-quality education for all. Artificial intelligence, if implemented with an ethical and user-centered approach and supported by appropriate public policies to ensure its safe and equitable use, can help overcome these barriers, reduce the education gap and improve the overall education system.

6 Ethics declaration

The authors declare that this study was conducted in accordance with the ethical standards generally accepted for scientific research. Where applicable, all experimental procedures were approved by the appropriate ethics committees and comply with national and international regulations. The authors declare no conflicts of interest.

7 AI declaration

During the preparation of this manuscript, generative Artificial Intelligence tools were used to assist with writing and editing. Specifically, the language model ChatGPT developed by OpenAI (GPT-4 version) was employed to improve textual clarity, harmonize linguistic style, and provide suggestions for rephrasing complex sections, under the direct supervision and final approval of the human authors. No part of the content was generated autonomously by AI without human oversight. The authors take full responsibility for the scientific content and conclusions presented.

The Role of Artificial Intelligence in Social Sustainability: A Socio-Technical Systems Perspective

Serena Strazzullo[1], Moacir Godinho Filo[2]
[1]University of Naples Federico II, Naples, Italy
[2]EM Normandie Business School Metis Lab, France; Federal University of São Carlos, Brasil.

Abstract

This paper examines the role of Artificial Intelligence (AI) in advancing sustainability, focusing on the intersection of AI and social sustainability. Given the substantial body of research in this field, a systematic review of over 2,000 articles was conducted. The sample was first analysed descriptively, followed by a thematic grouping based on sustainability dimensions. Notably, the social dimension of sustainability was underrepresented, prompting a more detailed exploration of AI's role in addressing social sustainability. To explore AI's role in advancing social sustainability, this study uses the Socio-Technical Systems (STS) framework. STS, developed by Emery and Trist (1960), examines the interplay between technology and social systems, focusing on five elements: technology, work processes, people, organizational structures, and the external environment. These elements guide the analysis of AI's effects across sectors such as healthcare, education, and governance. The study highlights AI's role in reshaping workflows, skill development, organizational hierarchies, and societal systems, while addressing global challenges like climate action and economic resilience.The study contributes to the field by integrating STS into AI and social sustainability, providing a structured lens to assess AI's impact. It offers actionable insights for policymakers, organizations, and researchers on how to leverage AI responsibly, ensuring ethical governance, fairness, and inclusivity. The study emphasizes the need for frameworks that balance AI's opportunities with potential risks, promoting responsible AI deployment across sectors.

Keywords: Artificial Intelligence**;** Socio-Technical Systems Perspective; Social; Sustainability; Thematic Analysis.

Paper type: Academic Research Paper

1 Introduction

From its inception, expectations for Artificial Intelligence (AI) have been exceptionally high, and today, experts increasingly view AI as a potential ally in addressing global challenges (Goralski & Tan, 2020; Kulkov et al., 2024; Nishant et al., 2020). However, the significant dual influence of AI—both enabling and inhibiting—requires careful examination. This critical issue has been explored by institutions such as the KTH Royal Institute of Technology, the AI Sustainability Centre, and the Massachusetts Institute of Technology (MIT), which jointly organised a roundtable discussion. Insights from this event are captured in the document *"Assessing whether artificial intelligence is an enabler or an inhibitor of sustainability at indicator level"*. It is essential to thoroughly analyse both the opportunities and challenges that AI presents for sustainable development. The Social Sustainability Goals provide a valuable framework for assessing AI's impact across various sectors. According to Vinuesa et al., (2020), AI has the potential to positively impact 79% of the Sustainable Development Goals (SDGs). However, when these results are examined by pillar, significant variations emerge. Environmental sustainability demonstrates the highest potential for positive influence from AI, with a remarkable 93% impact, while social sustainability records the highest rate of distrust towards AI, with a negative impact value of 38% (Gupta et al., 2021). Some of the positive effects of AI align with SDG 8 (Decent Work and Economic Growth) and SDG 9 (Industry, Innovation, and Infrastructure), where AI-enabled technologies can generate new employment opportunities and boost productivity. Similarly, SDG 7 (Affordable and Clean Energy) and SDG 13 (Climate Action) may benefit from the more efficient use of energy and the development of tools to predict and manage urban pollution. Further contributions extend to SDG 14 (Life Below Water) and SDG 15 (Life on Land), where AI can support the conservation and management of biodiversity and natural resources. However, a comprehensive understanding of this phenomenon requires an exploration of AI's potential negative effects. Notably, AI poses risks to achieving several SDG applications in the domains of economy and society. For instance, AI could lead to job displacement, exacerbate inequality in access to computing resources, or polarise societies through biased algorithms, thus undermining SDG 10 (Reduced Inequalities). These inequalities could also negatively impact SDG 4 (Quality Education). Another concern involves the growing energy demands of information and communication technologies (ICT), which are projected to increase from 1% to 20% of global electricity consumption by 2030. In conclusion, artificial intelligence represents a double-edged sword for sustainability.

Given the critical role of AI's influence on sustainability, this study aims to explore its role in advancing social sustainability by addressing two central research questions:

- **RQ1)** What are the key thematic areas where AI exerts the most significant influence on social sustainability?
- **RQ2)** How does Artificial Intelligence influence these thematic areas when analyzed through the lens of the Socio-Technical Systems (STS) framework?

To answer the second research question, this study adopts Socio-Technical Systems Theory (STS) as its theoretical framework. STS, originally developed by Emery and Trist (1960), provides a robust lens for analyzing the interaction between technological systems and social systems. The theory highlights the interdependence of technology, people, organizational structures, and the broader societal context. Later developments, particularly those by Baxter and Sommerville (2011), identify five interconnected elements critical to understanding technology's impact: technology, work processes and activities, people, organizational structures, and the external environment. These elements offer a comprehensive means to evaluate how AI is transforming specific domains of social sustainability.

2 Methodology

The methodology adopted to examine the interaction between AI and sustainability is a systematic literature review. A literature review serves two primary purposes: (a) to summarise the existing body of research on a topic, identifying key themes and issues while proposing directions for future investigation; and (b) to situate any new scholarly contributions within the context of established knowledge and theories (Maditati et al., 2018). The advancement of knowledge must build on prior work, and to push the frontiers of understanding, it is crucial to determine the current state of the field. By reviewing the relevant literature, one can grasp the breadth and depth of the existing research corpus and identify gaps that merit further exploration (Xiao & Watson, 2019). Given the substantial volume of publications on this topic, a hybrid approach combining traditional and bibliometric analysis was selected. This approach is outlined in the diagram below, detailing the steps of *Material Collection and Selection*, *Descriptive Analysis, and Content Analysis.*

2.1 Material Collection and Selection

The data collection process began in October 2024 and lasted approximately one month. The primary source used was Scopus, a database that provides abstracts, citations, and full-text articles. Owned by Elsevier, the world's largest publisher in the medical and scientific fields by the number of publications and journals, Scopus is described as a source-neutral database. It is curated and managed by an international and independent committee of researchers and experts known as the Scopus Content Selection & Advisory Board (CSAB). In addition to Scopus, the commonly used search engine Google also supported the data collection process.

The Scopus database facilitated the search and selection of articles using a variety of keywords, including *"artificial intelligence," "sustainability,"* and *"AI."* Below the query used for the database search:

("Artificial Intelligence" OR "AI") AND ("Sustainability")

Scopus returned a significant number of results more than 8.000 documents. Therefore, search filters were applied to refine and narrow down the selection.

The following criteria were implemented:

1. **Language:** English was chosen as it is universally accepted within the scientific community and is the language in which the vast majority of scholarly work is published.
2. **Timeframe:** Publications from 2010 to 2024 were considered. The period from 2010 to 2024 was chosen to ensure that the review captures both foundational works and recent advancements in the field. This timeframe reflects the emergence and rapid development of artificial intelligence (AI) technologies and their applications in sustainability-related domains. Beginning the analysis in 2010 allows for the inclusion of the foundational studies in AI and its early integration into sustainability initiatives. The endpoint of 2024 ensures the inclusion of the most current and up-to-date research, providing a comprehensive overview of the topic's evolution.
3. **Relevant Fields:** Scientific domains relevant to the research objectives were identified, including Environmental Science, Engineering, Social Sciences, Medicine, Psychology, Multidisciplinary, Health Professions, Decision Sciences, Earth and Planetary Sciences, Arts and Humanities, Economics, Econometrics, and Finance. The selection of scientific domains was guided by the interdisciplinary nature of the interaction between AI and sustainability. Fields such as Environmental Science and Engineering were included to capture studies on ecological applications and technological innovations. Social Sciences, Medicine, and Psychology address the societal and human-centric implications of AI in

sustainable practices. Other areas, such as Economics and Decision Sciences, were incorporated to explore the economic impact and strategic applications of AI. This diverse selection ensures a holistic understanding of the topic, reflecting the multifaceted nature of sustainability.

4. **Document Types:** Only *Articles* and *Reviews* were selected for this literature review. Articles and reviews were chosen as they represent the most rigorous and in-depth forms of academic literature. Articles provide original research findings, offering insights into novel methodologies, experiments, and case studies. Reviews, on the other hand, synthesize existing knowledge, identifying trends, gaps, and future research directions. This combination ensures that the literature review is both comprehensive and grounded in high-quality, peer-reviewed sources, supporting robust and reliable conclusions.

Following the application of the aforementioned filters, the sample of documents was significantly reduced, decreasing to *2431* documents, aligning with the first phase of our research.

2.2 Descriptive Analysis

The aim of this analysis is to provide a comprehensive and detailed overview of the selected document sample. The distinctive characteristics of the documents were examined, particularly their temporal distribution, to understand the evolution of research over the years and to identify periods of higher or lower concentrations of publications, which may indicate trends or seasonality. This analysis serves to carefully assess the quality and relevance of the extracted sample, ensuring that it constitutes a valuable and meaningful resource for the subsequent research. From the total sample, an initial analysis was conducted to categorise the documents based on the year of publication and number of citations, allowing for an evaluation of the trends in this area of study over time.

To delve deeper into the topic, the title and abstracts of 2431 documents were reviewed—a process that took approximately 40 days—and the documents were classified. This classification focused on the three pillars of sustainability: environmental, social, and economic. This approach was adopted to explore how artificial intelligence has been studied in relation to each of these dimensions of sustainability. Figure 1 illustrates the temporal distribution of articles and citations related to the AI and sustainability from 2010 to 2024. The bar graph (green bars) represents the annual number of articles published, while the line graph (grey line) shows the corresponding total number of citations per year. The number of articles published remained relatively low and stable, indicating limited research activity on the intersection of AI and sustainability during this period. A noticeable increase in publications occurred, suggesting growing awareness of the potential role of AI in addressing sustainability challenges. From 2020 onwards, there was a sharp rise in the number of articles, peaking in 2024 with the highest volume of publications. This period reflects heightened academic interest and research efforts in the field. Citations increased significantly starting in 2018, peaking in 2020. However, despite the highest number of articles in 2024, citations show a slight decline, likely due to the lag effect in citation accumulation for recent publications. The convergence of increased publications and citations highlights the growing recognition of AI and sustainability as a critical research domain.

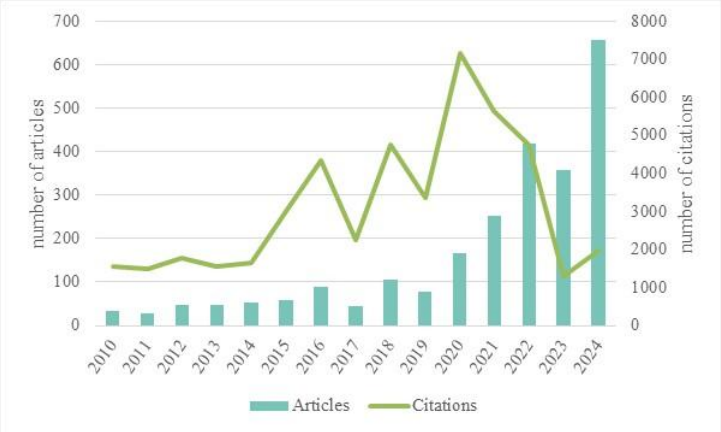

Figure 1 Temporal distribution of articles and citations

The prior descriptive analysis confirmed the suitability of the selected sample, paving the way for a more in-depth investigation. Given this results, the abstracts were classified into three categories of sustainability: social, environmental, and economic. Additionally, a fourth category, “non-relevant,” was introduced to catalog documents that were neither useful nor pertinent to this research. This classification provides a deeper

understanding of how AI aligns with each aspect of sustainability, highlighting areas of strength and weakness as well as potential challenges and opportunities AI presents in this complex domain. The classification process was carried out with meticulous attention to detail. Each abstract from the 2431 documents was carefully read and analyzed to determine if a predominant or exclusive category could be assigned among the three considered: environmental sustainability, economic sustainability, and social sustainability. During this process, each abstract was reviewed for clear and relevant indications that would allow it to be assigned to one of the categories. If the abstract lacked sufficient information for precise classification or was deemed non-relevant to the categories of interest, the document was categorized as "non-relevant." This methodical approach ensured an accurate organization of the documents, creating a solid and reliable foundation for further analyses. Figure 2 summarizes the distribution of articles based on their alignment with different dimensions of sustainability in the context of artificial intelligence (AI).

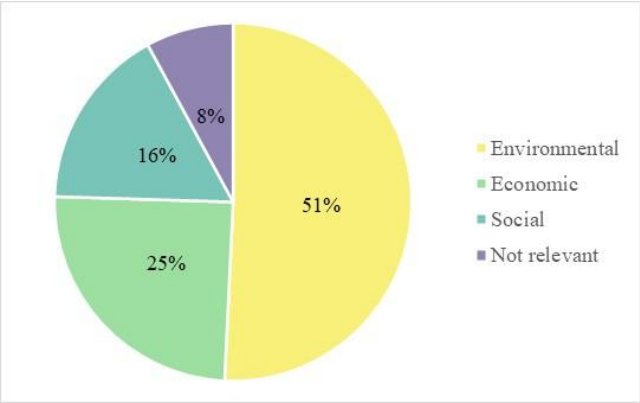

Figure 2 Articles per sustainability dimensions

Regarding the relevant documents, which constitute 92% of the total, the analysis reveals that 1234 of these discuss Artificial Intelligence (AI) in relation to environmental sustainability. This accounts for 51% of the total documents and over 55% when considering only the relevant ones.

This finding leads to a significant initial observation: among the various dimensions of sustainability, environmental sustainability is clearly the most discussed and explored. The predominance of this topic can be attributed to the growing global awareness of environmental issues and the urgent need for innovative technological solutions to address these challenges. Environmental sustainability has become a priority for many organisations, governments, and scientific communities, reflecting a collective commitment to safeguarding the planet. AI, with its vast applicative potential, emerges as a crucial tool for developing effective strategies for climate change mitigation and adaptation, natural resource management, and the reduction of environmental impacts.

The emphasis placed on environmental sustainability in the analysed documents also highlights the key role AI can play in this domain, fostering innovations ranging from energy consumption optimisation to advanced monitoring systems for pollution control. This prevalence of studies on AI and environmental sustainability therefore reflects not only a thematic priority but also an orientation towards the search for practical, immediately applicable solutions to tackle global environmental crises.

After environmental sustainability, the second most addressed topic in the relevant documents is economic sustainability, with 601 studies exploring AI in this context. This represents 25% of the total documents and 27% when considering only the relevant ones.

This figure suggests that, alongside the global environmental crisis, the scientific community and researchers are also strongly focused on economic challenges. Economic sustainability encompasses a wide range of topics, including operational efficiency, cost reduction, innovation in business models, and resource optimisation in businesses and industries. AI provides powerful tools to address these challenges, offering advanced solutions for financial management, economic data analysis, and market trend forecasting.

The significant number of studies centred on economic sustainability highlights the essential importance of creating resilient and sustainable economic systems. AI can support this adaptation by automating processes, optimising supply chains, and creating new business models that promote sustainable growth. Moreover, the global economic crisis, exacerbated by events such as the COVID-19 pandemic and wars, has heightened awareness of the importance of developing economies that are not only resilient but also capable of thriving under adverse conditions. Thus, the prominence of economic sustainability in the analysed documents reflects

a direct response to these urgent needs. This prioritisation of economic sustainability, following closely behind environmental sustainability, underscores the interconnectedness of the environment and economy, recognising that long-term economic prosperity is inextricably linked to the responsible and sustainable management of natural resources.

Finally, only 403 documents address the topic of AI in relation to social sustainability, representing 16% of the total documents and 18% when considering only the relevant ones.

This figure clearly indicates that among the dimensions of sustainability, social sustainability is the least explored. The reasons for this disparity may be manifold. Firstly, the impact of social sustainability is often more challenging to quantify compared to environmental or economic sustainability. While environmental impacts can be measured using concrete data such as carbon emissions or resource consumption, and economic impacts can be evaluated through financial and productivity indicators, social implications are more complex and elusive. They pertain to aspects such as equity, inclusion, quality of life, and human rights, which are not easily quantifiable with standardised metrics.

Unlike environmental sustainability, which has benefited from a high positive perception regarding AI's impact, social sustainability has often been viewed in a more negative light (Vinuesa et al., 2020) This perception may have limited the enthusiasm and commitment of researchers to explore how AI could be used to improve critical social aspects. Although social sustainability currently receives less attention than the other dimensions, there is largely untapped potential for the use of AI in this area.

2.3 Content Analysis

Following a detailed examination of the conclusions drawn from the descriptive analysis of the documents, we decided to concentrate our research exclusively on the social dimension of sustainability. This choice was made due to the substantial volume of studies addressing the other two dimensions. The social dimension, being the least explored among the three, presents a unique opportunity to deepen our understanding of the underlying dynamics. The primary objective of this step is to analyse and identify the main themes that currently contribute to the observed disparity in attention across the different sustainability dimensions. Identifying these themes is crucial for understanding why social sustainability receives comparatively less scholarly focus and for developing strategies to bridge this gap. This decision is driven by the belief that comprehensive sustainability can only be achieved when environmental, economic, and social dimensions are advanced in tandem. Neglecting the social dimension would mean overlooking a critical component of sustainable progress, potentially undermining achievements in the other dimensions. It is imperative that no aspect of sustainability is overlooked, as each contributes in an interconnected manner to the overall well-being of society and the planet. Addressing the social dimension is, therefore, essential to ensure a holistic and inclusive approach to sustainability.

The first step of the content analysis involved a meticulous review of the full text of the 403 documents classified under the category of social sustainability. This was undertaken to assign each document to a specific theme or sub-domain in line with the protocol suggested by Centobelli et al., (2022). Such phase was essential due to the broad scope and diversity of topics encompassed by social sustainability. Our primary aim was to identify the most recurring themes and examine how they are addressed in terms of both frequency and depth. This thematic classification allows for a more structured understanding of the current state of research on social sustainability and highlights areas that require further investigation. We identify nine different themes that are detailed as follows:

Education and Training category collects articles that address AI's transformative role in education and professional training. Research ranges from AI-enhanced digital learning platforms to integrating AI into education management systems for sustainable development. The focus is on using AI to personalise learning experiences, optimise educational outcomes, and foster lifelong learning.

Ethics and Governance explores the intersection of AI with ethical considerations, digital governance, and public policy. Articles examine participatory cities, digital public sphere dynamics, and responsible urban geospatial AI. Research also addresses ethical AI applications in governance, urban management, and fostering inclusive societies. The emphasis is on creating frameworks for fair, transparent, and socially responsible AI utilisation.

Health focuses on AI applications in healthcare and public health. Topics include AI-driven analyses for understanding global fishing activities' impacts on health and the environment, pharmaceutical modelling, and promoting one-health initiatives. The articles demonstrate AI's potential to improve healthcare delivery, enhance disease prevention, and support global health goals.

Sustainable Cities and Infrastructure category addressess AI's role in building smart, inclusive, and sustainable urban environments. Research includes studies on enhancing women's safety in transient environments, sustainable transport solutions, and AI's integration into urban infrastructure for better mobility and planning. The focus is on creating resilient cities and infrastructure that cater to diverse societal needs.

Tourism, Art, and Culture groups articles related to how AI is reshaping the tourism, arts, and cultural sectors. Research explores AI's role in creating sustainable tourism practices, enhancing cultural preservation, and fostering innovation in hospitality. The focus is on using AI to promote cultural sustainability and drive growth in these sectors.

Technologies and Industrial Innovation involves innovative AI applications in industrial and technological settings. Articles include the use of AI for assessing road performance, developing sustainable urban transport solutions, and integrating AI into industrial processes. These studies showcase how AI enhances efficiency, reduces costs, and supports sustainable industrial practices.

Economy and Productive Sectors includes studies that explore AI's impact on economic resilience and productivity. Topics include the readiness of AI for business ethics in micro, small, and medium enterprises (MSMEs) and the role of AI in sustainable marketing practices. These studies highlight AI's potential in fostering sustainable business practices and supporting economic growth.

Sustainability and Environment highlights AI's role in environmental sustainability. Studies focus on AI-driven solutions for sorting recyclable materials, mapping fishing activities, and monitoring environmental conditions. The overarching goal is leveraging AI to mitigate environmental degradation, optimise resource usage, and promote sustainable practices in various industries.

Agriculture and Food category focus on applying AI to enhance agricultural productivity, food safety, and sustainability. Examples include the development of AI-based platforms for food safety, improving traceability processes in meat quality, and diagnosing plant diseases using advanced machine learning techniques. These studies demonstrate the potential of AI to revolutionise traditional agricultural practices and address challenges in food supply chains.

Table 1 illustrates the distribution of articles across various macro-themes, with Education and Training (24%) and Ethics and Governance (23%) receiving the most significant focus. This prominence suggests a strong interest in leveraging knowledge dissemination, capacity building, and ethical frameworks to address societal challenges and advance sustainability. Health (13%) and Sustainable Cities and Infrastructure (12%) also account for a substantial share of research, reflecting efforts to explore the role of technology and innovation in improving public health systems, urban development, and infrastructure management. Conversely, other themes such as Tourism, Art, and Culture (10%), Technologies and Industrial Innovation (6%), Economy and Productive Sectors (6%), and particularly Sustainability and Environment (2%) and Agriculture and Food (2%), are comparatively underrepresented. This disparity indicates that while certain domains have garnered significant academic attention, others remain less explored, leaving room for further investigation. Within the broader theme of social sustainability, the substantial representation of Education and Training, alongside the notable share of Health-related research, underscores their critical importance to societal well-being. Education serves as a cornerstone for social progress, enabling skill development, equity, and inclusion, while health is fundamental to the quality of life and sustainable societal development. Despite their relative prominence, challenges persist in fully realising their potential for advancing social sustainability.

Table 1 Paper per Macro-themes

Macro-Themes	Number of Articles	Percentage
Education and Training	103	24%
Ethics and Governance	94	23%
Health	53	13%
Sustainable Cities and Infrastructure	47	12%
Tourism, Art, and Culture	40	10%
Technologies and Industrial Innovation	26	6%
Economy and Productive Sectors	23	6%
Sustainability and Environment	9	2%
Agriculture and Food	8	2%

We then developed a bubble chart (Figure 2), to analyse the evolution of the macro-themes over the time. The bubble chart visualises the evolution of research themes at the intersection of AI and Sustainability from 2010 to 2024. Each bubble represents a specific theme (e.g., Health, Education and Training, etc.), with the size of the bubble corresponding to the frequency of publications related to that theme in a given year. This analysis

highlights trends in research focus over time and provides insights into the shifting priorities in this multidisciplinary field. The number of publications across themes has grown significantly over the years, particularly from 2020 onward. This growth suggests an increasing interest in applying AI to tackle sustainability challenges. From the analysis of the chart, *Sustainability and Environment*, *Industrial Technologies and Innovation*, *Economy and Productive Sectors*, *Cities and Sustainable Infrastructure* result to be emerging themes with a gradual growth over time. These themes show consistent growth from around 2015 onwards, with notable increases in attention in recent years (2020-2024). They reflect a sustained focus on sustainability, technological advancements, and urban development. *Education and Training* and *Ethics and Governance* represent steadily growing themes. *Education and Training* emerges as one of the most researched, especially in recent years. The importance of equipping individuals with knowledge and skills for sustainable AI practices likely drives this trend. *Ethics and Governance* also grows steadily, underlining concerns about responsible AI use and its societal implications. Finally, *Agriculture and Food, Health, Tourism, Arts and Culture* can be considered as late-blooming themes because exhibit limited activity in earlier years but gain significant traction after 2018. Their growth may be tied to recent global challenges like food security, public health crises, and revitalization of cultural and tourism sectors after Covid-19.

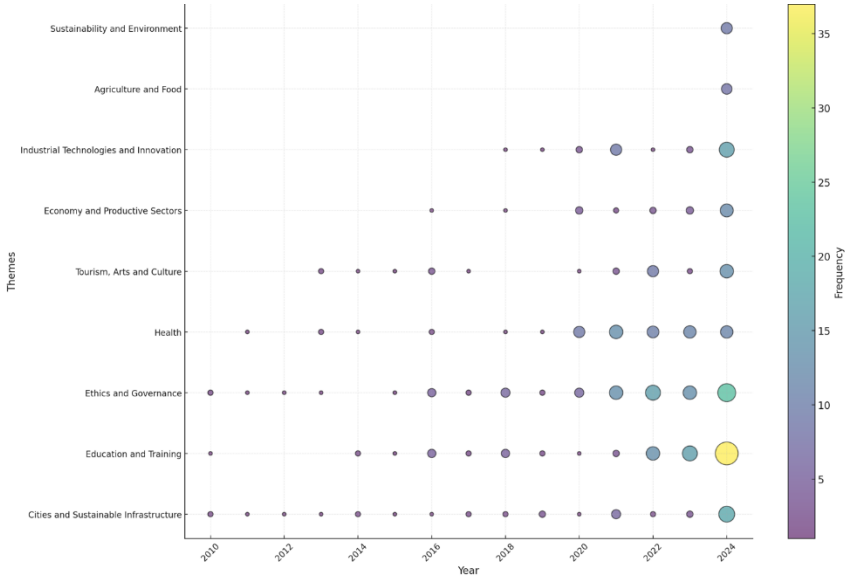

Figure 3 Bubble chart AI and sustainability

Given this context, our analysis will focus on applying the STS perspective to analyse the role of AI in each of the themes identified.

3 AI's Influence on Thematic Areas through the STS Lens: Socio-Technical Interdependencies

Adopting the STS framework enables a holistic understanding of how AI influences various macro-thematic areas by analysing the interplay among technology, people, organisational structures, work processes, and external environments. Within *Education and Training*, AI-driven personalised learning platforms are reshaping pedagogical models, yet their success is tightly coupled with teacher readiness, institutional adoption policies, and learner engagement (people and organisational structures). Similarly, in *Health*, AI applications such as diagnostic algorithms and predictive analytics enhance medical decision-making and care efficiency (technology and work processes), but their integration also demands new governance structures, medical training, and ethical oversight.

In *Ethics and Governance*, the development and deployment of AI raise complex questions regarding accountability, transparency, and fairness, especially when decision-making shifts from human to algorithmic agents. The STS lens underscores that ethical AI use cannot be addressed solely through technical solutions—it requires participatory governance models, regulatory adaptation (external environment), and organisational responsiveness. In *Sustainable Cities and Infrastructure*, AI is employed to optimise mobility, energy, and waste systems. However, its success hinges on inclusive urban planning, citizen participation, and equitable data governance—highlighting how technological advancements must co-evolve with social and institutional infrastructures. The STS framework also elucidates how AI interacts with socio-technical dimensions across

productive and cultural sectors. In *Technologies and Industrial Innovation*, AI-powered automation and predictive maintenance are revolutionising manufacturing and service processes (technology and work activities). However, these transformations require organisational agility, worker reskilling, and regulatory evolution to prevent digital divides. Within the *Economy and Productive Sectors*, AI contributes to operational efficiency and market analytics but may also lead to job displacement and changing labour dynamics, necessitating supportive policy and social adaptation mechanisms.

In the domain of *Tourism, Art, and Culture*, AI supports personalised experiences and digital heritage preservation, yet its success depends on cultural sensitivity, creative human input, and balanced governance (people and external environment). Regarding *Sustainability and Environment*, AI aids in climate modelling, biodiversity tracking, and resource management. However, socio-technical analysis reveals that outcomes are contingent on transparent data sharing, multi-stakeholder collaboration, and ethical considerations related to environmental justice. Finally, in *Agriculture and Food*, AI enhances precision farming and supply chain optimisation, but its implementation intersects with local knowledge systems, digital literacy, and land governance. These examples underscore how AI's impact is not deterministic but shaped by the dynamic alignment of social and technical subsystems.

4 Discussion

As illustrated in Table 2, each thematic area experiences AI transformation differently, depending on how the socio-technical components align or conflict. The framework's five key components—Technology, Work Processes, People, Organisational Structures, and External Environment—enable a multidimensional assessment of AI's integration across thematic areas.

In Education and Training, AI-driven tutoring systems and adaptive learning platforms exemplify how technological advancements reshape pedagogical methods (Luckin et al., 2016). These tools reconfigure the work processes of teachers and students, demanding changes in both classroom practice and school-level decision-making, while broader public education policies increasingly emphasise digital inclusivity (Holmes et al., 2021).

The domain of Ethics and Governance has seen the emergence of algorithmic accountability tools and AI risk assessment frameworks that influence regulatory workflows (Mittelstadt et al., 2016). This area highlights the need for interdisciplinary collaboration between ethicists, policymakers, and technologists, often institutionalised through policy think tanks and advisory committees, operating within complex legal environments (Floridi et al., 2018).

In Health, AI systems assist in diagnostics and treatment planning, altering clinical workflows and necessitating new competencies among healthcare professionals (Topol, 2019). Hospitals are adapting their organisational structures to accommodate AI, while ethical and regulatory frameworks strive to balance innovation with patient safety and privacy (He et al., 2019).

Sustainable Cities and Infrastructure benefit from AI-enabled smart sensors and urban analytics, enhancing planning capabilities and real-time decision-making (Batty et al., 2012). The integration of these technologies requires participatory governance models and regulatory mechanisms to address data privacy and algorithmic transparency.

In the context of Tourism, Art, and Culture, AI and XR tools offer new modalities for cultural storytelling and visitor engagement (Gretzel et al., 2015). The involvement of artists, curators, and tourists in co-creating experiences reflects the socio-technical nature of innovation in this space. Cultural institutions must navigate organisational change and comply with intellectual property and heritage conservation policies.

Technologies and Industrial Innovation see some of the most visible impacts of AI, particularly through automation, digital twins, and robotics (Kusiak, 2018). These developments reshape engineering workflows and call for flexible, innovation-oriented organisational structures supported by research and development centres. External influences such as industrial policy and intellectual property regulation are critical in shaping adoption.

In Economy and Productive Sectors, predictive analytics and intelligent supply chain management tools are transforming decision-making processes. This affects a wide range of human actors—from frontline workers to managers—within organisations adapting business models to harness AI-driven efficiencies (Brynjolfsson & McAfee, 2014). National labour laws and industrial policies must evolve to manage the resulting socio-economic shifts.

AI's contribution to Sustainability and Environment includes predictive modeling for climate change and AI-assisted environmental monitoring (Rolnick et al., 2019). These technologies support scientific work processes and require coordination among NGOs, public institutions, and regulatory bodies operating under evolving environmental governance frameworks.

Lastly, in Agriculture and Food, precision farming technologies enhance productivity and resource efficiency. These changes affect daily agricultural practices and demand capacity-building among farmers, while cooperatives and agencies act as key intermediaries. National and international regulations concerning food security and land use form the enabling or constraining external environment (Wolfert et al., 2017).

Table 2 AI and Sustainability through STS perspective

Thematic Area	**Technology**	**Work Processes**	**People**	**Organizational Structures**	**External Environment**
Education and Training	AI tutoring systems	Adaptive learning	Teachers & students	School policies	Public education systems
Ethics and Governance	Algorithmic accountability tools	Risk assessment	Regulators, ethicists	Policy think tanks, committees	Legal & regulatory frameworks
Health	Diagnostic AI tools	Clinical workflows	Medical professionals	Hospital management	Health policy and ethics
Sustainable Cities and Infrastracture	Smart sensors	Mobility planning	Urban residents	City governance models	Data regulations
Tourism, Art, and Culture	AR/VR & AI curation	Visitor experiences	Artists & tourists	Cultural institutions	Heritage and privacy laws
Technologies & Ind. Innovation	AI automation, digital twins	Manufacturing optimisation	Engineers, operators	Innovation labs, R&D centres	Industrial policy, IP regulations
Economy and Productive Sectors	Predictive analytics	Supply chain ops	Workers & managers	Business models	Labour and industrial policy
Sustainability & Environment	Climate AI models	Resource monitoring	Environmental scientists	NGOs & agencies	Environmental policy
Agriculture and Food	Precision farming	Crop cycle optimisation	Farmers	Cooperatives/Agencies	Land and food governance

5 Conclusion

This paper offers a comprehensive analysis of AI and social sustainability. A systematic review of the literature, drawing on over 2,000 articles published between 2010 and 2024, provides critical insights into the evolving relationship between AI and sustainability. The review reveals that, while there is significant research on AI's impact within the environmental and economic dimensions of sustainability, the social dimension—particularly its application in sectors such as healthcare and education—remains underexplored. The literature review highlighted several trends and gaps in AI adoption. Notably, the rapid growth in AI-related publications from 2019 to 2024 indicates an increasing interest in AI's potential to drive sustainable development. Furthermore, this paper detail the role of AI on social sustainability through the lens of the socio-technical systems (STS) framework. By applying the STS framework, which emphasizes the interplay between technology, people, processes, and environments, we have gained valuable insights into the multidimensional nature of AI integration across different areas. The framework enables a deeper understanding of how AI technologies are reshaping industries while also highlighting the social, ethical, and regulatory challenges that accompany these changes.

The analysis of the nine thematic areas—Education and Training, Ethics and Governance, Health, Sustainable Cities and Infrastructure, Tourism, Art and Culture, Technologies and Industrial Innovation, Economy and Productive Sectors, and Agriculture and Food—reveals how each sector experiences AI transformation differently based on the alignment or conflict of socio-technical components. This thematic approach underscores the importance of adopting a systems thinking perspective when examining AI's impact, as it is not just the technology itself that matters, but also the surrounding people, processes, structures, and external factors.

Through this analysis, we see that the socio-technical dynamics within each thematic area are pivotal in shaping the outcomes of AI adoption. The STS framework's multidimensional approach helps identify both opportunities and challenges in integrating AI across these sectors. It also points to the need for a more inclusive, interdisciplinary approach to AI research, one that considers not only the technological innovations but also the social, organizational, and regulatory factors that influence their success.

In conclusion, while AI presents significant opportunities for advancing sustainability, particularly in environmental and economic dimensions, its integration into the social dimension requires careful attention to the socio-technical complexities that shape its outcomes. By leveraging the STS framework and analyzing AI's impact across the nine thematic areas, this paper contributes to a more nuanced understanding of AI's role in

achieving social sustainability. Future research should continue to explore these socio-technical interactions to ensure that AI developments are aligned with the broader goals of equity, inclusivity, and social justice.

6 Ethics Declaration

The author confirms that no ethical approval was required for the research presented in this paper, as it did not involve any experiments with human participants, animals, or sensitive data.

7 AI declaration

The authors declare that AI tools were used for editing purposes in the preparation of this document. The AI assistance was limited to language correction, grammar improvement, and stylistic refinement.

Artificial Intelligence and Social Sustainability in the Energy Sector: Enhancing Stakeholder Perception and ESG Performance through Innovative Practices

Giovanni Spatola, Mario D'Avino, Antonio Capasso, Maria Zifaro, Andrea Presciutti
Mercatorum University, Rome, Italy

Abstract

The integration of Artificial Intelligence (AI) into sustainability practices is transforming industries by enabling innovative solutions to complex challenges. However, while the nexus between AI and economic or environmental sustainability has been the subject of substantial academic inquiry, its potential role in advancing social sustainability remains comparatively underexplored. Social sustainability, encompassing critical aspects such as health and well-being, equitable access to education, and community resilience, is fundamental to the development of sustainable societies and is explicitly linked to Sustainable Development Goals (SDGs) such as SDG 3 (Good Health and Well-being), SDG 4 (Quality Education), and SDG 11 (Sustainable Cities and Communities). In the energy sector, where innovation is a primary driver, AI is increasingly employed to address issues including energy equity, workforce safety, and community development. The success of such initiatives, however, critically hinges on stakeholder perception, which influences the legitimacy and acceptance of AI-driven practices. This study aims to bridge the gap between AI applications and their social implications by examining how AI-driven innovative practices in the energy sector can enhance social sustainability and Environmental, Social, and Governance (ESG) performance. Specifically, it focuses on the role of stakeholder perception as a key determinant of the success of socially sustainable initiatives. By integrating concepts from stakeholder theory and knowledge management frameworks, this research seeks to advance theoretical understanding while offering practical strategies for achieving sustainability goals in knowledge-intensive and innovation-driven industries. The paper presents a review of the extant literature and outlines a research proposal predicated on a mixed-methods approach, focusing on case studies of energy companies implementing AI for social sustainability.

Keywords: artificial intelligence, social sustainability, ESG performance, stakeholder perception, energy sector

Paper type: Academic Research Paper

1 Introduction

The advent of Artificial Intelligence (AI) has ushered in a new era of technological transformation, with profound implications for virtually every industrial sector. Its capacity to analyze vast datasets, identify complex patterns, and automate decision-making processes offers unprecedented potential to address intricate global challenges, including the transition towards sustainability. Sustainability, in its three interconnected dimensions – environmental, economic, and social – has become an imperative for organizations aiming to create long-term value and contribute positively to society.

While the application of AI to enhance environmental sustainability (e.g., optimizing energy efficiency or managing natural resources) and economic sustainability (e.g., improving productivity or creating new business models) has garnered considerable academic and industrial attention, the social dimension of sustainability in relation to AI remains an emerging and comparatively less explored field. Social sustainability pertains to improving quality of life, promoting equity, ensuring health and well-being, providing access to quality education, and building resilient and inclusive communities. These aspects are intrinsically linked to the United Nations' Sustainable Development Goals (SDGs), particularly SDG 3 (Good Health and Well-being), SDG 4 (Quality Education), and SDG 11 (Sustainable Cities and Communities).

The energy sector, characterized by rapid innovation and crucial strategic importance for socio-economic development, is central to this discussion. AI is finding increasing applications in this sector to address specific social issues, such as ensuring equitable energy access, enhancing worker safety, and promoting the development of local communities impacted by energy activities. However, the efficacy and acceptance of these AI-based initiatives depend not only on their technological validity but are also profoundly influenced by stakeholder perception. Stakeholders – including employees, local communities, customers, regulators, investors, and civil society – play a determinative role in conferring legitimacy upon new technologies and

corporate practices. Their perception can either facilitate or hinder the adoption and success of AI-driven innovations.

Environmental, Social, and Governance (ESG) performance has become a critical metric for evaluating a company's commitment to sustainability. Research has demonstrated that strong stakeholder engagement is positively correlated with improved ESG performance. Understanding how AI applications can enhance the social aspects of ESG performance, and how stakeholder perception modulates this relationship, is therefore of paramount importance.

This study aims to investigate in-depth how AI-driven innovative practices in the energy sector can contribute to the enhancement of social sustainability and ESG performance. The primary objective is to examine the critical role of stakeholder perception in determining the success and impact of such initiatives. Through a review of existing literature and the subsequent proposal of empirical research, this work intends to provide theoretical contributions, particularly by integrating stakeholder theory with knowledge management frameworks within the ambit of AI for social sustainability. Furthermore, it aims to offer practical insights for energy sector companies and policymakers on designing and implementing AI strategies that are technologically advanced, socially responsible, and positively perceived by stakeholders.

The paper is structured as follows: Section 2 presents a review of the pertinent literature on AI, social sustainability, the energy sector, stakeholder perception, and ESG performance. Section 3 outlines the research proposal, including the methodological design, case selection, and data collection and analysis strategies. Section 4 discusses the expected outcomes and potential contributions of the study. Section 5 explores the practical and theoretical implications. Section 6 addresses anticipated challenges and limitations. Finally, Section 7 offers conclusions and suggests directions for future research. This is followed by ethics and AI declarations, and the bibliography.

2 Literature review

This section examines the extant literature to establish the theoretical context and identify the lacunae that the proposed research intends to address. It is articulated into four main subsections: the intersection of Artificial Intelligence and sustainability; social sustainability specifically within the energy sector; the crucial role of stakeholder perception; and the relationship between AI and ESG performance.

2.1 Artificial intelligence and sustainability

Artificial Intelligence is defined as the capability of computer systems to perform tasks that typically require human intelligence, such as learning, reasoning, problem-solving, perception, and language understanding. The potential of AI to contribute to the Sustainable Development Goals (SDGs) has been recognized by several studies. Vinuesa et al. (2020) conducted an in-depth analysis, finding that AI can act as an "enabler" for 79% of SDG targets, ranging from combating climate change (SDG 13) to improving health (SDG 3) and promoting sustainable cities (SDG 11). However, the same authors caution that AI could also hinder 35% of the targets, for instance, through increased energy consumption, the propagation of algorithmic bias, or its impact on the labor market.

McKinsey & Company (2024) emphasize how AI can be employed for "social good," improving lives and protecting the planet through applications in domains such as healthcare, education, disaster response, and environmental conservation. Despite this potential, attention has often focused on environmental and economic aspects, leaving the social dimension of sustainability relatively under-investigated in the context of AI. Floridi et al. (2018) propose an ethical framework for a "good AI society," highlighting opportunities, risks, and recommendations to ensure that AI development aligns with human values and social well-being. The challenge lies in maximizing the benefits of AI for social sustainability while concurrently mitigating its risks.

2.2 Social sustainability in the energy sector

The energy sector is fundamental to economic and social development but also presents significant sustainability challenges. The transition towards cleaner and more sustainable energy systems involves not only decarbonization and efficiency (environmental and economic aspects) but also has profound social implications. These include energy equity (affordable energy access for all), a "just transition" (support for workers and communities dependent on fossil fuels), the health and safety of workers and communities proximate to energy facilities, and the impact on local development.

AI can play a role in enhancing social sustainability within the energy sector. For example, it can optimize energy distribution to ensure more equitable access, improve predictive maintenance to increase the safety of

plants and workers, support urban planning for more resilient and inclusive communities, and personalize training programs for workforce reskilling. Nevertheless, the implementation of such technologies raises issues concerning data privacy, surveillance, the potential for algorithmic discrimination, and the need to ensure that benefits are equitably distributed.

2.3 The Role of stakeholder perception

Stakeholder theory, introduced by Freeman (1984), posits that organizations should manage their activities considering the interests of all groups that can affect or are affected by their actions. This theory is particularly relevant when introducing transformative technologies like AI, whose social impact can be perceived in vastly different ways by various stakeholders. Stakeholder perception – encompassing their beliefs, attitudes, judgments, and expectations regarding AI and its applications – is a critical factor that can determine the acceptance, adoption, and ultimately, the success of AI-driven sustainability initiatives.

A positive perception, based on trust, transparency, and an understanding of benefits, can lead to greater collaboration, reduced friction, and more rapid achievement of objectives. Conversely, a negative perception, fueled by fears of job displacement, lack of control, algorithmic bias, or privacy violations, can generate resistance, skepticism, and even active opposition, thereby undermining the effectiveness of initiatives. Therefore, actively engaging stakeholders in the design, implementation, and evaluation processes of AI solutions is paramount to aligning these technologies with societal values and expect*ations.*

2.4 ESG performance and AI

Environmental, Social, and Governance (ESG) criteria have become a standard framework for assessing the sustainability and ethical impact of a company. ESG performance is increasingly considered by investors, consumers, and other stakeholders as an indicator of an organization's resilience and long-term value creation capability. Eccles et al. (2014) demonstrated that companies with strong sustainability performance tend to financially outperform in the long run, suggesting that integrating ESG principles into organizational processes is advantageous.

AI can contribute to improving ESG performance across all three dimensions. Regarding the social dimension (the "S" in ESG), AI can help monitor and enhance occupational health and safety, promote diversity and inclusion, manage supply chains more ethically, improve community relations, and enhance employee well-being. For instance, AI systems can analyze data to prevent accidents, identify mental health risks among workers, or personalize development and training programs. However, it is crucial that the implementation of such systems is itself socially responsible, avoiding the introduction of new risks or the exacerbation of existing inequalities.

2.5 Identified gaps and research questions

The literature review reveals that while AI's potential for sustainability is acknowledged, there is a limited understanding of how specifically AI-driven innovative practices in the energy sector influence social sustainability and ESG performance, and particularly how stakeholder perception modulates this relationship. Many studies focus on the technical aspects of AI or on environmental/economic benefits, neglecting the complex social and perceptual dynamics.

This study aims to address these gaps by posing the following main research questions:

1. *How do AI-driven innovative practices in the energy sector contribute to the enhancement of social sustainability (with reference to SDGs 3, 4, and 11)?*
2. *What is the role of stakeholder perception (e.g., employees, communities, regulators) in determining the success and social impact of AI initiatives in the energy sector?*
3. *How do energy companies implementing AI for social sustainability manage stakeholder expectations and concerns?*
4. *To what extent does the implementation of socially-oriented AI practices correlate with measurable improvements in the ESG performance of energy companies?*

3 Research proposal

To answer the research questions delineated above, a mixed-methods approach is proposed, combining qualitative and quantitative analysis to provide a rich and multifaceted understanding of the phenomenon under investigation.

3.1 Research design

The research will be structured in two main phases.

Phase 1: Systematic Literature Review

This phase, to be further deepened, aims to consolidate the theoretical understanding of the intersections between AI, social sustainability, the energy sector, stakeholder perception, and ESG performance. Academic articles, industry reports, policy documents, and publications from international organizations will be analyzed to identify key trends, challenges, opportunities, and best practices. This review will inform the development of data collection instruments for the empirical phase.

Phase 2: Multiple Case Study.

This empirical phase will focus on an in-depth analysis of three energy sector companies (ideally diversified by size, geographical focus, and type of energy activity) that have actively implemented AI-driven practices with the stated aim of improving social sustainability. The case study approach allows for a contextualized and detailed exploration of complex phenomena.

3.2 Case study selection

Companies will be selected based on the following criteria:

- Active and documented use of AI applications specifically targeted at social sustainability objectives (e.g., occupational safety, training, community development, energy equity).
- Availability of ESG performance data (e.g., sustainability reports, social audits).
- Evidence of stakeholder engagement strategies.
- Accessibility for data collection (willingness to participate in interviews and provide documentation).

3.3 Data collection

Data collection will utilize multiple sources to ensure triangulation and validity of the findings:

Semi-structured Interviews: interviews will be conducted with a variety of key stakeholders within and outside the selected companies. These will include:

- Corporate executives and managers responsible for AI and sustainability initiatives.
- Employees directly involved with or impacted by AI technologies (e.g., field operators, technical staff).
- Representatives of local communities where the companies operate.
- Regulators or representatives of relevant governmental bodies. Interviews will explore perceptions regarding the effectiveness of AI initiatives, perceived benefits, concerns, level of involvement, and trust in the technologies.

Documentary Analysis: relevant corporate documents will be collected and analyzed, such as sustainability reports, internal and external communications, AI policies, training materials, and ESG performance data (health and safety indicators, community investments, employee well-being metrics, etc.).

Quantitative ESG Performance Data: where available, longitudinal quantitative data (pre- and post-implementation of AI initiatives) on specific social indicators of ESG performance will be collected. This will allow for an assessment of the measurable impact of AI practices.

3.4 Data analysis

Data analysis will proceed in two parallel stages, followed by integration

Qualitative Analysis: textual data from interviews and documentary analysis will be analyzed using thematic analysis. This process will involve coding the data, identifying recurring themes, patterns, and significant relationships in stakeholder perceptions and experiences. Qualitative data analysis software (such as NVivo) may be used to support this process.

Quantitative Analysis: ESG performance data will be statistically analyzed (e.g., descriptive statistics, paired-samples t-tests, correlation analysis) to identify any significant changes in social indicators following AI implementation and to explore correlations between AI adoption and improvements in social sustainability.

Integration: the findings from qualitative and quantitative analyses will be integrated to provide a holistic understanding. For example, qualitative stakeholder perceptions may help explain patterns observed in quantitative ESG performance data.

4 Expected outcomes and potential contributions

This research is anticipated to provide significant insights into the complex relationship between AI, social sustainability, and stakeholder perception in the energy sector.

4.1 Expected outcomes

Identification of specific effective AI applications: the study should reveal which types of AI-driven practices (e.g., predictive analytics for safety, personalized e-learning platforms, AI-based urban planning tools) most effectively contribute to improving health and well-being (SDG 3), access to education (SDG 4), and the development of resilient communities (SDG 11) in the energy context.

Critical role of stakeholder perception: findings are expected to confirm and elaborate on the importance of stakeholder perception. Companies adopting transparent, inclusive, and participatory approaches in AI design and implementation should exhibit more positive social outcomes and greater stakeholder acceptance, consistent with Freeman's (1984) theory. Conversely, a lack of communication and trust could lead to skepticism and resistance.

Measurable improvements in ESG performance: analysis of ESG data is expected to demonstrate positive correlations between the strategic implementation of AI and improvements in specific social indicators, such as reductions in workplace accidents, increased investment in community development projects, and enhanced employee well-being.

Identification of persistent challenges: common challenges are anticipated to emerge, such as data privacy concerns, the risk of algorithmic bias, AI adoption costs, and the need for new skill sets, echoing concerns raised by Cath et al. (2018).

4.2 Potential contributions

Theoretical Contribution: the study will contribute to the existing literature by integrating stakeholder theory and knowledge management frameworks with the emerging field of AI for social sustainability. It may offer a more nuanced conceptual model for understanding how stakeholder perception influences the effectiveness of AI initiatives.

Practical Contribution: the research will provide actionable recommendations for energy sector companies on how to design and implement AI strategies that not only enhance operational performance but also promote social sustainability and are well-received by stakeholders. It may also inform policymakers on the development of regulatory frameworks and incentives that support responsible AI adoption.

Methodological Contribution: the mixed-methods approach and focus on case studies could serve as a model for future research in this domain.

5 Practical and theoretical implications

The implications of this research extend to academia, business, and policy-making**.**

5.1 Practical implications

For Energy Sector Companies: the findings will offer guidance on leveraging AI to improve their social and ESG performance. This includes strategies for effective stakeholder engagement, mitigation of AI-associated risks (e.g., bias, privacy), and transparent communication of benefits and challenges. Companies will better understand how to align AI investments with their sustainability objectives and stakeholder expectations.

For Policymakers and Regulators: the study could inform the development of public policies that encourage the ethical and socially beneficial use of AI in the energy sector. This might include creating standards, guidelines, or incentives to promote algorithmic transparency, data protection, and public participation in AI-related decisions.

For AI Developers: the results could sensitize developers to the social implications of their technologies and encourage the design of "socially-aware by design" AI systems.

5.2 Theoretical implications

Advancement of Stakeholder Theory: the research will apply and potentially extend stakeholder theory to the specific context of AI technologies, exploring how stakeholder dynamics of power, legitimacy, and urgency manifest in relation to these innovations.

Understanding of the AI-Social Sustainability Intersection: the study will contribute to a deeper and more critical understanding of how AI can be a tool for social sustainability, moving beyond purely techno-optimistic or pessimistic views.

Integration with Knowledge Management: AI adoption involves managing new forms of knowledge. The study could explore how organizations acquire, share, and utilize AI-related knowledge to achieve social sustainability goals, and how this process is influenced by stakeholder perception.

6 Challenges and limitations

Like any research project, this study presents potential challenges and limitations.

Data Access: obtaining full and transparent access to corporate data and key stakeholders may be challenging. The sensitivity of some information related to AI and ESG performance could limit availability.

Generalizability: being based on a limited number of case studies (three companies), the generalizability of findings to other companies or contexts within the energy sector may be constrained. However, the aim is to provide in-depth, contextualized understanding rather than broad statistical generalizations.

Complexity of AI: the complex and rapidly evolving nature of AI technologies can make it difficult to isolate their specific impact on social sustainability, distinguishing it from other concomitant factors.

Researcher Bias: the researcher must be aware of their potential biases and adopt measures to ensure objectivity in data interpretation, especially in qualitative analysis.

Temporal Dynamics: the social impacts of AI may manifest over the long term. A study with a limited time horizon might not fully capture these long-term effects.

Despite these limitations, the proposed research design is considered robust and capable of yielding valid and significant contributions.

7 Conclusions and future directions

This paper has delineated the growing importance of Artificial Intelligence in promoting social sustainability within the energy sector, emphasizing the crucial role of stakeholder perception and ESG performance. The literature review has highlighted AI's transformative potential in contributing to the achievement of SDGs, particularly SDGs 3, 4, and 11, but has also underscored the need for a greater understanding of its social implications and the factors determining its success.

The research proposal, based on a mixed-methods approach and multiple case studies, aims to address the identified gaps, offering theoretical and practical insights. It is anticipated that the findings will inform energy companies on how to implement AI in a socially responsible manner, effectively engaging stakeholders and enhancing their ESG performance. The identified challenges, such as algorithmic bias, privacy concerns, and adoption costs, must be proactively addressed to maximize AI's positive social impact.

For future research, it would be beneficial to explore the long-term impacts of AI initiatives on social sustainability across a broader range of industries and geographical contexts. Comparative studies of different regulatory approaches to AI and sustainability could offer further insights. Additionally, research could focus on developing more sophisticated metrics for measuring AI's social impact and on creating frameworks for the ethical governance of AI within organizations.

In conclusion, the integration of AI into the social sustainability strategies of the energy sector represents a significant opportunity, but it requires a thoughtful, inclusive, and human-centric approach to ensure that technological benefits translate into equitable and lasting social progress.

8 Ethics declaration

The proposed research will be conducted in accordance with the highest ethical standards. Informed consent will be sought from all study participants (interviewees). Participants will be assured of confidentiality and anonymity, and data will be handled in compliance with current data protection regulations (e.g., GDPR). The aim of the research is to generate knowledge for societal benefit and not to cause harm to any individual or organization. Should the research involve institutions requiring formal ethical review, approval will be obtained from a competent ethics committee prior to the commencement of data collection. Research findings will be disseminated transparently and responsibly.

9 AI Declaration

In the preparation of this document, Artificial Intelligence tools (such as large language models) were utilized to assist with drafting, grammatical and stylistic review, and the structuring of ideas based on the provided extended abstract. However, the conceptualization of the paper, critical analysis of the literature, formulation of the research proposal, interpretation of concepts, and ultimate responsibility for the content and accuracy of the text remain entirely with the human authors. AI was employed as a support tool to enhance efficiency and quality of work, not as a substitute for critical thinking and academic expertise.

Social Taxonomy, Balance Sheet and AI for Sustainability in Public Administration Policies

Marianna Mancino, Maria Zifaro, Giuseppe Ambrosio, Giovanni Spatola
Mercatorum University, Rome, Italy

Abstract

The European Union plays an important role in promoting the Sustainable Development Goals (SDGs) of the 2030 Agenda through the advancement of sustainable finance. The aim of sustainable finance is to direct financial resources toward initiatives aligned with ESG (Environmental, Social, and Governance) principles. However, unlike financial ratings based on recognized accounting standards, a globally shared framework for assessing ESG activities and investments is still lacking.
To fill this gap, the EU has launched a process to develop common standards for identifying sustainable economic activities, not only from an environmental but also from a social perspective.
In this context, the proposal for a European Social Taxonomy has emerged, developed by the Platform on Sustainable Finance (PSF). Its goal is to classify projects, investments, and policies based on their social impact. The three main objectives identified, decent work, well-being and adequate living conditions, and inclusive societies, are supported by sub-goals to facilitate implementation and reporting.
Nonetheless, the analysis of social variables remains particularly complex due to their qualitative, multidimensional, and often subjective nature, which makes objective and standardized measurement challenging. In the absence of a global social reporting standard, practices remain heterogeneous and fragmented, undermining data comparability and the development of evidence-based policies.
In this scenario, Public Administrations (PAs) are called upon to adopt effective tools to make their social actions visible, measurable, and communicable. The Final social balance sheet serves as a key tool for accountability and transparency, useful for strengthening the relationship with citizens and evaluating the public value generated.
The integration of the Social Report, the Social Taxonomy, and Artificial Intelligence (AI) represents a strategic opportunity to improve the analysis, monitoring, and implementation of social policies in alignment with the 2030 Agenda. This study analyzes the approach adopted by local administrations in social reporting and the potential of AI to enhance these processes, promoting more effective and sustainable public governance.

Keywords: European Social Taxonomy, Social Balance Sheet, Public Administration, Artificial Intelligence

Paper type: Academic research paper.

1 Introduction

Social sustainability represents a strategic priority for Public Administration (PAs), which is called upon to ensure transparency, inclusion, and the creation of public value in line with the principles of the 2030 Agenda. Tools like the social report help build trust, communicate policy impacts, and guide equitable, sustainable governance.

Nevertheless, what makes the adoption of social reporting practices still problematic is the combination of methodological fragmentation, limited standardization, and the lack of integration of innovative technologies.

By introducing the European Social Taxonomy and applying Artificial Intelligence (AI), Public Administration (PAs) is presented with new opportunities to better measure, monitor, and enhance the effectiveness of its social interventions. The use of these tools can turn social reporting into a strategic instrument for evidence-based policymaking, moving beyond narrative accounts to data-driven evaluations of social impact.

The study seeks to answer a central question: “How can Public Administration integrate Artificial Intelligence and the European Social Taxonomy into social reporting processes to improve the effectiveness of public policies?” The aim is to explore innovative approaches that make reporting more dynamic, inclusive, and aligned with sustainable development goals.

2 Literature review

2.1 Measuring social sustainability

Among the Sustainable Development Goals (SDGs) of the 2030 Agenda, the social sustainability pillar lacks a universally agreed-upon definition. However, it can be interpreted through the principles outlined by the United

Nations, which emphasize peaceful, inclusive societies based on human rights, equity, gender equality, and reduced inequalities, ensuring well-being and equal opportunities across generations (United Nations, 2015).

Social well-being is assessed through diverse methods due to its evolving and subjective nature. Recent innovations include social media sentiment analysis (Ismail et al., 2022) and the use of WELLBY to standardize quality-of-life measurement. Effective evaluation demands integrated tools using composite indicators to address fragmentation and lack of standardization (McGuinn et al., 2020).

Major challenges include data representativeness, the complexity of social phenomena, and risks of oversimplification. Indicators must adapt to changing socio-cultural conditions to remain relevant (OECD, 2020; Barlybaev et al., 2020). In this light, measuring well-being is a political and cultural imperative, guiding public institutions toward equitable and sustainable development.

2.2 PAs, social wellbeing and reporting challenges

Public Administrations (PAs) are tasked with addressing societal needs through actions that promote well-being, equity, and inclusion. Their role has evolved from a bureaucratic model (Simon, 1947; Weber, 1961) to one focused on creating public value, aligned with the EU's sustainability agenda (Moore, 1995).

Public value goes beyond service provision to deliver tangible improvements in quality of life. At its core, social well-being enhances resilience, institutional trust, and the capacity to manage complex crises, such as health or environmental emergencies (OECD, 2021). Within this context, PAs are key to advancing sustainable development models.

Social reports serve as essential tools for monitoring and communicating policy impact, reinforcing transparency and accountability (Koppell, 2005; Bovaird & Loeffler, 2016). More than summary documents, they are instruments for stakeholder engagement and co-creation of public value (Perano & Cerrato, 2017), encouraging innovation and participation.

At the municipal level, where administrations are closest to citizens, this role is even more strategic. Local governments implement essential services and foster participatory governance through collaboration with public, private, and territorial actors (Osborne, 2006). Their proximity to local needs supports targeted interventions that improve quality of life and protect vulnerable groups (ISTAT, 2024; Fontana, 2024).

Despite this potential, the lack of a shared social reporting framework leads to fragmented and inconsistent practices (Messeri et al., 2006). The complexity and variability of social variables further hinder the standardization of metrics (Sen, 1999), limiting comparability and policy coherence.

A flexible, unified European Social Taxonomy could address these gaps by standardizing language, methods, and indicators, aligning with ESG principles (Sansoni, 2025) and supporting integrated governance (Epifani, 2025). It would enhance reporting quality and complement existing planning tools in line with the 2030 Agenda.

Importantly, social reporting must go beyond description, evolving into a budgeting tool that fosters the creation of collective value (Douglas & Overmans, 2020).

The recent experience of the Social Innovation Fund (Formez, 2023) and successful local practices (ASviS, 2023) demonstrate that it is possible to implement reporting and governance models centered on collective well-being, inclusion, and long-term sustainability.

2.3 AI and the use of social data

Artificial Intelligence (AI) enables local administrations to process large volumes of heterogeneous data, from administrative sources to citizen feedback, to enhance the effectiveness of social policies (Sun & Medaglia, 2019). This shift is transforming how social data are collected, analyzed, and used in governance.

In social reporting, tools like Natural Language Processing (NLP), text mining, and machine learning extract complex indicators from unstructured data, offering timely insights into social dynamics (Jordan & Mitchell, 2015) and supporting ongoing evaluation of policy impacts (Van der Voort et al., 2019; Rosu, 2024).

AI also strengthens citizen participation through interactive platforms that use NLP and semantic analysis to gather real-time public input (Sun & Medaglia, 2019). Additionally, Explainable AI (XAI) enhances transparency by clarifying how algorithmic decisions are made (Arrieta et al., 2019).

Despite these benefits, AI raises ethical concerns around privacy, fairness, and transparency in decision-making (Floridi & Cowls, 2019). The opacity of algorithms challenges accountability and calls for responsible governance strategies (Yuan & Chen, 2025). The use of social scoring systems, in particular, demands caution to prevent discrimination and uphold fundamental rights (Cerrina Feroni, 2023).

Addressing these issues requires a strategic approach that promotes resilience, inclusiveness, and trust (OECD, 2021). This involves not only technical capacity building but also rethinking decision-making to align with democratic and sustainable values.

AI can support the SDGs if public, private, and civil actors collaborate to overcome barriers like limited data access and digital skills. It can transform social reporting into a dynamic tool for participatory governance, enhancing democratic decision-making (Pleșa et al., 2024). Integrating technology, social awareness, and ethics is essential for building innovative, sustainable, and citizen-focused institutions.

3 Methodology

This research adopts a qualitative analytical approach aimed at understanding how certain Italian municipalities integrate social reporting tools and, where applicable, applications of Artificial Intelligence (AI). The case selection was carried out rigorously to avoid one of the main criticisms often raised, namely, the subjectivity involved in choosing cases for analysis and the resulting difficulty in replicating the study in different contexts.

An operational classification of municipalities by resident population was used to select the sample, with categories defined as follows:

- small municipalities (up to 5,000 inhabitants);
- small-to-medium municipalities (from 5,001 to 15,000 inhabitants);
- medium municipalities (from 15,001 to 30,000 inhabitants);
- large municipalities (over 30,000 inhabitants).

The analysis intentionally excludes large municipalities to concentrate on medium and small-sized ones, as they better reflect the Italian institutional landscape and maintain a closer connection to citizens. These organizations, often operating with limited resources, offer a valuable setting for evaluating policy implementation.

The purpose of the selection was to analyze concrete cases in which social reporting was voluntarily adopted, even in the absence of legal obligations. The aim was to understand the motivations behind this choice, the methods used for its implementation, and the potential contribution of technological innovation. The initial screening followed three main steps:

- online searches using keywords such as *"social report" and "mandate report"* to identify documents or references to social reporting on the institutional websites of Italian municipalities.
- Confirmation of the existence and authenticity of the social report on each municipality's official website.
- Development of a screening table. The selected municipalities were entered into a preliminary table that included, for each entity: the name, region, size category, document title, and year of publication.

The procedure focused on analyzing social reporting practices, with particular attention to the presence of a formal social report. The use of AI was considered only when explicitly mentioned in the documents and examined qualitatively. Municipalities were selected based on the documented availability of a social report, regardless of their level of digitalization or adoption of innovative technologies.

Social reports were analyzed using the European Sustainability Reporting Standards (ESRS), developed by the European Financial Reporting Advisory Group (EFRAG). These standards are currently being aligned with other international frameworks to foster more coherent and comparable sustainability reporting practices (EFRAG PTF-NFRS, 2021, pp. 85–86).

This study was based on a direct review of social reports (primary data) and an analysis of secondary sources, including press articles, institutional reports, and academic studies, to investigate practices and innovations in local PAs.

It was a set of well-established national and international references that supported the theoretical and operational framework of the study. These included the UN 2030 Agenda, the European Social Taxonomy Report, the ESRS standards, and the Italian Guidelines on Social Reporting in PAs.

This approach aims to enhance the ability of PAs to measure, monitor, and report the effects of public policies in relation to the SDGs. What the research aims to deliver is a detailed account of how social reporting is used by the selected municipalities, with a focus on the potential for AI to strengthen transparency, accountability, and impact. The study will also provide actionable guidance to encourage a more sustainable and socially responsible integration of AI in the public sector.

4 Results and discussion

For the selection of municipalities to be analyzed, online research and direct consultations were conducted, leading to the identification of eight municipalities that publish documents comparable to updated social balance sheets (Table 1). Of these, only four refer explicitly to the 2019–2024 five-year period. For the in-depth

analysis, three municipalities, Pero, Strambino, and Argenta (Emilia-Romagna, medium-sized), were selected with the objective of examining how Italian local governments employ social reporting to enhance transparency, policy effectiveness, and social impact, as well as to assess the potential for integrating emerging technologies such as artificial intelligence (AI).

Table 1. Municipalities surveyed with social reporting

Municipality	**Region**	**Size**	**Document title**	**Issued Year**
Loiri Porto San Paolo	Sardegna	Small	Final social balance sheet	2017-2022
Pollina	Sicilia	Small	Social balance sheet	2014
San Martino di Venezze	Veneto	Small	Social balance sheet	2016-2020
Nembro	Lombardia	Small to medium	Social balance sheet	2023
Pero	Lombardia	Small to medium	Final social balance sheet	2019-2024
Strambino	Piemonte	Small to medium	Final social balance sheet	2019-2024
Argenta	Emilia Romagna	Medium	Final social balance sheet	2019-2024
Jesolo	Veneto	Medium	Final social balance sheet	2017 -2022
Valsamoggia	Emilia Romagna	Medium	Final social balance sheet	2019-2024

Source: own elaboration

4.1 Social reporting practices in the selected municipalities

What emerges from the analysis of the social reports of the municipalities of Argenta, Pero, and Strambino is a shared commitment to adhering to the 2007 Guidelines issued by the Ministry of the Interior, despite variations in implementation. In all cases, the social report is conceived as a tool for transparency and accountability, aimed at communicating the activities carried out during the 2019–2024 term, with particular attention to the impact of the COVID-19 pandemic on administrative management.

A cross-cutting element is the involvement of local stakeholders, including citizens, associations, and the third sector, following an inclusive governance model. However, significant differences emerge in the structure of the reports: Pero adopts a more strategic approach, with explicit references to the 2030 Agenda, while Argenta and Strambino take a predominantly narrative path.

Despite these efforts, the reports exhibit important methodological limitations. There are no standardized systems for outcome or social impact indicators, nor are there structured analyses comparing objectives with results. None of the documents underwent independent certification (Ministero dell'Interno, 2007), a factor that reduces their credibility and comparability. Moreover, the content is based almost entirely on qualitative descriptions, limiting the ability to objectively assess the effects of public policies. From a technological standpoint, while all three municipalities demonstrate a commitment to digitalizing public services (e.g., SPID, PagoPA, App IO), such innovation does not extend to the area of social reporting. The lack of AI tools reveals a traditional reporting approach. The main weaknesses identified in the reports are summarized below (Table 2).

Table 2. Critical Aspects of Social Reporting in Pero, Strambino, and Argenta

Area	**Issue Identified**
Structure	Lack of standardization.
Informational content	Emphasis on narrative over data-driven content.
Innovation	There is no use of AI, data analysis, or interactive tools to automate information collection and processing.
Alignment with Standards	Insufficient or absent alignment with applicable national or international voluntary standards.
Stakeholders Involvement	Stakeholder engagement remains poorly structured, with no ongoing dialogue or co-design mechanisms.
Validation and Transparency	There is no independent certification of documents, and reporting of deviations is either weak or lacking.

Source: own elaboration

Social reports from the municipalities of Pero, Strambino, and Argenta reflect a positive commitment to transparency and citizen engagement. To make these reports truly strategic and impactful, more structured actions are needed, including the definition of common standards, the integration of smart technologies, and the strengthening of participatory processes.

4.2 Limits

Building on the theoretical framework and methodological approach previously outlined, the initial phase of data collection on Italian municipalities encountered several significant obstacles. The lack of a national archive of social reports required fragmented searches across individual municipal websites. Additionally, the absence of a specific legal obligation for social reporting limits its dissemination, which remains inconsistent in both content and frequency. Even when social reports are available, limited levels of digitalization and inconsistent publication practices across municipal websites frequently hinder their accessibility.

Another critical issue is the absence of shared standards regarding the format, structure, and content of social reports. This heterogeneity made it difficult to carry out systematic comparisons or conduct cross-municipality analyses.

Temporal continuity is also lacking. In many cases, municipalities prepare a social report only at the end of their administrative term, with no regular updates or continuity over time. This discontinuity undermines the potential of the social report as a reliable tool for monitoring public policies.

In addition, many social reports lack structured information, such as the methodology used or the application of indicators, which makes critical evaluation and comparison across municipalities particularly difficult. This issue is further compounded by another important factor: most small and medium-sized municipalities do not adopt any form of social reporting, contributing to the limited and fragmented dissemination of such practices.

4.3 Social taxonomy and social indicators for PAs

The report on the "Proposal for a Social Taxonomy" developed by the PSF introduces a classification system designed for the private sector, based on the social impacts of economic activities. This framework adopts a stakeholder-centered approach, focusing on groups who are affected by those impacts. Within this approach, three main stakeholder categories are identified:

- workers (both employees and workers across the value chain);
- local communities and society at large;
- consumers (end users of products and services);

For each of these, the PSF defines social objectives and sub-objectives, closely aligned with the protection of fundamental human rights, as outlined in key international documents, such as the Universal Declaration of Human Rights (UN) and the Charter of Fundamental Rights of the European Union (PSF, 2022).

To strengthen the integration of social sustainability principles into public policies, it is proposed to adapt the Social Taxonomy framework to the context of PA, with a specific focus on local municipalities. Given that municipalities and local authorities interact daily with a broad network of stakeholders, their decisions have direct effects on critical social dimensions.

This context underscores the relevance of the PSF framework, which aligns closely with the institutional role of PA which is inherently oriented toward accountability, rights protection, and multi-level engagement.

Adopting a stakeholder-centric approach, as proposed in the draft Social Taxonomy, would therefore help reinforce inclusive governance, grounded in transparency, social impact measurement, and the creation of shared value. In this light, a summary table (Table 3) is presented, mapping each stakeholder category to the corresponding priority social objectives defined by the PSF.

Table 3. PA Stakeholders and Main Social Objectives of "Social Taxonomy"

Stakeholders	**Recipients**	**Macro objective**
1. Workers	PA employees, supplier workers, unions, operational bodies	Promote decent work, fair wages, workplace safety, continuous training, equality and inclusion, along the entire public chain.
2. Community/ Society	Local communities, NGOs, vulnerable populations, oversight institutions, media, government	Inclusive,resilient and participatory communities.
3. End users of public services	Citizens, businesses, schools, universities, research centers.	Ensure universal, quality and equitable access to public services: healthcare, education, housing, transport, digital and social services.

Source: own elaboration by *Final report on Social Taxonomy*. Brussels: European Commission

The PSF proposes a set of specific micro-objectives for each macro-objective (PSF, 2022). This approach could support the public sector in using the Social Taxonomy as a practical tool to define clear goals and allocate resources to activities that generate positive community impacts

In this perspective, extending the Social Taxonomy to the social reports of municipalities aligns naturally with the European Sustainability Reporting Standards (ESRS). The social standards S1 through S4 offer a range of Key Performance Indicators (KPIs) that can be adapted to the needs of PAs (EFRAG, 2022a–d).

In this study, we identified, for each macro-objective, a set of KPIs particularly suited to local authorities (Table 4). These KPIs are categorized into two types:

- qualitative indicators, which capture the presence or absence of specific policies (e.g., citizen listening mechanisms);
- quantitative indicators, which measure objective data (e.g., workplace accident rates, gender pay gap).

This approach would help assess the impact of policies in key areas (such as health and education) and ensure alignment of administrative actions with the SDGs. Implementing this method requires a flexible operational plan that can respond to social and economic changes, while also tracking, evaluating, and aligning social policies with sustainability standards

The evaluation of such actions should rely on an integrated set of social well-being indicators and social impact indicators, capable of offering a dynamic and updated interpretation of territorial change. The former measure improvements such as better working conditions or reduced inequalities (McGuinn et al., 2020), while the latter detect deeper transformations related to community empowerment, cohesion, and resilience (Grieco et al., 2013).

Establishing a harmonized system of social indicators, inspired by the Social Taxonomy and the ESRS standards, constitutes a crucial step forward. The integrated approach connecting stakeholders, macro-objectives, micro-objectives, and indicators offers an innovative methodology for a more results-oriented, accountable, and community-focused PA.

Table 4. Examples of Social KPIs for Pas

Type	**Indicator**	**Measurement /Formula**
	1 Workers. Sub-objective: Fair wages and inclusion	
Qualitative	Presence of fair wages and equal opportunities	"Present" (1) or "Absent" (0)
Quantitative	Pay Gap. (%)	[(Average salary for male – Average salary for female) / (Average salary for male)] x 100
	1 Workers. Sub-objective: Health and safety at work	
Qualitative	Existence of a health and safety training plan	"Present" (1) or "Absent" (0)
Quantitative	Workplace accident rate. (%)	(Number of accidents)/ (Total number of employees) x 100
	2 Community and society. Sub-objective: Social inclusion	
Qualitative	Existence of community engagement policies	"Present" (1) or "Absent" (0)
Quantitative	Percentage of vulnerable group involvement in engagement activities. (%)	(Vulnerable participants)/ (Total participants) x 100
	3 End users of public services. Sub-objective: Quality of services	
Qualitative	Perceived quality feedback collection system	"Present" (1) or "Absent" (0)
Quantitative	Satisfaction rate (%)	(Number of positive responses)/ (Total responses) x 100

4.4 AI and social taxonomy: innovating local government social reporting

Recent studies highlight AI's potential to advance the 17 UN Sustainable Development Goals (SDGs), especially in areas like social inclusion, sustainable urban development, education, and public health. AI enables automation in social data analysis, real-time KPI monitoring, and insight extraction from diverse sources, transforming social reporting into a strategic planning and monitoring tool.

The Social Taxonomy offers a structured framework for defining and measuring social rights, while AI allows public administrations (PAs) to monitor policy impact in line with sustainability standards (Lega & Pugliani, 2023). Natural Language Processing (NLP), for instance, automates the analysis of documents and citizen feedback, converting qualitative input into actionable metrics (Arrieta et al., 2019). Machine learning further enhances social reporting by detecting early signs of vulnerability, such as school dropout or housing exclusion, through

predictive models using historical and real-time data (Jordan & Mitchell, 2015). In practice, AI is helping local governments move beyond efficiency gains toward evidence-based, data-driven policymaking (Rosu, 2024).

Italian municipalities are beginning to adopt AI in smart city initiatives. Predictive dashboards monitor access to services and social inclusion levels (Löfgren & Webster, 2020). A key example is the AMPEL project, developed by Auser, Fondazione Cariplo, and the University of Milano-Bicocca, which leverages AI to detect early signs of poverty and social exclusion among the elderly and migrants (Rinaldi, 2025).

However, AI's integration into public decision-making raises concerns about transparency, accountability, fairness, and privacy (Floridi & Cowls, 2019), as well as the risk of bias in algorithmic outcomes (van der Voort et al., 2019). Explainable AI (XAI) is crucial to ensure that decision-making processes remain understandable and justifiable (Arrieta et al., 2019). For example, in allocating municipal housing subsidies, XAI makes it possible to clearly identify the variables, such as income or family status, that influenced a decision, ensuring transparency and auditability.

Nonetheless, the use of predictive analytics in governance necessitates ethical scrutiny. Cases like China's Social Credit System and the Dutch Toeslagen scandal reveal how opaque algorithms can lead to discriminatory practices and rights violations if not properly regulated (Cerrina Feroni, 2023).

In response, the EU has introduced frameworks like the AI Act (EU Regulation 2024/1689) and the Digital Decade strategy (European Commission, 2024) to promote safe, rights-based AI in the public sector. These policies also support innovative procurement models to encourage AI adoption aligned with democratic values (Rosu, 2024).

This evolving ecosystem reveals a growing convergence between the Social Taxonomy, AI, and municipal social reporting, paving the way for a shift from static accountability to stakeholder-centered, SDG-oriented governance.

5 Conclusions

The research explores how the European Social Taxonomy, Social Reporting standards (such as ESRS), and Artificial Intelligence (AI) can support local governments in Italy, particularly small to mid-sized municipalities, in enhancing accountability processes. These municipalities often show significant weaknesses in methodological, technological, and strategic aspects of social reporting. While the aim of social reporting is to increase transparency and civic engagement, current practices remain largely narrative and lack clear indicators, standardized formats, and sufficient quantitative data. This undermines the potential of social reporting as a tool for strategic planning and performance evaluation, making it difficult to compare results across municipalities or assess policy impact effectively.

To address this, the study investigates how integrating AI and the European Social Taxonomy into social reporting can enhance policy effectiveness. The European Social Taxonomy offers a structured framework rooted in shared social objectives such as decent work, inclusion, well-being, and cohesion. When adapted to local contexts, it can guide the selection of relevant indicators, making it easier for public administrations to monitor the social impact of their policies in a standardized way.

AI can play a key role by automating data analysis, identifying emerging social issues in real time, and making public reporting more accessible and interactive for citizens.

However, the adoption of these tools faces significant obstacles. Local governments face outdated infrastructure and limited training investments. Many lack the necessary digital and analytical competencies to manage AI-based systems effectively. Transformation requires not only technology but also strategic capacity-building

The study also notes certain limitations, particularly the narrow sample of municipalities analyzed, which limits the generalizability of findings. For the proposed model to be scalable, further research and formalization are needed, including international comparisons and the development of flexible roadmaps tailored to the diverse conditions of Italian municipalities. Operational priorities identified include:

- standardizing social reporting to ensure consistency and comparability;
- developing integrated digital platforms for automating data collection and visualization;
- providing continuous training to public employees to support ethical and effective AI use;
- launching pilot projects in collaboration with academic institutions to test and refine scalable models.

Ultimately, the integration of Social Taxonomy and AI is not just a technical upgrade but a transformative opportunity. It requires rethinking governance processes, promoting a culture of transparency and participation, and aligning public sector innovation with the broader goals of the 2030 Agenda for Sustainable Development. Through a coherent and collaborative strategy, local governments can turn social reporting into a powerful tool for driving measurable, inclusive, and sustainable public value.

6 Ethical Statement

This research did not involve human or animal subjects, nor did it collect any sensitive data; therefore, approval from an ethics committee was not required.

7 AI Declaration

No Artificial Intelligence (AI) tools were used in the creation or editing of this work. However, online translation tools such as Google Translate were used only to assist with language translation. All ideas, structure, and final content are the original work of the authors, and full responsibility for the accuracy and integrity of the work remains with the authors.

Enhancing Resilience in Agrifood Supply Chains: The Role of Technological Innovation for Risk Management

Roberto Mauriello, Livio Cricelli, Serena Strazzullo
Università di Napoli Federico II, Napoli, Italy

Abstract

The adoption of innovative technologies can help agrifood companies face crucial challenges related to meeting the food needs of a growing world population, adapting to and mitigating the effects of climate change, and increasing the resilience of supply chains against sudden disruptions. In fact, several studies highlight the advantages that technological innovation can bring to agrifood supply chains. At the same time, few studies examine the connections between technological innovation and risk management. This study aims to help bridge this gap by reviewing and organizing previous findings. Specifically, this paper provides a classification of the main risks affecting agrifood supply chains and investigates the role that technological innovations may play in helping agrifood companies address key risks. The results lead to the identification of five main risk categories: food safety, information management, environmental, geopolitical, and supply chain management risks. Furthermore, the literature review focuses on six key technologies, including blockchain, Internet of Things, big data, artificial intelligence, drones, and digital twins. From this perspective, the results show that blockchain tracking systems allow companies to monitor product conditions throughout the supply chain. This helps ensure product quality, combat counterfeiting, and support the management of information and product flows. IoT systems are especially useful for mitigating food safety risks by enabling real-time monitoring during cultivation, transport, and distribution. Big data and AI-based solutions mainly support precision agriculture activities, contributing to the mitigation of environmental risks. Finally, the study highlights emerging applications related to drones and digital twins. Ultimately, this study provides several relevant contributions. First, it helps organize the fragmented contributions on the impact of technologies on risk management in the agrifood industry. Second, it offers a solid theoretical foundation for analysing the implications of technological applications on different risk categories. Third, it provides useful insights for practitioners to assess how technological innovation may help manage and mitigate key risks.

Keywords: agrifood industry; risk management; Industry 4.0 technologies; supply chain resilience.

Paper type: Academic Research Paper

1 Introduction

The agrifood industry is facing unprecedented challenges. Companies are pressured to increase food production to meet the needs of a growing global population (Hrustek, 2020). The definition of sustainable development goals requires balancing economic growth with the safety, transparency, and accountability of agrifood supply chains (Chandan, John and Potdar, 2023). The effects of climate change, along with extraordinary events such as pandemics and international conflicts, demand that agrifood supply chains enhance their ability to respond to sudden disruptions (Ben Hassen and El Bilali, 2022).

Overall, the agrifood industry needs new solutions to improve supply chain resilience and manage key risks. In this context, technological innovation could be one of the main avenues to ensure the security of agrifood supply chains. In recent years, numerous studies highlighted the benefits of technological innovation in the agrifood industry. Technologies such as Internet of Things (IoT), big data, artificial intelligence (AI), blockchain, and digital twins enable agrifood companies to monitor all stages of the supply chain, improving the management of product and information flows. At the cultivation and production stages, real-time data can help manage natural resources, reduce waste, and mitigate environmental impact (Spanaki *et al.*, 2022). During transportation, blockchain technology and IoT systems ensure security and streamline product flows by improving coordination and fostering trust among supply chain partners (Ellahi, Wood and Bekhit, 2023). Big data can be used to develop decision support systems to enhance activity planning, product management and demand forecasting (Talari *et al.*, 2022). Overall, previous findings suggest that technological innovation could help agrifood companies address and mitigate crucial risks. Despite this, the literature currently lacks an established research stream focusing on the impact of technological innovation for risk management in the agrifood industry. Indeed, this perspective is notably absent from the literature, as few studies examine the implications of innovative technological applications for risk management. Most studies emphasize the advantages of the technologies but fail to consider how these may benefit agrifood supply chains' ability to address key risks related to modern grand challenges. This is a notable gap, hindering our understanding of how

technological innovations may shape the development of the agrifood industry. Furthermore, the literature appears highly fragmented, focusing on specific applications or supply chain stages. This is useful to analyse the impact of technologies on key issues affecting the agrifood industry but also highlights the lack of a shared theoretical foundation and hinders the generalizability of the findings. This study aims to help bridge this gap by systematizing the literature and providing a theoretical framework investigating the connections between technological innovation and risk management in agrifood supply chains. Consistently, this study aims to answer the following research questions:

1. What are the main risks affecting agrifood supply chains?
2. How can innovative technologies support risk management in agrifood supply chains?
3. What is the state of the literature on technological innovation for risk management in agrifood supply chains?

To answer these research questions, we perform a thorough literature review aimed at systematising available studies and achieving four main goals. First, provide a classification of the key risks affecting modern agrifood supply chains. Second, synthesize the main findings on the impact of technological innovation in the agrifood industry. Third, develop a theoretical framework to link the use of technologies with risk management in agrifood supply chains.

This study is structured as follows: the next section presents the literature review methodology, detailing the processes of data collection, selection, and analysis. Next, the results are presented, focusing on how technologies may impact the management of key risks affecting agrifood supply chains. The following section presents the conclusions, outlining the study's findings and its theoretical and practical contributions.

2 Methodology

This study aims to investigate how technological innovation can support risk management in the agrifood industry, by synthesizing and analysing previous contributions. To this end, a thorough literature review was performed. Literature reviews are useful to analyse the state of the art on a topic, highlight key contributions and outline research gaps. The methodology is comprised of three main phases: material collection, material selection, and content analysis.

2.1 Material collection

The material collection phase moved from the definition of a search string used to survey the online database of scientific publications Scopus. This was chosen due to its popularity and reliability in scientific research, as also proved by multiple studies reviewing innovative technological applications in the agrifood industry (Dal Mas *et al.*, 2023). The search string can be ideally divided into three sections, each relating to a key element of the study. The first section includes keywords related to risk management and assessment, and supply chain resilience. The second focuses on the agrifood supply chains, while the third considers the main innovative technologies applied in the agrifood industry. The query was performed in December 2024. Table 1 presents the search string, the keywords used, and the number of results obtained.

Table 1: Search string, keywords and number of results.

Search string	Results
("risk manag*" OR "supply chain risk manag*" OR "risk mitigat*" OR "resilien*" OR "supply chain resilien*" OR "risk assess*" OR "risk reduc*" OR "risk prevent*" OR "supply chain risk*" OR "risk detect*" OR "risk analys*" OR "risk modell*") AND ("agrifood supply chain*" OR "food supply chain*" OR "agriculture supply chain*" OR "Agrifood industr*" OR "Agrifood") AND ("Industry 4.0" OR "blockchain*" OR "IoT" OR "internet of things" OR "artificial intelligence" OR "AI" OR "big data" OR "data analytic*" OR "machine learn*" OR "deep learn*" OR "smart sensor*" OR "digital twin*" OR "drone*" OR "robot*" OR "3D print*" OR "additive manufactur*" OR "distributed ledger*")	802

2.2 Material selection

Moving from the initial sample of 802 studies, appropriate selection criteria were defined. First, we only selected studies published between 2015 and 2025. This allowed us to provide an updated perspective on technological innovation in the agrifood industry. Next, we limited the scope of the research to the subject areas of Engineering, Agricultural Sciences, Business, management and accounting, Economics, econometrics and finance. This allowed us to focus on studies investigating the technological, managerial, and economic implications of technological innovation in the agrifood industry. Subsequently, we further refined the selection

by including only research articles and reviews. This allowed us to focus on high-quality, peer-reviewed contributions. In the next step, we conducted a selection based on keyword analysis. Specifically, we excluded keywords that had no logical or semantic connection with the terms included in the search string.

The final two selection steps involved the abstract and a full read of the remaining documents. The goal was to identify studies that explicitly described how technologies support risk management in the agrifood industry. Finally, moving from the remaining sample of 73 documents, we applied a snowball sampling technique to identify relevant studies that may have been wrongly excluded by the initial search or in the material selection process. This led to the inclusion of an additional 26 studies, resulting in a final sample of 99 documents. Table 2 summarizes the material selection process.

Table 2: Material selection process.

Selection criteria	Description	Remaining documents
Focus on the latest applications of Industry 4.0 and 5.0 technologies	Selection of the documents published between 2015 and 2025	793
Focus on technological, managerial and economic perspectives	Selection of the documents pertaining to the subject areas: Engineering, Agricultural sciences, Business, management and accounting, Economics, econometrics and finance	603
Focus on high-quality documents in English	Selection of peer-reviewed research articles and reviews in English	414
Focus on content through keyword analysis	Selection of the documents with keywords matching search string terms	231
Focus on content through abstract read	Selection of the documents investigating risk management and technological innovation in the agrifood industry	138
Focus on content through full document read	Selection of the documents discussing at least one connection between technological applications and risk management	73
Focus on mitigating selection bias	Snowball sampling based on reference analysis	99

2.3 Content analysis

Following the selection of the sample, an in-depth content analysis was performed. This aimed to achieve two main objectives. First, outline the characteristics of the sample through a descriptive analysis, highlighting the evolution of research, the main thematic areas, and key contributions. Second, to identify and systematize fragmented contributions to develop a framework analysing the connections between technological innovation and risk management in the agrifood industry.

3 Results

The results are presented in three sections. The first section focuses on the descriptive analysis of the documents. The second presents a classification of the main risks affecting the agrifood industry, while the third discusses the connections between technological innovation and risk management in the agrifood supply chains.

3.1 Descriptive analysis

We begin this section by considering the temporal distribution of publications. This shows that interest in the topic has significantly increased since 2019. This is consistent with the rapid development of novel technological applications driven by the adoption of IoT, blockchain, and AI solutions in the agrifood industry. This also highlights the growing importance of technological innovation in a sector recently marked by a series of disrupting events, including pandemics, international conflicts, and extreme climate events.

Moving on, we classify documents by type, distinguishing between literature reviews, quantitative studies, and qualitative analyses. The prevalence of literature reviews reflects the effort of the scientific community in organizing a growing field of knowledge according to different perspectives. Notably, 30 quantitative studies are included in the sample. These focus primarily on assessing the impact of innovative technologies on key aspects of agrifood supply chain management, such as resilience, food security, and the management of information and product flows. As for qualitative studies, these provide crucial insights by focusing on investigating how the regulatory, technological, and organizational environment can affect technological innovation in the agrifood industry.

Moving on, the analysis of the most representative sources enables the identification of four key thematic areas. The presence of journals such as the Journal of Cleaner Production, Sustainability, and Business Strategy

and the Environment highlights the strong connection between technological innovation and environmental sustainability in the agrifood industry. The inclusion of journals like the Journal of Agriculture and Food Research, Foods, and the British Food Journal emphasizes the impact of innovative technologies on food safety, traceability, and food waste. On a different note, sources such as Supply Chain Management, IEEE Transactions on Engineering Management focus on supply chain management issues, investigating how technological innovation can support activity planning and enhance supply chain coordination and resilience in the agrifood industry. Finally, journals like Computers in Industry and Computers and Industrial Engineering focus on technology design and implementation issues, exploring the role that ICTs and digital technologies can play in agrifood supply chains.

3.2 Risk classification

This section presents a classification of the main risk categories affecting the agrifood industry. The purpose of this classification is to provide a theoretical foundation for assessing the impact of technologies on risk management in agrifood supply chains.

Thus, we move from the analysis of the first risk category, namely food safety risks. This includes three sub-risks. The first relates to the risk of compromising food quality. Many agrifood products are highly perishable and sensitive to parameters such as temperature, humidity, and light exposure (Patelli and Mandrioli, 2020). As a result, issues in storage or transportation conditions can lead to significant quality loss. This can result in food waste, the need to manage costly recall activities, or even endanger consumers' health (Kumar *et al.*, 2021). The second sub-risk concerns fraudulent commercial practices. In the agrifood industry, these involve fraudulent claims regarding product provenance or the characteristics of production methods. The third sub-risk concerns food losses and waste. These can occur at all stages of the supply chain from production to consumption and represent a well-documented issue affecting the agrifood industry (Hassoun *et al.*, 2023).

The second category of risks concerns data and information management and also includes three sub-risks. The first relates to product traceability issues. In the agrifood industry, product tracking is essential to ensure product quality and safety, comply with regulations, and contrast fraudulent practices (Ellahi, Wood and Bekhit, 2023). The second sub-risk relates to information management. Several studies show that the agrifood industry is affected by significant information asymmetries, which lead to unfair value distribution, supply chain coordination, and product flow management issues (Pakseresht *et al.*, 2023). Finally, this category includes risks related to cybersecurity threats, data leaks and privacy issues that may stem from the adoption of ICTs and digital technologies (Nayal *et al.*, 2022).

The third category of risks considers the effects of climate change and environmental sustainability concerns. The first sub-risk in this category concerns the increasing frequency of extreme natural phenomena and the need to adapt to the consequences of climate change (Talari *et al.*, 2022). The second sub-risk relates to inefficient use of natural resources. The last sub-risk in this category relates to the environmental impact of production activities, particularly the risk of permanently damaging natural resources (Yadav *et al.*, 2023).

The fourth category includes geopolitical risks and consists of two sub-risks. The first encompasses risks arising from extraordinary events such as pandemics, conflicts, or severe political instability. Notable examples in recent years include the Russia-Ukraine conflict and the recent COVID-19 pandemic (Hobbs, 2021). The second type of sub-risk includes sudden shocks in demand or supply. These can result from regulatory changes, food scandals, or other events that influence the availability or price of raw materials (Sharma *et al.*, 2022).

The final category of risks concerns agrifood supply chain management. This comprises four types of sub-risks. The first relates to vulnerabilities in supply chains, affecting roles and responsibilities, and coordination and communication mechanisms (Coral and Mithöfer, 2023). Another type of risk concerns disruptions or slowdowns in the logistics and transportation activities (Burgos and Ivanov, 2021). The third type of sub-risk relates to human errors, which can result in inefficiencies, delays, disruptions or increased costs (Birkel and Hartmann, 2020). The final sub-risk concerns relationships with consumers. Inconsistencies in labelling and communication undermine consumer trust and negatively impact brand reputation (Singh *et al.*, 2023). Figure 1 concludes this section by illustrating the five main risk categories and the corresponding sub-risks.

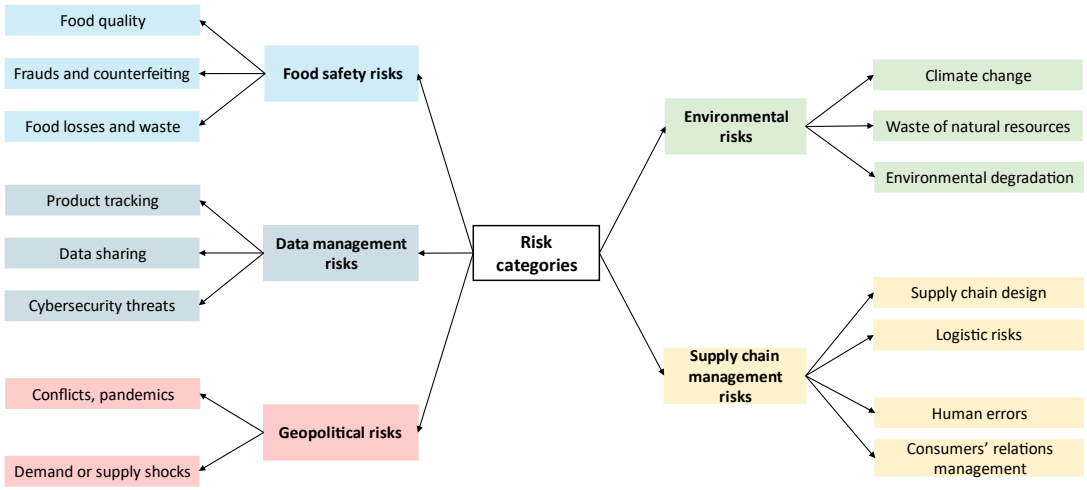

Figure 1: Risk categories and corresponding sub-risks.

3.3 Technological applications and risk management

This section aims to investigate how the adoption of innovative technologies may help agrifood companies manage or mitigate different types of risks. To this end, we referred to the five risk categories and corresponding sub-risks presented in the previous section. Subsequently, we identified the main technological applications in the agrifood industry and analysed their impact on risk categories. Table 3 synthesizes the findings, using shades of green to illustrate the impact of each technology in managing or mitigating different types of risk. This qualitative assessment was conducted by the three authors based on the triangulation of information sources and a shared understanding of the reviewed literature.

We start our analysis by considering blockchain applications (Ellahi, Wood and Bekhit, 2023). In the agrifood industry, blockchain applications mainly relate to the development of advanced product tracking systems. From this perspective, blockchain presents several advantages. First, high decentralization can lead to improved information sharing among supply chain partners (Mukherjee *et al.*, 2021). Second, the auditability and immutability of information uploaded to the blockchain enhance supply chain transparency and encourage actors towards responsible behaviours (Wünsche and Fernqvist, 2022). Third, the use of a shared digital ledger updated in real time supports the management of product flows (Kramer, Bitsch and Hanf, 2021). Due to these features, blockchain-based systems in the agrifood industry can have a particularly strong impact on the mitigation of food safety, information management, and supply chain management risks.

Regarding the first category, several studies illustrate how blockchain supports food tracking at all stages of the supply chain, providing insurances regarding food origin and production methods (Montecchi, Plangger and Etter, 2019). Additionally, many studies suggest that the use of shared tracking systems simplifies monitoring and recall activities, mitigating food safety risks and helping to reduce waste (Bumblauskas *et al.*, 2020).

Concerning the impact of blockchain on information and data management risks, one of the most documented advantages of blockchain applications in supply chains is the increased transparency and reliability of information (Rogerson and Parry, 2020). Finally, blockchain adoption can help agrifood companies also mitigate supply chain management risks. In this regard, particularly significant is the impact on the mitigation of risks related the management of the relations with consumers (Vern *et al.*, 2024).

The second technology we consider is Internet of Things. The use of IoT systems in the agrifood industry relate to two types of applications. The first concerns resource management. In this regard, the use of IoT systems and smart sensor networks enables acquisition of real time data to support the execution of precision agriculture and site-specific activities (Ouafiq *et al.*, 2022). Furthermore, this helps reduce waste and minimize the environmental impact of production activities (Jagtap, Garcia-Garcia and Rahimifard, 2021). The second type of applications concerns product tracking. From this perspective, IoT systems can be used to monitor key parameters such as temperature and humidity during storage and transportation phases (Al-Ansari *et al.*, 2020). On the one hand, this allows to mitigate food quality and safety risks. On the other, it helps streamlines logistics operations, improving the resilience of agrifood supply chains and mitigating risks in the distribution phase (Beker *et al.*, 2016).

Moving on, we continue our investigation by considering big data applications. These involve the development of decision support models, often leveraging the combination with AI-based solutions or IoT systems (Lokers *et al.*, 2016). From a risk management perspective, big data utilization mainly impacts food safety, environmental sustainability, and supply chain management risks. Regarding food safety risks, Talari et al. (2022) demonstrate how big data helps detect and mitigate risks associated with the diffusion of pathogens by supporting control processes based on geographic data or chemical analyses. Rejeb et al. (2021) analyse the role of big data in managing and preserving natural resources, while Donaghy et al. (2021) show that big data can support supply chain management, mitigating disruptions and market shocks. In these instances, big data are useful to predict the evolution of demand and to develop decision support models.

We now focus on AI-based applications in the agrifood industry. These impact primarily cultivation and production by enabling the automation of monitoring and control activities. In this regard, it is essential to consider how most AI applications rely on the utilization of drones and robots (Spanaki *et al.*, 2022). AI applications in the agrifood industry can be categorized into two main typologies. The first focuses on crop mapping and environmental monitoring (McCarthy *et al.*, 2023). The second type of application involves targeted interventions on crops. Here, the synergy between artificial intelligence, drones and robots can be used for the identification of pests and weeds, or for crop identification and counting. From this perspective, AI-based solutions can help mitigate food safety and environmental risks, and mitigate risks associated with human error (Badia-Melis *et al.*, 2018). Before moving on, it is worth considering some relevant emerging applications encompassing the use of drones for food delivery services. In this regard, the use of drones for last-mile deliveries could help mitigate logistical and distribution risks (Choe, Kim and Hwang, 2021).

We conclude this section by investigating the applications of digital twins. In essence, digital twins are virtual equivalents of physical objects, capable of replicating their features, state, and evolution over time by leveraging the integration of sensors, IoT systems, and multiple data sources (Verdouw *et al.*, 2021). Regarding their adoption in the agrifood industry, Pylianidis et al. (2021) highlight digital twins' great versatility by identifying 28 use cases, ranging from production monitoring, to product tracking, to supply chain management. Burgos and Ivanov (2021) show how digital twins can be used to assess the impact of the COVID-19 pandemic on the agrifood industry and to identify risk mitigation strategies. On a different note, several studies show that digital twins can support product monitoring and quality control, contributing to the mitigation of food safety risks (Defraeye *et al.*, 2019). Finally, the use of digital twins could also have a positive impact on supply chain management. Maheshwari *et al.* (2023) demonstrate how digital twins can enhance agrifood supply chain resilience by reducing inefficiencies and improving coordination and information management.

Table 3: Impact of innovative technologies on agrifood risks. Darker shades of green indicate stronger impact.

Risk categories	**Sub-risks**	**Blockchain**	**IoT**	**Big data**	**AI**	**Drones**	**Digital twins**
Food safety risks	Food quality						
	Frauds and counterfeiting						
	Food losses and waste						
Data management risks	Product tracking						
	Information management						
	Cybersecurity and privacy						
Environmental risks	Climate change						
	Waste of natural resources						
	Environmental degradation						
Geopolitical risks	Conflicts, pandemics						
	Market shocks						
Supply chain risks	Supply chain design						
	Logistic risks						
	Human errors						
	Consumers' relations management						

4 Conclusions

This study aimed to investigate how innovative technologies impact risk management in the agrifood industry. These include the need to ensure food production for a growing world population, the need to adapt to and mitigate the effects of climate change, and the need to improve the resilience of agrifood supply chains in response to disruptions. While the literature effectively investigated the advantages of technological innovation in the agrifood industry, it failed to thoroughly address implications for risk management. To help bridge this gap, this study conducted a literature review aimed at organizing the main findings, identifying the main categories of risks affecting the agrifood industry, and analysing the impact of recent technological applications.

This led to the identification of five main risk categories, encompassing food safety, information management, environmental, geopolitical, and supply chain management risks. Furthermore, this classification was useful to analyse how different technologies may impact risk management. In particular, the study focused on six technologies, namely blockchain, IoT, big data, artificial intelligence, drones, and digital twins. The results present the main applications in the agrifood industry, highlighting opportunities, and discussing implications for risk management.

Overall, this study has important theoretical and practical implications. From a theoretical perspective, the study advances the literature by providing a classification of the main risks affecting the agrifood industry. Furthermore, this study contributes by discussing the implications of key technological applications for managing different risk typologies, and by providing an overview of the impact of the most relevant technological solutions. As for practical implications, this study suggests how practitioners can leverage technological innovation to support risk management. In this regard, blockchain tracking systems help ensure product quality, combat counterfeiting, and support the management of information and product flows. IoT systems are particularly useful for mitigating food safety risks by enabling real-time monitoring of products during cultivation, transport, and distribution. The use of big data and AI-based solutions can effectively support precision agriculture activities. This contributes to the management of natural resources and helps mitigate environmental risks. Drones are used to automate monitoring and precision agriculture activities. Finally, digital twins show the potential to deeply impact agrifood supply chain management by improving resilience and mitigating food safety risks.

Acknowledgements

The authors would like to acknowledge the valuable contribution of Mario Scanu, for his support in the material collection and selection activities.

Ethics declaration

No ethical clearance was needed for the research referred to in this paper.

AI use declaration

No artificial intelligence software was used to develop the study. Artificial intelligence was used to proofread the paper.

Business Model Innovation and Digital Technologies in Agri-Food: Leveraging Boundaries for Sustainability

Stefano Marciano, Francesca Peluso
University of Naples "Parthenope", Naples, Italy

Abstract

The study aims to investigate the digital transformation processes within the agri-food sector and their influence on business model innovation (BMI) as a pathway toward sustainability. Specifically, it analyses how agri-food companies are exploiting the potential of digital technologies (DTs) to reshape their value creation processes, enhance competitiveness, and address environmental and economic challenges. In order to exploit DTs and integrate them into business operations, it is essential to innovate the companies' business model by rethinking traditional operational and strategic logics. This underscores the necessity of both the adoption of new technologies and the transformation of the business model. Despite the multiple opportunities offered by DTs, their introduction in agri-food companies presents significant obstacles due mainly to a lack of knowledge, limited digital skills or to the high costs associated with their implementation. Addressing these barriers, requires a growing emphasis on knowledge co-creation-oriented approaches, that integrate diverse disciplines and sectors. In order to pursue this objective, the study adopts a theoretical approach, based on an analysis of the existing literature on DTs and their role in fostering BMI and sustainability, and boundary management within the agri-food sector. The research focuses on the role of company boundaries as collaborative spaces that can facilitate the adoption of DTs and promote co-creation dynamics. The findings of the research lead to the development of a theoretical framework aimed at guiding agri-food companies in their transition toward more innovative and sustainable business models. This study offers theoretical contributions to support companies in leveraging DTs for sustainable development.

Keywords: Business Model Innovation, Sustainability, Digital Technologies, Boundary Management, Agri-Food Sector

Paper type: Academic Research Paper

1 Introduction

In a dynamic environment influenced by constant changes and emerging challenges, innovating the business model has become a key capability for surviving competition (Garzella et al., 2021; Li et al., 2024.). Over the last few years, one of the main driving forces behind BMI has been the increasing use of DTs in the business activities (Oguntegbe et al., 2024; Krishnan et al., 2025).

DTs are leveraged by companies to achieve a predominant position and maintain a high level of competitiveness in the market by reshaping their value creation process (Legowo et al., 2021; Dragos and Livia, 2023). In this scenario, characterized by growing economic and environmental challenges, the agri-food sector is at the centre of a crucial transition (Konfo et al., 2023; Finger, 2023). The widespread use and integration of DTs in this sector is proving to be a driver of BMI, enabling better results in terms of sustainability (Carmela Annosi et al., 2020; Capurro et al., 2023; Stefanini and Vignali, 2024).

Despite the numerous opportunities offered by DTs, their introduction in agri-food companies presents significant challenges (Maffezzoli et al., 2022; Fragomeli et al., 2024) due mainly to a lack of knowledge, limited digital skills or to the high costs associated with their implementation (Al-Moaid et al., 2024; Alkhamery et al., 2021). To address these challenges, there is an increasing necessity of knowledge co-creation-oriented approaches, integrating various disciplines and sectors (Caputo et al., 2019; Dentoni et al., 2023). In this context, boundary management has gained significant relevance in management studies (Alexander, 1997; Breschi and Malerba, 1997) and plays a pivotal role in enabling the adoption of DTs and BMI (Fiorentino et al., 2021; Capurro et al., 2024).

Despite the growing interest in digital transformation, its implications for BMI in the agri-food sector, particularly as a pathway toward sustainability, remain underexplored (Barth et al., 2017; Miranda et al., 2023). Based on a literature review of innovation and strategic management studies, there is still a limited understanding of how the role of boundary management can serve to facilitate the integration of DTs to address environmental challenges (Broccardo et al., 2023). In an attempt to fill this gap, the study aims to investigate how the integration of DTs by the agri-food companies can trigger BMI to foster sustainability. The investigation will focus on the use of company boundaries as spaces for collaboration and co-creation. In particular, the study

poses the following research questions: How can boundaries be leveraged to support the adoption of DTs? Which elements of agri-food companies' business models can be innovated to enhance sustainability?

To fulfil the research aim and questions, a theoretical approach is adopted, based on an analysis of relevant literature on sustainability, digital transformation, BMI and boundary management in the agri-food sector. By integrating the literature, a theoretical framework is developed to support agri-food companies in navigating current challenges.

This paper is structured as follows. The next section provides the theoretical background on DTs and their role in fostering BMI and sustainability within the agri-food sector, and the boundary management. Section 3 presents the theoretical framework developed through the literature analysis. Finally, section 4, outlines the findings of the study and the conclusion, offering insights and directions for future research.

2 Theoretical background

2.1 DTs and BMI for sustainability in the agri-food sector

The topic of sustainability is of particular relevance in the agri-food sector (Notarnicola et al., 2012; Poponi et al., 2022). Many future social challenges are related to sustainable agriculture and food production, which, according to various sources, will increase by 70% by 2050 (Barth et al., 2017; Van Dijk et al., 2021). The agri-food system - which includes the "actors involved in bringing food from the field to the table, from agricultural production and processing to distribution, consumption and waste management" (Von Braun et al., 2021) - is responsible for negative impacts on environmental sustainability due to its implications on water consumption, land degradation, greenhouse gas emissions, biodiversity loss and food waste (Poore and Nemecek, 2018). In this context, companies' transition towards more environmentally sustainable agri-food practices is no longer considered an optional choice, rather, it has become a global priority as stated in the EU Green Deal and the Farm to Fork strategy (EC, 2019, 2020). Sustainable development also contributes to the achievement of several Sustainable Development Goals (SDGs) introduced by the 2030 Agenda, producing positive effects such as improving farmers' and consumers' welfare through organic practices and food security, preserving environmental balance, biological pest management and sustainable fertilisation techniques (Herrero et al., 2021).

Nevertheless, the structural composition of the agri-food sector, characterised by the predominance of SMEs (EC, 2024), combined with the inherent complexity of environmental sustainability, makes the green transition particularly challenging (Farace and Tarabella, 2024).

The path towards sustainability in the agri-food sector is driven by a variety of internal and external factors (Borsellino et al., 2020). Externally, the pursuit of sustainability responds not only to EU environmental regulations but also to the growing demands from consumers and stakeholders for greater transparency and accountability. Internally, the ability to implement sustainable practices depends on financial and human resources, management processes, know-how, and technological skills (Prasanna et al., 2024; Pandey et al., 2023). In this context, agri-food companies are called to address the growing need for sustainability, which requires increased investments in R&D and the adoption of DTs. This trend is part of the current era of "digital agriculture", which is defined as "the use of detailed digital information to guide decisions along the agricultural value chain" (Shepherd et al., 2020). Digital agriculture is profoundly transforming the sector through the introduction of precision and digital agriculture technologies which have the potential to influence economic performance, external environment and social context.

In this scenario, the structural changes brought by digital transformation have created a new competitive environment: incumbents are under increasing pressure to integrate emerging DTs, while new market entrants are leveraging them to reshape value creation processes and innovate business models. In this evolving context, digital transformation is perceived as "an organisational transformation that integrates DTs and business processes in a digital economy" (Liu et al., 2011), emphasizing not only technological change but also organizational and strategic implications.

Digital transformation is recognised as a driver for improving company efficiency and promoting sustainable innovation. The sustainable development of agri-food companies is strongly linked to their capacity for innovation, which implies the integration of DTs that not only support operational optimisation but are also considered key enablers for BMI.

Business models contribute to innovation as they translate market opportunities into profits by delivering the value of a service/product through commercialization (Amit and Zott, 2012); companies thus commercialize technologies through their business models. Accordingly, scholars have consolidated the studies on product and process innovation with the radical rethinking of the business model as this can expand the potential scope of

innovation (Chesbrough, 2010). As a result, BMI has emerged as a potential mechanism to integrate sustainability into business strategies thereby encouraging the adoption of more innovative and sustainable business models and enhancing companies' competitive advantage and long-term value creation (Broccardo and Zicari, 2020).

DTs, therefore, play a crucial role which extends beyond operational efficiency transforming the ways in which companies generate value, innovate, and engage with stakeholders, while addressing societal and environmental challenges (Nambisan et al., 2019; Cefis et al., 2023).

2.2 Boundary management for digital transformation in agri-food sector

The growing pressure from the competitive environment requires a constant updating of the company's structure and value creation process (Garzella et al., 2021). The integration of DTs has become a fundamental prerequisite to operate in the competitive environment, to avoid the loss of competitiveness, strategic positioning and market share (Legowo et al., 2021; Dragos and Livia, 2023).

Currently, DTs represent a key resource for value creation, especially in the agri-food sector, where there is a strong pressure for efficiency and an increasing demand for information and transparency from stakeholders (Abbate et al., 2023; Lehtinen, 2017).

Despite this need, DTs' integration is not always easy to achieve as companies face a number of obstacles mainly related to the lack of sufficient financial resources, knowledge and skills necessary for their full implementation (Maffezzoli et al., 2022; Fragomeli et al., 2024). In this regard, a solution can be found in the co-creation through the development of knowledge, products or services in collaboration with other stakeholders (Ramaswamy and Gouillart, 2010). Knowledge co-creation is a key element in highly complex and interdependent contexts, like the agri-food sector, especially when addressing challenges related to sustainability and digital transformation. It refers to the integration of experiences, perspectives and knowledge held by a plurality of stakeholders, directly involved or influenced by the problem under consideration (Pohl et al., 2010), allowing the development of shared solutions.

In management studies, several research have shown that knowledge co-creation can facilitate innovation and promote more effective learning (Dentoni et al., 2023). In addition, it plays a crucial role in reducing information asymmetry and building collaborative capabilities, essential for the BMI in a sustainable perspective (Caputo et al., 2019).

In this context, organizational openness and ability to extend company's boundaries become strategic levers for accessing skills, knowledge and technologies otherwise inaccessible, thus facilitating sustainability-oriented BMI processes (Bouncken and Fredrich, 2016; Foss and Saebi, 2018). The concept of openness, understood as the permeability of company boundaries, translates in the agri-food sector as the willingness to collaborate with other stakeholders to co-design solutions, share production processes and strengthen relationships (Cohen and Kietzmann, 2014; Baden-Fuller and Haefliger, 2013; Fiorentino, 2016).

Boundary management can be a key factor for the effective adoption and integration of DTs and BMI, because it allows companies to manage and integrate resources that are neither internal nor external, and to create new inter-organizational relationships between company network (Garzella, 2000; Caputo et al., 2019).

Therefore, through the boundary management, agri-food companies can enable the implementation of new digital and collaborative business models which are more resilient and sustainable.

Nevertheless, the predominant management and organisational criticalities associated with boundary strategies pertain to the challenge of sustaining effective control over companies and individuals that gravitate to the boundary area, and which represent strategically relevant resources (Garzella et al., 2021). To effectively manage the partners involved, companies should adopt "linking" and "bearing" strategies (Capurro et al., 2021). Linking strategies aim to integrate partners' resources and core competencies within the company; while, bearing strategies allow to avoid the risk of external parties gaining access to resources, competencies and information that are critical to the company's competitive advantage.

Boundary management, therefore, plays a crucial role in creating balance and coherence among the various elements and activities at the border area, effectively integrating internal and external forces (Parmigiani and Mitchell, 2009).

3 Leveraging boundary strategies and DTs for sustainability: a theoretical framework

The theoretical framework is constructed (Figure 1) following the strategy-action-performance approach, a logic underlying several existing frameworks (Micheli and Manzoni, 2010; Garzella and Fiorentino, 2014; Capurro et al., 2024). It is developed starting from the boundary strategies, identified as pivotal actions in enabling the

development of BMI through leveraging DTs, which act as enablers for achieving positive outcomes in terms of environmental sustainability.

The theoretical framework adopts a boundary-based perspective, in which a company's boundaries are not perceived as a static space, but rather as a dynamic zone of exchange, cooperation and innovation. Thus, boundary management is crucial to mobilising resources, relational skills, digital know-how, trust and capital, which are vital for the successful adoption of DTs for BMI (Brehmer et al., 2018). BMI is positioned as a strategic lever through which companies can integrate environmental sustainability requirements not only by introducing technologies or incremental improvements but by radically rethinking how they create, distribute and capture value (Saebi et al., 2017; Ancillai et al., 2023; Capurro et al., 2023).

The boundary-based theoretical framework, thus, identifies boundary strategies as enablers for the integration of DTs to accelerate the transition to more sustainable business models. By implementing such strategies, companies can co-develop knowledge, access shared technologies and activate joint innovation processes. This approach, therefore, presupposes openness to external partners, the development of trusting relationships and the activation of technological partnerships. The creation of these networks helps converting external environmental and technological stimuli into opportunities of sustainable growth. Specifically, linking strategies aim to stimulate collaboration with technological partners and to enable access to critical knowledge and technologies, difficult to develop internally or to acquire externally. These elements facilitate BMI through several methods such as DTs' integration in value creation processes, partnerships with innovative actors – e.g. digital solution providers and agri-tech companies -, process optimisation and cost efficiency. Concurrently, bearing strategies are implemented with the purpose of preserving internal resources and strategic capabilities, thus ensuring the management of innovative processes in a safe and sustainable way (Garzella, 2000).

The synergistic use of DTs enables smart agriculture applications, including precision farming, traceability and food safety, climate analysis and forecasting of agricultural trends, and automation of agricultural processes, which involve a range of integrated DTs and support BMI by enhancing value creation, delivery and capture. In terms of value creation, smart agriculture applications extend the value proposition by offering new benefits to consumers, like greater safety and transparency, certified-origin products and consistent product quality, thus strengthening company's market reputation. These advanced technologies also allow to formulate data-driven strategic decisions, using real-time and predictive data, like the selection of the most suitable crops for the expected climate or the adoption of preventive measures. Concerning value delivery, smart agriculture applications can enable the creation of collaborative relationships with customers, also introducing digital channels where the customer is an active part of the value creation system, contributing with information and feedback, and the identification of new customer segments particularly sensitive to environmental issues. Regarding value capture, the improvements brought about by smart agriculture concern cost optimisation through efficient resource management and the possibility of increasing revenue streams.

Smart agriculture applications and BMIs can be translated into concrete environmental sustainability outcomes. In particular, the use of real-time and predictive data can enable more effective management of natural resources through targeted and timely interventions. Optimising the use of natural resources, fertilisers and pesticides can reduce the chemical impact on soils and ecosystems and the associated emissions. Climate analysis and agricultural trend forecasting can improve production planning, leading to a reduction in food waste. In addition, technological support for crop management can facilitate better crop rotation, contributing to the protection of agricultural biodiversity.

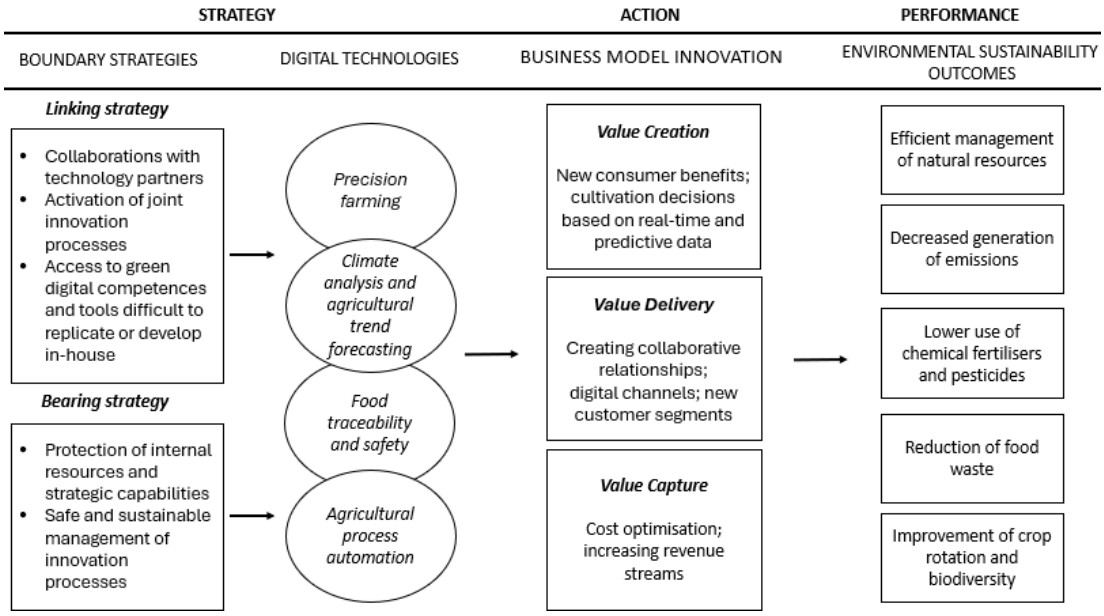

Figure 1: The boundary-based theoretical framework
Source: Author's elaboration

To trigger this process, a high level of managerial competences and skills is required, making it essential to identify specific figures dedicated to the management of boundaries and relationships between processes, activities and people, the "boundary managers". These professionals can integrate technical, entrepreneurial and relational skills to support innovation processes and foster the development of open and resilient networks. The role of the boundary manager is of particular importance as it assumes both operational and strategic centrality and is crucial for facilitating co-innovation, coordinating heterogeneous actors, mediating between diverging interests and promoting a culture and long-term vision toward sustainability (Capurro et al., 2024).

4 Findings and conclusion

The present paper proposes a theoretical framework grounded on a boundary-based perspective, aiming to explore how agri-food companies can address the challenges posed by digital and green transition. In a context characterised by increasing complexity, companies required to rethink their business models, adopting approaches that integrate technological innovation with environmental sustainability.

The proposed framework highlights the convergent influence of two major drivers currently shaping the business landscape: digital transformation and environmental sustainability. Digital transformation goes beyond the mere adoption of DTs; it represents a comprehensive process of organisational change that fundamentally reshapes how companies operate and generate value. Simultaneously, environmental sustainability serves as a strategic orientation, guiding technological and organisational decisions toward low-impact, resilient, and inclusive business models.

Based on the analysis conducted, several insights emerge. Although this is a preliminary study, the results obtained allow to provide answers to the research questions. With regard to the first research question, company boundaries - conceived not as static but dynamic spaces for interaction and exchange -, represent a strategic area for enabling the adoption of DTs. Through the implementation of boundary strategies, companies can access external resources that are otherwise difficult to develop internally or acquire from the market, such as advanced digital competences, technological tools and relational capital. These strategies facilitate co-innovation with external partners, creation of collaborative networks and activation of inter-organisational learning processes, crucial steps to overcoming barriers for the adoption of DTs.

In relation to the second research question, the study reveals how companies can promote sustainability through the innovation of different elements of their business model. In particular, the integration of smart agricultural applications impacts the three main dimensions of the business model: value creation, value delivery and value capture.

In terms of value creation, DTs can expand the value proposition by offering new benefits to consumers — like safety, transparency, product's origin certification and consistent quality — while enabling data-driven decisions such as crop selection based on climatic forecasts or targeted interventions, thereby improving both

productivity and environmental impact. Regarding value delivery, DTs can enable the development of collaborative relationships with customers through digital channels, engaging them in the value creation process and attracting customer segments particularly sensitive to environmental issues. Finally, in terms of value capture, DTs can optimise the use of resources and improve operational efficiency, leading to cost reductions and increased revenue streams.

The proposed framework is still at a conceptual stage and requires further theoretical investigations. Moreover, future research efforts will focus on its empirical validation, aiming to evaluate its effectiveness in supporting the adoption of DTs to innovate business models and enhance environmental sustainability outcomes.

Smart Responsible Innovative Cities: An Organisational Agenda

Mauro Romanelli
University of Naples Parthenope, Napoli, Italy

Abstract

Cities are identifying the smart city vision to develop the city an urban community and engine of responsible innovation. The analysis elucidates that European cities are rethinking on urban planning by adopting a smart city framework, leading to responsible urban innovation and future, fostering collaborative processes that contribute to sustainable and social urban growth and innovation to improve the quality of life. A smart city helps to shape the city a smart responsible innovative urban community. Cities are defining smart urban planning, enabling smartness as an ability to shape urban organisational, innovative and collaborative urban spaces. European cities are going smart, tracking a framework for collaborative innovation, leading to the urban community an engine of social innovation. Sustainable urban future relies on cities that will develop smart urban communities for responsible innovation and good life, promoting collaborative and multi-actor innovation, and following community-led and human-centred view to urban development and innovation.

Keywords: responsible innovation, smart cities, smart communities, organisational innovation

Paper type: Academic Research Paper

1 Introduction

Today, cities are designing smart city plan to construct the urban future, *more than human* cities, to develop responsible innovation conditions and issues (Yigitcanlar, 2018; Stilgoe, Owen and Macnaghten, 2013), meeting grand societal challenges (Voegtlin, Scherer, Stahl and Hawn, 2022), and overcoming techno-centric, business-led visions to smart growth (Grossi and Pianezzi, 2017). Cities are planning a smart city view to urban development, shaping smart innovative socially responsible communities, leading to a smart city development, and supporting collaborative frameworks to foster responsible urban innovation and ensure high quality of life improvement, meeting urban societal challenges (Mora *et al.*, 2023; Dolmans *et al.*, 2023; Yigitcanlar *et al.*, 2021). A smart city vision helps city to deal with grand societal challenges, avoiding harm to people and planet, leading to responsible development and innovation (Voegtlin and Scherer, 2017), and generating desired outcomes and futures for humans and nonhumans (Yigitcanlar, 2018), leading to smart social innovation as collaboration-led framework (Costales, 2022; Voegtlin, Scherer, Stahl and Hawn, 2022), and identifying smart city solutions for sustainable urban development and responsible innovation (Sharifi *et al.*, 2024)

Smart cities contribute to improving urban social innovation and quality of life and in long-term horizon (Appio, Lima and Paroutis, 2019). As organisational spaces (Knox, 2010), net action (Czarniawska, 2002), engines of social innovation (Costales, 2022), cities are rethinking on smart city urban planning towards next generation of a truly smart sustainable city, an urban healthy system of systems, meeting the challenges of Anthropocene epoch, leading to responsible urban innovation, doing good for urban community and society (Stilgoe, Owen and Macnaghten, 2013), preserving the future of ecosystems, promoting sustainable-balanced economy-society-environment practices (Yigitcanlar, 2018), and leading to an organised maturity to enable positive freedoms (Scherer, Neesham, Schoeneborn and Scholz, 2023), coherently supporting community engagement for smart sustainable city (Anthony, 2024), technology, community and policy for responsible innovation (Yigitcanlar *et al.,* 2021).

Smart city development fosters collaborative multi-actor innovation (Dolmans *et al.*, 2023), public-private partnerships (Fernandez-Anez, Fernàndez-Guell and Giffinger, 2018), empowering the urban community and citizenry to drive sustainable inclusive growth and open innovation (Paskaleva, 2011; Martin, Evans and Karvonen, 2018). Still few studies focus on the role of smart city planning for responsible urban innovation. How do cities rethink on responsible urban innovation? What makes the city a responsible innovative urban community? This study aims to elucidate how Paris, Wien and Berlin are rethinking on the urban future, adopting a smart city plan and design to make the city a smart responsible community, an engine of social innovation and growth. The paper is structured in five sections. After introduction and theoretical background related to cities as urban planners of smart city future for responsible innovation and communities, the methodological aspects are presented in the third section. Findings follow in the fourth section. Finally, discussion and conclusions are set out.

2 Cities dealing with smart responsible innovation: a collaborative and organisational view

As organisational spaces (Knox, 2010) and net action (Czarniawska, 2002), cities aim to plan a smart city framework, dealing with social challenges, meeting urban sustainability priorities, shaping urban collaborative as well as organisational ecosystems for driving responsible innovation processes (Mora *et al.*, 2020), leading to smart progressive cities that enhance citizenry contributions (Hollands, 2008), by combining technology, community, policies in order to shape a smart community, a *continuum* in which public-private urban actors think on and develop initiatives to improve the city a better place for life, focusing on community-led innovations (Gil-Garcia, Pardo and Nam, 2016; Yigitcanlar, 2021).

Cities adopt a smart city mind set to enable urban stakeholders to form alliances and collaborative partnerships in order to develop innovation processes and governance frameworks, avoiding harm and doing good for people and society (Eger, 2005; Meijer and Bolivar, 2016; Voegtlin and Scherer 2017; Yigitcanlar, 2018; Yigitcanlar *et al.*, 2021). Cities should drive intentionally their urban development, *humanising* technology, and meeting the needs of urban communities (Knight, 1995), dealing with urban technologies that co-shape the city life for driving responsible innovation (Stone, 2021), leading to responsible smart city innovation and growth to progress towards sustainable development goals (Sharifi *et al.*, 2024), developing next generations of smart city by developing distinctive informational ecosystems and community values, leading to strongly locally embedded open innovation within urban communities networking (Han and Hawken, 2018; Paskaleva, 2011).

The city acts for smart urban innovation (Joss *et al.*, 2019), a socio-technical intentional and proactive process, combining technology, collaborations, actors in order to engender creative ideas for urban qualitative change and improvement (Meijer and Thaens, 2018), and designing smart city frameworks to develop innovation as a process of creative collaboration, relationships, stakeholder involvement to change the way cities grow smart (Anttiroiko, Valkam and Bailey, 2014; Paskaleva, 2011). Rethinking the smart city planning helps shape smart responsible, sustainable cities (Yigitcanlar, 2018) towards smart city organised maturity, strengthening positive freedoms of pursuing an agenda, contrasting what decreases freedom in society (Scherer, Neesham, Schoeneborn and Scholz, 2023), for tackling social challenges, focusing on people and policies, leading to collaborative frameworks and community engagement for urban innovation and wellbeing (Anthony, 2024; Trencher, 2019), supporting a social and civic view to innovation (Grossi and Pianezzi, 2017), following an integrative smart technological model for community empowerment and participation in smart city development (Kummitha, 2024).

Smart city should develop as responsible urban innovation, aligning technological advancements with societal needs, values and ethics (Li *et al.*, 2023), meeting grand societal challenges, massive social and environmental issues worldwide leading to responsible innovation through multi-actor public-private partnerships, collaboration initiatives, stakeholder involvement, governance framework (Voegtlin, Scherer, Stahl and Hawn, 2022), supporting citizen and community empowerment (Paskaleva, 2011), social innovation (Costales, 2022), looking beyond technology towards collaborative and community-led smart city models (Mora, Deakin and Reid, 2019).

As urban innovation for sustainable urban future (Nam and Pardo, 2011; Yigitcanlar, 2021) smart city shapes smart communities, develops responsible urban innovation, meeting societal challenges through collective stewardship and framework of science and innovation (Stilgoe, Owen and Macnaghten, 2013) to improve the quality of policies and urban life coherently with smart societal, democratic, social justice-led view to urban growth (Alizadeh and Sharifi, 2023), long term urban planning-based approach, ethical willingness of municipality, citizenry active participation and engagement, beyond business-led, technology-driven visions (Grossi and Pianezzi, 2017), the technological optimistic rhetoric to justify the *status quo* (Bär, Ossewaarde and van Gerven, 2020).

3 Methodological section

The study employed a qualitative, descriptive and exploratory methodology to analyse how Paris, Berlin and Wien are planning a smart city strategy to drive future urban development Rethinking on smart responsible urban innovation helps plan future post-anthropocentric, *more than human* cities (Yigitcanlar, 2018). The study focuses on three illustrative case studies to explore a comprehensive understanding of a phenomenon still in progress, emerging in contemporary times, whereas the boundaries between the phenomenon and the context are not clearly evident following a multiple case study analysis whereas smart city framework and strategy provide a means for urban planning that serves urban development solutions (Eisenhardt, 1989; Mora, Deakin, Reid and Angelidou, 2019), following a case study methodology through an empirical inquiry without the rigidity of a predefined structure for observations and analysis (Yin, 2009). The research methods involved case selection and data collection from policy documents (smart city strategy framework from *Paris Smart and Sustainable*

Looking ahead to 2020 and beyond, *Gemeinsam Digital: Berlin (GD:B)* and *Smart Climate City Strategy Vienna*) as information sources to collect and analyse to understand the pathway cities are developing smart city planning for urban innovation (Sancino and Hudson, 2020; Yigitcanlar, 2018).

4 Findings

The case studies issues to smart city urban planning (Paris, Wien, Berlin) are presented. European cities are embracing a smart city view in order to make the city an engine of socially responsible innovation that supports the future of urban communities that aim at achieving urban sustainability.

In the smart city framework *Paris Smart and Sustainable. Looking ahead to 2020 and beyond* the role of technology is to enable urban communities to shape a smart sustainable city and contribute to urban innovation developing smartness as a collaborative capability to drive the city towards a sustainable future and quality of life improvement. As open platform, the smart city supports the experimentation and the development of new innovative services and solutions that contribute to wealthy urban communities and spaces, leading to healthy and safe urban environments. Smart city vision develops the city of the future and supports responsible innovation to achieve sustainable urban development and leading to smart sustainable city of the future that that brings together social, technological and organisational dimensions and stems on three pillars: the *connected city* (the tool) s on continually integrating technological advances; the *open city* (the method) relies on stimulating citizen participation and collaborative projects, leading to innovation through exchanging, sharing and co-creating with researchers, scientist and academics, by transforming public administration and simplifying processes. The *sustainable city* is the issue of responsible urban innovation design, a place where technology serves to improve city life, community inclusion and involvement, leading to co-producing public services, co-designing policy decision-making, smart city as responsible innovation for city effective social change agent.

Smart Climate City Strategy Vienna looking at the 2050 develops a smart city vision to enhance quality of living, sustainability, prosperity, education and workplaces opportunities. The role of technology is to simplify the urban life, support professional education boundary less. Driving smart urban innovation helps drive the urban future, social integration and inclusion within urban communities, and supports civic participation and engagement, leading to smart innovative communities to ensure top-level quality of living, focus on social participation and inclusion, safety and security, leisure quality and culture, and support both social openness and cultural diversity, strengthening high degree of social participation for sustainable urban development and inclusive growth. Technology serves for community development and supports the city as an innovative community, opening up to collaborative processes that drive urban value creation and social innovation. Technology supports co-participation, co-determination and co-decision-making as strategic and organisational framework to shape smart innovative urban communities.

Gemeinsam Digital: Berlin (GD:B) relies on enhancing collaboration and community for shaping a sustainable, innovative city, and smart urban growth making Berlin a sustainable, community-oriented, cooperative and resilient city for the future. The role of municipal administration is to facilitate urban cultural change digital transformation for the common good of communities. As a platform smart Berlin enables the relevant urban stakeholders, private-public actors to work together or *gemeinsam*, to cooperate to drive urban transformation and develop innovative solutions to urban problems and identify new ways to make the city a smart community socially cohesive and innovative. *GD:B* develops a responsible innovation framework to shape a sustainable, community-oriented, resilient and cooperative city, bringing together interconnected and needs-oriented interests of all urban stakeholders involved in urban transformation. The cooperative city relies on fostering creative participation of the entire urban community as the basis for the participatory development of the city. The role of public administration is to connect municipal institutions, citizens, business, academia and civil society to facilitate the opportunities for new governance structures development for cooperation and social engagement, promoting inclusiveness, transparency and openness.

5 Discussion and conclusions

Cities of tomorrow are planning their future as well as smart innovative urban communities, promoting high quality of life and achieving urban sustainability, making collaborative open urban spaces, leading to smart responsible urban communities, engines of social innovation. A variety of organisational and planning solutions is emerging within practices and design cities in Europe are embracing in order to develop organisational arrangements that enhance collaborative ways and approaches that strengthen the critical role of urban stakeholders that get involved in building conditions for urban sustainability, learning and innovation within urban spaces and communities.

European cities are planning their future to improve quality of life, and drive smart responsible urban innovation, shaping urban communities, engines of social inclusion and innovation, making collaborative open spaces. Cities drive responsible urban innovation and sustainable urban growth, leading to multi-actor collaborative innovation, beyond a technology-enabled towards a community-oriented and human-centric smart city approach, putting the people and community first, focusing on human and social capital, community development, leading to smart city responsible urban collaborative social innovation. Paris sustainable city vision stresses the connected city as a tool, the open city as method and sustainable city as a goal. The Wien smart vision uses technology to enhance co-participation, co-decision-making and inclusion as strategic and organisational framework for urban responsible innovation and sustainable growth. Smart city Berlin strategy focuses on sustainable, resilient, community-oriented and cooperative city as meeting place and pillar for responsible urban open social innovation. Cities are planning a smart city design, identifying a pathway for smart responsible communities, engines of responsible innovation, community participation, stakeholder engagement.

Increasingly, cities evolve as an organisational field of action and engine of collaborative frameworks for learning and innovation. Cities identify smart city plan to meet grand societal urban challenges, following human-centred, social-driven, participatory-led views to urban growth, and dealing with technology, combining smart city development and responsible innovation to make smart responsible city through collaborative innovation, citizen and community participation, leading to human-centered and community-led approaches to urban value creation and social innovation, making socially inclusive, innovation-driven cities, leading to smart responsible communities for innovation.

Smart urban responsible innovation implies the search for an organisational innovation within urban spaces and relies on fostering smart socially inclusive and technology-led urban communities that adopt a human-centred and participative-oriented view to urban growth dealing with technology to make the city a better place for value creation and social innovation, an organisational platform and engine of social value creation. Further research perspectives will refer to how Italian cities are planning the urban future, following a smart, responsible and sustainable vision to urban innovation and growth.

Managing Organizations between Artificial Intelligence and Technostress: A Typology Model

Raffaele Silvestre, Mauro Romanelli
University of Naples Parthenope, Napoli, Italy

Abstract

This study aims to model the relationships between the independent variables AI-implementation, techno-eustress and techno-distress and the dependent variable productivity, in business organizational context, to understand if an organization, that has, or not has, implemented AI-technologies, are more or less near the ideal organizational typology and to design the possible path to be competitive maximizing techno-eustress and minimizing techno-distress, deriving from the use of AI, impacting positively on productivity. The result is a Three-dimensional-Typology Model identifying 8 different organizational typologies that we named in a particular way for better to represent the situation identified and the distance from the ideal one of maximization of productivity. This work represents a framework for future research on the topic and offers a theoretical model for managers to understand which organizational typology is closest to their organization noting the level achieved by the productivity. In this way, they have the possibility to understand what actions to take to act on the independent variables to divert them towards the ideal typology of maximization of productivity identified as "Futuristic Oasis".

Keywords: AI-technologies, Technostress, productivity, Typology Analysis, Three-dimensional-Typology Model

Paper type: Academic Research Paper

1 Introduction

Technostress and Artificial Intelligence represent two topics much discussed in all fields of the literature.

Starting from the concept of technostress, for Tarafdar, et al. (2014), it is "the stress caused by the use of IS in the work-place" (Tarafdar et al., 2014, p. 51). Furthermore, according with Tarafdar, et al. (2019), techno-eustress explains how "individuals appraise IS as challenging or thrilling, and experience consequent "good" stress which motivates them to engage in coping behaviours that lead to positive outcomes" (Tarafdar et al., 2019, p. 13), while techno-distress explains "the processes by which individuals appraise IS as a threat, experience consequent "bad" stress, and are faced largely with detrimental outcomes" (Tarafdar et al., 2019, p. 13). In organizational context, for Tarafdar, et al. (2007), technostress is activated when the individual encounters difficulties in following and 'deal with the continuous changes that occur in information and communication technologies and in acquiring the increasingly new physical, social and cognitive requirements necessary for their use. While, Nayak, Budhwar, (2022), considering technostress, today, as a common problem for many organizations, investigated the technostress deriving from the enterprise social networks and the consequences.

About Artificial Intelligence, there are numerous definitions in the literature, also depending on the context in which it was necessary to define it but, the definition that seems to be more explanatory, can be found in the IEEE guide (2017) where it is qualified as "the combination of cognitive automation, machine learning, reasoning, hypothesis generation and analysis, natural language processing, and intentional algorithm mutation producing insights and analytics at or above human capability" (IEEE guide, 2017, p. 12). Numerous studies are conducted on AI. Zhang, et al. (2024) analysed the emotional expressions of chatbots to study and understand their impact on customer satisfaction, while Hashem, et al. (2024), faced with a progressive and incremental use of AI-technologies in education in the United Arab Emirates, focused on the possible burnout that may arise for teachers and on the search of possible solutions to address and resolve this problem. Finally, Sjödin, et al. (2023) sought to understand whether, the AI-technologies, can potentially foster the circular business model innovation for industrial manufacturers.

At this point, considering that the use of AI implies an approach with advanced and complex technologies, and considering that the use of technologies can contribute to the intensification of techno-eustress and/or techno-distress, it is reasonable to ask whether and how the integration and use of AI-technologies can impact these phenomenon and/or whether they can even help in their optimal management for better results and performances in all sectors and, in particular, in business, educational-training and medical-healthcare fields. So, it might be interesting to ask what type of relationships exist between AI and technostress. Recalling some of contributions in this sense, Santos, et al. (2024), analysing the use of AI in government and its risks, showed

both the existence of positive feelings and a small percentage of negative feelings resulting from the interaction of AI and the consumer. While, Pagán-Garbín, et al. (2024) explored the stress, burnout and technostress of teachers using the artificial neural network.

Analysing the literature emerged, is evident the scarcity of studies that model the relationships between AI and technostress and their impact on productivity, in particular in business sector. So, could be interesting to model the impact that technostress, resulting from AI-implementation, can have on productivity of organizational members, productivity defined as "The rate of output of a worker or a machine" (Statt, 2004, p. 121). This model may be useful to try to understand if different organizations that have, or not have, implemented AI-technologies, are more or less near the ideal organizational typology and to design the possible path to be competitive maximizing techno-eustress and minimizing techno-distress, deriving from the use of AI, impacting positively on productivity.

For these reasons, after an analysis of the papers that emerged in the literature on the topic in the specific business context, we tried to answer the following research questions:

- *What are the relationships between AI-technologies and technostress and their impact on productivity in business context?*
- *What are the emerging organizational typologies, and the ideal one that maximizes productivity in business context, considering as independent variables AI-implementation, techno-distress and techno-eustress and as dependent variable productivity?*

2 Theoretical framework

In the literature on the topic there are some contributions that offer interesting insight on the intriguing relationships between the use of AI, techno-distress and techno-eustress in various sectors such as business, medical-healthcare, consumer and educational-training.

Considering the specific business context, it was possible to detect various contributions that considered the relationships between AI and technostress with some of these that analyzed also the impact on productivity of workers and managers, and it is precisely on this context that we focused our attention for the development of our analysis and model. Recalling some of these, emerged the contribution of Verma, et al. (2024) which described a possible impact that the work exhaustion can have on the work performance and well-being of employees during the use of Responsible artificial intelligence for the various difficulties, concerns and uncertainties that can arise from its excessive use. Again, Kumar, et al. (2023), in their interviews and based on the data analysis, noted a stressful situation in organizations detected by managers linked to the complex nature of machine learning and AI-technologies and how, many of these organizations, were trying to activate a sort of collaboration between these technologies and human resources. Finally, Choudrie, et al. (2023) in their analysis identified, among others, some interviewees that, in light of the frustration and delays linked to the VPA function, stated how "these delays had a negative impact on productivity and customer relations" (Choudrie et al, 2023, p. 6), while from other interviewees emerged that "When individuals were aware of and actively used smartphones' AI functions, their digital skills and confidence grew, which contributed to enhanced management capabilities" (Choudrie et al., 2023, p. 6).

Therefore, considering this situation in the literature with reference to the relationships between AI and technostress and their impact on productivity, it was possible, using the typology analysis, to develop a model for identifying the different organizational typologies, albeit theoretically, with reference to the specific business sector, which would derive from particular combinations of these variables considering AI-implementation, techno-eustress and techno-distress as independent variables, even if techno-eustress and techno-distress in turn depends on the implementation of AI as well as on the implementation of other technologies, and productivity as dependent variable, as also emerged from the literature.

3 Research methodology

Considering D. Harold Doty and William H. Glick (1994) and Valbuena, et al. (2008): we analyzed the papers on the topic in business sector; we identified examples of organizations which, with reference to the variables considered and the relationships between them, present regularities; we identified and described independent and dependent variables and we highlighted all the relationships. After, we developed the typology model identifying different theoretical organizational typologies in which the dependent variable productivity assume a certain value, but only in ideal one realizes its maximization.

Figure 1 shows the flow chart of research methodology used.

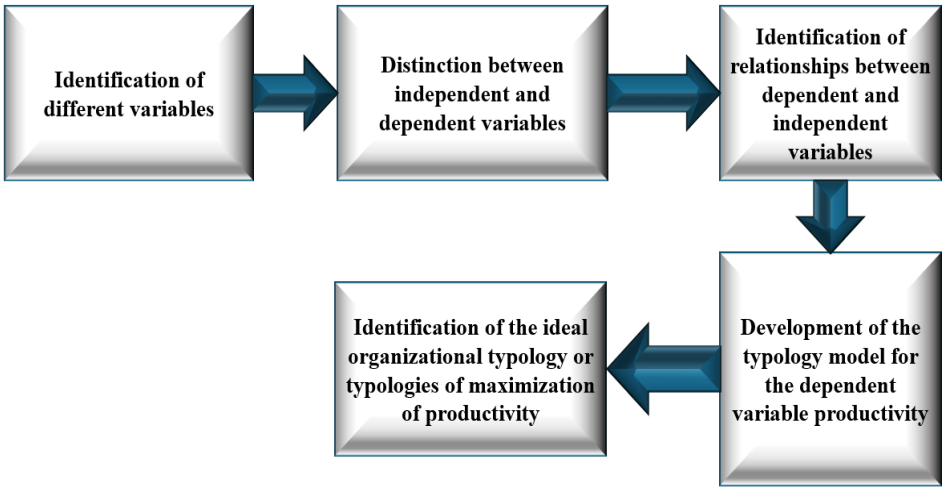

Figure 1: Flow chart of research methodology

4 Results

The principle variables emerged in the literature are: AI-implementation, techno-eustress and techno-distress as independent variables and productivity as dependent variable, to be maximize, among which we detected regularities in the relationships.

Indicating with AI the Artificial Intelligence technologies and with β and 1/β how much the dependent variable varies as a function of independent variables, we identified these relationships:

- Technostress = δ + βAI-implementation + Ɛ

The maximization of Technostress is:

maxTechnostress= δ + [max(βAI-implementation)] + Ɛ

- AI-implementation= δ + (1/βTechno-eustress – 1/βTechno-distress) + Ɛ

The maximization of AI-implementation is:

maxAI-implementation= δ + [max(1/βTechno-eustress)] – [min(1/βTechno-distress)] + Ɛ

- Productivity= δ + βAI-implementation + Ɛ

The maximization of productivity is:

maxProductivity= δ + [max(βAI-implementation)] + Ɛ

- AI-implementation= δ + 1/βProductivity + Ɛ

The maximization of AI-implementation is:

maxAI-implementation= δ + [max(1/βProductivity)] + Ɛ

- Productivity= δ + (-βTechno-distress) + Ɛ

The maximization of productivity is:

maxProductivity= δ - [min(βTechno-distress)] + Ɛ

- Productivity= δ + βTechno-eustress + Ɛ

The maximization of productivity is:

maxProductivity= δ + [max(βTechno-eustress)] + Ɛ

- Techno-distress= δ + (-1/βProductivity) + Ɛ

The minimization of techno-distress is:

minTechno-distress= δ - [max(1/βProductivity)] + Ɛ

- Techno-eustress= δ + 1/βProductivity + Ɛ

The maximization of techno-eustress is:

maxTechno-eustress= δ + [max(1/βProductivity)] + Ɛ

Starting from these relationships, and considering that our focus is on the maximization of productivity in organization, we considered this variable function of variables AI-implementation, techno-eustress and techno-distress. For this reason, considering only these variables in our model, without prejudice to all other dimensions which we didn't take into consideration to exemplify a complex reality, we assumed that productivity depends positively from the implementation of AI, positively from techno-eustress and negatively from techno-distress.

So, the multiple regression formula identified is:

- Productivity= δ + β_IAI-implementation + (β_2Techno-eustress - β_3Techno-distress) + Ɛ

Where β indicates how much the dependent variable varies as a function of independent variables.

While, the formula of maximization of productivity is:

- max productivity= δ + [max (β_1AI-implementation) + max ($\beta_2$techno-eustress) – min ($\beta_3$techno-distress) + $\mathcal{E}$

Considering this function of maximization of productivity, we can define the following hypothesis:

H1: If the organization wants to maximize productivity must maximize the implementation of AI technologies, maximize techno-eustress and minimize techno-distress.

Based on these relationships, we implemented a typological model capable of defining the different possible organizational typologies deriving from the intersection between the theoretical high and low values that independent and dependent variables, can assume.

Figure 2 shows this model identifying 8 different organizational typologies that we named for better to represent the situation identified and the distance from the ideal one.

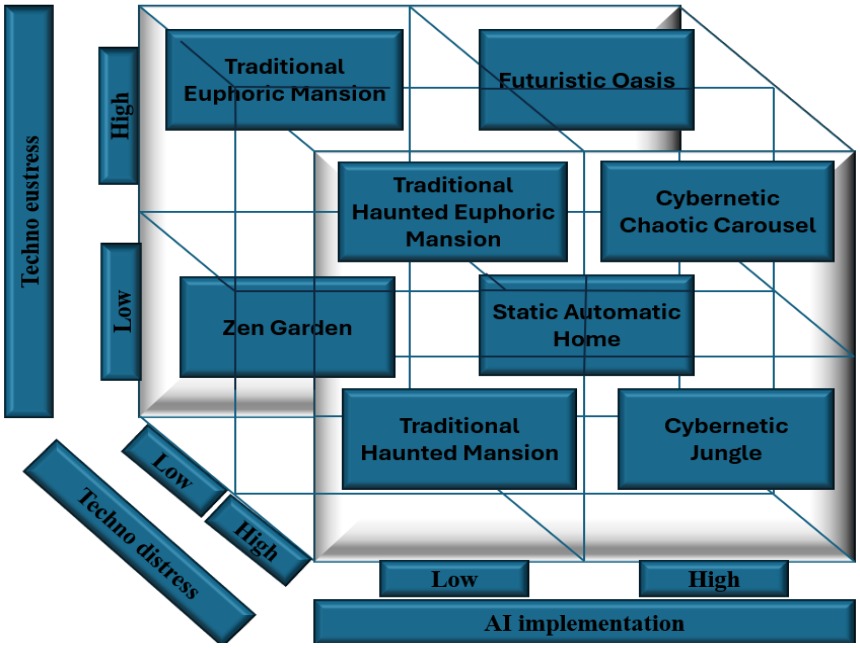

Figure 2: Three-dimensional Typology Model with AI-implementation, techno distress and techno-eustress

5 Discussion

Considering the values that AI-implementation, techno-distress, techno-eustress and productivity can assume, emerged 8 organizational typologies:

- "Zen Garden" with Low AI-implementation, Low techno-distress and Low techno-eustress. Recalling the formula described for productivity, its level is acceptable without the positive charge of AI-technologies and techno-eustress and without the negative effects of techno-distress. The actors accept a lower level of productivity.
- "Traditional Euphoric Mansion" with Low AI-implementation, Low techno-distress and High techno-eustress. The productivity is medium for the positive impact of techno-eustress, the absence of negative effects of techno-distress and the absence of positive charge of AI-technologies.
- "Traditional Haunted Mansion" with Low AI-implementation, High techno-distress and Low techno-eustress. The productivity is low for the absence of charge of AI-technologies and techno-eustress and for the negative impact of techno-distress.
- "Traditional Haunted Euphoric Mansion" with Low AI-implementation, High techno-distress and High techno-eustress. The productivity presents a medium-low level for the absence of positive impact of AI-technologies, for the negative effects of techno-distress and for the positive impact of techno-eustress.
- "Cybernetic Jungle" with High AI-implementation, High techno-distress and Low techno-eustress. The productivity is Low for the negative impact of techno-distress and the absence of the positive impact of techno-eustress, despite the positive charge of AI-technologies.
- "Cybernetic Chaotic Carousel" with High AI-implementation, High techno-distress and High techno-eustress. The productivity shows average levels for the positive charge of AI-technologies and techno-eustress and for the negative charge of techno-distress.

- "Static Automatic Home" with High AI-implementation, Low techno-distress and Low techno-eustress. The productivity shows averages levels for the positive impact of AI-technologies and for the absence of the positive effects of techno-eustress and of the negative effects of techno-distress.
- "Futuristic Oasis" with High AI-implementation, Low techno-distress and High techno-eustress. In this ideal organizational typology, productivity reaches optimal levels for the strong charge of AI-technologies and of the high techno-eustress and for the absence of the negative charge of techno-distress.

6 Implications, limitations and future research

This study provides interesting theoretical and practical implications.

Considering that in literature didn't emerge models of organizational typologies able to systematize and describe the relationships between AI-implementation, techno-distress and techno-eustress and their impact on productivity of workers and managers, the typologies model, that we developed, represents a step forward to allow future advancement of studies and knowledge on this topic and for the development of new and more effective management and organizational policies.

About theoretical implications, starting from this work Scholars can conduct research to modify or expand the model developed because only some variables and some factors have been considered to simplify the reality. Furthermore, Scholars can conduct field investigations, through questionnaires or interviews, and then to use this model. Then, taking into consideration, this study, only organizations that operate in business sector and considering a generic cultural context and organizational culture, Scholars can extend the work considering other sectors, cultural contexts and organizations that present different organizational cultures.

In terms of practical implications, managers can use the model to understand which organizational typology is closest to their organization, on the basis of the values assumed by AI-implementation, techno-distress, techno-eustress and productivity. In this way, they can understand what actions to realize to achieve the ideal typology of "Futuristic Oasis" that maximizes productivity. To give just a few examples, if the organization has a typological configuration that is far from the ideal one, managers can act on organizational levers to encourage the insertion of AI-technologies into the context by reducing techno-distress as much as possible and increasing the techno-eustress and this: through the creation of a specific department with the task of promoting the implementation of AI and of managing and resolving all the problems and doubts that may arise from its use; through the organization of periodic training courses to develop greater awareness of the potential of these technologies and to develop greater skills in the organizational actors who will have to use them; acting on specific mechanisms, such as those of rules or of the group, to encourage their harmonious integration without negative consequences; promoting correct communication aimed at bringing out all the problems that actors face in the use of AI-technologies; providing incentives, material or immaterial, to stimulate the motivation of the actors to accept the challenge and to use AI-technologies by looking at them in a positive and no longer negative way; or again, encouraging a generational exchange by ensuring that young technological natives, who have greater skills and familiarity in the use of AI-technologies, provide support and transfer their knowledge to differently young actors who, having lived between two technological eras profoundly different, have greater difficulty in approaching the new that is advancing. It is clear how all these organizational initiatives, together with many others, can have a positive impact on the variables AI-implementation and techno-eustress and a negative impact on techno-distress, guaranteeing a notable increase of productivity and, finally, of overall performances.

About limitations, the first is related to the nature of the topic in continuous evolution. So, the contribution will require to be constantly updated. Furthermore, this is an initial work that considers only some variables and contexts. We advise Scholars to carry out empirical studies for a better and more extensive understanding of the variables considered with reference to a greater number of organizational contexts. Finally, we advise to expand the study also considering other factors such as personality traits, personal factors, cultural contexts and organizational cultures.

AI-technologies are running fast. If we want collaborate with these technologies, we must learn to know them, to understand their positive and negative effects and to understand how to manage them identifyng and spreading those organizational practices that will help to maximize productivity creating an explosive fusion between Artificial Intelligence and Human Intelligence.

7 Ethics declaration

The research has not required ethical clearance and has been conducted in compliance with ethical principles that inform scientific research.

8 AI declarations

I declare that I have not used, in any step of paper writing, AI tools or applications.

The Integration between Artificial Intelligence, Knowledge Management, and Collaborative Innovation for the Creation of Sustainable Value in Industry 5.0

Anna Turchetta[1], Sara Gigli[2]
[1]Independent PhD
[2]University of Cassino and Southern Lazio, Cassino, Italy

Abstract

Over the past two decades, digital transformation has increasingly created links between human beings and technology (Nahavandi, 2019; Eriksson et al., 2024). We have moved from a company managed solely by human intelligence to a hybrid system where human talent is fused with artificial intelligence. At the same time, it is proven that the enhanced intellectual capital (eIC) helps intellectual property rights (IPR) intensive companies to innovate their business models (Trequattrini et al., 2022). Improving existing work and service experiences and enhancing sustainability are the goals of Industry 5.0 (Sindhwani et al., 2022). This led to a more efficient use of resources than Industry 4.0 (Demir et al., 2019) and a greater attention to human beings. While the Industry 4.0 model is firmly centred on technology, Industry 5.0 brings back the Human-Centric (HC) paradigm (Fani et al., 2024). In this Human-Centric (HC) perspective, human skills, interaction, critical thinking, and interpretation become a strong point again (Nahavandi, 2019). The lack of a Human-Centric (HC) paradigm can lose the potential positive effects of introducing new technologies (Carlsson, 2023; Olsson et al., 2025). Industry 5.0 is characterised by the importance of "concepts of sustainability, bioeconomy, and a collaborative environment of technology and human beings, thus establishing a resilient industry that incorporates human social values" (Sindhwani et al., 2022, p. 2).
This paper aims to study integration between artificial intelligence, knowledge management, and collaborative innovation for creating sustainable value, focusing on Industry 5.0. The interest is to see research progress on the Human-Centric (HC) paradigm.
The methodology used is content analysis (Krippendorff, 2018) on the final versions of demonstrators, pilots, and prototypes downloaded from the CORDIS EU website (https://cordis.europa.eu). The sample examined comprises six Effective Industrial-Human Collaboration Cluster Members projects. A quantitative analysis (counting the frequency of each category of codes, counting the words that make up each PDF file) and a qualitative (interpretation of the verbal expressions contained in the text) analysis were carried out. An analysis of the primary existing literature on the subject of artificial intelligence, Industry 5.0, and human intelligence was conducted before proceeding to the case study.
Among the limitations of this research is the availability of a small amount of information. It is crucial to notice that this is only the first step of the research on this subject. In the future, we want to have greater contact with companies operating in Industry 5.0 to carefully monitor the flow of knowledge in the internal system.

Keywords: Industry 5.0, Artificial intelligence, Human-centred approach, Knowledge creation, Knowledge management

Paper type: Academic Research Paper

1 Introduction

Recently, attention on human well-being in the workplace has become crucial in organizations through Industry 5.0 (Xu et al., 2021; Rožanec et al., 2023). Industry 5.0 is characterised by the importance of "concepts of sustainability, bioeconomy, and a collaborative environment of technology and human beings, thus establishing a resilient industry that incorporates human social values" (Sindhwani et al., 2022, p. 2).

Industry 5.0 returns the Human-Centric (HC) paradigm (Fani et al., 2024). The lack of it can cause the loss of potential positive effects of introducing new technologies (Carlsson, 2023; Olsson et al., 2025). The development of new technology, combined with artificial intelligence, has increased the automation of many activities, leading to a potential job disruption for middle management (Margherita and Braccini, 2021). At the same time, it is proven that the enhanced intellectual capital (eIC) helps intellectual property rights (IPR) intensive companies to innovate their business models (Trequattrini et al., 2022).

Today, there are more and more hybrid companies characterised by the centrality of the human being, a flat and fluid organisational structure, an innovative entrepreneurial culture, and greater awareness (Nahavandi, 2019; Nappo, 2020; Eriksson et al., 2024). Then the theme of intelligence is connected to intellectual capital that is divided into three different components: human capital, relational capital, and structural capital (Steward, 1991; Roos and Roos, 1997; Bontis, 1998; Youndt et al., 2004; Trequattrini, 2008; Trequattrini et al., 2022).

We use content analysis methodology (Krippendorff, 2018) on the final versions of demonstrators, pilots, and prototypes downloaded from the CORDIS EU website (https://cordis.europa.eu). The sample examined comprises six Effective Industrial-Human Collaboration Cluster Members projects. A quantitative analysis (counting the frequency of each category of codes, counting the words that make up each PDF file) and a qualitative (interpretation of the verbal expressions contained in the text) analysis were carried out. An analysis of the primary existing literature on the subject of artificial intelligence, Industry 5.0, and human intelligence was conducted before proceeding to the case study.

Our research question is:

- *What is the state of the art of integrating artificial intelligence, knowledge management, and collaborative innovation for creating sustainable value in Industry 5.0?*

2 Literature review

Industry 5.0 works to create a sustainable, human-centric, and resilient manufacturing industry with more flexible and adaptable production processes (Breque et al., 2021; Eriksson et al., 2024). The aim is to put the worker's well-being at the centre of the production process (Xu et al., 2021; Rožanec et al., 2023).

Ivanov (2023) states that if companies utilise Industry 5.0 properly, it can help them to improve efficiency and productivity while increasing resilience, sustainability, and viability of their manufacturing and supply chains. According to the European Commission (2024), "human centricity is a multidimensional framework that places human needs, characteristics, motivation, and experiences at the centre of design, development, and implementation of technological solutions and organisational practices that not only meet functional requirements but also enhance human well-being, capabilities, skills, and working conditions" (EC, 2024, p. 14).

Over the past two decades, digital transformation has increasingly created links between human beings and technology (Nahavandi, 2019; Eriksson et al., 2024). We have arrived at hybrid companies from a company managed solely by human intelligence. Hybrid companies are characterized by the centrality of human beings, a flat and fluid organizational structure, an innovative entrepreneurial culture, and greater awareness (Nappo, 2020). Human knowledge sharing is a complex phenomenon influenced by different elements such as human factors, organizational traits, and the environmental context (Zbuchea et al., 2019).

The development of technology, combined with artificial intelligence, has increased the automation of many activities. This led to a potential job disruption for middle management (Margherita and Braccini, 2021). At the same time, it is proven that the enhanced intellectual capital (eIC) helps intellectual property rights (IPR) intensive companies to innovate their business models (Trequattrini et al., 2022).

The theme of intelligence is connected to intellectual capital, an intangible company asset. Intellectual capital is divided into three different components: human capital, relational capital, and structural capital (Trequattrini, 2008). The intangible value of human skills like expertise, knowledge, and experience is called human capital (Pradana et al., 2020). The relational capital is the set of relationships between the company and its stakeholders (Hayaeian et al., 2022). Structural capital is "the knowledge embedded within the routines of an organization" (Bontis et al., 1999, p. 398). Over the years, several definitions of intellectual capital have been formulated (Steward, 1991; Roos and Roos, 1997; Bontis, 1998; Youndt et al., 2004). Intellectual capital is an essential determinant of the company's ability to create value (Trequattrini, 2008; Celenza and Rossi, 2014; Bartolini et al., 2021; Ahmad et al., 2023).

Improving existing work and service experiences and enhancing sustainability are the goals of Industry 5.0 (Sindhwani et al., 2022). This led to a more efficient use of resources than Industry 4.0 (Demir et al., 2019) and a greater attention to human beings. While the Industry 4.0 model is firmly centred on technology, Industry 5.0 brings back the Human-Centric (HC) paradigm (Fani et al., 2024). In this Human-Centric (HC) perspective, human skills, interaction, critical thinking, and interpretation become a strong point again (Nahavandi, 2019). The lack of a Human-Centric (HC) paradigm can lose the potential positive effects of introducing new technologies (Carlsson, 2023; Olsson et al., 2025).

Industry 5.0 is characterised by the importance of "concepts of sustainability, bioeconomy, and a collaborative environment of technology and human beings, thus establishing a resilient industry that incorporates human social values" (Sindhwani et al., 2022, p. 2). A human-centric, resilient supply chain capable of identifying, analysing, and accelerating operations to reduce demand fluctuation by merging human values with disruptive technology is created by Industry 5.0 (Modgil et al., 2022; Sonar et al., 2025).

3 Methodology

This study adopted the content analysis methodology (Krippendorff, 2018). As stated in the book "Content analysis: An introduction to its methodology" by Klaus Krippendorff, content analysis is a research methodology that can be used quantitatively and qualitatively. Its application is based on systematically analyzing texts, images, or other forms of communication to extract useful information to answer specific research questions. From a quantitative point of view, analysis can be used to count the frequency of certain symbols, words, or categories in a text. This approach is less in-depth from an interpretive perspective, but it gives you a clear overview of trends or patterns within your data. When content analysis is used qualitatively, the data is presented in words and themes, allowing the underlying meaning of the content to be interpreted. Qualitative analysis explores verbal expressions more deeply and seeks to understand the social or emotional contexts behind subjects' statements. Content analysis approaches can be inductive and deductive, and the researcher can choose whether to adopt a manifest analysis, which describes what is being said, or a latent analysis, which seeks deeper meanings in the text. Content analysis is, therefore, a flexible and accessible methodology used to interpret textual data and maintain integrity.

The sample examined comprises six Effective Industrial-Human Collaboration Cluster Members projects. Table 1 shows that each received an EU contribution under Horizon 2020, and they generally ran between 2018 and 2022.

Table 1**:** The Effective Industrial-Human Collaboration Cluster Members

Project name	**Amount of EU contribution**	**Period**
THOMAS	4.510.700,00 €	1 October 2016 – 31 March 2021
COLLABORATE	6.864.600,00 €	1 October 2018 – 31 March 2022
HR-Recycler	6.986.573,75 €	1 December 2018 – 30 November 2022
SHAREWORK	7.351.467,51 €	1 November 2018 – 31 October 2022
SHERLOCK	7.939.022,50 €	1 October 2018 – 30 September 2022
ROSSINI	7.978.176,25 €	1 October 2018 – 31 March 2022

Source: our elaboration

This research used secondary sources, such as the final versions of demonstrators, pilots, and prototypes downloaded from the European Union website. A quantitative analysis (counting the frequency of each category of codes, counting the words that make up each PDF file) and a qualitative (interpretation of the verbal expressions contained in the text) analysis were carried out.

The content analysis was conducted using MAXQDA software, which allows for synthesizing a single work project from the various codes previously created by reading the documents. We created the following codes:

- Security and its synonyms;
- Industry;
- Cooperation;
- Robot;
- Knowledge and its synonyms;
- Human and its synonyms.

For each of these codes, a lexical search was launched using the MAXQDA software, which aimed at quantifying the absolute frequencies of the words making up each code category. This process allows you to see how much a topic is present within each document and how it is addressed.

Table 2 shows the number of documents available for each project and downloaded from the CORDIS EU website (https://cordis.europa.eu).

Source: our elaboration

The projects with zero documents didn't upload final reports into the "demonstrators, pilots, prototypes" section. We analyzed these elements because "the prototype view underpins the behavioral assumptions behind most extant research on organizations and categorization" (Durand and Paolella, 2013, p. 1103).

4 Results and discussion

From a first reading of the results documents, we understood the object of each project.

Thomas worked for a mobile dual-arm robotic worker with embedded cognition for hybrid and dynamically reconfigurable manufacturing systems. Particularly, it aims to create dynamically reconfigurable shopfloors thanks to mobile robots with two arms, equipped with cognitive capabilities. Its experimentation in the automotive sector demonstrated a sound reduction of operating costs and increased security.

Collaborate stands for Co-production CeLL performing Human-Robot Collaborative AssEmbly. Its three documents show that it has developed a co-production cell where humans and robots collaborate to perform assembly activities. The system architecture is based on a modular platform integrated with ROS (Robot Operating System), including sensors, adaptive control modules, gesture and voice recognition systems, and AGV mobile robots.

Experiments conducted by Sherlock demonstrated clear gains in performance, ergonomics, and operator acceptance relative to previous HRC applications.

Finally, Rossini developed a collaborative robot prototype for the assembly of elevator panels, which is also suitable for general applications.

Analyzing the word frequency in these reports, the most common word is "robot", as shown in Figure 1.

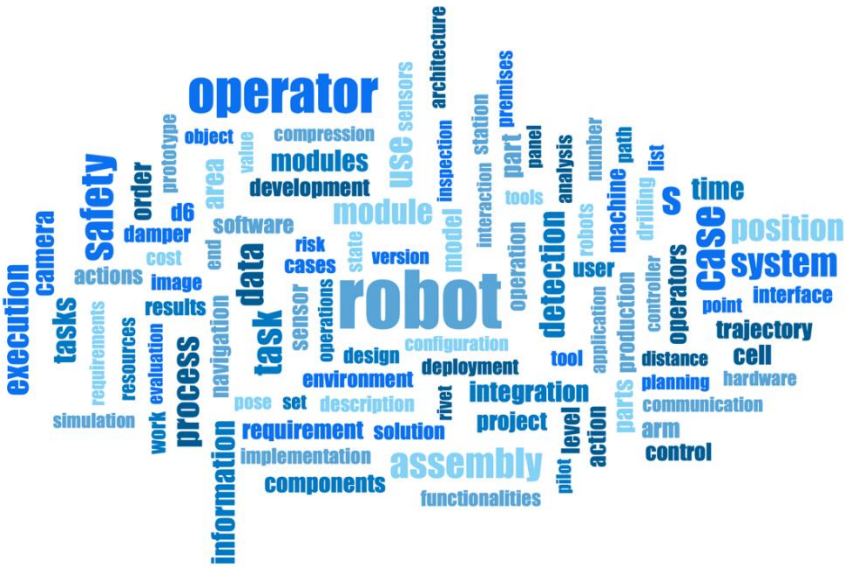

Figure 1: Word cloud
Source: our elaboration with MAXQDA software

The most standard combinations are: human robot (83 times), collaborative robot (62 times), robotic manipulator (57 times), robot interaction (56 times), and mobile robot (54 times). The collaboration between humans and machines is linked to the fifth industrial revolution that facilitates robots and skilled labor to work together to produce customized products and services in Industry 5.0 (Sindhwani et al., 2022). While the Industry 4.0 model is firmly centred on technology, Industry 5.0 brings back the Human-Centric (HC) paradigm (Fani et al., 2024). Other examples of human–robot collaboration are in previous literature like Gervasi et al. (2020), Pizon et al. (2022), and Hosseinian-Far et al. (2023) (Fani et al., 2024). Introducing robots into the industry is a delicate process because lacking a Human-Centric (HC) paradigm can lose the potential positive effects of introducing new technologies (Carlsson, 2023; Olsson et al., 2025). It is interesting to note that the term robot is widely cited in the analyzed documents. Yet, its usage ranges from technical specifications to collaboration scenarios, without clearly indicating whether such interactions are framed from a functional, ergonomic, or ethical standpoint.

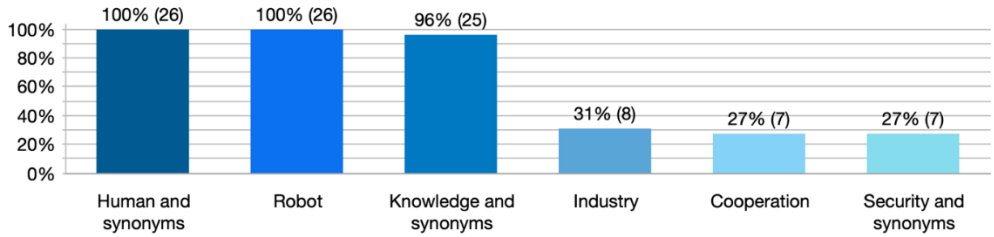

Figure 2: Documents with code
Source: our elaboration with MAXQDA software

Figure 2 shows that the only two codes in all 26 documents imported into the software are "human and synonyms" and "robot". This result aligns with the Industry 5.0 central focus, which promotes the presence of both humans and machines (Demir et al., 2019; Sindhwani et al., 2022). The models of value creation, production, and consumption are reshaped by adaptive robots (Xu et al., 2021; Ghobakhloo et al., 2023). Interestingly, they are only present in seven documents "security and synonyms" and "cooperation" codes. The European Commissioner for Innovation, Research, Culture, Education and Youth, Iliana Ivanova, says that "the notion of human centricity puts core values and principles such as trust, security, openness and inclusiveness at the heart of technology development. (European Commission, Directorate-General for Research and Innovation, 2024, p. 4). So, it is interesting that a central theme, such as worker safety, is only present in 27% of the documents analyzed.

5 Conclusions

Recently, companies have become hybrid systems where humans work together with technology (Nahavandi, 2019; Nappo, 2020; Eriksson et al., 2024). Human factors, organizational traits, and the environmental context are all elements that influence human knowledge sharing (Zbuchea et al., 2019). This phenomenon impacts intellectual capital, an essential determinant of the company's ability to create value (Trequattrini, 2008; Celenza and Rossi, 2014; Bartolini et al., 2021; Ahmad et al., 2023). In addition, new technologies, such as adaptive robots, reshape value creation models (Xu et al., 2021; Ghobakhloo et al., 2023).

This research studies integrating artificial intelligence, knowledge management, and collaborative innovation to create sustainable value, focusing on Industry 5.0. Improving existing work and service experiences and enhancing sustainability are goals of Industry 5.0 (Demir et al., 2019; Sindhwani et al., 2022). The focus is on research progress on the Human-Centric (HC) paradigm (Nahavandi, 2019; Carlsson, 2023; Fani et al., 2024; Olsson et al., 2025). In particular, we have analysed the results obtained from six projects that are the Effective Industrial-Human Collaboration Cluster Members and recipients of European funding from the Horizon 2020 program. A content analysis (Krippendorff, 2018) was conducted on 26 final versions of documents relating to demonstrators, pilots, and prototypes.

The research shows that the most common word is "robot" with the following combinations: human robot (83 times), collaborative robot (62 times), robotic manipulator (57 times), robot interaction (56 times), and mobile robot (54 times). Then, "human and synonyms" and "robot" are the only two codes in all 26 documents imported into the software MAXQDA. The "robot" term ranges from technical specifications to collaboration scenarios, without clearly indicating whether such interactions are framed from a functional, ergonomic, or ethical standpoint.

At the same time, it is interesting to see that a central theme, such as worker safety, is only present in 27% of the documents analyzed. These results partially align with the Industry 5.0 theory, especially the collaboration with humans and robots. Still, at the same time, the absence of a security theme in a large part of the documents isn't a good signal for creating sustainability value.

The main limit of this research is the small sample size and the availability of information. Notably, even if in the Effective Industrial-Human Collaboration Cluster there are six members, only for four of them we found final versions of documents relating to demonstrators, pilots, and prototypes on the CORDIS EU website (https://cordis.europa.eu). It is crucial to notice that this is only the first step of the research on this subject. In the future, we want to have greater contact with companies operating in Industry 5.0 to monitor the flow of knowledge in their internal system carefully.

6 Ethics declaration

This study did not require ethical approval because we used public data.

7 AI declaration

No AI-assisted technologies were used in this manuscript. We only used MAXQDA software without the AI tool.

Creative Urban Spaces: A Collaborative and Organisational View

Mauro Romanelli[1], Alexandra Zbuchea[2], Monica Bira[2]
[1]University of Naples Parthenope, Naples, Italy
[2]National School of Political and Administrative Studies, Bucharest, Romania

Abstract

The urban development processes rely on cities and urban communities that make efforts to support initiatives and policies that enhance the aims and the implementation of sustainable issues within urban spaces. In particular, cities are going smart not only by investing human and organisational energies to make technology as a driver for sustainable urban growth, but also promoting cultural, civic and creative assets and inputs that make the city a culture-led and knowledge-driven socially innovative urban community, opening to creative urban spaces. Post-industrial cities increasingly are working to make and develop creative collaborative urban spaces. Cities of tomorrow will invest knowledge sources in driving creative-led and culture-driven initiatives that contribute to making collaborative urban spaces and driving sustainable and inclusive urban growth, leading to community development and engagement. The future of urban growth relies on promoting culture as an opportunity to develop inclusive and cohesive communities that contribute to making creative urban spaces. Creative hubs develop bottom-up initiatives, by involving artists and other creatives who are able to meet the needs of an artistic community, making creative meeting places as well as urban spaces. Creative urban spaces develop creativity-led processes and rely on creative cities and hubs as socially inclusive communities that rediscover the importance of collaborative innovation as a framework that helps shape wealthy urban spaces into engines of social innovation. The study aims at investigating the relationships between creative cities and hubs that are following a collaborative view to organisational as well as urban spaces, in order to drive social innovation and achieve social sustainability within creative urban spaces.

Keywords: creative cities, creative hubs, collaborative spaces

Paper type: Academic Research Paper

1 Introduction

Creative cities promise sustainable urban growth and urban innovation engaging the urban citizenry and communities, leading to open urban creative spaces for collaborative frameworks. Creativity and culture contribute to rethinking urban redevelopment within post-industrial cities. Creative cities contribute to creative urban spaces following a creative-led view to urban growth and social development (Evans, 2009), shaping community-led innovation processes (Hall, 2000). As engines of culture-led and creative communities, cities shape urban creative processes (Florida, 2005), leading to urban community development, and driving social and economic growth (Anttiroiko, 2014), facilitating the rise of creative hubs, bottom-up initiatives, developed by artists and other creatives (Boswinkel and van Meerkerk, 2022) that are able to meet the needs of an artistic community or group. Culture, community, and creativity help support the collaborative frameworks leading to urban redevelopment, knowledge management and social innovation processes (Grodach, 2017; García, Eizaguirre, and Pradel, 2015; Romanelli and Zbuchea, 2020). Arts and culture help shape creativity, leading to an urban allure that fosters the city a magnet for cultural and creative urban growth (Goldberg-Miller, 2019).

The idea of conceiving creative cities as engines of collaborative spaces develops within post-industrial societies and relies on promoting culture-led activities that contribute to social and economic urban growth, enhancing energies, collective intelligence, knowledge sharing, and management, emerging issues within urban spaces. A creative city helps to rethink urban human-led and culture-driven innovation, influencing the choices of urban development and planning (Anttiroiko, 2014). Creative- and culture-led initiatives shape urban creative-led processes and improve urban social cohesion by involving urban communities in collaborative frameworks (Miles and Paddison, 2005).

The study aims to elucidate how the relationship between creative cities and hubs helps support socially collaborative frameworks for urban innovation. The rise of creative cities is opening to cooperative as well as organisational urban spaces for innovation. While there are studies that focus on several aspects that concern the rise and development of creative cities, few studies investigate the relationships between the creative city and the role of creativity-led urban projects and initiatives that support the rise of urban hubs, and contribute to social innovation processes within urban communities, fostering collaborative innovation that supports creative-led urban processes (Sørensen and Torfing, 2011). Culture, urban regeneration, and creative city develop engines of collaborative framework and drive social innovation and value (Della Lucia and Trunfio, 2018). Creative urban spaces contribute to social and knowledge innovation, developing conditions for urban

hubs' creation. Urban and artists' creativity helps shape the city an organisational space and social organism that strengthens creative and innovative ideas, energies, and resources emerging within urban communities in order to involve all the urban stakeholders that contribute to urban social value creation and innovation. The study is articulated in five sections. After introduction and theoretical background on creative cities and collaborative spaces, the methodological section follows in the third paragraph. Findings and results of the analysis on creative cities and hubs that support the making of creative urban spaces are elucidated in the fourth section. Finally, discussion and conclusions are set out.

2 Creative cities within collaborative spaces

Creativity, innovation and culture-led activities help the city to shape creative as well as organisational pathways to urban growth by fostering collaborative practices. A creative city supports a democratic and community-led process of social inclusion (Vivant, 2013), leading to bottom-up processes that help address social issues and innovation (Pratt, 2008). Creative cities promote culture-led urban development to support social-led urban growth (Power and Scott, 2010). Creative cities provide a place for engendering collaborative practices (Catungal and Leslie, 2009), relying on a creative milieu that supports social change (Betlej and Kaucerauskas, 2021). Creative cities develop open and meeting places for interaction and collaborative actions, by involving profit and no-profit urban stakeholders to construct a pathway for social innovation and value creation (Montanari, Mattarelli, and Scapolan, 2020). Collaborative spaces provide opportunities for the development of collaborative innovation that helps generate new and creative solutions through the collective knowledge and experience of actors that contribute to innovation genesis (Hartley, Sørensen and Torfing, 2013). Cities aim to invest in creative and innovative urban spaces, driving collaborative public-private partnerships (Kort and Klijn, 2011). Creative urban spaces enable collaborative and multi-actor involvement and innovation, supporting cooperative practices, and enabling the role of civil society in co-initiating collaborative processes (Sørensen and Torfing, 2018; Hartley, Sørensen and Torfing, 2013) that develop through collaborative spaces and foster multi-actor stakeholder collaboration to enhance the quality of life within urban communities (Sørensen and Torfing, 2011), leading to creative urban spaces, engines of collaborative innovation, that develops and implements solutions to urgent and relevant problems (Sørensen and Torfing, 2018). Creative cities contribute to engaging the urban community an engine of social change and transformation (Della Lucia and Trunfio, 2018), and structuring urban collaborative spaces (Yacoub and Hefliger, 2024), that enhance creative platforms and cross-pollination of ideas (Capdevila, 2019), and foster openness, collaboration and knowledge sharing and skills (Boutillier *et al.*, 2020).

3 Methodological section

The study employed a qualitative, descriptive and exploratory methodology to analyse how the interplay between the creative city framework and creative hubs enable the rise of collaborative as well as organisational arrangements that drive the practices and ways of working that contribute to making urban creative spaces, leading to culture-led and creative-driven urban value creation. The study is conceptual, exploratory and theoretical because the boundaries between creative cities and hubs, and the collaborative views to organisational innovation within urban spaces are not yet defined in a satisfying way. Conceptual papers regard untested relationships and aim to propose new relationships among constructs, focusing on integration and association of logical arguments, without providing data (Gilson and Goldberg, 2015). The study refers to the analysis of articles related to the rise of creative cities and hubs drivers of urban development by projects and experiences. The selected contributions are interpreted in a narrative synthesis to elucidate new perspectives and advance theoretical frameworks on emerging issues (Denyer and Tranfield, 2006; Dixon-Woods *et al.*, 2004).

4 Making creative urban spaces: a collaborative view to urban growth

Creative urban spaces are the result of the relationships and interactions between creative cities and creative hubs. The rise of a creative milieu within urban spaces is opening new opportunities for engendering conditions for value creation, leading to creative spaces and hubs, through projects and pathways, enabling all the urban stakeholders, private and public actors, to work together, developing cooperative frameworks and processes that foster social innovation.

4.1 Creative Cities

Creative cities contribute to social change and value, driving sustainable urban transformation and processes that support alliance building. The rise of cultural and creative activities within urban spaces enables the city an engine of creative communities (Florida, 2005). Creative cities rely on community-led and bottom-up initiatives that enhance the construction of social interaction and ties, by fostering community involvement (Sasajima, 2013). Culture-led and creative cities contribute to communal identity and belongingness, enhancing the sense of place and supporting a pathway for urban sustainability (Ratiu, 2013). Cultural resources, community, and creativity contribute to enhancing the collaborative view of urban redevelopment. A creative city develops by producing new knowledge and social capital relying on creative industries and workforces that contribute to the city's cultural life (Pratt, 2008). Urban creative processes and pathways let the city develop an effective urban community and engage the community, and reinvent sustainable urban futures, whereas the creative city model enhances a collaborative view of urban regeneration (Della Lucia and Trunfio, 2018). Culture enable cities to revitalize urban spaces for community development and re-orient the pathway of social growth, strengthening the local resources that open creative ideas and innovation. Urban and cultural spaces drive the rise of creative city an engine of community engagement and development in order to produce social issues and innovation (Della Lucia and Trunfio, 2018). Culture is an asset for identifying organisational frameworks that empower creative-led urban communities, and construct conditions for knowledge creation and social value. Culture-led urban regeneration processes contribute to shaping urban creative spaces and places through multi-actor cooperation by involving the local community in urban development itineraries (Pradel-Miquel, 2017). Creative cities foster urban community involvement, and engender social innovation issues and processes (García, Eizaguirre, and Pradel, 2015).

4.1 Creative hubs

Creative hubs can be organized in a network or infrastructure that is related to how they can actually support local needs, relying on artistic values and needs rather than on economic efficiency or contribution (Boswinkel and van Meerkerk, 2022). Creative hubs are usually considered both bottom-up initiatives, developed by artists and other creatives (Boswinkel and van Meerkerk, 2022) to meet the needs of an artistic community or group. Creative hubs are also the target of urban or cultural policy makers, especially where such initiatives contribute to developing local economy, and making attractive urban areas and spaces for social innovation and value creation. They are deeply depending on local economies as well as on the wider cultural diversification of the city they are located in (Pratt, 2021). Understanding how creative hubs are working is strongly linked to a rising practice associated with cultural industries and creative cities, coupled with new ways of fostering economic development. Creative hubs shape a cultural urban landscape and serve as places that enable cross-disciplinary interactions and provide platforms for both established and emerging creative professionals. The rise of creative hubs relies on cities that aim at supporting them in order to develop the social and cultural potential by experiencing constant growth (Chaloupková and Kunc, 2022). Creative hubs concentrate in those areas that have been the target of cultural and development urban policies or, generally, in central areas of a city where the proximity of urban improvements and infrastructure is more likely to ensure their economic success (Coll-Martínez and Méndez-Ortega, 2023). Creative hubs are associated by the literature with co-working spaces (Füzi et all. 2022) and maker spaces (Unterfrauner, *et al.* 2020). Creative hubs rely on a collaborative, creative space and/ or a maker space, fostering cooperative processes into a co-working space, focused on (more) on rentability (Chaloupková and Kunc, 2022), often prioritizing commercial viability over community-driven, artistic practices (Moriset, 2014). Creative hubs develop co-working spaces that favour remote workers and digital nomads, enabling a process of growth based on digitalization as well as on replicative entrepreneurship (Danko *et al.*, 2024). Creative Hubs contribute to making a network that supports the local dynamics of creativity, economy and social change (Flego and Tei, 2024).

5 Discussion and conclusions

A creative urban space makes collaborative meeting places for engendering social innovation and cooperative processes that involve the urban stakeholders to contribute to urban value creation. Urban regeneration processes rely on creativity and refers to culture-led initiatives that help shape creative and inclusive urban communities. The sustainable future of cities is creative-oriented and relies on bridging social and economic activities that contribute to wealthy and inclusive urban spaces able to generate sources and ideas, and conditions for creative solutions and projects that improve the quality of life within urban communities. As a kind of urban innovation, a creative urban space helps improve the social lives of citizens in urban environments. Urban spaces should follow a creative and sustainable pathway whereas the urban communities favour the conditions for developing more inclusive and creative urban communities that

contribute to promoting social and economic growth in order to improve the quality of life. Culture leads to communities able to develop creativity as a source that enhances social capital and collaborative processes that shape urban meeting places. Today, cities need to become creative and inclusive communities that support collaborative pathways for innovation, and contribute to sustainable urban growth, and ensure a better quality of life within urban landscapes. Culture helps creative cities to grow over time. The future of urban communities relies on cities that behave as engines of social innovation and supporters of creative ideas and forces that rely on human capital improvement and urban regeneration as drivers of social value and innovation within urban spaces. Culture-led urban regeneration processes foster community and citizen participation in cultural projects and enhance both social innovation issues and economic benefits. Creative cities and hubs contribute to strengthening urban creative forces, making creative urban spaces engines of sustainable urban development. The role of creative hubs is to restore and revitalize the creative and cultural soul of urban communities, leading to collaborative pathways and urban spaces that rely on stakeholder engagement for value creation and social innovation. This study has organisational, managerial, and social implications. Creative cities shape the urban space an organisational framework that enhances collaborative views and issues, involving several stakeholders to support urban innovation. Promoting the development of creative cities supports the design and the implementation of urban places and communities as collaborative arenas and spaces that involve all the stakeholders which are willing to construct a pathway for urban creative regeneration, and contribute to social value, knowledge creation, and innovation. Future research perspectives imply to investigate how cultural neighbours are emerging and developing within cities that aim to become creative communities that rely on requalifying the urban spaces in order to drive culture-led urban regeneration pathways that support innovation processes within cities which are becoming creative urban communities in order to improve the quality of urban life.

Abstract

This study contributes to the growing body of research on the phenomenon of zombie firms by adopting a novel perspective that links corporate zombification to CEO narcissism. In line with the behavioral corporate governance approach and the Upper Echelons Theory (Hambrick & Mason, 1984), the analysis explores how CEO narcissism can influence a firm's likelihood of entering a state of zombification. In this study CEO narcissism is measured through a composite index based on unobtrusive indicators such as the size of the CEO's photograph in the annual report, the frequency of personal pronouns in shareholder letters, and the dimensions of the CEO's handwritten signature, following the methodologies proposed by Chatterjee and Hambrick (2007) and Ham et al. (2018). Zombie firms are identified according to McGowan, Andrews, and Millot (2018), using a dummy variable that takes the value of 1 if the Interest Coverage Ratio (ICR) is below 1 for at least three consecutive years during the observation period. Using a balanced panel dataset that includes 232 publicly listed firms across five European countries (United Kingdom, Italy, France, Germany, and Spain), covering more than 2,552 firm-year observations from 2013 to 2023, we find that CEO narcissism negatively impacts on zombie firms. Specifically, the results obtained support our hypothesis, highlighting a negative and statistically significant relationship between CEO narcissism and zombification, also confirmed by the positive relationships between CEO narcissism and indicators of financial strength such as Altman's z-score, ICR and ICR2. Our results, despite all the weaknesses of the case, contribute to extend the literature that recognises CEO narcissism as a positive acceptance for the company, especially in relation to financial distress.

Keywords: CEO narcissism; Zombie firms, Behavioral corporate governance, Financial distress, Upper Echelons Theory

Paper type: Academic Research Paper

1 Introduction

The goal of the firm is to create value and avoid financial distress. In recent years, a growing body of literature has addressed the issue of "zombie firms", a term first coined by Edward Kane (1987) to identify those firms that are formally active, but economically insolvent and artificially kept alive thanks to public guarantees such as subsidies. Subsequently, various works have analysed this phenomenon in different countries and periods, developing different methods of measurement and thus contributing to the very definition of zombie firms. The earliest research on zombie firms focused on Japan in the late 1990s (e.g., Hoshi & Kashyap, 2000; Caballero, Hoshi and Kashyap, 2008; Fukuda & Nakamura, 2011) and then extended the analysis to a global scale (McGowan, Andrews and Millot, 2018). More recently, following the various financial crises, studies on zombie firms have progressively expanded by shifting the focus from the macroeconomic and financial perspective, as well as the impact of zombie firms on the credit system, to a more managerial, corporate finance, and corporate governance perspective (e.g., Fang et al., 2020; San José, Urionabarrenetxea and García-Merino, 2022; Rodríguez-Sanz, Vallelado and Velasco, 2024; Shome and Verma, 2024)

Altman et al., (2024) find that approximately 7% of the listed companies in the twenty countries with the highest GDP are classifiable as zombies.

The objective of this paper is to investigate the topic of zombie firms by adopting a different perspective than previous studies and in particular by investigating the empirical relationship between zombie firms and CEO narcissism. According to the guidelines of American Psychiatric Association (APA), narcissistic profile means: "Multifaceted personality trait that combines grandiosity, attention-seeking, an unrealistic inflated self-view, a need for self-view to be continuously reinforced through self-regulation, and a general lack of regard for others" (Diagnostic and Statistical Manual for Mental Disorders, 2013, p. 669)

Following the Upper Echelons Theory (Hambrick & Mason, 1984), the behavioural traits of CEOs impact the organisation by influencing its decision-making process. CEOs' narcissism leads them to prefer ambitious and risky strategies, which are often more oriented towards satisfying their own need for attention than meeting the company's needs (e.g., Chatterjee and Hambrick, 2007; 2011; Petrenko et al., 2016; Aabo and Eriksen, 2018; Buyl et al., 2019). However, the narcissistic trait does not always generate negative outcomes; several studies have pointed out that this trait of CEOs tends to perform better in contexts of uncertainty or crisis (e.g.,

Chatterjee & Pollock, 2017; Aabo, Kirch & Thomsen, 2024). Despite various empirical works there is a gap in the literature regarding the impact of CEO narcissism on zombie firms

Using a panel dataset of 232 listed firms in five European countries (UK, Germany, France, Spain and Italy) with a total of 2,552 firm-year observations, the present study analyses the relationship between CEO narcissism and zombie firms.

2 Literature review and hypothesis development

2.1 Zombie firms

The first studies on zombie firms are concentrated in Japan in what is called the lost decades, a period characterised by a strong allocation of credit by banks to low-productivity sectors, giving lifeblood to increasingly less profitable firms (e.g., Hoshi & Kashyap, 2000; Rodríguez-Sanz, Vallelado and Velasco, 2024). This behaviour, which disadvantages sectors with higher productivity, has contributed significantly to the spread of zombie firms in the Japanese economic fabric. Caballero, Hoshi and Kashyap (2008) analysing a sample of more than 1,800 firms during the period 1981 - 2002 find that in sectors with a higher presence of zombie firms there is stagnation in employment and slower growth of healthy firms. Andrews and Petroulakis (2019) document how the survival of inefficient firms is associated with weak banks, with negative effects on capital reallocation and aggregate productivity.

In contrast to previous studies, Fukuda and Nakamura (2011) shift the perspective of investigation by focusing on the identification of zombies through the use of firm performance indicators. More recently, a growing literature has extended the study on zombie firms in other countries by proposing new proxies for assigning zombie status. McGowan, Andrews and Millot (2018), using a sample of firms located in nine OECD (Organisation for Economic Cooperation and Development) countries, show that the prevalence of zombie firms, identified as having been in operation for at least ten years and having an Interest Coverage Ratio (ICR) of less than 1 for at least three consecutive years, increased between 2003 and 2013. Albuquerque and Iyer (2023) document that the presence of zombie firms reduces the financial performance and probability of survival of non-zombie firms, particularly in sectors most affected by 'zombification'. Altman, Dai and Wang (2024) find that, on average, 7% of the listed firms in the twenty countries with the highest GDP were classifiable as zombies in 2020. In addition to the study by McGowan, Andrews and Millot (2018), Altman et al., (2024) extend the identification criteria by adding the negative z-score for at least three consecutive years, as well as an ICR below 1, in order to make comparisons in cross-country analyses more homogeneous.

More recent studies instead focus on the role of corporate governance in the zombification process. Fang et al. (2020), for example, examining a sample of 3,500 Chinese listed companies, find that a higher presence of female executives is associated with a reduced likelihood of zombification and corporate risk-taking. San José, Urionabarrenetxea and García-Merino (2022) find that a higher number of female CEOs is associated with a lower risk of zombification. CEOs with multiple positions on boards in companies with lower ownership concentration tend to reduce the risk of zombification. While Rodríguez-Sanz, Vallelado and Velasco (2024) point out that the separation of CEO and chairman positions, a longer CEO tenure and a board of directors with more independent members can negatively influence zombification status by allowing a faster transition to a healthy state. In light of the above, zombification would seem to depend not only on exogenous factors, such as the banking or macroeconomic environment, but also on the peculiarities of corporate governance (Shome and Verma, 2024).

2.2 CEO narcissism

CEO narcissism is a topic that has gradually gained relevance in management literature since the pioneering work of Chatterjee and Hambrick (2007, 2011), who first provided a methodology, based on non-intrusive indicators, that does not require direct interviews with CEOs. The authors describe narcissistic CEOs as overly egocentric individuals, constantly seeking admiration, who tend to overestimate their own capabilities and attribute company successes to themselves, as well as ignore failures. This area of research fits within the framework of the Upper Echelons Theory (Hambrick & Mason, 1984), according to which the psychological characteristics of leaders directly influence strategic business decisions. The innovation of this work passes through unobtrusive indicators, which were associated with the four characteristics of narcissism identified by Emmons (1987): Exploitativeness/Entitlement, Leadership/Authority, Superiority/Arrogance and Self-absorption/Self-admiration. Following this methodological approach, it is possible to observe CEO behaviour through publicly available elements such as annual reports and interviews. Specifically, Chatterjee and Hambrick

(2007) use the size of the CEO's photograph in the annual report, the number of times the CEO's name recurs in press statements, the use and number of times they use the singular pronoun in interviews, and the ratio of the CEO's monetary (and non-monetary) compensation to the second highest paid executive (Chatterjee & Hambrick, 2007). This methodology, in accordance with the meta-analysis by Cragun et al. (2019), appears to be the most effective in identifying CEO narcissism

After the seminal work of Chatterjee and Hambrick (2007), a growing interest was registered towards the topic of CEO narcissism and in particular on the relationship between CEO narcissistic traits and corporate governance. O'Reilly et al. (2014) identify a positive correlation between CEO narcissism and CEO compensation, highlighting the fact that narcissistic CEOs with a long tenure tend to have significantly higher compensation than the rest of the executives. Petrenko et al. (2016), on the other hand, document that narcissistic CEOs resort to corporate social responsibility (CSR) for self-congratulatory purposes, reducing its strategic effectiveness.

Several studies point out that narcissistic CEOs have a greater propensity for risk, fuelled by their need for grandiosity, which drives them to make riskier strategic decisions (Buyl et al., 2019). Confirming this, Tuggle et al. (2024) find that companies led by narcissistic CEOs make riskier choices, while Aabo and Eriksen (2018) document a non-linear relationship between narcissism and corporate risk-taking, an inverted 'U-shape' between narcissism and volatility stock returns. In particular, a higher and lower level of narcissism is associated with a lower level of corporate risk-taking. In a complementary vein, Zhu and Chen (2015) observe that narcissistic CEOs tend to surround themselves with compliant and like-minded executives, amplifying the growing relationship between CEO narcissism and risk-taking, as well as a greater propensity for selective hedging behaviors in financial investments (Bajo et al., 2022). In contrast, other studies have documented how firms led by narcissistic CEOs exhibit a higher likelihood of fraud, earning management practices and worse credit ratings (Rijsenbilt and Commandeur, 2013; Capalbo et al., 2018; Buchholz et al. 2020; Hou, Fairchild and Perotti, 2024)

Kim and Anderson (2024) investigating a sample of 395 firms in the US, during the period 2012-2020, test the relationship between CEO narcissism and agency cost of debt documenting a positive relationship, i.e. as CEO narcissism increases, the cost associated with debt increases. However, there is no shortage of studies showing how CEO narcissism can benefit the firm. Yang et al. (2023), for example, investigating a sample of 245 Chinese listed manufacturing firms, find that narcissistic CEOs are positively correlated with cross-boundary growth domestically and internationally. Zhang et al. (2021) find that CEO narcissism is associated with a higher propensity to innovate in order to support risky but high growth potential projects. According to Chatterjee and Pollock (2017), narcissistic CEOs perform better during financial and economic crises than non-narcissistic CEOs. This is also confirmed by Aabo, Kirch & Thomsen (2024), who, examining a sample of 820 US firms from 2007 to 2020, find that narcissistic CEOs are able to improve firm performance in periods of high uncertainty, while in periods of low uncertainty they are a disadvantageous factor for the firm. Similarly, Shirokova et al. (2024) point out that, in contexts of high uncertainty, CEO narcissism reinforces the positive relationship between strategic entrepreneurial behaviour and firm performance

Benefiting from the previous literature, we formulate the following hypothesis:

- *Hypothesis 1. CEO narcissism is negatively associated with the likelihood that a firm exhibits zombie characteristics.*

3 Methodology and data analysis

To construct the sample, we used the FactSet database, through which we acquired the financial data of the individual firms in the sample consisting of listed European companies, excluding financial and utilities companies as they are highly regulated sectors. Starting from an initial sample of 1,550 firms, and using the revenue-based thirds, 232 firms active in five European countries were identified: 100 in the UK (common law), 30 in Germany (German civil law), 30 in France, 48 in Italy and 26 in Spain (French civil law) according to the classification of La Porta et al. (1998). For each firm, data was collected for the entire period 2013-2023, which allowed us to construct a balanced panel data of 2,552 firm-year observations. Consistent with previous literature (McGowan, Andrews and Millot, 2018), the choice of an 11-year time horizon is motivated by the need to examine firms that have been in operation for at least ten years, a necessary condition for the identification of zombie firms on the basis of the ICR. Specifically, this paper defines zombie firms as all those firms that have an interest coverage ratio (ICR) of less than 1 for at least three consecutive years. Following this methodology, we identify 83 firms that have been zombies at least once during the reference period. With regard to CEO narcissism, we collected qualitative data from annual reports, retrieved from companies' websites or, where available, from www.annualreports.com adopting the 'unobtrusive' indicator approach as proposed by Chatterjee and Hambrick (2007).

The econometric model OLS (Ordinary least squares) used for the regression analysis is presented below:

$$y_{i,t} = \mu_{i,t} + \alpha_1 CEO\ NARCISISSM_{i,t} + \alpha_2 CONTROL\ variables_{i,t} + \eta_{i,t} + \varepsilon_{i,t}$$

Table 1. Variables Definitions.

Variables	Definition	Source
Dependent Variables		
ZOMBIE	Dummy variable that takes value 1 if the firm is at least 10 years old and has an interest coverage ratio (ICR) below 1 for three consecutive years at least once between 2013 and 2023	Our calculation using FactSet
Z_SCORE	Altman score	FactSet
ICR	EBIT scaled by interest expenses	FactSet
ICR2	EBITDA scaled by interest expenses	FactSet
Independent Variables		
Narcisissm	Composite index based on photo prominence, personal pronoun usage, and signature size, following Chatterjee & Hambrick (2007) and Ham et al. (2018).	Our calculation is based on annual reports, shareholder letters, and, where possible, data from www.annualreports.com.
Control Variables		
CEO_OWNERSHIP	The percentage of shares held by CEO	FactSet
CEO_TENURE	Number of years the CEO has held the position	FactSet
CEO_AGE	The age of the CEO	FactSet
BOARD_SIZE	The total number of directors sitting on the company's board	FactSet
INDEPENDENT_DIRECTORS	The number of independent directors on the board (expressed as a percentage)	FactSet
SIZE	Total assets (in logarithmic form)	FactSet
CASH_FLOW	Cash flow from operation scaled by total assets	FactSet
FIRM_AGE	Years since firm was established (in logarithmic form)	FactSet
GROWTH_SALES	Annual change in a firm's sales compared to the previous year (expressed as a percentage)	FactSet
DEBT	Financial debt divided by total assets	FactSet
ROA	Yearly net income/average total assets*100	FactSet
INDUSTRY	Four-Digit SIC (Standard Industrial Classification) codes	FactSet

Source: Author's own work

3.1 Dependent variables

The identification of zombie firms was carried out following the methodology proposed by McGowan, Andrews and Millot (2018). In order to assign zombie status, the firm must have been active for at least 10 years, a criterion met ex ante in the sampling process, and have an ICR of less than 1 for three consecutive years at least once in the time span from 2013 to 2023. If these conditions are met, the dummy zombie takes the value 1, and zero otherwise. The other dependent variables are the Altman Z-Score, the ICR and the ICR2.

3.2 CEO narcissism score

As already mentioned, CEO narcissism was measured following Chatterjee and Hambrick's (2007) approach, which is based on the use of unobtrusive indicators to estimate this psychological trait using publicly observable data, without resorting to interviews or questionnaires. The CEO narcissism score was constructed as a composite measure combining three different indicators following the methodology of Chatterjee and Hambrick (2007) and Ham, Seybert and Wang (2018). The first indicator is the size of the CEO's photo in the annual report which was assigned a score from 1 to 4 based on the presence of the photo, the size of the photo and the presence of other managers in the photo. Specifically, the score was assigned as follows: 1 in the absence of a photograph of the CEO; 2 in the presence of a photograph of the CEO together with other managers or executives; 3 if the CEO appears in the photo alone, and with a size of less than half a page; 4 if the CEO appears in the photo alone, but with a size of more than half a page.

The second indicator corresponds to the frequency of use of personal pronouns (I, me, myself) versus plural pronouns (we, us, ourselves) in the letter to stakeholders or other statements in the annual report. The indicator was calculated as follows:

$$\frac{Singular\ pronouns}{Singular\ pronouns + Plural\ pronouns}$$

The third indicator does not follow the methodology of Chatterjee and Hambrick (2007), but rather incorporates the dimension of the handwritten signature as introduced by Ham, Seybert and Wang (2018). CEO signatures were collected from annual reports and measured by constructing a minimum area touching the extreme points of each signature, which is normalised by the number of letters of the CEO. The indicator was calculated as follows:

$$\frac{Handwritten\ signature\ area}{Number\ of\ letters\ in\ the\ name}$$

The mean and standard deviation over the sample was calculated for each indicator, a process necessary to standardise the variable in question. Finally, the CEO narcissism score was obtained as the simple average of the three indicators.

Table 2. Descriptive Statistics.

Variables	Average	Median	5th	95th
Dependent Variables				
Z SCORE	2.808	2.188	-0.232	8.238
ICR	14.52	5.598	-18.21	73.11
ICR2	24.50	11.23	-7.337	98.814
Zombie firm	0.355	0.000	0.000	1.000

3.3 Control variables

In order to neutralise firm-specific effects, we used a set of control variables (FIRM_AGE, SIZE expressed through the logarithm of total assets, CASH_FLOW, ROA, GROWTH_SALES, and DEBT) selected on the basis of the existing literature (e.g. Chatterjee and Hambrick, 2007; Altman, Dai and Wang, 2024) as shown in Table 1 and 2. In addition, we considered some specific variables related to the figure of the CEO and more in general to corporate governance (CEO age, CEO tenure, CEO ownership, board size, the percentage of independent directors). Finally, we have included a set of dummies variables that capture the industry.

4 Results

Table 3 shows the results of the econometric analysis.

As can be seen, the presence of narcissistic CEOs reduces the number of zombie firms and improves the z-score, ICR and ICR2. In line with the hypothesis formulated the coefficient associated with the narcissism variable is negative and statistically significant ($p < 0.01$), in other words it reduces the probability of a firm being classified as a zombie (($\beta = -0.0419$). This result suggests that the narcissistic traits of the CEO, while often considered negative for the firm, may act as a deterrent to the financial condition typical of zombie firms.

Table 3. Empirical Estimates Using OLS

Thus, companies led by narcissistic CEOs show better solvency indicators even under conditions of crisis and uncertainty. Regarding the control variables, firm size takes on an inconsistent sign in that while it would seem to reduce the risk of zombification, it also increases the risk of financial distress. In fact, there is a positive but non-significant sign with respect to the z-score and a negative and significant sign with respect to the ICR. In line with the literature, debt shows a positive and significant relationship with zombification ($\beta = 0.3015$, $p < 0.01$), while ROA is significantly and negatively associated with zombification risk ($\beta = -0.0049$, $p < 0.01$). This means that companies with higher profitability, as expected, incur less risk of financial distress. In contrast, debt utilisation pushes firms into the zombification zone and increases their risk of financial distress

An interesting result concerns CEO age, which is positively associated with zombification ($\beta = 0.2001$, $p < 0.01$), which could mean that "greyer" CEOs tend to adopt more conservative and less risky strategies. However, the CEO age coefficient is not statistically significant compared to the other variables. Finally, both the BOARD_SIZE and INDIPENDENT_DIRECTORS coefficient would seem to reduce the risk of financial distress.

5 Conclusions

In recent years, interest in zombie firms has grown while some areas as well as the link between zombification and CEO narcissism remain unexplored. This study aims to fill this gap by analysing a sample of European firms listed in the period 2013-2023, through the construction of a dataset composed of 2,552 firm-year observations, with the objective of investigating the relationship between zombie firms and CEO narcissism. The results obtained support our hypothesis, showing a negative and statistically significant relationship between CEO narcissism and zombification, also confirmed by the positive relationships between CEO narcissism

and indicators of financial soundness such as Altman's z-score, ICR and ICR2. Our results, albeit with all the limitations of the case, contribute to extending the literature that recognises CEO narcissism as positive for the firm, especially in relation to financial distress

6 Ethics declaration

The authors state that no ethical clearance was required for the research presented in this paper. The authors also declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

7 AI declaration

The authors state that artificial intelligence tools were used for the translation and linguistic revision of English texts.

Evaluating AI's Impact in Healthcare: a Systemic Approach through Key Performance Indicators

Giuliana Cavadi, Martina Vivoli, Federico Cosenz
Università degli Studi di Palermo, Palermo, Italy

Abstract

The combination of economic crises, a growing shortage of public resources, socio-economic disparities, and demographic shifts has significantly amplified the strain on healthcare systems globally. Rising healthcare demand and the goal of universal coverage highlight the need for improved resource allocation, infrastructure, and workforce planning. AI offers significant opportunities for enhancing efficiency and service quality, yet its integration is limited by regulatory, organizational, ethical, and environmental challenges. Although the literature broadly emphasizes AI's potential, empirical evidence on its actual impact on healthcare performance remains scarce.

Based on these premises, this study proposes a comprehensive set of key performance indicators (KPIs) to assess AI's tangible effects. The proposed set of KPIs provides a practical and adaptable toolbox for healthcare decision-makers to evaluate AI-driven changes and monitor their implementation.

This paper employs a Causal Loop Diagram (CLD) approach to explore how AI influences healthcare systems, focusing on two key areas: (i) optimizing resource allocation to improve efficiency and (ii) enhanced personalized care to elevate service quality. CLDs provide a structured and dynamic framework for understanding the complex interdependencies shaping healthcare organizations. The CLD approach serves as a foundation for developing KPIs to guide managers in evaluating AI integration. By combining systems thinking with the development of KPIs, this research provides a novel methodological framework for assessing the tangible impact of AI technologies in healthcare organizations. The resulting set of KPIs measures and evaluates the effect of AI integration within healthcare organizations. It is intended to guide future research regarding AI applications to healthcare management, as well as help managers assess the impact of AI implementation in healthcare settings. This research addresses the lack of empirical validation regarding the impact of AI in healthcare organizations by providing a set of indicators for evidence-based decision-making. Thus, it contributes to both academic research and practical applications of AI in healthcare management.

Keywords: Healthcare, Performance Management, Artificial Intelligence, Key Performance Indicators, Causal Loop Diagrams.

Paper type: Academic Research Paper

1 Introduction

Healthcare organizations operate within a rapidly evolving, intricate, and dynamic environment characterized by continuous changes and challenges (Homer & Hirsch, 2006).

Healthcare systems face constrained funding and rising demand from aging populations with complex needs (Khan, 2023), increasing pressure to optimize limited resources while maintaining care quality (Meskó et al., 2018). Against this backdrop, a shift to alternative paradigms of healthcare management seems necessary (Vainieri et al., 2020).

By addressing the dual pressures of financial constraints and growing patient demands for high-quality care (Bohr & Memarzadeh, 2020; Hindriks & Meyer, 2019), Artificial Intelligence (AI) stands out as a powerful means to significantly reshape both clinical and management practice (Brem et al., 2021; Briganti & Le Moine, 2020; Dicuonzo et al., 2023). An emerging body of literature explores the interplay between AI and healthcare (Secinaro et al., 2021), highlighting the potential of AI to improve administrative processes (Bhuyan et al., 2025; Glover et al., 2022), medical service quality, and, consequently, patient outcomes (Bates et al., 2021; Choudhury & Asan 2020; Su et al., 2020). As AI technologies continue to evolve and are expected to impact almost all medical fields (Haleem et al., 2019), it seems increasingly essential to critically assess their effects on healthcare organizations. Some studies also highlight the need to empirically assess the impact of AI on clinical practice, alongside its broader implications for organizational performance (van Leeuwen et al. 2022; Wu et al., 2021). However, although the literature generally expresses enthusiasm about the potential benefits of AI in healthcare, the empirical validation of these claims remains limited, particularly in the field of performance management (Di Falco et al., 2024), raising significant concerns about the extent to which AI can positively affect the performance of healthcare organizations.

Building on this foundation, the study focuses on the validity of claims regarding the positive impact of AI integration on healthcare performance, the extent of such effects, and how they can be evaluated. To effectively

answer the research questions and address a gap in empirical evidence, this study, after framing the potential effects of AI on healthcare systems as discussed in the literature through a Causal Loop Diagram (CLD) analysis, proposes a comprehensive set of key performance indicators (KPIs) designed to objectively measure the impact of AI technologies. In particular, this study focuses on two directions of research that could be impacted through AI integration in management practice: (i) optimization of medical resource allocation and (ii) provision of highly personalized care, fostering a patient-centered approach.

Following this introduction, the next section explores AI's potential in healthcare, focusing on resource optimization and personalized care. Section 3 describes the research approach, while Section 4 presents insights derived from the CLD-based analysis. Finally, Section 5 introduces a tailored set of KPIs to measure AI's impact in these contexts. Lastly, Section 6 discusses key insights emerging from the study and future research directions.

2 AI in healthcare systems: towards optimized resource allocation and improved personalized medicine

Thanks to sophisticated algorithmic architectures and connected capabilities, AI has been utilized or tested in various healthcare applications, particularly in reducing clinical staff workload, enhancing healthcare provision and prevention, supporting diagnosis and treatment, and enabling patient monitoring (Kocakoç, 2022; Saraswat et al., 2022). Hence, while the literature highlights barriers to AI integration (Ahmed et al., 2023), AI is expected to revolutionize healthcare management paradigms and clinical practices to ultimately enhance patient and community outcomes (Bohr & Memarzadeh, 2020; Chen & Decary, 2020; Davenport & Kalakota, 2019). Two emerging themes in the literature exploring the potential of AI in healthcare focus on resource optimization (Dawoodbhoy et al., 2021; Huang et al., 2021; Kasula, 2023a; Wu et al., 2023) and personalized healthcare (PHC) (Blasiak et al., 2020; Khan et al., 2020; Li et al., 2024; Schork, 2019; Subramanian et al., 2020).

In a resource-constrained sector like healthcare, AI technologies represent a groundbreaking tool in resource allocation and optimization, as they can potentially improve resource planning and efficiency (Deloitte, 2024). By accurately forecasting incoming workloads, AI can timely adjust resource allocation and staffing strategies, thereby optimizing operational efficiency and mitigating bottlenecks (Rathore et al., 2023). Additionally, AI-driven decisions on resource allocation can benefit healthcare professionals by ensuring an adequate workload (Badshah, 2024). Moreover, AI-driven predictive maintenance reduces costs and optimizes resource use by enabling early fault detection and minimizing equipment downtime (Shamayleh et al., 2020). In the supply chain domain, AI-driven demand forecasting optimizes procurement and inventory, preventing shortages and overstock, and reducing lead time (Khan et al., 2024; Kudrenko, 2024). This improves medical supply chain efficiency, enhancing resource management and allocation (Kasula, 2023b). Moreover, AI's data processing and pattern recognition optimize resource allocation and patient outcome prediction, reducing relapse risks and enhancing service quality and efficiency (Guo et al., 2021; Maeda et al., 2022).

PHC aims to tailor treatments to individual patient characteristics to improve outcomes (Lorkowski et al., 2021; Nardini et al., 2021). Traditional approaches face challenges in analyzing the extensive data required for personalized care. In contrast, AI technologies can process diverse data sources to enhance treatment accuracy and effectiveness (Alowais et al., 2023; Hindriks & Meyer, 2019). Furthermore, integrating AI in personalized medicine can improve disease discovery, treatment strategies, and drug administration, thereby advancing prevention, diagnosis, and individualized care (Awwalu et al., 2015; Taherdoost & Ghofrani, 2024).

Although the benefits stemming from the use of AI are acknowledged in specific clinical practices, particularly in diagnostic imaging (Jones et al., 2022; Rajpurkar et al., 2022), real-world clinical implementation remains limited (He et al., 2019; van Leeuwen et al., 2022). Moreover, empirical evidence validating its impact on performance management systems in healthcare organizations is even more scarce (Di Falco et al., 2024).

3 A systemic approach to mapping AI-related dynamics in healthcare organizations

To illustrate the dynamics of AI integration in healthcare organizations as highlighted in the literature, this research employs the CLD approach, a framework extensively used in the study of health systems (Beaulieu et al., 2022; Bradley et al., 2020; Cassidy et al., 2022; Gaveikaite et al., 2020; Katsamakas & Pavlov, 2020; Linnéusson et al., 2022). This method provides a visual representation of the interconnected effects of AI implementation, supporting the development of the indicators measuring its potential benefits within the healthcare system.

Rooted in systems thinking, an approach designed to deal with dynamic and complex environments such as healthcare organizations (Peters, 2014; Senge, 1990), CLDs capture a system's causal relationships and feedback loops, providing a language to express the dynamic nature of systems (Kim, 1992). While conventionally

employed as a supportive tool for quantitative modeling, CLDs have found independent application in system description and policy analysis, documenting relevant factors and their causal relationships (Wolstenholme, 1999). By facilitating the understanding of how behaviors manifest within a system and how to develop strategies to work with or counteract these behaviors, and by articulating the causalities between elements of the system, CLDs illustrate how these variables form dynamic circular influences rather than linear relationships. They build coherent narratives about specific problems by linking key variables and indicating their causal relationships (Haraldsson, 2004).

In summary, the CLD approach goes beyond traditional causal diagrams by identifying balancing and reinforcing feedback loops to provide an understanding of system structure and dynamics, enabling the design and evaluation of interventions (Hanger-Kopp et al., 2024). CLDs help visualize the connections between variables and reveal the underlying structure and dynamics of complex systems, serving as a foundation for developing indicators to measure AI's potential benefits within the healthcare system.

4 Dynamics of AI integration in healthcare organizations: insights from CLD analysis

By framing the potential benefits of AI implementation through a systems thinking method – whose CLDs represent the visual output – the research provides a systemic and dynamic perspective, highlighting the causal relationships between AI-driven efficiency gains, resource allocation, and improvements in patient care. The findings from the literature are summarized in the CLD depicted in Figure 1, representing the dynamics generated by integrating AI into a healthcare system.

The CLD illustrates the dynamics of hospital resource management and patient flow, incorporating the effects of AI integration on healthcare system efficiency and quality of health services. The diagram highlights several feedback loops shaping hospital performance. Loop R1 shows that increasing waiting times can extend the waiting list, which further exacerbates delays and discourages new admissions. In R2, higher patient inflow accelerates resource depletion, reducing capacity, lengthening treatments, and lowering discharge rates, reinforcing patient accumulation.

Balancing loops B1 and B3 capture how improved satisfaction and hospital image attract more service requests, which increase waiting times and ultimately reduce satisfaction. Loop B2 shows that rising patient numbers deplete resources, reducing capacity and limiting admission rates.

Loops B4 and B5 show that increased demand pressures infrastructure and HR workload, undermining service quality and staff motivation, which in turn reduce satisfaction and control demand. B6 and B7 link service quality to clinical relapse: more readmissions intensify patient flows, feeding back into longer waits and greater strain on capacity.

The implementation and continuous improvement of an AI algorithm for resource allocation in a generic hospital reduces pressure on infrastructure and staff workload, enhancing service quality and patient satisfaction, impacting the dynamics exemplified in Loop B4. Resource optimization enables more efficient management, ensuring an adequate workload. The integration of AI also positively affects the motivation and well-being of healthcare personnel, reducing burnout and fostering a more sustainable work environment, influencing the relationships described in Loop B5. Parallelly, the use of AI for treatment personalization directly improves the quality of care, reduces relapse rates, and optimizes waiting times.

In summary, the introduction of AI is expected to alleviate pressure on infrastructure and workforce, thereby contributing to improved service quality and reducing burnout, ultimately enhancing hospital efficiency. This CLD highlights the interdependent nature of hospital operations and emphasizes the potential role of AI-driven decision-making in improving resource allocation, clinical outcomes, and overall system performance.

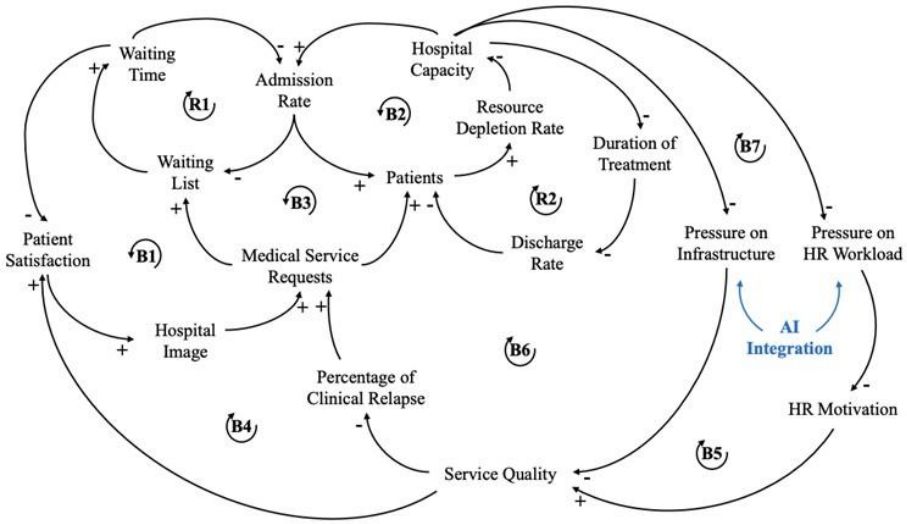

Figure 1: A CLD framing AI-driven dynamics in hospital resource management and patient flow

5 A set of KPIs for assessing AI integration in healthcare organizations

Considering the gap in the literature concerning the empirical application of AI technology in medical and management practices, following the exploration of the dynamics underlying AI integration in healthcare organizations emerging from the literature and conceptualized in the CLD in Figure 1, a set of KPIs measuring and evaluating the technology's impact is proposed in Table 1. The proposed set of KPIs provides a practical and adaptable toolbox for healthcare decision-makers to assess its effects and monitor its implementation, determining whether and to what extent it is affecting healthcare performance.

The KPIs are categorized into six domains - productivity, operational efficiency, AI predictive maintenance, supply chain, employee engagement and well-being, clinical outcomes, and treatment personalization - synthesizing AI's impact on the two main themes discussed in Section 2, namely, resource allocation optimization and PHC. The productivity category includes KPIs measuring resource utilization and clinical workload. Metrics such as average treatment cost per patient, patient turnover rate, and patient load per clinician quantify operational output, providing insight into efficiency and workforce distribution. KPIs grouped in the operational efficiency category measure hospital workflow performance. Admission rate, average waiting time, and average length of stay capture patient flow, while scheduling accuracy and operating room idle time assess the effectiveness of scheduling and resource allocation. Indicators such as resource utilization rate, equipment failure rate, and average maintenance cost per equipment unit provide a quantitative assessment of system downtime, predictive maintenance efficiency, and cost-effectiveness of AI-powered monitoring tools. Such metrics evaluate the reliability of AI-driven equipment management and are classified in the AI predictive maintenance group. AI's role in optimizing healthcare logistics is measured through lead time, stockout rate, expired stock rate, and AI-driven test optimization rate, indicators grouped in the supply chain category. These indicators reflect the ability of AI to enhance inventory management and reduce inefficiencies in procurement and distribution. The impact of AI integration on employee engagement and well-being is assessed using patient satisfaction rate, absenteeism rate, employee turnover rate, and staff weekly workload indicators. These KPIs provide insight into job satisfaction, retention, and the potential effect of AI integration on healthcare professionals' working conditions. AI's contribution to patient care quality is evaluated through KPIs in the clinical outcomes category. Medical error rate, clinical relapse rate, avoidable hospitalization rate, early diagnosis rate, AI diagnostic accuracy rate, and average AI-assisted diagnosis time quantify the effectiveness of AI in supporting clinical decision-making. The treatment personalization category captures AI's role in tailoring medical interventions. Indicators such as treatment customization rate, average time for personalized diagnosis, and percentage of customized treatments with positive outcomes measure the degree to which AI-driven tools enhance precision medicine and individualized patient care.

In summary, the set of KPIs presented in Table 1 provides a comprehensive assessment of AI integration in healthcare organizations, allowing for performance monitoring and optimization of AI-driven interventions across multiple areas.

Table 1: A set of KPIs for evaluating AI integration in healthcare organizations

Category	**Indicator**
Productivity	Average treatment cost per patient
Productivity	Patient turnover rate
Productivity	Patient load per clinician (total number of treated patients per clinician over a period/supporting staff)
Operational Efficiency	Admission rate
Operational Efficiency	Average waiting time (in waiting list)
Operational Efficiency	Average length of stay
Operational Efficiency	Scheduling accuracy (number of appointments completed on time without delays or overlaps/total number of scheduled appointments)
Operational Efficiency	Operating room idle time (percentage of unutilized operating room time)
AI Predictive Maintenance	Resource utilization rate (total operating time of a machine over a period/total available operational time)
AI Predictive Maintenance	Equipment failure rate (total number of machine failures over a period/total operating time of the machine)
AI Predictive Maintenance	Average maintenance cost per equipment unit (total maintenance cost for a machine over a period/total number of maintenance interventions)
Supply Chain	Lead time
Supply Chain	Stockout rate (percentage of times a product is unavailable)
Supply Chain	Expired stock rate (percentage of expired stock relative to total inventory)
Supply Chain	AI-driven test optimization rate (actual number of tests leading to confirmed diagnoses/total AI-recommended tests)
Employee Engagement and Well-being	Patient satisfaction rate (number of satisfied patients/total number of surveyed patients)
Employee Engagement and Well-being	Absenteeism rate (total number of absent days for an employee/total working days)
Employee Engagement and Well-being	Employee turnover rate (number of employees who left during the period/average number of employees during the period.)
Employee Engagement and Well-being	Staff weekly workload (average weekly hours worked per staff member.)
Clinical Outcomes	Medical error rate (total number of reported medical errors in a period/total number of treated patients)
Clinical Outcomes	Clinical relapse rate (number of patients readmitted for the same condition in a period/total number of discharges)
Clinical Outcomes	Avoidable hospitalization rate (number of avoidable hospitalizations due to AI-driven personalized prevention/total number of hospitalizations)
Clinical Outcomes	Early diagnosis rate (number of AI-supported diagnoses matching final confirmed diagnoses/total number of AI-supported diagnoses)
Clinical Outcomes	AI diagnostic accuracy rate (number of early diagnoses/total number of diagnoses)
Clinical Outcomes	Average AI-assisted diagnosis time (Average time for AI-assisted diagnosis/average time for traditional diagnosis)
Treatment Personalization	Treatment customization rate (number of customized treatments/total number of treatments)
Treatment Personalization	Average time for personalized diagnosis (total time spent on personalized diagnoses/total number of personalized diagnoses)
Treatment Personalization	Percentage of customized treatments with positive outcomes (number of customized treatments with positive outcomes/total number of customized treatments)

6 Concluding remarks and future research directions

Integrating AI technologies seems to hold significant potential to enhance healthcare services by optimizing resource allocation strategy and service quality. However, empirical validation of the positive impact of AI in healthcare organizations remains limited, both in clinical and management practice. To address this gap, this study provides a set of KPIs designed to evaluate the actual impact of AI implementation in healthcare settings.

The CLD presented, functional to the development of the relevant KPIs, offers a structured and visually intuitive framework for understanding the complex dynamics influencing healthcare organizations and for highlighting the causal interdependencies identified by the literature. The CLD highlights causal

interdependencies identified in the literature, particularly focusing on two emerging themes: AI-driven resource allocation and PHC.

The proposed KPIs are intended to guide future research, as well as help managers assess the actual impact of AI implementation in healthcare settings. The insights from this study offer guidance for healthcare managers seeking to assess and integrate AI technologies to enhance strategic decision-making in healthcare organizations. By providing managers with specific indicators to objectively measure and evaluate the impact of AI implementation, decision-making capabilities are strengthened, ensuring that AI adoption aligns with organizational goals and delivers tangible benefits regarding operational efficiency, resource allocation, and service quality.

However, this research relies on literature review and a systems thinking approach to analyze the possible relevant relationships stemming from AI integration in healthcare organizations. This approach, while insightful, does not substitute for direct stakeholder inputs. Additionally, contextual differences among healthcare systems and the rapid evolution of AI technologies suggest that the current framework may require further adaptation. Moreover, the KPIs proposed in this study are theoretical and have not yet been empirically tested. Future research should focus on empirically refining the KPI set through research incorporating both quantitative performance data and qualitative feedback from healthcare professionals and patients. Such studies would not only confirm the effectiveness of AI-driven interventions but also uncover potential ethical, regulatory, and organizational challenges.

Abstract

The 2030 Agenda for Sustainable Development highlights the transformative potential of digital technologies in accelerating human progress, reducing inequalities, and fostering sustainable knowledge societies. Within this context, Digital Health (DH) is recognized for enhancing healthcare systems' effectiveness, resilience, and equity—especially in addressing environmental and climate-related challenges. While various assessment methodologies exist—such as Health Technology Assessment, Health Impact Assessment, Social Impact Assessment, and Environmental Impact Assessment—the literature lacks reviews that explore the social and environmental impacts of DH. These dimensions are critical for evaluating healthcare systems' broader performance and alignment with long-term sustainability goals. This scoping review aims to map and synthesize existing frameworks and tools for evaluating the impact of DH, particularly in relation to social and environmental outcomes. The review is structured around the Sextuple Aim Framework, which extends the traditional Triple Aim by adding environmental impact. Following JBI methodology and PRISMA-ScR guidelines, searches were conducted in PubMed, Scopus, and the Cochrane Database. Eligible studies were published in English between 2014 and 2024 and had to address at least three of the six aims: Population Health, Experience of Care, Capital Cost, Care Team Well-Being, Health Equity, and Environmental Impact. Out of 8,243 identified records, 53 met the criteria and were included in the final review. None addressed all six aims comprehensively. Most studies focused on DH (30.19%) and m-Health (28.30%), with emerging technologies like AI and VR also represented. The most assessed aims were Experience of Care (98.11%) and Population Health (94.34%), while Environmental Impact appeared in only 11.32% of studies. Through thematic analysis, 157 unique items were identified, categorized into 17 domains, 62 topics, and 78 issues. The most developed topic was Experience of Care, particularly User Engagement and Process-related costs. In contrast, Environmental Impact was the least developed, with only two domains: carbon footprint and the clarity of environmental consequences of technologies. This review contributes to the development of a theoretical framework for evaluating the holistic impact of DH. By highlighting gaps—particularly in environmental and social dimensions—it supports more informed, balanced decision-making in DH strategies aligned with sustainability and equity principles.

Keywords: Digital Health, Performance Measurement, Artificial Intelligence, Social Impact Assessment, Environmental Impact Assessment.

Paper type: Academic Research Paper

1 Introduction

According to the World Health Organization, Digital Health (DH) includes the development and use of digital technologies to improve health. This field extends beyond e-health to involve digital consumers interacting with various smart devices and connected equipment. It also incorporates applications such as the Internet of Things, artificial intelligence (AI), big data, and robotics (WHO,2021).

The 2030 Agenda for Sustainable Development highlights that information, and communications technology can significantly accelerate human progress, bridge the digital divide, and foster knowledge societies. Literature indicates that DH can disrupt healthcare systems, enhancing their capacity, effectiveness, resilience, and equity in response to environmental and climate challenges (WHO, 2022). The ongoing digital revolution presents opportunities for product dematerialization, efficient resource utilization, and improved supply chain management, with DH recognized as essential for achieving sustainable development (Manjurul et al., 2022). When effectively integrated into healthcare systems, DH enables remote patient monitoring, virtual consultations, and personalized care improvements (Thompson M, 2021). Overall, DH can improve access to care by ensuring timely delivery of health services, facilitating access for rural and urban communities, addressing the needs of medically underserved areas, connecting patients with appropriate specialists, and increasing provider capacity (Hollander J et al., 2017). Despite global warming approaching the 1.5°C limit set by the Paris Agreement (2015), and the documented indirect effects of climate change on social equity and health

recognized by the WHO (2014), evaluating the environmental and social implications of health technology remains a voluntary choice for individual healthcare organizations. This evaluation is sometimes conducted through reports based on Corporate Social Responsibility models (Bowen, 1953), which define clear social goals, outline actions, and monitor results. One notable model is the Triple Bottom Line, introduced by Elkington (1999), which expands the traditional profit-loss perspective to include financial, social, and environmental dimensions. Currently, the most comprehensive approach for evaluating digital solutions is Health Technology Assessment (HTA), a multidisciplinary process that aims to determine the value of health technology throughout its lifecycle. HTA informs decision-making to promote equitable, efficient, and high-quality health systems, and includes over twenty recognized frameworks for digital solutions (O'Rourke et al, 2020). However, when examining social impacts, HTA tends to focus on a narrow range of concerns. A review of the HTA Core Model® (Lampe K., 2009). shows that related questions primarily evaluate implications for patients, caregivers, and targeted social groups. The Ethics domain addresses the "Benefit-harm balance," assessing the technology's benefits and harms for various stakeholders. This evaluation is often performed descriptively rather than through integrated assessment methods, using literature reviews, expert opinions, and stakeholder hearings Additionally, there is limited formal reference to the environmental impacts of technology, mostly focusing on safety and emissions of chemical substances (Vis ET al.2020). A report from Cambridge University confirms this, indicating that of 1,710 HTA articles, only two provided frameworks for incorporating environmental assessments, while others mainly described evidence-weighting practices (Marsh et al, 2016).

Given these limitations, applying more holistic methodologies for impact assessment in healthcare, such as Health Impact Assessment (HIA), Social Impact Assessment (SIA), and Environmental Impact Assessment (EIA), may be beneficial. These methodologies follow similar approaches: they determine the potential impacts, gather data to understand the current context, predict changes resulting from a project, and make recommendations to maximize benefits and minimize harm. Each methodology focuses on different aspects; EIA examines effects on the biophysical environment, SIA looks at social and economic impacts, and HIA considers community health impacts (Ross et al, 2014). These evaluation methods can enhance the recognition of the value created by DH in terms of reimbursement and accountability, as suggested by the Value-Based Health Care (VBHC) approach (Zhang et al,2025). The costs associated with implementing, adopting, and maintaining DH technologies remain significant challenges for healthcare organizations and authorities and can hinder innovation (Whitelaw et al., 2021). Porter's (2009) VBHC framework proposes a new competitive approach in healthcare, focusing on the value generated per money spent. According to Porter, VBHC principles have significant implications for reimbursement, suggesting that the reimbursement unit should align with the value unit. Over the past 20 years, the definition of value has increasingly included stakeholders involved in healthcare services (Berwick et al., 2008; Dipti, 2021). The new "Sextuple aim" framework (6AF) introduced by Alami et al. (2023) after the COVID-19 pandemic, recognizes the importance of valuing effective patient care, cost management, provider support, population health, equity, and environmental issues. Despite the various methodologies described, previous searches in PubMed, Scopus, Web of Science, and the Cochrane Database of Systematic Reviews indicate a lack of reviews assessing the literature on social and environmental impact assessments of DH. Therefore, this scoping review's main objective is to summarize the methodologies and frameworks used for impact assessment of DH, focusing on the social and environmental impacts while aligning with the six aims of VBHC. Based on this goal, we raised the following review questions (RQs):

- *RQ 1. Contribution types*: How many sources have presented new frameworks, methods/techniques, tools, metrics, or processes for the assessing of the social and environmental impact of DH?
- *RQ 2. Holistic approach:* How many sources adopt holistic approach and allow evaluation of three or more aim of the 6AF VBHC framework?
- *RQ 3. Value domains:* Mapping of domain, topic and issue that contribute to assessment of (Figure 1):

Figure 1: The Sextuple Aim framework (Alami et al.2023)

2 Methods

This scoping review was performed adhering to Joanna Briggs Institute's (Munn et al.,2020) methodology for scoping reviews and complies with the Preferred Reporting Items for Systematic Reviews and Meta-Analysis extension for scoping reviews guidelines (PRISMA-ScR) (Tricco et. al 2018).

2.1 Search Strategy

The Population, Concept, and Context (PCC) framework guided the formulation of the query and eligibility criteria (Munn et al.,2020):

Population: This review will consider studies involving individuals engaged in DH solutions, without requiring specific conditions or characteristics of the population.

Concept: The review will include studies that evaluate the impact of DH in alignment with three or more of the six aims of the VBHC framework.

Context: The review will encompass studies conducted within the last ten years in any context where DH technologies are utilized. To determine eligible technologies, we will apply the WHO (2021) definition of DH technologies, which includes the Internet of Things, virtual care, remote monitoring, artificial intelligence, big data analytics, blockchain, smart wearables, and platforms that facilitate data exchange and storage. These tools enhance health outcomes by improving medical diagnoses, enabling data-driven treatment decisions, facilitating digital therapeutics and clinical trials, supporting self-management of care and person-centered approaches, and contributing to evidence-based knowledge and skills for healthcare professionals.

Based on the search strategy outlined below, the following search query (Figure 2) was created:

((“digital health”) OR (“telehealth”) OR (“ehealth”) OR (“mhealth”) OR (“telemedicine”) OR (“mobile health”) OR (“big data”) OR (“blockchain”) OR (“health data”) OR (“health information systems”) OR (“infodemic”) OR (“Internet of Things”) OR (“interoperability”)) AND (((“technology assessment”) OR (“health technology assessment”) OR (HTA) OR (“social domain”)) OR ((impact assessment*) OR (impact*) OR (“health impact assessment”) OR (HIA)) OR ((“social impact assessment”) OR (“social impact*”) OR (equity) OR (“social change*”) OR (“social development”) OR (SIA)) OR ((“community impact”) OR (“patient impact”)) OR ((greenhouse) OR (“environmental sustainability”) OR (emissions) OR (“carbon footprint”) OR (“climate change”) OR (“pollution”)) OR ((“Social Return On Investment”) OR (SROI))) AND ((framework*) OR (methodology*)).

Figure 2: Search Strategy

This query was utilized in December 2024 to search the title and abstract fields of all records in PubMed, Scopus and the Cochrane Database of Systematic Reviews. The search strategy, including all identified keywords and index terms, was adapted for each database and information source. Studies published in English and Italian within the last ten years (2014-2024) were included, with no exclusions based on study type.

2.2 Data Extraction

All records identified through database searches were retrieved and stored using the Rayyan platform, where any duplicates were removed. Two researchers independently screened the articles in a blinded manner, following pre-established inclusion and exclusion criteria to ensure an unbiased selection process. Data were extracted from the articles, using a data extraction table designed to align with the review's objectives and research questions. The extracted data included the author, year, and country of the study, the technology assessed, the aims covered in the assessment, and the items used to evaluate the impact of DH. Through a thematic analysis (Clarke et al. 2014), the identified items were subsequently examined to eliminate duplicates and classify them based on their corresponding VBHC aim.

In the final phase, the selected items were categorized into the classes proposed by Deckers et al. (2022):

- Domain: Represents the broad areas of interest affected by the health technology.
- Topic: Refers to specific aspects or subjects within a domain that are relevant to the evaluation.
- Issue: Indicates questions or concerns that arise within a topic and need to be addressed.

Any discrepancies regarding article selection, data extraction, and analysis were discussed and resolved through group consensus among an expert in HTA and AI, an expert in SIA, an expert in DH, and an expert on Big Data.

3 Results

Given the increasing attention to DH over the past decade, the initial search returned 8,243 records. After removing 3,176 duplicates, 5,067 articles were screened by title and abstract. Following this first screening, 106 full-text reports were assessed for eligibility. Of these, 53 reports were included in this scoping review, as they addressed at least three of the six aims of VBHC framework. The inclusion process is detailed in the PRISMA flowchart shown in Figure 3.

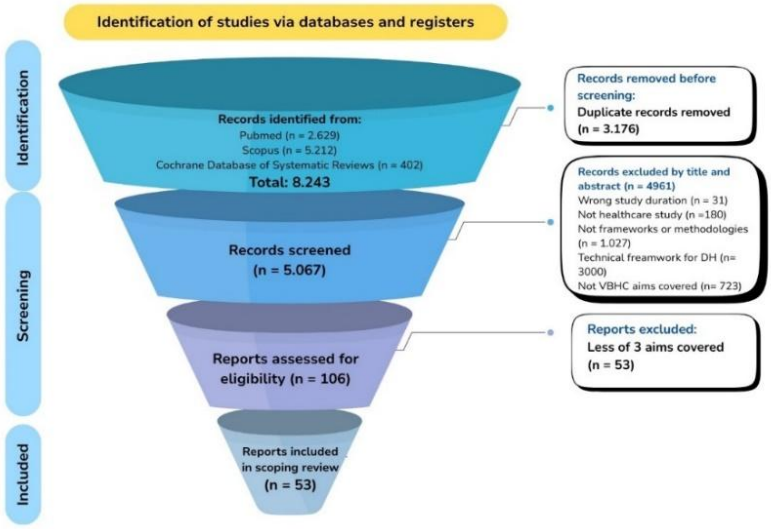

Figure 3: PRISMA Flowchart

3.1 Description of the included reports

As shown in the geographical distribution map (Figure 4), most studies (37.74%) originated from Europe. Within Europe, England contributed 9.47% of the studies, followed by Switzerland (7.55%) and Italy (3.77%). North America contributed 30.19% of the studies, primarily from the USA (24.53%). Oceania accounted for 11.32% of the studies, mainly from Australia. In terms of publication trends, there was a notable increase in studies published during the COVID-19 pandemic, with peaks in 2019 (15.38%) and 2020 (17.31%), reflecting heightened interest during the global health crisis. Additionally, a second peak was observed in 2024 (17.31%), likely influenced by anticipated developments in AI and HTA regulations. In terms of technological focus (Figure3), the studies primarily addressed DH (30.19%), m-Health (28.30%), and Telemedicine (20.75%). Emerging technologies were also represented, with AI (7.55%). Other topics, each contributing 1.89%, included Big Data, Chatbots, Virtual Reality, Wearables, Connected Care, e-Health, and integrated approaches combining m-Health, AI and Robotics.

The Accessibility, Relevance, and Impact conceptual framework of digital inclusivity for health information systems

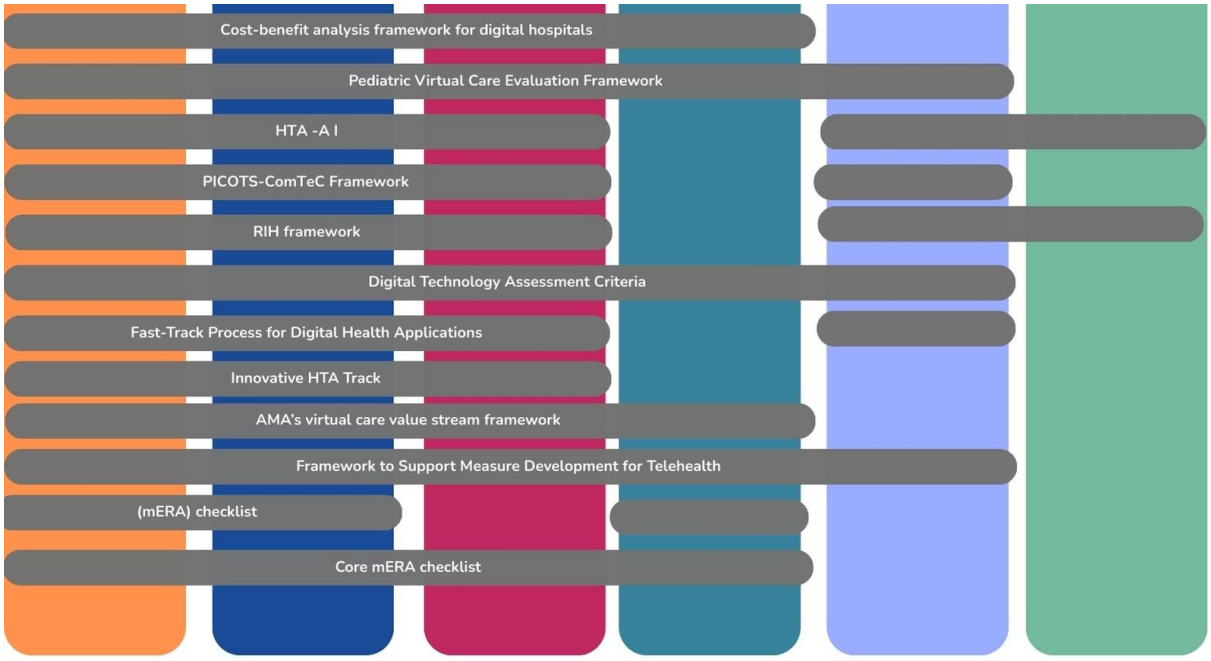

Table 5: Frameworks, tools, and methodologies included, and Aims covered

As shown in Figure 5, the most frequently assessed aims were Experience of care (98.11% of studies) and Population Health (94.34%). These were followed by Equity (71.70%) and Capital cost of health care (64.15%). Fewer than half of the studies (43.40%) considered the importance of care team well-being, and only six studies (11.32%) included an environmental assessment in their methodology. Only 13 studies adopted a more holistic approach to the assessment of DH; however, none addressed all six aims comprehensively.

3.1 Items identified and their categorization in Domain, Topic and Issue

Through a thematic analysis, 163 items were initially identified as relevant to the evaluation of the six aims. After eliminating duplicates, the final list was reduced to 157 unique items. These items were further refined and categorised into three classes: Domains (n = 17), Topics (n = 62), and Issues (n = 78). Following a review by an expert panel, the accepted items were assigned to their respective categories and aligned with the most appropriate of the six aims. This process led to the development of the Holistic Impact Framework for Digital Health, shown in Figure 6. Experience of Care is the most extensively developed within the literature, comprising 3 domains, 10 topics, and 39 issues. The domain with the highest number of topics and level of detail is Process-Related Cost, which includes 9 topics. The most thoroughly described topic in terms of issues is User Engagement for patients, families/caregivers, and the care team, with 9 issues. In contrast, Environmental Impact is the least developed, containing only two domains: Carbon Footprint and Clearness of technology environmental impact. The top five of domain most cited in the assessment of the DH are Accessibility (37,74% of studies); User engagement (18,87%), Cost assessment (16,98%), Quality of care and Safety (9,43%), Patient experience and Quality of life (7,55%). While the topic most citated are Ease of use (13,21% of studies) and Digital Health Literacy (7,55%).

HOLISTIC IMPACT FRAMEWORK OF DIGITAL HEALTH

I Aim - Population Health

Domain	Topic	Issue
Desease burden	Effect on mortality	Life expectacy
	Effect on disability	Number of years lost due to disability
	Effect on quality of life	Quality-adjusted life years saved
	Behavioural	Intention ; Life style changes; Disease onseat and severity
	Relevance	Purpose; Congruence; Credibility; Utility; Trastwortiness

III Aim - Capital cost of the Health Care

Domain	Topic
Financial burden for patient/family/ caregiver	Cost of device/service
	Cost of internet
	Cost of maintenance
Process related cost burden	Purchase Price
	Labour cost (h-team, engeeneers, technical, admistration and support staff)
	Cost of device and delivery
	Development & Implementation cost
	Mantainance and support cost
	Training cost
	Operational cost
	Uptake cost
	Economic/financial sustenability of technology
Cost-opportunity	Trasport reduction of h-team
	Cost savigs for staff turn-over
	Time savigs of staff in daily work
	Reduction of hospital and emergency department (ED) utilization rate
	Improve the number of custmers/patient
Cost assessment	Frugality
	Cost - effectivness
	Cost- utility
	Cost - Benefit
Financial burden	R&D
	Investment
	Regulatory cost

III Aim - Capital cost of the Health Care

Domain	Topic
Access to care	Availability across platform
	Financial burden for user
	Coverage (improve access in rural settings)
	Offline functionality
	Waiting time
	Fairness
	Corruption
Accessibility	Comprehensibility (Language availability, Linguistic accuracy,Numeracy ,Visual Interpretation, Font type and syze)
	Customizability
	Inclusivity
	Cultural appropriateness and political will
Advocacy	Stakeholder involvment
	Influence and endorsement between peers
	Motivation & Empowerment
	Social support
Skill equity	Health Litteracy
	Digital Health Litteracy

II Aim - Experience of care

Domain	Topic	Issue
User satisfaction (patient and family/caregiver)	Acceptability	Capacity to use ; Future use; Net promoter score ; Usability (short and long); Impression first and after using
	Aesthetics	Background color and content , button color, shape, icon ; Flexibility; Tailoring
	Easy of use (service and tech)	Interaction quality; Intuitive; Integration; Functionality
	Relationship aspect	Emphaty; Humanistic care; Patient/cargiver - clinician encounter; Patient - carer dependency
Quality	User engagement	Co-design; Collaboration and end-user participation; Adoption imput; Communication and information sharing ; Gamification or entrateinment; Persuasivness; Self-management ; Autonomy in health related decision ; User control
	Effectivness	Adherence; Apropriatness of service; Apropriatness of response; Context awereness; Continuity of care; Feasibility
	Safety	Tech reliability ; Accuracy ; Precision
	Timely	Time to event (to treat or decision); Timely assess to care and waiting time
Quality of life	Impact on morbidity	Life year saved
	Social aspect	Relationship (i.e. family dynamics, friends, and other relevant social relations); Patient dignity

I Aim - Population Health

Domain	Topic	Issue
H-team satisfaction	Acceptability	Capacity to use; Cultural appropriateness and political will; Net promoter score; Usability (short and long); Impression first and after using
	Impact rispect the h-team work	Agile ways of working ; Team work
	Aesthetics	Background color and content , button color, shape, icon ; Flexibility ; Tailoring
	Easy of use (service and tech)	Interaction quality ; Intuitive; Integration; Functionality
	Relationshisp aspect	Emphaty ; Humanistic care; Clinician - patient/caregiver encounter ; Relationship beetween peer; Relationship (i.e. family dynamics, friends, and other relevant social relations)
H-team experience	User engagement	Co-design; Collaboration and end-user participation; Adoption imput; Communication and information sharing ; Gamification or entrateinment; Persuasivness; Self-management ; Autonomy in health related decision; User control

III Aim - Capital cost of the Health Care

Domain
Clearness of tecnology environmental impact
Carbon footprint

Figure 6: Holistic Impact Framework for DH

4 Discussion and Conclusion

Our research highlights a growing attention to the evaluation of the socio-environmental impact of DH in the healthcare sector. This review contributes meaningfully to the scientific debate by offering a critical mapping of existing evaluation approaches and identifying key gaps—particularly in the social and environmental dimensions. While our findings reveal a wide range of methodological tools, none of the studies examined addressed all six value dimensions. Notably, the aims of "patient experience" and "population health" are the most represented, appearing in 98.11% and 94.34% of the studies, respectively. In contrast, environmental impact is largely overlooked, appearing in only 11.32% of the studies and limited to a narrow set of issue, such as carbon footprint and environmental transparency. This imbalance points to a persistent reliance on evaluation models centred on clinical and economic factors, often at the expense of a more holistic understanding of the value DH can generate in healthcare.

Even within the most frequently covered areas, relevant gaps remain. For example, when considering the impact of DH on the Care Team, studies tend to focus narrowly on aspects of experience and engagement, often neglecting the broader concept of well-being. Yet the IV aim of VBHC stresses the need to address the physical, psychological, and emotional health of healthcare professionals. A growing body of literature—especially from the COVID-19 period—highlights the impact of DH in terms of technostress and burnout (Golz et al., 2021).

The still limited adoption of integrated methodologies such as HIA, SIA, and EIA underscores the need for a cultural and methodological shift. Moving beyond siloed perspectives requires fostering collaboration across sectors, where corporate social responsibility frameworks help demonstrate social value through credible and measurable approaches. Moreover, to bridge the environmental evaluation gap, it is essential to incorporate standardized environmental metrics into HTA processes; strengthen collaboration between HTA and sustainability experts; and promote an evaluation culture oriented towards shared value and sustainability, consistent with the objectives of the 2030 Agenda. These steps are critical to ensuring that DH not only improves care but also contributes to social well-being and environmental stewardship, consistent with a triple-bottom-line perspective.

Indeed, the holistic framework proposed, enriched with currently underrepresented environmental aspects, offers a valuable tool for a more comprehensive evaluation of DH innovations, supporting informed and balanced decision-making. By broadening the evaluative lens beyond cost-effectiveness and clinical outcomes, it empowers decision-makers to integrate sustainability and equity criteria into policy and investment choices. Furthermore, it can support prioritization processes by helping stakeholders identify technologies that deliver not only technical value but also societal and environmental benefits. Future studies should aim to expand and refine this framework by addressing neglected yet crucial issues and dimensions—particularly those rooted in a triple-bottom-line perspective that, while scientifically grounded, are still rarely assessed in practice. This requires the active engagement of all stakeholders involved in the lifecycle of DH technologies, from design to implementation and evaluation. Incorporating diverse perspectives—including those of healthcare professionals, patients, policymakers, industry representatives, and environmental experts—can help ensure that value assessments truly reflect the multifaceted impacts of digital innovations.

Ultimately, empowering stakeholders to participate meaningfully in the evaluation process means giving voice to those most affected by technological change—transforming assessment from a top-down exercise into a shared responsibility that enhances legitimacy, accountability, and impact in DH decision-making.

5 Ethic declaration

This study does not involve human participants, animals, or sensitive data, and therefore no ethical approval was required.

6 AI Use declaration

Rayyan AI was used to support article screening and deduplication. Xmind AI was used to generate the mind map that visually presents the Holistic Impact Framework. All outputs were reviewed and refined by the authors.

Exploring Cardiologists' Perspectives on Wearable ECG Devices: Evidence from an E-focus Group

Valeria Schifilliti, Veronica Marozzo, Alessandra Costa, Augusto D'Amico
University of Messina, Messina, Italy

Abstract

This study explores the propensity of cardiologists to adopt wearable electrocardiogram (ECG) devices in cardiovascular patient care. Using a qualitative exploratory design, we conducted e-focus group sessions to gather in-depth insights into cardiologists' perspectives. This approach enabled both individual reflections and group interaction, revealing diverse opinions on the clinical usefulness and integration of wearable ECG technology. The findings revealed varying attitudes toward the use and perceived value of wearable ECG devices. Several key factors were identified as influencing cardiologists' openness to adopting such technologies, including perceived usefulness, technical accuracy, the reliability of results, the availability of resources within healthcare organizations, the dynamics of the doctor-patient relationship, and individual patient characteristics.

The study underscores the importance of a multi-dimensional strategy to support the integration of wearable technologies in cardiovascular care. While wearable ECG devices hold significant potential to improve cardiovascular health monitoring, strategic planning and supportive infrastructure are vital to ensure their effective and sustainable implementation in clinical practice.

Keywords: Wearable technology, ECG, cardiologists' perspective, propensity to adopt

Paper type: Academic Research Paper

1 Introduction

The integration of smart health-monitoring technologies into daily life has transformed how individuals and healthcare professionals interact with health-related data. These innovations, particularly minimally invasive smart devices, are increasingly used to track vital physiological indicators such as blood oxygen levels (SpO_2) and heart rate. The ability to generate and access this information in real time enables more proactive, data-driven healthcare, benefiting both patients and clinicians.

Smart wearable devices now span a wide range of formats. As classified by the International Electrotechnical Committee, these technologies fall into four categories: (i) near-body wearables, (ii) on-body wearables, (iii) in-body wearables, and (iv) electronic textiles. Devices such as fitness trackers, smartwatches, smart bands, health-enabled earphones, and smart patches are widely available and commonly used. Although many of these were not initially intended for clinical use, recent advancements have expanded their functionality to include real-time health monitoring. For instance, some smartwatches can now measure heart rhythms and perform electrocardiograms (ECGs), making them increasingly relevant in cardiovascular care. The data these devices collect is typically transmitted to connected applications and stored on cloud platforms, facilitating continuous monitoring and medical analysis.

Among these smart technologies, wearable ECG devices stand out for their potential role in cardiovascular health management. As reported by Elbey et al. (2021, pag. 5), "*while composite 12-lead ECG, Holter monitor, implantable loop recorders, or patch recording are the standards for AF detection, photoplethysmography based smartwatch technology is a simple, efficient, and non-inferior alternative that may expedite detection and treatment of subclinical AF, preventing morbidity and mortality from stroke and cardiovascular disease*". Despite promising technological capabilities, their integration into clinical practice presents challenges, particularly concerning the perceptions and acceptance among healthcare providers. As frontline decision-makers in heart health, cardiologists play a pivotal role in determining how and whether such tools are adopted in routine care.

This study aims to investigate how cardiologists view the use of wearable ECG devices in the context of cardiovascular patient management. By employing an e-focus group method, we gather rich qualitative insights into their attitudes, concerns, and the factors that shape their willingness to adopt these tools. The findings contribute to ongoing discussions on digital health transformation and provide practical recommendations for enhancing the clinical adoption of wearable ECG technologies.

2 Theoretical background

The emergence of wearable technologies in healthcare has significantly reshaped how health data is captured, interpreted, and utilized, particularly in the domain of cardiovascular monitoring. These technologies offer continuous, non-invasive tracking of vital parameters, fostering earlier detection of conditions and improved patient engagement. In this context, wearable electrocardiogram (ECG) devices have garnered considerable attention for their ability to record heart rhythms in real time and support the early identification of cardiac anomalies.

Several studies have explored the clinical reliability and diagnostic potential of wearable ECG tools. For instance, Kamga, Mostafa, and Zafar (2022) highlight the effectiveness of these devices in detecting arrhythmias and their overall comparability with traditional ECG equipment used in clinical settings. Wearable ECGs have been shown to enable timely diagnoses, increase the detection of atrial fibrillation (AF), and contribute to a reduction in emergency department visits. However, the authors also noted that while these benefits exist, they may come with increased healthcare costs. Similarly, Evans et al. (2017) emphasize the relevance of wearable ECGs in resource-constrained environments, particularly for AF screening, where they serve as accessible tools capable of identifying undiagnosed cases.

Beyond their clinical capabilities, wearable ECG technologies intersect with healthcare delivery dynamics, especially from the perspective of medical professionals. Aiello et al. (2022), through a qualitative study involving ten medical experts across diverse specialties, found that the majority perceived wearable devices as enhancing patient engagement and involvement in their own care. This finding aligns with the broader notion that digital health tools can facilitate more participatory healthcare experiences.

From a behavioural and organizational standpoint, the adoption of wearable health technologies by clinicians is influenced by various factors. Yao et al. (2023) conducted a large-scale survey with over 1.000 Chinese general practitioners and identified several key predictors of adoption intent. Performance expectancy, affordability, and social influence positively shaped practitioners' willingness to integrate wearable ECGs into clinical practice. As stated by Sana et al. (2020), the implementation of wearable health technologies in the general population is paving the way for new paradigms of healthcare and personalised medicine. However, perceived risks—such as concerns over data accuracy, privacy, and technology reliability—emerged as significant barriers. Additionally, Ferguson et al. (2021), highlighted the presence of many barriers and facilitators to the acceptance of wearable devices based on the skills of health professionals, older adults, and carers, by suggesting that the most important aspects related to the user-friendly technology, the design aspects of the devices, proper and timely feedback, and issues related to affordability and cost.

While substantial literature exists on the technical and patient-centered aspects of wearable ECGs, fewer studies have focused specifically on the perceptions of cardiologists, the primary clinical experts responsible for diagnosing and treating cardiovascular conditions. Given their specialized role, cardiologists are likely to assess wearable technologies through a more critical lens, considering both diagnostic rigor and the potential impact on clinical workflows and patient relationships. Understanding these perspectives is essential to designing more effective integration strategies and addressing barriers to widespread adoption in cardiovascular care.

3 Methodology

This study adopts a qualitative exploratory design to investigate cardiologists' perceptions and experiences related to the use of wearable ECG devices in cardiovascular care. Given the emergent nature of this technology in clinical practice and the need for in-depth understanding, we employed an e-focus group methodology. This approach enables the exploration of both individual views and group dynamics, providing richer insight into shared concerns, attitudes, and decision-making processes (Ruff, Alexander, and McKie, 2005; Easton, Easton, and Belch, 2003).

3.1 Sample selection and research design

Participants were selected using a combination of purposive and convenience sampling to ensure relevance and accessibility. The inclusion criteria required participants to be practicing cardiologists with experience in either public or private healthcare settings. A total of eight cardiologists (five men and three women) from Sicily, Italy, participated in the study. Their socio-demographic profiles, including gender, years of professional experience, healthcare setting, and area of specialization, are presented in Table 1.

The e-focus group was conducted on the Microsoft Teams platform, which, having no time limits, did not interrupt the flow of the discussion. Moreover, the platform allowed geographically dispersed professionals to participate in a flexible and convenient setting. Each participant was provided with a login to the virtual room

and instructions on how to proceed. They met in the virtual room at a pre−defined date and time. The session lasted 2.5 hours and was moderated by a trained facilitator using a semi-structured discussion guide inspired by the guidelines of Krueger (1998a). The moderator began with a broad, open-ended question and gradually introduced targeted prompts to encourage deeper discussion. A co-facilitator documented verbal and non-verbal cues, while the session was audio-recorded, with participants' consent for transcription and analysis.

Table 1: Key Information About the E-Focus Group's Participants

ID	Gender	Age	Operational City	Institution Type	Use of ECG Wearable Devices	Years of Experience
P1	Female	45	Palermo	Private	Yes	16
P2	Male	36	Messina	Public	Yes	5
P3	Male	48	Messina	Private	Yes	20
P4	Male	54	Messina	Private	Yes	27
P5	Male	41	Messina	Public	Yes	8
P6	Female	53	Messina	Public	No	25
P7	Male	64	Messina	Private	No	35
P8	Female	48	Messina	Private	No	20

3.2 Data analysis

Audio recordings and transcripts were reviewed iteratively to identify recurrent themes and significant statements. Thematic analysis was used to code responses and organize insights into core categories. Following Krueger's (1998b; 1998c) guidelines, a brief oral summary of the discussion was presented at the end of the session. Participants were invited to confirm the summary's accuracy and add any additional thoughts, ensuring validity through member checking.

Four key themes emerged from the analysis:

1. the clinical use and perceived value of wearable ECGs;
2. concerns around technical accuracy and trust in data;
3. individual and institutional readiness to adopt technology;
4. implications for patient engagement and doctor–patient trust.

4 Results

The thematic analysis of the e-focus group discussions revealed a range of perspectives among the eight participating cardiologists regarding the use of wearable ECG devices in cardiovascular health monitoring. Four principal themes emerged from the data, highlighting both convergences and divergences in the participants' views.

First, participants generally acknowledged the potential clinical usefulness of wearable ECG devices, particularly in supporting preventive care and long-term patient monitoring. Several cardiologists emphasized the advantages of these devices in detecting atrial fibrillation and other heart rhythm disturbances in outpatient settings. They suggested that wearable ECGs could serve as a valuable complement to traditional diagnostic practices by enabling continuous monitoring beyond the hospital environment. Nonetheless, some participants expressed caution, noting that while wearable ECGs are beneficial for preliminary screening or symptom tracking, their application in acute or complex clinical cases remains limited compared to hospital-grade equipment.

Second, the issue of technological reliability and accuracy emerged as a prominent concern. Although some cardiologists viewed the integration of wearable ECGs positively, others highlighted limitations related to signal quality, susceptibility to artefacts, and the variability of data depending on user behavior. The participants agreed that while wearable ECGs may offer acceptable reliability for basic monitoring, their diagnostic capabilities do not yet match those of standard 12-lead clinical ECG systems. This perceived shortfall contributed to a degree of skepticism about fully integrating these devices into formal clinical workflows without further validation.

Third, the willingness to adopt wearable ECG technologies varied considerably among participants. Cardiologists working within private healthcare organizations or those more accustomed to digital technologies displayed a greater openness toward adopting wearable solutions in their practice. They noted that wearable ECGs could support remote patient management and offer additional data for clinical decision-making.

Conversely, cardiologists in public institutions expressed more hesitation, citing barriers such as the lack of technical infrastructure, potential increases in workload, and insufficient integration of wearable data into existing clinical systems.

Finally, participants discussed the implications of wearable ECG devices for the doctor–patient relationship. Some cardiologists viewed wearable technologies as tools that could enhance patient engagement, fostering greater involvement in health management and facilitating shared decision-making. Others, however, raised concerns that frequent self-monitoring might heighten patient anxiety, particularly if patients misinterpret physiological variations as pathological events. There was a consensus that successful implementation would depend heavily on educating patients about the correct interpretation of wearable ECG data and maintaining strong communication channels between healthcare providers and patients.

Overall, the results highlight a complex and multi-layered perspective among cardiologists regarding the adoption of wearable ECG devices. While acknowledging the promise of these technologies, participants emphasized the necessity of addressing technical limitations, organizational barriers, and patient management challenges to ensure effective clinical integration. A summary of key Insights from the online focus group with cardiologists on wearable ECG device is presented in the Table 2.

Table 2: Summary of Key Insights from the e-Focus Group

Thematic Area	**Key Insights**	**Relevant Quotes**
Use and Perceived Usefulness of Wearable ECG Devices	Contrasting views: some cardiologists see significant diagnostic potential, others are skeptical due to risk of false positives and limited clinical utility.	P2: "[These devices] are invaluable resources [...] unlock immense diagnostic possibilities." P6: "[...] endorsed by European Cardiology Guidelines [...] they could serve as a diagnostic tes.t" P7: "[...] capture elusive symptoms [...] incredibly useful" P3: "Patients are a bundle of nerves [...] I'd practically snatch them right off their wrists." P7: "[...] require skilled personnel [...] under which legitimacy?"
Reliability and Accuracy of the Data	Devices are seen as accurate for basic parameters (e.g., heart rate, oxygen saturation), but less so for complex ECG measurements like atrial fibrillation. General lack of validated data is a concern.	P3: "If you're asking whether the data is accurate, the answer is a resounding yes." P7: "Accuracy cannot be extremely high [...] skin surface into electrical signals." P3: "Not quite as precise as what you'd get from a hospital facility."
Willingness to Adopt These Devices in Clinical Practice	No consensus. Some cardiologists are ready to use these devices selectively, while others are not yet convinced. Decisions often depend on patient demographics and clinical profile.	P2: "I would use them selectively [...] rather than utilizing them as a screening tool." P6: "my patients are elderly [...] their use could be more detrimental than beneficial." P5: "with young patients [...] I personally advocate the use."
Impact on the Doctor-Patient Relationship	Broad agreement that preserving the quality of the doctor-patient relationship is critical. The main concern is increased patient anxiety and unnecessary interactions driven by device alerts.	P2: "[These devices] could induce a high level of anxiety [...] in search of a pathology." P3: "If I perceive his anxiety, I would not dream of recommending it." P4: "Patients only marginally perceive their real utility." P7: "No one [of my patients] has specifically asked [...] smartwatch ECG."

Source: Authors' elaboration

5 Discussion and conclusions

The findings from the e-focus group with eight cardiologists reveal a complex set of perceptions surrounding the integration of wearable ECG devices into cardiovascular care. Participants generally acknowledged the clinical potential of these technologies, particularly for the early detection of arrhythmias and the ongoing monitoring of at-risk patients outside traditional healthcare settings. Wearable ECG devices were seen as capable of complementing standard diagnostic procedures by enabling continuous data collection, which can contribute to improved patient management and preventive strategies.

Nevertheless, significant concerns were expressed regarding the technological reliability and diagnostic accuracy of wearable ECGs. While previous research has highlighted their effectiveness in detecting conditions such as atrial fibrillation (Kamga et al., 2022; Evans et al., 2017), cardiologists emphasized the gap between the reliability of consumer-grade wearable devices and that of hospital-grade 12-lead ECG systems. Participants

noted the risk of false positives, measurement artifacts, and potential misinterpretation of results, suggesting that without further clinical validation, wearable ECGs should serve as supportive tools rather than replacements for traditional diagnostic methods.

The cardiologists' willingness to adopt wearable ECG technologies varied considerably, influenced largely by their working environments and digital familiarity. Those operating in private clinics or technologically advanced settings were more receptive to incorporating wearable monitoring into clinical routines, while those in public institutions faced barriers such as limited technical infrastructure, additional workload concerns, and organizational resistance. These observations are consistent with the broader technology acceptance literature, which points to performance expectancy, resource availability, and perceived risks as critical determinants of adoption (Yao et al., 2023).

A crucial dimension discussed was the impact of wearable devices on the doctor–patient relationship. On one hand, these devices were seen as empowering patients by increasing their involvement in health management. On the other hand, there were concerns that excessive self-monitoring could lead to patient anxiety and overdependence on device data, potentially undermining trust in clinical advice. This highlights the necessity of implementing wearable technologies alongside structured patient education programs and strong communication strategies to preserve and strengthen the therapeutic relationship.

In conclusion, the integration of wearable ECG devices into cardiovascular care is viewed with cautious optimism. While cardiologists recognize the value of these technologies for preventive care and outpatient monitoring, they also emphasize the need for further technological validation, thoughtful implementation, and tailored strategies that consider the variability of clinical environments and patient profiles. Successful adoption will depend not only on technological performance but also on institutional support, training initiatives, and efforts to align wearable health technologies with patient-centered care models. Then, based on the results obtained, it is possible to formulate the following propositions (see Figure 1:

Proposition 1: Perceived usefulness positively influences the propensity to adopt.

Proposition 2: Perceived reliability positively influences the propensity to adopt.

Proposition 3: The doctor-patient relationship may moderate the effect of perceived usefulness on ECG devices' adoption propensity.

Figure 1 shows the proposed conceptual model.

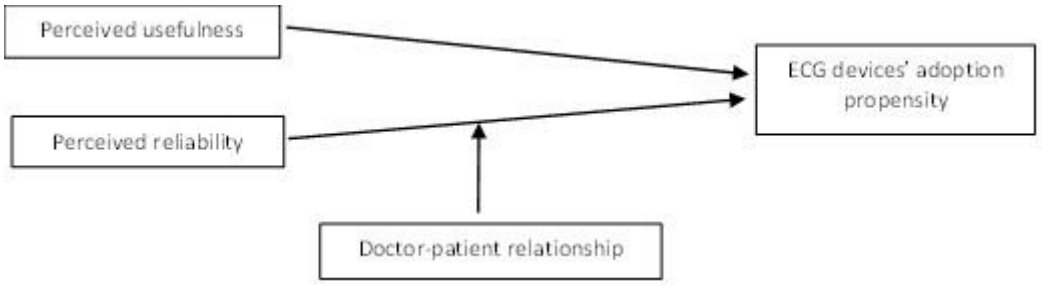

Figure 1: The proposed conceptual model

Future research should extend this exploratory work by including larger and more diverse samples across different healthcare systems and investigating the long-term clinical and economic impacts of wearable ECG integration. A future quantitative phase will empirically validate the proposed relationships of the conceptual model and identify key levers to facilitate the effective integration of these technologies into clinical practice.

Building a strong empirical foundation in these areas will be crucial for advancing the effective and sustainable adoption of wearable technologies in cardiovascular medicine.

6 Ethics declaration

All research is conducted in accordance with ethical principles.

7 AI declaration

The Role of AI in Waste Reduction and Sustainability of Pharmaceutical Industry

Małgorzata Runiewicz-Wardyn
Kozminski University, Warsaw, Poland

Abstract

The pharmaceutical industry, characterized by complex manufacturing systems and resource-intensive development cycles, generates significantly higher emissions and waste compared to other sectors—up to 55% more per revenue dollar than the automotive industry. Approximately 30% of raw materials are lost during drug production, highlighting urgent sustainability challenges. In response to growing environmental pressures, this study investigates the potential of Artificial Intelligence (AI) technologies to reduce waste and enhance sustainability within the pharmaceutical sector. Through a combination of quantitative data analysis and qualitative insights from major pharmaceutical companies—including Novo Nordisk, Pfizer, GSK, and AstraZeneca—this research explores how AI can transform various stages of the pharmaceutical value chain to improve efficiency and environmental performance. The study identifies three core applications of AI in the industry: business process optimization, waste classification and recycling infrastructure, and decision and policy support. Drawing from the principles of industrial ecology and circular economy, it evaluates how AI can be used to reduce defective drug batches, improve the recyclability of pharmaceutical waste, optimize resource flows, and enhance supply chain efficiency. Case study demonstrates AI's ability to significantly reduce maintenance costs, avoid production losses, and cut emissions. AI's role in optimizing pharmaceutical processes at different stages of the pharma value chain – from clinical trial design using digital twin simulations to forecast drug demand and reduce waste, to manufacturing optimization, predictive maintenance, and sustainable supply chain management – enables data-driven decisions, improves efficiency, and minimizes environmental impact. Despite these benefits, the adoption of AI faces numerous barriers including high implementation costs, regulatory challenges, data integration issues, and resistance to change within organizations. Technical limitations, cybersecurity concerns, and the lack of standardized industry frameworks further hinder widespread implementation. The study argues that overcoming these challenges will require coordinated efforts among stakeholders, including public institutions, to provide funding, develop digital skills, and establish policy frameworks that support the responsible use of AI for sustainability. While AI contributes positively to circular and climate-resilient healthcare systems, its energy demands and digital divides must be addressed. The research concludes that AI has the potential to be a pivotal enabler of sustainable transformation in Big Pharma, but its integration must be managed carefully to maximize benefits and minimize unintended consequences. Public investment should focus not only on AI innovation but also on building community readiness for the digital and green transition in healthcare.

Keywords: Artificial Intelligence, Waste Reduction, Sustainability, Pharmaceutical Industry, Big Pharma

Paper type: Academic research paper

1 Introduction

The pharmaceutical industry, a cornerstone of modern healthcare systems, has come under increasing scrutiny for its disproportionate environmental footprint. Characterized by complex, multi-stage manufacturing processes and long, resource-intensive drug development cycles, the industry is known for significant levels of waste production and emissions. Globally, it is estimated that the pharmaceutical industry generates up to 55% more greenhouse gas emissions per dollar of revenue than the automotive sector (Belkhir & Elmeligi, 2019). Furthermore, the European Environmental Agency (2024) reports that as much as 30% of raw materials are wasted during drug production, contributing to chemical pollution, water contamination, and ecological degradation. The environmental challenges linked to pharmaceutical production span across raw material extraction, synthesis, formulation, packaging, and distribution. During its life-cycle the industry contributes significantly to air and water pollution, with high levels of volatile organic compounds (VOCs), solvents, and active pharmaceutical ingredients (APIs) being released into the environment. A team of researchers coordinated by the University of York, comprising 127 scientists from 86 different institutions, collected and analyzed water samples from 1,052 sites across 104 countries. The investigation tested for 61 active pharmaceutical ingredients (APIs), including widely used compounds such as paracetamol, caffeine, metformin, and antibiotics like ciprofloxacin and sulfamethoxazole (Wilkinson et al., 2021). A notable example of pharmaceutical pollution is the discharge of antibiotics into aquatic ecosystems, particularly in regions where manufacturing is outsourced to countries with laxer environmental regulations. Studies by Larsson (2014) and Kristiansson et al. (2011) documented dangerously high concentrations of ciprofloxacin and other APIs in water

bodies near manufacturing plants in India, exacerbating the global crisis of antimicrobial resistance (Kristiansson et al., 2011; Larsson, 2014). These statistics highlight the environmental cost embedded in the pharmaceutical value chain and underscore the urgency of transitioning to more sustainable models of production and waste management. In addition to emissions and effluents, pharmaceutical production contributes to solid waste problems. Poor supply chain practices lead to overproduction, excess packaging, and the widespread disposal of expired or unused medications. In a study on pharmaceutical waste conducted in hospitals and households across Europe, Tong et al. (2011) found that over 70% of unused medications were discarded improperly, often flushed into sewage systems or disposed of in landfills, posing long-term environmental and public health risks.

From a regulatory perspective, frameworks such as the EU REACH Regulation (EC 1907/2006) and guidelines from the U.S. Environmental Protection Agency (EPA, 2023) have aimed to mitigate these impacts by enforcing stricter controls on hazardous chemicals and pharmaceutical waste. However, compliance is uneven, and enforcement challenges persist, especially in globalized supply chains. Additionally, the lack of standardized environmental benchmarks in pharmaceutical manufacturing further complicates sustainability efforts (Health Care Without Harm Europe, 2019).

Amid these mounting environmental concerns, AI has emerged as a transformative tool with the potential to significantly reduce the pharmaceutical industry's ecological footprint. AI technologies, particularly in the domains of predictive analytics, process optimization, and supply chain intelligence, offer scalable solutions for improving efficiency and minimizing waste. For example, AI-driven platforms can help companies predict and prevent defective drug batches by analyzing variables across production lines, thereby reducing the need for resource-heavy rework and disposal. AI-powered systems are capable of continuously tracking production processes by evaluating sensor and equipment data in real time. When irregularities from standard parameters are detected, the system can promptly identify the issue, enabling swift intervention to correct it (Inamdar et al., 2024). Companies like Novartis and GSK are increasingly investing in AI tools for continuous manufacturing. Novartis, in collaboration with researchers at MIT, developed machine-learning models that optimize drug formulation and predict yield outcomes, thus improving energy efficiency and minimizing waste (Wei et al., 2021). Similarly, GSK has deployed AspenTech's Aspen Mtell AI solution across its manufacturing sites to forecast equipment failures, reducing downtime and energy waste while avoiding costly product losses (AspenTech, 2024).

Beyond manufacturing, AI has the potential to foster circular economy principles in the pharmaceutical industry. AI-enhanced material tracking systems can identify and classify recyclable packaging, optimize the lifecycle of chemicals, and improve end-of-life waste processing. In Kalundborg, Denmark, pharmaceutical companies like Novo Nordisk are using AI-powered platforms to support industrial symbiosis networks, enabling shared use of water, steam, and waste heat between pharmaceutical firms and local industries. This initiative has led to 19–25% reductions in CO_2 emissions and improved resource utilization (Runiewicz-Wardyn, 2025).

Despite these promising developments, the integration of AI in pharmaceutical sustainability is not without challenges. Barriers include high implementation costs, limited interoperability between digital systems, data privacy concerns, and resistance to technological change within traditional organizational structures (Bailey et al., 2022). Additionally, the digital divide across regions and sectors creates disparities in AI readiness, potentially exacerbating sustainability gaps rather than closing them.

By integrating theoretical and empirical insights, the study seeks to assess the potential of AI-driven solutions in the Pharmaceutical industry for the waste and environmental impact reduction, and develop frameworks for implementing sustainable AI strategies to enhance efficiency and sustainability. More specifically it aims to: 1) Identify key areas within the pharmaceutical value chain where AI can have the most significant impact; 2) Quantify the potential reductions in waste and environmental impact achieved through AI-enabled solutions; 3) Provide a conceptual and empirical frameworks for implementing AI-driven sustainability strategies in the Pharmaceutical industry. The study addresses several supportive research questions: *How can AI be utilized to optimize manufacturing processes and reduce defective drug batches? What role does AI play in enhancing the recyclability of pharmaceutical waste and promoting circular economy practices, like Industrial Symbiosis? To what extent can AI improve supply chain efficiency and reduce resource wastage? What are the measurable environmental and economic benefits of AI-driven waste reduction strategies in Big Pharma – based on the empirical practice?*

The theoretical foundation of this study is rooted in the principles of industrial ecology and circular economy. In particular, in their role in the optimization of resource flows and waste management within industrial systems. AI, as an enabling technology, aligns with these principles by offering data-driven insights, predictive analytics, and process automation. Other studies, like Varriale et al (2024), Di Vaio et al. (2020) and Giordano et al. (2023) explore the role of individual technologies, such as IT, AI and blockchain technologies in achieving the sustainability goals and support industrial symbiosis indirectly by enhancing resource efficiency and reducing

waste . Yet other authors, like Kluczek et al. (2023) and Holzinger et al. (2023) emphasize the importance of application of specific digital technologies in the management of biotechnology, agriculture, food and supply chain industries. Still, the study of digital sharing platforms, particularly from a circular economy perspective, is just emerging (Runiewicz-Wardyn, 2025).

The study applies these theoretical foundations and systemic approach to the research problem and integrates three core elements of AI: AI for business process optimization, AI for infrastructure, waste classification and recycling, and AI for decision and policy support. It utilizes both quantitative (sector-specific environmental data) and the qualitative (big pharma companies statements and official strategies) including such Big Pharma players as Novo Nordisk, Pfizer, GSK, Novartis and AstraZeneca, to provide insights into the adoption AI for increasing sustainability of the whole pharma sector.

2 AI Applications in the pharmaceutical sector sustainability

The AI-based technology supports a shift from linear to circular value chains, and hence improves compliance with environmental regulations, and equips decision-makers with real-time insights for more resource-efficient operations. Presently major pharmaceutical companies—including Novartis, Pfizer, GSK, Roche, Sanofi, Johnson & Johnson, AstraZeneca, Eli Lilly, and Novo Nordisk—are leveraging AI to enhance drug discovery, optimize manufacturing, and streamline supply chains.

Table 1. AI Applications in the business processes optimization, infrastructure & waste management, and decision & policy support

Category	**Business Processes Optimization**	**Infrastructure & Waste**	**Decision & Policy Support**
Total Productivity	Automates repetitive tasks, streamlines workflows	Predictive maintenance reduces downtime; automated sorting improves efficiency	AI-driven insights streamline data-heavy policy-making
Cost Reduction	Lowers labour and operational costs	Cuts waste handling, disposal, and raw material costs	Reduces manual reporting efforts and improves resource allocation
Data Utilization	Enables data-driven decisions from large datasets	Leverages environmental and operational data for optimization	Integrates clinical, environmental, and supply data for comprehensive policy decisions
Scalability	Scales without proportional cost increases	AI systems handle varying waste volumes efficiently	AI scales to handle complex, cross-domain data for strategic planning
Strategic/Competitive Edge	Enhances customer experience and business performance	Supports ESG reporting, meeting regulatory pressure, and improving sustainability brand image	Enables sustainability leadership and responds to stakeholder/investor expectations
Technological Maturity	Mature automation and analytics tools support rapid deployment	Advancements in ML, computer vision, and IoT enhance reliability in waste management	Scenario modelling and forecasting tools aid in strategic decision-making
Compliance and ESG Alignment	Supports quality control and standardization	Ensures regulatory compliance and supports ESG reporting	Aids in meeting regulatory and ESG reporting requirements

Source: own elaboration.

It plays increasing role in business process optimization, by enabling more efficient operations, while its applications in infrastructure and waste management reduce resource consumption and emissions. Moreover, AI supports decision-making and policy development by delivering actionable insights that align operational strategies with long-term sustainability goals (Table 1).

The AI technology in drug development and manufacturing focuses on improving the efficiency, speed, and accuracy of internal business operations. For example, Novartis has integrated AI in drug development and manufacturing, collaborating with MIT on machine learning models and investing in continuous manufacturing to boost efficiency and reduce defects (Wei et al., 2021). Alongside Roche and Lonza, Novartis has also implemented shared energy recovery and water purification infrastructure, achieving up to 20% operational savings and significant greenhouse gas emission reductions (Lonza Annual Report, 2022).

GSK has deployed AI-driven predictive analytics through solutions like Aspen Mtell, which offer up to 35-day advance warnings of equipment failures. This has helped reduce maintenance costs, avoid production losses, and improve supply chain reliability across 30 sites in 18 countries (AspenTech, 2024).

At the Kalundborg Eco-Industrial Park, Novo Nordisk uses AI-powered platforms to predict resource needs and waste outputs, enabling efficient exchange of energy, water, and chemicals across industries. This industrial symbiosis model has led to a 19–25% reduction in CO_2 emissions and lowered primary resource consumption (Runiewicz-Wardyn, 2024).

Other pharmaceutical leaders are similarly embedding AI into their sustainability strategies:

- Eli Lilly applies AI for predictive maintenance, reducing downtime and increasing asset reliability (Pharmaceutical Technology, 2022).
- AstraZeneca employs AI-driven digital twins to optimize energy use and meet its net-zero carbon target by 2025 (World Economic Forum, 2024).
- Pfizer used AI extensively during COVID-19 vaccine production to anticipate bottlenecks and enhance supply chain efficiency (RSC Publishing, 2021).

These initiatives demonstrate how AI contributes to sustainability, waste reduction, and operational cost savings, becoming a core pillar of ESG strategies in pharmaceutical companies by supporting environmental targets and stakeholder collaboration throughout the product life cycle—from drug discovery through production to global supply chains that deliver safe and effective medicines to patients. The typical product life cycle in pharma is understood as a dynamic framework that integrates scientific R&D, process optimization, and regulatory compliance across distinct stages (Kotler, 2000) and serves as a strategic tool for managing innovation, resource allocation, and environmental impact over time. AI is transforming every stage of the pharmaceutical production life cycle (Figure 1).

Figure 1. AI Applications in the Pharmaceutical Production Life Cycle
Source: own elaboration based on Pharmaceutical Technology (2022), World Economic Forum (2024) and Kotler (2000)

The AI significantly enhances the drug discovery process by analysing vast datasets to identify promising compounds faster and more accurately. As Novartis CEO Vasant Narasimhan spoke “We only understand 5-10% of what's happening in the 40 trillion cells that are in you and me. Could AI help us understand that more quickly, and then (help us) when we try to design a drug to impact one of those processes in the body? Could we design the drug even better with AI?” (Bhan & Anand, 2024).

Additionally, AI technology helps optimize energy consumption during computational simulations and lab operations. In production, AI-driven predictive maintenance minimizes downtime by forecasting equipment failures before they occur, improving overall efficiency and reliability. AI also plays a critical role in supply chain management by anticipating bottlenecks and accurately predicting resource needs, ensuring timely delivery and cost-effectiveness. One powerful example of this integration is the use of AI in combination with digital twin technology discussed below.

3 Case study: AI + digital twins: The game-changers for sustainable pharma

The convergence of AI and Digital Twins has revolutionized the pharmaceutical industry, offering new opportunities for optimization and sustainability. Digital twins—virtual representations of physical entities—are used to simulate and analyze complex processes in real time, and when combined with AI, they enable predictive analytics, automation, and enhanced decision-making. The integration of AI with digital twins in pharmaceutical processes not only facilitates operational efficiency but also contributes significantly to sustainability by reducing waste, optimizing resource usage, and ensuring better compliance with regulatory standards. Recent case studies from leading pharmaceutical companies such as AstraZeneca, Pfizer, GlaxoSmithKline (GSK), and Novartis illustrate the transformative impact of these technologies when applied strategically across various stages of the pharmaceutical value chain (Table 2).

AstraZeneca has adopted a combination of AI, machine learning, digital twins, and predictive modelling to improve manufacturing precision and reduce resource inefficiencies. By simulating production environments and forecasting potential variabilities, the company has achieved a 22% reduction in drug waste, highlighting the role of predictive analytics in minimizing overproduction and batch rejections—key contributors to pharmaceutical waste streams. Pfizer has leveraged AI in conjunction with digital twins and environmental impact modelling to optimize manufacturing lifecycles from a sustainability perspective. By modelling the environmental consequences of production choices in real-time, the company successfully avoided 18 tons of plastic waste and achieved a 34% reduction in CO_2 emissions. These outcomes underscore the potential of AI-driven environmental modelling in facilitating more responsible materials use and emissions management at the design and execution phases of production. GSK has advanced sustainability by integrating digital twins with AI-powered material compatibility analysis and additive manufacturing techniques, including 3D printing. These technologies enable precise customization of components and processes, particularly in biologics production, where single-use systems have been prevalent. As a result, GSK reported a 40% reduction in single-use bioreactor waste, marking a significant move toward reducing reliance on disposable plastic components and promoting circular production practices. Novartis has employed reinforcement learning algorithms, electronic health record (EHR) data analysis, and digital twin technologies to revolutionize clinical trial design and execution (Table 2). This AI-enhanced framework allows for the dynamic simulation of trial scenarios, optimized patient recruitment, and personalized treatment strategies. The implementation of such tools led to a 60% increase in clinical trial success rates and a 40% reduction in required trial participants, indicating substantial improvements not only in trial efficiency but also in the ethical and environmental burden of large-scale clinical studies.

Table 2. AI + Digital Twins: The Game-Changers for Sustainable Pharma

Firm	Area of Impact	Problem Identified	Solution Implemented	Tools / Technologies Used	Outcome	Reference
AstraZeneca	Clinical Trials	Excess drug waste due to supply chain inefficiencies	Real-time simulation of 18 trial logistics variables	AI, Machine Learning, Digital Twin, Predictive Modelling	22% reduction in drug waste	J&K Technology (2023); Noirfalise, M. (2023)
Pfizer	Logistics & Waste Management	High plastic waste and CO_2 emissions in clinical logistics	Route optimization and usage prediction via digital twins	AI, Digital Twins, Environmental Impact Modeling	18 tons of plastic waste avoided; 34% CO_2 emissions reduction	Farsani et al. (2021) J&K Technology (2023)
GSK	Vaccine Manufacturing	High single-use bioreactor waste	Closed-loop tracking and AI-guided material reuse	Digital Twin, AI Material Compatibility, 3D Printing	40% reduction in single-use bioreactor waste	Technology (2023) GSK. (2023) Pharmaceutical Technology (2023)

Firm	Area of Impact	Problem Identified	Solution Implemented	Tools / Technologies Used	Outcome	Reference
Novartis	Clinical Trial Optimization	Low success rates and high clinical waste	Patient subpopulation modeling and adaptive dosing	Reinforcement Learning, EHR Data Analysis, Digital Twin	60% increase in trial success; 40% fewer trial participants required	Novartis. (2021; 2023; 24); J&K Technology (2023)
Boehringer Ingelheim	Biologics Manufacturing	Inefficient bioreactor operations and high media usage	CFD and AI simulation for process optimization	Computational Fluid Dynamics (CFD), AI, Bioprocess Digital Twin	31% media reduction; 18% faster cell development	Genengnews. (2021); J&K Technology (2023)
Roche	Energy Use in Manufacturing	High energy consumption per dose in biologics	Continuous manufacturing twin with AI perfusion optimization	Digital Twin, AI-optimized perfusion, Predictive Maintenance	56% reduction in energy per dose	J&KTechnology (2023); Roche. (2024); Outsourced Pharma. (2023)
Johnson & Johnson	Facility Energy Optimization	Need to maximize renewable energy use	Simulation of hybrid energy systems and battery degradation	Digital Twin, Energy Simulation, Battery Modeling, Wind Pattern Analysis	96% renewable operation at Cork facility	J&K Technology (2023); Johnson & Johnson. (2023a; 2023b)
Merck	Supply Chain Decarbonization	Emissions from cold chain logistics	Multi-factor environmental route optimization	AI, Environmental Modeling, Digital Twin	29% reduction in cold chain emissions; 99.97% product integrity maintained	J&K Technology (2023); Merck (2025)

Source: own elaboration based on Farsani et al. (2021), J&K Technology (2023), GSK (2023), Pharmaceutical Technology (2023), Novartis (2021; 2023; 2024), Genengnews (2021), Roche (2024), Outsourced Pharma (2023), Johnson & Johnson (2023a; 2023b), Merck (2025).

Collectively, these examples reflect a broader industry trend in which AI and digital twins are deployed not merely as process optimization tools, but as enablers of a more sustainable, data-driven pharmaceutical ecosystem. The convergence of simulation, predictive analytics, and real-time monitoring contributes to waste minimization, carbon footprint reduction, and enhanced resource circularity—key goals in the transition to green manufacturing.

These case studies affirm the potential of AI and digital twin technologies to serve as foundational elements of the next generation of sustainable pharmaceutical production systems. As regulatory and societal pressures intensify around environmental stewardship and resource efficiency, the adoption and advancement of such intelligent systems are likely to become central to maintaining both economic competitiveness and environmental responsibility in the life sciences sector.

4 Drivers and barriers to leveraging AI for sustainability

4.1 Drivers to AI implementation

AI is becoming a foundational element of ESG strategies in the pharmaceutical industry, supporting sustainability goals, reducing waste, and improving cost-efficiency throughout the entire product life cycle. From drug discovery to global supply chain management, AI transforms operations by accelerating research, optimizing energy use, predicting equipment failures, and managing resources more precisely. The integration of AI with digital twin technology enables real-time simulation and predictive analytics, greatly enhancing decision-making and operational sustainability. Case studies from AstraZeneca, Pfizer, GSK, and Novartis show measurable benefits such as significant reductions in waste, CO_2 emissions, and single-use plastics, as well as improved clinical trial outcomes. These examples illustrate how AI-driven innovation not only boosts efficiency and compliance but also drives environmentally responsible practices across pharmaceutical production.

4.2 Barriers to AI implementation

While AI holds transformative potential for the pharmaceutical industry, its adoption is hindered by a range of interconnected challenges. These include high implementation costs, poor data quality and integration, a shortage of skilled professionals, organizational resistance, legacy system constraints, and regulatory and ethical concerns. High upfront costs—for infrastructure, tools, and talent—can be prohibitive, especially when returns on investment are uncertain or long-term. Many pharmaceutical firms struggle with fragmented and outdated data systems, making it difficult to provide the clean, structured datasets that AI requires. The lack of talent combining technical expertise with domain-specific knowledge often leaves companies dependent on external vendors. Resistance to change within organizations—driven by concerns about job security and skepticism about AI—can further hinder adoption, especially in the absence of strong communication and change management. Integrating AI with legacy IT systems adds complexity and risk, threatening data integrity and operational continuity.

Strict regulatory environments and ethical issues around bias, transparency, and data privacy demand rigorous oversight and tailored compliance strategies. Additionally, the absence of industry standards and growing concerns around cybersecurity add to the complexity of implementation. Beyond internal hurdles, AI adoption in pharma has broader implications for building sustainable, circular, and smart healthcare ecosystems. On the positive side, AI can enhance resource efficiency and promote circularity. However, it also introduces negative externalities, such as increased energy consumption, digital divides, and safety concerns. Addressing these challenges requires coordinated action among stakeholders, continuous technological advancement, and supportive policies. Public funding and national programs should not only prioritize AI initiatives but also focus on enhancing digital readiness and promoting socially and environmentally responsible tools. Such strategic investments are critical to enable a climate-neutral and resilient healthcare system.

5 Summary and policy implications

The integration of AI in infrastructure, waste classification, and recycling within the pharmaceutical sector demonstrates a commitment to sustainability and operational excellence. By embracing AI technologies, companies not only comply with regulatory standards but also achieve cost savings, enhance efficiency, and contribute to environmental stewardship. The transformation of the pharmaceutical industry towards a greener, more sustainable future hinges not only on AI's technological capabilities but also on the readiness of both the industry's digital infrastructure and its broader organizational ecosystem. While AI can drive efficiency and innovation, its full potential can only be realized in environments that are digitally prepared and infrastructure-ready. This requires not only cutting-edge technology but also a strong foundation in data management, AI systems integration, and employee digital literacy. Moreover, soft factors—such as organizational culture, leadership vision, and employee engagement—are essential to unlock the power of AI for sustainability. Collaborative frameworks, underpinned by open innovation, must facilitate the flow of knowledge and technology across sectors, fostering rapid adaptation to environmental and regulatory challenges. Policymakers, therefore, must prioritize not just financial incentives and regulatory harmonization, but also the development of digital infrastructure, the fostering of AI and digital readiness, and the establishment of collaborative platforms that encourage innovation, capacity-building, and cross-sectoral knowledge exchange.

6 Ethics declaration

This study does not involve any human participants, human data, or animal subjects. All data used in the research were synthetic or obtained from publicly available sources that do not contain any sensitive personal information. Consequently, no ethical approval or informed consent was required. The author confirms compliance with all relevant academic and institutional ethical guidelines and standards. There were no collaborations or funding from pharmaceutical companies, and the research was performed independently, avoiding any potential conflicts of interest.

7 AI declaration

The use of AI in this work complies with principles of transparency, accountability, and ethical responsibility. No AI tools were used to replace human judgment in ethically sensitive or operational decisions, and no human subjects or personal data were involved. The AI techniques, specifically machine learning models, were employed solely as analytical tools to support the research objectives. The research adheres to best practices for responsible AI usage in academic and scientific contexts.

[1]Department of Engineering Technology - Technical University of Denmark, Ballerup, Denmark
[2]Department of Management and Engineering - University of Padua, Vicenza, Italy

Abstract

The emergence of the latest generations of generative artificial intelligence (GenAI) systems, particularly ChatGPT, has prompted knowledge management (KM) scholars to investigate how these tools can be effectively integrated into organizational KM systems. However, as this field of study is in its infancy, the literature remains scarce and provides fragmented results. Empirical evidence is especially limited, and numerous research questions awaiting answers. One such question is how work experience influences the use of AI in new knowledge creation. To address this issue, this paper examines how and for what purpose GenAI is employed to support the creation of new knowledge, specifically focusing on how its use differs according to users' seniority levels. The hypothesis is that work experience, which shapes users' knowledge pools, affects how they utilize GenAI to support knowledge creation. Past empirical research highlighted that there are differences in AI usage between more and less experienced workers. Given the exploratory nature of the study, we employed a qualitative research method, conducting interviews with 22 software engineers from various companies who use GenAI systems in their daily activities. We choose software engineers as they are knowledge workers and are currently among the early adopters of GenAI systems. Based on a common guideline developed from knowledge creation processes, the interviews were conducted online and in person between July and November 2024. Each interview was recorded, transcribed and translated into English for analysis. Empirical research shows differences between more and less experienced workers, particularly with respect to the complexity of the tasks performed and the type of knowledge created with GenAI support. The study's results contribute to our understanding of GenAI's impact on KM and offer managerial insights for introducing and using the new technology within business contexts.

Keywords: Generative AI, Knowledge Management, Work Experience, Software Engineers, Interview Study.

Paper type: Academic Research Paper

1 Introduction

It is a common opinion among scholars (Jarrahi et al., 2023; Sumbal and Amber, 2024) and practitioners (Accenture, 2023; APQC, 2024) that last advances in artificial intelligence (AI), first and foremost the development of always more powerful generative artificial intelligence (GenAI) models, is offering new foundations to transform Knowledge Management (KM) in depths. This is why recent research in the KM field is devoting increasing attention to analysing how GenAI can be effectively integrated within organizational KM systems (Buchatskaya et al., 2024; Jarrahi et al., 2023; Taherdoost and Madanchian, 2023). However, since the study of this topic is in its infancy, the literature is still scarce and provides fragmented results. In particular, available empirical evidence is sparse, and many research questions await an answer (Korzynski et al., 2023; Leoni et al., 2024).

Contributing to our understanding of the integration of GenAI within KM, the present paper investigates how and for what purpose GenAI is employed to support the creation of new knowledge and, more specifically, how its use differs according to the seniority level of users. The fundamental hypothesis of this study is that work experience, since it shapes the knowledge pool possessed by the user, affects how they employ the new technology to support the creation of new knowledge. The results of past empirical research suggest this hypothesis, which has highlighted how more experienced workers use artificial intelligence differently from less experienced ones (Brynjolfsson, 2023; Burtch et al., 2024; Hu et al., 2023; Peng et al., 2023).).

Given the exploratory nature of the study, we employed a qualitative research method, which involved conducting interviews with professional workers who use GenAI systems in their daily activities. Specifically, we interviewed 22 software engineers who regularly use GenAI. We chose software engineers for several reasons: they are knowledge workers, meaning they apply theoretical and analytical knowledge in their jobs (Drucker, 1959); they are currently among the early adopters of GenAI technology (Alavi et al., 2023; Ebert and Louridas, 2023); and some papers have already been published on the use of GenAI in the software industry (see, e.g., Rajbhoj et al., 2024), albeit not from a KM perspective.

What emerged from the empirical investigation confirms that there are differences between more and less experienced workers, especially regarding the complexity of tasks performed and, therefore, the kind of knowledge created with the support of GenAI. The analysis results increase our understanding of AI's impact on KM and offer some managerial suggestions about the introduction and use of GenAI within business organizations.

2 Background

2.1 GenAI and KM: a symbiotic relationship

The latest development of GenAI models has made AI a fundamental element of KM (He and Burger-Helmchen, 2024), so that it can be rightly considered a "game changer" for KM in organizations (Sumbal and Amber, 2024). According to Iaia et al. (2024), integrating AI in KM implies activating a virtuous circle where both benefit. KM and AI exist in a symbiotic relationship, given that both have knowledge at their core (Ojala, 2024).

In particular, GenAI has made a significant leap forward compared to previous AI models regarding its ability to support organizational KM effectively. Innovative tools like ChatGPT, Gemini, Copilot, and Claude, to name just a few of the most well-known, can find wide and practical applications within all KM processes (Alavi et al., 2024; Jarrahi et al., 2023). Specifically, they can create high-quality content; automatically summarize lengthy documents, research papers, or articles; power question-answering systems; provide personalized recommendations; translate documents; act as virtual assistants and chatbots capable of understanding and responding to user queries in natural language; create interactive learning environments; dynamically personalize content based on user context; track changes made to documents over time; automatically categorize documents; analyze unstructured data sources and extract information; generate visual representations, such as concept maps or diagrams; and convert spoken language into written text (Chui et al., 2023; Sumbal et al., 2024).

Since the integration of GenAI in KM is taking its first steps, to make the most of its opportunities, we need to fully understand the nature of this relationship, also by drawing inspiration from existing use experiences, which is what the present study intends to do.

2.2 Using GenAI in KM: The role of work experience

Due to its inherent flexibility and adaptability, GenAI can be considered a" malleable technology" as defined by MacKenzie and Wajcman (1999) and Orlikowski (1992). Unlike rigid technologies, which are characterised by fixed functionalities and limited scopes of application, malleable technologies are highly adaptable and customizable. Depending on the use case, domain, or user needs, they can be shaped or applied in many different ways. The malleable nature of GenAI systems lies in the fact that they can be adapted to various tasks and knowledge domains, which makes them versatile tools (Cimino et al., 2025). In fact, not only can GenAI be applied to numerous fields, from text and image generation to code writing and problem-solving, but users can also tailor the output of GenAI through prompts or specific instructions, shaping the results to their needs.

This malleable nature requires us to investigate how GenAI is used in various application contexts and by different users to better understand its potential impact. Considering the points discussed in the previous section, it would be particularly interesting and valuable to analyze the use of GenAI in the context of KM processes, specifically in creating new knowledge. Regarding users, a topic that deserves in-depth exploration is the role that work experience plays in shaping the use of these tools. Early studies suggest that work experience and associated skills influence how GenAI is perceived and used by workers and the performance they achieve through its use. The findings of three experiments conducted by Cui et al. (2025) on the adoption of Copilot among software developers revealed that adoption patterns and productivity gains varied according to tenure, with younger developers benefiting the most. Peng et al. (2023) and Gambacorta et al. (2024) corroborated these results, demonstrating similar productivity advantages for junior programmers over their senior counterparts when using GenAI. Sun et al. (2024) further explored this dynamic, showing that perceptions of GenAI's creativity vary with task requirements. They found that expert users are more critical of GenAI-generated content than novices. This critical stance among experts was also evident in Burtch et al.'s (2024) investigation, which revealed that the advent of GenAI led to a higher exit rate of junior and less experienced users from knowledge communities. Li et al. (2024) provided additional nuance, highlighting that while AI usage generally improves performance, it doesn't necessarily reduce individual performance variance. This suggests the emergence of new skill disparities in the AI era. Storey (2024) offered insight into the underlying mechanisms of these disparities. She posited that novices tend to rely on acquiring explicit knowledge, whereas experts

possess a more sophisticated ability to synthesize knowledge, often based on heuristics or case studies. Consequently, expert knowledge workers utilize GenAI differently: they apply it to more complex tasks and exercise greater scrutiny in assessing the validity of the obtained results.

In conclusion, research on the influence of work experience on GenAI usage is still in its infancy, presenting a fertile ground for further exploration (Hu et al., 2023). Given this context and focusing on knowledge creation as the application domain, this study aims to address the following research question:

- RQ: How do workers with varying levels of experience use GenAI tools for knowledge creation?

3 Research methodology

Given the exploratory nature of the research, this study adopted a qualitative interview-based approach (Given, 2008) with software engineers as a group of knowledge workers using GenAI in their daily jobs. Collected data were analyzed by applying thematic analysis, a method for identifying, analyzing, and interpreting patterns of meaning (themes) within qualitative data (Braun and Clarke, 2012). This approach effectively uncovers patterns within and across datasets, especially about the lived experiences, perspectives, and practices of participants. Thematic analysis provides a robust framework for examining qualitative information, allowing researchers to taking deep insights into the nuances of participants' responses and behaviors. We employed a convenience sampling method, a widely used technique in descriptive studies (Zhang and Liu, 2021). Between July and November 2024, we conducted 22 semi-structured interviews with software engineers selected from various countries and with a range of programming experience levels, from junior to senior professionals, as well as diverse organizational roles. Table 1 illustrates the profile of the interviewed people.

Table 1: Profile of respondents

Interview	Role	Age	Experience (years)
01	Co-founder (startup)	40	17
02	Senior software engineer	40	14
03	Founder and owner (startup)	38	7
04	CEO - Technical director	47	20
05	Solution specialist	50	20
06	R&D manager	56	28
07	Senior software developer	37	14
08	Head of AI team	40	10
09	Business analyst	31	3
10	President	65	40
11	Italian AI team leader	37	15
12	Project manager	25	1
13	Chief product officer	52	32
14	Chief innovation officer	55	37
15	Software developer	23	3.5
16	Senior software engineer	40	15
17	BI developer	27	2.5
18	Software engineer	27	2
19	IT consultant	56	36
20	Software engineer	27	2
21	Software developer	37	9
22	Advanced software engineer	38	6

4 Findings

4.1 Introduction

To answer our research question, we categorized knowledge workers into three groups based on their years of work experience: six juniors (0-5 years), eight mid-levels (6-15 years), and eight seniors (16+ years). While work experience can be linked to job roles, we opted for years of experience as a more objective measure. Additionally, the composition of the groups would not have differed significantly, as Table 1 shows a strong correspondence between work experience and role, with a general relationship between seniority and managerial positions.

4.2 Overview of interviews

The following paragraphs describe how different groups of respondents report using generative AI in their daily activities related to knowledge creation.

4.2.1 Junior workers

Junior respondents affirm that they frequently use Generative AI tools such as ChatGPT, Copilot, and Gemini to streamline their work and enhance productivity. They find these tools particularly beneficial for repetitive, low-level tasks, including generating code snippets, transforming data formats, and summarizing meeting notes.

"… I use it (ChatGPT) a lot, almost daily, whether it's for emails, responses, or similar tasks." (Interview 12)

"... Mainly for low-level activities, such as the technical side - for example, generating classes with random examples or having it transform some objects from JSON into objects in other languages like TypeScript or C#." (Interview 15)

"… I used it more to save time on routine tasks like summarizing the meeting and getting to-do lists during a group call." (Interview 20)

"… before generative AI, it was so time-consuming. We should, we had to think about that, and we should, we had to try to get the right number and write, for example, the DAX formula." (Interview 17)

Moreover, they appreciate the tools' ability to provide quick and coherent results, which they can subsequently refine and build upon. However, these professionals do not rely entirely on AI tools, citing concerns about data privacy and the accuracy of generated output. Instead, they utilize these tools as assistants, complementing their expertise rather than replacing it. Integration of GenAI has reduced the need for frequent interruptions and interactions with colleagues, as these tools can often provide the necessary information or solutions more efficiently. On the other hand, this could negatively affect teamwork and the culture of co-creation.

"… asking for formulas means I no longer have to bother my colleagues. Basically, we don't disturb each other anymore because we ask the chat, and if the formula is correct, there's no need to ask anyone else." (Interview 12)

"... in this way I get the correct solution like most of the time and in a faster time period … in conclusion, yeah it reduced the amount of interactions between colleagues." (Interview 18)

Junior respondents initially stick to default tools to build a solid foundation and align with organizational practices. As they gain experience, they can begin exploring GenAI tools, which they generally view as valuable assets. While many juniors are understandably cautious and may lack the skills to fully validate GenAI outputs, the technology helps streamline their workflow, enabling time savings and allowing them to focus on more complex knowledge tasks.

"… So it's very helpful. I cannot say that it's completely changed our job. No, because we cannot trust 100% in this tool". (interview 17)

"... I go through it and check it every time because sometimes it makes mistakes and it's just a good spot to start." (Interview 18)

In summary, junior workers utilize GenAI to handle simple and repetitive knowledge creation activities, the output of which can be validated even by less experienced professionals. While this enhances their independence and productivity, it also negatively impacts the collaborative creation of new knowledge. In essence, junior workers employ GenAI to produce "new-for-them" knowledge.

4.2.2 Mid-level workers

Respondents in the mid-level group also report using GenAI tools to enhance their productivity and efficiency, primarily for repetitive, routine tasks such as data transformation, code documentation, and implementing simple functionalities. They find these tools helpful in providing immediate assistance when working with unfamiliar languages or frameworks. Some mid-level workers also leverage them for more complex problem-solving, such as mathematical calculations and engineering-related tasks.

"... The other major category is implementing very simple functionalities or small scripts when there's limited knowledge of the required language or especially of the specific framework for that functionality." (Interview 3)

"… I use them quite a bit to enhance my personal productivity. This applies to tasks related to my role." (Interview 11)

"... I used the tools mostly for documentation, and repetitive tasks, and scripting. Not really for complex tasks, though I used them sometimes for complex code too, which needs personal skills with teams." (Interview 21)

Mid-level workers report using GenAI to bridge skill gaps and enhance team collaboration. However, they perceive the tools' effectiveness in these areas as still limited, often necessitating output validation before integration into their work. Generally, these respondents are more critical of GenAI tools' utility, highlighting limitations due to a lack of domain-specific knowledge and potential for hallucination, which can result in irrelevant or inaccurate outputs.

"... One is the lack of knowledge of our domain, and also the, you know, the thing that hallucination that these tools have and make some, for example, the other time, it created some action points, which is absolutely irrelevant to the meeting that we had." (Interview 2)

"... Sometimes I changed the entire prompt's structure, and sometimes I modified certain parts, but again, I encountered wrong answers. I felt that this was not the correct answer." (Interview 7)

This group of respondents actively explores GenAI tools to optimize their workflows and boost productivity, even for more complex tasks. They occasionally contribute to fine-tuning these tools to better align with team processes, demonstrating a level of engagement with tool customization. However, they maintain a cautious approach, avoiding over-reliance on these tools, particularly for critical or intricate assignments.

"... My team uses these tools regularly because [*name of the company*] *encourages all employees to use them depending on their roles. This has also led to significant cost savings, as it shifts employees from blue-collar functions and reskills them, thus initiating a reskilling process". (Interview 11)*

"… We're using it for code development, and gradually, they're also integrating it into some services on the database side, like SQL Server or Cosmos DB." (Interview 16)

In summary, mid-level workers utilize GenAI to handle both simple and complex knowledge creation activities, although they are aware of these systems' limitations when dealing with domain-specific knowledge. Moreover, mid-level workers often employ these tools to enhance the collaborative creation of new knowledge within their work teams. In essence, mid-level workers employ GenAI to promote the production of "new-for-the-team" knowledge.

4.2.3 Senior workers

According to their answers, senior workers are increasingly incorporating GenAI tools into their daily work routines, and the tools are being used for a variety of tasks, both repetitive and complex. For repetitive tasks, senior workers say they use GenAI tools to automate text generation, code completion, data formatting, and other mundane activities that previously required manual effort. The tools help to accelerate these routine processes, making developers more efficient. For more complex tasks, GenAI assistants kickstart and facilitate the engineering development process.

"... I know that other colleagues of mine, developers in my team, are already doing the same. They do work that's much more focused on development, and they're already using it increasingly often to solve coding problems." (Interview 6)

"... For complex tasks, we directly use ChatGPT, and recently we've had great success with O1, also from OpenAI, which we believe will make a substantial difference, as we've already seen." (Interview 14)

Senior workers use GenAI to quickly gather relevant information, synthesize insights, and generate initial drafts or prototypes. This helps overcome the challenge of starting from a blank slate, especially for technical writing, software architecture, and other knowledge-intensive work. The common opinion is that even if GenAI models cannot fully automate complex tasks, they can serve as valuable tools in the ideation and early stages of work, helping to generate initial ideas, text, code, etc., that can then be refined and built upon.

"... We also use it to create personalized summaries of calls and meetings we hold. We've also used it to create our own products." (Interview 1)

"... These tools are never able to provide a perfectly clean text ready for a presentation or a technical report, but they can often summarize the themes or points, thus guiding the drafting of the final document." (Interview 5)

"... I use it as support or an accelerator to kick-start complex tasks." (Interview 5)

Some senior respondents are also experimenting with integrating GenAI more deeply into their workflows by connecting them to internal knowledge bases or using them to generate entire software components. However, there are still limitations, especially for certain programming languages and more advanced use cases. Senior workers approach GenAI with a strong awareness of risks, using systematic validation methods and maintaining a critical perspective on its limitations. A hybrid approach is common, where GenAI tools are used in conjunction with traditional methods and human expertise. The adoption of GenAI also impacts how seniors collaborate and share knowledge within their teams. While some see the tools as a way to be more self-sufficient, others view them as a means to enhance teamwork, using AI as a "co-pilot" to discuss and refine solutions together.

In general, senior workers affirmed that they are actively exploring the entire range of capabilities of GenAI, from automatic substitutes for simple tasks to collaborative assistants for more complex ones, and finding ways to strategically incorporate them into their work processes.

"… I find it useful now as an accelerator for this initial synthesis—to quickly find information that's already correlated and aggregated, which allows me to take a direction early on and save myself the initial work of research and selection." (Interview 6)

"… We have this mix where Copilot is mainly adopted for repetitive tasks and knowledge mining, and then we integrate it with GPT, Cursor, and also Claude, as Claude is actually quite good at writing code as well. We use a combination of these tools for more complex tasks." (Interview 14)

In summary, senior workers make more intensive use of GenAI to foster the collaborative creation of new knowledge within their teams. Furthermore, they are striving to integrate these tools as an essential component of their knowledge creation strategy. In essence, senior workers promote using GenAI to produce "new-for-the-organization" knowledge.

4.3 Comparative analysis

Based on the results presented in section 4.2, we conducted a comparative analysis across the three groups of software engineers. This analysis focused on five key aspects: Task Complexity, Collaboration vs. Independence, Trust and Risk Awareness, Tool Customization and Impact, and Knowledge Creation. The findings, along with a comparison highlighting the differences among the three groups, are summarized in Table 2.

Table 2: Summary of comparative analysis

Aspect	**Work experience**			**Comparison**
	Junior	**Mid-level**	**Senior**	
Task Complexity	Juniors use GenAI for simple tasks like code snippets and meeting notes. It's mainly a time-saver and support tool	Mid-levels move into advanced uses like automation, prompt tweaking, and in-house tool development. They're cautious but exploring	Seniors use GenAI strategically—for prototyping, architecture, and integrating tools into team workflows	*More experience leads to deeper and more strategic GenAI usage*
Collaboration vs. Independence	Juniors rely on GenAI to work independently, reducing the need to ask colleagues	Mid-levels use it to fill gaps and make collaboration smoother	Seniors use GenAI to boost idea generation and co-creation within teams	*GenAI supports independence early on and enhances collaboration at higher levels*
Trust and Risk Awareness	Juniors are cautious but may lack the skill to fully validate AI outputs	Mid-levels test results more rigorously, and are aware of hallucinations	Seniors apply structured validation and remain highly critical of limitations	*More experience leads to more trust management and risk control*
Tool Customization and Impact	Juniors stick to default tools	Mid-levels help fine-tune tools for team use	Seniors lead integration and drive organization-wide AI adoption	*Experience enhances tool customization and scales impact from individual to organizational levels*
Knowledge Creation	New-for-them	New-for-the-team	New-for-the-organization	*Experience deepens knowledge creation reach*

5 Discussion and Conclusion

The findings of our empirical investigation confirm that the use of GenAI tools varies according to users' experience levels. Specifically, while junior workers employ GenAI tools to increase their productivity in performing simple tasks, essentially acquiring new knowledge for themselves, more experienced workers use these tools to enhance their ability to tackle complex problems. In addition, experienced workers use GenAI particularly to stimulate the production of new knowledge within collaborator teams and throughout the organisation.

From an academic perspective, this study confirms that GenAI is a malleable technology capable of adapting to users' specific needs and abilities, as well as to the context of use. From a KM standpoint, the study emphasizes that this technology can be employed to address cognitive problems of varying complexity and support knowledge creation processes ranging from individual to organizational levels.

Regarding managerial implications, the study suggests the need for a diversified approach in promoting the adoption and use of technology, depending on the experience level. While the focus for junior workers should be on illustrating the technical aspects of using these tools, for more experienced workers, attention should be directed towards the organizational implications of their use.

This paper has limitations, which nonetheless offer directions for future research. As it is based on a limited number of interviews, its results cannot be immediately generalized. Future studies could address this constraint through quantitative analyses, such as large-scale surveys involving more representative samples. Another limitation related to generalizability is that the investigation involved a specific group of knowledge workers, namely software engineers. Future studies should focus on different sectors. Lastly, the rapid evolution of GenAI systems presents a significant challenge to research in this field. Its dynamic nature necessitates ongoing and adaptive research approaches. In this regard, longitudinal studies could be invaluable in anticipating the future evolution of GenAI and its changing impact on knowledge workers over time.

6 Ethics declaration

No sensitive or personally identifiable information was collected. Prior to the interviews, all participants were informed about the purpose of data collection and recording, as well as the use of information for research purposes. Their verbal informed consent was obtained. Interview data is available upon request.

7 AI declaration

The authors manually conducted all analyses using MAXQDA, while its AI assistant was used to help in extracting quotes; all analyses and writing were done by the authors.

Generative AI Techniques for Data Aggregation and Summarization: Enhancing Decision Support in Healthcare

Giuseppe Loseto, Alessandro Massaro, Angelo Rosa
LUM "Giuseppe Degennaro" University, Casamassima (Bari), Italy

Abstract

Processing healthcare data presents significant challenges for clinicians, particularly in chronic disease management such as diabetes care. Traditional data aggregation and summarization methods often struggle to integrate the diverse data sources of health information, ranging from structured electronic health records to unstructured clinical notes. In response to this challenge, the paper proposes a reference framework that leverages generative Artificial Intelligence (AI) techniques and agentic AI architectures for enhancing health data management and decision support. By employing Large Language Models, the system is able to synthesize insights from collected data also deriving contextualized summaries and personalized recommendations useful for healthcare professionals. The paper outlines the architectural components of the framework and discusses key implementation strategies. Finally, a basic prototype has been developed to demonstrate the feasibility and usability of the proposed architecture in the context of telediabetology, supporting the management of diabetes patients during periodic clinical visits.

Keywords: Generative AI, Healthcare, Decision Support, Large Language Models

Paper type: Academic Research Paper

1 Introduction and motivation

With the exponential growth of clinical data, healthcare systems are generating vast volumes of information from diverse sources, including Electronic Health Records (EHRs), medical imaging, wearable devices (Massaro et al., 2020, Magaletti et al., 2021), laboratory reports, patient-generated data, and clinical research studies. Advancements in medical technologies drive this data explosion, the widespread adoption of digital health tools, and the increasing emphasis on personalized and evidence-based care (Van Woensel et al., 2022). However, this abundance of data often exists in highly heterogeneous silos of information. It contains a mix of structured and unstructured formats, making it challenging for healthcare professionals to process and analyze effectively. This research explores the application of generative AI techniques for data aggregation and summarization to enhance decision support, particularly in complex and dynamic domains such as healthcare. Generative AI tools offer several advantages over traditional techniques (Moulaei et al., 2024), including: (i) process unstructured data like clinical notes and free-text inputs, which traditional techniques often struggle with; (ii) automating the integration of different data sources, such as merging EHRs with real-time monitoring data; (iii) produce high-quality, human-readable summaries tailored to specific user needs (e.g., clinicians, administrators, or researchers) reducing the cognitive burden on healthcare professionals. By bridging state-of-the-art AI methodologies with real-world clinical applications, the study aims to investigate how generative AI techniques and tools, such as Large Language Models (LLMs), can streamline data integration and extract meaningful patterns (Yang et al., 2023), and contribute to the development of trustworthy decision support systems for healthcare providers. As stated in (Busch et al., 2025), LLMs represent recent and relevant tools for aggregating, summarizing, and interpreting data, helping physicians make informed decisions. By automating data summarization, LLMs ensure that physicians have a comprehensive view of a patient's health, eliminating the need for manual data gathering. During periodic check-ups, LLMs can instantly retrieve and summarize recent patient data, generate visual reports for quick analysis and suggest areas requiring further clinical attention.

The proposed work introduces a reference framework for health data management, specifically designed to support diabetes care through the integration of generative AI tools and agentic AI frameworks. This framework aims to enhance the way patient data is processed and analysed, providing physicians with intelligent decision support while maintaining a human-centered approach to healthcare. The paper is organized as follows: Section 2 provides a detailed description of the proposed health data management framework, outlining its core components, functionalities, and technological foundations; Section 3 presents a use case demonstrating how the proposed framework can support physicians during periodic visits with diabetes patients; Section 4 summarizes the key contributions of this work and highlights potential future improvements.

2 Generative AI-driven health data management

This research proposes a reference framework for health data management specifically tailored for diabetes patients. Diabetes-related data encompasses a wide range of formats, including numerical glucose readings, textual dietary logs, and other health metrics. Additionally, each diabetes patient presents unique characteristics, such as individualized nutritional habits, medication routines, and lifestyle factors, making personalized data interpretation essential. Rushed or insufficient analysis risks overlooking critical insights or correlations, potentially compromising the quality of care and decision-making. By combining the capabilities of generative AI, wearable technology, and advanced analytics tools, this framework aims to improve clinical decision-making, enhance patient engagement, and foster more personalized and effective diabetes care. A basic principle of the adoption of generative AI in telediabetology is illustrated in Figure 1. The framework leverages wearable devices and clinical-oriented mobile applications to continuously collect health-related data. While wearables track vital signs, physical activity, and lifestyle patterns, mobile applications enable patients to log symptoms, medication intake, and other relevant health information, effectively creating a personalized health diary. Several studies (Praino et al., 2020, Alvarez-Perea et al., 2021, Patton et al., 2022) have shown that such diaries enhance patient participation and awareness by fostering a more proactive approach to health management. By actively engaging with their health data, patients gain better insights into their condition, adhere more consistently to treatment plans, and collaborate more effectively with healthcare providers. Unlike traditional cloud-based systems, the collected data is securely stored locally on the user's smartphone to prioritize data privacy and give patients greater control over their health information. The framework enables seamless data sharing between patients and their healthcare providers through secure communication channels. Once shared, the data can be processed using generative AI frameworks, such as AG2[1] (formerly AutoGen), LangChain[2] and Microsoft LIDA (Dibia, 2023), to generate personalized suggestions and useful visualizations automatically. Collected data, including standard lifestyle and dietary guidelines, are processed by a generative AI engine using clinical data to enhance Integrated Care Pathways for diabetes care and prevention.

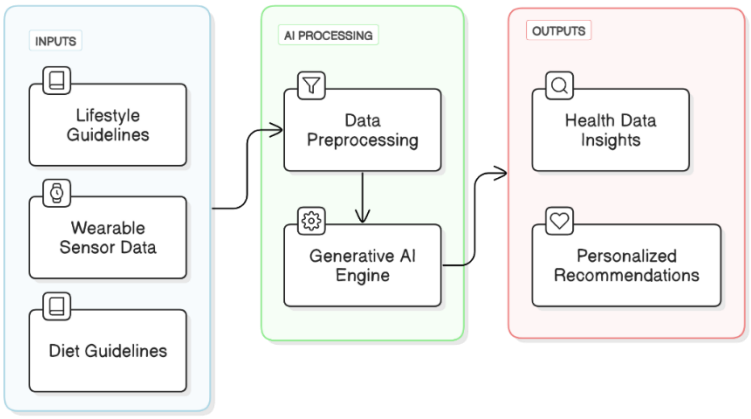

Figure 1: Generative AI improving Integrated Care Pathways for prevention and care of diabetics.

Key features of the framework include the usage of LLMs to interpret and summarize health data, ensuring that visualizations are contextually meaningful to the specific needs of diabetes management. Each output is designed to present complex health metrics in a clear and accessible format, helping both patients and physicians to understand trends, anomalies, and progress over time.

In the proposed approach, the generative AI module has been implemented using AG2, a robust agentic AI framework. AG2 was selected due to its flexibility, modular architecture, and ability to handle complex multi-step reasoning tasks, making it particularly well-suited for healthcare applications. This agent-based structure ensures scalability, allowing future expansion to additional medical conditions and datasets. The framework also integrates a Retrieval-Augmented Generation (RAG) architecture to enhance interaction with data collected by patients. Traditional generative AI models rely solely on pre-trained knowledge, limiting their ability to respond dynamically to patient-specific information. RAG architecture enhances the AI module by retrieving relevant data from uploaded patient documents (e.g., medical reports, glucose logs, lifestyle diaries) and providing contextualized answers, ensuring that insights are personalized and aligned with each patient's unique history.

[1] https://docs.ag2.ai
[2] https://www.langchain.com

To ensure data privacy, the system leverages Ollama[1] as the local LLM provider. The reference model used for AI-driven insights and summarization is LLaMA 3.2 7B, a lightweight yet powerful open-source model provided by Meta[2], optimized for on-device execution. Local LLMs enable real-time analysis while keeping patient information within secure environments, mitigating risks associated with data breaches and unauthorized access. Additionally, local LLMs optimize performance by reducing latency and enabling real-time decision support for both patients and healthcare providers. Improved communication of critical health information fosters better understanding and collaboration between patients and healthcare providers.

The system UI has been built using Streamlit[3], a python-based framework that enables rapid prototyping and deployment of interactive web applications. The streamlit-based dashboard includes: (i) interactive visualizations, essential for clinicians for exploring patient data dynamically; (ii) a conversational AI assistant, where physicians can ask natural language questions about patient health records and receive AI-generated insights. The AI-powered dashboard is designed to streamline data analysis for clinicians, allowing them to dedicate more time to patient care rather than manually processing large datasets. At the same time, it empowers patients by providing clear, personalized summaries and interactive visual feedback about their health metrics. This human-in-the-loop approach ensures that AI insights remain transparent, interpretable, and aligned with clinical needs.

3 Illustrative usage scenario

To illustrate the proposed approach, this section presents a reference case study illustrating how a physician can utilize a decision support dashboard, to enhance the management of a diabetes patient during periodic clinical visits. The dashboard streamlines the consultation process by structuring patient data and providing real-time data analysis and insights. The dashboard also integrates an AI-based agent assisting the physician in reviewing clinical progress, aggregating data and providing suggestions about the treatment plan of each patient. In the proposed scenario, input data have been simulated using *simglucose*, a Type-1 diabetes simulator. It is a recent python-based implementation of the UVA/Padova simulator (Dalla Man et al., 2014), approved by the Food and Drug Administration (FDA) for research purposes, featuring 30 virtual patient profiles (10 adolescents, 10 adults, 10 children). Each profile includes a comprehensive set of diabetes-related health metrics providing a detailed picture of the patient's metabolic control, enabling physicians to make data-driven decisions. Simulated attributes include:

- Time of measurement: each recorded data point is timestamped, allowing the system to track trends and variations over different time periods (e.g., fasting vs. post-meal glucose levels);
- Blood Glucose (BG) level: fingerstick blood glucose readings provide snapshot measurements at specific times of the day (e.g., fasting, pre-meal, post-meal, bedtime). BG values help assess short-term glucose fluctuations and inform medication and dietary adjustments;
- Continuous Glucose Monitoring (CGM) data: real-time glucose readings collected at frequent intervals providing glucose trends over time, highlighting rapid fluctuations, stability, and overall glycemic control. CGM also helps detect asymptomatic hypoglycemia or hyperglycemia episodes, which are often missed with traditional BG monitoring;
- Carbohydrate Counting (CHO) data: patients log carbohydrate intake per meal to help correlate diet with glucose variations. The system can analyze CHO intake patterns and their impact on postprandial glucose levels;
- Insulin data: records insulin doses administered (both bolus for meals and basal for long-term control) to evaluate the effectiveness of insulin therapy and detect underdosing or overdosing risks. AI-driven insights can suggest insulin dose adjustments based on past glucose responses;
- Low Blood Glucose Index (LBGI): quantifies the risk and frequency of hypoglycemic episodes and supports physicians detect patients at high risk of severe hypoglycemia, which requires intervention;
- High Blood Glucose Index (HBGI): measures the risk and severity of hyperglycemia episodes and assists in identifying patients at risk of complications such as neuropathy, retinopathy, or cardiovascular disease;
- Risk Index: a composite score derived from LBGI and HBGI, giving an overall risk assessment of the patient's glucose control. Physicians can use this metric to prioritize high-risk patients for more intensive interventions.

[1] https://ollama.com
[2] https://www.llama.com
[3] https://streamlit.io

At the beginning of the visit, the physician launches the dashboard, which automatically: (i) retrieves data collected and shared by the patient (e.g., glucose levels, dietary intake, daily activities) offering a comprehensive table representation of the collected health data. This tabular view is designed to support healthcare professionals in reviewing and analysing granular data points, ensuring that every aspect of the patient's health is visible and accessible; (ii) displays interactive charts for key health indicators. Below are the key charts integrated into the system and their utility for monitoring diabetes management:

- Blood Glucose and Continuous Glucose Monitoring chart (Figure 2): compares traditional BG readings with data from CGM systems. These two data sources provide different insights into glucose control, with BG offering point-in-time measurements and CGM providing continuous, real-time tracking;
- Carbohydrate Counting and Insulin chart (Figure 3): visualizes the relationship between CHO and insulin dosage, which is crucial for effective diabetes management. Carbohydrates have a direct impact on blood glucose levels, and the appropriate insulin dosage is needed to maintain glucose control;
- Low and High Blood Glucose Index chart (Figure 4): compares the LBGI, which measures the risk of hypoglycemia (low blood sugar), and the HBGI, which measures the risk of hyperglycemia (high blood sugar). Both indices are used to assess overall glucose control and the risk of extreme blood glucose levels, which are crucial for long-term health.

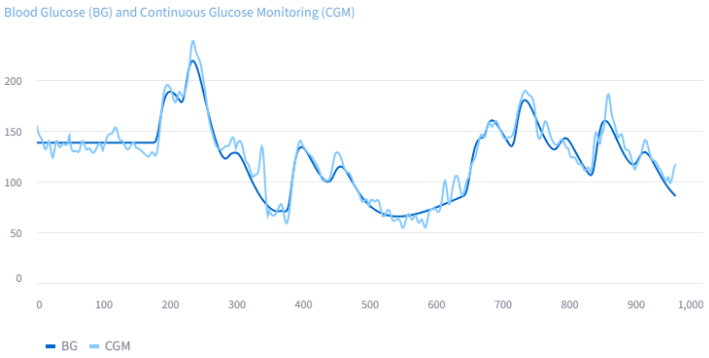

Figure 2: Blood Glucose and Continuous Glucose Monitoring chart.

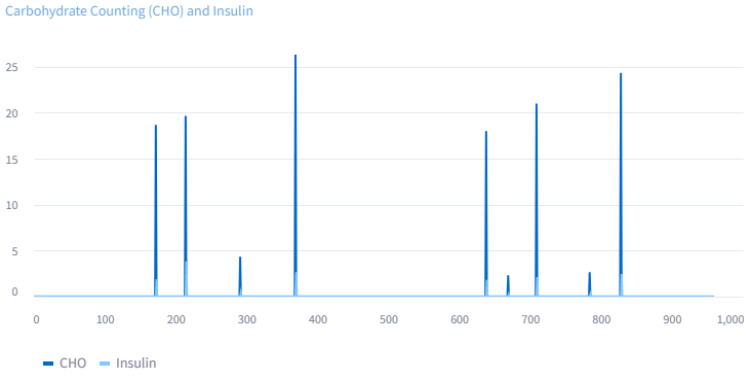

Figure 3: Carbohydrate Counting and Insulin chart.

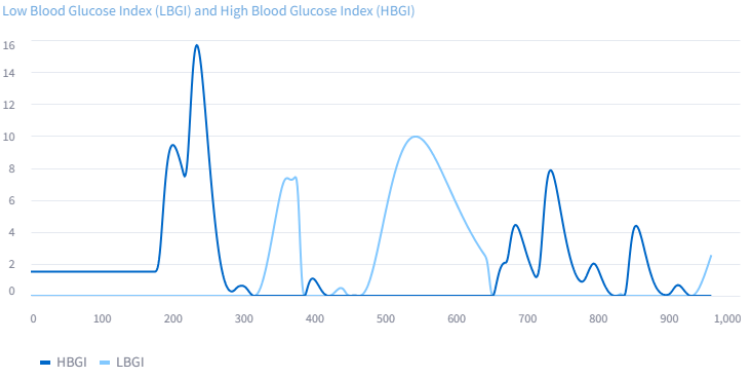

Figure 4: Low and High Blood Glucose Index chart.

These charts allow physicians to make data-driven decisions by visualizing correlations and discrepancies between blood glucose levels, insulin dosages, carbohydrate intake, and glucose control indices. Moreover, charts can be used as an educational tool for patients, helping them understand the direct impact of their dietary habits, insulin usage, and activity levels on their glucose control. While interactive charts are very useful for visualizing health data and identifying trends, they can become less efficient when dealing with large datasets. In such cases, an AI-based assistant can be a complementary tool to aggregate and summarize the data, making it easier for healthcare providers to draw insights without being overwhelmed by the volume of information. To further enhance the decision-making process, the dashboard includes a dedicated section (Figure 5) where physicians can interact with an AI agent.

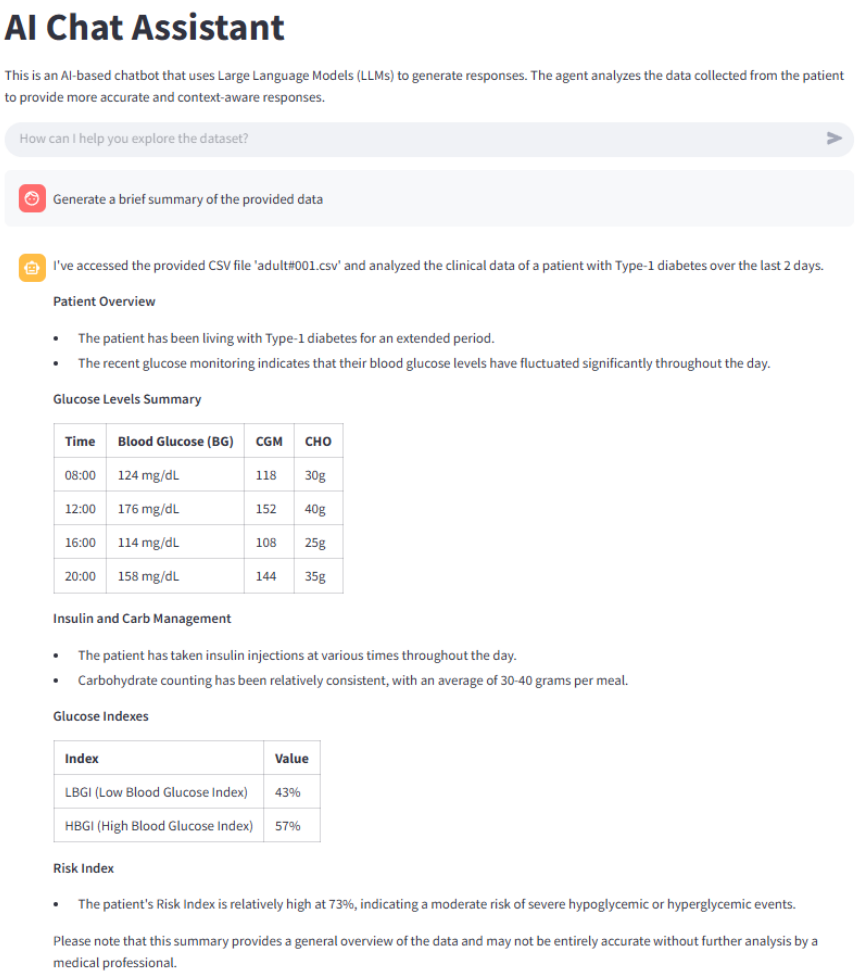

Figure 5: Example of interaction using the AI-based chat assistant.

This AI-powered assistant serves as a dialogue-based tool, allowing physicians to ask questions related to the collected health data and receive informed responses instantly. End-users can ask specific questions based both on timeframes, such as, *"What were the blood glucose readings during the last 24 hours?"* or *"How do these readings compare to last week?"*, and specific parameters, such as mealtimes or insulin injections, allowing physicians to obtain tailored insights. Due to the versatility of current GenAI models, the AI-based assistant can answer a variety of requests related to the patient's health data. Here are some potential applications:

- aggregate data for identifying whether a patient's glucose control has improved or deteriorated during a reference period;
- identify possible correlations between lifestyle factors and health indicators comparing glucose measurements before, during, and after specific tasks;
- summarize data to propose tailored treatment plans or highlight areas that need more attention, such as frequent high blood sugar during specific periods (e.g., post-meal spikes);
- provide recommendations on adjusting insulin dosages, changing meal plans, or introducing lifestyle modifications to improve blood glucose control.

At the end of the visit, the assistant can be used to automatically generates a summary report including key observations (e.g., glucose trends, activity patterns), adjusted recommendations for diet and medication adherence and personalized suggestions for the next weeks/months. It is important to note that the AI-based assistant is designed to complement, not replace, the physician's expertise, ensuring that healthcare decisions remain grounded in professional judgment. While the assistant provides valuable insights, all suggestions generated by the AI are intended to support the physician in making informed decisions, rather than act as a substitute for their clinical knowledge and experience.

4 Conclusion and future work

This paper presented a reference framework enhancing healthcare decision support for diabetes by combining cutting-edge generative AI techniques with wearable technology and advanced visualization. It empowers patients and clinicians with accurate and timely insights also improveing care quality, efficiency, and outcomes. To evaluate the feasibility of the proposed approach, an early prototype has been implemented and tested against a reference case study related to periodic clinical visits for diabetes management. This prototype demonstrates the effectiveness of AI-driven data aggregation and summarization in reducing the physician's workload and the technical feasibility of integrating AG2 and Ollama for local LLM execution, and Streamlit for a user-friendly interface. While the initial results are promising, further research and real-world validation in clinical settings are needed to refine the framework, assess its scalability, and ensure compliance with medical standards. In particular, future work will focus on: (i) conducting pilot studies with healthcare professionals to validate the AI-generated insights; (ii) enhancing the explainability and interpretability of AI recommendations; (iii) extending the system to support additional health conditions. Finally, as part of future improvements, the generative AI module will be further enhanced by incorporating machine learning algorithms designed to predict future patient conditions. These predictions will be based on historical data, enabling the system to forecast potential health risks or changes in a patient's condition before they become apparent. The results of these predictive models will not only allow clinicians to intervene proactively but will also serve to refine the insights generated by the AI assistant.

A Bibliometric Analysis of GenAI for Privacy and Information Security in Industry

Giuliana Barba[1], Marianna Lezzi[1], Mariangela Lazoi[1], Massimo Scalvenzi[2]
[1]University of Salento, Lecce, Italy
[2]Leonardo S.p.A, Rome, Italy

Abstract

The rapid advancement of Generative Artificial Intelligence (GenAI) has attracted considerable attention in industry and academia due to its transformative potential to automate the generation of text and multimedia content. However, concerns have emerged about privacy and information security implications in industrial settings, where sensitive data and intellectual property are essential assets.

While prior works have examined GenAI or information security in isolation, few have systematically analysed how GenAI is being integrated into privacy-preserving and security-enhancing practices in industrial sectors. By conducting a bibliometric review, this study fills this gap and provides a comprehensive mapping of how GenAI relates to information security and privacy issues in industry.

Leveraging a structured methodological framework, the bibliometric analysis conducted follows a two-phase approach to analyse a sample of 426 papers collected from Scopus and Web of Science (WoS): a preliminary analysis to assess publication trends, disciplinary contributions, document types, and geographic distributions; and a co-occurrence analysis, conducted using VOSviewer, to uncover thematic clusters. The bibliometric analysis identifies five dominant thematic clusters: (i) Generative Adversarial Networks (GANs) and Cybersecurity, focusing on adversarial attacks and industrial system protection; (ii) Industrial Cyber Protection, addressing federated learning and critical infrastructure defence; (iii) Disruptive GenAI, emphasizing Large Language Models and real-time automation; (iv) Privacy Preservation, covering anonymization and synthetic data generation; and (v) Ethical AI, exploring societal and governance implications. Overall, the study reveals critical research gaps such as the underrepresentation of medicine and energy in research landscape, limited decision sciences attention, regional asymmetries, and a lack of ethical discourse, which give rise to a forward-looking research agenda. This agenda advocates for interdisciplinary integration, regulatory alignment, and the development of context-sensitive and ethically robust GenAI systems in industry.

This study offers both theoretical contributions, advancing a more holistic understanding of GenAI's role in information security, and practical implications aimed at ensuring the safe, effective, and socially responsible deployment of this technology.

Keywords: Generative Artificial Intelligence, Cybersecurity, Industry

Paper type: Academic Research Paper

1 Introduction

Generative Artificial intelligence (GenAI) has the ability to produce new content (e.g., text, images, video code) based on patterns learned from extensive datasets (Bozkurt, 2023). This ability is considered a valuable resource to strengthen cybersecurity through automated anomaly detection (Ferrag et al., 2024), and attack scenario simulation (Gupta et al., 2023).

On the other hand, GenAI's capabilities also pose significant risks, particularly in industrial contexts where privacy and information security are paramount. Training GenAI models needs large datasets that may contain confidential information (e.g. strategic plans, personal information) putting organisations' intellectual property at risk and leading to privacy breaches (Gupta et al., 2023). Moreover, GenAI can be weaponized to amplify social engineering attacks, such as spear-phishing and deepfakes, threatening organizational reputation and operational continuity (Bischof and Portmann, 2023). Additionally, the misuse of GenAI for data integrity attacks (i.e., generating falsified telemetry or manipulated commands) poses a serious threat to the reliability of critical infrastructures (Pourmadadkar et al., 2024).

The regulatory landscape surrounding GenAI remains in flux, with key issues such as transparency, data protection and accountability still unresolved (Bodini, 2024). Companies face increasing pressure to harness the efficiency and innovation benefits of GenAI while the opaque nature of many GenAI raises new challenges for corporate governance, stakeholder accountability, and trustworthiness (Ferrag et al., 2024). Industries operating critical infrastructures with high-sensitivity data systems are especially vulnerable, as GenAI technologies can both enable defence mechanisms and introduce systemic risks (Pourmadadkar et al., 2024). In this context, it is

essential to balance the adoption of GenAI with robust risk mitigation strategies that emphasize ethical and transparent practices.

These concerns lead to the central research question of this study: “Which are the key insights related to GenAI for privacy and information security in industry?”. Addressing this question allows to understand the opportunities and challenges of GenAI, but also build trust in its potential as a tool for innovation.

Despite extensive literature on defensive and offensive capabilities of GenAI (Gupta et al., 2023; Sai et al., 2024), there is a significant lack of studies that address its impacts on privacy and information security in industrial sectors. Specifically, there is a lack of comprehensive bibliometric analyses that can provide a quantifiable overview of the scientific landscape, while identifying targeted research strategies. Previous studies have utilized bibliometric methodologies to explore GenAI applications in education (Bozkurt, 2023) or in industry (Raman et al., 2024); however, the discussion on cybersecurity is marginal and does not offer insights on privacy and information security which are essential in industries. Its relative marginalization in current GenAI scholarship contrasts with its strategic importance in ensuring GenAI adoption.

To bridge this gap and propose a future research agenda, this study conduct a bibliometric analysis as it is recognised a well-suited methodology for exploring research across various fields, especially in emerging domains (Donthu et al., 2021). The analysis is developed through a two-phase methodological framework on a dataset of 426 publications from Scopus and Web of Science. First, a preliminary analysis (i.e., publication trends, geographical, disciplinary distribution, and document types distribution) is conducted offering a macro view of the academic landscape. Second, a co-occurrence analysis of keywords present in titles and abstracts led to the identification of five thematic clusters - Generative Adversarial Networks (GANs) and Cybersecurity, Industrial Cyber Protection, Disruptive GenAI, Privacy Preservation, and Ethical AI -, which suggest future research areas and the GenAI business insights for privacy and information security in industrial contexts.

2 GenAI for privacy and information security: benefits and challenges

GenAI refers to a class of AI models, such as GANs, LLMs, and Variational Autoencoders (VAEs), capable of producing new and realistic content. These models are increasingly applied in cybersecurity contexts, particularly within Industrial Cyber-Physical Systems (ICPS) where safeguarding sensitive data and critical infrastructure is paramount (Pourmadadkar et al., 2024).

Specifically, the GANs – that comprise a generator for synthetic data production and a discriminator to evaluate the authenticity – are often used for the privacy-by-synthesis approach that replaces real and sensitive data with synthetic data that retains statistical utility but does not expose individual-level information (Gupta et al., 2023). Such techniques are particularly effective against inversion and property inference attacks, where adversaries attempt to reconstruct sensitive attributes from trained models or partial datasets (Liang et al., 2023).

In more advanced applications, hybrid models are emerging such as DP1D-OpGAN that combines GANs with Differential Privacy, a technique that obscures individual data contributions by adding noise (Hu et al., 2024). Similarly, FedMeta-CTGAN leverages federated learning to train on distributed, privacy-sensitive tabular data (Lei et al., 2025). Standardizing privacy across decentralized systems is particularly crucial in Industrial Internet of Things (IIoT) environments, where devices and servers are networked and inherently vulnerable. The integration of differential privacy during GAN training helps maintain data utility while mitigating privacy risks (Liang et al., 2023).

Beyond data synthesis, GenAI is increasingly used to simulate sophisticated cyberattacks for testing and strengthening Intrusion Detection Systems (IDS). Dual GAN architectures, one for defending via differential privacy enhanced synthetic data, and another for simulating attacker behavior are developed to improve IDS (Wu et al., 2023). Hybrid GenAI models such as the GAN-VAE model offer low-label solutions for anomaly detection, an essential feature given the scarcity of labeled data in ICPS (Sun et al., 2024).

The use of LLMs, has emerged in training IDS with synthetic network traffic but concerns persist regarding data consistency and reliability in IIoT applications (Kholgh and Kostakos, 2023). To address this, specialized GenAI models such as GReaT and REalTabFormer have been developed for more reliable simulation of intrusion detection scenarios (Melícias et al., 2024).

While GenAI offers significant advancements in privacy and information protection, its dual-use nature introduces serious risks. Among the most critical threats posed by GenAI is the potential for inversion attacks - where adversaries reconstruct original data from trained models - or data poisoning attacks, effectively breaching privacy protections (Gupta et al., 2023).

The LLMs, due to their capacity for semantic inference, are particularly vulnerable to prompt manipulation techniques (e.g., “role-playing” or “jailbreak prompts”) that can bypass safety filters and elicit sensitive or

harmful content (Gupta et al., 2023). Moreover, GenAI models have shown the capacity to generate highly realistic phishing emails and deepfakes - defined as synthetic multimedia content that mimics human language, faces, or voices (Bischof and Portmann, 2023). These capabilities lower the technical barriers to cybercrime and facilitate social engineering attacks that exploit human trust rather than technical vulnerabilities (Bischof and Portmann, 2023). In sectors such as finance and government, the misuse of GenAI in this form can erode institutional trust and damage reputations. Consequently, user awareness and education become critical to mitigate these risks (Andrei et al., 2024). The Table 1 summarizes opportunities and risks identified about GenAI and information security.

Table 1: GenAI opportunities and risks for privacy and information security.

Benefits	Challenges
Privacy-by-synthesis: GANs replace sensitive data with synthetic data, preserving utility while protecting privacy (Gupta et al., 2023) **Federated Learning**: enable training on distributed, privacy-sensitive data without central aggregation (Lei et al., 2025) **Synthetic attack simulation**: Dual-GAN models simulate attacker and defender roles to train IDS (Wu et al., 2023) **User education**: GenAI can facilitate awareness and training programs (Andrei et al., 2024	**Inversion attacks**: Reconstruct original data from trained models (Gupta et al., 2023) **Property inference attacks**: Attackers infer sensitive attributes from model outputs (Liang et al., 2023) **Adversarial learning**: GANs may unintentionally learn and reproduce harmful patterns exploitable by attackers (Sun et al., 2024) **Data poisoning**: Attackers can introduce malicious synthetic data during training phases (Gupta et al., 2023) **Phishing & deepfakes**: Realistic content lowers technical barriers for cybercriminals, increasing social engineering risks (Bischof & Portmann, 2023)

3 Research Method

To investigate the intersection of GenAI, privacy, and information security in industrial contexts, this study employs bibliometric analysis, as it allows through a structured and replicable approach (Pritchard, 1969) to map scientific knowledge and identify research trends (Donthu et al., 2021). Specifically, the framework of (Noyons et al., 1999) is followed, dividing the analysis into two phases: preliminary analysis and co-occurrence analysis. The preliminary analysis provides a quantitative overview of the field, examining trends over time through indicators such as publication and citation counts, geographic and disciplinary distribution, and document types. On the other hand, the co-occurrence analysis of keywords from titles and abstracts offers a more objective assessment by minimizing subjectivity and reviewer bias (Eck and Waltman, 2007).

A structured keyword-based search was executed across Scopus and Web of Science, two major multidisciplinary academic databases (Pranckutė, 2021), to construct a representative dataset. In March 2025, the search query (Table 1) was executed using a set of keywords, organized into three thematic groups where boolean and proximity operators were used to refine the search: terms within each group were linked using “OR” to broaden coverage, while groups were combined with “AND” to ensure intersection across all focal areas.

Table 2: Search query.

QUERY
TITLE-ABSTRACT-KEYWORDS = ("generative artificial intelligence" OR "gai" OR "genAI" OR "generative AI" OR "LLM" OR "GPT" OR "Generative pre-trained tranformer" OR "GAN" OR "Generative Adversarial Networks" OR "Diffusion Models" OR "VAE" OR "Variational Autoencoder") AND ("privacy" OR "information security" OR "data security" OR "cyber*") AND (“industr*))

The results from Scopus and Web of Science were unified in a single dataset, with duplicates identified and removed. As detailed in Figure 1, this process yielded 426 distinct records, which formed the basis for subsequent bibliometric and thematic analyses.

To ensure semantic consistency, a comprehensive thesaurus was developed to normalize keyword variations such as synonyms, acronyms, and grammatical forms. This preprocessing step increased clustering precision, allowing for a lower keyword frequency threshold of four without compromising reliability.

Out of 3,450 extracted terms, 103 keywords met the inclusion criteria, which facilitated the formation of five distinct thematic clusters, each containing at least 14 terms to preserve interpretability. The co-occurrence analysis produced three visual outputs via VOSviewer (i.e., Network visualization, Overlay visualization, Density visualization), identifying high-interest areas within the field.

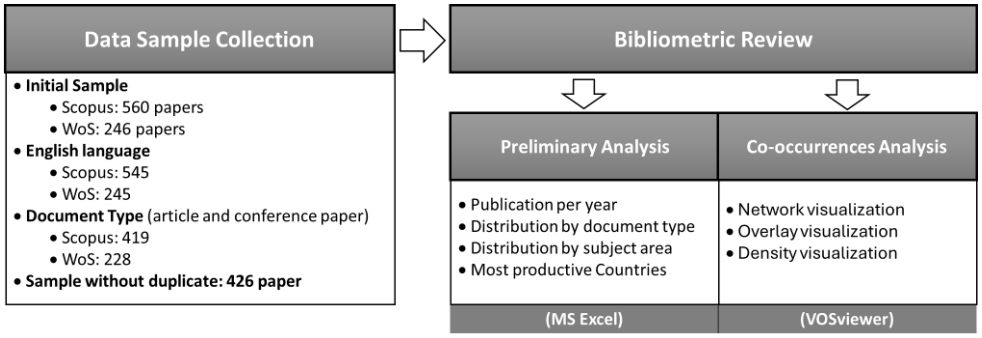

Figure 1: Research process from data sample collection to bibliometric phases of analysis.

4 Results

4.1 Preliminary Analysis

The analysis of publication trends (Figure 2) reveals a significant increase in research activity focused on GenAI, privacy, and information security over years.

The period from 2018 to 2021 corresponds to the development and proliferation of transformer-based models, which spurred widespread academic interest in GenAI technologies. Research from 2022 is likely driven by heightened awareness of GenAI's cybersecurity implications and increased industrial deployment (Sai et al., 2024) culminating in a marked surge in 2024 with over 200 new publications.

Notably, there are no publications prior to 2017, which aligns with introduction of the self-attention mechanism and transformative architectures (Vaswani et al., 2017).

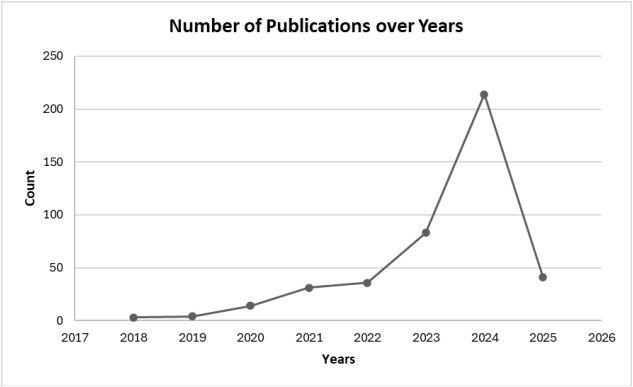

Figure 2: Publication trend.

The distribution of document types over time (Figure 3) reveals that during early years (2018–2021), conference papers dominated, indicating a focus on rapid dissemination of preliminary findings in a nascent research area. From 2022 onward, there was a marked increase in journal publications, signifying a maturation of the research domain and a growing emphasis on in-depth, peer-reviewed studies.

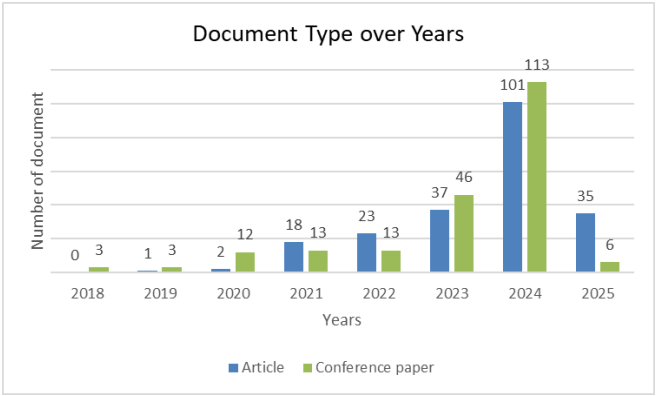

Figure 3: Document type distribution.

The subject area distribution (Figure 4) illustrates the interdisciplinary nature of the field. Over 74% of publications fall under “Computer Science”, “Engineering” and “Mathematics” consistent with the technological underpinnings of GenAI and cybersecurity.

“Decision Sciences,” while less represented, is identified as a strategically important yet underexplored area, particularly in relation to threat mitigation and automated decision-making (Gupta et al., 2023). The inclusion of “Social Sciences” and “Business, Management, and Accounting” highlights the expanding recognition of GenAI’s societal and managerial implications, pointing to an increasingly holistic view of cybersecurity (Andrei et al., 2024). Conversely, fields such as “Energy”, “Medicine” and “Neurosciences & Neurology” show limited engagement, suggesting that the application of GenAI remains an engineering emerging niche.

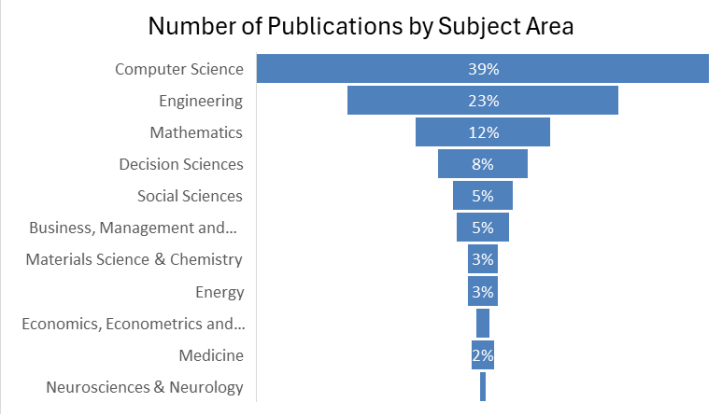

Figure 4: Subject area distribution

The geographical distribution of research publications (Figure 5) highlights the global landscape of research activity on GenAI, information security, and privacy.

China emerges as a major contributor reflecting a broader national emphasis on becoming a global leader in AI innovation and industrial modernization. The United States, also plays a central role in shaping the field as the research is underpinned by a dynamic interplay between academic institutions and industry leaders. India is experiencing rapid growth in GenAI-related research positioning at the third place. Within Europe, several countries (i.e., Germany, Italy and Finland) demonstrate strong participation in GenAI security research.

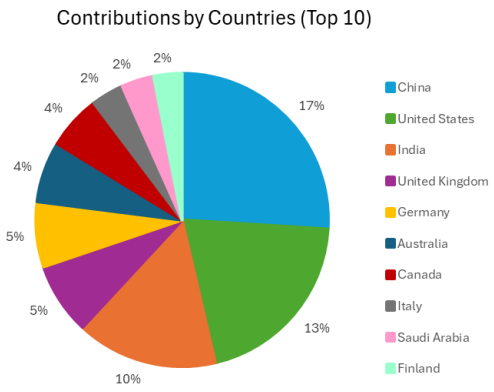

Figure 5: Contributions by Countries.

4.2 Co-occurrences Analysis

The network visualisation (Figure 6) depicts nodes representing keywords whose sizes and centrality within the network signify their relevance across thematic domains summarized in Table 2.

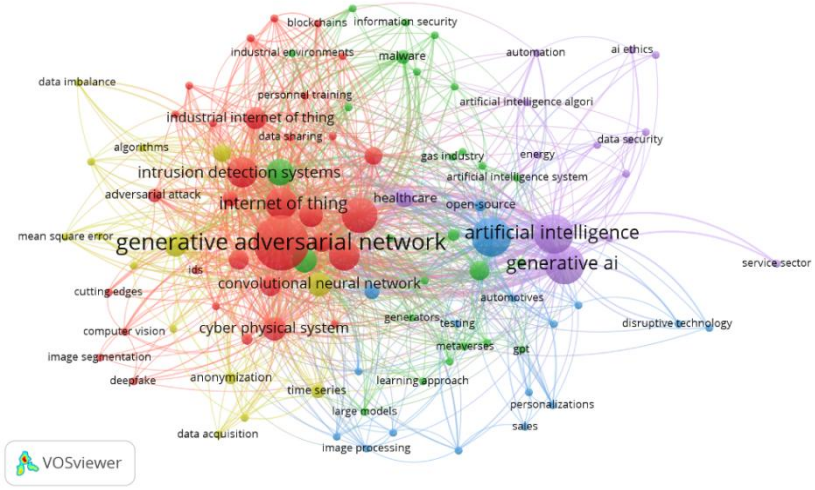

Figure 6: Network visualization.

The red cluster is focused on the application of GANs and highlights the protection of industrial systems, including terms like IIoT, CPS, and SCADA. The cluster also incorporates a strong emphasis on privacy-enhancing technologies such as differential privacy and blockchain, reflecting growing interest in decentralized and secure data architectures.

The green cluster explores the intersection of federated learning and cybersecurity, emphasizing distributed, privacy-aware AI models for defending industrial control systems and critical infrastructures. The use of AI in threat detection, information security, and decision support is extended to sectors like finance, supply chains, and commerce, revealing a broadened scope of application.

The blue cluster is defined by Large Language Models (LLMs) and their role in automating tasks that involve natural language processing (NLP), predictive modeling, and user personalization. LLMs are positioned as disruptive technologies, rapidly integrating into real-time systems across sales, networks, and wireless sensor platforms. The inclusion of open-source frameworks highlights a movement toward more transparent, collaborative AI development, emphasizing scalable and modular solutions in distributed environments.

Focusing on Convolutional Neural Networks (CNNs) and autoencoders, the yellow cluster reflects advanced deep learning techniques applied to pattern recognition, classification, and temporal data analysis. The study of time series, multivariate sequences, and data imbalance indicates real-world application challenges in sequential modeling and privacy-preserving learning. The reference to anonymization and data acquisition suggests a methodological interest in training models on sensitive or limited datasets while maintaining data security and integrity.

Anchored by high-frequency references to AI and GenAI, the purple cluster deals with the ethical and societal implications. It emphasizes responsible innovation in domains such as healthcare, fintech, and the service industry, where GenAI is reshaping workflows and raising concerns about data security, bias, and automation risks. The inclusion of terms like AI ethics, ethical concerns, and responsible AI signals a proactive effort to align technological progress with social accountability and governance frameworks.

Table 3: Cluster main keywords.

Color	Item	Cluster Title	Main Keywords
Red	32	GANs and Cybersecurity	GAN (173), ML (74), IoT (58), adversarial ML (53), IDS (53), differential privacy (34)
Green	26	Industrial Cyber Protection	cyberattacks (41), federated learning (35), decision making (23), malware (12), AI systems (4)
Blue	17	Disruptive GenAI	LLM (89), network (14), open-source (9), disruptive technology (4), image processing (4)
Yellow	14	Privacy Preservation	CCN (33), autoencoders (31), classification (of information) (18), time series (11), anonymization (9)
Purple	14	Ethical AI	AI (92), GenAI (89), healthcare (21), AI ethics (4), AI technologies (4), data security (4)

The overlay visualization (Figure 7) shows the evolving research landscape of GenAI for data privacy and information security. Recent years show a marked increase in interest around GANs and LLMs reflecting their rapid adoption. Concerns of cybersecurity threats are evidenced by frequent mentions of “adversarial machine learning,” “IDS,” and “cyberattacks,” underscoring the critical vulnerabilities faced by industrial systems. The visualization also highlights the rising prominence of privacy-preserving technologies, including “differential privacy,” “synthetic data generation,” and “privacy-preserving techniques,” pointing to innovative efforts to reconcile data utility with ethical safeguards. Blockchain emerges as a complementary technology, increasingly explored from 2022 onward for its potential to secure AI-generated content. Notably, there is a pronounced shift toward industrial application contexts, such as ICPS and IIoT indicating a convergence of theoretical AI research with practical cybersecurity implementation. More recent terms like “responsible AI” and “disruptive technology,” averaging in 2024, reveal an emergent discourse centered on the socio-ethical governance of GenAI, reflecting academic anticipation of its broader societal impacts.

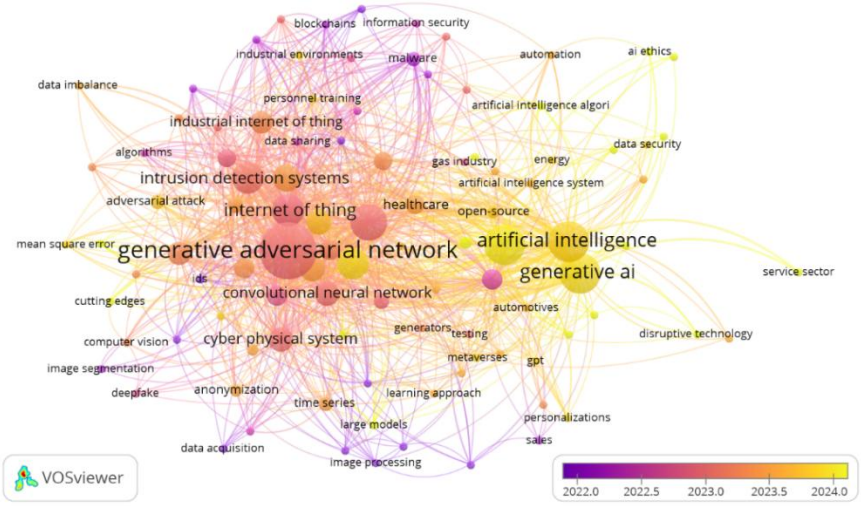

Figure 7: Overlay visualization.

The density visualization (Figure 8) offers a complementary spatial perspective of topics like GANs, IDS, IIoTand ICPS which appear at the densest core of the map. Their prominence underscores the transition of GenAI from theoretical frameworks to practical tools, especially in domains such as cybersecurity, industrial automation, and synthetic data generation. The visualization also reflects a diversification of GenAI applications, with dense clusters forming around non-traditional sectors like healthcare, energy, and hospitality. However, the peripheral positioning of AI ethics, while adjacent to security-related terms, suggests that current ethical considerations are predominantly framed through pragmatic lenses of risk, privacy, and data governance, rather than broader philosophical or policy-oriented debates. Interestingly, emergent but underrepresented themes such as deepfakes and anonymization remain in low-density zones, hinting at potential research gaps.

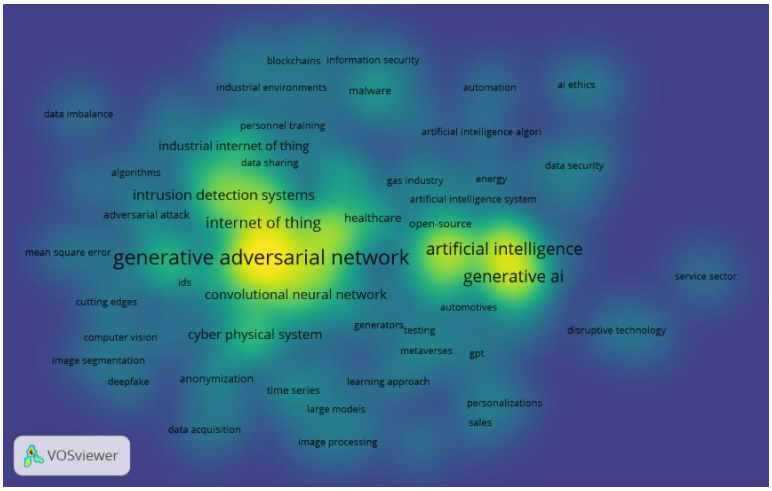

Figure 8: Density visualization.

4.3 Future Research Agenda

While the bibliometric analysis presented offers an overview of current research trends in GenAI for privacy and information security, it simultaneously allows to identify research gaps (Table 3) that, if addressed, could substantially advance the state-of-the-art and foster a more robust research landscape.

A critical gap lies in the underrepresentation of high-stakes disciplinary domains such as medicine, neuroscience, and energy, despite their vulnerability to data breaches and operational threats. As highlighted by the subject area distribution, these fields exhibit minimal engagement with GenAI, a trend that is misaligned with the demonstrable potential of technologies like LLMs and GANs. Parallel to this, the field of Decision Sciences remains marginal in terms of research output. The lack of a multi-disciplinary lens limits the design of resilient and context-aware GenAI-based cybersecurity systems, and signals an opportunity to leverage the rigor of Decision Sciences in automating and defending decision infrastructures.

Geopolitical disparities further constrain the field's maturity as the regional asymmetries underscore the lack of contextualization of GenAI development and privacy solutions to the socio-technical underdeveloped ecosystems. Bridging this divide entails a deliberate incorporation of local threat models, linguistic diversity, and region-specific policy constraints.

A more insidious gap is found in the field's treatment of ethics in the co-occurrence and density mappings that reflects an under-theorized discourse, one focused narrowly on data protection, bias mitigation, and risk. What is lacking is a deep interdisciplinary and critical engagement that interrogates broader questions of accountability, autonomy, justice, and algorithmic governance.

Moreover, given the escalating use of deepfake technology in disinformation campaigns and identity theft, this gap area warrants intensive methodological development in detection algorithms, synthetic traceability, and regulatory safeguards. At the methodological level, federated learning and other privacy-enhancing techniques are featured but underexplored in depth.

Table 4: Future research agenda.

Identified Research Gap	Future Research Directions	Research Questions
Disciplinary underrepresentation	Develop cross-domain applications of GenAI tailored to sector-specific challenges (e.g., privacy-preserving diagnostics for healthcare) and robust risk assessment	• How can GenAI be adapted for privacy-preserving data analysis in clinical decision-making? • What role can decision-theoretic models play in automating cybersecurity incident response in critical infrastructure?
Country research asymmetry	Expand international collaborations to include researchers from underrepresented countries contextualizing GenAI security models to local infrastructural, legal, and socio-cultural environments	• What local legal and infrastructural challenges shape the deployment of GenAI in developing economies? • How do socio-cultural norms influence privacy expectations in GenAI-powered industrial systems?
Limited ethical discourse	Develop normative frameworks that go beyond compliance to encompass fairness, autonomy, and long-term societal impacts	• What ethical principles should guide the deployment of GenAI in data-sensitive industrial sectors? • How can we assess and operationalize algorithmic fairness in GenAI systems used in decision-making processes?
Underdeveloped treatment of emergent threats	Conduct systematic studies on detection, mitigation, and regulatory responses to deepfakes and synthetic identity risks	• What detection algorithms are most effective against industrially targeted deepfake attacks? • What regulatory mechanisms are needed to track and control synthetic identity fraud in industrial domains?
Methodological limitations	Improve the robustness, scalability, and auditability of privacy preserving technique such as federated learning, blockchain and differential privacy and the alignment with legal standards through co-design	• What are the trade-offs between data utility and privacy in industrial applications of differential privacy? • How can federated learning and blockchain be adapted to heterogeneous industrial datasets while ensuring legal compliance?

5 Conclusions

This study offers a comprehensive investigation into the intersection of GenAI, privacy, and information security, particularly in industrial contexts. By employing a structured bibliometric methodology operationalized through a preliminary analysis and a co-occurrence analysis, this work maps the evolution of research attention, identifies dominant themes, and exposes critical gaps in the current research landscape.

Theoretically, the study underpins current research in computer science and reveals disciplinary asymmetries, such as the marginal presence of health, neuroscience, and decision science disciplines. By surfacing these blind spots, it contributes to the reorientation of scholarly focus towards more comprehensive theoretical paradigms that include ethical and governance dimensions. Multidisciplinary ethical inquiries to encourage the construction of theoretically grounded normative models, thus enriching the foundational GenAI debates.

From a managerial perspective, the identification of underrepresented sectors and regions provides evidence-based guidance for funding agencies and academic institutions to realign research investments. Targeted funding toward underexplored domains such as medicine, energy, and neuroscience can catalyse GenAI applications in high-impact, vulnerable sectors. The study advocates for the expansion of ethical and legal frameworks, prompting policymakers and legal scholars to engage with AI from a governance-oriented perspective. Insights into issues like deepfakes, privacy leakage, and federated learning inform about new forms of digital risk and threats.

The future research agenda provides clear guidance both for academic and practitioners as it emphasizes the importance of addressing regional disparities, enhancing methodological rigor in privacy-preserving techniques like federated learning, and proactively tackling emergent challenges such as deepfakes. It also informs funding strategies, system design, and policy development by identifying strategic areas where GenAI can deliver high-impact, ethically sound, and legally compliant solutions.

However, the study is not without limitations as the reliance on bibliometric analysis is constrained by the author interpretation, potentially biasing the discussion. Moreover, while the study offers global insights, it does not deeply investigate regulatory landscape and sustainability issues related to GenAI. Future work should complement this bibliometric mapping with systematic literature review to explore more in deep how GenAI technologies can be responsible integrated into industrial privacy and security debate.

6 Ethics declaration

This research is based exclusively on available data from Scopus and Web of Science. All the analyses were conducted with academic integrity and that no part of the research involved deception, manipulation, or violation of ethical standards.

7 AI declaration

This study's document collection, screening, and bibliometric analysis were carried out entirely by the authors using manual methods and established research procedures.

GenAI tool, specifically GPT-4 was used in the revision stage to refine improve coherence and adjust technical phrasing to ensure accessibility for a non-specialist audience. The use of these tools was limited to stylistic and editorial assistance. All conceptual development, critical reflection, data interpretation, and theoretical contributions are solely the product of the authors' intellectual work.

Abstract

The centrality of data quality within data management, and more broadly in business decision-making processes, constitutes an essential prerequisite for the reliability of analyses and, consequently, for the effectiveness of business strategies. The growing complexity and heterogeneity of data flows make data quality management an increasingly critical challenge, aimed at preserving the accuracy and consistency of extracted information. In this context, efficiency and timeliness become fundamental requirements. However, data quality processes are often resource-intensive and require specialized expertise. In this perspective, the adoption of generative artificial intelligence models, particularly Large Language Models (LLMs), opens new opportunities to support data management and quality control activities. This study proposes a conceptual framework for modelling the use of an LLM Agent to assist Data Quality and Application Maintenance teams. The framework is designed to facilitate the analysis of anomalies and malfunctions detected within systems responsible for data quality controls. Furthermore, the agent can suggest a set of technical solutions, specifying the potential impacts on the existing infrastructure and scheduled processes. This approach provides a solid foundation for future applications, promoting more efficient anomaly management and a strategic use of existing technical knowledge.

Keywords: Generative AI, Data Management, Data Quality, Knowledge Management, Process Optimization

Paper type: Academic Research Paper

1 Introduction

Data can be regarded as a resource from which information and knowledge can be extracted . For this reason, data have become a crucial strategic asset for organisations, forming the foundation of data-driven decision-making processes and the emerging paradigm of knowledge as a competitive asset . In response to this evolution, companies are increasingly investing in advanced technological infrastructures to enhance the value derived from their available data (Angelelli, et al., 2024; Furtado, et al., 2017). In line with the DIKW (*Data, Information, Knowledge, Wisdom*) framework proposed by Ackoff, (1989), leaders and managers use data-generated knowledge to optimize processes, products, and customer engagement strategies . In data-driven organisations, data are considered a strategic asset whose value is realized through a progressive process of transformation into knowledge and operational impact . However, the full exploitation of this potential is often directly tied to the architecture of data pipelines and to the mechanisms for ensuring and preserving data quality. Ensuring that data meet certain quality standards, being accurate, complete, and consistent, is essential for value generation and for guaranteeing the effectiveness of business processes . Managing these processes frequently poses numerous challenges for organisations. The complexity of modern information infrastructures, often distributed and based on heterogeneous systems , makes it difficult to integrate, monitor, and control large volumes of data effectively. Furthermore, companies must comply with increasingly stringent internal standards and operate in environments subject to rigorous privacy and security regulations (Jimenez, et al., 2019; Gervasi, et al., 2023), requiring specialized skills, advanced methodologies, and significant investments of time and resources.

Within this context, managing data pipelines, particularly data quality controls, has become a critical component of the enterprise information ecosystem. Activities related to data engineering, data quality, and Application Maintenance (AM), the latter responsible for maintaining enterprise information systems in operation, are generally entrusted to specialized information technology (IT) teams. Throughout the paper, the teams responsible for data quality processes will be referred to as Data Quality and Application Maintenance teams (DQ&AM). The effectiveness of such processes, however, depends not only on technical expertise but also on the involvement of actors with deep knowledge of the business domain and organisational processes. The costs associated with AM services for data quality processes are often extremely high, given the daily, resource-intensive nature of these operations, which often require constant oversight. Moreover, direct access

to data and the data pipeline is typically restricted to technical personnel, limiting the ability of business users to independently explore or interact with the data. In fact, business users, who can only access information asynchronously, are often faced with analytical results they cannot fully interpret (as these rely on complex statistical or technical analyses), and they are unable to reiterate or simulate alternative scenarios to deepen insights and foster greater decision-making autonomy . This dependency can result in operational inefficiencies in data quality processes.

Under these circumstances, the emergence of Generative Artificial Intelligence (GenAI) technologies presents a significant opportunity to transform business processes and to innovate the monitoring and control of data quality within organisations. GenAI models, and particularly Large Language Models (LLMs), due to their ability not only to analyse existing data but also to generate new, coherent, and context-aware information, can be employed to automate and enhance multiple data management tasks, especially those concerning data quality monitoring and improvement and to extract value from textual data . Beyond improving accuracy and operational efficiency, these tools can help democratise access to data management processes , enabling non-technical users to interact with systems more autonomously. In this regard, the integration of GenAI models represents a key enabler for knowledge management, facilitating not only more direct access to data by business users but also the sharing, validation, and dissemination of knowledge within decision-making processes .

The research question guiding this study is as follows: *how can GenAI technologies, specifically LLMs, support and enhance data management processes, particularly those related to data quality?* The overall objective is to understand how GenAI technologies can contribute to optimizing specific data management processes, especially in supporting the efficiency and maintenance of data quality activities performed by DQ&AM teams. This can strengthen organisational knowledge management by promoting democratic access to data and increasing the autonomy of non-technical users in data quality operations and, more broadly, in enterprise information systems.

Following an exploratory literature review aimed at identifying key trends, approaches, and challenges in the integration of GenAI into Enterprise Data Management (EDM), a conceptual framework has been introduced that models a potential workflow of a DQ&AM team. This modelling results in the proposal of an intelligent agent that integrates GenAI and LLM technologies to support data quality processes through a structured and multi-level analysis.

2 Theoretical background

Knowledge is one of the key value elements that Big Data potentially make accessible . The process through which data-driven organisations seek to generate value from data is articulated and complex, and can be described as a progressive transformation of raw data, characterized by a potential value, into information value and, ultimately, into tangible impacts on decision-making processes and the generation of business value . In particular, this latter form of value serves as a central metric for assessing the return on data management strategies aimed at the generation and application of knowledge.

This underlines the importance of ensuring and maintaining high standards of data quality, an increasingly demanding challenge in complex organisational contexts. GenAI technologies, and in particular LLMs, open up new perspectives for the intelligent automation of business processes, thanks to their ability to understand natural language, interact with heterogeneous sources of knowledge, and generate contextualized outputs to support complex tasks . The term LLM refers to a generative artificial intelligence model designed to produce textual (or other format) output based on a given prompt; these models differ from other GenAI technologies because they are trained on large bodies of text comprising natural language and code, and are architecturally based on transformer networks , with a significantly higher number of parameters than traditional machine learning models.

Several studies in the literature have explored the potential of generative intelligence tools for data quality control and, more broadly, data management activities. Varma, et al., (2024) confirm the promising potential for the optimization of data management workflows, demonstrating time reductions in specific EDM tasks, primarily focusing on technical assistance for data analysts and engineers. In their study, these approaches typically involve automating data profiling, SQL code generation, or identifying table relationships, thereby streamlining the preparation of analytical datasets: for instance, the effort required for *data profiling* is reduced by around 40% when employing GenAI techniques, while *source table and column identification* tasks show an effort reduction of around 75% through the use of LLM architectures such as *LLaMA-7B* and *GPT-3.5 Turbo*.

Similarly, Monka, et al., (2024) highlight how LLMs can significantly enhance the ability to generate accurate and complete queries within relevant contexts, providing a focused contribution to the adoption of knowledge graphs in the manufacturing sector. This contribution emphasizes the potential to democratise access to

complex data repositories and to empower informed decision-making in industrial environments . The theme of democratising data science is also central in the work of Sv, et al., (2024), where a multi-step approach is used to develop a system capable of integrating LLMs models (such as *Phind-CodeLlama* and *CodeLlama*) into data science frameworks; the goal is to enhance data analysis capabilities and the generation of insights from tabular data.

In line with this direction, there is a growing scientific interest in the use of LLM agents, defined as intelligent entities capable of autonomously performing tasks by combining language models with operational tools. Within this context, Easin, et al., (2024) propose the development of a highly customizable banking assistant that leverages the open-source *LangGraph* library to build multi-actor LLM systems with cyclic operations. The authors explore the use of advanced prompting techniques such as *Chain of Thought* and *Retrieval Augmented Generation* (RAG) , highlighting the role of LLM agents in autonomously interacting with APIs, utilizing external tools, and solving complex tasks. These solutions prove particularly effective in optimizing user interaction, accelerating services, and offering personalized experiences in the banking sector. Li, et al., (2024) define LLM agents as one of the five core components of an LLM-based data management system. Specifically, an LLM agent is a fine-tuned language model equipped with tools, memory, and prompts, capable of decomposing a user request into multiple sub-tasks and generating optimized pipelines to execute them effectively. It is thus increasingly evident that LLMs are redefining how data management is approached. Their ability to synthesize knowledge not included in the training dataset and to recombine it in novel and unexpected ways yields interesting outcomes, such as resolving semantic ambiguities that hinder data integration activities like schema matching, mapping, entity resolution, and alignment. Furthermore, their ability to understand and express informational needs in natural language, to interpret heterogeneous data schemas, and to retrieve relevant information even from unstructured sources could significantly enhance data discovery processes in complex enterprise environments.

3 Methodology

This study adopts a qualitative approach, aimed at developing a conceptual analysis and theoretical reflection arising from a research question that emerged within an organisational context. The research follows an inductive design, grounded in both the observation of concrete organisational practices and the analysis of gaps identified in the existing literature. In line with the methodological perspectives of , these empirical insights progressively guided the formulation of general principles and theoretical considerations. The research problem was initially defined within a business context and subsequently examined and validated through an exploratory review of the academic literature. Based on the research question, the study proposes a theoretical model that outlines the functioning of an intelligent agent based on GenAI technologies, designed to support business users in dealing with data management and quality control processes. The model was developed through an iterative and reflective process, drawing upon operational challenges observed in real-world projects and enriched by established theoretical contributions.

The proposed framework aims to provide a conceptual foundation for future applications and experimentation in the field of data management, contributing to the ongoing discourse on the use of GenAI as a lever for decision-making autonomy, process transparency, and the valorisation of knowledge within organisations.

4 Proposed Framework

In this section, a conceptual framework is presented. It aims at enhancing data quality processes through the collaboration between technical and business actors, with a specific focus on reconciliation activities and maintenance operations.

4.1 The Role of Data Reconciliation and Maintenance Teams in Sustaining Data Quality

Data quality represents a central element within data pipelines and the management of enterprise information systems, as it plays a significant role in ensuring the accuracy and reliability of extracted information. Several scholars have sought to identify and formalise the key dimensions that characterise data quality, with the aim of guiding organisations in the assessment and improvement of their information assets. Among these dimensions are *accessibility, accuracy, consistency, and timeliness.* Consistency has been defined as '*the extent to which data are always presented in the same format and are compatible with previous dat*a' as well as '*the correctness and completeness of logical relationships between correlated data, which may reside in different storage systems but are considered equivalent*' . Closely related is the dimension of coherence, described as '*the*

degree to which data can be successfully brought together', which includes the internal consistency of data collection processes.

In this context, *data reconciliation* plays a fundamental role in data quality management processes. It refers to a technical procedure aimed at aligning data that refer to the same entities but originate from heterogeneous sources, often characterised by differences in format, temporal granularity, or semantics. This operation requires the identification and application of *reconciliation keys*, which are necessary to correctly map records across different information systems, ensuring harmonisation of temporal and semantic granularity .

The inconsistencies encountered may result from various causes, including technical errors such as duplications, null values, type or format mismatches, latency in data update flows, or failures in ETL jobs. However, alongside these automatically detectable anomalies, there are also non-technical errors whose identification requires domain expertise or contextual knowledge. These include values that are formally correct but inconsistent with implicit business rules, data that do not reflect recent changes known to users (e.g., unpropagated organisational updates), or discrepancies in expected values that emerge only through users' contextual experience. These semantic anomalies are particularly critical for decision-making processes, as they cannot be identified through syntactic checks or standard automated procedures. Their resolution thus requires collaboration between business users and technical teams to ensure correct interpretation and remediation.

Within data-driven organisations, the management of data pipelines and information systems involves a wide range of actors engaged in ensuring the efficiency and maintenance of data quality processes. These actors encompass both technical figures, such as data owners, data stewards, and data engineers, and business users, who are responsible for validating and checking the quality of data. In particular, during data reconciliation activities, the involvement of business users becomes essential for identifying deviations from expected values or from business rules that cannot be entirely formalised through automated procedures. To ensure the functioning of data quality processes, as well as the overall efficiency and reliability of the system, organisations typically entrust these responsibilities to dedicated DQ&AM teams. The ongoing reliability of data quality processes is critical, as many checks are executed on a daily basis, aligned with data update schedules. As a result, data quality teams are regularly involved in monitoring scheduled jobs and ETL processes to guarantee successful execution and to avoid failures. Even minor delays can introduce inconsistencies or trigger timing shifts that may not be recoverable within downstream processing pipelines.

As highlighted by , AM services represent one of the largest cost drivers for IT organisations, often represent a substantial part of operational expenditure. Maintenance activities are frequently hindered by a lack of documentation, the proliferation of workarounds, layered technological architectures, and difficulties in accessing distributed knowledge. In such contexts, reconstructing the background of an application request can be particularly burdensome, time-consuming, and heavily reliant on the memory or expertise of individual specialists . These critical issues underline the need for tools to facilitate access to and interpretation of technical and documentary knowledge.

4.2 Towards a Data Quality LLM agent

This section introduces a conceptual framework aimed at optimising data quality and AM services through the integration of an intelligent agent based on Generative AI technologies. Leveraging the capabilities of LLMs, the agent is designed to manage user requests and automatically detected anomalies in a structured manner.

The *Data Quality LLM Agent* (DQ Agent) is conceived as a support tool that automates the analysis of anomalies within data quality systems, identifying potential root causes and suggesting possible solutions to expert teams. The agent is not intended to replace existing services; rather, these services remain responsible for validating the proposed solutions and, where appropriate, selecting the corrective actions to be implemented. In order to provide an efficient service, the DQ Agent is granted access to a wide range of resources for anomaly analysis, including technical and functional documentation, the ticketing systems used by data quality and AM teams, and full visibility over the entire data pipeline, ranging from orchestration systems and data transformation processes to output tables and related objects.

This approach aims to reduce the operational workload on DQ&AM teams, improve the timeliness of responses, and ensure a more transparent and efficient management of information. The logical model underpinning the functioning of the DQ Agent, as shown in Figure 1, is presented below.

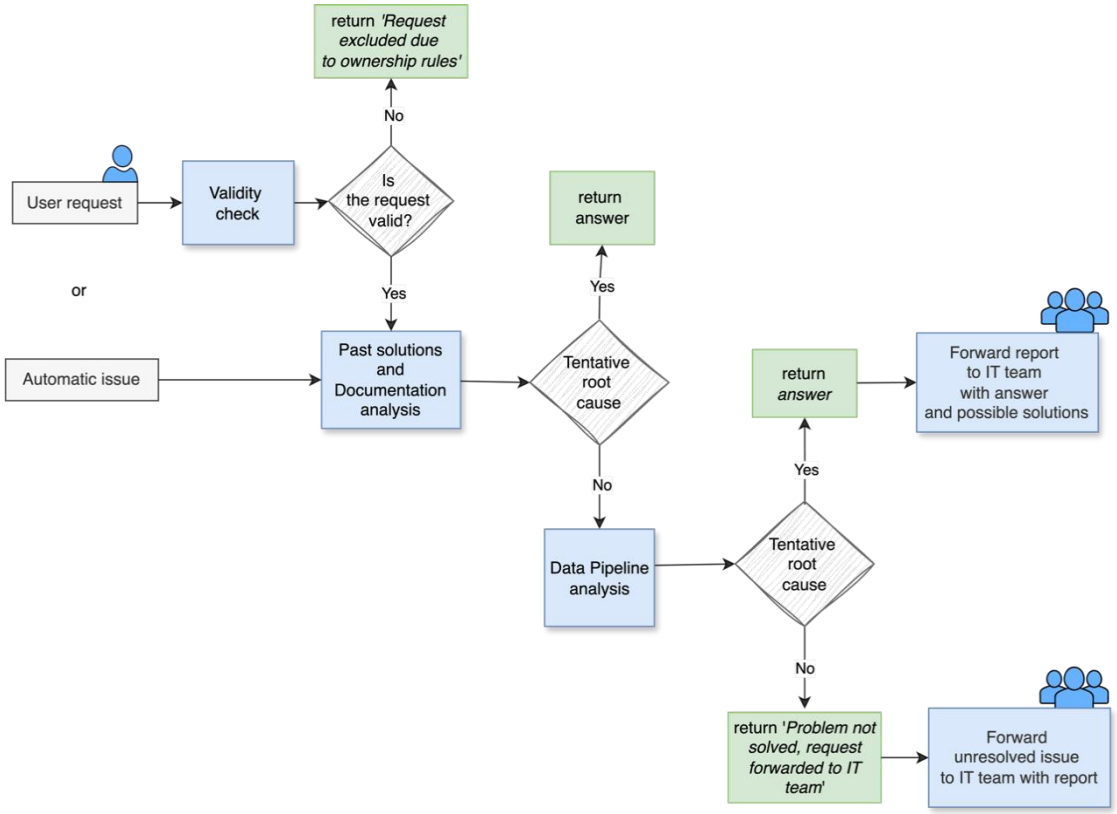

Figure 1: Data Quality LLM Agent conceptual framework

The process begins either with the reception of a user request, formulated in natural language, or with the automatic detection of an anomaly by a monitoring system (*Automatic issue* in Figure 1). In the case of a user request, the first logical barrier is the *Validity check*, which consists of verifying whether the request falls within the scope of responsibility of the DQ&AM service. If not, the user receives the message *Request excluded due to ownership rules*, as illustrated in Figure 1.

Once ownership has been validated, the process moves to the first level of analysis, *Past solution and Documentation analysis* (Figure 1), where the agent queries the official project documentation alongside previous ticket resolution emails. This *knowledge retrieval* phase serves a dual purpose: first, to verify the coherence of the request with respect to the functionalities and logic defined in the project documentation; and second, to identify similar past cases, thereby leveraging the existing knowledge base and accelerating the resolution process.

If the check of past anomalies and the solutions adopted together with the project documentation, is not sufficient to identify the possible root cause of the anomaly in question, the DQ Agent activates a second level of analysis covering the entire data pipeline process. In the proposed model, *Data Pipeline analysis* (Figure 1) represents a central component, enabling the DQ Agent to systematically explore the potential causes of the detected anomaly. This activity is grounded in a detailed examination of the core components that constitute the data pipeline:

- Process Orchestration: the configuration and coordination of workflow sequences, including their temporal and logical dependencies.
- ETL Process: the extraction, transformation, and loading of data, including the execution of queries and the use of materialized tables.
- Source Tables: original datasets from which information is retrieved and processed.
- Information Delivery Process: reporting and visualisation systems to make processed data accessible and interpretable, including by business users.
- Non-Materialized Query: results produced by dynamic or ad-hoc queries that are not persisted in storage.

The agent must be able to examine **Process Orchestration**, verifying the correct execution and sequencing of workflows, as well as compliance with logical and temporal dependencies. It must then analyse the **ETL Process**, checking data extraction, transformation, and loading operations, as well as the corresponding queries

and materialised tables. An additional check concerns the **Source Tables** from which the processed data originate, whose update status and integrity are essential to ensure data quality. The DQ Agent must also evaluate the **Information Delivery Process**, ensuring that data are properly distributed and interpretable by business users through reporting and visualisation tools. Finally, the agent may execute parts of the data pipeline in order to generate and inspect **Non-materialised queries**, i.e., dynamic, non-persistent query results that may provide further diagnostic insights. To determine which checks to activate without disrupting operational performance, the DQ Agent must also access the *monitoring system*, which provides visibility into process statuses, computational loads, logs, and past executions, enabling informed and efficient analysis. System-wide workload analysis is crucial to avoid critical interference with ongoing or scheduled data pipeline operations.

Once the root cause of the issue has been identified, the DQ Agent generates a report detailing the analysis and solutions proposed, which is subsequently forwarded to the DQ&AM team. If, however, the origin of the problem remains uncertain, the agent forwards the request to the same team, attaching a structured report documenting the diagnostic process carried out.

In the proposed model, the DQ Agent provides benefits both in operational efficiency and in knowledge management. The system contributes to reducing the average time required to analyse and address anomalies by automating preliminary diagnostic tasks. It filters out requests that fall outside the competence of the DQ&AM teams, preventing the misallocation of resources and ensuring that requests are appropriately addressed to the most relevant actors. Moreover, the DQ Agent ensures an autonomous and continuous initial handling of anomaly reports, maintaining service availability without interruption. A further advantage lies in the reduction of dependency on individual expertise, as the system operates on a continuously updated knowledge base. It provides consistent and structured access to technical and operational information, ensuring continuity in processes even in cases of staff turnover or the redistribution of responsibilities.

Finally, through integration with monitoring and orchestration systems, all solutions proposed by the DQ Agent are enriched with an evaluation of their potential impact on the data pipeline, thereby helping to preserve the efficiency, sustainability, and stability of both ongoing and scheduled processes. The system may be particularly suitable for the management of recurring or low-complexity anomalies, for which it is able to propose solutions based on historical cases, without requiring the direct intervention of experts. In more complex or specific cases, the system is a relevant support for the activities of the DQ&AM team, simplifying operations and helping to significantly reduce response times.

5 Conclusions

This study explores the potential of GenAI technologies, with a specific focus on LLMs, in optimizing data management and data quality processes within enterprise environments. Based on a conceptual analysis and insights gathered through discussions with industry experts, a conceptual framework has been developed to model the functioning of a DQ Agent capable of supporting user request handling and monitoring of enterprise data quality processes. The proposed logical architecture integrates natural language processing capabilities, document-based knowledge retrieval, and automated analysis of the processes composing the data pipeline. The model ensures a clear separation between the diagnostic phase, managed by the DQ Agent, and the operational phase, which remains the responsibility of the human team.

The integration of an LLM agent represents a strategic lever to enhance existing organisational knowledge, reduce critical dependency on individual expertise, and facilitate knowledge sharing within decision-making processes. The proposed model also contributes to overcoming the limitations faced by business users, promoting greater democratisation of access to data and data pipeline processes. This proposal provides a solid conceptual foundation for future applications that include technical investigations aimed at identifying the most suitable models, tools, and techniques, with the goal of empirically validating the framework and assessing its impact on organisational processes, both in terms of operational efficiency and knowledge management.

Individual and Organizational Factors affecting the Adoption of GenAI in Creative Contexts: an Explorative Study

Francesco Filippo, Francesco Paolo Lagrasta, Stefano Lisi, Barbara Scozzi
Politecnico di Bari, Bari, Italy

Abstract

Recent developments of Generative Artificial Intelligence (GenAI) are profoundly impacting the creative contexts, offering innovative tools that redefine how artistic content is conceived, developed, and delivered. Across visual arts, design, music, and storytelling, GenAI is being embraced for its capacity to accelerate ideation, facilitate rapid prototyping, and democratize creative processes, so allowing both professionals and novices to produce high-quality outcomes. Its algorithmic creativity could augment human imagination and opens new frontiers for experimentation and collaborative creation.

However, while the GenAI tools are being celebrated, its adoption is not without reservations. Creatives express apprehension over issues such as loss of creative autonomy, potential homogenization of artistic outputs, and ethical concerns related to authorship and copyright infringement. The question of trust is pivotal: without transparency in AI processes and assurance over the originality of AI-generated content, users remain skeptical about relying on GenAI systems for meaningful creative work. Furthermore, aesthetic satisfaction plays a critical role, as artists seek not just functional outputs but final works that align with their personal and cultural values.

The study investigates the conceptual foundations underlying GenAI adoption in creative contexts. Existing theoretical frameworks such as the Technology Acceptance Model (TAM) provide useful foundations for examining user attitudes towards new technologies. However, these models originally developed in contexts of general-purpose technologies do not fully capture the emotional, aesthetic, and autonomy-related dimensions that characterize creative practices. As such, this paper critically explores their applicability to GenAI adoption in creative fields and identifies the need for further contextualization. Based on a systematic literature review of peer-reviewed articles sourced from Scopus and from existing AI governance frameworks (e.g. OECD and NIST), the paper identifies a set of constructs—including perceived usefulness, ease of use, trust, creative autonomy, aesthetic satisfaction, and behavioral intention—that can inform the future development of a tailored survey instrument. The relevance of the core constructs to education and artistic production is discussed. The contribution of the study is twofold: it offers an academically rigorous synthesis of current knowledge on GenAI adoption within creative domains and proposes a refined conceptual framework that can inform future empirical studies. By aligning established theoretical models with the distinctive needs of creative practice, the study provides a critical foundation for educators, researchers, and policymakers committed to supporting a responsible, ethical, and inspiring integration of AI technologies in the arts.

Keywords: Generative Artificial Intelligence, Business Processes, Creative Industry, Technology Acceptance Model, AI Classification Frameworks

Paper type: Academic Research Paper

1 Introduction

All creative contexts are undergoing a profound transformation propelled by the accelerating evolution of Generative Artificial Intelligence (GenAI). Traditionally, creative production has been deeply rooted in human originality and personal expression. Yet, the advent of GenAI is reshaping the landscape not only enhancing creative processes in terms of efficiency but are also enabling new forms of artistic experimentation that transcend human limitations.

While the promises of GenAI are substantial, its adoption within creative fields remains complex and irregular. Artists' acknowledge the benefits of accelerated ideation and increased access new technologies but also express concerns regarding the loss of creative autonomy and the risk of producing standardized outputs lacking human nuance (Permana and Fajar, 2024; van Niekerk et al., 2025). Moreover, trust in AI generated content and transparency in algorithmic decision making emerge as critical determinants of adoption, particularly in sectors where authenticity and originality are paramount. The ethical dimension further complicates the landscape. Questions about intellectual property, cultural appropriation, and algorithmic bias are increasingly central to the discourse on GenAI integration in creative practices (Greiner et al., 2023; Mourtajji and Arts-Chiss, 2024). These concerns are mirrored in academic research, which highlights the necessity of frameworks that ensure ethical compliance and foster user confidence (Mourtajji and Arts-Chiss, 2024).

This study is part of a broader research project aimed at investigating the individual and organisational factors that influence the adoption of Generative Artificial Intelligence (GenAI) in creative contexts. The

overarching goal is to develop a comprehensive understanding of how creatives engage with GenAI tools, and to design a survey to assess their acceptance and use starting from the students of Academy of Fine Arts and early career practitioners. To design the questionnaire to be administrated in the survey and determine which constructs should be measured, the study followed four main steps: (i) theoretical analysis of existing models of technology acceptance. The research focused on the Technology Acceptance Model (TAM) that provide structured frameworks for understanding the factors that influence individuals' adoption and use of new technologies. Among these, the Technology Acceptance Model (TAM), originally proposed by Davis based on the Theory of Reasoned Action (Ajzen, 1985; Davis, 1989), remains the most widely used models. Technology Acceptance Models It posits that users' behavioral intention to adopt a technology is primarily shaped by two constructs: *perceived usefulness* and *perceived ease of use*. In the present study, the mentioned TAM serves as the foundational model but is complemented by two other TAM that offer a broader perspective: the *OECD Framework for the Classification of AI Systems* (2022) and the *NIST AI Risk Management Framework* (2024). Such frameworks allow for the inclusion of additional dimensions—such as trustworthiness, transparency, and organizational conditions that are particularly relevant when addressing the deployment of AI technologies in complex social and educational settings. However, while valuable, also such frameworks exhibit limitations when applied to creative domains. Specifically, they often overlook the emotional, aesthetic, and identity-based aspects that are central to artistic practice. Future empirical validation may reveal the need to adapt or expand existing models, but this remains a potential implication rather than an immediate objective. A comprehensive literature search was conducted on Scopus to identify peer reviewed articles that explore the adoption of GenAI in creative contexts. The search query focused on the intersection between "generative AI" and "technology acceptance" and was limited to journal articles published in English. This process yielded 63 articles, which were then reviewed for relevance and thematic coherence: (iii) selection and analysis of a focused corpus of 26 papers. From the initial set of 63 articles, 26 were selected for in depth analysis based on their explicit focus on creative settings and the presence of theoretical constructs compatible with TAM frameworks. The triangulation of data collected from theoretical models, international guidelines, and empirical literature ensured a robust foundation for the development of the questionnaire; (iiii) design of a TAM based questionnaire. Based on the identified constructs, a draft questionnaire was formulated. It includes items measuring perceived usefulness, perceived ease of use, trust, creative autonomy, aesthetic satisfaction, and behavioral intention, as well as additional constructs emerging from the frameworks (e.g. facilitating conditions, emotional engagement). The questionnaire, that reflects the contextual specificities of artistic creation augmented by AI, will be administered to students in art and design related disciplines.

Looking ahead, future phases of the project will include discussion and refinement of the questionnaire through expert consultation, followed by a pilot test involving students from selected Art Academies. Successively the administration of the questionnaire will be extended to other artistic contexts.

The study contributes to both academic research and professional practice. From a research perspective, it advances current understanding of how Generative AI is perceived and adopted in creative domains by identifying and contextualizing a set of acceptance constructs specifically relevant to the contexts wherein artists are educated. On the practical side, the study supports educators, cultural institutions, and policymakers in making informed decisions regarding the responsible integration of GenAI tools in high education and professional contexts (Zhang and Hou, 2024).

2 Research methodology

The SLR was conducted following the PRISMA guidelines (Page et al., 2021) to ensure transparency and methodological rigor. The process included six sequential steps: (1) problem formulation, (2) query definition, (3) literature search, (4) screening and eligibility assessment, (5) thematic coding, and (6) synthesis and reporting (Ammirato et al., 2023; Donthu et al., 2021). Scopus was selected as the primary database due to its extensive coverage of interdisciplinary peer reviewed literature. The search strategy was designed to retrieve articles that explicitly address the intersection of Generative AI and technology acceptance, with particular attention to creative applications. A total of 63 articles were retrieved and screened. Of these, 26 were selected for in depth analysis based on their thematic relevance to the creative sector and alignment with the theoretical lens of technology acceptance. Bibliometric and semantic analyses were conducted to explore keyword frequencies and co-occurrences. The semantic analysis of abstracts was implemented using a text mining pipeline in R, including tokenisation, stop word removal, stemming, lemmatization, and frequency analysis. That allowed for the empirical identification of recurring terms and themes that informed the conceptual mapping (see Figure 5) and the preliminary selection of candidate constructs for the design of the questionnaire (Goyal and Kumar, 2021)

The methodological flow diagram is reported in Figure 1, which illustrates the sequential steps of the research design. The process begins with the problem definition, then, a query was developed and used to select papers from the Scopus database. The specific terms "generative AI", "technology acceptance", and related keywords were used, while limiting the results to "Article", "Journal", and "English". As mentioned, a total of 63 relevant papers were retrieved.

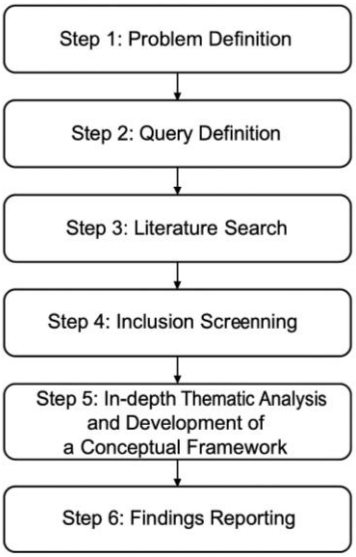

Figure 1. The sequential steps of the study.

The SLR was carefully designed to synthesize existing knowledge on the adoption of GenAI in creative contexts. The Scopus database, selected for its extensive coverage of peer reviewed journals, was utilized to ensure the inclusion of high quality studies across disciplines such as design, visual arts, education, and technology (Kanont et al., 2024).

The search strategy was meticulously crafted to retrieve articles focusing specifically on the intersection of generative AI technologies and technology acceptance, particularly in creative environments. The final query used in Scopus was as follows:

TITLE-ABS-KEY(("generative ai" OR "gen-ai" OR "gen ai") AND ("technology acceptance")) AND (LIMIT-TO (DOCTYPE,"ar")) AND (LIMIT-TO (SRCTYPE,"j")) AND (LIMIT-TO (LANGUAGE,"English")).

The search further filtered adopting the inclusion criteria document type "Article", source type “Journal", and language "English", yielded a total of 63 papers, of which 4 were published in 2023 and the remaining in 2024 and 2025. No further inclusion/exclusion criteria were applied. All 63 papers were fully considered in the analysis, so reflecting a deliberate choice to maintain a broad and inclusive scope given the novelty of the topic. The selected studies provided a rich foundation for identifying prevailing themes, including the critical roles of perceived usefulness, perceived ease of use, trust in AI systems, creative autonomy, aesthetic satisfaction, and behavioral intention (Wang et al., 2025). Alongside bibliometric insights, a content analysis was conducted to uncover the conceptual landscape of the field. A content analysis using lemmatization and frequency mapping of abstract keywords (using the R package “tidytext”) was conducted to identify recurring themes, concepts, and relationships relevant to the adoption of GenAI in creative domains. Through coding and thematic categorization, the analysis captured how scholars framed opportunities and challenges, mapped out user perceptions, and highlighted the factors influencing technology acceptance. Such an approach allowed for the identification of dominant narratives and emerging concerns across the literature, providing qualitative depth to the bibliometric findings. Based on the insights derived from the literature review, a questionnaire was developed to empirically explore the perceptions of students attending Art Academies, particularly those enrolled in courses dedicated to New Technologies of Art (Ebnali Harari et al., 2025). While our study focuses specifically on creative educational contexts, such as higher education institutions for the arts, it is embedded within a broader research agenda aimed at understanding GenAI adoption across diverse creative settings. These range from formative environments to professional creative contexts, where AI driven tools are increasingly shaping artistic production, distribution, and collaboration. The educational context is a particularly fertile ground for investigation, as it plays a crucial role in shaping the attitudes and competencies of future creative professionals. By examining the perceptions of students currently engaging with GenAI tools during their academic formation, this research provides valuable insights not only for educators and curriculum

designers, but also for software developers, cultural organizations, and policy makers aiming to foster responsible and meaningful integration of GenAI technologies across the wider creative ecosystem.

The survey design incorporated constructs validated in prior studies but adapted to capture dimensions crucial to creative contexts, such as creative autonomy and aesthetic satisfaction (Russo, 2024). Each construct was translated into multiple items to enhance the reliability of measurement, utilizing a 5-point Likert scale to capture degrees of agreement or disagreement.

3 Results and discussion

This section presents and discusses the results obtained from the study. The first paragraph (3.1 *Bibliometric analysis*) outlines the main findings derived from the bibliometric data associated with the selected publications. In the second paragraph (3.2 *In-depth thematic analysis*) the key themes emerging from the selected publications are organized into a conceptual framework structured around three thematic domains: Generative AI Dimensions, Creative Dimensions, and Constructs. The third paragraph (3.3 Constructs for GenAI acceptance in creative contexts) summarizes the constructs considered most relevant and instrumental for the subsequent development of tools aimed at assessing technology acceptance in creative settings.

3.1 Bibliometric analysis

The systematic analysis of the 63 selected articles revealed a complex and evolving landscape regarding the adoption of Generative AI in creative domains. The analysis showed the prominence of keywords such as creativity, autonomy, ethics, and collaboration, revealing how these concepts intersect in discussions of GenAI's role in creative practices (Mourtajji and Arts-Chiss, 2024). The semantic relationships underscored the importance of adapting established acceptance models to account for the unique priorities of creative users (Balaskas et al., 2025). What clearly emerged is that the discourse around GenAI is deeply intertwined with themes of empowerment and apprehension, reflecting both the enthusiasm for its creative potential and the caution surrounding its ethical and operational limitations (Zhang and Hou, 2024). A prominent finding from the literature is the perceived potential of GenAI to enhance creative processes, enabling unprecedented levels of ideation and content generation. Scholars highlight that GenAI systems, when appropriately integrated with other technologies, allow creators to transcend conventional barriers, offering tools that accelerate workflows and inspire novel forms of artistic expression.

The technologies facilitate rapid prototyping, provide instant feedback, and democratize access to sophisticated creative capabilities, making them particularly attractive to emerging artists and students. Figure 2 shows the exponential growth of publications in 2024 and 2025, indicating an intensified research focus on the theme. The Scopus research was carried out in March 2025.

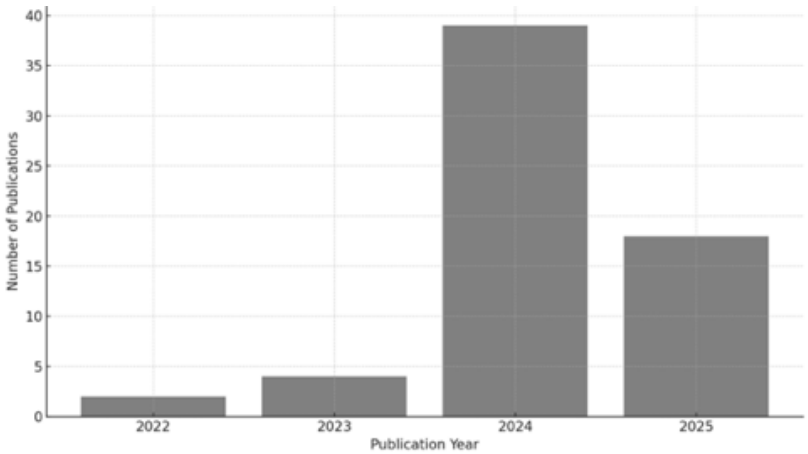

Figure 2. Scientific publications on Generative AI in creative sectors.

The adoption of GenAI across creative contexts remains highly fragmented. Numerous studies reveal persistent concerns about the dilution of creative autonomy and the fear of homogenization in outputs generated by AI systems (Chan and Zhou, 2023; Kim, 2025; van Niekerk et al., 2025). Creators often question whether reliance on generative systems might inadvertently lead to a convergence of styles and ideas, undermining the originality that defines artistic endeavor (Chan and Zhou, 2023; Wu et al., 2024). These concerns are amplified by the opacity of many GenAI algorithms, which complicates efforts to understand and

control the creative process. Further insights emerge from the geographical distribution of the studies analyzed, as shown in Figure 3, which highlights China and the United States as leading countries in research on GenAI for creative contexts, reflecting broader technological investments and academic engagement (Thüs et al., 2024).

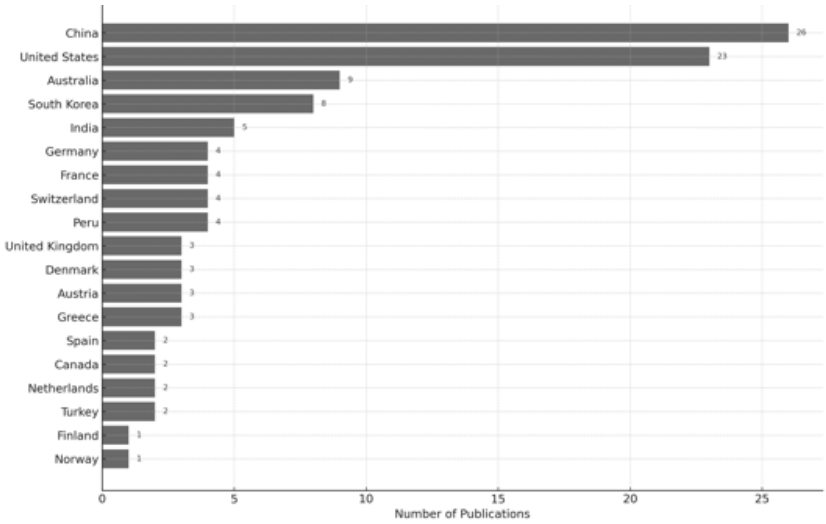

Figure 3. Geographical distribution of retrieved studies.

Trust in GenAI systems emerged as a decisive factor in determining user acceptance. Several studies emphasize that users are more likely to adopt GenAI tools when they perceive them as reliable, transparent, and capable of producing high quality outputs that align with their aesthetic values (Balaskas et al., 2025). Trust extends beyond technical performance, encompassing broader ethical considerations such as data provenance, authorship attribution, and fairness in algorithmic decision making. Additional layers of complexity were uncovered through a semantic analysis of keywords carried out in the abstracts of the 63 selected studies using VOSiewer (Figure 4).

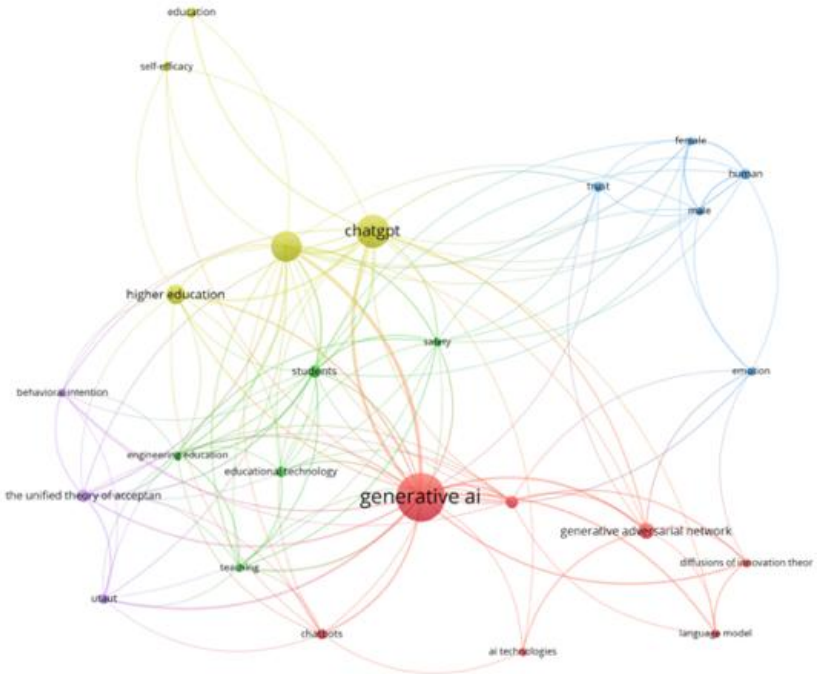

Figure 4. Co-occurrence network of keywords from selected studies on Generative AI and technology acceptance in creative sectors.

The co-occurrence map highlights clusters of terms such as "trust," "higher education," and "creative autonomy," indicating prevalent focal points in academic discussions and signaling areas requiring further empirical exploration.

3.2 In-depth thematic analysis

The conceptual framework presented in Figure 5 is the result of a multi-step thematic mapping process, aimed at organizing the main insights emerging from the literature. Such conceptual framework was developed by combining a semantic analysis of all 63 abstracts retrieved through the systematic literature review with an in-depth thematic coding of the 26 full text articles most relevant to creative contexts and technology acceptance.

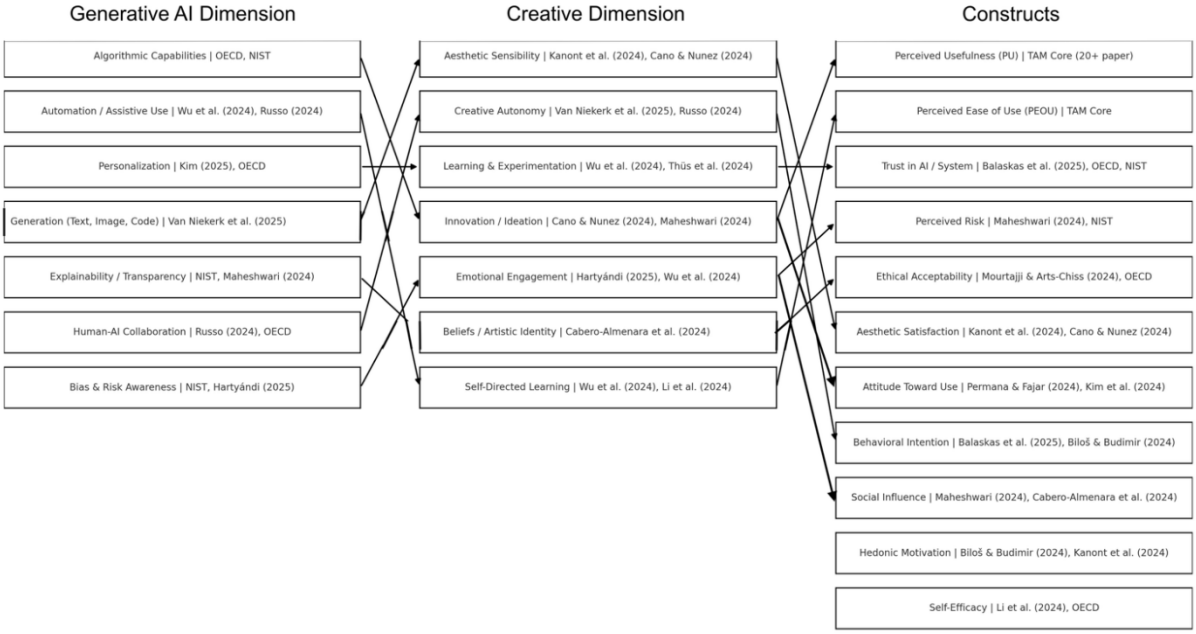

Figure 5. Conceptual framework of identified themes: connections between Generative AI dimensions, creative dimensions and Constructs.

The framework is structured into three **thematic domains**: *Generative AI Dimensions*, *Creative Dimensions*, and *Constructs.* Each group includes representative concepts or constructs, supported by specific literature sources. The connections between these elements were established manually based on patterns of co-occurrence in the abstracts and conceptual alignments observed in the full text papers.

Figure 5 report a conceptual framework that illustrates how specific technological features of GenAI (e.g. automation, explainability) relate to creative practices (e.g. innovation, self-directed learning), and how these, in turn, link to constructs mentioned in the retrieved papers to explain technology acceptance (e.g. perceived usefulness, trust, aesthetic satisfaction). This conceptual framework serves as a foundation for identifying and selecting the most relevant constructs for the subsequent development of the questionnaire to be administrated to potential GenAI creative tools users.

These linkages are visually represented by directional arrows in Figure 5, illustrating how technological features of GenAI interact with specific creative contexts and corresponding challenges or acceptance factors. Furthermore, extant literature underscores the increasing role of GenAI in educational settings, where it is employed to foster creative thinking, enhance learning outcomes, and prepare students for the evolving demands of the creative contexts (Chan and Zhou, 2023; Zhang and Hou, 2024). The analysis was implemented in R, a free and open-source software environment for statistical computing and graphics, widely used in academic and scientific research (Venables and Smith, 2025). Based on a text mining pipeline that included tokenisation, stop word removal, stemming, lemmatization, and frequency counting. The most recurrent terms ($n > 15$), visualized through a lemmatized frequency plot, provided the empirical basis for the thematic labels used in the conceptual mapping. It enables advanced data analysis, text mining, and the creation of high-quality visualizations through a vast ecosystem of specialized packages. In this study, R was employed to conduct semantic analysis on abstract data, supporting the identification of thematic constructs related to Generative AI adoption. The constructs listed under the “Constructs” were systematically derived through an in-depth thematic analysis of the 26 selected articles from the SLR. Each paper was examined to extract and classify all theoretical constructs explicitly or implicitly used to frame user acceptance of GenAI in creative dimensions. The extraction process followed a construct mapping approach: constructs were identified in the text. In addition, constructs were triangulated with those proposed in the NIST (2024) and OECD (2023) frameworks to ensure

conceptual alignment and to capture dimensions relevant to AI risk, trust, and organizational readiness. The final list includes both core TAM variables (e.g., perceived usefulness, perceived ease of use) and extended constructs (e.g., moral obligation, ethical acceptability), selected for their empirical relevance and contextual appropriateness (Ebnali Harari et al., 2025). The findings emerging from the study offer critical insights into the complexities surrounding the adoption of Generative AI in creative education and practice.

The insights not only inform the theoretical understanding of technology acceptance in creative fields but also may provide practical guidance for the design of GenAI tools and educational interventions aimed at fostering confident and critical engagement with generative technologies. For example, the identification of key acceptance constructs such as creative autonomy and aesthetic satisfaction can guide software developers in designing GenAI interfaces that allow users to customize algorithmic output, thus preserving personal expression. Likewise, educators in art academies can integrate modules on ethical AI use and critical digital literacy into their curricula, enabling students to engage with these tools not just as users, but as informed creators aware of both possibilities and limitations.

3.3 Constructs for GenAI acceptance in creative contexts

The insights gathered through the systematic literature review and the obtained conceptual framework constitutes a starting point for the development of tools (e.g. questionnaires, interview protocols) aimed at investigating the acceptance of GenAI among potential users in creative contexts.

Starting from the constructs identified in the conceptual framework (see Figure 4) the authors proceeded by grouping them, obtaining the results summarized in Table 1.

These results encompass both classical TAM constructs (e.g. perceived usefulness, perceived ease of use) and extensions particularly relevant to creative settings, such as trust, aesthetic satisfaction, and creative autonomy. At this stage the obtained constructs were furthered characterized according to their level of applicability (individual and/or organizational) including facilitating conditions and subjective norms, ensuring that the instrument reflects not only individual psychological drivers but also environmental and ethical factors.

Table 1. Constructs for assessing GenAI acceptance in creative contexts.

Constructs	Organizational	Individual	Definition	Source
Perceived Usefulness (PU)		X	The degree to which GenAI is perceived to enhance creative performance and output quality.	(Balaskas et al., 2025; Kim, 2025; OECD, 2022)
Perceived Ease of Use (PEOU)		X	The degree of ease associated with learning and using GenAI tools in creative practice.	(Chan and Zhou, 2023; NIST, 2024; Wu et al., 2024)
Trust in GenAI Systems	X	X	Confidence in the reliability, transparency, and fairness of GenAI outputs.	(Greiner et al., 2023; Kanont et al., 2024; NIST, 2024)
Creative Autonomy	X	X	Perception of control over the artistic process when using GenAI technologies.	(Mourtajji and Arts-Chiss, 2024; Zhang and Hou, 2024)
Aesthetic Satisfaction		X	Satisfaction with the aesthetic and cultural alignment of GenAI generated outputs.	(Cano and Nunez, 2024; Liu et al., 2024)
Facilitating Conditions	X		The degree to which users perceive that organizational or technical infrastructure exists to support the use of GenAI.	(Cabero-Almenara et al., 2024; Kim, 2025)
Attitude Toward Use		X	The degree to which users have a favorable or unfavorable evaluation of using GenAI tools.	(Kim, 2025; Permana and Fajar, 2024)
Subjective Norm		X	The perceived social pressure to use or not use GenAI tools in academic and creative practice.	(OECD, 2022; Zhang and Hou, 2024)
Behavioral Intention to Use		X	The likelihood of future use of GenAI tools in creative projects.	(Russo, 2024; Zhang and Hou, 2024)

Aesthetic satisfaction emerges as a crucial yet often overlooked factor in the adoption of GenAI tools. Creators engaged in artistic practices are not merely concerned with functional utility; they demand outputs that are emotionally resonant and culturally aligned with their creative identity. This aligns with the growing emphasis on aesthetic satisfaction as a relevant construct in creative education contexts, particularly when

GenAI is introduced into curricula that priorities experimentation and personal expression (Cano and Nunez, 2024; Liu et al., 2024). Similarly, the notion of creative autonomy is central to the discourse on GenAI integration. Several studies point to creators' desire to retain control over the artistic process, avoiding undue reliance on algorithmic outputs that might constrain originality (Mourtajji and Arts-Chiss, 2024; Zhang and Hou, 2024). These perspectives underscore the importance of complementing traditional TAM constructs—such as perceived usefulness and ease of use—with dimensions that reflect the emotive, cognitive, and ethical demands of creative disciplines. Building on these insights, a set of nine constructs has been identified through the systematic review and conceptual framework (see Figure 4). These are summarized and categorized in Table 1, which includes both individual and organizational dimensions. Alongside core TAM elements—such as perceived usefulness (PU), perceived ease of use (PEOU), and behavioral intention—the framework integrates extended factors like trust in GenAI systems, subjective norms, facilitating conditions, and attitudes toward use. This comprehensive view ensures that the proposed instrument does not limit itself to psychological readiness but also accounts for infrastructural support and normative expectations that shape the adoption process in creative educational settings. By doing so, the study not only clarifies which acceptance constructs are most relevant for GenAI in creative contexts but also offers a solid basis for the design of future survey instruments aimed at assessing their empirical validity. These tools may in turn guide educators, technology developers, and policymakers in aligning AI deployment with the needs and sensibilities of emerging creative professionals.

5 Conclusions

This study set out to explore the multifaceted dynamics underpinning the adoption of Generative Artificial Intelligence (GenAI) within creative contexts. Recognizing the potential of GenAI to enhance ideation, facilitate experimentation, and expand access to advanced creative tools, the research also acknowledges the complexity of integrating such technologies in domains where personal expression, aesthetic judgement, and authorial agency are central. By conducting a Systematic Literature Review of peer reviewed articles, the study offers an integrated perspective that bridges academic theory with the realities of creative practice (Balaskas et al., 2025; Zhang and Hou, 2024). The SLR findings confirm that GenAI technologies hold immense potential to redefine the creative landscape that could democratize access to sophisticated design tools and inspire novel forms of expression (Kim, 2025; Russo, 2024). The acceleration of ideation processes and the facilitation of rapid prototyping are consistently highlighted as key benefits, fostering new opportunities for experimentation and artistic growth (Cano and Nunez, 2024). The persistent concern over creative autonomy underscores the need for GenAI tools that empower rather than constrain human creativity. Creators are cautious of overreliance on algorithmic generation, fearing a potential homogenization of creative outputs and a dilution of personal expression (van Niekerk et al., 2025). Trust emerges as a critical determinant, not only in terms of technical reliability but also regarding the ethical dimensions of AI deployment. Transparent processes, respect for data integrity, and clear authorship attribution are essential to building user confidence and fostering responsible engagement with GenAI tools (Greiner et al., 2023; Mourtajji and Arts-Chiss, 2024).

Moreover, the aesthetic dimension of AI generated content proves pivotal. Creators expect outputs that do more than meet functional needs—they seek emotional resonance and alignment with their unique creative identities. This underscores the importance of designing GenAI systems that are not merely efficient, but also capable of producing outputs that evoke genuine artistic satisfaction (Ebnali Harari et al., 2025). The conceptual framework developed as part of this study (see Figure 4) served as a foundation for grouping and selecting a set of nine constructs considered most relevant for subsequent empirical investigation, as reported in Table 1. These constructs address both individual and organizational dimensions of acceptance, ensuring a comprehensive approach to future measurement efforts. The constructs selected—such as usefulness, ease of use, trust, creative autonomy, aesthetic satisfaction, behavioral intention, facilitating conditions, and subjective norms—were not chosen arbitrarily. Rather, they were systematically identified through an in-depth thematic analysis of 26 articles selected for their relevance to creative contexts and triangulated with frameworks such as the OECD Classification of AI Systems and the NIST AI Risk Management Framework. As discussed, such constructs provide a structured foundation to assess the multifaceted nature of GenAI acceptance in creative contexts. Future steps will include expert validation and pilot testing of the survey instrument, targeting students of Academy of Fine Arts to assess the reliability and construct validity of the proposed measurement model. This will enable the validation of the proposed constructs and offer deeper insight into the conditions that foster or hinder GenAI adoption. Comparative studies across cultural contexts and artistic disciplines would further enrich understanding, ensuring that the adoption of GenAI is not only technologically feasible but also culturally sensitive and ethically sound (Cabero-Almenara et al., 2024; Thüs et al., 2024).

Finally, the integration of GenAI into creative contexts offers transformative potential, if guided by thoughtful design, ethical integrity, and a deep respect for the human spirit of creativity. By synthesizing theoretical insights with practical tools, the research aspires to contribute meaningfully to GenAI, supporting a future in which technology complements, rather than replaces, the artist's hand and imagination.

6 Ethics Declaration

This study did not involve human participants, clinical trials, or personal data collection.

7 AI Declaration

No AI tool was used to develop this paper.

Abstract

The transition from linear to circular manufacturing systems (CMS) is essential for manufacturing firms aiming to enhance sustainability and mitigate resource depletion. Despite clear environmental and economic benefits, the adoption of circular economy (CE) principles within the manufacturing sector remains limited, largely due to significant technological, operational, and organisational barriers. This study addresses these issues by exploring the specific challenges that manufacturing companies face during their transition to CMS and proposes digital technologies to effectively overcome these barriers. Utilising an exploratory, qualitative, single-case study approach, we investigated a European white goods manufacturer implementing a refurbishment centre aimed at establishing circular practices within their laundry appliance segment. Through thematic analysis, we identified three primary challenges: uncertainty regarding the condition of returned appliances due to limited consumer data sharing, insufficient durability and longevity data from laboratory tests of new models, and operational inefficiencies due to inexperience with dismantling and refurbishing processes. To address these challenges, we propose advanced digital solutions leveraging Internet of Things (IoT), Artificial Intelligence (AI), and Augmented Reality (AR) technologies. Specifically, IoT and AI-based systems are recommended for comprehensive product tracking, real-time condition monitoring, predictive maintenance, and informed decision-making, significantly improving data availability and accuracy for refurbishment operations. Additionally, we suggest AR-enhanced workstations to assist workers in dismantling processes, enhancing operational efficiency, reducing error rates, and facilitating knowledge management across diverse product models. Our findings extend the current body of knowledge on CE barriers, particularly in relation to IoT capabilities and consumer data-sharing practices and highlight practical implications for manufacturers seeking effective digital interventions. This research underscores the critical role of technology integration and organisational readiness in achieving successful CMS transitions.

Keywords: Circular Manufacturing Systems (CMS), Circular Economy (CE), Digital Transformation

Paper type: Academic Research Paper

1 Introduction

The circular economy (CE) is being considered a transformative business and sustainability paradigm, grounded in recognising that natural resources are finite and that traditional linear production models are unsustainable (Geissdoerfer *et al.*, 2017; Jensen, 2023). Central to this paradigm, as outlined by the Ellen MacArthur Foundation (EMF, n.d.), are the principles of (i) eliminating waste and pollution, (ii) keeping products and materials in use at their highest value, and (iii) regenerating natural systems. These principles recognise the constraints of finite natural resources and degrading environmental conditions as major drivers for companies to become circular and sustainable. These CE principles are adopted by implementing different CE practices, which are increasingly enabled using digital technologies (Neri et al., 2023). The adoption of CE principles is even more important for the manufacturing sector to counter waste generation and increase the usability of products during their life cycle.

In manufacturing, the CE principles drive the development of Circular Manufacturing Systems (CMS), *designed intentionally for closing the loop of components or products, preferably in their original form, through multiple life cycles* (Rashid *et al.*, 2020, p. 345). The transition from linear to circular manufacturing is a complex, long-term initiative that linear companies usually undergo iteratively, focusing on three CMS pillars: product design, business model, and supply chains, which are enabled through ICT implementation and digital transformation. Companies usually pursue CMS through circular economy (CE) practices (Neri *et al.*, 2023). Despite the potential benefits of implementing CE, its adoption in linear manufacturing firms is still considered low. For example, the circular material use rate in the EU for 2023 was only 11.8% (EEA, 2025), indicating that the economy is primarily linear. To understand the reasons behind the slow adoption of CE, we explored the challenges that linear manufacturing companies face due to their current business model design, product design,

supply chain design, and existing ICT infrastructure. The research also explored the potential solutions to these challenges and the required knowledge and competencies.

To explore the challenges, we conducted an in-depth single case study of a European white goods manufacturer actively pursuing a transition towards CMS by establishing a dedicated return and refurbishment centre. This case was chosen because it reflects incumbent manufacturers' typical challenges when integrating CE practices into existing operations. Data were gathered for one year through a multi-method qualitative approach, including expert interviews, group interviews, focus groups and validation sessions. Subsequently, thematic analysis identified three challenges, and the participative design research approach generated potential ICT-based solutions.

This paper follows a standard structure, with theoretical background outlining the main theoretical concepts of this research, namely CMS, circular product design, circular business models, circular supply chains and digital support for CMS. Our qualitative methodology is described in the following chapter, focusing on data collection, thematic analysis, and a participatory design research approach. The identified challenges and the designed ICT-based solution are described in the results section. We contextualised our findings with respect to recent scientific developments in the discussion.

2 Theoretical background

The concept of CMS has finished the evolution of linear manufacturing from reverse approaches through closed-loop concepts, fuelled by the context of sustainability movements. The product design phase determines around 80% of the environmental impacts (European Commission, 2012) and is crucial for circularity as it determines the future reusability of the product. The most significant barriers hindering the transition towards circular product design are: financial constraints, inadequate infrastructure, government inaction, and global market barriers (Wang et al., 2022). If these barriers could be overcome, the design should focus on preserving product integrity, developing a longitudinal value proposition, and having a longitudinal business model (den Hollander, 2018). Including reducing, reusing, recovering, and rethinking principles into the product design phase (Tan et al., 2024) can dramatically reduce the environmental impact. These CE practices or principles could pave the way towards CMS (Neri et al., 2023). However, isolated implementation of CE practices or focus only on product design does not ensure transformation to CMS. The typical manufacturing pillars (product design, business model, supply chains, ICT) should be integrated and developed together (see Figure 1).

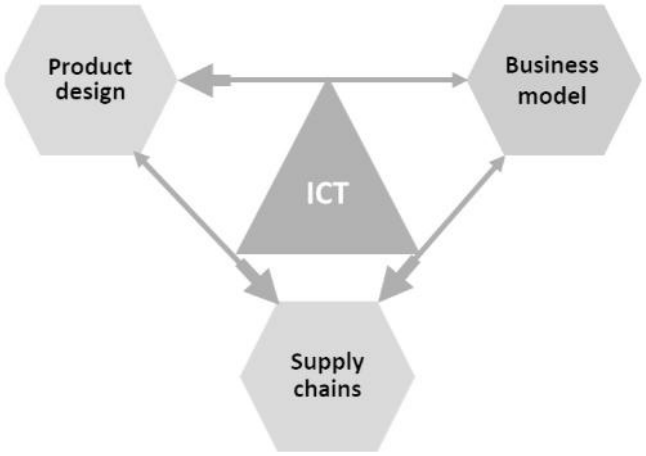

Figure 1: CMS framework (Rashid et al., 2020, p. 346)

The business model needs to evolve together with circular product design into a circular business model that could be understood as a business model that is cycling, extending, intensifying, and/or dematerialising material and energy loops to reduce the resource inputs into and the waste and emission leakage out of an organisational system. This comprises recycling measures (cycling), use phase extensions (extending), a more intense use phase (intensifying), and the substitution of products by service and software solutions (dematerialising) (Geissdoerfer *et al.*, 2020). Frishammar and Parida (2019) proposed a road map for circular business model transformation for linear companies, consisting from four phases i) analysing opportunities to initiate circular business model transformation; ii) review of current business model to identify gaps; iii) design and develop a revised business model based on the design elements of circular economy, iv) validate, implement and scale-up the circular

business model. Further integration of circular product design and business models with supply chain capabilities is needed.

The notion of circularity in supply chains emerged long before circularity became the central theme. Reverse logistics (Rogers and Tibben-Lembke, 2001; Tibben-Lembke and Rogers, 2002), or closed-loop supply chains (Guide and Van Wassenhove, 2006) have been studied for more than 20 years. However, these different concepts converged into circular supply chains (Wang *et al.*, 2022). The prevalence of linear manufacturing business models and thinking implies many barriers to successful circular supply chain implementation. For example, Taddei et al. (2024) identified seventeen barriers associated with circular supply chains. The authors ordered the barriers based on their importance, resulting in financial and economic barriers being the most important, followed by technical, legislative, political, organisational, and social barriers. In the recent study, Chen et al. (2025) identified factors affecting the implementation of circular supply chains. The immediate determinants were lower consumer costs, recycled raw material production, and energy conservation technology.

Technologies (mainly Industry 4.0) support all three pillars of CMS, as they play a significant role in the circularity transformation of supply chains, serving as enablers (Taddei *et al.*, 2024). Digital technologies were proven to support the circular economy strategies, especially in the areas of improving energy and resource efficiency, recycling, rethinking and reusing (Liu *et al.*, 2022). However, the same study highlighted that the repurpose strategy is the least supported by digital technologies. Digital technologies play a role of lower-order capability when supporting business performance through CE practices (Riggs *et al.*, 2024). This confirms the importance of digital technologies in CE initiatives, showing that digital technologies are a necessary but not sufficient condition for a successful CE initiative.

Some authors extended the focus on the four pillars (business model, product design, supply chain, ICT) by further areas. For example, Chirumalla et al. (2024) proposed a multi-level readiness framework to support the transition of manufacturing companies from linear to circular economy. They identified four key focus areas, each with five levels of progression: i) the ecosystem of external partners, ii) the customer and the business model, iii) the company's culture and internal capabilities, and iv) design and product development. The authors also identified four strategies for the successful transition to a circular economy: i) changing the mindset, ii) understanding of the circular economy concept and establishing own definition, iii) high-level planning and evaluation of scenarios, and iv) ensuring financial viability and environmental preservation.

3 Methodology

The goal of this research was to explore and describe the challenges of a manufacturing company aiming to transition from linear to circular manufacturing. The main research question this study addresses is: "What are the challenges that companies face when transitioning towards CMS, and how can digitalisation help address those challenges?" To answer this research question, we employed an exploratory, in-depth case study approach with features from design and action research strategies. The exploratory nature was derived from the lack of previous research that did not bring suitable testable outcomes. We chose the inductive qualitative approach because we wanted to provide details that could guide future confirmatory research. The design and action research elements were needed to answer the second part of the research question, as Company A could use the analysis of the barriers and our experience to design the solutions.

At the start of our research, we conducted several online interviews with relevant people from the organization. These interviews allowed us to understand the context of the company and its CMS transition initiatives. These interviews were recorded, and the transcripts were validated with the interviewees. After initial thematic analysis of the interviews, we designed a multiple-day focus group at the Company A facility to gather further data about the initial themes and ensure that we did not miss any themes during the initial interviews. The sample for the focus group was wider than the initial interviews, as we identified new respondents. The focus group was not recorded. However, multiple researchers were present during the focus group, and we created detailed notes that were validated after each session. The notes were used for further thematic analysis, both for conceptualising the existing themes further and identifying new themes. The themes were subsequently validated with relevant stakeholders through online interviews after the focus group.

After we concluded the thematic analysis, we designed another focus group that focused on exploring the design of digital solutions for overcoming the challenges. This focus group was conducted online using collaboration and co-creation tools both during and after the meeting to discuss and elaborate on different digital solutions. After the focus group, the authors prepared the circular flow diagram and mapped the digital solutions to different phases/stages of the circular value chain of the company (i.e., value use phase, reverse

logistics, and value recovery phase). Finally, the authors collected written feedback from the relevant people at the company on the need for different digital solutions and their design.

4 Findings

Company A operates in the white goods industry and manufactures a wide range of products that include refrigerators, freezers, washing machines, dishwashers, ovens, etc. For this research, only the business unit focusing on laundry appliances is considered, for which Company A is aiming to establish a refurbishment centre.

4.1 Current CMS maturity

Company A focused on CE activities and environmental awareness in the past decades by implementing an ISO-14001 environmental management system in 2000 and the EU Eco-Management and Audit Scheme (EMAS) in 2004. These activities helped reduce environmental impact in all the product life-cycle phases. Company A focuses on the long-term duration of appliances that support multiple lifecycles. The company tested a pay-per-use business model. Company A seeks to increase its value recovery activities by establishing and integrating refurbishment operations into its current processes. For this, Company A builds data infrastructure and data gathering capabilities through smart home features in their appliances, which are supported by IoT hardware to generate and gather data about the appliances.

To continue the transition to CMS, Company A wants to establish a refurbishment centre to refurbish appliances and harvest spare parts. Company A would like to use increased value recovery in the form of refurbished used parts to support their pay-per-use business model, to prepare to fulfil the future legislation about the right-to-repair, and to lower their costs on spare parts manufacturing. Therefore, Company A must ensure a sufficient volume of refurbished components and appliances, but it faces several challenges. The digital support for circularity remains limited. Company A also lacks the IT infrastructure to support the recovery and quality assessment of the used parts.

4.2 Challenges

During our thematic analysis, the following themes in the form of challenges emerged, which stand in the way towards CMS transformation:

- CHAL1 Uncertain condition of the appliance and its components
- CHAL2 Limited data about the longevity of the appliances for new models
- CHAL3 No experience with the dismantling process

The refurbishment centre will handle both unused and used appliances that have been returned. The first group will be easier to handle from the context of their condition. However, handling the used products will be challenging due to their uncertain condition (CHAL1). If the appliance has smart features, it could be connected, and Company A could have information (although usually impartial) about the use of the product. The real challenge will occur when there is no data about the use of the appliance online. The appliance stores a limited amount of data that could be retrieved and used for condition assessment; however, without further data that could be used to correlate the data from the appliance, it will be impossible to assess the appliance's condition.

Company A tests all models in a durability lab to check the average lifetime. The basic models take about eight months (non-stop usage) to test, whereas thoroughly testing the premium and heavy-duty models for their designed lifetime would take around seven years. This has two implications. First, some models cannot be adequately tested before entering the market. Second, Company A misses the data from testing for use in assessing the returned appliances. The extended testing time of the new models and limited data availability from their testing (although in laboratory conditions) make the efficiency of the refurbishment centre processes hard (CHAL2).

When establishing the new refurbishment initiative, the biggest challenge is the inexperience with the dismantling process and linear focus. The intake of many returned models contradicts the experience from linear manufacturing and complicates any (semi-) automation. Manual processes are prevalent and significantly depend on the expertise and knowledge of the inspection and dismantling workers. However, Company A has no extensive experience with these operations, and the lack of experience will result in errors and low efficiency of the inspection and dismantling processes (CHAL3).

4.3 Digital Solutions

We identified and designed two solutions (SOL) that are aimed at addressing the identified challenges. The first solution (SOL1) aims to enhance the IoT capability for tracing, tracking, and condition monitoring of washing

machines. It directly tackles CHAL1 and CHAL2 through Artificial Intelligence (AI) based decision support solutions with the aim to decrease testing time for new models of washing machines, increase uptime of washing machines during use phase, optimize reverse logistics of used appliances and parts, speed up end-of-life testing of used parts, and improve spare parts availability and inventory management. Table 1 provides a summary of IoT and AI-based digital solutions and their key requirements

Table 1: IoT & AI based circular support solutions and their key requirements

Area	Digital Solution	Key Requirements
Tracking & Tracing	Use of digital platform for collecting and storing operational data	a) 5 main data groups: settings, status, static, program status b) Cloud-based storage for long-term availability c) Requires enhanced firmware and software upgrades for cloud communication
Condition Monitoring of Critical Components	IoT-driven tracking of pump, heater, and motor performance	a) Monitoring of usage cycles, power consumption, and error codes b) Store data in a centralized data lake c) Data used for ML model training and maintenance forecasting
Durability Testing	Use of sensors for monitoring during lab testing	a) Custom firmware to read temperature and pressure sensors b) Streaming of raw sensor data (e.g., water temperature, pressure) c) IoT stack upgrade for low-latency, high-throughput data streaming
Reverse Logistics Decision Support	AI models to assess reuse and recovery decisions	a) Use of lifecycle data, error codes, and service logs b) ML pipeline using Apache Kafka and the Azure platform c) Support for end-of-life decision making (refurbish, recycle, buyback)
Predictive Maintenance	Machine learning for predicting component failures	a) Labelled training datasets from field failures b) Addressing the imbalance in data (rare failures) c) Use of supervised learning or anomaly detection d) Integration with historical error logs and operational patterns
AI Support for Durability Testing	Application of ML on lab testing data	a) Use of extended sensor logs b) Combination with historical technical data and component details c) Focus on improving label quality for model training
End-of-Life Testing	Data-based decision support for reuse or disassembly	a) ML models trained with sensor and statistical data b) Use of appliance and component-level information c) Labels such as “buyback” or “refurbish/recycle” guide decisions

The second solution (SOL2) should overcome CHAL3. To dismantle the appliances and recover the critical parts at the refurbishment centre, Company A will implement an AR-based solution to achieve a low error rate in value recovery of returned appliances. The proposed solution involves using an AR application in combination with a specific dismantling station to provide instructions for dismantling in a user-friendly manner.

Table 2: AR & AI-based digital solutions for disassembly and parts recovery

Area	Digital Solution	Key Requirements
Disassembly Support	AR-guided workstation for manual disassembly tasks	a) Physical station with camera setup and object tracking b) Adaptive instruction interface with text, images, videos, and 3D objects c) Latency under 40 ms for real-time response d) Validation of user interactions through object detection e) Offline mode capability f) Integration with Gorenje’s IT infrastructure and reverse logistics workflows

5 Conclusion

This study explored the challenges faced by manufacturing firms transitioning from linear to Circular Manufacturing Systems (CMS) and how digital technologies can address these challenges. Our research identified three key challenges: uncertain appliance condition due to limited user data sharing (CHAL1), inadequate product longevity data from laboratory tests (CHAL2), and operational inefficiencies arising from a lack of dismantling experience (CHAL3). We proposed advanced digital solutions, including IoT and AI for product tracking, condition monitoring, predictive maintenance, and decision support (SOL1), as well as augmented reality (AR) systems to assist manual disassembly processes (SOL2). These findings contribute to existing literature by expanding on identified barriers related to data complexity and IoT capability deficits (Ozkan-Ozen *et al.*, 2020). Specifically, we extended knowledge concerning user data-sharing barriers from supply chains into the white goods industry context. Additionally, our insights into operational inefficiencies due to workforce inexperience (see, Taddei *et al.*, 2024) align with social barriers identified in other sectors (Kazancoglu *et al.*, 2020), thereby broadening their applicability and relevance.

From a practical perspective, our study provides manufacturing firms with actionable insights into how digital transformation can facilitate the adoption of CMS. The integration of AI/ML and AR-assisted workstations represents a promising pathway to overcome existing challenges in data availability and operational inefficiencies. Such ICT-driven solutions improve the effectiveness of refurbishment processes and support the broader transition from linear to circular manufacturing models. For practitioners, the case study offers a replicable blueprint for designing and implementing refurbishment initiatives that are both technologically advanced and aligned with CE principles. This study contributes to the literature on digital transformation and circular manufacturing by exploring the challenges and opportunities associated with integrating ICT solutions in traditional manufacturing settings.

Our study provides actionable insights for practitioners aiming to transition toward circular manufacturing. Companies should invest in IoT technologies integrated with AI for real-time condition monitoring and predictive maintenance to improve decision-making in refurbishment operations. Manufacturing firms need to prioritise user-friendly Iot solutions to encourage consumer data sharing, addressing privacy concerns through transparent data management policies. Adoption of AR-guided workstations is recommended to enhance efficiency and accuracy in product disassembly and inspection processes.

Our findings underscore the importance of considering technological capabilities and organisational readiness when designing digital interventions. They also highlight the need for further confirmatory studies across diverse industrial sectors to assess the generalizability of the proposed solutions. Future research could extend our approach by incorporating multiple case studies, providing a more comprehensive understanding of how digital technologies can be leveraged to enhance CMS. Additionally, there is scope for investigating the socio-technical dimensions of digital transformation, particularly concerning workforce training and the user acceptance of smart technologies.

AI-driven Knowledge Futures: Digital Innovation in Cultural Heritage

Aelita Skarzauskiene, Kristina Kovaitė, Monika Mačiulienė, Paulius Šūmakaris
Vilnius Gediminas Technical University, Vilnius, Lithuania

Abstract

The rapid advancement of digital technologies has opened new possibilities for cultural heritage institutions (CHIs), enabling digitization and AI-supported initiatives that improve preservation, accessibility, and public engagement. However, CHIs often face significant challenges in evaluating and selecting appropriate projects due to fragmented resources, institutional complexity, and existing decision-support frameworks prioritize financial and technical feasibility while neglecting cultural and social dimensions. This study addresses a critical gap by presenting a micro-level decision-support framework specifically designed to guide CHIs in the evaluation of digitization and AI-supported projects. The framework was constructed through a three-stage mixed-method research design that combined a systematic literature review (SLR), focus group discussions, and the Delphi technique. It draws on the expertise of professionals from the European cultural and creative industries, including representatives from CH institutions and ethnic minority groups. Their diverse perspectives ensured that the framework reflects both technical and cultural priorities. The process resulted in a validated set of 43 criteria, grouped into six categories: finance and investment, employment and personnel, market, accessibility, social impact, and cultural heritage object. The framework offers CHIs a comprehensive but context-sensitive tool to guide structured, evidence-based decision-making. It captures both tangible and intangible project dimensions and supports strategic planning that aligns with institutional missions and stakeholder expectations. The study contributes theoretically by operationalizing cultural value and institutional priorities in micro-level evaluation, addressing the limitations of market-oriented models. It also offers practical value by enabling CHIs to navigate trade-offs between innovation, feasibility, and cultural integrity. While grounded in project-level application, the framework also serves as a foundation for the application of multi-criteria decision-making (MCDM) methods and future research on institutional-level decision making. The findings improve CHI's ability to make informed, inclusive, and forward-looking investment decisions in a rapidly changing digital world.

Keywords: cultural heritage, digitization, AI-supported projects, decision making criteria, micro-level.

Paper type: Academic Research Paper

1 Introduction

The expansion of the digital economy has recently intensified interest in digital innovation within cultural heritage (CH), leading to advances in storage, creation, and dissemination (Lin & Li, 2023; Wen et al., 2023; Zhang et al., 2024). Technological advancements such as artificial intelligence (AI) and augmented and virtual reality drive digitization and expand audience engagement, particularly in tourism, where digital heritage attracts visitors and boosts economic activity. The emerging AI agenda in CH is crucial to understand both the possibility and the dilemma of pushing heritage institutions into the digitalization era.

Consequently, the rapid pace of technological change in the CH domain makes early identification and evaluation of promising digital technologies essential (Schuh et al., 2023). For CHIs, strategic decision making around digitization and AI-supported initiatives is becoming increasingly critical, as accelerated technological development demands more deliberate and forward-looking approaches to implementation. However, many CHIs lack long-term evidence-based agendas, resulting in fragmented initiatives and an absence of coherent direction that impedes the integration of digital innovation into broader institutional goals (Schuh et al., 2023). This challenge is further compounded by fragmented funding structures and a limited pool of digital expertise, both of which undermine the development of comprehensive digitization strategies and constrain the potential for broader socio-economic impact (Zemlickienė et al., 2018).

Furthermore, from the perspective of decision makers, incomplete information and significant uncertainties further complicate the process of selecting and adopting the most suitable digitization projects, particularly in the early stages of technological adoption (Lapinskaitė et al., 2024). Furthermore, current decision-support methodologies for CHIs fail to adequately capture the complexity of CH digitization and AI-supported projects. Existing frameworks often emphasize financial viability and technological feasibility while neglecting the cultural, social, and ethical dimensions central to CHI's missions (Schuh et al., 2023). As a result, decision-makers are frequently left navigating the digitization process with tools designed for commercial enterprises. This misalignment risks steering investments toward projects that prioritize short-term technological novelty over long-term cultural value.

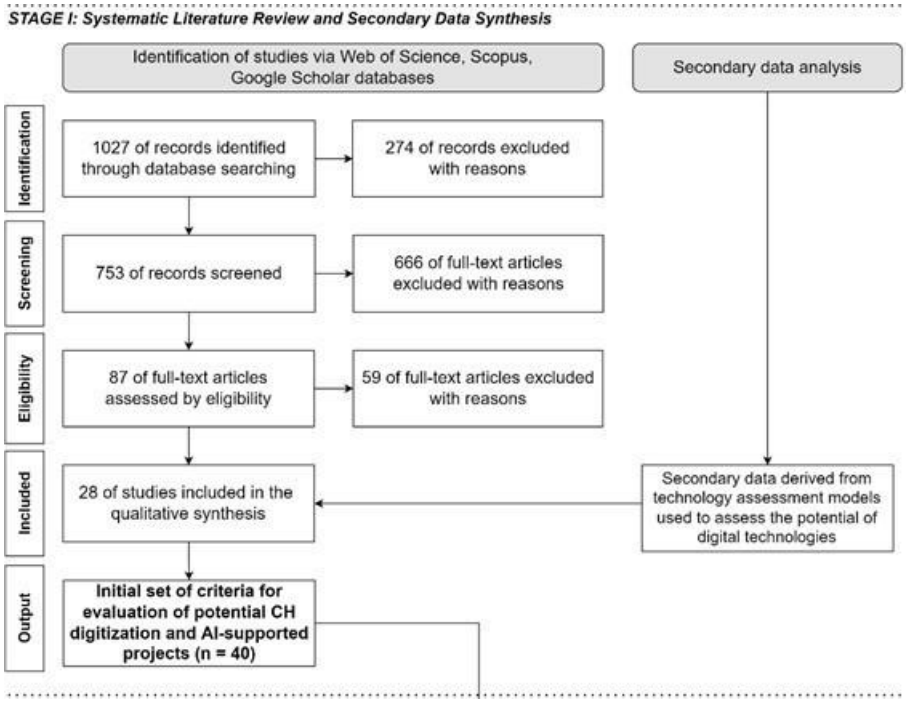
To address these challenges, this paper presents a framework and decision-support methodology designed to help CHIs evaluate potential digitization and AI-supported projects and avoid non-productive investments ensuring that selected initiatives align with long-term institutional, societal, cultural, and economic objectives. The framework is grounded in a three-stage research strategy that combines qualitative and quantitative methods, including a systematic literature review (SLR), focus group discussions, and the Delphi technique. Unlike broader regional or policy-level approaches, our methodology emphasizes the specific characteristics, constraints, and intended outcomes of individual CH digitization projects. It offers an expert-driven, institution-centered assessment framework that reflects the distinctive mission of CHIs taking into account fragmented funding environments, internal limitations, and the cultural, social, and ethical dimensions of digital transformation.

This study is structured as follows. The next section outlines the background on decision-making related to CH digitization and AI-supported projects, followed by a description of the research design and applied methods. The results section presents the full set of decision-making criteria, and the conclusion synthesizes key insights, discusses their implications for institutional strategy, and identifies directions for future research in advancing digital innovation in cultural heritage.

2 Background

Technological innovations, digitization, and the growing use of AI present significant opportunities for CHIs. For example, digital collections can attract virtual tourists, support digital exhibitions, and contribute to the creative economy by inspiring new forms of art and media. In addition, digitization enhances the preservation and dissemination of cultural assets, fosters public engagement, and stimulates economic activity. Vuoto et al. (2024) emphasize the wide range of digital technologies used in the CH sector, including immersive tools like virtual and augmented reality, as well as 3D modeling, image reconstruction, laser scanning, and AI applications. These technologies aim to improve engagement, preserve heritage, and offer immersive experiences without compromising cultural integrity. In particular, AR and VR have been shown to shape visitor interactions and deepen engagement at heritage sites (Wen et al., 2023), while gamification and educational technologies increasingly support learning in virtual and mixed reality environments (Zhang et al., 2024). Furthermore, AI has also become central to CH digitization for image analysis and restoration, object classification, text transcription and translation, automatic content analysis, recommendation systems, and multimodal interpretation. In addition, AI tools can also support user-generated artistic expressions by manipulating virtual 3D objects, audio-visual materials, or spatial data.

Despite their potential, CH digitization and AI-supported initiatives face a number of challenges. While the economic potential is significant, the reuse of mass-digitized content reveals a complex network of issues. For instance, AI usage in CH faces significant challenges, such as lack of standardization, legal and ethical concerns, and economic or technological barriers. Tiribelli et al. (2024) note that the absence of unified standards complicates data integration across institutions. Additionally, some studies also point to mixed results in user experience, while digital tools often enhance engagement, they can also introduce drawbacks such as simulator sickness and increased distraction (Ye et al., 2025). As Marto et al. (2019) and Wen et al. (2023) observe, the effectiveness of these projects depends on their alignment with user expectations and their ability to preserve cultural authenticity. Thus, CHIs are challenged to balance traditional offerings with digital innovation, navigating tensions between modern engagement strategies and heritage conservation. In addition, the complexity of digital projects, resource limitations, incomplete information, and uncertainties surrounding technological impact continue to hinder the ability of CHIs to develop strategic, long-term, and evidence-based agendas.



Therefore, a robust project-level decision support methodology is crucial for CHIs, as it provides a transparent and systematic approach to evaluate potential CH digitization and AI-supported projects. Technology assessment, as described by Liu et al. (2016), provides a framework for examining the implications of emerging technologies. It incorporates empirical methods, stakeholder engagement, and foresight analysis to reduce uncertainty and support informed decision-making. Understanding the life cycle and fundamentals of innovation, CHIs are able to adopt technologies that align with their institutional and socio-economic goals (Dereli & Altun, 2013). Although the commercial potential of new technologies is not the main concern for CHIs, it remains a relevant consideration. Effective decision-support tools help institutions avoid non-productive investments and ensure that adopted projects contribute to broader institutional and societal objectives (Zemlickienė et al., 2018).

Several methodologies have been developed to evaluate digitization and innovation projects, but their applicability to CHIs remains limited. For example, the STEP framework (Dereli & Altun, 2013) integrates technology, process, economic, market, perception and regulatory evaluations, yet lacks the nuance required to

address CH-specific concerns such as cultural significance and audience engagement. Similarly, IPscore® 3.01 (developed by European Patent Office) and WIPO's technology identification system (WIPO, 2010) offer structured approaches to assessing innovation. Still, they prioritize market-driven criteria that often sideline the broader societal impact of cultural heritage. Even frameworks that incorporate multi-criteria decision analysis (Zemlickienė et al., 2018) tend to underweight the values CHIs uphold, reducing their effectiveness in guiding strategic decision-making. However, a common consensus among these decision support methodologies emphasizes evaluating economic and market potential, stakeholder demands, and the integration of various assessment tools (Huang & Gu, 2009). These approaches highlight the importance of integrating multiple criteria to capture the diverse dimensions of the impact of the project. Since CHIs often face unique challenges that differ from purely commercial entities, existing tools may not adequately address multidimensional considerations, emphasizing the need for a problem-based approach that aligns with the specific needs of CHIs. Therefore, in this study we propose a methodology to aid CHI's decision-makers in evaluating potential CH digitization and AI-supported projects.

3 Research methodology

Our research design is guided by the following central research question (RQ): What are the relevant criteria for evaluating potential CH digitization and AI-supported projects? More specifically, the project level focuses on CHIs and organizations that implement digitization and AI-supported projects within specific institutional and community contexts. To answer the RQ and propose a decision support framework, we have employed a three-stage research strategy, integrating qualitative and quantitative methods for comprehensive data gathering and validation (Figure 1). This strategy provides distinct advantages through complementary methods and is built on previous studies (Lamoureaux et al., 2024; Rao et al., 2021; Tan et al., 2010) and methodological guidelines (Fathullah et al., 2023). Fathullah et al. (2023) highlight the benefits of combining systematic literature reviews (SLR), focus group discussions and the Delphi technique, and has been proven effective in previous research to consolidate baseline knowledge with expert-driven refinements.

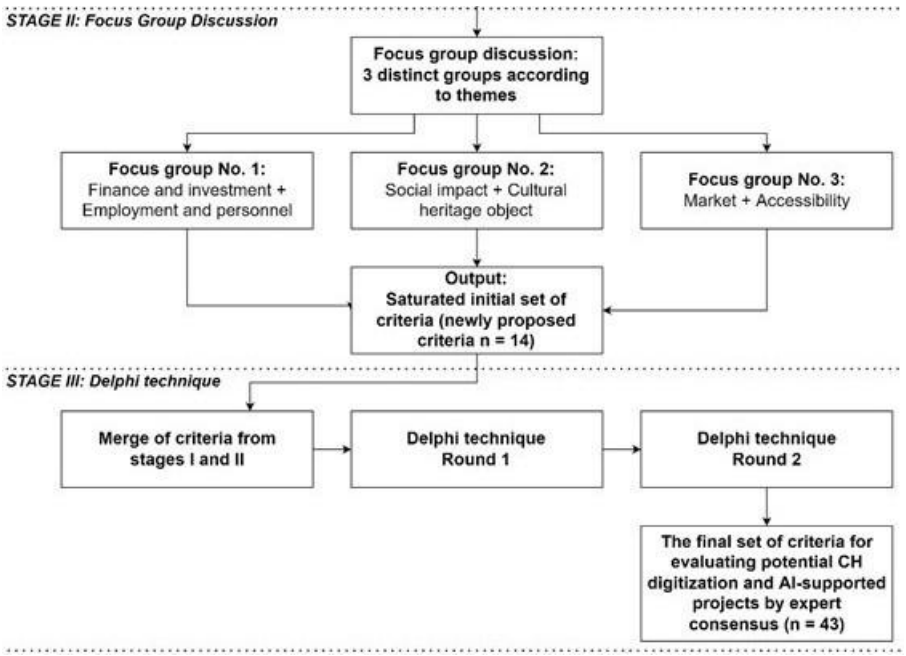


Figure 1: Research design to develop a decision support framework to evaluate potential CH digitization and AI-supported projects (Authors, 2025)

3.1 Systematic literature review and secondary data synthesis

The systematic literature review (SLR) formed the foundation for identifying decision-making criteria relevant to CH digitization at the institutional level. Studies were sourced from Web of Science, Scopus, and Google Scholar, selected based on their suitability as outlined by Pranckutė, (2021). The search strategy was structured around two streams: (1) cultural heritage and (2) decision-making. The second stream incorporated terms such as multi-criteria decision-making (MCDM), decision support, and prioritization frameworks to ensure methodological relevance.

An initial pool of 753 records was screened which included review of abstracts. Inclusion criteria were: (1) studies addressing decision-making processes related to CH digitization at the project level, and (2) studies presenting a defined set of criteria with clear descriptions. Exclusion criteria were: (1) studies focusing solely on selecting the best alternative without outlining underlying criteria; (2) topics unrelated to CH, such as biodiversity, construction, or restoration; (3) secondary research (e.g., SLRs, bibliometric analyses); (4) purely theoretical work lacking application to decision-making; (5) studies outside the institutional or geographical scope; and (6) papers lacking methodological transparency or sufficient description of decision-making criteria and context.

A total of 87 full-text articles were assessed for eligibility, and 59 were excluded due to: lack of project-specific criteria (n = 27), insufficient criterion descriptions (n = 8), topic irrelevance (n = 21), or minimal contribution (n = 3). These exclusions were possible only after full-text review due to insufficient detail at the abstract level. The final sample of 28 articles underwent qualitative synthesis, focusing on the applicability and clarity of decision-making criteria. To complement this analysis, a secondary data synthesis was conducted to examine existing technology and innovation assessment models and extract best practices. Following Cahyadi & Magda (2021) and Weston et al. (2019), these models were primarily derived from technology assessment literature. To structure the criteria, the generic technology potentials proposed by Schuh et al. (2023), including cost reduction, synergy, human impact, market potential and quality were adapted to the study context. This led to six final categories: (1) financial and investment (8 criteria), (2) employment and personnel (5 criteria), (3) market (4 criteria), (4) accessibility (7 criteria), (5) social impact (8 criteria), and (6) cultural heritage object (8 criteria). In total, 40 criteria were identified and used as input for the second stage of the research.

3.2 Focus group discussion

In the second stage, focus group discussions were used to integrate theoretical knowledge, namely, the criteria identified in the first stage, with expert insights, enriching, and refining the final set of criteria. Focus groups are particularly effective in exploratory research, offering a dynamic platform for capturing diverse perspectives, encouraging interactive dialogue, and facilitating the integration of multidisciplinary knowledge,

especially in complex decision-making contexts (Bandalos, 2018; Kramar et al., 2019; Prieto-Sandoval et al., 2019). We follow the methodological guidelines of Jacoby & Siminoff, (2007) and O.Nyumba et al. (2018). Three focus groups were organized as interactive workshops, each moderated by a dedicated facilitator and structured around themes derived from the initial criteria set. The first group addressed financial and investment criteria and employment and personnel criteria; the second focused on market and accessibility; and the third discussed social impact and cultural heritage object criteria. Experts were assigned based on their domain expertise, with 5–7 participants in each group. In total, 17 experts from the European cultural and creative industries, including representatives from CH institutions and ethnic minority groups, participated in this stage. Expert data are presented in Annex 2. The names of the experts are not disclosed due to privacy and legal rights, and experts have been codified with labels E1, E2, etc. Expert recruitment and surveying were carried out in September 2024.

The experts were presented with the central research question: What are the relevant criteria for evaluating potential CH digitization and AI-supported projects? An auxiliary question was also posed: What is important to consider when making decisions about the digitization of cultural heritage projects? These questions were explicitly formulated to saturate the set of criteria. The focus group setting proved highly informative, allowing participants to engage in nuanced discussions and share a wide range of perspectives. At the end of the sessions, each group proposed additional criteria that they believed should be incorporated. In total, 14 new criteria were suggested. After review, two were excluded because they fell outside the scope of the study, and three were merged with existing criteria due to overlap. As a result, nine new criteria were added to the initial pool and used as input for the third research stage.

3.3 Delphi technique

Finally, the Delphi technique was applied to refine and finalize the set of criteria, retaining only those deemed most important through expert consensus. The Delphi technique is a structured, multi-round survey process designed to facilitate consensus through iteration, controlled feedback, and aggregated responses (Schmalz et al., 2021). This study followed the methodological guidelines of (Afshari et al., 2012; Drumm et al., 2022), and previous applications in similar contexts (Schmalz et al., 2021)(Zavadskas et al., 2017).

A total of 20 experts participated in this third research stage. Expert data is presented in Annex 2. In the first round, all the criteria identified in stage one, along with those newly proposed during the focus groups, were merged and distributed to experts via a Delphi questionnaire. Experts were asked to evaluate each criterion's relevance on a 9-point scale (1 = “completely irrelevant”; 9 = “extremely relevant”) and were invited to select 3–4 criteria groups aligned with their area of expertise. They could also propose additional criteria or suggest refinements to existing definitions. Two auxiliary questions were included to guide expert judgment: (1) How relevant is the criterion when evaluating potential CH digitization and AI-supported projects? (2) What is important to consider when making decisions about the digitization project of CH? The responses were analyzed and criteria were advanced to the second round based on average relevance scores. Following the approach of Oroojeni Mohammad Javad et al. (2020), only criteria with a mean score of 7 or higher were retained. In the second round, a set of criteria, including newly added criteria, was returned to the experts to obtain consensus, and experts were asked again to evaluate the relevance of the criteria based on a scale of 1 to 9. Final consensus was reached at the end of this round, resulting in the validated set of decision-making criteria.

4 Results

The applied three-stage research strategy, integrating qualitative and quantitative methods, resulted in a final set of 43 criteria directly relevant for evaluating potential CH digitization and AI-supported projects (Figure 2). These criteria were classified into six thematic groups, drawing on the framework of generic technology potentials by Schuh et al. (2023) as an initial reference. While Schuh’s model offered a useful starting point, its orientation toward the private sector required adaptation to the distinct mission of CHIs. Through an iterative refinement process, the final grouping was developed to reflect the context of CHIs. The six resulting categories are: (1) Finance and investment (9 criteria), (2) Employment and personnel (6 criteria), (3) Market (4 criteria), (4) Accessibility (7 criteria) (5) Social impact (9 criteria), and (6) Cultural heritage object (8 criteria). The full list of criteria is provided in Annex 1.

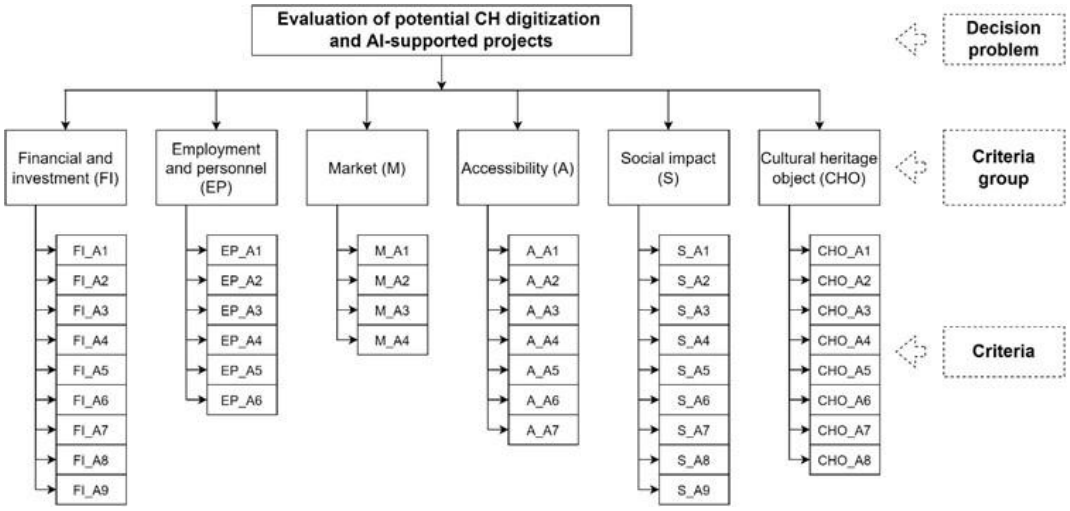

Figure 2: Hierarchical structure of the decision problem and framework to evaluate potential CH digitization and AI-supported projects (Authors, 2025)

4.1 Finance and investment criteria group

This group covers the economic dimensions of digitization projects, including financial feasibility, funding availability, and potential returns. It addresses both initial investment requirements and long-term financial commitments, including external funding, co-financing, and cost-efficiency. It also captures the potential for direct monetization or indirect savings, along with the broader economic implications for local communities.

4.2 Employment and personnel criteria group

This group covers the institutional readiness in terms of human resources and considers staff expertise in technology and cultural heritage, capacity for personnel allocation, and internal attitudes toward digitization. The group also accounts for job creation potential, workload distribution, and staff well-being, highlighting the organizational conditions required for successful implementation.

4.3 Market criteria group

The market group focuses on the project's positioning within the broader digital ecosystem. It evaluates readiness for public engagement, distinctiveness compared to similar initiatives, and both current and future demand. Technological maturity and growth potential are also considered, providing insight into a project's sustainability and relevance in a dynamic digital environment.

4.4 Accessibility criteria group

This group examines how users interact with and access digitized content. Key dimensions include user-friendliness, technological integration, and adaptability to future systems. It also addresses physical and remote access, technical support, and data security, ensuring that projects are inclusive, navigable, and resilient to changing user and infrastructure demands.

4.5 Social impact criteria group

Social impact criteria assess the alignment of projects with societal values, inclusivity, and educational potential. This includes public attitudes, social group responses, and the role of digitization in shaping cultural interpretation. It also captures contributions to public learning, international cooperation, and participatory design, reflecting the broader civic role of CHIs.

4.6 Cultural heritage object criteria group

This group focuses on the authenticity, quality, and preservation aspects of digitization. It considers the extent and fidelity of digital reproduction, the condition of the original object, and the potential risks or benefits to its conservation. The criteria also address the historical and symbolic significance of the object and the impact of digitization on its interpretation.

5 Conclusions

In this study, we present a robust project-level decision-support framework for CHIs and organizations implementing digitization and AI-supported projects within specific institutional and community contexts. Identifying micro-level evaluation criteria is a foundational step in enabling informed, strategic decision-making for CH digitization. The proposed classification offers a comprehensive and structured framework that captures the multifaceted nature of such projects. Each criteria group addresses critical factors influencing project feasibility, long-term sustainability, and broader socio-economic value. By integrating both qualitative and quantitative dimensions, the framework allows CHIs to assess tangible and intangible aspects of digitization, ensuring alignment with institutional priorities, stakeholder expectations, and available resources. In doing so, it enhances strategic planning while preserving cultural authenticity, promoting accessibility, and maximizing social benefit. This structured approach empowers CHIs to make well-informed, balanced and forward-looking decisions that reflect their unique missions and long-term objectives. Beyond the immediate scope of digitization projects, this framework contributes to a broader understanding of how cultural institutions can adapt technological innovation to serve public value rather than market imperatives. It offers a model for evaluating emerging technologies in ways that respect cultural specificity, institutional diversity, and community priorities.

5.1 Theoretical Implications

This study contributes to the theoretical discourse on decision-making related to digitization of cultural heritage by offering a domain-specific framework that addresses the limitations of market-oriented evaluation models. While existing methodologies often prioritize financial and technological feasibility, they frequently lack the nuance required to account for the cultural, ethical, and institutional dimensions unique to CHIs. This research introduces a micro-level classification of decision criteria that operationalizes these overlooked dimensions and can serve as a foundation for future studies in heritage informatics, cultural policy, and innovation governance. The framework also contributes to the creative economy literature by drawing attention to the strategic conditions under which cultural digitization projects are likely to produce sustainable, locally driven innovation. In addition, it invites further theoretical exploration of the extent to which cultural value can be meaningfully embedded in the assessment without reducing heritage to quantifiable metrics.

5.2 Practical Implications

For CHIs and organizations implementing digitization and AI-supported projects in specific institutional and community contexts, the findings offer a practical tool to guide structured evidence-based decision-making. The initial classification of criteria was grounded in a systematic literature review and informed by established decision-support models. More critically, the participation of experts from European cultural and creative industries, including representatives from CH institutions and ethnic minority groups, ensured that the framework was contextualized and responsive to real-world challenges. These expert insights helped refine criteria definitions and align the framework with the operational realities of CHIs, bridging the gap between technological feasibility and cultural sensitivity. This collaborative approach enhances the framework's applicability, enabling CHIs to manage and prioritize digitization projects in ways that reflect both institutional mandates and the expectations of cultural communities. However, as stakeholder priorities differ across institutional and cultural settings, project-level decision-making must also account for contextual variability. Digitization is not a uniform process; it is shaped by the values, constraints, and goals of distinct cultural groups. Therefore, effective implementation requires sensitivity to these differences and a commitment to inclusive and adaptive evaluation processes.

5.3 Limitations and agenda for future research

Although this study presents a robust and context-specific framework for evaluating CH digitization and AI-supported projects, several limitations should be acknowledged. First, the focus on European cultural and creative sector experts may limit the generalizability of the criteria across diverse geographical or institutional settings. Future research could expand the expert base to include perspectives from underrepresented regions and non-European cultural contexts. Second, while the Delphi method offered a structured approach to consensus building, the qualitative nuances of disagreement or divergence between experts were not explored in depth. Complementary qualitative methods, such as individual interviews or ethnographic case studies, could enrich understanding of context-dependent decision logics. Moreover, while the framework is developed for project-level evaluation, future research should explore its integration into multi-criteria decision-making

models, enabling CHIs to prioritize projects systematically under specific conditions. The finalized criteria set can serve as input for a range of MCDM techniques, such as AHP, BWM, TOPSIS, or PROMETHEE, to support structured decision processes.

6 Ethics declaration

Include a section at the end of your paper stating whether you needed ethical clearance for the research referred to in this paper and if you did provide a reference to the permission granted.

7 AI declaration

In developing the paper, AI tools were used exclusively to support language editing and facilitate textual refinement, with all outputs were reviewed and incorporated at the discretion of the authors.

Annex 1: Full list of criteria to evaluate potential CH digitization and AI-supported projects

Criteria	Description
GROUP: Finance and investment (FI)	
Funding potential	External financial support and funding potential
Initial costs	Initial costs of a digitisation project
Long-term costs	Long-term financial obligations
Project duration	Projected duration of the implementation of the project
Project Longevity	Expected longevity of the project
Monetisation	Monetisation opportunities and potential for new revenue streams
Cost savings	Cost savings and avoidance due to project
Impact on local economic activities	Effects on local economic activities
Co-funding	Potential for securing additional funding through contributions by partners
GROUP: Employment and personnel (EP)	
Personnel technological competencies	Technological competencies of personnel
Personnel CH object competencies	Competencies of the personnel related to the cultural heritage object
Personnel capacity and availability	Allocation of sufficient human resources with required skills and time
Personnel hostility and attitude	Staff's openness, resistance, or hostility towards the project
Potential for creating new jobs	Ability to generate new employment opportunities
Personnel well-being	Physical health, mental well-being, and overall stress levels of the staff
GROUP: Market (M)	
Level of uniqueness	Uniqueness of the digital cultural heritage project in the market
Market readiness	Degree of market readiness
Current market demand	Current market demand and the number of potential users
Future market demand	The anticipated interest, and emerging trends
GROUP: Accessibility (A)	
Complexity of the technology	How challenging or advanced digital technology is for end-users
Technological dependencies	Extent to which the project relies on existing or technological infrastructure
Compatibility	How well the project integrates with existing digital platforms
User Engagement	Features of the project that enhance user engagement
Physical accessibility	Accessibility regarding physical location and availability

User support	Availability and quality of technical support and help resources for end-users
Security	Measures implemented to safeguard user data and ensure the security
GROUP: Social Impact (S)	
Social hostility and attitude	How well the project aligns with social attitudes and expectations
Socio-Cultural Impact	Affect the cultural authenticity and value of cultural heritage
Educational and research value	Potential contributions to educational and research activities
Use Restrictions	Limitations on fair use, including public accessibility
Social inclusion	Impact of the project on fostering social inclusion,
International relations	How effectively the project fosters international collaboration
Digital outreach	Extent to which the project facilitates the creation of new communities
Diverse audiences	How well the project caters to a wide range of demographic groups
Co-design principles	Extent to which the project incorporates co-design principles
GROUP: Cultural heritage object (CHO)	
Representation accuracy	Digital representation accurately of the cultural heritage object
Technological quality	Technological specifications (resolution, colour depth, file format, etc.)
Significance of the CH object	Uniqueness, cultural, symbolic, historical, artistic significance
Current preservation	Current preservation level of the cultural heritage object
Preservation needs	Preservation needs of the object in its current state
Physical condition	Physical condition of the cultural heritage object
Level of digitisation	Extent to which a cultural heritage object is digitised
Digitisation impact on CH	Extent of the effects that the digitisation process has on the CH object

Annex 2: Data of experts who participated in the Focus groups and Delphi

Expert	Country	Area of expertise	Participated in stage II	Participated in stage III

Transforming Hotel Innovation Management through Innovation Labs: Lessons from Spain

Matias Celdrán Bonafonte[1], Francesco Santarsiero[2], Gustavo Morales-Alonso[1]
[1]Universidad Politécnica de Madrid, Madrid, Spain
[2]University of Basilicata, Potenza, Italy

Abstract

In this article, we will explore innovation management in such an important sector as tourism, focusing specifically on the hotel industry. Within the hotel industry, innovation has been a major focus for some years now, moving away from the popular phrase that traditionally circulates by word of mouth, "This has always been done this way." Proof of this is that highly important organizations in the sector such as ITH (Hotel Technology Institute in Spanish) are holding highly interesting events such as the one held in 2020: "Balance between technology and investment, common sense and people, key in ITH Hotel Virtual Innovation Lab". Because the current situation in the sector is changing, both for the hotelier and the customer, it is essential to be able to compare what has been studied so far with the current reality. In the past, guests would go to a hotel and find things they didn't have at home: a larger TV, a better mattress, a jacuzzi... this meant that innovation took a backseat to customer attraction. Nowadays, it's difficult to surprise guests with such basic items that they normally have at home that are just as good or better, so innovation has taken center stage and gained significant importance. We could say without fear of being wrong that today the hotel sector is one of the most interested in innovation in all its aspects (technological, marketing and processes) without a doubt. That's why we consider it important to conduct a study and see if the reality of the sector is surpassing the academic studies conducted on it. To contrast this reality, it is important to obtain information directly from the most relevant players in the sector and conduct as many interviews as possible.

Keywords: Innovation Lab, i-Lab, innovation, Hotel industry, Tourism

Paper type: Academic Research Paper

1 Introduction

The aim of this study is to analyse the management of innovation within a sector of great importance to the Spanish economy: the tourism industry, with a particular focus on the hotel sector.

According to data published by the Spanish National Statistics Institute (INE) on its website, the tourism sector accounted for 11.6% of Spain's Gross Domestic Product (GDP) in 2022. Within this sector, the hotel industry constitutes one of its key pillars, undergoing significant changes in recent years.

Historically, the hotel sector in Spain has been managed in a family-oriented manner, with varying levels of professionalism, and a common characteristic being the ownership of the properties operated. However, in recent years, new players have entered the market, including investment funds, external operators, and franchises.

This evolution has substantially transformed the sector, resulting in previously uncommon scenarios, such as the ownership of a property by an investment fund, its operation by an external manager, and its management under a franchise brand. These changes have made management more complex, with each case being unique.

This article will differ from a conventional article, because it will attempt to use two methodologies: a systematic reading of the literature and a case study.

With this particular structure we will try to compare the results obtained from the literature and those obtained from participants in the sector.

We will try to answer two basic questions from both points of view that give meaning to this article:

- *Is the management of innovation clearly defined within the hotel sector?*
- *Can an "Innovation Lab" be a useful tool for managing innovation?*

2 Theoretical foundations

Organizations are increasingly interested in creating dedicated physical spaces to foster innovation process. For more than ten years, universities, research institutes, incubators, accelerators, innovation centers, co-working spaces, start up spaces and more have grown at a considerable pace across the globe (Osorio et al., 2019). The concept of innovation lab, has grown in popularity in recent years, and, nowadays, a variety of

interaction spaces work with these principles in mind (e.g., 'living labs', 'hubs', 'fablabs') (Høegh-Guldberg et al., 2022).

This phenomenon is increasingly emerging in response to traditional Research and Development (R&D) centres' gaps in the digital age. Indeed, R&D labs, even when equipped with high-tech infrastructure and skilled personnel, cannot always sustain and improve the innovation capacity of companies. This is mainly because they are often still designed as monads, isolated from the rest of the company and where a highly technical language is spoken far from the rest of the company (Blank, 2007).

Innovation labs (or labs) in this study are collaborative innovation spaces that can be defined as 'physical or virtual spaces that enable and support the innovation (technological or otherwise) of those who participate in the space (Yati, 2024)

An innovation lab is mainly associated with an innovative space (Moultrie et al., 2007). One of the points that is gaining the most strength in terms of innovation labs is the use of a space dedicated and conceived exclusively for the purpose of facilitating innovation. Indeed, (Moultrie et al., 2007) suggest the physical space is essential for the innovation process in organizations.

As described in their article (van der Meer et al., 2021) we can classify innovation labs in to 4 types: Digital Enabler, Solution Insourcer, New Bussines Incubator and Joint Innovator.

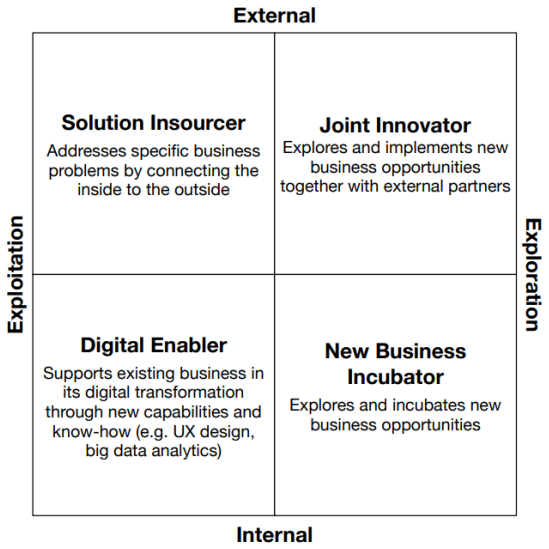

Figure 1. Innovation Labs Types identified by (van der Meer et al., 2021)

An Innovation Lab can be seen as an innovation management model based on three pillar dimensions distinguishing its structure: i) "atmosphere for innovation", i.e. the construction of an innovative space, which can be physical, virtual, hybrid, relational, promoting and supporting interactions and a context for innovation; ii) "time for exploration", i.e. the definition of time for creating and critical thinking spurring innovative ideas related to the challenges at hand; iii) "platform to experiment", i.e. the provision of tangible and intangible infrastructure and tools that can support the prototyping, experimentation and demonstration of possible innovative solutions. (Santarsiero et al., 2023)

3 Methodology

3.1 Systematic literature review

First of all, we conduct a systematic review of innovation labs in the hotel sector.

After an initial search of articles published in two of the most used databases; "Scopus" and "WOS", with different semantics, we observe that there are few publications on the topic in question.

3.1.1 Inclusion Criteria

It started with the search for the following string:

("Innovation Lab*" OR "Living Lab*") AND ("Tourism" OR "Hotel" OR "Lodge" OR "Accommodation" OR "Resort*")

In both databases, 72 documents were obtained in “Scopus” and 71 documents in “WOS”

We discarded publications that were not in Spanish or English this leaves us with a total of

62 documents in “Scopus” and 64 documents in “WOS”. Later we will stay with those that are in their final stage of publication leaving a total of 60 documents in “Sopus” and 64 documents in “WOS” because they don’t have this filter. Later we are left only with the documents catalogued as “articles”, 37 articles in “Scopus” and 43 articles in “WOS”.

We finally restrict the period to 10 years (2025-2025) giving us a total of 34 articles in “Scopus” and 41 articles in “WOS”.

Table 1**:** Resume

Initial documents	**Scopus**	**WOS**
	72	71
Filter 1, Language; English or Spanish	62	64
Filter 2, Publication stage: Final	60	---
Filter 3, Document type: Article	37	43
Filter 4, Range: 2015-2025	34	41

If we eliminate the duplicates in both databases, we are left with a total of 48 articles.

To the latter we added some articles that were very interesting from various magazines. This leaves us with a final result of a total of 51 articles to carry out the study.

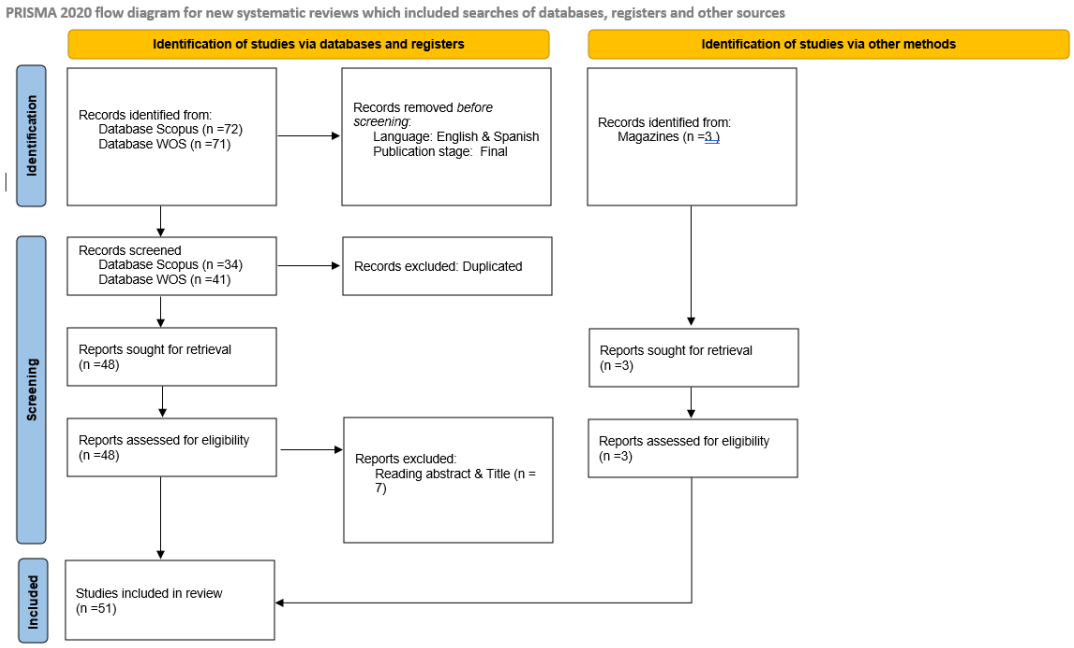

Figure 2. Prisma 2020. Flow diagram

3.1.2 Exclusion Criteria

A first reading of the title and the summary is carried out, and all articles that do not make direct reference to the indicated criteria, “Innovation Labs”, “Living Labs”, “Tourism” or “Hospitality”, are eliminated. 17 are discarded, leaving a total of 26 articles in this penultimate step.

3.2 Case study

As (Yin, 2014) defined, case study is “an empirical inquiry that investigates a contemporary phenomenon (the ‘case’) in depth and within its real-world context”.

We should start this chapter by compiling, according to various authors, the different types of case studies.

Table 2. Types of case studies

Initial documents	**Scopus**
	72
According to its purpose (Borges Méndez, 1995; Yin, 2014):	a) Pedagogical b) Clinical c) Investigative I.Explanatory II.Exploratory III.Descriptives
According to the number of cases (Yin, 2014):	a) Simple b) Multiple
According to the approach:	a) Quantitative b) Qualitative

In our case, we could categorize our study as an Investigative/Descriptive research study of a simple case using an intrinsic/qualitative approach.

Investigative, because we will seek to understand a specific phenomenon, the possible use of innovation labs. Descriptive, because the purpose is to examine and characterize the phenomenon.

Depending on the number of cases, if a single interview is initially conducted, it would be a simple type.

Finally, based on the approach, it would be a qualitative study, focusing on understanding the phenomenon, accepting the interviewee's subjectivity, and striving to interpret the research. It would also be intrinsic, due to the need to learn about the subject itself.

We have taken as references in this field the most renowned scholars of case studies, Robert Yin and Robert Stake.

To begin, we must assess whether the phenomenon we wish to study is a "case." For Stake, not everything is susceptible to being a case. To be considered a case, it must be something specific, with clear boundaries, and possessing a sense of identity and intentionality. However, the definition we believe best fits our particular case is the one described by Alonso G.(Alonso G., 2003): “A case study is a social science research strategy applied to a single, complex contemporary phenomenon, which is more specific than general in nature and which simultaneously represents a broader problematic situation. The research will seek to cover both the phenomenon and its real-life context in depth and will draw on multiple sources of evidence. It may aim to explain, describe, explore, evaluate, or diagnose.”

4 Results

4.1 From the systematic literature review.

After conducting a systematic literature review, we can observe, as the first and most important point, a small number of articles related to innovation labs and the hotel sector in particular.

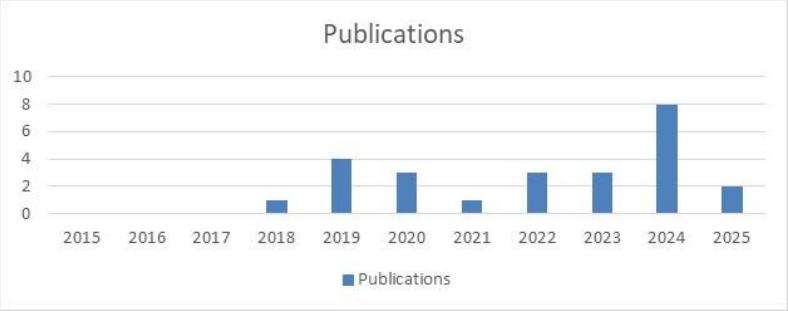

Figure 2. Publications by year

Almost all the articles found that deal with the topic start with the fact that the "innovation lab" is the appropriate tool, without really assessing whether it is or not and how innovation is initially managed.

Organizational culture and innovation today are components that together can be fruitful for the hotel sector, improving its profitability and, above all, contributing to the generation of innovative capabilities in human resources. Given the current competitive environment, it is imperative that they focus their attention on

strategies that allow them to grow and consolidate. In turn, the companies that will excel in the future will be those that make proper use of these components. (Padrón-Diaz de León et al., 2019)

The tourism sector's resistance to technological disruptions, which are integral to its offerings, has slowed the integration of Innovation Labs. Additionally, the prevalence of SMEs, often family-run, in the tourism and culture sector adds to the challenge. These SMEs face barriers to innovation and digital development due to limited economic and human resources, skills, cultural mindset, and dedicated time for innovation initiatives.(Najda-Janoszka and Kopera, 2014).

Innovation Labs have emerged as a valuable organizational practice that can help companies meet these needs by developing innovation strategies and promoting digital adoption.(Santarsiero et al., 2024)

There are also some articles that discuss "Living Labs" in the tourism sector, and since they are a derivative of an "innovation lab," they have been helpful in obtaining more information about alternatives in the sector.

Most of these articles based on "Living Labs" focus more on the general tourism sector and the destinations themselves in particular. This seems to be due to the fact that the members of a "living lab" are diverse and often include public administration among those involved.

(Osorio et al., 2019) Proposes an updated framework based on the experience of the projects described in his article. As has been shown, establishing a clear strategic intention at the early stage of the project is fundamental, and literature has actively evolved in that regard during the last few years. Among the other frameworks studied in this work, it is possible to identify common elements that define which aspects should be considered to set up the strategy for an innovation laboratory supported and shared by several stakeholders, such as companies, academics, open labs, factories, etc.

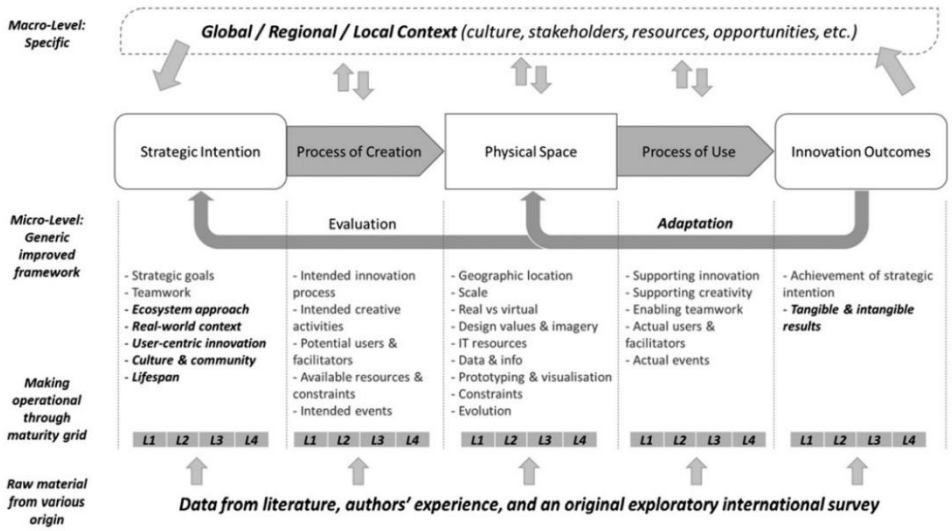

Figure 3. Updated framework based on (Osorio et al., 2019)

We can see that proper innovation management is crucial for the success of any new initiative. (Mellinas et al., 2016) describes how most Spanish hotels have adopted social media in recent years, but data indicate that many of them do it improperly, although a particularly intensive training for basic operation is not required.

Technology and innovation management is added to the relevant topics of technological innovation because one of the important issues in the innovation process is being able to measure them and evaluate their performance in this regard (Jiménez-Valero et al., 2012) They claim that there is no system of indicators that comprehensively evaluate GTI in the hotel industry.

Technological innovation, when used correctly, can be a very important point of connection with the customer, and Cardona (Cardona, 2016) demonstrates this in his study, where he analyzes the innovations implemented by Palladium Hotel Group in Spain for customer service, indicating which ones worked and which ones didn't.

Organizational culture and innovation today are components that, when combined, can be fruitful for the hotel sector, improving its profitability and, above all, contributing to the generation of innovative capabilities in human resources. Given the current competitive environment, it is imperative that they focus their attention on strategies that allow them to grow and consolidate. In turn, the companies that will excel in the future will be those that properly utilize these components. (Padrón-Diaz de León et al., 2019)

4.2 From the case study

Figure 4. Identified concepts

A parallel list of codes was created to assign to the concepts listed above, with the intention of evaluating the most important aspects. The list consisted of a total of 34 codes:

Figure 5. Identified codes

To summarize this first interview, we discussed how innovation is managed at the hotel chain where the interviewee worked. The interviewee mentioned that they are in the process of creating an "Innovation Lab" to channel innovative ideas. They currently do not have a physical space, so they plan to hold in-person meetings every four months. He emphasized that ideas can emerge from anywhere in the organization since the company's culture promotes creativity.

The interviewee explained that innovation is essential to differentiate themselves in a highly competitive sector, and although ideas initially come from senior management, any member of the organization can propose them.

To finance innovation projects, it is essential to present a short business plan along with the idea. Innovation is not limited to technology but also encompasses processes and services.

The barriers to innovation, according to the interviewee, are limited in his current organization but can be very significant in more traditional organizations. He points out that, in his view, measuring the success of ideas is based on three axes: generating new revenue, reducing costs, and improving the customer experience.

He considers the "Innovation Lab" vital for structuring the innovation process, enabling the creation of minimum viable products and the ability to scale these initiatives. The interviewee hopes to make innovation a habit in his organization and emphasized the importance of recognizing the people involved in these projects to foster a culture of innovation.

As we start in this investigation; Is the management of innovation clearly defined within the hotel sector? Can an "Innovation Lab" / "Living Lab" be a useful tool for managing innovation?

In response to these two main questions, we can say that innovation management does indeed appear to be clearly defined within the sector, and that an "Innovation Lab" is undoubtedly a useful tool for managing innovation in the hotel industry.

5 Discussion and conclusions

We can observe that the results of the literature surveyed, and the interviews conducted coincide on several relevant points, such as the fact that the sector has traditionally been reluctant to innovate, but that this is changing. In this case, they are completely in agreement, as an "Innovation Lab" is being implemented within the hotel chain studied. Interdepartmental communication and recognition of the members involved are essential if the company is to achieve long-term sustainability.

A crucial point to note is the importance of organizational culture within innovation and how this aspect significantly affects its development.

In addition to the contributions, this article has some limitations: The data for this study was obtained within the hotel sector in a global powerhouse such as Spain. Spain is a benchmark in the sector, and the various chains operating in Spain are international leaders, making the results highly valuable and a benchmark in other markets.

They were based only on the hotel sector, without considering other popular tourist activities such as “coliving”,” tourist apartments”, or “Hostels”.

This article has only included one interview, making it impossible to properly triangulate information.

The scope of the study, both in terms of proximity and ease of use, is limited to Spain; it should not be equivalent in other regions where both the way of working, and the organizational culture are different.

For future studies, other types of tourism business variants could be considered, such as “tourist apartments”, or even expanding the scope by evaluating chains in other geographical areas, of course, more interviews could be conducted to properly triangulate the results obtained.

6 Ethics declaration

To properly conduct and document this interview, an informed consent form was drawn up, which was accepted and signed by the interviewee. This document is filed with the transcript and recordings.

7 AI declaration

For this interview study, we used qualitative data analysis software that includes AI functionality. This software is Atlas.ti. The use given to this tool was basically the organization of information and generation of images.

Assessing Digital Maturity in Rural Tourism: Insights from Pilot Areas in Basilicata

Francesco Santarsiero, Daniela Carlucci, Antonio Lerro, Rosaria Lagrutta, Vincenzo Orsi
Università degli studi della Basilicata, Potenza, Italy

Abstract

Building on a previously developed Digital Maturity Model (DMM) tailored for cultural tourism, this paper explores the application of the model in rural tourism contexts. While digital transformation (DT) is widely recognized as a strategic imperative, rural areas often face unique barriers—including limited infrastructure, digital skill gaps, and organizational inertia—that hinder their digital evolution. This study aims to assess the digital maturity of rural tourism operators in selected pilot areas in the Basilicata region, offering insights to guide targeted DT strategies.

The research adopts an empirical approach by applying the seven-dimensional DMM—comprising Strategy, Organization, Culture, Employee, Tourists, Technology, and Operations—to a sample of rural tourism and cultural operators. Data were collected through surveys and interviews conducted within pilot areas engaged in the Tech4You PNRR initiative.

The assessment reveals heterogeneous levels of digital maturity across rural operators. While strengths emerged in cultural orientation and visitor engagement, significant gaps were observed in areas such as strategic planning, technological infrastructure, and operational data use. These findings suggest a need for differentiated support policies and context-sensitive digital transformation roadmaps.

This paper extends the applicability of the DMM to rural tourism ecosystems, demonstrating its relevance beyond urban or institutionalized cultural tourism settings. It contributes empirical evidence to the literature on digital transformation in marginal areas, helping bridge the gap between maturity models and real-world application.

The study provides a diagnostic tool for local authorities, innovation agencies, and tourism stakeholders to map digital readiness, prioritize interventions, and co-design tailored DT strategies in rural contexts. It also opens pathways for replicability in other regions with similar territorial challenges.

Keywords: Digital Maturity; Rural Tourism; Cultural Heritage; Digital Transformation; Assessment Framework

Paper type: Academic Research Paper

1 Introduction

In today's rapidly evolving socio-economic context, the integration of digital tools and technologies has become a critical enabler for the resilience and competitiveness of organizations across all sectors, including rural and cultural tourism. Digital Transformation (DT) is no longer a strategic option but a necessity that requires rethinking processes, capabilities, and business models in alignment with emerging trends such as sustainability, personalization, and the digital experience economy (Gimpel & Westerman, 2012; Teichert, 2019).

Despite its recognized importance, the tourism sector—especially in rural contexts—faces persistent barriers to digital advancement. These include infrastructural gaps, digital skill shortages, and limited strategic vision. For organizations operating in rural tourism, which is often characterized by micro or family-run businesses deeply embedded in local cultural heritage, the transition to digital maturity presents unique challenges. Resistance to DT in such contexts is frequently rooted in concerns over standardization, loss of authenticity, and the complexity of integrating technology without disrupting the experiential essence of tourism (Guimont & Lapointe, 2016; Santarsiero et al., 2023).

Previous research has emphasized the importance of assessing digital maturity as a foundational step to guide strategic interventions and transformation efforts (Cantoni, 2020; Carlucci et al., 2023). In response, a Digital Maturity Model (DMM) specifically designed for cultural tourism organizations was developed and presented at IFKAD 2024. This framework identified seven core dimensions—Strategy, Organization, Culture, Employee, Tourists, Technology, and Operations—each articulated into specific sub-dimensions, offering a comprehensive basis for evaluating the digital readiness of tourism actors.

This paper builds upon that theoretical foundation by applying the DMM in a real-world context: selected rural pilot areas in the Basilicata region of Southern Italy. The goal is to empirically assess the digital maturity of tourism operators through field data collected as part of the PNRR Tech4You project. The study seeks to explore how the DMM performs in practice, what gaps and strengths emerge across dimensions, and how the findings can support context-sensitive strategies for digital innovation in rural ecosystems.

The paper is structured as follows. Section 2 provides a review of relevant literature on digital maturity and rural tourism transformation. Section 3 describes the research design and methodology. Section 4 presents and discusses the empirical results. Section 5 concludes with reflections on theoretical contributions, practical implications, and future research directions.

2 Theoretical background

Rural tourism has increasingly emerged as a driver of sustainable development, cultural valorization, and territorial reactivation. Yet, its potential is constrained by a range of structural and systemic challenges, particularly in relation to digital transformation (DT). Compared to urban or institutionalized tourism sectors, rural tourism contexts often suffer from a persistent digital divide (López-Carril et al., 2020), manifesting in limited access to broadband infrastructure, insufficient ICT services, and technological obsolescence. This infrastructural gap limits not only the adoption of digital solutions but also the capacity to develop data-driven services and marketing strategies (Wroblowska, 2016).

Rural tourism enterprises—often small, family-run, or community-based—are further hampered by resource scarcity, low digital literacy, and a general reluctance towards innovation (Dias & Patuleia, 2021). Operators frequently lack dedicated personnel for digital management, and investment capacity is limited. Moreover, cultural resistance persists: many stakeholders fear that digitization may undermine the authenticity and experiential quality that define rural tourism (Guimont & Lapointe, 2016; Santarsiero et al., 2023). These barriers collectively hinder the ability of rural tourism operators to engage with digital transformation processes in a structured and strategic way.

Nonetheless, digital transformation remains a critical enabler of visibility, competitiveness, and resilience in rural tourism. Digital tools can help mitigate geographical isolation, improve internal processes, and personalize visitor experiences. However, to unlock such benefits, operators must reach adequate levels of digital maturity—a concept that encapsulates not just technological readiness, but also cultural, organizational, and strategic alignment with digital innovation (Valdez-de-Leon, 2016).

The notion of digital maturity has gained traction in both academic and policy literature as a multidimensional construct that captures the degree to which digital technologies are integrated and strategically leveraged within organizations (Berghaus & Back, 2016). Maturity models—structured frameworks that define dimensions and levels of digital capabilities—have been extensively used to guide transformation processes. However, many existing models are overly generic or tailored to large enterprises, thus failing to account for the specificities of the tourism sector (de Bruin et al., 2005).

In 2024, a sector-specific Digital Maturity Model (DMM) for cultural tourism organizations was proposed (Santarsiero et al., 2024). This model was developed through a comparative analysis of existing DMMs across various industries and adapted to the operational realities of tourism enterprises rooted in cultural heritage. It identifies seven core dimensions—Strategy, Organization, Culture, Employee, Tourists, Technology, and Operations—each articulated through key sub-dimensions such as digital skills, brand management, and infrastructure. The model further defines a staged maturity progression, from basic to proactive integration of digital solutions.

This DMM not only provides a diagnostic tool but also acts as a strategic guide for organizations seeking to navigate their DT journey. It bridges a gap in the literature by incorporating both operational and experiential aspects of cultural tourism within a coherent digital assessment framework.

Building on this foundation, the present study aims to apply the DMM (Santarsiero et al., 2024) to rural tourism contexts, where infrastructural limitations, cultural particularities, and resource scarcity require a differentiated approach. While maintaining the model's seven dimensions, we interpret each through the lens of rural dynamics. For example, the "Technology" dimension includes considerations such as mobile coverage and public access points; the "Employee" dimension must reflect multi-tasking, often informally trained staff; and the "Tourists" dimension considers expectations shaped by offline traditions alongside online planning habits.

This extension represents both a conceptual and practical contribution: it tests the adaptability of the DMM to new territorial settings and generates evidence to inform policy and practice. Moreover, it aligns with recent calls in the literature for more granular and place-based approaches to digital transformation (Marín Díaz et al., 2023). As rural destinations face increasing pressure to innovate while preserving identity, a tailored maturity framework can serve as a lever for inclusive, resilient, and sustainable tourism development.

3 Methodology

The research adopts a mixed-methods approach aimed at empirically assessing the digital maturity of rural tourism organizations in the Basilicata region, Southern Italy. The methodology is rooted in the application of the DMM for cultural tourism introduced by Santarsiero et al. (2024), here adapted to the rural tourism context.

3.1 Research Context

The study was conducted as part of the broader Tech4You initiative (PNRR, Missione 4 - Componente 2), which supports the digital and ecological transition of Southern Italian regions. Specifically, the assessment was implemented in selected pilot areas characterized by a strong presence of cultural heritage assets and a predominantly rural tourism offer. These areas were chosen in collaboration with local authorities and development agencies, considering criteria such as remoteness, tourism intensity, and infrastructural readiness.

3.2 Instrument Design

The evaluation tool was structured around the seven dimensions of the DMM—Strategy, Organization, Culture, Employee, Tourists, Technology, and Operations. Each dimension was operationalized into three to five sub-dimensions, resulting in a total of 20 indicators. A structured questionnaire was developed based on these sub-dimensions, incorporating both Likert-scale items (ranging from 1 to 5) and binary questions to capture qualitative nuances.

The questionnaire was reviewed by domain experts and piloted with a small group of tourism operators for validation and clarity. To enrich the quantitative data, semi-structured interviews were also conducted with selected stakeholders, including public administrators, local tourism associations, and innovation facilitators.

3.3 Data Collection

The fieldwork took place between January and March 2025. The survey was distributed both digitally and in paper format, depending on the technological access of each participant. A total of 45 tourism operators participated in the survey, while 12 in-depth interviews were conducted across three pilot areas. Participation was voluntary and informed consent was obtained from all respondents.

3.4 Data Analysis

Survey responses were analyzed using descriptive statistics and cross-tabulations to explore variation in maturity across dimensions and territories. Maturity levels were calculated by aggregating scores per dimension and then categorizing results into four levels: Basic, Emerging, Structured, and Advanced. Qualitative data from interviews were thematically analyzed to contextualize quantitative findings and highlight perceived barriers, opportunities, and support needs.

This methodology allows not only for benchmarking digital maturity across pilot areas but also for capturing the lived experiences and structural limitations affecting digital transformation in rural tourism contexts. The integration of both quantitative and qualitative evidence ensures a robust and context-sensitive understanding of rural digital maturity dynamics.

4 Results

The results reveal a complex and fragmented picture of digital maturity across the surveyed rural tourism organizations. Overall, the majority of operators are positioned at an "Emerging" or low "Structured" level of maturity. Only a small minority demonstrate characteristics associated with the "Advanced" stage, suggesting that digital transformation remains at an early or transitional phase for most actors involved.

In terms of strategic orientation, very few organizations reported having a defined digital strategy. Most digital actions are reactive and lack integration within a broader vision, revealing a limited capacity for strategic planning in this domain. Governance models tend to be informal and often rely on individual initiative rather than structured organizational processes. Although some associations have introduced shared tools or platforms (e.g., centralized booking systems), such practices remain exceptions.

A generally positive attitude toward innovation emerged among respondents, particularly among younger operators. However, this openness often coexists with a cautious, risk-averse mindset. Interviewees highlighted that generational differences strongly influence the willingness to adopt and experiment with digital solutions. Skills gaps remain a critical issue: only 27% of participants reported having engaged in digital training activities

over the past year, with micro-enterprises facing the greatest difficulties in allocating time and resources for skill development.

From the customer engagement perspective, social media platforms—especially Facebook and Instagram—are widely used for visibility and promotion, but are rarely leveraged for more sophisticated purposes such as personalization, data analytics, or long-term relationship building. Internet infrastructure presents another major constraint: high-speed connectivity is available to only less of half of surveyed organizations, and very few have adopted more advanced technologies such as CRM systems, e-commerce platforms, or immersive media tools like AR/VR.

The "Operations" dimension recorded the lowest scores overall. Fewer than one in five respondents monitor performance through digital KPIs or systematically integrate technology into their daily operational practices. This indicates that, despite some advances in external communication and marketing, the internal digital transformation of rural tourism enterprises remains limited.

Geographically, the results show clear disparities among the three pilot areas. The most digitally mature operators were found in territories with more reliable broadband infrastructure and stronger institutional support for innovation. Conversely, the most peripheral and infrastructurally disadvantaged areas tended to exhibit the lowest maturity levels, especially in the Technology and Operations dimensions.

The qualitative insights gathered from interviews provide further context. Stakeholders identified several enablers that could facilitate digital development: the availability of targeted funding, access to training tailored for small enterprises, and the creation of peer-learning networks. On the other hand, major obstacles include time constraints, fear of losing authenticity, and the lack of an overarching territorial strategy to coordinate and support transformation efforts.

Altogether, the findings underscore the importance of adopting a multidimensional and context-sensitive approach when assessing digital maturity in rural tourism. They also confirm the need for place-based policies and capacity-building initiatives to overcome both technical and cultural barriers to transformation.

5 Discussion

The empirical findings offer valuable insights into the current state of digital maturity in rural tourism contexts and contribute to validating the applicability of the Digital Maturity Model (DMM) originally developed for cultural tourism. While the core structure of the model—centered around seven dimensions—proved to be sufficiently comprehensive, its application to rural settings reveals the necessity of contextual calibration. Infrastructural constraints, informal governance, and deeply rooted cultural dynamics significantly influence how each dimension manifests and interacts.

One of the most critical observations relates to the disconnect between digital intention and strategic integration. Many operators express a willingness to innovate but lack a formal strategy or structured process to do so. This confirms the assumption that digital transformation in rural contexts is often opportunistic rather than planned, and reinforces the need for tools and support mechanisms that not only assess maturity but also foster capacity building and strategic alignment.

The results further emphasize the importance of digital skills as both an enabler and a bottleneck. While the DMM accounts for human capital within the "Employee" dimension, the rural setting exacerbates the impact of limited access to training and professional development. This suggests that future iterations of the model could include an additional focus on local ecosystems of support—such as training networks, innovation hubs, and peer-to-peer learning communities—that compensate for the isolation typical of rural environments.

The variation across territories also highlights the interdependence between digital infrastructure and organizational readiness. In areas with more developed broadband coverage and stronger institutional engagement, operators exhibit higher levels of maturity, confirming the hypothesis that digital transformation is not only an organizational challenge but also a territorial one. This points to the need for coordinated, place-based digital policies that address both supply- and demand-side limitations.

Another key insight concerns the underutilization of digital tools for operational management and customer relationship building. Although visibility through social media is widespread, its use remains superficial and disconnected from deeper customer insights or data-driven practices. This reveals an untapped potential within the "Operations" and "Tourist" dimensions that, if activated, could enhance both competitiveness and sustainability.

Taken together, these findings support the broader argument that rural tourism's digital transformation cannot be achieved solely through individual entrepreneurial effort. It requires an enabling ecosystem that combines infrastructure, skills, vision, and collaboration. The DMM thus serves not only as a diagnostic tool but as a framework for guiding multi-stakeholder engagement in rural innovation processes. Its application here

confirms its adaptability, while also pointing to future directions for refinement that incorporate rural-specific dynamics and collective enablers of change. However, several limitations must be acknowledged. First, the research is geographically confined to selected pilot areas within the Basilicata region, which may limit the generalizability of findings to other rural territories with different socio-economic, cultural, or infrastructural characteristics. Second, the self-assessment nature of the survey instrument may have introduced response biases, particularly in the evaluation of intangible dimensions such as strategic vision or organizational culture. Third, while the qualitative interviews provided valuable depth, the number of interviews was relatively limited and may not fully capture the diversity of stakeholder perspectives.

Future research should aim to replicate and expand the application of the DMM across a broader range of rural regions, ideally incorporating longitudinal data to track transformation trajectories over time. Additional refinements to the model could explore integrating external factors such as policy environment, community engagement, and digital ecosystems. Moreover, participatory approaches involving co-design with local stakeholders could strengthen both the diagnostic accuracy and the practical utility of the maturity model in guiding place-based digital innovation strategies.

Models and Tools to Support Innovation Processes in Cultural Tourism Ecosystems: Evidences and Implications for Basilicata

Antonio Lerro, Rosaria Lagrutta, Vincenzo Orsi, Francesco Santarsiero, Daniela Carlucci, Giovanna Andrulli
University of Basilicata, Potenza, Italy

Abstract

This study explores the role of models and tools in supporting innovation processes and digital transformation within cultural tourism ecosystems. It emphasizes the need for a shift for cultural tourism organizations towards digital innovation and innovation processes and highlights the importance of collaborative networks that actively engage stakeholders in the co-creation of smart tourism solutions. The research identifies participatory methodologies, particularly participatory events, as strategic levers to foster innovation and digital awareness in the sector.

A qualitative research design was adopted, combining desk-based analysis of existing literature with a multiple case study methodology. A series of thematic focus groups held in the Basilicata region provided empirical insights into how participatory formats can support digital transformation and innovation in cultural tourism.

The findings reveal key challenges and opportunities for fostering digital transformation and innovation in cultural tourism. The study outlines emerging models, tools, and participatory formats that enhance stakeholder engagement and co-design processes, while also identifying structural barriers and enablers critical to success.

The paper contributes to the literature by systematizing participatory practices as catalysts for digital transformation and innovation in cultural tourism. It offers practical guidelines and raises new questions for future research on innovation dynamics in rural tourism ecosystems.

Keywords: Digital transformation, cultural tourism, innovation, participatory events, co-creation lab

Paper type: Academic Research Paper

1 Introduction

Cultural tourism has gained increasing attention in recent decades from both scholars and practitioners, reflecting its growing significance within the broader tourism landscape. The convergence of tourism and culture offers not only economic opportunities but also rich, multifaceted experiences rooted in heritage, arts, lifestyle, and contemporary creativity (Lerro et al., 2023). The complexity of this convergence has made cultural tourism difficult to define, with various interpretations emerging (Michalkó and Rátz, 2011). However, as cultural tourism continues to evolve, a more nuanced understanding of its dynamics is required that encompasses not only what is consumed but also how it is experienced, interpreted, and co-created. In this context, innovation and digital transformation are no longer optional but essential. They are strategic levers for achieving smarter, more sustainable, and inclusive forms of tourism, enhancing the sector's competitiveness and resilience (Gretzel & Koo, 2021; Buhalis & Amaranggana, 2015). Nevertheless, the adoption of innovation and digital transformation in cultural tourism is often fragmented and uneven (Cavalheiro et al., 2019). Structural barriers, including resistance to change, and concerns over standardization, hinder progress. The sector's reliance on human-centered, differentiated experiences further complicates the integration of digital tools. To overcome these obstacles, organizations and destinations must adopt models and frameworks that support effective innovation management, digital literacy, leadership development, and stakeholder engagement (Elia et al., 2022; 2024). However, the success of digital transformation depends on the alignment of these strategies with the specific characteristics of local territories. This includes fostering a participatory culture in which tourists, citizens, and entrepreneurs are not merely passive recipients but active co-creators of value. In this scenario, co-creation, participatory design, and shared innovation processes are emerging as powerful approaches for reimagining destination development and governance (Tussyadiah and Zach, 2013; Mehraliyev et al., 2020). However, there is still limited evidence on how such approaches can be translated into operational models, practices, and tools. This study seeks to fill this gap by examining the design and the development co-participatory events, such as focus groups and co-creation labs, as tools to foster digital innovation in cultural tourism ecosystems with particular attention to experiences held within the Basilicata region, in Italy.

2 Theoretical background

2.1. Trends, challenges and opportunities for innovation and digital transformation in cultural tourism

In recent decades, cultural tourism has attracted growing interest from both academics and practitioners. **However, there is no single, universally accepted definition of cultural tourism; instead, various researchers have proposed their own interpretations to capture its multifaceted nature (**UN Tourism General Assembly, 2017; **Michalkó and Rátz, 2011;** European Travel Commission's 2024; Stebbins, 1996; Richards, 2003). For sake of simplicity, a useful definition of cultural tourism is provided by Richards and Pereiro (2006, p.1) in terms of "*the movement of persons to cultural attractions away from their normal place of residence, with the intention to gather new information and experiences to satisfy their cultural needs*" and as "*all movements of persons to specific cultural attractions, such as heritage sides, artistic and cultural manifestations, arts and drama outside their normal place of residence".* As the cultural tourism industry continues to grow and evolve, understanding its peculiarities demands a multidimensional approach that encompasses not only what is consumed but also how it is experienced and interpreted. Consequently**, innovation and digital transformation are pivotal to achieve smart, sustainable, authentic and inclusive tourism development (Calza et al., 2022; Jiang et al., 2019**; Guimont and Lapointe, 2016**). On the other hand, by incorporating technologies into their operations, tourism stakeholders can create unique, personalized experiences that enhance customer loyalty and drive sustainable growth.**

Despite their importance, their integration is far from linear and often presents significant challenges and risks (Psomadaki et al., 2019).

To address these gaps, on one side, it is important to seed digital and leadership skills and the adoption of new models, and tools to effectively lead the processes of digital transformation and business model innovation (Elia et al., 2024; 2022). On the other side, the creation of awareness and orientation towards a digital innovation culture and a business and entrepreneurial education recently emerges as a significant element to be considered as well as the role and the relevance that new forms of involvement of the stakeholders may play in activating and supporting these dynamics.

This requires not only meeting the needs of citizens, stakeholders, and tourists but actively involving them in the innovation process, positioning them as crucial playersAccordingly, the role of the participatory design and related participatory events has gained great relevance in the scientific and policy debate (Tussyadiah and Zach 2013).

2.2. The Participatory Events (PEs): aims, typologies, characteristics, actors

Participatory Events (PEs) are conceptually part of the wider theoretical research stream of the Participatory Design (PD), sometimes called also collaborative design and co-design. They are object of interest both by the managerial and the social sciences and aim to build a paradigm in which, in order to make a program/project/initiative as comprehensive as possible, all those who have an interest in it are involved in its elaboration and development (Sadd-Sulonen et al., 2018).

Along the time, scholarship has analysed different aspects of the PEs: purposes (Bossen et al., 2010), principles, rationale and values (Dalsgaard, 2012), characterizing elements (Di Salvo et al., 2012; NICE, 2008; Nicoli and Zani, 1998; Nicoli et al., 2010), actors involved (Bobbio, 2004; Dahl and Sharma, 2022), main areas of application (Dahl and Sharma, 2022): in particular, regarding these latter, the healthcare and the environmental issues, the security, and the urban planning sector (with a focus on the urban regeneration phenomena) have been identified as significant and consolidated areas of application.

More recently, it is possible to observe an increasing attention and application of the PD and, consequently, of PEs, in tourism, and specifically in the cultural tourism sector. This emergent trend finds significant roots in the industrial features of the cultural industries and of the cultural tourism as well as in the personal and social traits of the cultural tourist (Chiabai et al., 2013; Bole et al., 2017; Ashworth and Dietvorst, 1995). In fact, the wide range of assets and resources comprised in the notion of cultural tourism - ranging from archaeological sites and museums up to valuable architectural elements (ruins, buildings, cities), to various artistic elements (painting, sculpture, crafts, galleries, festivals, events), theatrical, film and drama events, and even language and literature studies, religious holidays, pilgrimages and folk culture) – determine a significative number of actors and stakeholders involved in preserving and managing them and, consequently, an increasing need to identify and develop new and effective "spaces" and "times" in order to balance their different, and often struggling, objectives, wants and orientations (Richards, 2018). The full understanding of the relationship that is established between the methods and the tools characterizing the PD and the development of PEs related to cultural tourism obviously requires, first, the identification and the analysis of the main PD-related methods, tools and

techniques. Secondly, it is important to evaluate their applicability, in order to figure out the empirical advantages for the specific sector under investigation, also and above all in accordance with the underlying digital transformation and innovation processes increasingly characterizing their elaboration and implementation. In the following paragraphs and sub-paragraphs, an analysis of the focus group method whose use is desirable from a digital innovation culture and innovation processes perspective will be carried out, trying to understand which tools are most consistent with the previously analyzed purposes of PD.

2.3 The focus groups

Focus groups represent a mature methodology, and have historically been used in managerial and marketing sciences for market research over the last few decades (Nyumba et al., 2018). As its name suggests, informally expressed with the meaning of "discussion group", its primary objective is to implement a "focus" on a specific topic, in order to implement the decision-making process, on the basis of the most precise possible understanding of a collective trend. The focus is implemented starting from the creation of small groups, typically made up of a number of participants ranging from six to twelve and previously selected using specific sampling techniques aimed at representing a specific market or interest-related segment. Considered as one of the most dynamic and flexible research methods (Kumer and Urbanc, 2019), it can be theorized in relation to PD, with respect to which it has the undoubted merit of implementing an active involvement of the participants. The usability of the focus groups on tourism and digitalization issues has been widely experienced (Maisarah et al., 2023; Strielkowski et al., 2012). The focus group methodology follows a structured process composed of several phases, each playing a crucial role in achieving the research objectives (Dickinger and Kolomoyets, 2024). The focus group thus provides a valuable foundation for decision-making by offering a deeper understanding of participants' views and perspectives (Li et al., 2020). In the following paragraph it explained how this methodology was extensively implemented within a multiple case study focused on cultural tourism organizations across the rural territories of Basilicata.

3 Methodology

From a methodological point of view, a multiple case study approach (Yin, 2009; 2013) has been rigorously elaborated and developed to provide empirical insights supporting the evidences emerging from the above proposed notions.

A series of thematic focus groups were systematically organized and analysed across various sample areas within the Basilicata region, aimed at collecting data through open discussions, interviews and participatory observations where participants were freely to express their views while ensuring thematic coherence across all sessions. This initiative aligns with broader objectives of facilitating organizational adaptation to digital technologies, enhancing knowledge exchange, and catalyzing systemic transformation within the cultural tourism sector. All the data collected were codified and transcribed, resulting in a reliable information base that perfectly reflected the interviewees' thoughts. Concerning the data analysis, an open coding process was applied to the transcripts to identify recurring concepts, phrases, and patterns across the four areas. Codes were grouped into broader themes through iterative comparison, allowing for both within-case and cross-case analysis. Thematic categories emerged inductively from the data, reflecting stakeholders' views. In the following, the findings derived from the workshops are presented and discussed.

4 Findings

The analysis focused on four sample areas, all located in rural parts of the Basilicata region: Vulture Melfese, Val d'Agri, Collina Materana, and the area of Tito and Satriano. Each focus group was meticulously structured around a participatory and co-design methodology, informed by participatory events and focus group practices discussed above. This methodology ensured an inclusive, hands-on approach, facilitating the active participation of stakeholders and ensuring that the focus groups were both contextually relevant and practical. The first step was to set common specific goals for the focus groups, specifically aimed at: *i)* exploring challenges and opportunities that digital transformation offers within the cultural tourism sector in the sample areas analysed; *ii)* activating engagement of cultural tourism organisations, involving local stakeholders in structured dialogues and collaborative exchanges, allowing for the sharing of best practices and fostering a culture of continuous improvement; *iii)* implementing practical tools and strategic models, to introduce actionable tools and frameworks that could guide organizations through the complexities of digital strategy development; *iv)* facilitating networking and synergies among local actors, including public and private stakeholders, and external experts; *v)* stimulating innovation through the presentation of impactful case studies, use cases, and digital

solutions that exemplify successful strategies and applications of digital technologies within cultural tourism contexts. Then, the preparation of activities and questions and the selection of moderators was essential. The facilitator team included five experts with specialized academic knowledge about digital innovation and cultural tourism, and each session also involved four professionals with practical experience in areas such as digital innovation, sustainability, and cultural tourism to enrich the discussion. Concerning the selection of participants, the focus groups included session with 15 heterogeneous participants and a knowledgeable group of stakeholders, from four different Basilicata rural areas. This approach not only ensured the relevance of the discussion but also facilitated the collection of valuable insights, particularly regarding the intersection of cultural heritage and digital innovation in tourism. The sampling process was aimed at ensuring a balanced and representative sample that accurately reflected the diverse stakeholders within the cultural tourism ecosystem. In this phase, participants were carefully analysed and chosen. Specifically, the selection process involved organizations from key areas of the cultural tourism landscape, including hospitality, tourism promotion, heritage preservation, local cultural organizations, youth advocacy, gastronomy, the performing arts, and inbound tourism services. This diverse representation was essential for capturing a wide range of perspectives and experiences related to the integration of digital innovation in the sector. The participants' recruitment began with formal invitations sent via email, where the focus group's objectives, expected contributions, and the significance of each participant's input were clearly outlined. This ensured that all invitees were well-informed about the purpose and scope of the discussion. Follow-up communications were then tailored to the individual needs of each participant, often involving personalized phone calls or additional emails that provided more detailed context, preparatory materials, and a clearer understanding of the topics to be discussed. The conduction of the discussion was organized into five distinct phases, each serving a unique function in promoting engagement, reflection, and collaboration. In the following table the phases implemented in the focus groups are summarized.

Table 1. Focus group's design

Welcome and Introduction	The workshop began by setting the stage, articulating the session's goals, and framing the broader contextual challenges and opportunities related to digital transformation in the cultural tourism sector. This introduction provided participants with a comprehensive overview of the workshop's scope and objectives.
Inspiration Space	This segment featured expert contributions from thought leaders, practitioners, and entrepreneurs, who shared best practices, innovative digital solutions, and real-world applications of digital technologies in cultural tourism. These presentations offered tangible examples of how digital tools could be leveraged to enhance visitor experiences, improve organizational efficiency, and promote sustainability within the sector.
Debate Space	The debate phase facilitated an interactive Q&A session, where speakers and participants engaged in open dialogue about the challenges and opportunities presented by digital transformation. This session was designed to foster critical reflection, enabling participants to exchange ideas and perspectives on the implementation of digital strategies in their own contexts.
Networking Space	An informal segment dedicated to fostering connections and dialogue among workshop participants. This space encouraged attendees to engage in peer-to-peer exchanges, share insights, and explore potential collaborations that could extend beyond the workshop setting.
Co-creation session	The final segment of each workshop provided participants with the opportunity to engage in facilitated co-creation activities. These activities were designed to address localized challenges, allowing participants to work together to develop actionable digital strategies and solutions tailored to their specific needs and objectives. This participatory approach ensured that the strategies developed were contextually grounded and relevant to the local realities of each organization. Specifically, the workshop incorporated a substantial co-creation phase, aimed at engaging participants in hands-on, problem-solving activities designed to address specific challenges within the cultural tourism sector. The facilitator team, including experts with specialized experience in digital innovation and cultural tourism, introduced the methodology for the session. Participants were presented with a set of nine plastic plates, each containing challenges written on cards of various colors. These challenges, specifically related to different aspects of the cultural tourism sector, were categorized into thematic areas such as: Engagement & Empowerment, Accessibility, Ecosystem, Booking & Flow Management, Sustainability, Data, Smart Tourism Information, Integration with the Local Economy, and Mobility. Each category was visually represented on a large display with a guided explanation of its relevance to the broader tourism ecosystem. Participants selected a card corresponding to one of the identified challenges, and based on the chosen issue, they were prompted to draw inspiration from a series of keywords projected on a

	slide. This served to stimulate creative thinking and support the development of innovative solutions to the challenges identified. The co-creation space aimed to foster collaborative problem-solving and generate actionable ideas, contributing to the overall goal of enhancing the digital transformation of the cultural tourism sector. Following the co-creation session, participants shared their developed solutions in a brief presentation format. This discussion phase was structured to provide an opportunity for the exchange of ideas and collective reflection on the problem-solving process. Participants were guided through a structured tool designed to facilitate the implementation of their solutions, focusing on identifying the necessary resources for execution. This included financial, human, infrastructural, and intangible assets, as well as a focus on communication strategies to improve visibility and outreach. This part of the workshop was crucial for ensuring that the co-created solutions were not only innovative but also feasible and practical in the context of the local tourism ecosystem. Through this structured approach, the workshop sought to promote both the generation of ideas and their practical application within the cultural tourism sector, encouraging participants to consider the holistic requirements for successful implementation and scalability.

The last phases concerned the analysis of results, to examine the data gathered during the discussion, identifying recurring patterns or trends, and extracting meaningful insights. Specifically, some key insights emerging from the sessions included: *i)* Heterogeneous level of digital maturity: a significant variance in the digital maturity levels across organizations was observed. While certain entities demonstrated a relatively high degree of familiarity with digital tools and strategies, many others exhibited a fragmented, reactive approach to digitalization. This disparity was often exacerbated by limitations in technical skills, inadequate human resources, and the absence of a coherent strategic vision for digital transformation. The findings highlight the need for tailored digital interventions that account for the diverse starting points of organisations; *ii)* Strong demand for capacity-building and peer learning: participants consistently expressed a desire for further capacity-building opportunities, particularly in areas such as digital marketing, data-driven decision-making, immersive technologies, and online visibility. This finding highlights the need for ongoing education and professional development programs to equip organizations with the requisite skills to harness the full potential of digital tools; *iii)* Structural barriers to innovation: across the focus groups, common structural barriers to innovation emerged. These included issues such as inadequate infrastructure (especially in rural areas with limited connectivity), bureaucratic constraints, and a lack of coordinated governance. These barriers highlighted the need for targeted policy interventions that address both infrastructural gaps and the need for more effective governance frameworks that facilitate digital transformation within the cultural tourism sector; *iv)* Value of storytelling and local identity: a recurring theme across the focus groups was the importance of leveraging storytelling and digital narratives to enhance the visibility of lesser-known destinations. Many cultural tourism stakeholders emphasized the potential of digital tools to showcase intangible heritage and local identity. The findings suggest also that digital storytelling could play a pivotal role in increasing the attractiveness and competitiveness of cultural tourism offerings, especially in regions with rich, yet underexploited, cultural assets; *v)* Emerging leadership roles: in several cases, innovation within the participating organizations was driven by individuals or small teams with high motivation, vision, and a proactive approach to digitalization. These individuals often acted as change agents, catalyzing innovation within their communities or organizations. This result highlights the critical importance of empowering local leaders to drive digital transformation, as they possess the necessary motivation and contextual understanding to implement effective change.

5 Conclusions and implications

This study examined how participatory events can support the digital transformation and innovation of cultural tourism organisations, with a specific focus on the Basilicata region. Through a combination of insights derived by desk research and empirical on-field research conducted through the organization and the development of structured focus groups, the research sheds light on the enabling conditions for fostering a digital innovation culture in cultural tourism. The findings address the importance of the stakeholder involvement in the co-design processes, particularly in contexts marked by fragmented innovation capabilities and limited digital maturity. Participatory events have proven to be valuable mechanisms not only for engaging local actors but also for generating context-specific, actionable solutions. These insights reinforce the value of co-creation methodologies in facilitating innovation and digital transformation processes in cultural tourism development. From a **managerial perspective**, the study provides practical guidance for cultural tourism organizations and policymakers. Specifically, this paper systematizes participatory practices as catalysts for

digital transformation and innovation in cultural tourism, with a focus on rural areas. It enhance the importance of structuring and codifying the steps and organization of focus groups, such as the selection of participants, thematic framing, and facilitation techniques, while maintaining a degree of flexibility that allows these practices to be adapted to the specific characteristics of local communities. This balance between structure and adaptability is essential for ensuring that participatory methods are both methodologically sound and locally meaningful, enabling more effective and inclusive digital innovation processes. From a **theoretical viewpoint**, the study contributes to the ongoing debate on innovation digital transformation in tourism by linking participatory design practices with innovation management in the cultural tourism sector. It also broadens the understanding of how innovation processes unfold in rural and peripheral tourism contexts. Despite its contributions, the study is not without limitations. First, the empirical analysis is geographically limited to the Basilicata region, which may affect the generalizability of the findings. Future research should consider comparative case studies across multiple regions or countries to validate the applicability of the proposed models and tools in different cultural and institutional settings. Second, while the focus groups offered rich qualitative insights, the absence of quantitative measures limits the ability to assess the long-term impact of participatory interventions on organizational performance or innovation outcomes. Future studies could integrate mixed-method approaches to capture both the qualitative dynamics and measurable effects of digital transformation strategies.

Digital Transformation in Rural Cultural Tourism: Insights from a SWOT Analysis in Basilicata

Antonio Lerro, Rosaria Lagrutta, Vincenzo Orsi, Francesco Santarsiero, Daniela Carlucci
Università degli Studi della Basilicata, Potenza, Italy

Abstract

This study investigates the dynamics of digital transformation in rural cultural tourism. It explores how rural territories can engage with digital innovation through context-specific strategies that enhance cultural heritage, territorial identity, and stakeholder collaboration.

The research adopts a qualitative methodology based on a SWOT analysis, drawing from semi structured interviews, participatory workshops, field observations, and desk research. This approach allows for a critical assessment of internal and external factors influencing digital transformation processes in rural tourism areas.

The analysis highlights a series of structural challenges, including limited digital infrastructure and skills gaps, but also identifies unique opportunities tied to community cohesion, authentic local narratives, and the potential for slow, sustainable tourism models. The findings emphasize the importance of bottom-up approaches and multi-actor engagement in shaping digital strategies that are both place-sensitive and innovation-oriented.

The paper contributes both to literature and to managerial and policy practices by offering a grounded perspective on rural digital transformation, moving beyond generalized frameworks to focus on localized innovation pathways. It positions cultural heritage not as a constraint but as a resource for co-creating digital solutions tailored to rural tourism contexts.

Keywords: rural cultural tourism, digital transformation, cultural heritage, SWOT analysis, innovation, participatory events

Paper type: Academic research paper

1 Introduction

Over the past decade, the integration of digital technologies in tourism has become a central concern for scholars and practitioners. Within this transformative landscape, rural cultural tourism presents unique challenges and opportunities. On one hand, it is rooted in rich local identities and heritage; on the other, it often lacks the digital infrastructure, competencies, and strategic coordination required for smart and sustainable innovation (Zhao et al., 2023). While urban destinations may benefit from economies of scale and robust digital ecosystems, rural areas face greater difficulty in attracting investment, developing digital skills, and coordinating fragmented tourism (Pasa, 2025). Digital transformation in tourism is receiving growing attention from both scholars and practitioners, however, existing literature tends to focus predominantly on technologically advanced destinations, where digital ecosystems are more mature and infrastructure is well-established. There is a relative scarcity of research that examines rural cultural tourism, particularly from the perspective of practitioners and professionals operating within these territories (Sainaghi, 2017).

In this vein, this paper seeks to fill this gap by adopting a SWOT analysis approach to explore the internal and external factors influencing the digital transformation of rural cultural tourism in Basilicata. This research draws upon qualitative insights from professionals and practitioners operating in the field. The goal of this article is not only to map existing strengths, weaknesses, opportunities, and threats, but also to understand the cultural, organizational, and governance dimensions shaping the digital evolution of this sector. Specifically, the study aims to identify the main drivers and barriers influencing the adoption of digital tools and innovation practices as well as to offer strategic, contextual recommendations to lead future digital innovation in rural cultural areas. This paper contributes to the ongoing discourse on digital innovation in cultural tourism providing a grounded, experience-based perspective from a rural area. Accordingly, it presents strategic insights for regional authorities, destination managers, and cultural tourism operators aiming to foster digital transformation in a socially inclusive and territorially embedded way.

2 Theoretical background

In recent decades, cultural tourism has attracted growing interest from both academics and practitioners. Generally, cultural tourism is considered as “the movement of persons to cultural attractions away from their

normal place of residence, with the intention to gather new information and experiences to satisfy their cultural needs" which encompasses all movements to heritage sites, artistic events, and cultural manifestations (Richards and Pereiro, 2006, p.1).

As the cultural tourism industry continues to grow and evolve, understanding its peculiarities demands a multidimensional approach that encompasses not only what is consumed but also how it is experienced and interpreted. In this context, innovation and digital transformation are pivotal to achieving a smart, sustainable, authentic, and inclusive model of tourism development. These processes are not only strategic levers for competitiveness but also essential for ensuring relevance in a rapidly changing and digitally mediated global tourism landscape (Bekele and Raj, 2025).

The concept of digital transformation in cultural tourism refers to the comprehensive integration of digital technologies into all areas of the tourism experience, including marketing, service delivery, customer interaction, and back-end operations. In the context of cultural tourism, digital transformation is not merely about adopting new tools, but about rethinking how cultural value is created, communicated, and consumed (Gretzel et al., 2015).

Specifically, digital transformation may allow tourism to offer personalized, immersive, and interactive experiences that foster visitor engagement and loyalty. From digital storytelling to augmented reality applications, technology can significantly enhance cultural value propositions, particularly in terms of heritage-driven storytelling, community engagement, and authenticity of experience (Trunfio et al., 2022).

However, the integration of digital tools in the cultural tourism sector is often non-linear and faces many challenges. These challenges are due to several structural and cultural characteristics: a high reliance on human labor, the uniqueness of local experiential offerings, and a deeply embedded emphasis on authenticity. There is also a widespread resistance to digital transformation, driven by concerns that standardization and technological mediation may weaken the uniqueness and emotional richness of cultural experiences (Psomadaki et al., 2019). These challenges are even more evident in rural areas, where there are specific obstacles such as infrastructural deficits, skills gaps, fragmented governance, and resistance to change (Salemink et al., 2017; Cavalheiro et al., 2019).

According to Elia et al. (2022; 2024), successful digital transformation requires the adoption of appropriate organisational models, business tools, and leadership competencies to guide change effectively. Moreover, the promotion of digital culture through training, entrepreneurship education, and stakeholder engagement is also crucial.

This calls for an integrated approach that aligns technological innovation with territorial identity and local socio-economic dynamics. Instead of imposing external models, digital transformation should be co-designed with local stakeholders, tailored to the cultural and institutional context of each destination (Gill and Larson, 2014).

In this vein, a growing body of literature emphasizes the importance of stakeholder involvement and participatory governance in driving digital transformation in cultural tourism (Borseková et al., 2019). The use of co-design, living labs, and participatory foresight exercises has been identified as a way to foster innovation ecosystems that are inclusive and place-based (Dredge & Jenkins, 2011; Baggio et al., 2010). In this regard, SWOT analysis can be a useful strategic planning tool, implemented during the participatory practices, to capture diverse stakeholder perceptions and to identify areas for coordinated action and for mapping complex change environments. A SWOT Analysis is a useful and simple tool that can give a snapshot of key digital transformation issues perceived in the areas investigated target, i.e. enterprises and institutions operating in cultural tourism based on cultural heritage. Through the SWOT analysis it is possible to map and evaluate the internal factors (Strengths and Weaknesses) and external factors (Opportunities and Threats) that can impact the decision of embarking in a digital transformation journey as well as the digital transformation implementation per se. It is especially useful when embedded within participatory processes, where it can serve not only as an analytical tool but also as a means of activating reflection and shared sense-making (Wasike, 2010).

3 Methodology

This study adopts a qualitative, participatory approach to investigate the enablers and barriers of digital transformation in the context of rural cultural tourism. The methodological framework applied is a SWOT analysis, designed and implemented as part of a broader analysis involving cultural tourism organizations and professionals operating in the Basilicata region, Southern Italy (Wasike, 2010).

The rationale for choosing the SWOT framework lies in its capacity to offer a structured yet flexible tool for identifying and organizing key issues affecting digital transformation patterns in cultural tourism. Unlike traditional diagnostic models that rely heavily on quantitative performance indicators, the SWOT approach

allows for a subjective, experience-based mapping of internal and external factors that shape digital innovation within small and rural cultural tourism organizations.

The SWOT analysis was integrated into a series of participatory events facilitated by researchers and moderators with expertise in cultural heritage, digital strategy, and organizational development. During these sessions, participants – such as local tourism operators, cultural heritage managers, and freelance professionals – working individually and as groups, were engaged in interviews, guided reflections and team-building exercises aimed at stimulating critical thinking about their current practices, challenges, and aspirations related to digitalization (Namugenyi et al. 2019). The group composition was intentionally heterogeneous in order to capture a broad spectrum of insights and to encourage peer learning. The sessions were designed around four thematic blocks corresponding to the SWOT quadrants: Strengths, Weaknesses, Opportunities, and Threats. For each quadrant, participants responded to a predefined set of key-questions related to digital assets, strategic orientation, infrastructure, skills, communication practices, and stakeholder relationships (Eastwood et al., 2016). Specifically, the set of specific objectives and key-questions related to each block are defined and reported in the following tables.

Table 1. SWOT Analysis framework for Digital Transformation in Rural Tourism

STRENGHTS (S)	**WEAKNESSES (W)**
Strengths identify issues where the organizations/institutions think to excel and can further grow to drive digital transformation. Strengths can come in many forms. Examples provided for the discussion were: • Digital assets and capabilities: This issue refers to the organization's existing digital infrastructure, such as its website, social media presence, and e-commerce platforms. It also includes the organization's capabilities to adopt and implement new digital technologies. • Talent pool: This issue includes the organization's employees, skills and experience, and ability to adapt to change. A capable and tech-savvy workforce can be a significant strength in driving digital transformation. • Brand reputation: This issue refers to the organization's reputation and credibility. A strong brand reputation can help build trust and credibility with customers and stakeholders during digital transformation. • Financial stability: This issue includes the organization's financial strength and stability. A solid financial foundation can provide the essential resources to invest in digital transformation initiatives. • Partnerships or collaborations: This issue refers to partnerships or collaborations that would Facilitate digital transformation.	The organizations evaluate the features that could be hindering their digital transformation journey. Mapping weaknesses allows to identify the issues where the organizations need to improve and take steps to address these weaknesses. Examples provided for the discussion were: • Legacy systems: This issue includes outdated technology or processes that are no longer powerful in the digital landscape. These legacy systems can gradual down digital transformation initiatives. • Lack of skills or expertise: This issue refers to the organization's lack of skills or expertise in digital marketing, data analytics, or user experience design, etc. Without the needed skills, the organization may struggle to execute its digital transformation strategy effectively. • Resistance to change: This issue includes the organization's culture or mindset, which may be hesitant or resistant to change to adopt new technologies or processes. This resistance can slow down digital transformation initiatives and make it difficult to achieve buy-in from employees and stakeholders. • Limited resources: This issue refers to the organization's limited financial or human resources, which may make it difficult to invest in digital transformation initiatives or hire the necessary expertise to implement them.
OPPORTUNITIES (O)	**THREATS (T)**
Identifying opportunities is about assessing external factors that might help digital transformation. The goal is identifying the issues where organizations can leverage external factors to its advantage and achieve digital transformation objectives. . Examples provided for the discussion were: • Customer/customers behavior: Due to numerous technological advancements, customers' behavior keeps changing. By understanding and adapting to changes in customer/user behavior, the organisation can better meet the needs of its customers/uses and drive virtual transformation. • Partnership opportunities consist of partnering with other organisations to leverage their expertise, resources, or technology. The business enterprise can boost up its digital transformation initiatives by means of forming strategic partnerships.	The goal is to identify the issues where the organizations could face challenges or obstacles in achieving digital transformation goals. Examples provided for the discussion were: • Cybersecurity threats: This area refers to the threat of cyberattacks or data breaches, which could compromise the organization's data, systems, or reputation. Organizations need strong cybersecurity measures to mitigate these threats and protect their digital assets. • Changes in technology: This includes changes in technology that could make the organization's existing technology or processes out of date. The organization needs to stay informed about emergent technologies and adapt to these changes to stay relevant in the digital landscape. • Economic and political factors: This consists of economic and political factors such as recessions, changes in government regulations, or trade policies, which could impact the organization's digital transformation initiatives.

The qualitative data collected from these sessions, through semi structured interviews and guided reflection, were organized into a cognitive map, highlighting patterns and linkages between enabling and hampering factors.

Concerning the data analysis, the process started by adopting a mixed approach, deductive and inductive, through a thematic analysis. Braun and Clarke (2006) defined thematic analysis as a method for identifying, analyzing and reporting patterns, within data that organizes and describes data sets in detail.

The coding process supported the identification of unforeseen areas (Karlsson, 2016; Charmaz et al., 2006). Specifically, first, all data obtained from participatory events, stakeholder interviews, and project documentation were first transcribed and organized. Then, a two-step coding process was applied. In the first phase, open coding was used to identify initial concepts and recurring expressions related to digital transformation, innovation challenges, stakeholder engagement, and cultural value. In the second phase, coding was employed to group similar codes and explore relationships between them, allowing for the construction of broader thematic categories. After that, the derived codes have been revised to identify patterns and develop initial themes within which codes have been clustered. Following the coding, a thematic analysis was conducted to systematically interpret and synthesize the data into core themes. This involved identifying patterns that reflected participants' perceptions of strengths, weaknesses, opportunities, and threats (SWOT) regarding digital transformation in the cultural tourism sector in their organizations and territory. This process-oriented approach to SWOT was not only diagnostic but also generative: it served as a shared cognitive exercise through which participants could identify priorities, prioritize unspoken challenges, and begin to envision strategic directions collaboratively. The findings from this analysis are presented in the following paragraphs.

4 Insights

The research questions driving this empirical investigation focus on identifying and analyzing the internal strengths and weaknesses, as well as the external opportunities and threats, that influence the digital transformation of rural cultural tourism in Basilicata. The main insights that emerging from the empirical analysis are presented in the following table and then discussed in the next paragraph.

Table 2. Main insights deriving from the SWOT Analysis framework for Digital Transformation in Rural Tourism in Basilicata

S	The cultural tourism sector in Basilicata exhibits several important strengths that can support digital transformation. First of all, there is the strong sense of belonging and deep cultural identity that pervades the region. This provides fertile ground for heritage-based storytelling and immersive digital content. Some operators have already experimented digital tools to narrate local history, traditions, and folklore, thus creating emotionally engaging visitor experiences. Moreover, a growing network of motivated professionals, though still fragmented, demonstrates interest in innovation and experimentation. These actors, often driven by personal commitment and community values, can serve as catalysts for broader digital adoption, provided they are supported by targeted training and institutional recognition.
W	Several critical weaknesses emerged from the analysis. Most organizations lack a coherent digital strategy and struggle to align technology use with long-term objectives. Brand management and communication are often inconsistent, with low visibility on social media and limited ability to control the destination's digital image. Relationship management is similarly weak, with few structured efforts to build partnerships or leverage digital tools for network creation. On the organizational side, there is a general lack of planning, and digital goals are often vague or poorly communicated. Cultural resistance to change is common, particularly in associations involving several volunteers. There is a widespread lack of digital mindset, compounded by insufficient training opportunities and limited awareness of digital tools' potential. Concerning a more technical perspective, digital infrastructure is outdated or lacking altogether, and there is minimal capacity for data collection and use, at the same time, human resources are often under-qualified for digital roles, and financial limitations restrict investment in digital innovation.
O	It emerges that various opportunities can be leveraged in rural areas such as Basilicata to accelerate digital transformation. Digital technologies offer new ways to enhance the tourist experience through storytelling, augmented reality, and interactive platforms. These tools can make cultural content more accessible and emotionally resonant. Bottom-up innovation processes, such as co-creation and participatory planning, can also be activated through digital means, fostering stronger community engagement and ownership. External resources, such as online training and funding opportunities, are increasingly available and can support capacity-building. Collaboration with digital professionals can help bridge internal skills gaps, and outsourcing specific tasks can improve efficiency. Finally, open data and digital tools can facilitate more informed decision-making and innovation in tourism offerings, such as themed itineraries and integrated visitor services.
T	Through the empirical research, a number of external threats emerge as hindering digital transformation and innovation processes. The first one is the lack of territorial coordination, with fragmented governance structures impeding the development of shared digital strategies. Moreover, training programs for digital skills are limited, poorly promoted, or inaccessible to small-scale operators. There are also cultural risks associated with digitalization, including concerns about losing the authenticity of the experience and reducing social interactions. Additionally, many tourists, especially older or less experienced individuals, may struggle to interact with digital content, reducing its impact and accessibility. In conclusion, persistent infrastructural deficits, such as slow internet connections and lack of access to modern hardware, further exacerbate the challenge. These barriers highlight the need for targeted investments and inclusive digital policies.

5 Discussion

The SWOT analysis reveals a complex picture in which cultural strengths and innovation potential coexist with structural fragilities and systemic gaps. The findings confirm previous research on the challenges of digital transformation in rural areas (Gretzel & Koo, 2021), but also introduce a more nuanced understanding of the role of professionals and community-based values.

On the one hand, the region's strong sense of belonging and distinctive cultural identity constitutes powerful endogenous strengths. These intangible assets create fertile ground for innovative digital storytelling and immersive experiences that can emotionally engage visitors and differentiate Basilicata from more mainstream destinations. In line with Trunfio et al. (2022), leveraging heritage-driven narratives via augmented reality or interactive platforms can, in turn, leverage regional identity to create immersive experiences.

However, these strengths coexist with significant weaknesses in strategic planning, digital skills, and infrastructure. This recalls the findings of Cavalheiro et al. (2019), who note that fragmented governance and skill gaps are key barriers in rural tourism digitalization. Without clear digital objectives, consistent brand management, and sufficient training opportunities, local organizations cannot capitalize on their narrative potential.

The lack of a coherent digital strategy and the prevalence of outdated systems obstacles the region's ability to translate cultural capital into sustainable digital services. Moreover, the lack of strategic alignment between digital tools and organizational vision emphasizes the need for training programs that go beyond technical skills to include strategic thinking and change management.

The opportunities identified - such as bottom-up co-creation processes, open data, and external funding schemes -point toward actionable pathways for overcoming internal weaknesses. For example, participatory events can simultaneously build digital competencies and foster a shared vision, mitigating resistance to change (Tussyadiah & Zach, 2013). Similarly. collaboration with digital professionals and universities can deliver targeted up-skilling and support the development of thematic digital itineraries, aligning with Élă et al.'s (2024) emphasis on capacity building.

Finally, the analysis also uncovers the threats emerged, for example infrastructural shortfalls, limited access to training for small-scale operators, and risks to experiential authenticity. In this context, policy interventions are therefore required to upgrade rural broadband and to subsidize hardware investments, ensuring that digital initiatives do not deepen existing disparities

6 Conclusions and Implications

This study has provided an in-depth analysis of the factors shaping digital transformation in rural cultural tourism, using the Basilicata region as a case study. Through a SWOT analysis, internal capabilities and external conditions that affect the adoption of digital tools and strategies have been identified and discussed.

This study offers both theoretical insights and practical takeaways for understanding digital transformation in rural cultural tourism, particularly in rural areas.

Theoretically, the study expands the understanding of digital transformation by framing it as a place-based process that, in rural contexts, is shaped by the interplay between cultural heritage, community engagement, and territorial identity. It suggests that rural areas are not passive recipients of innovation but active agents capable of developing digital pathways that reflect their specific socio-cultural configurations. This perspective invites a rethinking of digitalization as a process that can originate from local values and assets rather than being externally imposed. Moreover, the SWOT analysis used proves useful not only as a strategic tool but also as a conceptual framework to interpret local capacities and constraints in a structured way. It encourages a broader academic reflection on how cultural tourism, often perceived as resistant to change, can become a space of experimentation and adaptation when approached through a digital lens. Practically, the findings highlight the importance of designing digital transformation strategies that are aligned with the specific characteristics and needs of rural territories. Policymakers and practitioners should prioritize approaches that leverage local heritage, foster community participation, and support the development of digital skills within local networks. In sum, the findings enhance the urgency of creating tailored digital strategies that align with the cultural and social peculiarities of rural destinations.

Concerning the limitations of the study, while the SWOT analysis provided valuable insights, it also has limitations. The findings are context-specific and may not be generalized to other regions. Moreover, the subjective nature of the method means that some findings bay be biased. Future research could include comparative case studies across different rural regions, as well as longitudinal analyses to track the impact of digital initiatives over time.

The Role of Incubators in the Innovation Ecosystem

Michele Modina[1], Anna Vittoria Formisano[1], Aysan Bashirpour Bonab[2]

Abstract

In this paper, we rely on multiple correspondence analysis (MCA) to explore a complex ecosystem of Italian innovative enterprises. In this respect, we analyze more than 11.000 innovative SMEs and start-ups. We find that the Italian innovation ecosystem is mainly structured along two dimensions. The first and most significant dimension emphasizes the opposition between structured institutional elements that are typical of SMEs and leaner, more flexible arrangements closer to the start-ups. The second axis is that of social inclusiveness and innovation as opposed to sociocultural sedimentation, which is more representative of well-established SMEs in the industrial/artisanal sector. An additional analysis of concentration ellipses revealed that start-ups are prone to rely on higher female representation and are closer to the service sector category. If we treat the latter as a proxy category for incubators, which were all designated as services, then the unfortunate conclusion is that Italian innovative enterprises tend to lose their social innovativeness aspects, which include but are not limited to social inclusivity, once past the start-up phase. The ramifications of these dynamics are yet to be sufficiently understood in relation to the broader ability of enterprises to innovate.

Keywords: innovation, start-ups, SMEs, incubators, social inclusivity, MCA

Paper type: I a Practical Paper

1 Introduction

This study aims to investigate the complex arrangements within the Italian innovation ecosystem to understand how innovative start-ups and SMEs are structured in terms of their social, economic, and legal composition while also considering how these relate to incubators. For the in-depth exploration of the ecosystem of innovative Italian enterprises, we rely on multiple correspondence analysis (MCA), a technique designed to explore relationships between categorical variables (Clausen, 1998). This method is particularly useful for synthesizing large nominal data sets, representing them graphically in a few dimensions, and allowing an intuitive representation of associations between variables (Hoffmann and Franke, 1986).

Through the MCA, we analyze the complex relations between structural characteristics of start-ups and innovative SMEs in order to explore the internal field dynamics with regard to the two categories of enterprise. The study aims to identify common and diverging characteristics between successful start-ups and innovative SMEs, considering variables related to their activities, social composition, and institutional-legal arrangement. The results are an integrated overview of the innovation ecosystem in Italy, providing useful indications for improving their functioning, especially as related to their primary goal—i.e., how to become and remain innovative.

2 A brief overview of innovation ecosystems

An innovation ecosystem describes a network of structures, individuals, entities, and resources used to develop new ideas, systems, products, and methods. The rationale is to promote innovation in regional contexts and industries to maximize the creation of shared value (Adner, 2006; Cooke, 2016; Dedehayir et al., 2018; Jacobides et al., 2018). Ecosystems, consisting of research institutions, corporate inventors, industry clusters, marketplaces, infrastructure, government and academic institutions, customers, and investors, can be seen as a support system for the development of innovative and creative business ideas (Clarysse et al., 2014; Meng and Ma 2018; Peterková et al., 2022). Such organizations also include co-working centers, incubators, and science and technology parks (Popkova et al., 2020; Peterková et al., 2022), which are indicative of a functioning ecosystem (Audretsch et al., 2018).

Each component of the ecosystem creates a network of symbiotic relationships, which collectively keeps the system efficient (Granstrand and Holgersson 2020). On the one hand, the goal of the ecosystem is to accelerate the birth and development of start-ups and SMEs by fostering a widespread entrepreneurial culture (Roman et al., 2020). On the other hand, the goal of these actors is to innovate in order to solve emerging and existing problems affecting businesses and markets (Thurik & Wennekers, 2016). Indeed, the innovation ecosystem is based on value creation through customer-oriented collaborations (Adner, 2006). In fact, there is a symbiotic

relationship between entrepreneurship and innovation ecosystems. Alvarez et al. (2018) highlight that the former focuses on generating new products, services, and ideas to solve everyday problems by identifying gaps in the market. Moreover, an innovation ecosystem provides the necessary support structures for entrepreneurial activities. Innovation is harnessed as a factor that promotes entrepreneurship and builds synergies between actors (Mago and Van der Merwe, 2023). On the one hand, innovation provides resources to entrepreneurship through workspaces, accelerators, incubators, and funding networks; on the other hand, entrepreneurship requires resources such as talent, mentoring, capital, and infrastructure (Bruns et al., 2017). In this context, it is essential to promote open innovation through a collaborative approach that allows companies to access knowledge, technologies, and resources from outside while leveraging their own expertise to create value (Chesbrough, 2003).In this regard, incubators embody the principles of open innovation by offering not only access to physical and financial resources but also to networks of contacts and strategic expertise that accelerate the innovation process (Chesbrough et al., 2006; West and Gallagher, 2006; Colombelli et al., 2017; O'Connor and Ayers, 2005; Barile et al., 2024). Therefore, the purpose of incubators is to support start-ups in their early stages with different strategies (Grimaldi and Grandi, 2005; Mian et al., 2016). The resources made available by incubators, such as space, technology, and mentorship, are crucial for the competitive advantage of incubated enterprises, especially as seen from the Resource Based View perspective (Penrose, 1959; Barney, 2001).

3 Methodology

As anticipated in the Introduction, we have used MCA for the exploratory purposes of our study. MCA is a multivariate analysis technique used for exploring relationships between categorical variables, widely used to identify latent structures in qualitative data (Abdi & Valentin, 2007; Hoffman & De Leeuw, 1992; Vlacic et al., 2021). It constitutes an extension of simple correspondence analysis (CA), specifically designed to explore associations between multiple categorical variables (Clausen, 1998) in an n-dimensional space. As such, it can be considered a qualitative counterpart of principal component analysis for nominal variables (Abdi & Valentin, 2007). MCA is useful for synthesizing large nominal datasets, offering their geometric representation in a low-dimensional space that allows an intuitive analysis of associations between modalities and observations (Hoffman & Franke, 1986). The MCA was initially conceived to analyze cross tables and frequency matrices (Benzécri et al., 1973) but now also finds application in fields such as marketing and social sciences, where it is used to map thematic relationships and understand complex conceptual structures (Parchomenko et al., 2019; Vlacic et al., 2021).

The basic principle of MCA is the barycentric property, according to which observations are attracted to the local "centers of gravity" of the modalities to which they belong, thus allowing for a shared representation in factorial space (Hoffman & De Leeuw, 1992). Distances between points are calculated using the χ^2 metric, and the space obtained through the singular value decomposition allows for the representation of relationships between modalities and statistical units based on their proximity. Additionally, since the MCA tends to underestimate the inertia explained by the dimensions, it is necessary to correct the eigenvalues to obtain reliable interpretations (Abdi & Valentin, 2007; Hjellbrekke, 2018). The quality of a mode's representation is measured by means of squared cosines, while relative contributions indicate how much each mode influences the formation of principal axes (Greenacre, 1986). Active variables participate directly in the construction of the geometric space, while additional variables can be projected onto space (without contributing to its definition) to improve interpretation (Le Roux & Rouanet, 2010; Blasius & Thiessen, 2001). MCA results are represented on proximity maps, where spatial proximity between categories and observations reflects significant similarities in answer profiles (Hoffman & Franke, 1986; Abdi & Valentin, 2007). To further facilitate reading, graphical tools such as star plots and line plots are often used (Hoffman & De Leeuw, 1992).

3.1 Sample

The present study is based on a compound dataset updated to 2025, which collects information on incubators, start-ups, and innovative small and medium-sized enterprises (SMEs) operating in Italy. The data were obtained from official and public sources and organized so as to allow the application of MCA, favoring variables of a categorical nature with relatively few well-represented modalities.

In the case of incubators and SMEs, the categorical variables chosen as supplementary include the economic sector to which they belong, the production class referring to the last year, the size class in terms of employees, and the share capital class. Indeed, when these were included as active variables, the resulting geometric space was mainly structured by the respective size of an enterprise along one of the first two axes, hence precluding the deeper understanding of the nested dynamics within the innovation ecosystem.

In addition, eight categorical variables were retained as active variables (i.e., the ones that actively participated in the construction of the space). Among these, to capture certain socio-cultural-demographic characteristics of the space, three categorical variables were included to indicate whether (and to what degree) the enterprise has a female, youth, or foreign prevalence within the corporate structure, with reference respectively to the majority presence of women, persons under 35 years of age, or persons of non-Italian origin among partners and founders.

For each enterprise, the "type" categorical variable was also coded, denoting whether the single observation is a start-up or an SME. Additionally, a categorical variable indicating the activity sector was also treated as active. This has also solved the issue of incompatibility of the "incubators" observations with the remaining two categories (SMEs and start-ups) since these did not share the profile structure with incubators. In this regard, as all incubators in the original data were coded as "service," the *sector* variable acted as a proxy of sorts, allowing certain conclusions also in relation to incubators even if these did not make it to the final dataset.

In addition to the data listed above, three specific requirements for recognition as an innovative enterprise were treated as binary variables (yes/no). When it comes to start-ups, the first requirement consists of allocating at least 15 percent of the higher of costs and total production value to research and development activities. The second requires that at least two-thirds of the team be composed of personnel with a master's degree or at least one-third of PhD students, PhDs, or graduates with at least three years of certified experience in research activities. The third criterion refers to the ownership or licensing of an industrial patent or the registration of software. For SMEs, although the data structure was shared, the innovative requirements have different thresholds. In particular, the first requirement is that at least three percent of the higher of costs and value of production must be allocated to research and development activities. The second requires that at least one-third of the team possesses a master's degree, or at least one-fifth consists of doctoral students, PhDs, or graduates with at least three years of documented experience in research activities. Also, for SMEs, the third requirement concerns the presence of an industrial patent or software registered in the company's name.

After combining the two datasets (SMEs and start-ups), in order to not destabilize the analyses, all the individual observations for which one or more modalities were not available in the active set were eliminated. This allowed the preparation of the dataset for processing by MCA, facilitating the identification of latent configurations, the visualization of the relationships between structural and innovative characteristics of firms, and the analysis of sectorial differences within the Italian entrepreneurial fabric. In total, 14159 enterprises were analyzed.

4 Analysis of results

The MCA made it possible to construct a geometric space in which start-ups and SMEs are placed according to a series of categorical variables/their modalities. These include the activity sector, the presence of formal requirements for their identification, and the female, youth and/or foreign component. The two main dimensions that emerged from the analysis together explain 88% of the variance (according to the modified rates), of which 73% is attributed to the first dimension and 15% to the second. The result is substantial and allows us to clearly read the main lines of opposition between the entrepreneurial profiles observed. Moreover, the cloud of individuals (Figure 1) turned out to be regularly shaped, with no significant abnormalities around the origin, indicating no opposition on the axes beyond the second that could have significantly influenced the cloud.

The MCA produced a geometric space in which start-ups and SMEs are distributed according to differentiation logic related to the requirements for access to their respective legal qualifications. The first dimension (Figure 2), which alone explains more than 70% of the variance, shows a clear opposition between two groups of companies: on the one hand, innovative SMEs, which are characterized by the fulfillment of the second and third requirements, i.e. the presence of a team qualified for at least one third with a master's degree or doctorate, and the possession or use of intellectual property rights or registered software; on the other hand, start-ups, which are characterized by the fulfillment of the first requirement only, i.e. an R&D expenditure intensity of at least 15% of the greater of costs and production, but which are generally lacking patent assets and a consolidated organizational structure (requirement 1 and 2). This configuration suggests that the first dimension reflects the degree of organizational maturity and legal and technological consolidation, distinguishing firms that are already endowed with strategic intangible assets (formalized human and intellectual capital) from younger or start-up firms that focus mainly on R&D investment intensity but have not yet developed structural and protectable assets.

The second dimension (Figure 3), which explains a further 15% of the variance, shows an internal differentiation between companies adopting hybrid configurations of requirements. This includes, for example,

companies that fulfill the second requirement but have not yet consolidated investments in R&D or IP protection or, conversely, companies with patent assets that do not have formally qualified human capital. In addition, a greater female presence in start-ups than in SMEs clearly emerges. This data suggests a prevailing orientation of women towards leaner forms of enterprise, less structured according to traditional formal criteria, and with greater flexibility in organizational models.

Overall, the two-dimensional space described by the MCA allows a coherent map of different entrepreneurial trajectories to be drawn. The axis of structuration (first dimension) distinguishes enterprises according to the degree of formalization and consolidation, while the axis of inclusiveness and social innovation (second dimension) differentiates organizational and cultural models. The presence of these intermediate configurations suggests that the pathways towards formal recognition (as SMEs or innovative start-ups) are neither univocal nor simultaneous with respect to the three requirements but follow differentiated equifinal sequences dictated by internal factors (available resources, strategic objectives) or external factors (sector, access to protective instruments or specialized human capital).

5 Discussion

The results of the analysis are not limited to distinguishing between companies that “are” or “are not” in possession of the requirements but allow us to grasp the logic through which these requirements combine and manifest themselves in business models that differ in structure, strategy, and degree of consolidation. Positioning in the space of Italian innovative companies thus reflects not only legal-institutional conformity but

also the way in which companies build their legitimacy as innovation subjects over time. This makes the analysis particularly useful from a prospective viewpoint to understand which trajectories turn out to be more frequent, which configurations remain marginal, and which could benefit from targeted policy interventions to accelerate access to full innovative firm status.

Fig. 4 emphasizes the distribution of start-ups and SMEs in relation to their local barycenters; in fact, the concentration ellipse allows a clear visualization of the structural differences between the two groups. The ellipses enclose about 85% of the observations belonging to each group, thus representing an effective summary of the internal variability with respect to the category to which they belong. A particularly noteworthy element is the distinct position of the central points (barycenter) of the two ellipses: the “average” profile of the start-up is located on the left-hand side of the factorial plane, corresponding to negative coordinates on the first dimension, while the “average” profile of the SME is clearly on the right-hand side. This distance between the central points is not only geometric but also substantial, reflecting the opposition between the two organizational models. The first, represented by SMEs, is characterized by high internal structuring, often linked to the presence of qualified human capital and intellectual property protection instruments (second and third requirements). The second, associated with start-ups, tends to be less compliant from a regulatory point of view while presenting an intensity of investment in research and development (first requirement), indicating a propensity for innovation. The broader shape of the start-up ellipse highlights a greater heterogeneity of the group, consistent with the idea that start-ups go through different stages of development and adopt varying strategic configurations.

Figure 5 highlights the sectors that enterprises belong to and shows how the distribution of companies in the space reflects not only their organizational configuration but also the economic sector in which they operate. Enterprises active in the industry/craft sector are predominantly SMEs and are concentrated in an area of the plane associated with a high degree of structuring, in line with the fulfillment of the more complex requirements for innovative enterprises, such as the presence of highly qualified human capital and the ownership of intellectual assets. In contrast, the services, trade, and tourism sectors include a combination of start-ups and SMEs but are characterized by greater internal heterogeneity and less overall adherence to more structured requirements. In these sectors, it is common to find companies that only partially meet the regulatory criteria or are in the early stages of formalization, often with a predominant orientation towards R&D investment but without full consolidation of the other requirements. Finally, the agriculture/fisheries sector has companies that are generally located peripheral to the main axes, indicating a low incidence of requirements, regardless of legal form.

6 Implications and conclusion

Our study is of interest to managers and researchers who strive to better understand the dynamics of institutional structuring of a complex innovation ecosystem, in particular, within Italian context and contexts that are, in part, isomorphic to Italian (like that of EU). Overall, the results indicate that the economic sector conditions the degree of business structuring and the internal composition apropos a variety of legal aspects: in the more regulated and manufacturing-oriented sectors, consolidated SMEs prevail, while in the more flexible and dynamic sectors, like that of services, the coexistence of start-ups and SMEs, often with less formalized profiles, can frequently be observed.

This remark is in line with the consideration that all the incubators in the original dataset belonged to the service sector. Moreover, since it is closer to the local barycenter, denoting a strong female presence, a tentative conclusion is that, when they are still a part of incubators, start-ups are usually more socially innovative in terms of their workforce composition. However, once they move toward full-fledged SMEs, two things tend to happen: 1) the strong female presence is no longer there, and 2) the enterprise moves from the service sector toward the industry/craft. This is unfortunate since a degree of social innovation is lost in the move. This, in turn, might also humper other forms of innovation and diversity once the enterprise becomes more institutionally consolidated.

Resilience of Entrepreneurial Ecosystems (EEs) in Switzerland: Diversity, Coherence, and Digitalization

Eva Panetti, Viktoriia Apalkova, Maurizio Caon
University of Applied Sciences and Arts Western Switzerland (HES-SO) , Fribourg, Switzerland

Abstract

This paper investigates the factors that shape the resilience of entrepreneurial ecosystems (EEs) in the context of long-term structural and technological change. Drawing on a longitudinal dataset from the Global Entrepreneurship Monitor (GEM) for Switzerland (2003–2023), we examine how ecosystem diversity, coherence, and digitalization influence adaptive capacity in the face of external shocks. Building on recent literature, we conceptualize ecosystem resilience as the ability to sustain early-stage entrepreneurial activity over time, and explore whether digitalization contributes to resilience outcomes. We construct composite indexes for diversity, coherence, and digitalization, and estimate a series of linear regression models including interaction effects. Our results confirm that diversity has a significant positive impact on resilience, and that digitalization contributes independently and strongly to resilience as well. However, we find no significant interaction between diversity and coherence, suggesting that alignment and diversity do not always produce synergistic effects. Notably, we identify a negative and statistically significant interaction between coherence and digitalization, indicating that in ecosystems with high institutional alignment, the use of digital tools may be associated with reduced flexibility and adaptability. These findings contribute to the emerging body of research on entrepreneurial ecosystem resilience by introducing digital infrastructure as a dynamic moderating variable. The study also provides one of the few longitudinal assessments of ecosystem resilience in a European context, offering new insights into the interplay between diversity, institutional alignment, and technological capacity.

We discuss the implications for theory, highlighting the conditional nature of resilience mechanisms and the need to account for ecosystem maturity and saturation effects. For policymakers, the results suggest that coherence-building and digitalization strategies should not be treated as universally beneficial, especially in already well-structured ecosystems. Instead, interventions should aim to balance structure with openness, and stability with experimentation, in order to enhance long-term ecosystem resilience.

Paper type: Academic Research Paper

1 Introduction

Entrepreneurial ecosystems (EEs) are conceptualized as networks of interconnected and interdependent actors and resources that collaborate to foster productive entrepreneurship (Stam, 2015). In the wake of recent external shocks, such as the COVID-19 pandemic, and technological disruptions, including the widespread adoption of generative artificial intelligence, there has been growing scholarly interest in the resilience of EEs (Cannice et al., 2023; Iacobucci and Perugini, 2021; Khurana et al., 2022; Santoro et al., 2020). Resilience, in this context, is defined as the capacity of EEs to recover from external shocks and adapt to internal pressures (Cadenasso et al., 2006).

Much of the existing research emphasizes spatial heterogeneity, investigating how different regional ecosystems vary in their composition and capacity for resilience (e.g., Brown and Mason, 2017). In contrast, this study adopts a temporal perspective, examining how a single entrepreneurial ecosystem evolves over time in response to long-term structural and technological change. This approach enables a dynamic understanding of ecosystem resilience by capturing its evolution rather than treating it as a static attribute.

Building on Roundy et al. (2017), we analyze how the key structural and institutional dimensions of EEs — diversity, coherence, and digitalization — contribute to resilience when observed longitudinally. We propose a comprehensive framework, integrating three key EE characteristics:

Diversity: Degree of variety within the EE (e.g., stakeholders' characteristics, industries, venture types)

Coherence: Degree of alignment and connectivity among EE actors in terms of broad intentions and goals, behaviours and activities, common outcomes, values, and cultural rule sets.

Digitalization: Degree of use of digital technologies to generate value-creation opportunities among the EE actors.

While these dimensions independently may enhance resilience, their dynamic interactions are posited to create synergies that amplify their collective impact, resulting in more adaptive and robust ecosystems. For

instance, diversity expands an ecosystem's adaptive capacity by increasing the variety of resources and perspectives available. Coherence, on the other hand, facilitates the alignment of these resources toward shared goals, thereby minimizing inefficiencies and reducing fragmentation (Morris et al., 2015; Motoyama and Knowlton, 2017). Digitalization complements and enhances these processes by providing technological tools and platforms that facilitate coordination, foster innovation, and enable scalability (Autio et al., 2018; Zahra et al., 2023). While diversity and coherence are widely acknowledged as critical to entrepreneurial ecosystem resilience (Acs et al., 2017; Roundy et al., 2017), the role of digitalization in these interactions remains underexplored. By examining the interplay among diversity, coherence, and digitalization, this study offers a more holistic perspective on the drivers of entrepreneurial ecosystem resilience. By leveraging longitudinal data from the Global Entrepreneurship Monitor (GEM) spanning 2003–2023, this study explores how the evolution of these dimensions influences Switzerland's capacity to sustain entrepreneurial activity in the face of ongoing change. In doing so, we contribute to a more dynamic and temporally grounded understanding of EE resilience.

The remainder of the paper is organized as follows. Section 2 develops the research hypotheses, grounding them in existing literature on ecosystem structure, institutional alignment, and digitalization. Section 3 describes the data, index construction, and empirical strategy, including the use of longitudinal regression models. Section 4 presents the main results and statistical analysis. Section 5 discusses the findings in relation to existing theory and explores potential explanations for observed interaction effects. Finally, Section 6 outlines the main conclusions, implications for, and directions for future research.

2 Research Hypotheses

From the perspective of complex systems theory, entrepreneurial ecosystems can be conceptualized as complex adaptive systems characterized by diverse agents interacting non-linearly (Roundy et al., 2017). Portfolio theory suggests that *diversity* promotes resilience by increasing the range of responses available to a system under stress (Frenken et al., 2007; Markowitz, 2009) In the context of EEs, higher diversity in their composition improves the survival and adaptability of ventures during crises where cross-industry collaborations become essential (Boyd and Folke, 2011; Chaffin and Gunderson, 2016). Diverse ecosystems draw on a broader knowledge-base and provide more innovative solutions to adapt to shocks (Boyd and Folke, 2011). Diversity, therefore, broadens the ecosystem's knowledge base, enhances adaptability, and fosters innovative responses to crises. Based on these insights, we propose:

- *H1: Entrepreneurial ecosystems with higher diversity exhibit greater resilience.*

However, diversity alone may lead to fragmentation or inefficiency if it is not aligned with shared goals and collaborative behaviors among an EE's actors. Coherence has been argued to mitigate these potential inefficiencies by aligning actors through shared goals, values, and behavioral norms in socio-technical systems (Brown and Mason, 2017; Mack and Mayer, 2015). Drawing on institutional and social capital theories, coherence is deemed to facilitate cohesiveness and collective outcomes (Motoyama and Knowlton, 2017; Putnam, 2000). In the context of EEs, high coherence allows entrepreneurial ecosystems to fully realize the benefits of diversity by fostering alignment, reducing inefficiencies, and promoting collaboration (Roundy et al., 2017). Based on these insights, we propose:

- *H2: Entrepreneurial ecosystems with higher coherence exhibit a stronger positive relationship between diversity and resilience.*

Despite high levels of diversity and coherence, EEs may still face limitations in their adaptability, particularly when constrained by geographic, institutional, or resource-related constraints (Autio et al., 2018; Feldman et al., 2022). Scholars have shown how digital platforms and tools allow ecosystems to overcome traditional barriers, such as lock-in phenomena, and foster virtual collaboration and innovation (Nambisan, 2017). Therefore, in EEs with low diversity, digitalization may introduce external perspectives and expand the knowledge base by connecting regional actors to global networks (Chen et al., 2023; Zahra et al., 2011). Similarly, in EEs with low coherence, digital tools provide alignment mechanisms, enabling regional actors to coordinate effectively even without shared values or cultural norms. Collaboration platforms, data-sharing tools, and digital marketplaces, for example, facilitate efficient resource allocation and enhance ecosystem-wide coordination. Therefore, we propose:

- *H3a: Digitalization substitutes for diversity in fostering resilience in ecosystems with low diversity.*
- *H3b: Digitalization substitutes for coherence in fostering resilience in ecosystems with low coherence.*

3 Methodology

To test our hypotheses, we use longitudinal data from the Global Entrepreneurship Monitor (GEM) Adult Population Survey (APS) and National Expert Survey (NES) for Switzerland, covering the period 2003 to 2024. The analysis focuses on how diversity among ecosystem actors relates to entrepreneurial ecosystem (EE) resilience, and how coherence and digitalization influence this relationship over time.

To operationalize the key variables in our model, we construct four composite indices. The Entrepreneurial Ecosystem Resilience Index (EERI) is calculated as the five-year compound annual growth rate (CAGR) of the Total Early-stage Entrepreneurial Activity (TEA) rate. TEA, provided directly by GEM, captures the percentage of adults (18–64) engaged in nascent entrepreneurship or managing a new business under 42 months old. This indicator serves as a proxy for the ecosystem's capacity to regenerate entrepreneurial activity after disruptions. EERI is calculated as:

$$EERI_t = \left(\frac{TEA_t}{TEA_{t-n}}\right)^{\frac{1}{n}} - 1$$

where TEA_t represents the total early-stage entrepreneurial activity at year *t*.

The Diversity Index is computed as the mean of three Simpson Indices capturing diversity in age, gender, and sectoral distributions of early-stage entrepreneurs. Each Simpson Index is defined as

$$D = 1 - \sum_{i=1}^{n} p_i^2$$

where p_i is the share of entrepreneurs in category i (e.g., a specific age group or sector). The Diversity Index, is defined as:

$$DIV_t = \frac{D_{age,t} + D_{sector,t} + D_{gender,t}}{3}$$

To capture institutional alignment within Switzerland's entrepreneurial ecosystem, we constructed a Coherence Index (COH_t) using selected variables from the GEM National Expert Survey (NES). The initial pool included indicators related to government policy, infrastructure, and public–private collaboration. An exploratory factor analysis (EFA) was conducted to retain only those variables with strong loadings (≥ 0.6) on a dominant factor and internal consistency (verified via Cronbach's alpha). Retained items were standardized (z-scores), and the index was computed as:

$$COH_t = \frac{1}{k}\sum_{i=1}^{k} z_{it}$$

Where z_{it} is the standardized score of variable *i* in year *t*, and *k* is the number of retained variables. This index reflects the extent to which ecosystem institutions and support structures are coherent and aligned across time.

Finally, the Digitalization Index is the average of standardized scores on three NES items: NES_E02 (technology access), NES_E01 (knowledge transfer), and NES_H01 (infrastructure quality), computed as

$$DIG = \frac{1}{3}(z_{E02} + z_{E01} + z_{H01})$$

Tables 1 and 2 provide an overview of the variable construction process and data sources used in the analysis.

Table 1. Index variables and sources

	Description	Components	Data Source
Resilience Index - EERI	5-year CAGR of TEA	TEA % (Total Early-stage Entrepreneurial Activity, ages 18–64)	APS
Diversity Index - DIV	Average of Simpson Indices across age, gender, and sector	TEA by age group, gender, and sector-level participation	APS
Coherence Index - COH	Factor score capturing institutional and cultural alignment	PCA on NES_B, NES_E, NES_G, NES_H, NES_I variables (e.g. policy, collaboration, infrastructure)	NES
Digitalization Index - DIG	Composite z-score reflecting tech access and infrastructure	z(NES_E02), z(NES_E01), z(NES_H01) – technology access, knowledge transfer, infrastructure quality	NES

Table 2. Index sub-components and sources

	Sub-components	Calculation Method
Diversity Index	Simpson Index for Age Diversity (TEA by age 18–24, 25–34, 35–44, 45–54, 55–64)	$S = 1 - \sum p_i^2$
	Simpson Index for Gender Diversity (TEA by male/female)	
	Simpson Index for Sector Diversity (TEA by industry/sector categories)	
Coherence Index	NES_B: Government policy; NES_E: Entrepreneurial culture; NES_G–I: Infrastructure, Collaboration	PCA with varimax rotation
Digitalization Index	NES_E02: Equal access to new technology	Standardized (z-score), then averaged
	NES_E01: Knowledge transfer from universities	
	NES_H01: Physical infrastructure quality	

3.1 Model Specification

We estimate a series of linear regression models (OLS) to test the hypotheses H1 through H3b. Each model builds progressively by adding variables and interaction terms to assess both main effects and moderating influences of ecosystem characteristics. All variables were mean-centered to facilitate interpretation and reduce multicollinearity. Year was included as a control variable in all models to account for time-specific effects such as macroeconomic trends or policy changes. The general structure of the models can be expressed as:

$$EERI_t = \beta_0 + \beta_1 * DIV_t + \beta_2 * COH_t + \beta_3 * (DIV_t * COH_t) + \beta_4 * YEAR_t + \varepsilon_t$$

The individual models are specified sequentially to test each hypothesis. Model 1 estimates the baseline effect of diversity on ecosystem resilience (H1). Model 2 introduces coherence and the interaction between diversity and coherence, allowing us to assess whether institutional alignment moderates the relationship between diversity and resilience (H2). Model 3 incorporates digitalization and its interaction with diversity to examine whether digital infrastructure substitutes for or amplifies diversity in fostering resilience (H3a). Finally, Model 4 includes the interaction between coherence and digitalization to evaluate whether digitalization can compensate for low institutional coherence in enhancing ecosystem resilience (H3b). All models were estimated using ordinary least squares regression with robust standard errors. Their statistical significance and explanatory power were assessed via R^2 and F-tests.

4 Results

Table 3 presents the descriptive statistics for the variables used in the longitudinal analysis of Switzerland's entrepreneurial ecosystem from 2003 to 2023. All indices exhibit sufficient variability over time. The mean value of the Resilience Index is moderately negative, indicating a modest decline in early-stage entrepreneurial activity over this period. The Diversity Index shows relatively high diversity across the period, with an average score of 0.62 on a scale from 0 to 1. A categorized version of this index indicates that in most years, Switzerland's ecosystem exhibited high diversity (coded as 3). The Coherence Index averages 3.33 on a 1–5 scale, suggesting moderately high coherence in ecosystem structures and actor alignment. Its categorized version indicates that in most years, the coherence level was moderate (category 2). The average value of the Digitalization Index is approximately zero, indicating a balanced digital infrastructure trajectory during the period observed.

Table 3. Descriptive Statistics of Key Variables (2003–2023)

Variable	N	Min	Max	Mean	Std. Dev.
EERI	17	-9,56	1,75	-0,81	3,03
DIV (Diversity Index)	18	0,54	0,64	0,62	0,02
Categorized Diversity Index	18	2,00	3,00	2,94	0,23
COH (Coherence Index)	18	2,81	3,63	3,32	0,23
Categorized Coherence Index	18	2,00	3,00	2,17	0,38
DIG (Digitalization Index)	17	-1,61	1,27	-0,0	0,70
Categorized Digitalization Index	17	1,0	3,0	_	_
TEA (TEA proxy)	18	5,04	10,29	7,67	1,45
Year	18	2003	2023		

Note: EERI values are calculated as 5-year CAGR of TEA. Diversity and Coherence categorical variables range from 1 (low) to 3 (high). N for EERI is 17 due to the 5-year window required for CAGR computation.

Table 4 shows that all predictor variables are positively correlated with ecosystem resilience. The analysis reveals a significant positive correlation between the Entrepreneurial Ecosystem Resilience Index (EERI) and the General Diversity Index (r = 0,491, p = 0,046), supporting Hypothesis 1: diversity contributes to ecosystem resilience. Similarly, Coherence Index shows a strong and significant positive correlation with EERI (r = 0,689, p = 0,002), suggesting that higher alignment and institutional consistency are associated with increased ecosystem adaptability.

Additionally, a strong positive correlation exists between diversity and coherence (r = 0,717, p < 0,001), indicating that these two constructs may reinforce each other. Digitalization has a moderate correlation with resilience (r = 0,61), and is also highly correlated with coherence (r = 0,79), highlighting potential interaction effects. No multicollinearity concerns were detected, as no pairwise correlation exceeds 0,80. However, multicollinearity diagnostics suggest they remain distinct enough to be used in interaction analysis. The Year variable is also significantly correlated with EERI (r = 0,766, p < 0,001), reflecting general time trends in the data, and is therefore included as a control variable in the regression models.

Table 4. Correlation matrix

Variable	EERI	DIV	COH	DIG	Year
EERI	1	0,491* /(0,046)	0,689** / (.002)	0,606**/ (0,010)	0,766***/(<0,001)
DIV	0,491*/(0,046)	1	0,579*/ (.015)	0,539*/ (0,025)	0,447/ (0,063)
COH	0,689**/ (0,002)	0,579*/ (0,015)	1	0,790***/ (<0,001)	0,548*/ (0,019)
DIG	0,606**/ (0,010)	0,539*/ (0,025)	0,790***/ (<0,001)	1	0,470*/ (0,050)
Year	0,766***/ (<0,001)	0,447/ (0,063)	0,548*/ (0,019)	0,470*/ (0,050)	1

Notes: Pearson correlation coefficients shown. *p < 0,05, **p < 0,01, ***p < 0,001
N = 17 for EERI; N = 18 for other variables (listwise deletion applied for missing values).

Table 5 summarizes the results of four linear regression models testing the impact of diversity, coherence, and digitalization on entrepreneurial ecosystem resilience. **Model 1** confirms Hypothesis 1, showing that diversity has a significant positive effect on resilience. **Model 2** introduces coherence and its interaction with diversity (H2), but the interaction term is not significant, suggesting that coherence does not strengthen the diversity–resilience link in this context.

Model 3 tests the moderating role of digitalization (H3a). Digitalization alone significantly enhances resilience, but its interaction with diversity is not significant, indicating no clear substitution or amplification effect. Finally, **Model 4** (H3b) reveals a significant negative interaction between digitalization and coherence. This suggests that while digital infrastructure boosts resilience on its own, in highly coherent ecosystems it may reduce flexibility and adaptability.

Table 5. Linear Regression Models Testing the Effects of Diversity, Coherence, and Digitalization on Ecosystem Resilience

Predictor	Model 1 (H1)	Model 2 (H2)	Model 3 (H3a)	Model 4 (H3b)
Diversity	69,16 (< 0,05)	26,25 (< 0,05)	6,29 (n.s.)	
Coherence		3,78 (<0,05)		-0,76 (0,312)
Digitalization			2,1 (0,004)	1,95 (0,028)
Diversity × Coherence		-139,5 (n.s.)		
Diversity × Digitalization			-46,54 (0,181)	
Coherence × Digitalization				-5,92 (0,049)
R^2	0,73	0,81	0,88	0,89

Note: β coefficients shown with p-values in parentheses. n.s. = not significant.

5 Discussions

The findings confirm that diversity exerts a statistically significant and positive effect on entrepreneurial ecosystem resilience, reinforcing the notion that heterogeneous environments are better equipped to absorb shocks and adapt to changing conditions. This aligns with portfolio and complexity theories (Frenken et al., 2007; Boyd and Folke, 2011), which suggest that variety in actors, industries, and perspectives enhances systemic robustness by expanding the repertoire of responses available during crises.

Similarly, digitalization emerges as a strong and consistent enabler of ecosystem adaptability. The positive effect of digital infrastructure across models underscores its role in facilitating coordination, enabling access to

knowledge, and lowering barriers to innovation and collaboration—especially in geographically bounded or resource-constrained settings (Autio et al., 2018; Zahra et al., 2023). Digital tools thus appear to offer critical affordances for entrepreneurial renewal, especially in the face of systemic disruptions.

However, the interaction effects point to a more nuanced and conditional understanding of ecosystem resilience. The non-significant interaction between diversity and coherence challenges prevailing assumptions from institutional and social capital theories, which posit that institutional alignment should help integrate diverse elements into a cohesive and effective whole (Putnam, 2000; Motoyama and Knowlton, 2017). In the Swiss context, where baseline levels of institutional coherence are already high, additional alignment may yield diminishing returns. This could indicate a saturation effect, where further increases in coherence no longer contribute meaningfully to ecosystem adaptability—or worse, risk stifling the creative frictions that diversity is supposed to promote.

Most notably, the negative and statistically significant interaction between coherence and digitalization points to a potential trade-off that complicates conventional assumptions. While both factors independently support resilience, their combination appears to reduce adaptability under certain conditions. One plausible explanation is that digital tools, when implemented in already tightly structured and rule-bound environments, may reinforce existing routines and centralized control, thereby limiting flexibility and hindering experimentation. This interpretation is consistent with the warnings of Nambisan (2017) and Autio et al. (2018), who argue that the value of digitalization is not inherent but contingent on the ecosystem's institutional configuration.

Rather than acting as a universally beneficial force, digitalization may function as a double-edged sword: empowering adaptation in loosely structured systems while amplifying rigidity in ecosystems that are already institutionally aligned. In this sense, digital tools may inadvertently lock ecosystems into path-dependent trajectories, making them less responsive to unexpected challenges. These findings highlight the importance of viewing digitalization not as a one-size-fits-all solution, but as a context-sensitive mechanism whose effects are mediated by the broader institutional architecture in which it is embedded.

Overall, these results suggest that fostering resilience requires a careful balancing act between structure and openness, and between technological advancement and institutional flexibility. Ecosystem builders and policymakers should be cautious not to assume that more coherence or more digitalization will always lead to better outcomes. Instead, strategic attention must be paid to the interaction effects among ecosystem dimensions—and to the risk that well-intentioned interventions may produce unintended rigidity in ecosystems that are already highly structured and governed by well-established institutional arrangements.

6 Conclusions

This study set out to explore how diversity, coherence, and digitalization interact to shape the resilience of entrepreneurial ecosystems (EEs), using longitudinal data from Switzerland between 2003 and 2023. Building on prior theoretical work, we proposed a model in which diversity and coherence represent structural and institutional capacities, while digitalization serves as a moderating force capable of amplifying or substituting these effects.The empirical analysis confirms that both diversity and digitalization exert a positive and independent influence on ecosystem resilience. However, the interaction between diversity and coherence was found to be non-significant, suggesting that their complementarity may be context-dependent or subject to saturation effects in already mature ecosystems. Most notably, the interaction between coherence and digitalization was negative and statistically significant, implying that digital infrastructure—while beneficial in isolation—may reduce adaptive capacity in ecosystems that are already highly structured. The study makes several contributions to the entrepreneurial ecosystem literature. First, it introduces a dynamic, interaction-based view of ecosystem resilience that incorporates both structural diversity and technological readiness. Second, it offers rare longitudinal evidence from a European context, as most existing studies focus predominantly on Anglo-American or global metropolitan contexts. Third, it refines the understanding of digitalization's role, highlighting its potential downsides when combined with strong institutional alignment. Nonetheless, the study is not without limitations. The sample size constrains statistical power and generalizability. The indexes, while theoretically grounded, rely on secondary data and perception-based measures, which may not fully capture on-the-ground dynamics. Furthermore, the use of linear models may oversimplify what are likely to be non-linear and complex interactions. Future research should build on this work by employing mixed-method designs that combine quantitative analysis with case studies of ecosystems undergoing structural or digital transitions. Longitudinal studies with higher temporal resolution, or comparisons across countries with varying degrees of maturity and digital infrastructure, would also be valuable. In addition, future models might incorporate more granular data on innovation types, sectoral shifts, or entrepreneurial

demographics to better understand how different forms of diversity interact with coherence and technology. From a policy perspective, the findings suggest a need for nuanced consideration when promoting coherence and digitalization as levers of ecosystem resilience. In settings where institutional alignment is already relatively high, further efforts to enhance coherence might yield limited benefits—or, in some cases, could be associated with reduced adaptability if not accompanied by sufficient diversity and openness. Rather than treating coordination-heavy or technology-driven interventions as universally beneficial, policymakers and ecosystem builders may benefit from reflecting on the maturity and structural characteristics of their ecosystems. Approaches that emphasize flexibility, inclusiveness, and opportunities for experimentation could be more effective in fostering long-term resilience in certain contexts.

Leveraging External Knowledge: How Business Incubators Facilitate Open Innovation in Start-ups

Antonio Sonetto, Silvia Tommaso, Antonio Ricciardi
University of Calabria, Arcavacata di Rende (CS), Italy

Abstract

Start-ups represent one of the main sources of innovation and, consequently, national competitiveness. However, due to their limited size, they face several challenges, such as the scarcity of technical and financial resources, which significantly constrain their innovation capacity. To overcome these challenges, start-ups should engage in the adoption of open innovation (OI) processes, which enable them to collaborate with external organizations and exchange resources and knowledge. The effectiveness of such processes is amplified when start-ups are embedded in solid innovation ecosystems. Among the various actors that compose these ecosystems, innovation intermediaries — such as business incubators (BIs) — play a key role. BIs, through targeted networking services, enable incubated start-ups to more easily develop OI collaborations, either with one another or with external organizations. This study aims to explore the role of BIs as OI intermediaries — a topic that has received limited attention in the literature — by identifying the main operational strategies implemented to foster the openness of their incubated start-ups. To achieve this objective, a case study was conducted on the incubator of the University of Calabria (UniCal), "*TechNest*". The findings reveal a strong commitment by TechNest to supporting the development of both internal and external innovation networks. However, some limitations were observed in terms of openness among start-ups operating within the academic context. This research provides valuable implications. On a theoretical level, it contributes to the limited body of literature on the topic. On a practical level, it highlights the importance for incubator managers to integrate an OI perspective into their incubation programs, while also emphasizing the need for managers of incubated start-ups to open their innovation processes to external collaborations. At the same time, policymakers should work to improve innovation policies, providing greater support to incubators and, more generally, to local and national innovation ecosystems.

Keywords: Open innovation, Business incubators, Start-ups, Innovation ecosystems, Case study

Paper type: Academic Research Paper

1 Introduction

Start-ups are increasingly recognized as a crucial driver of national competitiveness. Their flexibility, risk-taking propensity, and ability to explore new market opportunities position them as key players in economic and technological development. Defined as a firm, a partnership, or a temporary organization designed to search for a repeatable and scalable business model (Blank, 2010), start-ups have the potential to create new industries and generate significant economic and social impacts (Audretsch *et al.*, 2020). However, these firms often encounter substantial challenges in developing and commercializing innovations due to their small size and limited resources, knowledge, and capabilities (Spender *et al.*, 2017). Therefore, start-ups should adopt OI practices to overcome these constraints by engaging with external entities and organizations (Bereczki, 2019; Bogers, 2011; Primario *et al.*, 2024; Spender *et al.*, 2017). Moreover, the adoption of OI processes is more effective when start-ups are part of a genuine "*innovation ecosystem*," comprising various agents, such as firms, universities, research centers, governments, intermediaries, and financial institutions, all interacting to foster innovation (e.g., Adner, 2006; Costa and Matias, 2020; Wei *et al.*, 2021). Within these ecosystems, innovation intermediaries play a pivotal role by connecting "*searchers*" (organizations facing an OI challenge) with "*solvers*" (individuals or entities providing potential solutions) (Chesbrough and Brunswicker, 2014). A prominent example of innovation intermediaries is business incubators (BIs) (Conroy *et al.*, 2023), which foster the adoption of OI processes by their incubated start-ups offering targeted networking services (e.g., Hansen *et al.*, 2000; Scillitoe and Chakrabarti, 2010; Soetanto and Jack, 2013). These services promote knowledge exchange and the creation of technological and market partnerships (Hansen *et al.*, 2000), both with external organizations and with other start-ups incubated within the same facility (Bøllingtoft and Ulhøi, 2005; Soetanto and Jack, 2013). As "*knowledge hubs*," incubators facilitate the development of new entrepreneurial ideas and the subsequent dissemination of knowledge and innovative technologies to market-oriented firms (Gassmann and Becker, 2006). However, the literature on OI collaborations between start-ups and other organizations, such as small and medium-sized enterprises (SMEs) (Mercandetti *et al.*, 2017) and large firms (Barile *et al.*, 2024) remains relatively underexplored. Similarly, research on incubators as OI intermediaries is still in its early stages (Leitão

et al., 2022; Theodoraki *et al.*, 2022). Indeed, there is a lack of detailed studies creating a theoretical basis for the use of the OI approach within BIs, which often leads to its implementation being unstructured and unintentional (Cirule and Uvarova, 2022). Therefore, the question of how these organizations can effectively facilitate the adoption of OI practices by their incubated start-ups remains unresolved (Leitão *et al.*, 2022).

Consequently, this research primarily aims to understand the key processes implemented by BIs to foster OI relationships between incubated start-ups and external organizations.

- *RQ_1 - How do business incubators facilitate the adoption of OI processes by start-ups?*

Moreover, this study aims to understand the actual outcomes achieved by incubators through the provision of these services, particularly in terms of increased openness of the innovation processes of the incubated start-ups.

- *RQ_2 – Do incubated start-ups effectively adopt OI processes?*

To address the research questions and contribute to the limited body of knowledge on this topic, a descriptive-exploratory case study was conducted. The selected case is the incubator of the University of Calabria (UniCal), "*TechNest*".

The paper is structured as follows. Following this introduction, the second section offers an overview of the theoretical framework. The third section describes the methodology employed in the study. In the fourth section, the case study findings are presented and analysed. Finally, the article concludes by discussing the main implications, as well as the limitations and future developments of the research.

2 Theoretical background

2.1 Open Innovation

The OI paradigm, introduced by Chesbrough in 2003, is based on firms' deliberate use of both inflows and outflows of knowledge and technology to accelerate internal innovation and expand markets for external innovation exploitation (Chesbrough *et al.*, 2006; Chesbrough, 2003). This approach contrasts with the Closed Innovation model, in which firms conduct R&D projects internally without engaging external partners (Chesbrough *et al.*, 2006; Chesbrough, 2003). As highlighted by Chesbrough *et al.* (2006), in a typical OI process, R&D projects can be launched using the firm's technological base and, at the same time, external technological sources. New technologies from outside can be introduced into the development process not only in the initial phase but also in subsequent ones. Finally, technological innovations (new technologies and/or innovative technological know-how) developed by the firm can be disseminated in markets through various channels (e.g., firm's marketing and sales channels; out-licensing; creation of new technological spin-offs).

2.2 Business incubators

The incubation process can be described as "*an interactive development process where the aim is to encourage people to start their own business and to support start-up companies in the development of innovative products. (…) Besides accommodation, an incubator should offer services such as hands-on management, access to finance (…), legal advice, operational know-how and access to new markets*" (Aernoudt, 2004, p. 127). The concept of business incubation is evolving and presents several knowledge gaps (Sohail *et al.*, 2023). Based on the contribute of Abduh et al. (2007), the services provided by BIs can be classified as follows: (i) facilities related services; (ii) counselling and business assistance related services; (iii) accessibility to internal and external incubator networks. Among the various classifications proposed in academic literature, the one by Grimaldi and Grandi (2005) identifies four main types of incubators: (i) BIC (Business Innovation Centers): established in 1984 through an initiative of the European Commission, they focus on offering basic services such as access to physical spaces, information on financing opportunities, administrative support, visibility, etc.; (ii) UBI (University Business Incubators): founded by universities, they promote the development, combination, and dissemination of new scientific and technological knowledge. UBIs offer specific services linked to the academic environment, including consultancy from professors, access to libraries, research laboratories, scientific infrastructure, R&D activities, and technology transfer programs (Mian, 1996); (iii) IPI (Independent Private Incubators): established by individuals or groups of investors (which may include firms) who acquire equity in start-ups with the goal of fostering their growth. They are often referred to as accelerators, as they typically support start-ups that have already launched their operations and require capital or know-how injection; (iv) CPI (Corporate Private Incubators): established by large corporations to develop new business ventures derived from internal projects that cannot be pursued within the parent company.

BICs and UBIs are typically non-profit organizations, as they are founded by public entities with the objective of promoting local economic development. As private incubators, the opposite holds true for IPIs and CPIs. Typically, UBIs and CPIs host business ideas originating from their parent organizations (universities and corporations, respectively), whereas BICs and IPIs support business ideas coming from external sources.

2.3 Business Incubators as promoters of OI among start-ups

Given the scarcity of resources and knowledge that typically characterizes start-ups, the implementation of OI processes is of fundamental importance for becoming part of a robust "*innovation ecosystem*," where various actors - such as firms, universities, research centres, governments, intermediaries, and financial institutions - interact to foster innovation (e.g., Adner, 2006; Costa and Matias, 2020; Wei *et al.*, 2021). Among these actors, BIs play a fundamental role as innovation intermediaries (Conroy *et al.*, 2023), providing targeted networking services that facilitate the adoption of OI processes by their incubated firms (e.g., Hansen *et al.*, 2000; Scillitoe and Chakrabarti, 2010; Soetanto and Jack, 2013). These services promote inter-firm collaboration, knowledge exchange, and the formation of technological and market partnerships (Hansen *et al.*, 2000). The networking services are primarily provided by private incubators and UBIs, whereas BICs tend to focus mainly on the delivery of more traditional services (Grimaldi and Grandi, 2005). Therefore, incubators facilitate start-ups' engagement with external organizations, such as SMEs, large firms, and universities (external innovation networks), while simultaneously fostering internal knowledge exchange among the incubated firms (internal innovation networks) (Bøllingtoft and Ulhøi, 2005; Cirule and Uvarova, 2022; Soetanto and Jack, 2013).

3 Methodology

To address the research questions, a case study was conducted. Specifically, a descriptive-exploratory study was carried out to thoroughly examine the topic and establish a solid foundation for future research, given the limited literature on the subject (Yin, 2018). The selection of the incubator was guided by two key criteria: (i) it had to be either a UBI or a private one, as these ensure extensive networks both within the facility, as well as with external organizations; (ii) it had to be located in a socio-economically disadvantaged area. Although the research does not explicitly focus on territorial development, this allows for the analysis of the main difficulties and positive outcomes associated with incubators operating in contexts characterized by limited access to resources, weaker entrepreneurial ecosystems, and structural barriers to innovation.

Based on these criteria, the selected case is the incubator of the UniCal, "*TechNest*". TechNest operates in a challenging territory characterized by structural difficulties (e.g., Eurostat, 2024), and it stands out for its strong commitment to fostering an OI culture among firms by offering targeted networking services that connect start-ups with both local and national innovation ecosystems.

The use of a single case study is particularly appropriate for exploratory research (McCutcheon and Meredith, 1993), especially when the phenomenon under investigation is dynamic and potentially uncertain (Yin, 2009) and enables the exploration of '*how*' and '*why*' questions concerning a set of contemporary events (Yin, 2009).

Multiple data collection methods were employed to expand the available information base and enhance data diversity, ultimately aiming to reduce biases (Patton, 2002). Accordingly, data were gathered from various sources, including a semi-structured interview of approximately 40 minutes with a TechNest's manager, a questionnaire sent via Google Forms to TechNest, incubator documents, online resources (e.g., the official website), and press articles. Building on the literature review, a specific analytical protocol was developed to facilitate the aggregation and discussion of the collected data (Battistella *et al.*, 2017). This protocol consisted of the following sections: (i) descriptive analysis about TechNest, including its main objectives, organizational structure, and services offered; (ii) analysis of the strategies adopted by TechNest to support the implementation of OI practices among incubated start-ups and of the latter's ability to effectively leverage this support; (iii) assessment of TechNest's contribution to the socio-economic development of the local ecosystem.

4 Results and discussion

4.1 Descriptive analysis

TechNest was inaugurated on November 30, 2010 and currently hosts 12 innovative start-ups (primarily operating in the ICT sector), with a total of approximately 40 start-ups supported throughout its history. Access to TechNest is reserved for spin-offs from the UniCal, start-ups emerging from entrepreneurial training programs established by the university (such as the Contamination Lab initiative known as "*UniCalLab*"), and start-ups that have won the regional entrepreneurship competition, "*StartCup Calabria*." TechNest offers access to both

physical and virtual incubation and pre-incubation programs. In addition to providing facilities-related services (e.g., access to dedicated equipped private offices, coworking areas, and other shared spaces, such as seminar rooms, meeting rooms, and laboratories), TechNest offers administrative and professional services, including intellectual property management, commercial channel activation, and internationalization support through research, feasibility analysis, and similar activities. It offers dedicated mentoring and training programs (e.g., in business management, strategic planning, business plan development, IP management, technology transfer, etc.), along with meetings with specialized tutors to analyse critical issues in the entrepreneurial idea and identify possible solutions. TechNest facilitates start-ups' access to public and private funding sources. TechNest ensures access to both internal and external incubator networks, thereby fostering the opening of the innovation boundaries of its incubated start-ups. TechNest provides additional specialized university services, such as access to the university's laboratories and libraries, the organization of training events open to both the academic community and start-ups, and the establishment of partnerships between the UniCal and incubated start-ups for joint research projects. According to contractual agreements, the incubation process should not exceed five years. However, if there are available spaces that are not needed to accommodate new applicants, firms may remain beyond this period. Once the incubation phase ends, TechNest aims to continue supporting the firms. Nevertheless, a dedicated post-incubation support program has not yet been formally established.

4.2 The strategies adopted by TechNest to support the implementation of OI practices among incubated start-ups

The analysis of the collected data clearly highlights TechNest's continuous commitment to adopting practices aimed at fostering the dissemination of OI among its incubated start-ups. Indeed, the manager stated that "*what we do most of all is constantly create networks among enterprises*". TechNest promotes the diffusion of OI processes facilitating the development of internal and external innovation networks. TechNest: (i) organizes networking events both internally, among incubated start-ups, and externally, with potential clients, partners, and investors; (ii) provides dedicated coworking spaces to facilitate knowledge sharing among start-ups incubated in the same facility; (iii) assists in scouting and connecting with potential external partners; (iv) offers partnership programs with external organizations for innovation development; (v) leverages its status as a university incubator to engage start-ups in research collaborations with the UniCal to develop joint research projects; (vi) supports the outbound flow of knowledge and technologies by providing incubated start-ups with specialized assistance in drafting business plans and pitch decks for presenting innovations to potential partners.

Beyond merely facilitating these connections, TechNest plays a crucial role in helping its incubated start-ups integrate OI principles into their growth and innovation processes through specialized training and mentoring activities. These initiatives help start-ups understand the importance and dynamics of technology transfer, fostering an open approach to external collaborations.

4.2.1 Incubator's external partners: an overview

TechNest connects its start-ups with: (i) established SMEs and large enterprises, particularly in the ICT sector; (ii) banks, financial institutions, and other investors; (iii) universities and research centres; (iv) institutional intermediaries in the entrepreneurial ecosystem; (v) national development and innovation agencies; (vi) public and governmental entities; (vii) other incubators, accelerators, and innovation players. The geographical reach of TechNest's networking activities extends beyond local boundaries, with strong national and even international connections.

The manager highlighted the success story of a start-up, specialized in advanced indoor localization technologies and applications. After winning the StartCup Calabria competition and being incubated at TechNest, it successfully established numerous OI projects with external organizations at local, national, and especially international levels, including collaborations in Japan and the United States.

TechNest manages relationships with numerous high-level entities, leveraging various projects promoted by the university as well. One example is the "*Tech4You*" project, which aims to establish a innovation ecosystem between Calabria and Basilicata and to stimulate innovation activities with a focus on developing sustainable products to mitigate climate change issues and improve the quality of life for local population.

4.2.2 The future incubation strategy

The interview revealed a radical shift in the incubation strategy. Alongside TechNest, which will continue to function as a first-level incubator supporting early-stage start-ups, a second-level incubator (named "Palazzo dell'Innovazione") will be created to assist already established start-ups seeking growth and scalability. It is expected to become operational by 2026. Access to second-level incubator will be granted through a dedicated

call for applications, open also to start-ups external to the university ecosystem. This new incubation strategy aims to preserve the entrepreneurial assets developed over the years, building a hybrid university innovation ecosystem composed of: (i) early-stage start-ups incubated in TechNest; (ii) firms in a more advanced development stage, previously incubated in TechNest and are currently located within TechNest or other UniCal premises; (iii) firms external to the university ecosystem.

Figure 1 provides an overview of the future innovation ecosystem of the UniCal.

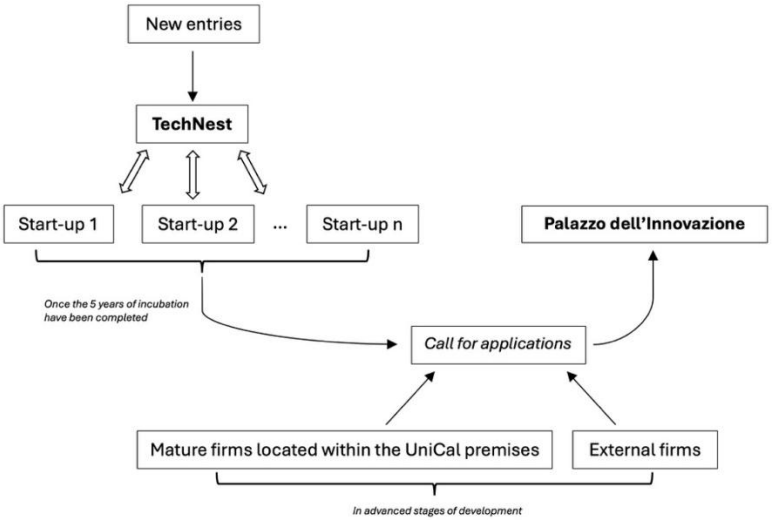

Figure 1: Future UniCal's Innovation Ecosystem (authors' elaboration)

4.2.3 A synthesis framework

Figure 2 graphically outlines the entire discussion conducted. The red rectangle encompasses the process through which TechNest fosters the development of external innovation networks, interconnecting its start-ups with external organizations, including potential firms from outside the university's innovation ecosystem, which will be hosted in the upcoming "*Palazzo dell'Innovazione*". At the same time, the firms that will be incubated within the second-level incubator could also establish connections with external organizations, expanding the external innovation network. The blue circle represents the process through which TechNest facilitates the development of internal innovation networks, enabling start-ups to interconnect and collaborate with each other. Finally, the green circle illustrates the process by which TechNest fosters hybrid innovation networks. This involves not only connecting its start-ups with other firms within the UniCal's innovation ecosystem but also linking them with external firms that will be located in the "*Palazzo dell'Innovazione*".

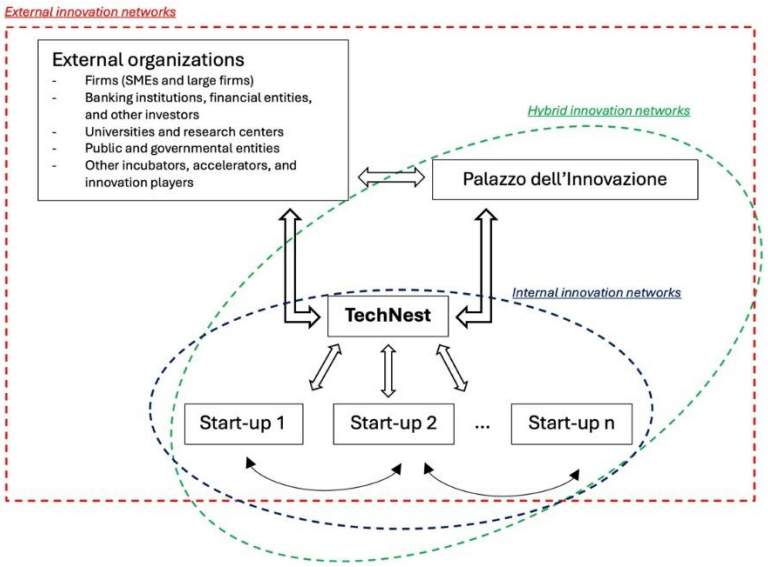

Figure 2: The process of OI diffusion by TechNest (authors' elaboration)

4.3 Limitations to overcome and untapped opportunities

Based on the collected data, incubated start-ups actively leverage the networking services provided by TechNest and demonstrate a growing inclination to open their innovation boundaries. This increasing openness is a significant trend, as the interview revealed that academic entrepreneurship start-ups are significantly affected by the "*Not-Invented-Here*" syndrome, a major barrier to OI adoption among Italian firms (Politecnico di Milano, 2024). This attitude leads firms to underestimate the products and ideas of other firms, considering them qualitatively inferior to those developed or potentially developable internally. As a result, establishing new partnerships for innovation development becomes more challenging. Consequently, TechNest start-ups often utilize networking opportunities to establish commercial collaboration agreements to compensate for their typical lack of marketing expertise, rather than engaging in pure OI projects. Our findings appear to align with previous studies, which have indicated that the OI approach is not entirely familiar to university spin-offs (Shutyak, 2016). Indeed, these firms often apply it unconsciously, by default (Shutyak, 2016). Specifically, as emphasized by van Geenhuizen and Soetanto (2012), such firms tend to develop highly closed innovation networks, as they primarily engage with a limited number of well-established actors, mostly at the local level. This, in turn, restricts their access to new knowledge and external resources.

Returning to our case study, in instances where OI projects have been implemented, the experiences have been overwhelmingly positive, with no major issues related to partner opportunism. This has been attributed both to the small firm's willingness to engage in an open manner and to the collaborative approach adopted by the external partner. As the manager remarked, "*this aspect is fundamental, because behaving in this way always leads to a win–win outcome for both parties*". Additionally, it was observed that start-ups engaging in OI achieved higher performance levels and revenue growth.

4.4 The challenges of operating in a disadvantaged region

TechNest's operations are significantly influenced by the regional economic and social context. Operating in an economically disadvantaged area presents numerous challenges, particularly in spreading OI processes among enterprises. The absence of major industrial hubs and large local players complicates efforts to integrate start-ups with the surrounding innovation ecosystem. While globalization alleviates some of these issues, the lack of investors remains a critical challenge. Unlike incubators in more developed regions such as Northern Italy—where venture capitalists routinely engage with start-ups—TechNest must actively seek out investors. To enhance Southern Italy's attractiveness for innovation investments, the manager advocates for policy improvements rather than new legislative measures. For instance, integrating targeted strategies within the Regional Operational Program could help sustain and finance incubators in the region. Despite these challenges, TechNest's achievements, although modest in absolute terms compared to incubators in more developed areas, are significant in relative terms within the regional context. Managing an ecosystem of firms generating millions in revenue underscores its success in fostering sustainable entrepreneurial growth in a challenging environment.

5 Conclusions

This research, through the case study of the UniCal's incubator "*TechNest*," investigates the role of BIs as OI intermediaries. Our findings confirm the crucial role played by incubators in promoting the adoption of OI processes by their incubated start-ups, thereby contributing to the development of both local and national innovation ecosystems. However, the analysis also reveals that start-ups operating in academic contexts tend to be more closed and less inclined to adopt pure OI processes in their innovation development. Furthermore, BIs emerge as key actors in fostering regional development, particularly in disadvantaged areas.

5.1 Theoretical and practical implications

From a theoretical perspective, this research contributes to the limited literature on the role of BIs as OI intermediaries, highlighting the operational strategies implemented by them to promoting the adoption of OI processes by their incubated start-ups.

Significant implications are provided for: (i) incubator managers, who should strategically implement specific activities in their incubation programs aimed at promoting the diffusion of OI among firms, as this services increasingly influence the attractiveness and competitiveness of incubators; (ii) managers of incubated start-ups, especially in academic context, who, by leveraging the networking activities provided by the hosting incubator, should open up to more partnerships with external organizations, as this can enhance their performance and thus their growth; (iii) policymakers, who should adopt actions that ensure the development of local and national innovation ecosystems, as this helps increase the level of innovations developed and thus

the country's competitiveness. Through specific changes in policy management, they should seek to increase funding for BIs, which are fundamental actors in the development of these ecosystems and, above all, in ensuring the growth of the entrepreneurial fabric of regions, particularly in disadvantaged areas. Moreover, they should look for ways to provide incentives to encourage start-ups and established firms to adopt partnerships for innovation development.

5.2 Limitations and future development of the study

The main limitation of this study lies in the fact that it analyzed only the perspective of a single incubator, without considering the viewpoint of the incubated start-ups. Therefore, this research represents only a starting point, as we intend to select and interview a sample of start-ups incubated in TechNest in the future to gain a more detailed understanding of their perspective on the adoption of OI processes, to identify the main motivations that drive them to establish or not establish collaborations. Moreover, for start-ups that report adopting OI processes, we aim to understand the main benefits and challenges they face throughout these types of relationships.

[2]University of the Republic of San Marino, Dogana, San Marino

Abstract

In a fast-changing and hyper-connected business environment, startups are increasingly challenged to innovate, scale efficiently, and remain competitive despite limited internal resources. This paper investigates how digitalisation and open innovation (OI) jointly impact the performance of innovative startups, with a particular focus on how digital technologies enable open innovation processes. To address this, the study adopts a systematic literature review (SLR) methodology, analysing 42 peer-reviewed articles retrieved from the Scopus database. The selected studies span various industries and geographic regions, although the majority are concentrated in developed economies and ICT-intensive sectors. The review identifies a growing interest in the role of technologies such as Artificial Intelligence (AI), Big Data Analytics (BDA), Internet of Things (IoT), Blockchain, and Cloud Computing as key enablers of both inbound (e.g., external knowledge sourcing) and outbound (e.g., licensing, platform participation) open innovation activities. Findings show that while digitalisation and OI are often studied in isolation, few models offer an integrated, startup-specific perspective. Moreover, most existing frameworks focus on financial performance, neglecting sustainable performance metrics such as environmental and social value creation. The analysis highlights several theoretical gaps, including a lack of longitudinal and cross-sectoral studies, and limited exploration of digital open innovation dynamics in early-stage firms. From a theoretical standpoint, the study maps the most frequently adopted frameworks—Resource-Based View (RBV), Dynamic Capabilities Theory (DCT), Knowledge-Based View (KBV), and Open Innovation theory—and proposes a conceptual model linking digital technology adoption, open innovation practices, and dual performance outcomes (financial and sustainable). This model provides a foundation for future empirical testing and theoretical refinement. On the managerial side, the paper offers practical insights for startup founders, innovation managers, and ecosystem developers, suggesting how digital tools can be strategically combined with open innovation practices to enhance agility, reduce costs, and drive long-term value creation. Overall, this study contributes to the literature by clarifying conceptual relationships, identifying key constructs, and outlining directions for future research at the intersection of digital transformation and collaborative innovation in startups.

Keywords: Digitalization, Digital technologies, Open innovation, Innovative Startups, Systematic Literature Review

Paper type: Academic Research Paper

1 Introduction

In an increasingly dynamic and interconnected business environment, organisations are under growing pressure to innovate continuously, adapt to market shifts, and leverage external sources of knowledge to sustain competitiveness. In this context, two concepts have emerged as central pillars of modern innovation strategies: digitalisation and open innovation (OI) (Wu et al., 2022). Digitalisation integrates digital technologies like AI, Big Data, IoT, Blockchain, Cloud Computing and digital platforms into business models and processes. These technologies enhance flexibility, improve data-driven decision-making and create pathways for innovation. (Hanelt et al., 2021; Wu et al., 2022). Open innovation, as described by Chesbrough (2003), involves using external knowledge to augment internal R&D and accelerate value creation. This approach involves actively seeking external resources (e.g. knowledge, technologies, ideas) through "outside-in" and "inside-out" processes (Holgersson et al., 2024). The former involves integrating external inputs (e.g. feedback, research, partnerships) to fuel internal innovation, while the latter allows companies to share their innovations with the external world, fostering new market opportunities and co-creation (Kraus et al., 2021). This stimulates product and service development, enhancing organisational adaptability and competitiveness. Digital transformation connects companies to external stakeholders, facilitating innovation. This integration fosters a dynamic, collaborative process. Customers can co-develop products and services, providing feedback (Gassmann et al., 2010), and suppliers and partners contribute expertise and innovations (Wu et al., 2022). Digital technologies therefore not only enable innovation but also expand the innovation ecosystem by facilitating collaboration.

Startups, by their very nature, operate in resource-constrained environments that often preclude large-scale internal R&D. This makes them particularly reliant on digital tools to scale efficiently and on external collaboration to develop and commercialise new products or services. Indeed, prior studies suggest that digital technologies can play a critical role in enabling startups to engage in open innovation practices, thereby reducing innovation costs, increasing speed to market, and enhancing performance (Del Bosco et al., 2021; Audretsch et al., 2023). Yet, the literature remains fragmented, with few studies offering a comprehensive framework that integrates these dimensions or focuses explicitly on early-stage firms. Against this backdrop, this paper seeks to answer the following research questions:

- *RQ1: How can the increasing pressure to adopt new digital technologies enable startups to open their boundaries for external collaboration?*
- *RQ2: How and to what extent does digitalization impact open innovation and startup performance?*

To address these questions, our study employs a SLR focusing on peer-reviewed publications analysing the intersection of digitalisation, open innovation and performance in startup contexts. It synthesises the theoretical insights of 42 selected articles to highlight research gaps and develop a model of digital technology adoption, open innovation and performance in innovative startups.

2 Methodology

This study conducted a SLR to examine how digitalisation drives open innovation and influences startup performance, adopting adopting a consolidated approach, the PRISMA Protocol (Page, 2021). This method primarily involves the planning, identification and appraisal of studies for the purpose of extracting and synthesising data from the literature (Tranfield et al., 2003). The protocol starts with defining how to identify and select articles for review. We retrieved the articles using a SCOPUS search query, as this database provides a comprehensive portfolio of scientific journals and is widely used in academic research (Filippelli, 2024). The query1 included variations of the term digitalisation and the keyword open innovation, to ensure the inclusion of a broad set of relevant documents. The initial search returned 118 results, which were subsequently filtered based on access to full-text articles and alignment with the research scope, in accordance with PRISMA protocol. This screening process led to the selection of 42 articles deemed most relevant to the investigation.

All the bibliographic information from the sample was exported into an Excel spreadsheet. The dataset was then enriched with additional variables aligned with the objectives of the review, to support a comprehensive coding process. We identified and applied a set of classification dimensions (e.g., year, journal, geographical scope, digital technologies, type of open innovation, performance indicators, methodological approach, theoretical frameworks, industry focus, firm type, main variables, and research objectives) that allowed us to systematically analyse and compare the 42 selected articles.

3 Bibliographic analysis

This analysis aimed to map the structure and characteristics of the literature, providing insights into the technologies discussed, temporal publication trends, geographical distribution, and journal coverage.

3.1 Publication by years

We analysed publications volume over time (Figure 1). The earliest publication was in 2005, with a rise in scholarly attention starting in 2015, reflecting industry digital transformation and open innovation (Hanelt et al., 2021). A peak in publications in 2023 is due to post-pandemic digital acceleration and new models (Jabeen et al., 2023). The slight drop in 2024 is due to data covering only the first four months of the year.

[1] (TITLE-ABS-KEY ("digitalization" OR "digitization" OR "digitalisation" OR "digitisation" OR "digital transformation" OR "digital technolog*") AND TITLE-ABS-KEY ("open innovation")) AND (LIMIT-TO (DOCTYPE , "ar") OR LIMIT-TO (DOCTYPE , "re")) AND (LIMIT-TO (SUBJAREA , "BUSI")) AND (LIMIT-TO (LANGUAGE , "English")).

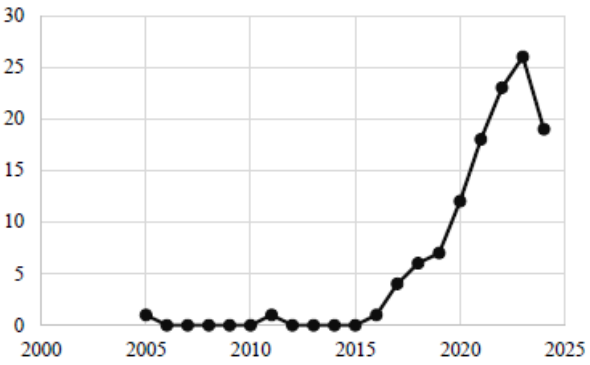

Figure 1: Publishing trend.

3.2 Publication by journal

Figure 2 illustrates the distribution of publications across journals. The European Journal of Innovation Management led the list with 8 articles, indicating its prominence in this domain. Technovation followed with 6 articles, while Journal of Business Research, Technological Forecasting and Social Change, IEEE Transactions on Engineering Management, Journal of Knowledge Management, and International Journal of Innovation and Technology Management each contributed 4 articles.

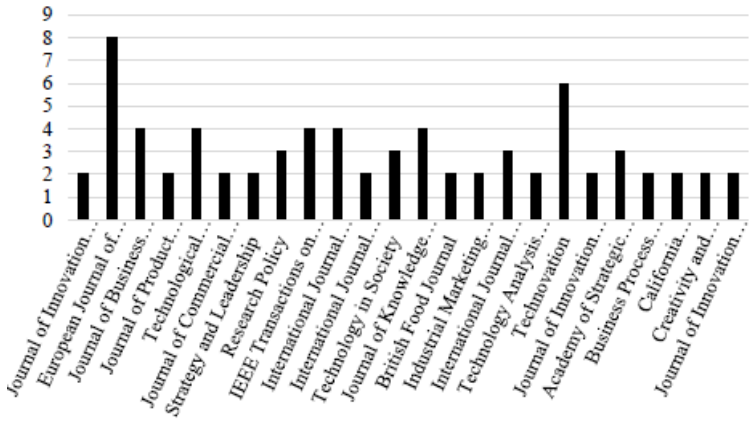

Figure 2: Publications by journals.

3.3 Country analysis

We analysed the geographical distribution of papers to understand global research trends at the intersection of digitalisation, open innovation and startup performance (Figure 3). While it's hard to assign a single country to each study, we can get an overview by considering the nationality of the corresponding author. This highlights the most active countries in the research and allows us to infer the impact of national innovation ecosystems on scholarly output. The United Kingdom led the field with 35 publications, reflecting its innovation ecosystem and strong institutions. The United States followed with 32 publications, likely driven by its global leadership in investment and infrastructure. The Netherlands ranked third, with 28 contributions, underscoring its startup environment, favourable regulations, and public-private collaboration. Singapore, Germany, and Switzerland also contributed significantly, benefiting from research infrastructures and policy support. These findings suggest that national policies and innovation ecosystems play a pivotal role in research output. Strong digital infrastructure and R&D investment leads to more impactful research.

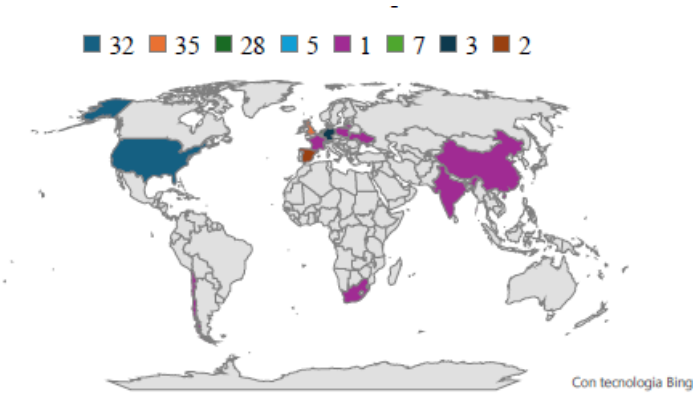

Figure 3: Paper distribution per country.

3.4 Mapping digital technologies

We tracked technologies across all 42 articles, identifying which ones were mentioned. Technologies such as AI, Big Data, IoT, Cloud Computing etc. were included, although not all articles explicitly referenced them. The resulting data mapped where digitalisation is being used in various contexts. Figure 4 shows the relative frequency of each technology. Big Data and Artificial Intelligence are the most frequently cited, highlighting their role in data-driven decision-making and automation. IoT is commonly linked to predictive maintenance and logistics, while Blockchain, Cloud Computing and Digital Platforms support secure, scalable and collaborative innovation. Robots are used less frequently and more specially.

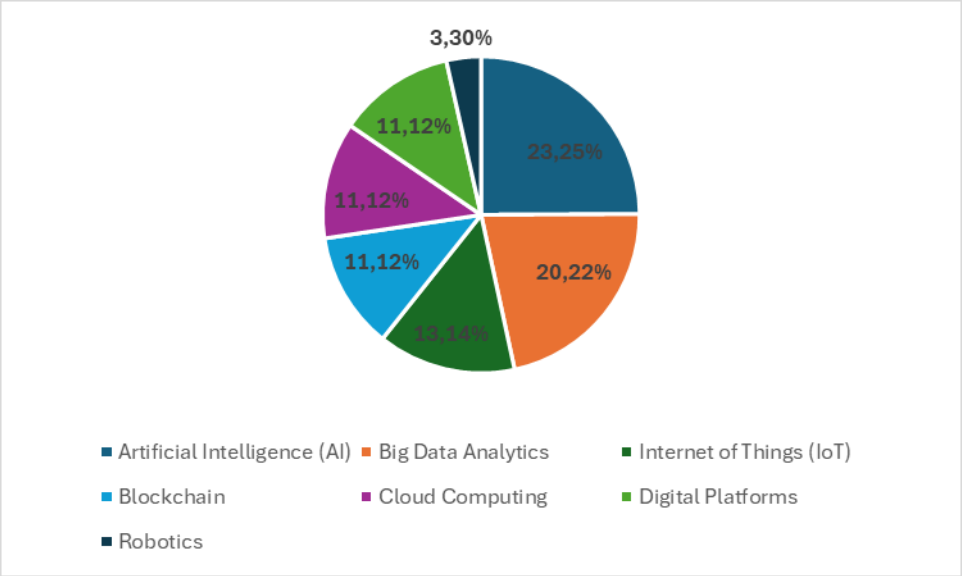

Figure 4: Frequence of technologies.

4 Content analysis

4.1 Thematic clusters and research objectives

The critical content analysis revealed that the 42 selected studies pursue three main research objectives, which form the basis of our categorisation:

- Assessing the impact of digital technologies on innovation performance: many studies investigate how technologies such as AI, IoT, BDA, and blockchain enhance firms' capabilities to innovate, collaborate, and remain competitive (e.g., Rialti et al., 2022; Oduro and De Nisco, 2023).
- Exploring the enablers and mechanisms of open innovation in digital contexts: several contributions focus on understanding the conditions under which open innovation flourishes in digitally advanced environments, identifying factors such as organisational culture, absorptive capacity, and digital maturity (e.g., Marshall et al., 2021; Bertello et al., 2024).

- Examining the interplay between internal resources and external knowledge sourcing: this stream of research delves into how firms balance internal innovation efforts with the integration of external knowledge, often through collaborative platforms or ecosystems (e.g., Bogers et al., 2018: Appio et al., 2024). To further structure the review, each article was also classified into one or more thematic clusters based on the technological focus and organisational context addressed.

The analysis led to the identification of eight key research domains, detailed in Table 1.

Table 1: Main research clusters.

Research cluster	Description	References
Management and strategy	Focus on how digital tools reshape organisational capabilities, innovation processes, and leadership models	e.g., Granig and Hilgarted, 2022; Yun et al., 2023
Industry 4.0 and manufacturing	Focus on smart factories, cyber-physical systems, and integrated production systems leveraging IoT, AI, and BDA	e.g., Crupi et al., 2020; Oduro and De Nisco, 2024
Digital Platforms and ICT	Address the role of digital ecosystems, platform-based business models, and virtual collaboration environments	e.g., Arias-Pérez et al., 2022; Appio et al., 2024
Startups and SMEs	Examine how small firms adopt digitalisation and open innovation to overcome resource constraints and accelerate growth	e.g., Jabeen et al., 2023; Tallarico et al., 2024
Agri-food and traceability	Investigate blockchain-enabled transparency, supply chain integration, and digital food safety systems	e.g., Bigliardi and Filippelli, 2022; Kafetzopoulos et al., 2023
Banking and finance	Explore digital financial services, open banking models, and the role of APIs in collaborative innovation	e.g., Stefanelli and Manta, 2023
Health and e-Health	Focus on remote healthcare services, health data sharing, and e-health platforms	e.g., Ghasemzadeh et al., 2022
Tourism and Smart Cities	Study co-creation in tourism, digital experiences, and smart infrastructure	e.g., Ferràs et al., 2020; Han, 2024

4.2 Theoretical frameworks and key variables

To ensure a systematic and comparable analysis of key theories, theoretical frameworks and variables, detailed information from the quantitative studies was coded across a set of specific dimensions. Each article was reviewed to extract theoretical frameworks and reference models, operationalised constructs (i.e. analysed variables) and formulated hypotheses about construct relationships.

4.2.1 Key theories

As far as the theoretical foundation is concerned, the most frequently encountered frameworks include:

- Resource-Based View (RBV) (Barney, 1991) is one of the most frequently used theoretical frameworks, particularly in studies assessing how digital technologies serve as valuable, rare, inimitable, and non-substitutable (VRIN) resources. Digital capabilities, such as data analytics and AI, are seen as strategic assets that enhance a firm's ability to exploit external knowledge and generate competitive advantage through innovation (e.g., Arias-Pérez et al., 2022).
- Dynamic Capabilities Theory (DCT) (Teece, 2007) extends RBV by focusing on a firm's capacity to sense, seize, and reconfigure internal and external competencies in rapidly changing environments. Many reviewed articles use DCT to explain how digital technologies facilitate the continuous renewal of innovation capabilities and support effective knowledge integration through open innovation practices (e.g., Čirjevskis 2022).
- Knowledge-Based View (KBV), a branch of RBV, regards knowledge as the most strategically significant resource of the firm. This perspective is often adopted in studies exploring the mechanisms by which digital infrastructures (e.g., platforms, data systems) support the capture, transformation, and application of external knowledge in open innovation processes (e.g., Crupi et al. 2020)
- Technology-Organisation-Environment (TOE) Framework (Tornatzky and Fleischer, 1990) to explain the factors influencing technology adoption. Within this view, digitalisation is shaped by the interaction between technological capabilities, organisational readiness, and environmental pressures. This

framework is particularly relevant in startup contexts where external conditions (e.g., ecosystem maturity, regulatory support) play a key role in shaping innovation strategies (e.g., Wang et al., 2025).

4.2.2 Key variables

Five core constructs were consistently found across the literature, though often studied in isolation or within limited scopes:

- Adoption of Digital Technologies (ADT): most commonly measured through the extent to which firms integrate AI, BDA, IoT, blockchain, cloud computing, and digital platforms. ADT is often framed as an enabler of organisational flexibility, innovation responsiveness, and knowledge management (e.g., Lorenz et al., 2020).
- Inbound Open Innovation (IOI): this refers to the firm's capacity to source external knowledge, collaborate with partners, or co-develop solutions with stakeholders. Measures often include R&D partnerships, customer involvement, and academic collaborations (e.g., Sisodiya et al., 2013; Lee and Roh, 2023).
- Outbound Open Innovation (OOI): less frequently studied, this involves the external exploitation of internal knowledge through licensing, spin-offs, or platform-based dissemination. When present, this construct was frequently operationalised in studies of ecosystems and platform strategies (e.g. Lee and Roh, 2023).
- Financial Performance (FP): commonly assessed through growth metrics, ROI, profitability, and innovation output. These were typically self-reported in survey-based studies, though a few used secondary financial data for validation (e.g., Arias-Pérez et al., 2022).
- Sustainable Performance (SP): an emerging dimension in the literature, this includes environmental outcomes, social responsibility, and long-term stakeholder value. While less developed than financial metrics, it is gaining importance as a criterion for measuring innovation success in broader terms (e.g., Danarahmanto et al., 2020; Lee and Roh, 2023; Autio et al., 2024).

4.3 Research gaps and future directions

Despite growing academic interest and methodological richness, the critical analysis revealed gaps and limitations that constrain understanding of how digitalisation and open innovation influence firm performance, particularly in the context of start-ups.

A recurring issue in the literature is the fragmented nature of models, with many studies analysing partial relationships in isolation. However, very few studies integrate all key dimensions into a single framework. This lack of integration makes it difficult to understand how digital tools and collaborative innovation affect business outcomes. As a result, there is insufficient insight into the effects of digitalisation on open innovation efficiency and how performance influences future innovation strategies.

Secondly, while several studies mention startups in a generic sense, very few articles adopt a startup-specific lens in their research design (Cirule and Uvarova, 2022). The majority of the reviewed literature focuses on general Small and Medium Enterprises (SMEs) or large corporations, particularly in the manufacturing and ICT sectors. Startups, however, differ substantially from both SMEs and large firms in terms of resource constraints (e.g., limited funding and staff), organisational structure (e.g., flat hierarchies, high flexibility) and strategic focus (Spender et al., 2017). These structural differences suggest that findings derived from SMEs or corporates may not be directly transferable to startups. Moreover, startups often exhibit Greater reliance on external networks for innovation (Marcon ad Ribeiro, 2021), higher adoption rates of digital tools for agility (Gonçalves et al., 2022) and distinct performance metrics, including survival rate, scalability and ecosystem fit (Kulkarni et al., 2023).

Thirdly, although sustainability has emerged as a critical business imperative, especially in European policy and ESG frameworks, very few studies treat sustainable performance as a primary outcome in models connecting digitalisation and open innovation in startups.

Another observed limitation is the lack of diversity in geographical and sectoral scope. The majority of reviewed studies are conducted in developed economies (e.g., UK, US, Netherlands, Germany), focused on manufacturing or ICT-intensive industries. This concentration limits the generalizability of findings to other contexts, particularly emerging markets, where digital infrastructure and regulatory environments differ. Moreover, few studies offer cross-country comparisons or longitudinal views, making it difficult to assess how institutional environments shape the adoption of digital technologies and OI practices.

5 Conclusion

The aim of this study was to deepen the understanding of the relationship between digitalisation, open innovation (OI), and the performance of innovative startups through a systematic literature review (SLR). By analysing 42 peer-reviewed articles, the research has made several contributions to both the theoretical and practical discourse on how emerging enterprises can leverage digital tools and collaborative approaches to enhance their innovation capabilities and performance outcomes.

The findings confirm that digital technologies, such as Artificial Intelligence, Big Data Analytics, Internet of Things, blockchain, and cloud computing, play a pivotal role in enabling open innovation processes. These technologies not only improve startups' internal operational efficiency but also facilitate external knowledge exchange, reduce transaction costs, and allow for greater scalability. In particular, digitalisation acts as a bridge that connects startups with broader innovation ecosystems, allowing them to compensate for their typical resource constraints. Moreover, the review highlights that open innovation, when enabled by digital capabilities, can significantly impact two main performance dimensions: financial performance, by improving time-to-market, customer responsiveness, and innovation return on investment, and sustainable performance, by supporting longer-term value creation, stakeholder engagement, and socially responsible innovation, though this second dimension is still under-represented in empirical models.

5.1 Theoretical and managerial implications

From a theoretical standpoint, the review contributes by mapping the dominant theoretical frameworks used in the field, such as the Resource-Based View (RBV), Dynamic Capabilities Theory (DCT), Knowledge-Based View (KBV), and the Open Innovation paradigm. This allows scholars to understand which perspectives are shaping the discourse and where overlaps or blind spots exist. Moreover, it highlights a lack of integrative models that combine digitalisation, open innovation (inbound and outbound), and dual performance outcomes (financial and sustainable). Most studies tend to adopt single-theory approaches and examine partial relationships, indicating the need for more holistic, multi-theoretical frameworks in future research. Finally, it identifies the underrepresentation of startup-specific theories. While general innovation or strategic management theories are frequently applied, few studies tailor their models to reflect the distinctive characteristics of early-stage ventures, such as agility, external dependence, or scalability potential. This gap calls for the development of startup-sensitive theoretical models in future research.

For practitioners, particularly startup founders, innovation managers, and ecosystem developers, this study offers several practical insights derived from the aggregated academic evidence. The review highlights the technologies most frequently associated with successful innovation strategies (particularly AI, BDA, IoT, and cloud computing) which can help managers prioritise digital investments aligned with collaborative innovation goals. By identifying how digitalisation enables open innovation practices, the paper shows that digital tools are not merely enablers of internal efficiency but also crucial facilitators of external collaboration. Startups can use this insight to design more effective partnership strategies, reduce innovation costs, and speed up product development cycles. The findings suggest that outbound open innovation, though less studied, holds untapped potential for startups aiming to monetise internal capabilities or integrate into larger platforms and ecosystems. The emphasis on sustainable performance in emerging literature encourages managers to broaden their KPIs beyond financial growth, considering long-term value creation, environmental responsibility, and stakeholder impact, which are dimensions increasingly important for investors and policy frameworks.

5.2 Limitations and future research directions

Despite the contributions made by this study in systematising and conceptualising the relationship between digitalisation, open innovation, and startup performance, several limitations should be acknowledged. These limitations offer useful guidance for future research directions aiming to expand, test, or refine the framework proposed.

Firstly, the study is based exclusively on publications available in the Scopus database and written in the English language. While this ensures a level of academic rigour and peer-review quality, it may also introduce a language and indexing bias, potentially excluding valuable research conducted in local contexts or published in non-English academic journals. For instance, regional innovation ecosystems, particularly in Latin America, Africa, or Asia, may be underrepresented despite exhibiting unique models of digital adoption and collaborative practices. Future reviews could integrate other databases (e.g., Web of Science) and include multilingual sources to provide a more comprehensive global picture.

A second limitation lies in the cross-sectional nature of most studies included in the review. Innovation processes and digital adoption strategies are dynamic and evolve over time. A startup's maturity level, funding stage, or market positioning can significantly influence its ability to engage in open innovation and scale through digital tools. Consequently, longitudinal studies are needed to capture the temporal evolution of digital and collaborative capabilities, providing a more nuanced understanding of their impact on long-term performance and sustainability.

Lastly, while financial performance remains the most commonly used outcome variable, sustainable and ESG-related performance metrics are still largely neglected. As the role of startups in shaping responsible innovation and contributing to socio-environmental goals becomes more prominent, future research should integrate non-financial indicators, such as environmental sustainability (e.g., carbon footprint reduction, circular business models), social impact (e.g., inclusion, well-being, ethical innovation) and governance quality (e.g., transparency, stakeholder engagement). This would allow for a multi-dimensional assessment of startup performance, aligned with the evolving priorities of investors, institutions, and society.

6 Ethical Statement

This research did not require ethical approval, as it did not involve human participants, nor the collection of personal data, nor any other elements that would have required review by an ethics committee.

7 AI Statement

ChatGPT (OpenAI) was used solely to assist with language-related tasks such as translating and editing the manuscript into English. All AI-generated content was carefully reviewed and edited by the author to ensure accuracy and consistency with the scientific objectives of the study.

Abstract

The concept of Innovation Ecosystem has taken on a central role in corporate innovation strategies and industrial policies, representing a key element for competitiveness and economic growth. Innovation Ecosystems differ from traditional ecosystems due to their emphasis on cross-sector cooperation and the integration of heterogeneous skills, facilitating the alignment of supply and demand for innovation and fostering knowledge dissemination. In this context, startups emerge as key players thanks to their agility, experimentation capabilities, and focus on technological discontinuity.

However, startups face numerous challenges, including a high risk of failure, technological and market uncertainty, and difficulties in accessing financial resources and strategic networks. To overcome these obstacles, they often engage in collaborations with established companies within an Innovation Ecosystem, in line with the Open Innovation paradigm. Despite the growing attention to these ecosystems, the startup perspective remains underexplored in academic literature.

This study aims to analyze the main factors influencing the success or failure of startups in Innovation Ecosystems, with a particular focus on the role of collaborations with large companies, sustainability, and digitalization. To achieve this goal, the research framework is structured into three main phases: (1) a systematic literature review to identify key variables and build a solid theoretical foundation; (2) the design of a questionnaire and a structured interview protocol based on the literature review findings; (3) an empirical analysis conducted through interviews with innovative startups operating in Innovation Ecosystems. The methodological approach combines quantitative and qualitative tools, enabling an in-depth understanding of collaboration dynamics.

The proposed analysis will contribute to expanding knowledge on interactions between startups and established companies, highlighting the necessary conditions for effective collaboration and the strategic role of digitalization and sustainability. The findings will provide valuable insights for both theory and practice, supporting businesses and policymakers in designing more effective and inclusive innovation ecosystems.

Keywords: Innovation Ecosystem (IE), Start-Ups, Open Innovation (OI), Digitalization, Sustainability

Paper type: Academic Research Paper

1 Introduction

In recent years, the concept of Innovation Ecosystem has become central in academic research and industrial strategies, promoting innovation and economic growth (Adner, 2006; Granstrand & Holgersson, 2020). These ecosystems comprise a network of actors, resources, and institutions that facilitate the innovation process (Jacobides et al., 2018), distinguishing themselves from traditional ecosystems through their emphasis on cross-sector collaboration, the integration of diverse competencies, and value co-creation (Kapoor, 2018).

Open Innovation (Chesbrough, 2003) has reinforced the role of Innovation Ecosystems by highlighting the importance of external collaborations in overcoming the limitations of closed innovation. Large corporations, research institutions, and startups are part of these ecosystems, leveraging knowledge sharing and technological advancements to accelerate innovation (Xiong et al., 2022). Startups play a crucial role due to their agility and disruptive potential (Spender et al., 2017), yet they face challenges such as financial constraints, limited access to strategic networks, and scalability difficulties (Gimenez-Fernandez et al., 2020).

Collaborations between startups and established companies present both opportunities and challenges: on the one hand, they provide access to resources and expertise; on the other hand, they may lead to dependency, strategic misalignment, and limitations on innovative autonomy (Polidoro & Yang, 2021). While research on Innovation Ecosystems has focused on their structure and benefits, it often lacks an analysis of dynamics from the startup perspective (Wang, 2021). Existing literature emphasizes the positive aspects of corporate-startup collaborations (Bereczki, 2019; Urbaniec & Żur, 2021), whereas more recent studies highlight critical issues such as power imbalances and the restrictive influence of large corporations on startups (Polidoro & Yang, 2021).

To address this gap, this study analyzes the enabling and constraining factors for startups within Innovation Ecosystems, with a particular focus on collaborations with established companies, sustainability, and digitalization.

The key research questions are:

- *What are the enabling and constraining factors in collaborations between startups and established companies within an Innovation Ecosystem?*
- *How do digitalization and sustainability influence these collaborations?*

The research adopts a mixed-method approach, including a systematic literature review, structured interviews, and case studies on startups operating within Innovation Ecosystems.

2 Method

The research methodology was structured into three main phases (Bigliardi et al., 2012). The first phase focused on a mixed-method analysis of existing literature, combining quantitative techniques such as bibliometric analysis with qualitative methods like a systematic literature review (Tranfield et al., 2003). This dual approach provided both a broad bibliographic overview and an in-depth understanding of key themes. Relevant articles were identified through a computerized search in Scopus and Web of Science (WoS), using keywords such as *start-up*, *entrepreneurial venture*, *new venture*, *young company*, *innovation ecosystem*, and *sustainable innovation ecosystem*. The search initially produced 254 results from Scopus and 114 from WoS.

After removing duplicates and applying a two-stage screening process, excluding incomplete records, unavailable full texts, and irrelevant content, the final dataset comprised 108 relevant articles. In the second phase, a questionnaire and a list of structured questions were developed based on the main issues identified in the literature. These tools formed the basis of a case study protocol designed to guide interviews. Finally, the third phase involved conducting structured interviews with innovative startups embedded in an innovation ecosystem. A case study approach, following Voss et al. (2002), was chosen to enrich and validate insights from the literature review through a deeper, context-specific exploration of innovation dynamics.

3 Description of Results

This section presents the results obtained from the data analysis, applying the previously described methodologies. First, the bibliometric analysis of the literature conducted on the examined sample of articles is explained. Then, the main findings of the systematic literature review are presented.

3.1 Bibliometric Analysis

This section presents the results of several bibliometric analyses conducted on a sample of 210 scientific articles. The scientific community's interest in this topic has been steadily growing, with a notable peak in publications recorded in 2023 (53 scientific contributions).

To conduct the keyword co-occurrence analysis, the open-access software VOSviewer was used, a specialized tool for the graphical representation of bibliometric maps. The resulting networks illustrate the connections between keywords, where node size is correlated with the number of articles each author has published on the topic or the frequency with which a keyword has been used. Figure 1 shows the keyword co-occurrence network, highlighting five main clusters.

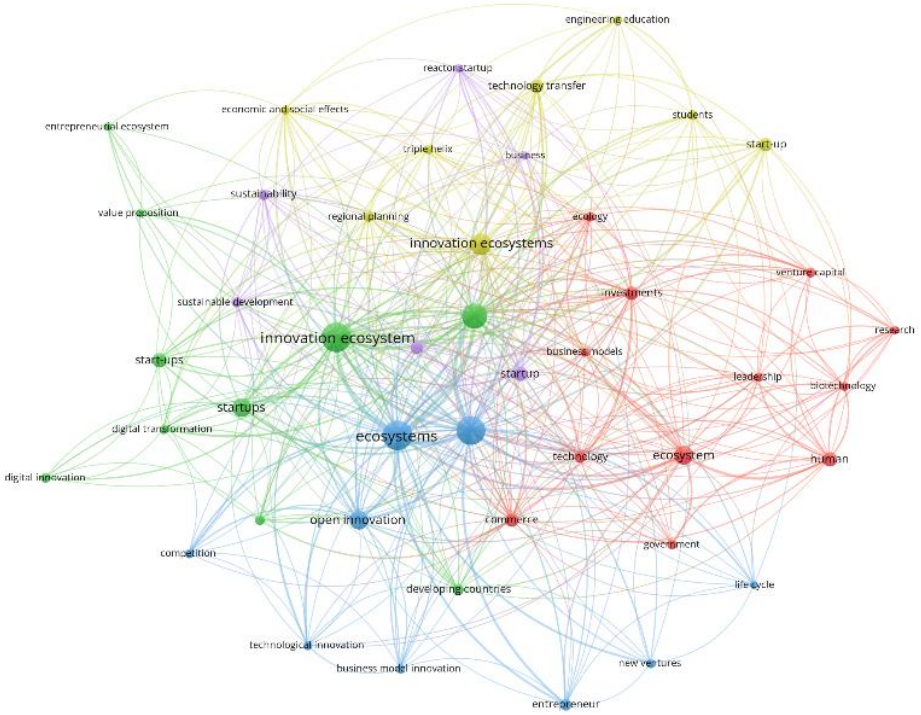

Figure 1: Co-occurence of keywords network carried out with VOSviewer.

The macro-areas investigated are easily identifiable thanks to the use of different colors in the network, while the nodes represent the keywords, and their size is proportional to the frequency of the keywords in the analyzed dataset. The content of the five identified clusters was carefully examined. The labels assigned to each cluster are reported in Table 1.

Table 1: Keywords co-occurence analysis

Keywords co-occurence analysis		
Color of the clusters	Name of the clusters	Main keywords included
Green	Digitalization	Innovation ecosystem; Digital transformation; Digital innovation; Entrepreneurship; Entrepreneurial ecosystem; Startup
Blue	Open Innovation	Open Innovation; Innovation; Business model innovation; Competition; New ventures
Purple	Sustainability Circular Economy	Sustainability; Sustainable Development; Startup; Business; Reactor startup
Yellow	Triple Helix	Triple Helix; Technology transfer; Startup; Innovation ecosystem; Regional planning; Economic and social effects
Red	Ecosystem Business Dynamics	Ecosystem; Venture capital; Leadership; Business model; Investment

3.2 Systematic Literature Review Analysis

The results of the sample article analysis, conducted following the methodology proposed by Gioia et al. (2013), are presented below. The adoption of this methodology made it possible to identify the main enabling factors, which facilitate the consolidation and growth of startups, as well as the hindering factors, which represent barriers and challenges in collaboration with established companies, the digitalization process, and the implementation of sustainable practices.

3.2.1 Risks and enabling factors for collaborations

In the innovation ecosystem, collaboration between different entities is a crucial challenge, as it involves the simultaneous sharing of various knowledge flows. Startups often find themselves needing to collaborate with established companies to access crucial expertise not available internally. However, such collaboration presents significant risks that can undermine the success of startups within the context of innovation ecosystems

(Kosorukova et al., 2023; Corvello et al., 2023). The results of the risk analysis for collaborations are summarized in Table 2.

Table 2: Risk analysis for collaborations

Risks analysis for collaborations	
First order concepts	Second order concepts
Complex integration within corporate goals; Continuous support from the innovation partners is critical; Ineffective use of underutilized incumbent resources; Organizational proximity embeds joint agreements between organizations; Short time for establishment	OPERATIONAL
Loss of IP control; IP risk exposure; knowledge transfer; Loss of autonomy; IP appropriation, Loss of control over their IP; Cocreation (sharing of intellectual property); Cooperation and exchange	IP
Conflict from diverging goals; Vision and goal misalignment	CONFLICT OF INTEREST
Limited resources; Extremely limited budgetary state funding; Financial instability; Large capital requirements; Limited resource	FINANCIAL
Risk of loss of autonomy due to premature acquisition by a larger company; Co-Existence; Co-Specialization; Heterogenous views; High level of interaction with other actor of ecosystem; Interdependence during collaboration; working cooperatively and competitively with other companies in order to co-evolve capabilities; Sharing goals; General risk of loss of autonomy within the collaboration; Imbalance of power that may lead to domination by the larger company; Operational autonomy hampered by dependence on the resources of the larger company; Collaboration should also be honest and transparent	LOSS OF AUTONOMY AND CONTROL
Absence of shared vision; Coordianational and organizational; Cross network alignment; Diverging interest and goals; Insufficient network leaderiship; Integration risk; Demoralisation of staff; Loss of support for the startup due to closure of critical outposts; Failure of collaboration without benefits to the startup; Minimal support of the incumbent due to underestimation of the startup's innovation; Misalignment of the solution with the requirements of the established company; Startup ideas are lost because the multinational company fails to develop or commercialize them	COLLABORATION
Loss of talent to established companies	RETENTION OF RESOURCE

At the same time, as previously mentioned, collaborations between large companies and startups promote the consolidation and growth of the latter. Being young entities with limited resources, collaboration with large companies allows startups to overcome this limitation, gaining access to global markets and strategic resources that would be difficult to reach on their own (Gupta et. al, 2021). The results of the enablers analysis for collaborations are summarized in Table 3.

Table 3: Enablers analysis for collaborations

Enablers analysis for collaborations	
First order concepts	Second order concepts
Having the opportunity to collaborate with leading companies provides access to markets and important resources, such as complementary technologies, complementary skills, funding, research and development, and research synergies; Creating platforms to attract investments in research development; Increasing access to venture capital, investment funds, and other necessary sources of financing to develop and expand technological activities.	RESOURCE
Having the opportunity to collaborate with leading companies provides access to markets and important resources, such as complementary technologies, complementary skills, funding, research and development, and research synergies; Assistance in technology transfer; Increased capacity to produce new methods and products; Being part of an innovation ecosystem can provide access to advanced technological resources that might otherwise be out of reach for a single startup; … a faster flow of innovative ideas, collaborative problem-solving, and sharing of best practices,	TECHNOLOGICAL
Having the opportunity to collaborate with leading companies provides access to markets and important resources, such as complementary technologies, complementary skills, funding, research and development, and research synergies; Creating links and alliances between actors; improved collaboration and sharing of goals; increased investment in R&D.	HUMAN COMPETENCE AND EXPERIENCE

Enablers analysis for collaborations	
First order concepts	Second order concepts
Collaboration has a significant effect on survival; Social networks and a collective dimension open to the "new"; Interaction with suppliers, customers, and organizations offering complementary services to stimulate innovation; Collaboration offers the opportunity to connect with a network of people and organizations, increasing the chances of future partnerships and relationship-building,	EXTERNAL INTERACTIONS
Increase in the number of patents.	IP
A successful innovation ecosystem is characterized by a well-organized, collaborative, and supportive environment, with vibrant exchanges among ecosystem members.	ORGANIZATIONAL

3.2.2 Risks and enabling factors for digitalization

Below, in tables 4 and 5 the factors that enable and hinder the digitization process, which profoundly influences the way startups and large companies operate, innovate, and interact with each other, will be analyzed (Chekanov, 2022; Felicetti et. al, 2023).

Table 4: Risk analysis for digitalization

Risk analysis for digitalization	
First order concepts	Second order concepts
Perception of risk; Administrative and legal barriers limiting the adoption of digital solutions; Fragmented ecosystem; Lack of support from the ecosystem.	GOVERNMENTAL
Rigidity of organizational structures; Complexity and rigidity of established companies; Need for physical interactions; Network limitations; External dependency; Limited functional connections.	OPERATIONAL
Cyber-attacks; Limited access to information; Data privacy issues.	IP
Uncertainty and lack of trust among potential partners; Power imbalance; Information asymmetry.	CONFLICT OF INTEREST
Limited resources and capabilities; High funding requirements and development costs.	FINANCIAL
Resistance to change from established companies; Coexistence; Co-specialization; Heterogeneous visions; Power imbalance that may lead to dominance by the larger company; Operational autonomy hindered by dependence on the larger company's resources; Collaboration should also be honest and transparent.	LOSS OF AUTONOMY AND CONTROL
Difficulties in collaborating with new entities such as startups; Inadequate collaboration among stakeholders; Lack of a shared vision; Diverging interests and objectives; Insufficient network leadership; Demoralization of personnel; Loss of support for the startup due to the closure of critical outposts; Failure of collaboration without benefits for the startup; Minimal support from the incumbent due to underestimation of the startup's innovation; Misalignment of the solution with the requirements of the established company.	COLLABORATION
Loss of talent to established companies; Disparity in access to digital technologies between large and small companies; Lack of awareness; Lack of technological skills; Difficulty in hiring employees with strong digital skills.	RETENTION OF RESOURCE

Table 5: Enablers analysis for digitalization

Enablers analysis for digitalization	
First order concepts	Second order concepts
Need for investments; Support for market access	RESOURCE
Technology integration; Structured phases of digital innovation	TECHNOLOGICAL
Access to digital skills; Training and Talent Development; Resilience and capabilities; Teaching and mentorship; Use of creativity and experience of end users; Support from leaders; Design Thinking	HUMAN COMPETENCE AND EXPERIENCE
Accelerators and incubators; Relationships with universities, startups, and research centers; Government support; Public-Private collaborations; Corporate engagement; Connections and relationships; Support for local networks and complementary resources; Collaborations with established companies	EXTERNAL INTERACTIONS
Cultural and physical spaces; Alignment among stakeholders; Facilitation by mediators; Creation of a collaborative ecosystem; High speed in innovation cycles; Lean methodology; Open Innovation ecosystem; Good openness in maintenance activities; Social Network structures; Integration of external stakeholders	ORGANIZATIONAL

3.2.3 Risks and enabling factors for sustainability

The integration of sustainable practices in companies and startups can be a complex process due to numerous obstacles that slow down their adoption and diffusion (Audretsch et. al, 2018). Table 6 presents the main obstacles to the implementation of sustainable practices.

Table 6: Risk analysis for sustainability

Risk analysis for sustainability	
First order concepts	Second order concepts
Standard organizations; Pollution issues; Climate change; Regulatory constraints; High taxes	GOVERNMENTAL
Distance between mature and growing ecosystems; Complexity in the food ecosystem; Changes in the supply chain	OPERATIONAL
Intellectual property issues; Disruptive technologies; Offices and patents	IP
Risk of greenwashing; High competitiveness	CONFLICT OF INTEREST
Financial conflicts; Economic crises; Limited access to funds for sustainable innovation; High costs; Financial and market constraints; High capital requirements; Insufficient competitive models	FINANCIAL
Cultural resistance	LOSS OF AUTONOMY AND CONTROL
Lack of customer interest; Lack of consumer information	COLLABORATION
Limited resources; Lack of skills	RETENTION OF RESOURCE

Startups show a greater inclination towards sustainable models, frequently adopting circular strategies inspired by the principles of Circular Economy to develop their business models (Bigliardi and Filippelli, 2021). Table 7 presents the main enabling factors for sustainability.

Table 7: Enablers analysis for sustainability

Enablers analysis for sustainability	
First order concepts	Second order concepts
Set of incubators and accelerators; Sustained business growth; Universities and research	RESOURCE
Innovative technologies	TECHNOLOGICAL
Entrepreneurial leadership; Long-term thinking; Management support	HUMAN COMPETENCE AND EXPERIENCE
Companies that stimulate knowledge variation; Growth in demand for sustainable products	EXTERNAL INTERACTIONS
Collaborations between entities; Pollution reduction; Diversification into the right market with an innovative product; Mission focused on innovation; Initiatives that support the innovation ecosystem; Transparency; Alignment in the value chain	ORGANIZATIONAL

4 Case Studies

This section presents two case studies of innovative Italian startups, based on semi-structured interviews that examine collaboration dynamics with large companies. The analysis focuses on the influence of digitalization and sustainability, aiming to identify key enablers, barriers, and the role of regulations and emerging technologies in supporting these partnerships.

4.1 The AgerTech case

AgerTech is an innovative Italian startup based in Turin, founded in 2024, and active in the Agrifood sector and artificial intelligence. Its core product, AgerIX, is a WhatsApp-based digital assistant that automates the collection and organization of business data. Through an intuitive dashboard, agronomists can manage farms and generate detailed reports, improving efficiency and communication with producers.

“Innovation ecosystems have been a key element for us, not only to receive feedback but also to build a solid network,” says Mara Verri, CEO and Founder of AgerTech.

After three years of activity, the company has pivoted to better align with market needs. While it is currently receiving positive feedback and expects substantial growth, it still faces major challenges such as intellectual property protection and cost management. Support from incubators and accelerators, such as Le Village, has

been “crucial in addressing these challenges, providing networking opportunities and facilitating entry into new markets.”

On a local level, AgerTech has leveraged innovation ecosystems to build collaborations with various institutions, allowing the company to adapt its solutions to the specific needs of different agricultural contexts.

4.1.1 Collaborations with Big Enterprises

Partnerships with large companies and incubators represent a key element for AgerTech. In addition to financial support, these collaborations offer business matching opportunities and access to new markets. Belonging to an innovation ecosystem facilitates strategic connections and enables the sharing of material and financial resources, reducing operational costs.

One of the crucial aspects of AgerTech's strategy is the protection of intellectual property: while collaborating with large companies, the startup aims to maintain its autonomy in product development and customization. "*Although large companies often seek more control, autonomy is non-negotiable for us: we want to innovate and compete without compromises*," explains the founder.

Thanks to partnerships with established players, AgerTech has developed strategic relationships that allow it to access new markets and strengthen its competitive position. However, for emerging startups, the risk of becoming overly dependent on large companies remains a challenge that must be managed carefully.

4.1.2 Digitalization

Digitalization is AgerTech's main strength, operating in a market with a growing demand for innovative technological solutions. However, the startup faces bureaucratic and regulatory obstacles that slow down the integration of their technologies. To overcome these barriers, AgerTech relies on specialized consultants and offers digital tools to simplify agricultural data management.

Despite the added value of their solutions, the startup does not receive adequate government support to foster the digitalization of the sector. "*A state intervention could make a difference, for example, by incentivizing companies that collaborate with startups*," suggests the founder. Such measures would help overcome difficulties related to high costs, training times, and a lack of digital skills, facilitating the technological transformation of Italian agriculture.

The adoption of new technologies in the agricultural sector represents an opportunity not only to optimize data management but also to improve the quality of the final product and the sustainability of the entire production process. However, the change requires a strong commitment from both institutions and companies in the sector, so that innovative solutions can be implemented on a large scale.

4.1.3 Sustainability

Sustainability is another central element in AgerTech's vision. The company is committed to developing solutions that not only improve operational efficiency but also promote more sustainable agricultural practices. Through the digitalization of processes, AgerTech helps agricultural businesses reduce waste of resources such as water and fertilizers, optimizing the use of agricultural inputs through intelligent data monitoring.

"*We have created a tool that enables more informed decision-making, with both economic and environmental benefits*," says the CEO. However, the transition to more sustainable agricultural practices is still hindered by resistance to change and the lack of specific incentives. AgerTech hopes for greater support from institutions to encourage widespread adoption of new sustainable technologies in the agricultural sector.

For AgerTech, sustainability is not limited to waste reduction: the startup is also committed to optimizing the agricultural supply chain, reducing emissions related to transportation and logistics. "*Making the supply chain more efficient means not only saving on costs but also reducing environmental impact*," emphasizes the CEO.

Furthermore, digitalization can promote the use of regenerative agricultural practices, helping farmers implement environmentally friendly cultivation techniques. AgerTech aims to become a reference point for those who want to innovate without compromising the sustainability of their production model.

4.2 The HumanWE case

Founded in 2023 and based in Emilia-Romagna, HumanWE is a startup in the Early Growth phase, currently employing five people. Operating in the environmental sustainability sector, it has developed ESGAnalytics, a software platform that automates sustainability reporting. The tool provides a centralized, reliable data repository, helping companies save time on manual tasks and focus on analyzing ESG goals and shaping sustainable business strategies.

4.2.1 Collaborations with Big Enterprises

HumanWE has built a strategic network of collaborations with incubators, universities, and major companies, such as Le Village and the RES.m HUB of Università Cattolica in Piacenza, gaining access to funding, scientific expertise, and business opportunities. A key partnership with the University of Parma has supported research on AI applied to ESG regulation.

"I strongly believe in collaborations with universities, especially in the scientific field," says CEO Antonello Bartolone. "Our first meeting with the University of Parma was based entirely on an exchange of ideas… with no financial request from the university. This shows there is a strong interest in developing innovative solutions together."

The startup has also partnered with large companies in tech and environmental sectors to enhance ESG data analytics. "We found companies willing to believe in our vision and actively collaborate to improve sustainability management in businesses," Bartolone notes. Still, he acknowledges the difficulties of working with large firms: "A mindset change is needed to value small innovative companies."

4.2.2 Digitalization

HumanWE invests in digitalization through the strategic use of Artificial Intelligence, collaborating with academic institutions to develop advanced algorithms. The company is also exploring the use of emerging technologies such as blockchain for ESG data certification and Big Data Analytics to improve the management of business information.

"*Artificial Intelligence should not just be a trend, but a real added value," emphasizes Bartolone. "We decided not to limit ourselves to integrating existing chatbots, but to develop proprietary algorithms capable of effectively supporting companies in managing their ESG strategies. Our goal is to provide an intelligent tool that can interpret data and guide managers in decision-making*."

HumanWE has also invested in automating internal business processes, reducing the time needed to process ESG reports and improving the accuracy of analyzed data. Digitalization must be a concrete support for companies, not an obstacle. For this reason, HumanWE develops user-friendly tools that facilitate the adoption of new technologies.

Despite the potential of digitalization, the startup faces difficulties in accessing funding for technological innovation. "*Funding opportunities for innovative startups exist, but they are often difficult to access. The application process is complex, and the available resources are not always sufficient to support large-scale technology adoption*," explains the CEO.

4.2.3 Sustainability

HumanWE is a benefit company committed to integrating sustainability into every aspect of its operations. "*Being sustainable is not just an obligation; it is our mission*," says Bartolone. The company uses data centers powered exclusively by renewable sources and adopts energy-efficient technological infrastructures.

HumanWE has also introduced corporate policies aimed at promoting diversity and inclusion because it firmly believes that sustainability is not just environmental but also social. In fact, "*an inclusive and diverse work environment contributes to creating a more cohesive and innovative team*."

However, HumanWE faces several challenges in pursuing its sustainable business model. The main obstacles include the high costs of sustainable practices and the need for adequate funding. Adopting sustainable practices involves significant initial investment. Therefore, it is essential for institutions and investors to recognize the value of sustainability and support companies that choose this path.

In this context, HumanWE has joined the GRI Community (Global Reporting Initiative), the leading international organization for sustainability reporting. "*Joining the GRI Community is a strategic step for us. It allows us to stay updated on regulatory developments and to develop solutions that are increasingly in line with the needs of companies*," says Bartolone. HumanWE's experience demonstrates that sustainability and digitalization can be drivers of growth for startups, provided there is a favorable ecosystem, made up of investments, collaboration, and an appropriate regulatory framework.

5 Conclusion

This research aimed to analyze the role of startups within Innovation Ecosystems, with a particular focus on enabling and hindering factors that influence digitalization, sustainability, and strategic collaborations with large companies. Starting from a literature review and a study based on a Multiple Case Study analysis, the paper provided a clear framework of the dynamics characterizing these interactions.

In terms of future developments, this research suggests several possible directions. In particular, it would be useful to focus on (i) the motivations for startups to enter into collaborative relationships, providing strategic information on how these collaborations can be effective and efficient; (ii) further studies could investigate the impact of specific digital technologies (such as artificial intelligence or blockchain) on the dynamics of Innovation Ecosystems; (iii) it would be useful to expand the sample of analysis by including startups from different industrial sectors and geographical areas to better understand the contextual variables influencing the success of strategic collaborations.

This approach will provide a more comprehensive and detailed understanding of the challenges and opportunities that startups face in innovation ecosystems, helping to develop more focused and sustainable strategies for their long-term success. In conclusion, this research provides useful insights both for the academic world and for businesses, offering tools to strengthen collaborations between startups and large companies and promote a more integrated and resilient innovation ecosystem.

6 Ethics declaration

This research is based on the analysis of two business cases using publicly available information and voluntary interactions with company representatives. No personal or sensitive data were collected, and no procedures were carried out that required approval from an ethics committee. Therefore, no formal ethical clearance was sought or obtained.

7 AI declaration

ChatGPT (OpenAI) was used exclusively as a language support tool for translating and revising the manuscript into English. All content generated by this AI tool was carefully reviewed and adapted by the author to ensure accuracy and alignment with the scientific objectives of the research.

Abstract

Entrepreneurial ecosystems are increasingly seen as complex, dynamic environments requiring effective coordination by ecosystem orchestrators. While prior research has focused on structural and institutional elements, little is known about the cognitive processes guiding orchestrators' decisions. This study addresses this gap by examining how mental models influence ecosystem performance. The study analyzes three key attributes of mental models: complexity, centrality, and accuracy. Data were collected through a simulation environment where eleven teams played the role of orchestrators across ten rounds of strategic decision-making. Using a fuzzy-set Qualitative Comparative Analysis (fsQCA), the study identifies two causal configurations sufficient for high performance: one based on high centrality and the other on high complexity, both combined with low accuracy. The findings suggest that orchestrators can adopt different cognitive strategies to achieve strong outcomes, challenging the assumed importance of accuracy. The study contributes to the literature on entrepreneurial ecosystems and managerial cognition, offering practical insights for those aiming to enhance ecosystem performance through cognitive and strategic design.

Keywords: entrepreneurial ecosystem; mental model; decision making

Paper type: Academic Research Paper

1 Introduction

Entrepreneurial ecosystems have enriched entrepreneurship theory by offering a systemic approach to support the creation and growth of new ventures (Cavallo, Ghezzi, and Balocco, 2019). Entrepreneurial ecosystem theory highlights the importance of a supportive environment for new ventures and entrepreneurs (Acs, Autio, and Szerb, 2014). The existing literature has expanded significantly, offering various educational frameworks to guide policymakers and strategists in creating or fostering entrepreneurial ecosystems in the real environment. These frameworks provide tools to interpret or manage ecosystems by focusing on actors and resources (Isenberg, 2010, 2011; Stam and Van de Ven, 2021) or governance structures (Colombo et al., 2019). However, due to the diversity of actors and resources involved in entrepreneurship, ecosystem managers—better referred to as orchestrators, i.e., those who perform orchestration activities that influence the network and its members (Hurmelinna-Laukkanen and Nätti, 2018)—often face challenges in managing innovation networks and identifying key actions or measures to effectively promote entrepreneurship (Jung, Eun, and Lee, 2017). While prior research has identified critical drivers and metrics to inform and guide orchestrators (Cavallo, Ghezzi, and Sanasi, 2021) or explored the roles orchestrators assume and their related capabilities (Hurmelinna-Laukkanen and Nätti, 2018; Tabas, Nätti, and Komulainen, 2023), the literature has not examined factors that influence orchestrators' decisions. Specifically, no studies have investigated how theoretical knowledge, experience, or entrenched assumptions affect their decision-making processes within entrepreneurial ecosystems.

This paper introduces a novel perspective by analyzing how ecosystem orchestrators interpret and apply theoretical knowledge in their decision-making—particularly how theories on entrepreneurial ecosystems guide their efforts to coordinate complex systems of actors and achieve positive performance. The analysis focuses on a micro-level perspective that analyse key concepts and schemas that guide decisions in complex contexts such as that of entrepreneurial ecosystem. A field not yet explored by any researchers.

Drawing on behavioral decision-making literature (Guiette and Vandenbempt, 2013; Schwab, 2007; Gavetti et al., 2012) and managerial cognition studies (Blettner, 2011; Gary, Wood, and Pillinge, 2012), this study examines how theories shape managerial mental models. Managerial mental models are defined as "*models that managers use to map the competitive landscape of their industries and rationalize their strategic decisions*" (Yang et al., 2016, p. 899).

While previous literature has primarily focused on firm-level decision-making and its impact on performance (Nadkarni and Narayanan, 2007), investigating the net effects of mental model variables on firm outcomes, this

study addresses a double gap. First, mental model theory has not yet been applied to the analysis of decision-making processes and performance in the context of entrepreneurial ecosystem managers. Second, whereas traditional research typically investigates linear relationships between variables, this study adopts a configurational perspective to explore how different combinations of mental model characteristics relate to ecosystem performance.

More precisely, it examines how orchestrators' mental models of entrepreneurial ecosystems influence ecosystem-level outcomes, by addressing the following research question: *How do different configurations of mental model attributes shape the performance of entrepreneurial ecosystems?*

Recognizing that top-level decisions are typically made by teams rather than individuals (Klimoski and Mohammed, 1994), we assess mental models at the team level. Managing ecosystems requires dialogue and negotiation among diverse stakeholders, each representing unique entrepreneurial perspectives. This research employs a simulation-based experimental design using The Entrepreneurial Ecosystem Game (TEEG), a web-based simulation tool designed to model the dynamics of entrepreneurial ecosystems. Participants, in the role of ecosystem orchestrators, played the game over ten rounds, making strategic decisions to manage ecosystem development. Each of the eleven teams aimed to maximize startup creation while navigating resource scarcity, competition, and causal ambiguity—key features of real-world ecosystem management. TEEG provides a high level of realism through mechanisms such as temporal delays, feedback loops, and uncertainty, making it a suitable environment for observing how mental models influence strategic decisions and ecosystem-level outcomes.

The mental models were captured through conceptual maps, reconstructed from the strategic declarations of participants. Building on the literature in managerial cognition, we analyzed three key characteristics of these mental models: complexity (Bogner and Barr, 2000), centrality (Kiss and Barr, 2015), and accuracy (Denrell, Fang, and Levinthal, 2004; Gary and Wood, 2011). Ecosystem performance was measured by the number of startups created. The simulation environment allowed us to systematically track team strategies, performance trajectories, and the feedback they received over time, enabling full data collection for each case.

Given the exploratory nature of the study and the small number of cases (n = 11), we employed a fuzzy-set Qualitative Comparative Analysis (fsQCA) to uncover causal configurations that link mental model characteristics to ecosystem outcomes.

The results offer a new lens for understanding entrepreneurial ecosystems by connecting orchestrators' cognitive structures to performance outcomes. Specifically, we find that variations in mental models lead to differences in ecosystem performance. Notably, high levels of centrality or complexity appear to be sufficient conditions for high performance, while accuracy does not emerge as a necessary condition, either alone or in combination.

These findings contribute to both the entrepreneurial ecosystems and managerial cognition literatures, while offering practical implications for policy-makers and educators interested in fostering high-performing entrepreneurial ecosystems.

2 Theoretical Background

2.1 Entrepreneurial Ecosystems: toward a new lens of analysis

The literature on entrepreneurial ecosystems can be considered widely discussed (see Saxenian, 1994; Cohen, 2006; Isenberg, 2010; Feld, 2012). Entrepreneurial ecosystems have emerged as a relevant academic field that has helped explain how the external environment can impact individual entrepreneurship and the economic development of local configurations. The entrepreneurial ecosystem concept has provided a more evolutionary, non-linear, and socially interactive explanation of entrepreneurial dynamics (Colombelli, Paolucci, and Ughetto, 2017). It argues that entrepreneurship occurs within a community of interdependent actors situated in a specific area (Isenberg, 2010; Malecki, 2011). The literature has devoted considerable attention to defining entrepreneurial ecosystems and identifying their key attributes (Roundy et al., 2017). Some scholars have focused on the antecedents of ecosystems, drawing from strategy and regional development literatures (Yun et al., 2017; Erina et al., 2017), while others have proposed frameworks identifying the principal components of entrepreneurial ecosystems. Most frameworks have adopted an actor-centric approach, listing the main—primarily economic—actors characterizing an ecosystem. Further streams of research have discussed measures for evaluating the performance of entrepreneurial ecosystems (Jung, Eun, and Lee, 2017). Additionally, a body of literature has explored governance mechanisms, aiming to move beyond the static perspectives provided by earlier studies and introducing dynamic considerations regarding the evolving role of actors within ecosystems (Colombo et al., 2019; Borissenko and Boschma, 2017).

Despite the variety of topics already addressed, the literature on entrepreneurial ecosystems still offers room for further investigation (Cavallo, Ghezzi, and Balocco, 2019). Cavallo, Ghezzi, and Balocco (2019) call for a deeper understanding of several aspects, including the effects of digitalization on entrepreneurial ecosystems and a more precise identification of the critical components that significantly impact ecosystem performance. The latter point represents fuel for thought. Beyond identifying which components affect performance, it is also important to explore which components are perceived as critical by decision-makers themselves. This perspective introduces a novel lens through which to interpret entrepreneurial ecosystems—one that focuses on the behavior of orchestrators and the cognitive schemas guiding their strategic choices.

This exploration of cognitive schemas and critical ecosystem elements, as perceived by orchestrators, will be conducted through the theoretical lens of mental models.

2.2 Mental Models

Decision-makers, and humans more generally, possess limited capacity for information processing. To navigate this limitation, they rely on simplified knowledge schemas or representations of how the world operates (March and Simon, 1958). These cognitive structures play a critical role in shaping the strategic choices of managers. The literature on managerial cognition has explored how managers' interpretations influence their decisions, giving rise to an extensive body of research on managerial mental models (Porac et al., 1995). Managerial mental models are defined as schemas or "models that managers use to map the competitive landscape of their industries and rationalize their strategic decisions" (Yang et al., 2016, p. 899). In other words, they function as lenses through which strategic decision-makers interpret information and translate it into organizational actions (Huff, 1982). Mental models are heterogeneous, and a significant portion of the literature has examined how information is classified and organized within cognitive frameworks (Barr et al., 1992). Among the various characteristics explored, three have gained particular prominence: complexity, centrality, and accuracy. Complexity refers to the degree of differentiation and integration within a strategic framework, reflecting the richness of concepts and relationships incorporated into the model (Bogner & Barr, 2000). Centrality concerns the extent to which a mental model is focused and hierarchical, often revolving around a central actor or resource. Accuracy pertains to the model's capacity to correctly link actions to outcomes (Denrell et al., 2004; Gary and Wood, 2011). Research has investigated how these characteristics influence decision-making effectiveness and firm performance. According to Nadkarni and Narayanan (2007) and Manral (2011), greater complexity enhances the amount of information perceived, generates alternative solutions, and fosters flexibility in the decision-making process - all factors positively associated with superior performance. Regarding centrality, scholars such as Kiss and Barr (2015) argue that managers often develop mental models centered around key concepts, thereby facilitating efficient decision-making and improving organizational outcomes. As for accuracy, although some authors question whether highly accurate mental models consistently enhance performance (Sutcliffe, 1994; Weick, 1990), other studies (e.g., Gary and Wood, 2011) have shown that accuracy in understanding key firm principles is positively related to organizational success.

Beyond individual-level cognition, scholars have increasingly recognized that strategic decisions often emerge at the group level. This insight has spurred extensive research on team mental models (Klimoski and Mohammed, 1994). Team mental models extend the concept of cognitive schemas to collective settings, emphasizing the need for consensus and shared understanding among team members. When team members hold similar mental models, they are better able to anticipate one another's actions and coordinate effectively, particularly under conditions that limit overt communication and debate (Mathieu et al., 2000). Much of this literature primarily focuses on team dynamics and task-specific effectiveness (see Yang et al., 2016).

Building on these insights, our study adopts a different perspective. While drawing on the concept of team mental models, we do not focus on team dynamics or intra-team performance per se. Instead, we examine the characteristics of mental models and investigate their combination and their relationship with the performance of ecosystems.

3 Methodology

3.1 The empirical setting

The simulation experiment was conducted using The Entrepreneurial Ecosystem Game (TEEG), a live, web-based simulation developed by Parthenope University of Naples. TEEG explores the dynamics of entrepreneurial ecosystems and aims to simulate the conditions necessary for the creation and survival of start-ups over time.

The primary goal of the game is to foster start-up creation, and to achieve this, players must design and implement a feasible entrepreneurship policy mix.

Players define and execute an ecosystem development strategy using three types of tools across ten rounds: analytical tools, meta-organizational tools, and intervention tools. In every round, teams can decide on specific interventions, such as financing resources or actors, selecting data for monitoring, and implementing coordination mechanisms. Through these instruments, teams make strategic decisions to enhance resource availability within the entrepreneurial ecosystem and to build trust among actors with diverse objectives. Their decisions are subject to a budget constraint spread over the ten rounds. At the end of each round, teams receive feedback on budget status and simulation results, particularly the number of start-ups created. This feedback mechanism encourages competition among teams.

Players are asked to articulate their strategic plan prior to starting the game and then revisit and revise it after five rounds (corresponding to five simulated years). More precisely, before playing, participants are required to write a detailed strategy aimed at stimulating start-up creation. While the strategy can be adjusted based on performance feedback, any revisions must be documented through textual annotations, preserving a trace of changes made to the original plan.

The TEEG simulation provides a high level of complexity, mimicking real-world conditions such as time delays, resource competition, scarcity, and causal ambiguity. Due to its realistic dynamics, TEEG has been adopted as both a research and pedagogical tool in universities and public and private institutions.

TEEG is particularly well suited to the purposes of this study for several reasons. First, it is a dynamic and competitive decision-making environment where participants act as a team, receive real-time feedback, and iteratively refine their strategy. Second, the complex algorithms underlying TEEG make the relationships between decisions and outcomes highly non-linear and unpredictable, thereby introducing meaningful complexity and uncertainty. Third, the simulation offers a controlled setting for tracking the evolution of strategists' mental models, with traceable decision data and performance feedback over time (Lant & Hewlin, 2002).

3.2 Data collection and analysis

A longitudinal dataset was collected from eleven teams acting as strategic decision-makers. The teams were composed of master's students in Innovation Management and Startup Management, who were considered knowledgeable rather than novice in the field of entrepreneurial ecosystems. Their academic programs include modules focused on innovation and ecosystem-related topics. Student simulations provide a valid environment for studying strategic decision-making processes (Lant & Hewlin, 2002; Gary & Wood, 2011). More specifically, we collected and analyzed team mental models for two main reasons: first, decisions within ecosystems are often made through group discussions; second, the complexity of the TEEG simulation requires the participation of more than one player.

Teams (hereafter referred to as "players") received the same instructions and were encouraged to take the simulation seriously, as game performance contributed to their final course evaluation. Data from the game sessions were collected via the TEEG platform, which includes a master dashboard that accurately tracks all decisions made during the game. Additional data were gathered through supporting materials in which players were required to explain the motivations behind their decisions. Each team submitted a file detailing their strategy, which they were free to describe in as much detail as they deemed appropriate. These written descriptions formed the basis for mapping mental models, while the TEEG dashboard data were used to assess strategic actions and ecosystem performance. We used causal mapping to capture mental models. Causal maps are a type of cognitive map that represent key concepts and the relationships among them, tracing the rationale behind decisions (Curşeu et al., 2010; Narayanan & Armstrong, 2005). In the first stage of analysis, the authors identified statements, key concepts, and causal links - i.e., phrases indicating cause-effect relationships. In the second stage, the cognitive maps were constructed using Draw.io. The maps were enriched with raw statements to support and contextualize the relationships among elements (Narayanan & Fahey, 1990).

In line with the purpose of our paper, cognitive maps were analyzed according to three characteristics: complexity (Bogner & Barr, 2000), centrality (Kiss & Barr, 2015), and accuracy (Denrell et al., 2004; Gary & Wood, 2011). In the context of entrepreneurial ecosystems, a complex mental model reflects the inclusion of a wide range of ecosystem resources (e.g., talent, services, funding, and technology) and actors (e.g., universities, corporations, governments, accelerators, incubators, and research centers). Centrality captures the presence of a hierarchical concept around which decisions revolve (e.g. centrality around actors or resources). Accuracy assesses the extent to which actions targeting ecosystem actors or resources are logically linked to desired outcomes, such as ecosystem growth. Each variable was measured on a 5-point Likert scale by each author, and

the average score was then calculated. Ecosystem performance is operationalized as the number of start-ups created, as reported on the TEEG dashboard. This numerical value was converted into a Likert scale for comparison purposes.

Given the exploratory nature of the study and the small number of cases (n = 11), we employed a fuzzy-set Qualitative Comparative Analysis (fsQCA) to uncover causal configurations (Ragin, 2008) that link mental model characteristics to ecosystem outcomes**.** This method is particularly well-suited to examining causal complexity, allowing for the identification of multiple, potentially non-symmetric combinations of conditions that lead to a given outcome.

All conditions were calibrated using the direct method, transforming original scores into fuzzy-set membership values ranging from 0 (full non-membership) to 1 (full membership). The midpoint value of 0.5 was treated as the crossover point, representing maximum ambiguity regarding set membership. Calibration was theory-driven and based on the distribution of empirical values across the cases. The analysis focused on identifying both sufficient and necessary conditions for high ecosystem performance.

The full analysis (including calibration, construction of the truth table, and calculation of consistency and coverage) was conducted manually using Microsoft Excel. While Excel does not automate fsQCA procedures, it enabled full control over the steps of the analysis and transparency in the logic of minimization. A consistency threshold of 0.8 was applied to identify sufficient configurations, in line with established methodological standards (Ragin, 2008). Solutions were interpreted by examining both raw and unique coverage values to understand the explanatory contribution of each configuration.

4 Preliminary Results and conclusions

The results of the fuzzy-set Qualitative Comparative Analysis (fsQCA) identified two distinct causal configurations as sufficient for achieving high levels of ecosystem performance.

The first configuration includes high centrality, combined with low complexity and low accuracy (0 1 0), while the second involves high complexity, low centrality, and low accuracy (1 0 0). These findings suggest that different cognitive strategies- each centered on either complexity or centrality- can independently support high performance, even in the presence of low accuracy (Table 1).

Table 1: Sufficient Configurations for High Ecosystem Performance

Configuration	Complexity	Centrality	Accuracy	Performance	Consistency	Coverage
1	0	1	0	1	1	0,16
2	1	1	0	1	1	0,16

In practical terms, ecosystem orchestrators who leverage complexity may attempt to stimulate entrepreneurship by involving a wide and diverse set of actors, embracing the systemic nature of the ecosystem. In contrast, orchestrators emphasizing centrality may rely on clear prioritization principles, giving prominence to selected actors and resources to coordinate collective action more efficiently. These results align with prior literature: they support Nadkarni and Narayanan (2007) and Manral (2011) regarding the relevance of complexity in strategic thinking, and Kiss and Barr (2015) in highlighting the role of centrality in cognitive structures. However, the results challenge the findings of Gary and Wood (2011), as accuracy did not emerge as a relevant or necessary condition for high performance in this context.

Importantly, the analysis did not identify any single condition as necessary, reinforcing the configurational logic of fsQCA, which assumes equifinality - the possibility of achieving the same outcome through different causal paths.Although the overall coverage of the solutions is relatively low, this is consistent with the exploratory and work-in-progress nature of the study. The limited number of cases and the simulation-based design aim to generate initial insights rather than generalizable claims. Nonetheless, these preliminary findings offer a valuable lens through which to explore how mental model configurations can shape ecosystem outcomes under uncertainty.

From a practical standpoint, the findings suggest that attempting to be highly accurate - that is, controlling all actors and relationships in a complex ecosystem - does not necessarily lead to better performance.

On the contrary, decision-makers may benefit more from adopting a complex perspective, which considers a broad array of actors and adapts to evolving conditions, or from asserting central coordination principles to structure collective behavior, even in fluid environments.

This study has several limitations. First, the sample size is limited and needs to be expanded with additional observations. Second, the conceptualization of mental model characteristics could be further refined, and future

research may explore additional cognitive dimensions that more fully capture mental models within entrepreneurial ecosystems.

Orchestrating Digital Innovation Ecosystems: A Case Study on Asymmetric Collaborations in Pharma Logistics

Alberto Michele Felicetti, Salvatore Ammirato, Roberto Linzalone, Laura Cutrì
University of Calabria, Arcavacata di Rende (CS), Italy

Abstract

The emergence of Digital Innovation Ecosystems (DIEs) is reshaping how innovation is generated, diffused, and scaled across sectors, especially within highly regulated domains such as pharmaceutical logistics. These ecosystems bring together startups, corporations, research institutions, and intermediaries to co-create digital solutions. However, such collaborations are inherently asymmetric—startups and corporates differ vastly in resources, legitimacy, and influence—posing challenges related to power imbalances, cultural misalignments, and governance.

This paper investigates how asymmetric collaborations are orchestrated within DIEs, drawing on a single in-depth case study: *Logi-farma*, a digital platform project aiming to optimize pharmaceutical distribution through AI, automation, blockchain, and data analytics. The case involves a large ICT corporation, an innovative SME, a logistics specialist, and a university research center. Guided by a conceptual framework derived from a prior systematic literature review on asymmetric collaborations, this study explores how stakeholders with diverging capabilities and motivations coordinate innovation efforts and mitigate power asymmetries.

Using semi-structured interviews, document analysis, and comparative assessments of digital innovation models, we investigate the governance mechanisms, collaboration dynamics, and innovation outcomes within the project. Findings are structured through a 6W-based framework—exploring who the actors are, how they collaborate and integrate technology, why they engage, and where/when the processes unfold. The analysis reveals that while startups benefit from legitimacy and scale, corporates leverage agility and niche expertise. However, unresolved asymmetries around data ownership, IP, and decision-making risk undermining trust and long-term viability.

This paper contributes to both theory and practice. Theoretically, it advances open innovation and ecosystem literature by integrating asymmetry as a structural component and proposing a novel conceptual lens for analyzing goal-oriented, multi-actor innovation networks. Practically, it offers guidance for ecosystem orchestrators, policymakers, and innovation managers on how to design inclusive governance structures that support fair value co-creation. The case study illustrates how digital health innovation can be scaled through collaborative orchestration, provided that power differentials are addressed and trust is actively managed. Ultimately, this work underscores the potential of orchestrated asymmetric collaborations to drive digital transformation and sustainability in complex, high-stakes sectors.

1 Introduction

In the current landscape of technological transformation and increasing regulatory complexity, the role of Digital Innovation Ecosystems (DIEs) has become central to organizational competitiveness and industry evolution. These ecosystems, defined by the interdependent collaboration of diverse actors—including startups, incumbents, universities, and intermediaries—facilitate the co-creation and diffusion of digital innovation through shared technological infrastructures, resources, and knowledge flows (Adner, 2006; Jacobides et al., 2018; Grandstrand & Holgersson, 2020). Within such ecosystems, startups bring agility, niche expertise, and disruptive innovation capabilities, while large corporations offer market access, capital, and infrastructural support (Chesbrough, 2003; Steiber, 2020; Kurpjuweit et al., 2021).

Despite this complementarity, collaborations between startups and corporates are inherently asymmetric, marked by imbalances in power, resources, organizational culture, and institutional legitimacy (Polidoro & Yang, 2021; Allmendinger & Berger, 2020). These asymmetries can create both synergies and tensions—startups may benefit from visibility and scale, but risk dependency and appropriation of intellectual property, while corporates might leverage innovation but struggle with cultural integration and trust-building (Spender et al., 2017; Steiber & Alänge, 2021).

This issue is especially pronounced in regulated industries such as pharmaceutical logistics, where digital innovation efforts are tightly constrained by compliance requirements, data governance, and stakeholder accountability (Bressanelli et al., 2019; Polidoro & Yang, 2021). While existing research has explored open innovation and collaborative strategies (Chesbrough, 2017; Corvello et al., 2023), few empirical studies have

investigated how these asymmetric partnerships are orchestrated in multi-actor, goal-oriented digital ecosystems within highly regulated contexts.

This paper addresses this gap by presenting a single in-depth case study of Logi-farma[1]—a collaborative innovation project involving a large ICT corporation, an innovative SME, a logistics specialist, and a university research center. Logi-farma aims to develop an integrated digital platform for pharmaceutical distribution, leveraging artificial intelligence (AI), big data, IoT, blockchain, and automation technologies.

Drawing on the 6W conceptual framework developed through a prior Systematic Literature Review (SLR) (Felicetti et al., 2025), this study explores the dynamics of asymmetric collaborations within a digital ecosystem. The research is guided by the following question:

How did a Big Corporation organize its Digital Innovation Ecosystem, and what are the functional roles, influence, and coordination mechanisms of the various actors involved in the project?

By analyzing Logi-farma through the lenses of actor roles, collaborative processes, digital technologies, motivations, and outcomes, this study contributes to a more nuanced understanding of how startup-corporate asymmetries are negotiated, mitigated, and transformed into sustainable innovation strategies.

Ultimately, the findings provide both theoretical insights for the evolving literature on DIEs and asymmetric partnerships, and practical guidance for orchestrating digital innovation in high-stakes, regulated environments.

2 Theoretical Background

Collaborations between startups and large corporations have emerged as a strategic response to the increasing demand for agility, innovation, and responsiveness in complex and fast-changing environments. These inter-organizational partnerships enable a blending of complementary resources: startups provide novel technologies, experimentation capabilities, and entrepreneurial energy, while corporates contribute market access, infrastructure, and institutional legitimacy. However, these relationships are rarely balanced. When actors with significantly different sizes, resources, organizational maturity, and strategic goals collaborate, the result is often an asymmetric partnership, where power, knowledge, and risk are unevenly distributed (Allmendinger & Berger, 2020; Felicetti et al., 2024).

The literature describes such asymmetries as both a source of value creation and a source of relational friction. On one hand, startups can accelerate innovation by leveraging the corporates' resources and networks, enabling faster market entry and scalability (Salvato et al., 2017; Virdi & Sinha, 2025). On the other hand, these same partnerships may generate dependency, loss of autonomy, and exposure to opportunism—especially when formal governance mechanisms and trust-building processes are weak (Sears et al., 2022; Prashantham & Madhok, 2023).

Scholars have applied a range of theories to interpret the dynamics of these collaborations. Transaction Cost Economics (Williamson, 1981) explains partnerships as cost-minimizing responses to uncertainty and asset specificity, while the Resource-Based View (Barney, 1991) emphasizes the strategic importance of accessing complementary capabilities. Institutional Theory (DiMaggio & Powell, 1983) adds a legitimacy perspective, where startups conform to the dominant norms and routines of corporate partners to gain acceptance and survival opportunities. Collective Action Theory (Olson, 1965) and Collaborative Network Theory (Camarinha-Matos & Afsarmanesh, 2005) further highlight the role of shared interests, relational embeddedness, and dynamic coordination across networked organizations.

Innovation Ecosystems have emerged as a new form for organizing innovations, often driven by large organizations that seek to establish alliances with complementary organizations such as startups, suppliers, and spin-offs to achieve mutual benefits (Konietzko et al., 2020; Ritala et al., 2013). These partnerships help integrate products and services through digital technology platforms, enabling value creation and collaboration (Dedehayir et al., 2018; Jacobides et al., 2018).

Existing literature on digital innovation ecosystems and startup-corporate collaborations highlights the potential of digital platforms, artificial intelligence (AI), and automated systems in optimizing supply chains. However, previous studies often focus on single-actor innovations rather than multi-stakeholder, goal-oriented networks in regulated industries. Furthermore, prior research primarily assumes positive outcomes from these collaborations, overlooking the potential risks and limitations, such as power asymmetries, resource control, and technology lock-in (Polidoro and Yang, 2021). Startups, despite their agility and innovative capabilities, face challenges related to credibility, resource constraints, and market access, which impact their ability to thrive within corporate-led innovation ecosystems (Spender et al., 2017; Inekwe, 2019). There is a need to understand better how collaboration lifecycle models evolve in startup-corporate partnerships, particularly in

[1] *"Logi-Farma" is a confidential project name used for anonymization purposes. It does not refer to any existing company or commercial initiative.*

pharmaceutical logistics, and how digital technologies shape integration efforts in such ecosystems (Baldwin, 2012).

Importantly, as these collaborations increasingly occur within Digital Innovation Ecosystems—interconnected environments mediated by digital technologies such as AI, IoT, and data platforms—the nature of asymmetry is further amplified. The digital layer introduces new forms of platform-based control, data asymmetries, and coordination challenges, particularly in regulated sectors such as healthcare and pharmaceuticals (Giglio et al., 2023; Corvello et al., 2023). In such contexts, large firms may dominate technological standards, control access to user data, and shape the pace and direction of innovation, limiting the startup's capacity to influence strategic decisions (Polidoro & Yang, 2021).

Although a growing body of literature investigates startup–corporate collaboration, significant gaps remain. Many studies overlook the startup's perspective, or focus exclusively on dyadic interactions, neglecting the broader ecosystemic configurations and the structural asymmetries embedded in these arrangements. Furthermore, conceptual overlap between related constructs—such as innovation ecosystems, digital ecosystems, and open innovation platforms—contributes to fragmentation and theoretical ambiguity.

In light of this, a deeper understanding of how asymmetries shape collaborative innovation—especially in multi-actor, digitally mediated, and regulated ecosystems—is both timely and necessary. It allows us to move beyond generic models of value co-creation, toward a more realistic portrayal of the tensions, trade-offs, and governance challenges that define asymmetric partnerships in digital transformation contexts.

3 Methodology

This research employs a qualitative, single-case study design (Yin, 2009) to investigate how asymmetric collaborations between startups and large corporations are orchestrated within Digital Innovation Ecosystems (DIEs). The case study approach is appropriate given the exploratory nature of the research and the aim to capture the complexity of a real-world, multi-actor innovation initiative in a regulated context.

3.1 Case selection

The Logi-farma project was selected through purposive sampling based on its relevance to the research objectives. It represents a digitally enabled innovation ecosystem involving:

- A large ICT corporation acting as the orchestrator;
- An AI-focused SME responsible for platform development;
- A SME acting as a logistics operator active in the pharmaceutical sector;
- A university research center offering technological validation and methodological support.

The project was funded by a public-private initiative and aims to develop a data-driven, AI-enabled digital platform for optimizing pharmaceutical logistics and distribution. Logi-farma provides a rich empirical setting to explore how diverse actors—characterized by unequal resources, influence, and expertise—interact and co-create innovation within a digital ecosystem.

3.2 Data collection

Multiple data sources were used to ensure triangulation and increase the robustness of findings (Eisenhardt, 1989; Gibbert et al., 2008):

- Seven semi-structured interviews were conducted with representatives of each participating organization, focusing on their roles, motivations, expectations, and experiences within the ecosystem.
- Project documentation, including partnership agreements, technical platform specifications, grant proposals, meeting minutes, and internal memos, was analyzed.
- Secondary materials, such as policy documents, press releases, and public communications, were used to complement and contextualize primary data.

Data were collected from semi-structured interviews with project stakeholders, archival documents, and comparative assessments of digital innovation models, spanning from June to December 2024. This dual-method approach broadens the scope of our analysis, offering a comprehensive view of Logi-farma's multi-actor ecosystem.

This approach allowed us to analyse the governance mechanisms, success factors, and innovation outcomes that emerge when an established ICT leader engages with innovative small enterprises to start a cooperative innovation project.

3.3 Data analysis

The analysis was conducted using a theory-driven coding strategy, grounded in the 6W Framework developed through the authors' prior systematic literature review (Felicetti et al., 2025). The 6W framework—Who, What, Why, Where, How, and When—provided an analytical lens to categorize and interpret data systematically across the following dimensions:

- What: Focuses on key themes such as market entry, innovation transfer, and strategic partnerships, emphasizing how startups and corporates exchange value to support innovation ecosystems (Chesbrough, 2003; Corvello et al., 2023).
- Who: Identifies core actors—startups, corporates, intermediaries, universities, and investors—each contributing specific resources, capabilities, and roles in collaboration (Giglio et al., 2023; Dos Santos & Benneworth, 2019).
- Why: Highlights motivations like funding, credibility, and agility for startups; and innovation, resilience, and sustainability for corporates—framed within the broader context of the digital and green transitions (Ricciardi et al., 2022; Geissdoerfer et al., 2018).
- How: Describes engagement mechanisms such as accelerators, venture capital, and orchestration by intermediaries. Success depends on effective coordination, resource sharing, and cultural alignment (Schepis et al., 2021; Steiber & Alänge, 2021).
- Where: Refers to physical hubs (labs, incubators) and digital platforms, which together enable real-time, scalable, and inclusive collaboration (Bereczki et al., 2022).
- When: Considers the timing of collaboration phases, from entry to scale-up, stressing the need for synchronization between startup agility and corporate innovation cycles (Wadhwa & Basu, 2013).

Emergent findings were discussed in relation to existing literature and validated through follow-up conversations with two project participants.

This approach enabled a structured yet flexible analysis of the Logi-farma project, allowing the study to surface both the commonalities and tensions inherent to asymmetric collaborations within digital innovation ecosystems.

4 Findings

The Logi-farma project represents a digitally enabled innovation ecosystem in the domain of pharmaceutical logistics, aiming to improve the traceability, efficiency, and sustainability of the drug distribution process through a collaborative digital platform. The ecosystem brings together a large ICT corporation (orchestrator), two technology-oriented startups, a logistics service provider, and a university research center acting as intermediary and methodological support. The initiative was funded through a regional innovation policy program supporting public–private partnerships, with a specific focus on the digital and green transitions in healthcare.

The project leverages technologies such as AI, IoT, automation, data analytics, and blockchain, integrated into a platform designed to manage the end-to-end flow of pharmaceutical products from wholesalers to pharmacies and hospitals. While the large corporate led the platform architecture and funding coordination, the startups contributed modules for real-time tracking and predictive analytics, and the logistics provider enabled operational piloting.

Despite strong complementarities among the actors, the collaboration was characterized by asymmetries in terms of organizational size, influence, and technological maturity. These asymmetries influenced how roles were distributed, how decisions were made, and how value was perceived and appropriated.

The collaboration targeted three innovation areas:

1. automation of warehouse and delivery processes;
2. data-driven traceability and condition monitoring of pharmaceutical products;
3. predictive analytics for demand planning.

These areas reflected strategic priorities for all actors—startups aimed to validate technologies in a real-world setting, while the corporate sought to integrate modular solutions into its platform-based service offering. These goals aligned with broader ecosystem needs related to efficiency, transparency, and compliance in regulated logistics.

Who: Key Actors and Their Roles

The ICT corporation acts as the orchestrator of the ecosystem, leading project governance, providing funding and infrastructure, and setting the technical direction of the platform. Its central position allows it to define timelines and coordinate partner contributions.

The AI-focused SME contributes advanced digital capabilities such as real-time tracking, demand forecasting, and IoT-based monitoring. They bring agility, rapid experimentation, and solution prototyping into the ecosystem, complementing the corporate's scale with technological niche expertise.

The logistics partner enables real-world piloting, providing access to warehousing and distribution operations, and ensuring regulatory compliance for pharmaceutical product delivery.

The university research center serves as a neutral intermediary and knowledge broker. It offers process modeling, validation of AI-based tools, and impact assessment. It also supports methodological rigor, trust-building, and alignment of expectations.

Although the ecosystem presents structural asymmetries in power, resources, and decision-making capacity, the university helps mitigate potential dominance by the corporate actor and reinforces a shared commitment to co-creation and research-based development.

Why: Motivations and Value Expectations

Motivations vary across actors but remain strategically complementary.

- The ICT corporation seeks to expand its portfolio in the digital health domain by integrating AI-driven logistics solutions. It also aims to enhance its position in public-private healthcare innovation and to develop scalable service models.
- The startups aim to gain market access, technological validation, and visibility. They benefit from the corporate's infrastructure, funding, and institutional credibility.
- The logistics partner participates to modernize its operations, experiment with automation and predictive analytics, and improve competitiveness in a tightly regulated market.
- The university engages to apply academic research to real-world challenges and to strengthen its role in regional innovation and knowledge transfer.

All actors share a common interest in contributing to the Twin Transition—aligning digital innovation with environmental sustainability. However, their differing strategic horizons and organizational speeds generate tensions that require continuous coordination.

How: Modes of Collaboration and Governance

The collaboration follows a hybrid governance model. Formal agreements define roles, funding flows, and intellectual property arrangements, while informal mechanisms—such as co-creation workshops, design sprints, and iterative prototyping—enable flexibility and mutual learning.

Three main collaboration types emerge:

- Co-creation and joint development of platform modules;
- Startup supplier integration, where the SME delivers AI solutions embedded in the corporate's infrastructure;
- Mentorship and knowledge exchange, supported by the university, which fosters alignment and methodological coherence.

The presence of the university as intermediary reduces transaction costs and manages asymmetries. However, challenges persist, particularly around:

- Data ownership and interoperability;
- Decision-making authority, with the corporate occasionally asserting control;
- Technological integration across partners.

Despite these issues, trust develops gradually through transparent communication, shared goals, and iterative validation.

Where: Collaboration Spaces

The collaboration unfolds across both physical and digital environments. Early engagement takes place in innovation labs and co-working spaces, enabling relationship building and co-design. As the project progresses, partners rely on digital tools and cloud platforms for remote coordination, data sharing, and development activities.

This hybrid setting provides flexibility but also generates occasional friction, especially during team onboarding or parallel project iterations. Nonetheless, the digital infrastructure proves essential for enabling distributed innovation and cross-organizational collaboration.

When: Timing and Development Stage

The Logi-Farma project remains in a very early stage. The current focus lies on partner alignment, ecosystem configuration, and the initial design of platform functionalities.

While collaboration agreements are in place and some exploratory work has started, operational deployment and full technological integration are still under development. This early phase offers insight into the challenges of initial orchestration, such as:

- Aligning timelines and expectations across diverse actors;
- Defining governance mechanisms in the absence of tested routines;
- Balancing flexibility with the need for clarity in roles and contributions.

The following table summarizes our findings:

Table 1. Summary of Findings from the Logi-Farma Case Study, according to the 6W Framework

Dimension	Categories	Description
Who	**Actors and roles**	**Big Corporate:** Orchestrates the innovation ecosystem, provides financial resources and ICT expertise. **Innovative SME:** Develops AI-driven software for logistics optimization. **Logistics Specialist:** Ensures supply chain efficiency and regulatory compliance. **Research Institution:** Provides research expertise, process modeling, AI validation, and impact assessment.
How	**Technologies**	**AI & Machine Learning:** Demand forecasting, stock optimization. **Big Data Analytics:** Real-time insights into pharmaceutical consumption. **Cloud Computing & IoT:** Smart inventory tracking and data exchange **Blockchain:** Secure drug traceability and compliance. **Automation & Robotics:** Smart dispensing units for last-mile distribution.
	Collaboration types	**Co-Creation & Joint Development:** Corporate and startup co-develop the digital platform. **Startup Supplier Program:** SME provides AI-driven solutions to corporate. **Mentorship & Knowledge Exchange:** Research Institution facilitates research integration.
	Collaboration Process	**Opportunity Detection:** Identifying inefficiencies in rural pharmaceutical distribution **Partner Search:** Selecting AI and logistics partners. **Design & Set-Up:** Developing AI-powered stock management tools.
	Collaboration Characteristics	**Duration:** Goal-oriented network. **Geographical Distance:** All partners operate within the same region. **Degree of Structuration:** Defined roles for corporates, startups, intermediaries, and research institutions. **Presence of Intermediaries:** Research institution acts as a neutral knowledge broker. **Funding & Reimbursement:** Corporate investment and public research grants.
WHY	**Motivations for Collaboration**	**Big Corporate:** Aims to expand its digital healthcare portfolio by integrating AI-driven logistics and automation solutions into pharmaceutical distribution. **Innovative SME**: Seeks market access and scalability, leveraging the corporate's resources and network. **Logistics Expert**: Participates to modernize and optimize its logistics operations, gaining access to cutting-edge solutions. **Research Institution**: Engages in the project to apply theoretical research to real-world challenges
	Challenges	**Power Asymmetries:** Corporate dominance in decision-making. **Regulatory Compliance:** Adapting AI models to strict pharmaceutical regulations. **Data Ownership & Integration:** Ensuring seamless interoperability between partners' systems

Dimension	Categories	Description
WHERE	**Domain and Context**	**Initial Deployment:** Regional pharmaceutical distribution **Scalability Potential:** National and international expansion to hospitals, global pharma logistics, and medical device tracking
WHEN	**Timing and development stage**	**Current Stage**: Very early stage of collaboration. Focus is on partner alignment, ecosystem design, and initial technological scoping. No full deployment yet; processes and governance mechanisms are still under development.

5 Discussion and conclusions

The findings from the Logi-Farma case study confirm that multi-actor collaborations, even when structurally asymmetric, can become powerful enablers of scalable digital innovation in regulated domains such as pharmaceutical logistics. By leveraging a structured and phased collaboration process—from opportunity detection to ecosystem design—Logi-Farma integrates advanced technologies including AI, blockchain, IoT, and automation to address inefficiencies in drug distribution, improve inventory management, and enhance patient adherence.

The collaboration in this study is marked by clear power asymmetries: the ICT corporation exercises control over project funding, strategic direction, and technological architecture, whereas the startups operate in a more reactive, executional role. This is consistent with literature indicating that such asymmetries can hinder trust and compromise innovation potential (Allmendinger & Berger, 2020; Polidoro & Yang, 2021). However, the presence of a neutral intermediary—in this case, the university research center—acts as a governance stabilizer, validating the SLR's emphasis on the role of intermediaries in moderating imbalances, aligning expectations, and promoting fairness within the ecosystem (Giglio et al., 2023).

The research institution plays a dual role: as a knowledge broker and a process facilitator.

The research institution plays a dual role: as a knowledge broker and a process facilitator. As a knowledge broker, it connects academic expertise with real-world challenges, translating theoretical models into actionable tools for logistics optimization (Howells, 2006; Dos Santos & Benneworth, 2019). As a process facilitator, it mediates between stakeholders with differing goals and capabilities, helping to structure collaboration workflows, align expectations, and maintain communication across organizational boundaries (Giglio et al., 2023; Schepis et al., 2021). This reflects the literature on Virtual Breeding Environments (VBEs) and Goal-Oriented Networks (GONs) (Camarinha-Matos & Afsarmanesh, 2005), where intermediaries enhance mutual understanding, reduce coordination costs, and bridge the logic gap between corporates and startups. The findings thus reinforce the theoretical claim that intermediaries are essential to managing complexity and ensuring continuity in asymmetric innovation ecosystems.

Logi-Farma illustrates how co-creation processes—such as joint development of platform modules, design sprints, and agile prototyping—can enable mutual value creation despite divergent incentives. As evidenced in previous research, motivations are often asymmetric but complementary: startups seek legitimacy, scale, and resource access; corporates pursue agility, innovation sourcing, and resilience; research institutions aim to apply and validate theoretical models. The key lies in creating a collaborative structure that allows these diverse goals to coexist and converge around a shared innovation agenda (Ricciardi et al., 2022).

Finally, the Logi-Farma ecosystem represents a goal-oriented, project-based network, a configuration particularly well-suited to contexts of uncertainty and regulatory constraint. The ecosystem is temporary, modular, and locally embedded, but designed with scalability in mind. This aligns with the concept of ecosystem fluidity and the shift from hierarchical integration to networked coordination in digital innovation (Jacobides et al., 2018). The case illustrates how such configurations support experimentation, risk sharing, and technological validation in early stages—while preserving optionality for future growth.

Stress Management and Organizational Strategies: Promoting Well-Being and Innovation in Healthcare Systems

Filomena Riemma[1], Davide de Gennaro[1], Filomena Buonocore[1], Rosario Marrapodi[2]
[1]University of Naples "Parthenope", Naples, Italy
[2]University of Campania "Luigi Vanvitelli", Italy

Abstract

The healthcare sector is characterized by intense emotional, cognitive, and physical demands that expose professionals to chronic stress, with significant consequences for their well-being and performance. Despite growing scholarly attention to stress in healthcare, little is known about the specific coping strategies that professionals employ and the organizational factors that facilitate or hinder these approaches. This study addresses this gap by examining how healthcare workers navigate daily stressors and how organizational structures can support or undermine their coping mechanisms.

Based on a qualitative research design, the study involved 41 semi-structured interviews with healthcare professionals—including doctors, nurses, psychologists, and other staff—operating in various settings. The findings reveal that organizational support plays a crucial mediating role between job demands and perceived job control. In particular, participants who reported supportive leadership, accessible resources, and open communication channels were better equipped to handle high workloads and emotional fatigue, even in contexts with limited formal autonomy.

The concept of perceived control emerges as a central theme, expanding traditional models of occupational stress. The study demonstrates that the subjective perception of being able to influence one's work environment—fostered by empathetic leadership and inclusive organizational culture—can significantly enhance resilience and reduce burnout risk. Moreover, the diversity of professional experiences in the sample underscores the importance of tailored organizational strategies that reflect the unique stressors and coping needs of different roles within the healthcare system.

By integrating insights from organizational behavior, human resource management, and health psychology, this research contributes to the development of more resilient and supportive healthcare organizations. The findings offer practical recommendations for policy-makers and managers seeking to promote employee well-being, improve job satisfaction, and sustain innovation in complex healthcare environments, particularly in the face of ongoing global health challenges.

Keywords: Stress management, Coping strategies, Healthcare, Organizational support, Professional development.

Paper type: Academic Research Paper

1 Introduction

The healthcare sector stands as one of the most demanding and high-pressure work environments in the modern world. Professionals in this field face unique stressors—ranging from the need to make swift, critical decisions, to the constant exposure to human suffering and illness, and the heavy responsibility tied to patient care (Fiabane, Giorgi, Sguazzin, & Argentero, 2013; Wang et al., 2021). Adding to this intrinsic burden are external factors, such as irregular working hours, long shifts, lack of sleep, and the unceasing need for professional updates (Shemtob, Good, Ferris, Asanati, & Majeed, 2022). These circumstances create a perfect storm, where burnout and emotional exhaustion can thrive. Furthermore, emergency situations, which are frequent in the healthcare field, exacerbate the mental and physical demands on professionals (Hijazi et al., 2022; Mirzaei, Mozaffari, & Soola, 2022).

It is within this complex environment that healthcare professionals operate daily, exposed to immense physical, emotional, and psychological stress (Søvold et al., 2021). In the long run, unmitigated stress can lead to severe consequences, affecting the mental health and well-being of these workers (Weinberg & Creed, 2000). Stress in healthcare is further compounded by chronic understaffing, which places additional workloads on already strained professionals (Cogin, Ng, & Lee, 2016; Dyrbye et al., 2017). This structural deficiency becomes more pronounced in times of global health crises, such as the COVID-19 pandemic, where resources are stretched thin, leading to higher levels of professional stress (Yusefi, Sharifi Nasabi, Rezabeigi Davarani, & Bastani, 2022).

Yet, despite the growing body of research on stress in healthcare, there is a notable gap in understanding the specific coping mechanisms that professionals employ to handle these stressors. Existing studies often focus on the general stressors of healthcare work but fail to delve deeply into the intricacies of how professionals,

individually and collectively, navigate such pressures. This lack of research is particularly pronounced when exploring the relationship between organizational structures and the efficacy of coping strategies.

While many studies have documented the stressors inherent in healthcare (Rollins et al., 2021), there is less comprehensive research into the specific strategies that professionals use to cope with these stressors and how organizations can better support these strategies. Most existing literature on coping strategies, particularly in high-stress environments, tends to generalize findings without addressing the experiences of healthcare workers.

This research aims to address the aforementioned gaps by taking a closer look at the coping strategies employed by healthcare professionals and how these strategies are supported or hindered by organizational structures. Specifically, we explore how healthcare professionals navigate their daily stressors, what strategies they find most effective, and how organizational policies can be adapted to support their well-being.

Our research seeks to answer the following questions: What are the main sources of stress for healthcare professionals? What coping strategies are most commonly employed, and how effective are they? How do organizational structures support or impede these strategies? By exploring these questions, this study aims to contribute to the growing body of literature on organizational well-being and stress management in healthcare, offering practical recommendations for improving the work environment for healthcare professionals.

This study is particularly relevant in light of the ongoing global health challenges that have placed unprecedented strain on healthcare systems. By understanding the specific coping strategies used by healthcare workers and how these strategies can be supported, healthcare organizations can make informed decisions to reduce stress, improve job satisfaction, and ultimately enhance the quality of care provided to patients. Through this research, we hope to provide actionable insights that bridge the gap between individual coping and organizational responsibility, offering a pathway toward more resilient healthcare systems.

2 Theoretical Background

Stress is a pervasive and critical issue within the healthcare sector, posing substantial risks to both the psychological well-being of healthcare professionals and the overall effectiveness of healthcare organizations. The complex and emotionally demanding nature of healthcare work frequently exposes workers to chronic stressors, which, if unaddressed, can lead to burnout, high turnover, and diminished quality of care. The Job Demands-Resources (JD-R) model (Demerouti et al., 2011) serves as a comprehensive theoretical framework for understanding how specific job characteristics contribute to these outcomes. Central to this model is the premise that each occupation is defined by a unique combination of job demands and job resources, which interact to influence employee health, motivation, and performance. In healthcare, job demands often manifest as heavy workloads, time pressure, emotional labor, and staff shortages. These demands require sustained physical or psychological effort and are associated with significant physiological and emotional costs (Bakker & Demerouti, 2017).

When these demands are not adequately balanced by job resources—defined as the physical, psychological, social, or organizational aspects of the job that support goal achievement, reduce job demands, or stimulate personal growth—the likelihood of stress-related outcomes increases significantly. Such outcomes may include emotional exhaustion, depersonalization, reduced professional efficacy, and overall dissatisfaction with one's work. On the other hand, the presence of job resources such as supportive leadership, effective communication, access to professional development, and organizational policies promoting well-being can buffer the impact of high demands. These resources not only mitigate the adverse effects of stress but also enhance motivation, engagement, and resilience among healthcare workers (Kinman et al., 2020).

The JD-R model also highlights the role of coping mechanisms in mediating the relationship between job characteristics and employee outcomes. In resource-rich environments, healthcare professionals are more likely to adopt adaptive coping strategies, including problem-solving, task prioritization, and time management. These strategies enable them to manage their workload more effectively and sustain their performance over time. Conversely, in environments where resources are lacking, workers may resort to maladaptive, emotion-focused coping mechanisms such as disengagement or emotional detachment, which may offer short-term relief but can ultimately contribute to long-term burnout (Bakker & Sanz-Vergel, 2013). This dynamic underscores the importance of organizational commitment to fostering a resource-enriched environment where healthcare workers are empowered to meet the demands of their roles.

Moreover, organizational support—particularly through leadership practices—is increasingly recognized as a critical job resource within the JD-R framework. Leaders who acknowledge the challenges faced by healthcare staff, provide emotional and instrumental support, and advocate for adequate staffing and professional development opportunities play a pivotal role in reducing occupational stress. Interventions such as resilience

training programs, mentorship initiatives, and stress management workshops can further enhance individual coping capacities and promote a healthier work culture. Through the lens of the JD-R model, it becomes clear that strategically investing in job resources is essential not only for improving employee well-being but also for ensuring the sustainability of healthcare systems. By addressing both the demands placed on workers and the supports available to them, healthcare organizations can better safeguard staff health, improve care quality, and maintain high levels of organizational performance.

3 Method

3.1 Research Design

This qualitative study explores coping strategies among healthcare professionals and how organizational structures influence them. Semi-structured interviews were used to examine stress perceptions and responses in high-pressure healthcare environments.

The sample included 41 healthcare professionals (15 doctors, 15 nurses, 6 psychologists, 5 others), selected via purposive sampling. The average age was 42, with 15 years of experience. Fifteen held managerial roles; all had at least one year in their current position.

3.2 Data Collection

Interviews lasted around 40 minutes, conducted in person or online. Questions focused on stress sources, coping strategies (problem- or emotion-focused), and available organizational support.

3.3 Data Analysis

Thematic analysis was conducted using ATLAS software in six steps, identifying key themes: (1) stress sources, (2) common coping strategies, and (3) role of organizational support. Staffing shortages and problem-focused strategies were prominent findings.

3.4 Ethical Considerations

Ethical standards were followed, including informed consent, anonymity, right to withdraw, and data protection.

3.5 Trustworthiness and Rigor

Research rigor was ensured through data triangulation, member checking, and peer debriefing with experts. that aim to respond to these gaps and guide future empirical inquiry.

4 Findings

The analysis of the interviews with 41 healthcare professionals uncovered three primary themes: sources of work-related stress, coping strategies, and the role of organizational support. These findings shed light on the day-to-day pressures healthcare professionals face, the strategies they use to manage stress, and the extent to which organizational structures support or undermine these efforts.

4.1 Sources of Work-Related Stress

A dominant theme emerging from the interviews was the range of stressors inherent to the healthcare profession. Participants frequently highlighted several critical factors contributing to their stress, and these can be grouped into three main subthemes.

4.2 Workload and Time Pressure

The overwhelming workload and time pressure were universally cited as major sources of stress. Participants reported having to care for an excessive number of patients, often under tight deadlines and high expectations. This constant rush not only left them feeling physically and mentally drained but also created a sense of ongoing pressure to perform flawlessly.

- *"The workload is really heavy, and we're always running against time. It's exhausting, both mentally and physically."* (Participant 12, nurse)

This quote reflects the almost inescapable feeling of being overwhelmed that many healthcare professionals experience. The repeated reference to exhaustion highlights how the cumulative impact of continuous high pressure leads to burnout, a common issue in the sector. Healthcare professionals are expected to manage multiple patients with complex needs, all while maintaining high standards of care, which is unsustainable in the long run. This exhaustion often compromises their mental well-being and their capacity to perform effectively.

4.3 Staff Shortages

Many participants identified staff shortages as a critical stressor that exacerbates their workload. With fewer staff to share the load, professionals found themselves juggling multiple tasks, which not only increased their workload but also heightened their emotional stress. The chronic lack of personnel in healthcare institutions made it difficult to ensure quality care, leading to feelings of frustration and helplessness.

- *"We're always understaffed, and it makes everything harder. You can't give your best when you're stretched so thin."* (Participant 21, doctor)

This statement powerfully conveys the sense of helplessness that comes from trying to provide optimal care in suboptimal conditions. The metaphor of being "stretched thin" illustrates the emotional toll that understaffing takes on healthcare workers, as they are forced to compromise the quality of care they can deliver. This not only affects their professional identity but also their sense of fulfillment, as many healthcare professionals enter the field with a desire to help, which becomes difficult when resources are scarce.

4.4 Emotional Pressure and Responsibility

Beyond the physical workload, the emotional pressure associated with patient care was a key source of stress. Healthcare professionals frequently deal with life-and-death situations, which naturally creates a significant emotional burden. The responsibility to provide high-quality care, often in emotionally charged situations, left many feeling psychologically strained.

- *"The hardest part is the emotional toll. You deal with people in pain every day, and it's hard not to take that home with you."* (Participant 8, psychologist)

This statement captures the intense emotional labor that healthcare professionals must manage. The phrase "take that home with you" poignantly illustrates how the boundaries between work and personal life blur, making it difficult to mentally disengage from the pain and suffering encountered at work. This emotional spillover can contribute to compassion fatigue, where professionals struggle to remain empathetic because they themselves are emotionally drained.

4.5 Coping Strategies

Healthcare professionals employ a variety of coping strategies to manage their stress. The interviews revealed two main categories of coping strategies—problem-focused and emotion-focused—as well as instances where participants used a combination of the two.

4.6 Problem-Focused Coping

The majority of participants preferred problem-focused coping, which involves actively addressing the causes of stress. This approach allowed them to feel more in control of their workload and gave them a sense of accomplishment by tackling problems head-on. For example, professionals emphasized the importance of task organization and time management to cope with their daily responsibilities.

- "*I always make a to-do list and prioritize the most critical tasks. It helps me stay on top of things."* (Participant 33, nurse)

This quote illustrates how organizational skills can be a powerful tool in managing overwhelming workloads. By creating a structured approach to tasks, participants felt they could regain some control over their work environment, reducing feelings of chaos. This proactive strategy contrasts with more passive approaches, allowing individuals to mitigate the sources of stress directly rather than only managing their emotional responses to it.

4.7 Emotion-Focused Coping

Some participants also engaged in emotion-focused coping to manage their emotional responses to stress. Although this approach did not necessarily reduce the actual workload, it helped individuals handle the emotional aspects of their job more effectively, especially in highly stressful or traumatic situations.

- *"I meditate for 10 minutes during my break just to clear my mind and reset."* (Participant 6, psychologist)

This excerpt highlights how techniques like meditation serve as emotional "resets" in the midst of stressful workdays. Such strategies help healthcare workers regain emotional equilibrium, allowing them to continue their tasks with a calmer mindset. While this coping method may not directly address the root causes of stress (such as high workload or emotional strain), it provides temporary relief, which is essential for maintaining psychological resilience over time.

4.8 Mixed Coping Strategies

A notable group of participants used mixed coping strategies, combining both problem-focused and emotion-focused techniques. These professionals understood that while organizing tasks was crucial, they also needed to manage their emotional well-being.

- *"I try to balance both. I focus on organizing my tasks but also make time for some deep breathing exercises during my shift to manage the emotional stress."* (Participant 29, doctor)

This response reflects a broad approach to coping, acknowledging that managing stress in healthcare requires attention to both practical and emotional dimensions. The balance between action-oriented coping (task organization) and self-care (deep breathing exercises) demonstrates an understanding of stress management, where both the mind and tasks need attention to sustain long-term well-being.

4.9 Role of Organizational Support

The role of organizational support emerged as a critical factor influencing how effectively healthcare professionals could manage their stress. Participants frequently mentioned that their coping success was strongly tied to the level of support provided by their organizations, particularly in terms of leadership, policies, and available resources.

4.10 Supportive Leadership

Many participants expressed that supportive leadership was essential in mitigating stress. Leaders who were approachable, empathetic, and involved in addressing the challenges faced by healthcare workers were seen as key allies in creating a less stressful work environment.

- *"When the leadership is supportive, it makes a huge difference. You feel like you're not alone in dealing with the stress."* (Participant 19, nurse)

This statement underscores the psychological relief that comes from knowing leadership is present and actively supportive. Feeling "not alone" in managing stress creates a sense of shared responsibility, reducing feelings of isolation and fostering a more collaborative environment. Leadership that is engaged in problem-solving can significantly reduce the burden healthcare professionals face, particularly when it comes to systemic issues like understaffing or resource shortages.

4.11 Professional Development and Training

Participants also valued opportunities for professional development and training, as these programs provided tools and techniques for managing stress and improving their skills in high-pressure situations.

- *"We have access to continuous training, and that's been really helpful. It helps you feel more equipped to handle the pressures."* (Participant 11, doctor)

This quote highlights the importance of professional growth in building resilience. Training programs not only equip healthcare workers with better tools to handle stress but also empower them by increasing their competence and confidence. Feeling "equipped" suggests that training gives professionals the mental tools they need to stay calm and effective under pressure, which can mitigate the negative effects of stress.

4.12 Inadequate Organizational Support

On the other hand, many participants felt that their organizations did not provide adequate support. They cited issues like lack of staffing, poor communication, and insufficient attention to worker well-being as exacerbating factors for their stress.

- *"We don't get the support we need from the administration. They know we're understaffed, but nothing changes."* (Participant 25, psychologist)

This quote encapsulates the frustration many healthcare professionals feel when their concerns are not addressed by the administration. The acknowledgement that leadership is aware of the problems but fails to act

intensifies feelings of powerlessness, leading to further stress. When organizations do not provide adequate support, it creates an unsustainable work environment, where workers are left to cope with systemic issues on their own.

4.13 Impact on Well-being and Performance

Effective coping strategies, particularly when supported by strong organizational frameworks, had a direct impact on the well-being and performance of healthcare professionals. Those who reported using effective strategies in conjunction with a supportive work environment noted improvements in their mental health, job satisfaction, and overall quality of care.

- *"When I feel supported, I'm able to manage my stress better, and that reflects in the quality of care I give."* (Participant 10, doctor)

This statement highlights the virtuous cycle of support and performance: when healthcare professionals feel supported, they manage their stress more effectively, which in turn enhances their ability to provide high-quality care. The link between organizational support and patient care outcomes underscores the importance of institutional responsibility in managing healthcare worker stress.

On the flip side, participants who felt unsupported or overwhelmed by stress reported diminished job satisfaction, higher levels of burnout, and a corresponding decline in their performance.

- *"The constant stress and lack of support have made me consider leaving the profession altogether."* (Participant 14, nurse)

This quote is a stark reminder of the real consequences of inadequate stress management. The consideration of leaving the profession altogether is a clear indicator of burnout, and it reflects the broader systemic issue of retaining healthcare talent in the face of mounting pressures.

5 Discussion

The primary objective of this study was to explore the coping strategies used by healthcare professionals to manage work-related stress, and to understand how organizational support structures influence these strategies. Through in-depth interviews with 41 healthcare professionals, we sought to identify the main sources of stress, examine the coping mechanisms employed by individuals, and assess the role of organizational frameworks in mitigating or exacerbating stress. The study provides new insights into the practical strategies that healthcare professionals use to navigate the high-pressure environments in which they work, while also highlighting significant gaps in organizational support.

The findings revealed several key stressors, including excessive workloads, staff shortages, and the emotional burden of caring for critically ill patients. Coping strategies employed by participants were predominantly problem-focused, such as task prioritization and time management, though emotion-focused coping strategies, like relaxation techniques and seeking social support, were also commonly used. The effectiveness of these coping strategies was heavily influenced by the level of organizational support provided, particularly in terms of leadership involvement and access to professional development resources. Conversely, inadequate organizational support, especially regarding staffing and resource allocation, often exacerbated stress levels.

6 Theoretical Implications

This study enhances the existing literature on stress and coping by applying the JD-R model (Demerouti *et al.*, 2011) specifically to the healthcare sector, a context characterized by unique demands and resource constraints (Fiabane *et al.*, 2013; Wang *et al.*, 2021). By examining the relationship between job demands, resources, and coping mechanisms, this study provides a clearer understanding of how organizational structures interact with individual strategies to mitigate or exacerbate work-related stress. The findings contribute to JD-R literature by reaffirming that resources play a buffering role against job demands (Bakker and Demerouti, 2017), while also extending the model to include relational and psychological resources as critical to managing stress in high-stakes healthcare environments.

In line with previous studies, this research identifies workload, emotional burden, and time pressure as primary job demands that intensify stress and burnout among healthcare professionals (Cogin *et al.*, 2016; Dyrbye *et al.*, 2017). The JD-R model posits that such high demands deplete employees' energy, leading to stress and burnout when left unmitigated (Bakker and Demerouti, 2017). Our findings corroborate this perspective and add depth by showing that these demands are exacerbated by chronic understaffing and the emotional toll associated with patient care (Søvold *et al.*, 2021). This study thus contributes to the growing evidence that specific healthcare stressors demand tailored resources, as outlined in the JD-R framework (Bakker *et al.*, 2014).

The buffering role of job resources is a core component of the JD-R model, as demonstrated in previous research showing that supportive leadership, professional development, and resource allocation are essential in reducing stress (Kinman, *et al.*, 2020; Strauss *et al.*, 2021). This study supports these findings by illustrating that resources like accessible leadership, continuous training, and adequate staffing not only reduce stress but also enable healthcare professionals to employ problem-focused coping strategies effectively. These insights expand on the JD-R model's assertion that resources foster resilience and job satisfaction (Bakker, 2011) by highlighting how resources tailored to healthcare can improve coping efficacy and, consequently, organizational outcomes such as patient care quality and job retention.

While the JD-R model traditionally emphasizes tangible job resources, our findings suggest that relational and psychological resources, such as perceived support from leadership and team cohesion, are equally important in high-demand settings like healthcare (Strauss *et al.*, 2021; Saha *et al.*, 2011). Healthcare professionals reported that supportive leadership enhanced their perceived control and mitigated feelings of helplessness, which aligns with the findings of Carrillo-García *et al.*, (2018) regarding the influence of perceived control on stress levels. This study suggests that integrating these relational and psychological resources into the JD-R framework could refine its applicability in high-stakes environments by recognizing that perceived support can buffer job demands effectively, even when formal autonomy is limited (Urbanetto *et al.*, 2013).

Consistent with Warr's (1994) Organizational Well-being Model, our findings reinforce that healthcare organizations need to align job demands with resource availability to reduce stress effectively. This study contributes to the JD-R framework by demonstrating that resource allocation strategies, such as improved staffing and training opportunities, are vital in high-pressure settings (Brand *et al.*, 2017). Aligning with the insights of Siegrist *et al.*, (2019), our research further suggests that organizations should implement both tangible and intangible resource strategies to maintain job satisfaction and engagement. The JD-R model can therefore guide healthcare organizations in making targeted resource investments to alleviate the demands associated with healthcare roles.

Finally, this study extends the JD-R model by emphasizing its relevance in healthcare and proposing its applicability across other high-stress professions. The findings suggest that relational and psychological resources—such as peer support, leadership empathy, and recognition—can buffer job demands effectively in high-stakes environments where traditional autonomy is limited (Kinman *et al.*, 2020; Strauss *et al.*, 2021). Future theoretical work could further refine the JD-R model to include relational resources, providing a more comprehensive framework for stress management in high-demand sectors where teamwork and leadership engagement are central (Bakker *et al.*, 2014).

7 Ethics Declaration

This research involved human participants and followed all institutional and national ethical standards. Participation was voluntary, and informed consent was obtained from all individuals involved. No personal or sensitive data have been disclosed.

8 AI Declaration

No generative artificial intelligence tools were used in the preparation of this manuscript.

Abstract

Workplace safety is increasingly recognized not only as a matter of regulatory compliance but as a collective, knowledge-based infrastructure that must be cultivated early and systemically. In response to this challenge, the "Let's Play 81!" project introduces a school-based, game-driven educational pathway aimed at promoting occupational safety awareness among students aged 8 to 13. Developed in alignment with Italy's updated safety legislation (Legislative Decree 81/2008, reform 2024), the project reframes prevention as a civic competence rooted in shared knowledge, care, and responsibility.

The initiative was piloted in four public schools in central Italy, involving 198 students, 20 teachers, and 4 certified safety trainers. It employs analog games—developed and validated by occupational health experts—as tools to activate learning through play. Three distinct games simulate safety challenges in fictional yet relatable settings. These tools enable students to interact with roles, rules, and consequences, encouraging reflection, dialogue, and collective problem-solving.

The study adopts a mixed-methods approach. Quantitatively, it measures knowledge acquisition using a pre/post quiz (81Questionnaire), revealing a significant improvement in the intervention group (+4.43 points on average, $p < 0.001$). Qualitative data from teacher and trainer feedback underscore increased engagement, emotional involvement, and transversal learning outcomes (e.g., collaboration, attention, civic sense).

From a knowledge management perspective, the project demonstrates how structured play can serve as a conduit for transmitting tacit and explicit knowledge in early education contexts. It also fosters interinstitutional collaboration among schools, Universities, and training bodies, suggesting a model for distributed governance in prevention.

"Let's Play 81!" offers a replicable framework to embed safety culture through experiential, inclusive, and cognitively rich learning. It contributes to the broader discourse on how public value can be co-generated through educational innovation and how knowledge-intensive processes—like risk awareness and prevention—can be activated far beyond the boundaries of formal workplaces.

Keywords: Safety Culture, Gamification, Knowledge Transfer, Preventive Education, Public Value Creation

Paper type: Academic Research Paper

1 Introduction

Workplace safety is a foundational component of social and economic sustainability. It is not only a matter of regulatory enforcement, but a cultural and educational issue that requires long-term investment in people, systems, and communities. The promotion of a shared safety culture is increasingly seen as a collective responsibility, to be cultivated throughout the life course, starting from early educational stages.

In Italy, this perspective has been reinforced by the recent reform of Legislative Decree 81/2008, approved in 2024, which expands institutional accountability and underlines the importance of preventive education (Quotidiano Sanità, 2024). The updated regulatory framework encourages the involvement of schools and local authorities in disseminating safety-related knowledge and values, in line with international recommendations promoting prevention as a civic competence and a shared ethical duty.

Within this context, the project "Let's Play 81!" introduces a structured and gamified approach to workplace safety education in primary and lower secondary schools. The initiative takes its name from the core Italian law on occupational health and safety (D.lgs. 81/08), but its objectives are pedagogical rather than juridical. Developed within a regional pilot framework, the project aims to promote risk awareness, responsibility, and care among children aged 8 to 13, through playful and accessible formats.

The activities are designed and implemented by certified safety educators, in collaboration with schools, institutional stakeholders, and local authorities. The tools used in the project—such as board games and interactive materials—are grounded in recognized pedagogical principles and validated content. They are meant to engage students emotionally and cognitively, helping them to internalize basic concepts of prevention and safety as part of their everyday experience.

"Let's Play 81!" responds to the evolving educational and legislative landscape by proposing an innovative yet grounded intervention model. It aims to contribute to a broader process of safety culture formation, in which schools play a proactive and strategic role in shaping future citizens who are not only aware of risks, but capable of managing them collectively.

2 Theoretical framework

The promotion of occupational health and safety (OHS) as a lifelong competence requires the integration of educational, cultural, and regulatory dimensions. In recent years, a growing body of literature has emphasized that safety culture cannot be reduced to procedural compliance; rather, it emerges through situated learning, social interaction, and value-based communication (Gherardi, 2006; Reason, 2000). In this view, schools are not merely preparatory spaces for future work—they are active contexts in which foundational attitudes toward prevention, responsibility, and care can be developed.

A key contribution to this approach comes from experiential learning theory, which highlights the role of direct engagement in consolidating both conceptual understanding and personal meaning (Kolb & Kolb, 2010). Educational experiences that combine action, reflection, and emotional involvement help learners construct durable knowledge structures and increase their sense of agency. These principles are particularly relevant in the context of safety education, where behavioural awareness and practical judgement are as important as factual knowledge.

Learning through play, especially in structured educational settings, has also been widely recognized as a valid pedagogical strategy (Singer et al., 2006; Barnett, 2007). Play enables learners to simulate real-life situations, manage emotional responses, and explore complex dynamics such as risk and interdependence in a safe and controlled environment. This is especially important for children, who benefit from multimodal, emotionally rich formats that sustain attention and foster retention.

From a policy and organizational standpoint, the integration of safety education in schools aligns with international strategies that promote prevention as a shared cognitive and civic infrastructure, rather than a task delegated only to employers and adult workers. In this context, the revised Italian law on OHS (D.lgs. 81/08, updated in 2024) explicitly invites schools and local institutions to play an active role in disseminating a culture of safety, with a focus on early educational engagement (Quotidiano Sanità, 2024).

This framework justifies the development of targeted interventions such as "Let's Play 81!", which aims to build knowledge and awareness around workplace safety by using methods that are pedagogically appropriate and emotionally resonant. It also underlines the strategic role of educational innovation in supporting national and regional policy objectives related to health, prevention, and social responsibility...

3 Project Overview: Let's Play 81!

"Let's Play 81!" is a pilot initiative that promotes early education in occupational health and safety (OHS) through playful, age-appropriate methods. It is addressed to students aged 8 to 13 and implemented in selected primary and lower secondary schools in central Italy. The project takes its name from Legislative Decree 81/2008—the cornerstone of Italian workplace safety regulation—and responds to recent normative developments that emphasize the involvement of educational institutions in the promotion of a shared culture of prevention (Quotidiano Sanità, 2024).

The initiative is promoted by a partnership of three Universities, Universitas Mercatorum, _University "San Raffaele" and Sapienza University of Rome, with professionals specialized in occupational safety. It was developed within a public call for proposals and funded as a regional pilot action, in line with broader educational and health promotion strategies at the local level.

The project aims to foster the acquisition of basic knowledge and attitudes related to workplace safety, risk awareness, and mutual care, using non-formal and game-based educational tools. The materials used—such as board games and printed resources—were designed and validated by certified OHS professionals to ensure pedagogical appropriateness and technical accuracy. These tools present safety concepts in an accessible and engaging way, adapted to children's cognitive and emotional development.

The intervention consists of classroom-based sessions led by qualified trainers, in collaboration with teachers. Each session is structured around the use of a game as a catalyst for reflection, discussion, and

participatory learning. The experience is further supported by an educational “toolkit” that includes visual aids and reference materials, designed to reinforce key prevention messages.

Beyond the educational activities, the project also facilitates collaboration among schools, local authorities, and training institutions, creating a network-based approach to safety education. Insights from the pilot schools are being analysed to inform future scaling and possible integration into broader civic education programmes.

4 Methodology

The “Let’s Play 81!” project adopts a structured pedagogical methodology based on experiential and active learning principles. The intervention aims to convey foundational messages related to occupational health and safety (OHS) to children aged 8 to 13 using analog, game-based tools designed specifically for educational contexts. The sessions are led by certified safety trainers in collaboration with classroom teachers.

The use of games as educational devices is supported by research on learning through play and engagement (Singer et al., 2006; Barnett, 2007). Structured gameplay facilitates memory, reflection, emotional involvement, and peer interaction—critical factors in internalizing complex concepts such as risk, responsibility, and prevention.

The study was conducted following CONSORT guidelines ().

A teaching kit was created, consisting of a box (30×20×10cm) containing an operational manual and the materials necessary for three different types of games: a role-playing game ("81 si gira!"), a board game ("Riduci il premio"), and a card game ("Mettici la mano").

81 Action! (81 si gira!) is a role-playing game in which each player takes on a character involved in workplace safety (e.g., employer, prevention officer, inspector, workers’ representative). Players collectively address safety scenarios presented through “story cards” and engage in dialogic problem-solving based on their assigned responsibilities. The game encourages cooperative reflection, active listening, and contextualized reasoning within safety frameworks.

Reduce the Premium! (Riduci il premio!) is a board game inspired by Monopoly mechanics, where each player represents a company seeking to reduce its insurance premium. Players navigate a board with 30 squares and interact with “True/False” questions, “Credits” knowledge tests, and “Action” cards representing correct or incorrect safety behaviours. Game dynamics simulate INAIL’s incentive system (“oscillation for prevention”) to enhance understanding of cost-risk relationships in prevention strategies.

Your Hand on It! (Mettici la mano!) is based on the Italian card game “Tappo”, this game uses character-based decks and reflex dynamics. Players attempt to collect four identical character cards and then quickly place their hands on the table to answer a safety-related question. Speed, memory, and correct responses determine the winner. The game reinforces vocabulary, roles, and basic concepts of responsibility in a competitive yet playful format.

Each activity is accompanied by an educational “toolkit” including printed materials, visual aids, and question decks. Trainers facilitate gameplay and support classroom discussions on key messages. Teachers help contextualize the content within broader civic and health education curricula.

Feedback was collected qualitatively through observation sheets and reflections from both students and teachers. The modular format of the activities allowed for local adaptation without compromising educational consistency. All materials were aligned with the content and spirit of Legislative Decree 81/2008 and updated guidelines on prevention in educational settings.

5 Preliminary results and observations

The field trial of the “Let’s Play 81!” gamified training course was conducted in three lower secondary schools in Rome. Ten third-year classes were invited to participate (n = 226 students, 100% adherence rate). On the day of the intervention, 36 students were absent, leading to 190 students actually participating (mean age: 13.08 ± 0.36 years; 49.5% female). Students were randomly divided into two arms: Intervention Group (IG, n = 97) and Control Group (CG, n = 93). Three students from the CG were later excluded due to incomplete questionnaires, resulting in n = 90 analyzable CG participants.

The learning outcome was measured using the Score81 tool, a 15-question multiple-choice test administered pre- and post-intervention (T0, T1). The quiz was validated in previous research (Cronbach’s $\alpha > 0.70$).

Statistical analysis showed:

- At T0 (baseline), no significant difference in Score81 between IG and CG ($p = 0.597$)
- At T1, IG showed a significant increase in knowledge: from 4.87 ± 2.41 to 9.30 ± 2.89 ($p < 0.001$)

while CG remained unchanged: from 4.69 ± 2.14 to 4.60 ± 2.41 ($p = 0.617$)

Δ Score81 (mean increase):

- IG: +4.43 points (SD = 2.98, $p < 0.001$)
- CG: +0.09 points (SD = 1.68, $p = 0.617$)

These results are summarized in the following table:

Table 1 – Score81 results: Comparison between Intervention Group (IG) and Control Group (CG)

Group	T0 Mean ± SD	T1 Mean ± SD	Δ (T1 – T0)	p (within group)
CG (n = 90)	4.69 ± 2.14	4.60 ± 2.41	+0.09	0.617
IG (n = 97)	4.87 ± 2.41	9.30 ± 2.89	+4.43	< 0.001

Legend: T0 = pre-intervention; T1 = post-intervention; p = paired t-test.

Qualitative observations collected by trainers and teachers indicated strong student engagement during the sessions. Feedback highlighted the games' capacity to stimulate memory, collaboration, and emotional connection to content. Teachers also noted improvements in cooperative behavior and class cohesion. These transversal benefits are consistent with the broader aims of civic education.

While promising, the results must be interpreted considering certain limitations: no long-term follow-up was conducted, the sample was limited to Roman schools, and randomization occurred at class level, not individual. These factors may limit generalizability but confirm feasibility and impact in school-based prevention education.

6 Policy and practical implications

The results of the "Let's Play 81!" pilot intervention underscore the strategic value of integrating occupational health and safety (OHS) education into the formal school curriculum, starting from lower secondary levels. The observed increase in safety-related knowledge among students in the intervention group, combined with positive feedback from teachers and trainers, points to the efficacy and relevance of non-formal, game-based methods in promoting a preventive mindset from an early age.

This educational approach aligns with the evolving normative framework at the national level. The 2024 amendment to Legislative Decree 81/2008 has explicitly strengthened the role of educational institutions in cultivating safety culture, emphasizing the need for early engagement, active methodologies, and territorial partnerships (Quotidiano Sanità, 2024). "Let's Play 81!" anticipates and operationalizes this policy direction, offering a concrete example of how schools, municipalities, and certified OHS trainers can collaborate to disseminate prevention principles in accessible and sustainable formats.

The implications of this model are both practical and systemic:

- Educational innovation: The project demonstrates that analog, low-tech games can be powerful tools for teaching complex safety concepts. This is particularly relevant in under-resourced contexts where digital infrastructures are limited.
- Scalability and replicability: The modular design of the toolkit and the structured delivery method enable adaptation across different school levels and regional contexts. The experience of "Let's Play 81!" can inform the development of regional or national guidelines for integrating safety into civic education.
- Transversal competencies: Beyond safety knowledge, the intervention supported broader learning outcomes, including collaboration, communication, and responsibility—skills that are central to both education for sustainable development (ESD) and lifelong learning agendas.
- Institutional coordination: The project illustrates the importance of cross-sectoral governance in health promotion. By involving schools, municipalities, and training bodies, it fosters an integrated approach consistent with international health and safety strategies (e.g., WHO, ILO).

These findings suggest that gamified OHS education can serve not only as a learning innovation, but also as a policy instrument to reinforce a systemic, community-based culture of prevention. Further development, including long-term evaluation and broader stakeholder engagement, could support its institutionalization within national educational frameworks.

7 Conclusions

The "Let's Play 81!" project represents a concrete and innovative response to the growing institutional and societal demand for the early promotion of a safety culture. By combining non-formal learning, analog gamification, and school-based delivery, the initiative has proven both feasible and effective in enhancing students' understanding of occupational health and safety (OHS) principles.

Quantitative results confirm a statistically significant improvement in students' knowledge following participation in the intervention, while qualitative feedback highlights strong engagement, emotional

involvement, and relevance to broader educational goals. These findings demonstrate that playful, interactive approaches—when pedagogically structured—can be powerful vehicles for developing civic responsibility and risk awareness.

At a policy level, the project aligns with the 2024 update to Legislative Decree 81/2008, which reinforces the educational sector's role in prevention. "Let's Play 81!" anticipates this shift by offering a practical model for inter-institutional cooperation and early intervention in the development of safety competencies.

Looking ahead, several areas of development are envisioned:

- Long-term evaluation: Future studies will assess knowledge retention, behavior change, and transversal impact over time, including follow-up with teachers and families.
- Toolkit optimization: Based on pilot feedback, the game materials and facilitation strategies will be refined to improve clarity, inclusivity, and alignment with curricular objectives.
- Broader dissemination: Institutional partnerships will support the scaling of the initiative to other regions, potentially integrating it into national health promotion or civic education programs.
- Research integration: Opportunities exist to expand the scientific evidence base on gamified prevention strategies in schools, contributing to interdisciplinary knowledge on health education and learning innovation.

In sum, "Let's Play 81!" affirms that promoting workplace safety is not solely a matter of compliance or training—it is a cultural investment that begins in school, through methods that are participatory, inclusive, and cognitively rich.

8 Ethics declaration

Ethical approval was obtained from Universitas Mercatorum Ethical Committee on March 13, 2025 (Prot. 0617). The study adheres to the principles outlined in the Helsinki Declaration of 1975, as revised in 2000 (The world medical association, 2008).

9 AI declaration

The authors declare they did not use AI tools in developing the paper .

Abstract

Digital transformation, board characteristics, and environmental performance are increasingly significant in the realm of corporate sustainability. Numerous scholars assert that digital transformation can serve as a powerful catalyst for sustainable corporate development, delivering substantial benefits to both businesses and society. Digital transformation refers to the process through which companies evolve from traditional industrial stages to the Industry 5.0 paradigm, which integrates technological innovation with human-centric approaches.

According to the stakeholder theory, firms operate within an interconnected system encompassing economic, social, environmental and political dimensions, and enhancing corporate profitability has become an essential requirement for stakeholders. In this context, digital transformation can substantially boost corporate productivity and contribute to achieving sustainable development goals, thereby acting as a primary factor through which stakeholders can compel firms to initiate transformation processes.

Furthermore, companies are increasingly subjected to pressures from stakeholders who are placing greater emphasis on environmental issues, compelling them to adopt proactive environmental governance strategies. However, despite the extensive development of literature on digital transformation and environmental performance, studies analyzing the potential moderating role of board characteristics remain limited. This paper aims to bridge this gap by exploring the relationship between digital transformation and environmental performance, considering the specificities of board characteristics.

The existing empirical literature often employs textual analysis to quantify the extent and quality of digital transformation. Similarly, in this study, the construction of the digital transformation indicator is achieved through keywords selected based on prior literature, including: big data, informatization, intelligence, robotics, Internet of Things, blockchain, automation, digitization, and cloud computing.

Based on this method to measure the digital transformation efforts, we investigated the potential moderating effect of board gender diversity on the relationship between digitalization and corporate environmental performance, using data from Italian publicly listed companies for the year 2023.

The results of the empirical analysis indicate that 1) digital transformation has a positive and significant impact on corporate environmental performance, and 2) that impact of digital transformation on environmental performance is reinforced by a higher presence of female directors on corporate boards.

These findings provide potentially valuable insights to a diverse audience. Firstly, to companies engaged in digitalization processes. Secondly, to developing countries still in the Industry 3.0 or Industry 4.0 phase. Thirdly, to governments of developed countries, to promote national technological growth, monitor companies, and establish appropriate regulatory frameworks for the digital era.

Keywords: digital transformation, female directors, critical mass, CSR performance

Paper type: Academic Research Paper.

1 Introduction

In recent decades, driven by the progress of industrialization, Italy has established itself as one of the leading global economies, with a strong manufacturing sector that has secured its position in major international markets (Ministry of Economic Development, 2018). As of 2019, Italy accounted for approximately 2.3% of global GDP and was the second-largest manufacturing economy in Europe, after Germany. However, industrial growth has also posed significant environmental challenges, with the industrial sector remaining one of the primary sources of CO_2 emissions (Ministry of the Environment, 2020). These figures underscore a critical challenge for Italian industry: how to reconcile economic development with environmental sustainability.

Within this framework, Italy's digitalization and Industry 4.0 transition policies play a pivotal role in ensuring that the industrial sector can effectively address sustainability challenges. Like other European countries, Italy has embraced the Industry 4.0 paradigm. The Italian government launched the National Industry 4.0 Plan to foster the digitalization of the manufacturing sector, aiming to modernize firms through the adoption of advanced technologies such as the Internet of Things (IoT), artificial intelligence (AI), and robotics (Ministry of Economic Development, 2018). Through the Transition 4.0 Plan, which later evolved into the Transition 5.0 Plan,

fiscal incentives were introduced to encourage the adoption of technologies capable of reducing energy consumption and enhancing firms' production efficiency.

However, several studies emphasize that, despite the growth in investment, Italian firms – while benefiting from public funding – frequently fail to introduce substantial strategic changes. Instead, these firms often prioritize utilizing the funds to secure short-term tax benefits, rather than pursuing meaningful enhancements in their production processes or business models (Bocci et al. 2023; Bronzini and Piselli 2016; Czarnitzki and Lopes-Bento 2014).

In the evolutionary transition toward the next phase of industrial development, Industry 5.0 (I5.0) emerges as a new paradigm that integrates technological innovation with human-centric approaches, aiming to overcome the limitations of Industry 4.0 (I4.0) and to foster sustainability across its economic, environmental, and social dimensions (Sarkar et al. 2024). This paradigm represents an advanced stage of industrial progress in which the synergy between technological capabilities and human creativity enables the implementation of highly customized, efficient, and sustainable Smart Manufacturing (SM) solutions (Grabowska, 2022).

Industry 5.0 is grounded in the integration of emerging technologies such as Artificial Intelligence (AI), the Internet of Things (IoT), collaborative robotics (cobots), and advanced big data analytics.

Unlike I4.0, which focused on automation and data-driven efficiency, I5.0 emphasizes the centrality of human involvement in production systems, promotes mass customization models, and advances a systemic commitment to sustainability.

Digital transformation has significantly increased the volume of data available to firms. In this context, technological innovations such as the Internet of Things (IoT), cyber-physical systems, and artificial intelligence are increasingly integrated with traditional enterprise information systems (Garzella, 2018), enabling the collection and analysis of large volumes of data to convert them into actionable insights that support decision-making processes (Nielsen and Montemari, 2021).

Corporate governance theory posits that the board of directors plays a critical role in aligning corporate strategy and promoting sustainable business development (Sahar et al. 2018). Moreover, the board can offer valuable support through technological expertise and experience, thereby helping to mitigate the risks associated with digital transformation (Davis and Cobb, 2010).

According to recent studies, the effectiveness of digitalization in improving corporate environmental performance may be influenced by the characteristics of the board of directors and top management (Sahar et al. 2018; Westerman and Bonnet, 2015; Orazalin and Baydauletov 2020). Corporate governance theory and resource dependence theory suggest that a diverse board in terms of age, gender, education and political ties can facilitate digital transformation, reduce the associated risks and enhance environmental performance (Cabeza-García et al. 2019; Song et al. 2020; Sarto et al. 2019)

However, the findings from empirical studies examining the relationship between board structure and corporate environmental performance (CEP) remain inconclusive (Beji et al. 2021; Khan et al. 2013). The existing research predominantly investigates the direct impact of board structure on either environmental performance or digital transformation, but tends to overlook the potential moderating role of board structure in both domains. This research aims to fill this gap, specifically by investigating the moderating role of board gender diversity. In order to do so, we performed a multiple regression (OLS) analysis on a sample of Italian listed firms.

The empirical findings suggest that digital transformation has a positive impact on environmental performance and that firms with a higher representation of women on their boards of directors appear more inclined to adopt digital transformation initiatives that enhance environmental performance. These results contribute in several ways to the existing research on digital transformation and environmental performance.

First, while previous studies have examined the impact of digital transformation on corporate sustainability, they have often relied on literature reviews and conceptual frameworks (Zhu et al. 2021). Instead, our study adopts a textual analysis approach to quantify the level of digital transformation and empirically assess its impact on environmental performance (Zhai et al. 2022). Second, we examine the interaction effect of board structure and digital transformation on environmental performance, thus verifying the strategic role of the board in shaping decisions related to the adoption of digital transformation initiatives.

The remainder of this paper is structured as follows: the *Literature Review* section presents prior research on digital transformation, corporate environmental performance (CEP), and the moderating role of board structure; the *Variable Description and Methodology* section outlines the data sources and econometric methods used; the *Regression Results and Discussion* section presents the empirical findings and their interpretation; and finally, the *Conclusion and Policy Implications* section summarizes the study, discusses practical implications and the study's limitations, while also outlining future research directions.

2 Literature review and hypotheses development

2.1 Digital transformation and Corporate Environmental Performance (CEP)

A growing body of scholarly research posits that digital transformation serves as a strategic enabler for corporate sustainable development, generating substantial value for both businesses and broader society (Shabur, 2025). According to stakeholder theory (Waheed et al. 2020), firms operate within complex and interrelated economic, social, environmental, and political domains, where enhancing corporate profitability has emerged as a core expectation among stakeholders (Iyigün 2015).

Within this framework, digital transformation is increasingly recognized as a critical driver for improving organizational productivity and advancing sustainability goals, thereby motivating firms to embrace digital technologies in response to stakeholder pressures (Bertani et al. 2020; Dyatlov et al. 2019).

Furthermore, drawing on information processing theory (Premkumar et al. 2005), digital technologies are understood to enhance the efficiency of information management processes, thereby improving organizational responsiveness and reinforcing competitive advantage (Khin and Ho 2019; Chen et al. 2015). By enabling real-time visibility into operational activities and facilitating more effective resource allocation, digital transformation supports agile and data-driven decision-making aligned with sustainable business practices.

Moreover, digital transformation enhances transparency in business management and operations toward stakeholders, contributing to building trust (Kyaw et al. 2022). In fact, companies are facing increasing pressure from various stakeholders—especially those focused on environmental issues—pushing firms to adopt proactive environmental governance strategies. These strategies are not only environmentally effective but also financially beneficial, attracting external capital (Cronkleton et al. 2008).

Based on the theoretical analysis above, we propose the following hypothesis:

- *Hypothesis 1. Digital transformation can improve corporate environmental performance.*

2.2 The moderating effect of board structure

Several studies have investigated how board diversity influences environmental and sustainability practices, examining aspects such as board diversity, greenhouse gas disclosures, and the presence of environmental committees (Liao, 2015), female directorship and corporate sustainability (Galbreath et al. 2011), and compliance-oriented approaches to sustainability practices (Nadeem et al. 2017).

Some research highlights that women tend to be more sensitive to environmental and social protection (Post et al. 2015). Other studies point to a direct impact of board diversity on actual environmental performance (Glass et al., 2016) and emphasize the relationship between board composition and corporate sustainability performance (Naciti et al. 2019). The presence of female board members has also been shown to facilitate communication and the dissemination of information, which in turn supports strategic innovation within the firm (Smulowitz and Smulowitz, 2024; Song et al. 2020; Sarto et al. 2019).

Furthermore, with the evolution of information technologies, more women are increasingly participating in corporate decision-making processes (Cabeza-García et al. 2019). Based on the above theoretical analysis, we propose the following hypothesis:

- *Hypothesis 2. Female directors can strengthen the positive relationship between digital transformation and environmental performance.*

3 Research methodology

3.1 Sample

Our initial sample comprised all firms listed in the Italian stock exchange in the year 2023. Data were collected from multiple sources. The ESG scores were collected from the Refinitiv Eikon database, now LSEG Data & Analytics. Financial and accounting data were sourced by AIDA. Corporate governance data such as the number of female directors, and board size were hand-collected from the corporate governance reports.

After removing firms with missing data and financial firms we were left with a final sample of 90 firms. This is mainly due to the limited number of ESG scores available on Refinitiv Eikon for Italian listed firms.

3.2 Variable measurement

The corporate environmental performance is measured using the environmental score provided from the Refinitiv Eikon database. This score measures firms' environmental performance based on public information

data, taking into account comparability, data availability, and industry relevance, ranging from a minimum of 0 to a maximum of 100.

The independent variables of interest in this study are digital transformation (DT) and board gender diversity as measured by the percentage of female directors on the board.

In order to measure digital transformation, this study builds upon previous empirical work, which established and validated a digitalization dictionary that identifies the words that a qualified public (made up of professors, PhD students, graduate and undergraduate students) associates with firms' digitalization efforts (Hossnofsky and Junge 2019). This study summarizes and organizes keywords related to digital transformation and uses Nvivo software to match text content in companies' annual reports to determine the number of words related to digital transformation, wherein more times words related to digital transformation appear in an annual report, the higher the degree of digital transformation is for that enterprise. To reduce statistical errors, we excluded judgmental words, such as none, not, and no, before and after the word field. Thus, we came up for each firm with the total number of digital transformation-related words, as a measure for the degree of firm digitalization.

As additional control variables at firm level, we include firm size, the debt-to-equity ratio and the return-on-assets (ROA) ratio. The control for firm size is particularly important because ESG scores can be subject to firm size bias (Drempetic et al. 2020) as bigger firms may use economies of scale to enhance ESG performance. We use the natural logarithm of employee number as a proxy for firm size. The debt-to-equity ratio is used as a proxy for firm leverage to control for the impact of financial risk on firm ESG performance (Simnett et al. 2009). As more profitable firms are more likely to have better ESG performance, we also control for firm profitability using the ROA ratio (Liang and Renneboog 2017). Industry effects are also accounted for.

Table 1 summarizes the definition and measurement of all the variables used in the econometric analysis.

Table 1. Variables definition and measurement

Variable	Description	Source
CEP	Corporate Environmental score	Refinitiv Eikon
DT	Number of digitalization related words in annual reports	Company annual Report
BGD	Percentage of female directors on the board	Corporate Governance Report
Lev	Leverage ratio	AIDA Database
Cash	Cash ratio	AIDA Database
Firm size	Log-transformed of number of employees	Corporate Governance Report
ROA	The percentage of return on assets	AIDA Database
Leverage	Total debt/total assets	AIDA Database

4 Results

In order to test our hypotheses, we estimate the following model by using an ordinary least squares (OLS) regression, where the digital transformation variable (DT), the percentage of women on board (BGD) and their interaction term (DT*BGD) are the main variables of interest:

CEP Performance (CEP) = b_0 + b_1DT + b_2 DT*BGD b_3 + b_4Firm size + $b_5$cash ratio + b_6Leverage + Industry + ε

Table 2 presents the descriptives statistics and pairwise correlations between the variables. The average value of the CEP performance is 64.74 with a standard deviation of 16.20 which indicates a large variation in this performance measure. The boards of Italian listed firms are composed on everage for the 39% by female directors.

The results of the correlation analysis show that the independent variable of interest, the percentage of female directors, has a positive and significant association with the CEP variable, providing some initial support to our first research hypothesis. Furthermore, as the variance inflation factors (VIF) values are well below the warning value of 10 (Myers 1990), we can conclude there are no significant multicollinearity issues in our regression.

Table 2. Means, standard deviations, VIF and pairwise correlations

	Mean	SD	VIF	1	2	3	4	5	6	7
1. CEP	54.8	16.9		1.00						
2. DT	2.31	1.44	1.88	0.271*	1.00					
3. BGD	38.72	12.14	2.87	0.484*	0.089	1.00				
4. Firm size	6.05	0.19	1.77	0.406*	0.190	0.096	1.00			
5. LEV	0.52	3.34	1.52	0.118	-0.009	0.155	0.207	1.00		
6. Cashratio	0.43	0.32	2.24	0.219*	-0.066	0.108	-0.122	-0.014	1.00	
7. ROA	1.83	7.80	1.64	0.238*	-0.01	-0.11	-0.15	0.10	0.07	1.00

***, **, * indicate significance at 0.1% and 1% and 5%, respectively.

Table 3 presents the estimation results of our econometric model with (model 1) and without (model 2) the interaction effect of board gender diversity. Our first hypothesis predicts that digital transformation can improve corporate environmental performance. As column (1) shows, the regression coefficient on the DT variable is positive and statistically significant ($\beta = 2.84$, $p < 0.05$). This would suggest that digital transformation can improve better CSR performance. H1 is thus supported. This result is consistent with previous research such as Chen and Hao (2022) and Wang et al. (2025) which also find a positive association between and digital transformation and environmental performance.

Column (2) shows the estimation results including the moderating variable. Our second hypothesis predicts that the proportion of female directors positively moderates the association between the digitalization and environmental performance. The positive coefficient on the interaction term DT*BGD ($\beta = 0.18$, $p < 0.05$) lends support to this hypothesis as well. It implies that board gender diversity reinforces the positive impact of digitalization on corporate environmental performance.

As regards the control variables at board level, we find that board size has a positive association with CEP, thus supporting the argument that large boards may boost the firm's environmental performance because they are more effective in balancing the interests of diverse stakeholders' groups.

Regarding the other control variables, we find that firm size is positively related to environmental performance, suggesting that the larger the firm size, the more likely the firm is to engage in CSR activities. The coefficient estimates on ROA and leverage are respectively positive and negative.

Table 3. Multiple regression analysis with main and interaction effects

	Environmental performance	
	Model 1	**Model 2**
DT	2.84*	1.94*
	(1.24)	(0.98)

***, **, * indicate significance at 0.1% and 1% and 5%. In parentheses are t statistics.

4 Conclusions

This paper sets the stage for further exploration into corporate environmental governance within the framework of Industry 5.0. To the best of our knowledge, empirical studies that investigate how digital transformation influences environmental performance through the lens of board characteristics are relatively limited. This research is an attempt to fil this gap. Specifically, we investigated the potential moderating effect of board gender diversity on the relation between digitalization and corporate environmental performance, using data from Italian publicly listed companies relating to the year 2023.

Our empirical findings reveal that digital transformation significantly enhances corporate environmental performance (CEP), providing a theoretical foundation for harmonizing economic growth with environmental sustainability. Additionally, the empirical findings indicate that gender diversity positively moderate this relationship. In other words, firms with a higher proportion of female directors would be more likely to embrace digital transformation initiatives that improve environmental outcomes. These insights underscore the importance for companies navigating the transition to Industry 5.0 to recognize the evolving composition of their boards and to adjust the gender balance accordingly to mitigate transformation-related risks and advance sustainable development.

Several policy and managerial recommendations may result from these findings.

Companies should increase diversity on corporate boards, particularly by involving more female directors, as a means to reduce the environmental risks associated with digital transformation. Second, companies should develop regular training programs to keep board members and executives informed about the latest industry trends and management innovations, helping to challenge outdated managerial mindsets.

Governments on their behalf should enhance the development of digital infrastructure to support the digital transformation of enterprises. Second, they should establish and refine environmental monitoring systems, along with incentive and penalty mechanisms, to help reduce the environmental management costs for businesses. By leveraging digital technologies, governments can monitor enterprises' environmental performance and offer targeted subsidies to encourage greater engagement in environmental protection (Chen and Hao 2022).

Nonetheless, this study presents several limitations. First, it uses textual analysis to evaluate digital transformation, which may not fully capture the nuances among the digital transformation strategies of firms. It should also be considered that firms may engage in narrative disclosures that may not reflect their actual digitalization efforts. Second, while this study examines the moderating role of board characteristics, it does not consider the underlying mechanisms by which digital transformation may improve corporate environmental performance. Additionally, our focus is limited to board gender diversity, neglecting other potentially influential attributes of corporate boards such as directors' professional backgrounds, cultural diversity and nationalities. Future research could address these limitations possibly by employing longitudinal data, as this study's reliance on cross-sectional data constitutes another limitation.

5 Ethics declaration

This study did not involve procedures requiring ethical clearance, and no ethical approval was necessary for the research conducted.

6 AI declaration

The authors confirm that no artificial intelligence tools were used in the preparation or production of this paper.

Navigating Sustainable Corporate Governance in the Age of Artificial Intelligence: Primary Evidence from Italy

Giacomo Gotti, Angela Oksana Fiorella, Carla Morrone, Valerio D'Ovidio
Sapienza University of Rome, Rome, Italy

Abstract

In the current economic and business context, Artificial Intelligence (AI) becomes a debated topic among academic and practitioners. Although the specific literature has outlined the relationship between top management and digitalization, sustainability topics remain less scrutinized, particularly concerning AI. With these premises, this study intends to investigate whether sustainable corporate governance (SCG) affects disclosure about AI.

To test the research hypothesis, we adopted a mixed approach (i.e., content analysis, structural equation modelling, ordinary least squares and lasso regression) working on a sample of 104 Italian listed companies.

Firms with higher levels of SCG scores display a greater impact on AI disclosure, suggesting that sustainable boards are demonstrating greater integration of AI in their disclosures as well as in their decision-making processes.

Although the literature is becoming increasingly interested in sustainable corporate governance issues, research is still lacking. To the best of the authors' knowledge, no study has previously investigated possible relationships between sustainable governance and the digitization process, especially with regard to the implications of AI.

Our findings provide insightful contributions to SCG- and AI-related literature, enriching the UET framework. In doing this, this study provides important implications for managers – especially at a strategic level – and policymakers.

The research is not free from limitations. First of all, AI disclosure is assumed to be representative of effective AI implementation, leaving room for doubt as a level of AI disclosure does not guarantee the same level of actual integration. Furthermore, it falls into a single-year analysis (2023) and Country (Italy). Therefore, future studies, survey-based, could increase the accuracy of the AI index and expand the analysis over time as well as to other countries.

Keywords: Sustainable corporate governance, Artificial intelligence, Disclosure, SEM, UET

Paper type: Academic Research Paper

1 Introduction

The expansion of the digital economy is fuelled by technologies like the Internet, artificial intelligence (AI) and cloud computing, which significantly influence industrial development and economic growth (Guo et al., 2023). In last years, AI is gaining higher interest from scholars and managers (Bevilacqua et al., 2025). AI can be defined as systems that mimic human cognitive abilities to perform tasks requiring intelligence (Mueller & Massaron, 2021). Hilb (2019) states that "the highest level of intelligence must be synergic, i.e. a state in which human and machine intelligence function and are superior in combination". The debate about AI becomes always more attractive in the business context, where corporate governance must cope with the advent of new technological challenges. AI integration in business processes is transforming industries by enhancing efficiency, innovation and decision-making processes (Kolbjørnsrud et al., 2016) but also raising ethical concerns, regulatory challenges and accountability risks (Duan et al., 2019). In this way, AI takes a central role for the so called sustainable corporate governance (SCG) that pays greater attention on aligning company's and stakeholders' interests (Velte, 2024). Against this backdrop, this paper intends to investigate if SCG affects disclosure about AI, focusing on a sample of 104 Italian listed companies on 2023 data. We applied a mixed method reaching out that companies with higher levels of SCG display a greater AI disclosure. The following of this paper is structured as follows: in Section 2, we review the literature to develop research hypothesis; in Section 3, we detail sampling and methods; in Section 4, we provide results then discussed in the final Section 5.

2 Literature review and hypothesis development

2.1 Theoretical framework

Considering AI, sustainability and corporate governance mechanisms, two theoretical lenses provide the framework for this study: the upper echelons theory (UET) and the innovation theory. Literature conveys that managers lead digital transformation, which plays a crucial role in decision-making processes (Bevilacqua et al., 2025; Guo et al., 2023; Lin et al., 2019). Based on the upper echelons theory, managers' characteristics shape

their behaviours and strategic decisions, ultimately influencing company's objectives, actions, and outcomes (Hambrick & Mason, 1984). Previous research highlights significant correlations between top executives and strategic corporate changes (Hambrick & Mason, 1984; Wiersema & Bantel, 1992). Additionally, several scholars suggest that senior managers influence organizations' innovation efforts (Smith & Tushman, 2005; Wrede & Dauth, 2020). Consequently, corporate leaders play a pivotal role in navigating digital transformation, fostering a digital culture, optimizing resource allocation and managing human capital (Avolio et al., 2000; Gupta et al., 2023). On the other hand, literature use innovation theory to explain how investments in research and development and technology improve governance efficacy and promote sustainable development (Khan et al., 2024).

2.2 Sustainable corporate governance and artificial intelligence

In recent years, a significant shift has occurred in corporate governance practices, moving from a short-term profit-driven orientation towards a long-term and sustainable approach. This transition has been largely influenced also by regulatory initiatives, such as the Corporate Sustainability Reporting Directive and the proposed Directive on Corporate Sustainability Due Diligence (Pizzi et al., 2021). The latter, jointly with the broader Agenda 2030, have intensified the pressure on companies to embed sustainability considerations within their governance frameworks (Velte, 2023), bringing academics and practitioners to emphasize the relevance of SCG. Aligned with the United Nations Sustainable Development Goals, SGC has emerged as a strategic mechanism for guiding companies toward responsible resource management and for addressing both current and emerging environmental and social challenges (European Commission, 2022; Kavadis & Thomsen, 2023). According to the European Commission (2020), sustainable corporate governance refers to a governance model that promotes long-term value creation by aligning corporate interests with those of shareholders, stakeholders and society as a whole. This approach requires firms to integrate sustainability into their strategic and operational decisions, encompassing issues such as social rights, climate change and environmental protection. Basically, SCG can be observed in a board of directors that properly incorporate environmental and social goals into strategy definition, fostering a successful and credible sustainable transformation while also enhancing corporate reputation (Johnstone, 2019; Velte, 2024). From a theoretical standpoint, SCG is often grounded in the triple bottom line framework (Elkington, 1994), which emphasizes the simultaneous pursuit of economic (profit), social (people) and environmental (planet) objectives. Similar to corporate disclosure, which has evolved to reflect sustainability concerns, corporate governance is increasingly embracing this multidimensional perspective aimed at improving the overall effectiveness of sustainability (Lozano, 2012).

Among the several management theories that study the decision-making processes, UET emphasize the relevance of top managers (Hambrick & Mason, 1984). A growing body of research points out that strategic changes within firms are closely associated with the influence exerted by executives (Åberg & Torchia, 2020; Wiersema & Bantel, 1992). In particular, top management teams are increasingly recognized as key drivers of organizational innovation, shaping the direction and intensity of firms' innovation efforts (Smith & Tushman, 2005; Wrede & Dauth, 2020).

Recent advancements in AI have raised fundamental questions about its integration within corporate governance systems. In this context, Hilb (2020) introduces a multidimensional framework that conceptualizes AI's impact on corporate governance across three interrelated domains: desirability (business perspective), feasibility (technological perspective), and responsibility (societal perspective). This framework identifies five potential scenarios of AI integration—from assisted to autopoietic intelligence—highlighting how boards may evolve from being merely supported by AI to co-governing or even being replaced by autonomous decision systems. Such developments call for a rethinking of governance practices, particularly in light of sustainability imperatives. As sustainable corporate governance aims to align corporate strategies with long-term societal and environmental goals (Velte, 2024; European Commission, 2022), it becomes essential to understand how AI can be harnessed not only to improve efficiency but also to enhance transparency, accountability, and ethical oversight in decision-making processes. By embedding AI within the governance structures of firms that demonstrate strong SCG profiles, organizations may foster what Hilb terms "synergic intelligence"—a combination of human and machine intelligence that amplifies corporate effectiveness and legitimacy. In line with this perspective, the present study empirically explores whether companies with more advanced SCG mechanisms are also those more likely to disclose and integrate AI within their strategic narratives, thereby positioning sustainable governance as a key enabler of responsible digital transformation.

2.3 Hypothesis development

Drawing upon UET (Hambrick & Mason, 1984), top management and the broader corporate governance play a crucial role in driving innovation efforts and shaping AI disclosure. Furthermore, according to the innovation theory, which allows us to link innovation with sustainable practices (Khan et al., 2024), we propose the following research hypothesis:

- *H1. Sustainable corporate governance is positively associated with AI disclosure.*

3 Data and methods

3.1 Sample

Our sample includes 104 Italian listed companies, for which both financial and non-financial data over 2023 are available. We retrieved financial data from AIDA Bureau van Dijk and non-financial disclosures from osservatoriodnf.it.

3.2 Variables

The study defines a set of variables to examine the relationship between SCG and AI disclosure.

The dependent variable, Artificial Intelligence disclosure (AI_D), results from a content analysis (Krippendorff, 1980) of the non-financial statements through NVIVO. The analysis evaluates the presence or absence of specific AI-related disclosure items: each item is valued 1 if it appears at least once and 0 otherwise and the arithmetical mean of all these dummies represents the AI_D score.

The main independent variable, Sustainable Corporate Governance (SCG), represents a multidimensional latent construct, starting from the approach of Velte (2022, 2023, 2024). It combines several indicators: the number of non-financial disclosure pages dedicated to environmental, social, and governance issues; the existence of a sustainability committee; the presence of a formal sustainability plan; the inclusion of long-term environmental and social targets; the implementation of a sustainable supply chain; and the disclosure of gender pay gap data. These indicators form the basis for the latent SCG variable, estimated through structural equation modelling (SEM).

We also include control variables to account for firm-level heterogeneity. These are: firm size (measured as the natural logarithm of total revenues) (SIZE), financial leverage (LEV), return on sales (ROS), board age diversity (AGE_D) and industry dummies.

3.3 Econometric models

To test the research hypothesis, we employed an OLS regression. The functional form is the following:

$$AI_D = \beta_0 + \beta_1 SCG + \Sigma contorls + industry + \varepsilon_i$$

4 Results

4.1 Preliminary tests and diagnostics

The following table displays the main descriptive statistics. An initial consideration regards the minimum value of AI_D, which is higher than zero, meaning that each company in the sample provides somehow disclosure about AI.

Table 1**:** Descriptive statistics

Variable	Obs.	Mean	Std. dev.	Min.	Max.
AI_D	104	3.90	0.80	1.95	6.57
SCG	104	0.02	2.27	-4.59	3.15
AGE_D	104	0.28	0.16	0	0.5
ROS	104	3.49	11.80	-33.66	29.22
SIZE	104	19.28	1.77	15.39	24.47
LEV	104	3.39	3.66	1.08	33.11

Moreover, we assessed the Pearson's correlation to detect potential multicollinearity among regressors, that does not occur. As shown in table 2, all coefficients are less then 0.80 (Weisberg, 2005). To be sure, we

performed an additional test – the Variance Inflation Factor (VIF) –, confirming no multicollinearity issues (mean VIF = 2.38 (< 5)).

Table 2: Correlation matrix

	AI_D	SCG	AGE_D	ROS	SIZE	LEV
AI_D	1					
SCG	0.33	1				
AGE_D	-0.09	-0.17	1			
ROS	-0.10	0.02	-0.01	1		
SIZE	0.34	0.28	-0.14	0.32	1	
LEV	-0.01	-0.15	0.03	0.01	0.10	1

4.2 Regression results

Regression results are displayed in Table 3. Given the single-year analysis, we employed an OLS regression; then, we included robust standard errors to avoid heteroskedasticity among data (White, 1980).

able 3: Regression results

y = AI_D	*Coeff.*	*p-value*
SCG	0.09	0.008
AGE_D	-0.11	0.814
ROS	-0.01	0.045
SIZE	0.15	0.000
LEV	-0.01	0.829
industry	Yes	0.000
constant	0.14	0.871
R-sq.	0.28	
Obs.	104	
Prob. > Chi2	11.29***	

The empirical findings reveal a positive and statistically significant association between SCG and AI_D, supporting the research hypothesis and suggesting that companies with more sustainability-oriented governance tend to communicate more about AI-related issues. The overall model exhibits a good explanatory power (R-sq. = 0.28) and the F-statistic further confirms the joint explanatory capacity of the independent variables, strengthening the reliability of the model.

4.3 Robustness checks: Lasso regression

To assess results' robustness, we employed a Lasso (least shrinkage and selection operator), as a machine learning-based technique able to improve the prediction accuracy and interpretability. Figure 1 reports the path-diagram from which the positive coefficient associated with SCG comes out.

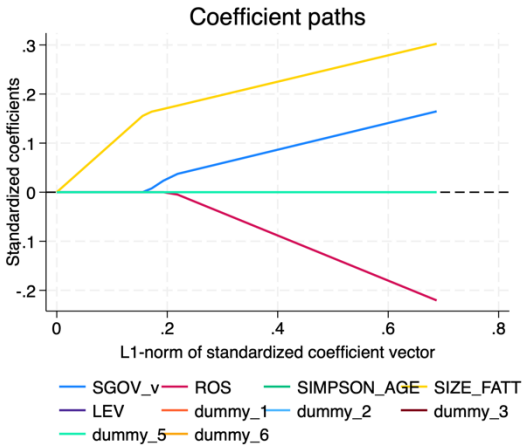

Figure 1: Path-diagram

Finally, we performed the double-selection Lasso linear regression, confirming previous findings (Table 4).

Table 4: Lasso regression results

y = AI_D	***Coeff.***	***p-value***
SCG	0.0920	0.007
N. of obs	104	
N. of controls	10	
Prob. > Chi2	7.26***	
R-sq. (training dataset)	0.60	
R-sq. (validation dataset)	0.67	

5 Discussion and conclusion

The increasing relevance of digital technologies is reshaping industries and managerial processes (Guo et al., 2023; Kolbjørnsrud et al., 2016). Among these technologies, AI stands out for its breakthrough, that simultaneously raises ethical concerns (Duan et al., 2019; Hilb, 2019).

At the same time, the need of long-term value creation has emerged, leading to a corporate governance that combines environmental and social goals within business strategy (European Commission, 2022; Velte, 2024). This integration has given rise to the concept of sustainable corporate governance, which embeds sustainability principles into board structures and strategic oversight mechanisms (Johnstone, 2019; Kavadis & Thomsen, 2023).

Despite the growing academic and institutional interest in both AI and SCG, little is known about how these dimensions interact – particularly in terms of how sustainability-oriented governance influences the disclosure and management of AI within firms. We aim to address this gap by investigating whether SCG acts as a driver of transparency in AI-related disclosure. In doing so, this study points out a positive and statistically significant association between SCG and AI_D. Companies that adopt a more sustainability-oriented governance model tend to be more transparent in disclosing information about AI-related initiatives. These findings support the Upper Echelons Theory (Hambrick & Mason, 1984), suggesting that the values and orientations of top managers, particularly their commitment to sustainability, significantly influence strategic decisions such as technological disclosure (Bevilacqua et al., 2025; Wrede & Dauth, 2020).

From a theoretical standpoint, this study contributes to the integration of UET with the dynamics of digital transformation. As suggested by Hilb (2019), governance in the AI era must be understood as a multidimensional process that balances desirability, feasibility, and responsibility. The concept of “synergic intelligence” – a collaborative interplay between human decision-makers and machine-based systems – emerges as particularly relevant in this context. Firms with advanced SCG practices are not only more inclined to disclose AI usage but may also be more likely to embed AI ethically and strategically within their corporate processes.

These results hold important implications for managers. First, managers should view SCG not only as a compliance requirement but as a strategic asset capable of driving innovation and digital transformation. A strong sustainability culture at the board level can stimulate more effective integration and communication of emerging technologies such as AI.

This research is not without limitations. The analysis is restricted to a single country (Italy) and a single year (2023), which limits the generalizability of the findings. In addition, the binary nature of the AI disclosure variable does not capture the depth, quality or sentiment of AI integration. Future research shall adopt survey-based methodologies to assess managerial attitudes toward AI and the real extent of its implementation. Furthermore, refining both the SCG and AI disclosure indicators could provide a more nuanced understanding of their interplay.

6 Ethics declaration

This research does not involve human participants, animal subjects, or sensitive personal data, and therefore did not require ethical approval. All data used in the study are publicly available from secondary sources, and no ethical clearance was necessary.

7 AI Declaration

No AI tools were used in drafting the paper.

Digital Transformation and Public-Private Partnerships to Enhance Local Cultural Heritage

Giovanna Muraglia[1], Laura Clemente[1], Gesualda Iodice[2], Mariavittoria Cicellin[2], Francesco Bifulco[2]
[1]Sapienza University, Rome, Italy.
[2]University Federico II, Naples, Italy.

Abstract

The present research aims to explore how digital transformation, when integrated within Public-Private Partnerships (PPPs) and social enterprise models, can foster inclusive, innovative, and sustainable approaches to cultural heritage governance. Anchored in the case study of JustMO', a cultural cooperative operating in Sepino (Molise, Italy), the study investigates how multi-stakeholder collaboration can activate new value creation processes in the cultural sector.

Adopting the SoPHIA evaluation model as a holistic analytical framework, the study examines the cultural, social, educational, and economic impacts of digitally supported heritage initiatives not only to enhance visitor experience and educational outreach but also to reinforce place identity and community ownership.

The analysis emphasizes the strategic role of Special Public-Private Partnerships (PSPPs) in enabling cross-sector collaboration, with social enterprises positioned as key orchestrators of digital ecosystems. These hybrid actors bridge institutional boundaries, channel public and private resources, and promote co-creation through participatory design and open digital infrastructures.

From a theoretical perspective, the paper contributes to current debates on PPPs by proposing an expanded view of social enterprises as drivers of digitally enabled cultural innovation. Ultimately, the study provides insights for cultural managers, policymakers, and scholars seeking to align heritage valorization with sustainability objectives and place-based development strategies.

Keywords: Cultural Heritage, Social Entrepreneurship, Digital Transformation, Public-Private Partnership, New Cultural Ventures

Paper type: Academic Research Paper

1 Introduction

Digitalization has revolutionized access to cultural content, exposing the lack of innovation and limited inclusiveness often associated with traditional top-down management models (Consiglio & Riitano, 2015). The digital transformation of cultural heritage institutions can be considered in relation to their evolution into less authoritarian and more inclusive organizations (Dąbrowska et al., 2022). Implementing new technologies and ways of working requires new knowledge and new collaboration strategies among cultural heritage institutions, which conceive and manage new relationships with external actors and offer innovative forms of participation.

Fostering collaboration among public, private, and community actors is key to reimagining cultural heritage as a shared resource and common good. In this context, bottom-up management approaches, based on collaboration between public and private actors, are emerging as effective models for enhancing cultural heritage and driving local development (European Agenda for Culture). In this context, participatory governance is essential for managing and enhancing cultural heritage, ensuring collaboration between public and private sectors at all decision-making levels.

Public-Private Partnerships (PPPs) exemplify this by integrating diverse actors, models, and tools into a holistic framework that maximizes heritage value, enhances cultural sustainability, drives economic growth, and empowers communities through social innovation, strengthened networks, and active participation in heritage preservation (Allegro & Lupu, 2018). Within this framework, collaboration among the public, non- profit, and private sectors takes the form of hybrid managerial models, such as social enterprises, which strive to achieve economic sustainability while also addressing social and ecological objectives, thereby integrating these aims within their operational frameworks (Murphy et al., 2022).

Despite social enterprises being considered key players in bridging the gap between innovation management and technology-focused stakeholders (Battisti, 2019), research on digital transformation and the implementation of public-private partnership (PPP) projects within social entrepreneurship is still in its early stages.

Recognizing this gap, the current study aims to contribute to the scholarly discourse by exploring the interplay between PPPs, social enterprises, and digital transformation.
On this basis, the authors aim to explore how bottom-up approaches and active multi-stakeholder participation can foster innovation in managing and valorizing local cultural heritage. In detail, focusing on inland areas, which are often marked by neglect and abandonment, the study highlights the potential of place- based approaches to deliver social, economic, and cultural benefits.

2 Literature review

The engagement of individuals and social collectives with the goods, activities, and values intrinsic to culture is paramount for fostering and preserving the collective memory and identity of communities. A comprehensive understanding and appreciation of cultural heritage not only enables local communities to discover the foundational reasons for their cohesion, mutual understanding, and shared purpose but also offers pathways to articulate their identity to external entities. This process stimulates a recognition of self that coexists harmoniously with the diverse identities of other communities, thereby positioning the local identity within a broader European context (Pretelli, 2020).

The public character of cultural heritage, intimately linked to its identity value and the sense of belonging it engenders, necessitates governance models that are inclusive and participatory, promoting efficient management practices (Žuvela et al., 2023; Vitale, 2024). Such models should foster active community engagement in the stewardship of cultural resources. In light of the pressing need to reconceptualize public intervention to address the multifaceted demands of the cultural sector, characterized by challenges such as delays in the protection and valuation of cultural assets, as well as inadequacies in their management, private intervention has increasingly emerged (Consiglio et al., 2020). This has surfaced in diverse legal forms, including private companies, associations, non-profit organizations, foundations, and social enterprises, which together lay the groundwork for co-responsibility between public and private entities and promote a socio-economic vision of cultural valorization (Petraroia, 2018).

Within this framework, scholarly literature recognizes public-private partnership (PPP) collaborations as pivotal in bridging the gap between governance hybridity and organizational logic. Such collaborations serve as crucial conduits for generating both economic and social value, particularly within sectors dedicated to culture and creativity (Quelin et al., 2017). Through the synergistic interplay between the state and private actors (Franch, 2020), PPPs augment the efficacy of public resources by integrating private funding and expertise to facilitate public works and the management of related services.

Public-private partnerships (PPPs) can be categorized based on their specific objectives and purposes. Typically defined as collaborations between public and private entities, PPPs are primarily established by private stakeholders to generate profit. The central goal of such partnerships is to achieve a return on investment for participants. Potential private stakeholders in these arrangements may include a diverse array of entities from the business sector. This category encompasses natural persons, profit-driven legal entities such as private universities, economic operators predominantly utilizing private capital and resources, such as construction firms, and financial institutions, including banks, pension funds, and insurance companies.

In contrast, Public-Private People Partnerships (PPPPs) represent a distinctive form of collaboration that integrates the efforts of public and private entities to support the needs and aspirations of ordinary citizens, the non-profit sector, and end users (Boniotti, 2023). The focus of PPPPs is on civic engagement, social solidarity, and fulfilling societal purposes rather than generating profit. Unlike traditional PPPs, these partnerships do not necessarily prioritize financial returns, and a profound commitment to civic responsibility and a strong inclination towards philanthropic initiatives characterizes the potential private stakeholders involved.

Public partnerships, particularly in the context of Public Special Purpose Partnerships (PSPP), serve distinct objectives aimed at enhancing the utilization and advancement of scientific research. These partnerships are specifically oriented toward the recovery, restoration, planned maintenance, and management of immovable cultural properties, as well as their accessibility to the public and effective exploitation. Such collaborations are vital for the preservation and promotion of cultural heritage, ensuring that these invaluable assets are maintained for future generations while also fostering scholarly inquiry (Sciullo, 2022).

In the context of public-private partnerships, social enterprises emerge as strategic intermediaries, enhancing operational efficiency by connecting disparate sectors and aligning diverse outcomes. The concept of "Social Enterprise" originally emerged in the third sector as a response to community needs through the development of tailored social projects (Iodice & Bifulco, 2024). This notion was catalyzed by the imperative to institutionalize innovations introduced by early "social solidarity cooperatives" (Borzaga et al., 2020). As a result, social enterprises are increasingly recognized for their capacity to generate positive externalities that enhance

community well-being (Jung & Park, 2023), fortify social ties, and create new epicenters for social engagement (Beck & Brooks, 2019).

Specifically, social enterprises contribute to PPP by functioning as strategic connectors that foster efficiency and stimulate social innovation through the following avenues:

- Acting as bridges between governmental bodies, private companies, and non-profit organizations (Battisti, 2019).
- Contributing to territorial impact and social innovation by aligning diversified institutional frameworks and funding models (Catala et al., 2025).
- Supporting capacity building and regional socio-economic development through collaborative efforts involving multiple stakeholders (Kovtun et al., 2022).

The collaboration between public-private partnerships and social enterprises is therefore essential in promoting cultural value and fostering community engagement. These partnerships bridge the gaps between governmental, private, and non-profit sectors, enhancing the management and appreciation of cultural heritage while driving social innovation and improving community well-being.

In this context, it is pertinent to highlight an emerging consideration within the scientific literature regarding public-private partnerships (PPPs) and social enterprises that facilitate digital transformation, specifically for culture-based activities. While less prevalent in existing studies, there are notable indications of the potential role of social enterprises as intermediaries in digital transformation processes. For example, Battisti (2019) underscores the function of social entrepreneurs as vital bridges connecting stakeholders in public-private partnerships, thereby enabling technology-driven social innovation. Additionally, Buyannemekh et al. (2023) identify public libraries as prospective strategic partners in smart city initiatives, positing that community-based organizations can function as significant intermediaries in these contexts.

Upon conducting a thorough analysis of the literature, the authors identified a notable gap concerning the interplay between PPPs, social enterprises, and digital transformation (see Table 1).

Table 1. Partnership models

Model Type	Key Features	Stakeholder Roles	Success factors
Public-Private Partnerships	Alignment of public needs and private competencies; Knowledge sharing; Co-creation of value (Casprini & Palumbo, 2022)	Public sector: Defines needs and provides access; Private sector: Provides technology and expertise	Leadership; Preexisting relationships; Agreement on initial aims
Data-Driven	Leveraging diverse	Public sector: Data	Data integration
Social Partnerships	data sources; Multi-sector collaboration; Focus on societal impact (Susha et al., 2019)	provision and regulation; Private sector: Technology and analytics; Non-Governmental Organizations (NGOs): Community engagement and impact assessment	capabilities; Ethical data use; Clear governance structures
Research and Development Collaborations	Open innovation practices; Focus on operational processes; Building digital ecosystems (Rocha et al., 2021)	Research institutions: Knowledge creation; Businesses: Application and scaling; Public sector: Facilitation and regulation	Engaged workforce; Customer-centric approach; Adaptive mindset
Strategic Partnerships for Platformization	Dynamic collaboration; Focus on digital platform development (Rocha et al., 2021)	Incumbent firms: Resources and market presence; Entrepreneurial partners: Innovation and agility	Flexible collaboration modes; Alignment of strategic goals; Complementary capabilities

Source: author's elaboration

Several studies suggest that digital transformation plays a critical role in the establishment of strategic partnerships that are highly context-dependent, with each model being tailored to specific objectives and environments. As illustrated in the table, the various data-driven modalities do not specifically address the intersection of PPPs, social enterprises, and digital transformation; instead, they adopt a holistic perspective on PPPs and digital transformation across diverse economic sectors, including healthcare, industry, and information technology. In contrast, the dynamics of collaboration and participation and forms of partnership that can

support the exchange of knowledge around these processes have received only limited attention (Li & Ghirardi, 2019).

The wide diffusion of digital technologies presents significant opportunities for both public and private organizations, prompting a growing interest in their impact on strategic, organizational, and collaborative processes (Agostino & Costantini, 2022; Nambisan et al., 2019). Digital transformation, as described by Hinings et al. (2018), refers not merely to the adoption of individual technologies but to the cumulative effect of digital innovations that disrupt traditional practices and reshape entire sectors or ecosystems. Within this conceptual framework, the cultural sector has emerged as a fertile domain for examining how digital tools reconfigure modes of production, distribution, and consumption of cultural content.

Focusing attention on the cultural scenario, recent contributions underscore the transformative capacity of digital technologies in enabling new forms of cultural engagement, participation, and co-creation (Agostino & Costantini, 2022). Cultural institutions, long anchored in hierarchical and custodial models, are increasingly experimenting with technology-enabled strategies that open up their functions to broader audiences and collaborative networks. In particular, digital innovation is proving essential in reshaping organizational dynamics within Public-Private Partnerships (PPPs), where technology acts not only as a tool but also as a catalyst for social innovation and multi-stakeholder collaboration (Battisti, 2019). The literature on digital transformation in the cultural sector has so far focused more on the impact on the public and the emerging possibilities for engagement and empowerment (Clemente et al., 2024; Graham, 2016), while the study of technology-enabled social innovations within PPP frameworks offers critical insights into how inclusive and adaptive governance models can emerge. This research positions itself within the identified gap, aiming to bridge the relationship between PPPs established by social enterprises through the lens of digital transformation.

3 Methodology

Given the explorative purpose of this research, the authors adopted a single case study following the “logic of replication” (Yin, 2009). This qualitative research method (Mariotto et al., 2014) makes it possible to identify the key elements of the individual case and, subsequently, apply them to new situations, thus initiating a process of knowledge dissemination.

In particular, the authors have chosen to conduct the empirical analysis using the SoPHIA framework, which is consistent with the evaluation of cultural heritage interventions due to its holistic approach (Marchiori et al., 2024). The framework's multi-dimensional structure, focusing on domains, people and time, allows for a comprehensive assessment of the expected impact of the project implemented by the selected case study. The authors have chosen to contextualize and implement this model using a longitudinal analysis (Thomson & McLeod, 2015), supported by secondary sources and interviews with key stakeholders, to ensure a robust understanding of the dynamics and outcomes.

The single case study selected is JustMO', a cultural cooperative based in Campobasso (Molise), which represents an exemplary case of adaptive reuse and implementation of the special public-private partnership (PSPP) model. The case was selected for the variety of outcomes it aims to achieve, including the generation of cultural impact, the promotion of community engagement and the exploitation of digital assets to create innovative cultural ventures.

4 Findings

This study explores how bottom-up processes and multi-stakeholder collaboration foster innovation in the management of local cultural heritage. The authors present first insights from the empirical research by applying the SoPHIA framework to the MAT Museum at Palazzo Tiberio in Sepino. Interviews with the cooperative Justmo, which implemented a Special Public-Private Partnership (PSPP) to guide the museum’s development, highlight the strategic value of synergies between public institutions, private actors, and the local community. The analysis reveals strong alignment with the dimensions of place identity, education, and creativity. Therefore the empirical data shows that digital technologies are pivotal not only for heritage preservation but also for enhancing community participation. The MAT Museum serves as a representative case of how digital innovation, through tools such as virtual reality, interactive archives, and touchscreen interfaces, can enrich visitor engagement and reinforce the bond with the territory. A key feature of the project is the co-creation of digital content, which involved local professionals, experts, and citizens, thereby fostering a narrative that is both inclusive and contextually rooted.

The general and specific objectives stated by MAT and the related actions focus on four main themes: Social Capital; Sense of Place; Education and Creativity, Quality of Life.

Regarding Social Capital, the project has prioritized the creation and strengthening of ties with the local community, not only through individual interactions with residents but also through collaborations with local associations such as Officina Creativa, which also acts as an official partner. One of the most relevant initiatives in this sense is the creation of a Community Hub, envisioned as a shared space for gathering and participation, where familiar objects and narratives recognized by the local population are integrated into the museum's environment. Although no formal co-design process was conducted in the early stages, a participatory approach is planned for the future, particularly through post-implementation feedback and collaborative planning of new spaces and initiatives.

In relation to the Sense of Place dimension, the project employed a geo-historical approach to recover local memories and vernacular traditions, placing underrepresented identities at the core of the museum narrative. This approach has not only contributed to redefining the museum as a space of shared memory and territorial identity, but also to strengthening the local community's sense of belonging. In collaboration with the Netherlands Institute in Rome, an aerial video was developed to simulate an archaeologist's perspective from a lightweight flying platform. By using a headset, visitors are able to virtually explore Sepino's territory and archaeological park, thereby deepening their connection to the site.

Focusing on the Education and Creativity dimension, the project leverages digital technologies to enhance local awareness, stimulate visitor creativity, and promote innovative learning models that are both immersive and inclusive. Educational strategies are woven into the museum experience through a blend of multimedia content, interactive storytelling, and experiential learning environments. Key activities, such as multimedia installations, thematic itineraries, and immersive VR experiences, transform the museum into a dynamic space where local history is shared through engaging, multisensory digital tools.

Regarding the dimension of Quality of Life, the project has yielded immediate positive impacts on the local economy, particularly benefiting artisans and creative workers, while also promoting sustainable, experience-based tourism. By enhancing cultural value and generating positive externalities, it effectively contributes to improving community well-being. Moreover, due to the involvement of local professionals and stakeholders, the initiative fosters sustainable territorial growth and paves the way for long-term regional development.

Turning to the stakeholder dimension of the SoPHIA framework, the MAT Museum project reflects a multi-layered collaboration among institutional, academic, professional, and community stakeholders. The University of Naples Federico II led the architectural design while technological support was provided by external consultants specializing in advanced digital systems. In addition, the Dutch Institute in Rome played a pivotal role in producing immersive content, such as the aerial video accessible through virtual reality. At the local level, the Municipality of Sepino provided archival materials and logistical assistance, working closely with the Sepino Archaeological Park and the Soprintendenza. Community engagement was further facilitated by local associations and a territorial coordinator who encouraged the participation of artisans and residents. These diverse stakeholders were classified based on their group affiliation, enabling a systematic evaluation of their respective roles and contributions. Together, these actors form an integrated system that blends academic, institutional, and local expertise, as shown in Table 2.

Table 2. Stakeholder involved in the project

Stakeholder	Role/Contribution
Federico II University – Department of Architecture	Design of exhibition spaces using sustainable materials
Artisan service providers	Crafting installations
Internal and external digital experts	Handling hardware/software, holographic and AR tools
Communication expert	Managing social and multimedia content
Netherlands Institute in Rome	Production of aerial video from archaeologist's perspective
Topography and cartography experts	Creation of a model of the Sepino geographic area
Various experts	Providing insights for different museum sections
Local community	Contributing to archive, ongoing feedback, and participation through associations
Municipal technical office and Mayor of Sepino	Archival material for museum content
Archaeological Park of Sepino	Lending artifacts to enrich museum narrative
Superintendency	Institutional collaboration
Local associations	Creation of the community hub

Source: author's elaboration

This collaborative framework grounds the project in a shared vision of cultural innovation, sustainability, and participatory development. Overall, the MAT Museum exemplifies the effectiveness of special public- private partnerships (PSPPs) in cultural heritage management, demonstrating how the convergence of digital innovation and community engagement can produce enduring territorial impacts.

5 Implications

The empirical analysis provides relevant theoretical and managerial insights for researchers and practitioners in cultural heritage management. Firstly, the study asserts the validity of the SoPHIA framework for evaluating cultural heritage initiatives within a Special Public-Private Partnership (PSPP) context. By addressing the lack of research on the interplay between PPPs, social enterprises, and digital transformation, the study positions social enterprises not merely as intermediaries but as key orchestrators of digital ecosystems. This perspective facilitates understanding of value creation processes in cultural heritage governance, highlighting their role in fostering multi-stakeholder collaboration.

In this vein, from a theoretical perspective, the study extends the application of the SoPHIA framework by testing its validity within a Special Public-Private Partnership (PSPP) context. The findings demonstrate the framework's robustness and adaptability as a multi-dimensional tool for assessing heritage projects, while also highlighting the need for further development. In alignment with Angrisano et al., (2024), according to which some adjustments (and integration) need to be made to make the indicators clearer and unambiguously interpretable, this study argues for the inclusion of a fourth axis of digital innovation to complement the existing triad of time, people and domains. This addition would allow for a more nuanced understanding of digital readiness, integration processes and the long-term sustainability of cultural initiatives, capturing the transformative potential of digitalization in enhancing access, participation, and innovation across the cultural sector.

In a manner akin to the application of the Sophia Framework Test within the context of Officine Culturali, a social enterprise dedicated to the enhancement of the Benedictine Monastery in Catania, Sicily, the utilization of this framework serves as a salient representation of the efficacy of public-private partnership agreements. Such collaborations have demonstrably succeeded in augmenting the cultural experience and rendering knowledge accessible to a broader audience. This transformation not only enriches the cultural fabric but also positions the initiative as a viable instrument for social entrepreneurship. In this direction, this work contributes to extending existing theoretical perspectives on public-private partnerships (PPPs) and hybridity (Hinings et al., 2018; Quélin et al., 2017) by positioning social enterprises as key players of digital ecosystems since they facilitate multi-stakeholder coordination, foster knowledge circulation, and embed technological experimentation in localised cultural strategies.

The conceptualisation of social enterprises as drivers of digitally-enabled social innovation offers a novel lens for understanding value creation in the cultural sector and calls for a broader integration of organisational, technological and social dimensions within PPP theory.

From a managerial perspective, the findings highlight the central role of digital tools in reconfiguring the design and management of cultural heritage projects. The evaluation of the museum through the applied model facilitated a nuanced understanding of the impact that active digital citizenship may have on policy making and intervention strategies. The MAT museum case illustrates how immersive technologies and open digital infrastructures can enhance visitor engagement and foster community co-creation. The findings support the idea that these hybrid models can effectively bridge gaps between innovation management and stakeholder engagement, thus aligning academic discussions with practical applications.

6 Conclusion

This study focuses on the evolving role of digital transformation within hybrid models of cultural heritage governance, highlighting the need to rethink how these elements intersect when mediated by social enterprises operating in local contexts.

However, some limitations of the paper must be acknowledged. The first is the use of a single case study which, although rich in contextual insights, limits the transferability of the results. Furthermore, the specificity of the socio-territorial context and the qualitative approach adopted require further investigation and comparative studies in different cultural and governance environments.

Future research should follow two main directions: first, the empirical verification of the proposed integration of a 'digital innovation' axis into multidimensional evaluation models such as SoPHIA; second, the exploration of how different configurations of public-private-community partnerships adapt to technological change, especially in contexts characterised by institutional fragmentation or infrastructure deficiencies.

Rather than offering definitive conclusions, this work opens up a line of inquiry into how digital transformation can reshape not only cultural practices but also the collaborative logics that underpin heritage enhancement in the contemporary era.

Measuring Museum Visitor Experience: Fresh Evidence from Bourbon Heritage Sites and potential Collaborations with Startups

Fabio Greco, Francesco Bifulco
University of Naples Federico II, Naples, Italy

Abstract

This study explores visitor satisfaction at Bourbon cultural heritage sites in Campania, with a focus on the Royal Palace of Naples and the National Archaeological Museum (MANN). Adopting a mixed-methods approach, researchers carried out 97 interviews to assess eight critical dimensions of satisfaction. Through the application of the expectancy-disconfirmation model, the study contrasts perceived quality with the importance attributed by visitors. Findings show strong appreciation for the cultural content offered but point to notable shortcomings in infrastructure, digital accessibility, and post-visit engagement. A clear mismatch between visitor expectations and the actual services provided—especially regarding online communication and complementary offerings—emerges.

The research incorporates a pilot phase conducted by the Siti Reali organization, which represents a foundational step in satisfaction measurement. This phase serves as a valuable input for future collaborations with innovative startups that could enhance and scale similar evaluation processes using digital and data-driven tools.

Demographic and behavioral data indicate a growing interest in thematic experiences and customized itineraries, underscoring the need for more responsive and flexible site management. Overall, the study contributes to the field of cultural tourism by aligning satisfaction analytics with heritage site operations. Strategic proposals aim to strengthen visitor engagement and reposition Bourbon sites within the global tourism landscape, supporting sustainable and visitor-focused growth for Southern Italy's cultural tourism sector.

Keywords: Cultural startups, visitor experience, heritage tourism, entrepreneurial opportunities, digital engagement

Paper type: Practical Paper

1 Introduction

In Southern Italy, Bourbon heritage sites embody a rich but underexploited cultural narrative. Despite their historical significance, these locations are often absent from mainstream tourism circuits, limiting their ability to attract international audiences. Enhancing their visibility depends on prioritizing visitor satisfaction—an essential factor in creating meaningful experiences, encouraging return visits, and ensuring long-term viability.

Improving the cultural tourism offer in Campania requires understanding the quality of interactions visitors have with heritage sites. Research confirms that satisfaction is key to fostering engagement and sustainable behavior (Fyall et al., 2012). However, Bourbon sites have not fully adopted satisfaction-based strategies. This study seeks to bridge that gap, offering insight into how these sites can better align with the expectations of today's cultural tourists. By combining qualitative and quantitative methods—including structured surveys and interviews—the research evaluates satisfaction across eight dimensions, such as accessibility, cultural content, and supporting services.

A key component of this work is a pilot phase conducted in collaboration with the Siti Reali organization, which tested a model for measuring visitor satisfaction at the Royal Palace of Naples and the National Archaeological Museum (MANN). This phase not only validates the methodology but also lays the groundwork for future collaborations with innovative startups that could enhance such assessments using digital tools and smart analytics.

Applying the expectancy-disconfirmation theory (Clemons & Woodruff, 1992), the study identifies mismatches between visitor expectations and service delivery—particularly in digital accessibility, online information, and post-visit engagement. These gaps signal the need for integrated improvements across both physical and digital touchpoints. The analysis supports a shift toward adaptive, visitor-focused management and encourages the development of themed itineraries and immersive experiences to strengthen site appeal.

Ultimately, this research aims to inform sustainable strategies for the revitalization of Bourbon heritage in Campania, helping these sites better connect with modern audiences and reposition themselves within the global cultural tourism landscape. The Research Question is:

- *How can cultural visitor satisfaction be enhanced at Bourbon heritage sites?*

2 Theoretical framework

Bourbon heritage sites in Southern Italy, rich in both tangible and intangible cultural assets, have strong potential to elevate regional cultural tourism. However, realizing this potential depends heavily on visitor satisfaction and the systematic integration of feedback into site management.

Engaging the Cultural Tourist

Effective engagement of cultural tourists requires a clear understanding of their motivations, desire for authenticity, and emotional involvement. Studies emphasize that heritage experiences must go beyond passive observation, fostering personal connections and emotional resonance (Bryce et al., 2015). Technologies like augmented reality (Villamediana-Pedrosa et al., 2018) and inclusive storytelling (Richards, 2018) have been shown to enhance engagement, particularly among diverse and digitally connected audiences.

Strategic tourism planning further supports engagement through integrated itineraries and resource coordination (Teutonico & Palumbo, 2002). Scholars advocate for participatory governance and creative industries as drivers of innovation and sustainability in cultural heritage (Jelinčić & Mansfeld, 2019). Bourbon sites, with their historical depth, are ideal for such strategies but remain largely underutilized. Digital platforms and 3D tools offer untapped opportunities to document, promote, and revitalize these locations (Apollonio et al., 2019).

Visitor Satisfaction and Experience Gaps

Visitor satisfaction is a key metric for sustainable heritage tourism but remains insufficiently explored in Bourbon contexts. The expectancy-disconfirmation theory (Clemons & Woodruff, 1992) is a proven model to evaluate satisfaction by comparing expectations with perceived outcomes. Though widely applied in heritage tourism research (Huh, 2002; Chen & Chen, 2010), it has yet to be fully used in assessing Bourbon sites.

Experiential quality, emotional attachment, and perceived value all influence satisfaction and repeat visitation (Buonincontri et al., 2017). However, studies focused specifically on the Bourbon context are rare. Integrating feedback into management could improve itinerary design and overall experience, aligning more closely with modern cultural tourists' expectations (De Rojas & Camarero, 2007).

Perceived Quality and Attributed Importance

Tourist satisfaction doesn't depend solely on the services offered, but also on how important visitors consider those services. The gap between perceived quality and visitor expectations is critical in shaping satisfaction (Parasuraman et al., 1985; Vajčnerová et al., 2014). Studies confirm that key factors include accessibility, authenticity, emotional resonance, and the perceived safety and comfort of the visit (Zhang et al., 2023; Costea et al., 2017).

Importantly, the role of tour guides and staff interactions also significantly impacts the quality of experience. Tailored, knowledgeable engagement enhances satisfaction and fosters deeper appreciation (Huang et al., 2010; Kara et al., 2023). Future evaluations of Bourbon sites should factor in these elements to refine service design and elevate the overall visitor journey.

3 Methodology

This study adopts a mixed-methods approach, combining qualitative and quantitative tools to assess visitor satisfaction. Using semi-structured interviews and a Likert-scale survey, it evaluates perceived quality versus the importance attributed by visitors across key dimensions of the museum experience, based on the expectancy-disconfirmation model (Parasuraman et al., 1985). The core metric—Satisfaction Index ($X = Q - P$)—captures the gap between expectations and perceived performance.

This methodology was developed and tested as part of a pilot phase through a collaboration between the *Siti Reali* association and the Department of Humanities at the University of Naples Federico II, under a PON research project. Applied to two key sites—the Royal Palace of Naples and the National Archaeological Museum (MANN)—the approach served as an experimental pivot, offering the first evidence of visitor experience trends.

More than a static evaluation, this pilot acts as a strategic starting point: it opens the door to potential future collaborations with innovative startups that could introduce new digital tools, analytics, and service design models. These partners may contribute fresh value propositions aimed at deeper, more dynamic assessments of visitor satisfaction, ultimately enhancing the overall cultural experience and supporting more adaptive, user-centered heritage management.

This qualitative approach enabled a detailed mapping of the visitor experience across key journey touchpoints. By comparing perceived quality with the importance attributed at each stage—from planning to post-visit—the study identifies where improvements are needed to enhance satisfaction. This analysis is

contextualized within the broader "phygital" (physical + digital) framework, increasingly relevant in cultural tourism, as highlighted in recent literature (Florida, 2016; Ballina et al., 2019; Greco, 2022).

Table 1: Phygital Visitors Journey phases

Phase 1: Pre-Visit *(Digital or "Phygital")* **Online Information Accessibility**: ● Visitors explore and access the necessary details for planning their visit through digital platforms such as websites, social media, and booking systems.
Phase 2: Access *(Physical)* **Accessibility of Facilities**: ● The ease of physically reaching the location, including transport options, signage, and infrastructure like ramps or elevators for inclusivity.
Phase 3: Arrival *(Physical)* **On-Site Welcome and First Impressions**: ● Quality of on-site reception, including staff friendliness, signage, and orientation upon arrival at the venue.
Phase 4: Information *(Physical or "Phygital")* **Informative Clarity Before and During the Visit**: ● Availability and clarity of information in physical formats such as brochures, signage, and staff guidance.
Phase 5: Experiential *(Physical or "Phygital")* **Cultural Offering and Immersive Experiences**: ● Interaction with exhibits, artifacts, or artworks and integrating immersive technologies for enriched engagement.
Phase 6: Additional Services *(Physical or "Phygital")* **Complementary Services**: ● Integrating digital and physical services to the core service, such as physical parking and hybrid activities (e.g., app-based audio guides, paper and digital support information materials).
Phase 7: Additional Services *(Physical)* **Accessory Services**: ● Integration services not directly linked to the basic service but can improve its performance, such as Catering, cafeteria, Bookshop
Phase 8: Post-Experience *(Digital or "Phygital")* **Post-Visit Assistance and Engagement**: • Follow-up through digital channels, offering further engagement, support, and personalized recommendations for future visits.

To ensure a comprehensive analysis, the methodological framework integrates both qualitative insights and quantitative metrics, allowing for a nuanced understanding of visitor satisfaction. This approach enables the identification of key strengths and areas for improvement, providing valuable data for enhancing the visitor experience across cultural heritage sites.

4 Results

The results are presented separately for each of the two cultural attractions analyzed: the National Archaeological Museum of Naples (*MANN)* and the Royal Palace of Naples (*Palazzo Reale).* This division allows for a more granular assessment of visitor satisfaction, highlighting site-specific trends and discrepancies between perceived quality and attributed importance. For each site, dedicated calculation tables and bar charts illustrate the satisfaction indices, providing a clear visual representation of visitor responses across different touchpoints in the *Phygital Visitor Journey*.

By structuring the findings in this manner, the analysis ensures that variations in visitor expectations and experiences are accurately captured, facilitating a more targeted approach to improving service quality. The results indicate that while both sites exhibit strong performance in core experiential dimensions, gaps are more pronounced in specific phases such as post-visit engagement and accessory services. The individualized presentation of data enables cultural site managers to develop tailored strategies to enhance visitor satisfaction, leveraging insights from both qualitative feedback and quantitative assessments.

4.1 The National Archaeological Museum of Naples (MANN)

Table 2 Satisfaction Index Archaeological Museum (MANN)

The satisfaction index for each dimension	Satisfaction index calculation formula	Satisfaction Index MANN
X1	Q1-P1	**-0,58**
X2	Q2-P2	**-0,65**
X3	Q3-P3	**-0,58**
X4	Q4-P4	**-0,58**
X5	Q5-P5	**-0,28**
X6	Q6-P6	**-0,53**
X7	Q7-P7	**-0,24**
X8	Q8-P8	**-0,43**

The National Archaeological Museum of Naples (MANN) exhibits both strengths and areas for improvement based on the analysis of visitor satisfaction. The museum's cultural offerings, such as exhibitions and the technologies employed, receive high ratings, indicating that these core aspects are highly valued by visitors. However, significant gaps emerge in areas of post-visit digital engagement and facility accessibility, which have scored lower in perceived quality. Satisfaction indices, negative across all dimensions, suggest that the museum is not fully meeting visitor expectations relative to the importance they place on these aspects. Enhancing support services and accessibility could significantly increase overall visitor satisfaction and encourage repeat visits.

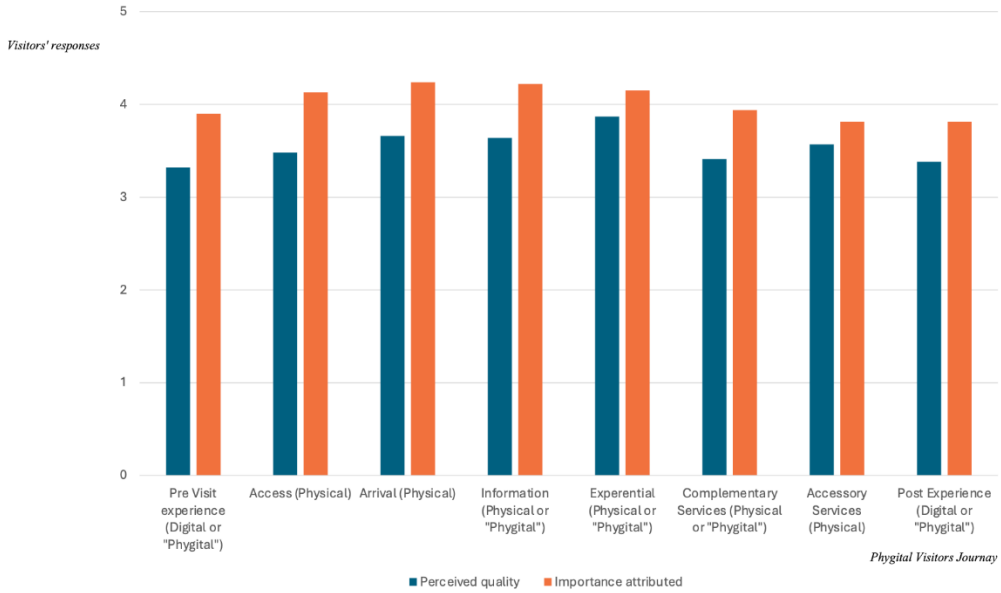

Fig 2: Histogram representation of the relationship between Perceived Quality and Importance attributed - MANN

4.2 The Royal Palace of Naples (Palazzo Reale)

Table 3 Satisfaction Index PALAZZO REALE

The satisfaction index for each dimension	Satisfaction index calculation formula	Satisfaction Index PALAZZO REALE
X1	Q1-P1	**-0,70**
X2	Q2-P2	**-0,31**
X3	Q3-P3	**-0.44**
X4	Q4-P4	**-0,48**
X5	Q5-P5	**-0,14**
X6	Q6-P6	**-0,73**
X7	Q7-P7	**-1,26**
X8	Q8-P8	**-1,12**

The Royal Palace of Naples (Palazzo Reale) exhibits strengths and weaknesses in visitor satisfaction across various dimensions. It performs well in core cultural offerings such as exhibitions, receiving a relatively high

satisfaction rating. However, significant gaps are evident in additional services like dining and digital post-visit engagement, which score notably low in perceived quality and satisfaction indices. These areas represent critical opportunities for improvement to enhance the overall visitor experience. Enhancing these services could lead to more comprehensive visitor satisfaction, contributing to a more positive perception and increased likelihood of repeat visits.

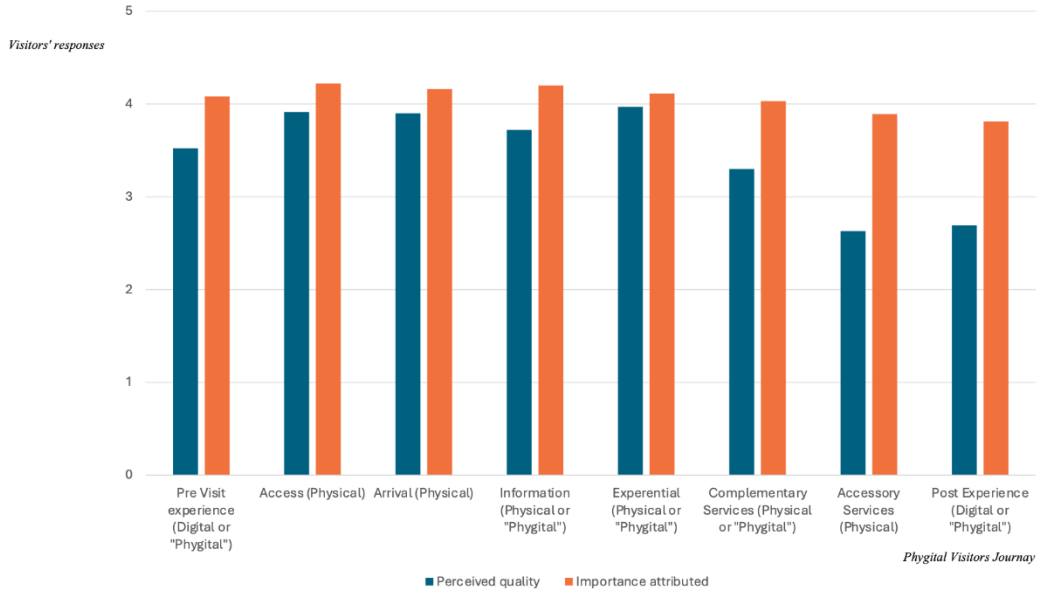

Fig 3: Histogram representation of the relationship between Perceived Quality and Importance attributed - PALAZZO REALE

Overall, the findings emphasize the need for a more balanced alignment between visitor expectations and service performance. While core aspects such as access and experiential engagement perform well, peripheral services and post-visit interactions exhibit notable gaps. Addressing these discrepancies through targeted improvements will be essential in fostering a more seamless and satisfying visitor experience.

5 Implications

5.1 Practical implications

This study provides actionable insights for improving visitor experience management at Bourbon heritage sites in Campania. By analyzing satisfaction indices across key dimensions—such as accessibility, digital communication, and ancillary services—it identifies areas that require strategic intervention. Aligning visitor expectations with the quality of service delivery is essential to enhance engagement and satisfaction. The research also highlights the potential of itinerant tourism models to connect Bourbon sites into cohesive cultural routes, strengthening their visibility and sustainability in a competitive tourism market.

Phase 1: Online Information

Both MANN and the Royal Palace show significant gaps in online information accessibility. Visitors consider this dimension highly important, yet the perceived quality remains low. Enhancing digital platforms is key to improving the pre-visit experience.

Phase 2: Accessibility

Accessibility scores reveal discrepancies, particularly regarding transportation and inclusive infrastructure. Improving access will broaden visitor inclusion and satisfaction.

Phase 3: Reception on Arrival

Visitors report a moderate mismatch between expectations and reception quality). Enhancing staff engagement and signage can improve first impressions.

Phase 4: Clarity of Information

The clarity of information—before and during the visit—needs improvement. Investment in better communication tools is necessary.

Phase 5: Cultural Offerings

This is a strength for both sites. Satisfaction levels are relatively high , confirming the appeal of exhibitions and content quality.

Phase 6: Complementary Services

Online booking and related services remain weak points. Improved systems could boost comfort and reduce friction during the visitor journey.

Phase 7: Ancillary Services

While MANN performs moderately well (−0.24), the Royal Palace shows a significant gap, particularly regarding food services and rest areas.

Phase 8: Post-Visit Digital Engagement

This is a critical shortcoming. Enhancing follow-up communication and digital engagement is essential to extend the visitor experience beyond the physical visit.

In summary, both sites are culturally compelling and attract a wide range of visitors. However, several service aspects—especially digital engagement, accessibility, and complementary offerings—need targeted improvement. Investing in physical-digital integration, thematic experiences, and immersive tools would align the sites with evolving visitor expectations. These findings reinforce the need for a holistic strategy that spans the entire visitor journey, fostering stronger emotional connections and long-term cultural value.

5.2 Theoretical implications

This study contributes to cultural tourism research by applying the expectancy-disconfirmation theory (Clemons & Woodruff, 1992) to Bourbon heritage sites, highlighting how mismatches between expected and perceived service affect satisfaction across various dimensions.

It advances the literature by integrating quantitative satisfaction metrics into heritage tourism analysis (Parasuraman et al., 1985), building on prior work on experiential quality, place attachment, and emotional engagement (Buonincontri et al., 2017; Chen & Chen, 2010).

The findings also emphasize underdeveloped areas such as post-visit digital interaction, echoing calls for research on digital heritage tools (Apollonio et al., 2019; Ford, 2020). In this context, the study advocates for broader application of immersive and interactive technologies to maintain visitor engagement.

Additionally, it supports a networked approach to heritage tourism (Russo & Van der Borg, 2002; Nicolais, 2023), promoting the development of interconnected itineraries that enhance regional tourism flow. This aligns with current discussions on sustainable tourism and participatory governance (Jelinčić & Mansfeld, 2019).

By offering a replicable model for evaluating service quality and expectations, the study provides a valuable tool for heritage managers and policymakers aiming to optimize visitor experiences. Future research should test this model in other historical settings to further refine its application and support the sustainable growth of cultural tourism.

6 Conclusions and future research directions

This study represents a foundational effort in evaluating visitor satisfaction at Bourbon cultural heritage sites through a structured, data-driven methodology. By applying the "Perceived Quality and Attributed Importance" framework across key touchpoints of the visitor journey, the research reveals not only the cultural strength of sites like the Royal Palace of Naples and MANN but also recurring weaknesses in accessibility, online communication, and post-visit engagement. These findings confirm that while the core cultural offerings are appreciated, peripheral services must evolve to meet the expectations of today's culturally active and digitally connected visitors.

Importantly, this study should be viewed as a pilot phase, developed in collaboration with the *Siti Reali* association and the University of Naples Federico II, laying the groundwork for broader applications. It opens strategic possibilities for future partnerships with innovative startups capable of developing digital tools, immersive technologies, and visitor analytics to enhance both measurement and management of visitor experiences. Such collaborations could scale the methodology to additional Bourbon sites—like Caserta, Carditello, and Capodimonte—transforming them into nodes of a wider, interconnected cultural network.

Future research should explore how digital innovation can be systematically integrated into heritage management, not only to assess satisfaction but to co-create new forms of engagement. A regional strategy based on open innovation and public-private cooperation can reposition Bourbon heritage as a dynamic driver of cultural tourism. Ultimately, this pilot demonstrates that heritage experience assessment—if supported by smart, scalable tools—can evolve from a static metric into a catalyst for sustainable and inclusive cultural development in Southern Italy.

Barriers to Web3 Technologies in Museums: A Qualitative Study in Turin

Chiara Vandoni, Guido Perboli
Politecnico di Torino, Turin, Italy

Abstract

The museum sector is undergoing a significant digital transformation, accelerated by the COVID-19 pandemic, which exposed vulnerabilities such as revenue losses and reduced visitor engagement. Emerging Web3 technologies, including blockchain and Non-Fungible Tokens (NFTs), offer potential solutions for monetization, visitor engagement, and accessibility. However, adoption in Italian museums remains limited. This study explores the barriers to Web3 technology adoption from an institutional perspective, using qualitative interviews with 23 museum professionals, including directors and curators.

Key findings reveal multifaceted challenges, including skepticism about the added value of NFTs, perceived technological complexity, financial constraints, and regulatory uncertainties related to copyright and data protection. Cultural concerns also emerged, with some stakeholders fearing that digital innovations might compromise museums' traditional roles or lead to excessive commercialization. The study aligns these themes with the Unified Theory of Acceptance and Use of Technology (UTAUT), extending the model to include sector-specific factors.

The research highlights the tension between innovation and tradition in museums, emphasizing the need for compelling use cases, robust regulatory guidelines, and dedicated funding to facilitate adoption. By contextualizing Web3 adoption within UTAUT, this study provides a theoretical foundation for future empirical investigations and practical insights for museums navigating digital transformation. The findings underscore the importance of balancing technological advancement with cultural preservation, ensuring that digital tools enhance rather than overshadow the core mission of museums as custodians of heritage and education. This study contributes to a broader debate on technology adoption in cultural institutions, particularly in contexts with strong historical traditions such as Italy.

Keywords: Cultural Ecosystem, UTAUT, Web3, NFT, Digital Transformation

Paper type: Academic Research Paper

1 Introduction

The museum sector is undergoing a profound transformation, accelerated by the disruptive impact of the COVID-19 pandemic. Museums, as cultural institutions, play a crucial role in preserving and disseminating heritage, fostering education, and contributing to the broader social, economic, and political landscape (Falk, J.H. and Dierking, L.D. 2018). However, the pandemic exposed structural vulnerabilities, including revenue losses, reduced visitor numbers, and budget cuts for exhibitions and educational activities (Ozdil, E. 2023). In response, museums are increasingly exploring digital innovations (Lazzeretti, L. et al. 2022) to ensure sustainability and enhance audience engagement (Pourmoradian, S. et al. 2021).

Among the emerging technologies, Web3 solutions—such as blockchain, Non-Fungible Tokens (NFTs), and Decentralized Autonomous Organizations (DAOs)—have been proposed as tools to revolutionize the museum experience. These technologies offer potential advantages, including authentication and provenance verification of digital artworks, novel monetization models, and enhanced visitor engagement (Valeonti, F. et al 2021). Despite these promising opportunities, the adoption of Web3 technologies in Italian museums remains extremely limited.

While previous research has explored the factors influencing visitors' behavioral intentions toward digital museums (Zheng et al., 2024; Ch'ng et al., 2019), less attention has been paid to the institutional perspective - specifically, the organizational and contextual factors affecting museums' decisions to adopt Web3 technologies. This study addresses this research gap by investigating adoption barriers through qualitative interviews with Italian museum professionals. The research has two primary objectives:

- to identify key adoption themes and evaluate whether existing theoretical frameworks (DOI, TAM, UTAUT);
- to analyze sector-specific factors influencing Web3 adoption, thereby expanding current technology adoption models for cultural institutions.

The paper is structured as follows: Section 2 reviews relevant theoretical foundations; Section 3 details the qualitative methodology; Section 4 presents the emergent themes and theoretical framing; Section 5 discusses

key conclusions; and Section 6 provides practical implications for museum management and digital strategy development.

2 Literature Review

2.1 Web3 Technologies in the Museum Sector

The museum sector faces cultural, economic, and technological challenges that impact its sustainability and relevance. One of the most pressing issues is cultural disengagement, particularly among younger audiences, who require innovative strategies, such as gamification and interactive experiences, to enhance their engagement with museums (Cranmer, E. et al. 2016, Ekinci, Z. 2023). Another significant challenge is the chronic underfunding of the museum sector. Following the COVID-19 pandemic, declining visitor numbers and rising operational costs have further constrained museums' ability to innovate, digital transformation remains uneven, with many institutions struggling due to skill gaps and technological maintenance challenges (Lampis, A. 2018).

In this context, Web3 technologies have emerged as transformative tools, offering innovative solutions for financial sustainability, visitor engagement, and cultural content accessibility. By leveraging decentralized systems such as blockchain and smart contracts, these technologies introduce novel interaction models that reshape audience participation and institutional strategies (Jones, M., 2023).

Among the most widely discussed applications of Web3 in the museum sector are Non-Fungible Tokens (NFTs), which facilitate digital ownership, provenance tracking, and new monetization opportunities. NFTs offer museums alternative revenue streams while enhancing audience engagement through digital collectibles (W. Lab, 2023). Major institutions, including the Museum of Modern Art (MoMA), Musée d'Orsay, and the Los Angeles County Museum of Art (LACMA), have launched NFT-based initiatives, showing a growing interest in these innovations (Musée d'Orsay, 2023; MoMA, 2024). These efforts reflect an increasing recognition of Web3's potential to reshape the cultural landscape and redefine museum engagement strategies.

Web3 technologies facilitate significant transformations in museum business models through three dominant approaches:

- Monetization: Museums generate revenue by tokenizing digital artworks, issuing limited edition NFTs, and leveraging blockchain for authentication and ownership verification.
- Engagement: Visitors interact with NFTs through QR codes, gamified experiences, and exclusive digital content, enhancing audience participation and loyalty.
- Accessibility: Web3 enables virtual exhibitions, immersive experiences, and metadata-enhanced collections, expanding global access to museum content and reducing geographical constraints.

These models illustrate the potential of Web3 in reshaping traditional museum operations (Jung, Y. 2023), yet adoption remains inconsistent, particularly within the Italian museum landscape.

2.2 Background and Theoretical Framing

Understanding Web3 adoption and barriers in museums requires a theoretical framework that explains the factors influencing technology acceptance. While this study adopts a qualitative approach—allowing key themes to emerge from interview transcripts—it also seeks to assess whether existing theoretical models can adequately explain these findings. Several models have been proposed to analyze technology adoption:

The Diffusion of Innovation (DOI) theory (Rogers E. M. et al. 2014) explains how innovations spread within a social system over time. It emphasizes the role of perceived advantages, compatibility, complexity, trialability, and observability in shaping adoption (Dearing, J.W. and Cox, J.G. 2018).

Technology Acceptance Model (TAM (Davis, F. D. 1985) focuses on how perceived usefulness and perceived ease of use influence an individual's intention to adopt new technology. TAM has undergone multiple refinements, culminating in more comprehensive frameworks such as UTAUT.

Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh et al., 2003) integrates elements from multiple adoption models, identifying four primary factors influencing technology acceptance:

- Performance Expectancy: The degree to which using a technology is perceived to improve job performance.
- Effort Expectancy: The perceived ease associated with the use of the technology.
- Social Influence: The extent to which important others (e.g., family, colleagues) influence the decision to use a technology.
- Facilitating Conditions: The extent to which an individual believes that organizational and technical infrastructure supports technology adoption.

Given the specific characteristics of Web3 technologies and the cultural heritage context, this study seeks to determine whether an existing theoretical framework—DOI, TAM, or UTAUT—can adequately explain adoption patterns in museums or whether an extended framework is needed.

3 Methodology

This study adopts an interpretative paradigm, as the primary objective is to understand the subjective experiences and beliefs of participants in the context of early technology adoption in museums. This approach acknowledges that reality is socially constructed, emphasizing participants' perspectives as a fundamental element of the research process. To ensure that participants' perspectives remained central to our analysis, we employed an inductive approach, allowing themes to emerge directly from the interview transcripts (Patton, M.Q. 2014). This methodological choice aligns with the study's goal of identifying both theoretical constructs related to adoption of technology and sector-specific factors influencing Web3 implementation in museums.

3.1. Data Collection

A total of 23 semi-structured interviews were conducted with a diverse group of museum stakeholders, including directors, curators, and employees. Museums were initially contacted via email, and upon agreement, a follow-up video call was scheduled to conduct the interview. The interview questions were designed to explore participants' perceptions of Web3 technologies, potential barriers to adoption, and institutional attitudes toward digital transformation.

Figure 1 provides an overview of the museums included in our study, detailing their size, specialization, and mission.

#	CODE	MUSEUM	MISSION	VISITORS/YEAR

Figure 1: list of museums interviewed

3.2. Data Analysis

The interviews were transcribed using Microsoft Word, and to ensure accuracy, a member of the research team manually reviewed and edited all transcripts before proceeding with the coding process.

A flexible coding approach was employed, allowing multiple codes to be assigned to a single unit of data when necessary (Patton, M.Q. 2014). Given our interest in identifying both existing theoretical constructs and novel sector-specific factors, we adopted an inductive coding process: The initial phase of analysis followed an open-coding approach, allowing key themes to emerge organically from the data. This ensured that the findings were grounded in the participants' perspectives rather than predefined theoretical categories. Then, during the coding process, themes were refined, consolidated, and categorized to capture the most significant insights.

4 Results

4.1 Emerged Themes

This section presents the key themes that emerged from the analysis of interview data, highlighting the barriers to Web3 adoption in museums. The findings are structured around these themes and are supported by representative quotes from participants.

4.1.1 Perception of Technology Value

The perceived usefulness of blockchain-related technologies varied among participants. Regarding the potential monetization of digitized museum-owned artworks through NFTs, interest was notably low; almost all participants did not perceive significant value in this model.

Conversely, more than half of the interviewees acknowledged blockchain's potential to enhance visitor engagement. Specifically, museums recognized blockchain's ability to increase visitor interaction, attract a broader audience, and improve accessibility as relevant factors in assessing adoption.

"We are currently investing in gamification and virtual reality projects that will launch in the coming months. We believe both approaches enhance visitor engagement and transform passive observers into active participants in the museum experience."

However, participants did not consider Web3 technologies to be the only, or necessarily the best, solution for increasing visitor engagement. Many interviewees expressed skepticism regarding the added value of NFTs or blockchain-based experiences compared to existing digital tools.

"...So what are the actual benefits? Compared to a photo I take on my phone of the artwork, what added value does it (NFT) bring? Maybe it creates a link with the museum, but often, a museum visit is perceived as a one-time event."

While there is openness to exploring new digital tools, the benefits of Web3 technologies remain unclear to many museum professionals, leading to hesitation in adoption.

4.1.2 Ease of Adoption

A high perceived level of complexity emerged as a significant barrier to Web3 adoption in museums. Many interviewees explicitly cited the technological difficulty of blockchain-based solutions as a primary reason for their reluctance. Participants emphasized that new technologies should integrate seamlessly into existing workflows without requiring drastic operational changes.

" There is a significant entry barrier due to the level of expertise required to develop these solutions—knowing whom to approach, understanding the market, and navigating the technical aspects."

Additionally, several respondents indicated that they would be more inclined to adopt blockchain-related technologies if other museums implemented them first. However, this hesitation was not driven by social pressure but rather by the need for concrete implementation models to follow.

"It would be helpful to have examples to follow—some initial cases that help museums like ours understand the pros and cons, administrative implications, and real impact. If a major national museum acted as an early adopter, it would certainly provide a reference point."

Reducing the complexity of blockchain adoption and providing clear, practical use cases could encourage wider adoption in the museum sector.

4.1.3. Propensity for Innovation

Participants' attitudes toward innovation emerged as a significant barrier to Web3 adoption. Some respondents expressed a strong preference for traditional museum experiences over investments in emerging technologies.

"Right now, I would rather invest in a high-quality exhibition, like a De Chirico retrospective, than spend a substantial amount on emerging technologies."

However, other museums demonstrated a strong belief in the potential of technology as a powerful tool for cultural dissemination. These institutions viewed digital innovation as an opportunity to expand audience engagement and accessibility, rather than as a distraction from traditional curatorial priorities. This divergence underscores the diverse perspectives within the museum sector, with some institutions embracing innovation as a strategic asset while others remain cautious about its implications.

4.1.4. Financial Resources

All museums in the study recognized cost as a major barrier to implementing blockchain-related technologies. Interviewees identified multiple financial constraints, including:

- High implementation costs associated with integrating blockchain technology.
- Limited museum budgets, restricting investment in new digital solutions.
- Competing financial priorities, where other areas require more immediate funding.
- Expenses related to staff training or the need to hire external experts.

"Cost is the fundamental issue. With adequate funding, anything is possible."

"There are two major limitations: first, the lack of a dedicated staff member responsible for digital development, and second, financial constraints. These two factors are clearly linked—the lack of resources prevents us from hiring the necessary expertise."

These financial considerations highlight the importance of funding availability and strategic resource allocation in evaluating blockchain adoption.

4.1.5. Market Perception

In all interviews, stakeholders identified visitor perceptions as a critical factor in Web3 adoption decisions. Concerns about whether visitors would understand or appreciate these technologies influenced museums' willingness to experiment with them. Some interviewees described blockchain-related innovations as *"… polarizing, potentially attracting certain visitors while alienating others".*

Additionally, some stakeholders expressed the belief that their museum's target audience was generally uninterested in such technologies and that Web3 did not align with their visitor demographic.

"Our museum is not suited for these types of technologies. Digitalization, yes, but beyond that, it becomes difficult to justify. Our target audience tends to be older and less familiar with these innovations, making their integration particularly complex."

Research on digital innovation in cultural institutions emphasizes not only the importance of audience attitudes toward novel technological experiences but also the need to educate the public on these topics (Cuseum, 2022 and Trends, 2021). Studies highlight widespread public skepticism toward NFTs, driven by: environmental impact, social perception, and trust (Barua, S. et al. 2025). Many people perceive NFTs as speculative assets rather than tools for social good, making them a divisive and often misunderstood technology. Public skepticism and concerns about financial speculation, can create resistance to their adoption in cultural contexts (Kaczynski, S. 2021).

4.1.6. Regulatory Concerns

Legal and regulatory considerations emerged as significant barriers to adoption. Many museum stakeholders expressed concerns about copyright laws, particularly regarding the digitization of artworks. A major challenge is the presence of rights managed by collecting societies such as SIAE, which limit museums' ability to freely digitize and distribute cultural assets.

"We cannot digitize the artworks for a very simple reason: most of them are protected by SIAE copyright regulations. It would be interesting to explore how this could change once a clear legal framework is established."

The lack of clear regulatory guidelines for blockchain applications in the museum sector was also a frequently mentioned concern. Additional challenges include intellectual property rights, data protection (GDPR compliance), and the legal validity of smart contracts, all of which further complicate adoption. Many interviewees indicated that regulatory clarity would be a determining factor in their institution's willingness to explore blockchain technologies.

The implementation of blockchain in museums introduces complex regulatory and privacy challenges, particularly in relation to data protection and intellectual property rights. As noted in the literature, compliance with legal frameworks such as the General Data Protection Regulation (GDPR), liabilities associated with smart contracts, and uncertainties surrounding digital ownership rights constitute major adoption barriers (Lohmer, J. et al. 2020, Barua, S. et al. 2025).

The largely unregulated nature of the NFT sector exacerbates these concerns, creating an uncertain ecosystem. The absence of standardized criteria for authenticity and value assessment further increases the risk of misinformation and skepticism toward the technology (Gherghelas, S. 2022). Establishing clear regulations and guidelines for NFT transactions, ownership rights, and intellectual property protection would provide museums with a more structured foundation for considering adoption.

4.1.7. Cultural Aspects

A significant number of respondents identified cultural considerations as key factors in adopting and utilizing new technologies. In this context, cultural aspects refer to individual beliefs about the role of museums in society. Many stakeholders expressed concerns that museums should uphold their cultural integrity, which they perceived as a barrier to integrating blockchain-related technologies. This perspective manifested in three distinct ways:

- Preserving the museum space: some respondents believed that museums should remain dedicated to traditional forms of curation and avoid unnecessary technological interventions.
- Risk of losing cultural mission: others were concerned that technology-driven experiences could shift museums toward entertainment rather than cultural enrichment.

"... The idea of enhancing the museum experience with technology seems problematic. If technology is used to create content rather than support existing content, then it feels completely misguided. I strongly oppose the notion of transforming the museum experience into mere entertainment."

"… We must be cautious, as there is a risk of falling into pure spectacle for its own sake. Scientific and cultural foundations must remain a priority, even when integrating new technologies. Otherwise, we risk turning museums into amusement parks, creating superficial entertainment rather than a meaningful cultural experience."

- Museums as spaces for slowing down, not accelerating technological consumption: Some respondents emphasized the role of museums as places for reflection and contemplation rather than environments that promote technological acceleration.

"We strive to create museum experiences that do not rely entirely on digital consumption. We live in a world where image consumption is already so intense and overwhelming that we prefer not to encourage that trend within our museum."

Beyond technical and financial considerations, the philosophical role of museums in an increasingly digital world remains a critical factor in decisions regarding Web3 adoption.

4.2 Theoretical Framing

Through an inductive analysis of museums' stakeholder interviews, several key themes emerged regarding the factors influencing museum adoption of Web3 technologies: Perception of Technology Value, Ease of Adoption, Propensity for Innovation, Financial Resources, Market Perception, Regulatory Concerns, and Cultural Aspects. These themes reflect both institutional and technological barriers, highlighting the complexity of Web3 adoption in the museum sector.

The research findings can be interpreted using the theoretical lens of the Unified Theory of Acceptance and Use of Technology (UTAUT), which has been widely applied in various contexts to assess technology adoption (Zheng, F. et al. 2024). The constructs embedded in UTAUT, performance expectancy, effort expectancy, social influence, and facilitating conditions, serve as a foundation for understanding the key factors influencing Web3 adoption among museums.

Each of the emergent themes aligns with and extends the constructs of UTAUT, as detailed below in Figure 2:

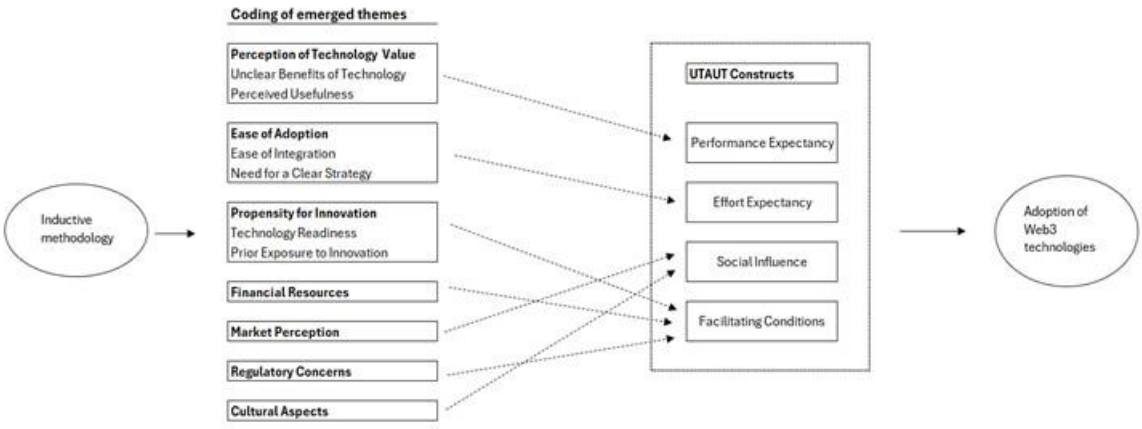

Figure 2: Emerged themes and UTAUT constructs relationship

- Performance Expectancy: This construct is reflected in Perception of Technology Value, as museums struggle to identify clear benefits of Web3 solutions, particularly regarding monetization. While most stakeholders questioned the added value of NFTs, some recognized blockchain's potential in enhancing visitor engagement and accessibility. The lack of compelling use cases and concerns about the long-term sustainability of Web3 initiatives further contributed to skepticism.
- Effort Expectancy: This corresponds to Ease of Adoption, as concerns about technological complexity and integration challenges emerged as major barriers. Participants highlighted the lack of internal expertise and the need for seamless integration into existing workflows. The demand for a clear implementation strategy and adequate training resources was frequently mentioned, emphasizing the necessity of structured support to facilitate adoption within museums.
- Social Influence: This construct aligns with both Cultural Aspects and Market Perception. Interviewees revealed concerns about sector-wide perceptions of museums adopting Web3 technologies, with particular anxiety that emphasizing digital experiences over traditional curation might compromise institutional credibility and lead to negative peer judgment. Additionally, external audience perceptions emerged as equally influential factors, creating pressure that either encourages or discourages adoption decisions.
- Facilitating Conditions: This construct is reflected in Propensity for Innovation, Financial Resources, and Regulatory Concerns. Museums already engaged in digital experimentation (e.g., virtual reality and gamification) showed greater openness to Web3 technologies. However, financial constraints—such as high implementation costs and competing budget priorities—acted as significant barriers to adoption. Furthermore, Regulatory Concerns, particularly regarding intellectual property rights, data protection (e.g., GDPR compliance), and copyright laws, added layers of complexity to decision-making, making institutions hesitant to fully embrace blockchain-based solutions.

By mapping the emerged themes from our qualitative analysis onto the UTAUT constructs, we provide a comprehensive framework for understanding the multi-layered challenges that museums face in adopting Web3 technologies. This alignment allows us to contextualize the findings within established technology adoption theories while emphasizing the unique institutional and cultural constraints of the museum sector.

5 Conclusions

This study advances the understanding of blockchain-related technology adoption in cultural institutions in several key ways.

The findings confirm that the constructs of the UTAUT model are highly relevant for analyzing the adoption of emerging technologies in museums, identifying the most suitable theoretical framework for understanding the behavior of cultural institutions.

Our study extends the classical understanding of social influence by emphasizing key aspects specific to the museum sector and emerging technologies. Two primary dimensions emerge:

- Sector Influence – The integration of Web3 technologies raises concerns about potential commercialization. Many institutions fear that prioritizing digital spectacle over curatorial rigor could undermine their credibility, making them appear more entertainment-driven rather than educational and cultural. As a result, museums are cautious about how their choices will be perceived by peers. This aspect, while not widely addressed in existing literature, is particularly relevant in cultural contexts with a strong historical heritage, such as Italy, where tradition significantly influences decision-making.
- Public Influence – Another emerging concern is the perceived lack of public education on Web3 technologies. Many museum professionals worry that audiences may not fully understand or appreciate blockchain-based initiatives, leading to skepticism or disengagement.

The study also refines the Facilitating Conditions construct by identifying specific dimensions that act as either drivers or barriers to the adoption of emerging technologies in museums. Three key factors are identified:

- Propensity for Innovation
- Financial Resources
- Regulatory Concerns

These dimensions are consistent with existing literature. Previous research has predominantly highlighted economic constraints (Valeonti, F. et al. 2021, Rennie, E. 2022), technical challenges (Cranmer, E. et al. 2016, Hackius, N. Petersen, M. 2017, Helliar, C. V. et al. 2020), and regulatory barriers (Valeonti, F. et al. 2021, Lohmer, J. et al. 2020) as primary obstacles to technological adoption (Venkatesh, V., 2012).

The proposed theory suggests that specific constructs should be integrated into the existing UTAUT framework. Given that this study is based on a qualitative approach, the outcome is a theoretical contribution.

The proposed theory enhances our understanding of the factors that influence behavioral intention in the adoption of blockchain-related technologies within museums. In an era of technological innovation extending into the museum sector, our findings contribute to the broader discourse on technology adoption by identifying constructs specific to blockchain-related adoption in cultural institutions. Our proposed theory has the potential to assist cultural institutions in understanding how to integrate emerging technologies, particularly within contexts deeply rooted in historical heritage. Indeed, the study highlights that one of the most significant barriers to implementation is the tension between digital innovation and the preservation of traditional museum values.

This extended framework will guide future empirical investigations into the adoption of Web3 technologies in Italian museums, bridging theoretical gaps and offering practical insights into digital transformation strategies for cultural institutions.

6 Managerial Implication

This study's findings extend beyond the Italian context, offering valuable insights for cultural institutions in regions with rich historical heritage. Successful Web3 adoption requires a strategic approach that addresses institution-specific barriers while balancing innovation with the preservation of traditional values. Museums must navigate competing expectations, embracing digital transformation while maintaining their role as custodians of cultural authenticity.

The identity paradox underscores how social influence in museums operates differently from conventional UTAUT models, peer perceptions and institutional reputation often outweigh potential technological benefits. To mitigate fears of negative peer judgment, leadership should foster internal alignment on digital strategy and clearly communicate how Web3 initiatives complement rather than compromise core cultural missions.

Adoption decisions are influenced by both horizontal (peer institutions) and vertical (audience) pressures. To effectively manage these influences, museums should actively engage in sector-wide dialogues to establish ethical and curatorial standards for emerging technologies. Rather than following technological trends, Web3 adoption should be assessed through the lens of institutional missions. Leadership teams must develop clear criteria for evaluating how blockchain applications support existing curatorial and educational goals. Additionally, visitor education initiatives, such as explanatory videos and guided NFT demonstrations, can help demystify Web3 technologies for traditional audiences.

Furthermore, museums should advocate for sector-specific regulatory frameworks with cultural policymakers to address challenges related to GDPR compliance and intellectual property rights. For practitioners, these insights highlight the importance of a phased, mission-aligned approach to digital transformation, one that prioritizes institutional readiness while proactively managing reputational risks.

Artificial Intelligence and Value Co-creation in Museums: Promoting Inclusion for People With Disabilities

Amelia Napolitano[1], Laura Clemente[2], Francesco Bifulco[3]
[1]University of Padua, Padua, Italy
[2]Sapienza University of Rome, Rome, Italy
[3]Federico II University of Naples, Naples, Italy

Abstract

The present study investigates the potential of Artificial Intelligence (AI) to foster inclusive cultural value in Italian museums, focusing on addressing the physical, sensory and cognitive barriers encountered by visitors with disabilities. The research employed a multiple-case qualitative design, engaging more than twenty museums through a semi-structured online questionnaire administered to accessibility managers. The museums varied in governance, location, and thematic focus, but all were committed to accessibility. The findings demonstrate a robust theoretical understanding of AI's potential to personalise experiences. However, its practical implementation remains predominantly experimental, constrained by infrastructural limitations, organisational rigidity and financial constraints. A significant proportion of institutions engaging with AI, specifically 87.5%, reported incorporating co-design processes with individuals living with disabilities. This finding serves to emphasise the pivotal role that participatory approaches play in ensuring technological solutions are aligned with the needs of the end-users. From a governance perspective, the study posits that truly inclusive innovation necessitates a systemic strategy: museums must invest not only in technological infrastructure but also in interdisciplinary processes that facilitate collaboration among curators, technical specialists and disability-community representatives. Furthermore, the sustainable integration of AI tools necessitates a coordinated commitment across multiple institutional levels, encompassing individual museums, governmental bodies, and disability-rights organisations, to ensure the availability of adequate resources, expertise, and policy support. To strengthen the evidence base, it is recommended that future research should expand the empirical scope by testing the proposed framework on a larger, more diverse sample of cultural institutions and by conducting longitudinal studies to track the long-term impacts of AI-driven accessibility initiatives. The work under discussion here establishes the foundations for human-centred technological innovation that extends beyond the scope of pilot projects and integrates inclusivity as a fundamental element of museum practice.

Keywords: Accessibility, Artificial Intelligence, Value co-creation, Museums, Person with disabilities

Paper type: Academic Research Paper

1 Introduction

Artificial Intelligence (AI) is increasingly transforming the cultural sector, offering innovative opportunities to enhance accessibility and personalize visitor experiences. While recent studies have explored the application of AI in museums, the focus has predominantly been on operational efficiency, marketing, or audience engagement, with limited attention to its potential in addressing accessibility challenges for people with disabilities. At the same time, the literature on value co-creation and inclusive design has emphasized the importance of involving marginalized users in the developing services, yet few empirical investigations have examined how these principles intersect with AI technologies in the museum context.

This study addresses this gap by investigating how AI can be employed to support inclusive value co-creation in Italian museums, with a specific focus on enhancing accessibility for visitors with sensory, motor, and cognitive disabilities. The research aims to map existing practices, identify perceived barriers to adoption, and assess the role of participatory processes in the development of AI-based solutions. By combining a conceptual framework with preliminary qualitative findings from a national sample of museums, the paper contributes to the emerging discourse on human-centered technological innovation in cultural institutions.

2 Theoretical framework

2.1 Value co-creation with people with disabilities

The dynamic economic landscape of the 21st century has precipitated a critical reappraisal of traditional value-creation paradigms, revealing that fostering high-quality interactions, through which individual customers actively co-create distinctive experiences with organizations, is essential for unlocking novel sources of competitive advantage (Prahalad & Ramaswamy, 2004a&b).

Considering this global scenario and the close connection with the ongoing changes in society of which they are a mirror, museums are gradually evolving from their traditional paradigm of value creation towards a model of co-creation of cultural value (Barnes & McPherson, 2019) considered as the best way to focus explicitly on the experiences of all visitors and make them rewarding (Ramaswamy and Gouillart, 2010) despite certain barriers and obstacles that may arise in the co-creation practice (Najda-Janoszka & Sawckuk, 2023b).

Value co-creation is a paradigm that redefines the relationship between museums and visitors, shifting the focus from a unidirectional model of value delivery to a collaborative and interactive approach that promotes collaborative problem solving and stimulates innovation, enabling cultural organisations to adapt dynamically to the expectations and desires of their audiences (Prahalad & Ramaswamy 2004a). Co-creation can benefit the design process (Ali and Liem, 2015), the organization, the entire society (Mazzucato, 2018) and therefore the single visitors. Inclusive co-creation can take the process of designing futures to a level where diverse users' needs can be used as the basis of the design process and consider intersectional and norm critical approaches (Kuuluvainen, 2022). Having a team member representing the end user's identity can enhance understanding of the end-users' needs for all the design team (Hewlett et al. 2013). So, in a co-creation process, the diversity of participants is paramount, because diversity has been proven to increase innovation capabilities in organizations (Nathan and Lee, 2013; Hewlett et al., 2013; Phillips, 2014). This requires cultural institutions to listen to the needs and expectations of their stakeholders, including disadvantaged audiences and people with disabilities (Muscarà & Sani, 2019; Mesquita & Carneiro, 2016).

The principles of co-creation align with the slogan 'Nothing about us without us', popular in the disability rights movements and which has been leading the fight of people with disabilities to see their rights respected since the 1970s. Agree with this view of co-creation, it is no longer just a mere tool for adapting content but becomes a dynamic and interactive process, highly respectful of the rights not only to enjoy but also to participate in the cultural life of people with disabilities, in which visitors themselves take on the role of co-protagonists of the museum experience, contributing with their own perspectives and suggestions to the definition of solutions that best meet their needs (Mulvale et al., 2024). Visitors with disabilities can contribute to the creation of such experiences through their direct involvement, active participation and the ability to personalize their interactions (Minkiewicz & Bridson, 2014). The ability to personalize the experience of enjoyment is configured as a strategic imperative, capable of creating a closer relationship with the end-users (Trischler et al., 2019), ensuring that diversity becomes a point of strength, promoting intercultural dialogue and active and shared participation through which co-creation takes place (Minkiewicz & Bridson, 2014). The personalization of the museum experience, in a context, such as those of people with cognitive, sensorial and physical disabilities, characterized by extremely heterogeneous needs, is the cornerstone for those museums that wish to embody the principles of equality and turn diversity into an asset rather than an obstacle in the context of the cultural offer.

Jung et al. (2017) emphasize the importance of the integrated use of multiple technologies in order to create an environment of value co-creation as part of the experience. The cultural and creative sector, with a particular focus on museums, has recognised the added value of digital tools (Del Vacchio et al., 2020): their diversity and adaptability make it possible to respond to different accessibility needs and broaden how cultural content can be enjoyed. Furthermore, research has applied the new perspective of 'co-creation through interactions' whereby interactions are central and technology is a strategic determinant for co-creating valuable experiences with people, artefacts, processes and interfaces (Ramaswamy, 2020), even if the studies in this regard are still few (Ramaswamy and Ozcan, 2018). This research gap highlights the need for further research that can contribute to a better understanding and implementation of targeted technological solutions that can make museum experiences truly inclusive and accessible for all visitors.

2.2 AI in the cultural sector

The rapid advancements that characterize the current technological era, marked by constant innovation, have significantly contributed to the widespread adoption of Artificial Intelligence (AI). This emerging phenomenon is increasingly recognized for its transformative potential across a wide range of sectors. Within the scholarly discourse, AI is defined as a digital technological application that provides an interactive learning environment and functions in a capacity close to human intelligence. In particular, Vidu et al. (2021) identify it as a form of intelligence that can operate at a cognitive level and has the ability to interpret, adapt to, and shape different environments and circumstances.

Recent studies (Kunz et al., 2024) also suggest that AI, particularly its generative component, is having a more powerful impact on marketing outcomes than previous generations of digital technologies, as its ability to

generate text, images, video and more generally human-like content enables more personalised customer experiences that are difficult to replicate by humans alone.

Artificial Intelligence is emerging as a transformative force also in the museum sector, revolutionizing how these institutions engage audiences, manage operations, and design inclusive cultural experiences.

In the context of cultural heritage, the integration of AI with data analytics can improve exhibition planning and operational efficiency by designing predictive models of crowd flows and visitor preferences, while supporting a shift from passive consumption to active participation, fostering visitor engagement and personalising the museum journey (Rosemary, 2025).

AI's impact extends to educational and curatorial functions: it facilitates the cataloguing of artifacts and supports the digital reconstruction of damaged heritage objects through advanced imaging and computational techniques. Furthermore, AI-driven tools such as natural language processing (NLP) and machine translation enrich the interpretative dimension of exhibitions by enabling multilingual content delivery. These capabilities help overcome linguistic barriers and contribute to creating more inclusive and globally accessible museum environments. Moreover, museums increasingly employ AI to analyze feedback and social interactions, enabling real-time adjustments to content delivery and exhibit design (Li et al., 2024). These advancements position AI not merely as a technological trend, but as a strategic enabler of value co-creation, where museum professionals and audiences, especially those traditionally marginalized, can collaboratively shape inclusive cultural experiences (Carignani et al., 2023; Ramaswamy & Ozcan, 2018).

Recent studies highlight AI's role in making cultural spaces more accessible and inclusive, particularly for individuals with disabilities. Applications range from AI-powered chatbots and virtual guides to automatic transcription tools, sign language avatars, and audio descriptions generated through natural language processing (Islek et al., 2024). Such tools have shown strong potential in reducing sensory, cognitive, and physical barriers to participation, thus aligning with the co-creation paradigm that values diversity and intersectionality (Mele et al., 2022; Kuuluvainen, 2022). Museums leveraging AI for accessibility not only improve visitor autonomy and personalization (Trischler et al., 2019), but also contribute to the broader societal goal of cultural democratization (Candello et al., 2020).

However, despite its promising advantages, the adoption of AI in cultural institutions raises critical questions and concerns regarding ethics and the depersonalisation of the human experience. It is therefore necessary that technological innovation continues to be guided by human-centred design (Wach et al., 2023). The challenge for museum professionals is to strike a balance between technological potential and ethical responsibility, ensuring that AI acts as a facilitator of access, inclusion and the sharing of cultural meaning.

Based on the research conducted by Islek et al. (2024), the authors identified five key areas where AI can assist in creating personalised museum experiences for people with cognitive, sensory and physical disabilities, summarised in Table 1. The table offers a systematic representation of museum accessibility needs broken down by type of disability, comparing traditional facilitators with potential artificial intelligence-based solutions.

In particular:

- Type of disability: five categories are identified that characterise the main challenges (sensory, motor and cognitive) faced by people with disabilities; the last category 'General' refers to all single disabilities and cases of multiple disabilities.
- Facilitators needed: for each category, the analogue or organisational supports usually used (e.g. tactile guides, subtitles, ramps, reduced stimulation environments) to ensure an inclusive and usable museum experience are listed.
- AI-based supports: for each disability domain, advanced technological solutions employing AI are proposed to meet the needs of each visitor; in addition, cross-disciplinary solutions of predictive analytics, visitor satisfaction analysis and advanced search engines are indicated to enhance the experience of all users.

In this way, the table serves as a framework for the design and evaluation of integrated interventions aimed at combining traditional facilitators and AI innovations with a view to universal accessibility.

Table 1: Classification of Artificial Intelligence Tools for Enhancing Museum Accessibility in Relation to Disability Categories

Type of Disability	Facilitator needed	AI support
Visual Impairments: blindness and low vision (VI)	To navigate independently, people with visual impairments need tactile and auditory supports—such as engaging audio guides, acoustic signage, tactile replicas, floor plans, and models—as well as voice-compatible websites and apps.	Automatic audio description of objects in exhibition: to translate the image into sound description
		Optical character recognition: to translate text from image in sound description
		Assist in the creation of tactile graphics, tangible representation of image and objects
		Voice interfaces for those who have difficulty using touchscreen devices or typing
Hearing Impairments: deafness and hard of hearing (HI)	People with hearing impairments require tactile or visual supports—such as captions or subtitles for all audiovisual content, real-time transcription at live events, written guides, sign language interpretation (in-person or virtual), and inductive loop systems for hearing aids.	Automatic textual description of images, videos and works: to translate image into text
		Multimodal chatbot assistants: to guide audiences step-by-step through museum itineraries using Vocal interaction and sign languages
		Sign Language Interpretation: to translate spoken language into sign languages
		Speech-to-text transcription: to translate the audio content in texts
Physical Disability: paralysis, amputations, motor impairments (PD)	People with physical disabilities may struggle to travel to or move around the museum. Remote telepresence systems (e.g., robot-guided virtual visits) address access from afar, while barrier-free design—wide, obstacle-free paths, ramps, lifts, adaptive exhibit equipment—and hands-free interaction systems ensure full on-site accessibility.	Mobile avatars guided by the visitors who cannot physically go to the museum
		Pre-constructed virtual tours to visit the museum from a distance
		Social robot that guides physically impaired visitors who go to the museum in person
Cognitive Disabilities: dementia, intellectual disabilities, learning disorders (CD)	People with cognitive disabilities benefit from simplified language that accurately summarizes captions and texts, along with easy-to-read materials, clear visual aids, structured navigation paths, and low-stimulus environments.	Tool that create texts in Augmentative Alternative Communication in real time
		Tool that create easy-to-read texts in real time
		Gamification to make learning more engaging and enjoyable
General Accessibility (GA)	To improve satisfaction and accessibility for all visitors, including those without disabilities, museums should implement systems that collect and respect users' needs, preferences, and abilities to offer personalised content, navigation, and support tools before and during the visit.	Predictive Analytics to predict visitor needs and preferences and enable museums to proactively address accessibility challenges
		Visitor Satisfaction Analysis to analyse visitor data and identify areas where accessibility could be improved in future exhibitions and programmes
		Advanced Information Retrieval to simplify searching for information on websites

Author's elaboration.

3 Methodology

In line with its exploratory nature, which aims to map the use of AI in Italian museums to increase accessibility and participation of the public with disabilities, this study adopts a qualitative approach (Turner et al., 2021) based on a multiple case research design (Stake, 2013).

The research design involves an initial sampling of Italian cultural institutions, to which a semi-structured questionnaire is sent to collect primary data. The data collection is based on a triangulation strategy (Creswell & Creswell, 2017) aimed at strengthening the reliability and validity of the results, and for this reason the data collected will be cross-referenced with information available on the official websites of the museums.

The selection of institutions was made through a combination of structured sources and independent research by the authors. In order to select the cultural institutions, the authors used ministerial databases and

reports from disability associations to identify those cultural institutions that are considered to be the most accessible for different disabilities.

The selected sample included over twenty Italian museums, chosen to ensure a broad and diverse representation of the national landscape. The selection spans the entire Italian peninsula, from northern regions down to southern regions, thus capturing the geographical diversity of the country. The sample also reflects a variety of governance models, ranging from major national museums to institutions managed by local authorities, private foundations, and non-profit organizations. Furthermore, the museums feature highly heterogeneous collections, encompassing fine arts, archaeology, science, ethnography, and multisensory experiences, allowing the study to investigate both consolidated accessibility practices and innovative, experimental approaches. The only common feature among the selected institutions is their commitment to providing high-quality accessible services for visitors with different types of disabilities.

Primary data have been collected through a semi-structured interview in the form of an online questionnaire. The questions address different areas of AI application, each related to a different type of disability and closely linked to the AI tools identified in Table 1. The questionnaire also explores the actual implementation of these tools in the surveyed museums, the presence or absence of co-design processes with people with disabilities, and the main perceived barriers (technical, economic, cultural) to the adoption of these solutions. The instrument is divided into a series of dichotomous questions, some open-ended and some multiple choice, on a Likert scale from 1 to 5. This multiplicity will allow the study to explore both qualitative and quantitative aspects and to serve as a starting point for more in-depth future studies.

The data will be systematically analysed to identify recurring patterns, good practices and areas for improvement, with the aim of contributing to the development of accessible technologies that are not only functional but also culturally and socially meaningful.

4 Preliminary results

Based on the adopted framework, several preliminary insights emerge. Of the 24 museums contacted, 10 completed the questionnaire (42% response rate). Despite the small sample, the diversity in museum types, governance, and accessibility practices provides valuable insights and helps lay the foundation for broader mapping and development of replicable AI-based accessibility models in Italian museums.

The analysis reveals a substantial openness among cultural institutions toward the potential of AI to enhance accessibility and inclusion. This aligns with the literature, which highlights how AI technologies can foster more autonomous, personalized and emotionally engaging experiences for people with disabilities, while also enriching the cultural experience for the general public (Islek et al., 2024; Trischler et al., 2019; Candello et al., 2020). Tools identified in the literature, such as speech-to-text systems, automatic audio descriptions, and personalized guidance, are consistently cited by respondents as promising solutions for removing physical, cognitive, and sensory barriers. Specifically, respondents rated as particularly useful those AI tools designed to translate or adapt content in real time, including automatic transcription, audio and text simplification, and chatbot interfaces capable of multimodal communication. These tools were especially valued in relation to visual and auditory impairments and in case of cognitive disabilities. The potential of predictive analytics, visitor satisfaction monitoring and advanced search functionality in support of overall accessibility was also recognised, confirming the wider cross-category benefits of such systems.

Despite this strong theoretical consensus, actual implementation remains limited. While 80% of responding institutions report having adopted or planned to adopt at least one AI-based accessibility tool, most applications are still confined to pilot programs or experimental use. Only a few tools, primarily automated subtitling, speech-to-text translation and chatbot guidance, appear to have been integrated more systematically, suggesting that AI adoption in the cultural sector is still in an exploratory phase.

The results also highlight the importance of participatory approaches to AI development. In line with the co-creation paradigm discussed in the literature, 90% of respondents report involving people with disabilities in the design of accessible content, and among those implementing AI, 87.5% say that co-design processes have been or will be part of the development cycle. This involvement is essential not only to ensure technological usability, but also to promote cultural relevance and user empowerment. However, the responses suggest that such participation is not always structured or continuous, raising questions about the depth of user involvement in different museums.

Barriers to AI implementation were frequently mentioned, reinforcing the gap between perceived potential and practical adoption. The most cited obstacles include the lack of internal technical expertise, difficulties integrating new tools with existing systems, and financial constraints. These issues point to a lack of institutional

readiness, and confirm the need for targeted capacity-building and supportive policy frameworks to enable museums to transition from isolated experimentation to sustainable, system-wide innovation.

These results confirm, as already highlighted in the literature, that AI technologies can be key factors in creating inclusive cultural value when combined with participatory design principles. At the same time, they reveal how infrastructural, organisational and economic limitations continue to hinder the spread of AI in the cultural sector.

5 Implications

From a theoretical perspective, this study contributes to advancing the paradigm of value co-creation by empirically demonstrating how Artificial Intelligence can function both as a medium and an agent within participatory processes in the cultural sector (Ramaswamy & Ozcan, 2018; Ramaswamy, 2020). Preliminary findings reinforce the new conception of museums as dynamic ecosystems, where co-creation emerges through continuous negotiation between human actors, technological artefacts and institutional logics.

The study confirms that inclusive AI implementation cannot be conceived outside of human-centered and intersectional design approaches. The high rate of self-reported co-design practices among responding institutions supports the claim that involving people with disabilities as co-creators, rather than passive recipients, increases both the usability and the cultural legitimacy of AI solutions (Mulvale et al., 2024; Minkiewicz & Bridson, 2014). These findings extend the literature on inclusive service design (Trischler et al., 2019; Kuuluvainen, 2022) by demonstrating how diversity and participatory engagement can help mitigate accessibility barriers. The positive perception of AI tools across disability sectors also highlights how personalisation and adaptability serve as strategic drivers of inclusive cultural value.

From a managerial standpoint, the research highlights the fundamental need for a strategic repositioning in the governance of accessibility and innovation. Although most institutions recognise the transformative potential of AI, the data shows that its actual adoption is still limited to specific use cases and early stage applications. This discrepancy suggests that AI-based accessibility needs to move beyond isolated projects towards systematic integration. To enable this shift, cultural organisations should invest in the development of collaborative governance infrastructures and interdisciplinary teams that can ensure that technological innovation is integrated into inclusive decision-making processes.

Furthermore, the institutional heterogeneity captured in the sample reveals significant asymmetries in readiness to adopt AI solutions. This disparity is compounded by recurrent barriers identified in the study, including lack of internal technical expertise, integration challenges with legacy systems, and insufficient financial resources. Acknowledging these barriers constitutes a strategic starting point for addressing them through coordinated institutional responses. Recognizing and systematically mapping these constraints can also inform the design of targeted training programs and support services, helping institutions to build long-term organizational capabilities. In this way, AI can evolve from a promising but underutilized resource into a sustainable driver of accessibility, participatory governance, and digital transformation in the cultural sector.

6 Conclusions and future research directions

The present research has outlined an initial methodological framework for mapping AI-mediated accessibility practices in Italian museums, identifying key areas where technology and participatory design converge to enhance inclusion. Preliminary results confirm the ability of AI to meet the needs of both people with and without disabilities, and highlight a recurring theme in different institutional contexts regarding the selection of AI solutions that have been implemented, those that are currently being implemented, and the obstacles encountered during the implementation process. At an empirical level, future research should include a large-scale dissemination of the questionnaire to a broader and more diverse set of museums. This will allow statistical validation of the patterns observed and facilitate comparative analyses across regions and types of governance. Another line of research involves an in-depth study of the reasons why AI-based solutions that promote the inclusion of all audiences have not yet been implemented, in order to identify the underlying causes of this phenomenon and propose targeted solutions. Furthermore, at a theoretical level, longitudinal studies of selected institutions could reveal the dynamics of organisational change, the cost-benefit trade-offs and the outcomes achieved by visitors over time. This in turn could deepen our understanding of how AI innovations mature from pilot projects to established practices.

7 Ethics declaration

Ethical clearance was not required for the present research.

8 AI declaration

No AI tools were used in the development of the present research.

Redefining Middle Management: How Generative AI Reshapes Roles and Competencies

Philippe Jean-Baptiste
Aix-Marseille University, Aix-en-Provence, France

Abstract

This ongoing research investigates how Generative Artificial Intelligence (GAI) technologies are reshaping the roles and competencies of middle managers. While much of the existing literature emphasizes macro-level impacts of AI—such as productivity gains and strategic transformation—this study focuses on micro-level changes, particularly managerial adaptation, decision-making, and skill reconfiguration.

Grounded in activity theory (Engeström, 1987, 2001) and informed by a critical realist epistemology, the study adopts a qualitative, inductive approach. Data is being collected through semi-structured interviews with middle managers from three contrasting organizational contexts: a large enterprise in the energy sector (30 interviews), a medium-sized digital services firm (15 interviews), and a small telecommunications company (15 interviews). This multi-site design enables the analysis of systemic tensions across different governance models and organizational cultures.

Preliminary findings reveal that middle managers are often at the forefront of GAI experimentation, initiating Bottom-Up innovation processes outside official IT channels. These informal practices—frequently associated with Shadow IT—allow for agile problem-solving but also pose significant risks in terms of data security and strategic misalignment. Managers report that GAI tools not only automate routine tasks but also support cognitive structuring, thereby transforming how they plan, communicate, and lead.

The integration of GAI calls for hybrid competencies that go beyond technical know-how. Conceptual skills (e.g., sense-making and system thinking), human skills (e.g., empathy, leadership, conflict mediation), and ethical awareness are increasingly vital. Middle managers thus emerge as key facilitators of digital transformation, mediating between frontline innovation and top-down strategic frameworks.

This paper contributes to the literature by offering a multi-dimensional reading of managerial transformation through the lens of activity theory. It proposes actionable insights for organizations aiming to responsibly integrate GAI, emphasizing the need for adaptive governance, targeted upskilling, and the creation of experimental safe zones. Future work will extend the dataset and explore longitudinal trajectories of GAI adoption and governance.

Keywords: Generative Artificial Intelligence (GAI); middle managers; organizational transformation; Shadow IT; managerial competencies.

Paper type: Academic Research Paper

1 Context and Research Problem

Recent advances in Generative Artificial Intelligence (GAI), such as ChatGPT and large language models, are profoundly transforming organizational environments. These technologies—capable of generating original content, producing ideas, automating complex cognitive tasks, and delivering strategic analyses (Jordan & Mitchell, 2015; Goodfellow et al., 2014; Vaswani et al., 2017)—are emerging as strategic intangible assets (Brynjolfsson & McAfee, 2014; Silic & Back, 2014). Their integration into companies is reshaping not only work practices but also the modalities of cooperation, decision-making, and control, in a context of continuous innovation (LeCun et al., 2015; Senge, 2006).

At the heart of this transformation, middle managers hold a pivotal position. Historically described as facilitators between strategy and operations (Mintzberg, 1973, 1989, 2006; Tengblad, 2006), they are now facing new expectations. On one hand, they are required to integrate GAI into their managerial practices and support their teams in adopting these technologies; on the other, they must navigate an environment where these tools are reconfiguring value chains and redefining professional agency (Sannino & Engeström, 2021; Baird & Maruping, 2021). These “agentic artifacts” shift traditional roles by delegating certain decision-making functions to the machine, thereby challenging the legitimacy and relevance of specific human competencies (Van Doorn et al., 2023).

The emergence of Shadow IT—unauthorized use of technological solutions by employees—illustrates these tensions. The accessibility of GAI fosters bottom-up innovation dynamics, sometimes in conflict with top-down technological governance structures, leading to organizational friction (Silic & Back, 2014; Hillebrand et al., 2025). This phenomenon highlights the need to rethink power structures, risk management, and strategic IT governance (Behrens & Sedera, 2004).

As strategic actors, middle managers must contend with these multiple shifts: new forms of leadership, trade-offs between innovation and compliance, and skill management within unstable technological environments (Tarakci et al., 2023; Wilden et al., 2023). This transformation calls for both conceptual and operational agility, whereby the manager's role extends beyond strategy execution to include the co-construction of technological and cultural innovation (Engeström, 1987; Engeström & Sannino, 2021).

Yet, current research lacks a robust conceptual framework to thoroughly analyze these changes—both in terms of managerial roles (Mintzberg, 1973; Kraut et al., 1989) and competencies (Katz, 1974; Peterson & Van Fleet, 2004). This gap is precisely what the present research aims to address through the following research question: How does the introduction of Generative Artificial Intelligence transform the roles and competencies of middle managers?

2 Research objectives

This research aims to understand how the introduction of Generative Artificial Intelligence (GAI) is reconfiguring the roles and competencies of middle managers in a context of rapid technological transformation and increasing organizational tensions. Using a systemic approach grounded in activity theory (Engeström, 1987, 2001), the study seeks to:

Identify the tensions and contradictions that emerge during GAI adoption;

Develop a robust conceptual framework to analyze the transformation processes of managerial practices;

Map the conceptual, human, and technical competencies required for the effective integration of these technologies (Katz, 1974; Peterson & Van Fleet, 2004);

Propose organizational strategies to support managers during this transition, particularly with regard to Shadow IT and bottom-up innovation dynamics (Behrens & Sedera, 2004; Silic & Back, 2014; Tarakci et al., 2023).

This work thus addresses the need to reconcile technological mastery, ethical awareness, and strategic adaptability in the evolving role of middle managers (Van Doorn et al., 2023; Baird & Maruping, 2021).

3 Theoretical Framework

3.1 Activity Theory

Used as the primary analytical framework, activity theory (Engeström, 1987, 2001) provides a systemic model to understand the organizational transformations triggered by GAI. It consists of six interconnected components: the subject (middle manager), the object (transformation of roles and competencies), the tools (GAI technologies), the rules (IT norms and policies), the community (stakeholders involved), and the division of labor (redistribution of responsibilities). This framework reveals systemic contradictions that may become drivers of expansive learning and organizational change (Sannino & Engeström, 2021).

GAI technologies, as agentic artifacts (Baird & Maruping, 2021), deeply transform the mediation between actors and activities. They create tensions between innovation and compliance (Jordan & Mitchell, 2015; Hillebrand et al., 2025), formal and informal practices (e.g., Shadow IT), and strategic centralization and local agility (Engeström, 2001; Silic & Back, 2014).

The conceptual model used in this study, grounded in activity theory, is presented below. It illustrates the core components of the managerial activity system reconfigured by the introduction of GAI and highlights the systemic tensions likely to emerge.

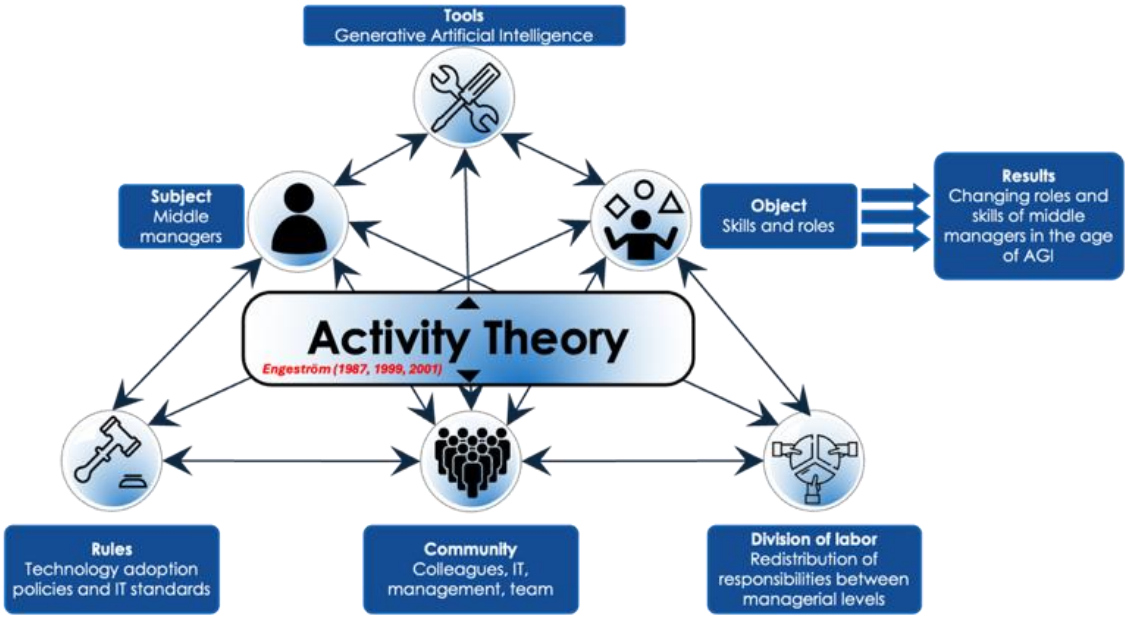

Figure 1: Conceptual model of the activity system applied to middle managers and GAI integration

This model, inspired by Engeström's activity theory, shows the six core elements (Subject, Object, Tools, Rules, Community, Division of Labor) and helps identify contradictions between governance structures and emerging GAI uses.

3.2 Bottom-Up Innovation Dynamics and Shadow IT

In addition, the study draws on bottom-up innovation models, which emphasize the proactive role of middle managers in technological adoption. These informal dynamics highlight both the agility of frontline actors and the risks of strategic and security misalignment (Behrens & Sedera, 2004; Haag & Eckhardt, 2017). Shadow IT—fueled by the accessibility of GAI tools—acts as both a signal of organizational creativity and a source of tension with top-down governance structures.

3.3 Synthesis of the Theoretical Framework

The articulation between activity theory and bottom-up innovation dynamics enables a multidimensional reading of the ongoing transformations. By combining:

- a systemic analysis of structures and tools (Engeström, 1987),
- a competency-based approach to managerial work in digital contexts (Katz, 1974; Wilden et al., 2023),
- and a socio-technical perspective on governance/innovation tensions (Silic & Back, 2014; Hillebrand et al., 2025).

This framework supports a better understanding of the conditions for a successful, ethical, and sustainable adoption of GAI. Positioned at the intersection of these tensions, middle managers emerge as key agents of this organizational transition.

4 Literature Review

4.1 Generative Artificial Intelligence as Strategic Resources

Generative Artificial Intelligence (GAI) technologies represent a major shift in organizational dynamics. Beyond their ability to generate content or automate complex cognitive tasks, they are becoming hybrid strategic resources, combining human and algorithmic intelligence (Brynjolfsson & McAfee, 2014; Jordan & Mitchell, 2015). These tools are actively reshaping decision-making processes, knowledge flows, and governance structures (Baird & Maruping, 2021; Van Doorn et al., 2023).

GAI contributes to the democratization of access to analytical and decision-making tools (Engeström, 2001), fostering greater autonomy among frontline actors. It also reconfigures value chains by enabling local innovations (bottom-up), often outside formal frameworks (Shadow IT)—a phenomenon that simultaneously enhances agility and creates friction with centralized structures (Silic & Back, 2014; Hillebrand et al., 2025).

4.2 Transformations in Managerial Roles and Competencies

The introduction of GAI disrupts the traditional roles of middle managers, who are increasingly expected to act as facilitators of technological transformation (Senge, 2006; Tarakci et al., 2023). Their intermediary position requires them to balance often conflicting demands: strategic vision, operational proximity, and resistance management.

The literature identifies three main categories of skills necessary for this transition (Katz, 1974; Peterson & Van Fleet, 2004):

- Conceptual competencies: systems thinking, the ability to structure and communicate the meaning of change (Engeström, 1987);
- Human competencies: leadership, relational intelligence, and group dynamics facilitation (Silic & Back, 2014);
- Technical competencies: understanding GAI technologies, data-related challenges, and ethical implications (Jordan & Mitchell, 2015; Wilden et al., 2023).

In light of growing automation, managers are also required to reprioritize their responsibilities—leading innovative projects, managing uncertainty, and balancing compliance with experimentation (Baird & Maruping, 2021; Van Doorn et al., 2023).

4.3. Conceptual Ambiguities Around Middle Managers

The literature highlights the lack of consensus on the definition of middle managers. This function is alternately described as frontline manager, operational supervisor, or cross-functional coordinator (Hales, 2005; Benedetto-Meyer et al., 2021), which often blurs the analysis of their strategic impact.

This terminological vagueness becomes particularly problematic in the context of digital transformation, where these actors perform complex and evolving roles that lie between execution and decision-making (Floyd & Wooldridge, 1994; Mahieu, 2007). The integration of GAI technologies further amplifies this complexity, placing middle managers at the center of tensions between technological innovation and organizational governance.

5 Methodology

This research adopts a qualitative approach rooted in a critical realist epistemology (Bhaskar, 1978; Archer et al., 1998; Meissonier, 2022), aimed at exploring the underlying mechanisms behind the transformation of middle managers' roles and competencies in response to Generative Artificial Intelligence (GAI). By combining contextual analysis, situated understanding of practices, and the exploration of systemic tensions, the study seeks to go beyond descriptive approaches and propose a structural and transformational reading of the phenomenon.

5.1. Methodological Framework and Epistemological Stance

Activity theory (Engeström, 1987, 2001; Engeström & Sannino, 2021) serves as the central theoretical lens. It allows the analysis of role and competency reconfigurations within an activity system composed of: the subject (manager), the tool (GAI), the object (managerial transformation), the rules (IT governance), the community (executives, IT, teams), and the division of labor. This systemic view aligns with critical realism, which posits a stratified reality and a continuous tension between structures and agency.

By contrast, other frameworks such as TAM (Davis, 1989), UTAUT (Venkatesh et al., 2003), socio-technical systems (Trist, 1981), or structuration theories (Giddens, 1984; Orlikowski, 2000) were set aside as less suited for capturing the multi-level, informal, bottom-up and often contradictory dynamics observed in the field.

5.2. Data Collection Method

At this stage, data is being collected through semi-structured interviews, primarily with middle managers. Additional perspectives (executives, team members, IT staff) will be integrated in upcoming phases to enrich the analysis. This method allows for an in-depth exploration of the perceptions, experiences, and strategies adopted by actors facing GAI-induced transformations. All interviews are recorded, anonymized, and fully transcribed to ensure rigorous qualitative analysis.

5.2.1 Diversity of Field Sites

Interview participants were selected for their key roles in technological change implementation and proximity to operational teams. Three organizational profiles were included:

Large Enterprise: A mature organization with structured processes and centralized governance, providing a view of planned GAI adoption.

Medium-Sized Enterprise (MSE): A growing company facing tensions between operational flexibility and strategic alignment.

Small and Medium Enterprise (SME): A resource-constrained company often adopting technology opportunistically.

The following figure presents a typology of the organizational settings included in this study, detailing their sector, size, and structure to contextualize the diversity of GAI appropriation.

		Typology	Sector of Activity	Revenue	Nb of Employees
30		**Large French enterprise (LE)**	Production and distribution of electricity	139,7 Md€	179 550
15		**Medium-sized enterprise (MSE)**	IT services and consulting	552 M€	540
15		**Small and medium-sized enterprise (SME)**	Telecommunications	75 M€	175

Figure 2. Typology of the three organizational contexts studied

This table summarizes the characteristics of the three cases: a large enterprise (LE), a medium-sized enterprise (MSE), and a small and medium-sized enterprise (SME), providing a comparative perspective on GAI adoption environments.

5.3. Sampling Strategy

A purposive and theoretical sampling strategy was used, targeting managers positioned between strategy and execution with significant exposure to technological issues. Selection criteria include hierarchical position, involvement in AI-related projects, and sector diversity (telecom, energy, digital services).

Particular attention was given to cross-organizational cultural consistency. Despite varied settings, a shared engineering culture—emphasizing rationality, technical mastery, and problem-solving—shapes how AI is represented and used (Van Maanen & Barley, 1984; Kunda, 1995; Faulkner, 2015).

5.4. Data Analysis

Data is analyzed using an inductive thematic approach (Braun & Clarke, 2006), combined with the dimensions of activity theory. The goal is to identify organizational tensions (technological, normative, human) and understand the mechanisms of managerial adjustment and practice reconfiguration.

Key stages include:

- Initial inductive coding, structured by activity theory components;
- Identification of systemic tensions, such as conflicts between Shadow IT and formal governance policies;
- Analysis of collective learning trajectories, including secondary, tertiary, and expansive contradictions (Engeström);
- Data triangulation through cross-checking with documents and field feedback.

5.5. Validity and Reliability

Methodological rigor is ensured through:

- Source triangulation;
- Validation sessions with interviewees (member-checking);
- A reflexive journal documenting analytical decisions;

- Attention to organizational learning conditions, especially regarding bottom-up innovation and systemic resistance (Sannino & Engeström, 2021; Silic & Back, 2014).

This qualitative method thus enables the identification of internal contradictions within activity systems and the formulation of managerial transformation trajectories adapted to the challenges of GAI

6 Preliminary Findings

The initial semi-structured interviews (32 out of the 60 planned) provide significant, though non-generalizable, insights into the evolving roles and competencies of middle managers in the age of Generative Artificial Intelligence (GAI). These exploratory results help formulate hypotheses about emerging dynamics that will be further investigated in later phases.

6.1. New Roles and Bottom-Up Dynamics

Middle managers appear as key actors in organizational transformation. They translate strategic objectives into concrete actions and facilitate the adoption of GAI within teams (Engeström, 1987; Brynjolfsson & McAfee, 2014). Numerous accounts point to informal and localized use of GAI, sometimes beyond official IT guidelines, illustrating a Bottom-Up innovation dynamic (Silic & Back, 2014). This proactive appropriation is a pragmatic response to operational needs, but it also creates tension with existing IT governance frameworks (Behrens & Sedera, 2004; Senge, 2006).

These grassroots initiatives often arise as adaptive responses to bureaucratic complexity, particularly in large matrix organizations. As one technical manager explains: *"To ask a question to a supplier, I have to send an email to Infrastructure, who contacts Intervention, who then reaches out to the manufacturer. […] That's three emails just to get to the supplier. […] It takes three weeks."*

The reorganization of priorities in constrained environments leads some managers to seek automation tools to compensate for increasing workload: *"We have meetings, but no time to write the minutes. Turning on the transcription tool is a productivity gain."* (Senior manager, B2B distribution)

6.2. Evolving Managerial Competencies

The interviews point to a reconfiguration of required competencies:

- Conceptual: strategic vision, anticipation of organizational impacts, and managing contradictions (Engeström, 2001)
- Human: transformational leadership, strategic communication, change facilitation (Jordan & Mitchell, 2015)
- Technical: familiarity with GAI tools, understanding of ethical and security challenges (Behrens & Sedera, 2004)

Managers must integrate these skills to effectively use GAI while preserving team cohesion and performance (Katz, 1974; Peterson & Van Fleet, 2004). The following figure presents a synthesized framework of managerial competencies required in the GAI era, combining insights from Katz (1974) and Peterson & Van Fleet (2004).

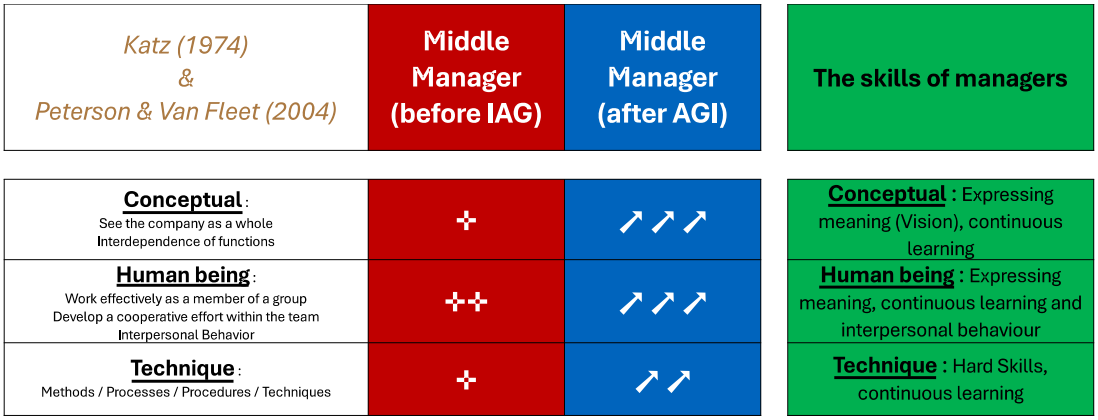

Figure 3. Evolving managerial competencies in the context of GAI

This table illustrates how conceptual, human, and technical skills are redefined in light of GAI integration, based on a cross-reading of foundational models of managerial competencies.

The growing complexity of managerial tasks reinforces the human and organizational dimensions of their role. In critical environments, managers must ensure safety, coordination, and workflow regulation: *"I have to ensure the safety of the site in all situations. […] It's highly precise team management."* (Manager, production site)

GAI is also changing how managers access knowledge, accelerating learning processes: *"I used to waste a lot of time reading forums or PDFs. Now AI gives me context and direction."* (Project manager, digital sector)

6.3. Shadow IT: Innovation or Risk?

Shadow IT is frequently cited as a pathway to GAI adoption. It allows operational agility but introduces risks related to compliance, data security, and strategic alignment (György et al., 2012; Zimmermann, 2014; Berente et al., 2021). Middle managers, acting as mediators, adopt awareness strategies, self-regulation, and even informal coordination with IT departments to mitigate these risks.

GAI usage by middle managers is not limited to technical or productivity-oriented applications—it also supports personal learning and relational development: *"I use AI a bit to help myself—it helps me grow in how I behave and carry myself."* (Technical lead, nuclear engineering)

Meanwhile, some internal training programs are beginning to formalize upskilling: *"We have e-learning training that teaches you how to prompt. […] It's totally autonomous."* (Engineer, engineering department)

In parallel with proactive use, symbolic or emotional forms of resistance are emerging, particularly among experienced staff. These fears, often irrational or shaped by science fiction imaginaries, reflect outright rejection: *"They don't want to use AI. I have a colleague who says it's the devil. […] He's stuck on Terminator. To him, Skynet is going to take over."* (Manager, large company, engineering).

In some cases, AI use is driven by a need for autonomy in the face of organizational inertia: *"I didn't want to wait until next week, so I used ChatGPT. […] I refined the prompt to get pictograms and flags for my slides."* (Product lead, B2B distribution).

6.4. Facilitators of Technological Change

Middle managers are emerging as facilitators of change:

- Managing internal resistance
- Aligning strategic vision with operational execution
- Gradually integrating GAI into work practices

However, this position also exposes them to strong tensions between compliance requirements and innovation pressures.

The integration of AI tools challenges the added value of certain managerial tasks, particularly administrative and reporting functions. One manager puts it bluntly: *"We need to become more efficient. […] I think an AI could handle all time tracking. […] Some managers will be left behind."* (Technical manager, engineering)

Some see AI as a tool for cognitive structuring, helping them with project planning: *"AI helps me structure my thinking—it reminds me of the steps I shouldn't skip when starting a project."* (Technical project manager, tech company)

AI adoption can also create tensions between business units and support teams, especially IT: *"I'm advocating for connecting Copilot Plus in Office 365. But IT says it won't work. […] I'm talking from a business need."* (Cross-functional manager, B2B distribution)

6.5. Summary of Preliminary Findings

The findings suggest that GAI is not merely a technological innovation but a structural and functional transformation of managerial work. The rise of hybrid skills, informal uses, and constant adjustment to internal tensions are key indicators of this ongoing shift.

Some respondents expressed clear awareness of the risk of skill obsolescence and are seeking to reposition themselves as informed technology partners: *"I'd rather be the one telling AI what to do than the one saying 'go away.' […] You need to identify your added value to stay relevant."* (Manager, technical project environment).

Finally, the rapid evolution of tools is creating growing concern over potential internal divides: *"There will be those who have AI—and those who don't."* (Technical lead, tech company).

7 Next Steps

The next phase of this research will focus on completing the qualitative data collection by reaching the target of 60 semi-structured interviews across three contrasting organizational settings (large enterprise, medium-

sized company, and SME). Special attention will be given to the diversity of respondent profiles, incorporating perspectives from senior management, IT teams, and HR departments to triangulate managerial perceptions.

The thematic analysis will be deepened using the Braun and Clarke method (2006), combined with activity theory, to highlight mechanisms of collective learning, sector-specific tensions, and GAI appropriation trajectories.

Furthermore, the conceptual articulation between bottom-up innovation, Shadow IT, and role transformation will be consolidated to develop a general interpretive model applicable to other organizational contexts. Lastly, a strong emphasis will be placed on the dissemination and valorization of the results across scientific and managerial communities (conferences, publications, professional reports).

8 Discussion and Conclusion

The preliminary findings of this study suggest that the introduction of Generative Artificial Intelligence into organizations is not merely a technological development but signals a deeper transformation of the managerial role. Through the lens of activity theory, middle managers are no longer seen as mere executors of strategic directives, but rather as active mediators of the organizational tensions generated by GAI—between autonomy and control, innovation and compliance, individual appropriation and collective governance.

Three key contributions can already be identified:

- Conceptual Contribution: The systemic approach adopted here makes it possible to articulate bottom-up innovation logics and the Shadow IT phenomenon within a robust theoretical framework, positioning contradictions as drivers of transformation.
- Empirical Contribution: The initial interview data reveal emerging managerial practices, often informal, reflecting the development of hybrid skillsets combining relational leadership, technological reflexivity, and ethical sensitivity.
- Managerial Contribution: This research initiates a competency mapping for middle managers who support GAI-related practices—especially in informal or “grey” innovation zones outside formal governance structures.

Beyond its contributions, the study raises several critical questions:

- What is the sustainability of the adaptation burden placed on middle managers?
- How can we prevent the isolation of these facilitators within organizations under pressure?
- Most importantly, how can we design ethical governance models for GAI usage that reconcile local agility with strategic coherence?

9 Ethics declaration

This research did not require formal ethical clearance, in accordance with standard practices in the field of social sciences and humanities. All interviews were conducted following fundamental ethical principles: informed consent, systematic anonymization of data, and respect for participant confidentiality. Participants were informed of the study’s objectives, their right to withdraw at any time, and the strictly academic use of the collected data.

10 AI declaration

Artificial Intelligence tools were used for language support, primarily to enhance the quality of the English translation of this paper, as the author is not a native English speaker. AI assistance was used to rephrase complex sections, harmonize academic style, and ensure terminological consistency across sections. No AI-generated content was included without human oversight, revision, or reformulation.

The author remains solely responsible for the argumentation, analysis, and all interpretations presented in the manuscript.

A (Fun)Nel Model for Knowledge Management

Gianluca Gherardi
University of Naples Federico II, Naples, Italy

Abstract

Think of a funnel. What is its shape? What does it do? It has a large end, larger and larger that allows many elements to pass through, such as grains of sand or kernels of rice; and it has a narrow end, narrowing to block the passage to most of them; funnel has a simple but useful function: it serves to pour a big mass of parts into a container with a small opening. This is, when you think about it, the same principle behind human information processing and knowledge management. This paper proposes a funnel-shaped conceptual framework, that integrates three dimensions of knowledge: complexity; intelligibility; innovability; as the three dimensions of the funnel. Such framework provides a more comprehensive form of understanding complex institutions, both political and economic. It highlights, also, the interaction between information and institutions, and how it can impact human behaviour.

Keywords: Information, Knowledge, Complexity, Relational language, Lateral thinking.

Paper type: Academic Research Paper

1 From cognitive revolution to institutional complexity

We are going through a period of deep and unexpected transformations, in a complex, interconnected world (Harari, 2024). Every day we are flooded with an incredible amount of news and information to which we are not always able to attribute a consistent meaning (Harari, 2019). Millions of years of evolution have given us the tools to decode this world and yet our most common, oldest reaction when faced with the unknown, remains to close in on ourselves. Studies in the fields of Cognitive psychology and Behavioural economics (e.g. Harlé and Sanfey, 2010) demonstrated a natural propensity of humans to withdrawal.

Yuval Noah Harari dates the beginning of the complexity to about 70000 years ago, at the time of the so-called "Cognitive Revolution" (Harari, 2022). In those days, the human species known as "Sapiens" began to develop new modes of thinking and communicating, which soon would make it the dominant species of the entire planet. These abilities, along with the imaginative and cooperative ones (typical of Sapiens), enabled the elaboration of the first collective narratives, such as clans, families, and religions. It is not too difficult to picture those primitive men and women forming their social orders through belief in these narratives; what instead we struggle to understand is that our modern institutions function exactly on the same assumptions. Of course, from a "structural" point of view, institutions nowadays are different: this diversity can be interpreted as a consequence of the degree of complexity achieved by modern societies. A Stone Age hunter-gatherer compared to most of his contemporary descendants had deeper and more varied knowledge whose mastering required years of learning and practice. In modern industrial societies, much of this would be worthless. Humans no longer need to know many things, beyond the field they directly deal with, and for the others they can still rely on experts (whose knowledge determines a circumscribed field as well). The result is that, collectively humans today know more than Sapiens did, but singularly the hunter-gatherers were the most knowledgeable of all times.

Most researchers believe that these achievements, unequaled before or since, were the result of a Revolution occurred in the cognitive abilities of Sapiens. Vera Zamagni (2015) emphasizes this finding, placing the focus on human ability of creating and telling stories: "the real strategic role in determining the degree of progressiveness of various societies is played by philosophical-religious worldviews and the resulting organization of society, its diverse political and economic institutions". The issue is to determine how our institutions can be defined as "complex" and what effects complexity has on knowledge management.

1.1 How to deal with complex institutions

Every idea of knowledge starts with the realization that the same reality can be looked from different points of view. This results in quite varied perceptions, representations, and belief systems, all of which have elements of truth, that need to be considered (Carofiglio, 2023). The Sociologist Ugo Morelli (2024) stated that: "We human beings are a symbolic species; this implies that our capacity for self-regulation and self-organization is based on a process of attributing meaning to what happens in our relationships with others and with the world". Although we have always had great imagination, we cannot deny that the idea of Sapiens for their own village

or tribe was far less elaborate than our modern conception of, for example, the Sovereign State, the European single market, or the global ecosystem.

A simple indicator of increased complexity is the amount of information. Humans are, in contrast to algorithms, not good at organizing large amounts of information, even when operating in small contexts. Perhaps this is why it took *millennia* with backward moments and stagnation to change agricultural pastoral to industrial civilization (Zamagni, 2015). If we want to understand this step we need to focus on the history between the 16th and 18th centuries, along the span of just three centuries that witnessed three revolutions: industrial revolution; scientific revolution; institutional revolution. Common foundation to all three, the exaltation of rationality, as an engine of progress, produced both positive and negative consequences. Whilst innovations in production and organization increased the efficiency of the process, they also fueled vicious mechanisms, accentuated inequalities, fostered the spread of poverty, epidemics, and discontent. Morin (2023) stated that there is a strikingly antinomian association between the wonderful works that resulted of technical rationality, and blindness about the human, social, and cultural consequences of that works. The final effects were, however, brought about by an "Institutional Revolution", which replaced the "old" institutions as the community and the family, with "new" institutions represented by the state and the market. Morin echoes and resumes Marx's main critique of the Capitalist system, and also introduces the dysfunction that he himself terms the "blind intelligence".

"Blind intelligence" is that intelligence that simplifies and tries to dissolve complexity not to make it more accessible, but to adapt it to the needs of new institutions. The market acts, in this sense, as a collector and simplifier of information. It lessens the informational pressure on individual agents and synthesizes the mass of information into values (i.e., the prices) that can be easily understood by anyone; what is lacking is a more in-depth quality of information, about the meaning of those values, and the processes that determined their formation. A similar thing has happened in the public sphere. An increasingly widespread fragmentation or – in extreme cases – polarization of political opinion makes it practically childish to choose who to vote for (the candidate or party that better represents my beliefs on sensitive issues that I do not fully understand). The worst part, even here, is finding out the contents and implications of the politics that will be implemented, by that candidate or party, after the vote. In sum, we need to come to terms with complexity, that increasingly, somehow unpredictable directly influences our decisions and our understanding of reality.

2 The (fun)nel model

2.1 Vertical dimension: complexity

For the direction given to this work, the first dimension of the funnel, the vertical one, is described by complexity. As progress advances, what was difficult to achieve, requiring great physical and mental effort, has become easier and easier to realize: complexity is the hallmark of modernity. It contains within itself all the potentialities that were precluded to our ancestors. There is no reason to avert it although many of us believe it is preferable or even possible to keep away from it. Indeed, the complexities – that have affected so many areas of society – require a more organic, active, and positive approach to their dilemmas.

Being a passive bystander does not help: in fact, this is probably why the immoral and corrupt aspects of modern social systems were able to impose themselves, with practically no resistance. Marcuse nicely illustrated this concept in his 1964 (still very relevant) book *One-Dimensional Man*: the "Welfare State" distributes its many benefits at the cost of the systematic restriction of technically accessible free time, the quantity and quality of goods and services technically available for the individuals vital needs, and most importantly the intelligence (conscious and unconscious) capable of understanding and accomplishing the possibilities of self-determination (Marcuse, 1964). On the other hand, this kind of *modus vivendi* has, in some way, justified and encouraged the status of consumers, making "pure existence" extremely convenient. No reasonable person would give up the achievement of modernity without receiving anything in return and, moreover, true "involution" would be technically impossible. Again, Marcuse warns us against rejecting the Welfare State, for a vague idea of freedom: the loss of the economic and political freedoms, the real conquests of the previous two centuries, may seem like little harm, in a State capable of making safe and comfortable "administered life" (Marcuse, 1964). So, if most individuals are satisfied, to the point of calling themselves happy, with the goods and services that the Government offers them, why would they ever want different institutions? Only in recent time we have started to realize the disaster caused by this trivializing view of complexity and this has at least spurred the urgency to tear away the Maya veil of ignorance and be more self-aware.

2.2 Horizontal dimension: intelligibility

Organizational forms of life have emerged more precisely as responses to complexity: we create and recreate them to process and try to contain uncertainty (Morelli, 2024). It is practically a process of approximation and reduction of differences, characterized by high degrees of undecidability and vulnerability. Strong examples of such distorting effects are advertisements or election programs: even though we know they may not be true, or right, we still listen to them and even agree to be guided by them in our important life decisions.

These behaviours reflect survival strategies, adopted by humans over millions of years with the objective of attributing meaning to reality. A second aspect to be analysed (or the second dimension of the funnel in this case horizontal) concerns the ability to explore this complexity, namely intelligibility. To use Morelli's words again: “complexity is primarily an epistemological and cognitive orientation” (Morelli, 2024); knowledge means trying to identify “windows of comprehensibility” when we are faced with seemingly impenetrable metaphorical walls. Morin (2023) argued that complexity is the challenge of intelligibility and understanding in situations of complexity. So, a greater comprehension of reality also requires a better organization of knowledge, a “socialization” of it, that is, a broadening of its social base. This corresponds in our model to a horizontal widening of the funnel, with new learning and training opportunities in society; the pattern may, however, be opposite.

Intelligibility should not be confused, by the way, with utilitarian intelligence: the last, is but a consequence of our need to overcome the uncertain and ambiguous, with accurate diagnoses lacking equivocation. It responds to a fundamental human function: to separate, to differentiate, and to bring complexity back to the classic true-false scheme. This way of reasoning is also useful (in certain circumstances) but it fails exactly when reality appears in all its ambiguity and contradiction. The price to pay concerns awareness and the risk of manipulation and mystification of reality itself. Morin states that: “simplification becomes closely related to manipulation linked to the idea – or rather the myth – of the conquest of nature and man's dominion over the universe” (Morin, 2023); consider, as an example, the very recent advances in the field of Artificial Intelligence. It can potentially solve endless, practical problems, but, at the same time, greatly reduces the human ability to prevent and correct those same problems in time. In this Morin’s foresight. The algorithm allowed and grew manipulation, hence its countless technical victories, and hence also its ignorance of the perverse effects that could have generated such victories. Perhaps, while technological innovations broaden the horizon of possibilities, they also require greater awareness, to be followed by an ever-increasing civil effort in education, training, and practicing activities.

2.3 Lateral dimension: innovability

The two-dimensional model – we have sketched so far – can be also applied to a three dimensions world. This need has been assimilated, into our case, through the addition of a third variable. The innovability of the model itself, that is, the continuous search for ideas, innovations and “lateral” solutions. Among others, we found most inherent the concept of “lateral thinking” originated by De Bono (2000) as an ideal of overcoming the established order. Lateral thinking consists, precisely, of altering the linear perspective of the problem and seeking a solution, not contemplated by the original situation. Linear logic was suited to reproduce that mechanistic worldview, in vogue until the 19th century and now in deep crisis. A determinist world would not allow any invention and could not have consistency.

Innovation is not only not linear but also not neutral. It depends on factors, such as the motivational structure, of the person applying it, and the use value of freedom it generates (Marcuse, 1991). A perspective, not excluding the economic and technological aspect, but reviving the importance of societal involvement and collective intelligence, in the process of change; stimulating transformative innovation requires an ecosystem that can foster the emergence of communities, based on mutual trust, participated by a plurality of members. It is not enough for innovation to react to societal problems; it must be designed in a more equitable and participatory context keeping in mind also the interest of future generations.

3 Flipping the funnel

So, what to do with the funnel, now that society is about to become more complex and global than ever before? Our proposal is a flip: a flipped funnel looks like a megaphone or an amplifier of ideas and best practices. Following Morin, one more time, we have only to overcome, then, once and for all, the simplification of society; we counterpoint this with a new path which is neither straight nor plotted *a priori* but is outlined as we go along. How the trend triggered now more than three centuries ago, by the three revolutions (scientific, industrial and institutional, or perhaps three separate aspects of one, epochal Revolution?) be reversed, and concreted into a

true mindset? The view from reading Morin's work aims for diversity of viewpoints, and constructive dialogue; it teaches us, not to suppress, but to absorb antinomies and conflicts, turning them into opportunities for growth and evolution.

We must, first, become familiar with relational, reliant language, which uses analogies and metaphors, and structures the world with simple images – hence the inspiration of the funnel. At the same time, it is vital to ensure that such language is not used, by those in an advantageous position, for opportunistic and demagogic purposes: it can be hazardous if it means approximation and confusion. For the same reason, experts need to be persuaded to make their knowledge available to the community, not as an exercise in erudition, but as a civic duty to share culture and translate complexity; culture requires the proper incentives.

However, the "flow" could also be inverted and, like going through the flipped funnel, bring new knowledge from below to the higher planes. This is – in the intend of this work – both a challenge and a lesson of complexity, which only collectively we can understand.

4 Ethics declaration

This work is, in all its parts, an original product of the Author. All quotes are provided with an indication of the reference. No violation of the professional conduct, and ethics of a research community, has taken place, in the opinion of the writer, in the writing process.

5 AI declaration

No part of this work is generated by artificial intelligence; however, some AI tools are used to check the accuracy of the translation from Italian. The final check is still personal.

Abstract

The fragmentation of data on the existing built environment is a critical obstacle to the governance of urban spaces. Although a wide range of data sources is available, from satellite imagery and environmental sensors to socio-demographic and cadastral datasets, these resources often lack interoperability and integration.
This deficiency limits the ability of governments and stakeholders to conduct accurate monitoring, implement informed real estate development strategies, and promote sustainable urban regeneration practices.
The research aims to explore how the integration of advanced Artificial Intelligence (AI) models, particularly Generative Adversarial Networks (GAN) based technologies, can contribute to the development of innovative approaches for urban management and the enhancement of disused building stock. In particular, the analysis aims to investigate the role of AI in Due Diligence (DD) processes, through a literature review in the areas of Smart Cities (SC) and Urban Management (UM), to define a theoretical-methodological framework to support data-driven urban regeneration strategies.
These technologies enable the generation of predictive urban models by combining heterogeneous inputs, such as geospatial frameworks, land-use data, environmental performance, and socioeconomic indicators. The research adopts a multidimensional approach based on a systematic literature review, which identified more than 1,200 academic contributions. Through a multi-stage filtering process, the most relevant analyses were classified into two main areas: *"Artificial Intelligence and Smart Cities"* and *"Artificial Intelligence and Urban Management",* with a focus on *"Due Diligence"* and models for *"Architectural Heritage Enhancement."* Integrating AI capabilities into the development of urban regeneration strategies has the potential to create resilient and smart cities. This can optimise resources while minimising land consumption and enhance inclusive and collaborative governance. Despite growing scholarly interest, analysis has revealed significant gaps in the development of these technologies.
The proposed approach is in line with emerging urban agendas and promotes a transition to resilient, circular, and smart cities. This study advocates for digital innovation that is not only technologically advanced but also ethically grounded and socially inclusive.

Keywords: Artificial Intelligence, Urban Management, Architectural Heritage Reuse, GAN models, Due Diligence

Paper type: Academic Research Paper.

1 Introduction

Contemporary cities are complex and constantly evolving systems, where social changes and internal dynamics continuously redefine the urban fabric. In the next three decades, it is estimated that nearly two-thirds of the world's population will live in urban settings, highlighting the acceleration of global urbanisation (Acioly et al. 2020). This scenario poses significant challenges for urban planners and real estate developers, who must design innovative strategies to efficiently manage urban land and infrastructure.

A key element in supporting such strategies is reliable, updated, and meaningful data availability. The integration of advanced technologies and large-scale data management processes offers significant potential to enhance urban functionality, quality of life, and the development of Smart City (SC) ecosystems (Singh et al. 2024). Since urban development processes often lead to an unequal distribution of opportunities, the inclusion of social equity objectives in enhancement strategies is becoming essential (Barberis et al. 2020). In this regard, SC technologies can support efforts toward greater inclusion and sustainability (Al-Rimawi and Nadler 2023; (Ahmad Afaneh and Isam Shahrour 2017).

Sustainability can be pursued through the conscious management of the existing building stock. Buildings that have lost their original functions risk abandonment and underuse. Transforming this heritage into a resource requires adaptations in governance structures, institutional frameworks, and financial mechanisms (Baud et al. 2021).

To address these challenges, the future of cities depends on the integration of SC, Smart Real Estate (SRE) solutions, and other innovative technologies. Collaborative public-private partnerships will play a crucial role in promoting sustainable and innovative development (Deakin and Al Waer 2011). Within this integrated vision, cultural heritage becomes a strategic asset for the transition to more resilient and sustainable urban models.

The research aims to explore how the integration of advanced AI models, particularly GAN-based technologies, can contribute to the development of innovative approaches for urban management and the enhancement of disused building stock. The analysis aims to investigate the role of AI in Due Diligence (DD) processes, through a literature review in the areas of Smart Cities (SC) and Urban Management (UM, to outline a theoretical-methodological framework to support data-driven urban regeneration strategies.

The paper is structured into three main sections: the first introduces the theoretical framework and methodology; the second offers a critical review of the literature on AI, SC, and UM, focusing on DD; and the third discusses the results and proposes final reflections on possible operational developments.

2 Materials and methods

This literature review is based on a filtering methodological approach divided into 3 phases. The analysis is oriented toward the systematic and integrative analysis of the scientific literature with the objective of outlining the state of play about AI applications in urban contexts (Figure 1).

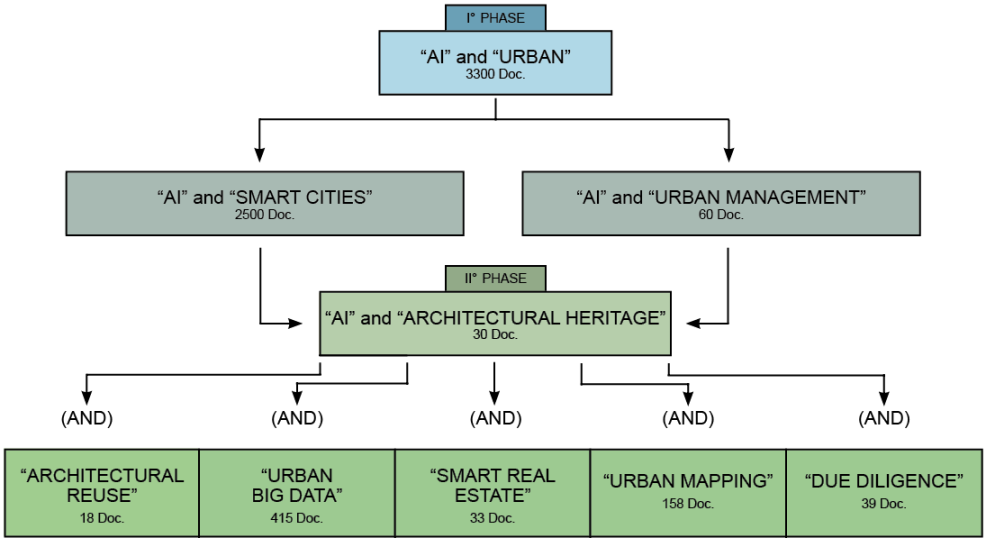

Figure 1: Methodological outline of research (Authors' elaboration)

The papers collection started in Phase 1 with the research of literature related to artificial intelligence and urban environment to define a general framework of reference for the application of AI in urban monitoring, development or transformation processes. In this research, the first extensive collection is composed of 3,300 scientific contributions. Papers were selected mainly through a targeted query on SCOPUS, focusing on its implications in urban ecosystems' governance, planning, and management, to trace emerging theoretical trajectories and identify the main areas of application of AI in the contemporary urban domain. The link between Generative AI and a more efficient and responsive management of cities is underlined in literature, as affirmed by Beroche, who stated that it can contribute significantly to urban management thanks to its ability to dramatically reduce the processing time and costs associated with analysing unstructured data. AI enables real-time scenario development and improves the decision-making capacity of public administrations (Beroche, 2023).

In the second phase of the data collection process, divide the research into two branches, and focus on the relationship between AI and smart cities or AI and urban management. In this research, the second step of the process collected 2,500 scholarly contributions regarding the relation between AI and smart cities and 60 papers relating to the link between AI and urban management. Both of these are sub-samples of the previous step.

Next, the bibliographic analysis focused on the exploration of AI applications in architectural heritage enhancement processes. This phase (Phase 2), by filtering papers collected in the steps 1 and 1b, led to the identification of 30 scholarly contributions deemed particularly significant for understanding the role of AI in the regeneration of the built environment and in defining strategies geared toward adaptive reuse. This phase investigated how AI-based theoretical models and technological tools support strategies for recovery, adaptive reuse, and regeneration of the built environment.

Finally, the last refined queries for the research are related to five subtopics (Phase 2b): architectural reuse, urban big data, smart real estate, urban mapping and due diligence. The selection of contributions favoured

those studies that present a data-driven and interdisciplinary perspective, integrating the knowledge of architecture, urban planning and data science. The thematic articulation that emerged from this phase confirms the centrality of an integrated and multidimensional approach, in which AI is configured not only as a technical support tool, but as a real catalyst for transformative processes oriented toward urban resilience, operational efficiency and long-term sustainability.

By filtering the final five subsamples on the basis of criteria such as consistency, completeness, innovation and the use of data, the final sample of analysis is composed by 23 papers, belonging to 1.200 different nationalities and 23 different authors (Table 1).

Table 1: Final paper sample (Authors' elaboration)

Just one of the 23 papers analysed covers all five topics underlined in the research, and just one analyses 4 to 5 topics, excluding urban mapping. Three contributions focus on different combinations of three topics, while most of the papers analysed face just one or two topics.

3 Results

The results outline the advancement of research in the respective fields analysed, but also highlight theoretical and operational gaps that need further exploration. Indeed, recent reflections on *"Urban Artificial Intelligence"* confirm the emergence of a hybrid field, in which AI is configured as an invisible but crucial infrastructure in the transformation of cities. Urban AI acts as a catalyst for complex processes, enhancing predictive analytics, data interoperability and future scenario building. As highlighted in the report *"The Future of Urban AI"* (Batty et al. 2023), the adoption of AI in cities still faces challenges related to data reliability and institutional fragmentation.

It has thus emerged how the adoption of AI tools allows for the expansion of the capacity for evaluative analysis of the built heritage, thanks to the possibility of cross-referencing heterogeneous data (morphological, structural, historical, energy, environmental, economic-social) and generating predictive outputs useful for the definition of sustainable regenerative scenarios. The most recent applications show the evolution of these tools from simple computer aids to intelligent analytical environments, which can integrate qualitative and quantitative assessments to identify the most promising use cases, minimising risks and maximising positive socio-economic impacts.

In general, the SC concept acquires an evolution from a purely technological paradigm toward an adaptive system capable of receiving and responding to citizens' needs in real time. This transition implies an increasing integration between innovative technologies, digital infrastructure, and civic participation, outlining scenarios

in which AI can become an enabling tool to improve operational efficiency and the equity and resilience of urban systems.

The emerging vision is to consider cities as *"smart ecosystems"* in which the digital infrastructure is intertwined with the physical and social components of the territory (Cugurullo and Acheampong, 2024). Addressing the scope of UM extends a second front of consideration, as the analysed papers tend to evaluate AI as a tool for supporting strategic planning, built asset management, and urban governance. From this perspective, AI is explored as a technology that can expand the analytical capacity of public and private actors, facilitating predictive asset valuation practices and environmental monitoring (Al-Rimawi and Nadler 2025). As highlighted in the report "*Generative AI for Urban Governance"*, generative AI technologies do not just support technical processes but also take on an inherently political nature.

Moreover, according to the Urban AI Guide, "Urban Artificial Intelligence" is a synthesis of co-production between cities and innovative technologies. AI transforms cities, but the cities themselves - with their data, infrastructure, and communities - shape the development of smart solutions (Popelka et al. 2023).

The first, related to AI and Architectural Reuse, comprised 18 scholarly contributions investigating the potential of AI in supporting adaptive reuse strategies of existing architecture. The analysed contributions highlight the growing role of smart technologies in assessing the conservation state of buildings, simulating sustainable transformation scenarios, and defining operational strategies aimed at rehabilitating the built environment. As a result of the last filtering process, some recurrent themes emerged that were used as keywords for the research. Five distinct sub-samples contributed to the final sample definition, each focusing on a different aspect. The first, related to AI and Architectural Reuse, was composed of 18 scholarly contributions investigating the potential of AI in supporting adaptive reuse strategies of existing architecture. The contributions analysed extol the growing role of smart technologies in assessing the conservative state of buildings, simulating sustainable transformation scenarios, and defining operational strategies aimed at rehabilitating the built environment. (Gravagnuolo et al. 2024) affirmed that effective decision-making processes in the context of cultural heritage require appropriate tools. In this sense, evaluation is central in constructing choices, recognising values, interests and needs, and exploring the different factors that may influence decisions.

From this perspective, the adoption of AI emerges as an enabling tool to address the multidimensional complexity characterising adaptive reuse processes (Gravagnuolo et al. 2024). Indeed, the literature highlights how the proper use of AI can contribute significantly to economic growth, social welfare and environmental regeneration, promoting more sustainable and circular urban development.

In parallel, the extensive literature on urban Big Data, numbering 415 scientific papers, has offered a solid methodological framework, highlighting the potential of AI in data management. his component has reinforced the paradigm of data-driven urban governance, where predictive analytics and advanced modelling are essential tools for adaptive and informed planning. In particular, Big data provides a lens through which the complexities of urban form can be analysed, understood, modelled, and even imagined and tested in different scenarios (Djokić et al. 2025).

Further reflections emerged from the comparison with the area of Smart Real Estate, represented by 33 studies, in which how AI can contribute to real estate valuation and the definition of sustainability-oriented investment strategies are analysed. In this area, it emerges how the integration of digital technologies, such as Internet of Things (IoT), BD, AI and digital twin (DT), enables more efficient real estate asset management and data-driven decision support, improving quality of life and promoting sustainable urban development (Al-Rimawi and Nadler 2023). In addition, recent studies show that the deployment of smart buildings and interconnection with urban infrastructure contribute significantly to reducing energy consumption and emissions, enabling new real estate valuation and investment models based on sustainability and operational efficiency (Al-Rimawi and Nadler 2023).

Also of considerable relevance is the area of Urban Mapping, which is explored in depth through 158 contributions highlighting the use of AI to create high-resolution urban representations capable of dynamically rendering the city's morphology. Geospatial Deep Learning (DL) technologies, applied to the analysis of satellite and aerial imagery, enable the precise identification of urban morphology and the development of three-dimensional models of built fabric and street networks. In particular, the adoption of advanced convolutional models, integrated into a GIS environment, enables the extraction of complex features such as building footprints and street networks from orthorectified imagery, improving the accuracy of urban analyses and supporting the definition of more informed and responsive spatial policies. (Orusa et al., 2024).

Finally, the theme of Due Diligence, investigated through 39 papers, highlighted how AI can optimise the preliminary stages of decision-making through a more efficient and transparent analysis of technical, legal, economic, and environmental information related to real estate assets. However, critical literature analysis

highlights a significant gap: the lack of structured theoretical frameworks and shared metrics to systematically assess the “urban reusability” of disused buildings.

3.1 “Artificial Intelligence” AND “Smart Cities”

From the analysis of the co-occurrences related to the combination of the keywords *“Artificial Intelligence”* and *“Smart Cities”*, elaborated through VOSviewer, by applying a co-occurrence analysis of terms, authors, or publications, using a distance-based visualisation approach where the proximity between nodes reflects the strength of their relationship, based on techniques such as the VOS (Visualization of Similarities) mapping method.

The relationships between the main key terms in the examined literature are illustrated in Figure 2. The network graph shows five large clusters that emerge, distinguished by the colours red, green, blue, yellow, and purple, with a total of 422 occurrences.

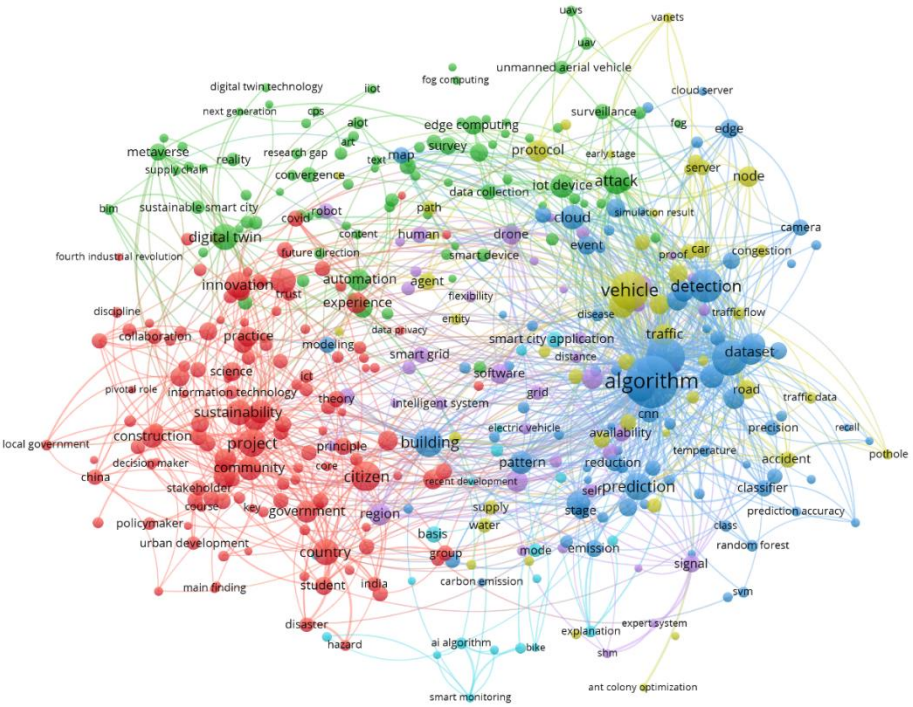

Figure 2: Map of co-occurrences emerging from the research. "Artificial Intelligence" AND "Smart cities"
Authors’ elaboration

The red cluster includes public policies, urban planning, and sustainability concepts. Keywords such as *“CO2 emissions”*, *“project”* and *“community”*, closely related to terms such as *“country”*, *“citizen”*, *“urban development”*, and *“government”*, highlight the centrality of regulatory and social aspects.

In the blue cluster, a focus on the relevance of IT, algorithmic and predictive is observed. The concentration of keywords such as *“prediction”*, *“probability”,* and *“machine learning”* underlines the importance of the data-driven approach. It is interesting to note how *“building”* and *“map”* occupy an intermediate position between the clusters belonging to the urban sphere and those belonging to the IT/technological sphere.

In the green cluster, on the other hand, concepts that recall the use of advanced technologies such as *“sensors”, “digital twin”*, and *“automation”* prevail. The presence of terms related to automation and robotics, combined with references to smart tracking, suggests potential solutions to transform the analysis and intervention processes.

The purple cluster can be interpreted as representing the “smart network” theme, encompassing both the physical and digital infrastructures, with particular emphasis on flexibility and the interaction between human and cyber interfaces.

The yellow cluster highlights the widespread application of AI in the mobility sector, which is traditionally one of the earliest fields to integrate artificial intelligence technologies. In this representation, network governance and innovation are in a form of dialogue and the relationships between the concepts analysed highlight an evolving panorama in which interdisciplinarity and the ability to integrate different skills appear crucial to promoting new urban policies (Figure 3).

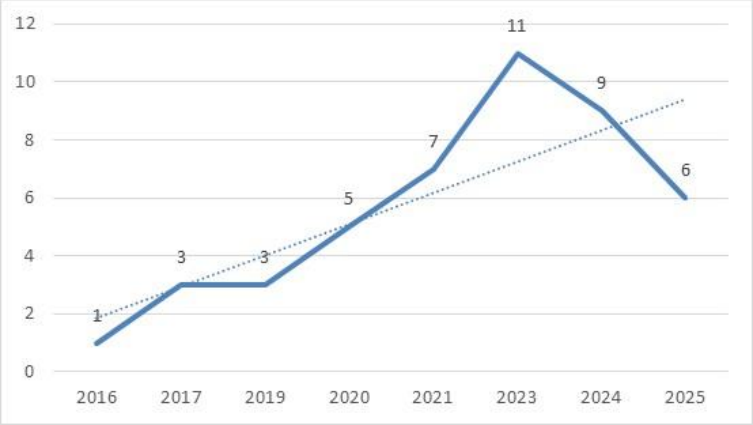

Figure 3. Trend of analyzed publications over the years (Authors' elaboration on Genuary 2025)

The emergence of a data-driven urban paradigm, currently in a phase of progressive consolidation, is characterised by an increasing integration of analytical methodologies, decision-making frameworks, and sustainability imperatives. However, this integration remains fragmented and inconsistent, underscoring the imperative for further theoretical elaboration and operational innovation to ensure that intelligent urban solutions enhance system optimisation and foster the development of more equitable, inclusive, and resilient urban environments.

3.2 "Artificial Intelligence" AND "Urban management"

The co-occurrences from the scientific literature relating to the binomial "Artificial Intelligence" and "Urban Management" are represented by the semantic map in Figure 4. The map is divided into two main sets, which reflect a polarisation between a conceptual and a technical-functional approach.

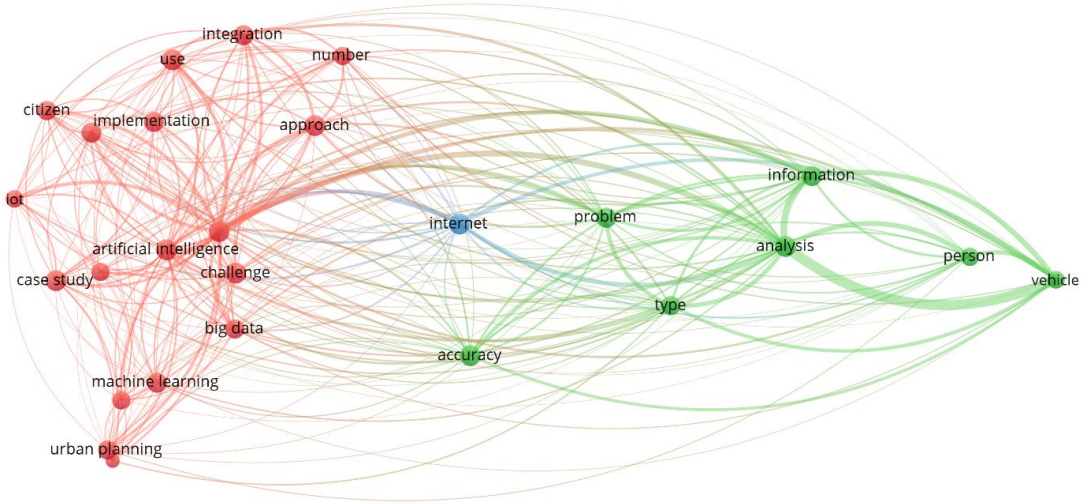

Figure 4: Map of co-occurrences emerging from the research. "Artificial Intelligence" AND "Urban Management"

The red cluster focuses on concepts such as "Artificial intelligence", "Urban planning", "Implementation", "Integration", "IoT" and "Big Data". This area signals a theoretical and methodological interest in the strategic role of AI in urban planning and management processes. The recurrence of terms such as "Use", "Challenge" and "Citizen" suggests a reflection on the potential, but also the critical issues, connected to the social, cultural and organisational dimensions of the introduction of AI in cities. The green cluster, on the other hand, focuses on more operational concepts such as "Analysis", "Information" and "Accuracy". This section outlines a literature focused on AI as a tool for optimisation and automation, particularly in traffic management, big data analysis, and the construction of predictive models. The focus is on analytical precision, data classification and the efficiency of intelligent systems in urban contexts.

Interestingly, the intermediate position occupied by the term internet seems to act as a conceptual node between the two clusters, reflecting the role of digital infrastructures in the connection between decision-

making processes and emerging technologies. A still fragile connection between the different conceptual structures emerges as an element of final critical reflection. The map confirms how AI is now recognised as an incentive for the evolution of urban management, but at the same time highlights how the scientific approach to the topic is still fragmented, with an evident separation between theoretical visions and practical applications.

3.3 "Artificial Intelligence" AND "Due Diligence"

The scarce presence of scientific contributions dedicated to AI and Due Diligence or the valorisation of unused Architectural Heritage underlines a gap in the current literature. These areas represent a promising research field, in which AI could evolve as a technical tool and cognitive decision-making infrastructure, capable of supporting more sustainable, inclusive and built-regeneration-oriented urban policies.

Although still marginal in the scientific debate, the topic of DD represents a strategic area for the application of AI, operating on two distinct levels: urban and architectural.

AI can enhance DD practices at the urban scale by supporting predictive assessments on brownfield sites, territorial risks and regenerative potential. The studies by (Al-Rimawi and Nadler 2023 - 2025) show how the integration of innovative technologies and data-driven tools strengthens the preliminary phases of decision-making processes in the real estate and urban planning fields, transforming DD into a strategic lever for sustainable planning.

At the architectural scale, several contributions explore the application of AI in the technical and performance assessment of the built environment, with a particular focus on adaptive reuse processes (Cinquepalmi et al. 2023; Gravagnuolo et al. 2021; Barberis et al. 2020). In these studies, AI enables the automated analysis of morphological, energy, and structural data, integrating multi-criteria approaches to support more informed and sustainable decision-making. Despite its potential, the literature points to a fragmented landscape, characterised by the absence of consolidated models and scalable applications. This highlights the pressing need to develop robust methodological frameworks that can establish AI as a reliable decision-making tool within urban and real estate regeneration processes.

4 Conclusions

The literature review reveals significant gaps, particularly the absence of tools specifically designed to support urban regeneration through the rehabilitation of disused spaces and buildings using AI technologies. While advanced technologies offer promising solutions, the risk of disproportionate and top-down applications remains, potentially neglecting social and cultural dynamics. Hence, it is crucial to integrate community engagement tools and participatory governance strategies to balance technological innovation with urban resilience (Allam and Dhunny 2019). The effectiveness of AI tools lies in their ability to process large volumes of data, refining analyses and automating resource optimisation. Various subcategories of AI — including GAN models, Generative Pre-Trained Transformers (GPT), Machine Learning (ML), Information and Communication Technology (ICT), Internet of Things (IoT), Cloud Computing, and Software as a Service (SaaS) — form the technological infrastructure for data-driven urban development (Talari et al. 2017). Successful SC and SRE solutions implementation requires high-tech information systems and sharing platforms to analyse collected data (Al-Rimawi and Nadler 2025). Moreover, the literature identifies the fragmentation of local policies and the difficulty in implementing data-driven strategies as significant barriers to efficient and sustainable urban development (Acioly et al. 2020). Although Urban Big Data (BD) represents a highly innovative sector, critical issues such as data source fragmentation and lack of interoperability persist. One notable weakness is the limited connection between real estate (RE) research and urban regeneration and sustainability efforts. While many studies apply AI to asset valuation and market trend prediction, few address the relationship between real estate markets and adaptive reuse strategies. This suggests that the real estate sector remains largely anchored to traditional development models focused on new constructions, rather than enhancing existing assets. The convergence of AI, BD, and property management models may offer a pathway to overcome these challenges, fostering more rational and effective urban resource management and promoting smart but also sustainable, inclusive, and adaptable cities to future challenges. The level of integration of AI into urban governance is still limited by theoretical and operational limits, even if the European Union tends to propose new operational applications oriented towards sustainability, circularity and territorial equity.

The research has highlighted how AI today represents a stimulus to rethink the contemporary city, especially in urban regeneration and valorisation of abandoned buildings. The adoption of generative models and predictive tools based on data opens up concrete operational scenarios to overcome the critical issues related to information fragmentation, lack of interoperability and the absence of systemic approaches.

SC technologies have reached sufficient maturity to be integrated into operational processes, but highlight also the lack of a structured model to guarantee interoperability between data and digital platforms (Al-Rimawi and Nadler 2025). A structural barrier that limits the real potential of AI in urban contexts, making it urgent to build open, integrated and scalable information ecosystems.

In this scenario, the issue of the reuse of abandoned buildings remains marginal in the scientific debate. The introduction of the Reusability Index (RI) by the European Commission represents a first step towards the definition of shared metrics (Barberis et al. 2020).

Future research developments will have to focus on the creation of interoperable frameworks capable of connecting predictive models and urban decision-making processes. Only a convergence between technological intelligence and social vision will transform cities into intelligent organisms capable of learning, evolving and generating social value. The challenge for the cities of the future is not only technological but profoundly cultural; integrating AI is not an end but a means to build safer, more resilient, and inclusive urban environments.

5 Ethics declaration

The authors declare that they have respected all ethical standards during the research process. All sources and references have been properly cited, and any potential conflicts of interest have been disclosed. The research was conducted independently and without external influences.

6 AI declaration

The authors confirm that Artificial Intelligence tools were used to assist only in language refinement and summarization. No AI system was employed for the generation of original scientific content, analysis, or critical evaluations included in this paper. The authors retain full responsibility for the originality, accuracy, and integrity of the research findings.

Let Me Entertain You: Managing Socially Sustainable Experience Economy Ecosystems

Heini Merkkiniemi
Tampere University MAB, Tampere, Finland

Abstract

This research aims at exploring and understanding the complex contemporary phenomena of socially sustainable Experience economy. It contributes to the academic discussion around Experience economy research, strategy and policy by developing understanding about managing social sustainability within Experience economy ecosystems in Finland. The core question of this doctoral thesis is *how to ensure everyone equal access to Experience Economy Ecosystems?*

The context of this research is the new *Experience Economy research program* conducted at Tampere University. This article is part of a doctoral thesis, focused in specifically on industry phenomenas *Accessibility of Experience* and *Paths and Communities of Experience.* The Experience economy research program generates a rich empirical context and metadatabase highlighting the ongoing transformation and market development within the uprising Experience Economy ecosystems in Finland.

In this article experience economy is studied through social sustainability and in specifically inclusivity, to identify and analyse the mechanisms for managing social development goal SDG implementation within the experience economy ecosystems. Empirical data is drawn from OAF Outsider Art Festival. OAF is a new multidiscipline art festival, organized in conjunction with the largest Nordic art festival Helsinki Festival. OAF promotes diversity, equity and inclusion (DEI) and contributes to Social Development Goal implementation (SDG) by managing innovative collaborations between industry outsiders and insiders. OAF provides an interesting case - an industry specific critical “node” -within the EE ecosystem, providing new knowledge from the perspective of industry outsiders.

In result, by identifying, analysing and mapping the critical nodes, access points and stages where social transformation and inclusivity actualise and create socially sustainable, experience driven business models, this research creates new knowledge of managing social sustainability within Experience economy ecosystems and networks, in research and practice. This research contributes to Sustainable Development Goals (SDG): *Sustainable cities and communities (11), reduced inequalities (10), partnerships for the goals (17), industry, innovation and infrastructure (9), decent work and economic growth (8).*

Keywords: Experience economy ecosystems, social sustainability, inclusion, co creation, festival management

Paper type: Academic Research

1 Introduction

This research aims at exploring and understanding the complex contemporary phenomena of socially sustainable experience economy. It contributes to the experience economy research, strategy and policy makers by developing understanding about managing social sustainability within Experience economy ecosystems in Finland. This research contributes to Sustainable Development Goals (SDG): *Sustainable cities and communities (11), reduced inequalities (10), partnerships for the goals (17), industry, innovation and infrastructure (9), decent work and economic growth (8).*

The core phenomena, social sustainability, is studied from the perspective of social transformation and inclusivity in the context of Experience economy ecosystems and networks. The core question of this research is *how to ensure everyone equal access to Experience Economy Ecosystems?*

The context of this research is the new *Experience Economy research program* conducted at Tampere University from 2024 to 2027, specifically on industry phenomenons "Accessibility of Experience”, "Events & Fairs", "Paths and Communities of Experience". The Experience Economy research project provides a rich empirical setting featuring private and public organizations such as the City of Tampere in Finland, National Hockey League (the largest professional sports organization in Finland), Nordic Hospitality restaurant group, Tampere Fairs, Live Nation Finland, Nokia Arena and many smaller actors and organizations from art festivals to film makers.

In this doctoral thesis experience economy is studied through social sustainability and in specifically inclusivity, to identify and analyse the mechanisms for managing social development goal SDG implementation within the experience economy ecosystems. By taking an industry mediator perspective, this research studies transformative experiences as a way to drive sustainable business innovation and inclusive management practices enabling open access to co-creation and co-innovation.

This article presents a case of Outsider Art Festival. OAF is produced by a social enterprise Pertti's Choice Outsider Art Agency, founded by four disabled musicians of the punk band Pertti Kurikan Nimipäivät (Pertti Kurikka's Nameday PKN). The band represented Finland in the Eurovision song contest in 2015. After touring around the world for two years, the band decided to start a business to drive societal change and disability employment. For the past five years, Pertin Valinta (Pertti's Choice) has been running *Outsider Art Festival OAF* to empower marginalised groups and for giving power to outsiders in taking over mainstream stages.

With the combination of relevant literature around Experience economy and empirical data collected from the field, this research aims at studying the social dimensions of experience economy and the accessibility of experiences by exploring (1) what are the assumptions behind the creation of experiences and moreover, what are the needs, expectations and lived experiences of people who deviate from these norms, and second (2), what are the mechanisms of managing accessible experiences and events and determining shared value for sustainable ecosystems to service that journey and third (3) what are the typologies of organizations staging and creating experiences and how to develop shared assets such as common language, forums, policies and support programs for these organizations?

2 Socially Sustainable Experience Economy

The political origins of social sustainability is grounded in the UN 2030 Agenda (UN report 2022). The Commission for Social Development (2022) stated that strengthening social sustainability is an essential in the current global situation marred by numerous crises. The implementation guidelines show the path to addressing societal challenges, growing inequalities within and between nations. Opportunities for the most vulnerable people to access education and finding decent work is stated as a human rights and security issue that must be actively improved. There is a need to develop multi-level cooperation and targeted programmes to guarantee security and opportunities for everyone.

According to the UN evaluation reports (2019, 2023) the development of SDG implementation has stopped and will not reach the goals in 2030. As a positive exception to this negative development, the Nordic countries, and in specifically Finland has taken a lead position in SDG implementation. The UN report points out future development goals towards sharing best practices and creating new knowledge for other countries to follow. The report shows, that it is important to promote inclusion and engagement in all levels, from the international through the national and the regional to the local and in the level of intersectoral policies and governance (Fancourt & Finn 2019).

WHO's implementation package (2019) highlights the importance of facilitating intersectoral collaborations through transformative and whole-of-system approaches. Thus, in this thesis, SDG implementation is examined as a whole of system complexity to fully grasp relevant managerial and entrepreneurial assets and the core values and future of the socially sustainable experience economy.

Socially sustainable experience economy offers a current research topic that challenges with its ambiguous and multidisciplinary nature. Experience economy is considered one of the fastest growing global markets and experiences are increasing in popularity as sustainability, urbanization and the evolution of competition have accelerated the impact. The power of experiences has reached acknowledgment for socially transformative capacity and the creative industry is seen as essential for the further development of European economies and societies by generating social cohesion (OMC Report, 2019). According to the World Economic Forum (2019) *"the experience economy is booming, but it must be for everyone"* (2019).

The interest towards experience economy has grown also among scholars during the last decade (Pine & Gilmore, 1998, 2011 Chevchouk & al. 2021). However, as a concept, experience economy is still unstructured and lacking scientific research and discussion among scholars and practitioners (Chevtchouk & al. 2021.) Experience economy is often conceptualized either through the perspective of specific industries or as an extension of the value chain for products and services. Moreover, experientiality constitutes as one of the most rapidly expanding phenomena of our time, driving profound transformations in consumer behavior and business models.

Currently, in the experience business, creative industries and corporate reality, social responsibility is increasing significance as part of employee, audience and customer experiences and corporate responsibility. Scholars of knowledge management have addressed the growing interest towards sustainability presenting many interesting viewpoints to sustainability and the organization's need to adapt their business models and values to prioritize social and environmental responsibility alongside economic success (Lerro, A. & al 2023). However, compared with ecological sustainability, social sustainability still lacks understanding on promoting SDG's within creative economies and ecosystems.

3 New Stages for Shared Value Creation

As economies have evolved from services and products towards the primacy of experiences it is interesting to explore experiences as the key phenomenon for creating social and economical transformation. In their Big idea (2011) Porter & Kramer introduced a new way to achieve shared value by three key ways that companies can create shared value opportunities: 1) By reconceiving products and markets, 2) by redefining productivity in the value chain and 3) by enabling local cluster development. However, they also pointed out that realizing shared value requires leaders and managers to develop new skills and knowledge, such as a deeper appreciation of societal needs, a greater understanding of the true bases of company productivity, and the ability to collaborate across profit-nonprofit boundaries.

The original idea of Pine & Gilmore, founders of Experience economy, presented "work as theatre and every business as a stage" (2011) leading to interesting multi-disciplinary developments showing positive results of integrating creative knowledge to other fields through intersectoral collaborations (WHO 2018; Anttonen & al. 2016; Berthoin & Strauss, 2013, Sorsa & al 2017) highlighting the value of collective and creative experiences in supporting organisational transformation, social cohesion and community building as effective, participatory, collective activities (Berthoin & Strauss, 2013, Schiuma 2018; Sorsa & al 2017).

From the perspective of social value, it's important to critically observe, *who has access to the ecosystem and who gets to get up on that stage, who has the power to decide*? By raising up these questions this research exhibits new actors to the stage and explores the deeper significance and transformative impact of experiences. Open strategy scholars (Vaara & al, 2019) highlight *participation* as a core concept in defining open strategy in terms of strategy agency and power dynamics and inclusion. However, questions remain on *who is included and who excluded* from participating (Samra-Fredericks, 2005; Mantere & Vaara, 2008, Whittington et al 2019). Although the term open strategy implies widespread transparency and inclusion in strategy-making, real-life examples and practices mostly tell a story of more limited participation and role of organizational members outside the core establishment such as lower-level employees or external actors is underrepresented over top- or middle management (Vaara & al, 2019, Seidl et al 2019). Increased inclusion and engagement results in wider range of ideas and efficiency in strategy implementation (Splitter, 2024). The way different people understand and communicate strategies varies, as well as the quality of discourses.

Socially sustainable experience economy offers a current research topic that challenges managers with its ambiguous and multidisciplinary nature. Shifting focus from single organisations to networks and ecosystem level strategy work, and from top-management to the marginal actors, it is possible to explore new stages, (Pine & Gilmore, 2011; Schiuma 2018; Berthoin & Strauss 2015; Sorsa & al. 2017), where participants experience new transformative ways of seeing, thinking, and doing things that add value for them personally (Ravasi & Rindova, 2017; Hautz et al., 2017). However, integration of different level actors engaged in the strategy process, demands high level discursive competence and open access to strategic knowledge (Splitter, 2024). Ford and Ford (2008) present the idea of critical focal points, 'nodes', featuring specific places and moments where different stakeholders of the network intertwine, share and create something truly meaningful. By identifying and studying these critical "nodes", events as focal points of the industry ecosystem, this research points out direction for inclusive open strategy work and shared value creation within the Experience Economy ecosystems (Ford & Ford, 2008; Porter & Kramer, 2011).

4 Inclusive festival management, case study of Outsider Art Festival OAF

Drawing from empirical data, Outsider Art Festival OAF provides an interesting case - an industry specific critical "node" -within the EE ecosystem. OAF is a new multidiscipline art festival, organized in conjunction with the largest Nordic art festival Helsinki Festival. OAF promotes diversity, equity and inclusion (DEI) and contributes to Social Development Goal implementation (SDG) by managing innovative collaborations between industry outsiders and insiders. OAF presents an interesting case example by engaging "outsiders" to induce viewpoints, discourses, and solutions outside the established paradigms and industry conventions (Hautz et al., 2017).

OAF serves as a connecting point, a stage and a platform for Finnish Outsider Arts, featuring multidiscipline network working in the fields of music, visual arts, film, performance arts and literature. Besides the artistic productions, OAF showcases new visions and abilities of the industry outsiders to promote a larger societal impact and agenda. In 2020, after the covid pandemia, OAF initiated an employment program to ensure everyone open access to the creative industries. Through the program, OAF facilitates collaborations between sustainable business partners, engaged in creating new employment paths to the industry outsiders. In five

years, the program has initiated various collaborations- co-creation, co-production and co-curating- of the industry outsiders and insiders to challenge discriminatory and exclusive industry practices and drive social transformation by introducing new, inclusive practices as a joint agenda.

OAF offers an interesting research environment to study social development goal SDG implementation within the experience economy ecosystems. In this research, OAF provides a collection of empirical data, policy documents, strategy documents, interviews and videos of the experiences of both outsiders and insiders of the experience ecosystem: artists, producers, curators and managers as well as sponsors, venue partners and the audience. Guided by the internationally recognised statement of the disability advocates *"nothing about us, without us"* (Charlton, 1998) creates the foundation for all OAF operations and the demand for developing inclusivity as a collective effort. OAF offers support in employment and advocacy for people marginalized for various reasons, such as disability, mental health, social issues and ethnicity. By *"giving power to the outsiders"* and helping them in *"taking over the stage"* OAF creates a new platform for radically open strategy making for marginalized populations to engage and present their lived experiences and life stories through creative encounters. Beside the creative content and capabilities, OAF showcases new, accessible and socially sustainable value chains and inclusive production models, promoting a wider recognition of disability employment and inclusion in the labour market.

5 Contribution and relevance

This research contributes to social development goals by identifying mechanisms for managing inclusive practices both in management and research within the Experience economy ecosystems. Drawing from current literature around experience economy, transformational experiences and the empiria from Outsider Art Festival OAF, this research introduces the 1) experiences and expectations of industry outsiders and insiders, 2) mechanisms for managing accessible experiences and 3) offering new insights on the discussion how accessibility and inclusivity is experienced and facilitated as shared value, communication and space.

With the combination of literature around Experience economy and the empirical data drawn from Outsider Art Festival OAF's networks, this research creates new knowledge to the complex and multifaceted issue of managing social sustainability within the experience economy ecosystems from the perspective of industry outsiders and insiders. In this case, outsider's position is used to refer to the way marginalised populations are represented and taken into account as equal actors in ecosystems of the industry ecosystem, engaged in decision-making and operations, as leaders, managers, curators and creators of events and creative content.

Based on the preliminary findings collected from the OAF strategy documentation and stakeholder interviews, the main reasons for being left outside the industry conventions are *the unaccessibility of qualifying education and supportive services.* Furthermore, outsider statements point out that *creative industries are not generally recognised as possible working opportunities for outsiders by their supporting networks.* From the perspective of the advocate organisations working with outsiders, *open strategy can offer new direction to supporting outsiders engagement in co-creation with the insiders*. Opening access can also lead the way for insiders to many ways perceived and even closed worlds of the outsiders. *Accessibility is discussed also as a communicative issue* besides the industry structures. As the open strategy scholars have argued, the demand for *professional discourse can create an obstacle* for open access, when people are using very distinct and industry specific language. As a part of communications, technology can also create an issue. Using technological systems for example in collecting experiences and data can also turn out to be challenging and even discriminating for people who don't have digital access due to guardianship or the lack of technical skills.

From the insider perspective, industry conventions appear to also cause challenges, but for different reasons. The *difficulties in finding a shared space, language and ways of co-working* become critical issues that require special knowledge and competence. Although industry insiders are seeking ways to drive societal impact by new, collaborative ways, they *lack the competence in managing or facilitating collaborations* with industry outsiders. To succeed in shared value creation, it appears critical to have support on a managerial level to fully engage in promoting open access and power shift on industry level. When succeeded, both insider and outsider experiences *state joy for giving and having a voice, space and power to decide*, make a difference and create experiences that are "*truly meaningful and transformational*".

In conclusion, open strategy and shared value creation are introduced as an inclusive practice and a way to look beyond the conventional practices and viewpoints and expand the scope beyond the organisation to ecosystem level and the society. Taking the mediator perspective, this research highlights how inclusivity challenges meditative actors and managers in facilitating the various stakeholder perspectives within the ecosystem in flux. Moreover, this research sheds light to the impact ecosystem level collaborations can have on driving industry conventions and societal transformation. Creating a shared space and agenda around shared

values and strategic goals, enables a more profound impact to the ecosystem level over single organisations and industries.

Looking beyond the Experience economy ecosystems, this research has relevance to social sustainability endeavors also on other industries. By identifying and mapping the critical nodes, access points where SDG implementation actualise, this research provides new knowledge on creating business models, managerial and entrepreneurial strategies on promoting social sustainability within Experience economy ecosystems and networks, in research and practice. Furthermore, this research points direction to inclusive research and engaging outsiders in creating scientific knowledge as a collective effort and calls for attention to engaging outsiders in the knowledge creation according to the fundamental statement of the disability agenda: Nothing about us without us.

Global or Local Player? – Cultural Diversity and Barriers in STEM Studies

Petia Genkova, Henrik Schreiber, Edwin Semke
University of Applied Sciences Osnabrück, Osnabrueck, Germany

Abstract
The aim of the current study is to examine the perception of cultural diversity among German STEM students. Previous research has mainly focused on the attitudes towards gender in the STEM field. This study undertakes an innovative approach and explores the opinions of German STEM students with and without a migration background on cultural diversity and educational barriers. To test this, we conducted semi-structured interviews with 90 STEM students from two German cities. The data was analysed with a qualitative content analysis. The results show that both students with and without a migration background are to a large extent unfamiliar with the topic of cultural diversity. Most STEM students think that cultural diversity has a positive impact on work performance. Some of the barriers which students with a migration background face are unfair university structures, lack of support in the educational system, challenges of cultural adaptation, and insensitivity or hostility from host-culture members. This study shows the need for a more inclusive university culture in the STEM field. It also emphasizes that diversity trainings can successfully prepare students for intercultural experiences.

Keywords: Cultural Diversity; STEM; Discrimination; Students

Paper type: Academic Research Paper

1 Introduction

Difficulties in integrating and utilizing diversity in the field of education in science, technology, engineering and mathematics (STEM) have existed for a long time. This issue has, however, not been fully addressed so far (Atadero et al., 2018; Best et al., 2013; Chédru & Delhoume, 2023; Maji et al., 2023). The current discussion refers to the lack of diversity in the STEM degree programs and professions which has become a major concern. The participation of underrepresented groups in STEM should be increased. This is considered critical for preserving the future vitality of the field, as demographic shifts and the complexity of modern problems have demonstrated a need for diverse perspectives and approaches (Atadero et al., 2018). Furthermore, a more diverse STEM workforce is seen as essential for meeting the ethical obligations and serving the needs of all populations (Atadero et al., 2018; Best et al., 2013; Chédru & Delhoume, 2023; Maji et al., 2023). Related to this discussion, an extensive body of scientific literature and policy papers emphasizes the importance of not only attracting future female scientist, engineers and mathematicians but of developing the professional culture, sensitivity related to gender issues, and professional stereotypes related to gender (Anger et al., 2018; Best et al., 2013; BMBF, 2020; Froehlich et al., 2022; Schäfer, 2006). At the same time, there is a noticeable gap in the discussion on diversity of cultural background and interculturality in this sector.

In the current German educational system, students with a migration background show a lower study success rate despite similar or higher study motivation, especially in STEM subjects (Miyamoto, 2018; Educational Report Germany 2018). A large body of research has identified several reasons for this discrepancy: unfair structures and lack of support in the educational system (Koehler & Schneider 2019), challenges of cultural adaptation (Deardorff & Arasaratnam-Smith 2017), as well as host-culture members' lack of sensitivity or hostility (Uslucan 2020). For the purposes of this study, persons who immigrated to Germany in the first or second generation are considered immigrants. This means that at least one parent or the participants themselves immigrated to Germany (Kemper 2010). Those categories are clearly unable to display the complexity of interpersonal variety in this group of participants (Atadero et al., 2018). However, people with a migration background might differ in the way they experience cultural differences and disadvantages. Furthermore, the topics of sensitivity or abilities related to cultural diversity are not widely addressed in German STEM curricula (Auferkorte-Michaelis & Linde, 2022).

The concept of diversity of the cultural background in German STEM education is related to the issue of reducing phenomena of discrimination (discrimination and fairness perspective; Auferkorte-Michaelis & Linde, 2018; Ely & Thomas, 2001) as well as to questions of abilities and skills necessary to deal effectively with different cultural orientation systems (integration-and-learning perspective). The discrimination and fairness perspective is related to the process of inclusion and refers to providing equity of conditions to access and participate in STEM education (Villanueva Alarcón et al., 2021). The integration and learning perspective focuses on the

utilization of diversity. One of the main aims of this perspective is not simply to avoid discrimination but to prepare students to interact effectively and appropriately in an international and complex context (Genkova & Schreiber, 2022).

As the STEM sector is the most internationalized sector in Germany, STEM-education just recently set a focus on addressing cultural / ethnic discrimination and on providing skills to succeed in this working environment (Anger et al., 2021). Previous research on organizational diversity could show that understanding the perception and connotation of cultural heterogeneity is a crucial precondition to effectively develop individuals' attitudes and skills to deal with it (Bergman et al., 2023; Genkova & Schreiber, 2022; Genkova et al., 2021). While the perceptions and attitudes related to gender have been thoroughly discussed in the literature and in the practice, hardly any studies have been conducted on the perception of cultural diversity in German STEM subjects. Given the urgency of including and utilizing cultural diversity in the STEM-education, the main aim of the current paper is to contribute to the understanding of the perception of diversity in the German STEM education. Our approach is to explore the perspectives of German STEM students with a migration background, as well as their non-immigrant fellow students on diversity and related barriers by means of a comparative, qualitative study.

2 Theory

Diversity management revolves around the composition of individuals within an organization, encompassing both their similarities and differences (Krell, 2013). Previous research shows that diversity at universities is reflected in demographic characteristics (e.g. migration background, age), cognitive aspects (knowledge structures, values), subject differences, functionality (skills, organizational cultures, communication) and institutional affiliation (Higher Education Awareness for Diversity, HEAD model, Gaisch & Aichinger, 2016). While all these characteristics hold varying degrees of significance, certain dimensions of diversity are particularly meaningful due to their impact on individual identity and the associated challenges and opportunities (Van Dick & Stegmann, 2016).

Research on the integration and learning perspective focuses on the pros and cons of heterogeneity in organizations and institutions referring to the information-processing perspective and the social identity approach (Schneid et al., 2016). The information-processing perspective posits that diversity is linked to the application and the thorough processing of relevant information, leading to enhanced performance within diverse teams. On the other hand, the social-identity approach suggests that the formation of subgroups in workgroups based on shared attributes, such as age or cultural background, can result in conflicts and hostile behavior (van Dick & Stegmann, 2016).

Culture and age are both significant components of an individual's social identity, serving as categorization tools for oneself and others, with particular emphasis on subjective differences between groups (social identity approach; Tajfel & Turner, 1979). Culture, in this context, refers to a psychological framework that shapes identity through norms governing perception, cognition, and behavior (Thomas, 2003). When the sense of belonging to a specific cultural or age group becomes more salient or subjectively relevant, individuals tend to view themselves and others less as unique individuals and more as representative members of a particular group (van Dick & Stegmann, 2016).

The categorization elaboration model (CEM, van Knippenberg et al., 2004) aligns with the social identity approach and provides an explanation for the performance disparities observed among diverse teams in a replicable manner (van Dick & Stegmann, 2016). The core premise of the CEM is that groups with diverse members possess a greater potential for diverse perspectives, knowledge, and general information, leading to more comprehensive information processing and, consequently, more innovative solutions. However, the formation of subgroups (based on subjectively relevant group characteristics and salience) can trigger negative emotional consequences, ultimately resulting in poorer performance if the subgroups develop a hostile relationship. This occurs when the subgroups fail to recognize each other or acknowledge their respective contributions, thereby threatening their identities (van Dick & Stegmann, 2016).

Beyond the direct negative impact on utilizing diversity-potentials, research indicates that subgroup formation based on cultural background has profound implications for fair opportunities and appropriate intergroup behaviour (Kunze, 2013). Certain professions exhibit a historical lack of diversity compared to others. This discourages minorities from considering them as viable career options. In the context of STEM education in Germany, individuals who deviate from the stereotypical image of a STEM graduate (e.g., male, white; Leicht-Scholten et al., 2009) in terms of their ethnic/cultural background and gender often encounter both direct and indirect forms of discrimination, making them vulnerable groups. Alongside the already existing obstacles faced by members of vulnerable groups, they also tend to have fewer resources to navigate through changes or crises, such as the ongoing COVID-19 pandemic (Lörz et al., 2016; Zimmer et al., 2021). As a consequence, people from

non-academic backgrounds (which are overrepresented among students with immigration background) have exhibited increased intentions to drop out during the pandemic (Becker & Lörz, 2020), and individuals with a migration background face higher dropout rates in STEM (aspiration-performance paradox, Miyamoto, 2018). These challenges are further compounded by intersectionality, which occurs when individuals face disadvantages due to multiple intersecting characteristics.

Following the CEM, the utilization of diversity in STEM-education and the workplace requires a positive and appreciating approach towards diversity from all institutional members. Considering the internationalized working environment as well as existing discrimination, STEM-graduates are thus expected to appreciate diversity, to understand existing power-asymmetries, and to develop the skills necessary to interact appropriately and effectively with individuals with other cultural orientation systems. One of the aims of STEM-education should thus be, to provide such attitudes, skills and knowledge to STEM-students (Atadero et al., 2018). Previous research shows that individuals in Western Europe evaluate, seek, or reject relationships with members of social outgroups based on the perception as beneficial (Stürmer & Benbow, 2017; Paolini, Harwood, & Rubin, 2010; van Dick et al., 2008). International studies on STEM-students' perception of cultural otherness highlight the need to prepare students appropriately for intercultural experiences (Bergman et al., 2023; Chédru & Delhoume, 2023) and record the naivety of unprepared STEM-students towards diversity (Atadero et al., 2018; Bergman et al., 2023; Maloshonok et al., 2022; Villanueva Alarcón et al., 2021). Students facing cultural otherness might also experience stress or threat related to their cultural orientation system not working or related to the social pressure to act politically correct (Chédru & Delhoume, 2023). At the same time, students with a migration background are facing open and hidden disadvantages (Koehler & Schneider, 2019; Miyamoto, 2018). However, little is known about how German students with a migration background and WIHTOUT-M perceive the issues of diversity and discrimination and how the STEM-education might address inclusion and utilization of diversity. To elaborate on diversity potentials for the education in STEM-subjects, the current study thus investigates the research question of how students with a migration background and WIHTOUT-M perceive educational barriers and diversity in the German STEM-education. This includes the following sub-questions:

- Are students aware of the cultural diversity in their social environment?
- What attitudes towards cultural diversity do students have?
- Are there barriers for students with a migration background?

3 Method

To answer the research question, we conducted a qualitative study by means of semi-structured interviews. The interviews were designed to provide a holistic picture of the subjective theories (Hilmer 1969) of students with students with a migration background and without a migration background students without a migration background towards cultural diversity and discrimination in the STEM-education context. The interview guideline contained a total of 47 both open questions and semantic differentials, plus questions for a possible specification of the answers. To ensure conceptual equivalence and comparability (Genkova 2019) across the subgroups, the final interview guideline was discussed by several experts on diversity with and without a migration background. The interviews took place from May to December 2019. Participants were approached on the premises of two colleges and universities. They were directly interviewed if they had been studying a STEM subject for more than one year. It was assumed that students must have spent some time at a university to be able to answer all relevant questions in a meaningful way. In the beginning, the participants were informed that the interviews would be recorded. In accordance with the applicable data protection guidelines, written consent was obtained that the anonymous recordings may be used for scientific purposes. The interviews were held in German language (all participants had a sufficient level of German) and took 20 to 60 minutes. Interviews were recorded and transcribed afterwards. The translated Interview-Guideline is attached to this submission.

We analyzed the transcribed interviews inductively using qualitative content analysis according to Mayring (2010). This method offers the advantage of remaining very close to the original statements and enabling a great depth of interpretation (Krippendorf 2004). Qualitative content analysis contains three steps, paraphrasing, generalizing, and categorizing. Paraphrasing involves restating the information or ideas from a source text in your own words while maintaining the original meaning. The goal is to express the content using different sentence structures and vocabulary. Generalizing involves identifying broader patterns or themes within the data or source text. It entails extracting the core concepts or ideas that are common across different instances or examples. Categorizing involves grouping similar ideas, concepts, or themes together based on their shared characteristics. It entails creating categories or codes that represent different aspects of the content being analyzed. Table 1 provides an example of the evaluation. The content analysis was conducted by the researcher

who also conducted the interviews. Subsequently, the formation of categories was discussed with three experts on diversity at universities to ensure better objectivity as a basis for interpretation (Bengtsson 2016).

Table 1. Example for paraphrasing, generalizing and categorizing an answer in the interview *(interviews have been conducted in German, this is a translation for exemplary purposes only and does not claim equivalence to the original content)*

Step	Interview content
Question	What do you personally understand by diversity?
Answer	And this refers to people, not Smarties? (laughs) Yes, so different character traits, different worldviews.
Paraphrasing	Different character traits and worldviews
Generalizing	Heterogeneity of Character traits, world views
Categorizing	Character, Perspectives

90 students in Osnabrück and Munich participated in the interviews. 16 of them belonged to the University [blinded for peer review] and 15 to the University [blinded for peer review]. Two belonged to the [blinded for peer-review] and 57 to the [blinded for peer-review]. The participants are on average 24 years old. 50 of the participants are male whereas 40 are female. 59 bachelor and 31 master students who studied a STEM subject from the third semester onwards were surveyed. 42 students had a migration background and 48 did not. In addition, 18 of the participants are first-generation migrants, the others are second-generation migrants.

4 Results

We tested the research question how students with a migration background and students without a migration background perceive diversity. More specifically, we focused on the ways cultural heterogeneity was utilized and included. To enable a thorough comprehension of the latent subjective theories of cultural diversity we analyzed two different sources of information: the interview transcripts and the derived categories.

4.1 Are students aware of the cultural diversity in their social environment?

To answer the first research question, are students aware of the cultural diversity in their environment, we examined several different aspects related to diversity. We addressed the general concept of diversity, its impact, and possible ways to approach it. The results showed that diversity was a topic of minor importance for the surveyed students. Even though most participant statements created the general impression that diversity is of huge relevance, many respondents expressed hesitation, and three explicitly stated that they did not have even a vague idea. Overall, multiple categories were enumerated, but mostly by individual respondents who listed a large number of terms. It was a common practice to mention only one term, such as biodiversity or diversity of character traits. This points to the vast unfamiliarity with the topic prior to that.

To identify the relative significance of specific diversity characteristics, we posed the following closed-ended question: "Which of the following characteristics do you consider important for diversity? Rate their importance on a scale of 1 (not important) to 7 (very important)." We observed that assigning a particular connotation to attributes such as age, gender, disability, religion/worldview, and 'race'/ethnic origin dismayed some students. Only the category 'race'/ethnic origin was evaluated differently by students with a migration background in comparison to students without a migration background. It received a higher rating overall. Subsequent parts of the interview covered the topic of the biased treatment of women in STEM fields. Nevertheless, this unfavorable practice was not evident in the assessment of the gender category: no difference was found between male and female participants.

students with a migration background and students without a migration background responded differently to the first question. There was no differentiation between first-and second-generation immigrants though. With the exception of one student, all students with a migration background mentioned terms like origin, cultures, or 'race', but felt clueless and could not provide further clarifications. students with a migration background and students without a migration background gave conceptually different answers about the elaboration on diversity in society. The opinion of almost all students without a migration background was that substantial efforts to a satisfactory degree were made for the topic of diversity in society (an example was the special access to the cafeteria building for people with disabilities). In sum, students without a migration backgrounds' answers created the impression of an oversimplified view on diversity in their environment. Participants who had a bare notion only avoided the topic more often and made more jokes and excuses during the interviews. Thereby, some interviewees were more conscious of the political relevance of the topic than of

the topic itself ("...But there are simple rules here, to which you have to stick!"). students without a migration background were convinced of the importance of diversity for society. The main reason for this was that participants felt insecure rather than interested or engaged.

Among students with a migration background, only 14 % believed that people paid enough attention to diversity, while 55 % explicitly expressed the view that cultural diversity in particular, was not given due consideration in society. Participants, however, were unable to provide clear reasons for the lack of sufficient concern for diversity. Just as students without a migration background displayed unawareness and insecurity, students with a migration background's awareness was limited by vague ideas rather than concrete knowledge about political or social issues. Furthermore, we observed that students with a migration background noticed differences between social classes, while for students without a migration background this was not a relevant criterion.

4.2 What attitudes towards cultural diversity do students have?

The answer to research question two, about attitudes towards cultural diversity, comprised the following interview questions : How is the impact of extensive diversity perceived in society? And how is it perceived in a university or within a workgroup? Additionally, the study investigated the students' perspectives on the appropriate approaches to of diversity and what they would recommend to a friend when dealing with diversity.

When asked "Do you perceive the impact of extensive diversity in society as positive or negative?" 25 % of the students responded that it is limited to negative. In contrast, 10% of the students with a migration background and 30% students without a migration background state that one should hide or ignore one's distinct cultural characteristics. The students with a migration background justify this attitude by disregarding cultural differences or trivializing them at the expense of their individual competence. For the question "In your opinion, does extensive diversity within a work or study group have a positive or negative impact on the group's outcomes?", it was expected that students would provide competent answers, as they regularly have practical experience in this context. It was found that the majority of responses were positive or tended to be positive. One-third of the participants, however, believed that a condition has to be met for diversity to be beneficial for group outcomes: there must be good communication.

This view was predominant among those who initially had only vague notions of the concept of diversity. One students with a migration background explicitly stated that he considered cultural differences to be nonsense but acknowledged that "there are a few values that one must adhere to here...". Some of the participants seemed to agree with this view and implicitly or explicitly challenged the value of diversity, despite initially being only partially aware of this issue.

students with a migration background demonstrated a more open-minded view and reported more positive attitudes towards cultural diversity. At the same time, they also enumerated various problematic issues such as language barriers, acculturation issues, and the difficulties of unfamiliar environments. Appreciation of diversity was positively related to mindfulness towards cultural differences and the resulting predicaments and opportunities. The participants displayed throughout the interview much doubt as to how to pertain to cultural diversity. Participants' insecurity was manifested in stress or evading reactions on the request of details about cultural diversity like e. g. the instrumental benefit of diversity. Participants who were only remotely familiar with the concept of diversity, felt more insecure and tended to perceive diversity as problematic. This was even more the case if participants reported that they have a lot of knowledge of political correctness but a low understanding for diversity. None of the participants received any previous diversity training.

4.3 Are there barriers for students with a migration background?

To identify potential barriers for students with a migration background, we first probed social integration as to how they appraise themselves in comparison to their peers. . Subsequently, we assessed to what extent and how they differ from the surrounding environment with 14 brief questions. The categories encompassed various aspects such as behavior, language, leisure activities, living conditions, religion/worldview, caregiving responsibilities, place of residence, ethnic affiliation or nationality, migration experience/background, educational background, appearance, age, mental and physical abilities, as well as any other characteristics they found relevant. Analysis revealed that the most prominent categories were language and communication style, leisure activities, educational background, ethnic background, and migration background/experience. Language differences were characteristic specifically for first-generation migrants. Concerning leisure activities, nine participants highlighted their experience of migrating to Germany as a turning point and reported that leisure opportunities they encountered were divergent in comparison to their home countries. This resulted in a sense of disorientation on campus and there was a need for time to adapt to these new leisure activities.

Furthermore, participants were queried about the size of their social circles and their characteristic features. WITHOUTH-M reported more frequently having large friend circles, compared to students with a migration background. Additionally, students with a migration background emphasized that they shared cultural heritage with their friends, whereas students without a migration background primarily highlighted that they had common academic pursuits and leisure activities. Second-generation migrants consistently expressed that individuals with a migration background went through similar hurdles and perspectives in their social circles. In particular, this included dealing with the complexities between their parents' cultures and Germany. One participant summarized the reasons as follows: “more common topics and views of the world. Less insensitivity or discussions.”.

The following question to participants assessed whether they perceived that all students received equal treatment by instructors. Surprisingly, twenty individuals responded negatively. Among them, three female participants expressed experiencing differential treatment or preferential treatment because of their gender. However, no supporting evidence of racist or sexist discrimination by instructors was provided. Regarding the question of whether their own cultural characteristics are perceived more as an advantage or disadvantage, 35% students with a migration background answered that they rather reckon their migration background a weakness. The main causes of this opinion were the physical appearance or the foreign name, four of them simply mentioned the migration background in general as a cause . Returning to the question of whether participants supported the display of their own cultural peculiarities, some individuals declared that their migration background gave rise to relatively low self-confidence. However, migrant participants who have stated that one should follow an assimilation strategy and renounce their own cultural characteristics showed bigger peer groups, mostly comprised of students without a migration background.

Regarding experiences of discrimination, there were differences in the answers between the cities. Students in Osnabrück do not report a single instance of discriminatory behavior on the part of lecturers or the university management. In Munich, twenty percent of students with a migration background reported that foreign students are generally discriminated against and that they have been subject to discriminatory behavior themselves (being ignored and receiving worse grades than others). Usually it was lecturers (white, male, older) who were convicted of discriminatory tendencies. Students though also committed this behavior.

Structural aspects of disadvantages did not seem to greatly affect in participants’ life. Most participants who migrated stated that they had problems with orientation. However, nearly all of them were aware that re-orientation is a natural process after moving to another culture and did not report extensive stress due to acculturation. Despite having sporadically strenuous interpersonal issues, most participants appreciated university organizations in Germany. They stated that they had access to all valid information and bureaucratic processes mostly do not last too long. In contrast, none of the participants received organized support for integration apart from German language courses. Furthermore, no knowledge about opportunities at the university or in general was, provided.

5 Discussion

In summary, the majority of participants demonstrated a limited or a simplified understanding of the concept of diversity. students with a migration background showed a greater awareness of the importance of their own cultural background. While the level of identification with their heritage culture varied, students with a migration background generally perceived themselves as distinct from others. Some students with a migration background had experienced discrimination before and many were aware of their vulnerability compared to others. However, most of them struggled to identify concrete options for promoting fairness in society or the university context. On the other hand, students without a migration background did not perceive their social environment as particularly diverse. They recognized the importance of cultural diversity for the future, but did not perceive any problems as long as they don’t get confronted with otherness personally. Nevertheless, their lack of understanding became evident when discussing specific dimensions of diversity, causing stress and a tendency to overlook the topic's importance and practical implications.

Students with a migration background appeared to be less socially integrated on average. Some attributed this to feeling different from the majority. The perception of discrimination was prevalent among a portion of the interviewees, as described by Blasco and Paunova (2018). Awareness of belonging to a stereotyped group, according to Massey and Fischer (2005), can lead to a decrease in individual performance and a heightened susceptibility to stereotype threat. This aligns with the finding that students who were more aware of their differences, perceived their migration background as a disadvantage.

Two coping strategies were observed among students with a migration background. While the majority tended to embrace their cultural characteristics, some believed that hiding their cultural attributes would

facilitate success in the host culture, similar to Berry's (1980) concept of assimilation. The perception that diversity had no or a negative impact on their performance played a central role in this strategy. As a result, they adopted a skeptical or avoiding attitude towards cultural diversity, in general, which supports previous studies on diversity management suggesting that negative beliefs about the effectiveness of diversity increase identification with one's own subgroup (van Knippenberg et al., 2004; Wang et al., 2019). In contrast, other participants had grown accustomed to feeling less included and tried to make the best of their situation through integration. While sensitive to discrimination in their social environment, none of the participants had a scientific understanding of diversity. Consequently, they showed little or no reflection on their situation at the university or possible ways to address it. Problems or challenges related to diversity were perceived as "off-topic" issues that might hinder their studies. This could be attributed to the lack of inclusion of cultural diversity topics in the STEM curriculum (Koller & Rudolph, 2017). Structural disadvantages described by Auferkorte-Michaelis and Linde (2018) or Koehler and Schneider (2019) did not seem relevant to the experiences of the participants in the current study. While students acknowledged the challenges of cultural adaptation and reorientation, most were able to cope individually, challenging the arguments put forth by Jungbauer-Gans and Gottburgsen (2021). However, the participants' perception of few disadvantages does not negate the need for systematic support, as low sensitivity and intercultural interaction competence in the social environment could indirectly impact academic performance by limiting access to social resources.

The current study has some limitations. Due to the small sample, representativeness cannot be assumed. By applying a structured interview guideline, the range of possible answers of the respondents was limited. Moreover, it is questionable whether results can be transferred to other subject areas, as relevant training is much more widespread there. While no differences between men and women appeared in the interview, their specific points of view have not been considered in the current study.

6 Conclusion

The current results contribute to the discussion about implementing diversity in STEM-education (comprehensively described by Atadero et al., 2018) by providing insights in the existing lack of sensitivity and knowledge about diversity among German STEM-students. We could show the tendency to neglect diversity among students with a migration background and students without a migration background that is connected to this unawareness. Simultaneously, the study reveals the challenges faced by students with a migration background, such as difficulties in cultural adaptation and a hesitant or even hostile attitude towards heterogeneity in their social environment. Given students without a migration background appear largely insensitive to diversity, it is essential to establish a positive and inclusive diversity culture among university lecturers and students as a key objective in STEM education. Moreover, there is a need for systematic diversity education within the STEM field. Although STEM is highly culturally diverse and internationalized, only a minority of students receive structured education to develop intercultural attitudes and competencies. This lack of adequate education poses a risk of problematizing and avoiding diversity. The results show that its vitally important to provide at least some orientation on the nature and effects of culture, interculturality and discrimination.. International studies could already demonstrate the effectiveness of interventions or trainings on diversity sensitivity or competences in STEM-education (Bergman et al., 2023; Chédru & Delhoume, 2023; Schäfer, 2006). Future studies should investigate the effectiveness of different forms of diversity education in fostering inclusive attitudes and reducing othering among STEM students, ideally through comparisons with other academic disciplines.

A Country's Innovativeness as a Determinant of Income Convergence

Maja Bacovic
University of Montenegro, Podgorica, Montenegro

Abstract
Disproportion in the level of economic development is more of a historical fact than a recent phenomenon. The empirical analysis in this study, based on ten selected countries, six of which are the high-income and innovation leaders and four middle-income countries (of which one is the regional innovation leader), shows that in the last decades, the income gap has increased in absolute terms while decreasing slightly in relative terms. The income gap (absolute) increased less for middle-income countries ranked as more innovative. This study investigates whether the difference in knowledge becomes a more relevant determinant of income convergence than capital growth. This study's empirical analysis is based on two samples. To evaluate the impact of innovations on economic growth and income convergence, we used a sample of ten economies, which were grouped into two categories (high-income and middle-income), and compared their average income over time. It spans the period from 2004 to 2023. The income gap between the two groups of countries has increased from 41,330 (constant 2015 US$) in 2004 to 49,989 (constant 2015 US$) in 2023. If we compare individual middle-income countries with a group of high-income countries, we see that the gap has increased less in those more innovative. The analysis also shows a strong positive relationship between the average value of four Global Innovation Index components (Human capital and research, Business sophistication, Knowledge and technology outputs, and Creative outputs) and GERD per capita. Based on an evidenced positive relationship between innovativeness and expenditures for R&D, we estimated aggregate production function on a sample of 35 European economies from 2000 to 2023 (annual data). Estimation shows that gross fixed capital formation growth of 1% leads to output growth of 0.32%. Employment growth leads to output growth of 0.214% and R&D investment growth of 0.157%. Growth in other exogenous factors (TFP) contributes to output growth by 0.02%. The estimation results show a highly positive impact of expenditures on R&D on economic growth. The country's educational outcomes strongly determine research and innovative activities, especially regarding science education. Observing the strong relevance of the expenditures for R&D and the innovative potentials for economic growth, what are the options if a country cannot provide innovative growth internally? Technology transfer is one possibility, therefore, less innovative countries should encourage and support technology transfers through FDI or other forms to narrow the knowledge and income gap if they cannot increase R&D investments.

Keywords: Income convergence, Innovativeness, GERD, Technology transfer

Paper type: Academic Research Paper

1 Introduction

Disproportion in the level of economic development is a more historical fact than a recent phenomenon. Historically, most countries still have a development gap compared to developed economies. Although the gap diminished in some parts of the world in the second half of the 20th century, such as Southeast Asia and China, European middle-income countries, despite higher rates of economic growth at the beginning of the 21st century, have an income that is, on average, 4.6 times lower than that in developed European countries (Popov & Jomo, 2018).

Solow's model implies that the rate of return on capital is lower in countries with more capital per worker; thus, there is an incentive for capital to flow from rich to poor countries, which will also tend to cause convergence. In addition, if there are lags in the diffusion of knowledge, income differences can arise because some countries do not yet employ the best available technologies (Romer, 2001). This study investigates whether the difference in knowledge becomes a more relevant determinant of income convergence than capital growth. Knowledge accumulation (expansion of scientific and technical expertise) has been widely seen as an essential factor of economic development through its impact on labor productivity and other production inputs. According to Powell and Snellman (2004), the key component of a knowledge economy is a greater reliance on intellectual capabilities than on physical inputs or natural resources.

Alcidi et al. (2018) show that in the EU, overall income convergence has taken place over the last 15 years at both regional and country levels in terms of higher growth of the poorest (beta-convergence) as well as reducing differences in GDP per capita (sigma-convergence). Central and Eastern countries lead the convergence process, while Southern regions have systematically underperformed relatively to the EU average, further deteriorating their relative position and diverging to the bottom. On the other hand, country aggregates hide different

patterns at the regional level. This is the case in Central and Eastern European countries, where capitals accelerate the convergence process while the rest of the country lags behind.

The empirical analysis in this study, based on ten selected countries, of which six are the high-income and innovation leaders and four middle-income countries (of which one is the regional innovations leader), shows that in the last decades, the income gap has increased in absolute terms (income is measured as GDP per capita in constant US$) while decreasing slightly in relative terms (share of middle-income countries in GDP of high-income countries).[1] The income gap increased less for middle-income countries ranked as more innovative, while less innovative countries struggle to reduce the income gap despite significant investments in fixed assets.

Why do middle-income countries progress slowly in terms of their innovativeness? Moreover, how can they catch up with more innovative countries?

Innovations are essential to economic growth through their impact on labor productivity and other production inputs. Empirical evidence shows the value of intellectual property in creating economic growth, enhancing productivity and profitability, and increasing enterprise value.

R&D investments were seen as the most crucial determinant of the country's innovativeness and are significantly higher in developed countries than in most middle-income countries (China is an example of an exception to this rule, with high investment in R&D and the value of innovation index). However, R&D investments are not determined only by financial resources. The human capital of the country is also significant. The share of STEM graduates is positively associated with R&D expenditures, meaning that to increase R&D activities and innovativeness, the country also needs adequate human capital (Baćović et al., 2022).

What are the options if a country cannot provide innovative growth internally? Technology transfer is one possibility. UNCTAD (2004) reported that many developed countries have adopted measures that directly or indirectly facilitate technology transfer. These measures include financing support, training, matching services, partnerships and alliances, and equipment purchase or licensing support. Technology transfer through FDI is also commonly seen as a good path to increase innovativeness. Phi et al. (2024) analysed the effects of FDI in Vietnam in transferring technology. They showed that FDI positively contributed to technology development, stimulating innovation in science and technology applications while improving competitiveness for domestic enterprises. They also emphasize that, due to the need for R&D activities and management capabilities, there are numerous difficulties in applying and transferring technology to the country. Najabat et al. (2023) show that FDI has positively impacted technological innovations in BRICS countries.

This study aims to investigate possible causes of income divergence between high and medium-income economies and suggest potential solutions to reverse the trend. Therefore, we will examine trends in income and innovativeness in selected countries. Also, to estimate the impact of investment in R&D on income growth, we will calculate production function on a sample of 35 European economies and the period from 2000 to 2023 (panel data). To investigate variations between innovativeness and income, we will examine the relationship between selected components of the Global innovation index produced by WIPO and GDP per capita.

The study has four sections. After the introduction, the most relevant findings from the literature are presented in the second section. In the third section, we offer empirical analysis, followed by a discussion and a conclusion in the fourth section.

2 Literature review

Literature on the relevance of research and innovation is vast, providing much evidence of the positive impact of knowledge growth on economic prosperity. Kaur and Singh (2016) studied the effect of knowledge on an economic level and economic growth across 42 selected developing economies. They found a positive correlation between the knowledge economy index and economic level, but there is a very weak marginal effect of the knowledge economy on economic growth. Barkhordari, Fattahi, and Azimi (2019) studied the empirical relationship between the knowledge-based economy and economic growth in MENA countries and found that institutions, human capital, research, infrastructure, and business sophistication are the pillars of the knowledge-based economy that influence a significant and positive economic growth. Pece et al. (2015) analysed if the long-term economic growth is influenced by the innovation potential of an economy for Poland, the Czech Republic, and Hungary and provided evidence of a positive relationship between economic growth and innovation. Maradana et al. (2017) examined the long-run relationship between innovation and per capita

[1] *The terminology of* convergence *— understood to mean declining dispersion in per capita incomes across countries — and catch-up — understood to mean increases in average incomes relative to the developed countries — can be helpful in distinguishing between these two concepts, particularly when ostensibly similar measures move in opposite directions. (The World Bank blogs: Convergence or Catch-Up? Aart Kraay, February 28, 2023)*

economic growth in 19 European countries over the period 1989–2014. Using the cointegration technique, the study finds evidence of a long-run relationship between innovation and per capita economic growth.

3 The empirical analysis

2.1 Data and sample

This study's empirical analysis is based on two samples. To estimate aggregate production function, we used a sample of 35 European economies from 2000 to 2023 (annual data)1. To evaluate the impact of innovations on economic growth and income convergence, we used a sample of ten economies, three of which are leading European economies in innovativeness (Switzerland, Sweden, and the United Kingdom), three leading Asian economies (Singapore, South Korea, and China), the United States of America, and middle-income European economies (Bulgaria, Montenegro, and Serbia). It spans the period from 2004 to 2023.

Data used in this study are presented in Table 1.

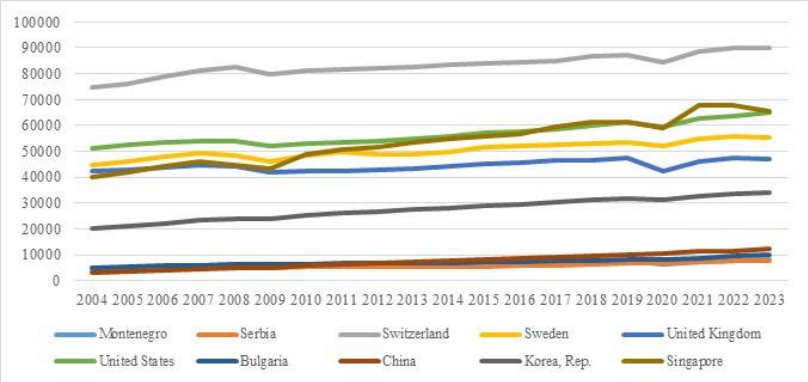

Table 1. List of variables

Indicator	Source	Data extracted
GERD per person, €	Eurostat, GERD by sector of performance [rd_e_gerdtot]	02/12/24
GERD, % GDP	Eurostat, GERD by sector of performance [rd_e_gerdtot]	02/12/24
GDP per capita, €	Eurostat, Main GDP aggregates per capita [nama_10_pc__custom_14327640]	06/12/24
GDP per capita, constant 2015 US$	WDI (World Bank national accounts data and OECD National Accounts data files)	10/12/24

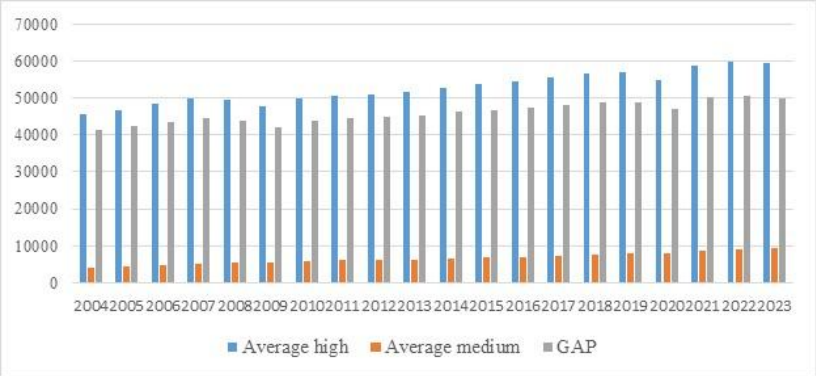
Global Innovation Index 2023	WIPO	10/12/24

Source: Author's compilation

3.1 Income divergence



We grouped ten countries from the sample into two categories (high-income and middle-income) and compared their average income over time. Switzerland, Sweden, the United Kingdom, the United States, Singapore, and South Korea are high-income countries that are also highly innovative. China, Bulgaria, Montenegro, and Serbia are middle-income countries, and China's innovation index is significantly higher than the other three countries. The income level of individual countries is presented in Graph 1.

Graph 1. GDP per capita (constant 2015 US$), ten economies, 2004-2023
Source: WDI database

[1] *Dataset is available on request*

The income gap between the two groups of countries has increased from 41,330 (constant 2015 US$) in 2004 to 49,989 (constant 2015 US$) in 2023 (Graph 2). If we compare individual middle-income countries with a group of high-income countries, we see that the gap has increased less in those more innovative. In China, the gap has increased by 11%, in Bulgaria by 22%, but in Montenegro and Serbia by 25%.

Graph 2. The average income of groups of high-income and middle-income countries and the income gap
Source: Author's computation based on the WDI database

3.2 Country's innovativeness and investment in R&D

We analyze the relationship between the country's innovativeness and economic development measured with GDP per capita, using data on investment in R&D measured with GERD per capita and components of the Global Innovation Index 2023 produced by WIPO (Human capital and research, Business sophistication, Knowledge and technology outputs, Creative outputs). Table 2. presents the average values of four components of the GII (2023), investment in R&D measured with GERD and economic development level measured with GDP per capita for ten selected economies.

Statistics show that the innovative capacities of high-income economies are significantly higher than those of middle-income economies in all areas (except in China, which is considerably more innovative than other middle-income economies in the group). Montenegro has the lowest score in knowledge and technology outputs, while Serbia has the lowest value of the creative outputs indicator.

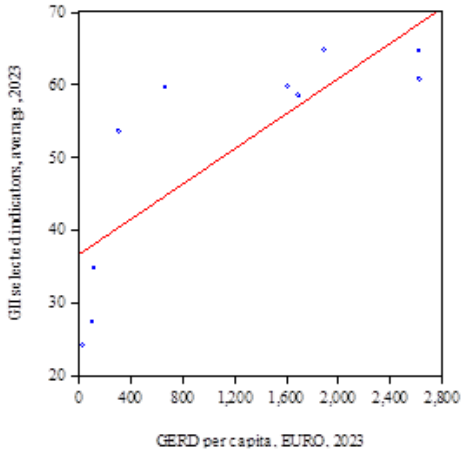


Table 2. Components of the GII, GERD, and GDP per capita, Selected Economies, 2023.

	Human capital and	Business sophisticati	Knowledge and	Creative outputs	Average	GERD per capita 2023*	GERD, % GDP,	GDP per capita, 2023 (constant	GDP per capita, 2023 (€ market

The empirical analysis shows a strong positive relationship between the average value of four GII indicators and GERD per capita (Graph 3).

Graph 3. The relationship between GII and GERD per capita components, ten countries, 2023.

The empirical analysis shows a strong positive relationship between economic development level measured with GDP per capita and GERD per capita (Graph 4).

Graph 4. The relationship between GDP per capita and GERD per capita, ten countries, 2023.
Source of data: Eurostat

3.3 Production function

In this study, the aggregate production of an economy is a function of gross fixed capital formation, labor, gross domestic expenditures on R&D (GERD), and total factor productivity (TFP):

$$Y_t = A_t K_t^{\alpha} L_t^{\beta} R_t^{\gamma}, 0 < \alpha + \beta + \gamma < 1\,, \qquad (1)$$

Yt represents the economy's output at time *t*, A_t is TFP, and K_t, Lt and $R_t$represent capital stock, labor, and gross domestic expenditures on R&D (GERD), respectively. The constants *α, β*, and γ represent the capital, labor, and R&D share in income, respectively.

After taking natural logs, the following equation is obtained:

$$LY_t = c + \alpha LK_t + \beta LL_t + \gamma LR_t + \varepsilon_t, \qquad (2)$$

Where *c* is the intercept, *α*, *β*, and γ are constant elasticities, and ε_t is the error term.

The aggregate production function was estimated in 35 European countries from 2000 to 2023 (the panel OLS (fixed effects) model). The estimated results are presented in Table 3.

Table 3. Panel Least Square (fixed effects), equation (2)

Variable	Coefficient	Std. Error	t-Statistic	Prob.
Gross fixed capital formation growth	0.325525	0.015682	20.75843	0.0000
Employment growth	0.214727	0.064592	3.324366	0.0009
Gross domestic expenditures on R&D growth	0.157642	0.018040	8.738536	0.0000
C	0.021959	0.001904	11.53101	0.0000
R-squared	0.618805	Durbin-Watson stat		1.909748

Source: Authors' calculation

All exogenous variables defined in Equation (2) positively impact output growth. A growth in gross fixed capital formation of 1% leads to output growth of 0.32%. Employment growth leads to output growth of 0.214% and R&D investment growth of 0.157%. Growth in other exogenous factors (TFP) contributes to output growth by 0.02%.

4 Discussion and conclusion

Disproportion in the level of economic development is a more historical fact than a recent phenomenon. Historically, most countries still have a development gap compared to developed economies. The empirical analysis in this study shows that in the last decades, the income gap between the most innovative high-income countries and middle-income countries has increased in absolute terms (income is measured as GDP per capita in constant US$) while decreasing slightly in relative terms (share of middle-income countries in GDP of high-income countries). The income gap increased less for middle-income countries ranked as more innovative, while less innovative countries struggle to reduce the income gap despite significant investments in fixed assets. This study investigated whether the difference in knowledge becomes a more relevant determinant of income convergence than capital growth.

Knowledge accumulation (expansion of scientific and technical knowledge) has been widely seen as an essential factor of economic growth through its impact on labor productivity and other production inputs. According to Powell and Snellman (2004), the key component of a knowledge economy is a greater reliance on intellectual capabilities than on physical inputs or natural resources. The country's educational outcomes strongly determine research and innovative activities, especially regarding science education. The study by Baćović and Milović (2024) investigated possible causes of declining innovativeness in Europe. Their analysis shows that expenditures for R&D and education in STEM programs are essential determinants of the country's innovativeness.

This study's empirical analysis shows that the innovative capacities of high-income economies are significantly higher than those of middle-income economies in all areas (except in China, which is considerably more innovative than other middle-income economies in the group). The analysis also shows a strong positive relationship between the average value of four GII (The Global Innovation Index) indicators and GERD per capita. The estimated production function on the sample of 35 economies (panel data) shows a highly positive impact of expenditures on R&D on economic growth.

The European Commission – Joint Research Centre's EU Industrial R&D Investment scoreboard for 2024 shows that leading investors (top ten) originate from the USA, China, Japan, Switzerland, South Korea, the UK, Taiwan, India, Canada, and Israel. Those are also highly innovative countries. The less innovative countries do not catch up in investment in R&D or innovations, widening the income gap compared to high-income countries.

Observing the strong relevance of the expenditures for R&D and the innovative potentials for economic growth, what are the options if a country cannot provide innovative growth internally? Technology transfer is one possibility. UNCTAD (2004) reported that many developed countries have adopted measures that directly or indirectly facilitate technology transfer. These measures include financing support, training, matching services, partnerships and alliances, and equipment purchase or licensing support. Technology transfer through FDI is also commonly seen as a good path to increase innovativeness. Karagiannis (2007) shows that R&D expenditure originating from abroad affects GDP growth rates significantly and positively, as do human capital, educational characteristics, and investments in Information and Communication Technology (ICT). Therefore, less innovative countries should encourage and support technology transfers through FDI or other forms to narrow the knowledge and income gap if they cannot increase R&D investments.

Abstract

This study tackles the absence of a unified framework for categorizing knowledge workers, a gap that constrains effective management and strategic alignment in knowledge-driven organizations. While these workers are central to innovation and value creation, existing definitions and taxonomies remain inconsistent and fragmented.

A systematic literature review of 26 peer-reviewed articles from Scopus and Web of Science was conducted. The study applied structured keyword searches and inclusion criteria to identify thematic patterns, classification criteria, and conceptual models relevant to knowledge workers and their roles.

The analysis uncovers a broad set of classification dimensions, including task complexity, educational background, organizational roles, and engagement with knowledge processes. It introduces a typology of eleven functional roles—knowledge Handlers—anchored in how individuals create, apply, and transfer knowledge. The study also delineates ten core processes and thirteen activities integral to knowledge work. These findings reflect a shift from static categorizations toward dynamic, context-sensitive interpretations of knowledge workers' roles.

The scope is limited to published literature, which may omit practitioner insights and sector-specific nuances. The absence of empirical validation also constrains immediate practical application.

The synthesized framework offers a structured basis for human resource management, knowledge management, and leadership strategies, enabling more precise role alignment, task design, and integration with digital tools in diverse organizational settings.

By consolidating dispersed research into an integrative taxonomy, this study advances theory and practice in knowledge management. It provides a foundation for future empirical studies and supports the development of adaptive classification systems for managing knowledge-intensive roles.

Keywords: Knowledge workers, Categorization, Systematic literature review.

Paper type: Academic Research Paper

1 Introduction

Knowledge work involves converting information into actionable insights applicable across contexts, yielding tangible and intangible outcomes. These tasks are complex, non-repetitive, and lack predefined structures. Knowledge workers (KWs) use tools and frameworks to generate, share, or apply knowledge vital to problem-solving, innovation, and organizational success (Bosch-Sijtsema, et al., 2011);(Eugenia, 2024).

KWs are highly qualified professionals across fields like IT, law, education, and science, who transform specialized information to achieve organizational goals (Garcia, 2007). They combine deep expertise and broad knowledge to drive innovation, requiring strategic alignment with evolving goals and adaptive leadership (Mannucci & Yong, 2017); (Kaur, et al., 2019); (de Weerd, et al., 2024). As organizational growth increasingly depends on their contributions, KWs are key to sustaining innovation and managing change in dynamic environments (Carleton, 2011); (Regan, 2023).

The shift to a knowledge-based economy requires strategic adaptation, yet categorizing and aligning knowledge work with organizational needs remains difficult (Pricopoaia, et al., 2024). Inefficiencies like poor integration and manual processes hinder innovation, while vague definitions weaken HR strategies and task management (Robberts, et al., 2015); (Hannola, et al., 2018). Robust frameworks are essential for streamlining processes, enhancing agility, and enabling sustainable growth (Wang, et al., 2011); (Mortimore, et al., 2023).

The lack of a systematic categorization of KWs poses challenges for strategic workforce management, limiting the alignment of unique competencies with evolving demands. Despite extensive studies, the absence of a comprehensive framework restricts the adaptation of diverse skills to organizational goals (de Weerd, et al., 2024); (Molina, et al., 2024). Effective management requires tailored strategies that address autonomy, motivation, and lifelong learning, rather than uniform approaches (Eugenia, 2024). Leadership must recognize

diverse motivations to harness team strengths fully (Talajić, et al., 2024). Clarifying the categorization of intellectual capital is crucial for effective workforce strategies that support growth and innovation.

Developing a unified framework for categorizing knowledge work and workers requires understanding the principles that shape this domain. Without this, fragmented definitions overlook role complexity. Identifying core competencies, context, and collaboration supports an integrative model for managing KWs in dynamic settings. This study systematically reviews classifications, revealing themes, criteria, and gaps. It maps patterns to organizational needs and promotes incremental discovery over fixed schemes. It contributes to KM by advancing evidence-based categorization and offers insights to guide strategic decisions and future research.

2 Background

In the knowledge-based economy, KWs are vital for innovation and value creation, reflecting growing global demand for their expertise(Che, et al., 2021); (Han, et al., 2023). Despite their importance, classifications remain fragmented and contested across disciplines (Yau, 2003); (Wang, et al., 2011); (Heidary Dahooie & Ghezel Arsalan, 2012); (Surawski, 2019). Traditionally based on work nature and occupational role, these classifications now reflect diverse approaches and methodologies(Wang & Yan, 2010).

Knowledge work has been categorized based on task content, processes, and complexity (Wang, et al., 2011). Perrow's distinction between complex and routine tasks clarifies its cognitive demands (Cool & Belkin, 2002);(Corso, et al., 2006).

KWs are commonly classified by educational background, the breadth of expertise, and traits like creativity, independence, and problem-solving (Pyöriä, 2005); (Kelly, et al., 2011); (Prataksita, et al., 2023). A classification system identifies three primary criteria for KWs: knowledge stock, skills, and personal qualities, with specific attributes like academic background, innovation ability, and psychological traits(Wang & Yan, 2010). Another categorizes them by work content, personal traits, work style, and the centrality of knowledge in their roles (Han, et al., 2023).

Knowledge work is complex and multidimensional, yet existing definitions lack a unified perspective (Yau, 2003);(Wang, et al., 2011). The fragmented studies and the absence of an overarching framework hinder alignment with organizational goals across sectors (Franek & Grublova, 2011); (Wymbs, 2012). Static classifications further limit understanding of its dynamic and evolving roles (Pyöriä, 2005).

Despite extensive research, KWs remain inconsistently classified due to varying definitions, leading to unclear data on their prevalence and growth (El-Farr, 2009);(Surawski, 2019);(Nisula & Olander, 2023). A unified categorization is lacking, and a limited understanding of their roles, workflows, and skill development hinders effective classification and contribution enhancement (Garcia, 2007).

The fragmented definitions of knowledge work highlight the need for a unified framework (Cool & Belkin, 2002); (Wymbs, 2012). Studying its core properties and evolving complexities is essential to reflect its true nature (Wang, et al., 2011). Such a model would help organizations adapt and optimize processes through technology-driven solutions (Syed, 1998).

As knowledge-intensive roles grow more complex, a clear framework is needed to distinguish KWs and address their specific needs. Tailored categorizations improve workforce management, role alignment, and utilization (Wang & Yan, 2010);(Han, et al., 2023). Without it, inconsistent definitions will persist, fragmenting research and limiting cross-field application (El-Farr, 2009).

Research on knowledge work remains fragmented, lacking a unified, adaptable framework. Prior studies explored cognitive demands, skills, and motivations but failed to address role complexity. Synthesizing existing categorizations and core elements is crucial. This study sets the foundation for developing an integrated framework suited to varied contexts and organizational needs.

3 Methodology

This study analyzes 26 articles to examine how knowledge work and workers are categorized, identifying key themes and patterns. Using a systematic literature review (SLR), it applies defined research questions and keyword-based searches with consistent selection criteria. The SLR outlines initial categorizations and supports future research and practice. For this research, the following questions are explored:

- What frameworks and criteria define and classify knowledge work and workers?
- What are KWs' roles and responsibilities in managing organizational knowledge assets?

Keywords were selected to capture concepts related to KWs, knowledge work, and their classification, ensuring relevant studies were included. The selected keywords include: "knowledge work*" OR" knowledge job*"OR" knowledge worker*"OR" intellectual work*" OR" intellectual job*"OR" cognitive work*" OR" cognitive

job*"OR "knowledge-based work*" OR" knowledge-based job*" OR" knowledge-intensive work*" OR" knowledge-intensive job*"OR "knowledge occupation*" OR" knowledge-based occupation*"OR "knowledge employee*" OR" creative worker*" OR "expert worker "OR "knowledge professional "OR" knowledge duti*"OR" knowledge task". Additional keywords were included to refine the search and ensure a targeted focus on categorizing knowledge work and KWs. These terms include "categor*" OR "class*" OR "typolog*" OR "taxonom*" OR "segment*" OR "framework" OR "model*". This approach ensured a thorough search for pertinent articles.

A thorough search was conducted using Scopus and Web of Science, chosen for their relevance and access to quality scholarly sources. Figure 1 shows the exclusion criteria: peer-reviewed, English-language studies focused on knowledge work and KWs. The search had no date limits and concluded in late October 2024.

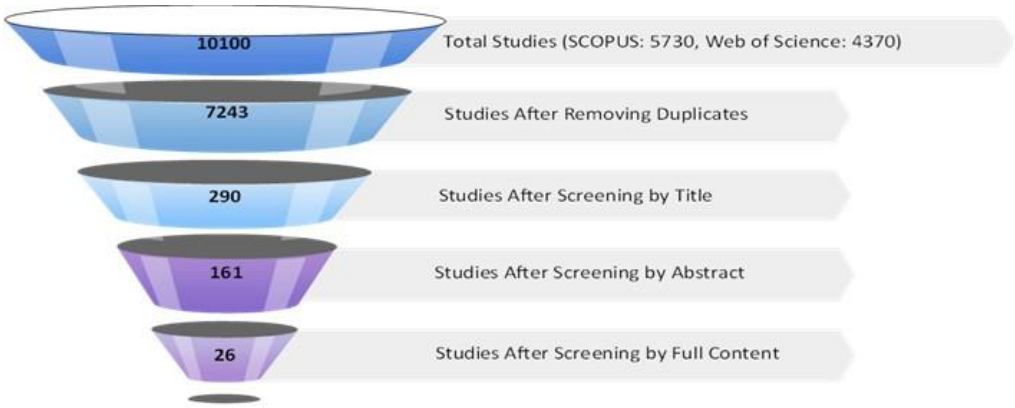

Figure 1. Article Screening Flow Overview

4 Results and Discussion

4.1. Overview of Selected Studies

4.1.1. The Progression of Publications Over the Years

The publication trend on the categorization of KWs and knowledge work, as shown in Figure 2, demonstrates a relatively stable trajectory over time.

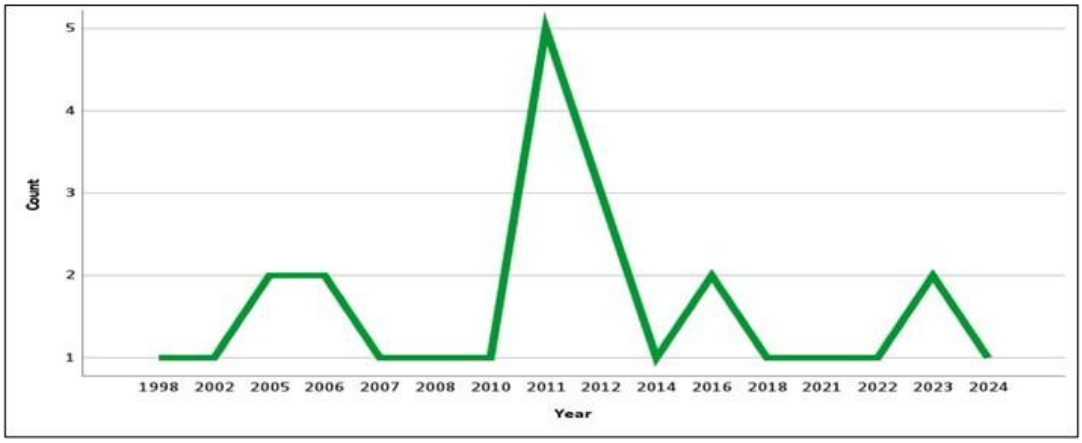

Figure 2. Trends in Research on the Categorization of KWs and their Work.

A significant peak in 2011 highlights a period of intensified academic interest, potentially linked to notable developments or challenges in the field. Research activity has remained steady but moderate, characterized by sporadic surges rather than continuous growth. This pattern suggests that, although the topic remains relevant, it has not consistently been a primary focus of scholarly attention outside of specific periods of heightened interest.

4.1.2. Analysis of Research in the Reviewed Papers: Types and Approaches Explored

As shown in Figure 3, the reviewed articles present a balanced methodological mix. Empirical studies (46.15%) dominate, followed by theoretical (30.77%), with mixed methods (15.38%) and reviews (7.69%) less common. Qualitative methods lead at 50%, while quantitative (30.77%) and mixed approaches (11.54%) are less used. This reflects a focus on real-world contexts but signals a need for more theoretical and integrative work.

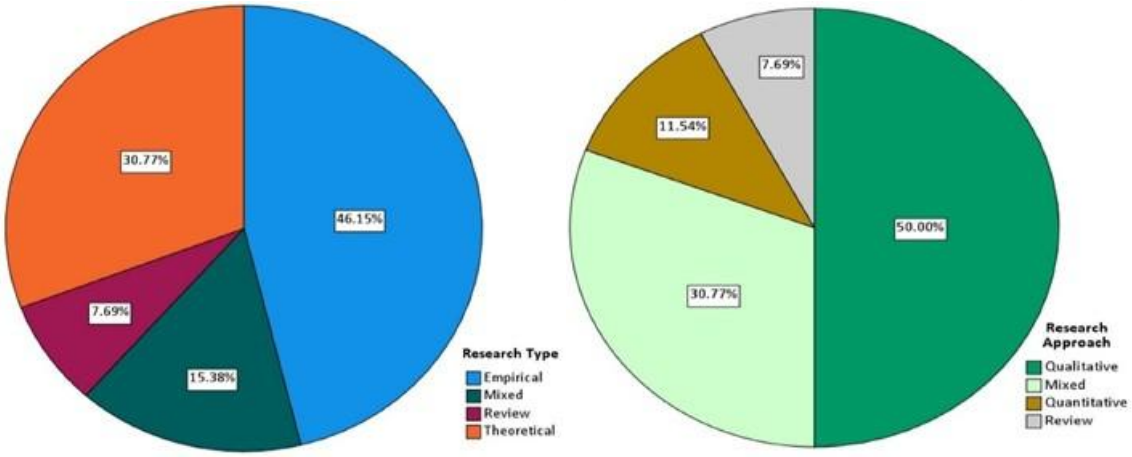

Figure 3. Types and Approaches of Reviewed Studies.

4.1.3. Assessment of Articles by Research Methodologies

As shown in Figure 4, the SLR reveals diverse methodological approaches. Mixed methods are most common (38.46%), followed by literature analysis and case studies (15.38% each). Surveys, reviews, and content analysis represent 7.69%, while ethnography and conceptual synthesis are the least used (3.85%). This indicates a preference for integrated approaches and highlights underused methods for future exploration.

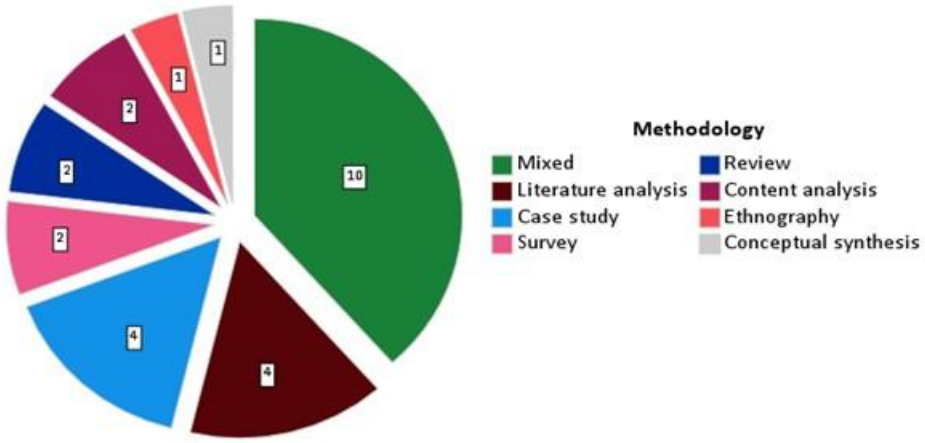

Figure 4. Methods of Research.

4.2. Exploring the Definitions and Categories of KWs, Their Work, and Associated Concepts

4.2.1. Criteria and Categories of Knowledge Work

Table 1 summarizes the dimensions of knowledge work, highlights the criteria used in the reviewed studies, and identifies categories.

Table 1. The Analyzed Research on Knowledge Work: Classification and Criteria.

Criterion	Description	Citations
Workflow Structure	Fully to weakly structured systems reflecting task management.	(Schwarz, 2005); (Scherp, et al., 2012).
KM Processes & Activities	Core processes: acquisition, transfer, sharing, transformation, and application.	(Reinhardt, et al., 2011); (Hannola, et al., 2018).
Base of Activities	Knowledge-based (analysis, creation) vs. communication-based (collaboration, coordination).	(Heidary Dahooie, et al., 2011).

Criterion	Description	Citations
Sequence of Activities	Ordered steps taken to meet goals or solve problems.	(Pan, et al., 2007).
Tasks	Defined by procedural clarity (analyzability) and variability.	(Corso, et al., 2006); (Robberts, et al., 2015).
Interaction with Information	Mode (recognition/specification), method (scanning/searching), goal (learning/selecting), and resource type.	(Cool & Belkin, 2002).
Information load	Variability (similar/diverse) and amount (small/large).	(Hashemian Bojnord & Afrazeh, 2006).
Types of Knowledge	Factual, conceptual, procedural, metacognitive, contextual, and operational knowledge dimensions.	(Salisbury, 2008); (Muhammed, et al., 2010).
Mediating Tools	Boundary and epistemic objects supporting localized, embedded, and invested knowledge for collaboration.	(Dionne & Carlile, 2024).
Collaborative Knowledge Systems	Communities emphasize tacit knowledge and shared understanding; Collectivities focus on goals and processes.	(Lindkvist, 2005).
Functionality	Purpose-driven: collection, connection, communication, criticism, and consumption.	(Iliescu, 2021).

4.2.2. Processes Involved in Knowledge Work

This study identifies six core, interconnected processes—acquisition, sharing, transfer, organization, application, and learning—central to the knowledge lifecycle. A *process* is a structured series of activities aimed at a specific goal, forming a consistent workflow. The following sections detail these processes, offering a framework for how knowledge is generated, disseminated, and applied in organizations:

- Knowledge Acquisition: Learning new knowledge from within or outside the organization (Watanabe & Benton, 2013).
- Knowledge Creation: Generating new ideas or solutions (Schwarz, 2005); (Salisbury, 2008).
- Knowledge Discovery: Uncovering new, previously unknown patterns, insights, or relationships within data using analytics or data mining techniques (Hannola, et al., 2018).
- Knowledge Retrieval: Accessing and locating relevant information through activities such as searching and reading documents (Schwarz, 2005).
- Knowledge Organization: Systematically structuring and storing knowledge into accessible and formalized structures to classify, archive, and preserve information (Schwarz, 2005); (Salisbury, 2008); (Watanabe & Benton, 2013).
- Knowledge Sharing: A bidirectional and collaborative process of distributing and communicating knowledge to enhance learning, problem-solving, and its broader application (Schwarz, 2005); (Salisbury, 2008); (Watanabe & Benton, 2013); (Hannola, et al., 2018).
- Knowledge Transfer: A unidirectional and purposeful process of moving knowledge between individuals, teams, or organizations to ensure understanding, usability, and practical application (Hannola, et al., 2018).
- Knowledge Application: Practical use of knowledge to perform tasks, solve problems, or improve workflows (Schwarz, 2005); (Salisbury, 2008).
- Knowledge Reuse: Leveraging previously created knowledge across different contexts.
- Knowledge Repurposing: Modifying or adapting knowledge assets to meet new requirements or address objectives in varying contexts (Salisbury, 2008).

4.2.3. Activities Associated with Knowledge Work

An *activity* is a specific action within a process that produces an output. Dissemination, networking, and sense-making are vital for creating, refining, and spreading knowledge. The following sections explain these activities, offering a systematic understanding of their role in knowledge work:

- Dissemination: Spreading information through tailored communication, product integration, and refined knowledge transfer to stakeholders(Syed, 1998);(Reinhardt, et al., 2011);(Widmann, et al., 2012);(Iliescu, 2021).
- Sense-Making: Cognitive Interpreting of information by recognizing patterns and implications to convert data into actionable insights(Syed, 1998);(Widmann, et al., 2012).
- Networking: Establishing relationships and interacting with people or organizations to leverage expertise, bridge knowledge gaps, and exchange information.

- Feedback: Critically assessing information, propositions, or objects to evaluate risks, identify inconsistencies, and provide constructive evaluations(Reinhardt, et al., 2011);(Iliescu, 2021).
- Refining: Adapting, filtering, improving, and experimenting with methods or approaches to align with contextual needs, tool limitations, and collaborative environments(Syed, 1998);(Dionne & Carlile, 2024).
- Modeling: Questioning existing methods, articulating their value, and aligning benefits across various approaches to sustain collaboration.
- Mapping: Identifying connections between knowledge elements, questioning feasibility across domains, and organizing combinations for later negotiation(Dionne & Carlile, 2024).
- Selection: Filtering and identifying relevant knowledge within internal resources by valuing and prioritizing key elements(Widmann, et al., 2012).
- Search: Retrieving specific resources, such as experts or specialized web services offering functions like translation or problem-solving.
- Authoring: Creating textual and media content, either individually or collaboratively, using software systems such as word processors or presentation tools.
- Analyzing: Examining and thinking about information carefully to understand and evaluate it thoroughly.
- Learning: Acquiring new knowledge, skills, or understanding during work execution or through formalized learning material.
- Monitoring: Keeping oneself or the organization updated about selected topics to ensure relevance and awareness(Reinhardt, et al., 2011).

4.2.4. Tasks Related to Knowledge Work

Knowledge work is classified into four types based on task analyzability and variability: routine (standardized), non-routine (creative), semi-routine (tacit knowledge-based), and complex routine (variable but analyzable) (Corso, et al., 2006). *Tasks* are the smallest goal-oriented units requiring critical thinking and specialized skills. Embedded in activities, they support KM by addressing specific objectives through methods that enhance clarity, organization, or problem-solving. Below is a breakdown of key tasks within knowledge-intensive environments:

- Information Discovery: Finding a (partially) known information object.
- Information Recognition: Recognizing useful information objects by scanning through an information resource.
- Information Evaluation: Evaluating the usefulness of information objects.
- Information Organization: Determining the content/structure of a set of information objects(Cool & Belkin, 2002).
- Collaboration: Collaborating with peers to share ideas, information, and feedback to achieve work goals.
- Communication: Communicating with employers, peers, clients, and suppliers to exchange updates and maintain alignment.
- Problem-solving: Solving problems by interacting and researching available online material.
- Time Management: Organizing and scheduling meetings to ensure efficient workflow(Robberts, et al., 2015).
- Resource Interaction: Accessing and interacting with company resources.
- Document Management: Creating and updating documents and reports.
- Work Management: Managing workflows efficiently through planning, resource allocation, and coordinating with others to ensure productivity(Heidary Dahooie, et al., 2011).

4.2.5. Criteria and Categories of KWs

KWs are categorized across multiple dimensions based on specific criteria highlighting their organizational roles, skills, and contributions. Table 2 provides an overview of these dimensions, detailing the requirements from the reviewed studies and the corresponding categories used to classify KWs.

Table 2. Criteria and Categories of KWs.

Criterion	Description	Citations
Education, Skills, and Abilities	Advanced education, diverse skills, and traits like creativity and autonomy.	(Kelly, et al., 2011);(Prataksita, et al., 2023).
Client Interaction and Revenue	Client relationship management and revenue generation.	(Wymbs, 2012).

Hierarchical Roles	Organizational roles from decision-makers to entry-level positions.	(Kelly, et al., 2011); (Wymbs, 2012).
Knowledge Engagement	Interacting with knowledge and participating in KM.	(Franek & Grublova, 2011); (Watanabe & Benton, 2013).
Task and Workflow Alignment	Creative versus operational tasks and alignment with workflows.	(Scherp, et al., 2012); (Mortimore, et al., 2023).
Connectivity and Interaction	Communication, mobility, and interaction patterns within and outside organizations.	(Greene & Myerson, 2011); (Geiger, et al., 2016); (Dionne & Carlile, 2024).
Organizational Integration	Integration of human expertise and algorithmic enhancements.	(Mortimore, et al., 2023)

KWs are distinguished by education—often advanced degrees or multidisciplinary qualification—and by skills, which may be specialist (domain-specific) or generalist (cross-disciplinary and managerial). Abilities like creativity, autonomy, and initiative enable innovation and task independence(Kelly, et al., 2011); (Prataksita, et al., 2023). KWs also differ by client interaction and revenue roles: finders drive new business, minders manage clients, and grinders offer task-based support (Wymbs, 2012). Organizational roles span decision-makers (finders), managers (minders), and entry-level staff (grinders), as well as functional types like bench scientists and expert generalists (Kelly, et al., 2011); (Wymbs, 2012). Engagement with explicit/tacit knowledge and time spent on KM further distinguish advocates, skeptics, busy people, and hopefuls (Franek & Grublova, 2011);(Watanabe & Benton, 2013). Task type and workflow alignment also matter: HKWs perform creative, cognitively demanding tasks; NHKWs execute predefined or computationally intensive ones (Scherp, et al., 2012); (Mortimore, et al., 2023). Workflows may be organizational (structured), individual (dynamic), or integrated (cross-functional). Connectivity and interaction behaviors define types such as Pragmatists, Bricoleurs, Passengers, and Maniacs, and mobility patterns further distinguish Anchors, Connectors, Gatherers, and Navigators (Greene & Myerson, 2011);(Geiger, et al., 2016);(Dionne & Carlile, 2024). Organizational integration balances human expertise and algorithmic support: HKWs contribute innovative solutions, while non-HKWs enhance efficiency through predefined tasks, from idea generation to applied knowledge (Mortimore, et al., 2023).

4.2.6. Knowledge Handlers' Roles

In organizations, a role refers to the responsibilities, behaviors, and expectations that guide task execution. This study identifies Knowledge Handlers (KHs) as individuals who manage knowledge through eleven key roles—detailed in Table 3—that support knowledge flow, decision-making, and workflow efficiency while addressing KM gaps and optimizing asset use.

Table 3. Knowledge Handlers' Roles.

KH Role	Role description	Citation
Knowledge Applier	Utilizes knowledge, resources, and expertise to achieve practical objectives.	(Schwarz, 2005); (Salisbury, 2008); (Franek & Grublova, 2011); (Heidary Dahooie, et al., 2011); (Watanabe & Benton, 2013).
Knowledge Creator	Develops innovative ideas, solutions, and systems.	(Schwarz, 2005); (Salisbury, 2008); (Franek & Grublova, 2011); (Heidary Dahooie, et al., 2011); (Widmann, et al., 2012); (Iliescu, 2021); (Mathieu, 2022); (Prataksita, et al., 2023).
Knowledge Evaluator	Evaluates knowledge quality based on accuracy, relevance, risk, and value.	(Cool & Belkin, 2002); (Iliescu, 2021).
Knowledge Facilitator	Maintains functional, accessible knowledge systems to support effective sharing.	(Lindkvist, 2005); (Greene & Myerson, 2011); (Widmann, et al., 2012); (Watanabe & Benton, 2013); (Mortimore, et al., 2023).
Knowledge Learner	Learns by applying knowledge to build skills and proficiency.	(Reinhardt, et al., 2011).
Knowledge Arranger	Structures and classifies data for efficient retrieval and use.	(Syed, 1998);; (Schwarz, 2005); (Salisbury, 2008); (Mathieu, 2022); (Mortimore, et al., 2023); (Dionne & Carlile, 2024).
Knowledge Protector	Safeguards knowledge through secure, durable storage and maintenance.	(Mathieu, 2022).
Knowledge Refiner	Refines information to suit specific needs and evolving demands.	(Salisbury, 2008); (Robberts, et al., 2015).

Knowledge Retriever	Retrieves relevant data from internal and external sources.	(Syed, 1998); (Cool & Belkin, 2002); (Schwarz, 2005); (Reinhardt, et al., 2011); (Widmann, et al., 2012); (Watanabe & Benton, 2013); (Robberts, et al., 2015); (Hannola, et al., 2018); (Iliescu, 2021).
Knowledge Sharer	Shares knowledge via platforms like repositories, email, and communities.	(Syed, 1998); (Salisbury, 2008); (Reinhardt, et al., 2011); (Hannola, et al., 2018); (Iliescu, 2021).
Knowledge Transferer	Transfers knowledge to ensure clarity and shared understanding.	(Syed, 1998); (Reinhardt, et al., 2011); (Widmann, et al., 2012); (Hannola, et al., 2018).

5 Conclusion

This study systematically examines the classifications and roles of KWs, addressing gaps and inconsistencies in the existing literature. By analyzing 26 key studies, it identifies recurring themes, emerging dimensions, and criteria that define knowledge work and its processes. The findings lay the groundwork for developing a comprehensive framework for categorizing KWs, emphasizing their diverse roles, skill sets, and organizational contributions. Critical dimensions such as task complexity, educational background, organizational integration, and evolving cognitive demands highlight the importance of KWs in driving innovation and competitiveness in knowledge-intensive settings. The next step can be to combine these different dimensions of analysis to detect and determine specific practical use situations in businesses and organizations.

While this research offers valuable contributions, it has certain limitations. Its reliance on existing literature introduces the potential for biases inherent in prior studies, and the limited dataset may not fully capture the spectrum of knowledge worker roles across different sectors. Furthermore, the absence of empirical validation restricts the practical application of the proposed framework.

Future research should synthesize the identified dimensions into a coherent framework for categorizing KWs. This framework can be validated through case studies, longitudinal research, and large-scale surveys. Integrating cross-disciplinary perspectives, technological advances, and cultural contexts will enhance its relevance. Emerging technologies such as artificial intelligence and machine learning offer opportunities to automate tasks, streamline workflows, and redefine knowledge work. Sector-specific adaptations could address the distinct needs of industries like healthcare, education, and IT. By addressing the identified limitations and further developing the framework, future research can provide transformative insights for academia and practice in an increasingly knowledge-intensive global economy.

Do Mentors Influence the Effects of the Entrepreneurial Programs of Early-Stage Start-Ups Pivot Decisions? An RCT Experiment

Micol Di Vita, Emilio Paolucci, Elisabetta Raguseo
Department of Management and Production Engineering, Politecnico di Torino, Turin, Italy

Abstract

Do mentors influence the effects of the entrepreneurial programs of the early-stage start-ups pivot decisions? We address our research question investigating the role of mentors supporting entrepreneurs' decisions in an early-stage training program, receiving the scientific method or the effectuation approach. In order to achieve our goal, we based our research on Kram's Mentor Role theory (Kram, 1985) and we applied it to the scientific method, according to the theory-and-evidence-based approach (Agarwal et al., 2024), and to Saras Sarasvathy's theory of Effectuation (Sarasvathy, 2008), related to the evidence-based approach. Previous research, in fact, has considered mentors as experienced people who can support mentees' decisions, career-development and activities within organizations, by coaching, challenging, and directing (Kram, 1985; Wilson and Elman, 1990). Moreover, mentorship is an important building block of educational programs within entrepreneurial support programs (Yitshaki, 2025). Nevertheless, little is known about the role of mentors in start-ups that have received an Entrepreneurial training (ET) program specifically based on the scientific and effectuation approach to decision-making. In this vein, we discuss how mentors' support can change decision-making processes, in terms of radical and incremental pivot decisions, of entrepreneurs adopting the scientific approach and the effectuation approach. To investigate our question, we collected evidence via a randomized control trial (RCT) in which 308 early-stage start-ups from Italy of a pre-acceleration program were randomly assigned to "treatment" (scientific, effectuation) and "control" group. Each start-up in treatment and control groups had from 0 to 7 mentors, from the beginning of the program. We observed firms throughout and post-training and we compared differences concerning radical and incremental pivot decisions between firms with mentors and without mentors in the treatment and control group, focusing on mentors' support. We find that start-ups with mentors are not more likely to pivot radically, on the other hand they make more incremental pivots than firms with no mentors. In particular, firms with mentors trained by scientific method are more likely to pivot incrementally than firms in the effectuation and control group. We suggest that it is due to mentoring that reinforces the scientific approach and realigns what entrepreneurs have learnt during the training program. These findings highlight important insights for mentorship research, showing how mentors can shape decision-making processes in ET programs, for the literature on entrepreneurial decision-making and for stakeholders involved in designing training programs that support entrepreneurs.

Keywords: decision-making, scientific approach, startup mentors, randomized control trial, pivot

Paper type: Academic Research Paper

1 Introduction

Early-stage start-ups typically have to face several critical decisions characterized by extreme uncertainty (Shepherd and Gruber, 2020). To address this uncertainty, recent research has proposed various interventions to help entrepreneurs' decisions, typically provided in the form of entrepreneurial training (ET) programs (Alexandria et al., 2014; Bacigalupo et al., 2016; Morris et al., 2023). ET programs aim to enhance entrepreneurs' decision-making processes by helping them gather relevant information to refine their value proposition and better understand whether to pivot radically their business idea or to implement other solutions, such as incremental pivot. Moreover, there is an existing research stream showing that entrepreneurs who learn specific decision-making approaches through ET programs perform differently from those who do not (Camuffo et al., 2024). In particular, researchers indicate that entrepreneurs trained in a scientific approach to decision-making are more likely to make fewer pivots. These outcomes occur because these entrepreneurs, by leveraging specific decision-making frameworks, collect different types of information that ultimately shape their decisions and performance. Prior research also indicates that entrepreneurs may rely on additional sources of information not strictly related to their decision-making approach, which can influence the evolution of their business ideas, thus affecting the impact of the ET programs in which they are included (Shepherd and Gruber, 2020). Indeed, prior work highlights that entrepreneurs' decision-making approaches can be influenced by external factors, particularly during the early stages of a start-up. For instance, previous literature has considered mentors as external factors that can support mentees' decisions, career-development and activities within organizations, by coaching, challenging, and directing, fostering Mentor Role Theory (Kram, 1985; Wilson and Elman, 1990). As well, there is evidence that mentoring has a relevant effect on entrepreneurs because it helps to develop

successfully their career (Hetty van Emmerick, 2004; St-Jean and Mathieu 2015). Furthermore, there is evidence that the role of mentoring in assisting people who start their own business requires to be transferred to new start-ups through entrepreneurial programs (Waters et al., 2002). Despite these elements, we lack evidence on how external mentor support might affect the impact of ET programs focused on specific decision-making approaches, such as the scientific approach (Camuffo et al., 2020) and the effectuation approach (Sarasvathy, 2008). This gap is particularly relevant for both scholars and practitioners, as different training programs can prompt entrepreneurs to seek different types of information when assessing the viability of their ventures, thus affecting their performance. Given these premises, this research aims to investigate how being supported by an external mentor may affect the impact of entrepreneurial training programs that teach specific decision-making approaches during the early stages of developing an entrepreneurial idea. Building on this, we address the following research question: *"Do mentors influence the effects of the entrepreneurial programs of early-stage start-ups pivot decisions?"*. To address our question, we based our research on Kram's Mentor Role theory (Kram, 1985) and we applied it to the scientific method, according to the theory-and-evidence-based approach (Agarwal et al., 2024), and to Saras Sarasvathy's theory of Effectuation (Sarasvathy, 2008), related to the evidence-based approach. In order to achieve our goal, we leveraged data collected through a randomized control trial (RCT) embedded in a pre-acceleration program. We randomly assigned 308 Italian entrepreneurs to three different groups, each exposed to a distinct entrepreneurial training. One group received training in a scientific decision-making approach (Camuffo et al., 2020), another group in effectuation (Sarasvathy, 2008), and the last group in a heuristic approach emphasizing trial and error. We then assessed the presence of an external mentor and its interaction with an early-stage start-up through a survey conducted before the intervention. Our econometric results show that the presence of an external mentor influences the effect of learning a specific decision-making approach on the number of incremental pivot made. Specifically, the scientific approach is reinforced by mentors, who help start-ups to make efficient strategic shifts, thus their entrepreneurs understand mentor's recommendations properly, since they are exposed to the scientific approach to entrepreneurial decision-making.

2 Theoretical background and hypothesis development

Previous literature has focused on entrepreneurial training programs (ET) for early-stage startups due ETs play a vital role in supporting their development (Camuffo et al., 2020; Kotha et al., 2023; Leatherbee and Katila, 2020; Novelli and Spina, 2024). These programs seek to provide entrepreneurs with competencies that enable them to mitigate the uncertainty inherent of shaping a new business model. In particular, ETs affect how entrepreneurs collect information, enhancing their decision-making ability, such as making pivotal decisions about their business idea. More precisely entrepreneurs, who learn specific decision-making approach through ETs have a better understanding of the value of their project, thus the number of pivots made (Camuffo et al., 2020). For instance, research on programs based on teaching a scientific approach to decision-making has shown that entrepreneurs who learn this approach are more likely to make fewer changes to their value propositions or customer segments (Camuffo et al., 2024). Despite previous research on the impact of teaching specific decision-making approaches, relatively little is known about external factors that may influence their effects (Battaglia et al., 2024). Indeed, studies on early-stage start-ups have suggested that external factors can influence both the type of information entrepreneurs collect and their decision-making strategies (Shepherd and Gruber, 2020). Among these external factors, prior literature highlights the significant role that external mentors can play in shaping entrepreneurs' decisions (Hetty van Emmerick, 2004; St-Jean and Mathieu 2015). In particular, researchers consider mentors as experienced people who can support mentees' decisions, career-development and activities within organizations, by coaching, challenging, and directing (Kram, 1985; Wilson and Elman, 1990). Mentors' role is relevant, since they can share success stories of local startups and entrepreneurs that may not be procured in other forms (like books, publications, or news). They also help entrepreneurs crossing the Valley of death phase successfully, that otherwise would occur without their support (Al-Shaikh et al., 2021). Moreover, mentors can act as facilitators, encouraging entrepreneurs to test their ideas (St-Jeanne and Tremblay; 2020) and adjusting their entire business model (Cohen et al., 2019). Building on this, the relationship between external mentors and early-stage startups leads to different outcomes compared to those of unsupported entrepreneurs. Indeed, previous studies indicate that entrepreneurs supported by an external mentor are more likely to persist with their ventures (Chatterji et al., 2019). In addition, research has observed that external mentors can prompt entrepreneurs to make incremental adjustments to their business ideas (Welbourne Eleazar et al., 2022). Furthermore, previous research has shown that mentorship is an important building block of educational programs within entrepreneurial support programs (Yitshaki 2025). As a result, public organisations have implemented programmes to support entrepreneurs during the first years of

their business start-up and mentoring is part of such programmes (St.-Jean and Tremblay, 2020). Building on these considerations, we found out that little is known about the role of mentors in start-ups that have specifically received an entrepreneurial training (ET) program based on the scientific and effectuation approach to decision-making. Indeed, we argue that external mentor support will influence the impact of learning a specific entrepreneurial decision-making approach on pivoting decisions associated with the scientific and effectuation approaches (Camuffo et al., 2024; Battaglia et al., 2024). For this reason, we propose the following hypotheses:

- *H1: Entrepreneurs who learn a scientific or an effectuation approach to decision-making and are supported by an external mentor will make more incremental than radical pivot.*
- *H2: Entrepreneurs who learn a scientific approach to decision-making and are supported by an external mentor will make more incremental pivot than other entrepreneurs.*

3 Methodology and data

3.1 Methodology

We collected evidence via a randomized control trial (RCT) in which 308 early-stage start-ups from Italy were randomly assigned to "treatment" (scientific, effectuation) and "control" group. Similarly to previous studies (Battaglia et al. 2024; Camuffo et al., 2024), we embedded a field experiment in a pre-incubation program targeting early-stage start-ups. During the experiment, we randomly assigned entrepreneurs to two treatment groups (being taught how to develop a business model using the scientific approach; and being taught how to develop a business model using the effectuation approach). We also assigned entrepreneurs to a third control group where they have been taught how to develop an entrepreneurial idea using heuristics, like trial-and-error.

The pre-incubation program was delivered online (due to Covid-19 lockdowns) and it provided training to early-stage start-ups for a short period of time. After the call for application, our initial samples include 308 early-stage start-ups. Using randomization, we divided the 308 start-ups between the two treatment groups and the control group. We checked that each treatment group (102 start-ups for the scientific approach and 105 start-ups for the effectuation approach) and the control group (101 start-ups) were balanced on several key covariates that might affect the absorption of the treatments and subsequent outcomes, including if an early-stage start-up was supported by an external mentor. Differences between the treatment groups and control are small in magnitude, and there are no significant differences between the three groups. The pre-incubation program lasted from October 2020 to February 2021. The program was focused on market validation. The contents and length of each session was the same for each group, but with different logics in the decision-making approaches taught to each group. The first treatment group learnt to develop an idea using a scientific approach; entrepreneurs assigned to the second treatment group learnt to develop an entrepreneurial idea using an effectuation approach. The control group learnt how to develop an entrepreneurial idea using the same tools of the two treatment groups, but without learning how to use these tools following a scientific approach or an effectuation approach. We avoided possible contaminations among the three groups following previous best practices used in field experiments regarding decision-making approaches (Camuffo et al. 2024). Each firm in treatment and control groups had from 0 to 7 mentors, from the beginning of the program. We observed firms throughout and post-training and we compared differences concerning radical and incremental pivot decisions between firms with mentors and without mentors in the treatment and control group, focusing on mentors' support.

3.2 Data collection

We collected data following a two-step approach. The first stage of data collection was performed before the beginning of the pre-acceleration program, during the enrolment phase. Before enrolling in the pre-acceleration program, we asked entrepreneurs to fill out a survey regarding the characteristics of their entrepreneurial idea and about the demography characteristics and human capital of the founding team. Moreover, we asked to the entrepreneurs if they were supported by an external mentor in developing their entrepreneurial idea. If a startup was followed by one or more mentor, we asked to entrepreneurs to specific the relation with each mentor and the human capital characteristics of each mentor. These data collection was used to randomize the entrepreneurs between the three treatments and to create part of the independent variables. During the second stage of the data collection, we collected data for 10 points of observation over XXX months since the program started using interviews. Each interview was led following a semi-structured approach to collect information about the entrepreneur decision-making, whether they pivoted or not.

Moreover, after the training (3rd point of observation) and at the end of the observation period (10th point of observation) we updated information on whether a startup was supported by an external mentor.

3.3 Dependent Variables and Independent Variables

3.3.1 Dependent Variables

We used two dependent binary variables to capture pivoting. First, we employed a binary variable, *Radical Pivot*, taking the value 1 whenever an entrepreneur made a radical pivot and 0 otherwise. Second, we employed a binary variable, *Incremental Pivot*, taking the value 1 whenever an entrepreneur made an incremental pivot and 0 otherwise. To collect this information, in each interview, we asked entrepreneurs to explain whether they had made radical or incremental changes of their business model.

3.3.2 Independent Variables

To assess whether the presence of mentors affects the outcomes of the ET, we used an independent binary variable *Has Mentor* taking the value 1 whenever an entrepreneur had almost one mentor and 0 otherwise. We collected this information through the baseline survey to assess the mentor's support. Thus, we employed two categorical variables, *Intervention* taking the value 1 whenever an entrepreneur was in the control group, 2 whenever an entrepreneur was in the scientific group, 3 whenever an entrepreneur was in the effectuation group, and *Number of interview* taking the value from 0 to 10. Following previous studies on the effectiveness of entrepreneurial training programs (ETs), we collected this mentor-related information before the treatment, at the end of the treatment, and at the conclusion of our data collection. Table 1 presents the descriptive statistics for both the independent and dependent variables.

Table 1**:** Descriptive statistics

Variable	**Observations**	**Mean**	**Standard deviation**	**Min**	**Max**	**Description**
Dependent						
Radical pivot	3,388	0.13	0.41	0	3	Binary variable. 1 whenever an entrepreneur makes a radical pivot; 0 otherwise.
Incremental pivot	3,388	0.94	1.14	0	7	Binary variable. 1 whenever an entrepreneur makes an incremental pivot; 0 otherwise.
Independent						
Has Mentor	308	0.29	0.45	0	1	Binary variable. 1 if a mentor has almost one mentor, 0 otherwise.
Intervention	308	2.01	0.82	1	3	Binary variable. 1 if an entrepreneur belongs to Control group, 2 to Scientific group, 3 to Effectuation group.
Number of interview	3,388	5	3.16	0	10	Categorical variable from 0 to 10.

3.4 Statistical approach

We tested our hypotheses using econometrics analysis, leveraging on data collected along the 10 points of observation. Given the nature of our dependent variables, we adopted negative binomial model for testing the cumulate amount of radical and incremental pivot of early-stage start-ups. As far as our independent variables are concerned, similar to previous studies on testing the boundary conditions of teaching decision-making approach (Battaglia et al. 2024), we created a set of exclusive dummy variables mapping the presence of having learnt a decision-making approach or not and having an external mentor or not (Wooldridge, 2015). Finally, we include a vector of control variables to capture potential differences in the instructors' teaching styles, and we cluster standard errors at both the instructor and intervention levels.

4 Results

Models (1) and (2) present the empirical analysis of the number of radical and incremental pivot. We find that start-ups trained by the scientific approach or the effectuation approach and have external mentors are not more likely to pivot radically, on the other hand they make more incremental pivot than firms with no mentors. These results confirm H1. Specifically, firms with mentors trained by scientific method are more likely to pivot incrementally than firms in the effectuation and control group. We suggest that it is due to mentoring that

reinforces the scientific approach and realigns what entrepreneurs have learnt during the training program. Conversely, entrepreneurs in the control group do not understand mentor's recommendations properly, since they are not exposed to the scientific approach to entrepreneurial decision-making. On the effectuation group, the mentor's effect is even less because entrepreneurs are more practical and less driven by a structured method, like the scientific approach. Furthermore, mentors are experienced people, who strengthen entrepreneurs' knowledge absorbed through the scientific training and develop the start-up's network. Specifically, they help entrepreneurs to make efficient strategic shifts, shown by incremental pivot decisions that are more accurate and precise improvements than radical pivot decisions. This effect is evident not only during the scientific training but also in the long-term period, because mentors help entrepreneurs to take decisions, making them recall what they learnt during the program. Collectively, these results confirm H2.

Table 2: Regressions with *Radical pivot* and *Incremental pivot* as dependent variables.

Variables	**(1)** **DV: Cumulative** **Radical Pivot** **Negative Binomial Cross Sections**	**(2)** **DV: Cumulative** **Incremental Pivot** **Negative Binomial Cross Sections**
Control X Has Mentor	0.324 (0.180)	0.160 (0.246)
Scientific X No Mentor	-0.176 (0.513)	0.007 (0.951)
Scientific X Has Mentor	-0.039 (0.941)	0.600*** (0.000)
Effectuation X No Mentor	0.224 (0.374)	0.243** (0.027)
Effectuation X Has Mentor	-0.562 (0.337)	0.320** (0.024)
Constant	-1.650*** (0.000)	-0.002 (0.984)
Observations	308	308
Dummies for Instructor	Yes	Yes
Clustered errors	Intervention Instructor	Intervention Instructor

Standard errors in parentheses. DV stands for "dependent variable".
***$p < .01$, **$p < .05$, *$p < .10$.

5 Conclusions

This work makes three contributions. First, it contributes to the literature on ET (Alexandria *et al*., 2014, McKenzie and Woodruff, 2014) and the role of mentors, by offering evidence that mentors influence the effects of the entrepreneurial programs of the early-stage start-ups' pivot decisions. Second, given the focus of this work on a scientific approach to decision-making, it offers a contribution to the research stream regarding the use of methods applied to entrepreneurial decision-making (Camuffo et al., 2020; Novelli and Spina, 2024). The scientific approach, in fact, is consistent and recommended to be adopted but, as element of novelty, we suggest that the role of mentors is required to strengthen the scientific approach and to realign it after the entrepreneurial training's period. Third, by showing mentors' effects on entrepreneurs participating in training programs, we offer useful insights for policymakers, universities and other institutions involved in the creation and supply of ETs to support entrepreneurs.

Navigating Uncertainty through Knowledge Sharing: Lessons from Tourism in Times of Pandemic. Case Study from Poland

Ewa Stolarek-Muszyńska[1], Malgorzata Zieba[2]
[1] Doctoral School, Gdansk University of Technology, Gdańsk, Poland
[2] Division of Management, Gdansk University of Technology, Gdańsk, Poland

Abstract

Crises in tourism have become increasingly common. Yet, COVID-19 stands out as the most disruptive event, causing significant damages to the global economy, severely impacting the tourism sectors across the regions. Even though it has been five years since the crisis started, the pandemic's influence on global tourism can still be noticeable. This study focuses on Polish tourism organisations with the purpose to explore in-depth the role of knowledge sharing processes and their usefulness in mitigating the effects of crisis in tourism.

Analysis of the case suggests that the organisation's key role during a crisis was to serve as a knowledge broker. The analysed case indicates that different types of information and knowledge were significant during that period. For the industry, key knowledge concerned the information related to legislation and the proposed changes. For municipal and governmental level, quantitative data from tourist traffic was important. For tourists, a focus was put on navigating the restrictions. Given the numerous constraints imposed by the pandemics, the organisation adapted to the new reality by increasing its dependence on ICT systems. This includes the creation of a dedicated subpage, ongoing e-mail and newsletters communication, video chats with training, regular online team meetings and employees' conversations via online chats.

This study is based on qualitative in-depth analysis and the semi-structured interviews with representatives of a local tourism organisation in Poland. This research employs a single case study design, focusing on the organisation as the unit of analysis. This study contributes to the body of literature by expanding the understanding of the role of knowledge sharing processes within the context of the tourism crisis. It offers valuable insights for researchers exploring the application of knowledge management to crisis management.

Findings of this study deliver food for thought for both the academic community and tourism organisations eager to facilitate their operational activity during hazardous events. The results offer practical guidance for managers regarding the knowledge sharing practices on how to enhance the resilience and performance of their organisations during crisis, while simultaneously supporting the tourism industry.

Research output is limited to the analysis of a single organisation (illustrated through a case study example) and thus, the analysis presented may not fully capture the complexity of the entire sector. The organisation is operating in Poland, and this can additionally limit the usefulness of analysis to one country specifics.

Keywords: KM, Knowledge sharing, Crisis management, Tourism, COVID-19

Paper type: Academic Research Paper

1 Introduction

Due to the escalating impacts of climate changes and dynamic geopolitical context, crises in tourism have become increasingly common. Yet, COVID-19 stands out as the most disruptive event so far (Higgins-Desbiolles, 2020), causing significant damages to the global economy, also severely impacting the tourism and travel sectors across the regions and destinations. Even though it has been five years since the crisis started, the pandemic's influence on the global tourism industry can still be noticeable. Regardless of the negative consequences, for some companies COVID-19 served as a catalyst for internal changes, highlighting new organisational roles and strengthening existing mechanisms and processes. Tourism organisations, as key players integrating companies within the tourism sector, exemplify this type of organisation.

This study focuses on Polish tourism organisations, concentrating on their internal knowledge sharing practices and operational roles during crisis situations. Based on review of the existing literature, recognizing the potential contribution of knowledge management to enhance crisis management effectiveness (Mistilis and Sheldon, 2006; Racherla and Hu, 2009; Orchiston and Higham, 2016; Barišić et al, 2020; Ng et al, 2022; Kir Kuščer et al, 2021), the purpose of this study is to explore in-depth the role of knowledge sharing processes and their usefulness in mitigating the effects of crisis in tourism. This preliminary study is based on a single case-study, presenting the results of qualitative research conducted via the semi-structured interviews from a local tourism organisation in Poland.

This paper is structured in the following way. In the next section, a theoretical background is presented, describing the contribution of KM to crisis management and knowledge sharing practices during a crisis. In the third section, the methodology of the study is presented and in the fourth - results and discussion.

2 Theoretical background

2.1 Contribution of KM to crisis management

Knowledge management and its applications in tourism and hospitality organisations has not been intensively examined so far. One of the papers discussing this topic is provided by Racherla & Hu (2009), where the authors propose a framework for knowledge-based crisis management in the hospitality and tourism industry. According to the authors, the application of KM in hospitality and tourism organisations can significantly improve their crisis management capabilities through the improved acquisition and dissemination of critical information. Knowledge management practices not only support decision-makers in performing their roles more effectively but also facilitate the efficient sharing and reuse of organisational resources (Racherla & Hu, 2009). Also Orchiston & Higham (2016) highlight that crisis knowledge management in tourism can significantly improve destination recovery, increase resilience to future disruptive events, and improve communication with all relevant stakeholders during a crisis. By systematically capturing and sharing knowledge gained from past crises, organisations can better predict challenges, offer better crisis responses, and speed up the recovery phase (Orchiston & Higham, 2016). Knowledge management plays a critical role in supporting the effectiveness of Destination Management Organisations (DMOs) during a crisis, becoming a key tool for their management strategies. Furthermore, effective knowledge management supports the evolving role of DMOs, namely going beyond marketing functions and including responsibilities such as stakeholder coordination, strategic communication, and crisis response (Blackman et al., 2011). To sum up, while approaches to crisis management may be different, they all highlight anticipation, preparedness, quick dissemination of accurate and up-to-date information, response from the authorities and sustainable long-term solutions. Effective knowledge management, defined as the timely provision of relevant information to stakeholders, combined with suitable knowledge management practices for gathering, organising, and applying knowledge, can significantly support tourism crisis management (Jia et al., 2012). On the basis of the above, it can be stated that knowledge management is useful for better crisis management in various types of entities and this topic should be further examined in practice among tourism organisations.

2.2 Knowledge sharing practices during crisis

Among the processes of knowledge management, one of the key ones is knowledge sharing. Effective knowledge sharing is a crucial element of crisis management for tourism destinations, helping stakeholders to respond timely and in a coordinated manner. According to Mistilis and Sheldon (2006), effective knowledge sharing requires destinations to explicitly identify and encode their critical knowledge within structured information systems, facilitating efficient dissemination to all relevant parties. Furthermore, the authors highlight that collaboration and reliable communication of information among stakeholders and response organisations are fundamental during crises, contributing to quick knowledge exchange, so crucial during a crisis (Mistilis & Sheldon, 2006). Therefore, knowledge sharing not only helps in coordination among stakeholders, but also significantly improves the resilience and capacity of destination organisations for crisis recovery.

Effective knowledge sharing in crisis management requires proper channels and interactive mechanisms. According to Racherla and Hu (2009), the optimal way to disseminate and use crisis-related knowledge is by establishing networks and communities, within which stakeholders can engage, exchange knowledge, and learn from their mutual experiences. Such interactions create a dynamic feedback loop, supporting organisational capabilities in knowledge acquisition, storage, and preparedness for future crises (Racherla & Hu, 2009). Therefore, creation of collaborative networks not only helps in real-time crisis responses but also significantly contributes to building sustainable, knowledge-based resilience for future events of this type.

Apart from knowledge transfer, it is also important to prevent the loss of valuable organisational experiences and lessons learned. According to Toubes at al. (2021), destinations that want to recover successfully from a disaster, should implement knowledge transfer processes together with deliberate strategies for minimizing organisational forgetting. Those processes and strategies are necessary to make sure that the knowledge gained from the previous crises is retained, disseminated, and successfully applied in future situations (Toubes et al., 2021).

What is important is that this knowledge sharing should not be limited only to selected actors within a sector. According to Ghaderi et al. (2014), tourism organisations that shared knowledge with other sectors demonstrated greater preparedness in addressing future crises. Therefore, it can be assumed that cross-sectoral knowledge exchange contributes to organisational resilience and improved responsiveness in future crises (Ghaderi et al., 2014) and this kind of knowledge sharing (cross-sectoral) should be encouraged and supported.

However, according to the study by Ghaderi et al. (2014), knowledge sharing practices were often limited - almost 60% of managers declared that they shared information only within their own professional groups. In contrast, only 40% indicated a willingness to disseminate new information across the broader tourism industry. Managers who limited their sharing practices during a crisis to their professional group indicated that all parties must take joint responsibility for problem-solving and exchanging experiences (Ghaderi et al., 2014).

As far as various actors engaged in knowledge sharing are concerned, their role is crucial both during and after a crisis. Boundary spanners and knowledge brokers—such as DMOs at national, regional, and local levels, as well as industry associations and government agencies—are particularly important to support the flow of information between diverse stakeholders (Blackman, Kennedy, & Ritchie, 2011). In particular, DMOs possess better capacity than individual small and medium-sized enterprises (SMEs) to keep knowledge from past crises and promote its transfer. It is due to the fact that SMEs often lack the resources or willingness to engage in organisational learning processes (Toubes, Araújo-Vila, & Fraiz-Brea, 2021). For better crisis knowledge management, DMOs should undertake actions to facilitate communication and knowledge exchange across the sector, including the selection and empowerment of boundary spanners to eliminate organisational and sectoral divisions (Blackman, Kennedy, & Ritchie, 2011).

To sum up, knowledge sharing and knowledge transfer are important elements of successful crisis management in the tourism sector both during its occurrence and afterwards. It is important to create proper channels and interactive mechanisms, as well as to engage various actors and stakeholders.

3 Methodology

This study aims to explore in-depth the role of knowledge sharing processes in mitigating the effects of crisis in tourism. In order to address this purpose, the following research questions have been stated:

- RQ1: What activities did the organisation perform for knowledge sharing during the COVID-19 pandemic?
- RQ1: What knowledge was important during the pandemic for tourism organisation?
- RQ2: What knowledge sharing tools were used by tourism organisation in the period of crisis?

This research employs a single case study design, focusing on the organisation as the unit of analysis (Yin, 2003). According to Mariotto et al. (2014), employing a single case study strategy might prove advantageous for academic investigation, as it facilitates a profound understanding of the phenomenon in focus. This study is based on qualitative in-depth analysis and the semi-structured interviews with representatives of a local tourism organisation in Poland, which served as the primary data collection method. The study informants were two employees representing managerial and specialist positions. Data collection process took place in December 2023 and January 2024. Interviews were recorded and transcribed *verbatim* (Poland, 1995) to be translated afterwards to English. For data coding MAXQDA software was used.

Tourism organisations act within the framework of Destination Management Organisations. They bear responsibility for the management and marketing of tourism destinations, including attractions, amenities, cities or whole regions. Tourism organisations function as key sectoral bodies, having a pivotal role in the coordination of a multi-faceted network of stakeholders across the entire tourism industry (UNWTO, 2007). This intermediary role enables these organisations to have a constant access to external knowledge and to connect various sources of such knowledge.

4 Results and discussion

Analysis of the case study suggests that the organisation's key role during a crisis was to serve as a knowledge broker, which goes in line with the understanding of such organisations as institutions acting in the role of "information brokers" provided by UNWTO (2007). The organisation acted as a central hub of knowledge, integrating various stakeholders (including members, business partners, employees, governmental and municipal entities, tourists) and facilitating the constant knowledge exchange during the pandemic crisis. The transfer of knowledge was from various levels and sources, as indicated by the CEO of the organization:

"They (i.e. access and management of knowledge) were key and fundamental. We basically became an information broker in the first months, if I may say so. That is, we had the opportunity to obtain information

firsthand from the government level, from the municipal level, and pass it on to the industry and vice versa." - CEO of the organisation

The analysed case also indicates that different types of information and knowledge were significant during that period. These can be categorised according to the main stakeholder groups that were the recipients. For the industry, key knowledge concerned the information related to legislation and the proposed changes. For municipal and governmental level, quantitative data from tourist traffic, as well as data regarding occupancy and average prices in hotels/restaurants were very important. For tourists, on the other hand, a focus was put on navigating the restrictions, i.e. the availability of services, such as museums, cultural centres, etc. All these types of knowledge were needed for the sector and its various stakeholders. The role of the examined organisation was to receive, verify and disseminate this knowledge.

"It depends a bit. [...] we played such a gatekeeper role, where data came from both sides, and we had to authenticate them, but these data were different depending on who expected from us." - CEO of the organisation

An important aspect of the analysed case is the use of knowledge sharing tools during this crisis. Given the numerous constraints imposed by the pandemics, the organisation adapted to the new reality by increasing its dependence on ICT systems for their day-to-day activity, and this technology adoption goes in line with the observed trend in tourism and travel industry (Yepez & Leimgruber, 2024). This includes the creation of a dedicated subpage on the organisational website with all the pandemic-related information (dedicated to all members of organisations), ongoing e-mail and newsletters communication, video chats with training, regular online team meetings and employees' conversations via online chats. Both the knowledge and ways of presenting it was useful and suitable for various stakeholders in times of the crisis. These activities were supposed to help the partners surviving and navigating through the crisis.

"The subpage of our tourism portal, where we gathered information [...] - it was about collecting knowledge that, from our perspective, was useful for our partners, for entities that cooperated with us." - Specialist representing the organisation

"We did a video chat once a week for our members, but we invited essentially the whole industry. These were general, there were also ones specifically for hotels and specifically for guides, there were meetings with lawyers who explained how to even prepare a company for restructuring, what it entails, how to properly submit an application, how to appeal if necessary. " - CEO of the organisation

Additionally, the preliminary results indicate that close cooperation and networking with external organisations and partners was of a great significance in knowledge sharing processes in a time of crisis, which has been already indicated in the literature (Ghaderi et al., 2014).

"We try to cooperate with everyone willing to work with us, starting from guides, managers of attractions, the gastronomy sector, hoteliers, various governmental and non-governmental institutions, of course, the Polish Tourism Organisation, and so on - I could list them for a long time. Being somewhat in the middle, I feel that we often know more and know it faster. - Specialist representing the organisation

To sum up, the presented case study shows that during the crisis the key role of a tourism organisation in Poland was to become a knowledge broker. Due to its position and network of partners, the organisation was able to collect, verify and disseminate knowledge crucial from the perspective of various stakeholders. The role of collaboration and various types of knowledge needed during a crisis were highlighted.

5 Conclusion

This study contributes to the body of literature by expanding the understanding of the role of knowledge sharing processes within the context of the tourism crisis. It offers valuable insights for researchers exploring the application of knowledge management to crisis management. On the basis of the literature analysis, several key points can be noted. First of all, effective crisis management in tourism relies on sharing various types of knowledge for different stakeholders and organisational learning. Tourism organisations should explicitly capture and encode critical knowledge to enable quick communication among stakeholders and support coordinated responses within the sector (Mistilis & Sheldon, 2006; Racherla & Hu, 2009). Second, keeping knowledge through transfer processes and eliminating organisational forgetting are essential for the creation of resilience and sustainable recovery after the crisis (Toubes et al., 2021). Unfortunately, despite its importance, knowledge sharing often remains limited within professional groups, showing the need for better and broader collaboration across the tourism sector (Ghaderi et al., 2014). Finally, Destination Management Organisations, industry associations and government agencies act as important boundary spanners, keeping crisis experiences and supporting knowledge flow between stakeholders to better prepare for future crises (Blackman, Kennedy, & Ritchie, 2011; Toubes et al., 2021).

As far as case study is concerned, it shows that during the crisis, the key role of this Polish tourism organisation was to act as a knowledge broker, using its position and partner network to collect, verify, and disseminate critical knowledge to various stakeholders. The findings also highlight the importance of collaboration, and the diverse types of knowledge required for effective crisis management of different stakeholders (not all types of crisis knowledge were equally important to each partner/stakeholder).

All in all, findings of this study deliver food for thought for both the academic community and tourism organisations eager to facilitate their operational activity during hazardous events. The results offer practical guidance for managers regarding the knowledge sharing practices on how to enhance the resilience and performance of their organisations during crisis, while simultaneously supporting the tourism industry with relevant knowledge and assistance.

Research output is limited to the analysis of a single organisation (illustrated through a case study example) and thus, the analysis presented may not fully capture the complexity of the entire sector. The organisation is operating in Poland, and this can additionally limit the usefulness of analysis to one country specifics. Those limitations will be overcome in the future by additional cases and analysis at international level.

Open Innovation for Virtual Worlds: A Design-Driven Theoretical Framework for the Creation of User-Generated Experiences

Riccardo Ventura, Ilaria Mariani
Politecnico di Milano, Milano, Italy

Abstract

This paper investigates the evolving role of users in Virtual Worlds (VWs), emphasizing their transition from passive consumers to active creators of immersive experiences. In the context of platforms like Roblox, Decentraland, and Fortnite, the study explores the dynamics of User-Generated Content (UGC) and User-Generated Experiences (UGEs), drawing on principles from Open Innovation and User-Centered Design, the research develops a design-driven framework that integrates co-creation, co-design, and co-production processes within the Double Diamond model and expands the theory with tailored design phases. Through a comparative analysis of three leading VWs, the study identifies key challenges and proposes a structured framework to enhance creativity, inclusivity, and business opportunities. The framework is validated against academic literature and case study insights, offering an approach to participatory innovation in digital environments. The paper concludes by outlining future directions for ethical integration and hybrid physical-virtual applications.

Keywords: Virtual Worlds, User-Generated Content, Open Innovation, Virtual economy

Paper type: Research paper

1 Introduction

1.1 Landscape: Virtual Worlds and UGC

As defined by the European Commission (2023), Virtual Worlds (VWs) are immersive, persistent digital environments that simulate real and imaginary settings through various technologies—spanning from 3D graphics, Blockchain Technologies, Virtual Reality (VR), Mixed Reality (MR), Extended Reality (XR). These environments are characterized by user-driven innovation, customizable avatars, and real-time interaction within spatially and socially coherent digital ecosystems, as pioneered long ago by Bartle (2003). Over the years, these platforms have evolved from entertainment spaces into complex socio-technical systems that host collaborative, economic, and educational activities (Dionisio, Burns and Gilbert, 2013). Over time, VWs have evolved from being primarily entertainment-oriented spaces into sophisticated socio-technical systems that support collaborative, economic, and educational interactions (Dionisio, Burns and Gilbert, 2013). These environments enhance users' sense of immersion and presence (Schultze, 2010), enabling a wide spectrum of activities—from simulation and design to learning, socializing, and conducting transactions (European Commission, 2023). More recently, their integration with emerging technologies such as generative AI (Wang, Wang and Siau, 2024) has further accelerated their development by lowering participation barriers and expanding creative and co-creative possibilities.

The shift toward users as active creators (Goanta, 2020) lies at the core of User-Generated Content (UGC), which Naab and Sehl (Naab and Sehl, 2016) define as digital content produced outside professional routines and made publicly or socially accessible. UGC includes a wide range of outputs—texts, data, and user actions—such as virtual objects, avatar customizations, interactive narratives, and immersive spaces, all shared through independent channels with communicative or expressive intent (Santos, 2021). Contemporary VWs like Roblox, Decentraland, and Fortnite actively support large-scale UGC creation by embedding developer tools that empower users to easily build content (Lee and Law, 2023; Zhang, Gui and Kou, 2024). This evolution reflects the democratization of content creation, now embedded in participatory digital cultures that previously marginalized non-professional contributors (Główczyński, 2022).

A prominent and growing typology of UGC is User-Generated Experiences (UGEs)—immersive, interactive activities and environments authored by users within virtual worlds (de Freitas *et al.*, 2009; Blascovich and Bailenson, 2011; Acharya and Wardrip-Fruin, 2019). UGEs enable users to engage with rich and immersive spaces where to design, often collaboratively, using tailored tools like Fortnite Unreal Editor and Roblox studio (Epic Games, 2024b; Roblox Corporation, 2025). They span applications in education, entertainment, and social collaboration, supporting UGE creation through modular development, and feedback mechanisms (Maloney and Freeman, 2020).

Currently, VWs are recognized as mainstream digital spaces, engaging millions of users daily in active content creation (Decentraland, 2017; Epic Games, 2024a; Roblox Corporation, 2024). This participatory nature positions them as relevant arenas for community-driven innovation (Moritzen, 2022), enabling a broad spectrum of innovation—from products and services to processes and entire systems. These contexts provide strategic opportunities for research on how open innovation (Chesbrough, 2003, 2019) can support the development of inclusive, user-driven, and co-creative virtual ecosystems (Kohler *et al.*, 2011). Specifically, when it comes to exploring the design of UGC within VWs, the scientific literature remains notably scarce, opening up a relevant space for exploration.

2 Theoretical Background

2.1 VWs Sectors of Application

As enabling infrastructures, VWs span diverse professional domains, extending beyond their entertainment origins. In education, they support immersive, simulation-based pedagogy, experiential and collaborative learning (Johnson and Levine, 2008; de Freitas *et al.*, 2009). In healthcare, they simulate medical procedures, enhance patient-practitioner interaction, and enable safe, controllable settings for health interventions (Castronova *et al.*, 2009). In urban planning and architecture, they are leveraged for virtual prototyping and collaborative design (Kashiripoor, 2023), while cultural institutions utilize them for cultural heritage and interactive exhibitions (Hutson, Weber and Russo, 2023). In corporate contexts—particularly post-pandemic—VWs are employed for remote work, onboarding, and training, offering spatialized alternatives to conventional video conferencing (Hew and Cheung, 2010).

When for entertainment—and especially gaming—VWs host complex, hybrid economies that largely depend on users adopting and engaging with user-developed content. These economies center on the exchange of digital assets—avatars, environments, interactive objects—often mediated by platform-specific currencies and linked to real-world financial systems (Castronova, 2005; Dionisio, Burns and Gilbert, 2013). The integration of decentralized technologies has introduced new monetization models such as play-to-earn, creator royalties, and blockchain-based ownership (Ramadhan, Suryodiningrat and Mahendra, 2023). Platforms like Roblox and Decentraland allow users to earn income through virtual goods, events, and mini-games, supported by marketplaces and smart contracts that empower creator agency (Główczyński, 2022). Despite their potential, these systems also raise concerns about labor exploitation, digital inequality, and platform governance (Zhang, Gui and Kou, 2024).

2.2 Open Innovation: From Co-creation to Co-Production

As discussed, the creation of UGEs signals a shift from traditional top-down content production toward a bottom-up model, where users act not only as consumers but as active creators. This evolution redefines the participatory paradigm, involving users in the ideation, design, and delivery of digital products and services. Such an approach closely aligns with the principles of Open Innovation, which emphasizes distributed knowledge and collaborative value creation across organizational boundaries (Chesbrough, 2003). Open innovation can manifest through early-stage co-creation, where users contribute ideas and contextual insights (Prahalad and Ramaswamy, 2004); co-design, which engages users in shaping the design of products, services, and beyond (Burkett, 2012); and co-production, where users participate in the implementation, becoming autonomous agents in the production system (Brudney and England, 1983).

2.3 Emerging Gaps and Research Question

While UGC in VWs is gaining scholarly and practical traction for its potential to foster creativity and participatory innovation, several challenges persist. First, the lack of unified design frameworks that integrate VWs possibilities with creative practices (Friedman and Hendry, 2019). Second, difficulties in sustaining long-term user engagement, often resulting in content homogenization and limiting the democratization of content creation (Kohler & Fueller, 2011; Maloney & Freeman, 2020), especially considering cross-platform possibilities. Third, support for opening new business opportunities within virtual economies, which demands a rethinking of UGE ecosystem design and governance to ensure participatory equity and inclusive innovation (Maloney and Freeman, 2020; Zhang, Gui and Kou, 2024). Ultimately, although the literature offers insights within each domain—and at the intersection of any two—a key gap lies at the convergence of all three: UGC, VWs, and open innovation, particularly when viewed through a design lens.

To address these gaps, this study poses the following research question: *How can creative processes for UGE creation be designed to enable cross-platform collaboration, foster creativity, sustain user engagement, and support the generation of desirable content—ultimately supporting business opportunities in VWs?*

In light of this, Design Thinking (Brown, 2008) and structured models like the Double Diamond process (Figure 1) (Design Council, 2005; Nessler, 2016) provide relevant design approaches for developing UGEs, adopting an iterative (Zhu and Lin, 2023) and user-centered perspective (Mattelmäki and Visser, 2011). Complementing them is participatory design (Namioka and Schuler, 1993), which bridges co-creation, co-design, and creative exploration.

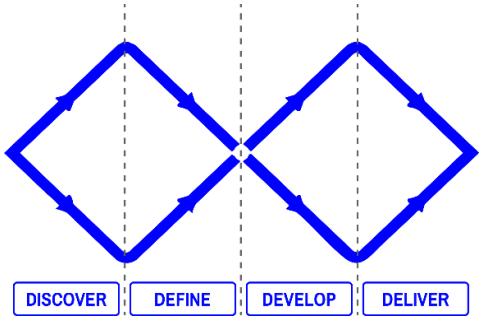

Figure 1: The Double Diamond process (Design Council, 2005)

3. Methodology

The methodology consists of six sequential steps that guide the process from analyzing current discourse in the literature to conducting a case study, ultimately supporting the development and validation of a comprehensive framework.

Phase 1: Literature review. Covering from 1970 to 2024, and spanning the domains of VWs, UGC, and open innovation, a total of 203 sources were analyzed (Ventura, 2025), both academic (Google Scholar, Scopus, Web of Science, JSTOR) and grey (EU reports, industry documents). The review identified theoretical gaps and emerging challenges, informing the research question and the case studies analysis. The review was limited to accessible resources in English and Italian.

Phase 2: Case study analysis. An initial set of 15 VWs, based on Barrett (2024), was shortlisted using eight criteria derived from the literature: Presence of monetization systems (Gupta, S. *et al.*, 2022), Persistence (Dionisio, Burns and Gilbert, 2013), Real-time collaboration (Dionisio, Burns and Gilbert, 2013), Brand collaborations (Joy *et al.*, 2022), UGC Creation (Naab and Sehl, 2016), Commerce opportunities (Dibbell, 2006), Usage of advanced technologies (Brunet, Mattavelli and Chiariglione, 2023), and Broad audience outreach (Dionisio, Burns and Gilbert, 2013). Three VWs are selected as case studies: Roblox, Decentraland, Fortnite are selected representing diverse approaches to UGE, monetization, and community engagement. Analytical dimensions and sub-dimensions for analysing cases were also literature-informed: Open Innovation (Co-creation, Co-design, Co-production)(Chesbrough 2003, 2019; Prahalad & Ramaswamy, 2004; Burkett, 2012; Brudney & England, 1983), Role of a VW Environment (Immersive Experiences, Brand Collaborations) (Bartle, 2004; Joy et alt. 2022; Acharya & Wardrip-Fruin, 2019), Community engagement (User to User Interaction, Community Collaboration) (Bartle, 2003; Kohler et alt, 2011), UGC Creation (UGC Design and Monetization Opportunities) (Naab and Sehl, 2016; Gupta, 2022) and Intellectual Property Rights (Safitra *et al.*, 2023).

List of cases

15 Virtual Worlds analyzed in literature review, from Barrett (2024)

Selection Criteria to Shortlist Barrett

- Persistence of the platform
- Presence of real-time collaboration
- Presence of brand collaborations
- Includes creation of UGC
- Commerce opportunities
- Usage of advanced technologies
- Presence of monetization systems
- Broad audience outreach

Literature-Inspired Dimensions & Sub-dimensions of Analysis

Dimensions	Sub-dimensions	Reference
Open Innovation	Co-Creation, Co-Design, Co-Production	(Chesbrough, 2006; Voorberg, Bekkers, & Tummers, 2015; Prahalad & Ramaswamy, 2004; Graham et al., 2013)
Role of a Virtual World Environment	Immersive Experiences	(Bartle, 2003; Schroeder, 2016; Girvan, 2017; Juul, 2005)
	Platform for Brands	(European Commission, 2023; Castronova, 2005; Graham et al., 2013; Bartle, 2003)
Community Engagement	User to User Interaction	(Schroeder, 2016; Parkkila, 2017; Nevelsteen, 2017; Lastowka, 2008; Juul, 2005)
	Community Collaboration	(Schroeder, 2016; Juul, 2005; Lastowka, 2008; Graham et al., 2013)
Generation of Content	Monetization Opportunities	(Lastowka, 2008; Zhang, Cui, & Kou, 2023; Główczyński, 2022; Bartle, 2003; Friedman & Hendry, 2019)
	UGC Design	(Bartle, 2003; Castronova, 2005; Mayer-Schönberger, 2006; Nevelsteen, 2017)
Intellectual Property Rights		(Lastowka, 2008; European Commission, 2023; Bartle, 2003; Mayer-Schönberger, 2006)

Figure 2: Phase 2 of Methodology summarized

Phase 3. Theoretical framework. Integration of the Open Innovation approach with the co-creation, co-design and co-production processes, the Double Diamond design model (Design Council, 2005) and the phases identified in the literature.

Phase 4. Validation against literature. The framework is validated through cross-referencing with existing literature. A comparison matrix, developed for this purpose, is integrated into the theoretical framework presented in the result paragraph.

4 Case Studies Analysis

The three selected VWs—Roblox, Decentraland, and Fortnite—serve as representative cases for examining the interplay between UGC, design, and open innovation. Figure 3 displays a comparative analysis that describes each case across key dimensions for a structured identification of similarities, differences, and emerging patterns aimed at informing critical insights for the theoretical framework development.

	Case 1	Case 2	Case 3
	ROBLOX. Free to play online game platform and game creation system for users to program and play games created by themselves or other users. In-game purchases are available through a virtual currency called Robux.	**DECENTRALAND.** 3D VW browser-based platform where users can buy in-platform plots of land as NFTs via the MANA cryptocurrency (Ethereum blockchain). Designers can create and sell clothes and accessories for avatars in WWs.	**FORTNITE.** A multiplayer online video game evolved into a multifaceted VW and creative platform serving as an ecosystem that integrates UGC, branded collaborations and live virtual events.
		Open Innovation	
Co-Creation, Co-Design, Co-Production	Users ideate, build, and refine content collaboratively using Roblox Studio, blurring lines between developers and players, with monetization through DevEx.	Users ideate through the DAO and events, co-design with tools like the Builder, and refine content via feedback before publishing as NFTs or interactive experiences.	Creators brainstorm ideas, build with UEFN, and refine content through collaboration and playtesting. The Creator Economy 2.0 shares 40% of revenue, promoting global, user-driven innovation.
		Role of a VW Environment	
Immersive Experiences	Roblox offers low-barrier tools, global feedback, and fast iteration, enabling creators of all skill levels to build and distribute innovative content.	Decentraland offers diverse virtual worlds, from art galleries to concerts and educational games, providing boundless creative expression without physical limits.	Fortnite blends gaming, music, and storytelling through iconic virtual events like concerts by Travis Scott and Ariana Grande, transforming entertainment into interactive, shared experiences.
Brands Collaborations	Luxury brands like Gucci and Givenchy use Roblox to create interactive virtual spaces, engaging younger audiences and expanding digital brand presence.	Brands like Adidas and Gucci create branded spaces and events in Decentraland, merging marketing with immersive virtual experiences to engage digital audiences.	Brands like Nike, Balenciaga, and Marvel collaborate with Fortnite to launch virtual goods and events, merging fashion, pop culture, and gaming to engage younger audiences.
		Community engagement	
User to User Interaction	Chat, multiplayer gameplay, and events foster community and real-time social engagement among users across experiences.	Social tools, multiplayer games, and community events foster user interaction and collaboration, enhancing the social fabric of the platform.	Collaborative gameplay, live events, and social sharing on platforms like TikTok and YouTube enhance community engagement and feedback among users.
Community Collaboration	Forums, groups, Discord, and social platforms support teamwork, feedback, mentorship, and co-creation, strengthening the creator community.	DAO proposals, forums, Discord, and hackathons enable idea sharing, feedback, and co-creation, empowering creators through open, community-led collaboration.	UEFN, forums, and Discord support teamwork and mentorship. Hackathons and challenges drive innovation, while social media helps creators connect, learn, and co-create.
		Generation of Content	
UGC Design	User-generated content drives Roblox's diversity, with AI tools streamlining creation and lowering entry barriers for 3D assets and environments.	Creators design wearables, land, and games using the Builder, with blockchain ensuring ownership. Content reflects global diversity and innovation.	Tools like Fortnite Creative and UEFN enable users to design diverse, AI-enhanced content. Continuous community contributions keep the platform fresh and engaging.
Monetization opportunities	Creators earn Robux by selling items and experiences, with conversion to real currency via DevEx and exclusive programs enhancing earning potential.	Creators earn through NFT sales, event tickets, rentals, and MANA transactions, supported by an open economy that incentivizes innovation and income.	Creators earn through V-Bucks sales, subscriptions, and Creator Economy 2.0 payouts based on engagement. Transparent systems convert virtual income into real-world revenue.
		Intellectual property rights	
	Creators retain content ownership under IP laws; Roblox enforces DMCA compliance and protects rights through reporting and takedown systems.	Assets are owned as NFTs with blockchain-based governance, ensuring creator rights, transparency, and fair revenue sharing while resolving disputes effectively.	Creators own their work but grant Epic usage rights. DMCA enforcement and reporting tools ensure IP compliance and protect original content.

Figure 3: Case study analysis

4.1 Insights from Case Study Analysis

The comparative analysis of three virtual worlds Roblox, Fortnite, and Decentraland enabled the identification of critical insights into the dynamics of UGE creation within digital environments. The analysis highlighted key factors such as the fragmentation of tools and processes across platforms, which revealed the need for a unified and structured framework. Second, the importance and the diffusion of real-time collaboration and community-led practices underscored the need for sustained support mechanisms that facilitate collective creativity and engagement. Third, the analysis identified limitations in current systems for onboarding novice creators, particularly in non-professional contexts, thus pointing to the need for accessible, inclusive design methods that accommodate diverse levels of technical and creative expertise. Fourth, issues regarding intellectual property rights and value distribution models highlighted the need for equitable governance, protecting and empowering creators within virtual economies. These emergent needs directly informed the construction of the proposed design-driven open innovation framework, which integrates co-creation, co-design, and co-production processes across the Double Diamond model, thus responding to both systemic and experiential challenges, providing methodological support for designing user-generated experiences in ways that are participatory, technologically enabled, and economically sustainable.

5. Theoretical Framework

This study conceptualized a framework integrating (i) the three core dimensions of Open Innovation—co-creation, co-design, and co-production— and (ii) the four stages of the Double Diamond model (Design Council, 2005)—Discover, Define, Develop, and Deliver, alongside a set of tailored sub-phases specific to UGE development. Specifically, this study builds on Nessler's (2016) version of the Double Diamond, extracting from its 15 phases a seven-phase model (Figure 4) for UGE creation in virtual worlds, spanning from need identification to iterative testing.

Figure 4: Seven Design phases for UGE creation in VWs.

The proposed framework (Figures 5 and 6) is designed to enhance UGE creation within VWs, focusing on the design of immersive experiences while addressing the existing gaps. Each open innovation mode is mapped onto corresponding stages of the design process to highlight the evolving role of user participation, and tailoring the Double Diamond model to the specific needs of immersive experience design thus deriving adapted phases for UGE Development.

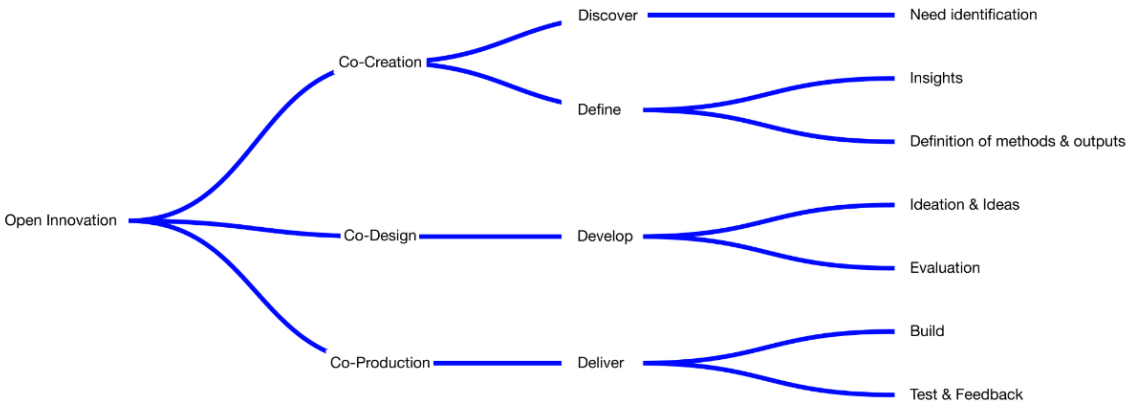

Figure 5: Theoretical Framework: Structure

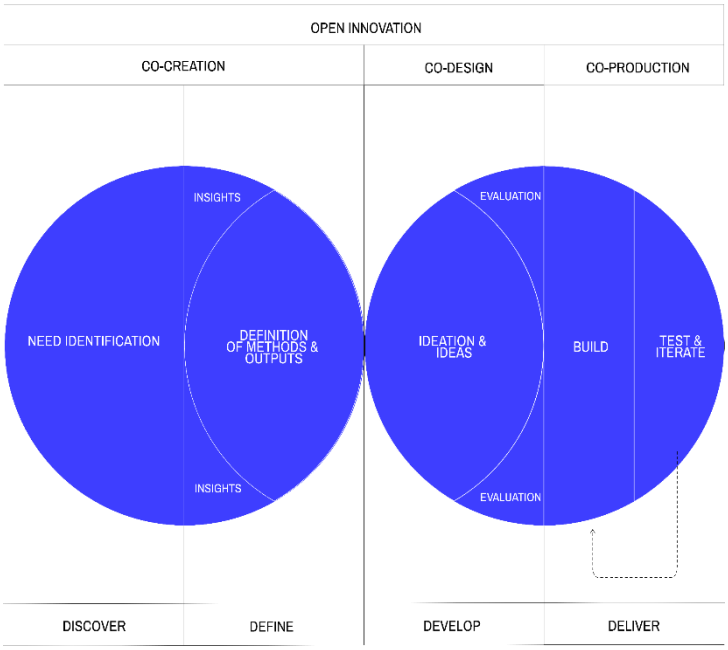

Figure 6: Theoretical Framework: Interaction of the instances

Co-creation is mapped onto the *Discover* and *Define* phases, which form the foundation for contextual understanding and strategic framing. In *Discover*, the **Need Identification** focuses on uncovering and articulating the core needs and challenges faced by users and stakeholders. It involves analyzing the user context, mapping user journeys, understanding their environments, behaviors, and motivations, identifying barriers and opportunities, as well as environmental and social factors that shape user experiences in virtual worlds. As a consequence, it fosters reflective thinking and helps surface what matters most, thereby ensuring that user-centered solutions are grounded in real-world concerns. In *Define*, the **Insights** phase involves translating raw data into meaningful narratives that explain why users behave the way they do, what matters most to them, and where existing systems fail to meet their expectations. It synthesizes data and observations into meaningful, actionable takeaways, revealing patterns in user behavior, reframing challenges, and serving as a springboard for innovation by shifting perspectives and anchoring the process in deep user empathy—they provide the interpretive lens through which design challenges are reframed. The **Definition of Methods & Outputs** phase shifts toward structuring the design problem in a clear and actionable way. It involves crafting a well-framed design challenge, by translating user insights into clear, strategic design questions. It helps structure the design challenge, define outcomes, and guide teams toward targeted ideation, thus supporting a reflective activity that ensures alignment across stakeholders and creates a coherent brief for the next phase.

Co-design takes place during the *Develop* phase, where users actively contribute to generating and refining solutions. The **Ideation & Ideas** phase encourages creative exploration, where diverse concepts are brainstormed and articulated in response to the defined challenge. Emphasis is placed on encouraging divergent thinking and avoiding premature convergence. Ideas are shaped to address specific user needs while considering feasibility, impact, and implementation strategies. In the **Evaluation** phase, concepts are systematically assessed to identify those with the highest potential. It involves assessing and prioritizing these ideas based on criteria such as user value, technical viability, and innovation potential, through a structured decision-making process aimed at identifying the most promising concepts to be selected for further development. Evaluation methods may include comparative matrices, user voting, expert panels, feasibility analyses, and so on. Importantly, users remain engaged during this phase through co-evaluation techniques, ensuring that their voices continue to shape the selection and refinement of ideas. The outcome is a shortlist of well-founded, high-impact concepts that are ready for prototyping and implementation.

Co-production is embedded in the *Deliver* phase, where users become key collaborators in shaping and implementing the final experience. The **Build** phase involves developing and refining prototypes that translate conceptual ideas into tangible prototypes. Prototypes can range from low-fidelity mockups (e.g., paper sketches, wireframes) to high-fidelity interactive prototypes or immersive digital models, allowing creators to test core features and interactions. It also considers technical feasibility and usability, laying the groundwork for implementation in virtual environments. Technical teams collaborate with user-creators to experiment with different formats and functionalities. This stage also involves planning for production and implementation,

addressing project management dimensions such as timeline, resources, and stakeholder responsibilities. Finally, the **Test & Feedback** phase focuses on structured testing of prototypes with end users through usability sessions, live trials, playtests, and feedback loops. The aim is to assess how well the prototype performs in real or simulated conditions and to identify areas for improvement. Testing protocols are designed to capture qualitative and quantitative feedback, validate key assumptions, and ensure alignment with user expectations. This phase often includes rapid iteration cycles—implementing changes, re-testing, and refining until a stable and user-approved version emerges. The outcome is a validated solution with a clear pathway for full deployment in the VW.

The theoretical framework presented was validated across all its phases through a systematic comparison with the analyzed literature. This validation process, summarized below, highlights the conceptual alignment between Open Innovation, the Double Diamond model, and the extensive scientific discourse on VWs. It identifies supporting literature for each phase, thus demonstrating the relevance and coherence of the framework in addressing the complexities of UGE creation within VWs.

	Instance	Description	References
Approach	Open Innovation	In the context of VWs, Open Innovation emphasizes participation, shared governance, and community-driven insights, enabling a wide range of contributors—users, developers, and stakeholders—to engage in the creation of User generated content. By lowering barriers to entry and leveraging collective intelligence, this approach enhances both creative diversity and technological adaptability. The framework also ensures that collaboration aligns with the platform's ecosystem and evolving user needs, fostering an environment where content generation is continuous, user-driven, and capable of scaling efficiently. This enables virtual worlds to remain engaging, sustainable, and responsive to emerging trends, reinforcing their role as interactive and evolving digital spaces.	Chesbrough (2003, 2019); Wielinga & Robijn (2023); Friedman & Hendry (2019); Nolte et al. (2022); Kou & Gui (2023)
Process	Co-creation	Co-Creation is the collaborative process where users, designers, and platform stakeholders actively contribute to shaping interactive content, virtual environments, or digital assets. This phase emphasizes participatory ideation, where users are not just consumers but also co-developers of experiences within a platform. It involves investigating the creative and technical possibilities, aligning user motivations with platform affordances, and fostering an open innovation environment.	Prahalad & Ramaswamy (2004); Chesbrough (2003);
	Co-design	Co-Design is a collaborative approach where ideas transition from concept to prototype, enabling creators to actively develop and refine User-Generated Content ideas for immersive experiences. This phase focuses on transforming conceptual insights into tangible ideas, ensuring that solutions are feasible, original, and user-centered.	Brown (2008); IDEO (2013); Mattelmäki & Visser (2011)
	Co-production	Co-Production is the implementation phase where prototypes are developed, integrated, and tested within the platform's ecosystem. This stage emphasizes turning designs into functional content, ensuring that UGC meets both user expectations and platform standards. Through modeling, publishing, playtesting, and iteration, creators refine their work, leveraging user feedback to enhance engagement, usability, and overall quality.	Rzeszewski & Evans (2020); Maloney & Freeman (2020)
DD Phases	Discover	The Discover Phase serves as the foundation for understanding how users interact with UGC in virtual worlds. This phase investigates the motivations, barriers, and behavioral patterns that shape user participation in creating, engaging with, and living UGC-driven experiences. Through qualitative research, it seeks to uncover insights that inform the design and development of more engaging and accessible platforms.	Design Council (2005), Nessler (2021)
	Define	The Define Phase synthesizes insights gathered during the Discover Phase to establish clear, actionable goals. This phase serves as a bridge between research and implementation, ensuring that identified challenges, opportunities, and user needs translate into strategic, well-defined objectives that guide the next steps in the process.	Design Council (2005), Nessler (2021)

	Develop	The Develop Phase is dedicated to the ideation, and refinement of ideas and workflows that facilitate collaborative User-Generated Experiences creation. This phase builds upon the insights generated during Co-creation, focusing on enhancing efficiency, usability, and co-creation dynamics within immersive platforms.	Design Council (2005), Nessler (2021)
	Deliver	The Deliver Phase is the stage where the UGE framework is implemented through prototyping, testing, and iterative refinement. This phase ensures that User-Generated Experiences are functional, engaging, and aligned with user expectations before full deployment. By gathering feedback, addressing technical issues, and enhancing usability, teams refine their solutions to deliver high-quality, immersive outputs.	Design Council (2005), Nessler (2021)
Phases	Need identification	The Need Identification Phase is focused on understanding and defining the core needs of users and stakeholders. Through tools like Problem Framing, Sense-Making Wall, User Map, and User Value Map, this phase analyzes the problem, maps users, and identifies the values and motivations driving their needs. It sets the foundation for user-centered solutions by clarifying what matters most to those involved.	Mattelmäki & Visser (2011); Friedman & Hendry (2019)
	Insights	The Insights Phase is dedicated to highlight deeper understandings from gathered data and observations, ensuring that user needs, behaviors, and motivations are synthesized into meaningful, actionable insights. These insights serve as the foundation for reframing challenges and driving innovative solutions.	Schuler & Namioka (1993); Voorberg et al. (2015); Maloney & Freeman (2020)
	Definition of Methods and Outputs	The Definition of Methods and Outputs Phase focuses on reframing the problem and structuring it into actionable questions that drive creative and strategic ideation. By utilizing tools like Problem Reframing and How Might We (HMW) statements, this phase ensures that teams consolidate their understanding of the challenge while articulating it.	IDEO (2013); Design Council (2005); Zhu et al. (2019); Nessler (2016)
	Ideation and Ideas	The Ideation and Ideas Phase is centered on generating, exploring, and naming concepts that address key challenges. This phase encourages unconstrained creativity, allowing teams to brainstorm diverse solutions that can later be refined and evaluated.	Prahalad & Ramaswamy (2004); Füller et al. (2011); Kou & Gui (2023)
	Evaluation	The Evaluation Phase is a structured process designed to assess, compare, and prioritize ideas using the Evaluation Matrix. This phase ensures that the most feasible and original ideas are selected for further development. By systematically rating concepts against predefined criteria, this tool ensures that the chosen solution aligns with project objectives and user needs.	Rzeszewski & Evans (2020); Friedman & Hendry (2019); Maloney & Freeman (2020)
	Build	The Build Phase is dedicated to creating, testing, and refining prototypes to advance the development of solutions. This phase transitions ideas into tangible forms, allowing teams to explore feasibility, usability, and functionality in a structured and iterative manner. By leveraging tools like the Experimentation Card, Lo-Fi Prototypes, and Advanced Prototypes, this phase ensures that solutions evolve based on user feedback and technical validation.	Brown (2008); Hollensen et al. (2022)
	Test & Feedback	The Test & Feedback Phase is a crucial step in refining solutions, ensuring that both the prototype and its supporting operational processes function effectively. By continuously testing, refining, and optimizing, teams validate assumptions, enhance user experience, and streamline operational efficiency before full deployment	Flanagan & Nissenbaum (2014); Füller et al. (2011); Schuler & Namioka (1993); Friedman & Hendry (2019)

Figure 7: Framework validation against literature

6 Discussion & Conclusions

6.1 Addressing Key Gaps

The design-driven framework presented directly addresses the key gaps identified in the literature. (i) It responds to the lack of unified frameworks by offering a structured, collaborative process that guides creators through all stages of UGE development, drawing on both theoretical foundations and insights from real-world platforms. (ii) It mitigates the limited support for inclusive, broad, and sustained creative participation by integrating methodologies such as UCD, enabling contributions from both novice and expert users, and thus

empowering various users to actively engage in the creation process. This accessibility-oriented approach lowers technical entry barriers, fosters creative inclusiveness, and encourages diverse content creation. (iii) At the same time, it addresses the challenge of balancing creativity with desirability by embedding engagement-focused methods and phases that prioritize user relevance and meaning. In doing so, it enhances creator agency while ensuring alignment with the values and expectations of target communities. (iv) It responds to the need for tailored support to sustain new business opportunities emerging from the evolving economies of VWs. Drawing from Maloney and Freeman (2020), the framework incorporates methods and principles that enable creators not only to contribute creatively but also to engage meaningfully in the economic structures of the platforms, by embedding mechanisms and could possibly implement technologies that emphasize transparency, intellectual property awareness, and value co-creation. Furthermore, the framework fosters the emergence of participatory business models that are both scalable and inclusive, positioning creators as key stakeholders within VW economies, allowing them to co-define outputs and to benefit from more equitable innovation dynamics.

6.2 Study limitations and future research directions

While the proposed framework offers a robust and theoretically grounded contribution to the design and governance of UGE creation in VWs, several limitations must be acknowledged. (1) The framework was developed through a limited number of case studies—specifically Roblox, Fortnite, and Decentraland. Although these platforms represent leading models in the current VW landscape, the focus on three cases may limit the generalizability of the findings across other emerging platforms with different configurations. (2) The framework emphasizes qualitative and design-based methods, which, although appropriate for exploring user-centered innovation processes, do not include quantitative assessments or longitudinal impact evaluations, thus restricting the capacity to measure long-term effects of the framework on user engagement, content quality, or economic returns.

Building upon this, promising directions emerge for future research concern expanding the framework's validation across a broader sample of VWs including smaller platforms, educational environments, and open-source services would enhance the generalizability of findings. Furthermore, including comparative studies to test the adaptability in diverse contexts, and longitudinal studies to evaluate the sustained impact on creator engagement, content diversity, and business outcomes over time.

7 Ethics Declaration

No ethical clearance was required for the research presented in this paper.

8 AI Declaration

No artificial intelligence tools were used in the design, execution, or analysis of this study.

Managing Prices in the Age of AI: A Taxonomy of AI Applications to Support Pricing Decisions

Ludovica Nardi, Andrea De Mauro
Luiss University, Rome, Italy

Abstract

In an increasingly digitized and hypercompetitive market landscape, pricing is evolving from a static, cost-based process into a dynamic, strategic function powered by Artificial Intelligence (AI). Organizations are moving beyond traditional pricing models by leveraging real-time analytics, predictive modelling, and behavioural insights to enhance pricing decisions. AI enables large-scale automation and personalization of prices, allowing firms to adapt continuously to changes in demand, consumer behavior, and competitive signals. However, this shift also raises critical concerns regarding transparency, fairness, and algorithmic accountability—especially in consumer-facing markets, where price sensitivity and perceptions of justice directly influence trust and loyalty. This study shows how AI reshapes pricing across four impact areas—predictive modelling, real-time optimisation, behavioural adaptation, explainability and fairness—and, through a systematic literature review, distils a two-level taxonomy of AI applications in pricing. The findings demonstrate that AI-powered pricing enhances forecasting accuracy, enables granular and dynamic price optimization, and improves behavioural targeting through the integration of cognitive heuristics such as anchoring and loss aversion. These benefits, however, must be balanced against the heightened risks of opacity, unfair discrimination, and regulatory non-compliance, which can erode consumer trust. The study emphasises that AI is not merely a technological tool, but a transformative agent that reshapes market dynamics and redefines consumer expectations. As such, the adoption of transparent, explainable, and ethically aligned AI models is essential—not only to ensure compliance with emerging regulatory frameworks, but also to foster long-term consumer confidence and sustainable competitive advantage. The paper concludes by calling for interdisciplinary research to explore the longitudinal effects of AI-based pricing, ethical governance mechanisms, and the integration of social responsibility into algorithmic pricing strategies.

Keywords: Price Management; Behavioural Economics; Artificial Intelligence; Systematic Literature Review; Marketing

Paper type: Academic Research Paper

1 Introduction

The increasing digitalization of global markets has profoundly transformed pricing, elevating it from a rule-based administrative function to a strategic, data-driven lever. Once grounded in cost-plus logic or fixed price lists, pricing is now shaped by real-time analytics, algorithmic models, and, increasingly, behavioural insights. More recently, Artificial Intelligence (AI) has become a prominent driver of this transformation. AI empowers organizations to automate pricing determinations while simultaneously enhancing these processes through predictive capabilities, contextual responsiveness, and psychological attunement (Prithi & Tamizharasi, 2025; Li et al., 2022).

In recent years, the literature has highlighted growing interest in the strategic potential of AI applied to pricing. Erdmann et al. (2024) propose a framework for evaluating AI-based pricing systems through the lenses of sustainability, regulatory alignment, and economic efficiency, underlining the importance of predictive accuracy and customer value creation. Gerlick and Liozu (2020) delve into the ethical and legal implications of algorithmic personalised pricing, emphasizing that perceptions of fairness and transparency are critical for consumer acceptance. This transition—from manual segmentation to algorithmically optimised targeting—reflects a broader shift toward AI-driven value extraction and reinforces the need for transparency and explainability in automated systems.

Agarwal et al. (2024) stress that algorithmic opacity may hinder not only regulatory compliance but also managerial capacity to interpret and govern pricing logic. In response, tools from the field of Explainable Artificial Intelligence (XAI)—such as SHapley Additive exPlanations (SHAP) and Local Interpretable Model-agnostic Explanations (LIME)—help reconstruct pricing rationale, thereby enhancing interpretability and trust (Peng et al., 2023). Concurrently, the integration of behavioural economics into AI models is gaining momentum. Shan and Li (2025) demonstrate that cognitive biases such as anchoring and loss aversion significantly affect price perception and can be embedded in intelligent systems to reinforce personalisation. In the tourism sector, for

example, Nguyen and Nguyen (2025) show how reinforcement learning-based dynamic pricing algorithms can adjust in real time to consumer preferences, improving financial performance.

This study contributes to this interdisciplinary dialogue by synthesising insights from machine learning, behavioural economics, and algorithmic governance to explore how AI is reshaping pricing architectures. Through a systematic literature review, four thematic dimensions are identified through which AI impacts pricing decisions: predictive modelling, real-time optimisation, behavioural adaptation, explainability and fairness.

The remainder of the paper is structured as follows: Section 2 outlines the theoretical background, with particular attention to AI methodologies and behavioural pricing theories. Section 3 describes the research methodology, including the literature review strategy and the development of the taxonomy. Section 4 presents the key findings, organised around the four thematic dimensions. Finally, Section 5 offers theoretical, managerial, and policy-related implications and suggests avenues for future research.

2 Theoretical Background

This section outlines the interdisciplinary theoretical foundations that inform the integration of Artificial Intelligence (AI) in pricing systems. The focus is placed on the convergence of computational methods, behavioural economics, and governance frameworks. Special attention is given to the mechanisms through which AI technologies shape, and are shaped by, consumer psychology and regulatory imperatives. The section is structured in two interrelated subsections: AI methodologies in pricing, and behavioural pricing theories.

2.1 AI Methodologies in Pricing

Artificial Intelligence (AI) has introduced new paradigms in pricing by enabling firms to shift from reactive, rule-based strategies to proactive, data-driven optimisation (Duan et al., 2019; Davenport et al., 2020). Among the most widely adopted methodologies are supervised learning, unsupervised learning, and reinforcement learning. Supervised learning techniques—such as eXtreme Gradient Boosting (XGBoost) and Long Short-Term Memory (LSTM) networks—are commonly used to forecast demand, estimate price elasticity, and analyse market dynamics based on historical, behavioural, and contextual data (Ma & Sun, 2020; Kumar et al., 2019). These models support a wide array of pricing applications, including dynamic price adjustment, personalised promotions, and contextual targeting. In AI-powered environments like e-commerce, these capabilities allow companies to adapt offers in real time, increasing pricing precision and relevance (Huang & Rust, 2021; Corbo et al., 2022). Unsupervised learning, typically implemented through clustering algorithms, enables the identification of latent customer segments without the need for predefined labels. These clusters serve as a foundation for differentiated pricing strategies based on behavioural profiles and contextual relevance (Erevelles et al., 2016; Sestino & De Mauro, 2021). In practice, this enables more accurate segmentation and microtargeting, especially in environments where consumer preferences are dynamic and unstructured. Reinforcement learning offers a more autonomous and adaptive approach, where pricing algorithms learn over time by interacting with consumers and market signals. These models adjust prices dynamically, responding to real-time feedback such as user behaviour, conversion rates, and competitive movements (Guda & Subramanian, 2019; Campbell et al., 2020). Applications of reinforcement learning are particularly effective in scenarios such as surge pricing, auction-based platforms, and real-time bidding. As these AI-driven methodologies advance, they bring growing concerns about algorithmic opacity and the need for explainability. Tools from the field of Explainable Artificial Intelligence (XAI)—including SHapley Additive exPlanations (SHAP) and Local Interpretable Model-agnostic Explanations (LIME)—enable stakeholders to interpret, audit, and validate automated pricing decisions (Peng et al., 2023; Davenport et al., 2020). These tools play a crucial role in maintaining transparency, regulatory compliance, and consumer trust in complex algorithmic environments.

2.2 Behavioural Pricing Theories

Behavioural pricing theories are grounded in the notion that consumers do not respond to prices in fully rational ways, but are influenced by heuristics, cognitive biases, and emotional factors. Integrating these principles into AI-supported pricing systems enables the development of more persuasive, adaptive, and personalised strategies (Shan & Li, 2025; Huang & Rust, 2021). Among the most relevant biases are the anchoring effect, whereby consumers evaluate prices relative to an initial reference point, and loss aversion, which amplifies the perceived impact of a price increase compared to an equivalent discount. These psychological mechanisms are increasingly embedded into machine learning models, allowing prices to be tailored to individual thresholds of acceptability (Ma & Sun, 2020; Kumar et al., 2019). In digital environments, such approaches manifest through techniques like charm pricing (e.g., €9.99 instead of €10), urgency framing, and

perceptual customisation of offers. The literature also highlights that the application of AI in personalised pricing must balance persuasive effectiveness with ethical and reputational considerations. Corbo et al. (2022) emphasise the importance of transparent models capable of explaining the rationale behind price recommendations. Excessive opacity can generate perceptions of manipulation or discrimination, undermining consumer trust and diminishing purchase intent (Davenport et al., 2020; Erevelles et al., 2016). Moreover, AI technologies allow real-time monitoring of consumer behavioural responses, enabling dynamic adaptation of pricing strategies. In particular, reinforcement learning models can learn which psychological patterns are most effective for each customer segment, thus enhancing the precision of personalisation (Campbell et al., 2020; Guda & Subramanian, 2019). Finally, the adoption of Explainable AI (XAI) approaches is equally crucial in behavioural pricing: explaining not just what is proposed, but why, can significantly increase consumer acceptance of AI-driven recommendations and reduce psychological resistance (Sestino & De Mauro, 2021; Duan et al., 2019). In this sense, algorithmic governance should not be viewed solely as a regulatory constraint, but as a strategic lever for building long-term relationships with increasingly fairness-sensitive customers.

3 Methodology

This research adopts a Systematic Literature Review (SLR) methodology as a structured, transparent, and replicable approach to synthesising existing knowledge, consistent with best practices in management and artificial intelligence adoption research (De Mauro et al., 2019; Duan et al., 2019). Unlike narrative reviews, often characterised by a higher degree of subjective interpretation, SLRs minimise bias through the application of rigorous protocols and standardised procedures. To ensure methodological transparency, the review process was aligned with the PRISMA framework (Moher et al., 2009), which provides a structured guideline for article identification, screening, eligibility assessment, and inclusion. The PRISMA method is widely recognised for enhancing the transparency, replicability, and methodological rigour of systematic reviews across management, information systems, and data analytics research (De Mauro et al., 2019). The methodological approach was articulated into three main phases: (i) selection of the article corpus; (ii) extraction and categorisation of article content; (iii) analysis of AI-related pricing dimensions through structured content analysis. This multi-layered process ensured both analytical depth and procedural replicability, enabling the development of a dual-level taxonomy that illustrates how artificial intelligence technologies are reshaping pricing decision-making across predictive, behavioural, and ethical dimensions.

3.1 Review Scope and Selection Criteria

The scope of this review was defined at the intersection between AI-driven pricing models, behavioural pricing mechanisms, and the ethical and regulatory challenges associated with algorithmic governance. The literature search was conducted exclusively using the Scopus academic database by employing a structured query:

((TITLE (price) OR TITLE (pricing)) AND (TITLE ("artificial intelligence") OR TITLE (ai) OR TITLE ("analytics"))) AND PUBYEAR > 2009 AND PUBYEAR < 2026 AND (LIMIT-TO (DOCTYPE , "ar") OR LIMIT-TO (DOCTYPE , "cp")) AND (LIMIT-TO (LANGUAGE , "English"))

Because this string already limits results to English-language journal articles (“ar”) and conference papers (“cp”) published between 2010 and 2025, several inclusion criteria were operationalised at the search stage. To ensure relevance and quality, four inclusion criteria were applied: (i) peer-reviewed journal articles or conference papers written in English; (ii) publication years 2010-2025; (iii) explicit focus on AI applications to pricing with managerial, behavioural, strategic, ethical, or regulatory implications; and (iv) availability of the full text. Studies were excluded when they (a) addressed purely technical AI issues without a pricing or managerial dimension, (b) reported single, non-generalisable case studies, or (c) lacked retrievable full texts.

In the first phase, a preliminary screening was conducted based solely on the titles and abstracts of the identified documents. As a result of the initial bibliographic search conducted through Scopus using a structured query string, a total of 337 contributions were identified. A first screening phase was carried out to filter out articles that were not relevant to the scope of the research, leading to the exclusion of 237 contributions that did not align with the intended research domain. A refined set of 100 articles was then subjected to a deeper review, with a focus on the presence of specific keywords, thematic alignment with the field of AI in pricing, and overall methodological robustness. This qualitative assessment led to the final selection of 52 contributions, which represented the most relevant and insightful works for the purposes of the structured content analysis and taxonomy elaborated in the study. Figure 1 summarizes the resulting article selection process.

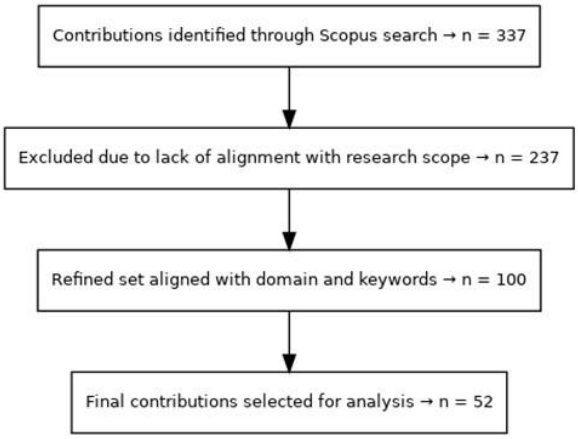

Figure 1: Funnel diagram of the article selection process.

3.2 Structured content analysis

Following the article selection phase, a Structured Content Analysis was conducted to classify the main pricing mechanisms and themes identified across the reviewed articles. Inspired by the methodological approach proposed by Kohlegger, Maier, and Thalmann (2009), a human-coding procedure was used. Key concepts were grouped into recurring thematic patterns through an iterative categorization process, which resulted in the four dimensions shown in Table 1. In the taxonomy, each dimension represents a high-level impact area; within every impact area, we further identified recurrent use-case scenarios that specify how AI supports pricing practice. This method enabled the development of a coherent and replicable taxonomy, systematically capturing the strategic, behavioural, operational, and ethical dimensions underpinning AI applications in pricing systems.

Table 1: Summarized output of the structured content analysis: impact-area clusters, document count, corpus share, and representative keywords.

Impact area	Papers (n)	Share of corpus	Representative keywords
Predictive Modelling	20	39%	demand forecast, price elasticity, time-series
Real-Time Optimisation	11	21%	dynamic pricing, surge, RL
Behavioural Adaptation	8	15%	anchoring, loss aversion, personalisation
Explainability and Fairness	13	25%	SHAP, LIME, transparency

4 Findings and Discussion

This section discusses the key findings, organised around the four impact areas and their associated use-case scenarios, as identified in this study. Each branch of the taxonomy, shown in Figure 2, reflects a distinct pathway through which Artificial Intelligence (AI) is reshaping pricing mechanisms across industries.

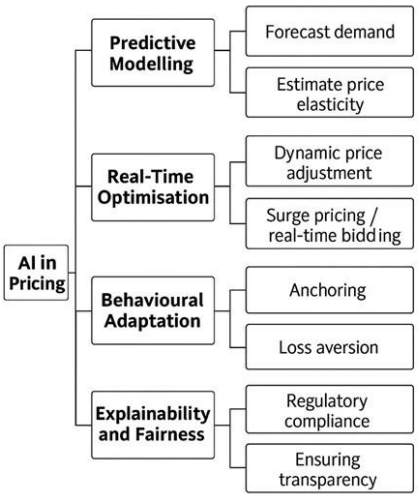

Figure 2: Two-level taxonomy of AI in pricing: impact areas (Level 1) and illustrative use-case scenarios (Level 2).

4.1 Predictive Modelling

Predictive modelling refers to the use of supervised learning algorithms to anticipate demand trends, forecast price elasticity, and optimise pricing strategies based on historical and contextual data. Techniques such as Extreme Gradient Boosting (XGBoost) and Long Short-Term Memory networks (LSTM) have proven highly effective in this area (Ma & Sun, 2020; Kumar et al., 2019). Applications in industries like e-commerce and transportation demonstrate the strategic advantage of leveraging demand forecasting to drive dynamic price adjustments (Li et al., 2022; Nguyen & Nguyen, 2025). Moreover, research indicates that predictive models increasingly incorporate external variables—such as competitor behaviour and macroeconomic indicators—to refine their accuracy and business relevance (Duan et al., 2019).

4.2 Real-Time Optimisation

Real-time optimisation focuses on deploying reinforcement-learning (RL) algorithms that enable dynamic price adjustments and surge-pricing or real-time bidding schemes in response to market signals. This approach is particularly critical in sectors where supply and demand conditions fluctuate rapidly, such as tourism and ride-sharing (Guda & Subramanian, 2019; Nguyen & Nguyen, 2025). For instance, dynamic pricing algorithms allow companies to optimise occupancy rates and revenue by adapting to real-time consumer behaviour and booking patterns (Sidlauskiene, Joye, & Auruskeviciene, 2023). Recent advances in RL not only improve financial performance but also enhance customer satisfaction by offering contextually appropriate prices (Peng, Peng, & Xu, 2024).

4.3 Behavioural Adaptation

Behavioural adaptation highlights how AI models integrate cognitive biases into pricing strategies, aligning offers with consumer decision-making heuristics. Anchoring effects, loss aversion, and charm pricing are increasingly embedded within algorithmic designs (Huang & Rust, 2021; Erevelles, Fukawa, & Swayne, 2016). For example, charm pricing techniques—such as setting a price at €4.99 instead of €5.00—have been shown to significantly affect purchase intention (Jeong, Choo, & Yoon, 2021). Moreover, recent studies emphasise the role of behavioural targeting enhanced by AI in personalising price offers to individual cognitive profiles, thereby optimising perceived value and conversion rates (Prithi & Tamizharasi, 2025; Shan & Li, 2025).

4.4 Explainability and Fairness

The final dimension addresses the growing need for transparency and ethical safeguards in AI-based pricing systems. Explainable Artificial Intelligence (XAI) frameworks, such as SHapley Additive exPlanations (SHAP) and Local Interpretable Model-agnostic Explanations (LIME), are increasingly adopted to provide understandable rationales for algorithmic pricing decisions (Sestino & De Mauro, 2021; Davenport et al., 2020). This concern is particularly critical in pricing contexts where customers may perceive algorithmic adjustments as unfair or opaque (Peng, Peng, & Xu, 2023). Furthermore, regulatory frameworks like the General Data Protection Regulation (GDPR) are compelling firms to design pricing algorithms that are transparent, accountable, and free from discriminatory practices (Gerlick & Liozu, 2020; Elyakim, 2025). Research suggests that explainability not only supports legal compliance but also enhances consumer trust and loyalty, ultimately contributing to a more sustainable competitive advantage (Raphael et al., 2024; Zhou et al., 2025).

5 Conclusions and Implications

The present study contributes to the growing body of literature at the intersection of AI, behavioural economics, and pricing strategy by proposing an integrated framework that describes the four impact areas of AI in pricing and how they are linked to concrete use-case scenarios. It enriches existing theory by demonstrating how AI not only automates pricing decisions but actively co-shapes market dynamics and consumer behaviour. In line with Erdmann et al. (2024), the analysis highlights that ethical and sustainability dimensions must now be considered core criteria in evaluating AI-enhanced pricing models.

From a managerial perspective, the paper underscores that AI-powered pricing systems represent both a technological opportunity and an organisational challenge. Managers must not only select appropriate AI techniques—such as Extreme Gradient Boosting (XGBoost) for demand forecasting or Reinforcement Learning (RL) for real-time price adjustments—but also ensure their alignment with strategic objectives and ethical principles. As demonstrated by Harley-Davidson's experience with AI-driven campaign optimisation (Power, 2017), pricing engines achieve superior results when designed to iteratively learn from behavioural and

contextual data. Furthermore, for small and medium-sized enterprises (SMEs), a focused approach is critical: prioritising specific high-impact pricing applications over generic AI adoption optimises resource utilisation and strategic fit.

From a regulatory standpoint, the study reinforces the urgent need to develop coherent legal frameworks capable of addressing the opacity, discrimination risks, and asymmetries of power generated by algorithmic pricing systems. Gerlick and Liozu (2020) caution that unchecked personalised pricing can erode consumer trust and exacerbate social inequalities. In this regard, the integration of Explainable Artificial Intelligence (XAI) tools — such as SHapley Additive exPlanations (SHAP) and Local Interpretable Model-agnostic Explanations (LIME) — should be mandated for consumer-facing algorithms, particularly when price discrimination practices are involved. While initiatives like the European Union's AI Act and the General Data Protection Regulation (GDPR) lay critical foundations, issues related to enforcement and practical interpretability remain significant challenges.

The evolution of AI-driven pricing systems presents several promising avenues for future research. Empirical studies are needed to assess how different AI techniques — such as Reinforcement Learning (RL) and Explainable Artificial Intelligence (XAI) — influence consumer trust and long-term loyalty in dynamic pricing contexts (Sestino & De Mauro, 2021; Davenport et al., 2020). As new tools for algorithmic transparency are developed, it becomes increasingly important to evaluate not only their technical performance but also their perceptual impact on consumers. A relevant direction concerns the interaction between AI-based pricing and sustainability objectives. As highlighted by Raphael et al. (2024), the integration of AI in price management must increasingly incorporate environmental and social governance (ESG) criteria to ensure responsible innovation. Investigating how pricing algorithms can be optimised not only for profit maximisation but also for sustainable consumption behaviours represents a key opportunity for future studies. Interdisciplinary research is also essential to understand the broader socio-economic consequences of AI-powered price personalisation. Insights from behavioural economics, digital ethics, and consumer protection law can contribute to designing algorithms that balance personalisation with fairness and inclusivity (Gerlick & Liozu, 2020; Elyakim, 2025). Finally, long-term empirical investigations are necessary to explore the organisational capabilities and cultural transformations required for the successful implementation of AI-based pricing. We corroborate recent contributions (De Mauro & Pacifico, 2024) stressing that technological adoption alone is insufficient without corresponding changes in data governance, leadership strategies, and continuous learning practices. By addressing these areas, future research can enhance the effectiveness of AI-based pricing systems while contributing to the development of a more transparent, ethical, and sustainable digital economy.

6 Ethics Declaration

This study did not involve human participants, personal data, or ethically sensitive content requiring formal clearance. No ethical approval was necessary.

7 AI Declaration

This paper was developed with the support of an AI-based assistant for drafting and language refinement. All content has been reviewed and validated by the authors to ensure academic accuracy, integrity, and originality.

Knowledge Management in Diverse Organizations: A Meta-Data Analysis

Amarildo Zane, Fátima Guadamillas Gómez, Mario Javier Donate Manzanares
Universidad de Castilla-La Mancha, Toledo, Spain

Abstract

The concept of Diversity in the Workplace (DiW) and the Knowledge Management (KM) concept have been the subject of extensive analysis from a wide range of perspectives, typically at the micro, meso or macro level. However, there remains a paucity of research addressing the interrelation between these two concepts. The present study adopts an exploratory approach, utilising a bibliometric co-citation and coupling technique in conjunction with a comprehensive literature review. This approach offers novel insights into the past and present dynamics of the intellectual structure. The co-citation study reveals three predominant clusters within the intellectual structure, two of which are associated with the primary variables, i.e. KM and DiW, while a third serves as a theoretical framework for the interrelation between KM and DiW. In contrast, contemporary research trends are oriented towards the role of the TMT (or upper echelons in general) in KM, the significance of inter-organizational collaboration, and the management of "distance" due to heterogeneity. This study aims to explore the interrelation between DiW and KM. The findings reveal that the intellectual evolution of research commences with the concept of DiW, progressing to KM, and culminating in the theoretical nexus between them.

Paper type: Academic Research

1 Introduction

According to the latest report published by Eurostat (2024), the foreign-born represent 13% of the total EU population. Things get even more interesting when considering the age range between 15 and 64 years old as very close to the age of the active European workforce. The data indicates that 15.6% of the European workforce is composed of foreign-born employees. In other words, considering a team of 10 members, very probably, that there will be two almost two foreign-born members. The situation seems to be even more intense when considering the United States of America. In fact, according to the data published by the Federal Reserve Bank, in January 2025, 19,5% of the total American workforce is foreign-born. In 2007, only 15,58% of the workforce was foreign-born, confirming an exponential increase of almost 27%.

The increasing international interdependence among organizations, partly driven by globalization, has introduced significant challenges that must be addressed Fischer (2003). Among these challenges, the effective management of DiW—both within and beyond organizational boundaries—stands out as particularly critical (Nishii & Özbilgin, 2007; Singh, 2018). This necessity is even more pronounced in today's VUCA (volatile, uncertain, complex, and ambiguous) environment, where rapid and appropriate strategic adjustments are essential (Rathore et al., 2021). In this regard, scholars such as Urbancová et al. (2020) and Erburu et al. (2005) argue that if managed effectively, DiW can lead to a sustainable competitive advantage, as theorized by Barney (1991).

Conversely, KM has emerged as one of the most critical capabilities for contemporary organizations, as it serves as a key driver of sustainable competitive advantage (Mahdi et al., 2019). In this context, Torres et al. (2018) analyzed the relationship between knowledge-related factors, such as human capital while Johannessen and Olsen (2003) emphasized the importance of dynamic, context-specific training.

Nevertheless, there has been a paucity of attention paid to the interrelation between DiW and KM. By "interrelation," we refer to the bidirectional interactions among these variables. In essence, this entails the inquiry into whether DiW exerts a driving influence on KM practices, or if effective KM practices engender DiW.

To shed light on this "black box", the authors adopted a mixed methodology, combining the bibliometric approach, based on co-citation, and bibliometric coupling techniques, as well as a selective literature review. The bibliometric study was conducted following the PRISMA protocol (Moher et al., 2015) and adhered to the guidelines proposed by Donthu et al. (2021) and Zupic and Čater (2015).

Based on this framework, the following research questions were established:

- *RQ1: What are the general dynamics surrounding the interaction KM-DW*
- *RQ2: What is the intellectual structure of the research*
- *RQ3: What are the current research trends*

2 Theoretical frameworks

2.1 Knowledge Management

To manage knowledge as an asset in an effective manner, it is first necessary to develop a comprehensive understanding of the concept since there is not a general and universally accepted definition. Among the most salient definitions of knowledge is that proposed by (Davenport and Prusak 1998: 5) which define it as *a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information.* In contrast, I. Nonaka (1994) defines knowledge as being *"justified truth".* However, to properly exploit this valuable asset it is extremely important to properly manage it (Alavi and Leidner 2001; Omotayo 2015). In this regard, generally, scholars refer to KM as the process of capturing, organizing, storing, and sharing knowledge within an organization to enhance its overall performance and competitive advantage.

Grant (1996a), posits that, under the knowledge-based theory of the firm, the most salient characteristics for effective knowledge utilization are transferability, capacity for aggregation, appropriability, specialization in knowledge acquisition, and the knowledge requirements for production. The whole KM process is comprised of various phases, which are categorized into two fundamental categories: knowledge creation and knowledge application. The former encompasses activities such as knowledge creation and acquisition, with consideration for the knowledge's origin, whether internal or external. Conversely, the second category is more focused on activities such as integration, transferability, storage, measurement, and protection.

In the field, special relevance has the SECI model proposed by L. Nonaka et al. (1996). The model distinguishes between tacit and explicit knowledge and based on their interaction explains how knowledge is created and converted. Other authors have highlighted the relevance of knowledge as a strategic resource that can further improve the competitiveness of an organization (Boisot 1998; Donate and Canales 2012; Tallman et al. 2004) or lead to a sustained competitive advantage (DeNisi et al. 2003)

2.2 Diversity in the workplace. Dimensions, benefits, and challenges

Despite the absence of a universally accepted definition of the concept of diversity, it is generally understood within organizational contexts to denote the presence of individuals from diverse backgrounds, encompassing, but not limited to, factors such as race, ethnicity, gender, age, religion, sexual orientation, disabilities, and cultural backgrounds. This concept encompasses a range of dimensions that contribute to the richness and variety of perspectives within an organization (Cox & Blake, 1991).

Different authors have enhanced the benefits that DiW can generate in an organization (Smith & Schonfeld, 2000). Among them, DiW enhances innovation and creativity as it fosters the generation of new ideas and solutions by bringing together individuals with different perspectives and knowledge being in some specific situations a source of conflict as well (Bassett-Jones 2005). Diverse teams are more likely to challenge conventional thinking, encouraging creativity and innovation (Hoever et al. 2012; Paulus 2000). In addition, Cummings (2004) has pointed out the significant improvement in problem-solving and decision-making. Diverse teams consider a wider range of viewpoints and approaches when addressing complex problems. They bring different insights and experiences, leading to more comprehensive and effective decision-making processes. Also, DiW might generate increased adaptability and flexibility capabilities. Organizations with diverse workforces are better equipped to adapt to changes in the business environment. Different backgrounds and perspectives facilitate flexibility and agility in responding to market shifts and customer demands (Boone & Hendriks, 2009).

Proper management of the DiW can lead to other benefits such as enhanced employee engagement and satisfaction. Inclusive environments that value diversity create a sense of belonging and psychological safety for employees(Downey et al. 2015). When individuals feel respected and valued for their unique contributions, it leads to higher levels of engagement, job satisfaction, and retention (Rich et al. 2010). Also, there are many challenges related to the concept of diversity such as discrimination, communication and language barriers, resistance to change, Inclusion and lack of representation, group dynamics, and internal conflict.

3 A mixed methodology

The present research proposes a mixed methodology, combining a systematic literature review with a bibliometric approach. Specifically, the literature review identified the top 10 most relevant articles in the field, based on the received citations (Liang et al. 2011) which are considered to be one of the most relevant and used indicators of scientific production (Abramo et al. 2015). This combination of strategies has been implemented in various research studies, as these techniques are considered to be complementary (Zupic and Čater 2015). For instance, Feng et al. (2017) employed the same methodology to investigate the relevance of corporate social responsibility for the supply chain. Conversely, Bawack et al. (2022) utilized the same methodology to analyze the utilization of Artificial Intelligence in E-Commerce. In addition, Rashmi and Kataria (2022) utilized the same methodology in the context of work-life balance.

In general, the complementarity between the systematic literature review and the bibliometric techniques has been approached in two different ways. Firstly, according to Linnenluecke et al. (2020), the proper bibliometric visualization of the findings and discussion generated from the literature review renders the entire process replicable and more scientific. Consequently, the authors propose a guideline to be followed to properly enlarge the literature review section by using bibliometrics as a tool to visualize the data. Additionally, Marzi et al. (2025) have proposed a mixed methodology, termed the Bibliometric Systematic Literature Review (B-SLR), which combines the strengths of both approaches while mitigating their respective limitations. In this research, the literature review was conducted considering articles as research unit rather than at a cluster level, since one of the objectives was to properly identify the dynamics surrounding the research topic.

3.1. A bibliometric approach

Bibliometric studies generally retrieve the data from the Web of Science (WoS) or Scopus database. In cases where the data set is limited, both databases can be used, or other databases such as Google Scholar, PubMed, or JSTOR can be added. In this instance, the decision was taken to utilize the WoS platform, primarily due to its historical academic relevance and the current trends observed in metadata studies. Despite the increasing relevance of Scopus, WoS continues to lead the field, with 50.1% of published articles relating to meta-data analysis (Zhu and Liu 2020).

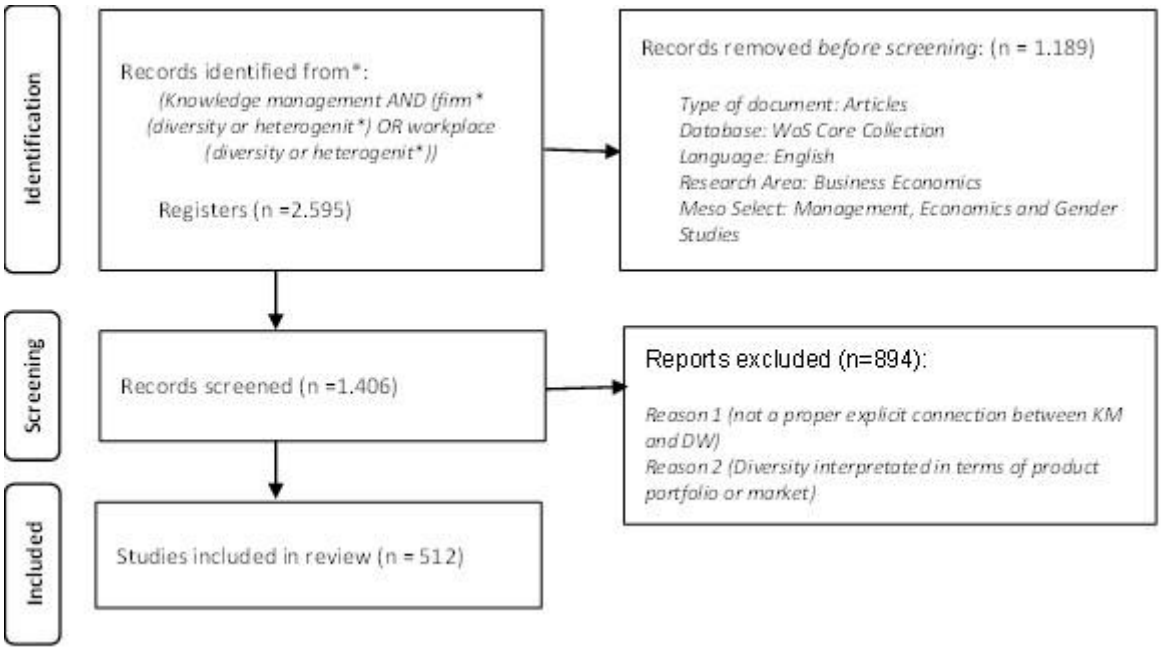

Figure 1: PRISMA Flow-Chart

Following the guidelines proposed by Donthu et al. (2021), Zupic and Čater (2015), and PRISMA Flow-Chart after launching the query *(Knowledge management AND (firm* (diversity or heterogenit*) OR workplace (diversity or heterogenit*))* a total of 2.595 articles were obtained. To further increase the coherence of the research during the before-screening process a total of 1.189 articles were removed mainly because not part of the WoS Core Collection, Social Sciences Citation Index (SSCI); Research Area (Business Economics), and Meso Criteria.

Based on previous bibliometric studies, the initial 50 articles were revised by all the authors part of the research. Then, in a second moment, all the results were shared among them to analyze the coherence of the selective criteria implemented. After a second round of reviews the total selective criteria coherence was reached based on the previously established selective criteria: a) there must be a proper and explicit link between KM and DW, b) Diversity should be interpreted in terms of workplace, either permanent or ad hoc teams. Therefore, out of the initial dataset of 2.595 articles just 512 of them meet the selection criteria.

3.1.1 Descriptive statistics

As a response to the RQ1, according to the "*analyse results"* section that the WoS Platform offers, 428 articles have been classified under the management Wos category hence very close to 81%. The second most relevant category is Business with 278 articles or 54% of the total of the articles. The rest of the categories are economics (n=40: 7.8%), engineering industrial (n=38: 7.4%), and psychology applied (n=34: 6.7%). Also, considering the number of articles published per year, the trend has always been positive till 2021, where certain maturity can be noticed but with a strong recovery trend. In fact, from 2014 to 2024 there has been an increase of 84.2% in scientific production. Also, interesting insights emerge while analyzing the micro topics related to the research. The data indicates that knowledge management is the core micro topic (n= 259: 50.5%) followed by job satisfaction (n=78:15.2), corporate governance (n=43: 8.3%), and internationalization (n=36: /%). On the other hand, considering the country of origin, the USA is the leading country almost 33% of the total scientific production has been generated there. The second place is held by the People's Republic of China (PRC) with almost 14% of the production. The rest of the top 10 country contribution follows the following trends England 13%, Italy 8.7%, Spain 8%, Netherlands 7%, Taiwan 7%, Germany 6.6%, Australia 6.3% and finally France 5.4%.

3.1.2 Top ten articles literature review

The below table illustrates the top ten most relevant articles according to the citation received in WoS out of the original dataset of 512 articles. We decided to use the citation instead of other filters such as pertinence as it is the selected indicator generally and traditionally has been linked to the quality of the research. It is important to mention that not all the articles have as their main objective to analyze the interrelation between KM and DiW, however, it is secondarily mentioned as part of the model or the theoretical framework.

Table 1: Literature Review: Top 10 most-cited articles.

Year	Tot Cit.	Author	Knowledge stage	Diversity type/locus	Output	Underlying theory	Main findings
2000	2027	(Dyer and Nobeoka 2000)	Sharing Creation	Deep-end/Meso: Macro /Inter-Organizational	Knowledge Network	Knowledge-Based Theory of Firms	A well-managed and structured knowledge sharing-network fosters the knowledge sharing and creation
2004	998	(Cummings 2004)	Sharing	Deep-end/Meso Inter-Organizational	External Knowledge Sharing	Social Capital	Structural diversity enhances knowledge-sharing
2010	832	(Volberda et al. 2010)	Acquisition Integration	Deep-end/Macro	Homogenize the concept of Absorptive Capacity	Absorptive Capacity Dynamic Capabilities	A model highlighting the antecedents, processes, and outcomes of absorptive capacity
2004	785	(Rodan and Galunic 2004)	Sharing Integration	Deep-end/Micro	Managerial performance and innovativeness	Knowledge-Based Theory of Firms	To foster managerial performance and innovativeness It is essential to have a heterogeneous network.
2007	746	(Sampson 2007)	Acquisition Integration	Deep-end/ Inter-Organizational	Innovation	Absorptive Capacity Organizational Learning	An inverted U shape relationship between partner's knowledge heterogeneity and innovation
2005	613	(Hinds and Mortensen 2005)	Sharing	Not Specified (Geographical)/Meso	Conflict Management	Social Identity	How geographical dispersion affects team conflict and the roles that shared identity, shared context, and spontaneous communication play in moderating this relationship

Year	Tot Cit.	Author	Knowledge stage	Diversity type/locus	Output	Underlying theory	Main findings
2011	597	(Bell et al. 2011)	Creation Sharing	Surface: Deep-end/ Meso	Team performance	Value in diversity	Diversity in functional background, education, and organizational tenure is closely tied to knowledge variety. Traits like age, gender, and race/ethnicity are less directly connected to knowledge content, but they can still influence knowledge exchange via
2004	568	(Almeida and Phene 2004)	Creation Integration	Deep-end/ Inter-Organizational	Knowledge creation	Knowledge-Based Theory of Firms	By leveraging the technological strengths of the MNC and fostering robust relationships with local firms, subsidiaries can enhance their knowledge creation and innovative performance.
1992	531	(Michel and Hambrick 1992)	Integration Creation	Deep-end/Meso	Need for managerial characteristics	Upper Echelons Resource Based View	The greater the need for interdependence posed by a firm's diversification strategy, the greater its top team's firm-wide operating knowledge base.
2011	523	(Østergaard et al. 2011)	Creation	Surface:Deep-end/ Meso	Innovation	Knowledge-Based Theory of Firms Value in diversity	A positive correlation exists between diversity in employees' educational backgrounds and the introduction of innovations

In constructing the literature review matrix, the authors elected to incorporate fields associated with each of the primary variables encompassed by the research, including the knowledge stage in relation to KM as outlined by Grant (1996b). Furthermore, diversity type and locus, referring to the superficial and deep-end diversity and the micro, meso, and macro level, were included as directly linked to the DiW variable. To comprehensively identify the mechanisms underlying the interrelationships, the underlying theory, outcomes, and primary findings were incorporated.

The findings indicate that the interrelation KM-DiW follows specific dynamics. Firstly, regarding the dimension of diversity, the results indicate that deep-end diversity is of particular relevance in the proposed interrelation. Indeed, of the ten most cited publications, Østergaard et al. (2011) highlight aspects of surface diversity, including gender, age and ethnicity. However, only gender and education (deep-end diversity dimension) were found to be relevant to innovation. About the locus of diversity, the meso level is worthy of particular attention, given that most of the research has been focused on the effect on team performance. In certain instances, the TMT should be considered, while in others, a more generalist team perspective should be adopted. It is also noteworthy to observe that this interrelation is, in certain instances, associated with the emergence of a novel diversity locus, such as inter-organization, consequent to the firm's diversification, thus giving rise to novel diversity dynamics.

Furthermore, the interaction between DiW and KM has been approached under different theoretical frameworks according to the literature review conducted. For instance, the resource-based view (RBV) provides a theoretical framework to understand how firms can leverage unique resources such as knowledge and DiW or capabilities such as KM to gain a competitive advantage. The framework suggests that DiW can enhance the knowledge available within the organization, leading to increased innovation, problem-solving ability, and adaptability especially relevant in VUCA environments.

In addition, the knowledge-based theory (KBT) initially proposed by Grant (1996a) as an extension of the RBV framework provides valuable insights, highlighting the mechanisms through which KM practices can facilitate and enhance diversity within organizations. The core idea behind the KBT theoretical framework is diverse teams hold varied tacit and explicit knowledge based on their personal characteristics and functional backgrounds. Therefore, the diversity of the explicit and implicit outputs con further increases the organizational knowledge base. This theory shares important aspects with the organizational learning theory as well since further highlights the process through which an organization creates, retains, and transforms knowledge.

Furthermore, the social capital theory seems to carry special relevance while considering the proposed interrelation since it enhances the relevance of the formal and informal networks within our abroad organization. In the proposed interrelation the theory closely interacts with the cognitive diversity theory sharing the idea that different cognitive frameworks lead to new knowledge. This is due to the fact, as previously mentioned that DiW in the proposed interrelation has been generally analyzed under the deep-end dimension. Men et al. (2019) demonstrated that cognitive team diversity has a moderating role in two relationships such as knowledge sharing - absorptive capacity and knowledge sharing - knowledge integration.

The Dynamic Capabilities Theory as proposed by (Teece et al. 1997) very often closely interacting with the absorptive capacity theory has also been implemented. The main idea is that DiW by interaction with KM leads toward new capabilities very relevant to the current VUCA environment. For instance, Roberson et al. (2017) analyzed the relevance of diversity management while considering knowledge management under the dynamic capabilities prospect, indicating a direct impact on the market, operations, and stockholders.

Finally, the value in diversity and the upper echelons diversity are more related to the relevance of the DiW concept. The main idea is that DiW should be considered a strategic asset since it can generate unique resources and capabilities for the organization. Generally, scholars have highlighted in the process of value creation the characteristics of the top management teams (TMT) since directly involved in the decision-making process.

3.1.3 Co-citation

In response to RQ1, which pertains to the identification of the intellectual structure, or, as defined by Donthu et al. (2021) the *"past"* of the research, the authors implemented a bibliometric co-citation technique. It indicates the number of times two articles are co-cited in other works; therefore, it provides some useful insights to properly identify the intellectual ground of the proposed research topic. The resulting scientific network map is indicated in the figure below:

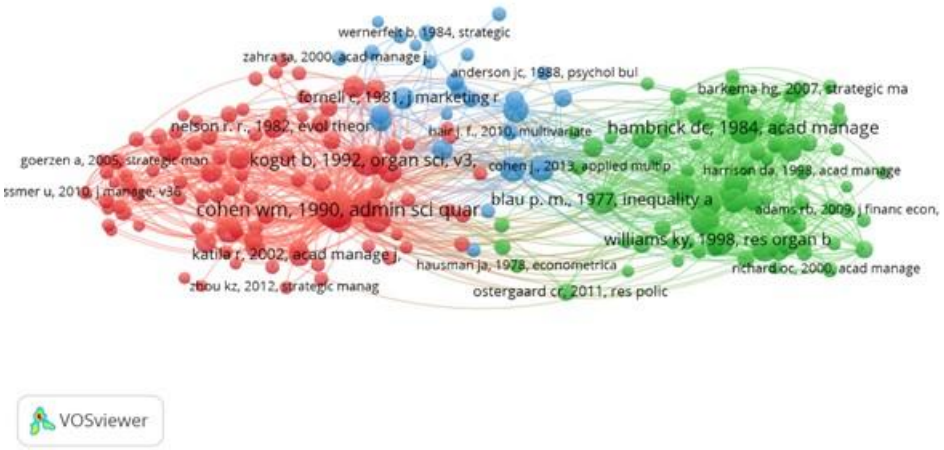

Figure 2: Co-Citation Network

The results obtained indicate a scientific network map composed of three clusters, indicated with red, blue, and green colors. In order to further understand the dynamics of the clusters, table number one indicates the most relevant co-cited articles according to the total link strength. This is interpreted as the general relevance of the articles among all the links.

Table 2: Top 10 most co-cited articles

Year	Autor	Title	Cluster	Links	Total link strength
1990	Cohen et al	Absorptive capacity: A new perspective on learning and innovation	1	194	1918
1984	Hambrick et al	Upper Echelons: The Organization as a Reflection of Its Top Managers	2	176	1278
1992	Kogut et al	Knowledge of the Firm, Combinative Capabilities, and the Replication of Technology	1	190	1206
1998	Williams et al	Demography and Diversity in Organizations: A review of 40 years of research	2	176	1183
1977	Blau P.	Inequality and Heterogeneity	2	191	1140

Year	Autor	Title	Cluster	Links	Total link strength
2007	Harrison et al	What's the difference? diversity constructs as separation, variety, or disparity in organizations	2	180	1093
1999	Pelled et al	Exploring the Black Box: An Analysis of Work Group Diversity, Conflict and Performance	2	183	1091
1991	March JG.	Exploration and Exploitation in Organizational Learning	1	192	1029
2006	Laursen at al	Open for innovation: the role of openness in explaining innovation performance among U.K. manufacturing firms	1	180	1013
1989	Bantel et al	Top management and innovations in banking: Does the composition of the top team make a difference?	2	169	972

As is can be noticed, clusters one and two are of particular significance. Forty per cent of the ten most cited articles are in cluster one, while the remaining articles are in cluster two. There is an absence of cluster three. The first cluster appears to be more closely associated with KM, with an approach encompassing diverse perspectives, including absorptive capacity Cohen and Levinthal (1990), firm knowledge (Kogut and Zander 1992), and the significance of exploration and exploitation in organizational learning (March 1991) considering the possible effects of KM over firms innovation capabilities. Consequently, the designation of the cluster as "Knowledge Management" appears to be a rational proposition. However, a general tendence of the cluster is that DiW has been paying special attention to the surface level of the diversity under a meso level, very often for the upper echelons perspective.

Conversely, cluster number two appears to be more oriented towards the DiW concept, approaching it from different perspectives and locus. Hambrick and Mason (1984) analyzed the DiW through the lens of the Upper Echelons theory, thus focusing on senior management roles. A similar trend was followed by Bantel and Jackson (1989), but with a focus on the banking sector. Conversely, alternative authors have approached the DiW concept from a macro perspective (Blau 1977; Harrison and Klein 2007; Williams and O'Reilly III 1998).

Finally, although the three articles under the third cluster do not appear in the top ten, they are of particular significance as they elucidate the methodology of the interaction between KM and DiW. Among the most salient theories, as previously indicated, some are more closely associated with the theoretical component, while others are more closely associated with the theoretical arguments. For instance. Aiken (1991) proposed the guidelines to be followed while considering multiple regressions while Podsakoff et al. (2003) paid special attention to the common method biases in behavioral research and to use of self-report measures in organizational research (Podsakoff and Organ 1986). Additionally, Fornell and Larcker (1981) proposed the use of structural equation models considering unobservable variables. Besides, the relationship KM-DiW lies on theories such as RBV as proposed by Barney (1991). In addition. Teece et al. (1997) proposed the dynamic capability theory to integrate, build, and reconfigure resources as a response to the always-changing network. Furthermore, I. Nonaka (1994) proposed the Knowledge-Based Theory of Firms. Also, Cyert and March (2015) established the ground for the Behavioral theory of the firm. In addition, Grant (1996b) highlighted the relevance of a firm's ability to integrate knowledge based on RBV, Dynamic Theories, and the Knowledge-Based Theory of Firm highlighted the relevance of a firm’s ability to integrate knowledge. Finally, Hitt et al. (1997) based on BRV and the Knowledge-Based Theory of Firms proposed an international perspective establishing a positive relationship between international diversification and R&D activity.

Considering the average publication year for top five articles of each cluster, the research flow seems to start with the DiW concept (1992) by then switching to Knowledge Management (1994) and finally on the theoretical connection between the two previously mentioned concepts.

3.1.4 Bibliometric coupling

In Donthu et al. (2021) words, the bibliometric coupling corresponds to the “current” dynamics of the chosen research topic. Following Rojas-Lamorena et al. (2022) in the bibliometric coupling we only considered the last five years of the research activity, in other words, 2024, 2023, 2022, 2021, and 2020. The technique refers to bibliometric coupling when two documents cite a common third one, therefore it very relevant in order to undercover the current research dynamics.

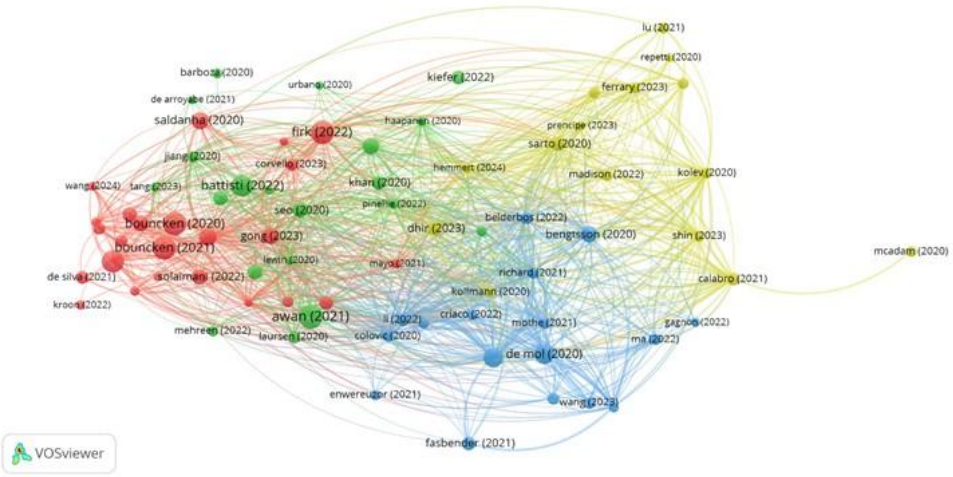

Figure 3: Bibliometric coupling

The data indicate a scientific map composed of four clusters, each one of them indicated with a different color. More specifically, cluster one is indicated with red color, cluster two with green color, cluster three with blue color, and finally cluster four with golden color. To properly analyze the dynamics surrounding the current research, below are indicated the top 10 most relevant articles in bibliometric coupling according to the total link strength considered as the total number of the shared articles between the specific articles, following therefore the same methodological as in the case of co-citation study.

Table 3: Top 10 biometric coupling articles

Year	Authors	Title	Cluster	Links	Total Link Strength
2021	Richard et al	The Effects of Racial Diversity Congruence between Upper Management and Lower Management on Firm Productivity	3	60	257
2021	Li et al	Leveraging age diversity for organizational performance: An intellectual capital perspective	3	62	242
2022	Li et al	From inclusive climate to organizational innovation: Examining internal and external enablers for knowledge management capacity.	3	59	236
2020	Kolev et al	Board demography and divestitures: The impact of gender and racial diversity on divestiture rate and divestiture returns	4	42	226
2022	Belderbos et al	Top management team international diversity and the performance of international R&D	3	53	200
2021	Calabro et al	Entrepreneurial Orientation and Family Firm Performance: The Moderating Role of TMT Identity-Based and Knowledge-Based Faultlines	4	48	193
2023	Shin et al	Faults and Faultlines: The Effects of Board Faultlines on CEO Dismissal	4	40	193
2020	Sarto et al	Human capital and innovation: mixing apples and oranges on the board of high-tech firms	4	47	191
2024	Hemmert et al	Enhancing innovation through gender diversity: a two-country study of top management teams	4	56	183
2020	Colovic et al	Group culture, gender diversity, and organizational innovativeness: Evidence from Serbia	3	56	179

Some interesting insights emerge from the bibliometric coupling. First, according to the total link strength the current research is dominated mainly by the green and golden cluster, since the red and blue are blue one seems to be not primarily relevant as not part of the top 10 articles. Considering the main research topics of every cluster the cluster have been have named:

The blue cluster (3) “Approaching the surface diversity” as the articles part of it pays special attention to this dimension even though in some cases international work experience (Belderbos et al. 2022) or external contingency (Li et al. 2022) is mentioned. The authors generally agree on the fact that surface diversity leads to a wider knowledge base that can serve as a mediator or directly impact firms’ innovations and, therefore, their general performance.

On the other hand, the golden cluster (4) was denominated as “TMT activity” analyzing the effects of the TMT characteristic’s composition on outcomes such as divestiture rate, CEO dismissal, and innovation generally under a deep-end diversity since it leads to new knowledge base or sharing.

Regarding the rest of the clusters, the red one (cluster 1) seems to be more related to the KM paying special attention to the distance due to the heterogeneity that might exist at a meso, macro, or inter-organization level and to its repercussion over the innovation (Wen et al. 2021) in some cases, either digital (Firk et al. 2022) or radical (Gong et al. 2023).

Finally, the green clusters (number 2) seem more related to the inter-organization partnership considering the effects of the partnership heterogeneity either over firms' strategies such as internationalization (Haapanen et al. 2020; Lewin et al. 2020), HRM politics related to the cross-border collaboration (Seo et al. 2020) or new Venture (Yu and Wang 2021).

4 Conclusions

A paucity of research has been identified while explicitly linking DiW with KM. This has prompted our exploratory research, the findings of which generate interesting practical and theoretical implications. The performed literature review reveals that the interrelation pays special attention to the deep-end dimension of the diversity, frequently under a meso level that quite often corresponds to the TMT level. In certain instances, a novel dimension of heterogeneity, such as inter-organizational, is incorporated. The proposed interrelation gives rise to a variety of outcomes, including the creation and consolidation of knowledge networks, the generation of new knowledge, knowledge sharing, enhanced innovation, improved problem-solving capabilities, and enhanced firm performance whether under a financial or non-financial perspective.

In addition, in response to the RQ1, the results indicate that the proposed interrelation has been analyzed under a management focus primarily highlighting therefore the relevance of proper management. Also, data indicate that the two most relevant countries in terms of research are the USA and China. As for the intellectual structure composition, it is composed of three main clusters. Two of them correspond to the main research variables such as DiW and KM and the third one corresponds to the theoretical framework linking them such as the Organizational Learning, Knowledge-based view of firms, the Resource-based view, and dynamic capabilities. The findings are quite reasonable since to properly understand the proposed interrelation and the correspondent dynamics it is extremely important to better understand each one of the variables. Finally, regarding the bibliometric coupling, the data confirms that the current research topic is generally concentrated on KM, the role of the TMT characteristics generally under a surface.

The proposed research suffers some limitations such as the researcher’s subjectivity during the bibliometric implementation. Also, the fact that in some papers there was not a direct and explicit relation between DiW and KM but an indirect mention of it generally considering the role that KM covers in the interaction between. Therefore, for future research lines, would be interesting to uncover the new trends, perhaps with the use of a bibliometric study based on keywords.

5 Ethic declaration

During the elaboration of the present paper there was no need for ethical clearance since the secondary information was provided from official scientific databases such as Web of Science (WoS).

6 AI declaration

During the elaboration of the present paper, DeepL has been used from time to time to properly traduce and format the text.

Bibliometric Ensemble-Based Community Detection Analysis of AI, Knowledge Management, and Emerging Technologies Convergence in Business Paradigms

Carlo Drago[1], Francesca Valentina Giglio Moro[1], Angelo Leogrande[2]
[1]University Niccolò Cusano, Rome, Italy
[2]LUM University Giuseppe Degennaro, Casamassima (BA), Italy

Abstract

This work has investigated the convergence of the business paradigms of artificial intelligence, knowledge management, and emerging technologies. This work uses a relevant new database that considers the scientific literature on the field. The bibliometric methods used were related to the multiple correspondence analysis, which helped construct a conceptual map, and ensemble community detection clustering, which helped identify the relevant "cores" of the literature. As a relevant result, we found the key role of data-driven strategies but also the necessity of rethinking education and training. In fact, the rise of AI as a very relevant technology in knowledge management can impact how firms create and store knowledge. Of course, these changes necessitate adequate organizational changes to facilitate the integration with the systems, process, and, most, people.

Keywords: Artificial Intelligence, Technology, Knowledge Management, Bibliometric Analysis, community Detection

Paper type: Academic Research Paper

1 Introduction

Artificial intelligence (AI)1 Other new technologies are increasingly finding their way into knowledge management (KM) (see Krüger, 2023; Nurlia, 2023). Knowledge management is concerned with increasing the value of intangible assets in organizations (Liebowitz, 1999). It is related to organizations' strategy to gain a competitive advantage in various areas, such as human resources, technology systems, and artificial intelligence (Liebowitz, 2001).

Artificial intelligence enables companies to manage large amounts of data, recognize patterns in the data, and gain insights to act on them. These capabilities enhance important aspects of traditional knowledge management, particularly digitizing knowledge creation, retrieval, and sharing (Gao et al., 2018).

Integrating new technologies such as blockchain, the Internet of Things (IoT), and cloud computing into direct knowledge-sharing platforms enables secure, scalable, and efficient knowledge dissemination. At the same time, blockchain ensures data integrity and trust, while IoT enables real-time data integration, and cloud computing provides the necessary computing power and scalability (Christidis & Devetsikiotis, 2016). Consequently, integrating these technologies has proven to be a key element in developing novel business accelerators that enable scalable, innovative, and sustainable solutions (Stiegler, 2021).

Emerging technologies combined with knowledge management form a revolutionary approach encompassing organizations' three main pillars: People, Processes, and Technologies (Obermayer & Tóth, 2021). Jarray et al. (2023) highlight the beneficial support that AI provides in the fundamental areas of knowledge management: creation—in the sense of reorganizing existing or acquired knowledge—storage and retrieval—for classifying and storing business information and practices—sharing—in the sense of improving communication between colleagues and employees—through AI platforms.

First, a growing body of literature on AI emphasizes its potential to improve knowledge-based processes (Fowler, 2000). In this context, for example, machine learning is increasingly used to automatically classify, store, and quickly retrieve knowledge assets (Zhou et al., 2020).

In this regard, the proposed analysis would show how new technologies can contribute to disseminating and collaborating knowledge and information.

Another future perspective from an initial literature review before the bibliometric analysis is the significant new subfields beginning to be explored more deeply. These include the increasing focus on ethics in AI and its impact on knowledge management work, particularly on eliminating bias and the transparency of decisions (see

[1] We thank an anonymous referee for their constructive suggestions.

Feldman et al. 2022). Linking sustainability and AI is another emerging area of research that testifies to the global demand for sustainability and ethically rewarding business behavior (see, e.g., Yiğitcanlar, T. 2021).

The present bibliometric approach can provide a framework for interdisciplinary research. This analysis is important for gaining insights into evolving research topics, themes, and opportunities. It is a solid approach to capturing the existing scientific literature in the field (Donthu et al., 2021; Aria & Cuccurullo, 2017; Drago et al., 2021; Gatto et al., 2023; Drago & Aliberti, 2019). The advantage of bibliometric analysis concerning a narrative or systematic literature review is that quantitative methods can be used to identify some "hidden patterns" that can be discovered. In this way, the bibliometric analysis is best suited to explore the literature to identify some relevant patterns like "cores" of the literature as groups of keywords considered together in scientific words and clusters of keywords indicating new research areas.

2 Data and Methodology

Bibliometric analysis, a systematic study of the scientific literature, allows researchers to track the evolution of this interdisciplinary field over time (Donthu et al., 2021; Aria & Cuccurullo, 2017). Based on citation networks, co-authorship patterns, and keyword co-occurrence, the most cited publications, prolific authors, and relevant research clusters with matching keywords can be extracted. Using an ensemble community detection approach, we can discover the literature's relevant and stable "core" (Drago, 2018; Drago et al., 2021).

The following analysis can provide a general picture of how AI and new technologies are integrated into KM and how this impacts organizational practice.

A bibliometric study can uncover some key emerging trends. In this way, starting from the initial query on Scopus using a relevant source for bibliometric studies, we obtained the bibliometric valuable database in the analysis of the literature (see Baas et al. 2020). The query considered was:

("artificial intelligence" OR "AI") AND "knowledge management" AND ("emerging technolog " OR "new technolog*" OR "digital technolog*").*

The query was performed on the day 25/12/2024. Then, it was possible to proceed to the exploratory analysis of the literature and identify the most relevant data structures using MCA multiple correspondence analysis and network analysis. Then, considering the publications' co-occurrence network, the authors identified the different communities using several community detection approaches (Fortunato 2010). Finally, it was considered an ensemble community detection MCA-based approach to synthesize the results obtained by the different community detection algorithms. In this way, the final results are reliable because they come from a hierarchical clustering validation process in which we identified the final number of clusters (Brock et al., 2008).

In this topic, a bibliometric analysis ensemble community-based approach (Drago, 2018) can obtain more robust results than a single algorithm. This approach has the potential to explore the foundations of the intellectual debate driving this change.

3 Results

The bibliometric analysis is performed using different methodological tools, as seen in the previous section. In particular, the starting point is to consider multiple correspondence analysis to identify a specific concept structure map with the literature's most relevant topics and themes. According to this premise, in Figure 1, which was obtained by performing the initial bibliometric dataset, the multiple correspondence analysis, we can identify three clusters of themes that can be considered mostly together. In this respect, when some themes are particularly close to others, these terms are considered together in the scientific articles, so they are the basis of a debate. In this respect, mapping the existing literature and identifying relevant themes is possible. Dimension 1 is related to the educational paradigms (on the left) versus the technological and methodological ones. Dimension 2 is related to human concerns (on the upper half) and technological concerns (on the lower half). It is possible to consider various themes in the literature, like education-related computing, e-learning, engineering education, and curricula. This last statement is relevant because education is a significant concern in this literature. This concern is also relevant on the second axis (dimension 2), where it is possible to consider various technologies and approaches. Considering the three clusters identified (the red, the blue, and the green), it is possible to identify the first relevant cluster on education (curricula, education concern, e-learning, engineering education). The fact that these technologies and approaches are so close means intense conceptual proximity of the different topics considered in the publications. In this first cluster, the proximity is not as high as in the second case, the blue cluster. Here is a stronger proximity of the concepts considered together in the scientific publications (for instance, knowledge transfer, emerging technologies, and information systems). Three focuses here are implementing artificial intelligence, knowledge management in practice in organizations,

and strategic aspects. Finally, the green cluster can be considered centered on the ethical aspects of the new technologies.

Then, it is possible to analyze the co-occurrence network of the keywords in the different studies to identify stable communities, which can be obtained from the consensus process described in Drago (2018). In particular, the multiple correspondence analysis achieved from the different memberships of the different community detection approaches used allows us to identify robust clusters.

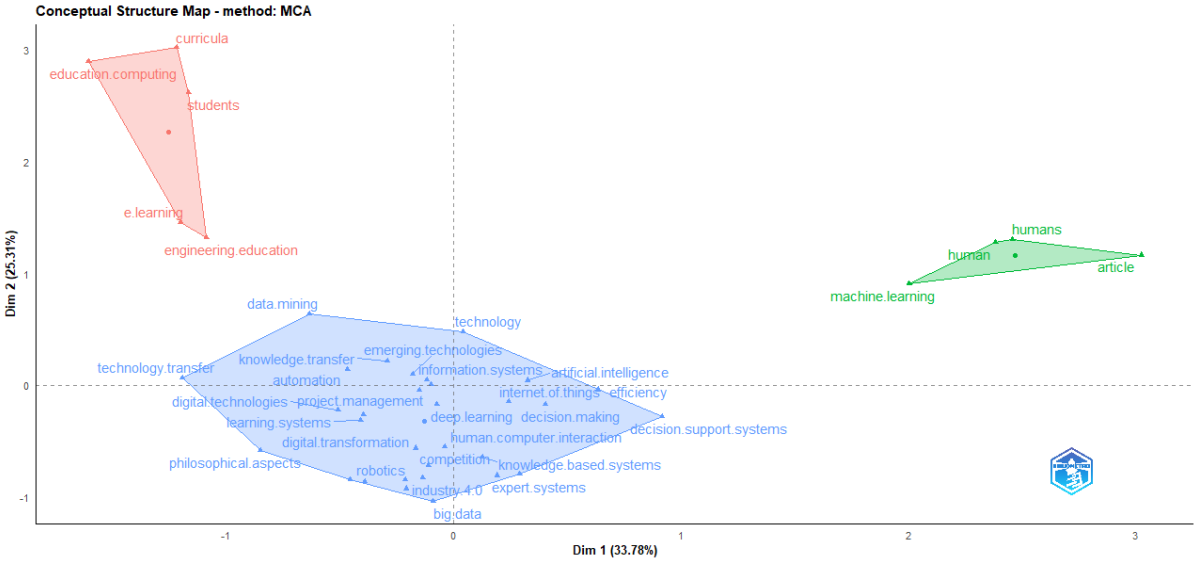

Figure 1. The Conceptual Structure Map using the MCA

The interpretation, from Figure 2, of the different clusters identified as relevant groups of concepts simultaneously considered together in the literature is the following:

- AI-driven knowledge management as standard practice: AI-supported knowledge platforms will become standard in companies, promoting automated and extended knowledge processes.
- Rise of knowledge analytics and predictive insights: Data-driven decision-making enabled by AI and machine learning will become a pivotal element of business strategies.
- Emerging paradigms such as e-health and digital health and their positive effects on the social ecosystems
- Emerging technologies transforming KM ecosystems and the associated effects: Blockchain, and new technologies impacting the workforce (and relative problems of training of the actual workers)
- Human-AI collaboration and cognitive augmentation in knowledge processing: AI can increase the workers' human capital
- Ethical AI in knowledge management: A new research direction is emerging that emphasizes ethical AI and sustainable knowledge management.

These can be identified as significant and economically relevant.

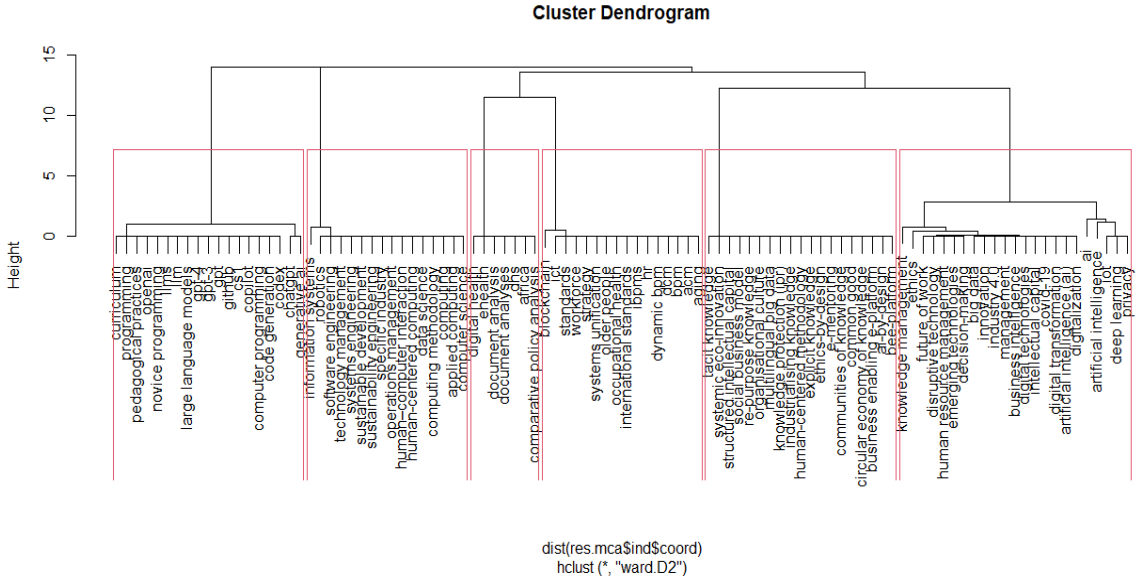

Figure 2. Hierarchical Clustering to identifying the relevant "cores" of the literature

4 Conclusions

This work has analyzed a new bibliometric dataset on the convergence of AI, Knowledge Management, and Emerging Technologies in Business Paradigms. The analysis was conducted using a bibliometric analysis focused on concept mapping and ensemble community detection, which is useful for identifying relevant groups of keywords maximally related to each other in the scientific literature.

The final result is that all agents' relevant aim is to maximize the benefits of these technological breakthroughs for growth and sustainable competitive advantage. Companies that effectively integrate AI and new technologies into their knowledge management strategies will gain a sustainable competitive advantage, improve decision-making, and drive innovation.

The introduction and development of AI in the KM strategy could be complete when organizations adopt generative AI and Narrow or Machine learning AI. The use of different kinds of AI can empower companies' performances and create a ground where capabilities are continuously enhanced.

To stay ahead, companies should take a data-driven, AI-powered approach to knowledge management while considering ethical, regulatory, and sustainability concerns. For this reason, education in this context is very relevant for companies and could be an important asset at every level.

5 Ethics declaration

The authors declare that ethical clearance was not required for the research due to the nature of the data used in the scientific study.

6 AI declaration

AI was used only to improve the readability and language of the work. This technology was used with control, and the results were carefully reviewed. We are ultimately responsible and accountable for the contents of the work.

Employee Withdrawal and Knowledge Management Processes

Martyna Skorupko, Malgorzata Zieba
Gdansk University of Technology, Gdansk, Poland

Abstract

This conceptual paper aims to identify and present the potential impacts of employee withdrawal on knowledge management processes in organizations i.e.: knowledge sharing & transfer, knowledge creation & development, knowledge application, and storage. Employee withdrawal is a subtype of counterproductive work behaviour and a critical issue for organisations. Specifically, it refers to a set of attitudes and behaviours used by employees when they stay at the job but for some reason decide to be less participative in duty engagement. Employee withdrawal may take either a physical or a psychological form and may begin with small and irrelevant actions like being late, or daydreaming, but they might culminate in more serious and significant behaviours like absenteeism, missing meetings, cyberloafing, or quitting that can be detrimental to the organization. Most research frames employee withdrawal behaviours as negative behaviours from the organizational point of view, mostly due to cost. However, a large proportion of organizational knowledge is personalized and resides in individuals' heads, therefore researching employee withdrawal behaviours is particularly critical in the context of knowledge management. To the best of the authors' knowledge, there are no publications that comprehensively describe the potential impact of employee withdrawal on different knowledge management processes. In the face of the above, there is a clear need to investigate how employee withdrawal behaviours may potentially harm knowledge sharing & transfer,, knowledge creation & development, knowledge application, and storage in organisations.
To do so, the authors of this paper related the found literature and described the potential impact of employee withdrawal behaviours on different knowledge management processes. Furthermore, the selected sources have been analysed in relation to each other, identifying conceptual overlaps which help in understanding how employee withdrawal behaviours may impact various knowledge processes.
Originality/value – The paper contributes to the understanding of the relationship between employee withdrawal behaviours and knowledge management processes.
Practical implications – The study provides food for thought for managers and owners on how the withdrawal behaviours of their employees might potentially hinder knowledge sharing, transfer, creation, development, application and knowledge storage in their organizations.

Keywords: Employee withdrawal, knowledge management, knowledge management processes

Paper type: Academic Research Paper

1 Introduction

Although employees are expected to exhibit positive attitudes and behaviours in the workplace, unfavourable behaviours may also be observed. Job satisfaction and motivation of employees fluctuate throughout their careers for various reasons. Withdrawal behaviours may result from occupational stress, unsatisfactory working, decreased job satisfaction (Beehr and Gupta, 1978) and may manifest themselves in many different forms in organizations. The researchers most often group the behaviours into two forms, namely physical and psychological withdrawal behaviours (Colquitt, Lepine and Wesson, 2013). Psychological withdrawal consists of actions that provide a mental escape from the work, and actions that allow the employee to physically escape from the work environment are referred to as physical withdrawal behaviours (Lehman & Simpson, 1992). Specifically, employee withdrawal refers to a set of attitudes and behaviours used by employees when they stay at the job, but for some reason decide to be less participative in their duty engagement (Kaplan *et al.*, 2009).

Globalisation and decentralisation in workplaces make it harder for supervisors to oversee their employees' performance, particularly in desirable but hard-to-achieve areas such as proactivity and creativity (Eldor and Harpaz, 2016). Similarly, not all managers or leaders are capable of readily recognizing signs of employee withdrawal in order to react promptly. Withdrawing employees, whose morale and motivation to work decrease can also demotivate others, which in turn can cause serious damage to the organisation and hinder its long-term development (Zhang *et al.*, 2023). Considering the high importance of employee commitment for the success of effective knowledge management in organisations (Stankiewicz and Moczulska, 2015), it may be expected that withdrawing employees may threaten it. Moreover, research by Deloitte has shown that technology alone is not enough to harvest the value of knowledge management, and argues that managers need to move beyond the narrow techno-centric knowledge paradigm because "traditional views of how to deal with knowledge no longer apply" (Weiss, Becker and Behme, 2021). In the context of generating, sharing, and managing knowledge,

organisations cannot underestimate the human factor (Weiss et al., 2021). Despite the growing importance of human factors in knowledge creating, sharing, preserving, and other knowledge processes, little is known about how employee withdrawal might influence them. To fill this knowledge gap, this paper aims to identify and present the potential impacts of employee withdrawal on knowledge management processes in organizations i.e.: knowledge sharing & transfer, knowledge creation & development, knowledge application and storage.

The paper develops in the following way. The second part presents the methodology, and the third section the concept of employee withdrawal. In the fourth section, potential impacts of employee withdrawal on knowledge processes are described. The last section concludes the paper.

2 Methodology

This present study contributes to the academic literature on employee withdrawal, knowledge management, and human resources management in general. This study is based on the analysis of the literature related to employee withdrawal and knowledge management processes. The authors related the found literature and assessed the potential impact of psychological and physical withdrawal behaviours on different knowledge management processes. To ensure methodological rigor and transparency, this paper adopts a structured approach to analysing and categorizing the literature on employee withdrawal and knowledge management processes. The research process involves a review of relevant academic literature. Furthermore, the selected sources are analysed in relation to each other, identifying conceptual overlaps, and divergences in understanding how employee withdrawal behaviours impact various knowledge processes. To provide valuable input, the authors assessed the relevance, empirical grounding, and applicability of each source. This systematic approach ensures that the paper moves beyond a simple synthesis, offering a structured and valuable contribution to knowledge management in the context of employee withdrawal.

3 Employee withdrawal

The theory on behavioural responses to adverse work events, declining organizational performance, and job dissatisfaction suggests that employees might react in one of four general ways - Exit, Voice, Loyalty, and Neglect (Kolarska and Aldrich, 1980). Two of them have been classified as withdrawal behaviours - Psychological withdrawal (neglect) and physical withdrawal (exit) (Colquitt, Lepine and Wesson, 2013). The withdrawal behaviour of the employee is defined by Spendolini (1985) as some form of volitional response to the perceived deterrent conditions designed to increase the psychological and physical distance between the employee and the organization. Since some withdrawal behaviours may share common antecedents, such as occupational stress or dissatisfaction with working conditions, they may be positively related (Beehr and Gupta, 1978). In Table 1, there are presented some forms of withdrawal behaviours identified in the literature, together with their definitions.

Table 1. Definitions of selected forms of employee withdrawal behaviours.

Physical withdrawal behaviours	
Long breaks	"Involve longer-than-normal lunches, soda breaks, coffee breaks, and so forth that provide a physical escape from work." (Colquitt, Lepine and Wesson, 2013)
Absenteeism	"Occurs when employees miss an entire day of work." (Muchinsky, 1977)
Missing meetings	"When employees neglect important work functions" (Colquitt, Lepine and Wesson, 2013)
Psychological withdrawal behaviours	
Daydreaming	"When employees appear to be working but are distracted by random thoughts or concerns." (Colquitt, Lepine and Wesson, 2013)
Cyberloafing	"Any voluntary act of employees' using their companies' internet access during office hours to surf non-job related Web sites for personal purposes and to check (including receiving and sending) personal e-mail." (Lim, 2002)
Employee silence	"Deliberate intention to withhold ideas, information, opinions, or questions about the job or organizational possible issues and improvements." (Van Dyne, Ang and Botero, 2003)
Turnover intention	"Voluntary, conscious, and intentional wilfulness to leave the present employer" (Tett and Meyer, 1993).
Looking busy	"An intentional desire on the part of employees to look like they're working, even when not performing work tasks."(Feizi *et al.*, 2012)

Importantly, employee withdrawal behaviour is difficult to detect because it can happen either physically or psychologically without others noticing, highlighting the significance of the problem for example during remote work (Syrek et al., 2022). Employee withdrawal may begin with small and irrelevant actions like longer breaks or daydreaming, but they might culminate in more serious and significant behaviours like absenteeism, missing meetings, employee silence, or even turnover intention, which can threaten knowledge management in organisations. In the following section, the potential impacts of these behaviours on knowledge processes will be discussed.

4 Potential impacts of employee withdrawal on knowledge processes.

Any knowledge activities require the involvement of employees, their focus on work, organization, and environment, and the effectiveness of knowledge processes depends on employees' behaviours and their skills (Stankiewicz and Moczulska, 2015). Taking this into account, employee withdrawal may adversely impact various processes related to knowledge management in organizations. The authors of this paper analysed the found literature and described the potential impact of psychological and physical withdrawal behaviours on different knowledge management processes. Furthermore, the selected sources are analysed in relation to each other, identifying conceptual overlaps, which helps in understanding how employee withdrawal behaviours may impact various knowledge processes.

4.1 Knowledge sharing & transfer

The first, most intuitive and researched impact of employee withdrawal relates to knowledge sharing, because its effectiveness largely depends on the willingness of knowledge workers to share their intellectual resources with others (Hajric, 2018). Employee withdrawal refers to a range of negative behaviours that distance the employee from the organisation and weaken ties (Liao *et al.*, 2022). Since knowledge sharing is an act of voluntary exchange of information, skills, or insights (Davenport, 1997), one can also expect a high negative impact of withdrawal on knowledge sharing. According to Jacobs and Roodt (2007), those employees who intend to leave in the future avoid sharing knowledge with their coworkers, and according to Tian *et al.* (2021), employee withdrawal behaviours negatively impact employee willingness to share tacit knowledge. A sign of employee withdrawal is exhibiting less effort and work motivation than usual, therefore knowledge sharing might be completely neglected. If employees withdraw physically, meaning they are absent for the entire day, miss meetings, or make long breaks to avoid work, it is apparent that their knowledge cannot be shared when someone needs it. Frequent or prolonged absenteeism, and missing meetings, mean less opportunity for knowledge transfer, which in consequence can create delays in projects where knowledge transfer is crucial. For new hires, the absenteeism or quitting of experienced employees can lead to incomplete knowledge transfer during onboarding. In contrast, psychological withdrawal can be particularly dangerous in terms of its impact on knowledge sharing. When an employee is engaging in psychological withdrawal, “the lights are on, but nobody’s home.” (Feizi *et al.*, 2012). All activities like cyberloafing, daydreaming, and looking busy, provide mental escape from work. Therefore, even if individuals may seem to be physically present at work, they may be psychologically dispatched and do not engage in sharing their knowledge with others. Formalised training may be an employee's responsibility and a task delegated by a superior. Nevertheless, the quality of the training may be worse, causing fragmentation and potential loss of critical organizational knowledge. Knowledge sharing is perhaps the single most important aspect of the knowledge processes since the vast majority of knowledge initiatives depend upon it (Hajric, 2018), and may potentially be the most exposed to the negative impact of employee withdrawal.

4.2 Knowledge creation & development

Employee withdrawal undermines an organizational capability to effectively create and develop knowledge. Creating new knowledge is an important goal for most organizations, but it is difficult to achieve. According to Nonaka and Takeuchi (1995), effective knowledge creation depends on a high degree of personal commitment. Therefore, one can expect that both forms of employee withdrawal may severely hinder the creation of new knowledge. Knowledge creation involves tapping into the tacit and often highly subjective insights, of individual employees (Nonaka and Takeuchi, 1995). Those who withdraw from organizations might not take part in any form of discussion, reflection, or brainstorming sessions and may abandon sharing their insights to not make them available for testing and use by the company as a whole. Developing new ideas, improving processes, and finding creative solutions to challenges require a lot of commitment, which the withdrawing employee is certainly lacking. Similarly, the withdrawal of an employee will have a negative impact on the development of

knowledge. One of the factors on which the process of individual knowledge development relies is creativity (Probst and Rohmhardt, 1997). Collective knowledge development involves the learning dynamics of teams, and it is necessary to have an atmosphere of openness and trust to allow the intensity of communication so that the results of collective learning are superior to individual learning (Probst and Rohmhardt, 1997). Creativity means the production of new and useful ideas and fuels innovation in organizations (Amabile, 1996; Zhou & Shalley, 2008). Employee creativity is necessary to spark the types of innovations that enable organizations to stay ahead of their competition (Colquitt, Lepine, and Wesson, 2013). The disengaged employees who withdraw both physically and psychologically become emotionally disconnected from co-workers in ways that disguise their "thoughts, feelings, creativity, beliefs, and values" (Kahn, 1990, p.702). Therefore, if withdrawing employees are distancing themselves from the team, become silent, and are no longer creative, this can have a potential negative impact on the knowledge development process, as creativity and collective learning are crucial for the process to be successful.

4.3. Knowledge application

As knowledge application is closely related to knowledge sharing (Chang and Lin, 2015), and inadequate application encompasses weak dissemination of knowledge (Coleman and Casselman, 2016), it is reasonable to assume that employee withdrawal may also negatively impact this knowledge process. According to Saifi (2015), three factors seem important for knowledge application, they are creativity, problem-solving, and working with others. The process of knowledge application involves retrieving and using knowledge in support of making decisions, and solving problems (Saifi, 2015). Knowledge application in research is among others measured by the extent to which employees apply their ideas in their job (Parayitam *et al.*, 2021). Employee withdrawal often manifests through employee silence - "deliberate intention to withhold ideas, information, opinions, or questions about the job or organizational possible issues and improvements"(Van Dyne, Ang and Botero, 2003). Moreover, absenteeism can delay the application of knowledge in ongoing tasks, delay some projects, or result in temporary knowledge gaps. If employees are quitting- voluntarily leaving the organizations, they may not make the effort to apply stored and shared knowledge, ideas, and new information to enhance work, make decisions, solve problems, and innovate. Therefore, employee withdrawal can have a potential negative impact on knowledge application, particularly in time-sensitive or knowledge-intensive activities.

4.4 Knowledge storage

People have been and will always remain natural repositories of knowledge (Cong, Li-Hua and Stonehouse, 2007). If knowledge is buried inside the heads of individuals, the organization becomes very vulnerable if those individuals start to engage in withdrawal behaviours. Knowledge storage refers to the process of recording knowledge and storing it in repositories such as archives, databases, and filling systems (Gao, Chai and Liu, 2018). Effective transferring of an individual's memory into an information system so that everyone can continue to access that person's knowledge even after the person has left the organization is crucial. This requires a lot of effort to ensure that employees are willing and able to analyse their own knowledge and make it available to others. Although the process of storing knowledge seems to be more technical, the human factor is also of great importance here. Therefore the knowledge documenting or storing process is in most of the organization's continuous, meaning a regular, but not daily activity. Short term physical withdrawal of an employee should not harm this process (unless some crucial and valuable knowledge is not documented), similarity the absenteeism does not lead to the loss of the already stored knowledge. Probably what brings more noticeable consequences on the process of knowledge storage is the psychological withdrawal of employees. Employees who have been withdrawing psychologically for a long time may be demotivated to document their newly acquired knowledge and may neglect their duty to update the knowledge that is already written down. Because of this, the knowledge stored in the organization may be incomplete, outdated or inadequately organized, making it less useful to others.

To sum up, it can be stated that withdrawal behaviours have potentially negative impact on knowledge management processes. The type of this impact or its intensity might be different, depending on kind of withdrawal behaviour that can be observed in an employee, as well as the requirements of the knowledge process. All in all, this impact is potentially negative for the organization also from the perspective of its operations and continuity of functioning. In table 2, there is the relation of particular knowledge management processes and withdrawal behaviours presented on the basis of the existing literature.

Table 2. Relation of particular knowledge management processes and withdrawal behaviours.

	Literature on KM:	**Literature on EW:**	**Conceptual overlaps:**
Sharing	Knowledge sharing is people to people process (Tangaraja *et al.*, 2016), its effectiveness largely depends on the willingness of knowledge workers to share their intellectual resources with others (Hajric, 2018).	Employee withdrawal refers to a range of negative behaviours that distance the employee from the organisation and weaken ties (Liao *et al.*, 2022). Those employees who intend to leave in the future avoid sharing knowledge with their coworkers (Jacobs and Roodt, 2007). Employee withdrawal behaviours negatively impact employee willingness to share tacit knowledge (Tian *et al.*, 2021).	Willingness to share
Creation	Effective knowledge creation depends on a high degree of personal commitment (Nonaka and Takeuchi, 1995).	"Employees who are not committed to their organizations engage in withdrawal behaviours" (Colquitt, Lepine and Wesson, 2013)	Personal commitment
Development	"The process of individual knowledge development relies on creativity (…) collective knowledge development requires an atmosphere of openness and trust" (Probst and Rohmhardt, 1997).	The disengaged employees who withdraw both physically and psychologically become emotionally disconnected from co-workers in ways that disguise their "thoughts, feelings, creativity, beliefs, and values" (Kahn, 1990, p. 702)	Creativity Emotional connection
Application	"Three factors seem important for knowledge application, they are creativity, problem solving and working with others." (Saifi, 2015)	"Deliberate intention to withhold ideas, information, opinions, or questions about the job or organizational possible issues and improvements." (Van Dyne, Ang and Botero, 2003).	Creativity Working with others
Storage	Knowledge storage requires a lot of effort on the part of organization to ensure that employees are willing and able to analyse their own knowledge and make it available to others. (Cong, Li-Hua and Stonehouse, 2007)	Withdrawal behaviours are any employee behaviour of withdrawal from duties and responsibilities as a result of a distance that grows between the employee and the organization. (Erdemli, 2015)	Connection with organization

Source: Own compilation, on the basis of sources presented in the table.

5 Conclusions

To sum up, the employee withdrawal and knowledge management literature have a few conceptual overlaps, which help in understanding how employee withdrawal behaviors may impact various knowledge processes. The characteristic features of withdrawal behaviors include reduced creativity, intent to withhold ideas, emotional disconnection, lack of commitment, and increasing distance between the employee and the organization. All of this has a potentially negative impact on all knowledge management processes, to a greater or lesser extent. It can be noticed that psychological withdrawal is potentially more severe in implications, as it can be done by an employee even if he or she is at work and is expected to conduct their duties, without noticing by a colleague or a manager. Such mentally distanced employees may neglect to engage in any knowledge activity and it will not be easily noticed by other peers or supervisors. In a sense, physical withdrawal is easier to manage, as there are no expectations from an employee who is not present at work or a meeting. However, frequent or prolonged absenteeism, and missing meetings, mean less opportunity for knowledge transfer, creation, development, or greater risk of knowledge misapplication.

The article contributes to the existing state of knowledge in both management and psychology fields. On the one hand, it presents employee withdrawal behaviors, and on the other hand, it identifies the potential link between two concepts - employee withdrawal and various knowledge processes. It presents how interdisciplinary the work of managers or leaders has become – they need to focus on humans and their motivation or its lack, as their withdrawal may harm also knowledge-related processes.

The main limitation of this study is that it is theoretical nature. By combining insights from psychology and management, it has been possible to outline some conceptual overlaps and potential relationships between employee withdrawal behaviors and knowledge processes. This relationship needs to be further explored both from a theoretical and practical perspective. Future studies could present a systematic literature review on this topic, as well as research from organizations on the perceptions of managers of withdrawal behaviors and their impact on knowledge management processes.

All in all, the paper has established the basis for a better understanding of the potential impact of employee withdrawal on knowledge processes that organizations may face nowadays. As such, the paper offers food for thought for researchers dealing with the topic of knowledge management, employee withdrawal, and human resources management in general. It also supports managers and company owners in the development of their leadership skills, indicating a new area for observation and handling.

Generative Artificial Intelligence: Knowledge, Perception and Use among White-Collar Employees in Companies

Claude Meier, Ursula Häfliger
HWZ Zurich University of Applied Sciences for Business, Zürich, Switzeland

Abstract

For companies, it is critical that their white-collar employees develop the necessary skills and knowledge to leverage the potential of Generative Artificial Intelligence (GAI) to improve productivity and organizational performance. To explore how employees perceive and use GAI in their daily work, and what measures companies are taking to support skills development, we conducted a practice-oriented empirical study.

The literature discusses the impacts of GAI on the economy and employment, particularly regarding efficiency gains, job transformation, and evolving skill requirements (Budhwar et al. 2023; Gmyrek et al. 2023; Haase 2024; Bremen 2023; McKinsey 2023). Several studies highlight productivity benefits and the dissemination of best practices (Brynjolfsson et al. 2023), while others, such as Slack (2025), emphasize employee skepticism as a barrier to realizing these gains. A central focus across the literature is the need for skills and knowledge referring GAI models as such (Al Naqbi et al. 2024; Cardon et al. 2024; Chandra et al. 2024).

Against this backdrop, we surveyed white-collar employees in Switzerland to assess the actual state concerning skills and knowledge in the following three areas: (1) perception of GAI-relevant skills and knowledge, (2) application of GAI in daily tasks and corporate functions, and (3) employer measures for supporting skill development.

The survey was distributed among members of Switzerland's largest white-collar professional associations. After data cleaning, responses from 1,843 participants were analyzed. As participation was based on self-selection (opt-in), the sample is not fully representative; distortions were mitigated using iterative proportional fitting (Kolenikov, 2014; Choupani et al., 2016).

A key finding shows that 80% of participants perceive a need for more GAI knowledge (25% report to almost no knowledge; 55% to have only basic knowledge), while only 15% consider themselves sufficiently knowledgeable. A second key finding show that GAI models are most used for writing, editing, and translating texts (48%). The most cited reason for non-use was a perceived lack of necessity (24%), though it remains unclear whether this reflects actual need or inexperience. Only 23% reported that their employer has a GAI strategy. Practical implications, including offering task-oriented GAI training, are discussed in the full paper.

Keywords: Generative Artificial Intelligence, skills and knowledge, white-collar employees, companies

Paper type: Practical Paper

1 Introduction and research problem

For companies it is critical that their white-collar employees have the relevant skills and knowledge in using the potential of Generative Artificial Intelligence (GAI) to increase work productivity and organisational performance. To find out more about how explicitly white-collar employees see and use GAI in their daily work and what measures companies are taking to support them in acquiring the needed skills we conducted an empirical study. The study was particularly practice-oriented, it had a strong focus on the actual workplace of the employees.

The goal of the study was to provide employees and companies insights about where they stand as well as help them with these insights to derive possible measures for using the potential of GAI in a most beneficial way.

2 Theoretical part

In the literature, much is written about the benefits and drawbacks of GAI in the economy and on jobs. Fundamental questions are discussed, such as whether it either leads to new jobs or to their displacement or if it simply promotes the efficiency of employees in doing their daily tasks (Bremen 2023, Gmyrek et al. 2023; Haase 2024, McKinsey 2023). Some studies discuss the actual and potential future advantages that the use of GAI and its models are providing for organisations (Al Naqbi et al. 2024; Brynjolfsson et al. 2023; Chandra et al. 2024; Haase 2024). Brynjolfsson et al. (2023) e.g. suggests that the use of GAI tools can increase productivity and that GAI models help to disseminate best practices of competent employees among newer and less experienced colleagues. However, a study from Slack found that most employees still are critical towards GAI which is why potential productivity gains aren't realised yet (Slack 2025; Vereckey 2024).

2.1 The question of required skills and knowledge for using GAI

Overall, most of the analysed studies discuss more or less centrally the question of which skills and knowledge are required or can/should be acquired by employees in connection with GAI and its models. Therefore, it is not surprising that many considerations, sets or frameworks of skills and competences/knowledge have been established and proposed by different authors (e.g. Cardon et al. 2024; Chandra et al. 2024; Haase 2024; Vuorikari et al. 2022). In the various contributions, there are central recurring terms, which are understood (slightly) differently from authorship to authorship. Moreover, they often overlap (e.g. data literacy or digital literacy). Generally, it does not make much sense to compare and contrast the frameworks and terms too deeply. A discussion that that goes into too much detail concerning skills-terms often gets lost in these details. The reason is that the terms and concepts themselves are simply not that precise in nature and therefore can't be defined and delimited with all accuracy. Moreover, terms and concepts in the field of GAI-relevant skills and knowledge are often changing (especially on a detailed level) because of the fast technological development in GAI.

2.2 A general categorization of skill and knowledge areas

However, on a more general level, a rough horizontal categorisation of skills-terms or areas is appropriate. Vuorikari et al. (2022) have established such a general and practice-oriented "digital competence framework" for the European Commission. Because of its characteristics[1], we oriented the followingly presented skills and knowledge areas at this framework (in spite of its title it is not only relevant for digital skills, but also for skills concerning GAI).

The first skills and knowledge area is *information and data literacy*. This includes skills in filtering, evaluating and managing data as well as information adequately. That white-collar employees have knowledge in this area is relevant for them when using GAI. The gathering of information (i.e. doing "research") for example bases more and more GAI-supported technologies. It is decisive to know how to retrieve relevant information thereof.

The second skills and knowledge area is *communication and collaboration*. This means the interactions and cooperation of employees through digital and AI technologies. For example, in their daily work white-collar employees communicate more and more also with bots, internally[2] and externally. Another part of this skill area is the management of a digital identity according to Vuorikari et al. (2022).

A third general skills and knowledge area is *developing digital content*. This skill is highly relevant for the use of GAI when writing texts (or making images etc.). For example, when somebody needs to establish a certain (digital) content and uses GAI therefore, it is decisive that she knows how to interact and use the GAI adequately to achieve her goal. Depending on the content to be written or established, the process to establish the content differs more or less fundamentally from the classical writing process. To be goal-oriented and successful it is necessary to know how to steer GAI properly in the wished direction to receive valuable content. This requires (a) the provision of adequate instructions to the GAI tool, (b) writing appropriate prompts and (c) understanding the fundamental principles of how AI works. Only then GAI tools can be managed or even customized in a way that effective object-oriented outcomes result (e.g. Haase, 2024).

Overall, there are signs that GAI is blurring the boundaries of these three general skill and knowledge areas. The reason is that GAI-supported technologies are increasingly present in the area of information and data provision, as well as in communication and digital content developing (i.e. in writing). Gathering information with support from GAI, using it for writing a contribution and later communicating it with support of GAI goes hand in hand.

2.3 Technical skills and development of GAI

Furthermore, Vuorikari et al. (2022) mention also *problem solving* as a relevant skill. This is based on the idea that employees have especially *technical skills* to solve existing or upcoming problems (e.g. "identifying needs and technological responses", "creatively using digital technology" (Vuorikari et al. 2022, p. 1)). Cardon et al. (2023) address also technical skills and describe them as hard skills as opposed to soft skills, like e.g. communication. Based also on other literature they say: "[…] the need for technical skills will change in a variety of ways. Many suggest that AI-specific digital literacies will grow in importance. These literacies involve aligning the tool with the task and understanding the strengths and limitations of various AI tools." (Cardon et al. 2023, p. 226). This is similar to what has been said under 2.2 in the skills and knowledge area developing digital content (see list (a) to (c) there).

[1] i.e. being general and practice-oriented.

[2] Many middle and large companies meanwhile have their own company-bots that are based on their internal data (documents, numbers etc.).

At the same time GAI tools are becoming more and more sophisticated and perform increasingly complex tasks by providing them with fewer or simpler (but still focussed) command inputs. Moreover, prompting as a form of quasi-programming is increasingly taking place in natural language. The need math-based or classical IT-based knowledge for users seems therefore to decrease, even for more complex command tasks. Regardless of this, knowledge of how the GAI functions in principle remains key for employees. What stays unclear up until now is the question if in the future the skills set of white-collar employees requires more or less technological and mathematical competences in view of the further development of GAI.

But, independently of how GAI will develop, the literature in this field assumes, as shown, that skills and knowledge of employees concerning GAI are crucial to the future success of a company.

Against the background of this discussion, we aimed in this study to determine firstly the current state of perception and secondly the use of GAI and its models among white-collar employees at their workplace. By taking perceptions into account, potentially critical attitudes towards GAI, as mentioned by Slack (2025), can also be recognised (see introduction to the theoretical part). Thirdly, we wanted to find out more about the GAI-related measures taken on the organisational level to support the employees. This is because not only the individual skills-level of employees is of importance for success but also what is being done on an organisational level (e.g. Haase, 2024).

As mentioned, the goal of the study was to use the findings to help employees and companies recognise where they stand and to derive possible measures to use the potential of GAI in a most optimal and effective way.

3 Methods

3.1 Perception of GAI-relevant skills and knowledge

To receive the necessary data or information we conducted the study based on a survey. Structurally, the survey considered the following three areas (oriented at the last section of theoretical part):

1. *Perception of GAI-relevant skills and knowledge* that focussed on how employees see their knowledge and that of their workplace in the context of the developments in GAI. Aspects such as how they believe they are keeping pace with the GAI developments were taken into account.
2. *Use of skills and knowledge for GAI* which considered the use of GAI models by employees in their daily work, as well as its use in different types of tasks of companies (e.g. in recruiting, efficiency control or brainstorming and strategy).
3. *Measures taken by the employer* that analysed what companies are doing to support GAI-relevant skills and knowledge among their employees as well as (e.g. if they provide education and training; how they communicate to the topic).

3.2 Distribution of survey and of respondents

The survey was distributed among the members of eight of the largest professional associations of white-collar employees in Switzerland. While the claim of these associations that they together represent 80 percent of the workforce in the service and knowledge professions (i.e. of white-collar employees) cannot be independently verified, the best-known professional associations in Switzerland in this area are certainly among them.

Furthermore, we have been able to record a statistically sufficient number of survey respondents for all sectors of the Swiss economy as well as of gender and age groups of the service and knowledge professions.

In the raw data, 58 percent of respondents identify as female and 42 percent as male. In the membership data of the professional associations (and our analyses because of the weights applied), the ratio is 52 percent female and 48 male. In the Swiss Labour Force Survey by the Federal Statistical Office (2023), we find a ratio overall professions of 47 percent female and 53 percent male.

As for the age groups, 35 percent of respondents in the raw data are under 35 years old, 53 percent are between 35 and 55 years old and 12 percent are above 55 years old. In the professional associations' membership lists, the shares are 37 percent (under 35), 46 percent (between 35 and 55) and 17 percent (above 55). The Swiss Labour Force Survey shows 22, 51 and 25 percent, respectively.

After adjustment and checking, the data of 1843 persons could be used for the analysis. As the participants recruited themselves (opt-in survey), the composition of the sample is not representative of the basis population. However, the distortions in the sample such as self-selective biases are counteracted by weighting for gender an age using the "iterative proportional fitting" method (Kolenikov, 2014; Choupani et al., 2016).

Moreover, it is important to note that surveys are reactive processes: participants are persons and answer (also) based on their subjective experience. I.e. they may under- or overestimate facts or circumstances in fact on an individual as well as on a group level (e.g. persons from different functions on a hierarchical level assess things differently).

4 Results

The results are presented along the three areas (1) perception of GAI-relevant skills and knowledge, (2) use of skills and knowledge for GAI and (3) measures taken by the employer.

4.1 Perception of GAI-relevant skills and knowledge

In this area we first show the general attitude of the participating white-collar employees towards AI at the workplace (figure 1). As can be seen with 57%[1] over half of the respondents have a basically positive attitude towards the development of new technologies based on AI. Only just over 10% are opposed to such a development. But a full 28% say that they do not have an opinion to this topic. This is a high value for the "not know"-category and show an existing insecurity among more than a quarter of the white-collar employees.

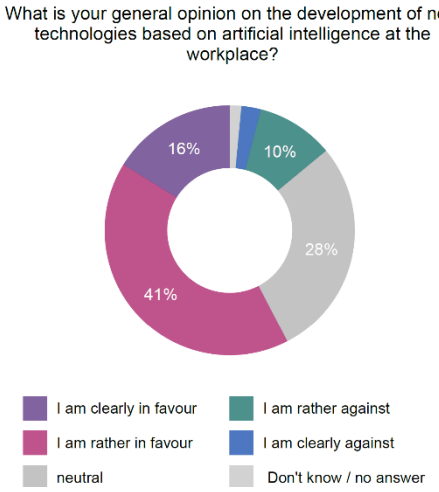

Figure 1: General attitude of white-collar employees towards AI at the workplace
Source: Authors, 2024

In the next figure 2 we move a step further down to recognise how participating employees assess their own knowledge in using GAI at work. 80% of them perceive to need more skills and knowledge to use GAI at work (thereof 25% declared to have nearly no knowledge and 55% to have basic knowledge), see figure 1. Only 15% stated to know enough and to have no need of more knowledge. Thus, overall, the feeling that one needs more knowledge concerning GAI at work is indeed widespread. What of course could be is that if someone who has already tried to work with GAI models on a basic level is more likely to realise that she or he needs more knowledge. At the same time a majority of 80% may also show a premature technological adoption: the technology is here, but it is in fact it is not clear how it can be appropriately used. Hence, there is a skills gap.

[1] = 41% + 16%.

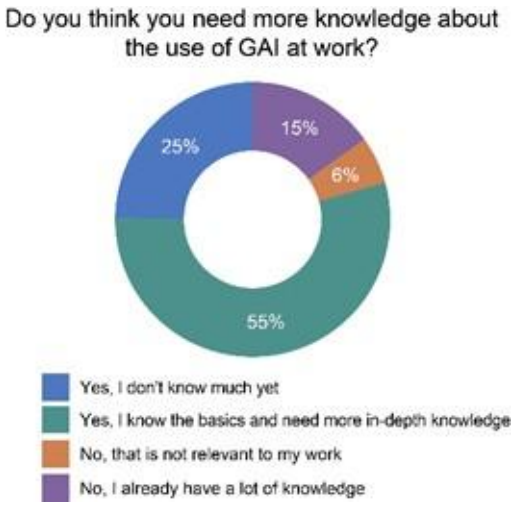

Figure 2: Perception of individual knowledge to the use of GAI at work
Source: Authors, 2024

A breakdown of participants by function showed that managers (senior, middle, lower) clearly declare to have more basic knowledge on average, namely 63%, than their non-managerial colleagues (technical experts, project managers, administrators, assistance) with 40%, see figure 3. However, if the two areas 'I don't know much' and 'I know the basics' are taken together, the differences between managers and non-managers are becoming smaller, namely maximum 10 percentage points[1]. This means overall that the knowledge and skills are distributed rather similar across the hierarchical levels. But, the difference of having basic knowledge versus (nearly) no knowledge between managers and non-managers with a maximum of 24 percentage points stays large.

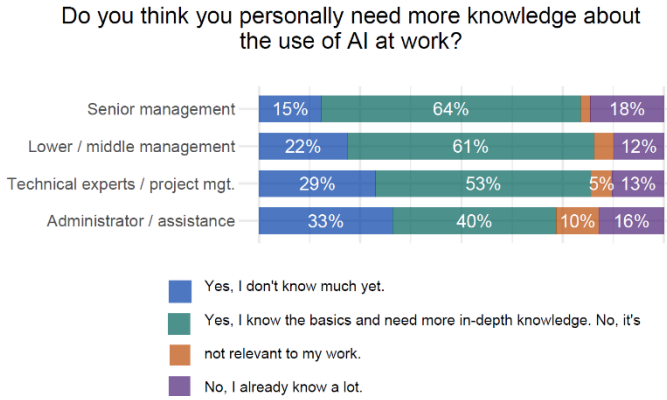

Figure 3: Perception of individual knowledge to the use of GAI at work: along functions
Source: Authors, 2024

Figures 4 and 5 go beyond the finding of figure 3 while also confirming it to a certain extent. The figures show the answers to the question 'In your opinion, what is the level of knowledge about the use of GAI in your company?'. The answers differ quite strongly between "middle and senior management" (figure 4) and "employees without managerial function" (figure 5). While the first group perceive with 44%[2] that the level of knowledge is good or very good the latter group perceive this with only around 27%[3].

Not surprisingly, on the other side there is a mirror image: "only" 38% of the middle and senior manager assess the knowledge-level as bad (27%) or even very bad (11%) whereas high 58% of the employees without managerial competences assess it as bad (41%) or very bad (17%). Hence, perceptions between high and low hierarchical levels differ quite strongly. At the same time both values of assessing the knowledge-level as bad or very bad are very high (38% and 58%, respectively) and implicate hat there is still a long way to go in companies to increase the know-how and skills of using GAI on an aimed or desired level.

[1] The difference between 83% (22%+61%) of lower/middle management and 73% (33%+40%) of administrators and assistance.
[2] = 38% + 6%.
[3] = 25% + 2%.

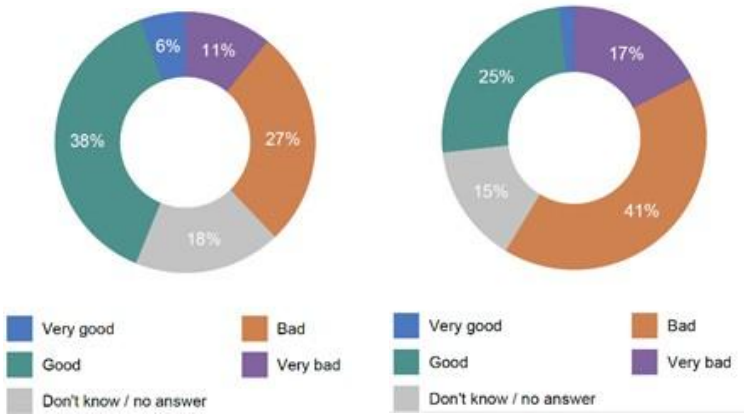

Figure 4 (left) and 5 (right): Perception of level of knowledge about the use of GAI in the own company. Left: middle and senior management, right: employees without managerial functions

Source: Authors, 2024

4.2 Use of skills and knowledge for GAI

A key item in this area asked how employees use GAI at work (see figure 6; multiple answers were possible). With 48% the option 'I use GAI models to write, edit, translate etc. texts' was rather clearly chosen most, followed by the options that GAI is used for creative support and to get inspiration (42%) and to receive answers to questions (39%). Overall, the options saying that somebody uses *no* GAI models at work are clicked clearly much less (see purple bars in figure 6 with 24% and 10%, respectively) than the options that somebody uses such models at work (turquoise bars in figure 6). Indeed, the existing basic knowledge of GAI models (see figure 2) is used in a wide variety of contexts. Presumably, employees using such models on a basic level are likely to realise while working with AI that they need deeper knowledge to be able to use their full potential.

Furthermore, the most frequently mentioned reason why GAI models aren't used by employees is that they aren't needed by them (24%). However, it remains unclear whether participants who said this indeed do not need such models or whether they just say so but never tried it.

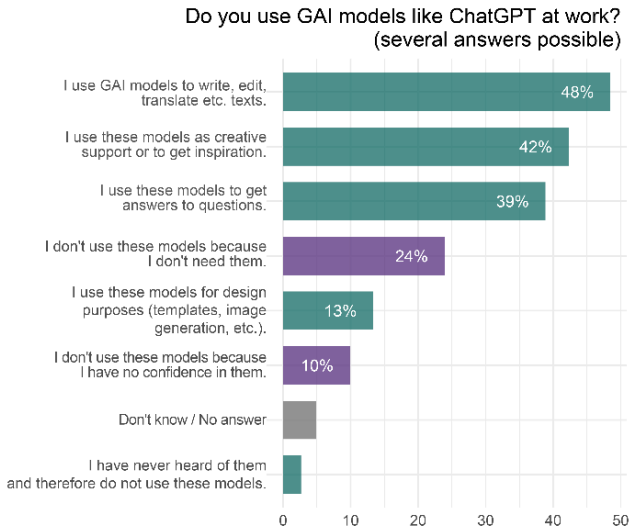

Figure 6: Fields of application of GAI in participants own work

Source: Authors, 2024

In the following figure 7 the focus is on where GAI is used in a company. As in the question to figure 6 it was possible to give multiple answers. The answer option marketing and communication has with 28% the highest value. On the second and third place follow 'don't know / no answer' (25%) and 'nowhere'" (24%). It is noteworthy that these two options do figure on such top places, even if the reasons can only be interpreted. An obvious explanation may be that employees being in certain departments do not know what is being done elsewhere. But it is also plausible to assume that the companies do not communicate enough or adequately towards employees about GAI and its use or implementation in the company. Therefore, the awareness about

GAI and how it is used across the company is low among employees. Assumingly, under such conditions the support for the employees in GAI through the company then is also low. Especially the answer option 'nowhere' with its 24% could support an interpretation in this direction because employees simply know or assume that GAI is used 'nowhere'.

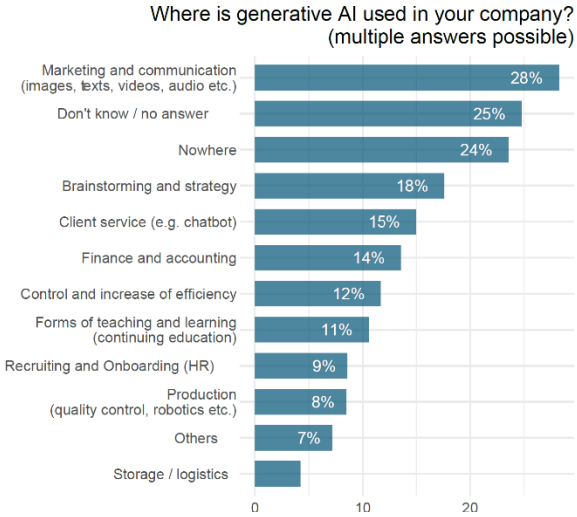

Figure 7: Fields of use of GAI in the company
Source: Authors, 2024

4.3 Measures taken by the employer

A first key finding in the third area of the survey was that only 23% of the respondents declared that their company has an AI strategy whereas 56% said no, it doesn't. 21% said that they do not know (figure 8). This finding suggests that only just under a quarter of companies have a GAI strategy that employees are indeed aware of. The question is also whether there is effectively no strategy in over 75% of the cases or whether such a strategy is not sufficiently communicated and/or visible initiatives are lacking.

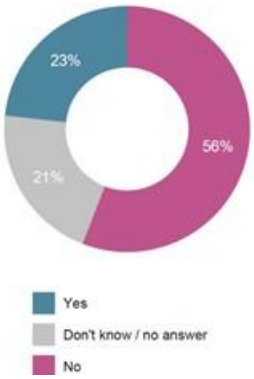

Figure 8: Answers to the question "Does your employer have a GAI strategy?"
Source: Authors, 2024

In the next figures the answers about the support of companies for employees in different subareas are shown. The basic question to all five subareas is always the same: "How does your employer support employees for GAI and its areas of application? Please evaluate the support in the following area".

The first subarea considered if guidelines for the use of GAI does exist in a company (figure 9). 31% of the respondents answered that this is the case in their company, while 47% said that this isn't the case. The picture to the subarea of sensitisation and awareness raising (figure 10) differs a little bit. Here at least 39% of participating employees said that a sensitisation of employees for GAI is existing in their company. Still 42% say that this is not the case.

In the last three subareas, which require a more active role of a company than just providing guidelines, the picture is overall similar. We begin with the support in the form of training and education: Only 29% declared that their companies offer this. 48% said that this does not apply (figure 11). In the subarea of supporting the motivation to use GAI the distribution of answers is the following: 33% say that this is applies to their company,

44% say that this doesn't (figure 12). Finally, also the subarea of supporting the integration of GAI in process optimisation is similar to the others but in fact has the lowest application-rate: only 28% say that support exists thereto (46% say that this does not apply) (figure 13).

These low rates show that there is clearly room for improvement in the (perceived) support of companies for employees. In none of the five subareas the rate of application is higher than 39%. Particularly also the low support concerning the integration of GAI in process optimisation is potentially problematic. The reason is that process optimisation is in many cases a field in which a valuable integration of GAI is quite obvious. The reason is that steps in processes normally are clearly defined and arranged why a step-by-step integration of GAI can be planned well. And, especially at the beginning but also later (when more specific knowhow is needed) the learning curve in the use of GAI is quite high. This is why training and education as a form of support is so important. Often trainings are key for getting started, they are a help for self-help. Moreover, an adequate training and education program impacts the motivation of employees positively.

5 Conclusions and practical implications

The results overall show that the assumed full potential of GAI isn't utilised yet. This can be seen clearly among others in figure 2 where a vast majority of participating employees of 80% declares to have no or not enough knowledge for the use of GAI. Such a large majority indicates a knowledge and skills gap. The GAI technology is just there and the employees see it and try it out. However, often they cannot work with it on a highly effective level what may be interpreted as a premature technological adoption. Simultaneously, it seems not to be the case that companies require or motivate employees actively to use GAI. On the contrary, only 23% of the participants stated that their employer has a GAI strategy (figure 8). This speaks against a requirement or an active motivation to use it. Moreover, there is generally a low support of employees from the companies' side (figure 9 to 13).

The phenomenon combined of low utilisation and lack of strategy is probably related to the technological disruption reflected in the GAI models. GAI models are now on the market, they have become accessible to everyone, including unskilled users such as white-collar employees. Before, it was for years mainly used exclusively by experts. It is therefore difficult for both the individual employee and the company to find an suitable way of dealing with this situation.

By looking at *how* employees use GAI models at work (see chapter 4.2), we see indeed that they are using them in different ways and with different frequencies (figure 6) (although 36% of the respondents still declare to have no use of them because they do not benefit from or have no confidence in them).

Our practical recommendations, which are based on the study's results, start right here: Providing training on GAI models and areas of application that employees have to deal with in their daily work. In this way a more effective and goal-oriented proceeding should become possible. Taking this as the starting point for leveraging knowledge and skills means starting directly where the employees need it. Moreover, this serves also as help for self-help.

In a next step guidelines may be developed (if needed) because the exchanges in trainings help to establish them in a more user-friendly and focussed way. In a step after the next the ongoing development of training and education (eventually including certificates) supports assumingly also the motivation to use GAI models.

GAI measures taken by a company that are based on the needs of the employees and the experiences gained in the subsequent development steps, should facilitate the definition of a company-wide strategy for GAI.

The study presented has shown that there is still little in-depth knowhow on the employees' level and little commitment to GAI on the part of companies. As indicated, it is therefore crucial that a start with measures is initiated by a company at all. After that, a continuous further development of measures should make it easier for a company to deal appropriately with the constant advancements in GAI technology itself.

A question that is always latent in the room is how much and how deep specific knowledge is really necessary for an effective deployment of white-collar employees. Being able to program is probably going to far. But being able to prompt in a focussed, aim-oriented matter is essential (e.g. Cardon et al. 2023). Prompting in the end is a form of programming and actual developments show that this *programming by natural languag* increases in importance because it enables achieving valuable outputs.

No matter how much/less mathematical knowhow employees need to have in the future or how fast the technological developments will be: for a focussed approach of GAI, it will be important to understand the basic principles of how it in fact works (see chapter 2.3). This considers the individual employees as well as the company on its managerial basis.

6 Ethics declaration

We did not need an ethical clearance for research done in this paper.

The reasons therefore were that the recipients of the survey were able to decide for themselves whether they wanted to take part or not (opt-in survey). The participants' answers were anonymous. No conclusions could be drawn from the answers to individuals. Results in the paper are exclusively shown at an aggregated level. The survey was distributed to employees by eight of the largest professional associations of white-collar employees.

7 AI declaration

Deepl Translate was used for certain sentences. Certain sentences were written first in German and then translated by Deepl Translate to English. The sentences received in English were then checked for correctness of content and, if necessary, corrected manually before being incorporated into the paper. Moreover, to shorten the length of the abstract ChatGPT 4.0 was used. Our prompt asked ChatGPT to shorten the text without cutting

key content. The shortened text was then checked by the authors and was further adapted and refined manually by them until it was as they wanted to have it. No further AI tools were used to establish this paper.

Improving Clinical Evidence for Medical Devices: A Lifecycle Approach

Marco Praticò, Salvatore Tallarico, Luisa Pellegrini, Simone Lazzini
University of Pisa, Pisa, Italy

Abstract

Background: The European Medical Devices Regulation (MDR) 2017/745 seeks to minimize clinical uncertainty – especially regarding the generation, dissemination, and quality of clinical evidence – across all phases of the medical device lifecycle: pre-market, market approval, post-market, and disinvestment. Although the MDR promotes using gold-standard methodologies, such as Randomized Controlled Trials to address clinical uncertainty, healthcare organizations face significant challenges in applying these methods. These challenges affect the effectiveness of evidence generation, dissemination, and quality. As a result, healthcare systems must incorporate technological, organizational, and managerial tools to manage these difficulties throughout the medical device lifecycle. This study aims to identify the tools that can reduce clinical uncertainty associated with medical devices.
Methods: The research adopts a case study approach, focusing on the Tuscany Regional Healthcare System, which is recognized nationally for its effectiveness, efficiency, and appropriate care delivery.
Results: The findings indicate that the majority of the identified tools are concentrated in the pre-market and post-market stages. Examples include study coordinators (organizational tools), standardized templates (technological tools), and case report forms (managerial tools), all of which improve the quality of clinical evidence. In addition, tools such as patient diaries (managerial) and surgical trainers (organizational) play a crucial role in enhancing both the generation and dissemination of evidence during these phases.
Discussion and Implications: This research provides useful insights for policymakers in guiding healthcare organizations on how to implement the MDR effectively. A key takeaway is the importance of introducing clinical registries, surveillance systems, and data collection platforms to gather real-world evidence, which are essential in the post-market phase. The study contributes to the ongoing discourse surrounding medical devices' clinical uncertainty by identifying technological, organizational, and managerial tools that can strengthen clinical evidence for medical devices.

Keywords: Clinical uncertainty; MD; Medical devices; MDR 2017/75

Paper type: Academic Research Paper

1 Background

The European Union's Medical Devices Regulation (MDR) 2017/745 represents a major step forward in the development and regulation of Medical Devices (MDs), defined as "*any instrument, apparatus, appliance, software, implant, reagent, material, or other article intended by the manufacturer for human health purposes"* (MDR Art. 2). In comparison with earlier Directives (90/385/EEC; 93/42/EEC), the MDR introduces substantial changes aimed at reducing clinical uncertainty – particularly in how clinical evidence is generated, disseminated, and how its quality is improved – across all stages of the MD lifecycle: pre-market, market approval, post-market, and disinvestment phases[1] (McDermott & Kearney, 2024; Kearney & McDermott, 2023; O'Rourke, Oortwijn & Schuller, 2020; Tarricone et al., 2020).

Table 1 outlines the primary tools recommended by the MDR to address these goals.

[1] Pre-market: phase of MD development before it is commercially available (Matinolli et al., 2019); Market approval: phase of MD evaluation by regulatory authorities to determine if it can be legally marketed (Martin and Barnett, 2012); Post-market: phase of ongoing MD monitoring to ensure safety and effectiveness (Ross et al., 2015), including Health Technology Assessment for MD introduction into clinical practice; Disinvestment: phase in which a MD is withdrawn from the market and its use discontinued due to newer technologies, obsolescence, safety concerns, or economic factors (Polisena et al., 2019).

Patient's involvement	■	■	■	■

Previous literature brings some insights on how these tools contribute to the generation, dissemination, and improvement of clinical evidence quality throughout the lifecycle of MDs.

For example, in the pre-market phase, the MDR highlights the use of Randomized Controlled Trials (RCTs) to produce clinical evidence (Tarricone et al., 2020). Despite their status as the gold standard, RCTs have well-documented limitations (Rosner, 2012), including small and specific patient populations, ethical dilemmas, and the fast-paced evolution of medical technologies (Tarricone et al., 2020). Additionally, outcomes are often influenced by user experience and learning curves, as well as being highly dependent on the clinical setting – factors particularly relevant to MDs compared to pharmaceuticals (Jakab et al., 2020; Fuchs et al., 2017).

The Post-Market Clinical Follow-Up (PMCF) process, also mandated by the MDR, is designed to ensure continued surveillance and enable comparisons between real-world evidence and RCT data. This is intended to enhance evidence reliability. However, real-world implementation remains complex, with difficulties in patient engagement and challenges in collecting and tracing data that can compromise the quality of post-market evidence.

These are just some of the issues that impact the ability to generate, disseminate, and maintain high-quality clinical evidence across the MD lifecycle. If not adequately addressed, such challenges can lead to suboptimal outcomes – for instance, the approval of an MD that later proves ineffective, or the abandonment of a promising technology that never reaches patients.

To address these barriers, healthcare organizations involved in various lifecycle stages must integrate technological, organizational, and managerial tools to support the generation, dissemination, and improvement of evidence quality.

This research seeks to answer the following question:

- *RQ. What technological, managerial, and organizational tools can healthcare organizations adopt to support the generation, dissemination, and improvement of clinical evidence quality across the MD lifecycle?*

The identified tools may assist policymakers in shaping effective MDR implementation strategies within their local healthcare systems. While the MDR is legally binding, its practical application is delegated to each EU Member State, with implementation often decentralized further – especially in healthcare systems such as those in France and Italy.

To explore this question, we adopt a case study approach focused on Italy's Tuscany Regional Healthcare System (RHS).

The following sections describe the methodology used and present our findings and analysis.

2 Methods

A single-case study design was adopted to thoroughly explore the complex phenomenon under investigation (Eisenhardt, 1989), focusing on the RHS of Tuscany, Italy.

Tuscany's RHS was selected due to its high healthcare performance, strong integration of hospitals, universities, and research centres, and its commitment to reducing clinical uncertainty through initiatives like the Clinical Trial Offices and Health Technology Assessment developments. This collaborative and innovation-driven environment makes Tuscany an ideal case for examining challenges in generating and evaluating clinical evidence across the MD lifecycle.

Between March and July 2024, interviews were conducted both in person at the interviewees' workplaces and remotely via Microsoft Teams. Participants included professionals from various organizations within the Tuscany RHS – such as University Hospitals, CTOs, and Research Centres – who were directly involved in the development or oversight of clinical evidence related to MDs. Table 2 presents the roles of the interviewees, the phases of MD lifecycle in which they are involved, along with the number and duration of the interviews.

Table 2 - List of the interviewees, number and duration of interviews conducted with each of them

Interviewees	Number of interviews	Involvement phase of the MD's lifecycle	Duration
Director of the Business Development, Active Agreements, and Special Projects Unit at a University Hospital and her team	1	Post-market	1h 26m
Director of the Clinical Trial Centre at a University Hospital and her team	2	Pre-market; post-market	1h 30m + 1h 40m
Director of the Clinical Trial Office at a Research Hospital Foundation and her team	1	Pre-market; post-market	1h 40m
Study coordinator of a Complex Unit at a University Hospital	1	Pre-market; post-market	2h 08m
Two researchers at the Italian National Research Council	1	Market approval	58m
Director of the Operational Unit for Biomedical Technology Planning and Organization at a University Hospital	1	Disinvestment	40m
Director of the Research and Educational Centre for Computer Assisted Surgery at University Hospital and his team	1	Pre-market; post-market	35m
Director of the Pharmaceutical Services Unit and Director of Healthcare Technology Unit at a Research and Healthcare Institute and their team	1	Pre-market; post-market; disinvestment	1h 08m

The interview guide was designed to identify technological, organizational, and managerial tools that support the generation, dissemination, and enhancement of clinical evidence quality for MDs – aiming to address clinical uncertainty. Each participant discussed tools relevant to the specific lifecycle phase they were involved in.

To preserve the richness and accuracy of the collected data, all interviews were fully transcribed.

The analysis involved coding the transcripts to extract content aligned with the study's objective: identifying tools that help manage clinical uncertainty.

Coding was independently conducted by two researchers, and subsequently integrated to ensure thorough and inclusive coverage of the data. Where possible, interview findings were cross-referenced with documentation and online resources to enhance the reliability of the data and provide a more in-depth understanding.

3 Results

The results are presented according to the four phases of the MD lifecycle.

3.1. Pre-market

In the pre-market phase, clinical investigations – either commercially or institutionally sponsored – are conducted. Manufacturer-funded trials (profit) generate financial returns for hospitals, while those led by public institutions (non-profit) do not.

Trials commence with a site initiation visit, during which the sponsor or, more often, the Contract Research Organization (CRO) presents the research protocol to the hospital staff. These studies follow Good Clinical Practices (GCPs), international standards for ethical and scientific conduct in human trials. As noted by a University Hospital's Clinical Trial Centre Director, *"originally focused on medicinal products, GCPs now also apply to MDs".* Italy's Ministerial Decree of July 15, 1997, outlines these standards for trial sponsors. GCP compliance includes thorough documentation and supervision in line with quality assurance systems.

Case Report Forms (CRFs) are essential tools for data collection, requiring more detailed information than regular medical records – such as full patient history, concurrent therapies, dosages, treatment dates, and all adverse events, regardless of their relation to the MD. Early inclusion of comprehensive data in CRFs prevents the need for protocol amendments, which require complex ministerial approval. Such amendments should be reserved for MD modifications due to technological progress.

Hospitals often appoint study coordinators to manage non-clinical aspects of trials. These coordinators support the principal investigator (usually a physician) by ensuring adherence to protocol, managing follow-ups, and entering data. Their contribution is vital for maintaining data quality. One study coordinator described preparing a Word template listing CRF data field, which is added to the patient's medical chart to aid clinicians in capturing relevant information.

Both profit and non-profit trials utilize digital CRFs, which have replaced paper versions. While digital tools streamline data handling, they complicate version tracking. Commercial trials often rely on advanced, manufacturer-provided software, while institutional studies may use simpler Excel sheets. As one study coordinator explained, *"the strict documentation requirements for profit studies are too demanding to apply to non-profit studies."*

CRO monitors verify that CRF entries match source data. Monitors with clinical coordination backgrounds often better understand ward dynamics. As noted by a study coordinator, *"monitors with experience as study coordinators better understand ward activity and demand precision in data entry when needed."*

CRFs play a critical role in ensuring high-quality, consistent, and accurate data, which supports rigorous analysis and traceability. Other evidence sources include patient diaries reviewed during follow-up visits, pre- and post-operative questionnaires (sometimes left incomplete due to sensitive questions), and investigator feedback on device usability and procedural duration. These tools enrich clinical evidence by integrating patient and clinician perspectives.

Technology also supports evidence generation. For example, the Research and Educational Centre for Computer-Assisted Surgery, selected as a case study, conducts preclinical in vitro tests using simulations developed with clinician input. According to a member of the centre team, *"simulators are developed with input from the investigating clinician, who specifies the real-world surgical steps."* Clinical researchers adjust simulations to account for anatomical and procedural variations. Some variables are tested in vitro, while others may require animal studies or cadaveric trials before human use.

These simulation technologies help assess MD performance in realistic settings, enhancing both the depth and reliability of pre-market evidence.

3.2. Market approval

Two researchers from the Italian National Research Council, who developed cardiology software, observed improvements in how clinical evidence is assessed under MDR. Previously, certification review was handled by regulatory experts. Now, clinical specialists designated by the Notified Body[1] evaluate the evidence and issue formal reports, occasionally requesting additional data from hospitals.

These researchers highlighted support from scientific societies: *"The European Society of Cardiology pushed for more clinical evidence for high-risk MDs."* Involving clinical experts ensures thorough evaluation of safety and efficacy, strengthening evidence standards and benefiting healthcare outcomes. However, there is concern that these experts may lack domain-specific expertise, indicating a need for broader specialist involvement.

3.3. Post-market

Post-market studies monitor MD safety and effectiveness through vigilance and surveillance systems, as required by MDR. These are particularly critical for high-risk devices. Manufacturers must compare pre-market trial results with real-world data via structured monitoring plans.

Despite differences, pre- and post-market studies share tools: GCP standards, CRFs, study coordinators, Word and Excel templates, CROs, and monitors. Tools like patient diaries and questionnaires also remain in use. Additional post-market instruments include supplier-led training, internal surgical trainers, pre-purchase software trials, conditional supply agreements, registries, and vigilance systems.

Regarding training, the Director of the Business Development, Active Agreements, and Special Projects Unit at a University Hospital outlined two approaches: vendor-led sessions (typically covering 10–20 procedures) and

[1] A Notified Body is an organisation designated by an EU country to assess the conformity of certain products before being placed on the market. These bodies carry out tasks related to conformity assessment procedures set out in the applicable legislation, when a third party is required. The European Commission publishes a list of such notified bodies.

peer observation programs that disseminate expertise across institutions. Certified clinicians benefit from this by enhancing skills, supporting innovation, and contributing feedback to manufacturers.

Software-based MDs can be trialed for 15 days before purchase. This trial helps determine functional adequacy and clinical relevance. Likewise, "supply on approval" schemes allow temporary use of MDs before purchase decisions. Clinicians submit evaluation reports based on real-world use, improving evidence quality.

Outcome registries, such as the national breast implant registry, gather long-term safety data. Vigilance systems assign staff to validate incident reports and conduct risk assessments. As a Clinical Trial Office Director explained, pharmacists validate these reports before submission to regional and national authorities. In serious cases, MDs may be recalled, and manufacturing processes reviewed.

According to the Director of the Pharmaceutical Services Unit and Director of Healthcare Technology Unit at a Research and Healthcare Institute, *"new MDs are monitored through device-vigilance for six months. Afterwards, a report is prepared considering the purchase price, the number of orders, and reported issues."* These reports, while initially internal, inform regional procurement decisions. Nonetheless, *"everything is not formalized; shared procedures are needed to formalize this information sharing."*

Though not fully standardized, this post-market surveillance process strengthens clinical evidence and informs safer, more effective MD use.

Simulators from the pre-market phase are reused to train clinicians on existing MDs, particularly for patients with unusual anatomy. Director of the Research and Educational Centre for Computer Assisted Surgery at University Hospital remarked, "In these cases, the clinical evidence generated in earlier phases of the MD lifecycle and the clinician's learning curve are insufficient for implanting the MD on patients with uncommon anatomical conformations."

3.4. Disinvestment

Clinicians are typically the first to identify signs of MD underperformance, which can prompt disinvestment to avoid compromising care quality. As confirmed by the Director of the Pharmaceutical Services Unit and Director of the Healthcare Technology Unit at a Research and Healthcare Institute, *"every six months, a meeting is organized with ESTAR's healthcare technologies to analyse the issues that have arisen."* These regular reviews allow for evidence-based decisions on whether to retain, replace, or phase out devices, ensuring continued patient safety and care quality.

Table 3 shows the main results.

4 Discussion

The generation, dissemination, and improvement of clinical evidence quality take place across all phases of the MD lifecycle. Evidence generation is particularly critical in both the pre-market and post-market phases. Even when excluding incremental innovations – which can quickly heighten uncertainty – clinical uncertainty does not decline linearly over time. It can persist even after a MD has been approved and marketed. Unlike traditional consumer products, evidence generation for MDs cannot be limited to the pre-market phase. Instead, continuous evidence development is necessary throughout the entire lifecycle, as early-stage data may be insufficient due to the limitations of traditional RCTs in real-world contexts (Tarricone et al., 2020).

Evidence dissemination occurs throughout the MD lifecycle, except for the market approval phase. This is likely due to regulatory bodies being primarily focused on evaluating whether the device meets the criteria for legal marketing (Martin & Barnett, 2012). As a result, healthcare organizations generating evidence in the pre-market phase must wait until CE certification is granted before they can proceed with post-market dissemination.

Improving the quality of clinical evidence is relevant to all lifecycle phases except disinvestment. This may be because evidence accumulated in earlier phases reaches a maturity level that no longer requires enhancement at the end of the product's life.

Notably, there is no one-to-one relationship between a tool's nature – whether technological, managerial, or organizational – and its function. For example, evidence generation is supported by organizational tools (e.g., study coordinators active in both pre- and post-market stages), technological tools (e.g., Word templates and Excel sheets), and managerial tools (e.g., patient diaries).

Similarly, dissemination activities rely on a mix of tools: technological (e.g., templates), organizational (e.g., surgical trainers in the post-market phase), and managerial (e.g., Case Report Forms).

A closer look at tool usage across phases shows that, apart from the monitor used exclusively in the pre-market phase, nearly all tools adopted before market entry are reused afterward for similar purposes. The post-market phase, however, introduces additional tools tailored to real-world application – managerial tools like device vigilance systems and simulations for evidence generation, and registers or pre-purchase trials for dissemination. Organizational additions include supplier specialists and surgical trainers, who help ensure quality in evidence dissemination.

In contrast, the market approval and disinvestment stages employ fewer tools, typically organizational in nature. For instance, clinical expert consultations during approval support evidence quality, while collaborative meetings in the disinvestment stage facilitate knowledge sharing. These stages likely share functions with adjacent lifecycle phases – approval often finalizes pre-market activities, while disinvestment concludes post-market processes – so tools from those phases may still apply.

In the pre-market phase, evidence quality is often ensured by roles such as study coordinators and monitors who operate independently of the clinical team. In the post-market phase, evidence integrity is further reinforced through external training led by supplier specialists and surgical educators. Delegating tasks like data entry to non-clinical staff allows clinicians to concentrate on patient care.

Interestingly, although RCTs are considered the gold standard for evidence generation in early stages, practitioners often find Real-World Evidence (RWE), generated later in the lifecycle, to be more actionable. This reflects a broader trade-off between the methodological rigor of RCTs and the external validity of RWE (Kim, Lee & Kim, 2018). While RCTs offer precision through controlled settings and selective populations, this comes at the cost of generalizability. Conversely, RWE encompasses broader, more diverse populations and practical settings, albeit with reduced experimental control. A combined use of both approaches offers a more robust, balanced understanding of MD effectiveness.

5 Contributions

From a theoretical perspective, this work contributes to ongoing academic discussions on managing clinical uncertainty in the MD field by identifying tools that improve the generation, dissemination, and reliability of clinical evidence (Graili et al., 2023; Klein et al., 2022; Torbica et al., 2022; Pongiglione et al., 2021; Dreyer, Bryant & Velentgas, 2016; Rosner, 2012).

In practical terms, the tools outlined here offer healthcare organizations and relevant stakeholders actionable solutions to strengthen clinical evidence practices – particularly in contexts where high-level evidence is limited or difficult to obtain.

From a policy standpoint, MDR 2017/745 brings heightened scrutiny to MDs, presenting healthcare organizations with the complex task of generating, disseminating, and improving the quality of clinical evidence – in other words, managing clinical uncertainty. To support this effort, policymakers should equip organizations with clear guidelines for implementing the MDR, including practical recommendations on the use of technological, organizational, and managerial tools to reduce uncertainty around MD clinical evidence.

This study offers a set of such tools for policymakers to consider, allowing for tailored recommendations aligned with the specific needs of their local healthcare systems. Importantly, it illustrates how these tools can be effectively employed at various stages of the MD lifecycle.

The findings underscore the importance of incentivizing and funding clinical evidence generation throughout all phases of a device's lifecycle – pre-market, post-market, and continuous monitoring in real-world contexts. This process should aim to integrate data from formal clinical trials with operational insights, ensuring a balance between scientific robustness and practical feasibility.

Given the critical role of RWE in the post-market phase, there is a clear need for policy initiatives that promote the adoption of clinical registries, surveillance infrastructures, and data platforms. These systems should prioritize interoperability and be designed for access by a wide range of stakeholders.

In terms of broader policy design, the research calls for a multidisciplinary strategy that fosters close collaboration among clinical, technical, and managerial professionals. This collaborative approach should operate within a regulatory environment that is adaptable to emerging innovations.

As this study is based on a qualitative design, the findings are not intended to be generalizable. Further research involving additional RHS will be necessary to validate the results and enhance the breadth and transferability of the insights.

Abstract

This paper explores the growing significance of frugal and reverse innovation, two key concepts that address challenges in resource-constrained environments, particularly in developing economies. As businesses expand globally, these innovation models offer cost-effective and sustainable solutions. Frugal innovation focuses on creating affordable, efficient solutions in developing countries, while reverse innovation involves adapting innovations from emerging markets to developed economies. Though both aim for low-cost solutions, they stem from different contexts and raise important strategic questions about their integration into corporate strategies for growth, sustainability, and competitive advantage.

The paper investigates how the intersection of frugal and reverse innovation can enhance the understanding of global business strategies in emerging markets. By examining both conceptual foundations and practical applications, this study highlights their roles in global business dynamics and their potential to transform industries such as healthcare, energy, and education.

The study reviews existing literature through a bibliometric analysis. Out of 554 publications, 365 are bibliographically coupled and assigned to 6 clusters. These interrelated clusters capture the multifaceted nature of frugal and reverse innovation, via the exploration of conceptual frameworks, organizational strategies, social impacts, real-world applications, product-market challenges, and specific sectors like water and sanitation. The findings reveal that frugal and reverse innovations are not isolated but interconnected processes that shape global innovation trajectories.

The paper contributes to both academic and practical knowledge, offering a synthesized understanding of the field, identifying gaps in research, and providing insights for businesses and policymakers. It calls for future research on the co-evolution of North-South innovation flows and empirical studies on user perceptions and adoption dynamics in reverse innovation pathways. Despite its limitations, this study provides a solid foundation for advancing the theory and practice of frugal and reverse innovation.

Keywords: Innovation Strategies, Emerging Markets, Comparative Analysis, Bibliometric Study, Corporate Strategy

Paper type: Academic Research Paper

1 Introduction

This study delves into the growing importance of frugal and reverse innovation, two prominent concepts that have attracted significant attention in business and economic literature due to their potential to address the challenges faced by resource-constrained environments, particularly in developing economies. As the global landscape becomes increasingly interconnected, businesses are recognizing the value of these innovative approaches in expanding their reach while maintaining cost-effectiveness and sustainability. Frugal innovation is primarily characterized by the ability to create affordable, efficient, and resource-conscious solutions, often in response to the challenges of limited resources and infrastructure in developing countries. In contrast, reverse innovation focuses on the development of solutions within emerging markets, which are then adapted and implemented in developed economies, challenging traditional innovation pathways.

Although these two models of innovation share a similar emphasis on creating low-cost solutions, they originate in different contexts and have evolved in parallel, each responding to distinct sets of market conditions and consumer needs. This divergence raises key questions regarding the strategic implications of frugal and reverse innovation, particularly in terms of how they can be integrated into corporate strategies to foster growth, sustainability, and competitive advantage in both emerging and developed markets.

In this context, the paper aims to address the question: "*how can the intersection of frugal and reverse innovation contribute to a more comprehensive understanding of global business strategies in emerging markets?*". By exploring both the conceptual underpinnings and the practical applications of these innovation

models, this study highlights their distinct roles in global business dynamics and examines their potential to drive change in various industries, including healthcare, energy, and education.

In this paper, the following terms are used interchangeably to refer to developing economies, including "developing countries," "developing economies," "low- and middle-income countries," "the Global South," and "emerging markets."

The remainder of the paper is structured as follows. The next section summarizes the literature context and highlights the theoretical concepts dealt with in this study. The methodology is detailed in Section 3, while the results of the study are presented in the fourth section. The paper closes with the conclusions section, followed by the ethical and AI use considerations, and the bibliography in use.

2 Literature context

Innovation is a key driver of economic progress and business growth. It encompasses technological advancements and novel approaches to problem-solving and value creation (Govindan, 2024). Within this broad spectrum, frugal and reverse innovation have emerged as significant paradigms in corporate strategy and product development.

Frugal innovation is characterized by the creation of simplified yet effective solutions that maintain product quality while reducing costs and unnecessary complexity (Qin, 2024). This approach enables companies to design affordable products that serve large and often underserved markets, particularly in resource-constrained environments (Iqbal, Piwowar-Sulej and Kallmuenzer, 2025). It supports sustainability goals by optimizing resource use and minimizing waste,, making it an attractive strategy for companies seeking to balance profitability with social responsibility.

In contrast, reverse innovation describes the process of developing products in emerging markets and subsequently adapting them for wealthier economies (Wang and Wang, 2024). This model leverages the cost advantages of developing regions to create competitive, high-value solutions that, after initial success in price-sensitive markets, are refined and repositioned for high-income consumers (Jack *et al.*, 2024). Reverse innovation allows firms to experiment with lower-cost production methods and consumer-driven adaptations before scaling up to more demanding markets.

3 Methodology

The methodology employed in this article involves a comparative bibliometric analysis to comprehend the evolution of concepts over time, drawing on information published in major research databases such as Scopus. Bibliometrics is a robust approach that can be applied to a wide array of research areas ranging including but not limited to management (Merigó and Yang, 2017) innovation (Albort-Morant *et al.*, 2017; Fisac, Morales-Alonso and Rasool, 2024) and economics (Wang and Li, 2023). It differs from literature review since it presents accurate and objective findings because of its lower subjectivity (Moral-Munoz *et al.*, 2019). Therefore, it presents a complete overview of research trends and is therefore a handy tool when measuring the research field of a specific area (Broadus, 1987; Melnikova and Gilsanz, 2024).

To understand the interconnectedness and thematic evolution within this body of work, we conducted co-citation and bibliographic coupling analyses, following methodologies established by Small (1999) and Cobo et al. (2011), respectively. Bibliographic coupling, in particular, helped identify closely related research clusters by examining shared references among papers, facilitating a deeper exploration of the research subdomains within frugal innovation. The subsequent data visualization, crafted with tools like Microsoft Excel and VOSviewer, provided insightful graphical representations of the publication trends and relationships among the analyzed documents, enriching our comprehension of the field’s developmental trajectory.

4 Data analysis

Bibliographic coupling analysis appears once two papers cite a third mutual publication in their bibliographies. It would be supposed that the more mutual references have two papers the stronger thematic connection there will be between them (Cobo et al., 2011). Out of 554 publications, 365 are bibliographically coupled and assigned to 6 clusters. As shown in Figure 1, clusters represented by green, blue and yellow colors are connected more tightly, while those coloured Red, and purple are more isolated. However interestingly the cluster represented by Cyan colour is not linked to other clusters highlighting diversity in the literature encompassing the field. The size of the bubbles indicates the frequency of citations: the larger the bubble, the higher the frequency. The distance between the bubbles indicates the coupling strength and resemblance. The

colour of the bubble indicates the research area. Coauthorship analysis shows the extent to which authors in the field collaborate, see Figure 2.

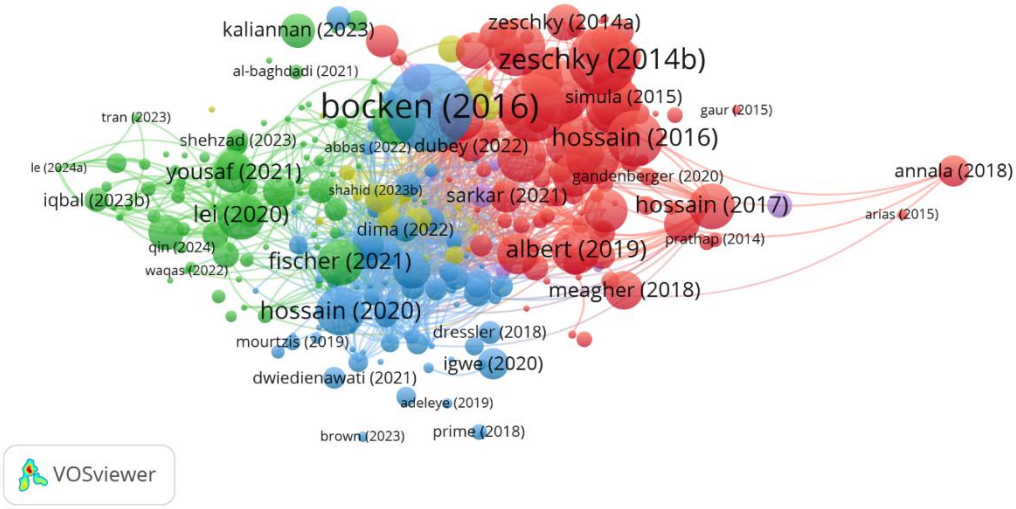

Figure 1: Results of the Bibliographic coupling analysis

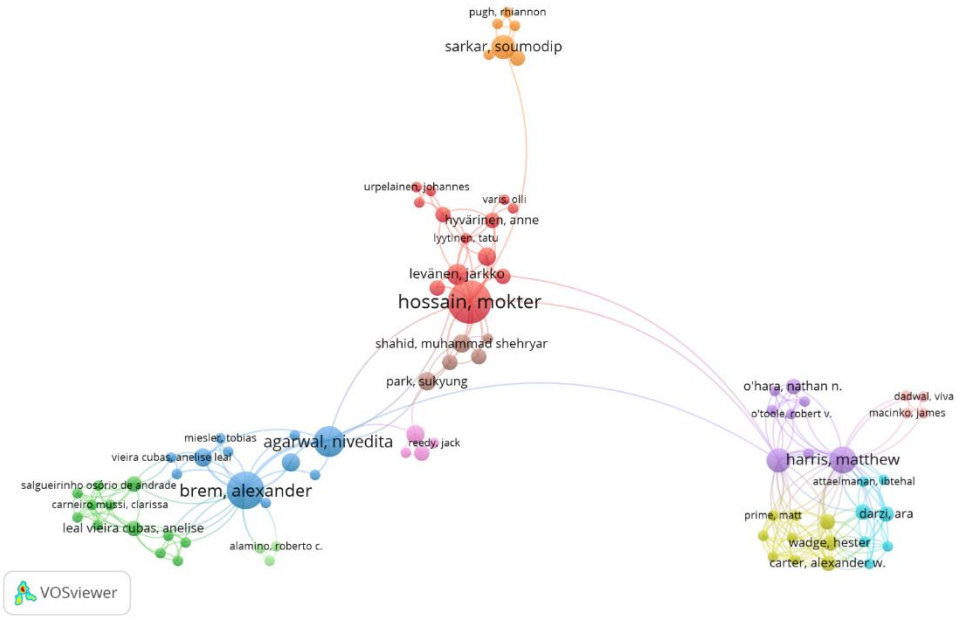

Figure 2: Results of the Coauthorship analysis

4.1 Common research trends by subject areas

This section presents the six thematic clusters of research on frugal and reverse innovation, derived from a keyword coupling analysis of the literature. Each cluster represents a dominant research theme, reflecting how scholarly attention in frugal and reverse innovation has coalesced around particular topics. Notably, while most clusters are interrelated, one cluster (Cluster 6) appears largely disconnected from the rest (Figure 1), indicating a niche research thread with minimal bibliographic overlap. Below, we outline each cluster's focus and significance, citing representative works from the dataset to illustrate the dominant research trends and knowledge gaps.

4.1.1 Cluster 1: conceptual and global perspectives on frugal and reverse innovation

This cluster focuses on the foundational and global discourse on frugal innovation, often intertwined with the concept of reverse innovation. This cluster explores frugal innovation conceptual frameworks and its links to reverse innovation and broader innovation theory. For example, Agarwal and Brem (2012) provides an early overview that explicitly links frugal and reverse innovation, using case studies of a Western multinational innovating in India and China. Such studies articulate how innovations developed under resource constraints in emerging markets can find broader application, thereby bridging global knowledge flows from the "South" to the "North" (the essence of reverse innovation).

Another key theme in this cluster is the role of frugal innovation in achieving sustainability and inclusive growth. Brem and Ivens (2013) introduce a conceptual framework asking whether frugal and reverse innovations foster sustainability, reflecting a prevalent view that cost-effective innovations can align with social and environmental objectives. Additionally, studies in this cluster examine the **institutional and policy contexts** that enable or hinder frugal innovation diffusion. For instance, some studies investigate how regulation and institutional environments affect the **commercialization of frugal solutions** in developing economies (Agarwal and Brem, 2012; Knorringa *et al.*, 2016). Others highlight how **knowledge transfer** between academia, industry, and communities is often facilitated through **social entrepreneurship** or inclusive innovation models—plays a critical role in shaping frugal innovation outcomes (Annala, Sarin and Green, 2018; Fischer *et al.*, 2021). These processes emphasize the importance of collaboration and local contextualization in achieving sustainable frugal innovation, particularly in sectors like healthcare, water, and education. Therefore, it is reported that this cluster highlights the bidirectional flow of ideas where innovation not only trickles down from high-end to low-end markets, but also "trickles up" from resource-constrained settings to affluent markets.

4.1.2 Cluster 2: organizational capabilities and business strategy in frugal and reverse innovation

Cluster 2 moves inside the firm. It asks: how do companies embed frugality in day-to-day practice? Three capability sets recur. First, dynamic sensing-seizing-reconfiguring loops. Leaders scan unmet needs, spot slim cost windows, and rebundle assets fast. Vietnamese SMEs reorganised supply chains within weeks (Le et al., 2022) , and Saudi manufacturers tied the same agility to cultures that reward disciplined improvisation (AlMulhim, 2021) . Second, digital leverage. AI surfaces hidden demand, cloud CAD slashes prototype cycles, and low-cost IoT tracks post-sale use. An Indonesian case cut design time from sixty days to eight by shifting modelling to open cloud rigs (Achmad and Inrawan Wiratmadja, 2024). U.S. med-tech start-ups crowd-sourced firmware fixes overnight with similar gains (Howell, van Beers and Doorn, 2018). Third, strategic framing. Blue-Ocean logic steers firms away from price wars, while adversity sparks bricolage that later hardens into process (Zeschky, Widenmayer and Gassmann, 2011; Winterhalter *et al.*, 2017). Framing constraint as opportunity doubled project survival odds in Ghanaian agritech ventures (Adomako *et al.*, 2024). Tensions persist. Low price points squeeze cash; premium brands fear dilution; classic KPIs ignore carbon saved or users reached. A new dashboard ranks "impact per dollar" beside ROI, helping boards balance money and meaning (Abbas and Liu, 2022). Taken together, these studies show frugal and reverse innovation succeed when capability, data, and narrative lock tightly, turning constraint into a continuous source of strategic renewal.

4.1.3. Cluster 3: frugal and reverse innovation for sustainable development and social impact

Cluster 3 frames frugal innovation as a lever for the Sustainable Development Goals. Its studies show lean design cutting emissions while improving daily life. Firm-level work links innovation capabilities to greener practice and higher export competitiveness among Indian manufacturers (Adhikari and Momaya, 2021) and identifies lean start-ups in emerging economies that turn eco-innovation into market traction (Abbas and Liu, 2022). Many papers highlight grassroots co-creation. Quadruple-Helix partnerships—community makers, NGOs, universities, local government build mobile clinics and low-cost farm tools, then refine them in fast feedback loops (Bhattacharjya, Bhaduri and Kakoty, 2023; Akhtar and Ramkumar, 2024). These bottom-up models treat users as co-owners, not beneficiaries, strengthening uptake and maintenance. Reverse flows give the cluster its second strand. Low-cost diagnostic kits born in rural India now serve remote clinics in Europe, while solar water-heating concepts tested in Brazil inform resilience plans in the United States (Busch *et al.*, 2018). SMEs in Germany have even adopted sufficiency-oriented business models inspired by these Southern experiments (Dellermann, 2017). Authors argue that such "trickle-up" learning challenges the idea that advanced economies are always technology donors and positions frugality as a source of climate-aligned disruption (Albert, 2019).

Technology alone, however, cannot secure impact. Studies on mobile health vans and water-filter roll-outs show diffusion sticks only when users keep data rights and share revenue streams (Bhatti *et al.*, 2017). Business-model research reinforces this point: framing offers as "smart and sustainable" rather than "cheap" boosts

status and adoption in affluent niches (Rosca, Arnold and Bendul, 2017). Overall, Cluster 3 redefines frugal and reverse innovation as a social–ecological contract. Cost savings matter, but the bigger prize is inclusive ownership, carbon relief, and knowledge that flows both south–north and north–south. Future work the cluster recommends includes tracing value capture along these bidirectional journeys and developing metrics that record lives improved per dollar spent, not just units sold.

4.1.4. Cluster 4: implementation and adoption of frugal and reverse innovation in practice

Cluster 4 leaves the whiteboard and enters the field. Case papers track how frugal ideas survive the jump from pilot to daily use. A well-cited example is Vortex Engineering's solar-powered ATM network in rural India; by mixing ultra-low-power chips with rooftop panels, the firm brought banking to villages that lacked stable grid access (Agarwal and Brem, 2017). Health studies echo the story. Mobile primary-care vans built on recycled bus shells serve remote patients for a tenth of the cost of fixed clinics (Akhtar and Ramkumar, 2024), while community makers in Assam co-created drip-irrigation kits that cut water use by half (Bhattacharjya, Bhaduri and Kakoty, 2023). Method papers explain how such projects move fast on thin budgets. Constraint-based thinking offers a step-by-step playbook: freeze a hard price or energy cap, then "engineer backward" to fit it (Agarwal, Oehler and Brem, 2021). Scrum sprints adapted for hardware keep prototypes rolling every two weeks; one med-tech team reported an eight-to-one cut in design time after switching to this cadence (Endres, Bican and Wöllner, 2022). Co-creation widens the safety net. University labs, NGOs, and local user groups meet in weekend build-athons, making tacit know-how explicit and locking in community ownership (Annala, Sarin and Green, 2018; Bhattacharjya, Bhaduri and Kakoty, 2023).

Adoption research digs into perception. Survey work in Jordan finds that value, peer cues, and quality signals explain 70 % of purchase intent for frugal appliances; stigma around "cheap" still bites, but "smart-green" framing helps neutralise it (Al-Refaie, Abu-Ghannam and Al-Hawadi, 2023). Crisis tests add another angle. Indonesian SMEs with modular product lines pivoted to pandemic gear in weeks, showing that frugal architectures boost resilience when supply chains snap (Achmad and Inrawan Wiratmadja, 2024). Taken together, Cluster 4 argues that successful roll-out blends tight engineering routines, inclusive design spaces, and branding that elevates thrift to savvy. When those pieces click, frugal and reverse innovations leap the "valley of death" and prove that low-resource contexts can host world-class implementation playbooks.

4.1.5. Cluster 5: design and market challenges in frugal and reverse innovation

Cluster 5 zooms in on the design bench and the showroom. The central task is a paradox: slash cost and complexity without stripping the value cues that trigger purchase. Studies start with constraint-based playbooks. Agarwal et al. (2021) describe teams fixing a non-negotiable retail ceiling often US $20 or half the incumbent's carbon load—and then "engineering backward" to meet it, trading plastics for bio-composites and combining off-the-shelf chips with open-source firmware . Brem et al. (2020) add staged filters need, usability, ecosystem to keep frugality from drifting into under-performance; one Kenyan water-pump project passed all three gates at one-third rival cost . Market trials expose the psychology behind "cheap." Al-Refaie et al. (2023) show status stigma still lingers in upper-middle segments, yet framing products as "smart-green" rather than budget lifts willingness to pay by 22 percent . Rosca et al. (2017) report similar results for modular solar kits that let households upgrade over time, turning thrift into future-proofing . Premium brands tackle cannibalisation risk by creating spin-off labels, separating low-cost lines from flagship offerings while highlighting durability and eco-benefits.

Regulation tightens the puzzle. Auma et al. (2023) document a portable diagnostic device that met EU safety norms at one-tenth incumbent cost only after early co-testing sessions with regulators, saving six months in certification . Health and energy sectors replicate this path, pairing minimum viable prototypes with "compliance sprints." Across cases, three design levers surface: rigorous cost ceilings, narrative repositioning that shifts "cheap" to "savvy," and iterative regulator dialogue. Cluster 5 thus recasts frugal design as strategic craftsmanshipbalancing engineering trade-offs, consumer perception, and rule-of-law hurdles inside one tight feedback loop.

4.1.6. Cluster 6: frugal and reverse innovation in water and sanitation technologies (isolated cluster)

Cluster 6 is the smallest node on the map yet tackles a basic need: safe water. Its papers are heavily technical, coming from environmental engineering and materials science rather than management. The signature solution is the metallic-iron (Fe^{o}) filter. By letting a thin rust layer form on cheap iron granules, these filters strip arsenic, fluoride, and microbial contaminants while staying decentralized, gravity-driven, and almost maintenance-free (Btatkeu-K. *et al.*, 2016). Field pilots in Cameroon, Tanzania, and India show toxin reductions that meet WHO

drinking-water limits with bucket-scale units costing a few dollars (Ndé-Tchoupé *et al.*, 2015, 2018). Much of the research optimizes Fe/sand ratios, corrosion kinetics, and filter life, supplying rigorous design criteria that earlier "jugaad" devices lacked. Bibliometric positioning, however, reveals an island. Cluster 6 cites almost no work from the broader frugal-innovation community and is likewise ignored by management scholars . The silo stems from disciplinary focus journals prize removal efficiency over adoption models but it creates a lost handshake. Without market studies, promising filters stall at prototype. Without the filter data, frugal-innovation theory lacks material depth.

Authors in the cluster now call for bridges. Pair lab tests with ethnography to learn why users abandon filters, enlist micro-finance to fund household uptake, and frame water devices as climate-adaptation assets to unlock public grants. Community stewardship boards already extend filter life and trust faster than top-down campaigns . In short, Cluster 6 shows that hardcore science can meet radical affordability, but scalable impact will require boundary-spanning teams that blend corrosion chemistry with business modelling and policy design.

5 Conclusions

The review shows that frugal and reverse innovation research has moved from scattered anecdotes to a coherent conversation about how scarcity, knowledge flows, and social purpose that reshape global innovation practice. By coupling 365 papers into six clusters we traced a route that loops from theory to strategy, to grassroots action, and back again, revealing a field cohesive enough to guide managers yet flexible enough to welcome new voices. Three insights stand out. First, frugality is no longer a stereotype of the Global South; multinationals now treat constraint-led design as a proving ground for resilience, then re-import streamlined solutions to mature markets where cost and carbon pressures converge, which can lead innovations that spring on developing countries to be used in developed settings (reverse innovation). Second, social value is not a by-product but the hinge that lets low-cost ideas cross borders. Case work on water filters, mobile clinics, and off-grid devices shows adoption rises when organisations share ownership, data, and gains with local users; technical brilliance alone stalls at pilot stage. Third, blind spots between disciplines still block scale. Engineering research on sanitation, for instance, rarely cites management studies and so misses distribution models that could lift laboratory success into daily life.

These patterns suggest a practical agenda. Firms should form mixed teams that pair material scientists with market strategists early, embed constraint metrics into stage-gate reviews, and track "impact per dollar" alongside return on investment. Policymakers can tilt incentives by granting premiums to products that document south-north knowledge transfers and by supporting shared-IP deals that leave part of the upside in origin communities. Scholars should shift from static taxonomies to longitudinal tracking of real product journeys, using network analysis, ethnographic shadowing, and replication studies to expose where idea flows thicken or dry up. Business schools can reinforce the shift by capping cash, carbon, and material budgets in design studios so that frugality becomes muscle memory for the next generation of innovators. Finally, the bibliometric lens reminds us of its limits: it maps dialogue but cannot hear it. Fresh ethnographies and comparative fieldwork are needed to catch nuance, measure stigma, and follow cash. Even so, the map is a useful compass. It shows that when resource mindfulness, inclusive intent, and iterative learning reinforce one another, frugal and reverse innovation cease to be niche labels and become a general method for building affordable, sustainable, and context-sensitive solutions, a lesson practitioners, policymakers, and researchers can carry forward.

The Use of Generative AI and Lean UX in Knowledge Engineering Projects

Ranieri Alves dos Santos, Fernando Alvaro Ostuni Gauthier, Marcelo Macedo, Vanessa Roberg
Federal University of Santa Catarina (UFSC), Florianopolis, Brazil

Abstract

The need for user-centered and agile solutions has driven the adoption of methodologies such as Lean UX in knowledge engineering projects. While Lean UX focuses on thinking, making, and checking to enhance user experience, knowledge engineering is dedicated to building intelligent systems grounded in formalized expert knowledge. Despite the conceptual alignment between these approaches, the integration of Generative Artificial into this context remains underexplored. This study proposes a model that incorporates generative AI tools into the Lean UX process to accelerate and enhance the development of knowledge-based systems. Based on the Design Science Research (DSR) methodology, a narrative literature review and exploratory research were conducted to identify generative AI techniques applicable to each Lean UX phase: Think, Make and Check. A total of 10 generative AI approaches were mapped and organized into a model that supports small and agile teams in knowledge engineering projects. The model was instantiated through the development of GPT-based agents customized for specific tasks, such as persona generation, empathy mapping, requirements analysis, and prototype creation. These agents leverage prompts containing transcripts, observations, or interview data to generate detailed and realistic outputs, streamlining processes that are traditionally manual and time-consuming. One example presented is the Persona Generation Agent, which creates structured user profiles and illustrative images from simple textual input. This integration contributes both theoretically and practically by demonstrating how generative AI can be used to enhance user experience (UX) focused design processes in knowledge engineering. The proposed model promotes more efficient workflows, while keeping the user at the center of development. It also supports interdisciplinary collaboration, faster iteration cycles, and the creation of intelligent systems that are more aligned with user needs. Future work includes empirical validation of the model in diverse application contexts, aiming to refine its use and encourage widespread adoption in knowledge engineering and related fields.

Keywords: lean ux; knowledge engineering; generative ai

Paper type: Research Paper

1 Introduction

With the growing demand for more effective, personalized, and adaptable digital solutions, user-centered methods with iterative cycles have gained prominence in the development of products and services. Among these methods, Lean UX stands out for its agile, collaborative, and user experience (UX) oriented approach, promoting a culture of continuous experimentation, rapid learning, and hypothesis validation based on real usage evidence. By integrating cross-functional teams and reducing reliance on heavy documentation, Lean UX fosters more dynamic processes aligned with end-user needs.

These characteristics make Lean UX particularly promising for fields such as knowledge engineering, whose main goal is to develop intelligent systems based on specialized and structured knowledge. Knowledge engineering, in turn, demands methodologies that allow for a deep understanding of usage contexts, user profiles, and the specificities of the domains in which the systems will be applied. The convergence between Lean UX and knowledge engineering thus emerges as a strategic opportunity to enhance the creation of more effective, usable, and context-aware technological solutions.

Despite the potential synergies between these approaches, the literature still lacks in-depth investigations into how emerging technologies such as Generative Artificial Intelligence (Generative AI) can be integrated to improve development processes in both areas. Generative AI, with its ability to create original content from large volumes of data and interact through natural language, presents itself as a powerful tool for automating tasks, generating insights, and accelerating iterative cycles.

In this context, this study aims to conduct a narrative review and exploratory research to identify Generative AI techniques that can be applied at different stages of the Lean UX process. Based on this investigation, the study proposes a model that combines Lean UX principles with the strategic use of Generative AI tools, aiming to support the development of intelligent systems in the field of knowledge engineering, especially in environments with small teams, tight deadlines, and high demand for innovation.

2 Methodology

This study adopted the Design Science Research (DSR) model as its methodological foundation, as it is a widely recognized approach in the field of information systems and well-suited for the development of innovative and applied solutions. DSR is characterized by the construction and evaluation of artifacts—which may take the form of models, methods, system instances, or frameworks with the goal of solving real-world problems based on scientific rigor (Hevner et al., 2004). Furthermore, DSR proposes an iterative cycle that includes problem identification, artifact construction, demonstration, evaluation, and, finally, communication of the results, ensuring that the knowledge produced is relevant to both practice and academia.

In this context, the model proposed in this study is conceived as the central artifact of the research, and its applicability to knowledge engineering projects is treated as the practical instantiation of that artifact. Instantiation refers to the application of the model in real or simulated contexts, with the purpose of assessing its feasibility, usefulness, and potential for generalization.

To support the construction of the model, the study was structured around a narrative literature review aimed at identifying previous approaches that explored the use of Lean UX methods in the context of knowledge engineering. The review also encompassed foundational literature in the involved domains, particularly the conceptual and methodological underpinnings of Lean UX and knowledge engineering. The analysis focused on recent publications that highlight emerging trends and underexplored gaps, especially concerning the integration of emerging technologies, such as Generative Artificial Intelligence, into iterative and collaborative system development processes.

3 Lean UX in Knowledge Engineering

Lean UX, a method focused on the development of user-centered products, especially digital products (Gothelf and Seiden, 2021) shows potential for application in knowledge engineering, a field dedicated to intelligent, knowledge-based software system solutions (Schreiber et al., 2000), by incorporating its principles and phases into the development of intelligent systems.

The principles of Lean UX, such as cross-functional teams, product focus, and a culture of experimentation, have proven effective in knowledge engineering projects. Collaboration between human experts and the engineering team is essential for knowledge capture, while a product-focused approach—without prioritizing documentation as the main deliverable enhances the efficiency of developing knowledge management systems. Furthermore, tolerance for failure and continuous experimentation make it possible to measure user satisfaction in each iteration. Finally, keeping the user at the center of the process involves stakeholders and experts, promoting testing and contributing to the success of the solution.

The phases of Lean UX can be applied to knowledge engineering projects by drawing parallels with the CommonKADS models (Schreiber et al., 2000). The "think" phase, aimed at conception and needs elicitation, corresponds to the organization, task, agent, knowledge, and communication models of CommonKADS. The "make" phase includes the design model for system architecture and implementation, while the "check" phase focuses on user evaluation, initiating new development cycles based on the results of usability testing.

4 Generative AI in Lean UX

Several studies were identified that explore the application of Generative AI techniques in tasks traditionally carried out manually during the design of digital products. Among these contributions, those focused on automating collaborative dynamics stand out, such as the analysis of sticky notes, which are often used in workshops and brainstorming sessions. For example, the work of Walch and Karagiannis (2020) demonstrates how algorithms can interpret and cluster content written by users on physical or digital notes, generating thematic summaries and facilitating collective knowledge construction in the early stages of the Lean UX process.

Another innovative area involves the automatic generation of personas based on transcripts of user interactions, such as interviews or observational data. These approaches apply natural language models to extract behavioral traits, goals, and recurring user needs, enabling the creation of realistic, data-driven user profiles that support more informed design decisions.

Additionally, there is a growing body of research focused on the automated generation of storyboards and user flow narratives, tools that are essential for mapping user journeys and visualizing interaction logic with systems and interfaces. Studies such as those by Jansen et al. (2021), Salminen et al. (2019), Chung (2024), and Liang et al. (2024) show that AI-based tools can not only structure these elements from textual requirements but also suggest creative alternatives and flow variations, fostering innovation in interaction design. In the field

of requirements engineering, works by Ronanki et al. (2024) and Sami et al. (2024) demonstrate the feasibility of automatically extracting and organizing software requirements from textual transcripts, significantly reducing elicitation time and improving the consistency of the generated documentation.

Regarding the prototyping phase, studies by Takaffoli et al. (2024) and Chivukula et al. (2024) propose AI-based solutions for automated wireframe generation and layout optimization, drawing on usability patterns and user preferences identified in large datasets. These solutions enable faster creation of visual interface drafts, allowing for more frequent testing and refinement cycles. Other approaches, such as those by Suleri et al. (2019) address the automatic transformation of low-fidelity prototypes into medium- and high-fidelity versions, using sketch recognition and visual completion techniques to produce more detailed and interactive interfaces.

In the evaluation stage, notable contributions include the use of simulator agents, usability analysis tools based on predictive metrics, and emotion recognition systems that assess users' emotional states during interaction with prototypes. Research by Wallach et al. (2020) and Chivukula et al. (2023) suggests that combining sensors, computer vision, and predictive models can provide accurate feedback on the user experience, anticipating usability issues, measuring engagement levels, and identifying critical frustration points along the user journey. These advances make interface evaluation more robust and objective, enabling more confident decision-making in the iterative design process.

5 Proposed Model

Based on the theoretical framework explored throughout this study and focusing on the strategies, trends, and contributions of Generative AI analyzed in the research, this work proposes a Knowledge Engineering project model that leverages Generative AI to accelerate product development processes with a focus on user experience.

The core premise of this model is to involve users, domain experts, and the technical development team throughout the entire process, aiming to ensure the success of knowledge engineering projects by grounding them in Lean UX principles applied to the development of intelligent knowledge management systems. The proposed model is informed by narrative literature reviews of previously proposed approaches regarding the use of Lean UX methods in knowledge engineering, as well as foundational literature on both knowledge engineering and Lean UX, with an emphasis on identifying unexplored potential highlighted in recent studies.

To systematize the proposed model, a graphical representation was developed using the stages of Lean UX arranged in a circular format, aiming to illustrate the iterative nature of the process as applied to knowledge engineering projects. This representation is shown in Figure 1.

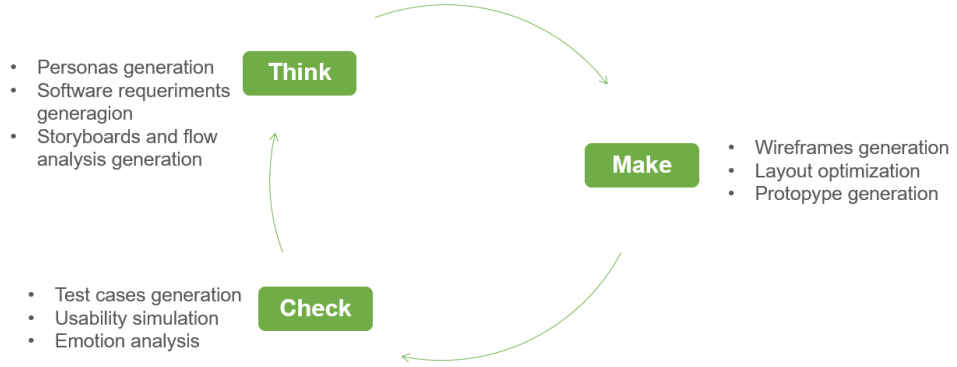

Figure 1: Proposed Model

In the “Think” stage, the use of agents and GPT models is proposed to analyze transcripts of meetings, observations, and interviews for the automatic generation of personas, software requirements, flow analyses, and storyboards. In the “Make” stage, tools for generating graphics and optimizing prototypes are suggested, aiming to test the product's MVP. In the “Check” stage, processes for testing and automatically evaluating the analyses of the prototyped product from the previous stage are proposed.

6 Results

Following the premise of DSR, in which artifacts are realized through their instantiation, and aiming to demonstrate how the model can be used in practice, the instantiation of this artifact was based on the operationalization of the proposed stages and Generative AI agents. To materialize this artifact, the stages based

on Lean UX, proposed for the development of knowledge engineering projects—were enhanced by the integration of Generative AI agents.

These agents were implemented according to the structure proposed by the model, using GPT (Generative Pretrained Transformers) technology, specifically customized versions of OpenAI's ChatGPT. GPTs are agents developed to perform specific tasks and meet particular needs. These models can be trained using databases, manuals, historical records, or other relevant sources, enabling them to understand technical terminology and the specificities of particular domains.

GPT agents can be created using tools such as OpenAI's GPT Builder and can be made available through the GPT Store, OpenAI's platform for creating, publishing, and monetizing custom GPTs. This marketplace provides an environment for developers and organizations to share their GPT-based solutions with the public.

To illustrate the instantiation of the proposed model through GPT agents, Figure 2 presents the persona generation agent. This agent accelerates the work of the knowledge engineering team by automatically constructing the ideal persona framework for use in knowledge management systems.

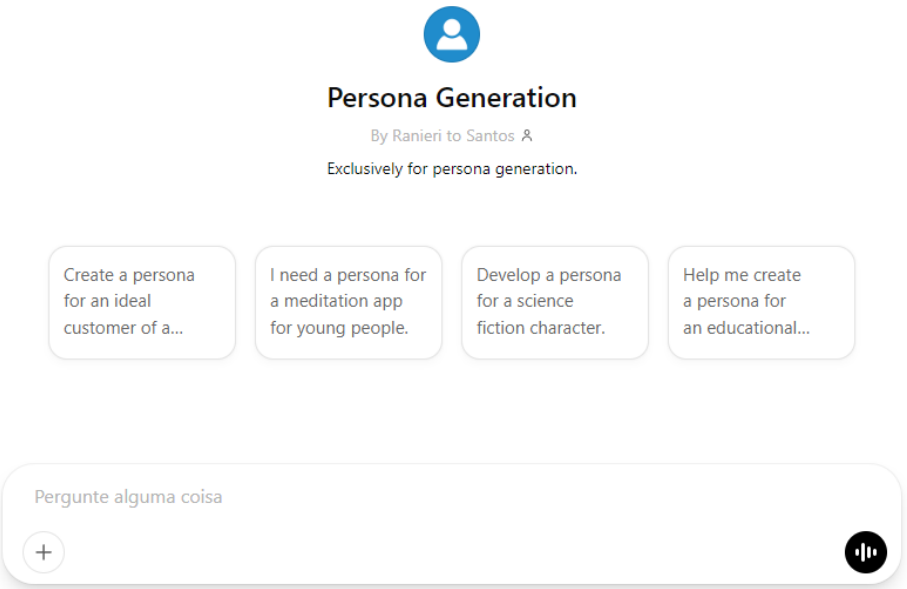

Figure 2: Persona Generation Agent

Using the specific GPT agent, the knowledge engineering specialist can generate a persona for their product by entering a prompt. The prompt may include transcripts of interviews, observations, and other details regarding the behavior of the product's users.

To demonstrate this process, Figure 3 shows a sample result from the persona generation agent, representing a user of a knowledge management product designed for higher education faculty. In the figure, it is possible to see that, in addition to a detailed persona profile, a representative image of the ideal user is also generated.

The implementation of this agent is based on the GPT's ability to process and generate personalized content from specific prompts. This allows personas to be created efficiently and tailored to the specific needs of a given product or service. The methodology used for persona generation involves the collection of demographic, behavioral, and social data, which are essential for creating realistic and relevant user profiles. This information is entered via prompt and can take the form of simple imperatives or transcripts from conversations, interviews, and observations. These inputs are then processed by the GPT to generate personas that reflect the characteristics, goals, and challenges of the target users.

The inclusion of elements such as name, illustrative photo, and contextual background helps make the personas more tangible and easier to understand for design and development teams. This promotes a deeper understanding of user needs and facilitates more informed decision-making throughout the user experience design process.

Name

Dra. Camila Ribeiro

Data

- **Age:**36 years old
- **Profession:** University Professor of Mathematics
- **Training**PhD in Applied Mathematics from the State University of Campinas

Personality

Camila is analytical,

Context

Camila teaches at a university

Wishes

It seeks to make mathematics teaching more accessible.

Figure 3: Persona Generation Agent Result

As can be observed, the output generated by the persona agent delivers a detailed and realistic profile that encompasses the essential characteristics of the target user, based on the agent's programmed pattern even from a simple prompt. The persona generated by the GPT agent not only provides general and illustrative data but also delves into personality traits, life context, desires, needs, and motivations, as well as common pains and frustrations of the intended user group.

This depth of information enables design and development teams to better understand who their users are and how they interact with the product or service.

7 Conclusions

The practical instantiation of the model through the development of agents based on customized GPTs demonstrated how traditionally manual and time-consuming processes, such as persona creation, can be transformed into faster, more systematic tasks that are deeply connected to users real needs. The customization of agents, combined with the flexibility of data input via prompts, enables their application across diverse contexts while respecting the specificities of each knowledge domain.

In addition to contributing to the theoretical advancement at the intersection of Lean UX and Knowledge Engineering, this work also offers a practical contribution by demonstrating how Generative AI tools can be integrated into project teams workflows, even in resource-constrained environments. The proposal aims not only to increase productivity but also to maintain user centrality throughout all stages, enhancing teams' ability to deliver more relevant, empathetic, and effective solutions.

As future work, there is a need for empirical validation of the model in different application contexts, through case studies and experiments with real users. It is expected that, with the advancement of AI technologies and the growing accessibility of such tools, the integration proposed here will become a common practice in Knowledge Engineering projects and related fields. Thus, the model can continue to evolve, incorporating new techniques, tools, and practical insights that will feed back into its cycle of continuous improvement.

Food Waste Valorisation: A Comparative Study with a Hybrid AHP-Fuzzy Approach

Stefano Abbate[1], Piera Centobelli[2], Maria Di Gregorio[2]
[1]Pegaso Telematic University, Naples, Italy
[2]University of Naples Federico II, Naples, Italy

Abstract

The wine industry generates different waste and by-products that can be converted into high-value goods, such as biogenic products or energy, offering new market opportunities and reducing the environmental implications. However, the variety of technologies available complicates the selection of the best valorisation option. An effective evaluation system integrating economic, technical, environmental, and social factors is essential for choosing appropriate valorisation strategies. In this study, we apply the Analytic Hierarchy Process and Fuzzy Set Theory to comprehensively assess food waste valorisation within the wine industry. Our results indicate that anaerobic digestion technology is the best option to valorise winery waste. This framework helps decision-makers evaluate waste valorisation strategies holistically, highlighting the need for investments in sustainable technologies tailored to specific company characteristics.

Keywords: Analytic hierarchy process; Fuzzy logic; Food waste valorisation; Sustainability; Technologies

Paper type: Academic Research Paper

1 Introduction

Food waste is a major concern today, negatively impacting the environment, society, and economy, affecting individual companies and the entire community (Stone et al., 2019). Every year, one-third of all food produced worldwide is lost or wasted somewhere along the food supply chain (Dora et al., 2021). This impressive statistic highlights the inefficiency of production and consumption systems and represents a significant environmental and economic challenge. In the context of a circular economy, recovering and valorising food waste is critical for the environmental and economic sustainability of the supply chain (Dora et al., 2021). The wine industry offers a relevant example of food by-product generation, such as pomace, grape seeds and peels. These by-products, if mismanaged, represent a disposal problem; however, at the same time, they offer a unique opportunity for valorisation (Abbate et al., 2024). Innovative technologies have the potential to significantly transform food waste into high-value goods, encompassing a range of valuable items, including phenolic compounds, which are essential in various industrial applications, food supplements that enhance nutritional value, cosmetics that promote skin health, and biofuels that provide renewable energy sources. Notably, producing renewable energy from waste contributes to a transition towards more sustainable systems. By converting organic waste into energy, reliance on fossil fuels is reduced, greenhouse gas emissions are minimised, and a circular economy is promoted where resources are continuously reused and recycled.

Recent research is lacking in comparing technological advancements for valorising food waste generated during production. Nevertheless, it is crucial to identify the most effective methods for disposing of and reusing such waste based on specific contexts and related variables (Eseoglu et al., 2022). As a result, this study assesses and compares different food waste valorisation technologies mainly used in the wine-growing context (i.e. anaerobic digestion and pyro-gasification) according to various economic, environmental, and social parameters. In particular, this research combines the fuzzy set theory (FST) and the analytical hierarchy process (AHP) to weigh each parameter, rank the different food valorisation technologies based on the evaluation criteria, and identify the most suitable solution.

The paper is organised as follows. The next section presents a literature review on the topic. Section 3 shows the methods adopted for the empirical investigation. Section 4 presents the study's results. Finally, section 5 highlights the conclusions, implications, and future research avenues.

2 Literature review

Given the technical, economic, environmental, and social aspects, selecting the most sustainable approach to managing food waste is challenging. A prevalent method in the food industry for recycling waste is composting. This process converts waste into a nutrient-dense natural fertiliser, enhancing crop yields and offering a sustainable and eco-friendly solution for handling food waste (Ciclia, 2021). Composting technologies,

such as the in-vessel system and the vermicomposting system, have different approaches but share the same goal of transforming organic waste into nutrient-rich compounds (Shukor et al., 2018). In addition, through polyphenol extraction processes from grape marc, it is possible to improve the nutritional and sensory attributes of foods such as meat burgers, muffins, and yoghurt (Rodriguez et al., 2023).

Furthermore, technologies that produce bioenergy from food waste (e.g. anaerobic digestion and pyro-gasification) are seen as innovative solutions, generating renewable energy and reducing the environmental impact of the sector. Different researchers (e.g. Adenuga et al., 2020; Mahjouri et al., 2017) showed that anaerobic digestion is the most eco-friendly technology when compared to other methods. This approach enables the treatment of waste with high water content to generate biogas and digestate as a by-product of processing. Similarly, pyro-gasification technology converts by-products into synthetic gases suitable for energy production. In particular, this technology works through the partial combustion of dry waste, also generating biochar, which serves as a biofuel and soil amendment, thus offering an environmentally friendly option for carbon capture (Rodriguez et al., 2023).

Compared to previous research, the originality of this study lies in several key aspects. First, we have integrated social and community criteria into the evaluation system; these factors are often overlooked in traditional models. Notably, we included considerations such as the social acceptance of the technology and its impact on sustainable development goals (SDGs), encompassing aspects like job creation and public health. Additionally, we considered technical factors, including the amount of product or energy recovered from waste relative to the total amount of waste processed and safety considerations. Finally, we performed a Delphi study to confirm the relevance of the chosen criteria and sub-criteria.

3 Methods

A thorough review of scientific literature was initially conducted to establish diverse criteria for evaluating waste-to-value technologies. In addition, we conducted a Delphi study to validate the proposed framework and ensure the relevance of the selected criteria and sub-criteria. We involved experts and professionals working in the wine sector with knowledge/experience on the sustainability (both academically and practically) of technologies used for waste/sub-product valorisation and management. This is a well-recognised approach for gathering expert input, featuring participant anonymity and structured feedback (Diamond et al., 2014). An initial questionnaire gathered expert feedback on the evaluation system based on criteria from a systematic review of scientific literature. Experts confirmed that the first-level criteria effectively captured essential aspects of evaluating waste and by-product valorisation technologies in the wine sector. However, some adjustments to the sub-criteria were suggested. The second Delphi study iteration revealed unanimous consensus among participants, leading to the final validation of the criteria and sub-criteria for evaluating wine waste and by-product valorisation technologies (Figure 1).

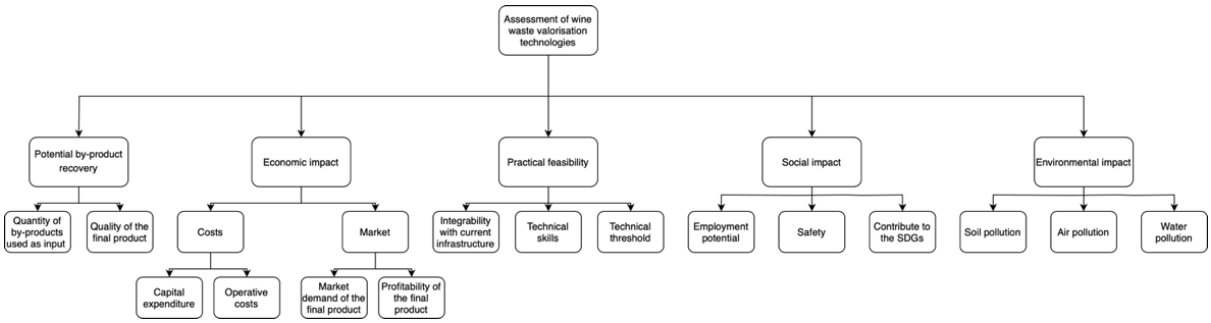

Figure 1. Evaluation system

Subsequently, we combined the AHP methodology with the FST to enhance flexibility and accuracy in addressing uncertainty (Bruno et al., 2016). In this phase, data was gathered via individual interviews and questionnaires submitted to experts from companies in the agricultural and clean-tech sectors. This heterogeneous group of participants provided a broad spectrum of skills and perspectives crucial for a comprehensive assessment of the technologies. Notably, the AHP is a structured method used to address complex decisions. It decomposes the problem into a hierarchical structure, enabling decision-makers to make comparative assessments among various criteria and available options in an organised and rational way (Jiang et al., 2011). The AHP process is developed through five main stages (Saaty, 1980), which are outlined below:

1. Organising the problem into a hierarchy, which is structured in different levels, ensuring consistency in scale and size.
2. Conducting the pair-wise comparison assessment. It defines the relative importance of criteria through two-sided comparisons. Saaty's scale, from one to nine, was used to weigh the relative importance of each item.
3. Determining the relative weights, derived from the eigenvector-based methodology.
4. Assessing the consistency ratio. It is essential to ensure that the weights of the alternatives accurately represent the judgments of the individuals who conducted the comparisons.
5. Aggregating the relative values assigned to each group of alternatives across different levels of the hierarchy.

Furthermore, the FST is a research approach that deals with uncertainty in information by using fuzzy sets instead of traditional sets (Attri et al., 2022). This method employs membership functions to assign a truth degree to each element, ranging from 0 to 1. This approach demonstrates its effectiveness in processing inaccurate data or concepts that cannot be strictly classified as true or false (Mahjouri et al., 2017). Next, defuzzification is applied to change the ambiguous ratings into measurable and clear values (Centobelli et al., 2018). Notably, our case study examines five qualitative levels to define performance criteria, and a triangular fuzzy term-set was used (Figure 2).

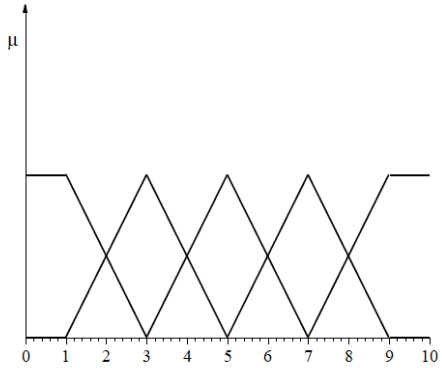

Figure 2. Triangular fuzzy term-set

In the performance evaluation phase, criteria-related indicators are evaluated through an extensive data collection process (Centobelli et al., 2018). The numerical indicators are converted into fuzzy numbers, allowing for a more nuanced and precise depiction of performance. These fuzzy performance metrics and weights are then merged with the weighted average operator, which reduces entropy spread and yields an accurate final assessment. In the final step, alternatives can be ranked according to their final fuzzy scores.

4 Results

The results of the AHP method highlight that the economic sphere (0.393) and the technological aspect related to resource recovery potential (0.325) are the factors that most influence the choice to implement a technology. In the agribusiness sector, it is vital to prioritise the economic sustainability of technology, considering both capital and operational expenses first. A technology's capacity to lower operational costs via energy efficiency and waste reduction significantly impacts its adoption. Additionally, the potential for resource recovery is essential as it enhances the value of farm by-products. This allows for the recovery of disposal costs and aids in producing high-quality outputs for successful marketing. Another critical factor is the quality of the outputs generated by these technologies. Effectively positioning products in the market, responding to demand, and meeting quality standards are crucial for economic viability. Furthermore, a technology's ability to produce marketable products at competitive prices can significantly affect the decision to implement it.

To implement the FST, two interviews were conducted with experts in anaerobic digestion and pyro-gasification. After obtaining performance values for each sub-criterion of the evaluation system, it was necessary to cross-reference these values with the triangular term set to associate each criterion with a fuzzy value. After determining the fuzzy performance values for each criterion, it was necessary to weigh these numbers with the respective AHP weights, implementing a combined approach. Tables 1 and 2 present the procedure for evaluating anaerobic digestion technology.

Table 1. Fuzzy values of the sub-criteria (anaerobic digestion)

First level criteria	***Sub-criteria***	***Crisp performance values***	***Fuzzy values***
Potential by-product recovery	Quantity of by-products used as input	7	(5, 7, 7, 9)
	Quality of the final product	9	(7, 9, 10, 10)
Economic impact - Costs	Capital expenditure	7	(5, 7, 7, 9)
	Operative costs	8	(6, 8, 8.5, 9.5)
Economic impact - Market	Profitability of the final product	8	(6, 8, 8.5, 9.5)
	Market demand for the final product	8	(6, 8, 8.5, 9.5)
Practical feasibility	Integrability with current infrastructure	6	(4, 6, 6, 8)
	Technical skills	7	(5, 7, 7, 9)
	Technical threshold	7	(5, 7, 7, 9)
Social impact	Employment potential	7	(5, 7, 7, 9)
	Safety	8	(6, 8, 8.5, 9.5)
	Contribute to the SDGs	8	(6, 8, 8.5, 9.5)
Environmental impact	Air pollution	6	(4, 6, 6, 8)
	Soil pollution	4	(2, 4, 4, 6)
	Water pollution	5	(3, 5, 5, 7)

Table 2. Weighted fuzzy values of the second-level criteria (anaerobic digestion)

First level criteria	***Sub-criteria***	***Fuzzy values***	***AHP weights***	***Weighted fuzzy values***
Potential by-product recovery	Quantity of by-products used as input	(5, 7, 7, 9)	0.482	(2.41, 3.37, 3.37, 4.34)
	Quality of the final product	(7, 9, 10, 10)	0.518	(3.63, 4.66, 5.18, 5.18)
Economic impact	Costs	(5.68, 7.68, 8.02 9.34)	0.25	(1.42, 1.92, 2.01, 2.34)
	Market	(6.00, 7.82, 8.50, 9.50)	0.75	(4.50, 5.87, 6.38, 7.13)
Practical feasibility	Integrability with current infrastructure	(4, 6, 6, 8)	0.372	(1.49, 2.24 2.23, 2.98)
	Technical skills	(5, 7, 7, 9)	0.332	(1.66, 2.32, 2.32, 2.98)
	Technical threshold	(5, 7, 7, 9)	0.296	(1.48, 2.07, 2.07, 2.66)
Social impact	Employment potential	(5, 7, 7, 9)	0.205	(1.03 1.44, 1.44, 1.85)
	Safety	(6, 8, 8.5, 9.5)	0.708	(4.24, 5.66, 6.02, 6.72)
	Contribute to the SDGs	(6, 8, 8.5, 9.5)	0.087	(0.52, 0.70, 0,74, 0,82)
Environmental impact	Air pollution	(4, 6, 6, 8)	0.29	(1.16, 1.74, 1.74, 2.32)
	Soil pollution	(2, 4, 4, 6)	0.097	(0.19, 0.39 0.39, 0.58)
	Water pollution	(3, 5, 5, 7)	0.613	(1.84 3.07, 3.07, 4.29)

To determine the fuzzy number for the top-level criteria, we summed the weighted fuzzy numbers linked to various sub-criteria and multiplied this total by the corresponding weight of the top-level criteria. Therefore, we summed them to produce the final evaluation judgment. This resulting fuzzy number was then defuzzified using the arithmetic mean to yield the precise number needed for evaluating the two technologies.

Table 3. Final evaluation

Technologies	***Fuzzy values***	***Crisp values***
Anaerobic digestion	(5.59, 7.53, 7.97, 9.21)	7.58
Pyro-gasification	(4.49, 6.51, 6.58, 8.41)	6.48

Therefore, the results of the hybrid AHP-fuzzy approach indicate a higher value for the anaerobic digestion technology. Data analysis reveals that anaerobic digestion integrates various aspects, including operational efficiency, economic benefits, and environmental impacts, which is not always true for pyro-gasification plants. Anaerobic digestion systems can achieve technical and economic sustainability by processing tens of thousands of tons of biomass. In contrast, pyro-gasification plants are typically smaller in scale and, as a result, can process a limited amount of biomass.

5 Conclusions, implications, and future research directions

This research proposes an innovative framework for evaluating and comparing different food valorisation strategies based on economic, technical, social, and environmental factors, offering a practical tool for decision-makers to choose the most suitable technological solution. By integrating these dimensions into a unified framework, this study acknowledges the multifaceted sustainability challenges in the food industry. This approach ensures that technologies are not only analysed for their immediate outputs but also for their broader impacts, fostering decisions that align with SDGs. This study emphasises that sustainable solutions in the food industry should not rely on one-dimensional assessments; instead, they should consider multiple interconnected aspects. Further, this holistic assessment is essential in a complex context such as the food industry, where technologies must not only be analysed for their technical efficiency or economic viability but also for their long-term implications on sustainability and social welfare.

While this study focuses on the wine industry, the model's variables allow the decision tree to be utilised in other food production sectors to explore additional waste valorisation options. Consequently, further research could compare the findings of this study with those derived from evaluating additional food waste valorisation technologies, such as co-composting and pelletising, for a deeper assessment.

A Framework for Assessing the Sustainability of P2P Platforms

Fiengo Vincenzo, Passaro Renato, Quinto Ivana
University of Naples Parthenope, Naples, Italy

Abstract

The growing awareness of social and environmental topics such as climate change, social inequality, and poverty from humanity has driven global efforts toward sustainable development through concrete policy initiatives. In this changed socio-economic context and with the rise of IT technologies, the Sharing Economy model has spread thanks to digital economy platforms. The growth of digital sharing platforms has raised concerns about their role in supporting social and environmentally sustainable consumption. In line with this, the evaluation of the governance of these platforms also raises questions regarding the management of power and the balance between the interests of users and owners. In this context, current literature lacks a comprehensive framework for assessing the social-environmental sustainability of these platforms and the form of governance that characterises them. To tackle this issue, the paper proposes an innovative holistic framework to assess the sustainability of digital platforms, with a focus on Peer-to-Peer platforms. The framework is created adapting and integrating protocols, variables and framings already presents in the literature. The study aims to provide a comprehensive evaluation of the social, environmental impacts and types of governance of these platforms. Then the framework obtained is applied to a pool of forty P2P platforms, enabling a detailed assessment of their current sustainability practices and governance structures. The findings contribute to the literature by proposing a holistic framework to evaluate the sustainability of digital platforms in the sharing economy and provide a systematic approach to understanding their role in the global transition towards sustainability.

Keywords: Business Model Innovation, Circular Economy, Digitalisation, P2P Sharing Platforms, Sustainability

Paper type: Academic Research Paper

1 Introduction and Theoretical Background

Citizens in the western part of the hemisphere have experienced a continuous chase for progress and an ever-increasing lifestyle. In a globalised world, social and job opportunities have increased significantly, but along with these, the climate change is one of the most relevant which causes and consequences are now evident to everyone every day. In response to evolving social and environmental demands, the 'Circular Economy' (CE) has been introduced as "*a high-level strategy to move our societies to a state where we no longer compromise the carrying capacity of our planet's ecosystems while also meeting social goals like job* creation *and social cohesion*" (EC, 2015). This new context has stimulated the private sector to integrate sustainable development practices into their business strategies (Blinova, Ponomarenko and Knysh, 2022). Companies have engaged in efforts to integrate sustainability into their operations and better contribute to making societies more sustainable. In line with this, different tools, initiatives and approaches (TIAs) have been applied for a more sustainable society (Lozano, 2019). Among the most widely used TIAs by companies to foster sustainable management are the ESG (Environmental, Social, and Governance) standards. In general, a paradigm shift beyond the traditional model of production, consumption and disposal is essential (Bosman and Rotmans, 2016; Grin, Rotmans and Schot, 2010). According to this, the Sharing Economy (SE) has emerged in various sectors (e.g. tourism, mobility) through different modalities, such as *'sharing, bartering, lending, exchanging, renting, donating or swapping*' (Botsman and Rogers, 2010, p. 11). Although the concept of sharing is not something new, but it has always been present in human habits and life since ancient times (Khalek and Chakraborty, 2023), the digitalization has profoundly changed it (Zhu and Liu, 2021). These platforms facilitate the connection between users enabling the sharing of goods and services on a global scale and supporting the transition to a CE (Tian et al.,2024). However, the study of digital sharing platforms, particularly from a circular economic perspective, is a recent topic (Schwanholz and Leipold, 2020). Several works have analysed the socio-environmental impacts of such platforms (Lamberton and Rose, 2012; Boar et al, 2020), showing that these last can be positive or negative. A clear example of their contradiction can be, for instance, accommodation platforms like Airbnb. While they offer consumers the opportunity to enjoy the benefits of housing without owning it (Lamberton and Rose, 2012), they are also accused of contributing to gentrification of cities (Boar et al, 2020. Airbnb's case demonstrates that the impact of SE-related platforms remains unexplored (Mont et al., 2020) and highlights the need for more structured and rigorous tools to ensure a comparable and reliable assessment (Martin, 2016). The lack of clarity of the environmental and social sustainability of digital platforms is also linked to a lack of understanding of the types of governance that drive them. Indeed, digital platform

owners have accumulated power and influence over the years, playing a key role in guiding key stakeholders in creating value for their platforms (Rietveld, Schilling and Bellavitis, 2019). This implies that, without a controlling organisation, platform owners can sometimes manage digital platforms to pursue activities that benefit themselves at the expense of other stakeholders (Zuboff, 2023). These criticalities concern the stakeholders of digital platforms (Dixon, 2018). Generally, it is possible to underline that there is a lack of frameworks in the literature to assess digital platforms considering the three elements of ESG scores: Environmental, Social and Governance. These three aspects are commonly used to assess the sustainability of private corporations, which is not the case for sharing platforms. For this reason, this study aims to fill this gap by proposing an innovative framework to assess the overall sustainability of P2P platforms through the lens of ESG framework. In this way, our approach provides a more precise and comprehensive assessment, based on a combination of variables, protocols and approaches developed by other scholars (Martin, 2016; Chen, Richter, and Patel, 2020; Oberg, 2021) that focus mainly on single dimensions of sustainability, but fail to interconnect the various aspects. The developed framework is applied to a selection of forty P2P platforms. The result will be a clear understanding of P2P platforms contribution to the transition to a circular economy. Therefore, this paper aims to address the following research question:

- *How is the sustainability of digital sharing platforms evaluated according to the ESG pillars?*

The paper is structured as follows. The data and methodology of the implemented research are presented in Section 2. Subsequently, Section 3 descriptive analysis results of framework application. Finally, Sections 4 present the discussion and conclusions of the paper.

2 Data and methodology

The first step involved identifying a list of P2P platforms that aligned with the objectives of our research. Specifically, only platforms enabling a circular approach to goods were included in the study. Subsequently, it was developed a framework that enables a more holistic evaluation to assess the platforms' alignment with the three pillars of ESG scores. This approach goes beyond partial assessments, providing a clearer and more comprehensive view of the platforms' environmental and social impacts and their type of governance. For the evaluation of the impact of each of the three aspects considered, we adapted as evaluation variables different concepts, elements derived from different studies (Chen, Richter, and Patel, 2020; Martin, 2016; Öberg, 2024) and two researchers which were assigned to make independent evaluations. In cases of disagreement, a third researcher provided a final judgment. The assessment of each aspect and of the platforms' overall attitude towards social-environmental sustainability and governance was carried out through a quantitative score model, with values from -3 to +3. This range captures impacts from clearly unsustainable to highly virtuous. The model has two interpretations: for governance and social aspects, positive scores (+2/+3) indicate 'high', i.e. positive impacts, while negative scores (-2/-3) are labelled 'low'. For environmental aspects, the logic is reversed: positive scores reflect greater (i.e. negative) environmental impact and are labelled 'low', while negative values indicate low environmental impact and are labelled 'high'. This choice is made intentionally to reflect the different nature of impact in the various areas: a high impact on the environment is negative, while a high impact on society or the economy is generally positive. While in all three cases, a score between -1 and +1 (including 0) indicates an intermediate score. Next, different rating bands were defined to reflect varying levels of impact of each platform on society, and these quantitative ratings were then associated with qualitative labels: low, medium, and high, indicating the platform's impact in specific areas of interests as shown in Table 1. While in the following sections, the evaluation of each dimension is explained in detail.

Table 1**:** Different rating band for the three aspects considered.

	Low	**Medium**	**High**
Environmental	Promote sustainability through ecological practices.	Adopt some sustainable practices, but not fully oriented to sustainability.	Lead to negative environmental consequences.
Social	Limited or negative social impact.	Platforms that foster a certain inclusiveness, but do not have a radical social impact.	Improve social conditions by empowering individuals.
Governance	Decisions made by a few actors and the management of the commons is monopolistic.	Limited user participation in the management of the commons, but without a fully inclusive system.	Collective management of the commons, with broad user participation in decision-making.

2.1 Social evaluation

To assess the social dimensions of P2P platforms the frameworks developed by Martin has been used (2016). We adapted Martin's framework for evaluating platforms from a social perspective. This study offers a structured analysis to assess the social impacts of platforms on people's lives and social dynamics. This approach allows us to examine P2P platforms through the following six different perspectives: economic opportunity, sustainable form of consumption, path towards a decentralised, fair and sustainable economy, creation of unregulated markets, reinforcement of the neo-liberal paradigm and inconsistent innovation field. The first three variables (table 2) have been listed as positive indicators of social impact because they represent aspects that promote collective well-being and sustainability. While the others three variables (Table 3) are considered negative as they can tend to generate inequality and instability. Table A.1 in the appendix provides the evaluation of five SE platform out of forty as practical examples.

Table 2**:** Positive variables from Martin (2016)

Positive framings	**Meaning**
Economic Opportunity	SE provides individuals with the possibility to monetize their unused goods, free time, and skills. Those who successfully earn money within this model are often celebrated as micro-entrepreneurs
Sustainable form of consumption	SE is viewed as a new and sustainable way of consuming, where individuals no longer own goods but instead access them as needed.
Pathway to a Decentralised, Equitable, and Sustainable Economy	SE approaches are considered as a diverse field of innovation that weakens the power of centralised corporations, empowering individuals, and communities.

Table 3: “Negative” variables from Martin (2016)

Negative framings	**Meaning**
Creation of Unregulated Marketplaces	Platforms in this space are criticised for transferring risk to consumers, creating unfair competition, establishing illegal, black, or grey markets, and promoting tax avoidance.
Reinforcing neoliberalism paradigm	This perspective critiques the model for contributing to the neoliberal economic paradigm. Key drawbacks include corporate appropriation, the casualisation of labour, neglect of environmental sustainability, the assumption that individual actions alone drive social change, and the exclusivity of the peer-to-peer mode.
Incoherent field of innovation	Stronger definitions of its scope, the development of a more cohesive movement, and increased collaboration among public, private, and non-profit actors are necessary to address the perception that it lacks coherence as a field of innovation.

Once defined the ‘social variables’, a binary voting system has been implemented to evaluate each platform (yes/no system). A point was given only for each "yes" to positive aspects and for each "no" to negative aspects to evaluate how positively platforms impact society. This approach made easy to measure and compare P2P platforms’ social impacts. Based on this approach, the forty platforms selected have been categorised into three macro-categories based on their social impact score: low (ratings 1 and 2), medium (ratings 3 and 4), and high (ratings 5 and 6).

2.2 Governance evaluation

For the governance evaluation of P2P platforms, Chen, Richter, and Patel, 2020 (2020) ’s study has been considered. From the different elements they considered, three are chosen as in line with our context: incentive compatibility, community participation and role of leadership (Table 4). These three elements have been adapted as variables to analyse the governance of platforms and to understand whether they effectively favour a democratisation model or consolidate a monopolistic one. Following the literature (Petschow, 2016; Chen et al., 2021), we chose to consider platforms with decentralized governance as a sustainable form, since they promote user autonomy and foster greater collective involvement.

Table 4**:** Chen, Richter, and Patel (2020) variables for governance evaluation

Framings	**Definition**
Incentive Compatibility	Incentive compatibility is achieved when participants in a system are motivated to truthfully reveal their preferences or information, aligning their individual incentives with the overall system goals. This ensures that the system leverages all available information efficiently, promoting informational efficiency and favourable governance outcomes.
Role of Leadership	The extent to which platform leaders influence governance, balancing centralised control with decentralised participation.
Community Involvement	The degree to which platform participants (e.g., developers, users) are involved in governance processes such as decision-making and implementation.

Once the evaluation framings were identified, such qualitative evaluation have been converted in quantitative one. According to this, for each platform, a rating was given ranging from -1 (when the platform was far from the concept of decentralisation) to 1 (in the case of platform close to the concept of decentralisation) with 0 included (neutral attitude of the platform). This rating system was used for all 3 framings considered (table 5). Table A.2 in the Appendix the evaluation of five SE platform out of forty as practical examples.

Table 5: Rating system for platforms' comparison

Variable	**Ranking**	**Explanation**
Incentive Compatibility	-1	The platform fails to align individual and collective goals, creating inefficiencies and reducing stakeholder engagement.
	0	The platform achieves partial alignment, balancing stakeholder incentives with some gaps in addressing collective objectives.
	1	The platform effectively aligns individual stakeholder goals with system-level objectives, enhancing overall functionality and performance.
Community Participation	-1	Community involvement is minimal or symbolic, limiting the inclusion of diverse perspectives and shared governance.
	0	Community participation is moderate, allowing for some influence in decision-making while maintaining significant control by platform owners.
	1	Community members actively participate in governance and decision-making, fostering inclusivity, accountability, and collective action.
Role of Leadership	-1	Leadership is highly centralised, resulting in strong hierarchical control and reduced stakeholder influence in decision-making processes.
	0	Leadership provides guidance while allowing some community input, creating a balanced but still semi-centralised governance structure.
	1	Leadership empowers community members by decentralising governance control, fostering shared decision-making and collaborative platform management.

A total score ranging from -3 to -2 represents a low attitude to decentralisation model; a score of -1, 0 or +1 indicates a medium alignment with the decentralisation concept. Finally, a total score between +2 and +3 reflects a high attitude towards the decentralisation model.

2.3 Environmental evaluation

To evaluate the environmental impact of platforms, the concepts of resource use, sustainability, and scalability from Öberg (2024) has been adopted as variables in our analysis (Table 7). These concepts have been used as reference variables for the environmental assessment of platforms because they allow for an integrated analysis of how resources are used, how much a model reduces environmental impact and whether the growth of a platform compromises its sustainability. An excerpt of five examples can be found in Table A.3 in the appendix.

Table 7**:** Variable explanation by Öberg (2024).

Variable	**Meaning**
Resource Use	Describes how a platform uses and manages resources in its sharing economy model (e.g. simultaneous sharing, reuse, lending)
Sustainability	It indicates how environmentally sustainable a model is, i.e. whether it reduces waste of resources, promotes sharing.

Variable	Meaning
Scalability	It refers to the ability of sharing economy models to grow, expanding geographically or increasing the scope of operations.

In Öberg's work (2024), the variables considered take on specific values, representing different operational configurations of sharing economy models (Table 8). Since the values assumed by the variables affect the environmental impact in different ways, a quantitative evaluation has been provided, assigning a rating between -1 (negative environmental impact) and 1 (positive environmental impact), including 0 (neutral impact). In the cases of the variables “Resource use” and “Scalability” no factors are associated with the value 0, because each variable is very ‘polarising’.

Table 8: Resource use, Sustainability and Scalability factors from Öberg (2024) classification

Variable	Factors	Rate	Explanation
Resource Use	Service Created Specifically	-1	These services are designed to create new offerings, often leading to additional resource consumption and environmental impacts.
	Co use	1	Maximizes resource efficiency by allowing multiple users to share the same product or service, reducing overall consumption.
	Re use	1	Promotes sustainability by extending the lifecycle of resources.
	Repeated use of latent resource	1	Utilising latent resources, like underused assets, minimizes waste and maximizes value.
Sustainability	Not more sustainable than traditional service.	-1	The service may not provide sustainability benefits compared to traditional options.
	No added depletion	0	While the service does not cause further resource depletion, it also does not contribute positively to sustainability or resource efficiency.
	Increasing efficiency of resource.	1	Improving resource efficiency leads to reduced waste and more effective use of materials, directly supporting sustainability goals.
	Efficient use of latent resource.	1	Utilising underused or idle resources avoids unnecessary consumption.
	Sustainability created.	1	Services that actively promote sustainability contribute to environmental and social improvements.
Scalability	Scaled, spread around the globe.	-1	Global scaling often requires significant resource consumption, increased transportation, and infrastructure demands.
	Large-scale operations.	-1	Large-scale operations can lead to inefficiencies, increased waste, and a higher carbon footprint.
	Coordination issues.	-1	As services scale, moving goods and resources across locations becomes necessary, increasing transportation emissions and logistical inefficiencies.
	Provision issue.	-1	Scaling strains resource availability, requiring the movement of goods from surplus to deficit areas, which adds to environmental impacts through transportation.
	Scaling issue based on free premises	-1	Scaling strains resource availability, requiring the movement of goods from surplus to deficit areas, which adds to environmental impacts through transportation.
	Local presence required.	1	A local presence ensures shorter supply chains and reduced environmental impact, while fostering community-based sustainability practices.

2.4 Overall platform rating

The last stage of the developed framework allows a quantitative assessment of the overall sustainability of the analysed platforms. This assessment was based on a scoring system ranging from -1 to +1 (including 0) for each aspect. The score assigned to each platform depends on its performance in each aspect, as indicated in the following description: a score of -1 indicates that the platform is rated ‘low’ in a given aspect, a score of 0 indicates a ‘medium’ rating and a score of +1 indicates a ‘high’ rating in that aspect. Thanks to this last evaluation step, the framework can provide a comprehensive and clear assessment of the impact of each platform in the society, considering the three ESG pillars. The framework allows to evaluate the sustainability of the platform to

be examined and weighed on several interconnected dimension. An extract of five P2P platforms evaluation is the Table A.4 in appendix.

3 Results

Social results shows that only 17.5% of platforms have been assessed with a low social impact, while the remaining platforms are equally distributed between medium and high impact evaluations, respectively 40% and 42,5%. This indicates that, generally, P2P platforms tend to have a positive social impact. Despite it, there is room for improvement.

About environmental results, the 30% of platforms are characterised by having a minimal impact on the environment, and over 60% are classified as having a "medium" impact. Interestingly, only two platforms (five percent of the total) show a "high" environmental impact, this can be considered a positive result. In line with their wider reputation as sustainable alternative to conventional models, these findings prove that P2Ps platforms avoid serious environmental harm.

Governance results prove that platforms predominantly operate with low decentralisation (62.5%). While only 15% of P2P platform adopt medium decentralisation models and 22,5% of them operate with high decentralisation. This polarisation highlights the challenge of creating and implementing hybrid governance models that balance centralisation and decentralisation. It may also reflect a preference for more well-defined and extreme governance systems rather than intermediate approaches. This result underscores a clear market trend favouring distinct governance systems, either highly decentralised to empower users or highly centralised for efficiency. Platforms with low decentralisation prioritize reliability, efficiency, and managerial control, while highly decentralised models often aim to foster autonomy and community-driven interactions A practical example of the application of Chen's (2020) variables (Table 20). While Table A.3 in the appendix an extract of 5 examples.

IN conclusion it is worth underlining that 52.5% of platforms exhibit a medium "attitude for the sustainability", indicating that the majority adopt a balanced approach. These platforms integrate both growth-oriented and sustainability-driven elements, seeking to achieve operational and societal goals without heavily prioritising one over the other. Meanwhile, 32.5% of platforms are categorised by a high attitude, highlighting a stronger alignment with limiting society's growth. This indicates a commitment to principles like sustainability, resource efficiency, and societal equity, often at the cost of rapid scalability or expansion. These platforms may have the potential to bring significant positive change, albeit with challenges in scaling or resource allocation. The remaining 15% of platforms are categorised as ‘low’ reflecting a limited alignment with the principles of limiting societal growth. These platforms are more likely to focus on traditional growth models, emphasising efficiency and profitability over broader societal or environmental considerations. This distribution highlights a clear trend where most platforms aim for a middle-ground strategy, while a significant portion leans toward transformative models aligned with growth limitations, offering avenues for innovation and sustainable development.

4 Discussion and conclusion

This research emphasises the importance of taking a balanced and sustainable approach to the development and governance of P2P platforms. The results of the application of the framework highlight several key elements. The prevalence of platforms with a “medium” environmental impact suggests the existence of significant potential for improvement, as demonstrated by the presence of low-impact platforms that have successfully integrated resource efficiency, waste reduction and circular economy principles. On other hand, the social analysis indicates a positive trend, with most platforms exhibiting medium to high levels of social impact, particularly in terms of economic inclusion, sustainable consumption practices, and community engagement. Nevertheless, the presence of platforms with lower social impact highlights the persistence of areas requiring further development. Regarding governance, the limited diffusion of semi-decentralised models points to a lack of governance structures capable of effectively balancing user autonomy and centralised control. These findings not only provide a detailed picture of the current state of P2P platforms but also generate a series of operational and strategic implications for policy makers, companies and academic world. For policy makers, this research can offer a basis to develop policies that encourage the adoption of sustainable practices and at the same time reducing negative effects such as job casualization or gentrification of cities. Companies, on the other hand, can use this framework to analyse their business models, improving their practices in a sustainable perspective and responding to growing social and environmental expectations. Finally, in the academic world, the developed framework allows overcoming the difficulties caused by the lack of clear and structured evaluation tools by offering a methodological basis for future empirical and comparative studies on the sustainability of P2P

platforms. However, the research has limitations due to the small sample and the subjective component of the evaluations. Future studies could expand the sectors areas analysed, improve metrics and analysis techniques, and explore clustering methodologies to identify homogeneous groups of sustainable platforms.

Abstract

Innovative start-ups play a crucial role in fostering innovation and driving economic growth while enhancing technological competitiveness. In Italy, the emergence of these start-ups has significantly influenced the landscape of economic development and technological advancement, acting as a key engine for generating and integrating knowledge into new products and services. This introduction sets the stage for a deeper exploration of the dynamics surrounding Italian innovative start-ups and their impact on the broader economic and technological landscape. This study analyzes the factors affecting the economic performance of these start-ups, with a focus on governance aspects and corporate resources, particularly team composition, company size, and the impact of gender diversity. It also investigates how sector and geographic location may influence access to resources, often linked to public policies and local innovation ecosystems. Using the AIDA (Analisi Informatizzata delle Aziende) database, managed by Bureau van Dijk—a leading global provider of financial information specializing in the collection and storage of economic-financial data on Italian companies—we studied a sample of 5,669 innovative start-ups across Italy. Through OLS regression models, the article reveals how regional context and policies can serve as either a competitive advantage or a barrier for firms. The findings indicate a positive effect of female leadership on business growth in terms of profitability and sustainability, suggesting that diverse governance and locations within developed entrepreneurial ecosystems can significantly enhance business performance. These insights are valuable for policymakers and entrepreneurs, contributing to a deeper understanding of the economic dynamics of innovative start-ups in Italy. To our knowledge, this is the first attempt to examine regional differences in the performance of Italian start-ups by including all Italian regions.

Keywords: Innovative Start-up, gender, regional development, economic growth, OLS

Paper type: Academic Research Paper

1 Introduction

The landscape of economic growth and technological advancement in Italy has been significantly influenced by the emergence of innovative start-ups, which serve as a crucial engine for the generation and integration of knowledge into novel products and services (Ghio et al., 2016). Recognized under the Italian Startup Act, formalized by Legislative Decree 221/2012, these high-tech enterprises benefit from a supportive regulatory framework designed to foster their establishment and growth through various incentives, including tax benefits and support for innovation investments (Cavallo et al., 2018; Reina et al., 2018). Operating predominantly in advanced sectors, these innovative start-ups thrive within an institutional ecosystem that encourages collaboration among universities, research institutions, and private enterprises. This introduction sets the stage for a deeper exploration of the dynamics surrounding Italian innovative start-ups and their impact on the broader economic and technological landscape. Understanding the unique challenges and opportunities faced by these start-ups will provide valuable insights into their contributions to innovation, job creation, and competitiveness in an increasingly globalized market. Moreover, the geographical distribution of innovative start-ups across Italy reveals significant disparities that could influence their overall effectiveness in driving economic growth. Addressing these discrepancies is crucial for ensuring that the benefits of innovation are more evenly distributed throughout the country, potentially leading to broader national competitiveness and resilience in the face of global economic challenges. Creating targeted policies that support entrepreneurial ecosystems in underserved regions can help bridge this gap, empowering local talent and fostering innovation outside the traditional hubs. In this context, the gender of the business leader, the size and composition of the management team, and the region in which the company is based emerge as key factors in the economic performance of start-ups, influencing variables such as profitability and growth potential. Gender diversity within founding teams can foster more prudent management and a greater focus on long-term sustainability, aspects that are reflected in improved economic performance (Harris and Jenkins, 2006). In particular, in start-ups led by women, the focus also includes objectives of social well-being and job quality, distinguishing them

from male-led firms (Justo et al., 2015). However, female entrepreneurs often face significant challenges, including reduced access to capital and limited networking opportunities, which can hinder the growth of their businesses (Fairlie and Robb, 2009). The territorial context represents another determining factor for the success of innovative start-ups. Northern Italian regions, equipped with more advanced entrepreneurial ecosystems and developed infrastructure, offer greater networking opportunities and access to financial resources than southern regions, where start-ups encounter more obstacles and less institutional support (Balata et al., 2016; Fasano et al., 2023). Local public policies also play a crucial role, with initiatives aimed at supporting entrepreneurial development through funds and incentives, especially in high-tech sectors such as IT and biotechnology, where technology transfer represents a competitive advantage (Ramaciotti and Rizzo, 2017; Neffke et al., 2011). This study aims to analyze the main governance, territorial context, and gender factors that influence the economic performance of Italian innovative start-ups to identify the variables that promote the profitability and sustainable growth of these enterprises.

2 State of the art

The concept of an innovative start-up is linked to the ability to combine new ideas with practical solutions, transforming scientific and technological knowledge into valuable products or services (Ghio et al., 2016). These companies often emerge in cutting-edge sectors such as biotechnology, artificial intelligence, and renewable energy, and are characterized by a specific lifecycle that goes through various stages, each with unique challenges and opportunities (Passaro et al., 2016). In Italy, the Italian Startup Act has been a turning point for this sector, providing tax incentives and easier access to venture capital to foster the growth of knowledge-intensive start-ups (Cavallo et al., 2018). In this context, the literature has dedicated significant attention to the role of gender diversity in start-up performance, offering important insights into the differing approaches between male- and female-led businesses. Many studies shown that gender-diverse leadership teams are associated with higher ROA, ROE, and overall financial success (Maji and Saha, 2021; Imes et al., 2024; Fairlie and Robb., 2009). Female-led start-ups tend to adopt more sustainable business models focused on employee well-being and promote strategies that encourage corporate social responsibility (Harris and Jenkins, 2006; Justo et al., 2015). The literature suggests that encouraging female participation in start-up leadership roles could contribute to more inclusive and sustainable growth across the sector (Demartini, 2018; Welsh et al., 2016). Gender diversity impacts startup performance through several interconnected mechanisms. It influences strategic orientation, innovation, and fundraising outcomes, while also being shaped by gender stereotypes and biases in investor evaluations (Nguyen et al., 2023). These dynamics indicate that promoting gender diversity in startup management not only advances social equity but also improves the overall performance and resilience of emerging ventures (Guzmán and Kacperczyk, 2019; Ebersberger and Pirhofer 2011). The composition of a startup's management team, including its size and diversity, plays a critical role in influencing the venture's performance. Research has examined several aspects of team composition (Debrulle et al., 2021), including team size (Agarwal et al., 2013), functional diversity (Eesley et al., 2014), heterogeneity (Wang et al., 2017), and how well team characteristics align with the firm's strategy and environment. Smaller teams are typically more agile and efficient in decision-making, which can be advantageous in the early stages of a startup, however, as startups expand, larger teams may be better suited to manage the growing complexity of operations (Forbes et al., 2006; Agarwal et al., 2013). Startups with a larger team often see improved sales and funding performance. This is largely due to their greater market visibility, access to diverse talents, and enhanced networks that attract more investor interest (Gloor et al., 2020). It is important to strike a balance, as overly large teams can encounter coordination difficulties and communication breakdowns that can hinder decision making (Qian, 2018; Hernandez et al., 2018). Team diversity is important, as research shows that teams with diverse backgrounds often demonstrate higher levels of innovation and creativity (Chen et al., 2023; Moussa et al., 2024). The sector in which an innovative start-up operates is another crucial aspect of its success. Start-ups in high-tech industries, such as biotechnology, nanotechnology, and artificial intelligence, require significant investments in research and development and often need privileged access to advanced scientific knowledge to remain competitive (Barra and Zotti, 2018; Neffke et al., 2011). These sectors are characterized by rapid technological evolution and intense global competition, which necessitates continuous skill and production capacity updates. Additionally, the presence of a favorable entrepreneurial ecosystem, such as incubators and accelerators, is often crucial for the success of start-ups in high-tech sectors, as it facilitates access to strategic resources and industrial partners (Reina et al., 2018). The geographic context is another factor influencing the performance of innovative start-ups. Recent studies have shown that regions with an advanced innovation ecosystem, such as Lombardy and Emilia-Romagna, offer better growth opportunities for start-ups, thanks to the presence of universities, research centers, and adequate infrastructure (Fasano et al., 2023). These regions provide a favorable environment for

technology transfer and interaction with other companies, facilitating access to financial and knowledge resources (Balata et al., 2016). Conversely, southern Italian regions are characterized by a less developed entrepreneurial ecosystem, with limited public and private funding availability and lower density of professional networks (Reina et al., 2018). According to Colombelli et al., (2023) digital knowledge spillovers and digital skill endowment support the creation of digital innovative start-ups. The rapid diffusion of digital technologies has generated new opportunities for developing innovative entrepreneurship, which is essential for employment growth, new job creation, and socio-economic wealth. Therefore, investigating the enabling conditions of digital innovative startup creation is essential to define appropriate support policies (Barilli, 2015).

3 Sample and data

Using the AIDA (Analisi Informatizzata delle Aziende) database, managed by Bureau van Dijk, a leading global provider of financial information specialized in the collection and storage of economic-financial data on Italian companies, an initial sample of 12,781 innovative start-ups located across Italy was identified. After a careful data-cleaning process using R software, we have cleaned the dataset of missing values (NA), unavailable data (n.b.), and outliers—anomalous values that could have compromised the accuracy of the analyses and results. By eliminating values that rendered some observations without essential attributes, the sample was reduced to 5,669 innovative start-ups. Most variables in the dataset were formatted as "character," meaning that most numerical values would have been interpreted by the software as strings. For this reason, we performed a mass conversion of these variables into numeric values, while categorical variables were simply converted into factors. From the AIDA database, the relevant variables were extracted for analysis in the following sections. Among the most significant variables are those related to sector (industry), geography (region), and gender. Particular attention was given to the gender of the highest-ranking figure on the board of directors within each start-up, focusing specifically on the board composition. The study expanded upon the studies by Sciarelli et al. (2021) and Algieri et al. (2013), which analyzed university spin-offs in Southern Italy and across Italy by grouping them into three clusters: North, Center, and South, while we have categorized with respect to all 20 Italian regions. We identified the top 20 sectors by the number of observations and grouped the rest under the "Others" category. Finally, we proceeded by grouping the top 20 sectors into 5 macro-sectors to ensure a more generalized and less specific analysis. The macro-sectors are: 1.Production and Online Trade; 2.Consulting and Professional Services; 3.IT Services and Software Products; 4.Marketing, Web Portals, and Training Courses; 5.Research and Development and Design

The remaining less frequent sectors were aggregated into a single residual category.

4 Methodology

This study employs Ordinary Least Squares (OLS) regression models to analyze how independent variables influence the economic performance of innovative Italian start-ups, consistent with Sciarelli et al. (2021). The dependent variables considered are revenue growth (Δ REV), EBITDA Margin (EM), and Return on Assets (ROA), transformed using the asinh function to improve data distribution and reduce the influence of outliers. The independent variables include governance indicators, such as the size of the management team (N_EX) and the leader's gender (GEN); economic variables, such as total assets (TA), intangible assets (IA), and net worth (PN); and contextual variables, such as sector (SECTOR) and geographic region (REGION). Additionally, interactions between key variables, such as gender and macro-sectors, were analyzed to highlight combined effects.

4.1 Variables

To ensure comparability with previous studies (Sciarelli et al., 2021), we used proxy measures consistent with existing literature, employing dichotomous and ratio measures for the dependent and independent variables, along with specific transformations for variables with high distributional skewness. In selecting the variables, we considered both endogenous factors relevant to the operations of innovative start-ups. Finally, we included analysis of the gender of the prominent board member, as well as the start-up's sector and region, to understand how these factors influence the economic and financial performance of the start-ups. Variables are presented in a detailed view in Table 1.

Table 1: Definition of Variables

Variables	Description	Measure
Performance Variables		
∆ REV	Measure of startup revenue growth compared to the second-to-last available year in €	asinh
EM	EBITDA/Revenues, measures the operating profitability of start-ups	asinh
ROA	EBIT/assets, measures the efficiency with which start-ups use resources to generate revenue	asinh
Governance Variables		
N_EX	Total number of members on the board of startups, represents the size of the governance team.	Nr.
GEN	Gender of the leader of the governance team, influencing gender diversity in corporate management.	Factor with 2 levels
EMP	Number of employees of the start-up, related to organizational structure and internal management capacity.	Nr.
Control Variables		
TA	Total assets, an indicator of the total economic value of the start-up.	Log
IA	Value of intangible assets such as patents and other intellectual property.	Value
MA	Value of physical assets such as buildings or machinery, indicating the tangible assets of the enterprise.	Value
PATENTS	Number of patents held by the start-up	Nr.
CR	Total accounts receivable	Value
Control Variables		
PN	Net worth of the company, which is the difference between assets and liabilities.	Value
DB	Total debts of the start-up	Value
YEARS	Age of the start-up	Nr.
SECTOR	Industrial sector	Factor with 6 levels
REGION	Geographical region	Factor with 20 levels

5 Results

Understanding the data's structure and key patterns is a crucial step in any research, as it lays the foundation for interpreting analytical results and deriving meaningful insights. In line with this, the descriptive analysis and data visualization provided an initial overview of the sample characteristics, offering valuable context for the subsequent regression analysis. This approach is consistent with prior studies that emphasize the importance of exploring the dataset to identify potential biases, trends, or anomalies that could affect the robustness of the results

5.1 Descriptive statistics

In this chapter, the main numerical variables of the dataset, both dependent and independent, will first be analyzed statistically (Table 2). Next, a series of graphs will be presented to illustrate the correlation between the key variables. Table 3 below presents descriptive statistics for the numerical variables. Most variables are expressed in thousands of euros, except for EBITDA Margin and ROA, which are expressed in percentages, and for the number of employees (EMP), board members (N_EX), and YEARS, which are expressed in units. For the variable Δ REV, a significant variation can be observed between the minimum and maximum values, highlighting a high dispersion in revenue growth among start-ups, indicating that a minority of companies achieved considerable revenue growth, while the majority of firms are closer to modest or negative values. The negative mean and very low minimum value (-996.93%) of EM (EBITDA Margin) indicate that many start-ups are operating with substantial operational inefficiencies. ROA shows a negative mean (-6.903%), which points to a low capacity among firms to generate income relative to their assets.

Table 2: Descriptive Statistics

Variables	Min	Median	Mean	Max	Standard Deviation
REV	-3356	17	98.96	23343	*504.92*
EM	-996,93	8,16	-35,1	482,04	*147,65*
ROA	-925,660	0,650	-6,903	192,31	*38,87*

5.2 Main results

In this study we conducted the analysis using Ordinary Least Squares (OLS) regression, with the aim of examining how independent variables influence the economic performance of innovative startups. To this end, three distinct models were developed, each focused on a different dependent variable: Revenue Delta, ROA, and EBITDA Margin. The models incorporate governance and control factors, which are detailed in Table 3. The purpose of these models was to test the validity of the three hypotheses, related to revenue growth, profitability, and operational performance. To identify the best models, we adopted a stepwise procedure with backward elimination, which removes variables based on their statistical significance. As reported in Table 3, the OLS results are presented. The variable TA (Total Assets) has a positive and highly significant effect on revenue growth (TA: 0.668; $p < 0.001$), contrasting with some studies, such as Sciarelli et al. (2021). Female gender (GEN_F) has a positive and significant effect on revenue growth (GEN_F: 1.353; $p < 0.05$), in line with Demartini (2018), but the interaction between Female Gender and various macrosectors is predominantly negative. The analysis of regional variables shows a complex picture, with disparities between Italian regions. None of the variables are significant after the stepwise approach, but it can be noted that regions in the North, such as Veneto, show negative and significant coefficients in relation to revenue growth for startups led by women, highlighting greater difficulties compared to regions like Abruzzo (reference category).

In the ordinary least squares (OLS) regression model, with ROA (Table 3), it can be observed that TA (Total Assets) emerges as one of the most significant variables (being strongly correlated with ROA), with a positive effect on ROA (TA: 0.336; $p < 0.001$), consistent with what was observed in the model for ΔREV and with findings reported by Sciarelli et al. (2021). Sector analysis shows significant and somewhat contrasting results. In particular, the Marketing and Web Portals and Production and Trade sectors show a significant negative impact on ROA (SET_Marketing & Web: -0.667; $p < 0.01$, SET_Production and Trade: -1.037; $p < 0.001$). In contrast, the Consulting and Professional Services sector (reference category) seems to represent an exception, where startups perform better, as also suggested by Sestino and Guido (2021).

In the OLS regression model on EBITDA Margin (Table 3), interesting results emerge, very similar to the ROA analysis. However, the variable related to the gender of the leader (GEN_F) does not show significant results, unlike other analyses where gender diversity had a more significant impact (Demartini, 2018). Sectoral analysis confirms that startups in the "Marketing & Web" and "Production and Trade" sectors face significant challenges in maintaining high operational margins (SET_Marketing & Web: -0.855; $p < 0.01$; SET_Production and Trade: -1.322; $p < 0.001$), and this impacts EBITDA Margin more than ROA. Regional disparities for EBITDA Margin show regions such as Lombardy and Piedmont presenting significant negative coefficients (REG_Lombardy: -1.258; $p < 0.001$; REG_Piedmont: -1.320; $p < 0.01$).

In addition, we undertook a series of steps to ensure the reliability of the estimates. Initially, we employed an Ordinary Least Squares (OLS) regression to estimate the coefficients; however, we suspected that some of the independent variables might be endogenous, meaning they could be correlated with the model's error term. To formally test for endogeneity, we applied the Wu-Hausman test, which compares the OLS and Instrumental Variables (IV) estimates. The test returned a statistically significant result (p-value = 0.0125), confirming the presence of endogeneity in our model. Therefore, OLS estimates would not have been consistent, providing strong justification for the use of an IV approach. In constructing the IV model, we selected exogenous instruments for the variables suspected to be endogenous, namely N_EX, TA, and EMP. Specifically, we used IA, MA, PATENTS, CR, PN, DB, REGION, SECTOR, and GEN_F as instruments. The results showed very strong instruments across all three variables, with highly significant F-statistics (N_EX: F = 22.174, p-value < 2e-16; TA: F = 35797.491, p-value < 2e-16; EMP: F = 109.067, p-value < 2e-16), thus ruling out concerns about instrument weakness. Given these diagnostic tests, the use of the IV approach via Two-Stage Least Squares (2SLS) was fully justified, providing consistent estimates in the presence of endogeneity. The first-stage regressions, indicate that female governance (GEN_F) is significantly associated with a reduction in firm size indicators. Specifically, firms led by women show a reduction of 0.276 in the number of board members ($p < 0.001$), 0.095 in total assets ($p < 0.05$), suggesting that gender plays a meaningful role in shaping the structural dimensions of startups. Regionally, firms in Lombardia and Veneto display significantly higher board sizes (+0.523 and +0.440 respectively) and total assets, while Southern regions like Calabria and Sicilia exhibit strong negative associations with the number of employees (−1.452 and −0.817 respectively), pointing to territorial asymmetries. In terms of sector, IT & Software services show a positive association with employees (+0.640; $p < 0.01$), reinforcing the importance of digital industries in job creation. In the second stage, the fitted values from the first-stage regressions are used to estimate the impact on performance outcomes. The number of employees (fitted_EMP) shows a positive and significant effect on all three metrics: +0.114 on sales growth ($p < 0.01$), +0.327 on EBITDA margin ($p < 0.001$), and +0.292 on ROA ($p < 0.01$). In contrast, total assets (fitted_TA) have a negative association: −0.193 on sales growth (weakly significant), −0.314 on EM ($p < 0.05$), and −0.477 on ROA ($p < 0.01$), suggesting diminishing returns or inefficiencies related to capital intensity. The number of board members (fitted_N_EX) positively influences sales growth (+0.385; $p < 0.05$), but negatively affects EM and ROA (−2.409 and −1.661 respectively, both $p < 0.001$), highlighting the possible cost or coordination burden of larger governance bodies.

6 Discussion of the results

The results for economic variables such as TA (Total Assets), IA (Intangible Assets), and PN (Net Worth) have shown consistent findings across all three models, suggesting that the idea of having greater asset availability

can foster business development. These results contrast with studies like Sciarelli et al. (2021), who, analyzing data on revenues from university spin-offs in Southern Italy, found a negative relationship between total assets and revenue growth, suggesting that an excess of resources could, in some contexts, reduce business efficiency. The results highlight a positive impact of female leadership on business growth in terms of profitability and sustainability. This is likely due to a less risky and more sustainable approach to managing startups, with goals that prioritize preserving business integrity, employee well-being, and not just economic targets. However, challenges faced by female-led startups in sectors like marketing and research and development may be related to cultural barriers or the lower representation of women in STEM disciplines. In this regard, in the Consulting and Professional Services sector, female managers seem to achieve better results than in other macro-sectors, aligning with literature that highlights the sector's greater opportunities for female entrepreneurs, as over 75% of female-led startups operate in the professional services sector, which offers greater opportunities for women entrepreneurs (Paoloni and Modaffari, 2018). The regional disparities show surprising results. While northern regions such as Veneto and Emilia-Romagna present greater challenges for female-led startups, Southern Italy, particularly Abruzzo, Calabria, and Campania, seem to offer a more favorable environment. In the analysis of EBITDA Margin, in particular, the reduction in operating profitability in these regions appears even more pronounced, possibly due to specific local challenges influencing business resource management, as suggested by Algieri et al. (2013). These results are entirely new in a literature that typically highlights a historical North-South disparity in terms of opportunities for women entrepreneurs, and they contrast strongly with recent studies indicating that operating in Northern Italy increases the likelihood of success by 71% compared to the South, while operating in Central Italy increases the likelihood of success by 45% (Algieri et al., 2013). From a sectoral perspective, startups in the marketing, production, and trade sectors struggle to achieve positive results. The 2SLS estimates offer a deeper understanding of the structural and performance determinants of innovative startups, especially in how gender, region, and sector dynamics interact with firm governance and scale. The OLS model had suggested a less pronounced gender effect, possibly because it failed to address the potential simultaneity between governance choices and firm outcomes. Regionally, the 2SLS model reinforces the presence of strong territorial asymmetries. Compared to OLS, where regional effects may be diluted or confounded by other correlated variables, the instrumental approach confirms that geography independently constrains organizational capacity, especially when coupled with gender. Sectoral effects are also more visible in the 2SLS estimation. Turning to the second stage, the 2SLS model reveals that expanding the workforce has a consistently positive impact on performance outcomes, particularly in profitability and growth. This suggests that human capital plays a central role in scaling startups and that employment levels are a meaningful lever of success.

7 Conclusion, implication, limitation and further research

Several relevant implications emerge for Italian start-ups and the actors who support them, including investors, policymakers, and institutions. The negative result associated with the number of members on the board (N_EX) indicates that a governance team that is too large can hinder decision-making speed and efficiency. Start-ups are advised to maintain lean boards composed of members with complementary skills but without an excessive number of components, which could slow business dynamics. A lean governance structure could favor faster decision-making and more flexible adaptations in highly competitive contexts. The positive effect of Total Assets (TA) and the importance of net worth suggest that start-ups with a solid capital base can operate more efficiently and better face operational challenges. The Marketing & Web and Production and Commerce sectors appear to be more exposed to low operating profit margins, suggesting the need for more aggressive strategies to increase margins or explore new business models. Start-ups in these sectors should consider expanding into niche markets or integrating high-value-added services to compensate for the sector’s structural challenges. Start-ups located in Southern Italy, as evidenced by regions like Calabria and Campania, show signs of positive growth compared to traditionally more favorable northern areas. This suggests an opportunity to continue investing in regional development policies, promoting innovation and supporting start-ups in these regions, as less developed areas can represent fertile grounds for entrepreneurship. The use of indicators such as EBITDA Margin and ROA offers a limited view of economic performance, which might not see immediate returns from investments in research and development (R&D). These indicators may not fully capture the long-term growth potential, particularly for businesses focused on innovations with a long economic return cycle. Future studies could adopt more comprehensive measures, including long-term success indicators such as innovation rate, human capital growth, or international market penetration. The analysis also relies solely on quantitative data, without considering more qualitative aspects that could better explain performance differences among start-ups. Corporate culture, leadership style, and the quality of human capital are crucial factors not included but

could significantly impact innovation capacity and business growth. Including these elements in future research would help understand how internal dynamics influence economic performance. Finally, although the model considers differences between Italian regions, a finer segmentation of local dynamics could reveal further nuances not explored. In the future, it would be useful to consider more specific regional factors to understand how start-ups can fully leverage the local ecosystem.

Meaningfulness Reshaping Technology, Knowledge Co-Creation, and Leadership

Mirva Hyypiä
LUT University, School of Engineering Science, Lahti, Finland

Abstract

The development of human skills through technology, knowledge co-creation, and meaningful work drives successful change, well-being, and societal cohesion. Technological advancements have raised concerns about job displacement and skills shortages, necessitating a human-centric approach to leadership. The study explores the relationship between meaningfulness and meaninglessness (m&m) experiences at work, emphasizing that meaningfulness is not tied to formal job descriptions and can be supported by leadership. Transformational leadership, with its four dimensions Idealized influence, Inspirational motivation, Intellectual stimulation, and Individual consideration, is examined for its potential to foster meaningfulness in education and elderly and caregiving sectors. The research, based on the "The m&m of work" project, aims to enhance organizational practices by leveraging employees' experiences of meaningfulness and meaninglessness. This research focuses particularly on transformational leadership (TL) entity of the survey and the identification of four dimensions of TL (visioning, challenging, engaging, and leading by example) in the real-life experiences of the education and elderly and caregiving sectors at both individual and organizational levels. The study found that Transformational Leadership (TL) had significant influence in the education and caregiving sectors. At the organizational level, TL influenced areas such as responsibility and ethics, work environment safety, and discussions about the meaningfulness of work. At the individual level, TL fostered trust within the work community, encouraged the use of employees' creativity, and supported their success. Additionally, a method was co-created during the research to enhance leadership, facilitate knowledge sharing, and promote discussions within organizations, addressing even challenging experiences of meaninglessness and their effects.

Keywords: Meaningfulness, Knowledge Co-Creation, Transformational Leadership, Change

Paper type: Academic Research Paper

1 Introduction

Developing and enhancing human skills and capabilities through technology, knowledge co-creation, and meaningful work are key drivers of successful change, individual well-being, and societal cohesion. The past decade of technological advancement has brought about the looming possibility of mass job displacement, untenable skills shortages, and challenges to the unique nature of human intelligence posed by artificial intelligence. These challenging prospects in the digital era require human-centric approach and leadership to reshape a future of work that fulfils individual potential and experiences and creates broadly shared prosperity in diverse organizations and industries (World Economic Forum, 2020; Henderikx & Stoffers, 2022).

The experiences and relationship between meaningfulness and meaninglessness (m & m) for employees are not yet fully understood. The experience of meaningfulness does not depend on the profession or job role. A waste management professional can experience as much meaningfulness in their work as a teacher, nurse or a doctor. Managers or leadership theories are not the sources or providers of the experience of meaningfulness at work. However, they can easily destroy the perception of work's meaningfulness – even create a sense of meaninglessness. Generally, creating meaning in work is an individual endeavour, while reflecting the experience and attributing meaning requires other people or support for community from the entire organizational system. (Martikainen & Oikarinen, 2023; Martikainen, 2022; Bailey & Madden, 2016)

The study specifically examined the theoretical model of transformational leadership to determine whether its four dimensions (Idealized influence, Inspirational motivation, Intellectual stimulation, and Individual consideration) can be identified in the work of education and healthcare professionals, and whether it could be developed to foster experiences of meaningfulness and protect against experiences of meaninglessness. Additionally, various leadership models and theories were explored, as the experience of meaningfulness is strongly associated with discussions on values, trust, emotional intelligence, ethics, and hope. (Goleman 1998; Piccolo ym. 2010; Mathew & Gupta 2015; Lips-Wiersma et al., 2020; Sahimaa 2020)

The data for this study is based on the research project called "The m&m of work" in 2022-2023 and the survey data collected in spring 2022. This research focuses particularly on transformational leadership (TL) and the identification of its four dimensions in the real-life experiences of the basic and higher education and caregiving sectors at both individual and organizational levels. In this context, this study aims to enhance

technology, knowledge co-creation and leadership within organizations by leveraging both meaningful and meaningless (m&m) experiences of employees.

2 Transformational leadership supporting m & m experiences at work

In leadership research, there is usually an effort to define the difference between management and leadership. On the other hand, it can be thought that only people can be led. Things cannot be led – they can only be managed well or poorly (Rousu & Lanne-Eriksson, 2021, 8). Achieving good leadership results generally requires expertise in the field, but leadership is usually viewed as a phenomenon independent of the specific field. Leadership is typically given a formal managerial position within the organization, but it is also a role that can be held by someone without a formal leadership position. Leadership can also be shared among different individuals, and various forms of leadership are practiced simultaneously in the workplace, regardless of official job descriptions. Leadership can also be understood as influencing another person, in which case it can be thought that all members of the organization practice leadership, particularly in the education and healthcare work environments, and leadership is always a two-way and interactive social activity. (Rousu & Lanne-Eriksson, 2021; Ojala, 2016; Hyypiä & Parjanen 2013)

Experiences of meaningfulness at work can become blurred due to factors such as continuous technological advancement, high-pressure work environments, limited opportunities for influence, or a lack of appreciation. Experiencing contemporary work as meaningful affects employee well-being, motivation, and endurance. In the workplace, this is reflected in the atmosphere, commitment, knowledge sharing, and interest in developing collective activities. Conversely, experiences of meaninglessness lead to feelings of alienation, distress, and worthlessness, as well as organizational inefficiency. (Bailey et al., 2019; Bailey & Madden, 2016; Martikainen, 2022; Martikainen et al., 2022)

Research on transformational leadership (TL) emphasizes the importance of shared information and goals, collaboration, and interaction, and previous studies show a positive impact on work efficiency, workplace atmosphere, well-being, and innovation. The transformational leadership aims to align the needs and goals of both leaders and employees into a unified effort, supporting for innovations and new ways of thinking. On a moral level, TL should be an uplifting form of leadership, "where people collectively pursue ultimate values that are higher ideals than the individual goals of any single person." (Bass & Riggio, 2006; Hyypiä & Parjanen, 2013) The four dimensions (Idealized influence, Inspirational motivation, Intellectual stimulation, and Individual consideration) of transformational leadership is introduced next in the figure 1.

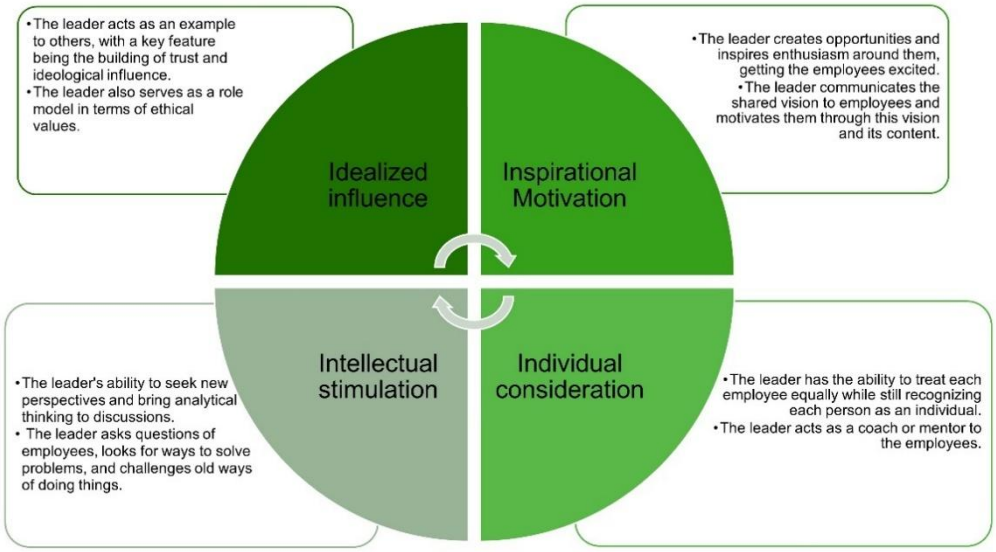

Figure 1: Four dimensions of transformational leadership

TL does not shy away from or avoid conflicts; instead, it leverages the tensions and conflicts that arise within employees' value structures. These are used to guide the formation of employees' individual meaning structures, and their effects should be visible, for example, in the distribution of responsibility, knowledge sharing and in encouraging innovation and development. (Birasnav et al., 2011; Boer et al., 2016; Mathew & Gupta, 2015)

Hence, this study demonstrates the necessity to reshape leadership requirements and the crucial importance of human-centric approach of transformational leadership in an increasingly digitalized world (Henderikx & Stoffers, 2022).

3 Data, method and analysis

This study is based on the wider research project called "The m&m of work" in 2022-2023. The study utilized various data collection methods, employing both quantitative and qualitative approaches. Collaborating partners in this research project were services for the elderly and caregiving and basic education, in Finland.

3.1 Data gathering and methodological approach

The research collaboration was initiated in early 2022 with a survey. Representatives of the collaborating parties received the designed questionnaire for approval and distributed the survey as a Webropol link to be answered within their own organizations. The survey received a total of 63 responses from elderly and caregiving services and 125 responses schools from basic education. Additionally, the survey was distributed to employees of higher education and received 116 responses. Thus, the total number of responses to the survey was 304.

A 4C-evaluation method was developed to collect assessment and experiential data on the meaningfulness and meaninglessness of work. The evaluation is based on experience dimensions identified in previous qualitative research (Martikainen et al., 2022). The 4C-evaluation includes four experience dimensions: contribution, connection, conversion, and confinement (Martikainen & Oikarinen, 2023). The survey was firstly constructed by operationalizing these experience dimensions into different statements. The survey was further developed with the dimensions of transformational leadership (TL), including 14 statements (further details of the statements available in the tables 1, 2, 3 and 4 below).

The leadership statements were a separate entity of the survey. Responses to the statements were given on a five-point Likert scale: 1 strongly disagree – 2 somewhat disagree – 3 neither agree nor disagree – 4 somewhat agree – 5 strongly agree. Additionally, there was a "cannot answer" option available. Thus, the responses related to the TL entity of the survey is analysed on this study.

In the section of the survey related to the 14 statements on transformational leadership, the four different dimensions (Idealized influence, Inspirational motivation, Intellectual stimulation, and Individual consideration) of TL were not distinguished in advance, nor were respondents required to specify whom they were reflecting on in terms of leadership (e.g., immediate supervisor or top management team). Moreover, the background information of the respondents (age, gender, workplace, length of employment at the workplace, and length of employment in the education or healthcare sector) is not further acknowledged in the analysis.

3.2 Analysis

There were 63 respondents from elderly and caregiving services and the average of responses for all 14 statements of TL was 3.6. The highest average was 4.2 and the lowest was 3.2. There were 125 respondents from schools of basic education and the average of responses for all 14 statements of TL was 3.6. The highest average was 4.2 and the lowest was 3.2. There was a total of 116 respondents from higher education and the average of all responses for all 14 statements of TL was 3.3. The highest average was 4.1 and the lowest was 2.6.

Table 1**:** Responses rates and average relative to Idealized influence statements

Idealized influence in elderly and caregiving services							
Statements	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree	Cannot answer	Average
1. It is important for our organization to act responsibly and ethically.	3,2%	3,2%	14,5%	21,0%	53,2%	4,9%	4,2
2. Our organization has a safe working environment.	1,6%	8,1%	11,3%	43,5%	33,9%	1,6%	4,0
3. In our work community, we are united by mutual trust.	4,8%	8,1%	12,9%	37,1%	33,9&	3,2%	3,9

Idealized influence in basic education							
Statements	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree	Cannot answer	Average
1. It is important for our organization to act responsibly and ethically.	1,2%	0,0%	12,6%	47,1%	35,6%	3,5%	4,2
2. Our organization has a safe working environment.	1,2%	4,6%	5,7%	48,3%	39,1%	1,1%	4,2
3. In our work community, we are united by mutual trust.	3,5%	9,4%	12,9%	24,7%	2,4%	2,4%	3,8
Idealized influence in higher education							
Statements	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree	Cannot answer	Average
1. It is important for our organization to act responsibly and ethically.	1,8%	7,8%	12,2%	36,5%	40,0%	1,7%	4,1
2. Our organization has a safe working environment.	0,9%	14,8%	8,7%	43,5%	29,5%	2,6%	3,9
3. In our work community, we are united by mutual trust.	7,0%	14,8%	13,9%	45,2%	16,5%	2,6%	3,5

With idealized influence dimension trust and respect from employees must be earned through honesty, ethical behavior, and consistent actions.

Table 2**:** Responses rates and average relative to Inspirational motivation statements

Inspirational motivation in elderly and caregiving services							
Statements	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree	Cannot answer	Average
4. Management communicates clearly about the future of the organization's operations.	6,4%	22,6%	6,4%	35,5%	19,4%	9,7%	3,4
5. In our organization, employees' creativity is utilized.	6,4%	19,4%	21,0%	35,5%	16,1&	1,6%	3,4
6. At our workplace, the meaningfulness of work is discussed.	8,1%	12,9%	24,2%	32,2%	22,6%	0,0%	3,5
7. I am proud of my workplace.	4,8%	6,5%	16,1%	33,9%	4,8%	4,8%	3,9
Inspirational motivation in basic education							
Statements	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree	Cannot answer	Average
4. Management communicates clearly about the future of the organization's operations.	10,6%	16,5%	20,0%	42,3%	9,4%	1,2%	3,2
5. In our organization, employees' creativity is utilized.	5,8%	6,9%	13,8%	49,4%	21,8%	2,3%	3,8
6. At our workplace, the meaningfulness of work is discussed.	8,0%	18,4%	27,6%	36,8%	8,0%	1,2%	3,2
7. I am proud of my workplace.	2,3%	6,9%	11,5%	51,7%	26,4%	1,2%	3,9
Inspirational motivation in higher education							
Statements	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree	Cannot answer	Average
4. Management communicates clearly about the future of the organization's operations.	7,8%	23,5%	9,6%	45,2%	12,2%	1,7%	3,3
5. In our organization, employees' creativity is utilized.	6,1%	28,1%	17,6%	29,8%	14,9%	3,5%	3,2
6. At our workplace, the meaningfulness of work is discussed.	19,1%	35,7%	13,9%	21,7%	6,1%	3,5%	2,6
7. I am proud of my workplace.	2,6%	8,8%	25,4%	29,0%	34,2%	0,0%	3,8

By inspirational motivation dimension and a shared vision, a sense of purpose and direction is created, which helps employees and colleagues connect their work to a larger value.

Table 3**:** Responses rates and average relative to Intellectual stimulation statements

Intellectual stimulation in elderly and caregiving services							
Statements	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree	Cannot answer	Average
8. In the development of the organization, employees' perspectives are considered.	6,5%	22,6%	17,7%	37,1%	12,9%	3,2%	3,3
9. In our organization, old working methods are challenged.	4,9%	14,5%	29,0%	37,1%	11,3%	3,2%	3,4
10. I have the freedom to develop the organization's operations and working methods.	8,1%	21,0%	24,2%	30,6%	11,3%	4,8%	3,2
Intellectual stimulation in basic education							
Statements	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree	Cannot answer	Average
8. In the development of the organization, employees' perspectives are considered.	8,0%	20,7%	16,1%	39,1%	14,9%	1,2%	3,3
9. In our organization, old working methods are challenged.	4,6%	10,4%	19,5%	51,7%	11,5%	2,3%	3,6
10. I have the freedom to develop the organization's operations and working methods.	7,0%	16,3%	16,3%	37,2%	20,9%	2,3%	3,5
Intellectual stimulation in higher education							
Statements	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree	Cannot answer	Average
8. In the development of the organization, employees' perspectives are considered.	11,4%	31,6%	19,3%	27,2%	7,0%	3,5%	2,9
9. In our organization, old working methods are challenged.	9,6%	21,7%	20,0%	34,8%	9,6%	4,3%	3,1
10. I have the freedom to develop the organization's operations and working methods.	10,5%	22,6%	22,6%	31,3%	7,8%	5,2%	3,0

Intellectual stimulation dimension encourages curiosity, creativity, critical thinking, and innovation. These create opportunities for colleagues and employees to explore new ideas, take risks, and advance their unique perspectives.

Table 4**:** Responses rates and average relative to Individual consideration statements

Individual consideration in elderly and caregiving services							
Statements	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree	Cannot answer	Average
11. We dare to give constructive criticism.	7,9%	19,1%	20,6%	33,3%	15,9%	3,2%	3,3
12. In our organization, employees' wellbeing is valued.	11,1%	14,3%	20,6%	36,5%	15,9%	1,6%	3,3
13. My personal needs are recognized in my work.	6,5%	14,5%	14,5%	50,0%	12,9%	1,6%	3,5
14. Management supports success in my work.	6,6%	14,8%	16,4%	34,4%	22,9%	4,9	3,6

Individual consideration in basic education							
Statements	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree	Cannot answer	Average
11. We dare to give constructive criticism.	3,4%	11,5%	16,1%	56,3%	11,5%	1,2%	3,6
12. In our organization, employees' wellbeing is valued.	10,4%	10,5%	18,6%	38,4%	22,1%	0,0%	3,5
13. My personal needs are recognized in my work.	4,6%	10,3%	27,6%	39,1%	14,9%	3,5%	3,6
14. Management supports success in my work.	6,9%	8,1%	26,4%	34,4%	21,8%	2,3%	3,6
Individual consideration in higher education							
Statements	Strongly disagree	Somewhat disagree	Neither agree nor disagree	Somewhat agree	Strongly agree	Cannot answer	Average
11. We dare to give constructive criticism.	7,9%	14,0%	14,9%	49,1%	8,8%	5,3%	3,4
12. In our organization, employees' wellbeing is valued.	9,6%	19,1%	18,3%	33,9%	15,6%	3,5%	3,3
13. My personal needs are recognized in my work.	4,3%	12,2%	27,0%	40,0%	13,9%	2,6%	3,5
14. Management supports success in my work.	14,9%	17,5%	16,7%	35,1%	14,0%	1,8%	3,2

Individual consideration dimension prioritizes and recognizes each employee's and colleague's unique strengths, needs, and aspirations. This supports guidance and development opportunities, enabling individuals to reach their full potential.

4 Findings

According to the results, the influence of Transformational Leadership in the experiences of education and elderly and caregiving sectors were evident at the organizational level in areas such as responsibility and ethics, the safety of the work environment, and discussions about the meaningfulness of work. At the individual level, TL's impacts were highlighted in aspects such as trust within the work community, utilization of employees' creativity, and support for success. Generally, role modelling and inspirational motivation are more required from higher strategic leadership levels, while intellectual stimulation and individual consideration dimensions are primarily addressed by immediate supervisors and colleagues. However, no single dimension of TL emerged as more or less important in the study, indicating that each of the four dimensions is beneficial for supporting experiences of meaningfulness and sharing common meaning within organizations through leadership.

Leading meaningfulness at work means creating an environment where employees feel connected to a sense of purpose, find value in their work, and experience satisfaction. Meaningfulness is a personal and individual experience. It is important to understand and respect the unique perspectives, values, and aspirations of employees and colleagues. By creating an encouraging and future-oriented work environment, leadership can nurture meaningfulness and ultimately support greater commitment, satisfaction, and productivity among employees. (Ojala 2016; Mathew & Gupta 2015; Hyypiä & Parjanen 2013; Birasnav et al. 2011; Bass & Riggio 2006).

By acting as an example and role model (*Idealized influence*), leadership creates a sense of trust and authenticity and aims to align colleagues and employees' values with the organization's values. This alignment enhances the meaningfulness of work, as employees see their contributions as part of a larger purpose. A vision-driven approach (*inspirational motivation*) enhances motivation and the meaningfulness of work. By showing and involving employees in how their contributions are essential for achieving common goals. *Intellectual stimulation* aims to promote autonomy and a sense of growth and development, which enhances the meaningfulness of work by leveraging engagement and continuous learning. By caring for employees' growth and well-being, with *individual consideration*, transformational leadership can create an environment where employees feel valued and understood, leading to a greater sense and experiences of meaningfulness.

According to the results and previous studies in meaningfulness and leadership research it is also suggest that supervisors and management can achieve and support more meaningful work experiences by showing appreciation, providing feedback (including on personal skills and expertise), offering responsibility and freedom, ensuring adequate resources and frameworks, improving communication, creating a culture of care, engaging in active leadership, and serving as role models. (Sahimaa, 2020)

5 Conclusions

Transformational leadership (TL) requires skills in nurturing emotional connections. Leadership demonstrates empathy, compassion, and genuine care for the well-being of employees and colleagues. By creating an encouraging and positive atmosphere, a sense of belonging, trust, and psychological safety is achieved. This emotional connection enhances the sense of meaningfulness when employees feel valued and supported in their work (Goleman 1998; Caruso et al. 2002; Mathew & Gupta 2015).

Although the literature also criticizes TL theory for its relatively positive perspective and broad applicability, the digital era require human-centric approach and leadership to reshape a future of work. The transformational leadership approach offers several advancements over other leadership theories when it comes to fostering meaningfulness at work.

Additionally, it should be noted that the TL approach surpasses immediate task-oriented goals and focuses on long-term development and growth (Birasnav et al. 2011; Hyypiä & Parjanen 2013). By investing in the personal and professional growth of employees, transformational leadership can support employees see the long-term impact and significance of their work. This emphasis on development and growth enhances the meaningfulness of work by allowing individuals to see how their contributions align with their own aspirations and future goals.

The most important "tool" of leadership and means of influence, however, is the organization and the people (Ojala 2016; Rousu & Lanne-Eriksson 2021). With the help of a discussion card set developed together with the staff of basic education and the healthcare sector, it is possible to gather in the same place virtually or in person and discuss meaningfulness or experiences that affect meaningfulness. The level and tone of the discussion may differ from the original idea – through the themes, the organization's operations may also be developed as such or a common meaning may be created for different experiences. The role of leadership in this is to enable time and place, as well as to listen to open discussion and sharing of experiences. Of course, it is also possible that through the discussion, concrete areas for development are identified in the work community, and new ways of working are agreed upon to promote or support the work, technology, knowledge co-creation and meaningfulness in organizations.

The study has some obvious limitations: the basic analysis is part of a wider survey and therefore, any findings can be treated as exploratory, and no generalizations can be made. For further analysis, software, for example SPSS will be utilized. Furthermore, the study was conducted in an elderly and caregiving services and education in Finland and thus does not represent a ‘conventional’ business environment in management and leadership research.

6 Ethics declaration

The ethical clearance for the research referred to in this paper was not required.

7 AI declaration

AI-based tool assistance of Enterprise Microsoft Copilot 365 was utilized in proofreading parts of the text.

Materiality Analysis for SDG Prioritization: Is Multi-Criteria Decision Making Helpful?

Tamara Menichini, Gennaro Salierno, Nicoletta Maria Strollo
University of Rome Niccolò Cusano, Rome, Italy

Abstract

The UN Agenda 2030 and its 17 Sustainable Development Goals (SDGs) represent the most comprehensive framework ever formulated to address the global environmental, social, and governance (ESG) challenges. Prioritizing SDGs is crucial for companies to integrate SDGs into corporate decision-making by identifying the most relevant goals and making informed strategic decisions for corporate sustainability. Materiality analysis, as identifying the sustainability issues most relevant to a company and its stakeholders, becomes thus a valid tool to determine priority SDGs. Nevertheless, the existing international managerial guidelines that promote materiality analysis for aligning corporate initiatives with SDGs are often too generic difficult to implement, and open to ambiguous interpretation, which hampers its practical adoption. The present paper proposes an exploratory study by adopting the qualitative approach of semi-structured interviews to gather insights from strategic decision-makers on the relevance, applicability, and potential challenges concerning the adoption of a Multi-Criteria Decision Making (MCDM) method for performing materiality analysis in the process of SDG prioritization. As a result, the multi-criteria approach to materiality analysis is widely accepted by all involved interviewees, who agree on its usefulness in providing a standardized procedure for the prioritization of SDGs. In addition, as highlighted by the suggestions of the experts involved in the study, integrating the potentialities of Artificial Intelligence (AI) technologies into materiality analysis appears to be a promising direction for shaping future developments in the application of materiality analysis to SDG prioritization decisions.

Keywords: Sustainable Development Goals (SDGs), Materiality Analysis, Multi-Criteria Decision-Making Method (MCDM), Semi-structured interview, Artificial Intelligence (AI)

Paper type: Academic Research Paper.

1 Introduction

With the 17 Sustainable Development Goals (SDGs), the United Nations' Agenda has presented the most urgent need to safeguard a responsible future for people and society as a whole (Fiandrino et al., 2022; Elalfy et al., 2020; UN, 2015). Engaging with the SDGs goes beyond an ethical obligation and becomes a strategic pathway for companies that can catch concrete advantages (Boar et al., 2020), such as improved cost efficiency, greater corporate attractiveness, enhanced risk mitigation, and stronger stakeholder relationships (GRI, 2018). However, several challenges characterize the strategic integration of SDGs into corporate decision-making. The relevance of each of the 17 SDGs varies depending on a company's operational context, the nature of its business activities, and the specific expectations of its stakeholders (Ike et al., 2019). As a result, prioritizing SDGs becomes crucial for companies to identify the most relevant goals and make informed strategic decisions for corporate sustainability (Berrone et al., 2023; Patuelli et al., 2022). Indeed, priority SDGs refer to the goals that best capture the areas where the most significant impacts on the economy, environment, and people, both positive and negative, occur (Menichini & Salierno, 2023; Adams et al., 2021). To this aim, a large body of literature recognizes that materiality analysis, identifying the sustainability issues most relevant to a company and its stakeholders, is a valid tool to determine priority SDGs (Heras-Saizarbitoria et al., 2022). Materiality analysis helps in gaining an overview of the company's performance, enhancing company credibility and stakeholder awareness, and ensuring the inclusion of stakeholder needs in company decisions (Torelli et al., 2020; Gromis di Trana et al., 2024). Open-source managerial guidelines, developed to support companies in transparently accounting to stakeholders, such as those proposed by the Global Reporting Initiative (GRI), focus on materiality analysis (GRI, 2016; 2021). Particularly, the "SDG compass" proposes materiality analysis to guide the SDGs prioritization process, by defining those Goals that the company acknowledges it can actively pursue through viable initiatives (GRI, 2015). Accordingly, managerial literature emphasizes the importance of effective stakeholder engagement, as it ensures that stakeholders' perspectives and expectations actively shape corporate sustainability (Torelli et al., 2020; GRI, 2018; GRI, 2016).

Nevertheless, how companies effectively set their decision-making process to operationalize their commitment to the SDGs is yet to be clearly defined (Fallah Shayan et al., 2022; Grainger-Brown & Malekpour, 2019). According to existing international standards for sustainability reporting and accounting, materiality

analysis certainly represents an important first step in helping companies prioritize their efforts toward the achievement of the SDGs (van Tulder & Lucht, 2019; GRI, 2015). However, relevant literature highlights how the provided managerial guidelines allow ambiguity in interpretation, hindering materiality analysis practical adoption within the company's strategic decision-making (Fiandrino et al., 2022; Hsu et al., 2013). This is especially true for Small and Medium-sized Enterprises (SMEs), which often lack the necessary resources (in terms of financial and human resources, specific skills, and/or time) to undertake an effective materiality assessment process (Cantele & Zardini, 2020; Verboven & Vanherck, 2016).

By leveraging materiality assessment potentialities, researchers have developed different models, with MCDM methods emerging as a practical approach for conducting the materiality analyses and aiding SMEs (Cinelli et al., 2014). Indeed, MCDM methods are widely recognized as suitable to handle the complexity and subjectivity of corporate sustainability decisions, making them a potentially effective approach to standardize the integration of SDGs into SME strategic decision-making (Calabrese et al., 2017; 2016). As common practice, the MCDMs are often enhanced by incorporating fuzzy logic to effectively manage the ambiguity and fuzziness that may affect experts' evaluations (Chowdhury and Paul, 2020; Faizi et al., 2020; Sahoo and Goswami, 2023). In addition, recent studies have highlighted a clear evolution in MCDM methods from conventional frameworks to advanced AI-driven models (Kumar, 2025). Particularly, the integration of AI along with machine learning and other evolving technologies such as IoT and blockchain emerges as a significant improvement for MCDM approaches, marking a major development in decision-making processes (Kumar, 2024). By making them more accurate, responsive, and capable of handling real-time data, the MCDM approaches, together with the AI solutions, are proving essential for optimizing decision processes in environments characterized by massive and continuously updated data (Abdulla & Baryannis, 2024).

Accordingly, the present paper proposes an exploratory study to understand the perception and acceptability of a standardized MCDM method for performing materiality analysis for SDGs' prioritization. The study adopts a qualitative approach using semi-structured interviews to gather insights from strategic decision-makers on the relevance, applicability, and potential challenges concerning the adoption of an MCDM-based approach to prioritize SDGs.

The rest of the paper is structured as follows. The next section details the proposed interview protocol, including the process of the experts' involvement. This is followed by results. Finally, the discussion and conclusions complete the paper.

2 Method

Qualitative research aims to understand the perspectives and experiences of individuals or groups, as well as the contexts in which these perspectives or experiences are placed (O'Brien et al., 2014). Particularly, semi-structured interviews go beyond merely collecting information, providing a deeper understanding of the motivations, opinions, and reasons behind respondents' answers (Flick, 2018; Kallio et al., 2016). Therefore, the approach becomes particularly effective for exploratory studies aimed at understanding attitudes and perceptions about a topic (Brinkmann, 2014). Indeed, semi-structured interviews involve identifying and administering a predefined set of key questions while maintaining the flexibility needed to explore emerging topics and dynamically manage participants' contributions (Brinkmann, 2014). Several studies highlight the effectiveness of semi-structured interviews in gathering information to understand decision-making dynamics within sustainable development contexts characterized by various complex factors (Flick, 2018; Kuckertz & Wagner, 2010). The in-depth and contextualized data collected from the different responses of interviewees provide valuable insights, helping to refine a methodological proposal and ensure the relevance and practical applicability of a method (Kallio et al., 2016). Therefore, the present paper involved the development of an interview protocol and its subsequent administration to reach the aim of the present research. The interview protocol was specifically designed for semi-structured interviews, ensuring flexibility and depth in data collection. A set of 17 questions, listed in Table 1, was identified to cover all the key aspects of an MCDM method based on a materiality analysis approach to prioritize SDGs.

Table 1: Final Interview protocol

	Questions
General Questions	**Q1.** Is your company currently engaged in sustainability initiatives?
	Q2. Are you aware of the 17 SDGs established by the United Nations as part of the 2030 Agenda for Sustainable Development?
	Q3. In your opinion, are companies aware of the economic and social implications (benefits, opportunities, efforts, and commitments) related to integrating the SDGs into their business practices?
Specific Questions	**Q4.** Do you think it is necessary to clearly understand, identify, and select the most relevant sustainability issues to prioritize the SDGs most relevant for the company?
	Q5. Do you consider it useful to examine the alignment between sustainability initiatives and the company's long-term strategy to identify the most relevant sustainability issues?
	Q6. Do you think it is useful to consider sustainability performance and achieved results to identify the most relevant sustainability issues for the company?
	Q7. Do you consider it useful to integrate stakeholders' specific needs and, therefore, take into account the sustainability issues they consider most relevant?
	Q8. Do you find it beneficial to adopt a structured method that considers multiple criteria simultaneously to identify the most relevant sustainability issues and prioritize the SDGs accordingly?
	Q9. Do you believe that involving different stakeholders or groups, both inside and outside the company, can improve the quality of decision-making?
	Q10. When identifying the most relevant sustainability issues for the company and prioritizing the SDGs, do you think it is useful to assign different weights to each evaluation criterion to ensure decisions that align with the company's specific context?
	Q11. In your opinion, is it important to adopt an approach that allows stakeholders to provide their evaluations in linguistic form?
	Q12. When identifying the most relevant sustainability issues for the company, do you find it effective to start from a predefined and standardized list of topics (such as those provided by GRI)?
Questions on implementation	**Q13.** How realistic do you think it is (in terms of time and resources) to implement a method like this proposed?
	Q14. What aspects do you think have not been considered in the proposed method and should therefore be improved?
	Q15. Do you believe that the proposed method can provide useful information to make the reporting of corporate sustainability initiatives more transparent, rigorous, and effective in communicating with stakeholders?
	Q16. Do you think the proposed method could support internal monitoring of the sustainability initiatives undertaken by the company?
	Q17. Do you believe that the results obtained from the application of the proposed method could enable comparisons between different companies?

It should be noted that the numbering assigned to each question does not reflect the actual order in which they were posed. Indeed, to accurately capture the respondents' perceptions, the semi-structured approach enabled the interviewer to follow a flexible guide, adapting the order of questions according to the flow of the conversation and the respondents' answers (Bhattacharyya & Shah, 2022). Moreover, questions Q14, Q16, and Q17 were initially designated as follow-up questions, intended to further explore the discussion whenever a respondent's initial answer warranted additional clarification. The questionnaire was structured to begin with general questions aimed at engaging participants while preventing the main research objectives from being immediately evident. Only afterward, based on the respondents' actual level of engagement, were more specific questions introduced. Particularly, the final interview protocol consisted of three main groups of questions. The first group was composed of general questions aimed at understanding the level of awareness of companies about the integration of the SDGs into their business practices. The second set of questions was designed to assess the perceived usefulness of different aspects and procedural steps of an MCDM approach to materiality analysis. Particularly, the latest GRI guidelines, the "Universal Standard" (2021), which recommend identifying and assessing both actual and potential material impacts, along with stakeholder demands, have been considered as a reference framework for materiality analysis and, thus, decisional criteria of the standardized multicriteria approach. As suggested by the guidelines, the relevance of economic, environmental, and social impacts needs to be evaluated taking into account their likelihood of occurrence considering the company's strategic decisions, as well as the intensity of the benefits/malus generated by the company's performance (GRI, 2021; Menichini & Salierno, 2023). Finally, the remaining questions were designed to explore the managerial implications of the approach and its practicability. The interview was conducted involving three experts with different professional backgrounds (Table 2), enabling an extended picture of different points of view by SMEs as well as feedbacks on long-term strategic complexities of large industries.

Table 2: Interviewees' details

Details	Interviewee A	Interviewee B	Interviewee C
Position/role	CEO	CEO	ESG manager
Size of company	SME	SME	SME, MNE, Large
Sector	Consultancy	Consultancy	Automotive
Temporal perspective	Short-term	Short-term	Long-term
Application context	Company	Company	Industry

Indeed, Interviewee A and Interviewee B are CEOs of two distinct Italian SMEs operating in the consulting sector, actively engaged in developing practical, short-term measures to quickly respond to external demands for sustainability certifications. Meanwhile, Interviewee C was an ESG manager at an association representing companies of various sizes committed to sustainability initiatives within the automotive industry. The contribution of Interviewee C offered a multi-perspective view of the level of involvement across different business dimensions. This feedback allowed for an assessment of how the method can support companies in managing sustainability-related risks and opportunities, with a particular emphasis on a long-term perspective throughout the entire value chain.

3 Results

The present section describes the results of the proposed exploratory study conducted through semi-structured interviews. All interviewees are aware of the 17 SDGs of the UN 2030 Agenda and confirm their involvement in sustainability initiatives (Q1, Q2). Nevertheless, a common and interesting aspect that emerges from all responses, particularly highlighted by the two SMEs involved, is the need for greater awareness of the actual business benefits that can be achieved by engaging with the SDGs (Q3). According to Interviewee A, the guarantees of an economic return on investment in adopting sustainability practices remain unclear. For Interviewee B, the SDGs are designed to address global issues, making them very ambitious and not particularly relevant to the daily activities of SMEs. This perspective is further confirmed by Interviewee C, who argues that the larger the company, the greater the level of attention and involvement in sustainability issues. The ability to facilitate a structured approach to prioritization has emerged as a key factor to ensure the usefulness of MCDM approach to identify material SDGs. All interviewees consider prioritization essential to clearly understand the most relevant sustainability issues to select the SDGs that are most aligned with the business (Q4). Indeed, according to Interviewee A, prioritization is essential for SMEs, as not all sustainability issues can be effectively addressed due to their limited resources. For Interviewee B, it is crucial to identify the most relevant sustainability issues to implement targeted operational measures aimed at obtaining the necessary certifications that ensure compliance and business continuity in the market. Interviewee C also confirms the importance of prioritization, emphasizing the long-term responsibility of companies, particularly large enterprises, in managing the most pressing sustainability issues.

The use of evaluation criteria based on the GRI materiality's principle has been widely embraced, since defining the most effective path to achieving the SDGs requires not only a clear understanding of the impacts of both current and future initiatives but also a systematic consideration of all external stakeholder demands (Q5, Q6, Q7, Q8). Particularly, all interviewees emphasize the importance of a careful selection of different stakeholders, so that the company can effectively address their requests (Q9), thus confirming the validity of the multistakeholder approach to decisions. The possibility to assign different weights to the different evaluation criteria has been confirmed as effective to ensure that the final decisions are more closely aligned with the company's specific context (Q10). In addition, the ability to express stakeholders' evaluations in linguistic form has been appreciated by all interviewees, confirming the validity of fuzzy logic for the design of the MCDM-based approach (Q11).The adoption of the GRI standard to support the selection of the most relevant sustainability topics was universally welcomed by all interviewees (Q12). However, Interviewee C suggested that, despite the recognized effectiveness of the GRI Standards, it would be beneficial to allow for customization to avoid excluding topics that may emerge and do not currently fit within the existing standards.

Regarding the adoption of a MCDM approach to materiality analysis in real cases, all interviewees acknowledge its potential usefulness. However, SMEs emphasized the challenges of investing in the implementation and management of a structured decision-making process (Q13). Once again, the need emerges for a targeted approach to raise awareness among management and key stakeholders about the importance of integrating the SDGs into business strategies, clearly and concretely highlighting the tangible benefits that can be achieved. To facilitate the effective adoption of an MCDM-based approach to prioritize SDGs, the interviewees suggested organizing training sessions aimed at supporting its practical implementation. Additionally, they emphasized the need for broader training to help companies concretely recognize the

importance of adopting a structured decision-making to prioritize sustainability issues (Q14). Finally, the multi-criteria approach to materiality analysis was positively evaluated as helpful for sustainability reporting (Q15). The usefulness is also recognized as valuable for internal monitoring (Q16) and benchmarking with companies operating in the same sector (Q17).

4 Discussion and conclusions

The present paper proposes an exploratory study to understand the perception and acceptability of a standardized MCDM method for prioritizing SDGs through materiality analysis. Accordingly, a qualitative approach based on semi-structured interviews was adopted, allowing for the collection of contextualized insights from the stakeholders involved. The distinctive procedure of semi-structured interviews, based on a flexible protocol, allowed the interviewers to maintain a balance between ensuring the comparability of responses and exploring emerging themes, tailoring the sequence and focus of questions to each participant's expertise and perspective (Bhattacharyya & Shah, 2022).

The MCDM approach to materiality analysis results as widely accepted by all interviewees, who agree on its usefulness in providing a standardized procedure for the prioritization of SDGs. Particularly, interviewees confirmed that the adoption of GRI-based criteria, the inclusion of multi-stakeholder perspectives, and the integration of fuzzy logic represent valuable features to enhance the clarity, transparency, and sustainability of corporate decision-making. Nevertheless, the study also highlights significant barriers, consistent with the main challenges identified in the literature—namely, the limited awareness of the tangible business benefits of engaging with the SDGs, and the operational complexity of implementing structured decision-making processes in resource-constrained contexts (Cantele & Zardini, 2020; Verboven & Vanherck, 2016). Wider training initiatives are required to help companies fully grasp the strategic importance of using structured decision-making processes to address sustainability challenges. In addition, the direct interaction with the different interviewees enabled the identification of strengths and suggestions for defining future developments about the use of a materiality analysis to SDG prioritization. Integrating the potentialities of Artificial Intelligence (AI) technologies into materiality analysis through the use of machine learning algorithms and natural language processing (NLP) seems to be a promising direction (Suarez & Caetano, 2021). AI technologies support the automated analysis of large volumes of data from various sources, such as social media, industry regulations, and stakeholder feedback, enabling companies to gain a more dynamic and predictive understanding of material sustainability issues, and then align strategies to evolving economic, environmental, and social contexts.

5 Ethics declaration

This study did not require formal ethical clearance as it involved interviews with voluntary participants and did not collect any personal or identifiable data.

6 AI declaration

Artificial intelligence tools (Grammarly, ChatGPT) were used to avoid grammar mistakes and improve the language style. All conceptual content, research design, data analysis, and critical interpretations were entirely developed by the authors.

Enhancing the Acceptation of Insects as Food: A Sustainable Strategy?

Fabrizio Baldassarre, Savino Santovito, Raffaele Campo, Pierfelice Rosato
University of Bari Aldo Moro, Bari, Italy

Abstract

Entomophagy, so the consumption of insects as food for humans, is a contemporary topic of discussions on food security, sustainability, and cultural adaptation. Scientific literature has shown growing interest in the acceptance of insect-based foods but also a marketing potential, also with reference to the 4Ps model, for example Specifically, high prices have been identified as a significant deterrent to the purchase of insect-based food products while, in terms of products consumer responses are strongly influenced by packaging visuals and wording. In this paper, which represents an ongoing research, we further show the first results of a survey between Italian consumers.

Keywords: Food, Insects, sustainability, marketing, consumers

Paper type: Academic Research Paper

1 Introduction

The advancement and commercialization of sustainable protein sources have become an urgent global imperative in light of the escalating challenge of feeding a rapidly growing population with nutritionally adequate, environmentally sustainable, and economically viable food. Among the most compelling solutions to this complex "diet-environment-health trilemma" is the promotion of entomophagy—the human consumption of insects as food.

According to the Food and Agriculture Organization (FAO) of the United Nations, entomophagy is not a marginal or novel phenomenon; it is a long-standing dietary practice embraced by an estimated 2 billion people globally (FAO, 2013). Historically rooted and culturally embedded, insect consumption has persisted from prehistoric times to the present across numerous regions, particularly in Asia, Central America, and Africa. Over 2,000 insect species have been identified as edible and are consumed as traditional food sources, underscoring the ecological and cultural validity of insect-based diets (van Huis et al., 2013).

Despite these precedents, Western societies remain deeply resistant to adopting insects as food. This aversion is primarily cultural, with insects frequently perceived as contaminants or survival food associated with poverty and underdevelopment (Ruby et al., 2015). Such stigmatization persists even in the face of robust evidence regarding the environmental, nutritional, and socioeconomic advantages of incorporating insects into the human diet. Compared to traditional livestock, insects require significantly less land and water, emit fewer greenhouse gases, and offer high feed conversion efficiency (Oonincx & de Boer, 2012). Nutritionally, they are rich in high-quality protein, essential amino acids, and micronutrients such as iron and zinc (Rumpold & Schlüter, 2013).

Regulatory approaches to edible insect commercialization vary widely across the globe. Broadly, three legal and cultural trends are observable. In Anglo-Saxon countries like the United States, regulatory authorities such as the Food and Drug Administration (FDA) have adopted a relatively permissive stance, allowing commercialization with minimal regulatory hurdles (EFSA, 2015). In contrast, non-English-speaking Western nations—particularly within the European Union—have opted for stricter controls, requiring comprehensive safety assessments and formal authorizations under the Novel Food Regulation (EU Regulation 2015/2283). Meanwhile, in non-Western countries where insects are traditionally consumed, formal systems for packaging, exporting, and importing insect-based foods remain limited, often preventing these practices from achieving commercial scale (van Huis, 2020).

Entomophagy, therefore, occupies a critical intersection in contemporary discussions on food security, sustainability, and cultural adaptation. Realizing its full potential requires not only scientific and regulatory progress but also a profound cultural shift in consumer attitudes—especially within Western food systems where acceptance remains low.

2 Literature review

The development and commercialization of sustainable protein sources are becoming increasingly crucial in addressing the global challenge of providing protein-rich foods for a growing population while minimizing health and environmental costs.

Scientific literature has shown growing interest in the acceptance of insect-based foods. Valesi et al. (2024) conducted a study involving 929 participants and found that acceptance of insects as food is not primarily driven by sustainability or health concerns but rather by hedonic motives, which positively influence willingness to try them. Similarly, Hemar-Nicolas et al. (2022) observed that cultural disgust towards insect consumption could be mitigated through social interactions, making the experience more engaging and enjoyable. Other research, such as that by Puteri et al. (2023), applied the 4Ps framework to encourage novel food consumption. Additionally, studies by Wang and Park (2023) explored the impact of anthropomorphism as a strategy to promote insect-based foods. Given the strong cultural association between insect consumption and disgust, Pozharliev et al. (2023) suggested that product design and packaging—such as avoiding direct imagery of insects—could help enhance consumer willingness to try these products.

Puteri et al. (2023), in particular, summarize findings from various studies within this domain, and organizing them according to the classic 4Ps of marketing—Product, Price, Place, and Promotion—it is possible to obtain a comprehensive overview of the most effective marketing strategies aimed at fostering consumer acceptance of insect-based food products. Special attention is given to those interventions that have been empirically tested for their impact on Western consumers' preferences, acceptance, and willingness to try, consume, or purchase these products.

2.1 Price

Across multiple studies, high prices have been identified as a significant deterrent to the purchase of insect-based food products, particularly when coupled with negative perceptions related to taste or limited availability. For instance, research conducted in Germany revealed that consumers often associate price with product quality, using it as a heuristic to judge the overall value of insect-inclusive foods. Conversely, in New Zealand, after receiving information about entomophagy, many consumers perceived such products as expensive. Price variability is substantial across product types and formats. Cricket flour-based snacks, such as protein bars or crackers, typically range from €2 to €5 per unit, while insect flour for home use may cost between €15 and €20 per 100 grams. More complex preparations—such as burgers or pasta incorporating insect powder—tend to be up to 50% more expensive than conventional counterparts. These prices reflect the relatively nascent and specialized nature of production, as well as the need to position these items as sustainable alternatives to traditional animal proteins. It is anticipated that prices will decrease as production scales and consumer acceptance grows.

2.2 Place (Distribution)

The integration of a novel food product into mainstream diets hinges on its accessibility and distribution. While insect-based foods are primarily sold through online platforms, some studies have explored their presence in health food stores and convenience outlets. Strategic placement within retail environments is also crucial; for example, it has been suggested that insect-based burgers should be stocked alongside vegetarian or meat-alternative products in supermarkets.

Restaurants may play a particularly effective role in introducing insect-based foods, as consumer apprehension tends to be lower in dining contexts compared to retail settings. This channel not only facilitates initial exposure but may also lend credibility and reduce perceived risk.

2.3 Promotion

Effective promotion in Western markets hinges on the communication of benefits that can reshape consumer perceptions and stimulate trial behavior. Since many consumers have no prior experience with insect-based foods, clear messaging regarding environmental benefits, food safety, cooking methods, social value, sensory attributes, and novelty is essential. However, informational content alone often fails to overcome psychological barriers such as disgust.

The success of promotional strategies varies according to the promotional mix employed. For instance, emphasizing sensory quality without additional reinforcement may be insufficient, but combining such messages with celebrity endorsements can significantly enhance consumer engagement. Segmenting the audience and

tailoring messages accordingly improves promotional efficacy. First-time consumers appear more receptive to advertising than those already familiar with these products.

Health-related claims tend to positively influence willingness to pay more than environmental arguments — particularly for products like insect-based pasta, which is often selected for its nutritional value. In contrast, environmental messaging has greater long-term influence for items such as insect-based chocolate bars.

Message framing also plays a critical role. Emotionally charged, affective messaging—focusing on personal well-being—has proven more persuasive than fact-based content, especially among audiences less attuned to environmental or health issues. Additionally, providing opportunities to sample insect-based foods through tasting events or product trials can significantly enhance acceptance.

Social influence has also emerged as a key factor. Endorsements from peers, experts, or celebrities, and interactions on social media, can positively shift consumer attitudes. For example, favorable reviews from friends or influencers have been shown to increase trust in product quality and taste. Visible support—such as "likes" and shares on social media—can make marketing messages more compelling. However, simply knowing that others consume insect-based foods does not automatically increase willingness to try them. The effectiveness of such strategies depends heavily on the product type, the spokesperson involved, and the resonance of the messaging with the target audience. Poorly aligned celebrity endorsements, for instance, may backfire, underscoring the need for carefully designed, audience-specific marketing tactics.

2.4 Product

Packaging and labeling serve not only functional purposes but are also instrumental in shaping consumer perceptions. Packaging design—through visual appeal, protective function, and convenience—can attract consumer attention, ensure product integrity, and enhance user experience, particularly in the context of e-commerce where unboxing becomes a pivotal brand interaction. Eco-conscious packaging using recyclable or biodegradable materials can further reinforce brand reputation.

Labels, on the other hand, are the product's voice, conveying essential information such as ingredients, nutritional content, and usage instructions. In food and cosmetic sectors, these details are not just informative but also legally mandated. Labels also act as persuasive tools by highlighting product strengths via claims like "100% natural" or "preservative-free," quality seals, and QR codes linking to additional digital content. Together, packaging and labels form a cohesive communicative unit that enhances the product's market positioning and informs purchase decisions.

When it comes to insect-based foods specifically, consumer responses are strongly influenced by packaging visuals and wording. Studies indicate that using vague, rather than realistic, insect imagery and descriptions on retail packaging or restaurant menus can reduce perceptions of risk and mitigate negative emotional responses such as fear and disgust. For example, in Belgium, labeling insect-based burgers as containing insects—accompanied by statements about their benefits and food safety—positively influenced consumer quality perceptions.

Interestingly, Wang and Park (2023) discussed about the effect of anthropomorphism of insects as food. In recent years, the consumption of edible insects as a sustainable food source has garnered increasing attention from both the general public and the academic community. It is estimated that by 2050, the global population will reach approximately 9.6 billion people, leading to a 73% increase in food demand. This projected growth raises critical concerns about the sustainability of current food systems and the future availability of food resources. Edible insects are emerging as a viable solution to this challenge, offering high-quality protein in a more sustainable, cost-effective, and environmentally friendly manner compared to conventional meat production. This potential has fueled the growth of the edible insect market, which is expected to reach a global value of $9.6 billion by 2030. However, despite growing interest in certain Western countries, low consumer acceptance remains a significant barrier to the widespread adoption of insect-based foods. Among the various strategies aimed at improving consumer acceptance, the development of appealing product packaging has proven particularly effective. In this context, anthropomorphism—defined as the tendency to attribute human-like characteristics, motivations, intentions, or emotions to non-human agents, whether real or imaginary—has emerged as one of the most commonly used marketing techniques. Research has shown that anthropomorphism can influence consumer purchase intentions, particularly in the case of insect-based foods. Incorporating anthropomorphized images of insects on packaging has been found to enhance consumers' willingness to purchase these products. While insect illustrations are often used to highlight ingredients, realistic depictions may evoke feelings of disgust and reduce product appeal. Conversely, using anthropomorphized imagery can foster a sense of familiarity and comfort. Drawing on the familiarity theory, studies have demonstrated that anthropomorphizing insects can create a sense of psychological closeness in consumers,

thereby increasing their interest in purchasing such products. However, the effectiveness of this strategy varies depending on individual levels of food neophobia—the tendency to avoid novel or unfamiliar foods.

A study conducted in Japan explored this phenomenon for two main purposes: first, to examine whether anthropomorphism influences psychological closeness and purchase intention; and second, to determine whether psychological closeness mediates the relationship between anthropomorphism and purchase intention. The findings revealed that anthropomorphizing a cricket image on packaging can indeed enhance consumer purchase intentions for cricket-based food products. Furthermore, the study confirmed that psychological closeness mediates the effect of anthropomorphism on consumer behaviour.

3 A first empirical analysis and findings

To gain deeper insight into the perception of insect-based foods in Italy, we initiated an ongoing study using a questionnaire combined with images of packaging referenced in existing literature. The survey aims to examine consumer attitudes toward insect-based foods, particularly focusing on the influence of anthropomorphic packaging in facilitating acceptance. Questions addressed participants' willingness to try insect-based foods, their perceptions of visual packaging elements, and the impact of anthropomorphic design on purchase intention. The study involved 101 respondents, with a demographic profile predominantly consisting of women (63.4%) and young adults (aged 18-24 and 25-34, making up 28.7% of the sample). Additionally, 79.2% of participants did not have children.

To assess consumer familiarity and openness to insect consumption, the questionnaire included specific inquiries about previous exposure, experience, and overall attitudes toward entomophagy. The findings provide valuable insights into awareness and potential market acceptance of insect-based foods in Western societies. Notably, 95% of respondents reported having heard of insect-based foods, indicating that the concept is widely recognized, even if its integration into daily diets remains unclear. However, actual consumption remains low, with 97% of participants never having tried insects and the remaining 3% consuming them only once or twice a year. The majority of participants expressed feelings of disgust, while 23.8% had a neutral attitude. Only one participant was enthusiastic about eating insect-based foods. These data suggest that, despite some open-mindedness, most people are still hesitant about consuming insects. Culturally, this hesitation aligns with the fact that 79.2% of participants had never encountered insect-based products in supermarkets, confirming their limited market availability.

The study also explored the role of packaging in influencing consumer behavior, particularly how anthropomorphic packaging impacts purchase intent. Most participants considered packaging an important factor. On a scale from 1 (not important) to 5 (very important), the majority selected option 3 (36.6%) and 4 (32.7%), while 16.8% rated packaging as "very important." This suggests that well-designed packaging can positively influence purchasing decisions. However, most respondents remained hesitant to buy insect-based foods, even with appealing anthropomorphic packaging (40.6% had no intention, 31.7% showed slight curiosity, and 17.8% expressed moderate curiosity). Health benefits appeared to be the primary motivation for considering this diet, followed by taste.

Participants also evaluated different insect-based food packaging. The first comparison was between chili larvae and dark chocolate-covered crickets.

Most participants preferred the crickets, as the anthropomorphic packaging reduced the sense of disgust. Conversely, when packaging displayed realistic images of insects, as with the chili pepper larvae, consumers were less inclined to purchase. The second comparison involved edible dehydrated insects (grasshoppers, crickets, worms, silkworms) versus spiced cricket cereal.

Again, anthropomorphic packaging was the preferred choice.

When asked about their willingness to pay extra for insect-based foods with attractive packaging, most participants indicated they would pay an additional 1 to 5 euros. However, a significant portion stated they would not pay any extra, highlighting resistance to associating added value with packaging alone.

These findings indicate that insect-based food consumption is still uncommon in Italy, primarily due to cultural barriers and Western eating habits. However, the growing curiosity and openness to trying novel foods suggest potential market development. Packaging design could play a crucial role in increasing acceptance, as anthropomorphic elements are perceived as more appealing and approachable, particularly for first-time buyers. Moving forward, enhancing consumer confidence through widespread supermarket distribution, along with emphasizing taste, quality, and nutritional benefits, will be essential in fostering long-term adoption of insect-based foods.

Enhancing Organizational Knowledge Management through Retrieval-Augmented Generation and Large Language Models

Dijana Oreski
University of Zagreb, Varazdin, Croatia

Abstract

Retrieval-Augmented Generation (RAG) systems address critical limitations of large language models (LLMs) such as hallucinations, static knowledge, and context constraints-by dynamically integrating organizational data to enhance accuracy and relevance in knowledge management (KM). This RAG LLM development integrates the generative strengths of large language models with the precision of real-time information retrieval, enabling responses grounded in both structured and unstructured organizational data. The development process involves data collection, preprocessing, embedding, and indexing, followed by retrieval and prompt augmentation, ensuring that the model can access and utilize up-to-date, domain-specific knowledge at response time. By leveraging authoritative internal sources and advanced vector search, the RAG system overcomes the static knowledge and hallucination limitations of traditional LLMs, delivering more accurate, contextually relevant, and transparent answers. This approach not only enhances the reliability of generative AI in business scenarios but also offers a scalable, low-code framework adaptable to diverse enterprise needs. Our research employs low code approach for RAG system development and open source LLM.

Research results demonstrate how a low-code RAG architecture, leveraging open-source LLMs and real-time data retrieval, transforms KM through three key contributions: (i) enhanced accuracy and operational efficiency, (ii) cost-effective scalability and customization, (iii) managerial and strategic impact. The RAG system reduced hallucination rates compared to standalone LLMs, achieving higher accuracy in various tasks.

Future work aims to integrate multimodal data and hybrid architectures, further advancing collaborative human-AI knowledge ecosystems. Addressing these challenges involves robust system architecture, scalable data pipelines, advanced retrieval and ranking techniques, and strong governance over data quality and security.

Keywords: Generative artificial intelligence, Large Language Models, Retrieval Augmented Generation

Paper type: Academic Research Paper

1 Introduction

The rapid evolution of generative artificial intelligence (genAI) and large language models (LLM) presents transformative opportunities for organizational knowledge management. LLMs have great abilities in creating content and natural language processing (NLP), solving NLP tasks with just few simple instructions, performing math reasoning, and demonstrating human-level on standardized tests (Naveed et.al., 2023). LLM comes with various advantages: understanding and generating human-like text across languages, task versatility (handling translation, summarization, coding, analysis, and creative writing), scalability (handling multiple queries simultaneously), quick learning from prompts without requiring traditional programming, pattern recognition, and cost-effectiveness compared to human labour. On the other hand, LLMs suffer from various limitations including: (i) hallucinations: LLMs can generate convincing but incorrect information, especially when faced with questions outside their knowledge base, (ii) lack of context: models don't have access to specific contextual information that may be crucial for accurate responses, (iii) limited context: LLMs can only process a limited amount of text at once. Retrieval augmented generation (RAG) is an innovative approach that solves LLM limitations and enhances LLM by dynamically retrieving relevant external information from a knowledge base to supplement the model's internal knowledge during answer generation. RAG refers to the process of retrieving information from external knowledge sources and generating result with the help of LLM (Gao et.al., 2023). Unlike traditional LLM that rely only on pre-trained parameters, RAG systems first search through a corpus of documents to find contextually relevant information and then use this retrieved context to generate more accurate, informed, and contextually precise responses. In this way, RAG addresses limitations of LLM enhancing organizational knowledge management.

This research presents an implementation of a RAG system, leveraging open LLM and organizational data, to transform processes in business environments. Main research objective is to develop and evaluate RAG system based on LLM for one business organization.

Key research steps include: (i) designing a low-code RAG system architecture, integrating open-source LLMs with organizational data, (ii) performance evaluation of the developed system and analyzing practical

implications for knowledge management strategies. Comprehensive methodological approach encompassing a systematic method of RAG system development was employed. Components of the RAG are (Wang et.al., 2024): Vector store, Retriever, Embedder, Indexer and LLM. Retriever function is applied to use vector store for finding documents and send that augment the prompts (Salemi and Zamani, 2024). Embedder does an encoding of documents into vector representations that the retriever can use (Zhang et.al, 2024). An indexer breaks source documents into manageable parts for embedding (Fleischer et.al., 2024). Phases of the system development are as follows. First, the selection of an appropriate LLM for RAG integration is performed based on these factors: model quality, model reliability in retrieving relevant and current data and model customization capabilities. Second, an effective document retrieval strategy is employed for optimizing RAG system performance including indexing strategy and advanced embedding techniques. Particular focus in RAG system development in this research is in examination of different types of data sources for RAG implementation, exploring various text chunking strategies for optimal performance. The study also analyzes how different LLM temperature settings affect response generation, where lower values produce more focused, predictable outputs and higher values increase response diversity and creativity.

2 Related work

Large Language Models (LLMs) are advanced AI systems capable of processing and generating text with coherent communication, as well as generalizing across various tasks. The historical progress in natural language processing (NLP) has evolved from statistical to neural language modelling, and then from pre-trained language models (PLMs) to LLMs (Naveed et.al., 2023). Their capabilities include handling a wide range of natural language tasks, pattern recognition, content generation, and providing answers and recommendations across different domains. However, LLMs have limitations such as a tendency toward hallucinations (generating inaccurate information) and challenges with accuracy on specialized or less-represented topics. Retrieval-Augmented Generation (RAG) is an approach designed to mitigate hallucinations in large language models. The RAG system extends the capabilities of LLMs by dynamically retrieving relevant data from external knowledge bases (Lewis et.al, 2020.). RAG combines two components: (i) retrieval, which fetches relevant documents from external sources using vector search, and (ii) response generation, which integrates the retrieved information with the LLM's inherent knowledge. This approach enables the system to avoid hallucinations and provide verified answers, making it crucial for applications across a wide range of domains.

3 Methodology

The study employs a comprehensive, multi-phase methodological approach, encompassing both technical development and empirical validation in a business context:

1. *System Architecture Design*: A low-code RAG system architecture was designed, integrating open-source LLMs (Llama and DeepSeek) with diverse organizational data sources. The architecture consists of five key components: an Embedder (for encoding documents into vector representations), an Indexer (for segmenting source documents into manageable chunks), the Vector Store (for efficient similarity search), the Retriever (for identifying contextually relevant documents), and the LLM generator (for producing final responses).
2. *Data Integration and Preprocessing:* Organizational data, including structured databases (Excel files), unstructured documents (PDFs, emails, reports), and semi-structured sources (internal knowledge bases), were ingested and normalized. Various text chunking strategies (256–1024 tokens) were tested to optimize retrieval performance, with a chunk size of 512 tokens and 10–15% overlap yielding the best balance between context preservation and search efficiency.
3. *Model Selection and Customization*: Open-source LLMs were evaluated based on model quality (BLEU, ROUGE, and F1 metrics), reliability in retrieving relevant and current data, and customization capabilities. Llama demonstrated 89% factual extraction accuracy in preliminary benchmarks.
4. *Retrieval Strategy Optimization*: The retrieval pipeline combined semantic search (BM25, dense vector search) and metric learning for document ranking. The FAISS library was used for efficient vector similarity search.
5. *Empirical Validation*: The RAG system was deployed in a public sector organization over. Evaluation involved A/B testing with end-users across few business units, benchmarking against ISO/IEC 25022 software quality standards, and ROI analysis based on productivity gains.
6. *Performance Metrics:* Key evaluation metrics included response accuracy, reduction in hallucinations, average information retrieval time, user satisfaction, onboarding time for new employees, and maintenance costs.

4 Research results

The empirical validation of the RAG system demonstrated significant improvements over both traditional LLM-based solutions and existing AI-driven knowledge management systems:

- Reduction in Hallucinations: The RAG system reduced the rate of hallucinated (incorrect or fabricated) responses from 23% (pure LLM) to 4.1%.
- Response Accuracy: Achieved 89% accuracy in contract analysis tasks, compared to 54% for baseline LLMs and 81% for advanced chatbot solutions.
- Information Retrieval Time: Average time to access relevant information was reduced from 34.7 seconds (legacy NLP systems) to 9.2 seconds.
- Onboarding Efficiency: Time required for onboarding new employees was reduced by 40%, as the RAG system enabled personalized knowledge delivery and contextual Q&A.
- Cost Savings: Monthly maintenance costs were reduced from $4,500 (traditional systems) to € 1,200, with a projected annual savings of € 45,000.
- Comparison with Existing Solutions: A comparative analysis was conducted between the proposed RAG system, traditional knowledge management systems, and advanced AI-based chatbots.

Table 1 compares three approaches by six metrics.

Table 1**:** A sample table

Metric	**RAG System**	**Traditional Knowledge Base**	**AI Chatbot**
Data Accuracy	Auto-sync	Manual weekly updates	Static data sets
Scalability	Linear (€ 0.12/GB)	Exponential (IT overhead)	Variable (licensing)
Query Flexibility	Semantic, contextual	Boolean search	Limited intents
Onboarding Time	89% reduction	Baseline	40% reduction
Regulatory Risk Detection	3.4× higher precision	Moderate	High (but static)
Maintenance Cost	€ 1,200/month	€ 4,500/month	€ 2,900/month

The RAG system outperformed both traditional and AI-driven alternatives in terms of data accuracy, query flexibility, cost efficiency, and precision in regulatory risk identification.

5 Results discussion

Research results are interpreted in terms of managerial implications and practical recommendations for decision-makers.

5.1 Managerial implications

The deployment of the RAG system has direct and measurable impacts on managerial decision-making and operational efficiency:

- Strategic Decision-Making: Integration with business intelligence platforms (e.g., Tableau) enables automated generation of SWOT analyses, with high alignment to human expert evaluations. Managers can access synthesized insights from both structured and unstructured data sources, supporting more informed and timely decisions.
- Process Optimization: The system automates 6high level of routine queries to support teams, freeing up human resources for higher-value tasks. This leads to a significant increase in overall operational efficiency and a significant reduction in response times for critical business queries.
- Risk Management: Real-time monitoring of regulatory changes across multiple jurisdictions is enabled, with automatic compliance report generation achieving high accuracy. This reduces the risk of non-compliance and associated financial penalties.
- Change Management: The phased implementation approach-starting with non-critical processes and gradually integrating with core systems +minimizes disruption and facilitates organizational buy-in. Training “AI champions” in each department ensures effective adoption and continuous feedback.
- Ethical and Governance Considerations: The system incorporates audit trails for generated content and regular bias checks in retrieved documents, supporting transparency and compliance with data governance standards.

In summary, the adoption of RAG systems empowers managers with faster, more accurate, and context-rich insights, directly supporting better decision-making and operational agility. By streamlining knowledge access and automating routine queries, RAG enhan

5.2 Practical recommendations for decision-makers

Retrieval-Augmented Generation (RAG) supports quick and informed decision-making by combining real-time information retrieval with advanced language generation. Unlike traditional AI models that rely solely on pre-trained data, RAG dynamically searches organizational knowledge bases or external sources to provide accurate, up-to-date, and contextually relevant answers. Key ways RAG accelerates and improves decision-making include:

- Instant Access to Relevant Information: RAG retrieves and synthesizes pertinent data from vast, distributed sources, drastically reducing the time decision-makers spend searching for information. This enables faster responses to market changes and operational challenges, which is especially critical in industries where timely decisions impact outcomes.
- Enhanced Accuracy and Consistency: By grounding responses in current, verified knowledge, RAG reduces errors and inconsistencies that can arise from outdated or siloed information, ensuring that decisions are based on the latest and most reliable data.
- Reduced Cognitive Load: RAG distills complex data into concise, actionable insights, allowing decision-makers to focus on evaluating options rather than gathering or interpreting raw information. This streamlining is particularly valuable in complex or high-stakes scenarios.
- Context-Aware Responses: RAG tailors information to the specific context and intent of the query, providing nuanced and directly applicable recommendations rather than generic answers. This contextualization helps leaders act confidently and appropriately in dynamic environments.
- Operational Efficiency: By automating information retrieval and knowledge synthesis, RAG minimizes manual research and analysis, freeing up time and resources for higher-value strategic activities.

In practice, organizations using RAG report significant reductions in decision latency, improved productivity, faster onboarding, and greater consistency in knowledge sharing-all of which contribute to more agile and informed decision-making at every level

5.3 Scientific Implications

The deployment and evaluation of the RAG (Retrieval-Augmented Generation) system offer several significant scientific contributions that advance both the theoretical and practical understanding of AI-driven decision support:

- Advancement of Hybrid AI Architectures:

This study demonstrates the practical viability and benefits of hybrid models that combine retrieval-based and generative AI components. By empirically validating the performance of RAG in real-world contexts, the research contributes to the growing body of evidence supporting hybrid approaches as superior to standalone generative or retrieval models for complex, knowledge-intensive tasks.

- Methodological Contributions:

The research introduces a robust methodology for evaluating RAG systems, including metrics for operational efficiency, accuracy, and user adoption. These evaluation frameworks can serve as a reference for future studies aiming to assess AI-driven knowledge management solutions across various industries.

- Implications for Explainable AI (XAI):

This study addresses a number of things that really are core challenges to having AI be explainable and, importantly, to having it be something that humans can trust. Because if humans can't trust it, then why use it? And if we use it, then we must be accountable for the decisions it makes. One way to enhance both our collective interpretability and our individual understandings of how something like a core decision-making system can produce outputs is to audibly trail every decision it makes.

- Cross-Disciplinary Relevance:

The impact of RAG systems clearly cuts across many disciplines. Natural language processing, information retrieval, and even the behavioral sciences have been advanced by what these systems can do. And the enhancement of decision-making and operational agility that this work promotes appears to be useful in an impressive variety of contexts—finance, healthcare, compliance with regulations, and many more.

The scientific implications of this research extend beyond immediate business applications, offering foundational insights into the design, evaluation, and deployment of retrieval-augmented generative models.

The findings pave the way for future research on scalable, transparent, and context-aware AI systems that can effectively augment human expertise in complex environments.

Based on the empirical findings, the following recommendations are proposed for organizations considering RAG adoption:

1. Start with Pilot Projects: Focus initial deployment on non-critical knowledge management processes to demonstrate value and build organizational confidence.
2. Iterative Evaluation: Regularly assess the impact on key performance indicators (KPIs) and adjust system parameters (e.g., chunk size, temperature settings) for optimal performance.
3. Invest in Change Management: Provide targeted training and support to ensure smooth adoption and maximize the benefits of the new system.
4. Monitor and Update Data Sources: Implement automated data synchronization and regular audits to maintain data freshness and relevance.
5. Address Ethical Considerations: Establish clear guidelines for content generation, bias monitoring, and data privacy compliance.

The implementation of a low-code RAG system powered by open-source LLMs demonstrates substantial benefits for organizational knowledge management, including enhanced decision-making, operational efficiency, and cost savings. The system's ability to dynamically integrate and contextualize information from diverse sources addresses critical limitations of both traditional and AI-driven knowledge management solutions.

5 Conclusion

Research results demonstrates that low-code RAG systems powered by open-source LLMs brings added value to organizational knowledge management. By reducing technological complexity and implementation costs, RAG system, provides businesses with a practical pathway to leveraging advanced genAI capabilities. RAG systems are already changing how LLMs interact with data in real-time. The future of RAG systems points to a synergy between artificial and human intelligence, fostering collaborative problem-solving and innovation and thus enhancing knowledge management practices.

Key scientific contributions here include an innovative approach for integrating generative AI technologies with existing organizational knowledge infrastructure, providing actionable insights for businesses while reducing time and costs for performing tasks.

Future research will focus on developing multimodal RAG systems that integrate textual, visual, and numerical data, further enhancing the comprehensiveness and utility of organizational knowledge platforms. Additionally, the exploration of hybrid architectures-combining RAG with long-context LLMs and multi-agent frameworks-holds promise for addressing increasingly complex business challenges.
