Abstract

Ovarian dysfunction and lower circulating anti-Müllerian hormone (AMH) feature women living with HIV (WLWH). Because treated human immunodeficiency virus (HIV) infection is characterized by a pro-inflammatory/oxidative phenotype resulting in residual comorbidity, we sought to investigate possible associations between plasma AMH and markers of inflammation, immune activation/senescence/exhaustion, oxidative stress as well as comorbidities in a cohort of combined anti-retroviral therapy (cART)-treated WLWH versus age-matched HIV-uninfected, healthy women.

Eighty WLWH on effective cART aged 25 to 50 years and 66 age-matched healthy women were enrolled. We measured: plasma AMH, IL-6, reactive oxygen species modulator 1 (ROMO1) (ELISA); plasma tumor necrosis factor α, IL-10, soluble vascular cell adhesion molecule 1, osteopontin (Luminex); CD4/CD8 activation (CD38/CD69), apoptosis (CD95), exhaustion (PD1), maturation (CD45RA/CD45R0/CD127/CCR7), recent thymic emigrants (CD31/CD103) (flow cytometry). Mann Whitney and chi-squared tests were used. Univariate and multivariate logistic regression analyses were used to assess factors associated with low AMH (≤1 ng/mL).

Compared to healthy women, WLWH were more frequently non-Caucasian, drug/alcohol abusers, with history of late menarche, lower hormonal contraceptive use, with higher gravidity and lower parity. WLWH showed significantly lower AMH (P = .004) as well as higher ROMO1 (P = .0003) and tumor necrosis factor α (P < .0001). The multivariate analyses revealed ROMO1 (adjusted odds ratio [AOR]: 1.42, P = .03) and HIV infection (AOR: 8.1, P = .0001) as independently associated with low AMH. The logistic regression model with both HIV status and ROMO1 (a marker of oxidative stress) confirmed HIV as the only predictor of low AMH (AOR: 17, P = .0003).

Despite effective cART, WLWH showed lower AMH compared to age-matched peers, indicating pre-mature ovarian ageing. Both HIV and oxidative stress are independently associated with low AMH, emphasizing the impact of HIV-associated oxidative stress on reproductive aging.

Keywords: anti-Müllerian hormone, HIV infection, inflammation, ovarian reserve, oxidative stress, reproductive aging

1. Introduction

The majority of human immunodeficiency virus (HIV) infections among women occur early in reproductive life, supporting the need of better understanding the impact of HIV on reproductive functions, as well as the implications of reproductive aging on HIV course. Although ovarian dysfunction has been reported in women living with HIV (WLWH),\textsuperscript{1,3} the mechanisms behind this phenomenon are still unclear. Several hypotheses have been proposed, including the direct effect of HIV itself, the effect of combined anti-retroviral therapy (cART), the effects of chronic
inflammation/activation on the neuroendocrine axis and coexisting factors, such as smoking, body mass index (BMI), and substance abuse.\[^{[5]}\]

A clear definition of ovarian reserve is still lacking; however, it is well known that its decline results in lower fertility.\[^{[3,4]}\]

Numerous tests have been developed to assess the ovarian reserve in order to evaluate the prognosis of spontaneous fertility. Among them, recent studies indicate that anti-Müllerian hormone (AMH) may offer the most accurate, simple, and non-invasive method for determining ovarian follicle reserve and reproductive aging.\[^{[5–7]}\] Since it can be measured in serum at any stage of the menstrual cycle.\[^{[8]}\] The AMH is produced by the granulosa cells of pre-antral and small antral follicle pool,\[^{[9]}\] and its mutations with reduced in vitro bioactivity have been linked to pre-mature ovarian insufficiency.\[^{[10]}\]

In HIV infection, data on serum AMH levels are conflicting. While some authors reported that age, BMI, CD4 count, and viral load were independent contributors of lower levels of AMH in WLWH,\[^{[11,12]}\] Scherzer et al\[^{[13]}\] described higher levels of AMH in HIV-infected women, even after adjustment for CD4 counts and age. AMH levels in WLWH has also been linked to comorbidities. Indeed, the reduced ovarian reserve seems to be associated with increased risk of subclinical coronary atherosclerotic plaque even after controlling for cardiovascular diseases risk factors (including age) and immune activation, supporting the hypothesis of a role of ovarian reserve in contributing to cardiovascular diseases burden.\[^{[14]}\] Besides, circulating 25-hydroxycholecalciferol was positively correlated with serum hydroxycholecalciferol was positively correlated with serum vitamin D levels, suggesting that circulating vitamin D is associated with cardiovascular diseases burden.\[^{[14]}\] Besides, circulating 25-hydroxycholecalciferol was positively correlated with serum vitamin D levels, suggesting that circulating vitamin D is associated with cardiovascular diseases burden.\[^{[14]}\]

Whereas the occurrence of, or the lack of, altered patterns of reproductive aging in WLWH still needs to be fully elucidated, it is undoubted that hallmarks of HIV infection are the chronic low-grade inflammatory phenotype, coupled with significant immune remodeling and persisting oxidative stress that lead to pre-mature aging.\[^{[16,17]}\]

Given that elevated levels of inflammatory cytokines play a critical role in damaging ovarian functions,\[^{[18]}\] and that long-term moderate oxidative stress has been demonstrated to decrease the ovarian reproductive function by reducing follicle quality and progesterone production,\[^{[19]}\] we hypothesized that the HIV-associated chronic inflammation and oxidative stress may negatively impact the ovarian reserve.

Thus, we decided to investigate whether AMH levels might be associated with systemic inflammation (plasma IL-6, tumor necrosis factor α [TNF-α], IL-10); markers of comorbidities, particularly bone and cardiovascular diseases (plasma osteopontin and soluble vascular cell adhesion molecule 1 [sVCAM-1], respectively); immune activation/senescence/exhaustion/matura-

2. Methods

2.1. Patients

We consecutively enrolled 80 HIV-infected and 66 HIV-uninfected women attending the Clinic of Infectious Diseases and the Clinic of Obstetrics and Gynecology, ASST Santi Paolo e Carlo, Department of Health Sciences, University of Milan, Italy, for routine check-up examinations. HIV-infected subjects were on stable cART for at least 36 months, with undetectable plasma HIV-RNA viral load (<40 copies/mL) in at least 3 consecutive assessments and any CD4 count. Inclusion criteria for both HIV+ and HIV– women were: age ≤50 years, no menopause, no pregnancy.

All the enrolled patients provided written informed consent in accordance with the Declaration of Helsinki and approved by the Ethical Committee of our Institution (Comitato Etico, ASST Santi Paolo e Carlo, Milan, Italy).

Questionnaires were administered to all the study participants. Study interviews included queries regarding menstrual periods, obstetrical history, gynecological surgery, tobacco and drugs use, use of exogenous steroids or other medications, and medical conditions. For HIV-infected women, data on the viral infection were also collected.

2.2. Immunophenotype analyses

Lymphocyte surface phenotypes were evaluated by flow cytometry on fresh peripheral blood of HIV-infected women alone, using fluorochrome-labeled antibodies: L/D-BV510 (Miltenyi Biotech, Germany); CD4-APC-H7, CD8-PE-Cy7, CD38-PE, CD45R0-PerCPCy5.5, CD45RA-PerCPCy5.5, CD127-APC, CD31-FITC, CCR7-APC, CD103-PE, CD95-FITC, CD69-FITC, PD1-PE (BD Biosciences, Palo Alto, CA).

T-cell subsets were defined as: naive CCR7+CD45RA+, central memory CCR7+CD45RA−, effector memory CCR7−CD45RA+ terminally differentiated CCR7−CD45RA− subsets. Besides, we measured: activation (CD45R0/CD38/CD69), apoptosis (CD95), exhaustion (PD-1), IL7R (CD127), and Recent Thymic Emigrants (CD31 or CD103) on both CD4 and CD8 T-cell subsets.

Briefly, 1 × 10⁶ peripheral blood mononuclear Cells were stained with the appropriate antibodies for 20 minutes at 4°C in the dark, washed and then acquired using FACSDiva cytometer (BD Biosciences, Palo Alto, CA).

2.3. AMH quantification

On frozen plasma samples of both HIV-infected and uninfected women, we quantified the circulating levels of AMH (Human MIS/AMH, DuoSet, R&D Systems, Minneapolis, MN, catalog number: DY1737). Samples were thawed at room temperature and then 2 dilution in phosphate-buffered saline was required to avoid inhibition of the reaction. Each plasma sample was measured in triplicate.

2.4. ROMO1 quantification

Plasma levels of ROMO1 in HIV-infected and uninfected women were measured in duplicate by ELISA assay (Human ROMO1 ELISA Kit, FineTest, Wuhan, Hubei, China, catalog number: EH2003), according to manufacturer’s instructions. Fresh-frozen plasma samples were thawed at room temperature and then 2× diluted before running the assay.

2.5. IL-6 quantification

IL-6 levels on undiluted thawed plasma of HIV-infected and uninfected women were measured in duplicate by ELISA assay (Human IL-6 Immunoassay, R&D Systems, Minneapolis, MN,
catalog number: HS600C), according to the manufacturer’s instructions.

### 2.6. Multiplex assays

The relative content of IL-10, TNF-α, sVCAM-1, and osteopontin in thawed plasma of HIV-infected subjects and HIV-uninfected healthy women was quantified using Luminex Assay (R&D Systems, Minneapolis, MN, catalog number: FCSTM09-02 for IL-10 and TNF-α; LXSASHM-03 for sVCAM-1 and osteopontin). A 2× dilution factor was used. All samples were run in duplicate. The raw data were analyzed using Bio-Plex Manager software (Bio-Rad Laboratories, Hercules, CA, USA). Standard curves were generated from lyophilized standards provided with each kit. The concentration for each analyte in each sample was determined via interpolation from each corresponding standard curve.

### 2.7. Statistical analyses

All data were collected in a computerized database and analyzed by GraphPad 6.2 Prism (GraphPad Software Inc). Continuous variables were expressed as median and interquartile range, whereas categorical variables were expressed as absolute numbers and percentages. When HIV and controls groups were analyzed, we used non-parametric statistical tests, as appropriate.

Correlations analyses were examined using the non-parametric Spearman rank correlation test. To identify independent determinants of serum AMH levels, we performed univariate and multivariate linear regression analyses (SAS software 9.4, SAS Institute Inc., Cary, NC, USA). Based on literature, we defined low AMH as values ≤1 ng/mL. Directed acyclic graphs (DAGs) were generated in order to have visual representation of causal assumptions and confounding factors, that may obscure the real effect. A 2-tailed P value less than .05 was considered statistically significant.

### 3. Results

#### 3.1. Characteristics of HIV-infected and HIV-uninfected women

A total of 80 HIV-infected women and 66 age-matched seronegative women were included in the study. The baseline (enrollment) characteristics of the participants are listed in Table 1.

The racial distributions were slightly different in the 2 groups, with 15% of Black/African-American and 5% of Hispanic in the HIV-infected group (P = .0006, Table 1). Current smoking and drug/alcohol abuse were more common in HIV-infected women than in uninfected ones.

The number of pregnancies (gravidity) and history of irregular menses were higher in HIV-infected women (P = .001, P = .044, respectively, Table 1), while the number of births (parity) and the hormonal contraceptive use were less often reported by HIV-infected women (P = .005 both, Table 1).

Table 2 illustrates the HIV-related features. HIV-infected women were virologically suppressed, with a median CD4 current count and nadir of 592 (431–821) cells/μL and 260 (163–316) cells/μL respectively. The median time of HIV infection and cART duration were 14 (7–21) years and 6 (4–9) years, respectively. 32% of HIV+ women were on protease inhibitor-based

3.2. Levels of soluble markers in HIV-infected and HIV-uninfected women

We first assessed circulating levels of AMH, ROMO1 (a marker of oxidative stress), inflammatory markers (IL-6, TNF-α, IL-10), and surrogate markers of cardiovascular and bone damage (i.e., sVCAM-1 and osteopontin, respectively) in the 2 groups.

HIV-infected women showed significantly lower levels of AMH (1.40 [1.06–1.05] ng/mL vs 1.05 [0.83–1.08] ng/mL; \(P = .024\)). (B) HIV-infected women showed significantly higher levels of ROMO1 (4.38 ng/mL vs 6.11 ng/mL; \(P = .0003\)). (C) HIV-infected women showed significantly higher levels of TNF-α (2.48 [1.48–3.37] pg/mL vs 3.66 [2.79–4.71] pg/mL; \(P < .0001\)). (D) HIV-infected women showed a trend towards higher levels of osteopontin (24.14 [15.57–32.07] ng/mL vs 27.14 [18.53–39.98] ng/mL; \(P = .068\)). (E) HIV-infected and uninfected women showed similar levels of IL-6 (1.93 [1.61–3.18] pg/mL vs 1.72 [1.09–3.03] pg/mL; \(P = .152\)). (F) HIV-infected and uninfected women showed similar levels of IL-10 (0.45 [0.19–0.65] pg/mL vs 0.36 [0.23–0.59] pg/mL; \(P = .441\)). (G) HIV-infected and uninfected women showed similar levels of sVCAM-1 (0.79 [0.59–0.97] μg/mL vs 0.81 [0.65–1.12] μg/mL; \(P = .198\)). AMH = anti-Müllerian hormone, HIV = human immunodeficiency virus, ROMO1 = reactive oxygen species modulator 1, sVCAM-1 = soluble vascular cell adhesion molecule 1, TNF-α = tumor necrosis factor α.

By univariate analysis there was no association between AMH and the classical confounding factors known from the literature to affect AMH levels, such as age (odds ratio [OR]: 0.9, confidence interval [CI] 95% 0.9–1; \(P = .07\)), BMI (OR: 0.9, CI 95% 0.8–1; \(P = .7\)), smoking status (OR: 1, CI 95% 0.5–2; \(P = .9\)), and hormonal contraceptive use (OR: 0.3, CI 95% 0.1–1; \(P = .05\)).

Among the inflammatory and surrogate markers of cardiovascular/bone damage, we decided to investigate only those significantly different between HIV-infected and uninfected women, finding no association between AMH and TNF-α (OR: 1.1, CI 95% 0.9–1.5; \(P = .2\)), as well as between AMH and osteopontin (OR: 0.9, CI 95% 0.9–1.1; \(P = .4\)).

Interestingly, the multivariate analysis revealed the oxidative stress and the HIV seropositive status as the only 2 factors associated with low circulating AMH. In particular, low levels of circulating AMH were associated with higher levels of plasma ROMO1 (OR: 1.4, CI 95% 1.07–1.95; \(P = .01\)), even after adjusting for age, BMI, and smoking status (adjusted odds ratio [AOR]: 1.42, CI 95% 1–1.9; \(P = .03\)).

Similarly, the HIV seropositive status was associated with low AMH (OR: 3.4 CI 95% 1.6–7; \(P = .001\)), even after adjusting...
Figure 2. Predictors of low circulating AMH levels in HIV-infected and uninfected women. (A) Directed acyclic graph model was generated to have visual representation of confounding factors. ▶️ = exposure; I = outcome; green color = ancestor of exposure, blue color = ancestor of outcome, red color = ancestor of exposure and outcome; grey color = other variables; green arrow = causal path; red arrow = biasing path. (B) Univariate and multivariate regression analyses showed that HIV seropositive status was independently associated with low values of AMH. In the logistic model low AMH was defined as AMH ≤1 ng/mL. *mutually adjusted. AMH = anti-Müllerian hormone, BMI = body mass index, HIV = human immunodeficiency virus.
for age, BMI, smoking status (AOR: 8.1, CI 95% 2.7–24, \(P= .0001\)).

The logistic regression model with both HIV status and oxidative stress variables, confirmed the HIV seropositive status as the only independent predictor of low AMH (AOR: 17, CI 95% 3.7–83; \(P= .0003\)).

Given the number of confounders that might influence or mask the effect of HIV on AMH, we decided to generate a DAG, that helped us in identifying and clarifying the minimal sufficient adjustment for estimating the total effect of HIV infection on AMH levels.

The DAG showed the age and the smoking status alone as confounding factors (Fig. 2A). Thus, we generated a new regression model, confirming the HIV status as the only independent factor associated with low AMH (Fig. 2B).

### 3.4. AMH and immune profile in HIV-infected women

Since the presence of HIV infection itself seems to negatively affect circulating levels of AMH, we focused on cART-treated women alone, trying to identify HIV-related factors that might be responsible for the low ovarian reserve in WLWH on suppressive cART.

While we failed to find any association between plasma AMH and T-cell immune activation, senescence and exhaustion (data not shown), we did find a modest association between AMH and plasma TNF-\(\alpha\) (\(r=0.310; P= .016\); Fig. 3A), as well as a positive correlation with cART duration (\(r=0.241; P= .043\); Fig. 3B) and a negative correlation with time between HIV infection diagnosis and cART initiation (\(r=−0.25; P= .037\); Fig. 3C).

### 4. Discussion

The advent of cART has dramatically improved the life expectancy of people living with HIV. Nevertheless, this prolonged survival is associated with an increased prevalence of comorbidities, due to chronic proinflammatory state. An increasing number of studies showed that inflammation is associated with the occurrence of aging; this phenomenon known as inflamm-aging comprises different mechanisms: oxidative stress, inflammation, cytokines, DNA damage, autophagy, and non-enzymatic glycation.

Data to specifically assess how exactly the inflamm-aging process affects WLWH, however, are conflicting and inconclusive. To date, it is still unclear the reason why WLWH show a reduced ovarian reserve and how this reduction is associated with fertility dysfunction and pre-mature menopause.

In the attempt to clarify the interplay between the HIV infection and the ovarian reserve, we decided to investigate the possible associations between AMH levels and markers of inflammation, immune activation/senescence/exhaustion, oxidative stress, and comorbidities in cART-treated WLWH.

In line with some previous observations, our cohort of cART-treated WLWH showed lower levels of circulating AMH.
compared to age-matched HIV-uninfected peers, indicating premature ovarian aging. Interestingly, when we explored the possible factors associated with this finding, HIV infection per se and oxidative stress were the only 2 factors independently associated with low AMH. The association between AMH and oxidative stress is not surprising, given that high levels of reactive oxygen species (ROS) notoriously lead to a gradual decline in follicle quantity and quality.[19] Nonetheless, this is the first time that high levels of circulating ROMO1 (a marker of oxidative stress) have been reported to associate with low levels of AMH in cART-treated WLWH, emphasizing the role of oxidative stress on reproductive aging.

ROMO1 is a mitochondrial inner membrane non-selective cation channel with redox sensor functions involved in the regulation of mitochondrial dynamics and intra-cellular ROS production.[25] Upregulation of ROMO-1—which is reflected in heightened plasma ROMO1 levels—, with subsequent increased release of endogenous ROS, has been described in several pathologic conditions characterized by high oxidative stress and inflammation, such as cancer, idiopathic pulmonary fibrosis, chronic obstructive pulmonary disease, and obstructive sleep apnea syndrome.[26,27,28] Given the direct correlation between circulating ROMO1 and ROS production, plasma ROMO1 levels can be used as a surrogate marker of oxidative stress.

Remarkably, however, when applying a logistic regression model accounting for both HIV status and oxidative stress variables, HIV seropositivity was the only independent predictor of low AMH, suggesting that, despite full HIV viremia suppression by cART, HIV still exerts a strong and direct negative impact on ovarian reserve.

We therefore decided to investigate whether the increased risk of lower AMH in our cohort of WLWH may be mediated by circulating activated/senescent/exhausted T lymphocytes, given that the interactions between leukocytes, ovarian follicles, and inflammatory responses are crucial for ovulation.[29] We did not find any evidence of a possible association between AMH and immune activation/senescence/exhaustion. Similarly, we failed to find a link between low AMH and markers of bone and cardiovascular diseases. The lack of association with residual HIV-driven hyperactivated/senescent/exhausted immune profile, as well as co-morbidities markers, suggests that other factors should be taken into consideration, such as tissue HIV reservoirs, coinfections, and microbial translocation.

Interestingly, we found a positive correlation between AMH and TNF-α in cART-treated WLWH, supporting the role of certain cytokines in modulating the functions of granulosa cells, possibly through a direct effect on serum reproductive hormones.[30,31]

Finally, we observed a weakly positive correlation between AMH and cART duration in WLWH as well as a negative correlation with time between HIV infection diagnosis and cART initiation, likely supporting the protective role of anti-retroviral therapy in preserving the ovarian reserve, possibly through partially restoring the CD4 T-cell compartment and/or abating viral replication.

Several limitations need to be acknowledged. First of all, the limited sample size. Secondly, the lack of information on polycystic ovarian syndrome and the lack of matching for ethnicity, drug/alcohol abuse, smoking habits, all factors known to affect AMH levels. Thirdly, the absence of ovarian biopsies, that might have shed light onto the pathogenesis of reduced ovarian reserve in WLWH, allowing us to directly study the proper function of granulosa cells, the HIV reservoirs, the CD4 quantity and quality, the integrity of tight junctions possibly linked to microbial translocation. Lastly, the absence of controls such as cART-un-treated WLWH and/or patients at different stages of disease, that might have allowed to discern whether the heightened oxidative stress observed in WLWH is a direct consequence of HIV viral activity or else a side effect of certain cART regimens; however, we believe that the higher oxidative stress in our cohort is likely a combination of both factors.

In conclusion, to our knowledge this is the first study investigating the role of inflammation, oxidative stress, immune activation/senescence/exhaustion, and comorbidities markers on ovarian reserve in cART-treated WLWH, as compared to age-matched peers. Despite the correlative nature of the study, the findings of an association between low circulating AMH, high plasma levels of ROMO1, and HIV infection above all other factors indicate that the HIV-associated oxidative stress play a pivotal role in promoting reproductive aging. Further studies are still needed to understand the pathogenesis of ovarian dysfunction and the possible role of cART in WLWH.

Acknowledgments

We thank all the patients who participated in the study and the staff of the Clinic of Infectious Diseases and Tropical Medicine and of the Clinic of Obstetrics and Gynecology at ASTT Santi Paolo e Carlo who cared for the patients.

We are particularly thankful to Professor Alessandro Cozzi-Leprì for his precious help and support in statistical analyses.

Author contributions

EM performed lab experiments, analyzed and interpreted the data, designed the figures and wrote the manuscript. CT, MAu, VB and MAI contributed to interpreting the data and wrote the manuscript. VS administered and collected the gynecological questionnaires. ESC performed lab experiments. LG performed the statistical analyses. ADM and AMM contributed to data interpretation and reviewed the manuscript. MR conceived and supervised the study. GM conceived and supervised the study and finalized the draft of the manuscript.

Conceptualization: Esther Merlini, Giulia Marchetti.

Data curation: Valentina Sacchi.

Formal analysis: Esther Merlini, Lidia Gazzola.

Investigation: Esther Merlini, Elvira Stefania Cannizzo.

Methodology: Lidia Gazzola.

Supervision: Antonella d’Arminio Monforte, Anna Maria Marconi, Marina Ravizza, Giulia Marchetti.

Validation: Camilla Tincati, Matteo Augello, Valeria Bono, Marina Allegrini, Giulia Marchetti.

Writing – original draft: Esther Merlini.

Writing – review & editing: Camilla Tincati, Matteo Augello, Valeria Bono, Marina Allegrini, Antonella d’Arminio Monforte, Anna Maria Marconi, Marina Ravizza, Giulia Marchetti.
