ABSTRACT

Background: Prenatal exposure to infectious or inflammatory insults increases the risk of neurodevelopmental disorders. Using a well-established mouse model of prenatal viral-like immune activation, we examined whether this pathological association involves genome-wide DNA methylation differences at single nucleotide resolution.

Methods: Prenatal immune activation was induced by maternal treatment with the viral mimetic poly(I:C) in middle (gestation day 9) or late (gestation day 17) gestation. Following behavioral and cognitive characterization of the adult offspring, unbiased capture array bisulfite sequencing was combined with subsequent matrix-assisted laser desorption/ionization time-of-flight mass spectrometry and quantitative real-time PCR analyses to quantify DNA methylation changes and transcriptional abnormalities in the medial prefrontal cortex of immune-challenged and control offspring. GO term enrichment analysis was used to explore shared functional pathways of genes with differential DNA methylation.

Results: Adult offspring of immune-challenged mothers displayed hyper- and hypomethylated CpGs at numerous loci and at distinct genomic regions, including genes relevant for GABAergic differentiation and signaling (e.g., DLX1, LHX5, LHX8), Wnt signaling (WNT3, WNT8A, WNT7B), and neural development (e.g., EFNB3, MID1, NLGN1, NRX2). Altered DNA methylation was associated with transcriptional changes of the corresponding genes. The epigenetic and transcriptional effects were dependent on the offspring's age and were markedly influenced by the precise timing of prenatal immune activation.

Conclusions: Prenatal viral-like immune activation is capable of inducing stable DNA methylation changes in the medial prefrontal cortex. These long-term epigenetic modifications are a plausible mechanism underlying the disruption of prefrontal gene transcription and behavioral functions in subjects with prenatal infectious histories.

INTRODUCTION

Prenatal exposure to infectious or inflammatory insults is an environmental risk factor for brain disorders with neurodevelopmental components, including schizophrenia (1,2), autism (3,4), and bipolar disorder (5,6). This epidemiological association is further supported by translational work in animal models demonstrating abnormal brain development and behavioral dysfunctions following prenatal administration of infectious pathogens or immune activating agents (7-10). Cytokine-associated inflammatory events, together with downstream pathophysiological effects such as oxidative stress and (temporary) macronutrient and micronutrient deficiency, seem to be critical in mediating the adverse effects of maternal infection on the fetal system (2,11,12). These pathological processes can affect somatic cell development and change the offspring's neurodevelopmental trajectories, which in turn can lead to the emergence of behavioral and cognitive disturbances in later life (13-16).

Epigenetic modifications may be critical for mediating alterations in brain development and behavioral functions in response to in-utero immune challenges. Epigenetic mechanisms stably program genome activity and gene expression without altering the DNA sequence (17-19). Rodent models of prenatal immune activation now begin to reveal epigenetic alterations in the offspring's brain and have already provided evidence for altered DNA methylation (20,21), histone modifications (22,23), and micro-RNA expression (24) that persist into adolescence and/or adulthood. Some of the epigenetic modifications induced by prenatal immune activation have been found to correlate with altered transcription of the corresponding genes and with behavioral deficits (21). These studies, however, were based on targeted approaches and did not assess global DNA methylation profiles across the entire genome. Hence, it remains unknown whether prenatal immune activation may cause altered DNA methylation in selected genomic regions or loci, or alternatively, whether such changes extend to the entire genome.

The present study is the first to examine genome-wide DNA methylation differences at single nucleotide resolution by capture array bisulfite sequencing of promoters and

enhancers using a well-established mouse model of prenatal viral-like immune activation. The model is based on maternal administration of the viral mimetic poly(I:C) (= *polyriboinosinic-polyribocytidilic acid*), which induces a cytokine-associated viral-like acute phase response in maternal and fetal compartments, including the fetal brain (10). Prenatal poly(I:C) treatment in rodents leads to multiple behavioral and cognitive disturbances in offspring, many of which are implicated in developmental psychiatric disorders such as schizophrenia and autism (7-12). The prenatal poly(I:C) exposure model thus offers a unique opportunity to explore genome-wide DNA methylation changes following prenatal exposure to an etiologically relevant risk factor of developmental psychiatric disorders. Since the precise timing of prenatal immune activation can critically influence the nature and/or severity of the long-term brain abnormalities (25-27), we compared alterations in DNA methylation in response to prenatal immune activation in middle and late gestation. We focused on DNA methylation profiles in the prefrontal cortex (PFC) in view of its role in developmental psychiatric disorders such as schizophrenia and autism (28-30).

MATERIALS AND METHODS

Animals and Prenatal Immune Activation

C57Bl6/N mice were used throughout the study. Female mice were subjected to a timed mating procedure as established previously (31,32). As described in the **Supplementary Information**, pregnant dams on gestation day (GD) 9 or 17 were randomly assigned to receiving either a single injection of poly(I:C) (potassium salt; Sigma–Aldrich, Buchs, St. Gallen, Switzerland) or vehicle. Poly(I:C) (5 mg/kg) was dissolved in sterile pyrogen-free 0.9% NaCl (vehicle) solution to yield a final concentration of 1 mg/ml and was administered intravenously (i.v.) into the tail vein under mild physical constraint. The two gestational windows (i.e., GD 9 and 17) were selected based on our previous studies assessing the influence of the precise timing of prenatal viral-like immune activation (25,26). GD 9 in the mouse roughly corresponds to human gestational weeks 4 to 5 in

terms of limbic neurogenesis, whereas GD 17 corresponds to human gestational weeks 28 to 29 in terms of cortical neurogenesis (<http://translatingtime.net/translate>).

The allocation and housing of neonatal and adult offspring of dams injected with poly(I:C) on GD 9 (POL-GD9 offspring) or GD 17 (POL-GD17 offspring) and vehicle-exposed control offspring (CON offspring) are described in the **Supplementary Information**. All procedures described in the present study had been previously approved by the Cantonal Veterinarian's Office of Zurich, and all efforts were made to minimize the number of animals used and their suffering.

Behavioral Testing

Behavioral testing in adult offspring started on postnatal day (PND) 100. The tests included paradigms assessing spatial recognition memory, social interaction, and prepulse inhibition (PPI) of the acoustic startle reflex. These tests were selected based on their relevance to neurodevelopmental disorders with infectious and inflammatory components, including schizophrenia and autism (33,34). A detailed description of the test apparatuses and procedures is provided in the **Supplementary Information**. Each animal underwent each behavioral test in the following order: (i) spatial recognition memory test, (ii) social interaction test, and (iii) PPI test. A test-free resting period of 2 days was imposed between individual tests.

Collection of Brain Samples

All adult offspring were first subjected to behavioral testing prior to the molecular analyses (**Supplementary Information**). They were killed by decapitation two weeks after completion of behavioral testing. The brains were rapidly extracted from the skull (within < 20 s) and placed on an ice-chilled plate. Coronal sections were prepared using razorblade cuts along the following coordinates with respect to bregma: anterior–posterior: +2.0 to +1.0, +1.0 to 0.0, 0.0 to -1.0, -1.0 to -2.0, and -2.0 to -3.0 mm. Discrete brain regions were then collected using a micropunch needle (1 mm in diameter) generating

micropunches of distinct brain areas as described previously (35). In the present study, we focused on PFC specimens (bregma: +2.0 to +1.0 mm; including anterior cingulate, prelimbic and dorsal parts of the infralimbic subregions), which were collected in 96-well microtiter plates kept on dry ice and allowed to freeze before storage at -80°C until further use. Neonatal offspring were killed by decapitation on PND 1; and neonatal PFC specimens were prepared as described for adult offspring.

DNA and RNA Isolation and Quantitative Real-Time PCR Analyses

Total DNA and RNA were isolated using the Qiagen AllPrep DNA and RNA Mini kit (Qiagen, Italy) according as described in the **Supplementary Information**. mRNA levels were quantified by TaqMan qRT-PCR (CFX384 real-time system, Bio-Rad Laboratories) using the iScript one-step RT-PCR kit for probes (Bio-Rad Laboratories) (see **Supplementary Information**).

SureSelectXT Capture Sequencing Assay

Genomic DNA was converted into bisulfite-sequencing samples for the Illumina paired-end multiplexed sequencing platform (Illumina, Canada) as described in the **Supplementary Information**. Bisulfite-converted samples were amplified with PCR using Takara EpiTaq HS enzyme (Clontech, Canada) and further processed to obtain a purified bisulfite-treated library, which was sequenced with Illumina HigSeq2000 (**Supplementary Information**).

Data Processing and Differential Methylation Detection

After sequencing, an average of 31 million reads per sample was obtained (150 to 180 million reads per condition). These were aligned to the mouse genome (mm9 build/assembly) using Bismark (<http://www.bioinformatics.babraham.ac.uk/projects/bismark/>), leading to an average of 26.6 million reads per sample. 25% of the reads was then removed, as they were duplicate reads. Cytosine methylation states were determined using Bismark.

The BAM files generated by Bismark were then used to calculate the methylation differences at different context cytosine-phosphodiester-guanine (CpG) regions. For this last passage, the BAM files were loaded into R using the methylKit package that took into account methylation information of cytosines with at least 10 reads for each animal. In a first step, logistic regression was applied to identify methylation differences at 1000 sliding base-pair regions using corrected P-values (sliding linear model) (36) set at a 20% threshold ($q < 0.2$). Subsequently, methylation differences at single CpG resolution were determined by considering those CpGs that were significant ($q < 0.2$) in the preceding analysis of the 1000 sliding base-pair regions. Hierarchical clustering of differentially methylated CpGs was performed using Partek Genomics Suite (Partek, USA; see [Supplementary Information](#))

Validation of Methylation Differences by EpiTYPER

To validate methylation differences observed with the SureSelectXT capture sequencing assay, specific CpGs were analyzed using EpiTYPER. This technique detects and quantifies DNA methylation using base-specific cleavage and Matrix-Assisted Laser Desorption/Ionization Time-of-Flight Mass Spectrometry (MALDI-TOF MS) (37). Genomic DNA was treated and analyzed as fully described in the [Supplementary Information](#).

Statistical Analyses

All behavioral and RT-PCR data were analyzed using analysis of variance (ANOVA) followed by Fisher's least significant difference (FLSD) post-hoc comparisons or restricted ANOVAs whenever appropriate. All statistical analyses for the behavioral tests and RT-PCR analyses were performed using the statistical software SPSS (version 13.0), and statistical significance was set at $p < 0.05$. In the capture-sequencing assay, FDR-corrected ($q < 0.2$) methylation differences were calculated using the Benjamini-Hochberg correction. Methylation levels measured at selected genomic regions using EpiTYPER

were analyzed using ANOVA followed by FLSD post-hoc comparisons whenever appropriate, and statistical significance was set at $p < 0.05$.

RESULTS

Behavioral and Cognitive Deficits Following Prenatal Immune Activation in Middle or Late Gestation

First, we ascertained the effects of prenatal immune activation in middle or late gestation on adult behavioral and cognitive functions. Consistent with previous studies (22,26), we found that prenatal immune activation in late but not middle gestation impaired performance in a Y-maze spatial recognition memory test. In this test, the critical measure of spatial recognition memory is the relative time spent in the novel (previously unexplored) arm during the choice phase. CON and POL-GD9 offspring displayed a noticeable preference towards the novel arm, indicating intact spatial recognition memory in these groups (**Figure 1A**). In contrast, POL-GD17 offspring exhibited a marked reduction in this measure and performed below chance level (**Figure 1A**). There were no group differences with respect to the total distance moved (**Supplementary Figure 2A**), indicating that the negative effects of late prenatal immune activation on spatial recognition memory were not confounded by possible differences in basal locomotor activity.

In line with previous studies (21,32,38), offspring exposed to prenatal immune activation also displayed impaired sociability in a social interaction test, in which they were allowed to concomitantly explore an inanimate dummy object and an unfamiliar live mouse (**Figure 1B**). Whereas CON offspring showed a clear preference for the live mouse versus the inanimate dummy object, POL-GD9 and POL-GD17 offspring did not display such a preference (**Figure 1B**). There were no group differences with respect to the total distance moved during the social interaction test (**Supplementary Figure 2B**),

suggesting that prenatal immune activation leads to genuine deficits in social approach behavior regardless of the precise prenatal timing.

Prenatal immune activation further caused deficits in sensorimotor gating as assessed using PPI of the acoustic startle reflex. Consistent with previous reports (26,27,32,39), a significant PPI impairment emerged only after prenatal poly(I:C)-induced immune activation in **middle** (GD 9) but not late (GD 17) gestation (**Figure 1C**). The prenatal manipulations did not affect startle reactivity per se: The reactivities (mean \pm s.e.m., in arbitrary units) to pulse-alone trials were 106.06 ± 7.72 in controls, 111.26 ± 11.29 in offspring exposed to poly(I:C) treatment on GD 9, and 126.97 ± 12.20 in offspring exposed to poly(I:C) treatment on GD 17.

Genome-wide DNA Methylation Profiles Following [Prenatal Immune Activation in Middle or Late Gestation](#)

Using the behaviorally characterized cohort of poly(I:C)-exposed and control offspring, we then sought to identify genome-wide DNA methylation changes in the [adult PFC](#). Using capture-sequencing techniques, we first performed regional analysis to detect significant methylation differences in 1000 base-pair sliding regions ($q < 0.2$) and then detected differences at single CpG resolution ($q < 0.2$) by focusing on those significant 1000 base-pair regions. 9488 sliding regions were differentially methylated in POL-GD9 offspring [relative CON offspring](#) (**Supplementary Table 1**), and 10360 sliding regions were differentially methylated in POL-GD17 offspring [compared to CON offspring](#) (**Supplementary Table 2**). Within those regions, 2365 and 3361 single CpG sites were differentially ($q < 0.2$) methylated in POL-GD9 and POL-GD17 offspring, respectively (**Supplementary Table 3 and 4**). These single-base methylation changes clustered according to the prenatal treatment conditions (**Figure 2A**). Among the 2365 differentially methylated sites present in POL-GD9 offspring, 65% were hypomethylated and 35% were hypermethylated (**Table 1**). A similar global methylation profile was found in POL-GD17 offspring, where 63% and 37% of the 3361 CpG sites were hypo- and hypermethylated,

respectively (**Table 1**). Comparable global methylation profiles were also observed when considering the 1000 base-pair sliding regions (**Supplementary Table 5**).

There was a positive correlation between all CpG sites that were differentially methylated in POL-GD9 (2365 sites) or POL-GD17 (3361 sites) offspring (**Supplementary Figure 4**), suggesting a similar direction of methylation changes between the two prenatal treatment conditions. However, only 335 single CpG sites (and 2499 sliding regions) were commonly affected by both prenatal manipulations, as confirmed by hypergeometric distribution testing (**Figure 2B, Supplementary Table 6**). The direction of methylation changes in these common CpG sites correlated between the two prenatal treatment conditions: Those regions or sites that were hypermethylated (or hypomethylated) in POL-GD9 offspring were also hypermethylated (or hypomethylated) in POL-GD17 offspring (**Figure 2B, Supplementary Figure 4**).

To validate the findings obtained by capture sequencing, we measured methylation levels at individual CpG sites using an EpiTYPER assay that quantifies differential CpG methylation using MALDI-TOF mass spectrometry (38). First, we measured the methylation levels of individual CpGs within three distinct regions of the midline 1 (MID1) gene. MID1 stood out as the gene showing the most extensive changes in adult methylation, with a predominance of hypermethylated regions in correspondence of both the gene body and various transcription enhancer sites (**Supplementary Figure 5, Supplementary Table 8**). These effects appeared to be more pronounced in POL-GD17 relative to GD9-POL offspring (**Supplementary Figure 5, Supplementary Table 8**). Analyzing methylation profiles using EpiTYPER confirmed that prenatal immune activation caused hypermethylation of multiple CpGs sites in distinct MID1 gene segments (**Figure 3A**). Consistent with the findings revealed by capture sequencing, EpiTYPER showed that prenatal immune activation in late (GD 17) gestation caused more extensive methylation changes in different MID1 gene segments compared to prenatal immune activation in middle (GD 9) gestation (**Figure 3A**). Importantly, the two techniques used to assess DNA

methylation (bisulfite capture sequencing and EpiTYPER) yielded consistent results in terms of differential methylation of MID1 (see **Supplementary Table 9**).

In addition to MID1, we further validated the methylation differences of a number of other specific CpGs using EpiTYPER, including sites annotating to wingless-type MMTV integration site family member 3 (WNT3), distal-less homeobox 1 (DLX1), neuroligin 1 (NLGN1), and neurofibromin 2 (NF2). Initial bisulfite capture-sequencing showed that WNT3 and DLX1 were hypomethylated specifically in POL-GD9 and POL-GD17 offspring, respectively, whereas differential methylation of NLGN1 and NF2 occurred in both prenatal treatment conditions relative to controls (**Supplementary Table 3,4**). Consistent with these results, EpiTYPER revealed that WNT3 was hypomethylated selectively in POL-GD9 offspring relative to controls (**Figure 3B**), whereas reduced methylation of DLX1 occurred specifically in POL-GD17 offspring (**Figure 3C**). EpiTYPER further confirmed that both prenatal treatment conditions showed reduced and increased methylation levels at NLGN1 (**Figure 3D**) and NF2 (**Figure 3E**) gene segments, respectively, as predicted by capture sequencing (**Supplementary Table 9**).

Enrichment of Genes Affected by Prenatal Immune Activation in Middle or Late Gestation

The 2365 CpGs affected by prenatal immune activation in middle gestation (GD 9) matched to 1408 unique genes, whereas the 3361 CpGs affected by the late (GD 17) prenatal manipulation corresponded to 1756 unique genes. We incorporated these genes into GO term enrichment analysis to explore whether the affected genes in POL-GD9 and POL-GD17 offspring share specific functional features. For both prenatal treatment conditions, the most significant enrichment occurred in GO-term category “biological process” involving genes annotating with the term “single organism cellular process”, followed by “cell differentiation” (**Supplementary Table 11**). Within the latter, “neuronal differentiation” resulted as the biological process characterized by the highest enrichment score in both prenatal treatment conditions (**Figure 4**). However, different sets of genes

annotating with “neuronal differentiation” were affected by prenatal immune activation in middle (GD 9) and late (GD 17) gestation (**Figure 4**). For example, late prenatal immune activation changed the methylation profiles of various genes that are involved in the differentiation of γ -aminobutyric acid (GABA) (**Figure 4B; Supplementary Tables 4 and 11**), including members of the LIM homeobox (Lhx) and distal-less homeobox (Dlx) transcription factor families (40-42). In contrast, genes included in the canonical Wnt signaling pathway (**Figure 4A**) were affected primarily by prenatal immune activation in middle gestation (**Figure 4A, Supplementary Tables 3 and 12**).

Besides these timing-dependent effects, however, prenatal immune activation in middle and late gestation also affected a number of common genes: the 335 CpG sites that were commonly affected by the two prenatal manipulations matched to 167 genes (**Supplementary Tables 3 and 4**). Notably, some of the commonly affected genes have previously been associated with neurodevelopmental disorders, including neuregulin 1 (NRGN1) (43,44), neurexin 2 (NRXN2) (45,46), neuronal differentiation 6 (NEUROD6) (47), and ephrin-B3 (EFNB3) (48,49). GO enrichment analysis of the commonly affected genes further revealed a strong enrichment of genes annotated with the term “neuron part” under the GO-term category “cellular component” (**Supplementary Table 13**). This term encompasses several neuronal elements such as neuronal projection, presynaptic and postsynaptic membranes, and axonal parts (**Figure 5A**), the development of which are under the control of genes commonly affected by prenatal immune activation in middle and late gestation (**Figure 5B**).

Altered Gene Transcription Following Prenatal Immune Activation in Middle or Late Gestation

We examined whether the identified DNA methylation changes translate into altered gene expression (17-19,50). First, we measured the mRNA levels of those genes, for which DNA methylation differences were validated using EpiTYPER (i.e., MID1, WNT3, DLX1, NLGN1, and NF2; see **Figure 3**). As predicted by the preceding DNA methylation

analyses, the mRNA levels of WNT3 were altered selectively in POL-GD9 offspring, whereas DLX1 mRNA levels were altered specifically in POL-GD17 offspring (**Figure 6**). On the other hand, the mRNA levels of MID1, NLGN1 and NF2, which were differentially methylated in both prenatal treatment groups (**Figure 3, Supplementary Tables 3 and 4**), were similarly altered in POL-GD9 and POL-GD17 offspring (**Figure 6**).

We further confirmed that the mRNA levels of several genes, which were differentially methylated according to the initial genome-wide capture sequencing approach, were altered in prenatally infected offspring relative to controls (**Supplementary Figure 6**). These included genes that are part of the canonical Wnt signaling pathway, GABAergic cell differentiation, and neuronal development (**Supplementary Figure 6**).

Ontogeny of Altered DNA Methylation Following Prenatal Immune Activation in Middle or Late Gestation

To explore the ontogeny of the DNA methylation changes that are manifest in adult offspring of infected mothers, we assessed possible methylation differences in neonatal (PND 1) offspring of immune-challenged and control offspring. To this end, we focused on MID1, NLGN1 and NF2, all of which were differentially methylated in the adult offspring of infected mothers. EpiTYPER analyses showed that there were no significant group differences in neonatal DNA methylation levels (**Figure 7**). Consistent with these findings, there were also no group differences with respect to mRNA levels of MID1, NLGN1 and NF2 during the neonatal stage of development (**Figure 7**).

DISCUSSION

The present study shows that maternal immune activation causes long-term and genome-wide changes in the offspring's prefrontal DNA methylome. These changes are characterized by hyper- and hypomethylated CpGs at numerous loci and at distinct genomic regions. Hence, the epigenetic effects of prenatal immune activation are not restricted to specific DNA sequences but readily extend to the entire genome. These

epigenetic modifications likely have functional consequences in terms of modulating the transcription of the corresponding genes. Indeed, we found altered mRNA levels of various genes showing differential methylation levels in prenatally infected offspring relative to controls. Consistent with the repressive effects of DNA hypermethylation on gene transcription (50-52), the mRNA levels of predominantly hypermethylated genes, including MID1 and NF2, were decreased in adult offspring of infected mothers, whereas the mRNA levels of some genes with a predominance of hypomethylated regions (e.g., WNT3 and NTM) were increased. Interestingly, however, the mRNA levels of several hypomethylated genes, including DLX1, LMO4, FEZF2, SOX1 and SOX5, were decreased rather than increased in adult offspring exposed to prenatal immune activation. These effects are consistent with recent lines of evidence suggesting that the functional impact of DNA methylation on gene transcription is critically determined by the genomic location at which methylation occurs (50-52).

Our study further shows that the effects on the adult DNA methylome are influenced by the precise timing of the prenatal immune challenge. Whilst immune activation in middle (GD 9) and late (GD 17) gestation affected a relatively small number of common genes, the two prenatal conditions mostly showed methylation differences in distinct loci. The differential epigenetic effects of middle versus late prenatal immune activation may, at least in part, be accounted for by differences in the precise maternal and fetal immune responses to poly(I:C) at the selected gestational time points (**Supplementary Discussion**). One intriguing distinction between the epigenetic effects of the two manipulations relates to methylation differences in genes that are crucial for GABAergic cell development and functions. We show that the late prenatal insult leads to differential methylation and transcription of members of the Lhx and Dlx transcription factor families, whereas similar effects were absent following prenatal immune activation in middle gestation. Lhx and Dlx transcription factors play pivotal roles in the phenotypic specification, migration, and/or survival of GABAergic cell populations (41-43,54). Previous work in rodent models has repeatedly demonstrated that prenatal immune

challenge can induce functional and structural abnormalities in prefrontal (and other) GABAergic systems (16,26,54,55), and these tend to be more pronounced following immune activation in late as compared to middle gestation (26,35,56). For example, prenatal poly(I:C)-induced immune activation has been shown to reduce basal GABA contents in the offspring's brains when the exposure takes place in late (GD 17) gestation (35), whereas identical immune activation in middle (GD 9) gestation fails to do so (56). Mice prenatally exposed to poly(I:C) on GD 17 also show an overall reduction in the GABA-synthesizing enzymes GAD₆₅ and GAD₆₇ in prefrontal and hippocampal regions (16,57), whereas similar effects are absent (58) or appear to be cell-specific (59) when the same immune exposure takes place on GD 9. Despite this, however, prenatal immune activation in middle gestation can still alter GABAergic neurotransmission, even in the absence of overt morphological abnormalities (59). The current state of research thus suggests that discrete GABAergic functions may be impaired by prenatal immune activation regardless of the precise prenatal timing, whereas late prenatal immune activation may have more overt effects on (prefrontal) GABAergic cell morphology and gene expression compared to identical exposures during earlier gestational periods. Against this background, our findings indicate that GABAergic abnormalities following late prenatal immune activation may involve methylation-related epigenetic modifications of transcription factors that are critical for GABAergic cell development and functions.

On the contrary, Wnt signaling stood out as one of the pathways markedly affected by prenatal immune activation in middle gestation. Wnt signaling is fundamental in embryogenesis and controls various early events in the developing nervous system, including specification of the anterior-posterior axis of the neural plate, neural tube formation, neuronal polarization, and early development of neural circuitries (60). Wnt signaling also participates in later stages of brain development and various adult brain functions, including synapse formation and remodeling, neuroplasticity, and neurotransmission (61,62). Given that Wnt signaling is disrupted more extensively by prenatal immune activation in middle as compared to late gestation, one may speculate

that the earlier exposure leads to more severe neurodevelopmental deficits compared to the later prenatal exposure. In support of this notion, it has previously been shown that prenatal poly(I:C)-induced immune activation in middle gestation (GD 9), but not in late gestation (GD 17), leads to enlarged lateral ventricles in adulthood (27). Moreover, adult mice prenatally exposed to poly(I:C) on GD 9 show more extensive changes in white matter microstructure compared to mice exposed to the same insult on GD17 (63). These findings tentatively suggest that immune activation at earlier fetal stages may indeed be associated with more pronounced brain morphological changes compared to immune activation at later fetal stages. However, additional studies are warranted to further examine this hypothesis and to ascertain whether (methylation-induced) changes in Wnt signaling contribute to these effects.

The differential effects of prenatal immune activation in middle and late gestation on the prefrontal methylome are consistent with and extend previous findings emphasizing a critical influence of the precise prenatal timing in shaping the specificity of long-term behavioral and cognitive abnormalities (22,25-27,35). Here, the inclusion of two prenatal time points of immune activation allowed us to identify possible relationships between differential DNA methylation profiles and specific behavioral and cognitive deficits. On speculative grounds, altered methylation of GABA-related genes may contribute to the emergence of cognitive deficits in offspring exposed to late prenatal immune activation, whereas altered Wnt signaling may contribute to the sensorimotor gating impairments in offspring exposed to immune activation in middle gestation (see **Supplementary Discussion**).

Despite these possible associations, it should be pointed out that prenatal immune activation appears to cause differential methylation of a large number of genes, which in turn likely affects the differentiation and/or functional properties of various other neuronal subtypes. One of the genes that were markedly affected by both prenatal manipulations was MID1. MID1 was first identified as part of the genetic basis of Opitz BBB/G syndrome, a rare hereditary disorder characterized by ventral midline malformations (64). Since then,

MID1 has been associated with numerous cellular and developmental functions, many of which relate to brain development and maturation (65). Of particular interest is MID1's involvement in axonal growth, cerebellar development, and corpus callosum formation (66,67), the disruption of which likely plays an important role in neurodevelopmental disorders such as schizophrenia and autism (68-71). Moreover, both prenatal treatment conditions caused differential methylation of genes relevant for the differentiation of dopaminergic neurons. The latter effects support previous findings indicating that prenatal immune activation affects dopaminergic development (14,72) and further suggest that multiple neurotransmitter systems and pathways may contribute to the emergence of behavioral and cognitive abnormalities in prenatally infected offspring.

Another intriguing finding of our study is that the pattern of prefrontal DNA methylation in prenatally infected offspring changes over time. We found that MID1, NLGN1 and NF2, all of which were differentially methylated in the adult offspring of infected mothers, did not show abnormal methylation patterns in the neonatal offspring. It therefore seems that the changes in the adult DNA methylome are not the direct consequence of the maternal immune response. Rather, our findings suggest the involvement of dynamic and age-dependent epigenetic processes in infection-mediated neurodevelopmental pathologies. According to this notion, prenatal immune activation may interfere with epigenetic programs that are crucial for normal brain maturation and may disrupt the developmentally regulated expression of factors governing DNA methylation at different stages of brain development (18,73). For example, prenatal immune activation may lead to age-dependent changes in the expression of DNA-methylating enzymes such as DNA methyltransferases (17,18,50), which in turn may modulate the prefrontal methylome in an age-dependent manner. Additional research is needed to examine this hypothesis.

Our study has a number of limitations. Firstly, we only assessed genome-wide DNA methylation profiles in the PFC. It thus remains elusive whether the identified epigenetic changes induced by prenatal immune activation are specific to the PFC, or alternatively, whether they can be extended to other brain regions or even peripheral tissues. Secondly,

we focused on epigenetic modifications in the form of DNA methylation. Prenatal immune activation, like various other early-life adversities such as prenatal or neonatal stress (74-76), might further induce various other epigenetic modifications across the entire genome, which would not have been captured here. Thirdly, even though we find a striking correspondence between altered DNA methylation and transcriptional activity for selected genes, our study does not provide circumspect statistical analyses of the overall relationship between altered DNA methylation and gene expression following prenatal immune activation. Finally, additional research will be needed to validate our findings at the protein level and in peripheral tissues such as blood, the latter of which may help to define methylation-related biomarkers for prenatal infection-induced pathologies.

There is increasing recognition of and evidence for altered DNA methylation in the pathogenesis of neurodevelopmental disorders, including schizophrenia, autism, and bipolar disorder (50,77-83). Against these backgrounds, our findings raise the intriguing possibility that prenatal exposure to immune challenges may be one of the environmental factors causing genome-wide methylation abnormalities in these disabling brain disorders. Since at least some of these epigenetic modifications may be modifiable throughout life (17,84), our data may help to open new avenues for symptomatic or even preventive treatments in subjects with prenatal infectious histories.

ACKNOWLEDGMENTS AND DISCLOSURES

The present study was supported by grants from the Swiss National Science Foundation (Grant Nr. 310030_146217) awarded to UM. Additional financial support was received from grants from the Italian Ministry of University and Research (PRIN – Grant number 20107MSMA4_002) to MAR, and the Canadian Institute of Health Research MOP 42411. All authors declare no conflict of interest. The funding organizations were not involved in the study design, the collection, analysis, and interpretation of the data, the writing of the report, or the decision to submit the article for publication.

TABLES & FIGURES LEGENDS

Table 1. Genomic distribution of differentially methylated CpGs (single base resolution) measured by capture sequencing in adult offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation relative to adult control offspring (CON). The columns describe the number of affected genomic regions, the enrichment of each affected region relative to the total number of affected regions, and the percentage of hyper- and hypo-methylated regions. Promoter defined as -1kb to +100 bp to TSS.

Figure 1. Cognitive and behavioral deficits in adult offspring exposed to prenatal immune activation in middle or late gestation. Mice were subjected to prenatal poly(I:C) treatment on gestation day 9 (POL-GD9) or 17 (POL-GD17), or they were exposed to prenatal control (CON) treatment. **(A)** Percent time spent in the novel arm during the Y-maze working memory test. * $p < 0.05$ and ** $p < 0.01$, based on post-hoc comparisons following significance ($F_{(2,33)} = 6.85$, $p < 0.01$) in one-way ANOVA. **(B)** Percent time spent with an unfamiliar live mouse, relative to an inanimate dummy object, during the social interaction test. * $p < 0.05$ and ** $p < 0.01$, based on post-hoc comparisons following significance ($F_{(2,33)} = 5.63$, $p < 0.01$) in one-way ANOVA. **(C)** The line plot shows percent prepulse inhibition as a function of different prepulse intensities, and the bar plot depicts mean prepulse inhibition across all prepulse levels. * $p < 0.05$ and ** $p < 0.01$, based on post-hoc comparisons following the presence of a significant main effect of prenatal treatment ($F_{(2,33)} = 4.96$, $p < 0.05$) in the initial 3×5 (prenatal treatment \times prepulse intensity) ANOVA. $N = 12$ in each group and test; all data are means \pm s.e.m.

Figure 2. Unique and common DNA methylation differences in adult offspring exposed to prenatal immune activation in middle or late gestation as revealed by capture sequencing. Mice were subjected to prenatal poly(I:C) treatment on gestation day 9 (POL-GD9) or 17 (POL-GD17), or they were exposed to prenatal control (CON) treatment. **(A)** Hierarchical clustering of differentially methylated CpGs in POL-GD9 and POL-GD17 offspring relative to CON offspring. Hypo- and hypermethylated CpGs are represented in purple and yellow color, respectively. **(B)** Venn Diagram depicting the number of CpGs that are uniquely and commonly affected in POL-GD9 and POL-GD17 offspring (hypergeometric distribution test for common sites: $p = 3.86E-2830$). The commonly affected CpGs show a significant positive correlation between the two prenatal treatment conditions. The inter-rePLICATE correlations for each group are given in Supplementary Table 7. All data are based on $N(\text{CON}) = 6$, $N(\text{POL-GD9}) = 5$, and $N(\text{POL-GD17}) = 5$.

Figure 3. EpiTYPER validation of DNA methylation differences in adult offspring exposed to prenatal immune activation in middle or late gestation. Mice were subjected to prenatal poly(I:C) treatment on gestation day 9 (POL-GD9) or 17 (POL-GD17), or they were exposed to prenatal control (CON) treatment. The line plots depict percent DNA methylation of specific CpGs in selected amplicons, and the bar plots show the mean percent DNA methylation across all individual CpGs included in the corresponding amplicon. Amplicon sequences and position of CpGs in each amplicon are provided in *Supplementary Table 10*. **(A)** MID1: ${}^+p < 0.05$ between individual CpGs of CON and POL-GD9 or POL-GD17 offspring, ${}^{\#}p < 0.001$ between individual CpGs of CON and POL-GD17 offspring, ${}^{\$}p < 0.01$ between individual CpGs of POL-GD17 and CON or POL-GD9 offspring, and ${}^{\circ}p < 0.01$ between individual CpGs of POL-GD9 and POL-GD17 offspring based on post-hoc tests following the presence of a significant interaction between prenatal treatment and position in ANOVA (Amplicon 1: $F_{(6,39)} = 2.34$, $p < 0.05$; Amplicon 2: $F_{(4,26)} = 2.43$, $p < 0.05$; Amplicon 3: $F_{(12,72)} = 2.913$, $p < 0.001$). ${}^*p < 0.05$, reflecting group differences in mean percent DNA methylation based on post-hoc tests. **(B)** WNT3: ${}^*p < 0.05$, reflecting group differences in mean percent DNA methylation based on post-hoc tests following the presence of a significant main effect in ANOVA ($F_{(2,13)} = 4.47$, $p < 0.05$). **(C)** DLX1: ${}^*p < 0.05$ and ${}^{**}p < 0.01$, reflecting group differences in mean percent DNA methylation based on post-hoc tests following the presence of a significant main effect in ANOVA ($F_{(2,13)} = 6.20$, $p < 0.05$). **(D)** NLGN1: ${}^*p < 0.05$, reflecting group differences in mean percent DNA methylation based on post-hoc tests following the presence of a significant main effect in ANOVA ($F_{(2,13)} = 5.23$, $p < 0.05$). **(E)** NF2: ${}^+p < 0.05$ and between ${}^+p < 0.001$ individual CpGs of CON and POL-GD9 or POL-GD17 offspring based on post-hoc tests following the presence of a significant interaction between prenatal treatment and position in ANOVA ($F_{(8,52)} = 6.39$, $p < 0.001$). ${}^*p < 0.05$ and ${}^*p < 0.01$, reflecting group differences in mean percent DNA methylation based on post-hoc tests. All data are means \pm s.e.m.; N(CON) = 6, N(POL-GD9) = 5, and N(POL-GD17) = 5.

Figure 4. GO enrichment analysis of genes showing differential methylation in adult offspring exposed to prenatal immune activation in middle **(A)** and late **(B)** gestation. The bar plots summarize the 10 most enriched processes encompassed by the term “cell differentiation” under the category “biological processes”. “Neuronal differentiation” (highlighted as filled red bars) showed the highest enrichment score in both prenatal treatment conditions. The networks (generated by the Ingenuity Pathway Analysis software) illustrate the interactions between the individual genes that are encompassed as

sub-terms (displayed as bars with diagonal red patterning) in the term “neuronal differentiation”. Hypo- and hypermethylated genes are represented in purple and yellow color, respectively.

Figure 5. GO enrichment analysis of genes showing common methylation differences following prenatal immune activation in middle and late gestation. **(A)** The bar plots summarize the 10 most enriched terms encompassed by the category “cellular component”. “Neuron projection” (highlighted as filled red bar) showed the highest enrichment score and included genes enriched for dendrite, axonal and spine development (displayed as bars with diagonal red patterning). **(B)** The network (generated by the Ingenuity Pathway Analysis software) illustrates the interactions between individual genes in relation to their biological functions they are enriched in.

Figure 6. Expression of selected genes that were differentially methylated in adult offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation relative to adult control (CON) offspring. The scatter dot plots show individual mRNA levels in terms of fold changes measured by TaqMan qRT-PCR. * $p < 0.05$, ** $p < 0.01$, and *** $p < 0.001$, based on post-hoc test following one-way ANOVA (DLX1: $F_{(6,39)} = 2.34$, $p < 0.05$; NF2: $F_{(4,26)} = 2.43$, $p < 0.05$; NLGN1: $F_{(12,72)} = 2.913$, $p < 0.001$; MID1: $F_{(12,72)} = 2.913$, $p < 0.001$; WNT3: $F_{(4,26)} = 2.43$, $p < 0.05$). $N = 9-12$ per group.

Figure 7. DNA methylation and gene expression profiles in neonatal offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation relative to adult control (CON) offspring. Mice were subjected to prenatal poly(I:C) treatment on gestation day 9 (POL-GD9) or 17 (POL-GD17), or they were exposed to prenatal control (CON) treatment. DNA methylation and gene expression of selected genes were measured on postnatal day 1 using EpiTYPER and TaqMan qRT-PCR, respectively. The line plots depict percent DNA methylation (means±s.e.m) of specific CpGs in selected amplicons, and the bar plots show the mean percent DNA methylation (means±s.e.m) across all individual CpGs included in the corresponding amplicon. Amplicon sequences and position of CpGs in each amplicon are provided in *Supplementary Table 10*. The scatter dot plots show individual mRNA levels in terms of fold changes. For EpiTYPER, $N(\text{CON}) = 6$, $N(\text{POL-GD9}) = 5$, and $N(\text{POL-GD17}) = 5$; for qRT-PCR, $N(\text{CON}) = 8$, $N(\text{POL-GD9}) = 7$, and $N(\text{POL-GD17}) = 8$.

SUPPLEMENTARY MATERIAL AND METHODS

Animals

C57Bl6/N mice were obtained from Charles River Laboratories (Germany) and kept in our in-house specific-pathogen-free (SPF) facility until breeding began to generate poly(I:C)-exposed and control offspring (see below). All animal breeding and holding rooms were temperature- and humidity-controlled (21 ± 1 °C, $55 \pm 5\%$) and kept under a reversed light-dark cycle (lights off: 7:00 A.M. to 7:00 P.M.). All animals had *ad libitum* access to food (Kliba 3430, Kaiseraugst, Switzerland) and water throughout the entire study.

Prenatal Immune Activation

Female mice were subjected to a timed mating procedure as established and described previously (1). Pregnant dams on gestation day (GD) 9 or 17 were randomly assigned to receiving either a single injection of poly(I:C) (potassium salt; Sigma–Aldrich, Buchs, St. Gallen, Switzerland) or vehicle. Poly(I:C) (5 mg/kg; calculated based on the pure form of poly(I:C)) was dissolved in sterile pyrogen-free 0.9% NaCl (vehicle) solution to yield a final concentration of 1 mg/ml and was administered intravenously (i.v.) into the tail vein under mild physical constraint. The dose of poly(I:C) was selected based on previous dose-response studies (1). 12 pregnant dams were injected with poly(I:C) on GD 9, 12 were injected with poly(I:C) on GD 17, and another 12 were injected with vehicle solution. We previously verified that poly(I:C) administration at these gestational time points are effective in terms of eliciting cytokine-associated inflammatory response in maternal and fetal tissues (2). Half of the vehicle-treated dams were injected on GD 9, and the other half on GD 17, in order to control for the two timings of poly(I:C) injections. The two vehicle groups were combined into a single control group as they did not differ from each other in terms of behavioral and cognitive performances (see **Supplementary Figure 1**) and genome-wide methylation levels (see **Supplementary Figure 3**).

Allocation of Offspring

Except when used for molecular analyses during neonatal stages (see below), offspring of dams injected with poly(I:C) on GD 9 (POL-GD9 offspring) or GD 17 (POL-GD17 offspring) and vehicle-exposed control offspring (CON offspring) were weaned and sexed on postnatal day (PND) 21. Littermates of the same sex were caged separately and maintained in groups of 3 to 4 animals per cage. Only male animals were included in all experiments because our previous research using the mouse prenatal poly(I:C) administration model did not reveal sex-dependent effects on behavioral and cognitive functions of primary interest, including social interaction, prepulse inhibition, and short-term spatial memory (1,3,4). For adult testing, 1 male offspring per litter was randomly selected for the subsequent behavioral and molecular analyses in order to avoid litter effects (5,6). This led to initial group sizes of $N = 12$ adult offspring per experimental group, which were used for behavioral tests and gene expression analyses (see below). All DNA methylation analyses in adult offspring were performed using a subset of animals. The group sizes in these latter analyses were $N(\text{CON}) = 6$, $N(\text{POL-GD9}) = 5$, and $N(\text{POL-GD17}) = 5$. For adult investigations, all animals were first subjected to behavioral testing prior to the molecular analyses.

Neonatal CON ($N = 8$), POL-GD9 ($N = 7$) and POL-GD17 ($N = 8$) offspring were generated as described above and were killed for molecular analyses on PND 1. The neonatal DNA methylation analyses were performed using a subset of animals, yielding a group size of $N(\text{CON}) = 6$, $N(\text{POL-GD9}) = 5$, and $N(\text{POL-GD17}) = 5$ offspring. The neonatal gene expression analyses were conducted using all offspring (i.e., $N = 7-8$ per neonatal group).

Spatial Recognition Memory Test

Spatial recognition memory was assessed using the Y-maze as established and validated before (7,8). This test uses the natural tendency of rodents to explore novel over familiar spatial environments. The apparatus was made of transparent Plexiglas and consisted of three identical arms (50 × 9 cm; length × width) surrounded by 10-cm high transparent

Plexiglas walls. The three arms radiated from a central triangle (8 cm on each side) and were spaced 120° from each other. A removable opaque barrier wall was used to block access to each arm from the central area. The floor of the maze was covered with sawdust bedding, which was changed between sample and choice phases. The maze was elevated 90 cm above the floor and was positioned in a well-lit room enriched with distal spatial cues. A digital camera was mounted above the Y-maze apparatus. Images were captured at a rate of 5 Hz and transmitted to a PC running the EthoVision tracking system (Noldus Information Technology, The Netherlands), which calculated the time spent and distance moved in the three arms and center zone of the Y-maze.

The spatial recognition memory test consisted of two phases, called the sample and choice phases. The allocation of arms (start, familiar, and novel arm) to a specific spatial location was counterbalanced across the experimental conditions.

Sample phase: The animals were allowed to explore two arms (referred to as “start arm” and “familiar arm”). Access to the remaining arm (“novel arm”) was blocked by the opaque barrier wall. To begin a trial, the animal was introduced at the end of the start arm and was allowed to freely explore both the start and the familiar arms for 5 min. Test timing was initiated once the subject had made an entry into the central triangular area, as detected by the EthoVision tracking system. The animal was then removed and kept in a holding cage prior to commencement of the choice phase. The barrier door was removed and the sawdust flooring changed to avoid olfactory cues.

Choice phase: The animal was introduced to the maze following a retention interval of 1 min. During the choice phase, the barrier wall was removed so that the animals could freely explore all arms of the maze for 2 min. The animal was then removed from the maze and returned to the home cage. The sawdust flooring was changed in preparation for the next trial.

On each trial, the time spent in each of the three arms was recorded. The relative time spent in the novel arm during the choice phase was calculated by the formula ($\frac{\text{[time spent in the novel arm]}}{\text{[time spent in all arms]}}$) $\times 100$ and used as the index for short-term spatial

recognition memory. In addition, total distance moved on the entire maze was recorded and analyzed in order to assess general locomotor activity.

Social Interaction Test

Social interaction was assessed by analyzing the relative exploration time between an unfamiliar congenic mouse and an inanimate dummy object using methods established before (4,9). The test apparatus was made of Plexiglas and consisted of three identical arms (50 cm × 9 cm; length × width) surrounded by 10-cm high Plexiglas walls. The three arms radiated from a central triangle (8 cm on each side) and spaced 120° from each other. The Plexiglas walls of apparatus were covered by brown self-adhesive paper. Two out of the three arms contained a rectangular wire grid cages (13 cm × 8 cm × 10 cm, length × width × height; bars horizontally and vertically spaced 9 mm apart). The third arm did not contain a metal wire cage and served as the start zone (see below).

All animals were first habituated to the test apparatus on the day before social interaction testing. This served to familiarize the test animals with the apparatus and to reduce novelty-related locomotor hyperactivity, which may potentially confound social interaction during the critical test phase. The rectangular wire cages (located at the end of two arms) were left empty during the habitation phase. During habituation, each test mouse was gently placed in the start arm and allowed to explore the apparatus for 10 min.

The critical test phase took place one day after the habituation day. During the test phase, one metal wire cage contained an unfamiliar male C57BL6/N mouse (10-12 weeks of age), whereas the other wire cage contained an inanimate dummy object. The latter was made of black LEGO™ bricks and took the shape of a mouse. The allocation of the unfamiliar live mouse and inanimate dummy object to the two wire cages was counterbalanced across experimental groups. To start a test trial, the test mouse was gently placed in the start arm and allowed to explore freely for 5 min. Behavioral observations were made by an experimenter blind to the experimental conditions, and social interaction was defined as nose contact within a 2-cm interaction zone. The relative time spent with the live

mouse was calculated by the formula ($[time\ spent\ with\ the\ mouse]/[time\ spent\ with\ the\ inanimate\ object + time\ spent\ with\ the\ mouse]$) $\times 100$ and used to compare the relative exploration time between the unfamiliar mouse and the inanimate dummy object. The animals were placed back to their home cages following completion of the social interaction test.

Prepulse Inhibition Test

Sensorimotor gating was assessed using the paradigm of prepulse inhibition (PPI) of the acoustic startle reflex. PPI of the acoustic startle reflex refers to the reduction in startle reaction in response to a startle-eliciting pulse stimulus when it is shortly preceded by a weak prepulse stimulus (1). The apparatus consisted of four startle chambers for mice (San Diego Instruments, San Diego, CA, USA) and has been fully described elsewhere (1). During a 45-min test session, the animals were presented with a series of discrete test trials comprising a mixture of four trial-types as fully described previously (1). In brief, these trial stimuli included pulse-alone, prepulse-plus-pulse and prepulse-alone trials, as well as no-stimulus trials in which no discrete stimulus other than the constant background noise (65 dB_A) was presented. The startle program consisted of one 40-ms pulse of white noise (120 dB_A) combined with five different pre-pulses. Pre-pulses were a 20-ms burst of white noise at five different intensities (69, 73, 77, 81, and 85 dB_A, which corresponded to 4, 8, 12, 16, and 20 dB_A above background). The stimulus onset asynchrony (SOA) of the pre-pulse and pulse stimuli in prepulse-plus-pulse trials was 100 ms. Following a 2-min acclimatization period, 6 consecutive pulse-alone trials were presented in order to habituate and stabilize the animals' startle response. Subsequent to this startle habituation phase, each trial stimulus was presented 12 times in a pseudorandom order with an average interval between successive trials (ITI) of 15 ± 5 s. The session was concluded with 6 consecutive pulse-alone trials. Boxes were cleansed with warm tap water and dried between each animal. For each animal and at each of the 5 possible prepulse intensities, PPI was indexed by percent inhibition of startle response obtained in the prepulse-plus-pulse-trials compared to pulse-alone trials by

following expression: [1-(mean reactivity on prepulse-plus-pulse trials / mean reactivity on pulse-alone trials) × 1/100]. The first and last six trials were not included in the calculation and analysis of percent PPI. In addition to PPI, the reactivity to pulse-alone trials was also analyzed.

DNA and RNA Isolation and Quantitative Real-Time PCR Analyses

Total DNA and RNA were isolated using the Qiagen AllPrep DNA and RNA Mini kit (Qiagen, Italy) according to the manufacturer's instructions, and quantified by spectrophotometric analysis. An aliquot of each RNA sample was then treated with DNase to avoid DNA contamination. RNA was analysed by TaqMan qRT-PCR instrument (CFX384 real-time system, Bio-Rad Laboratories) using the iScript one-step RT-PCR kit for probes (Bio-Rad Laboratories). The samples were run in 384-well formats in triplicates as multiplexed reactions with a normalizing internal control (36B4). We choose 36B4 as internal standard for gene expression analyses since its expression was not affected by the prenatal treatments (10).

Thermal cycling was initiated with an incubation at 50°C for 10 min (RNA retrotranscription) and then at 95°C for 5 min (TaqMan polymerase activation). After this initial step, 39 cycles of PCR were performed. Each PCR cycle consisted of heating the samples at 95°C for 10 s to enable the melting process and then for 30 s at 60°C for the annealing and extension reaction. Relative target gene expression was calculated according to the 2(-Delta Delta C(T)) method (11). Custom-designed probe and primer sequences used for the various genes of interest and reference gene (36B4) are summarized below (see *next page*) and were purchased from Eurofins Genomics GmbH (Germany).

SureSelectXT Capture Sequencing Assay

DNA concentrations of the samples were measured with a Qbit Fluorometer (Thermo Fisher Scientific, Canada). Genomic DNA was converted into bisulfite-sequencing samples for the Illumina paired-end multiplexed sequencing platform (Illumina, Canada) according to the manufacturer's instructions. Briefly, gDNA was sheared to fragments of 150-200 bp using a focused-ultrasonicator Covaris according to manufacturer's parameters (Covaris, D-Mark Biosciences Inc., Canada). Methylated adaptors were ligated according to SureSelect Methyl-Seq Capture protocol (Agilent, Canada). Samples were then hybridized for 24 hrs using the SureSelectXT Methyl-Seq kit, captured with streptavidin beads and eluted. Purified samples were then bisulfite converted with EZ DNA Methylation-Lightning kit (Zymo Research, Canada) and amplified with PCR using Takara EpiTaq HS enzyme (Clontech, Canada). The amplified bisulfite-treated library was then purified using AMPure XP beads (Agilent, Canada). The modified libraries were then indexed by PCR amplification and pooled

for multiplexed sequence analysis (16 samples on 3 lanes of flowcell). Purified libraries were then amplified on the Illumina flow cell with TruSeq PE Cluster Kit v3-cBot-HS (Illumina) and sequenced with Illumina HiSeq2000 (2 x 50 cycles). All the Illumina quality controls were found to be in order, including sample-independent controls, sample-dependent controls, staining controls, extension controls, target removal controls, hybridization controls, bisulphite conversion I and II controls, specificity controls, non-polymorphic controls and negative controls.

Hierarchical Clustering of Differentially Methylated CpGs

The methylation values of differentially methylated CpGs ($q < 0.2$) were loaded into Partek Genomics Suite (Partek, USA) and were clustered according to the Hierarchical Clustering function of Partek Genomics Suite (4). For this purpose, the data was normalized with standardization (each column mean is zero, and the standard deviation is scaled to one), and then multidimensional scaling with a Euclidian distance metric was performed on the normalized samples to allow visualization of the distance between them.

Validation of Methylation Differences by EpiTYPER

To validate the methylation differences observed using the SureSelectXT capture-sequencing assay (see above), specific CpGs were analyzed with EpiTYPER for the detection and quantitative analysis of DNA methylation using base-specific cleavage and Matrix-Assisted Laser Desorption/Ionization Time-of-Flight Mass Spectrometry (MALDI-TOF MS) (12). Genomic DNA was treated and analyzed according to manufacturers' instructions (Agena Bioscience, Germany). Briefly, genomic DNA was treated with bisulfite and amplified by PCR with primers specific to genomic regions of the genes of interest (DLX1, MID1, NF2, NLGN1, and WNT3): 95°C for 2 min, followed by 49 repeated cycles (95.0°C for 40 s, 56.0°C for 40 s, 72.0°C for 40 s) and a last step at 72.0 °C for 5 min. Unincorporated dNTPs leftover from amplification were neutralized using shrimp alkaline phosphatase (SAP). Then, to obtain fragmented RNA molecules, in-vitro RNA transcription with subsequent base-specific

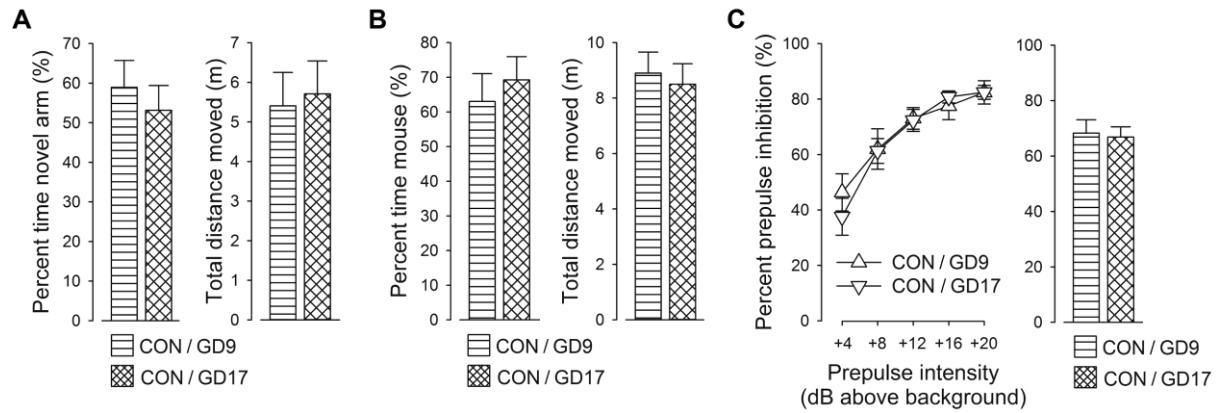

cleavage using RNase A was performed. Both methylated and non-methylated regions were cleaved at every T to produce fragments that are identical in length and differ only in their nucleotide composition. The samples were then conditioned so that the products could be processed in the MALDI-TOF mass spectrometer and could be analyzed by their mass spectra. In analyzing the mass spectrum, the relative amount of methylation can be calculated by comparing the difference in signal intensity between mass signals derived from methylated and non-methylated template DNA (12).

The primer sequences used to amplify specific genomic regions of the genes of interest (DLX1, MID1, NF2, NLGN1, and WNT3) were as follows:

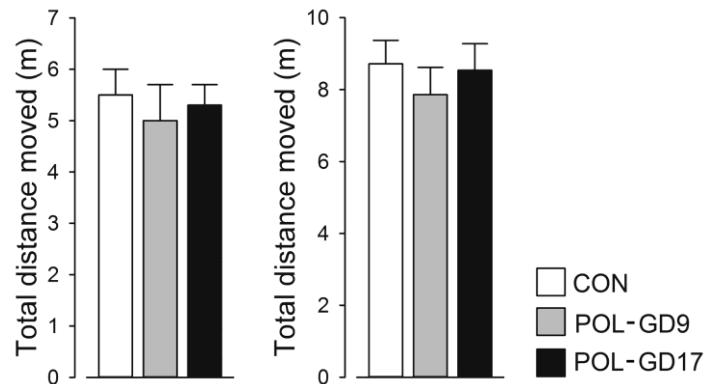

Amplicon	Forward Primer (<i>bold letters: gene specific</i>)	Reverse Primer (<i>bold letters: gene specific</i>)
MID1-A1	5'-aggaagagagGTGGTTGGAAGTATAGGTATGGTTG-3'	5'-ggagaaggctCCAAAACCTCAAAACTAAAATTAC-3'

[?]

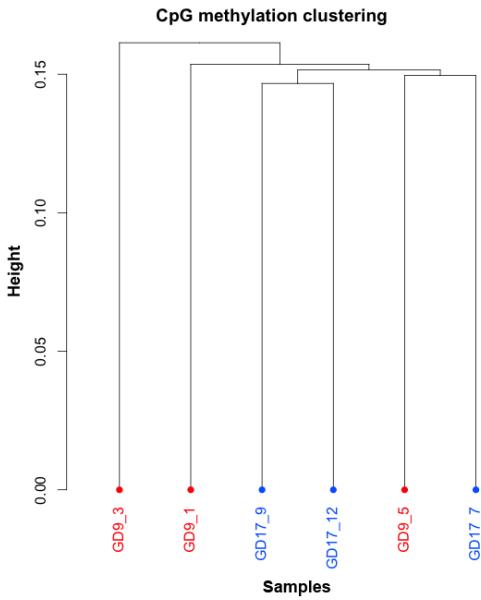

SUPPLEMENTARY RESULTS

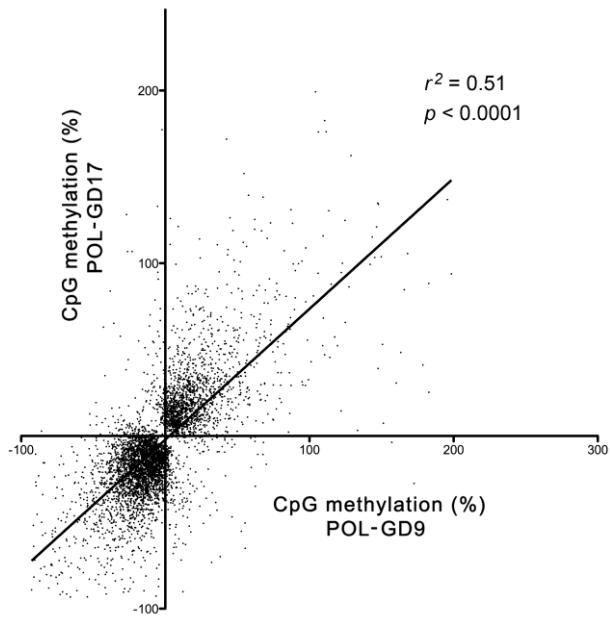

Supplementary Figure 1. Behavioral and cognitive performances of the two vehicle-exposed control subgroups. In order to control for the two timings of poly(I:C) injection, half of the vehicle-treated dams were injected on GD 9, and the other half on GD 17, resulting in CON/GD9 and CON/GD17 control offspring. The graphs show the performances of the two control subgroups in adulthood. **(A)** Percent time spent in the novel arm and total distance moved in the Y-maze test of spatial recognition memory. **(B)** Percent time spent with an unfamiliar mouse and total distance moved during the social interaction test. **(C)** Percent prepulse inhibition (PPI) as function of different prepulse intensities (line plot) and mean percent PPI (bar plot). $N(\text{CON/GD9}) = 6$ and $N(\text{CON/GD17}) = 6$; all data are means \pm s.e.m.

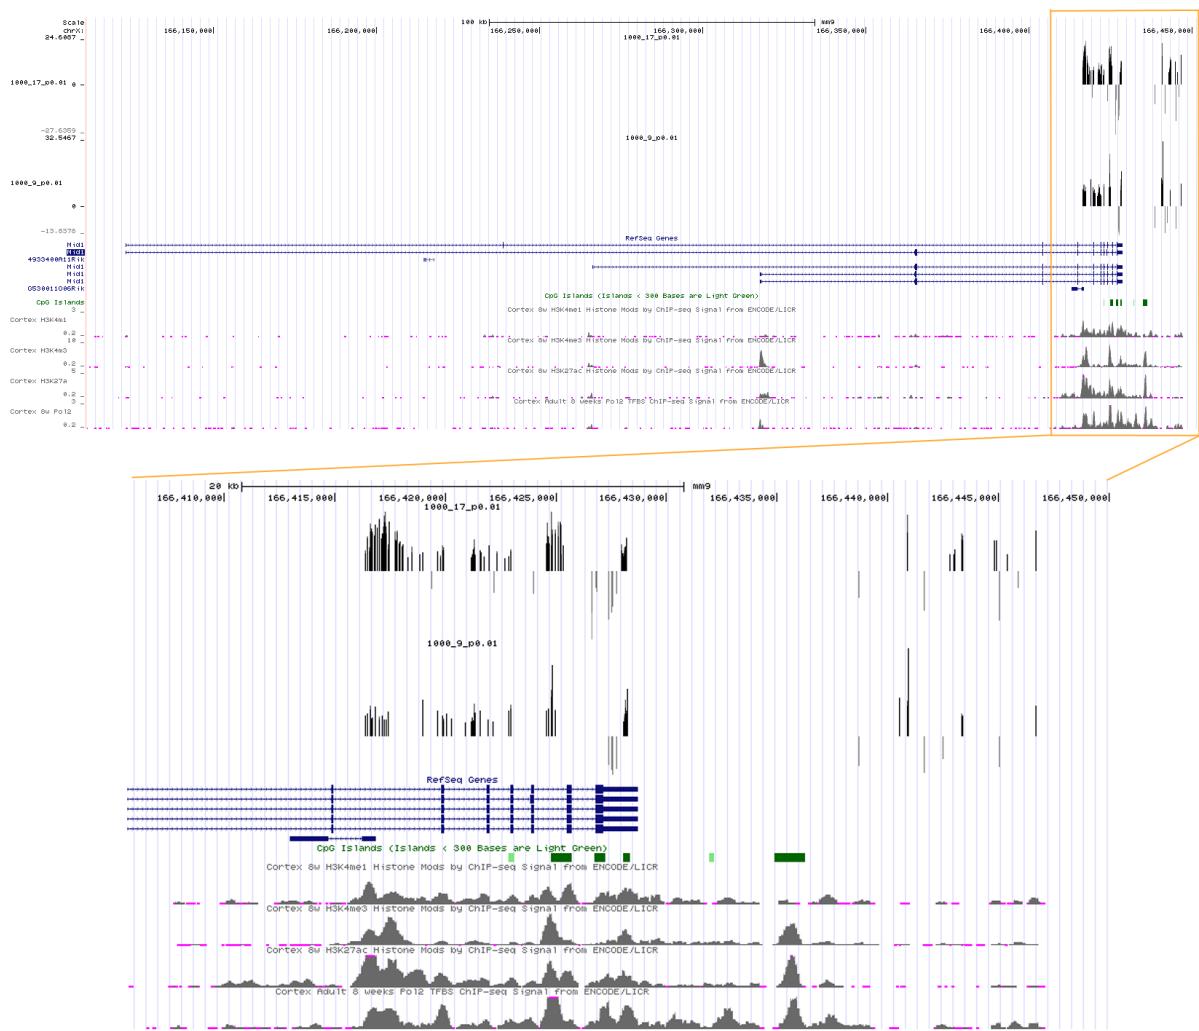

Supplementary Figure 2. Locomotor activity in adult control (CON) offspring and adult offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation. **(A)** Total distance moved during the working memory test in the Y-maze, corresponding to *Main Figure 1A*. **(B)** Total distance moved during the social interaction test, corresponding to *Main Figure 1B*. $N = 12$ males in each group; all data are means \pm s.e.m.

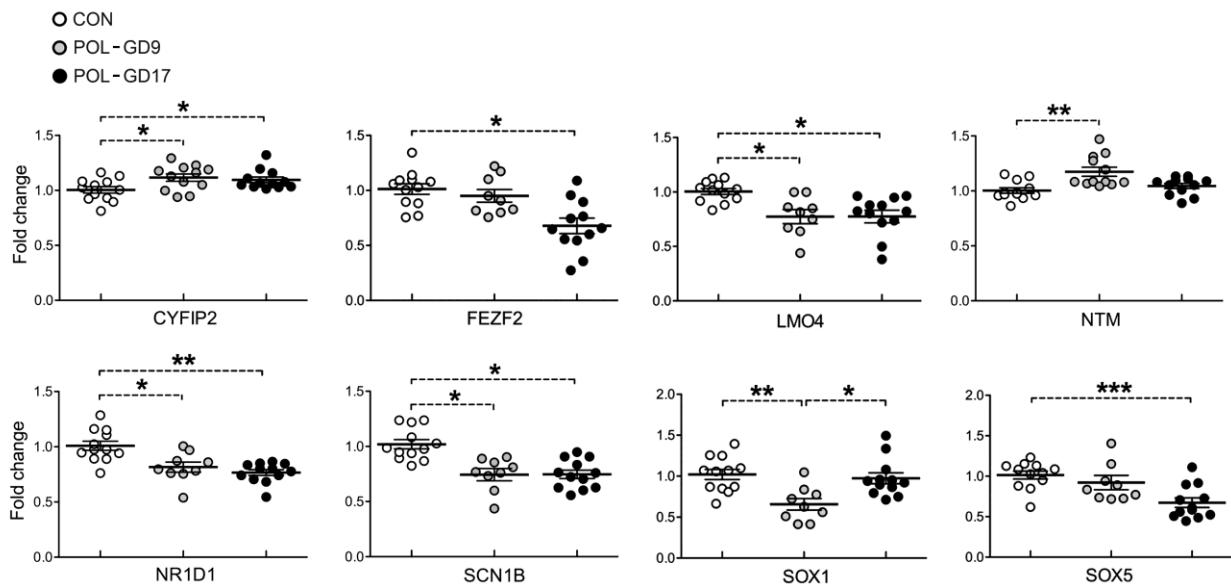

Supplementary Figure 3. CpG methylation clustering of individual samples that were included the merged prenatal control group. In order to control for the two timings of poly(I:C) injection, half of the vehicle-treated dams were injected on GD 9, and the other half on GD 17. The graph shows that there was no clustering between adult offspring of dams injected with vehicle control solution on GD9 (red color; sample GD9_1, GD9_3, and GD9_5) and offspring of dams injected with vehicle control solution on GD17 (blue color; sample GD17_7, GD17_9, and GD17_12). Therefore, offspring born to GD9-injected and GD17-injected control dams were merged into a single control group for the final analyses presented throughout the manuscript.

Supplementary Figure 4. Correlation between single CpG sites that were either affected by poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation. 2365 CpG sites were significantly affected in POL-GD9 relative to CON offspring, and 3361 CpGs were significantly affected in POL-GD17 relative to CON offspring. Each dot represents a single CpG site, which was significantly affected in POL-GD9 and/or POL-GD17 offspring. The data are expressed as percent methylation differences from control offspring (CON, N = 6) and are based on N(POL-GD9) = 5 and N(POL-GD17) = 5.

Supplementary Figure 5. Graphical representation of differentially methylated CpGs in the MID1 gene of adult offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation. The figure was created by the online genome browser hosted by the University of California, Santa Cruz (UCSC) and highlights the differentially methylated CpGs revealed by the capture sequencing analysis in the context of different RefSeq isoforms of the MID1 gene (represented by blue lines). The black and grey bars represent hyper- and hypomethylated CpGs, respectively. The length of the bars indicates the magnitude of the methylation difference. The highlighted area (orange color) is given at higher magnification. Bottom tracks show genomic enhancer sites and polymerase II binding sites in the cortex of 8 weeks old mice (H3K4m1, H3K4m3, H3K27a and Pol2 tracks as given by the ENCODE/LICR database). CpG islands are also indicated in the green track.

Supplementary Figure 6. mRNA expression levels of selected genes that were differentially methylated in adult offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation relative to adult control (CON). Differential methylation of these genes was revealed by the genome-wide capture sequencing approach (see *Supplementary Tables 1-4*) but was not validated by EpiTYPER. The genes were selected based on their involvement in GABAergic cell differentiation and functions (FEZF2, SOX5), Wnt signaling (LMO4, SOX1), and neural development (CYFIP2, NTM, NR1D1, SCN1B). * $p < 0.05$, ** $p < 0.01$, and *** $p < 0.001$, based on Fisher's post-hoc test following one-way ANOVA.

Supplementary Table 1 (ST1) is provided as a separate file under the online Supplementary Material. The corresponding data are also provided in *bedGraph* format and can be uploaded to the genome browser of the University of California, Santa Cruz (UCSC).

Supplementary Table 1. Differentially methylated genes that are affected in adult offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) gestation. The table summarizes CpG methylation differences that were revealed by genome-wide capture sequencing at a resolution of 1000 base-pair sliding regions. The columns describe the location of the 1000 base-pair sliding region, the magnitude of methylation difference (percent change from controls), the *q*-values, and the corresponding gene to which the changes annotate. The regions are sorted according to gene names.

Supplementary Table 2 (ST2) is provided as a separate file under the online Supplementary Material. The corresponding data are also provided in *bedGraph* format and can be uploaded to the genome browser of the University of California, Santa Cruz (UCSC).

Supplementary Table 2. Differentially methylated genes that are affected in adult offspring exposed to poly(I:C)-induced immune activation in late (POL-GD17) gestation. The table summarizes CpG methylation differences that were revealed by genome-wide capture sequencing at a resolution of 1000 base-pair sliding regions. The columns describe the location of the 1000 base-pair sliding region, the magnitude of methylation difference (percent change from controls), the *q*-values, and the corresponding gene to which the changes annotate. The regions are sorted according to gene names.

Supplementary Table 3 (ST3) is provided as a separate file under the online Supplementary Material. The corresponding data are also provided in *bedGraph* format and can be uploaded to the genome browser of the University of California, Santa Cruz (UCSC).

Supplementary Table 3. Differentially methylated genes that are affected in adult offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) gestation. The table summarizes CpG methylation differences that were revealed by genome-wide capture sequencing at single-base resolution. The columns describe the location of the specific CpGs affected, the magnitude of methylation difference (percent change from controls), the *q*-values, and the corresponding gene to which the changes annotate. The CpGs are sorted according to gene names.

Supplementary Table 4 (ST4) is provided as a separate file under the online Supplementary Material. The corresponding data are also provided in *bedGraph* format and can be uploaded to the genome browser of the University of California, Santa Cruz (UCSC).

Supplementary Table 4. Differentially methylated genes that are affected in adult offspring exposed to poly(I:C)-induced immune activation in late (POL-GD17) gestation. The table summarizes CpG methylation differences that were revealed by genome-wide capture sequencing at single-base resolution. The columns describe the location of the specific CpGs affected, the magnitude of methylation difference (percent change from controls), the *q*-values, and the corresponding gene to which the changes annotate. The CpGs are sorted according to gene names.

POL-GD9 versus CON offspring – 1000bp sliding regions

Supplementary Table 6. Differentially methylated genes that are commonly affected in adult offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation. The table summarizes methylation differences that were revealed by the analysis of CpG methylation at single-base resolution. The columns describe the location of the specific CpGs affected, the magnitude of methylation differences (percent change from controls), the *q*-values, and the corresponding gene to which the changes annotate. The CpGs are sorted according to gene names.

Supplementary Table 7. Summary of the inter-replicate methylation level correlations (at single CpG resolution; r^2) between individual samples obtained from adult offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation and adult control (CON) offspring.

Supplementary Table 8. Differentially methylated CpG sites in the MID1 gene (chromosome X) of offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation. The table summarizes methylation differences that were revealed by the analysis of CpG methylation at single-base resolution. The columns describe the location of the specific CpGs affected, the magnitude of methylation difference (percent change from controls), and the *q*-values.

CpG Site		Methylation Difference in POL-GD9 (Percent from CON)		Methylation Difference in POL-GD17 (Percent from CON)

Supplementary Table 9. Comparison between the bisulfite capture-sequencing (Capture-S) and EpiTYPER techniques used to assess differential DNA methylation in adult offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation. The columns describe the specific CpG affected in each of the selected genes (corresponding to *main Figure 3*), the specific genomic location of each CpG, and the differences between immune-challenged relative to control (CON) offspring as measured with the two techniques. Symbol (*) indicates significance at specific CpG sites; symbol (a) indicates a significant main effect of prenatal immune activation across all CpG sites (see *main Figure 3*); ns = no significance. The precise genomic location of the CpG sites measured with EpiTYPER is provided the *Supplementary Table 10*.

Supplementary Table 10. Sequences of the selected amplicons assessed with EpiTYPER and position of CpGs in each amplicon. Methylation of the numbered CpGs (in bold font) was accessible to quantification by EpiTYPER and corresponds to the CpG numbers presented in main *Figure 3* and *Figure 7*. The underlined CpGs were not measurable for technical reasons.

Supplementary Table 11. GO enrichment analysis of genes affected by methylation differences in offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation. For both prenatal treatment conditions, the most significant enrichment occurred in GO-term category “biological process” involving genes annotating with the terms listed in the table. The table also specifies the enrichment score and the enrichment *p*-value for each term.

Supplementary Table 12. List of affected genes that annotate to the GO term ‘neuron differentiation’ in offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation. Each column describes the affected gene, the genomic location of the differentially methylated CpGs, the methylation difference (percent change from controls) and the q-value of the methylation difference.

GO Term		
Cellular Component	Enrichment score	Enrichment p-value
Cell Part	7.80459	4.07E-05
Neuron Part	11.2713	1.27E-05
Neuron Projection	8.81076	1.49E-05

Supplementary Table 13. GO enrichment analysis of genes with methylation differences commonly found in offspring exposed to poly(I:C)-induced immune activation in middle (POL-GD9) or late (POL-GD17) gestation. The most significant enrichment occurred in GO-term category “cellular component” involving genes annotating with the terms listed in the table. The table also specifies the enrichment score and the enrichment *p*-value for each term.

SUPPLEMENTARY DISCUSSION

Our study demonstrates that the effects on the adult DNA methylome are influenced by the precise timing of prenatal immune challenge. These differential epigenetic effects may, at least in part, be accounted for by differences in the precise maternal and fetal immune responses to poly(I:C) at the selected gestational time points. Using the same maternal immune activation model and mouse strain, we previously found that the effects of maternal immune challenge between middle and late gestational periods are dissociable in terms of the pro- and anti-inflammatory cytokine responses to maternal poly(I:C) treatment (2). For example, whereas maternal poly(I:C) treatment on GD9 leads to more extensive maternal and fetal IL-6 responses compared to poly(I:C) treatment on GD17, the maternal and fetal IL-10 responses to poly(I:C) are protracted when the immune-stimulating agent is given on GD17 as compared to GD9 (2). Interestingly, different cytokine classes are known to modulate different epigenetic processes such as DNA methylation (13,14). Therefore, the specificity of poly(I:C)-induced inflammatory responses may be critical in determining the nature of long-term epigenetic effects in the offspring. Additional studies are warranted in order to examine this hypothesis more thoroughly.

The differential effects of middle versus late prenatal immune activation on the adult prefrontal methylome and gene expression profiles may also explain some of the differences in behavioral and cognitive outcomes that are induced by the two prenatal manipulations. The present study confirms that poly(I:C)-induced immune activation on GD 9 causes sensorimotor gating deficiency (1,4,15-17), whereas the same manipulation on GD 17 impaired performance in a Y-maze spatial recognition memory test similarly to what has been reported before (7,8,18,19). The latter test is often taken to index spatial working memory (7), suggesting that prenatal immune activation in late gestation leads to deficits in this cognitive domain. There is an ongoing debate, however, as to whether the Y-maze test measures spatial working memory or habituation (20,21). Hence, the poly(I:C)-induced impairments in Y-maze test might reflect abnormal spatial habituation rather than genuine deficits in spatial working memory. Whilst this hypothesis warrants further examination, it

should be pointed out adult mice prenatally exposed to poly(I:C) in late gestation (GD 17) were found to be impaired in other tests that more readily measure (spatial) working memory (7,19,22). Hence, whether or not captured by the current Y-maze test, accumulating evidence supports the notion that prenatal immune activation during late fetal periods can lead to working memory impairments in the adult offspring. In the present study, we used the Y-maze test primarily because it is associated with only minimal stress for the test animals, as it does not involve any major deviations from general housing conditions (such as single caging and/or food and water deprivation) or exposure to adverse stimuli such as foot shock. Our study followed a within-subjects design, in which all animals were first characterized at the behavioral/cognitive level before the initiation of the molecular analyses. This experimental approach necessitated the use of tests that are characterized by a relatively low amount of stress in order to minimize stress-induced confounds on methylation and gene expression profiles.

Whatever precise neurocognitive and -psychological constructs involved in the Y-maze test, the inclusion of two prenatal time points of immune activation allowed us to identify possible relationships between differential DNA methylation profiles and specific behavioral and cognitive deficits. In view of the proposed role of prefrontal GABAergic signaling in cognitive functions (23-26), altered methylation of GABA-related genes may readily contribute to the emergence of cognitive deficits in offspring prenatally exposed to immune activation in late gestation. On the other hand, methylation-induced changes in Wnt gene transcription and signaling may contribute to the emergence of sensorimotor gating impairments, as highlighted by previous studies (27,28). These possible associations, however, should be interpreted with caution and should be further explored using approaches that can determine causality. Furthermore, it should be pointed out that prenatal immune activation caused differential methylation of a large number of genes, which in turn likely affects the differentiation and/or functional properties of various other neuronal subtypes. Hence, abnormalities in multiple neurotransmitter systems and pathways may

contribute to the emergence of behavioral and cognitive dysfunctions in prenatally infected offspring, as previously suggested (29).

16. Li Q, Cheung C, Wei R, Hui ES, Feldon J, Meyer U, et al (2009): Prenatal immune challenge is an environmental risk factor for brain and behavior change relevant to schizophrenia: evidence from MRI in a mouse model. *PLoS One* 4:e6354.
17. Lipina TV, Zai C, Hlousek D, Roder JC, Wong AH (2013): Maternal immune activation during gestation interacts with Disc1 point mutation to exacerbate schizophrenia-related behaviors in mice. *J Neurosci* 33:7654-7666.
18. Labouesse MA, Dong E, Grayson D, Guidotti A, Meyer U (2015). Maternal immune activation induces GAD1 and GAD2 promoter remodeling in the offspring prefrontal cortex. *Epigenetics* 10:1143-1155.
19. Connor CM, Dincer A, Straubhaar J, Galler JR, Houston IB, Akbarian S (2012): Maternal immune activation alters behavior in adult offspring, with subtle changes in the cortical transcriptome and epigenome. *Schizophr Res* 2012 140:175-184.
20. Sanderson DJ, McHugh SB, Good MA, Sprengel R, Seeburg PH, Rawlins JN, et al. (2010): Spatial working memory deficits in GluA1 AMPA receptor subunit knockout mice reflect impaired short-term habituation: evidence for Wagner's dual-process memory model. *Neuropsychologia* 48:2303-2315.
21. Sanderson DJ, Bannerman DM (2012): The role of habituation in hippocampus-dependent spatial working memory tasks: evidence from GluA1 AMPA receptor subunit knockout mice. *Hippocampus* 22:981-994.
22. Bitanihirwe BK, Weber L, Feldon J, Meyer U (2010): Cognitive impairment following prenatal immune challenge in mice correlates with prefrontal cortical AKT1 deficiency. *Int J Neuropsychopharmacol* 13:981-996.
23. Volk DW, Lewis DA (2014): Early developmental disturbances of cortical inhibitory neurons: contribution to cognitive deficits in schizophrenia. *Schizophr Bull* 40:952-957.
24. Tse MT, Piantadosi PT, Floresco SB (2015). Prefrontal cortical gamma-aminobutyric acid transmission and cognitive function: drawing links to schizophrenia from preclinical research. *Biol Psychiatry* 77:929-939.
25. Bissonette GB, Bae MH, Suresh T, Jaffe DE, Powell EM (2014): Prefrontal cognitive deficits in mice with altered cerebral cortical GABAergic interneurons. *Behav Brain Res* 259:143-151.
26. Paine TA, Slipp LE, Carlezon WA Jr (2011): Schizophrenia-like attentional deficits following blockade of prefrontal cortex GABAA receptors. *Neuropsychopharmacology* 36:1703-1713.
27. Lijam N, Paylor R, McDonald MP, Crawley JN, Deng CX, Herrup K, et al. (1997): Social interaction and sensorimotor gating abnormalities in mice lacking Dvl1. *Cell* 90:895-905.

28. Maguschak KA, Ressler KJ (2012): A role for WNT/β-catenin signaling in the neural mechanisms of behavior. *J Neuroimmune Pharmacol* 7:763-773.
29. Meyer U, Feldon J (2009): Neural basis of psychosis-related behaviour in the infection model of schizophrenia. *Behav Brain Res* 204:322-334.

In this Issue, Richetto et al. identify large-scale epigenetic changes in offspring of mice who were infected during pregnancy. These abnormalities affect gene expression in adulthood and likely contribute to behavioral deficits as seen in neurodevelopmental disorders, such as schizophrenia and autism.
