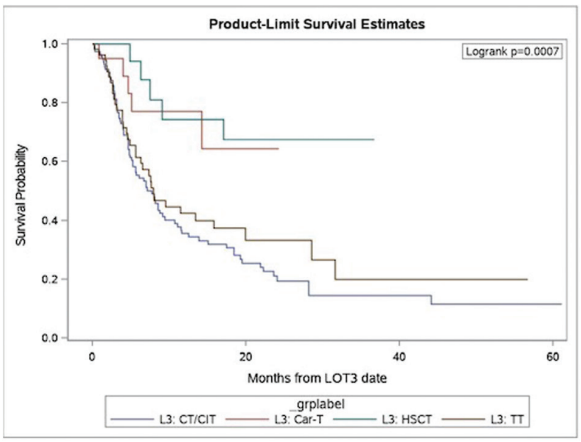
Methods: This retrospective analysis included adult pts, diagnosed with DLBCL [01/01/2014 to 31/08/2019], who received ≥3L of therapy. Data were abstracted from COTA, a de-identified database of real-world data, derived from the electronic health records of healthcare providers in the United States. Pts were categorized as receiving 1) chemotherapy or chemoimmunotherapy (CT/CIT), 2) targeted therapy (TT) [brentuximab, vedotin, ibrutinib, venetoclax, lenalidomide, obinutuzumab, nivolumab, polatuzumab, and pembrolizumab], 3) chimeric antigen receptor T cells (CAR-T), or 4) salvage therapy consolidated with hematopoietic stem cell transplantation



(HSCT). Patient characteristics, response rates, and overall survival (OS) were reported by line of therapy (3L, 4L) for the overall study population and stratified by treatment category. HSCT being a consolidation therapy for pts achieving a complete or partial remission (CR or PR) following salvage treatment, hence; response rates following HSCT were not reported.

Results: Of the 435 pts identified, 212 received 3L and 128 received 4L. At 3L initiation, pts had a mean age of 61yrs (range 18-90) and 59% were male. At 4L initiation, pts had a mean age of 60yrs (range 20-84) and 61% were male. Within a median follow-up of 22.5 months, 14.9% of pts treated with 3L CT/CIT or TT received subsequent CAR-T. Within a median follow-up of 19.3 months, 10.9% of pts treated with 4L CT/CIT or TT received subsequent CAR-T.

CR rates of pts receiving non-cell therapy were substantially lower than pts receiving CAR-T, in both 3L and 4L settings [**Table1**]. OS results for 3L therapy are presented in **Figure 1**. Median OS of non-cell therapy was 7.7 months (CT/CIT: 7.7 months; TT: 7.9 months), and 4.5 months (CT/CIT: 4.5 months; TT: 5.1 months) for 3L and 4L, respectively. Median survival time of pts receiving cell therapy (CAR-T and HSCT) had not reached in either the 3L or 4L setting.

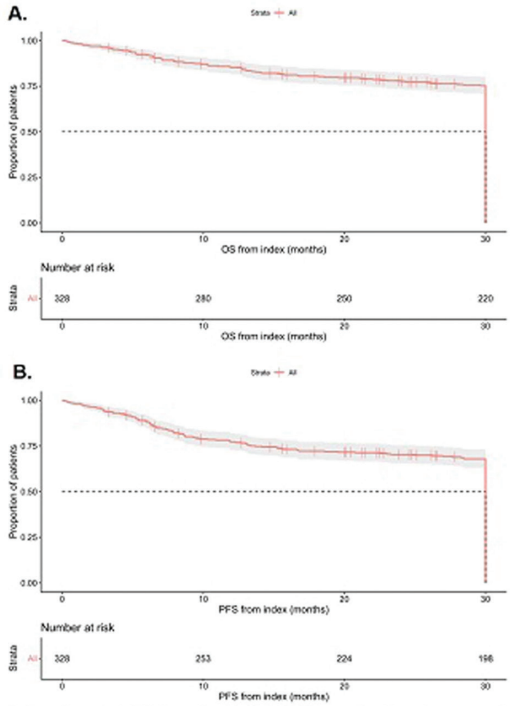
Table 1: Treatment patterns and complete response rates for 3rd Line and 4th Line pts

	3L		4L	
	n (%)	CR rate	n (%)	CR rate
CT/CIT	117 (55)	9.4%	66 (52)	7.6%
TT	57 (27)	8.8%	44 (34)	15.9%
CAR-T	20 (9)	60%	12 (9)	50%
HSCT	18 (8)	N/A	6 (5)	N/A

Summary/Conclusion: Results from this real-world study illustrate that majority of pts treated with 3L CT/CIT or TT, had poor clinical outcomes, which were exacerbated in the 4L setting. Pts who received cell therapy had better clinical outcomes, however, the proportion of pts receiving these treatments is low. Preliminary data suggests that survival outcomes among CAR-T and HSCT pts, are similar in the 3L and 4L settings. Despite various novel treatments, prognosis for pts with R/R DLBCL remains very poor, underscoring the need for more efficacious treatment options.

EP529 REAL WORLD CLINICAL EFFECTIVENESS AND SAFETY OF CT-P10 IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: RESULTS FROM A EUROPEAN NON-INTERVENTIONAL POST AUTHORIZATION SAFETY STUDY

M. Bishton [1,*], K. Laribi [2], G. Salles [3], J. Harchowal [4], A. Bosi [5], W. Knauf [6], M. Bocchia [7], S. Kim [8], Y. N. Lee [8], P. L. Zinzani [9]



[1]City Hospital, Nottingham, United Kingdom, [2]Centre Hospitalier du Mans, Le Mans, [3]Centre Hospitalier Lyon Sud, Pierre-Bénite, France, [4]Royal Marsden Hospital, London, United Kingdom, [5]Azienda Ospedaliero Universitaria Careggi, Florence, Italy, [6]Centrum Für Hämatologie und Onkologie Bethanien, Frankfurt, Germany, [7]Hematology Unit, Azienda Ospedaliero-Universitaria Senese, University of Siena, Siena, Italy, [8]Celltrion Healthcare, Incheon, Korea, Republic Of, [9]Institute of Hematology, "Seràgnoli" University of Bologna, Bologna, Italy

Background: The rituximab biosimilar CT-P10 was granted European Medicines Agency approval in 2017 for the treatment of rheumatoid arthritis (RA) and specific blood cancers, including non-Hodgkin's lymphoma (NHL). Diffuse large B-cell lymphoma (DLBCL) accounts for 30–50% of NHL cases. Clinical similarity between CT-P10 and rituximab was accepted based on evidence in populations of patients with RA and follicular lymphoma. To-date, DLBCL patients have not been included in clinical trials of CT-P10 and no studies have investigated the effectiveness or safety of CT-P10 treatment in patients with DLBCL in a European real world clinical setting.

Aims: To evaluate the real world clinical effectiveness and safety of CT-P10 in patients with DLBCL in Europe.

Methods: This non-interventional post-authorisation safety study involved collection of patient-level data from hospital medical records for patients with DLBCL who received CT-P10 treatment prescribed in accordance with the marketing authorisation in five European countries (United Kingdom, Spain, France, Germany and Italy). Patients were treated as per routine clinical practice. Effectiveness (overall survival [OS] and progression free survival [PFS], CT-P10 responses), safety (adverse events [AEs] and infusion-related reactions [IRRs]) and CT-P10 treatment pattern data were collected during the 30-month observation period following the index date (date of CT-P10 initiation) or until death, if sooner.

Results: This study included 389 (58% male) patients with a median disease duration at index of 23.0 (Interquartile range [IQR] 12.0–46.0) days. The median age at index was 69.7 (IQR 60.3–76.1) years. Of patients with available data at index, 42% (n=98/191) had Ann Arbor stage IV disease while 21% (n=49/237) had an Eastern Cooperative Oncology Group performance score ≥2; 50% (n=131/263) of patients were classified as intermediate-high or high risk (International Prognostic Index score ≥3). CT-P10 was received as a first-line treatment for DLBCL by 84% (n=328) of patients, second-line for 11% (n=41), and third-line or greater for 5% (n=20). R-CHOP was the most administered chemotherapy regimen at index (68%, n=266/389). The best recorded response to CT-P10 (n=382) was complete response in 82% (n=312) of patients, partial response in 12% (n=46), no response or stable disease in 4% (n=16) and progressive disease in 2% (n=8). At 30-months post-index, for patients taking first-line CT-P10, 74% (95% confidence interval [CI] 69.2–79.1%) of patients were still alive and 67% (95%CI 61.3–72.1%) had not progressed. Kaplan-Meier curves depicting OS and PFS are shown in Figure 1; median OS/PFS was not reached. Overall, 90% (n=351) of patients reported at least one AE (n=2504 total AEs); 46% (n=178) had ≥1 Grade 3 AEs, most commonly neutropenia (9% [n=35/369] of all Grade 3 AEs). 9% (n=180/2100) of AEs were recorded as definitely, probably or possibly related to CT-P10 and 6% (n=24) of patients discontinued CT-P10 due to AEs. IRRs were reported on day 1 or 2 for 8% (n=31) of patients.

A. Overall survival (OS) for patients taking CT-P10 as a first-line of treatment. B. Progression-free survival (PFS) for patients taking CT-P10 as a first-line of treatment. The assessment of disease progression was based on the Revised Response Criteria for Malignant Lymphoma, if these criteria were used and documented locally.

Summary/Conclusion: This study provides new insight into the real world effectiveness and safety of CT-P10 for the treatment of DLBCL. Over three quarters of patients initiated on CT-P10 achieved complete or partial response by 30 months, with CT-P10 appearing to be generally well tolerated by patients. The response and survival rates and overall safety profile for CT-P10 appear consistent with those reported for reference rituximab, supporting CT-P10 use in combination with chemotherapy as a therapeutic option for DLBCL.

EP530 LYMPHOCYTE COUNT EFFECT ON EFFICACY AND SAFETY OF SINGLE AGENT ORAL SELINEXOR IN PATIENTS WITH RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): A POST-HOC ANALYSIS FROM PHASE 2B SADAL STUDY

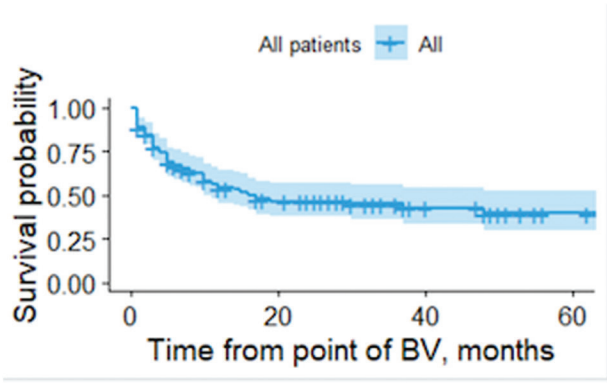
Background: Selinexor is a first-in-class, oral Selective Inhibitor of Nuclear Export (SINE) compound that blocks XPO1, forcing the nuclear retention and functional activation of tumor suppressor proteins including p53, p73, FOXO, IkB and Rb. The phase 2b SADAL study included 134 patients with relapsed or refractory DLBCL with single agent selinexor twice weekly. The overall response rate (ORR) was 29.1%, median duration of response (DOR) 9.3 months and the median overall survival (OS) 9 months. Based on these data, selinexor was approved by the US FDA for the treatment of relapsed or refractory DLBCL, de novo or transformed from follicular lymphoma. Studies have shown that a lower absolute lymphocyte counts (ALC) is a strong prognostic factor for reduced PFS and OS in patients with DLBCL.
Aims: To performed post-hoc analyses of results from the SADAL study to determine the impact of baseline ALC on the efficacy and safety of selinexor.
Methods: The SADAL study was multi-center, open-label Phase 2b study that enrolled patients with DLBCL treated with 2-5 lines of therapy treated with oral selinexor 60mg twice weekly until disease progression. Patients may have recurrence after stem cell therapy (SCT) or were not candidates for SCT. The primary endpoint was ORR, and other endpoints included DOR, OS and safety assessments. For the current analysis, patients were divided into categories based on baseline ALC (≥1000/μL and <1000/μL) in order to compare outcomes.
Results: Of the 134 patients enrolled in the SADAL study, 61 (46%) had baseline ALC of ≥1000/μL and 71 (53%) had levels <1000/μL. The majority of patients in both groups were <65 years old, 79% and 72%, respectively. In this population, *de novo* and transformed DLBCL accounted for 82% and 18% with ALC ≥1000/μL and 72% and 28% in patients with ALC <1000/μL and, respectively. DLBCL subtype was also similarly distributed among patients with GCB and non-GCB in those with ALC ≥1000/μL (51% and 43%) and in those with ALC <1000/μL (44% and 55%), respectively.
The ORR in patients who had baseline ALC ≥1000/μL was 32.8% compared to 25.4% for ALC <1000/μL (p=0.455; complete responses (CR) rates were 13.1% vs 14.1% respectively. The median DOR in patients who had ALC ≥1000/μL was 23.0 months compared to 4.9 months in patients with ALC <1000/μL (p=0.228). The median PFS were 3.6 and 2.1 and median OS were 15.5 and 7.6 months in patients with ALC ≥1000/μL and <1000/μL, respectively (p=0.129; p=0.013).
The most common grade ≥3 treatment-related adverse events (AEs) for patients with ALC ≥1000/μL and <1000/μL were thrombocytopenia (42.6% vs. 38.0%), nausea (6.6% vs. 4.2%) and fatigue (9.8% vs. 11.3%). The incidence of treatment-related serious AEs and AEs leading to discontinuation in patients who had a lymphocyte count of ≥1000/μL vs <1000/μL were 26.2% vs. 16.9% and 11.5% vs. 4.2%, respectively; these differences may have been related to duration of response.
Summary/Conclusion: In this post-hoc analysis in patients enrolled in SADAL with relapsed/refractory DLBCL treated with single agent oral selinexor, those with baseline ALC ≥1000/μL had a ALC a slightly higher ORR (33% vs 25%) but similar CR rates and PFS to those with ALC<1000/μL. Significantly longer overall survival was observed in patients with higher baseline ALC, and responses in these patients trended to longer duration. While consistent with many reports in the literature regarding the poor prognosis of baseline ALC <1000/μL, these results need to be confirmed in larger studies with longer follow up.

EP531 CLINICOPATHOLOGIC DESCRIPTORS OF MONOMORPHIC EPITHELIOTROPIC INTESTINAL T-CELL LYMPHOMA (MEITL): ANALYSIS OF A POOLED DATABASE OF A NEW ENTITY

P. Haddad [1,*], N. Dadi [1]

[1]Louisiana State University Health Science Center/Overton Brooks VAMC, Shreveport, United States

Background: MEITL is a rapidly progressive rare extranodal T-cell lymphoma that arises from the intestinal intraepithelial T lymphocytes. In its 2016 classification, the WHO established MEITL as a separate entity of what was previously known as type 2 enteropathy-associated T-cell lymphoma. While morphologic characteristics are codified in its name, this entity tends to have its own clinicopathologic characteristics.
Aims: We conducted this analysis to explore the clinicopathologic descriptors and prognosticators of this little-known newly established T-cell entity.
Methods: In order to study the demographic characteristics, molecular and immunohistochemical signatures, therapeutic interventions, survival, and prognostic factors, we compiled a pooled database of 116 cases. Descriptive statistics were calculated. Cox proportional-hazards model and Log-rank tests were used to assess the influence of demographic and clinicopathologic factors on overall survival (OS).
Results: A total of 116 patients with confirmed MEITL were identified. The median age was 59.5 years with a peak incidence between ages 56 and 68. There was a male predominance with M:F ratio of 2. As the only involved gastrointestinal (GI) site, Jejunum was the most involved site of the disease (Jejunum (J) 21%, Duodenum (D) 7%, Colorectal (CRC) 10%, Ileum (I) 6%, Gastric (G) 2%). Jejunum was also the most involved site when the disease involved multiple GI sites (J 71%, I 57%, D 46%, C 30%, R 3%). The most frequently involved anatomic combinations were multifocal small intestine 26%, small intestine with colorectal 21%, J&I 7%, D&J 2%. While 25% of patients presented with lymphadenopathy (79% regional, 14% distal, 7% both), only 6% had bone marrow involvement and none had hepatosplenomegaly. Extra-nodal and extra-gastrointestinal involvement comprised lung (5%), CNS (3%), and skin (1%). Stage distribution consisted of Stage I (69%), II (9%), III (6%), IV (16%). Most cases expressed CD2 (77%), CD3 (100%), CD7 (86%), CD8 (80%), CD56 (89%), CD103 (86%), and Granzyme-B (52%). MEITL cases expressed TCR-αβ (39%), γδ (56%), and null (5%). There were no significant differences in age, sex, and CD profiles with respect to TCR-status. The most common clinical presentations were abdominal pain, followed by perforation, diarrhea, and weight loss. The median duration of symptoms prior



to diagnosis was 4 months. Median OS of the whole group was 11 months. Compared to no treatment, combination chemotherapy and stem cell transplant (SCT) were statistically superior with a median OS of 2, 9, and 34 months respectively (p=0.0005). Furthermore, quality of response and surgical resection imparted a survival advantage. OS was not impacted by sex, presentation with obstruction or perforation, or anatomic site involvement. While older age, weight loss, and TCRγδ seemed to negatively impact OS, they did not reach statistical significance.
Summary/Conclusion: This study presents a comprehensive clinicopathologic data from a pooled cohort of patients with MEITL. It describes the clinicopathologic features of MEITL and identifies major determinants of OS in this rare disease.

EP532 POPULATION-BASED COHORT STUDY OF THE EFFICACY OF BRENTUXIMAB-VEDOTIN IN RELAPSED SYSTEMIC ANAPLASTIC LARGE CELL LYMPHOMA USING PUBLIC HEALTH ENGLAND DATA

S. Halligan [1,*], M. J. Grainge [2], N. Martinez-Calle [3], C. P. Fox [3], M. Bishton [3]

[1]Nottingham University Hospitals NHS Trust, [2]Division of Epidemiology and Public Health, School of Medicine, University of Nottingham, [3]Department of Haematology, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Background: Systemic anaplastic large cell lymphoma (sALCL) is a T-cell lymphoma, historically associated with low cure rates following relapse. Expression of the ALK protein is more common in younger patients and associated with improved survival outcomes. Following a pivotal phase II study (Pro et al) and European licence, the immuno-conjugate Brentuximab Vedotin (BV) became available in England via the Cancer Drugs Fund (CDF) in 2013. To date, no large-scale population-based studies have described outcomes following BV. Public Health England (PHE) collects information on all cancer diagnoses in England, and since April 2012 all delivered Systemic Anti-Cancer Therapy (SACT).
Aims: We aimed to evaluate whether routinely collected PHE data can reliably assess outcomes of patients with lymphoma. Survival outcomes for BV monotherapy in relapsed ALCL in all England was chosen as a pilot project to explore the value of PHE data due to the well-defined disease and SACT cohort.
Methods: Following NHS REC approval, we requested anonymised Office of Data Release (ODR) information on sALCL patients ≥18 years treated with BV monotherapy between 1st Jan 2014-31st Dec 2019. We excluded primary cutaneous and breast-implant associated ALCL, patients in the ECHELON-2 trial and BV received in combination. We requested baseline demographics, ALK status, dates and number of BV cycles, and SACT data prior to and following BV, prior autologous/allogeneic stem cell transplantation (SCT). Kaplan-Meier survival methods were used to compare the primary outcome of all-cause mortality between groups defined on the basis of age, gender and ALK status (positive vs. negative) in univariate analyses.
Results: 173 patients were identified, of whom 46 were excluded. The final cohort comprised 127 patients with r/r ALCL with a median age of 60 years at initiation of BV and median follow up time of 10 months. 49 (38.6%) patients were ALK+ve and 78 (61.4%) ALK-ve. The median time from diagnosis to BV was nine months (range 1-143). 106 (83.5%) received BV second line, and 13 (10.2%) third or fourth line. 95 (74.8%) received CHOP first line. Based on SACT data 18 (14.2%) received SCT in first remission (16 auto, 2 allo). The median number of BV cycles received was five. Median 2-year overall survival (OS) was 46.6%. The majority (59) of deaths occurred within the first 18 months, followed by a survival plateau with only four subsequent deaths. There were 20 (15.7%) deaths prior to cycle 5, the timepoint where the CDF mandates response assessment. There was no difference in OS between ALK+ve and ALK-ve (p=0.78), age <40 vs ≥40 years(p=0.89), age <60 vs ≥60(p=0.96), between genders(p=0.25), or receiving prior SCT (p=0.55). Two patients received SCT after BV, with both alive 20+ months post-transplant. Receiving BV second line therapy was associated with improved survival, with 2-year OS of 50.3% versus 29.7% for those third or fourth line(p = 0.03).

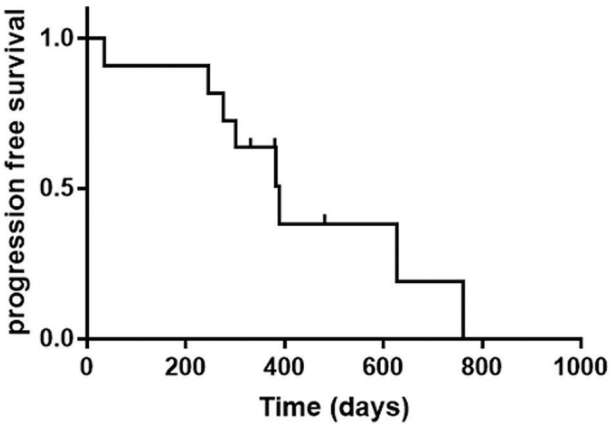
Summary/Conclusion: We confirm BV is a highly effective treatment for r/r sALCL with real world survival outcomes across sub-groups highly comparable with clinical trial data. Weaknesses of this study include lack of information on toxicity and data from double blind studies, although this data is now being collected. Analysis of routinely collected PHE data offers the opportunity to undertake high quality, nationwide population-based studies, to inform the efficacy of high-cost drugs such as BV in routine clinical practice.

EP533 COMBINED TREATMENT OF AUTOLOGOUS HEMATOPOIETIC STEM CELLS TRANSPLANTATION WITH CAR T-CELL THERAPY IMPROVES OUTCOMES IN MANAGEMENT OF ADVANCED RELAPSED/REFRACTORY CENTRAL NERVOUS SYSTEM B-CELL LYMPHOMA

F. xue [1], K. hu [1,*]

[1]Beijing Boren Hospital, Beijing, China

Background: The Chimeric antigen receptor (CAR) T-cell therapy has shown very promising future in relapsed/refractory B-cell lymphoma while the central nervous system lymphoma(CNSL) remained one of exclusion criterion in CAR T-cell therapy due to its fatal neurotoxicity.Recently several studies reported CAR T-cell therapy was safe and effective in treatment of advanced CNS disease, however, its resultant remission seemed short-lasting.
Aims: 1.Investigate the effect and safety of CAR T-cell therapy in advanced refractory/relapsed central nervous system B-cell lymphoma(R/RCNSBL).2.Compare effects of combination of autolougs hematopoietic stem cell transplantation(ASCT)with CAR T-cell therapy, and sequential multiple targets of CAR T-cell therapy towards survival of the subjects.
Methods: 17 patients (aged 19-66 years) with advanced R/RCNSBL were enrolled from 01/10/2018 to 01/10/2020,and are reviewed. Prior to administration of CAR T-cell therapy, all of the patients received chemotherapy and targeted drugs treatment to reduce tumor loads. Only patients who had responded to chemotherapy would be treated with stem cell mobilization and collection. The ASCT combined with CD19, CD20 or CD22 CAR T-cell therapy would be then administered to patients whose stem cells were successfully collected or had been already prepared. While other patients would be given with sequential therapy with targeting CD19, CD20 or CD19-22 CAR T-cell therapy. After CAR T-cells were infused, mannitol was also given for prophylaxis. The T-cells with specific CAR expression in peripheral blood and cerebrospinal fluid were dynamically detected by flow cytometry. After CAR T-cells infusion, PET-CT, PET-MRI or contrast-enhanced MRI were performed every 3 months. Patients were followed up till 1/31/2021
Results: 1.8 cases of 17 patients, who completed treatment of ASCT and CAR T-cell therapy, and the other 9 cases with completed multi-target sequential therapy. 2.The incidence of cytokine release syndrome (CRS) was 94.11%, of which 41.17% was severe CRS(≥grade 3), as the incidence of immune effector cells associated neurologic toxicity(ICANS) was 35.29%, of which 29.41% was severe ICANS. In comparison, in ASCT group and non-ASCT group, the incidence of severe CRS(≥grade 3)were 50% and 33.33%(P=0.486),respectively;and that of severe ICANS (≥grade 3) were 25% and 33.33% (p=0.14), respectively. There were no death related to the treatment.3. In 3 months, complete remission rate was 64.70% (11/17), partial remission rate was 5.88% (1/17) and the objective response rate was 70.59% (12/17). The remission rate of the ASCT group was higher than that of the non-ASCT group (100% vs 44.4%, P < 0.01). the median of progression-free survival length(PFS)



was 8 months (ranging 2-17 months). The overall survival length (OS) was 6 to 21 months. In comparison, in the group of ASCT combined with CAR T-cells therapy, patients in remission had longer PFS (11 months vs 4 months, P=0.02), with no significant difference in the overall survival length between the two groups (11 months vs 9 months, P =0.52).
Summary/Conclusion: 1.The CAR T-cell therapy could augment its efficacy in treatment of advanced R/RCNSBL.2.The neurotoxicity of CAR T- cells therapy could be mitigated, and there was no death related to treatment.3.The combined treatment of ASCT and CAR T-cell therapy could increase sustained response and longer survival length.

EP534 LENALIDOMIDE AND RITUXIMAB REGIMEN COMBINED WITH INTRAVITREAL METHOTREXATE FOLLOWED BY LENALIDOMIDE MAINTENANCE FOR PRIMARY VITREORETINAL LYMPHOMA: A PROSPECTIVE PHASE II STUDY

Y. Zhang [1,*], X. zhang [2], D. Zou [3], M. Zhang [2], W. Zhang [1], D. Zhou [1]

[1]Department of Hematology, [2]Department of Ophthalmology, Peking Union Medical College Hospital, [3]Department of Hematology, Beijing Xuanwu Hospital, Beijing, China

Background: Primary vitreoretinal lymphoma (PVRL) is a rare variant of primary central nervous system (CNS) lymphoma, for which currently there are no optimal treatment options.
Aims: To balance the adverse events (AEs) of chemotherapy and achieve sustained control of lymphoma, we conducted a single-arm, phase II trial for newly diagnosed B-cell PVRL to evaluate the efficacy and safety of the R2 regimen with intravitreal MTX
Methods: This prospective single-center study enrolled immunocompetent patients with newly diagnosed PVRL between August 2018 and January 2020. Patients received local and systemic therapies: intravitreal methotrexate (MTX, 400 μg, 0.1 mL) injections for 1 year (total 16 injections) and six cycles of the rituximab (375 mg/m^2 on day 1) and lenalidomide (25 mg on day 1–21; R2) regimen. Lenalidomide was maintained for 2 years in patients who had achieved a response. This trial is registered with ClinicalTrials.gov (number NCT 03746223).
Results: We enrolled 11 patients with a mean age of 58 (range, 48–70) years, of which 10 achieved complete remission at the first evaluation. The median follow-up period was 18.3 (range, 10.6–27.8) months, and the median progression-free survival was 12.7 months. Moreover, a total of eight patients relapsed. The most common adverse event (AE) was neutropenia, which occurred in seven patients (63.6%), followed by grade 3 ocular toxicities, including cataract formation, in six patients (54%).

Summary/Conclusion: These findings suggest that the R2 regimen combined with intravitreal MTX, followed by lenalidomide maintenance, is a safe option for PVRL with moderate efficacy.

EP535 BASELINE TUMOR BURDEN CORRELATES WITH RESPONSE BUT NOT TOXICITIES IN PATIENTS TREATED WITH BISPECIFIC ANTI-CD20, ANTI-CD19 CAR-T CELLS

J. Zurko [1,*], D. Bucklan [2], T. Luo [1], B. Johnson [1], M. Hamadani [1], T. Fenske [1], N. Shah [1]

[1]Department of Medicine, [2]Department of Radiology, Medical College of Wisconsin, Wauwatosa, United States

Background: Bispecific anti-CD20, anti-CD19 (LV20.19) CAR T-cells may improve outcomes in relapsed, refractory (R/R) B-cell non-Hodgkin lymphoma (NHL) by limiting relapse due to single antigen downregulation. We reported outcomes of a phase I trial of LV20.19 CAR T-cells in R/R NHL & CLL (Shah et al. Nature Med. 2020). There is evidence that higher LDH and baseline tumor burden (as measured by total lesion glycolysis [TLG] and metabolic tumor volume [MTV]) predict inferior response and increased toxicities for single antigen targeted anti-CD19 CAR-T cells. In the context of bispecific CAR T-cells, the impact of tumor burden on outcomes is not known.
Aims: We analyzed whether baseline LDH and tumor burden assessed by whole-body TLG correlated with response and/or toxicities for bispecific CAR T-cells.
Methods: To evaluate the relationship of baseline LDH and tumor burden on day 28 response and toxicities (cytokine release syndrome [CRS] and neurotoxicity), we included patients from the previously mentioned Phase 1 clinical trial treated with LV20.19 CAR T-cells (NCT03019055) who had a pre-CAR-T PET/CT within 45 days of lymphodepleting chemotherapy (LDC). Patients with CLL were excluded. Baseline tumor burden was assessed by measurement of whole body TLG on most recent pre-CAR-T PET/CT within 45 days of LDC. LDH was assessed on day 0 of LDC. Threshold values for high and low tumor volume groups were selected based on the median TLG as previously reported. Continuous and categorical variables were analyzed using t-test, Pearson's chi-squared test and Fischer's exact test where appropriate. All tests were two sided. A p value <0.05 was considered significant.
Results: 15 patients were included in the analysis (9 DLBCL, 6 MCL). Patient characteristics are summarized in table 1. Median age was 56, median lines of prior therapy was 7 (range 3-11) and 67% received bridging therapy after apheresis. Median baseline LDH was 228.5 U/L. Median TLG was 592 (range 3-9775) and served as the threshold value for low and high tumor burden groups (≤592 and >592 respectively). On day 28, 53% (n=8) had a complete response (CR), 20% (n=3) a partial response (PR), and 27% (n=4) had progressive disease (PD). CRS occurred in 60% and neurotoxicity in 27% of patients. Mean baseline LDH was significantly lower in patients who had a response (CR or PR) (243 vs 600, p=0.03) and in those with CR (196 vs 504.2, p=0.046). Low tumor burden on PET/CT was associated with overall response (CR or PR) vs PD (p=0.026) but not with a CR (p=0.13). High tumor burden was not associated with the development of any grade CRS (p=0.83) or neurotoxicity (p=0.18).

Table 1

Demographics and outcomes	n=15
Age, median (range)	56 (47 – 69)
Sex	80% male (n=12) 20% female (n=3)
Disease	DLBCL 60% (n=9) MCL 40% (n=6)
Lines of prior therapy, median (range)	7 (3-11)
Prior autologous HCT	53% (n=8)
Prior allogeneic HCT	20% (n=3)
Prior CAR T-cell therapy	7% (n=1)
Pre-CAR-T tumor lesion glycolysis (TLG), median (range)	592 (3 – 9775)
Received bridging therapy	67% (n=10)
Days between pre-CAR-T PET/CT and LDC, median (range)	19 (11 – 43)
LDH (U/L) at day 0 of LDC, median (range)	228.5 (142 - 863)
Day 28 response	CR 53% (n=8) PR 20% (n=3) PD 27% (n=4)
CRS	60% (n=9)
Grade ≥3 CRS	7% (n=1)
Neurotoxicity	27% (n=4)
Grade ≥3 Neurotoxicity	7% (n=1)

Summary/Conclusion: This is the first study demonstrating that baseline tumor burden (by TLG on PET/CT) correlates with clinical outcomes in the context of bispecific CAR T-cells for NHL. Moreover, both patients with CR and CR+PR had a significantly lower baseline LDH than patients who had PD +/- PR on day 28 scans. Interestingly, baseline tumor burden did not correlate with development of CRS or neurotoxicity with bispecific LV20.19 CAR T-cells. In single targeted CD19 CAR T-cells, high baseline tumor burden has previously been correlated with toxicity as well as lower response rates. In our LV20.19 experience, overall CRS and neurotoxicity rates were low and the low overall incidence

may limit statistical power to detect an association with tumor burden. With accumulating evidence that higher pre–CAR-T tumor burden is associated with inferior response rates, developing novel approaches to debulk patients safely prior to CAR-T is indicated.

EP536 IMPACT OF TP53 AND RECURRENT SOMATIC MUTATIONS ON THE OUTCOMES OF DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH ANTI-CD19 CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY (CAR-T)

V. Phuoc [1,*], T. Knepper [2], M. Jain [3], F. Khimani [3], A. Lazaryan [3], T. Nishihori [3], J. Pinilla [1], B. Shah [1], F. Locke [3], J. Chavez [1]

[1]Malignant Hematology, [2]Individualized Cancer Management, [3]Blood and Marrow Transplant and Cellular Immunotherapy, H. Lee Moffitt Cancer Center & Research Institute, Tampa, United States

Background: Diffuse large B-cell lymphoma (DLBCL) exhibits clinical and molecular heterogeneity, and prior studies identified genetic subtypes of DLBCL associated with different trends in response rates and survival. Chimeric antigen receptor T-cell therapy (CAR-T) is approved for the treatment of relapsed/refractory (R/R) DLBCL, but relapses post-CAR-T still occur. Clinical and biological predictors of response to CAR-T remain unclear.
Aims: We investigate the impact of pre-CAR-T next generation sequencing (NGS) results in outcomes of R/R DLBCL post-CAR-T.
Methods: This is a single center experience of R/R DLBCL patients treated with CAR-T between 1/1/2017 and 12/31/2019 who had NGS results via Foundation Medicine (FoM) platform available from prior to CAR-T infusion. The primary objective was to identify predictive mutation profiles with endpoints of overall response rate (ORR), complete response (CR), day 90 CR, and 3-month progression rate. Progression free survival (PFS) probability was calculated with log-rank testing and Kaplan Meier method. Outcomes compared based on NGS results included *TP53* mutation (*TP53mut*) versus wild-type (*TP53wt*), presence of *CDKN2A/B* loss, *BCL2* rearrangements, and tumor mutation burden (TMB).
Results: We identified 15 patients with DLBCL who had available NGS results prior to receiving CAR T-cell infusion. Fourteen out of 15 (93%) received axicabtagene ciloleucel, and 1/15 (7%) received tisagenlecleucel. Median age at time of CAR-T was 65 years (range 33-81 years), and 5/15 (33%) were female. FoM specimens were from tumor in 14/15 (93%) and peripheral blood in 1/15 (7%). The most common mutations identified were *TP53mut* in 7/15 (47%), *BCL2* rearrangements in 7/15 (47%), and *CDKN2A/B* loss in 5/15 (33%). TMB was low (0-5) in 4/15 (27%), intermediate (6-10) in 4/15 (27%), and high (> 10) in 6/15 (40%). One TMB could not be determined.
Outcomes are depicted in Table 1. Best ORR and CR rates were 13/15 (87%) and 8/15 (53%) respectively. ORR (CR) rates were 100% (71%) for *TP53mut* and 75% (38%) for *TP53* wild-type (*TP53wt*). Day 90 CR rates were 71% for *TP53mut* and 13% for *TP53wt*. At last follow-up, 8/8 (100%) *TP53wt* progressed, but only 2/7 (29%) *TP53mut* progressed with 5/7 (71%) remaining in CR. The 3-month progression rate was 2/7 (29%) for *TP53mut* and 6/8 (75%) for *TP53wt* with significantly higher PFS probability in *TP53mut* patients (p = 0.002). The 3-month progression rates for *CDKN2A/B* loss and wild-type were 5/5 (100%) and 3/10 (30%) respectively with lower PFS probability in patients with *CDKN2A/B* loss (p<0.001). There was no significant difference in PFS based on *BCL2* rearrangement or TMB.
There was no significant difference in patients' age, gender, lactate dehydrogenase, international prognostic index score, extranodal disease, stage, number of prior lines of therapy, history of autologous stem cell transplant, or frequency of bridging therapy between *TP53*, *CDKN2A/B*, and TMB groups.

Table 1: Responses by Mutation for DLBCL Post-CAR-T

Mutation	# Patients n (%)	ORR n (%)	CR Day 90 n (%)	Progressed Post-CART n (%)
All Patients	15 (100%)	13 (87%)	6 (40%)	10 (67%)
TP53mut	7 (47%)	7 (100%)	5 (71%)	2 (29%)
TP53wt	8 (53%)	6 (75%)	1 (13%)	8 (100%)
CDKN2A/B loss	5 (33%)	3 (60%)	0 (0%)	5 (100%)
CDKN2A/Bwt	10 (67%)	10 (100%)	6 (60%)	5 (50%)
TMB 0-5	4 (27%)	4 (100%)	3 (75%)	2 (50%)
TMB 6-10	4 (27%)	3 (75%)	2 (50%)	2 (50%)
TMB > 10	6 (40%)	5 (83%)	1 (17%)	5 (83%)

Summary/Conclusion: In this small dataset, our findings show a potential prognostic role of NGS in R/R DLBCL treated with CAR-T. Significant differences were seen with better outcomes post-CAR-T associated with the presence of *TP53* mutations and worse outcomes with *CDKN2A/B* loss. Improved responses with *TP53mut* may be related to higher T-cell infiltration, tumor inflammation signature, expression of immune checkpoints, and tumor microenvironment changes that have been reported in *TP53mut* acute myeloid leukemia (Vadakekolathu J et al. *Blood Adv* 2020). Larger studies are needed to further characterize the impact of NGS and molecular changes on outcomes in DLBCL post-CAR-T.

EP537 CHIDAMIDE PLUS CHOP VERSUS CHOP AS FRONTLINE TREATMENT IN PERIPHERAL T CELL LYMPHOMA: A RETROSPECTIVE CASE-CONTROL STUDY

Q. Cai [1,2,*], N. Su [1,2], Y. Fang [1,2], J. Wang [1,2], X. Tian [1,2], S. Ma [1,2], J. Cai [1,2], Y. Zhang [1,2], H. Huang [1,2], Z. Li [1,2], H. Huang [1,2], Y. Xia [1,2], P. Liu [1,2]

[1]Department of Medical Oncology, [2]State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Peripheral T-cell lymphoma (PTCL) is a heterogeneous group of aggressive non-Hodgkin lymphoma. The most common frontline regimen for PTCL is cyclophosphamide, doxorubicin, vincristine, and prednisone (CHOP) or CHOP-like regimens. Several histone deacetylase inhibitors(HDACi) have been approved for relapsed and refractory PTCL patients(pts). Chidamide is a novel and orally active benzamide class of HDACi, which has been approved for treatment of PTCL after failure of at least one prior systemic therapy in China. However, whether the frontline treatment with combination of HDACi andCHOP could benefit PTCL is still controversial.
Aims: To retrospectively evaluate the efficacy and safety of chidamide plus CHOP versus CHOP as the frontline treatment for PTCL.
Methods: Medical records of 408 PTCL pts in Sun Yat-sen University Cancer Center between January 2014 and July 2020 were reviewed. We included newly diagnosed PTCL pts treated with chidamide plus CHOP(C-CHOP) or CHOP alone as frontline treatment. Pts with insufficient clinical data or treated with other regimens were excluded. A total of 22 C-CHOP pts and 22 CHOP-based controls were included after a 1:1 ratio case-control matching procedure was conducted, according to International Prognostic Index (IPI). Chidamide was administered at 20 mg, P.O., twice per week. Pts achieving complete response (CR) or partial response (PR) were arranged to chidamide maintenance treatment. Overall response rate(ORR), progression free survival (PFS), overall survival (OS) and adverse events (AEs) were analysed. Baseline clinical characteristics were compared using non-parametric test, $\chi 2$ test or Fisher's exact test. Survival outcomes were assessed with Kaplan-Meier method. All statistical analyses were performed using SPSS v.24.0 software (IBM SPSS Statistics). A P value < 0.05 was considered significant.
Results: Median age of C-CHOP and CHOP group were 54.5 years (range 27-78) and 56.0 years (range 32-86) respectively. After matching, 10 female pts(45.5%) and 11 female pts (50%) were included in C-CHOP and CHOP alone group respectively. 31.8% (7/22) pts and 68.2%(15/22) pts were IPI 0-1 and IPI≥2 respectively in both groups. Baseline clinical characteristics were well balanced between two groups (P>0.05, Table 1). ORR of patients in C-CHOP group versus CHOP group was 86.4% versus 76.3%, with CR rate of 68.2% versus 59.1%(P>0.05). With a median follow-up of 22.3 months (range, 5.3–23.1 months), PFS of patients in C-CHOP group showed a statistically significant improvement versus CHOP group. Median PFS of patients in C-CHOP group versus CHOP group was not reached versus 14.2 ± 5.7 months(P=0.035, Figure 1A). However, no benefit in OS was found when CHOP was combined with chidamide in frontline treatment (not reached versus 53.1, P=0.783, Figure 1B). Most grade 3–4 AEs in C-CHOP or CHOP group were hematological toxicity, including neutropenia (36.4% versus 22.7%), thrombocytopenia (22.7% versus 9.0%) and anemia (22.7% versus 4.5%) (P>0.05).

Table 1 Baseline clinical characteristics

Charactersitics	Chidamide + CHOP (n=22)	CHOP (n=22)	P value
Age (years)			
Median	54.5	56.0	0.217

< 70%	14(63.6%)	13(59.1%)	
≥70%	8(36.4%)	9(40.9%)	

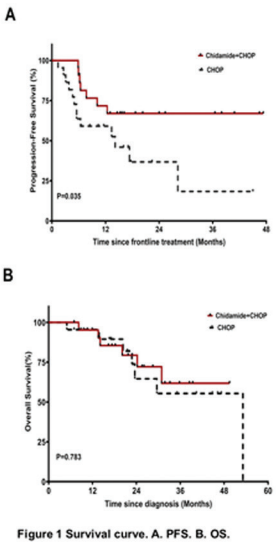

Figure 1 Survival curve. A. PFS. B. OS.

Summary/Conclusion: Our preliminary data suggests that the addition of chidamide 20mg twice per week to frontline CHOP regimen is effective and well-tolerated in PTCL. Although chidamide plus CHOP may prolong PFS in PTCL, no benefit in OS and ORR were observed. The hematological toxicity of chidamide plus CHOP should be cautioned. The combination of chidamide and CHOP as frontline treatment for PTCL deserves further extended clinical trial.

EP538 HIGH PREVALENCE OF CONSTITUTIONAL MISMATCH REPAIR DEFICIENCY IN A PEDIATRIC T-CELL LYMPHOBLASTIC LYMPHOMA COHORT

E. Kroeze [1,*], J. Meijerink [1], M. Hagleitner [1], D. Weijers [1], H. de Groot-Kruseman [1], M. Jongmans [1], R. Kuiper [1], R. Pieters [1], J. Loeffen [1]

[1]Princess Máxima Center, Utrecht, Netherlands

Background: Pediatric T-cell lymphoblastic lymphoma (T-LBL) arises from the malignant transformation of immature T-cells. T-LBL is characterized by massive infiltration of blasts in the mediastinum and lymph nodes mostly without or occasionally with low percentages of blasts in the bone marrow (<25%). Patients are assigned to different treatment regimens based on Murphy staging, which is determined by disease localization and dissemination. These treatment protocols have not been essentially changed over the last decades, showing the need to improve our knowledge on T-LBL.

Aims: This study investigated the clinical characteristics and the occurrence of secondary malignancies and comorbidities in an unselected cohort of pediatric T-LBL patients.

Methods: We present a retrospective pediatric T-LBL cohort (n=88) for patients who were diagnosed between January 2007 and September 2020 and who were treated according to the EURO-LB02 protocol in one of the former pediatric oncology centers in the Netherlands.

Results: Median age at diagnosis for this T-LBL cohort was 9 years (range 0-18), with a male to female ratio of 1.7:1. Disease localizations mainly involved the mediastinum which was enlarged in 94% of the patients and enlarged lymph nodes in 68% of the patients. Nine percent of the patients had evidence of blast infiltration in the bone marrow (BM) (range 5-16% blasts). Two patients presented with CNS3 and had more than 5 white blood cells/µl (WBC) in the cerebral spinal fluid (CSF), whereas nine patients presented with CNS2 and having less than 5 WBC/µl CSF fluid. In total 10.2% (9/88) of the patients were diagnosed with a cancer predisposition syndrome, almost exclusively constitutional mismatch repair deficiency (CMMRD) (8/88), based on their presentation with multiple café-au-lait maculae in all patients and a history of previous or secondary cancers in various patients. All CMMRD patients in our cohort had biallelic germline mutations in either *PMS2* or *MSH6*. Clinical and patient characteristics of CMMRD patients at time of T-LBL diagnosis were compared to sporadic T-LBL patients and summarized in **Table 1**. Whereas their clinical presentation was comparable, the percentage of CMMRD patients who had one or multiple enlarged lymph nodes seemed lower than for sporadic patients albeit not significant (p=0.1179). None of the CMMRD patients presented with BM involvement at T-LBL diagnosis in comparison to 25% of sporadic T-LBL patients who had >1% blasts in their BM at time of diagnosis (and 8% having >5% blasts). Two sporadic patients presented with CNS3 while nine patients had CNS2 (9/80) in contrast to none of the CMMRD patients, indicating that the T-LBL manifestation for CMMRD patients is more localized compared to sporadic T-LBL patients. Currently, the presence of preceding or secondary (childhood) malignancies is the main indicator for the presence of an underlying cancer predisposition syndrome. Therefore, diagnosis of a cancer predisposition syndrome is often missed at time of diagnosis of the first (childhood) malignancy, highlighting the alertness of the treating physician as crucial factor for diagnosis.

	T-LBL sporadic n=80	T-LBL CMMRD n=8
Age year (median, range)	9 (0-18)	10 (0-16)
Sex (n)		
Male	50	5
Female	30	3
Localizations (n, %)		
Mediastinal enlargement	75 (94)	8 (100)
LN involvement	55 (68)	3 (38)
Bone marrow involvement (n, (%))		
1-4%	15 (19)	0 (0)
≥5%	7 (9)	0 (0)
CNS status (n, (%))		
CNS1	58 (84)	8 (100)
CNS2	9 (13)	0 (0)
CNS3	2 (3)	0 (0)

Summary/Conclusion: This study describes the high prevalence of CMMRD patients in a complete T-LBL cohort. As the frequency of an underlying predisposition syndrome among T-LBL patients may be underestimated at present, we advocate for screening all pediatric T-LBL patients with café-au-lait maculae for the presence of germline mutations in mismatch repair genes.

EP539 CLINICAL OUTCOMES IN PATIENTS WITH RELAPSED/REFRACTORY LARGE B-CELL LYMPHOMA RECEIVING CONVENTIONAL THIRD-LINE THERAPY: A MULTICENTER, RETROSPECTIVE, REAL-WORLD STUDY IN THE UNITED KINGDOM

C. Fox [1,*], W. Townsend [2], J. Gribben [3], T. Menne [4], N. Kalakonda [5], J. Lynes [6], P. Williams [6], C. Parker [7], K. Noon [7], M. Cooper [8], J. Radford [9]

[1]Nottingham University Hospitals NHS Trust, Nottingham, [2]University College Hospital, [3]St Bartholomew's Hospital, London, [4]Newcastle Upon Tyne Hospitals NHS Trust, Newcastle, [5]University of Liverpool, Liverpool, [6]Celgene, a Bristol-Myers Squibb Company, [7]Bristol Myers Squibb Pharmaceuticals Ltd, Uxbridge, [8]BresMed Health Solutions, Sheffield, [9]The Christie NHS Foundation Trust and the University of Manchester, Manchester, United Kingdom

Background: Large B-cell lymphomas (LBCLs), including diffuse LBCL (DLBCL), primary mediastinal B-cell lymphoma (PMBCL), and transformed follicular lymphoma (tFL), are treated with combination chemoimmunotherapy at diagnosis. First-line treatment can result in a cure in approximately 60% of cases; however, 10%–15% of patients do not respond and a further 20%–25% relapse. For those patients with

chemotherapy-sensitive disease who relapse, autologous hematopoietic stem cell transplantation (auto-HSCT) is an option. For patients who are ineligible for or relapse post–auto-HSCT, the prognosis is poor. Less than 50% of patients respond to subsequent third-line (3L) treatment and few are cured. Median overall survival (OS) with 3L conventional chemotherapy treatment is 4–10 months. Few publications report outcomes of patients treated with 3L conventional chemotherapy in the UK.
Aims: To describe real-world clinical outcomes of patients with relapsed or refractory (R/R) LBCL initiating conventional 3L treatment in the UK.
Methods: This multicenter retrospective analysis was conducted across 6 centers in the UK. Eligible patients were ≥18 years of age with a documented diagnosis of LBCL in 2003 or later. Diagnoses included DLBCL not otherwise specified (NOS; de novo or tFL), high-grade B-cell lymphoma with *MYC* and *BCL2* and/or *BCL6* rearrangements with DLBCL histology, follicular lymphoma grade 3B, or PMBCL. Patients had to have received 2 prior lines of systemic treatment, which included an anthracycline and anti-CD20–targeting monoclonal antibody (mAb). Patients with primary central nervous system lymphoma or who had received chimeric antigen receptor (CAR) T cell therapy were excluded. Progression-free survival (PFS) was calculated based on available information for response assessments, receipt of subsequent treatment, and death. PFS and OS were summarized from the start of 3L therapy to progression or death using the Kaplan-Meier method.
Results: A total of 129 patients met the stringent eligibility criteria. The median age of patients was 58 years (range, 22–87 years), 64% were male (n=82), 76% had a disease histology of DLBCL NOS (n=98), 76% had an Eastern Cooperative Group performance status of 0–2 (n=98), and 44 of the 66 patients (67%) who had an International Prognostic Index score had a score of 0–2. The median time from diagnosis to start of 3L treatment was 14.6 months (range, 4–161 months). All patients had received rituximab, 11% received prior auto-HSCT (n=14), and 57% were chemotherapy refractory (n=73). The most common 3L treatment regimens were salvage chemotherapy without an anti-CD20 mAb (44%, n=57), salvage chemotherapy with an anti-CD20 mAb (22%, n=28), salvage chemotherapy followed by auto-HSCT (10%, n=13) or allogeneic HSCT (8%, n=10), pixantrone (4%, n=5), and lenalidomide (4%, n=5), respectively. Clinical and/or imaging assessment data related to 3L treatment was available for 104 patients. The overall response rate was 38% (n=40). Median PFS from the start of 3L treatment was 1.97 months (95% CI, 1.68–2.56 months). Median OS from the start of 3L treatment was 7.00 months (95% CI, 4.73–9.23 months). Additional analyses for patient subgroups will be presented.
Summary/Conclusion: This UK real-world analysis provides insights into clinical practice and highlights the poor outcomes achieved with conventional (non–CAR T cell) 3L treatment options in the UK, demonstrating the need for more effective treatments in patients with R/R LBCLs.

EP540 EARLY GCSF AFTER ANTI-CD19 CAR T-CELLS DECREASES INCIDENCE OF FEBRILE NEUTROPENIA WITHOUT WORSENING TOXICITIES AND EXPANSION OF CAR T-CELLS IN REFRACTORY/RELAPSED B-CELL LYMPHOMA.

R. Lievin [1,*], R. Di Blasi [1], F. Morin [2], E. Galli [1], V. Allain [2], L. Vercellino [3], N. Parquet [4], E. De Kerviler [5], P. Lemaire [6], I. Madelaine [7], J. Larghero [8], S. Caillat-Zucman [2], S. Chevret [9], C. Thieblemont [1]

[1]Hemato-oncology, APHP, Saint-Louis Hospital, Université de Paris, [2]Immunology, [3]Nuclear Medicine, [4]Apheresis, [5]Radiology, [6]Biology - Hematology, [7]Pharmacy, [8]Cell Therapy, [9]Biostatistics, APHP, Saint-Louis Hospital, Paris, France

Background: Anti-CD19 chimeric antigen receptor cells (CAR T) integrated treatment algorithm for relapsed/refractory large B-cell lymphoma (R/R LBCL). GCSF use is controversial regarding safety and efficacy of CAR T-cells and protection towards infection is not established.
Aims: To evaluate safety, cytopenia, infectious risk and expansion with GCSF in patients (pts) with R/R LBCL treated with Tisagenleuclecel (Tisa-cel) or Axicabtagene-ciloleucel (Axi-cel).
Methods: We included 122 pts treated with CAR T-cells (Axi-cel=63, Tisa-cel=59) between 06/2018 and 11/2020. After 03/2019, GCSF administration from Day (D)5 until ANC >1 G/L showed no impact on CAR T-cells safety and efficacy (1). Hence, after 03/2020 systematic GCSF prophylaxis at D2 was proposed. We identified 3 Groups (G) based on GCSF use: 35 pts in G1 did not receive GCSF during first 10 days, G2 included 33 pts who received systematic D2 GCSF and 54 pts in G3 received GCSF between D5-D10 after CAR T. We analyzed neutropenia duration, infection rate during the first 30 days, cytopenia at month (M)1 and M3, CRS and ICANS incidence and CAR T expansion in the whole population and between groups.
Results: Except for older age (median 52 in G1 vs 65 and 62 in G2 and G3, p=.022) and prior median lines of treatment (G1=3, G2=2, G3=2.5, p<.0001), demographics did not differ in groups. A difference was found for ANC (1570 [0;6540] in G1, 990 [0;4820] in G2 and 920 [0;3630] in G3, p=.007) and lymphocyte count (40 [0;410] in G1, 20 [0;790] in G2 and 30 [0;250] in G3, p=.004) at day 0. Hemoglobin and platelet counts were similar (p=.63 and p=.24 respectively). More pts in G2 had abnormal LDH levels at D0 without significance (p=.059). Median follow-up was 9.6 months after CAR T-cells infusion. Median duration of grade 4 neutropenia was 3 days [0;16] in G1, 4 [0;31] in G2 and 5 [0,63] in G3 (p=.11). 75% of pts experienced febrile neutropenia, with a difference between G1 (74%), G2 (58%) and G3 (85%) (p=.018). 34% of pts in G1, 33% pts in G2 and 26% pts in G3 developed infections in the first month, mostly bacterial (23% in total, 20% in G1, 30% in G2, 20% in G3). Viral infection incidence was 15% in G1, 12% in G2 and 13% in G3 (p=.75). Fungal infections occurred in 3% pts in G1, 3% in G2 and 2% in G3 (p=1). 37% of pts had persistent Grade 3 cytopenia at M1 evaluation, neutropenia being the most frequent (29% vs 8% anemia, vs 28% thrombocytopenia). The same pattern was observed at M3 (21% overall, neutropenia 18% vs 1% anemia, vs 9% thrombocytopenia). CRS occurred in 73% pts overall, mostly of grade 1 (46%) and 2 (27%) without difference on prevalence between the 3 groups (p=.93) nor when considering severe CRS (grade 0-1 vs grade ≥ 2) (p=.28). ICANS, mainly of grade 1 (13%), occurred in 25% patients without difference on prevalence (p=.62) nor on severity (p=.88) when comparing the 3 groups. CAR T-cell expansion did not significantly differ among groups (Fig1A). Tisa-cel and Axi-cel pts were analyzed separately. For Tisa-cel, median relative Cmax CAR T/CD3+ T-cells was 4.3% (median absolute 28 CART/µL) without differences in Gs (median 8.6% and 50/µL in G2 and 3.6% and 13/µL in G3, vs 4.3% and 13/µL in G1) (Fig1B). For Axi-cel, median relative Cmax CAR T/CD3+ T-cells was 21.9% (median absolute 32 CART/µL) without differences according to GCSF use (median 16.5% and 26/µL in G2 and median 24% and 53/µL G3, versus median 3.3% and 12/µL in G1)(Fig1B).

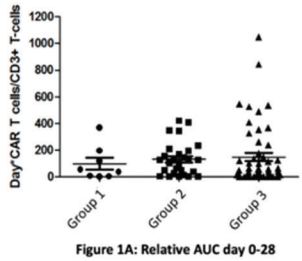

Figure 1A: Relative AUC day 0-28

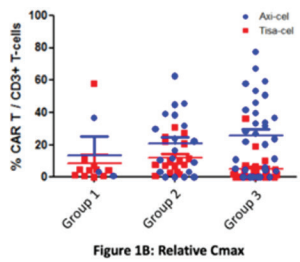

Figure 1B: Relative Cmax

Summary/Conclusion: In our experience, early GCSF administration decreases the incidence of febrile neutropenia, with no impact on severity of CRS, ICANS, and CAR T-cells expansion.

EP541 OUTREACH: PRELIMINARY SAFETY & EFFICACY RESULTS FROM A PHASE 2 STUDY OF LISOCABTAGENE MARALEUCEL (LISO-CEL) IN THE NONUNIVERSITY SETTING

[1]Providence Cancer Center, Earle A. Chiles Research Institute, Portland, [2]Cancer Center of Kansas, Wichita, [3]Colorado Blood and Cancer Institute and Sarah Cannon Research Institute, Denver, [4]Sarah Cannon Center for Blood Cancer, Nashville, [5]Norton Healthcare, Louisville, [6]Intermountain Healthcare, Loveland Clinic for Blood Cancer Therapy, Salt Lake City, [7]Advent Health Blood and Marrow Transplant Program, Orlando, [8]Atlantic Health System, Carol Simon Cancer Center, Morristown, [9]Prisma Health, Greenville, [10]Oncology Hematology Care, Cincinnati, [11]Texas Oncology-Tyler, Tyler, [12]Texas Oncology, Medical City Dallas, Dallas, [13]Willamette Valley Cancer Institute, Eugene, [14]Bristol Myers Squibb, Seattle, [15]Bristol Myers Squibb, Princeton, [16]Sarah Cannon Transplant and Cellular Therapy Program, Methodist Hospital, San Antonio, United States

Background: Concerns about adverse event management related to CAR T cell therapy have resulted in administration of this therapy largely in an inpatient setting. Infusion and monitoring of patients (pts) who

receive CAR T cell therapy at nonuniversity medical centers (NMCs) and in outpatient settings have not been studied specifically.
Aims: To evaluate safety and efficacy of liso-cel in pts with relapsed/refractory (R/R) large B-cell lymphoma (LBCL) across inpatient and outpatient settings at NMCs in OUTREACH (NCT03744676).
Methods: This open-label, multicenter, phase 2 study enrolled adult pts with R/R LBCL at NMCs, including centers naïve to CAR T cell therapy. Eligible pts had R/R PET-positive disease after ≥2 lines of prior systemic therapy, ECOG PS ≤1, and adequate organ function. Prior autologous HSCT was permitted. After leukapheresis and lymphodepleting chemotherapy, pts received sequential infusions of equal target doses of $CD8^+$ and $CD4^+$ cells at a total target dose of 100×10^6 CAR^+ T cells. The primary endpoint was incidence of grade ≥3 cytokine release syndrome (CRS) graded per 2014 Lee criteria, neurological events (NEs), prolonged cytopenias (Day 29 grade ≥3 lab values), and infections. Secondary endpoints were safety and overall response rate (ORR). All study sites had a multidisciplinary CAR T cell therapy team and standard operating procedures (SOPs) for toxicity monitoring/management of pts treated and/or monitored as outpatients.
Results: At data cutoff, 46 pts (inpatients, n = 16, outpatients, n = 30) were treated with liso-cel. Median age was 63 (range, 34–83) y, 63% had diffuse LBCL not otherwise specified, and 91% were refractory to last therapy. Inpatients and outpatients had similar demographics and baseline disease characteristics. CRS was reported in 6 (38%) inpatients and 13 (43%) outpatients, with no grade ≥3 events. NEs were reported in 5 (31%) inpatients and 9 (30%) outpatients, with 1 grade 3 event in the inpatient group and 2 grade 3 events in the outpatient group. Median (range) time to onset of CRS and NEs, respectively, was 2.5 (1–3) and 10 (3–16) days for inpatients and 5 (2–9) and 9 (6–14) days for outpatients. Tocilizumab and/or corticosteroid use for CRS and/or NE management was generally low (inpatients, n = 3 [19%]; outpatients, n = 6 [20%]). Overall, the most common treatment-emergent adverse events (TEAEs) were neutropenia (32, 70%), leukopenia (22, 48%), and anemia (18, 39%). Any grade infections occurred in 3 (19%) inpatients and 8 (27%) outpatients, with 1 grade 3 bacterial infection in inpatients and 5 grade 3–4 pathogen unspecified infections in outpatients. Prolonged cytopenias (grade ≥3 lab values at Day 29) were reported for 2 (13%) inpatients and 9 (30%) outpatients. No grade 5 TEAEs were reported. Early (study Day ≤4) and overall hospitalization in outpatients was reported in 27% and 63%, respectively; median time to hospitalization was 5 (2–61) days and median length of stay was 6 (1–28) days. For efficacy-evaluable pts (n = 44), ORR was 75% for inpatients and 79% for outpatients; CR rates were 50% and 61%, respectively.
Summary/Conclusion: Liso-cel was successfully administered to pts with R/R LBCL in the outpatient setting and pts were monitored for CAR T cell therapy–related toxicities by multidisciplinary teams using SOPs. Incidences of severe CRS and NEs and tocilizumab and/or corticosteroid use were similar in inpatients and outpatients. Data were consistent with pivotal study observations (Abramson, *The Lancet* 2020). Updated data with longer follow-up will be presented.

EP542 CONCURRENT GAIN/AMPLIFICATION OF MYC, BCL2 AND/OR BCL6 GENES BY FLUORESCENCE IN SITU HYBRIDIZATION: ANOTHER SUBGROUP OF HIGH-GRADE B-CELL LYMPHOMA WITH POOR PROGNOSIS?

B. Siska [1,*], H. Devos [1], J. Emmerechts [1], B. Cauwelier [1]

[1]Laboratory Medicine, AZ Sint-Jan Brugge, Brugge, Belgium

Background: Double/triple hit lymphoma (DHL/THL) is classified as high-grade B-cell lymphoma (HGBL) and is known to have a poor prognosis. These lymphomas present with concurrent rearrangements (R) of MYC and BCL2 and/or BCL6, detected by fluorescence in situ hybridization (FISH) (Swerdlow, 2017; Li, 2015; Riedell, 2018). However, little is known about other genetic alterations (e.g. gain (G) or amplification (A)) in these genes and their impact on protein over-expression detected by immunohistochemistry (IHC) and overall survival (OS).
Over-expression of MYC, BCL2 and BCL6 is currently analyzed by IHC and entities with concurrent MYC and BCL2/BCL6 over-expression are called 'double/triple expressor lymphomas' (DEL/TEL) and are classified as DLBCL according to WHO (Swerdlow, 2017). Nevertheless, IHC is subjective and definition of positivity is not universally standardized.
Aims: The aim of this study was is to analyze whether genetic alterations of MYC/BCL2/BCL6 genes other than rearrangements (e.g. gain/amplification) detected by FISH, contribute to the identification of a new subtype of DHL/THL and if these gains/amplifications are correlated with IHC over-expression.
Methods: FISH results from 166 samples between 2011 and 2021 were retrospectively collected and categorized into several groups: 'DHL/THL' (n=29), 'Alternative DHL/THL' (concurrent MYC R and BCL2 and/or BCL6 G/A or concurrent MYC G/A and BCL2 and/or BCL6 R; n=22), 'Lymphomas with concurrent MYC G/A and BCL2 and/or BCL6 G/A' (n=25), 'single BCL2 and/or BCL6 alterations' (R or G/A; n=35) and 'No alterations' (n=55). Available IHC results from these samples (DHL/THL samples excluded; n=82) were divided into 'DEL/TEL' (n=39) and 'No DEL/TEL' (n=43). FISH and IHC results were compared and correlated with OS. All statistical analyses were performed using MedCalc windows (MedCalc Software, Ostend, Belgium). OS was estimated according to Kaplan-Meier and compared by the log-rank test. FISH and IHC results were compared using the Chi-squared test. P values < 0.05 were considered significant.
Results: According to FISH results, patients with 'DHL/THL' and 'Alternative DHL/THL' had significantly worse overall survival while this was not the case for the other groups (Fig. 1A). On the contrary, 'DEL/TEL' determined by IHC had no significant difference in outcome in comparison with samples without double expression (Fig 1B).
There was a significant correlation between BCL2 G/A detected by FISH and protein over-expression detected by IHC (p=0.0212). On the other hand, no statistically significant correlation was seen between MYC/BLC6 FISH G/A detected by FISH and protein over-expression detected by IHC (p=0.5518 resp. p=0.6627).

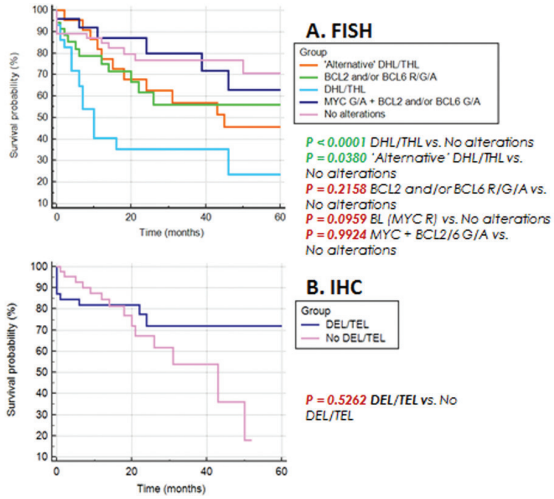

Figure 1. Kaplan-Meier survival curve for overall survival by FISH (A) and IHC (B).

Abbreviations: FISH = fluorescence in situ hybridization – IHC = immunohistochemistry – DHL/THL = double/triple hit lymphoma – R = rearrangement – G/A = gain/amplification – DEL/TEL = double/triple expressor lymphoma

Summary/Conclusion: In the present study, the previously reported adverse prognosis of DEL/TEL (Li, 2015; Riedell, 2019; Huang, 2019; Amrallah, 2019; Ting 2019) could not be confirmed. FISH results, on the other hand, showed that only 'DHL/THL' and 'Alternative DHL/THL', which both carry MYC and BCL2/BCL6 alterations with at least one R, showed worse prognosis. Taken together, samples with only G/A in MYC and BCL/BCL6 are not correlated with adverse outcome. In addition, IHC does not effectively predict the MYC, BCL2 and BCL6 G/A detected by FISH.
In conclusion, FISH remains the golden standard and should always be performed when a HGBL is suspected in order to identify entities with poor outcome, such as 'DHL/THL' and 'Alternative DHL/THL'.

EP543 VENETOCLAX AS SINGLE AGENT IN BCL2-POSITIVE RELAPSED/REFRACTORY PERIPHERAL T-CELL LYMPHOMAS. A PHASE 2 STUDY OF THE FONDAZIONE ITALIANA LINFOMI.

Ematologia, AUSL-IRCCS di Reggio Emilia, Università di Modena e Reggio Emilia, Reggio Emilia, [9]Divisione di Ematologia e Trapianto Cellule Staminali, Istituto Nazionale dei Tumori, Fondazione IRCCS, Università di Milano, Milano, [10]UOC Ematologia, ULSS8 Berica, Vicenza, [11]Ematologia, Ospedale di Circolo e Fondazione Macchi - ASST Sette Laghi, Università degli Studi dell'Insubria, Varese, [12]Unità Complessa di Ematologia, Spedali Civili, Brescia, [13]Area Gestione Dati e Statistica, Fondazione Italiana Linfomi, [14]FIL, Fondazione Italiana Linfomi, Modena, [15]Divisione di Emolinfopatologia, Istituto Europeo di Oncologia IRCCS, Milano, Italy

Background: Relapsed/refractory (R/R) peripheral T-cell lymphoma (PTCL) patients have a poor prognosis with an expected survival of less than one year. Recent acknowledgement in the biology of PTCLs (*Zaja F, et al. Am J Hematol 2016*) lead to identification of BCL2 protein as a potential therapeutic target. Indeed, BCL2 is over-expressed in about 30% to 88% of PTCL patients. Venetoclax is an orally, selective BCL2 inhibitor with proved activity in B-cell malignancies.
Aims: FIL (Fondazione Italiana Linfomi) sponsored an open-label, multicenter, prospective, Simon two-stage, phase II study to determine the efficacy and safety of Venetoclax in R/R BCL2-positive PTCL.
Methods: Patients aged ≥18 years with biopsy-confirmed R/R PTCLs (PTCL not otherwise specified [PTCL-NOS], angioimmunoblastic T-cell lymphoma [AITL] and other nodal T-cell lymphomas of T-follicular helper origin [TFH]) with a percentage of BCL2 positive tumor cells ≥ 25% were included into the study. Venetoclax was administrated after 1 week ramp-up at 800mg once daily on 28-day cycles until progression or unacceptable toxicity. The primary endpoint was to evaluate the overall response rate (ORR) after the first 3 cycles according to the Lugano 2014 criteria. Treatment would have been considered active with an ORR 30% or more (according to the Simon two-stage design: 3 out of 18 patients of stage 1 phase and 7 out of overall 35 patients). Secondary objectives were to further assess the efficacy and to determine the safety of Venetoclax.
Results: Between May 2018 and November 2019, 17 patients were enrolled. Median age was 70 years (range 55-76) with 58.8% of males. Histologies were PTCL-NOS (76.5%) and AITL (23.5%). The majority (64.7%) had stage IV lymphoma and patients had received a median of 2 prior systemic therapies (range 1-15; in 8 patients > 2). ECOG performance status was > 1 in 29% of patients. We observed 1 complete response (6%) (CR) and 2 stable disease (12%) (SD) with an overall therapeutic activity in 3/17 patients (18%); at a median follow up of 8.2 months [0.85-17.5 months] two patients are currently still on treatment (1 CR and 1 SD). Because of the ORR rate < 30%, the enrollment was stopped. The majority of patients (76.4%) interrupted the treatment due to disease progression, all but one within cycle 5 of therapy. Median overall and progression free survival were 8.8 months (7.1-not reached) and 3.6 months (2-3.8), respectively. A total of 12 patients experienced grade 3-4 hematological toxicities: neutropenia (42%), thrombocytopenia (25%) and anemia (25%). Nine patients experienced grade 3 extra-hematological toxicities while no cases of tumor lysis syndrome were registered.
Summary/Conclusion: In this preliminary experience Venetoclax monotherapy showed therapeutic activity in a small proportion of patients with BCL2-positive R/R PTCL, with manageable toxicity. Better understanding of the mechanism of response might allow in the future to select patients to be treated with this agent.
This research was supported by a grant from AbbVie Srl.

EP544 POLATUZUMAB VEDOTIN IN COMBINATION WITH BENDAMUSTINE AND RITUXIMAB IN PATIENTS WITH RELAPSED OR REFRACTORY B-CELL NON-HODGKIN LYMPHOMA: INTERIM ANALYSIS.

O. Smykova [1,*], V. Markelov [1], K. Lepik [1], L. Fedorova [1], E. Borzenkova [1], E. Kondakova [1], L. Stelmakh [1], V. Baykov [1], I. Moiseev [1], N. Mikhailova [1], A. Kulagin [1]

[1]RM Gorbacheva Research Institute, Pavlov University, St. Petersburg, Russia, Saint Petersburg, Russian Federation

Background: The outcomes of relapsed or refractory B-cell non-Hodgkin lymphoma (r/r B-NHL) are very dismal with no standard of therapy. Relapsed or refractory B-NHL are heterogeneous group of lymphoproliferative malignancies with histological, cytogenetic and molecular differences, but all of them have a B-cell receptor. CD79b is a B-cell receptor component and the antibody-drug conjugate polatuzumab vedotin is an anti-CD79b antibody linked to antimitotic agent – monomethyl auristatin E. Polatuzumab vedotin in combination with bendamustine and rituximab (Pola-BR) demonstrated efficacy in patients with r/r B-NHL.
Aims: To evaluate the safety and effectiveness of Pola-BR in patients with r/r B-NHL in real clinical practice.
Methods: This is interim analysisof single-center prospective study evaluates efficacy and safety of Pola-BR for treatment patients with aggressive r/r B-NHL. All patients received bendamustine 90 mg/m2 on days 1 and 2, rituximab 375 mg/m2 on day 1 and polatuzumab vedotin 1,8 mg/kg on day 1 of each 21-day cycle. The PET-CT scan was performed before treatment initiation and after 2, 4, 6 cycles of Pola-BR. The responses were evaluated using Lugano 2014 criteria. Toxicity was graded according to the Common Terminology Criteria for Adverse Events (CTCAE) v 4.03.
Results: Total of 26 patients with relapsed or refractory diffuse large B-cell lymphoma (DLBCL) (n=18), primary mediastinal B-cell lymphoma (PMBCL) (n=7) and gray zone lymphoma (GZL) (n=1) were included. All diagnoses were histologically confirmed. Median age was 43 years (range 20-68). Most of the patients 73% (n=19) had primary chemoresistant disease. The median number of prior therapy lines was 3 (range 2-10). Five patients underwent autologous stem cell transplantation and four patients received anti-CD19 CAR-T cell therapy. At the start of Pola-BR treatment stage III-IV disease had 73% (n=19) patients and 27% (n=7) of patients had bulky disease. Median number of Pola-BR cycles was 4 (range 2-6). Nine patients (35%) completed 6 cycles of Pola-BR. Eight patients (31%) interruptedPola-BR treatment due to disease progression. The overall response rate (ORR) in the group was 61% (n=16) with 46% (n=12) of complete responses (CR) and 15% (n=4) of partial responses (PR). Two patients (8%) had stabilization of the disease as best response. The ORR in patients with DLBCL was 57% (CR 44%), in patients with PMBCL ORR was 57% (CR 43%) and one patient with GZL achieved CR. The ORR in patients with bulky disease was 14% (CR 14%) and ORR 79% (CR 58%) in patients without bulky disease. In patients with relapsed disease ORR was 86% (CR 57%) and in patients with primary chemoresistant disease ORR was 53% (CR 42%). Two patients (50%) with primary CAR-T cell therapy achieved CR. With a median follow up time 6,8 (range 2-12) month overall survival and progression free survival were 71% and 57%, respectively. During Pola-BR treatment grade 3-4 anemia, neutropenia, and thrombocytopenia developed in 19% (n=5), 42% (n=11) and 12% (n=3) patients, respectively. Other adverse events included febrile neutropenia 8% (n=2) and maculopapular rash 8% (n=2). None of the patients had peripheral neuropathy. Two patients with PR died due to Covid-19 infection.
Summary/Conclusion: Our real-life data confirms that Pola-BR has an acceptable toxicity profile and it is
promising method of immunochemotherapy for patients with r/r B-NHL.

EP545 RATIONALE FOR TREATMENT SELECTION, AND COMORBIDITIES IN OLDER PATIENTS (PTS) WITH PREVIOUSLY UNTREATED DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): INSIGHTS FROM REAL WORLD DATA (RWD)

N. Pace [1], A. Shewade [1,*], M. Kent [2], L. Mueller [1], G. Sellam [3], C. O'Hear [1], A. J. Olszewski [4]

[1]Genentech, Inc., South San Francisco, CA, [2]Genesis Research, Hoboken, NJ, United States, [3]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [4]Alpert Medical School of Brown University, Providence, RI, United States

Background: Not all elderly pts with DLBCL will receive first-line (1L) rituximab (R)-CHOP or R-miniCHOP regimens; those who do not may have suboptimal outcomes (Williams et al. Cancer 2015). There is a lack of data regarding comorbidities or other factors (e.g. pt preference) that influence 1L treatment choice.
Aims: To use RWD to describe factors influencing 1L treatment decisions in elderly pts with DLBCL.
Methods: This study used the nationwide Flatiron Health (FH) electronic health record-derived de-identified database. The FH database is longitudinal, comprising de-identified patient-level structured and unstructured data, curated via technology-enabled abstraction. To analyze treatment rationale and pt comorbidities at diagnosis, trained clinical abstractors performed a detailed review of clinic notes. Pts aged ≥71 years at diagnosis, with a DLBCL diagnosis on or after January 1, 2011 and with follow-up until May 31, 2020, were included. Selected pts were untreated, or treated with: R-CHOP (standard dose), reduced-dose R-CHOP (<80% standard dose cyclophosphamide and doxorubicin), R-monotherapy (R-mono), R-Benda, R-CVP or R-Len. We analyzed pt demographics, comorbidities, treatment details and treatment rationale (categorized as: age, comorbidity, disease burden, International Prognostic Index [IPI], pt request, performance status [PS], or other).
Results: Pts (N=404) were aged ≥71 years, 94% were treated in a community setting, 90% had DLBCL-not otherwise specified, and 45% had Stage III/IV disease at diagnosis. A proportion of pts had comorbidities at

diagnosis (anemia: 24.8%; arrhythmia: 19.6%; congestive heart failure: 6.7%; diabetes: 18.3%; hyperlipidemia: 36.6%; hypothyroidism: 14.6%; previous myocardial infarction: 9.7%; chronic kidney disease: 13.4%; previous stroke: 6.9%). Treatments over the study period (n [%]) were: R-Benda (56 [14]); R-CHOP (59 [15]); R-CVP (58 [14]); R-mono (57 [14]); reduced-dose R-CHOP (115 [28]); no treatment (57 [14]). R-Len-treated pts (n=2) were not included due to small sample size available. Median time from diagnosis to 1L treatment was 24 days (interquartile range: 12–39). Overall, 315 treatment rationales were given, with 122 pts having one rationale and 90 pts having ≥2 rationales. Rationale by 1L treatment is shown in the **Table.** Comorbidity was the principal rationale for several pts receiving: reduced-dose R-CHOP (19.1%), R-Benda (26.8%), and R-CVP (34.5%). Age was a reason for attenuated regimen selection in pts receiving: reduced-dose R-CHOP (35.7%); R-mono (36.8%); R-CVP (37.9%). No evidence of a rationale could be found for 86.4% of pts who received the standard-of-care, R-CHOP, potentially indicating that factors related to age or frailty were not significant in the choice of their treatment. In pts not receiving any treatment (systemic therapy or radiotherapy) for whom a rationale was given, this was pt request for 30.4%, and was age, comorbidities, PS, or disease burden for most other pts (>60%).

Table 1. Clinical rationale for treatment assignment by 1L regimen in elderly patients with previously untreated DLBCL

Treatment group	Treatment rationale							
	Age	Comorbidity	Pt request	Disease burden	IPI	PS	Other	No rationale stated
Total (N=404)	24.5%	17.3%	5.0%	4.5%	0.5%	12.1%	2.5%	36.6%
R-CHOP (n=59)	3.4%	1.7%	5.1%	0.0%	0.0%	5.1%	1.7%	86.4%
Reduced-dose R-CHOP (n=115)	35.7%	19.1%	3.5%	6.1%	1.7%	11.3%	3.5%	40.0%
R-CVP (n=58)	37.9%	34.5%	3.5%	5.2%	0.0%	20.7%	0.0%	29.3%
R-Benda (n=56)	21.4%	26.8%	3.6%	3.6%	0.0%	12.5%	5.4%	41.1%
R-mono (n=57)	36.8%	19.3%	15.8%	10.5%	0.0%	24.6%	1.8%	19.3%
No treatment (n=57)	15.8%	12.3%	12.3%	0.0%	0.0%	5.3%	3.5%	50.6%

Benda, bendamustine; CHOP, cyclophosphamide, doxorubicin, vincristine, and prednisone; CVP, cyclophosphamide vincristine prednisone; DLBCL, diffuse large B-cell lymphoma; IPI, International Prognostic Index; mono, monotherapy; PS, performance status; Pt, patient; R, rituximab; 1L, first-line.

Summary/Conclusion: Age, comorbidities and PS are decisive factors in 1L treatment selection for older pts with DLBCL; disease burden or IPI are rarely stated as the rationale. The main reasons for not treating pts appear physician-driven rather than pt-requested, suggesting more pts may receive treatment if physicians have better options. If more tolerable chemotherapy-free options were available, fewer pts may refuse therapy, as illustrated by more R-mono-treated pts requesting their therapy compared with chemotherapy-treated pts. Further analysis of the impact of pt-related factors on treatment decision-making is warranted.

EP546 VALIDATION OF THE BURKITT LYMPHOMA INTERNATIONAL PROGNOSTIC INDEX (BL-IPI) IN PATIENTS FROM TWO CHEMOIMMUNOTHERAPY TRIALS (BURKIMAB-08 AND BURKIMAB-14) BY THE PETHEMA AND GELTAMO GROUPS

Background: The Burkitt Lymphoma International Prognostic Index Consortium has developed an International Prognostic Index for Burkitt Lymphoma (BL-IPI)(J Clin Oncol 2021: DOI https://doi.org/10.1200/JCO.20). From analysis of a cohort of 633 patients (pts) with BL, four independent variables were identified: age >40 yrs, performance status >2, serum lactate dehydrogenase (LDH) >3 x upper limit normal (ULN), and CNS involvement. This score was externally validated in an independent cohort of 457 patients.

Aims: Our objective was to validate this score in two sequential chemoimmunotherapy trials for patients with BL or leukemia (BLL).

Methods: From 2008 to 2020 two consecutive prospective trials of chemoimmunotherapy for patients with BLL (BURKIMAB-08 and BURKIMAB-14, (Ribera et al Cancer. 2013;119:1660-8, Ribera et al Blood 2019;134 (Suppl 1): 2584) were developed by the Spanish PETHEMA and GELTAMO groups. As the complete response (CR) and overall survival (OS) were similar (CR 85% vs. 80%, 5-yr OS 72% vs. 68%), both trials were merged for validation of the BL-IPI.

Results: 277 pts were included (BURKIMAB-08: 185, BURKIMAB-14: 92), median age (range): 47 (15-83) yrs, Burkitt lymphoma: 193 (70%), Burkitt leukemia: 84 (30%), HIV positive: 74 (27%). Age >40 yrs: 181 (65%), performance status ≥2: 105/272 (39%), LDH ≥3 xULN: 129/220 (59%), CNS involvement: 39/276 (14%). The distribution of patients according to the number of risk factors was: 0: 22 (10%), 1: 65 (28%), 2: 85 (37%), 3: 44 (19%), and 4: 14 (6%). With a median (range) follow-up of 5.4 (0.1-15.5) yrs, the 5-yr progression-free survival (PFS) (±95% CI) for the whole series was 69±6%, and the 5-yr OS (±95% CI) was 71±5%. The 5-yr PFS according to risk groups was: low-risk (0 risk factors; 10% of patients; 93 ±13%), intermediate risk (1 risk factor; 28% of patients; 78±11%), and high-risk (≥2 factors; 62% of patients; 54±8%)(p<0.001, Figure 1A). In turn, the 5-yr OS (±95% CI) according to risk groups was: low-risk (0 risk factors; 10% of patients; 93 ±13%), intermediate risk (1 risk factor; 28% of patients; 82±10%), and high-risk (≥2 factors; 62% of patients; 56±8%)(p<0.001, Figure 1B).

Figure 1. Progression free survival (A) and Overall survival (B) by BL-IPI score in the present series

Summary/Conclusion: The outcome of our series of pts with BLL was similar to that of BL-IPI series, making feasible the validation. The distribution of patients according to the number of risk factors, as well as the 5-yr PFS and OS according the BL-IPI risk groups were superimposable to that of the BL-IPI. Consequently the BL-IPI was fully validated in our series of pts with BLL.

Supported in part by grant 2017 SGR288 (GRC) Generalitat de Catalunya and "La Caixa" Foundation.

EP547 EXTRANODAL DISEASE IS AN INDEPENDENT NEGATIVE PREDICTIVE MARKER FOR PROGRESSION-FREE SURVIVAL AFTER CD19-CAR T-CELL THERAPY FOR RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA

V. Bücklein [1,2,*], V. Blumenberg [1,2,3], J. Ackermann [1], L. Frölich [1,3], M. Winkelmann [4], C. Schmidt [1], K. Rejeski [1,2], M. Ruzicka [1,2], N. Müller [1,2], L. von Baumgarten [5], F. Schöberl [6], A. Humpe [7], M. Hildebrandt [7], W. Kunz [4], E. Hoster [8], M. von Bergwelt [1,3], M. Subklewe [1,2,3]

[1]Department of Medicine III, University Hospital, University of Munich, [2]Laboratory for Translational Cancer Immunology, Gene Center, University of Munich, Munich, [3]German Cancer Consortium (DKTK) and German Cancer Research Center, Heidelberg, [4]Department of Radiology, [5]Department of Neurosurgery, [6]Department of Neurology, [7]Department of Transfusion Medicine, University Hospital, University of Munich, [8]Institute for Medical Information Processing, Biometry, and Epidemiology, University of Munich, Munich, Germany

Background: CD19 CAR T cells induce complete remissions in ≥40% of heavily pretreated patients with relapsed/refractory (r/r) diffuse large B-cell lymphoma (DLBCL). However, a significant proportion of patients shows refractory disease or relapses early after therapy. Thus, the identification of predictors of durable responses is of interest not only to guide patient selection, but also to investigate resistance mechanisms and improve efficacy.
Aims: We assessed the predictive value of clinical and laboratory parameters for progression-free survival (PFS) of r/r DLBCL patients treated with CD19 CAR T cells.
Methods: Patient and disease characteristics, toxicities, PET/CT response and survival of r/r DLBCL patients treated with Axicabtagene Ciloleucel or Tisagenlecleucel at our institution were retrospectively assessed. We assessed pre-defined patient and lymphoma characteristics known to confer adverse outcomes in DLBCL for their association with PFS by univariable log-rank tests, as well as multivariable forward stepwise Cox regression analyses. Analysed Characteristics encompassed age, refractoriness to first-line therapy and no. of prior therapy lines. Additionally, tumor volume, presence of bulky disease (>10cm), presence of extranodal disease (END), Ann Arbor stage, IPI, LDH and ECOG, all assessed at time of lymphodepletion, were included in the analysis.
Results: As of November 2020, 41 DLBCL patients have been leukapheresed, and 35 patients have been transfused. Median age was 60 years (range 19-82). ECOG was 0-1 in 23, and 2-3 in twelve patients at time of CAR T-cell transfusion. Only 3 of the 35 transfused patients (9%) would have met the inclusion criteria of the pivotal clinical trials at all timepoints (enrolment, apheresis, and time of lymphodepletion).
CRS occurred in 32/35 patients (80% CRS °1-2, 11% °3). 16 patients (45%) experienced ICANS (29% °1-2, 14% °3-4, and 3% °5). Median follow-up was 4.4 months. Response assessment after three months was available for 34/35 patients. Objective response rate was 53%, with complete remission in 15 (44%) and partial remission in three patients (9%).
In univariable analyses, apart from primary refractory disease (p=0.79), all pre-selected markers were suggestive to be associated with PFS (p=0.002-0.061). We therefore included all variables that were indicative of shorter PFS (p<0.1) in univariable analyses in multivariable AIC-based forward stepwise Cox regression analyses. In the resulting model, presence of END was associated with inferior PFS (Hazard ratio [HR] 11.3, p=0.02), adjusted for prior therapy lines (HR 1.3, p=0.06) and ECOG>1 (HR 2.3, p=0.12). Other variables did not improve the prognostic validity of the model. The relevance of END for PFS was confirmed in additional two-variable Cox regression analyses, each adjusted for one marker from the multivariable model.
Summary/Conclusion: We provide real-world evidence that CD19 CAR T cells induce remissions in a substantial proportion of r/r DLBCL patients, although only 9% of our patients would have met the inclusion criteria of the pivotal trials. In the patient cohort, extranodal disease at transfusion was associated with significantly shorter PFS both in uni- and multivariable analyses. To understand and overcome this potential resistance mechanism, we have set up a comprehensive immunomonitoring program with specific focus on the lymphoma microenvironment in nodal and extranodal sites.

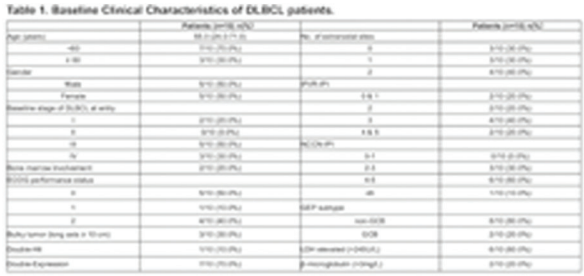
EP548 ZANUBRUTINIB, LENALIDOMIDE PLUS R-CHOP (ZR2-CHOP) AS THE TREATMENT FOR DIFFUSED LARGE B-CELL LYMPHOMA (DLBCL)

H. Zhu [1,2,*], Y. Sha [1,2], W. Wu [1,2], R. Chen [1,2], Y. Yang [2], J. Qiu [2], H. Mi [2], C. Peng [2], C. Ding [1], Z. Wang [1], L. Fan [1,2], W. Xu [1,2], J. Li [1,2]

[1]The First Affiliated Hospital of Nanjing Medical University, [2]Pukou CLL Center, Pukou division of Jiangsu Province Hospital, Nanjing, China

Background: R-CHOP is the standard first-line therapy of DLBCL. Although over half of patients have been cured under R-CHOP, the remaining patients shared poor prognosis with median OS less than 1 year when progression after front-line treatment. Zanubrutinib, a second-in-class inhibitor of BTK, disrupts BCR signaling and decreases NF-κB activity. Lenalidomide is an oral immunomodulatory agent which downregulates IRF4 and MYD88 signaling. Both two drugs have demonstrated activity in DLBCL.
Aims: To evaluate the safety and efficacy of zanubrutinib, lenalidomide plus R-CHOP (ZR^2-CHOP) as the treatment for DLBCL patients, we conducted this single-arm retrospective observational study.
Methods: We enrolled patients aged 18 to 75 years old with high-risk DLBCL (including but not limited to double-hit, double-expression DLBCL). Oral zanubrutinib was given continuously (160mg twice daily) from Day 0, lenalidomide 25mg daily Day 1-7. Patients were administered intravenously rituximab (375mg/m^2 on Day 0), cyclophosphamide (750mg/m^{2}on Day 1), doxorubicin (50mg/m^2 on Day 1), vincristine (1.4mg/m^2 on Day 1), and oral prednisone (50mg/day Day 1-5). All patients were recommended to receive 6 cycles of ZR^2-CHOP (R-CHOP or R^2-CHOP were allowed in cycle 1-2 due to poor physical condition at treatment) and patients older than 70 years old were administered ZR^2-miniCHOP (**Figure 1**). CT or PET-CT scans were conducted to assess mid-term efficacy and assessment after 6 cycles was made by PET-CT scan. ctDNA was dynamically detected before treatment, after 3 cycles and 6 cycles to evaluate tumor mutational burden. The primary endpoint was complete response ratio (CRR) after mid-term and 6 cycles. The secondary endpoint was overall response rate (ORR), ctDNA and the number of adverse events (AE). AEs were graded based on CTCAE (version 5.0).
Results: 10 DLBCL patients diagnosed in Pukou CLL Center were enrolled in this cohort between July 2020 and February 2021, with 9 treatment-naïve DLBCL and 1 Relapsed/Refractory DLBCL (PD after 4 cycles of bendamustine plus rituximab). The median age of patients was 55 years old and all patients had ECOG-PS ≤2. 1 patient (1/10) was diagnosed as double-hit DLBCL and 7 patients (7/10) as double-expression. 8 patients were non-GCB and 2 were GCB. 7 patients (7/10) were classified as high-intermediate and high-risk group according to NCCN-IPI (**Table 1**). At data cutoff (1st March, 2021), the median follow-up was five months (3-8 months) with all patients have completed at least 3 cycles and mid-term assessment could be conducted. The ORR was 100.0%, with 9 patients achieved CR (9/10) and 1 patients achieved PR (1/10). ctDNA was dynamically detected in five patients. The median number of baseline somatic mutation was 5 and all 5 patients showed undetectable ctDNA after 3 cycles. 4 patients have received 6 cycles, all of them achieved CR (4/4) and undetectable ctDNA (4/4) (**Figure 1**). The most common hematological toxicity events were lymphocytes count decreased, neutrophil count decreased, thrombocytopenia and anemia, with 3-4 level occurrence rate was 70.0%, 30.0%, 20.0% and 20.0%. The most common non-hematological toxicity events were nausea and fatigue. One patients discontinued oral zanubrutinib and lenalidomide more than seven days due to drug rash.

Table 1. Baseline Clinical Characteristics of DLBCL patients.



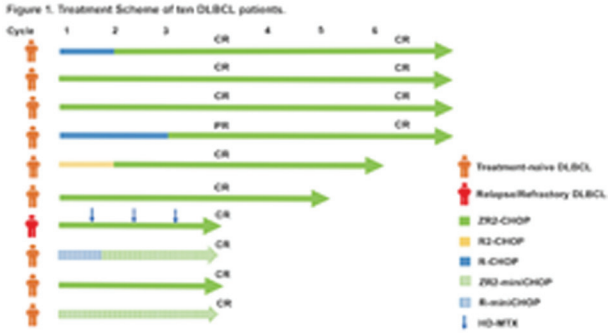


Figure 1. Treatment Scheme of ten DLBCL patients.

Summary/Conclusion: ZR²-CHOP for high-risk DLBCL patients with fair physical condition could achieve high CRR and high proportion of early-stage undetectable ctDNA. The overall tolerability was under control. ZR²-CHOP could be one of the promising choice for the treatment of high-risk DLBCL.

EP549 COMPARISON OF CHIDAMIDE-CONTAINED TREATMENT MODALITIES VERSUS CHEMOTHERAPY IN RELAPSED OR REFRACTORY PERIPHERAL T-CELL LYMPHOMA

Q. Cai [1,2,*], J. Wang [1,2], N. Su [1,2], Y. Fang [1,2], X. Tian [1,2], S. Ma [1,2], J. Cai [1,2], Y. Zhang [1,2], H. Huang [1,2], Z. Li [1,2], H. Huang [1,2], Y. Xia [1,2], P. Liu [1,2]

[1]Department of Medical Oncology, [2]State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Peripheral T-cell lymphoma(PTCL) are characterized by an aggressive clinical behavior. Outcome and treatment options for relapsed or refractory (RR) PTCL patients are poor. Chidamide, an oral novel histone deacetylase inhibitor, has been approved for the treatment of RR PTCL in China.
Aims: We compared the efficacy of chidamide-contained regimens with chemotherapy in RR PTCL patients, in order to identify potentially effective regimens for this cohort.
Methods: We collected the clinical data of ninety-six RR PTCL patients managed in Sun Yat-sen University Cancer Center from January, 2014 to July, 2020. retrospectively. Eligibility criteria included those with R/R disease who had received one prior systemic therapy. Based on the first retreatment regimen, patients were divided into three groups, including chemotherapy(ChT), chemotherapy combined with chidamide(chidamide+ChT) and chidamide combined with or without other targeted agents (targeted therapy) group. Progression-free survival(PFS), overall survival(OS), overall response rate(ORR) and complete response(CR) among three groups were compared. Statistical analysis was performed using IBM SPSS Statistics software (version 24.0). Clinicopathological variables of three treatment groups were assessed by $\chi 2$ test or Fisher' s exact test. Survival curves were plotted using the Kaplan-Meier method and were compared using the log-rank test, with P <0.05 considered to be statistically significant.
Results: The median follow up time was 20.1 months (range, 4.5-162.4 months). Baseline characteristics of these patients, including the median age, gender, second-line International Prognostic Index (IPI), subtypes of PTCL, CD30 expression and EBV infection, were listed in Table 1. ChT group included more patients with PTCL-NOS, targeted therapy group included more paitents with AITL, other characteristics were well balanced across treatment groups. Chidamide+ ChT group had a significantly better PFS (p=0.046, Figure 1). Median PFS for Chidamide+ChT group was 4.5 months (range 0.4-35.4 months), compared with 3.5 months (range 0.5-65.8 months) for the ChT group and 1.8 months (range 0.4-13.6 months) for the targeted therapy group. No difference in OS was observed(p=0.912, Figure 2). Among patients with high second-line IPI(3-5), there was a significant difference in PFS among three groups(p=0.045, Figure 3). Among patients younger than 60 years, chidamide+ChT group demonstrated a PFS benefit (p =0.027, Figure 4) over other groups. In the subgroup of CD30(-) patients, PFS was superior in the Chidamide+ChT group as compared with other groups (p =0.002, Figure 5). In contrast, there was no statistical difference between the three groups in patients with low second-line IPI (0-2) (p=0.075), or patients older than 60 years (p=0.446) or CD30(+) patients (p =0.575). We found a trend for improved OS for patients with high second-line IPI who received chidamide+ChT as compared with ChT(p=0.188, Figure 6).The ORR for patients in ChT group, chidamide+ChT group and targeted therapy group were 54.8% 64.9% and 64.7%(p=0.607), respectively, with CR rate of 16.7% 18.9% and 35.3%(p=0.262).

Table1.Baseline characteristics of 96 R/R PTCL pts

Characteristics	Overall n=96 (%)	ChT n=42(%)	Chidamide+ChT n=37(%)	Targeted therapy n=17(%)	P
Median age (range)	57(25-90)	55(30-77)	56(29-76)	65.5(25-90)	0.225
Gender					0.680
Male	62(64.6%)	28(66.7%)	22(59.5%)	12(70.6%)	
Female	34(35.4%)	14(33.3%)	15(40.5%)	5(29.4%)	
IPI2					0.841
0	7(7.3%)	4(9.5%)	3(8.1%)	0	
1	23(24.0%)	11(26.2%)	8(21.6%)	4(23.5%)

AITL	22(22.9%)	4(9.5%)	11(29.7%)	7(41.2%)	
ALCL,ALK-	7(7.3%)	2(4.8%)	4(10.8%)	1(5.9%)	
ALCL,ALK+	4(4.2%)	0	3(8.1%)	0	
EATL	6(6.3%)	4(9.5%)	1(2.7%)	1(5.9%)	
SPTCL	6(6.3%)	3(7.1%)	3(8.1%)	0	
Others	8(8.3%)	3(7.1%)	3(8.1%)	3(17.6%)	
CD30					0.535
Positive	45(46.9%)	21(50.0%)	19(51.4%)	5(29.4%)	
Negative	34(35.4%)	15(35.7%)	12(32.4%)	7(41.2%)	
Unknown	17(17.7%)	6(14.3%)	6(16.2%)	5(29.4%)	
EBV					0.125
Positive	35(36.5%)	12(28.6%)	14(37.8%)	9(52.9%)	
Negative	53(55.2%)	28(66.7%)	19(51.4%)	6(35.3%)	
Unknown	8(8.3%)	2(4.8%)	4(10.8%)	2(11.8%)	

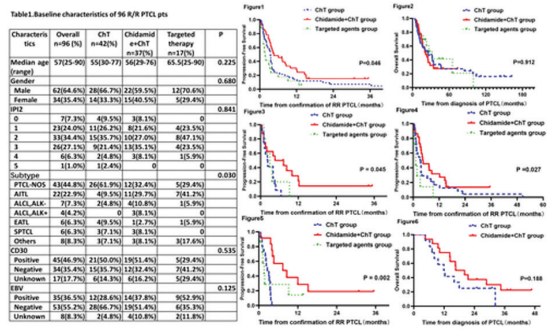

Figure1. PFS curve based on types of therapies; Figure2. OS curves based on types of therapies; Figure3. PFS curves of patients with high second-line IPI(3–5) based on types of therapies; Figure4. PFS curves of patients younger than 60 years based on types of therapies; Figure5. PFS curves of CD30(-)patients based on types of therapies; Figure6. OS curves of patients with high second-line IPI(3–5) based on types of therapies.

Summary/Conclusion: Despite this retrospective study with a small sample size, first retreatment with chidamide+ChT regimen showed more PFS benefit than ChT and targeted therapy for RR PTCL patients, especially those with high second-line IPI, younger than 60 years and CD30(-). The combination of chidamide with ChT may be an effective treatment strategy for RR PTCL patients but requires further investigation.

EP550 CELL OF ORIGIN IMPACTS DELTASUVMAX CUTOFF FOR PREDICTION OF RELAPSE IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL)

C. Feres [1,*], G. F Perini [2], L. Arcuri [1], L. Teixeira [2], M. Kerbauy [1], D. Pasqualin [3], N. Hamerschlak [1]

[1]Hematology, [2]Hospital Israelita Albert einstein, São Paulo, Brazil, [3]Pathology, Hospital Israelita Albert einstein, São Paulo, Brazil

Background: The role of interim positron emission tomography (PET) as a predictor for progression free survival (PFS) in patients with DLBCL remains controversial. The incorporation of volumetric and quantitative parameters aims to improve the identification of patients with high risk for treatment failure. Recently, the role of delta SUVmax, defined as a reduction between the maximum uptake at initial PET and interim PET(iPET) has been tested as a predictor of PFS. In most studies, a cutoff of 66% reduction successfully identified patients at high risk for treatment failure.
Aims: We aimed to analyze the role of DeltaSUVmax in predicting relapse in a cohort of Brazilian patients with DLBCL, and the impact of cell of origin (COO) in this analysis.
Methods: We retrospectively analyzed a cohort of patients with DLBCL from Sao Paulo, Brazil. All diagnoses were made by the same hemepathologists, and COO was defined using Hans algorithm. PET scans were obtained at baseline and after 2-3 cycles of therapy (iPET). All PET-CTs were read by the same physician, blinded for the COO and other clinical features. Delta SUVmax was calculated by the difference in % between initial PET SUVmax and iPET. Event free Survival was defined as the time from diagnosis to the time to progression or death.Initially a cut off 66% reduction was used for analysis, but due to low number of patients not achieving a 66% reduction in the activated B cell (ABC) subgroup, the optimal cutoff was selected based on the ROC curve.
Results: A total of 54 patients were available for analysis. Median age of all patients was 61 years old, and 61% of patients had a germinal center B-Cell (GCB) phenotype. The median maximum uptake at baseline was 31 for the germinal B-cell (GCB) and 34.1 for the activated B-Cell (ABC) phenotype. For all patients, ΔSUVmax <66 was strongly related to relapse (HR=0.065, p=0.0005). In the GCB cohort (n=33), ΔSUVmax <66 was also strongly related to relapse (H=0.02, p=0.0004). In the ABC cohort (n=21), only one patient failed to achieve ΔSUVmax>66. A ROC curve identified a ΔSUVmax>90 as a better cutoff for relapse, and patients not achieving 90% reduction had a higher risk for relapse (p=0.03). MYC/Bcl-2 expression was also compared, and ΔSUVmax <66 was related to events in both double-expressors (DE, p=0.0003) and in non-DE (p=0.036).
Summary/Conclusion: A reduction <66% in SUVmax from baseline PET to iPET was strongly related to the risk of relapse in a cohort of 54 patients with DLBCL. However, the cutoff of 66% was only significant in patients with GCB DLBCL, mostly due to the low number of ABC patients who did not reach a 66% in SUVmax. For ABC patients, a ΔSUVmax>90 improved the identification of patients at high risk for relapse. Larger cohorts of patients are needed to validate our exploratory findings.

EP551 COMPARISON OF IMMUNOCHEMOTHERAPY WITH RITUXIMAB-DOSE-ADJUSTED EPOCH (R-DA-EPOCH) OR RITUXIMAB-CHOP (R-CHOP) IN PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA (PMLBCL)

T. Vassilakopoulos [1,*], Z. Mellios [2], E. Verigou [3], S. Papageorgiou [4], C. Chatzidimitriou [1], C. Kalpadaki [5], E. Katodritou [6], H. Giatra [2], V. Xanthopoulos [7], G. Gainaru [7], E. Background: Further to the impressive results with R-da-EPOCH in a phase 2 NCI trial, retrospective comparisons have shown a modest, non-significant benefit in disease control but also a reduced need for consolidative radiotherapy (RT) administration with R-da-EPOCH vs R-CHOP in PMLBCL. However, the choice of treatment was at the discretion of the treating physician, inevitably introducing systematic bias.
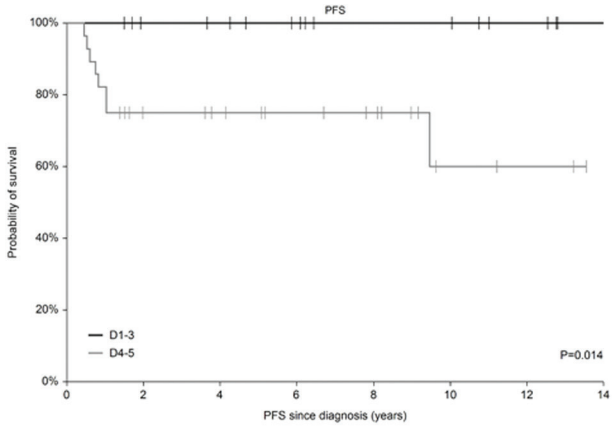
Aims: To compare the efficacy of R-da-EPOCH vs R-CHOP with an as much as possible unbiased selection of controls and to investigate the physicians' compliance with the dose escalation protocol in routine practice.
Methods: R-da-EPOCH was adopted as the treatment of choice in all consecutive patients with PMLBCL <60 years (n = 86) in 16 participating Centers in Greece, all of which administered R-CHOP as standard of care until then. The first control group (CG) of R-CHOP-treated patients (CG-1) was devised without any bias from the same Centers' patient database, selecting in reverse chronological order an equal number of patients to those treated with R-da-EPOCH at the same Center if possible, thus minimizing selection bias. Due to lack of an equal number of controls (13 patients less in the R-CHOP arm) and the administration of R-CHOP-14 to 18 patients in 5/16 Centers, the core group of 55 patients was maintained (86-13-18=55) and 2 more R-CHOP-21 CGs were devised. In CG-2, the 31 missing patients were replaced by 27 patients all treated at Nicosia General Hospital, Cyprus. In CG-3, 29 consecutive patients from 4 already participating Centers of similar care services capacity to the 4/5 aforementioned Centers were included, and 2 from another similarly suitable Center. Hence, all 86 CG-3 patients had received R-CHOP-21 and were consecutively selected from a previously created patient list.
Results: The groups of R-da-EPOCH-treated patients and R-CHOP CG-1 (n = 73), CG-2 (n = 82) and CG-3 (n = 86) were comparable at baseline except for worse PS in the former. Two patients developed acute myeloid leukemia (AML) 10.4 and 22 months after starting R-da-EPOCH and having reached dose escalation levels 6 and 4, respectively. The 5-year freedom from progression (FFP), event-free survival (EFS) and overall survival (OS) rates did not differ significantly and are shown in table 1 [there was a marginal difference regarding FFP only in comparison to CG-3 (p = 0.06)], while RT was administered to far fewer potentially eligible for RT patients in the R-da-EPOCH group. In the multivariate analysis of FFP, the difference between R-da-EPOCH and R-CHOP remained non-significant when comparing to CG-1 and CG-2 but became statistically significant when compared to CG-3 [p = 0.035, HR = 0.40 (0.16 - 0.94)]. Only 40 (61%) out of the 65 patients who had completed R-da-EPOCH and had available data received the regimen completely according to the protocol, reflecting real-world data on R-da-EPOCH administration. These patients had a 5-year FFP ratio of 92% and 55% of them had reached ≥4 dose escalation level (Table 1), similarly to the original NCI study.

Table 1. Comparison of efficacy and long-term complications between R-da-EPOCH-treated patients and 3 patient control groups (CGs) receiving R-CHOP.

	R-da-EPOCH	R-CHOP (CG-1)	p (CG-1)	R-CHOP (CG-2)	p (CG-2)	R-CHOP (CG-3)	p (CG-3)
Patients (#)	86	73		82		86	
5-year FFP	88%	80%	0.33	78%	0.22	75%	0.06
5-year EFS	85%	78%	0.31	76%	0.21	73%	0.13
5-year OS	96%	90%	0.32	91%	0.39	88%	0.14
Radiotherapy (%)	14%	73%		76%		58%	
Secondary neoplasias	2 AML	Thymoma		Thymoma		Thymoma, Hodgkin lymphoma	
R-da-EPOCH parameters	**5-year FFP**	**p**	**AML (#)**	**AML (%)**	**5-year OS**	**p**	**% of patients receiving dose level 4-6**
Strict protocol adherence	92%	0.30	1/40	2.5%	95%	0.56	55%
Protocol deviations	84%		1/25	4.0%	100%		25%
Received dosage level ≥4	87%	0.89	2/29	6.9%	95%	0.98	
Received dosage level <4	86%		0/40	0%	96%		
Received dosage level ≥3	90%	0.18	2/52	3.8%	94%	0.45	
Received dosage level <3	78%		0/17	0%	100%		

Summary/Conclusion: This comparative study between R-da-EPOCH and R-CHOP carried the least possible systematic error in the retrospective setting. Five-year FFP and EFS rates appeared less impressive than initially reported and 2 AML cases have been reported so far. However, R-da-EPOCH minimized the need for RT and demonstrated a numerically better disease control. Finally, in real-world situations, R-da-EPOCH is seemingly not given *lege artis* in a considerable proportion of patients.



EP552 PREDICTIVE VALUE OF INTERIM FDG-PET/CT SCAN IN PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA

V. Hanáčková [1,*], V. Procházka [1], L. Henzlová [2], E. Buriánková [2], J. Ptáček [2], T. Papajík [1]

[1]Dept. of Hemato-Oncology, [2]PET-imaging center, dept. of Nuclear Medicine, University Hospital in Olomouc, Olomouc, Czech Republic

Background: Primary mediastinal large B-cell lymphoma (PMBCL) is a specific clinicopathological and molecular subtype of non-Hodgkin lymphoma characterized by rapid progression of anterior mediastinal mass, commonly affecting younger patients. Standard therapeutic approach to PMBCL is immunochemotherapy with antracyclines followed by mediastinal radiation. PMBCL is nowadays considered to have better outcome than DLBCL, with PFS approximately 80% and OS 90%, respectively. Considering new therapy options (immune checkpoint inhibitors) seems to be important to identify chemorefractory patients with early relapse regarding early indication of novel drugs. As a powerful tool for response assessment is positron emission tomography with fluorodeoxyglucose (FDG). Even though this method is commonly used, the prognostic value of interim PET/CT is considered to be unclear and controversial.
Aims: To assess a predictive value of interim PET/CT as potentially useful tool for early recognition and further management of chemorefractory PMBCL.
Methods: We conducted a retrospective study of patients diagnosed with PMBCL. Between 2005-2019 we identified 53 patients, interim FDG PET/CT has been performed in 45 of them. Imaging studies were conducted using the Siemens Biograph 16 HI-REZ (2008-2015) and Siemens mCT 40 (2015-2017) systems with the same image acquisition protocols at the same centre. Both PET/CT scanners were accredited by EARL, a European Association of Nuclear Medicine research initiative. Images were read by two independent experts blinded for patient outcome.
Results: This cohort consisted of 27 females and 18 males with median age of 33 years. All of the patients have been treated with immunochemotherapy regimen containing rituximab and antracyclines, 30 of them have undergone autologous stem cell transplant and 4 of them had radiotherapy. All but two patients had final PET/CT, according to this 33 (73.3%) of them achieved CR, six (13.3%) PR, four (8.8%) had progressive disease. Interim FDG PET/CT was considered positive in 27 (60%) from 45 patients using visual evaluation. Interim PET/CT was assessed as negative (Deauville 1-3) in 17 (37.8%) patients and positive (Deauville 4-5) in 28 (62.2%) patients, respectively. In the negative interim FDG-PET/CT group no patient has relapsed, in positive interim PET/CT group 8 patients relapsed with median time to progression 9

months. Five-year PFS reached 75% and 100% (p=0,014) and 5-y OS 78.2% and 100% in groups D4-5 vs D1-3. Positive and negative predictive values were 28.6% and 100% for PFS-event.

Summary/Conclusion: Interim FDG-PET/CT negativity is associated with high negative predictive value for lymphoma progression. We can consider negative interim FDG-PET/CT as single valued method in detection of early response in chemosensitive patients. Regarding positive predictive value, for better identification of chemorefractory disease and patients suspect of early progression further analyses are needed. Extensive studies to estabilish the role of the interim PET/CT should contain assessment of specific metric values available in PET/CT scan as SUV max (maximum standardized uptake volume), MTV (metabolic tumor volume), TLG (total lesion glycolysis) or metabolic heterogeneity.

EP553 ESTIMATION OF LONG-TERM SURVIVAL WITH TAFASITAMAB + LENALIDOMIDE (LEN) IN RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA (R/R DLBCL)

G. Salles [1,*], B. Goswami [2], V. Bagnardi [3], D. Dey [2], M. Winderlich [2], S. Ambarkhane [2], D. Huang [2], G. S. Nowakowski [4]

[1]Memorial Sloan Kettering Cancer Center, New York, NY, United States, [2]MorphoSys AG, Planegg, Germany, [3]Department of Statistics and Quantitative Methods, University of Milan-Bicocca, Milan, Italy, [4]Division of Hematology, Mayo Clinic, Rochester, MN, United States

Background: L-MIND (NCT02399085) is an ongoing, open-label, single-arm, Phase II study of tafasitamab + LEN in patients (pts) with R/R DLBCL who are ineligible for ASCT. Progression-free survival (PFS) strongly correlates with overall survival (OS); however, while PFS estimates study drug treatment effect, OS also includes effects of subsequent cancer treatments or palliative care. Given that not all OS and PFS events may occur even during a long follow-up, traditional survival analyses may underestimate survival benefit for tafasitamab + LEN by assuming the same mortality rate for the whole study population.
Aims: To estimate the proportion of long-term survivors (LTS) and survival benefit associated with tafasitamab + LEN treatment using mixture cure models.
Methods: In the L-MIND study (data cut-off: Oct 30, 2020), 80/81 enrolled pts with R/R DLBCL received tafasitamab + LEN, with a median and maximum follow-up duration of 42.7 months (95% confidence interval (CI): 38.0–47.2) and 54.6 months, respectively. Kaplan–Meier (KM) plots of PFS and OS were observed to plateau after 30 months, with the majority of events (PFS: 45/46 [97.8%]; OS: 36/41 [87.8%]) reported up to that time-point. LTS exhibit a high survival benefit from tafasitamab + LEN treatment and were defined as pts without a PFS event and who did not decease after the observed plateau. Thus, the pt population can be considered to consist of two sub-populations: LTS and non-LTS. A 'mixture cure model' was fitted on L-MIND observed PFS and OS data to estimate the proportion of LTS and associated mean survival for the two sub-populations. To incorporate background mortality, age- and sex-specific US mortality rates were factored in for the entire study population (enrolled in Europe and US). The weighted average of the mean survival for the two sub-populations provided an estimate of the mean survival for the whole population. For comparative purposes, standard parametric models without considering an LTS proportion were also fitted on PFS and OS data. Sensitivity analyses were performed considering different survival distributions (exponential distribution, Weibull distribution and log-logistic distribution).
Results: Using a mixture cure model fitted to PFS and OS data, the estimated proportion of LTS for the tafasitamab + LEN combination was 41.7% (95% CI: 30.0–54.5) and 44.6% (95% CI: 28.1–62.4), respectively. The predicted mean survival when the mixture cure model was fitted on PFS data was 16.7 years for LTS pts vs 0.5 years for non-LTS pts, yielding 7.4 years for the overall population. Further, survival rates for pts with tafasitamab + LEN treatment were predicted as 40.7% and 36.5% at 2 and 5 years, respectively. Similar results were obtained when the mixture cure model was fitted on OS data. By comparison, using a standard parametric model (Weibull distribution), the predicted mean survival in the overall population was 3.6 years fitting PFS data (Figure 1A) and 5.2 years fitting OS data (Figure 1B).

Figure 1: Kaplan-Meier plot of (A) investigator-assessed PFS and (B) OS as observed in L-MIND and predicted outcomes by mixture cure model and Weibull survival model

Summary/Conclusion: PFS and OS KM curves for the L-MIND study reaching a long plateau and not following a standard Weibull distribution suggest the presence of an LTS subgroup. Standard parametric models may fail to capture the survival plateau of LTS, leading to a poor estimate of OS benefit in such pts. The mixture cure model suggests that the treatment of R/R DLBCL pts with tafasitamab + LEN is associated with a high LTS proportion of 41.7%.

EP554 SAFETY OF AMBULATORY HIGH-DOSE METHOTREXATE (HDMTX) ADMINISTRATION AMONG HEMATOLOGICAL MALIGNANCIES PATIENTS IN TERTIARY CARE CENTER

I. Motabi [1], M. Al-Ammari [1,*], B. Albtoosh [1], A. Alrajhi [2], F. Alnajjar [2]

[1]Adult hematology and BMT, [2]Department of Clinical Pharmacy, King Fahad Medical City, Riyadh, Saudi Arabia

Background: Methotrexate (MTX) is an antimetabolite, that mainly acts through the inhibition of the enzyme dihydrofolate reductase and the subsequent depletion of intracellular folate stores. High-dose MTX (HDMTX)is defined by the dose of more than 1 g/m^2. The utilization of HDMTX is commonly used in solid malignancies such as osteosarcoma and hematological malignancies such as acute lymphoblastic leukemia and non-Hodgkin's Lymphoma. Urine Alkalinization using intravenous sodium bicarbonate and calcium folinate to facilitate clearance of MTX are crucial two steps in MTX clearance and to avoid or minimize side effects such as nephrotoxicity and hepatotoxicity. For that reason, most institutions are requiring patients to be admitted with a minimum length of stay of 72 hours until methotrexate clearance is achieved with a serum level of < 0.1 micromol/L.
Aims: Here, we are assessing the safety of ambulatory HDMTX among adult patients. Regular laboratory monitoring, adequate oral hydration and oral medications were utilized to enhance methotrexate clearance

without the necessity to use devices at home for infusion or admitting the patient

Methods: This trial is open-labeled, single arm study that aims to evaluate the safety of high dose methotrexate administration in an outpatient setting among adult patients with hematological malignancies in a tertiary care center. The study aims to cover a cohort of patients with hematological malignancies from 14 to 60-years-old treated at KFMC scheduled to receive HDMTX from (February-2020) to (February-2021). treatment protocol is showing in figure 1.

Results: Twenty-seven (n=27) cycles were done until now. Around 70.37% of the patients were diagnosed with diffuse large B cell lymphoma (DLBCL).

Thirteen patients (48.1) % of the patients achieved MTX level less than 0.1 micromol/L by 48 hours and 24 patients (88.8%) achieved the same level by 72 hours.

Only three (11.1%) patients did not clear their methotrexate by the end of 72 hours; one patient was admitted due to acute kidney injury, the second was managed as outpatient as that occurred at the mid of COVID-19 bed crises, and the third one refused admission and was following his labs at the hospital at his hometown. By 72 hours, 29.63% had reversible asymptomatic elevation of creatinine, and all of them were grade one.

By 72 hours, around 44.44% had reversible asymptomatic hepatotoxicity, and all of them were grade 1. Among the 27 patients, only one suffered from acute kidney injury that necessitated admission for supportive care, which was totally reversible. The patient was not compliant to the treatment protocol and was excluded for subsequent cycles.

Figure 1

Pre-Chemo	Start the following medications 24 hours prior to methotrexate administration and continue until methotrexate level is less than 0.1 micromol/L				
	Sodium bicarbonate 1950 mg PO q4 h				
	Acetazolamide 250 mg PO q6h.				
	Oral water intake 3 L/day				
Chemotherapy	If urine pH is ≤ 7, start sodium bicarbonate 100 mEq + 20 mEq Kcl in 1 Liter D5W IV @ 150 mL/hr. Start 4 hours prior to methotrexate infusion and continue until the end of the methotrexate infusion. Keep urine out put (UOP) >100 mL/hr				
	Methotrexate 3000 mg/m² = mg IV in 1 L normal saline over 3 hours on day 1 (% dose reduction)				
	Avoid/Discontinue: Bactrim, Flouroquinolones, NSAIDs, Penicillins, and PPIs) at least 48 hours prior HDMTX and Resume when the level of methotrexate is less than 0.1 micromol/L				
Anti-emetics	Granisetron 1 mg IV 30 minutes prior to chemotherapy If granisetron not available, give ondansetron 8 mg PO BID (give 1st dose prior to methotrexate)				
	Dexamethasone 8 mg IV/PO 30 minutes prior to chemotherapy on day 1				
	Ondansetron 8 mg PO BID on days 2-3				
	Metoclopramide 10 mg PO/IV q6h PRN nausea/vomiting				
Post-HDMTX	Leucovorin 30 mg PO q6h. Start exactly 24hr after the start of methotrexate infusion and continue until methotrexate level is less than 0.1 micromol/L.				
Time from the start of methotrexate	Methotrexate Level (micromol/L)				
	< 0.1	0.1 – 2	2-20	20-100	>100
At 24 hours	None	Continue as ordered	30 mg PO q4h	10mg/m2 IV q6h	100 mg/m² IV q6h
At 48 hours	None	30 mg PO q4h	15mg/m² IV q6h	10mg/m² IV q3h	100 mg/m² IV q3h
At 72 hours	None	15mg/m² IV q6h	10mg/m² IV q3h	100mg/m² IV q3h	1000mg/m² IV q3h

Summary/Conclusion: Our preliminary results suggest that ambulatory HDMTX is safe, cost effective, more comfortable for patients.

These results encourage the use of this approach more frequently as it decreases hospitalization and thus reduces cost, increases patient satisfaction and helps to solve the issue of bed crisis.

EP555 OUTCOME OF RITUXIMAB-POLATUZUMAB-BENDAMUSTINE IN THE TREATMENT OF RELAPSED/ REFRACTORY HIGH GRADE LYMPHOMA AND TRANSFORMED HIGH GRADE LYMPHOMA – A MULTI-CENTRE ANALYSIS.

L. Sodhi [1,*], A. Robinson [2], R. Spackman [3], V. Ceidiene [3], D. Lobo [3], T. McKerrell [4], J. Padayatty [5], G. Campbell [5], S. Young-Min [2], M. Karanth [2], I. Lentell [2], N. Gill [3], J. Cunningham [4], A. Hodson [3], M. Prahladan [6], S. Sadullah [4]

[1]Masters in Genomics project, University of Cambridge, Cambridge, [2]Haemato oncology, West Suffolk Hospital, Bury St Edmunds, [3]Haemato oncology, East Suffolk and North Essex NHS foundation Trust, Ipswich, [4]Haemato oncology, James Paget Hospital, Great Yarmouth, [5]Haemato oncology, East Suffolk and North Essex NHS foundation Trust, Colchester, [6]Haemato oncology, University of Cambridge/ East Suffolk and North Essex NHS foundation Trust, Cambridge, United Kingdom

Background: The combination chemotherapy incorporating polatuzumab along with rituximab and Bendamustine has shown a significant response in relapsed /refractory high grade lymphoma. .

Aims: To review the response of all patients who received rituximab, polatuzamab and bendamustine (RPB) for relapsed /refractory diffuse large B cell lymphoma (DLBCL) and transformed high grade lymphoma in 4 district general hospitals in the East Anglia Cancer Network.

Methods: Retrospective analysis of data from 4 district general hospitals which serves a population of 1.26 million. All patients who had combination chemotherapy of rituximab, polatuzumab and bendamustine as stand-alone treatment or for bridging to Chimeric Antigen Receptor T cell (CAR T) therapy were identified from from June 2019. Patients were given 1.8mg/kg of polatuzumab, 375mg/m2 of rituximab on day 1 and 90mg/m2 of Bendamustine on day 1 and day 2 in a three weekly cycle. Objective clinical and radiological responses were assessed using modified Lugano Classification on interim staging CT scan after 3 cycles of treatment and positron emission tomography (PET) scan at the end of treatment.

Results: A total of 24 patients were identified from four district general hospitals in the East of Anglia Cancer Network. The mean age is 70.6 years (range 27-87) with M:F ratio of 2:1. The median ECOG was 2. De novo cases constituted 66% (16/24) of the patients. 29.1% (7/24) of the patients had transformed low grade lymphoma – 5 from follicular lymphoma and 1 each from marginal zone lymphoma and chronic lymphocytic lymphoma). There was 1 patient with primary mediastinal B cell lymphoma. 62.5% (15/24) of the patients had stage IV disease and 20% (5/24) of the patients had stage III disease. 16% (4/24) of patients had bulky disease prior to RBP cytotoxic chemotherapy. 75% (18/24) of the patients had extranodal involvement ranging from 1-5 extranodal sites. Mean IPI of the study group was 2.83. 29% (7/24) had double expresser phenotype on immunohistochemistry with 1 case of double hit lymphoma. Mean number of lines of therapy before RBP was 1.73. Only one patient was exposed to Bendamustine prior to RBP. All patients has had rituximab combination as a line of prior therapy and 37% (9/24) of patients were refractory to RCHOP chemotherapy. 54% (13/24) of patients were refractory to one line of prior therapy. 62.5% (15/24) of patients had less than 12 months of remission before RBP therapy. None of the patients had CAR T, autologous or allogeneic bone marrow transplant prior to the therapy. 75% (18/24) patients had the treatment as a standalone treatment, while 25% (6/24) had RBP as a bridge to CAR T cell therapy. In the standalone group, the median number of cycles of RBP was 4.33 with infection and peripheral neuropathy manifested in 3 and 1 patients respectively. Of the patients who had an interim and end of treatment scan, 31% (6/19) had complete remission, 36% (7/19) had partial remission (PR), with an overall response rate of 66% (13/19). 66.6% (4/6)of patients who had treatmet to bridge to CAR T cells had 25% (1/4) had complete remission, 50% (2/4) had partial remission and 25% (1/4) had progressive disease following CAR T cell therapy

Summary/Conclusion: Rituximab, polatuzumab along with Bendamustine is an effective treatment strategy in patients with relapsed / refractory high grade lymphoma. More data are required to consider RBP as a salvage treatment, with or without consolidation autologous bone marrow transplant for ralpased DLBCL.

EP556 TREATMENT EFFICACY AND OUTCOMES OF RARE HIV-RELATED PLASMABLASTIC LYMPHOMA: THE RESULTS OF MULTICENTER RETROSPECTIVE STUDY IN RUSSIA

M. Popova [1,*], Y. Rogacheva [1], I. Tsigankov [1], M. Demchenkova [2], T. Tshneyder [3], K. Lepik [1], V. Baykov [1], N. Mikhailova [1], A. Kulagin [1]

[1]RM Gorbacheva Research Institute, Pavlov University, St. Petersburg, Russia, Saint Petersburg, [2]Irkutsk Regional Cancer Center, Irkutsk, [3]Leningrad Regional Clinical Hospital, Saint Petersburg, Russian Federation

Background: Plasmablastic lymphoma (PbL) is a rare and aggressive B-cell malignancy highly associated with HIV. Despite improved understanding of this disease, its prognosis remains poor with short overall survival. There is no standard of care for this entity. Recent advances in the therapy of HIV-associated and aggressive lymphomas do not seem to have had a positive impact on the outcome of patients with PbL.

Aims: To estimate epidemiological characteristics and the results of the treatment of the HIV-related PbL

Methods: We investigate epidemiological characteristics and the results of the treatment of the HIV-related PbL in large cohort of HIV-related lymphoma patients for a 7-year period (2014-2020). During the observation period, 22 cases of HIV-related PbL were registered in three centers and selected for the analysis from the national multicenter retrospective study database. The median follow-up was 17,8 (4-57,4) months.
Results: The PbL accounted for 8,9% of lymphomas in HIV-infected patients (22/247). The median age was 42 years (32-61), males – 9 (41%). Most of the patients (n=19, 86%) had III-IV stages and B-symptoms were present in 8 patients (36%). CNS involvement was diagnosed in 8 patients (36%). The median of ECOG score was I (I-III). Half of patients had viral hepatitis as a co-infection including HCV (n=9), HCV and HBV (n=1), HCV, HBV and HDV (n=1). In 7 patients (32%) HIV and lymphoma were diagnosed simultaneously. Median time from HIV infection to the lymphoma onset was 4 years (1,5 month – 17,5 years). The only one patient did not receive cART for an unknown reason. The median number of CD4+ cells at the moment of chemotherapy (CT) started was 151 cell/mcl (13 – 374). Frontline CT were following: CHOP±E – 9 (41%), EPOCH – 11 (50%), hyper-CVAD – 1 (4,5%), dexamethasone – 1 (4,5%), bortezomib was added to frontline treatment in 3 (13,6%) patients, HDC with auto-HSCT had been done as a first line therapy in 2 (9%) patients. A total of 16 patients responded to the first line therapy with the overall response rate (ORR) of 72,7% including CR and PR in 4 (18,2%) and 12 (54,5%) patients respectively. Remaining patients had progression disease (n=5, 22,8%) and stable disease (n=1, 4,5%). The median course to achieve the ORR was 4 (2-6) cycles. Overall (OS) and progression-free survival (PFS) at 2 years after first line treatment was 59,1% and 40,9%, respectively. The median time to progression (TTP) was 7,95 (0,33-23,93) months. The addition of bortezomib and auto-HSCT in first-line chemo improved OS (100% vs 47,1%, p=0,027, Fig.1), but non PFS (p=0,1) and TTP (p=0,4). Nine patients received second-line CT: DHAP – 4 (44,4%), ICE – 4 (44,4%), EPOCH – 1 (11,2%). Response was evaluated in 8 patients. CR, PR and progression disease was registered in 1 (12,5%), 2 (25%) and 5 (62,5%) patients respectively. PBSC harvesting was only successful in 1 of 3 cases (33%) and this patient received HDC with auto-HSCT. OS and PFS at 2 years after second line treatment was 44,4% and 22,2%, respectively.
Two years after second line CT, 4 patients were still alive, including those after ICE, EPOCH (n=2), HDC with auto-HSCT (n=1) and nivolumab (27 cycles) as a third line therapy (n=1).
Summary/Conclusion: In a large cohort of patients PbL accounted for 8.9%.of all HIV-related lymphomas. The bortezomib addition and auto-HSCT in first-line chemo significantly improved OS. Prospective studies are needed for optimization of HIV-related plasmablastic lymphoma therapy.

EP557 ANALYSIS OF PROGNOSTIC FACTORS IN PATIENTS WITH PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA TREATED BY DA-EPOCH-R AND R-CHOP

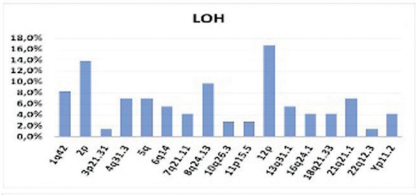
Y. Stepanishyna [1,*], T. Skrypets [2], Y. Pastushenko [1], I. Tytorenko [1], I. Kriachok [1]

[1]Oncohematology, National cancer institute, Kyiv, Ukraine, [2]PhD Program in Clinical and Experimental Medicine, University of Modena and Reggio Emilia, Modena, Italy

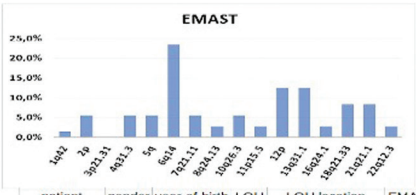
Background: Primary mediastinal large B-cell lymphoma (PMBCL) is distinct clinical, pathological and molecular entity of diffuse large B-cell lymphoma (DLBCL) which accounts less than 3% of all non-Hodgkin's lymphomas (NHL). The standard 1st line treatment of PMBCL does not currently exist. A lack of prospective data comparing the efficiency of R-CHOP and DA-EPOCH-R regimen, does not allow to establish the best front line treatment options. Due to the age specificity and mediastinum localisation the implementation of the International Prognostic Index (IPI) in PMBCL is limited. Thus, this clinical entity needs better definition of prognostic factors and a standard of treatment approach.
Aims: The purpose of the study was to assess the treatment outcomes (5-year OS and PFS), and the potential prognostic factors for patients with PMBCL.
Methods: The study included 84 patients with PMBCL from 6 Ukrainian centers (Aug 2011 to Dec 2015). Patients were randomized into two groups: DA-EPOCH-R (44 pts) and R-CHOP (40 pts). Median age in DA-EPOCH-R group was 29 years (range 24.5-34) and in R-CHOP group - 32.5 (27-44) (p=0.036). Initial data included age, sex, stage, presence of B symptoms, bulky disease, ECOG, IPI score, pleuritis and pericarditis (Table 1). To analyse prognostic factors which may have impact on OS and PFS (treatment regimen, age > 40 years old, stage III-IV, ECOG≥2, ≥ 2 exstranodal sites, elevated LDH, male sex, presence of B-symptoms, pleuritis, pericarditis, bulky disease, and number of risk factors) we provided a multivariate Cox analysis.
Results: ORR and CR rates were significantly higher in the DA-EPOCH-R group: 97.7% vs 85% (p = 0.049) and 81.8% vs 50% (p = 0.003), respectively. The 5-year PFS in the DA-EPOCH-R group reached 90.9% vs 64.1% in the R-CHOP-regimen group (p = 0.002). The 5-year OS rate was also higher in the DA-EPOCH-R arm compared to R-CHOP – 97.7% vs 73.8%, respectively (p = 0.002). The median OS was not reached in either group. Using the Cox proportional-hazards model to assess the effect of a treatment regimen on OS, a significant reduction in the risk of death was seen for the patients in the DA-EPOCH-R group [p=0.016 (HR = 0.08, 95%CI 0.01 - 0.63)]. When adjusted for age and IPI, the risk of death from PMBCL in the DA-EPOCH-R group was also lower [p=0.010 (HR=0.046, 95%CI 0.005 - 0.478)]. Moreover, the higher risk of deaths due to PMBCL occurred with an increase in number of risk factors [p=0.01 (HR = 1.8, 95%CI 1,2 – 3,0). Additionally was defined that the risk of disease progression in the first 14 months after end of treatment was associated with 3 prognostic factors: treatment regimen, ≥ 2 extranodal sites and number of risk factors [Se 100% (95CI 80.5% - 100%); Sp 76.7% (95CI 64.0% - 86.6%)].

Characteristic	*DA-EPOCH-R*	*R-CHOP*	*p value*
No of patients	44	40	
IPI	n=40	n=43	
Low	17 (42.5)	26 (60)	
Intermediate	22 (55)	15 (34.9)	0.179
High	1 (2.5)	2 (4.6)	
Median age	29 (24.5-34)	32.5 (27-44)	0.036
LDH > upper limit of normal (n=43/40)	25 (58.1)	29 (72.5)	0.170
Age > 60 years old	0	2 (5)	0.224
ECOG>2	18 (40.9)	21 (52.5)	0.381
Extranodal lesions ≥2	5 (11.4)	9 (22.5)	0.243
Pericarditis	18 (40.9)	16 (40)	>0.999
B symptoms	17 (38.6)	11 (25)	0.356
Pleurisy	18 (40.9)	15 (37.5)	0.825
Stage III-IV, *N* (%)	11 (25)	10 (25)	>0.999
Bulky>10cm, *N* (%)	28 (63.6)	24 (60)	0.823

Summary/Conclusion: The DA-EPOCH-R regimen might overcome the effect of adverse prognostic factors. Our model could stratify patients with PMLBC and help guide selection of treatment. Thus, more prognostic studies that take into account novel biomarkers and novel prognostic features are warranted.



EP558 VALUE OF MICROSATELLITE INSTABILITY MARKERS IN PRIMARY MEDIASTINAL B-CELL LYMPHOMA DIAGNOSTICS



N. Risinskaya [1,*], Y. Mangasarova [1], E. Nikulina [1], Y. Kozhevnikova [2], A. Yushkova [1], V. Zheleznova [1], S. Kravchenko [1], A. Sudarikov [1]

[1]National Research Center for Hematology, [2]School of Medicine, Lomonosov Moscow State University, Moscow, Russian Federation

Background: Loss of heterozygosity (LOH) in STR loci, elevated microsatellite alteration at selected tetranucleotides (EMAST) and instability of mononucleotide tandem repeats (MSI - microsatellite instability) are intrinsic features of diverse tumor cells and appropriate analysis might be used as indication for the therapy with immune checkpoint inhibitors. For primary mediastinal B-cell lymphoma (PMBCL) these molecular factors to determine the prognosis of the disease have not been described yet. A set of five mononucleotide microsatellite repeat markers BAT-25, BAT-26, NR-21, NR-24, and NR-27 might not be informative in aggressive lymphoma cases since low occurrence (up to 5%). Furthermore, in about half of the cases, the altered allele may also present in the control material, possibly characterizing not the tumor, but the genetic features of the patient. According to the literature data, EMAST-H (high degree) is associated with MSI-H in solid tumors. Overlapping combinations of enzymes of the DNA repair complex are responsible for the repair of unpaired bases and the removal of oligonucleotide insertion loops. Therefore certain defects in the DNA repair complex (MMR) may lead to both MSI and EMAST.
Aims: To analyze the frequency of LOH and EMAST in tumor cells of PMBCL patients at diagnosis and to check possible association with PD-L1 mRNA overexpression.
Methods: STR profiles of the DNA of tumor cells were analyzed on a cohort of 72 de novo diagnosed PMBCL patients undergoing treatment

at the National Research Center for Hematology (Moscow, Russia). DNA was isolated from tumor biopsy samples taken at diagnosis. Control DNA samples were taken from the blood of patients in complete remission or from the buccal epithelium. STR-profiles for LOH and EMAST analysis were assessed by PCR with COrDIS Plus multiplex kit for amplification of 19 STR-markers and amelogenin loci (Gordiz Ltd, Russia). The fragment analysis was performed on ABI3130 Genetic Analyzer. For 15 patients LOH and EMAST status was evaluated relatively PD-L1 mRNA expression level checked at diagnosis.
Results: LOH was revealed in 37 out of 72 patients (51.4%). EMAST was found in 40 patients (55.5%); in 24 of them, EMAST was accompanied by LOH. For all EMAST-positive patients, the number of involved loci was no more than 4 from 19 (EMAST low, less than a third of the microsatellite markers panel). Among 15 patients with a known level of PD-L1 mRNA expression, six patients have no EMAST and no PD-L1 overexpression. Three patients have EMAST with 2-3 involved loci and PD-L1 overexpression. For 4 patients combination of EMAST and normal PD-L1 expression and for 2 patients no EMAST and PD-L1 overexpression were found. Standard therapy failure should be noted for patients with EMAST and PD-L1 overexpression.

STR-marker	Locus

SASH	f	1988	-	-	+	1 (6q, 13q)	+
POT	f	1968	+	1 (12p)	+	1 (6q, 7q, 8q)	+
DANCH	f	1968	-	-	+	1 (4q, 13q)	+
IVAN	f	1969	-	-	-	-	+

Summary/Conclusion: The high incidence of LOH and EMAST in PMBCL can cause standard therapy failure in a significant number of patients. EMAST as a variant of microsatellite instability might be useful for further consideration as a predictor of response to checkpoint inhibitor therapy. The patients with EMAST and a high level of PD-L1 expression should be considered as the first candidates for immunotherapy. *This study was supported by Rakfond grant 2/2020*

EP559 DIAGNOSTIC YIELD AND SAFETY OF IMAGE-GUIDED PERCUTANEOUS SPLENIC BIOPSY – A TWO-CENTRE EXPERIENCE FROM THE EAST OF ENGLAND

F. Anyanwu [1,*], A. Hart [2], N. Thayur [3], S. Smith [4], P. Jennings [4], G. Campbell [1], M. Mohan [1], K. F. Saja [1], M. Hamblin [1], A. Hodson [2], M. Prahladan [2], J. Padayatty [1]

[1]Haematology, East Suffolk and North Essex NHS foundation Trust, Colchester, Colchester, [2]Haematology, East Suffolk and North Essex NHS foundation Trust, Ipswich, Ipswich, [3]Radiology, East Suffolk and North Essex NHS foundation Trust, Colchester, Colchester, [4]Radiology, East Suffolk and North Essex NHS foundation Trust, Ipswich, Ipswich, United Kingdom

Background: Incidental or symptomatic abnormalities in the spleen can be found in a large spectrum of diseases. In most cases a diagnosis can be reached without splenic histology. Image-guided core biopsy of the spleen would be helpful in selected cases but is performed less often due to the perceived bleeding risk and low diagnostic utility.
Aims: To assess the diagnostic yield and safety of the image-guided splenic biopsy performed between January 2011 and October 2020 at 2 centres.
Methods: Retrospective data of all image-guided splenic biopsies performed at Colchester Hospital and Ipswich Hospital over 10 years were reviewed
Results: A total of 41 splenic biopsies were performed in 38 patients- 20 male and 18 female patients. The mean age was 66.5 years. The mean platelet count was 198 x 10^9/L (range 27 x 10^9/L – 558 x10^9/L). Only one patient received a prophylactic platelet transfusion. All biopsies were performed under ultrasonographic guidance. For the forty-one procedures 18-gauge needles were used in 90.2%, 16-gauge in 7.4% and 20-gauge in 2.4%. The mean number of core biopsy samples obtained were 3 (range 1-5 cores). 4 patients subsequently had elective splenectomy.
Adequate tissue for histological analysis including immunohistochemistry was obtained in 38 procedures (92.6%). Lymphoproliferative disorder was confirmed in 17 patients and was suspected in further 2 cases. These 2 patients later underwent splenectomy which confirmed the initial suspicion of DLBCL and low grade lymphoma. Of the 17 confirmed cases, DLBCL (10 cases) was the most frequent diagnosis and the remaining included 2 cases each of low grade B cell lymphoma, Hodgkin lymphoma, T-LGL and one case of T-cell rich B cell lymphoma. Non-haematological neoplasm was diagnosed in 4 patients. These included 2 cases of metastatic adenocarcinoma, 1 case of metastatic testicular germ cell tumour and 1 case of Littoral cell angioma.
Other histological diagnoses included 6 cases with reactive changes, 3 cases of sarcoidosis and one case each of Leishmaniasis, necrotising granulomata and extra-medullary haematopoiesis. A patient with reactive changes on splenic biopsy had features of extramedullary haematopoiesis identified on a subsequent splenectomy. Of the 5 remaining patients with reactive changes, 3 were discharged, 1 patient was later diagnosed to have chronic liver disease and 1 case remains under annual follow up.
Sufficient splenic tissue was not gained in 3 procedures (7.4%). 2 of these patients were later diagnosed to have low grade lymphoma – one following splenectomy and the other subsequent to molecular anaylsis of blood. The remaining patient with insufficient tissue declined further investigations. Three patients underwent a second splenic biopsy. The initial sample in these cases were deemed adequate but proved non diagnostic. The second biopsy secured a diagnoses of DLBCL, Hodgkin lymphoma and sarcoidosis in these patients.
1 patient developed peri-splenic haematoma which required an overnight admission for blood transfusion. This patient with thrombocytopenia (27 x 10^9/L) and a normal coagulation screen underwent a splenic biopsy using a 16-gauge needle following a single prophylactic platelet transfusion.
Summary/Conclusion: This case series demonstrates that ultrasound guided splenic biopsy by an experienced operator using a 18-gauge needle is a straight forward and minimally invasive procedure with a low complication rates and a high diagnostic yield.

EP560 IDENTIFYING THE INTRAVASCULAR LARGE B-CELL LYMPHOMA BY FDG PET/CT IMAGING: A SINGLE-CENTER, MATCHED CASE-CONTROL STUDY

S. Yang [1,*], L. Qiu [2], Q. Wang [3], X. Huang [1]

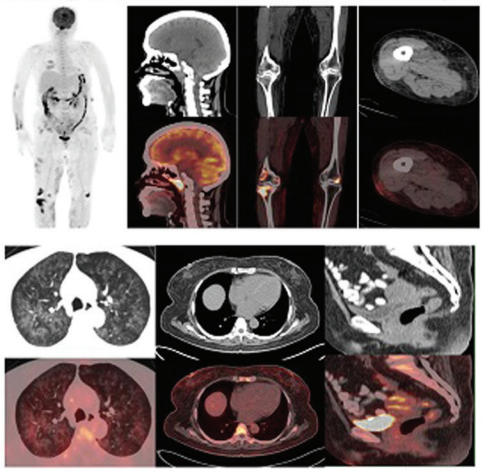
[1]Peking University Institute of Hematology, [2]Nuclear medicine department, Peking University Peoples' Hospital, [3]Nuclear medicine department, Peking University Peoples' Hospital, Beijing, China

Background: Intravascular large B cell lymphoma (IVLBCL) is a rare and aggressive lymphoma. Early diagnosis of IVLBCL is difficult. Random skin biopsies and repetitive bone marrow biopsies are recommended to improve discrimination. Few studies focus on feasibility of PET/CT directed diagnosing in IVLBCL.
Aims: We conducted a single-center retrospective case-control study to explore the significance of PET/CT scans in patients with IVLBCL.
Methods: Data of consecutive 6 patients with IVLBCL from October 2018 to May 2020 were analyzed. 24 cases were extracted from patients with DLBCL NOS stage IV admitted and received treatment during the same period at a ratio of 4:1. The age of the patient in both IVLBCL and DLBCL cohorts was well matched. 5 patients in IVLBCL cohort received R-CHOP for 8 cycles and high-dose MTX (HD-MTX) for 2 cycles. 1 had the central nervous system (CNS) involvement besides systemic disorder at the diagnosis received autologous transplantation after 6 cycles of R-CHOP and 2 cycles of HD-MTX. 24 patients in DLBCL cohort received 8 cycles of R-CHOP. Patients who were at a high risk

of secondary CNS lymphoma stratified with CNS-IPI or had involvement of sinus, bone marrow, adrenal glands or kidney received 2 cycles of HD-MTX. Patients were evaluated with PET/CT scan at diagnosis, interim and at the end of treatment. A comparison of clinical characteristics, PET/CT findings and outcome of patients in both cohorts was conducted.

Results: The characteristic PET/CT imaging of IVLBCL was summarized by comparing with DLBCL NOS. (Figure 1) IVLBCL involves multiple extranodal organs rather than lymph nodes, with a non concordance of PET and CT findings: 1). Patches without clear contour along the vessels traced by 18FDG; 2). Variable mild increase of SUVmax; 3). Normal CT imaging of solid organs; 4). Thickening subcutaneous/submucosal tissue or interstitial of the lung. All IVLBCL patients were diagnosed with the PET/CT directed biopsy, which led to a similar duration from the first symptom to diagnosis with those patients with DLBCL NOS (2.5 (1-10) vs. 2.5(1-12) months, P=0.798). No patients had concomitant hemophagocytic lymphohistiocytosis in both cohorts. Patients with IVLBCL achieved a complete metabolic response at both interim and at the end of treatment. With comparable IPI, COO and the time from diagnosis to treatment, there was a trend that patients with IVLBCL had superior progression-free survival than those with DLBCL stage IV (2-year PFS 100% vs. 50%, P= 0.057). (Figure 2)

Figure 1. Multiple organs involvement and a nonconcordance of PET and CT findings in IVLBCL.



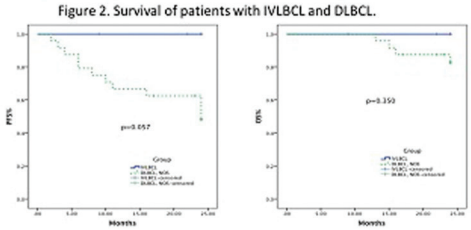


Figure 2. Survival of patients with IVLBCL and DLBCL.

Summary/Conclusion: A PET/CT-directed biopsy may be helpful for an early diagnosis of IVLBCL. Earlier chemoimmunotherapy may improve the prognosis of IVLBCL.

EP561 GLOMERULAR FILTRATION RATE (GFR) IS AN INDEPENDENT PROGNOSTIC FACTOR AFFECTING SURVIVAL OF PATIENTS WITH B-LARGE CELL LYMPHOMAS (B-LCL)

V. Premuzic [1,2], S. Basic-Kinda [3], I. Radman [3], D. Dujmovic [3], I. Ilic [2,4], N. Zivkovic [2], L. Maleta [5], M. Kralik [6], M. Dobrenic [2,7], L. Galunic-Bilic [8], P. Roncevic [3], M. Vodanovic [3], I. Aurer [2,3,*]

[1]Division of Nephrology, Department of Internal Medicine, University Hospital Centre Zagreb, [2]Medical School, University of Zagreb, [3]Division of Hematology, Department of Internal Medicine, [4]Department of Pathology, University Hospital Centre Zagreb, [5]Department of Emergency Medicine, University Hospital Dubrava, [6]Department of Radiology, [7]Department of Nuclear Medicine, [8]Department of Oncology, University Hospital Centre Zagreb, Zagreb, Croatia

Background: GFR is an independent prognostic factor for survival in some types of cancer, but its effect on outcome of patients with B-LCL has not been systematically analyzed.

Aims: To analyze the effect of GFR on outcome of patients with B-LCL, independently and in relation to IPI factors, bulk and treatment.

Methods: We analyzed overall survival (OS) and progression-free survival (PFS) of newly diagnosed patients with B-LCL treated at our institution between 2012 and 2019 and correlated these outcomes to the international prognostic index (IPI), bulky disease at diagnosis, treatment and GFR, calculated according to the CKD-EPI equation. Patients were excluded from the study if they had previous chronic kidney disease or obstructive nephropathy at diagnosis.

Results: We identified 288 patients fulfilling entry criteria, 151 (52%) male and 137 (48%) female. Median age was 58 and range 18-87. 136 patients were treated with R-CHOP21, 82 with R-CHOEP14 (patients younger than 60 with aaIPI 2-3), 38 with DA-R-EPOCH (fit patients older than 60 with aaIPI 2-3 since 2016) and 32 with R-miniCHOP or R-CEOP (unfit or patients with significant cardiac comorbidities). Responding patients with bulky or extranodal disease or in partial remission were irradiated after end of systemic treatment.

Age (p<0.001), IPI (p<0.001), treatment (p=0.02) and GFR (p=0.01) were statistically significantly associated with overall survival in univariate analysis. Only age (p=0.013) and GFR (p=0.004) remained significant in multivariate analysis. The effect of GFR was similar in all subgroups irrespective of treatment or IPI. Adding GFR to IPI resulted in 3 groups of patients with significantly different prognosis.

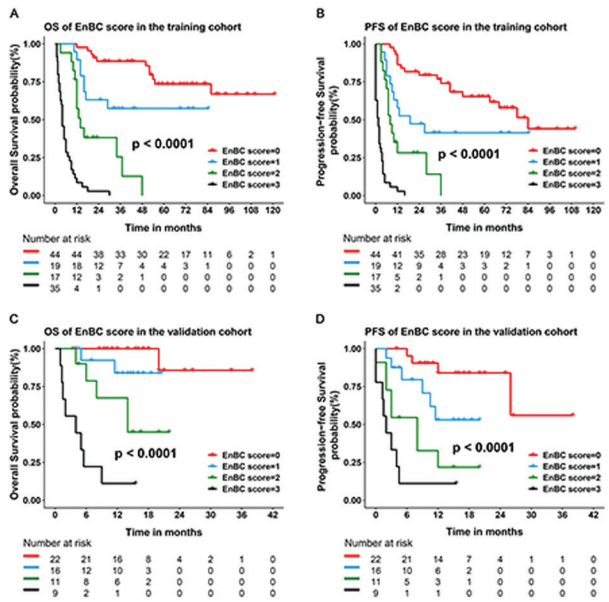
Summary/Conclusion: GFR is a significant prognostic factor in patients with B-LCL independent of IPI, bulk or treatment. The combination of GFR with IPI might result in better prognostic stratification of patients than IPI alone.

EP562 A NOVEL LIPID-COVERED PROGNOSTIC SCORING MODEL FOR NEWLY DIAGNOSED MATURE T AND NK CELL LYMPHOMAS

T. Lu [1,2,*], X. Fang [1,2], Y. Jiang [1,2], J. Liu [1,2], Y. Cai [1,2], S. Hu [1,2], M. Ding [1,2], X. Wang [1,2], X. Zhou [1,2]

[1]Department of Hematology, Shandong Provincial Hospital Affiliated to Shandong University, [2]Department of Hematology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: The current prognostic scoring systems for mature T and NK cell lymphomas have been found limitations in predicting survival outcomes. Novel predictors and precise risk stratification systems are lacking. Abnormal lipid metabolism was reported to influence the initiation and progression of malignancies. Nevertheless, the significance of dyslipidemia in mature T and natural killer (NK) cell lymphomas remains unexplored.



Aims: To investigate the association between serum lipid metabolism level and clinical outcomes, and further develop a lipid-covered prognostic model for newly-diagnosed mature T and NK cell lymphoma patients.

Methods: A total of 173 patients (1/2006-6/2020) were enrolled in this study, of which 115 constituted the training cohort while 58 composed the prospective validation cohort. The basic data comparison of the two cohorts was performed by Student *t* test or Mann-Whitney U test for continuous variables and the chi-square test or Fisher's exact test for categorical data. Univariate analysis and multivariate Cox regression analysis were performed to detect independent predictors and generate a novel prognostic model, whose performance was further assessed in the training and validation cohort from multiple aspects, including Harrell's C-index, calibration curves, Kaplan-Meier survival analysis, time-dependent receiver operating characteristic curves, Brier score and decision curve analysis.

Results: Univariate analysis verified declined cholesterol (TC), high-density lipoprotein cholesterol (HDL-C) and increased triglycerides (TG) were associated with inferior survival outcomes in mature T and NK lymphomas. Multivariate analysis revealed extranodal involved sites≥2 (HR: 2.505; P=0.031), β2-MG≥3mg/L (HR: 3.964; P=0.005) and TC<3.58mmol/L (HR: 3.320; P=0.000) were three independent predictors. Thus, a novel prognostic model, EnBC score, was constituted with these three variables. EnBC score possessed satisfactory discrimination and calibration since the Harrell's C-index for OS prediction was 0.840 (95% CI, 0.810-0.870) and the calibration curves showed an optimal agreement between the prediction and actual observation. The prognostic significance of the novel model was verified in Kaplan-Meier survival analysis by dividing patients into four risk groups with different long-term survival (median OS, NA vs. NA vs. 14.0 vs. 4.0 months, P <

0.0001; median PFS, 84.0 vs. 19.0 vs. 8.0 vs. 1.5 months, P < 0.0001) (**Figure 1**). Compared with the present International Prognostic Index (IPI), EnBC score presented better discrimination (time-dependent AUCs of OS, EnBC 0.883-0.963 vs. IPI 0.785-0.873, P<0.001) and better calibration (Brier score of OS, EnBC 0.146-0.271 vs. IPI 0.154-0.296, P=0.023). Moreover, the decision curve analysis showed that EnBC score provided larger net benefits than IPI in the entire patient population.

Figure 1

Summary/Conclusion: Serum lipid metabolism level was firstly demonstrated significantly prognosis-related in mature T and NK cell lymphomas. Furthermore, a novel lipid-covered prognostic scoring system was established and performed well in predicting the prognoses of treat-naïve mature T and NK cell lymphoma patients.

EP563 UTILITY OF PROGNOSTIC INDICES IN DIFFUSE LARGE B-CELL LYMPHOMA FOR THE DETECTION OF HIGH RISK PATIENTS.

P. López-Menargues [1,*], O. Mompel [1], M. Uribe [1], R. García-Serra [1], C. Játiva [1], M. Roig [1], M. J. Lis [1], P. Pérez [1], A. Mena [1], F. Ibáñez [1], M. López-Pavia [1], C. Amorós [1], R. Collado [1], M. T. Orero [1], F. Hernández [1], M. Linares [1]

[1]Hematology and Hemotherapy, Hospital General Universitario Valencia, Valencia, Spain

Background: In recent years, different prognostic indices have been developed for diffuse large cell B-cell lymphoma (DLBCL) like the IPI, the R-IPI, the NCCN-IPI and, in our environment, the GELTAMO-IPI which is the only that includes the beta-2 microglobulin. Since the introduction of rituximab, an improvement in response rates and survival has been observed. Nevertheless, patients with an adverse clinical course continue to be observed and their identification is essential to assess alternative therapies

Aims: To analyze the reproducibility of prognostic indices for LBDCG in our serie of patients treated outside of clinical trials; and assess the capacity of the prognostic indices to detect in high-risk patients.

Methods: 137 patients diagnosed with DLBCL between June 2004 and June 2020 were included. The treatment was R-CHOP or similar (39 with liposomal doxorrubicin and 5 with etoposide associated to treatment). Furthermore, 29 patients received a 2nd-line treatment, 7 of them with auto-HSCT. We analyzed the prognostic characteristics at diagnosis and the overall survival. We applied 4 prognostic indices: IPI, R-IPI, NCCN-IPI and GELTAMO-IPI.

Survival was studied using the Kaplan-Meyer method and the survival curves were compared with the Log-Rank test. The Cox method was used to calculate the Hazard ratio

Results: Table 1 shows the main prognostic characteristics at diagnosis in our group of patients. With a median follow-up of 25 months, the median overall survival was 120 months (95% CI 42-198). Table 2 shows the different prognostic indices depending on the risk group. In the table 3 we observe the 5-year overall survival, with significant differences in the Log-Rank test with all indexes. All prognostic indices have been significant for the correct distribution of patients according to the risk group, being the GELTAMO-IPI index the best to identify high-risk group patients.

TABLE 1: DATA AT DIAGNOSIS

Age: middle	Sex (M/F)	ECOG>2	High LDH	Stage III/IV	High Beta-2 microglobulin
66 (16-88)	58/79	34(28%)	90 (66%)	88 (64%)	63(45%)

TABLE 2: PROGNOSTIC INDICES DISTRIBUTION BY RISK GROUP PATIENTS

	IPI	R-IPI	NCCN-IPI	GELTAMO-IPI
LOW	39 (28%)	8 (6%)	10 (7%)	15 (11%)
INTER-LOW	31 (23%)	62 (45%)	48 (35%)	81 (59%)
INTER-HIGH	29 (21%)		52 (38%)	32 (23%)
HIGH	38 (28%)	67 (49%)	27 (20%)	9 (7%)

TABLE 3: 5-YEARS OVERALL SURVIVAL BY RISK GROUPS.

	IPI	R-IPI	NCCN-IPI	GELTAMO-IPI
LOW	0,82 (0.57-0,93)	1	1	1
INTER-LOW	0,73 (0,47-0,87)	0,74 (0.56-0,86)	0,77(0,55-0,89)	0,65 (0,50-0,76)
INTER-HIGH	0,57 (0.34-0,75)		0,54 (0,37-0,69)	0,51 (0,27-0,71)
HIGH	0,40 (0,22-0,58)	0,47(0,33-0,61)	0,42 (0,20-0,63)	0,18 (0,01-0,53)
Long-Rank; p	0,002	0,002	0,002	<0,001
R, Cox: HR and p value	4,3 (1,8-10,5) 0,001	7,64 (1,0-57,8) 0,049	10,9 (1,4-86,6) 0,024	22,9 (4,3-121,3) <0,001

Summary/Conclusion: - The application of the prognostic indices to our serie of patients, shows the reproducibility of prognostic indices in real life patients.

- The GELTAMO IPI is the best index to differenciate high-risk patients group, despite the small number of cases.

EP564 MODIFIED R-BFM IMMUNOCHEMOTHERPY RESULTS HIGHER FREQUENCY OF COMPLETE REMISSION THAN R-DA-EPOCH/R-CHOP IN PATIENTS WITH HIGH-GRADE B-CELL LYMPHOMA DOUBLE-HIT TRANSFORMED FROM FOLLICULAR LYMPHOMA.

A. Misyurina [1,*], S. Kravchenko [1], F. Babaeva [1], K. Sychevskaya [1], V. Misyurin [2], A. Magomedova [1], A. Kovrigina [1], T. Obukhova [1]

[1]Intensive and high-dose chemotherapy department, National Research Center for Hematology, [2]Laboratory of experimental biotherapy of tumor, N.N. Blokhin National Medical Cancer Research Center Ministry of Health of Russia, Moscow, Russian Federation

Background: High-grade B-cell lymphoma double-hit (HGBL DH) can arise from follicular lymphoma (FL). In the case of transformation of FL it accumulates a large number of additional mutations and secondary *c-MYC* gene rearrangement, which can make it resistant to standard immunochemotherapy.

Aims: To evaluate an efficacy of induction regimen R-CHOP/R-DA-EPOCH and modified BFM chemotherapy with rituximab in treatment of HGBL DH raised from FL.

Methods: We studied 13 FL pts with double- (9 - with *c-MYC/8q24* and *BCL2/18q21;* 4 - with *c-MYC/8q24* and *BCL6/3q27*) and one pt with triple translocations involving *c-MYC/8q24*, *BCL2/18q21* and *BCL6/3q27*

genes and deletion of 17p13. 10 pts had morphological signs of transformation into aggressive lymphoma; 4 pts had FL 3A. There was 8 women and 6 men aged from 30 to 60 y. o. (median 47 y.o.). Lymph node with the highest FDG-accumulation according to PET-CT was chosen for biopsy and consequent immunohistochemistry and cytogenetics.
The majority of pts had high 12/14 and 2/14 - high-intermediate FLIPI score. All pts had advanced (III-IV) stage according to Ann-Arbor classification. 3 out of 14 pt had a history of low-grade FL (16-96 months) without *c-MYC* rearrangement in primary biopsy samples, in other 11 cases - anamnesis varied from 0,5 to 4,0 months. Lymphoma manifested by rapidly spread aggressive tumor with bulky disease: 2 pts had leukemic presentation of FL; 1 pt had FL cells in cerebrospinal fluid; 12/14 out of pts had several extranodal sites of involvement such as ovaries (2/8), kidneys or adrenals (6/14), paranasal sinuses (1/14); bones (3/14); soft tissues (4/14); lungs (3/14); stomach or intestine (4/14); spleen (4/14); liver (1/14). Ki-67 varied from 40 to 90%. An expression of c-MYC protein higher than 40% in 11/13 of FL pts. We didn't revealed *TP53* mutation within 7 out of 7 analyzed pts.
Results: None of pts had previous therapy. 4 pts were treated with R-CHOP-21. 3/4 (75%) out of pts died due to progressive disease (PD), 1/4 (25%) had partial remission (PR) after consequent therapy including obinutuzumab. 7 pts underwent modified BFM-protocol with Rituximab. 6/7 (86%) out of pts achieved complete remission (CR) after first-line treatment, 1 pt died due COVID-19 in PD status (14%). Autologous stem cell transplantation (auto-SCT) was performed in 4 out of 7 pts. 3 pts underwent R-DA-EPOCH. 1 pt achieved a CR after 6 courses, 1 pt - after second-line 2 R-DHAP; auto-SCT was performed for consolidation. 1 pt (33%) had PD after R-DA-EPOCH and another therapy. Rituximab supportive treatment was administrated only in 4 cases due to epidemiological situation. Median of observation was 9 months (1,0-59,5). We couldn't study *TP53* mutation status in pts with PD, but we observed PD in one case with deletion of 17p13.
Summary/Conclusion: For better diagnostics of FL transformation into HGBL DH we should perform biopsy of lymph node with the most active FDG accumulation according to PET-CT. We observed a higher rate of CR in this pts cohort when treated with intensive induction immunochemotherapy (modified BFM chemotherapy with rituximab) in comparison with R-CHOP/R-DA-EPOCH (86% vs 25% and 33%, respectively), and lower rate of primary resistance/PD (14% vs 75% and 33%). Our data needs consequent confirmation or consideration within metanalysis due to rare diagnostics of FL with double translocations of *c-MYC* and *BCL2/BCL6*. We should initiate a randomized study to estimate if auto-SCT had any benefits in comparison with a new immunotherapy modalities in FL transformed into HGBL DH.

EP565 DEVELOPMENT AND VALIDATION OF A PROGNOSTIC NOMOGRAM FOR PATIENTS WITH PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA

G. Chen [1], C. Li [1], B. Fu [1], X. Peng [1], Y. Liang [1], H. Wang [1,*]

[1]*Hematological oncology, Sun-yat university cancer center, Guangzhou, China*

Background: Primary mediastinal large B-cell lymphoma (PMBCL) is rare, and most patients present with large anterior mediastinal tumors that progress rapidly. In PMBCL, the predictive effectiveness of the International Prognostic Index (IPI) is limited by the age composition of the disease and the fact that lesions are usually confined to the mediastinum. This is reflected clinically by the fact that more than half of the patients exhibit lower IPI score. Therefore, a new risk stratification profile is needed to guide the prognostic stratification of PMBCL patients. In addition, the certainty of existing models needs further validation in the era of modern treatments. The nomogram, as a graphical representation of a mathematical model, can be used in clinical practice to combine different information from various features to predict specific outcomes. By combining various important factors, a nomogram can estimate the feasibility of each patient event, such as the likelihood of death or recurrence. Thus, the nomogram has developed into an important tool for predicting clinical outcomes in various types of cancer and can provide physicians with optimal treatment options.
Aims: Our goal was to develop a reliable nomogram to predict overall survival (OS) and progression free survival (PFS) in patients with PMBCL.
Methods: Based on data from Sun Yat-Sen University Cancer Center and the First Hospital of Guangzhou Medical University,116 patients diagnosed with PMBCL were enrolled in this study. Independent prognostic factors were screened by Cox regression analysis. R-coding was used to construct nomograms predicting OS and PFS. Discriminations and corrections of the new model were evaluated using the consistency index (C-index), subject operating characteristic curves (ROC) and calibration curves, and compared with the conventional International Prognostic Index (IPI) using decision curve analysis (DCA) to assess its accuracy and benefit.
Results: Multivariate models showed that post-treatment Deauville score, Ann Arbor staging and hemoglobin level were significantly associated with PFS, while post-treatment Deauville score, MUM1 expression and Ki67 index were significantly associated with OS, and the corresponding nomograms were plotted. In the training cohort, the C-index of the nomogram for PFS and OS was 0.833 and 0.931, respectively. The C-index of the validation cohort was 0.649 and 0.661, respectively. The calibration curves of the nomogram also showed high predictive accuracy. Compared to the IPI scores,the C-index and ROC curves of the Nomogram had better results and also showed better results in the decision curve analysis, yielding better net benefits.

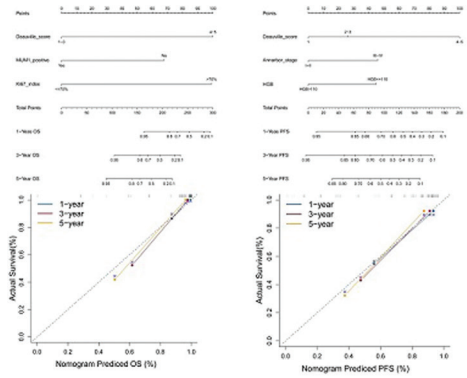


Figure Nomogram for predicting the 1-, 3-, and 5-year OS and PFS of PMBCL.

Summary/Conclusion: In summary, we have successfully established a valid nomogram for predicting OS and PFS in PMBCL patients, which can help clinicians to select appropriate individualized treatment for their patients.

Bleeding disorders (congenital and acquired)

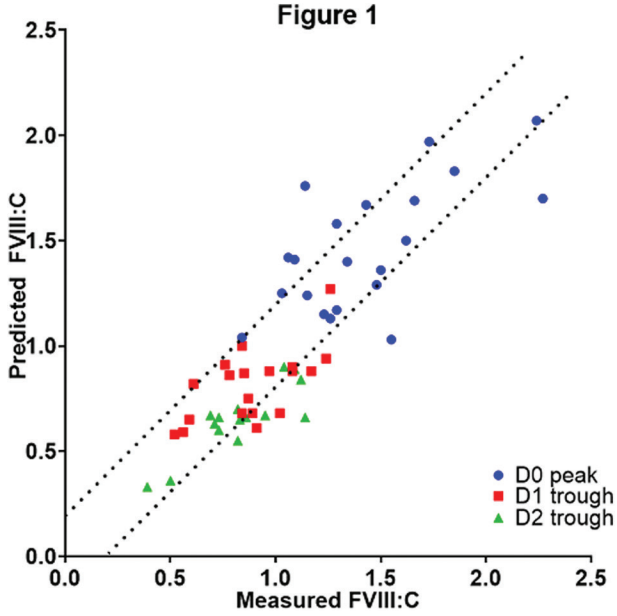
EP566 EFFICACY AND SAFETY OF EFGARTIGIMOD PH20 SUBCUTANEOUS IN ADULT PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA: ADVANCE SC, A GLOBAL PHASE 3 CLINICAL TRIAL IN PROGRESS

V. McDonald [1,*], C. Broome [2], S. Jain [3], S. Babu [4], E. Oliva [5], W. Parys [6], A. Hultberg [6], K. De Beuf [6], D. Gandini [6], Y. Miyakawa [7], W. Ghanima [8]

[1]*Barts Health NHS Trust, London, United Kingdom,* [2]*Georgetown University, Washington D.C.,* [3]*RUSH University Medical Center, Chicago,* [4]*Fort Wayne Medical Oncology and Hematology, Inc, Fort Wayne, United States,* [5]*Haematology Unit, Grande Ospedale Metropolitano, Reggio Calabria, Italy,* [6]*argenx, Ghent, Belgium,* [7]*Saitama Medical University Hospital, Saitama, Japan,* [8]*Departments of Medicine, Hematology-Oncology, and Research, Østfold Hospital Trust, Kalnes, and the Department of Hematology, Oslo University Hospital and Institute of Clinical Medicine, University of Oslo, Oslo, Norway*

Background: Primary immune thrombocytopenia (ITP) is an acquired autoimmune bleeding disorder characterized by a low platelet count, increased risk of bleeding and fatigue. Immunoglobulin G (IgG) autoantibodies directed against platelet surface antigens can be detected in most patients with ITP. These autoantibodies accelerate platelet clearance, can inhibit platelet production, and may impair platelet function. IgG homeostasis is regulated by the neonatal Fc receptor (FcRn). Efgartigimod, a human IgG1 antibody Fc-fragment, is a natural ligand of the FcRn engineered to competitively bind to FcRn and prevent the recycling of endogenous IgG. In a Phase 2 trial in 38 patients with primary ITP, efgartigimod 5 mg/kg or 10 mg/kg administered in 4 weekly IV infusions was well tolerated compared to placebo (Newland AC. *Am J Hematol*. 2020;95:178-187. NCT03102593). Efgartigimod induced a rapid reduction of total IgG levels (up to 63.7% mean change from baseline), which was associated with clinically relevant increases in platelet counts (38% vs 0% achieved ≥50×10^9/L for at least 10 cumulative days), and a reduced proportion of patients with bleeding. These data warrant further evaluation of FcRn antagonism as a novel therapeutic approach in ITP. A subcutaneous (SC) formulation (efgartigimod PH20) has been developed to offer additional flexibility and convenience for patients.

Aims: ADVANCE SC, a Phase 3, multicenter, randomized, double-blinded, placebo-controlled trial (NCT04687072), will evaluate the efficacy and safety of efgartigimod PH20 in adults with persistent or chronic ITP.
Methods: Eligible patients must have a mean platelet count <30×10^9/L over a minimum of 3 qualifying platelet evaluations and have received at least 2 prior ITP treatments or 1 prior and 1 concurrent treatment, with response to at least one. Patients will enter a 24-week treatment period and receive SC treatment with either efgartigimod (fixed dose of 1,000 mg) co-formulated with PH20 (recombinant human hyaluronidase PH20, an enzyme used to increase the dispersion and absorption of co-administered substances when administered SC) or matching placebo (randomization 2:1). Permitted concurrent ITP treatments include corticosteroids, oral immunosuppressants, dapsone/danazol, fostamatinib and/or oral TPO-RAs. Efgartigimod PH20 or placebo PH20 will be given weekly from visits 1 to 4 and then either weekly or every other week from visits 5 to 16, as determined by platelet counts. Dosing schedule will be fixed from visits 17 to 24. The primary endpoint is the proportion of patients with a sustained platelet count response defined as platelet counts of ≥50×10^9/L for at least 4 of the 6 visits between study weeks 19 and 24 (study visits 20 to 25). Secondary endpoints include overall platelet count response, safety and tolerability, bleeding severity, use of rescue therapy, quality of life and patient-reported outcome measures, and the immunogenicity and pharmacokinetic/pharmacodynamic effects of efgartigimod PH20. Efficacy analyses will be performed on the full analysis set, consisting of all randomized patients. Safety will be assessed in all patients who receive ≥1 dose of study treatment.
Results: ADVANCE SC recruitment is ongoing with a target of approximately 117 patients with chronic ITP and up to 39 patients with persistent ITP across approximately 170 sites in Asia-Pacific, Europe, Japan, Latin America, Middle East, Africa and USA.
Summary/Conclusion: Trial participants will be eligible for continuation into ADVANCE SC+, a long-term open-label extension trial.



EP567 PERI-OPERATIVE PK-GUIDED DOSING OF DESMOPRESSIN COMBINED WITH FVIII CONCENTRATES IN HEMOPHILIA A: FINAL RESULTS OF THE DAVID STUDY

L. G. Romano [1,*], L. M. Schütte [1], R. M. van Hest [2], K. Meijer [3], B. A. Laros - van Gorkom [4], L. Nieuwenhuizen [5], J. Eikenboom [6], F. C. Heubel - Moenen [7], N. Uitslager [8], M. Coppens [9], K. Fijnvandraat [10,11], M. H. Driessens [12], S. Polinder [13], M. H. Cnossen [14], F. W. Leebeek [1], R. A. Mahtôt [2], M. J. Kruip [1]

Background: Patients with non-severe hemophilia A can perioperatively be treated with desmopressin or factor VIII (FVIII) concentrate. Desmopressin produces an increase of FVIII plasma levels. However, interpatient variability in the FVIII response is high. If the response is sufficient, minor procedures can be performed with desmopressin only. In case the response is insufficient, FVIII concentrate needs to be administered. The 2020 WFH guideline states that this combination therapy can overcome downsides associated with use of only DDAVP or FVIII concentrate. However, treatment of desmopressin combined with FVIII concentrate is not common practice and difficult to implement. Furthermore, as desmopressin is less expensive than FVIII concentrate, combination therapy may lead to considerable FVIII savings and would be useful in case of limited FVIII concentrate resources.
Aims: To assess accuracy, safety and FVIII concentrate savings of peri-operative pharmacokinetic (PK)-guided dosing of desmopressin combined with FVIII concentrate in non-severe hemophilia patients.
Methods: Hemophilia A patients responsive to desmopressin undergoing a procedure were included. Desmopressin was administered intravenously (0.3 µg/kg) once a day. Based on previously determined FVIII response on desmopressin, additional FVIII concentrate dosing was calculated using PK-guidance. Modelling technique was continuously adapted and improved based on study data. Desmopressin was administered for a maximum of three consecutive days. FVIII activity was determined before and after combination therapy (trough and peak levels). Hypothetical FVIII concentrate loading dose was calculated, assuming an increase of 0.02 IU/ml per IU FVIII concentrate per kilogram bodyweight. A predicted FVIII level by the desmopressin-FVIII PK-model was considered accurate if difference between predicted and measured FVIII level was ≤ 0.2 IU/ml.
Results: Twenty-one procedures were performed in 20 hemophilia A patients, of whom 19 mild and 1 moderate. Median age was 47 years (interquartile range (IQR) 40 - 59). Model predictions were accurate in 13/21 (61.9%) pre-operative peak levels at day 0 (D0, day of surgery), 14/19 (73.7%) at day 1 (D1) and 13/17 (76.5%) at day 2 (D2) post-operative trough levels. Figure 1 describes model accuracy, comparing measured FVIII levels with predicted FVIII levels and with dotted lines signifying +/- 0.2 IU/ml. FVIII concentrate loading dose per patient was 1250 IU (median; IQR 1000 - 1750) lower than hypothetical loading dose. Two patients had bleeding complications, with both patients having supraphysiological (>1.0 IU/ml) FVIII activity at the time of bleeding.

Figure 1

Summary/Conclusion: Peri-operative combination therapy of desmopressin and FVIII concentrate under PK guidance in non-severe hemophilia A patients provides a feasible and accurate treatment in the majority of patients. This novel approach resulted in considerable FVIII concentrate savings.

EP568 APPLICATION OF THROMBOELASTOGRAPHIC MARKERS TO PREDICT THE SURVIVAL IN ACUTE TRAUMA PATIENTS.

H. Kim [1,*], H. K. Lee [1], J. Lee [1]

[1]Laboratory Medicine, College Of Medicine, The Catholic University Of Korea, Seoul, Korea, Republic Of

Background: Coagulopathic hemorrhage is one of the major modifiable causes of death in trauma. Despite its clinical significance, there is a lack of adequate tests to rapidly diagnose the various aspects of trauma-induced coagulopathy (TIC). Routine coagulation tests, such as PT, aPTT, fibrinogen, platelet count, D-dimer and FDP have a limitation in diagnosis of TIC. Thromboelastography (TEG) is the viscoelastic coagulation monitoring device that measures the entire clotting cascades from fibrin polymerization to fibrinolysis.
Aims: This study aimed to investigate factors related to mortality and blood transfusion requirements based on coagulation profile with fibrinolytic status using thromboelastrography in trauma patients.
Methods: We included 452 trauma patients who visited the trauma center of Uijeongbu St. Mary's Hospital. Citrated blood samples were

analyzed using the TEG 5000 Thrombelastography Hemostasis Analyzer (Haemonetics, Niles, IL). The following indices were obtained from the TEG: R-time, K-time, α-angle, maximum amplitude (MA), and lysis 30 minutes after MA (LY30). Patients were stratified based on LY30% results into fibrinolysis shutdown (SD) (LY30% <0.8%), physiologic fibrinolysis (0.8-3.0%), and hyperfibrinolysis groups (LY30% >3.0%) Also, we investigate transfusion requirement and mortality during hospitalization period.
Results: The mean age was 52.3 years and the mortality rate was 39/452 (8.6%). Lower GCS, longer TEG K-time, and lower TEG MA were independent factors associated with mortality. The lower MA group demonstrated the highest probability of survival (odds ratio 0.207), followed by prolonged R-time (odds ratio 0.220). The patient numbers in fibrinolysis shutdown (SD), physiologic fibrinolysis and hyperfibrinolysis groups were 219 (52.3%), 131 (31.4%), and 68 (16.3%), respectively. The mortality rates of fibrinolysis SD group (11.9%) and hyperfibrinolysis (8.8%) were higher than the physiologic fibrinolysis groups (3.8%). The cutoff obtained from ROC analysis was found to be suitable for predicting survival. R-time, MA, and LY30 were effective to predict survival or death when applying the cutoff value from the ROC analysis (Table 3A). About probability (comparison of prediction power) of survival, the lower MA group (under the cutoff level) showed the highest probability of survival (odds ratio 0.207), followed by prolonged R-time (odds ratio 0.220).The transfusion requirements were significantly higher in the fibrinolysis SD group than in the other two groups.
Summary/Conclusion: TEG based markers were shown to be more useful to make a diagnosis coagulopathies including dysfibrinolysis and predict the survival than routine coagulation tests. Dysfunctional fibrinolysis showed higher mortality than physiologic group. If multiple integration of each TEG markers are used, it would be helpful for prompt diagnosis and management of coagulopathies and to decrease a preventable death in trauma.

EP569 POPULATION PHARMACOKINETIC MODELING OF FACTOR CONCENTRATES IN HEMOPHILIA: A DETAILED OVERVIEW FOR CLINICIANS AND EVALUATION OF OUR BEST PRACTICE.

T. Goedhart [1,*], L. Bukkems [2], M. Zwaan [3], R. Mathot [2], M. Cnossen [3]

[1]Department of Pediatric Hematology and Oncology, Erasmus MC Sophia Children's Hospital, University Medical Center Rotterdam, Rotterdam, [2]Department of Clinical Pharmacology - Hospital Pharmacy, Amsterdam University Medical Centers, Amsterdam, [3]Department of Pediatric Hematology and Oncology, Erasmus MC Sophia Children's Hospital, University Medical Center Rotterdam, Rotterdam, Netherlands

Background: The accuracy of pharmacokinetic (PK)-guided dosing of factor concentrates in hemophilia A and B patients is dependent on the clinical and laboratory data used to construct the applied population PK model, next to the individual PK profile of the patient.
Aims: This review aims to supply a detailed overview of the data used for these models as reported in literature and to evaluate best practice, in order to enable physicians to establish which models best suit the individual patient.
Methods: A literature search was performed on PubMed; publications describing prophylactic population PK models for factor VIII (FVIII) or factor IX (FIX) concentrates based on original patient data and constructed using non-linear mixed-effect modeling (NLMEM) were included. The following data was collected: detailed demographics of study populations, severity of hemophilia, type of product, assessed and included covariates, laboratory specifications and validation of models. According to our recommendations of best practice, included models were scored on 10 criteria as complete (+), incomplete (±) or absent (-) to evaluate their quality. Figure 1 depicts the evaluation of our best practice.
Results: This review comprehended twenty and seven models for FVIII and FIX concentrates respectively. Although most models (22/27) included pediatric patient, only four models reported complete pediatric demographics. The wide range of body weight suggested that overweight and obese adults were represented in the models. However, other morphometric variables (mostly BMI) were described in only 13/27 publications. Almost all models (26/27) reported the applied assay to measure the factor level, whereas only 15 models specified the reagent. Eight models were validated using a second dataset.

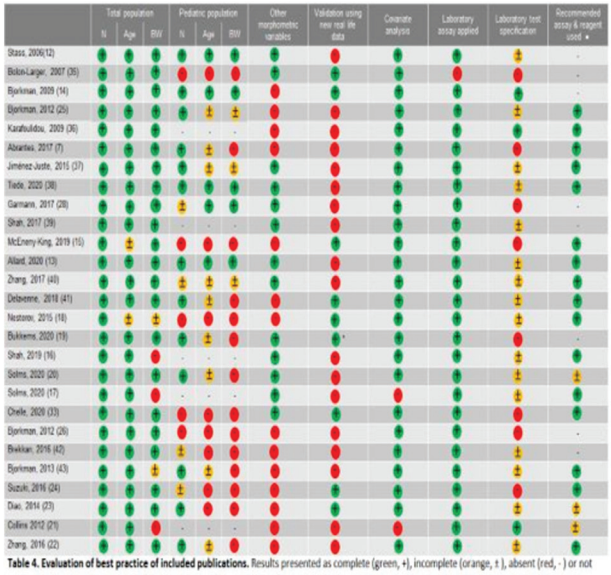

Table 4. Evaluation of best practice of included publications. Results presented as complete (green, +), incomplete (orange, ±), absent (red, -) or not applicable (-). N: Number of subjects. BW: body weight. HT: height. ● According to UK guidelines Grey et al Haemophilia 2020. * Bukkems et al. have externally validated the model of Nesterov et al.

Summary/Conclusion: This evaluation of available prophylactic population PK models for FVIII and FIX shows a wide variation in detail of included clinical and laboratory data used to construct these models. We provide an overview and give recommendations with regard to best practice to increase the reliability of PK-guided dosing of factor concentrates for prophylaxis in hemophilia A and B.

EP570 FACTOR XI DEFICIENCY IN PREGNANT WOMEN: A GENOTYPE TO PHENOTYPE CORRELATION AND ANALYSIS

G. Sacchi De Camargo Correia [1,*], L. Cytryn [2], S. Rajeeve [3]

[1]Department of Medicine, [2]Division of Hematology and Oncology - Department of Medicine, Icahn School of Medicine at Mount Sinai West & Morningside, [3]Division of Hematology and Oncology - Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, United States

Background: Factor XI (FXI) deficiency (FXIDef) is an otherwise rare bleeding disorder that commonly affects Ashkenazi and Iraqi Jews, with a homozygous prevalence of 1:450, and a heterozygosity rate of 8%. In the general population, however, heterozygosity rate is estimated to be 1%. Pregnancy in these women poses a potential increased bleeding risk during delivery.
Aims: We describe the experience of an Outpatient Hematology Service in New York to which pregnant women with FXIDef are referred. Different genotypes of FXIDef and their impacts on patients' phenotypes were analyzed.
Methods: We identified 39 patients with FXIDef evaluated by a single provider between October/2016 and February/2020. Diagnosis was established on routine genetic screening during pregnancy. Epidemiological, clinical, and laboratory data were reviewed. Anesthetic modalities and routes of delivery were also extracted from the records. FXI activity (FXIAct) was measured at initial visit, and near term, at approximately gestational week 37. Basic statistical data for relevant parameters were calculated. Comparisons between FXIAct at first visit and near term, and between genotypes, were made with two-sample T-test.
Results: In the sample, 61.54% presented mutation c.901T>C, p.F301L (c.901); 28.20% had mutation c.403G>T, p.E135X (c.403); and 10.26% had 4 different mutations. In the c.901 group, 87.5% showed Jewish ancestry, while 72.73% in the c.403 group presented this ancestry. No statistically significant difference (p=0.43) in FXIAct at first visit was seen between the commonest mutations, also without difference near term (p=0.45). Comparing FXIAct between the first appointment and near term within the c.901 group showed no significant difference (p=0.96), and no difference was noted when comparing the same parameters within the c.403 group (p=0.29). Most patients had a normal vaginal delivery, with no complications recorded, with no need for therapeutic interventions secondary to excessive bleeding. One patient (c.901 group) received a prophylactic intervention before delivery, receiving intravenous tranexamic acid before delivery due to a FIXAct of 42%. Only a single patient from our analysis was homozygous, and she presented mutation c.901. This patient did not receive any special prophylactic or therapeutic interventions before or during delivery. See the attached table for further data.

	c.901T>C, p.F301L	c403G>T, p.E135X
Number of patients (n)	24	11
Mean Age (years)	33.12 ± 3.94	33.91 ± 3.83
Number of homozygous patients (n; %)	1; 4.2%	0; 0%
Jewish ancestry (n; %)	21; 87.5%	8; 72.73%
Mean FXI activity on 1st appointment (%)	54.92 ± 18.68	68.00 ± 51.69
Mean aPTT on 1st appointment (s) (normal range: 24.6- 34.7s)	30.90 ± 3.19	31.85 ± 2.51
Mean INR on 1st appointment (normal range: 0.9-1.1)	0.97 ± 0.07	1 ± 0.04
Mean Platelets on 1st appointment (x10⁹/L) (normal range: 150-450x10⁹/L)	234.96 ± 32.16	211 ± 40.55
Mean FXI activity near term (%)	55.26 ± 23.13	50.11 ± 11.13
Mean aPTT at birth (s)	30.04 ± 2.16	30.48 ± 2.54
Mean Blood Loss on Delivery (mL)	348.89 ± 198.60	290.25 ± 68.26
Mean Postpartum Blood Loss (mL)	103.12 ± 245.78	28.67 ± 52.60
Neuraxial Anesthesia (n; %)	15; 62.5%	5; 45.45%
Normal vaginal delivery (n; %)	20; 83.3%	11; 100%

Summary/Conclusion: No significant differences were noted between genotypes in our series. Genotypes correlate with ethnicity, with mutations c.901 and c.403 associated with Jewish ancestry. Comparing our data with other cohorts may allow for broadening of the finding that different genotypes do not affect presentation during pregnancy. Nonetheless, monitoring for FXIDef allows for prophylactic treatment in cases of increased bleeding risk, and it also contributes when deciding the best type of anesthesia for these patients, as neuraxial block is usually contraindicated in cases with FXIAct <40% in our institution. Therefore, genetic tests are valuable for counseling and diagnostic purposes, as well as measuring FXIAct is still relevant in pregnancy. However, as no significant difference in FIXAct was noted between initial visits and near term visits, similar to what has been described in other cohorts, reassessing FXIAct throughout pregnancy may not be necessary. Further studies and continuation of this project will assist in answering this question.

EP571 ACQUIRED VON WILLEBRAND DISEASE: THE DIAGNOSIS AND MANAGEMENT OF AN UNDERDIAGNOSED COAGULOPATHY

A. Ferretti [1,*], E. Baldacci [2], S. Lancellotti [3], F. Barone [1], G. Lapietra [1], M. Basso [4], A. Pallotta [1], A. Chistolini [5], E. De Candia [6], C. Santoro [1]

[1]Department of Translational and Precision Medicine, Sapienza University, [2]Department of Translational and Precision Medicine, Sapienza University, Hematology, [3]Unità Operativa Malattie Emorragiche e Trombotiche, Area di Ematologia, Fondazione Policlinico Universitario "Agostino Gemelli", IRCCS, [4]Unità Operativa Malattie Emorragiche e Trombotiche, Area di Ematologia, Fondazione Policlinico Gemelli IRCCS, [5]Department of Translational and Precision Medicine, Sapienza University, Sapienza University, [6]Unità Operativa Malattie Emorragiche e Trombotiche, Fondazione Policlinico Universitario "Agostino Gemelli", IRCCS, Rome, Italy

Background: Acquired Von Willebrand Syndrome (AVWS) is a rare acquired coagulopathy, often associated to an underlying disorder (lymphoproliferative, cardiovascular, myeloproliferative, neoplastic, and autoimmune disorders). The diagnosis is not easy and relies on a negative familial and personal clinical hemorrhagic history and a late onset in life of bleeding symptoms, associated with a laboratory pattern for Von Willebrand Disease (VWD).
Aims: Aim of this study is to describe the experience on diagnosis and management of AVWS patients (pts) in two Italian centers.
Methods: Between 2004-2020 we have diagnosed and managed 14 pts [8F, 6M; median age 62.45 years (45.4-85.9)] affected by AVWS. Determination of coagulation parameters, including FVIII, were carried out on an automatic coagulometer (ACL Top 700, Werfen). VWF:antigen (VWF:Ag) and VWF:activity (VWF:RCo) were measured by chemiluminescence assays (HemosIL AcuStar, Werfen). VWF propeptide (VWFpp) level was measured by ELISA immunoassay (Sanquin, Amsterdam, NL). The screening for VWF:RCo inhibitor was made utilizing mixing studies
Results: Reasons for diagnosis were: recent onset of bleeding symptoms in 9 pts, increased aPTT in 5. At diagnosis, for all pts we observed these results: median VWF:Ag 15%, range 1.6-51% (n.v. blood group 0: 41-101%; no 0: 50-130%); median VWF:RCo 13%, range <6.25-33% (n.v. blood group 0: 41-97%; no 0: 52-124); median FVIII:C 19.2%, range 2.1-53% (n.v.58-130%)]. VWF:RCo inhibitor was searched in 4 cases: 3 were negative, 1 positive. We could study VWFpp and multimers in 9 pts. Except VWFpp median level (81.5%, range 42.9-154.3) all other VWF-related median parameters (VWF:Ag, VWF:RCo and FVIII:C) were significantly reduced in patients, respectively 7.3%, 4.5% and 15.2%. VWFpp/VWF:Ag ratio was significantly higher in all 9 patients: 20 (n.v.<3). Multimers were absent in 6 pts, normal in 2; in 1 patient were present just low molecular weight multimers. All the pts did not have either a family or past personal history of bleeding disorders/symptoms. The spontaneous hemorrhagic events presented at diagnosis and during follow up were: GI and gum bleeding, muscle hematomas, hematuria, ecchymoses, epistaxis. Three pts bled after dental extractions/procedures, although they were prophylactically treated with VWF/FVIII concentrate. Desmopressin, Tranexamic Acid, VWF/FVIII concentrate and recombinant FVIII were used as prophylaxis or treatment of bleedings in all pts, with variable responses on clinical symptoms. Thirteen/14 cases showed a concomitant disorder: 1 gastric B cell MALT lymphoma, 1 indolent B cell lymphoma, 7 MGUS, 2 Waldenstrom Disease and 2 patients with breast cancer and concomitant MGUS. In one case AVWS was idiopathic. In the table, therapies either for underlying disorders if present or AVWS and outcomes are shown.

Management of the patients with lymphoproliferative disorders		
Type	Treatment	Response
Gastric B cell MALT lymphoma	Rituximab	Complete remission of lymphoma and AVWS
Waldenstrom Disease (1st patient)	R-CVP Ibrutinib	After 2nd line, stable lymphoproliferative disease and persistent AVWS
Waldenstrom Disease (2nd patient)	Rituximab After two years for disease progression: Rituximab+- Bendamustine	Partial response Persistent AVWS and partial response of lymphoma
Indolent B cell lymphoma	watch and wait strategy Rituximab	 Complete remission of lymphoma and AVWS
Strategies to manage AVWS in all patients		
Type of disorder	Treatment	Response
MGUS 1 patient	Prednisone + cyclophosphamide and then high dose immunoglobulins	No response to either therapies
MGUS 3 patients	infusion of high dose immunoglobulins (2 cases are under chronic treatment with iv Ig every 6-8 weeks)	Transient CR as regard VW disease laboratory
MGUS 4 patients	No treatment	
1 patient with breast cancer	prednisone	Response to bleeding's symptoms
Idiopathic AVWS	Prednisone At relapse Prednisone + cyclophosphamide	CR on VW disease laboratory parameters CR on VW disease laboratory parameters

Summary/Conclusion: AVWS is a rare syndrome, probably underdiagnosed because unrecognized. AVWS must be suspected whenever a patient presents with a late onset in life of bleeding symptoms associated to laboratory characteristics compatible with VWD. The VWFpp/VWF:Ag ratio could be a valuable biomarker to be considered in these complicated diagnoses. It is mandatory to search for concomitant diseases.

EP572 INVESTIGATION OF PRETERM INTRAVENTRICULAR HEMORRHAGE-INDUCED INFLAMMATORY RESPONSE AND MICRORNA LEVELS IN HUMAN CHOROID PLEXUS EPITHELIAL CELLS

Z. Fejes [1,*], M. Pócsi [1], A. Balla [1], E. Balogh [2], A. Tóth [2], V. Jeney [2], Á. Rusznyák [3], F. Fenyvesi [3], A. Nagy [4], J. Kappelmayer [1], B. Nagy Jr. [1]

[1]Department of Laboratory Medicine, [2]Research Centre for Molecular Medicine, Faculty of Medicine, University of Debrecen, [3]Department of Pharmaceutical Technology, Faculty of Pharmacy, University of Debrecen, [4]Department of Pediatrics, Faculty of Medicine, University of Debrecen, Debrecen, Hungary

Background: Intraventricular hemorrhage (IVH) is a severe complication of prematurity that results in an increased risk of neonatal mortality and neurodevelopmental impairment. After preterm IVH, subsequent destruction of red blood cells (RBC) and oxidation of extracellular hemoglobin (Hb) with the release of heme may cause a local inflammation with cellular dysfunction in the subarachnoid space. We have recently reported elevated expression of pro-inflammatory cell-free microRNA (miRNA) in cerebrospinal fluid (CSF)

samples obtained from preterm infants with grade III or IV IVH in correlation with high levels of oxidized Hb forms and soluble adhesion molecules.
Aims: In this study, our aim was to investigate the IVH-induced inflammatory cellular events in human choroid plexus epithelial cells (HCPEpiC) among *in vitro* conditions.
Methods: Primary HCPEpiC cell cultures were first exposed to CSF samples of preterm infants with IVH vs. clinical control samples (10 v/v %) for 24 hours. To observe the direct effect of hemorrhage, cells were treated with heme (25 µM) or TNF-α (100 ng/mL) as a positive pro-inflammatory agonist for 1-24 hours. After treatment, total RNA was extracted using TRI reagent, and HMOX1, IL8, IL1B, VCAM1 and ICAM1 messenger RNA (mRNA) expression were quantified by RT-qPCR. miR-155 and miR-223 were also analyzed intracellularly and in the supernatants of the cells using normalization to "spike-in" cel-miR-39. Concentrations of soluble IL-8, VCAM-1 and ICAM-1 were measured by ELISA. Nuclear translocation of the NF-κB p65 subunit was investigated with fluorescence microscopy. Cell viability was evaluated using MTT assay and via the measurement of LDH leakage in cell culture medium.
Results: Exposure to IVH CSF samples a substantial cell activation was triggered in HCPEpiCs with significant elevation in HMOX1, IL8, IL1B and ICAM1 mRNA expression in comparison to controls. Interestingly, VCAM1 mRNA level did not change after 24 hours. When cells were preincubated with heme, there was a time-dependent up-regulation in IL8, IL1B and ICAM1 mRNAs in the presence of induced *HMOX1* expression. Furthermore, significantly elevated protein levels of IL-8 and ICAM-1 were observed similar to TNF-α. Importantly, both mediators induced the nuclear translocation of the NF-κB p65 subunit. The expression of miR-155 and miR-223 were elevated in the cell culture supernatants after treatment with heme and TNF-α that underlines our former results in IVH CSF. In contrast, intracellular miR-223 was decreased, which may be related to up-regulated *ICAM1* expression. Based on the results of cell viability assay and LDH leakage, we did not find any substantial heme- or TNF-α-induced cellular damage in our experimental conditions.
Summary/Conclusion: In IVH, choroid plexus epithelial cells are highly affected by the consequences of bleeding that may contribute to the development of different complications of the disease.

EP573 THE ANALYSIS OF THE TREATMENT OUTCOME OF PATIENTS WITH ACQUIRED HEMOPHILIA IN CROATIA

M. Vodanovic [1,2,*], D. Pulanic [1,3], S. Zupancic Salek [3,4], A. Boban [1,3], D. Coen-Herak [5], M. Miloš [5], R. Zadro [6,7], I. Aurer [1,3]

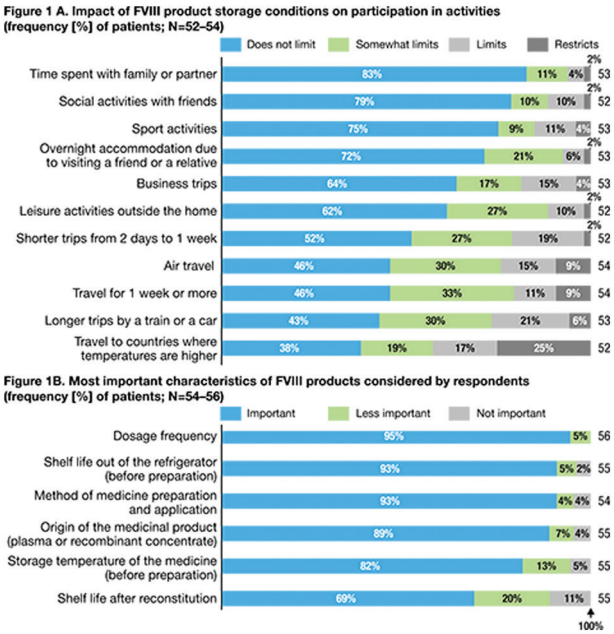
[1]Department of Internal Medicine, Division of Hematology, UHC Zagreb, [2]University of applied Health Sciences, [3]School of Medicine, University of Zagreb, Zagreb, [4]Faculty of Medicine, Josip Juraj Strossmayer University of Osijek, Osijek, [5]Department of Laboratory Diagnostics, UHC Zagreb, Zagreb, [6]Laboratory Medicine, St Catherine Specialty Hospital, Zabok, [7]Faculty of Pharmacy and Biochemistry, University of Zagreb, Zagreb, Croatia

Background: Acquired haemophilia A (AHA) is a rare autoimmune disease, caused by antibodies (inhibitors) against coagulation FVIII and characterized by spontaneous hemorrhage in patients with no previous history of bleeding. Risk factors for the occurrence of AHA include advanced age and underlying diseases (malignancy, autoimmune disorders, pregnancy, and the postpartum period).
Aims: The aim is to analyze treatment outcomes of patients with acquired hemophilia A during the last ten years at the University Hospital Center Zagreb.
Methods: We analyzed retrospectively treatment outcomes of patients with AHA in the Department of Hematology, University Hospital Center Zagreb from 2010-2020. Response to treatment was assessed as partial (PR) or complete remission (CR).
Results: We analyzed the outcomes of twenty patients (11 (55%) male, 9 (45%) female), median age was 68 (33-81) years, and with median FVIII activity 5 (1 – 15) IU/dL and median inhibitor titer at the time of AHA diagnosis was 9 (2,3 – 2000) BU/ml. Severe bleeding had 75 % patients requiring erythrocyte transfusion. In 12 patients (60%) were identified underlying diseases: malignancies 2 (oligodendroglioma, B-CLL), autoimmune diseases 9 (autoimmune haemolytic anaemia - 2 rheumatoid arthritis - 2, polymyalgia rheumatica - 3, pemphigus -1 and myasthenia -1). One patient had postpartal AHA. The last female patient with myasthenia was diagnosed in December 2020. and she developed COVID19 bilateral pneumonia with ARDS. 90% of patients recieved hemostatic treatment (65 % - aPCC, 10% aPCC and rFVIIa, 25 % - rFVIIa). All patients were treated with immunosuppressive therapy, combination of cyclophosphamide and steroids in 18/20, steroids alone in 2/20 patients, while 3/20 patients (15%) were treated in the second line therapy. The response rate to the first line eradication therapy was 90%. Inhibitor eradication time was 18 (3-300) days, time to achieve CR was 32 (15-300) days. At follow up of 31 (1-90) months 13 patients (65%) are alive, 7 (35%) dead. No death was due to bledding. Two patients died of pneumonia, two deaths were associated with sepsis, one with progressive malignant disease and one with cardiogenic shock. One female patient died of COVID19 at the age of 55 years, 25 days after AHA was diagnosed. Higher inhibitor activity, known underlying cause of AHA with advanced age, comorbidities were unfavourable factors of survival.
Summary/Conclusion: Our treatment outcomes are very similar to the large European Registries, with the quite high response rate of eradication therapy in the first line treatment (90%). Infective complications and comorbidities were the leading causes of death. Patients with AHA and COVID19 could have a worse outcome due to immunosuppressive therapy.

EP574 HAEMOPHILIA B LEYDEN, AN AGE-RELATED MECHANISM FOR AN INCREASE OF FACTOR IX: CASE REPORT AND LITERATURE REVIEW

C. Alburquerque-Prieto [1,*], M. V. Aznar-Moreno [1], P. Millacoy [2], J. Coll-Vallier [1], M. J. Paloma-Mora [1], M. Rodriguez-Calvillo [1], E. Gómez-Arteta [1], J. M. Sánchez-Iglesias [1], C. Ceballos-Bolaños [1], I. Múgica-Muñagorri [1], A. M. Redondo-Izal [1]

[1]Hematology Service, Complejo Hospitalario de Navarra, Pamplona, [2]Hematology Service, Hospital Reina Sofía, Tudela, Spain



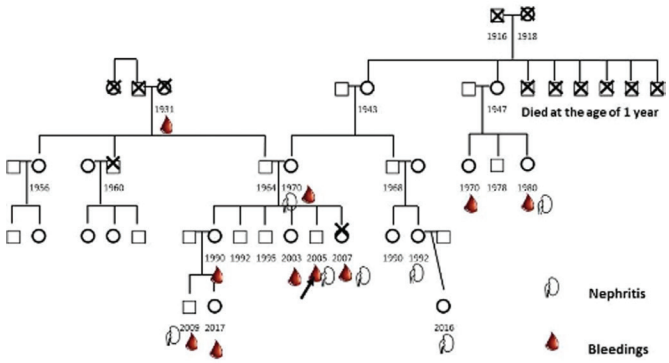
Background: Haemophilia B is a male-dominant human bleeding disorder that it is produced by mutations at the F9 gene located at Xq27; and it is characterised by reduced levels of factor IX. Haemophilia B Leyden is a subtype of haemophilia B with a phenotype of abnormal bleeding in the first period of life, increasing levels of factor IX during the puberty by an unknown and controversial mechanism. From previous assays it has been reported an 1.9% of patients with haemophilia B Leyden.
Aims: To visualize an unknown subtype of haemophilia B, and to underwrite the importance of the existence of the worldwide database to improve its knowledge.
Methods: We report clinical, phenotypical features of a clinical case of Haemophilia B Leyden in a newborn; and genotyping analysis of FIX performed by Sanger sequencing or Next Generation Sequencing according to local practice.
Results: At 2 days of age, the patient was referred to our centre because of an important bleeding after heel neonatal screening done in a regional hospital. There were no other localizations of bleeding at the time of the examination. During and after delivery no bleeding was observed. Laboratory assays revealed a prolonged activated partial thromboplastin time (APTT) with a reduced factor IX level of 1%. During follow-up the FIX:C has gradually increased (4% with 3 months and 6% with 8 months).
At 6 months of age, the patient suffered a mild head trauma after a fall. The patient waited for 24 hours to attend to the hospital. A brain computed tomography was performed, without any visible external bleeding. He was under active surveillance during 24 hours.
There was no history of haemophilia in his family. Genotyping analysis of FIX was performed by Next-Generation Sequencing (NGS) and a point mutation (c.-35G>A, variant NM¬_000133.) was detected, located in the F9 promoter region. The familiar study confirmed that his mother was a carrier. She had no history of bleeding and her FIX level was 163%.
Summary/Conclusion: Haemophilia B Leyden is an illness mediated by a genetic mechanism that produces an age-related increase in FIX levels. Patients with haemophilia B Leyden present a rise in the level of FIX, being this increase more pronounced after puberty. This mechanism is associated with growth hormone secretion, that is low during infancy and increases during early childhood until puberty, going the levels of FIX from the severe range to the mild, normal range progressively. This correction in plasma FIX levels occurs as well in female carriers of haemophilia B Leyden; according to this fact, an androgenic effect is not needed.
Thirteen different point mutations concerning haemophilia B Leyden have been identified, and just 35 cases with the c.35G>A variant have been reported in Factor IX Variant Database. Haemophilia B Leyden remains as a biological challenge, with more studies needed. In this respect, it is worth noting that the existence of a worldwide database can be very useful to improve our knowledge about this curious haemophilia.

EP575 HEMOPHILIA A SELF-MANAGEMENT – PATIENTS' PERSPECTIVES AND CHALLENGES

I. P. Zupan [1,2,*], K. Rener [1,2], S. A. Doma [1,2]

[1]Department of Haematology, University Medical Centre Ljubljana, [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

Background: Despite major advances in the treatment of hemophilia A, limitations experienced by patients still remain. Good clinical treatment outcomes such as low annualized bleeding rates depend on careful patient adherence to the regimen of their factor VIII (FVIII) product. Another important aspect of patient self-management is portability and storage of recombinant FVIII (rFVIII) products. Patients with hemophilia A can benefit from the use of rFVIII products such as turoctocog alfa and turoctocog alfa pegol since, unlike other products, they can be stored at temperatures ≤40°C for ≤3 months.
Aims: To identify limitations regarding compliance, storage conditions and understanding of treatment with FVIII products among patients with hemophilia A.
Methods: Patients with hemophilia A in Slovenia who use different FVIII products completed a 10-minute, self-administered questionnaire comprising 22 questions. Questions focusing on patients' hemophilia burden, everyday limitations, their perceptions and understanding of FVIII product storage were included.
Results: Data were collected between February and July 2020. Of 63 individuals surveyed (n=61 patients, n=2 caregivers), most were >18 years old (59 patients, 94%), had severe hemophilia A (43 patients, 68%), were treated prophylactically (44 out of 60 respondents, 73%) and dosed 3 times per week (19 out of 37 respondents, 51%) with different FVIII products. Mean (median) numbers of bleeds within the current 12 months were 5.7 (3.0) and 2.3 (1.0) for prophylactically and episodically treated patients, respectively, due to severe disease for patients on prophylaxis. Almost half of the respondents (26 out of 56 respondents, 46%) reported missed or forgotten doses. Of the 21 prophylactically treated patients who had their pharmacokinetics (PK) assessed, the reported trough FVIII activity ranged from 0-24%.
Bleed frequency within the last 12 months was higher for patients reporting missed/forgotten doses (mean [median], 5.9 [4.0]) compared to those patients with no missed/forgotten doses (4.6 [3.0]) during the same period. Most patients (42 out of 53 respondents, 79%) stored their product in a refrigerator and believed that FVIII products should always be stored at ≤25°C (49 out of 54 respondents, 91%). Perceived storage conditions limited daily activities for 76% (42 out of 55 respondents) of patients; travel (business trips and work activities) was the activity most frequently impacted (**Figure 1A**). Forty-six patients (73%) indicated that treatment satisfaction would be improved by a FVIII product that could be stored at >25°C (reasons included improved convenience [29 respondents, 63%], improved quality of life [9 respondents, 20%] and fewer restrictions on activities [8 respondents, 17%]). Interestingly, there was no difference between younger and older patients. Most patients considered dosing frequency, shelf life out of the refrigerator and method of product preparation/application as the most important characteristics of their FVIII product (**Figure 1B**).



Summary/Conclusion: Patients of all ages with hemophilia A often feel restricted in their daily activities by the perceived need to store FVIII products at <25°C. These restrictions have an impact on adherence to treatment. From the patients' perspective, the most important FVIII product characteristics were dosage frequency followed by shelf life out of refrigerator. Improved patient awareness and understanding of FVIII treatment could improve compliance and treatment outcomes in patients with hemophilia A.

EP576 CONGENITAL COMBINED VITAMIN K-DEPENDENT CLOTTING FACTORS DEFICIENCY, CASE REPORTS

D. Florinskiy [1,*], D. Fedorova [1], A. Poletaev [1], E. Seregina [1], P. Zharkov [1]

[1]Hemostasis Research Group, Dmitry Rogachev National Medical Research Center Of Pediatric Hematology, Oncology and Immunology., Moscow, Russian Federation

Background: Congenital combined vitamin K-dependent clotting factors deficiency(VKCFD) is a very rare bleeding disorder, few cases have been described worldwide.
Aims: To describe clinical manifestations in 2 patients with bleeding disorder.
Methods: Retrospective medical chart review. Coagulation factor measurement was performed using standard kits and ACL TOP-700 coagulometer (IL, USA).
Results: 1st Patient: 12yo boy who had unexplained bleeding episodes from the age of 1 year (easy bruising, epistaxis) was admitted an outpatient unit of our Centre because of excessive bleeding. By the time of admittance he had already had recurrent episodes of joint bleedings (elbow, ankle and shoulder joint 2 times), haematuria 5 times, bleeding after tooth extraction, easy bruising, epistaxis, bleeding from oral cavity (PBQ=19). that required plasma transfusions. At the initial laboratory assessment combined PT and APTT with normal fibrinogen and vWF:Rco had been revealed. Intestinal malabsorption and severe liver dysfunction were excluded, and clotting factors activity(CFA) were measured: FII 12%(79-131), FIX 30,4%(65-150), FV 85,4%(62-139), FVII 4,8%(50-129), FX 12,5%(77-131), FXI 93,4 % (N 65-150), FXII 83,8% (N 50-150), protein S 43.1% (70-130), protein C 41% (70-140). An increase in the CFA was detected 24 hours after of subcutaneous 10 mg Vitamin K1 injection, with a rapid loss of response after 48 hours.
2nd patient, his sister, who has been suffering from recurrent mild haematuria and menorrhagia (PBQ=5) and debuted at the age of 3 years with haematuria also had low CFA: FVII 11,4%, FII 13%, FIX 24%, FX 8%. No mutations in *VKORC1* и *GGCX* genes using NGS were detected, so MLPA is planned. Other affected family members were suspected (Pic. 1).

Summary/Conclusion: The bleeding symptoms vary significantly even within the same family, despite comparable factor activity. No mutations in *VKORC1* и *GGCX* genes were found, which doesn't exclude VKCFD.

EP577 IS ANTI-NUCLEAR ANTIBODY POSITIVITY A FACTOR FOR AFFECTING TREATMENT RESPONSE IN IMMUNE THROMBOCYTOPENIA PATIENTS ON ELTROMBOPAG?

M. Baysal [1,*], V. Bas [1], E. Umit [1], O. Kirkizlar [1], A. M. Demir [1]

[1]Trakya University Medical Faculty, Department of Hematology, Edirne, Turkey

Background: Immune thrombocytopenia (ITP) is an autoimmune disease characterized by a low platelet count which is caused by increased destruction of thrombocytes due to platelet autoantibodies and impaired platelet production.The antibodies that aim at proteins within the nucleus of a cell are called antinuclear antibodies (ANA). ANA positivity was reported between 25-39 % in studies conducted with ITP patients. Thereafter; testing for ANA was suggested as a test of potential utility according to the International consensus report on the investigation and management of primary immune thrombocytopenia. The first-line treatment of ITP consists of corticosteroids and IVIG. In patients who are corticosteroids dependent or do not have a response to corticosteroids; recommended treatment options are thrombopoietin receptor agonists (TPO-RAs), splenectomy, and rituximab. Eltrombopag and romiplostim are the currently licensed TPO-RAs for ITP. Eltrombopag is an orally available non-peptide TPO-RA and accessible in Turkey.
Aims: Despite being widely used, markers to show the response for eltrombopag are lacking and needed. In the present study, we tried to show the association between ANA positivity and eltrombopag response in ITP patients.
Methods: Patients who were diagnosed with ITP at Trakya University Faculty of Medicine Hematology Department between 01.01.2016 and 31.12.2020 and who received eltrombopag treatment due to their resistance to steroids and other treatments were included in our study. ANA measurement was made with indirect fluorescent antibody and titers of 1:160 and above were considered positive. Response criteria are listed as follows:complete response (CR): platelet count ≥100 × 10^9 / L and no bleeding, response (R): platelet count ≥30 × 10^9 / L and no bleeding, no response: defined as platelet count <30 × 10^9 / L or bleeding. For statistical analysis, SPSS 22.0 was used and a two-sided p-value below or equal to 0.05 was considered as statistically significant. Chi-square and Fisher's exact test was used in the analysis of variables. Chi-square contingency analysis was also performed due to lack of sample size.
Results: A total of 45 patients were included in our study. 33 were female and 12 were male. The mean age of the patients was 45, 73. There were 14 patients with ANA positivity and 31 patients found to be ANA negative. Response rates of the patients were evaluated according to their thrombocyte count during the treatment 1st month, 3rd month, and 6th month. One patient developed pulmonary emboli and grade 3 hyperbilirubinemia occurred in another patient while eltrombopag treatment and eltrombopag discontinued in both cases. Response rates were higher in ANA positive patients compared to ANA negative patients in the first and sixth months of the eltrombopag treatment ($p < 0.05$).

Response Rates According to ANA Positive and Negative Patients

	ANA positive N= 14	ANA negative N= 31	P value
1st Month			0,034
Complete Response	2 (14,3 %)	17 (54, 8 %)	
Response	9 (64,3 %)	9 (29, 0 %)	
No Response	3 (21,4 %)	5 (16, 2 %)	
3rd Month			0,640
Complete Response	7 (50 %)	21 (67, 7 %)	
Response	5 (35, 7 %)	6 (19, 3 %)	
No Response	2 (14, 3 %)	4 (13, 0 %)	
6th Month			0,019
Complete Response	7 (53, 8 %)	22 (73, 3 %)	
Response	4 (30, 8 %)	7 (23, 3 %)	
No Response	2 (15, 4 %)	1 (3, 3 %)	

Summary/Conclusion: Various autoimmune antibodies have been shown to be more positive in ITP patients than in people in the healthy normal population. Positive ANA test in ITP patients was associated with poor response to steroids and a more chronic disease outcome in retrospective studies. Our study population includes steroid resistant or dependent patients which could be a factor for low response rates seen in ANA positive patients. To conclude, ANA positivity in ITP may indicate unresponsiveness to eltrombopag treatment, and this should be supported by prospective studies involving more patients

EP578 NEW LIKELY PATHOGENIC VARIANTS IN THREE SPANISH PATIENTS WITH MILD HEMOPHILIA A AND B: GENETIC COUNSELING.

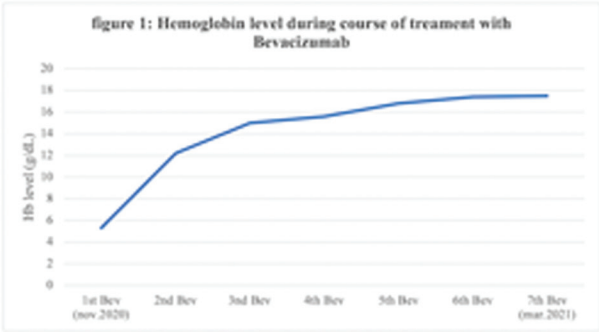
M. Civeira Marín [1,*], R. Lahoz Alonso [2], A. López Peña [1], C. Rodríguez Lefler [1], C. F. Hernández Mata [1], M. Moreno Carbonell [1], E. Gonzalez [1], A. Gomez Martínez [1], S. Martin-consuegra Ramos [1], R. González Tarancón [2], S. Izquierdo Álvarez [2], N. Fernández Mosteirín [1], J. M. Calvo Villas [1]

[1]hematology, [2]genetics, Hospital Universitario Miguel Servet, zaragoza, Spain

Background: Mild hemophilia A (HA) and B (HB) are X-linked recessive hereditary diseases, characterized by factor VIII and IX deficiency, respectively. Patients with mild or moderate hemophilia mostly present specific mutations in *F8* gene (Xq28) or *F9* (Xq22), detectable by direct sequencing. More than 4000 mutations have been detected so far and genotype analysis should be offered in selected patients. Therefore, genetic assessment is important to provide reproductive options.
Aims: We report three new likely pathogenic variants in three male Spanish patients. Patient 1 presented asymptomatic prolonged pre-operatory aPTT and the others were studied due to hemorrhagic complications of surgery. All presented isolated reduced factor VIII or IX activity levels.
Methods: Molecular genetic studies: DNA was extracted from peripheral blood. Coding exons and adjacent intronic regions of F8 and F9 gene were amplified by polymerase chain reaction (PCR) and sequenced on Applied Biosystems® 3500DX Genetic Analyzer. The results were checked in HGMD, ClinVar, dbSNP, gnomAD, and 1000G international databases and different in silico prediction algorithms, such as: PolyPhen-2, SIFT, Mutation Taster, Align GVGD, REVEL and others were consulted.
Results: Three new missense variants were found (table 1). These variants have not been previously reported in the literature or in any of the databases consulted. They do affect the physical-chemical characteristics of the protein (*in silico* prediction). Therefore, they are classified as likely pathogenic. Because of this, we extended the study to first-degree relatives; finding carriers that were not diagnose at that time. A 20-year-old daughter (patient 1) and a sister (patient 2) received genetic counseling.

Patients	Hemophilia type	Age at diagnose (years)	Factor activity (%)	DNA variations				*In silico* prediction
				Gene	Exon	Amino acid (nucleotide) change	Genotype	
P1	A	42	13.3	*F8*	4	p.Val181Leu (c.541G>T)	hemizygous	4/4
P2	A	55	10.5	*F8*	3	p.Asp101Glu (c.303T>A)	hemizygous	4/4
P3	B	30	23.2	*F9*	7	p.Glu259Gly (c.776A>G)	hemizygous	12/16*

Table 1. **Genotypic results of the three patients.** *In silico* prediction algorithms used in the three cases: PolyPhen-2, SIFT, Mutation Taster and Align GVGD. *In patient 3 the following algorithms were also utilized: FATHMM, FATHMM-MKL, DEOGEN2, MVP, MetaSVM, MetaLR, DANN, Mut. Assessor, SIFT, SIFT4G, Provean, REVEL and GERP.



Summary/Conclusion: These new genetic variants confirm the clinical suspicion of mild hemophilia. The molecular genetic analysis in the family members helps finding asymptomatic carriers so we can provide them genetic counseling. Future reproductive options will be considered in the youngest patient and any family members if needed, firstly and foremostly, prenatal fetal sex chromosome testing by maternal plasma DNA sequencing on female carriers.

EP579 BEVACIZUMAB AND RESCUE TREATMENT FOR SEVERE GASTROINTESTINAL BLEEDING IN VON WILLEBRAND DISEASE

D. Rochate [1,*], C. Pavão [1], A. R. Leal [1], A. Moreira [1], J. Oliveira [1], A. R. Dias [1], F. Oliveira [1], C. Viveiros [1], A. L. Araújo [1], C. Fraga [1]

[1]Department of Hematology, Hospital do Divino Espírito Santo de Ponta Delgada, PONTA DELGADA, Portugal

Background: Von Willebrand disease (VWD) is a disorder predominantly attributable to a deficiency or dysfunction of the Von Willebrand factor (VWF) glycoprotein. It is typically characterized by recurrent episodes of mucocutaneous bleeding. Gastrointestinal (GI) bleeding associated with angiectasy is a rare but challenging complication which can result in frequent hospitalizations for red cell transfusion. Management options have been limited to off license use of anti-angiogenic and hormonal agents lacking supporting data. Since the discovery of elevated vascular endothelial growth factor (VEGF) expression in patients with VWD, reports of Bevacizumab, a monoclonal antibody against VEGF, in managing complications of VWD have emerged, with most of the reported experience in recurrent epistaxis. We present a case of VWD with refractory and progressive transfusion requirements secondary to severe GI bleeding that did not respond to conventional therapy.
Aims: Present a case of VWD with refractory transfusion requirements secondary to severe GI bleeding.
Methods: Clinical case report.
Results: A 60-year-old man with Type IIA VWD chronically medicated with VWF/FVIII prophylaxis and recurrent epistaxis, presented recurrent GI bleeding associated with small intestine angiectasies. Treatment with VWF/FVIII prophylaxis and octreotide resulted in only temporary cessation of bleeding and the patient had enduring transfusion weekly requirements with frequent need for hospitalization. Despite endoscopic and medical treatment attempts with hormonal agents and octreotide, the patient developed persistent hemorrhage and severe anemia, leading to red blood cell transfusions dependency. Subsequently he commenced on a course of Bevacizumab (5mg/kg, every 15 days). Immediately after initiating Bevacizumab, complete cessation of bleeding episodes was observed and hemoglobin levels anticipated a growing trend, as demonstrated in figure 1. The patient has been transfusion-independent since beginning anti-VEGF therapy. Currently, after 4 months of follow-up, he maintained sustained complete response without the occurrence of adverse events.

Summary/Conclusion: Our patient shown to gain noteworthy benefit from anti-VEGF therapy (Bevacizumab) with total transfusion independence and significant improvement in quality of life. This case illustrates the challenging nature of angiodysplasia-related GI bleeding in patients with VWD and shows that Bevacizumab seems to be a safe, well tolerated and efficient treatment in this group of patients. Nevertheless, the optimal dosage and duration of bevacizumab for GI bleeding in VWD, remains to be determined, and requires balancing the clinical benefits against potential adverse events of systemic treatment such as hypertension and thromboembolic events.

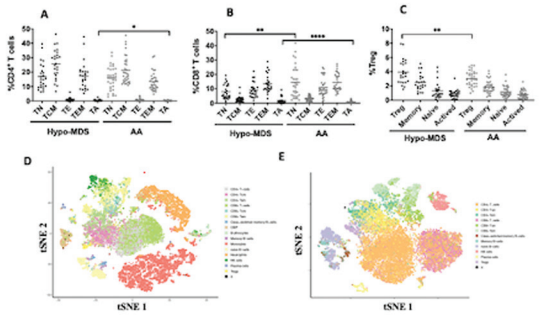
Bone marrow failure syndromes incl. PNH - Biology & Translational Research

EP580 ANTI-COX-2 AUTOANTIBODY AS A NOVEL DIAGNOSTIC MARKER IN APLASTIC ANEMIA

T. Kelkka [1,*], M. Tyster [1], S. Lundgren [1], C. Kerr [2], K. Hosokawa [3], J. Huuhtanen [1], M. Keränen [1], X. Feng [4], T. Kawakami [5], Y. Maeda [6], O. Nieminen [1], T. Kasanen [1], P. Aronen [1], B. Yadav [1], H. Rajala [1], H. Nakazawa [7], T. Jaatinen [8], S. Ogawa [9], F. Ishida [7], H. Nishikawa [6], N. Young [4], S. Nakao [3], J. Maciejewski [2], S. Mustjoki [1]

[1]University of Helsinki, Helsinki, Finland, [2]Cleveland clinic, Cleveland, United States, [3]Kanazawa University, Kanazawa, Japan, [4]National Heart, Lung, and Blood Institute, NIH, Bethesda, United States, [5]Shinshu University, Matsumoto, [6]Osaka University, Osaka, [7]Shinshu University, Shinshu, Japan, [8]Finnish Red Cross Blood Service, Helsinki, Finland, [9]Kyoto University, Kyoto, Japan

Background: In immune aplastic anemia (IAA) severe pancytopenia results from the destruction of blood-forming cells by the patient's own immune system. Although the detailed pathomechanism is unknown, most of the experimental and clinical data point towards lymphocyte-mediated autoimmunity. A number of autoantibodies have been reported to associate with IAA, but no clinically applicable autoantibody tests are available for IAA diagnostics.
Aims: We sought to identify novel diagnostic autoantibodies in IAA.
Methods: A microarray containing more than 9000 full length proteins was used to identify autoantibodies from IAA patients' plasma samples. A sandwich immunoassay was developed to examine the presence of the novel autoantibody against cyclo-oxygenase 2 (COX-2) in a large IAA (n=334) and control cohort (n=791) including patients with other autoimmune diseases and healthy controls. Both linear and conformational COX-2 autoantibody epitopes were identified using an epitope mapping platform (PEPperPRINT). Publicly available single cell RNA-sequencing (sc-RNA-seq) datasets were reanalyzed to study COX-2 expression patterns in the bone marrow samples.
Results: The protein microarray-based screening method revealed anti-COX-2 antibodies (aCOX-2 Ab) in three out of the five tested IAA patients, but not in any of the control samples. In a larger confirmation cohort 37 % (124/334) of the adult (>18 yo) IAA patients were tested aCOX-2 Ab positive. No aCOX-2 Ab seropositivity was detected in the healthy controls (n=74), in patients with non-autoinflammatory diseases (n= 162), rheumatoid arthritis (n=51) or in LGL leukemia (n=68). Sporadic positive cases were observed in multiple sclerosis (n=2/98) and in type I diabetes (n=2/45) as well in closely related bone marrow failure diseases including myelodysplastic syndrome (MDS, n=2/75) and idiopathic thrombocytopenia (n=4/105).
Logistic regression analysis revealed that aCOX-2 Ab positivity was tightly associated with increasing age and with the HLA-DRB1*15:01 genotype. 83 % of the IAA patients over 40 years of age with the HLA-DRB1*15:01 genotype were aCOX-2 Ab positive, thus, indicating an excellent test sensitivity in this age group.
In most seropositive patients, the aCOX-2 Ab was confirmed as an IgG1 isotype antibody, while in some IAA patients an additional IgG3 isotype signal was observed. In seven out of the ten tested patients the antigenic epitope was linear, and it was mapped to the very C-terminal end of COX-2. In addition, conformational mapping with cyclic peptides revealed two additional C-terminal epitopes that were also mapped to the C-terminus of COX-2. Lastly, sc-RNA-seq revealed that *COX-2* was mainly expressed in hematopoietic stem cells (HSC) as well as in myeloid cells, mostly in monocytes. Interestingly, elevated *COX-2* expression levels were identified in IAA patients' HCSs when compared to healthy controls and MDS patients.
Summary/Conclusion: aCOX-2 Ab is a highly specific diagnostic tool for IAA and has a potential to become a routine biomarker in bone marrow failure diagnostics. HLA-association, isotype distribution, and expression pattern in the bone marrow suggest that it also may participate in the pathogenesis of IAA.



EP581 COMPARISON OF LYMPHOCYTE SUBSETS IN HYPOPLASTIC MYELODYSPLASTIC SYNDROMES AND APLASTIC ANEMIA

M. Ge [1,*], X. Ren [1], Y. Shao [1], Y. Zheng [1]

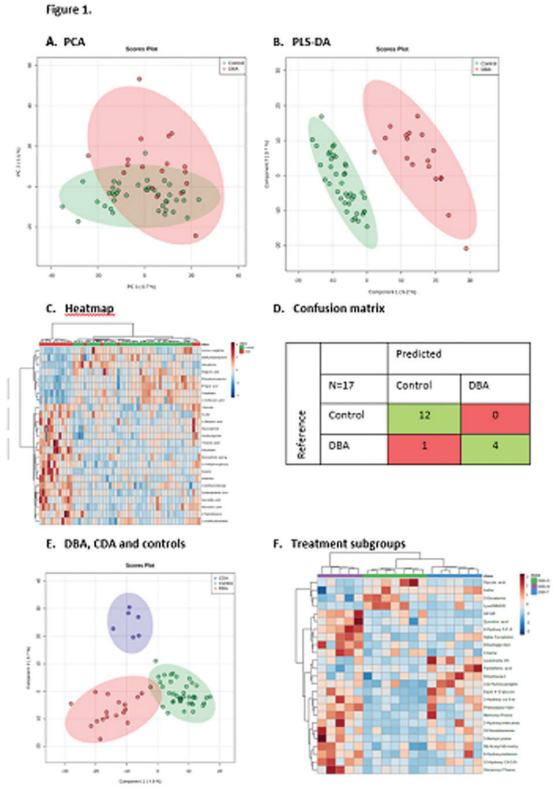
[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Tianjin, China

Background: Both hypoplastic myelodysplastic syndrome (hypo-MDS) and aplastic anemia (AA) are bone marrow failure. Although they display multiple similarities in clinical characterizations, there are great differences in the treatment and prognosis. It is necessary to distinguish them. It is now well established that abnormal lymphocyte subsets play an important role in hypo-MDS and AA. However, there was no report about the difference of lymphocyte subsets between hypo-MDS and AA.
Aims: This study aims to compare the proportion of peripheral blood lymphocyte subsets between patients with hypoplastic myelodysplastic syndrome (hypo-MDS) and aplastic anemia (AA).
Methods: A total of 25 patients with hypo-MDS and 33 patients with AA were collected, and the proportions of peripheral blood T lymphocyte subsets, $CD3^-CD16/CD56^+$ NK cells and $CD19^+$ B cells were detected by flow cytometry. The landscape of infiltrating lymphocyte cells in hypo-MDS and AA were detected by single-cell sequencing.
Results: Although the proportions of total lymphocyte, $CD3^+$ T cells and $CD3^+CD8^+$ T cells were higher in AA patients than those in MDS patients, there was no significant difference. The $CD4^+/CD8^+$ ratio was statistically lower in AA than that in hypo-MDS ($P<0.05$). There were no significant difference in the proportions of $CD3^-CD16/CD56^+$ NK cells and $CD19^+$ B cells. Furthermore, we divided the $CD4^+$ T cells and $CD8^+$ T cells to five subgroups, which named naive T cell (TN), central memory T cell (TCM), effector T cell (TE), effector memory T cell (TEM), and activated T cells (TA), and the Treg to three subgroups, which containing memory Treg, naive Treg and activated Treg. The TA proportions of $CD4^+$ and $CD8^+$ T cells in AA patients were obviously lower than those in the hypo-MDS group ($P<0.05$ and $P< 0.0001$). The TN proportion of $CD8^+$ T cells in the AA patients was obviously higher than that in the hypo-MDS patients ($P < 0.01$). The Tregs in AA patients was obviously lower than that in hypo-MDS patients ($P<0.05$). There were no significant difference in other subgroups between AA and hypo-MDS patients. There was difference in the landscape of infiltrating lymphocyte cells in hypo-MDS and AA detected by single-cell sequencing.

Fig1

Comparison of lymphocyte subsets in Hypo-MDS and AA: $CD4^+$T cell subsets(A) ; $CD8^+$T cell subsets(B) ; Treg subsets(C);Landscape of infiltrating lymphocyte cells in hypo-MDS(D) and AA (E) by single-cell sequencing.
TN, naive T cell; **TCM**, central memory T cell; **TE**, effector T cell; **TEM**, effector memory T cell; **TA**, activated T cells

Summary/Conclusion: Changes of lymphocyte subsets and the different landscape of infiltrating lymphocyte cells can be utilized as indexes in the differential diagnosis between AA and hypo-MDS.



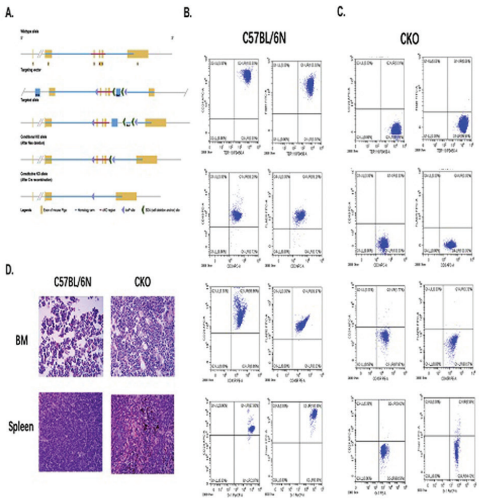
EP582 DRIED BLOOD SPOT METABOLOMICS REVEALS A METABOLIC FINGERPRINT WITH DIAGNOSTIC POTENTIAL FOR DIAMOND BLACKFAN ANEMIA

B. Van Dooijeweert [1,*], M. Broeks [2], E. van Beers [3], N. Verhoeven-Duif [2], W. van Solinge [4], E. Nieuwenhuis [5], J. Jans [2], R. van Wijk [4], M. Bartels [6]

[1]Pediatric Hematology/ Central Diagnostic Laboratory Research, [2]Genetics, Section Metabolic Diagnostics, [3]Van Creveldkliniek, [4]Central Diagnostic Laboratory Research, [5]Pediatric Hematology, [6]Pediatric Hematology/Van Creveldkliniek, University Medical Center Utrecht, Utrecht, Netherlands

Background: Diamond Blackfan anemia (DBA) is a rare inherited bone marrow failure syndrome characterized by erythroid hypoplasia, congenital malformations, growth defects and an increased risk of developing malignancies. From a clinical and genetic perspective the disorder is highly heterogeneous, and clear genotype-phenotype correlations are absent. Despite advances in our understanding of the genetic basis, the pathophysiology of DBA is still not fully understood. One of the major unresolved issues is how RP gene mutations result in the specific erythroid defect that characterizes DBA. Establishing the diagnosis of DBA can be particularly difficult since, in contrast to other IBMFS, no validated functional screening tests exists. Furthermore, the clinical presentation is highly heterogeneous, even within families with identical molecular defects. Currently, the diagnosis relies on consensus criteria and exclusion of other IBMFs and causes of anemia. In order to improve the diagnostic evaluation of DBA as well as our understanding of phenotypic heterogeneity and clinical severity, novel functional approaches are needed.
In this study we explore the potential of untargeted metabolomics on dried blood spots (DBS) to diagnose DBA.
Aims: Defining a metabolic signature for DBA from DBS, could **1.** Contribute to improvement of the diagnostic evaluation, and **2.** Increase our understanding of phenotypic heterogeneity and treatment response.
Methods: Untargeted metabolomics was applied on DBS samples obtained from 18 DBA patients and 40 healthy controls by direct infusion high resolution mass spectrometry using a previously established protocol (1,2). Statistical analyses were performed in MetaboAnalyst and predictive modelling was executed within R-software.
Results: A total of 1752 unique metabolite features were identified in the respective DBS samples from patients and controls. Distinct metabolic profiles were identified by principal component analysis and partial least squares discriminant analysis (Figure 1A-B). Distinctive metabolites in this metabolic fingerprint include methylmalonylcarnitine, inosine and threonic acid (Figure 1C). The metabolic fingerprint of DBA was incorporated into a machine learning algorithm, and a binary classification model was constructed using a training set. The model showed high performance characteristics (average accuracy 93.5%) and correct prediction of class was observed for all controls (n=12) and all but one patient (n=4/5) from the validation or 'test' set (accuracy 94%) (Figure 1D). Importantly, in patients with congenital dyserythropoietic anemia (CDA), an erythroid disorder with overlapping features, we observed a distinct metabolic profile, indicating the disease specificity of the DBA fingerprint and underlining its diagnostic potential (Figure 1E). Furthermore, when exploring phenotypic heterogeneity, DBA treatment subgroups yielded discrete differences in metabolic profiles, which could hold future potential in understanding therapy responses (Figure 1F).

Figure 1.



Summary/Conclusion: In this study we performed untargeted metabolomics in dried blood spots in a relatively large cohort of DBA patients with diverse genotypes and clinical phenotypes. We report here for the first time a specific metabolic fingerprint for DBA. By incorporating this fingerprint into a machine learning algorithm we demonstrate that untargeted metabolomics in dried blood spots is a promising new diagnostic tool for DBA.

EP583 A PIGA CONDITIONAL KNOCK-OUT MOUSE MODEL MEDIATED BY VAV-ICRE: STABLE GLYCOSYLPHOSPHATIDYLINOSITOL-DEFICIENT AND MILD HEMOLYSIS

R. Fu [1], Y. Chen [1,*], H. Liu [1], H. Wang [1], L. Zeng [1], L. Li [1], Z. Liu [1]

[1]*Tianjin Medical University General Hospital, Tianjin, China*

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare clonal disease caused by PIGA mutation of hematopoietic stem cells. Vav is a specific expression promoter of hematopoietic system, and hematopoietic system-specific knockout mice can be obtained by using Vav-iCre.
Aims: This study aims to construct an animal model with a PNH disease phenotype by using Vav-iCre targeted knockout of PIGA gene in the hematopoietic system.
Methods: C57BL/6N ES cells was used for gene targeting. Exon 3-5 was selected as conditional knockout region (CKO region) (Figure 1A). The KO allele was obtained after Vav-iCre-mediated recombination. Vav-iCre mediated deletion of the CKO region resulted in the loss of Piga gene function in mouse hematopoietic stem cells, thus a Piga conditional knockout (CKO) mouse model was constructed. Flow cytometry was used to detect the expressions of Glycosylphosphatidylinositol (GPI) and GPI-anchor protein (GPI-AP) on the surface of erythrocytes, granulocytes, T lymphocytes and B lymphocytes in peripheral blood of normal C57BL/6N mouse and CKO mouse. In addition, hemolysis related indicators (hemoglobin concentration (Hb), lactic dehydrogenase (LDH), total bilirubin (TBIL), indirect bilirubin (IBIL), free hemoglobin (FHb)) and mouse complement levels of C3a, C5a, and C5b-9 of normal C57BL/6N mouse and CKO mouse were measured. Finally, the spleen and bone marrow of two groups of mouse were taken for pathological examination.
Results: The expressions of GPI and GPI-AP in peripheral blood cells of normal C57BL/6N mouse were positive (Figure 1B) and were almost completely absent in CKO mouse (Figure 1C). What's more, the proportion of the deficiency remained stable from birth. In normal C57BL/6N mouse group, the Hb were (152.7±11.07)g/l, the level of LDH were (439.8±45.11)U/L, the level of TBIL were (1.868±0.646)μmol/l, the level of IBIL were (2.006±0.308)μmol/l,the level of FHb were (168.1±61.00)mg/l; in CKO mouse group, the Hb were (120.6±17.22)g/l, the level of LDH were (832.9±208.9)U/L, the level of TBIL were (3.830±0.493) μmol/l, the level of IBIL were (3.318±0.293) μmol/l,the level of FHb were (354.1±91.03)mg/l. The above hemolysis related indexes were statistically different between the two groups ($p < 0.0001$, $p=0.0034$, $p=0.0006$, $p=0.0001$, $p=0.0029$).The level of C5a,C5b-9 in normal C57BL/6N mouse group were (83.80±13.45)ng/ml and (174.3±10.79)ng/l; in CKO mouse group were (116.3±28.45)ng/ml and (217.2±26.39)ng/l, which had statistical difference between two groups($p=0.0495$,$p=0.0098$). The pathological examination showed that the volume of hematopoietic tissue(VOL) in bone marrow of CKO mouse was increased(95%VOL) compared with that of normal mice(90%VOL), and the granulosiderin cells in the spleen of CKO mouse were distributed in small clusters and aggregated in clumps(Figure 1D).

Summary/Conclusion: A Piga conditional knock-out mouse model mediated by Vav-iCre was constructed which had stable GPI-deficient and mild hemolysis.

EP584 CYTOKINE-PRODUCING ABILITY OF MESENCHYMAL CELLS OF THE BONE MARROW STROMA IN CASE OF NEUTROPENIA IN CHILDREN

K. Vetoshkin [1,*], M. Butolina [1], E. Nazarova [1], O. Tselousova [1], E. Vaskina [1]

[1]*Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation*

Background: Acquired idiopathic neutropenia is a rare disorder associated with impaired proliferation and differentiation of neutrophil precursors. The stromal microenvironment plays an important role in the regulation of the maturation of granulocyte colony-forming units (CFU-G). The bone marrow stroma regulates hematopoiesis locally in hematopoietic niches and by producing cytokines and growth factors in normal conditions and in various hematologic diseases. Thus, the efficiency of hematopoiesis directly depends on the functional state of the mesenchymal stromal cells (MSC) of the bone marrow. The study of the mechanisms of interaction and ways of regulating of the development hematopoietic and stromal cells` is necessary to establish the hypoplastic variant of neutropenia.
Aims: To assess the cytokine-producing ability of MSC of the bone marrow in patients with hypoplastic neutropenia.
Methods: The bone marrow of 17 patients with neutropenia at the age from 2.5 to 17 (median - 9.5) years was researched. The determination of the proliferative potential and differentiation ability of the bone marrow was carried out by counting the CFU-G formed in a 14-day culture based on the morphological recognition of their cellular elements. Cultivation of MSC carried out on the surface of plastic flasks under conditions of 5% carbon dioxide at a temperature of 37 ° C. The levels of interleukins (IL) -1β, -2, -6, tumor necrosis factor α (TNFα) and transforming growth factor β (TGFβ) determined by enzyme-linked immunosorbent assay in supernatants of MSC cultures
Results: In 13 of 17 (76.5%) patients the content CFU-G was decreased to 20-60 (with a normal range of 70-350) per $1x10^6$ nuclear cells. It made it possible to establish a hypoplastic variant of neutropenia. The absolute content of neutrophils of peripheral blood in these patients was 170-1325 (Me = 920) in 1 μl. There was no significant correlation between the number of bone marrow CFU-G and the level of neutrophils in the peripheral blood (Pearson's correlation coefficient r = 0.07). The levels of MSC cytokine production were: IL-1β 0.49-0.82 (Me = 0.70) pg / ml / day, IL-2 0.369-1.591 (Me = 0.589) pg / ml / day, IL-6 87.7-127.3 (Me = 108.0) pg / ml / day, TGFβ 5.26-28.91 (Me = 13.76) pg / ml / day. An inverse relationship between the number of CFU-G and the concentration of IL-1β, IL-6 and TGFβ was found (r = -0.59, -0.84, -0.50, respectively). The correlation coefficient between the production of IL-2 MSCs, TGFβ and the content of neutrophils in peripheral blood was -0.66 and 0.50, respectively.
Summary/Conclusion: A cultural research of the myeloid lineage of the bone marrow and the stromal microenvironment with an assessment of the functional activity of MSC is an important part of diagnostic of a hypoplastic variant of neutropenia. The depth of CFU-G decreasing is associated with the level of secretion IL-1β, IL-6 and TGFβ by of MSC, and neutrophil quantity – IL-2 and TGFβ.

Bone marrow failure syndromes incl. PNH - Clinical

EP585 BCX9930, A NOVEL ORAL FACTOR D INHIBITOR, HAS POSITIVE EFFECTS ON HEMOLYSIS AND CLINICAL OUTCOMES IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) NAÏVE TO COMPLEMENT INHIBITORS

A. McDonald [1,*], J. L. R. Malherbe [2], M. Cornpropst [3], S. Dobo [3], M. Farmer [3], D. Kargl [3], J. M. Best [3], W. P. Sheridan [3], A. Risitano [4]

[1]*Netcare Pretoria East Hospital, Moreleta Park,* [2]*University of the Free State, Bloemfontein, South Africa,* [3]*BioCryst Pharmaceuticals, Inc., Durham, United States,* [4]*AORN Moscati, Avellino, Italy*

Background: PNH, a rare, chronic, life-threatening disease is characterized by hemolysis due to uncontrolled activity of the complement alternative pathway (AP), and is associated with bone marrow failure,

and thrombosis. Terminal complement pathway inhibition with C5 inhibitors may not be sufficient for disease control as up to half of PNH patients remain transfusion dependent with C5 inhibitor treatment. BCX9930 is an orally administered small-molecule factor D inhibitor targeting the proximal AP with the potential to inhibit intravascular hemolysis and prevent extravascular hemolysis in patients with PNH.

Aims: The objectives of this part of the study were to evaluate the safety, tolerability, and effectiveness of BCX9930 in complement inhibitor-naïve patients with PNH.

Methods: Study BCX9930-101 (NCT04330534), an open-label dose-ranging study, enrolled PNH subjects with no prior history of C5-inhibitor treatment into one of three multiple dose cohorts. Subjects in each cohort received BCX9930 at starting doses of 50mg-400mg twice daily (BID) titrated to a maximum of 500mg BID. Safety endpoints included the incidence and severity of treatment-emergent adverse events (TEAEs). Effectiveness endpoints included clinical measurements of hemoglobin (Hb), number of transfusions, lactate dehydrogenase (LDH), absolute reticulocyte count (ARC), and percent PNH red blood cells (RBCs). Fatigue was assessed by the Functional Assessment of Chronic Illness Therapy (FACIT) Fatigue Scale; a 3-point change is considered a minimal important difference. This abstract includes data from screening through data cut-off of 22 January 2021 in an open-label extension.

Results: 10 adult patients (mean age 30 years) were enrolled in 3 cohorts with starting dose regimens of 50mg BID (n=4), 200mg BID (N=4), and 400mg BID (N=2). Mean time since clinical diagnosis of PNH was 4 years. Six patients required a total of 31 transfusions in the 12 months prior to treatment. The median duration of BCX9930 treatment was 147 days (range 28-340); 9 patients remain on treatment at 400 or 500mg BID and 5 have been treated > 5 months. BCX9930 was well-tolerated. Nine subjects (90%) had TEAEs; 5 patients had 5 Grade 3 TEAEs of which 2 were considered treatment related and resolved with continued treatment. Two serious adverse events unrelated to study drug were reported (gastritis in 1 patient and fatal disseminated varicella zoster infection in 1 patient).

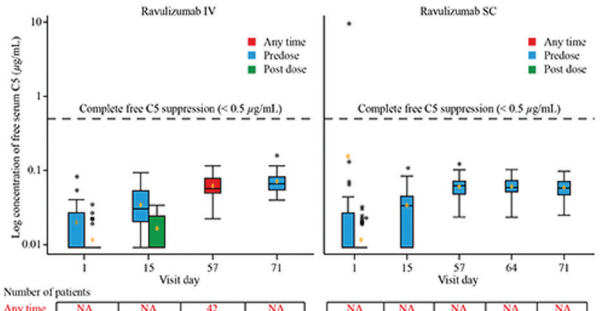
Hb improved in all patients with a mean improvement from baseline (BL) to the last treatment visit (LTV) of 3.3g/dL. Only 1 patient required 1 transfusion which occurred during the 100mg BID treatment period. Mean ARC decreased from 180.3 x 10^9/L to 115.8 x 10^9/L at LTV. The relative percent of PNH Type II+III RBC to percent PNH WBC increased from 56% at BL to 90% at LTV. Meaningful improvements in FACIT fatigue score were observed with an increase of 7.3 points. During the treatment period with 400mg BID/500mg BID, BCX9930 demonstrated a mean (SD) reduction of 67% (13.4) in LDH from BL.

Summary/Conclusion: BCX9930, an orally administered potent and specific factor D inhibitor, was safe and generally well-tolerated as monotherapy in complement inhibitor-naïve patients with PNH at doses up to 500mg BID. Inhibition of the AP with BCX9930 reduced hemolysis, with reduction in transfusions and improvements in laboratory parameters. Improvements in fatigue were also observed. This study successfully identified a safe and tolerable BCX9930 dose range with dose-related meaningful clinical improvement, supporting progression to controlled clinical trials of BCX9930 in PNH.

EP586 RAVULIZUMAB ADMINISTERED SUBCUTANEOUSLY VERSUS INTRAVENOUSLY IN ADULT PATIENTS WITH PNH PREVIOUSLY TREATED WITH ECULIZUMAB: RESULTS FROM A PHASE 3 RANDOMIZED, OPEN-LABEL STUDY

M. Yenerel [1,*], F. Sahin [2], M. Ogawa [3], P. Singh [3], J. Szer [4]

[1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Hematology, Istanbul, [2]Department of Hematology, Ege University Bornova, Izmir, Turkey, [3]Alexion Pharmaceuticals, Inc., Boston, MA, United States, [4]Clinical Haematology at Peter MacCallum Cancer Centre and The Royal Melbourne Hospital, Melbourne, Australia



Background: The intravenous (IV) complement C5 inhibitors eculizumab and ravulizumab are the current standard of care for patients (pts) with paroxysmal nocturnal hemoglobinuria (PNH) and atypical hemolytic uremic syndrome (aHUS) where available. Ravulizumab self-administered via a subcutaneous (SC) on-body delivery system will offer an alternative to ravulizumab IV and allow administration outside of clinic which can improve patient independence.

Aims: Evaluate the pharmacokinetic (PK) non-inferiority of ravulizumab SC versus ravulizumab IV in adult pts with PNH.

Methods: This ongoing phase 3, multicenter, randomized, open-label study (NCT03748823) enrolled clinically stable (lactate dehydrogenase [LDH] level ≤ 1.5 upper limit of normal) adult pts (aged ≥ 18 years) with PNH treated with eculizumab for ≥ 3 months prior to entry. In the 10-week primary evaluation period, pts received a weight-based loading dose of ravulizumab IV on Day 1. On Day 15, pts on ravulizumab IV received a single weight-based maintenance dose of ravulizumab, and those randomized to ravulizumab SC received a 490mg maintenance dose and then every week (qw) thereafter. During the extension phase (up to 3.5 years), all pts will receive ravulizumab SC qw. Primary endpoint was Day 71 serum ravulizumab predose concentration (Day 71 C_{trough}). Non-inferiority was determined between the two groups using a one-sided test at an α level of 0.05, and a PK non-inferiority boundary of 0.8. Secondary endpoints included C_{trough} and free serum C5 concentration over time and incidence of anti-drug antibodies (ADA). Efficacy indicators were change in LDH level, breakthrough hemolysis (BTH), hemoglobin stabilization (Hgb-S), transfusion avoidance (TA) and PNH symptoms. Safety indicators included adverse device events (ADE), serious ADE (SADE), adverse events (AE) and serious AE (SAE).

Results: This primary analysis of PK non-inferiority of ravulizumab SC versus IV administration included 70 pts in the SC group and 43 pts in the IV group. Patient demographics were comparable between groups. Day 71 geometric mean C_{trough} concentration for ravulizumab SC demonstrated PK non-inferiority with ravulizumab IV (559.9 µg/ml and 445.3 µg/mL, respectively; ratio of geometric least squares means SC/IV: 1.26 [90% CI: 1.16–1.36; $p < 0.0001$]). All C_{trough} levels were above target trough serum concentration, and no pts tested positive for ADA at Day 71. Complete and sustained suppression of serum free C5 (mean concentration < 0.5 µg/mL) was achieved in both groups at all timepoints after the first dose (**Figure 1**). Mean (SD) percentage change in LDH from baseline was 1.7% (34.8%) and 5.1% (29.6%) in pts on ravulizumab SC and IV, respectively. Only 1 BTH event due to unknown cause was reported in a patient on ravulizumab IV. Hgb-S was achieved by 93.6% and 81.8% of pts, and TA was achieved by 94.0% and 86.7% of pts on ravulizumab SC and IV, respectively. PNH symptoms were observed in 45.2% and 46.7% of pts on ravulizumab SC and IV, respectively. Pts on ravulizumab SC with ≥ 1 ADE were 45.2% (23.8% device use), and no SADE were reported. Proportion of pts experiencing ≥ 1 AE were comparable between -ravulizumab SC and IV when ADE were excluded. Five (6.0%) pts on ravulizumab SC experienced ≥ 1 SAE versus 1 patient (2.2%) on ravulizumab IV; none were related to study treatment.

Figure 1 Free serum C5 concentration during the primary evaluation period (pharmacokinetic analysis set)

For free C5 values below the limit of quantification, lower limit of quantification/2 = 0.00915 µg/mL was utilized. Y-axis is presented on the log scale. The dashed horizontal line indicates serum free C5 concentration of 0.5 µg/mL. The horizontal line in the middle of each box indicates the median, a diamond indicates the mean and the top and bottom borders of the box mark the 75th and 25th percentiles, respectively. The whiskers represent the minimum and maximum within the interval spanning 1.5 x interquartile range from each of the 1st and 3rd quartile. Outliers are represented by asterisk beyond the whiskers.
Ravulizumab SC group has samples collected at Day 1, 15, 57, 64 and 71 predose, and Day 1 and 15 postdose.
Ravulizumab IV group has samples collected at Day 1, 15 and 71 predose, and Day 57 anytime.
C5, complement component 5; IV, intravenously; NA, not available; SC, subcutaneously.

Summary/Conclusion: Ravulizumab SC C_{trough} levels were non-inferior to those obtained with ravulizumab IV. Ravulizumab SC provided complete and sustained free C5 inhibition comparable to ravulizumab IV at all timepoints.

EP587 LONG-TERM FOLLOW UP AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT FOR IDIOPATHIC SEVERE APLASTIC ANEMIA. THE EXPERIENCE OF THE SPANISH GROUP OF HEMATOPOIETIC STEM CELL TRANSPLANT (GETH).

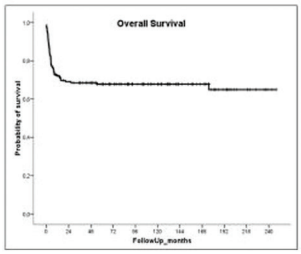
Marqués de Valdecilla, Santander, [21]Hematology, Hospital Universitario 12 de octubre, Madrid, Spain

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is considered the only curative option for severe aplastic anemia (SAA). However, it is not currently recommended as the first choice for patients older than 40 years old, even they have a matched sibling donor. The HSCT procedures have been improved in the recent years. Therefore, updated information about the long-term results of patients who undergo HSCT for SAA may be of interest.
Aims: To determine the overall survival (OS) at 5 and 10 years after HSCT in patients with SAA, as well as and the rate of patients alive in complete remission (CR). Secondly, we evaluated the causes and factors related to mortality.
Methods: Between the years 2000 and 2019, the Spanish Group of Hematopoietic Stem Cell Transplant and Cellular Therapy (GETH-TC) performed 722 allogeneic HSCT due to bone marrow failure (BMF) syndromes. The follow-up has been updated in 333 patients, 271 due to SAA (including 188 (76%) idiopathic SAA) and 62 due to congenital disease (72% Fanconi anemia). To evaluate the factors related to mortality. Univariate analysis included: previous immunosuppressive therapy (IST) (yes or no), time from diagnosis to HSCT (< or ≥6 months), age at transplant (<20 y/o, 20-39 y/o, 40-59 y/o, >60 y/o), year of transplant (2000-2004, 2005-2009, 2010-2014, 2015-2019), stem cell source (BM, PB, CB), and the experience of the center in SAA HSCT (< or ≥10 in the last 20 years). Multivariate analysis includes all variables with p value <0.2 in the univariate analysis.
Results: We present here the updated results from the series of 188 patients with idiopathic SAA and HSCT. The median age at diagnosis was 25 years (range 2-69) and 55% were male. 108 (57%) patients were previously treated with IST (≥ 2 cycles, 36 patients; unknown 2 patients). 91 (47%) patients received the HSCT before the year 2010. The median age at HSCT was 27 years (IQR 17-40). The stem cell source was BM (62%), PB (30%) and CB (7%) and the HSCT was performed from a matched donor in 153 (81%) patients [sibling 111 (59%); unrelated 42 (22%)]. The most frequent conditioning regimen was FluCyATG (41%) followed by Cy-ATG (37%) and cyclosporine combined with methotrexate (59%) or prednisone (23%) were the most common GVHD prophylaxis. 106 (54%) patients received the HSCT ≥6 months after the diagnosis. Factors related to delayed HSCT were prior IST (p <0.001) and lack of matched related donor (p<0.001). With a median follow-up of 114 months (IQR 68-173), the OS at 5 and 10 years were 67.8±3.6% for both moments (Figure 1a). Among the 119 patients alive, 97 (82%) are currently in continued CR. 61 patients died, mainly due to infections (40 patients, 65%) and other HSCT related causes (16 patients, 26%). Cumulative incidence of TRM at 1 year was 25.4% (95% CI 19.1-32.2%) and 29% at 5 and at 10 years (95% CI 22.3-36.0%), respectively. Previous IST (HR 1.93, 95%CI 1.04-3.81, p=0.04) and the age at transplant ≥20 years (HR 2.29, 95%CI 1.21-4.35, p=0.01) were associated to mortality in the multivariate analysis. In patients older than 20 years, the use of previous IST doubles the probability of death (Figure 1b).

Figure 1a



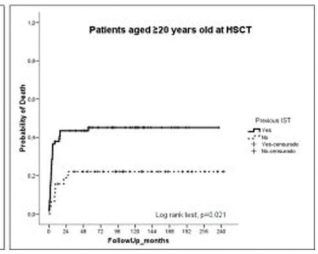


Figure 1b

Summary/Conclusion: In this large series of transplanted patients due to aplastic anemia, we observed high rates of survival in CR after a long follow-up. The major causes of death are post-HSCT infections and, since older age at transplant and the use of previous IST confers high risk of mortality, our data support the need of new strategies to prevent infectious complications and the reassessment of the role of frontline HSCT in older patients.

EP588 LONGITUDINAL CLINICAL AND LABORATORY DATA AND OUTCOME OF PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

S. G. Papadakis [1,2,*], P. Kanellou [3], E. Boutakoglou [1,2], G. Tsaknakis [1,2,4], A. Damianaki [1,2], I. Fragiadaki [1,2], S. Velickovic [5,6], A. Catić- Đorđević [6], I. Mavroudi [1,2], C. Pontikoglou [1,2], A. Gallì [7], L. Malcovati [7], G. Xalkiadakis [8], H. Papadaki [1,2]

[1]Haemopoiesis Research Laboratory, University of Crete School of Medicine, [2]Department of Hematology, University Hospital of Heraklion, [3]Department of Hematology, Venizeleion General Hospital, [4]Precision Medicine Unit, Foundation for Research & Technology – Hellas, Heraklion, Greece, [5]Clinic of Hematology and Clinical Immunology, University Clinical Centre Nis, [6]Faculty of Medicine, University of Nis, Niš, Serbia, [7]Department of Molecular Medicine, University of Pavia & Department of Hematology Oncology, IRCCS S. Matteo Hospital Foundation, Pavia, Italy, [8]Department of Information System, Center of Information and Communications Technologies, University of Crete, Heraklion, Greece

Background: Patients with persistent, unexplained neutropenia who do not fulfil the diagnostic criteria of any underlying disease are characterized as chronic idiopathic neutropenia (CIN) cases. Real-world data based on longitudinal studies of large number of CIN patients are rare. A cooperation in science and technology (COST) Action, the EuNet-INNOCHRON, has been recently launched, aiming to promote the research on chronic neutropenias, including CIN, across and beyond Europe.
Aims: We present longitudinal laboratory and clinical data from adult patients with CIN registered in a database within EuNet-INNOCHRON aiming to provide insights in the natural history and outcome of patients with this rare disease.
Methods: Patient data are registered in the "NeutroReg" electronic registry hosted in the University of Crete Data Center in compliance with the European General Data Protection Regulation. The enrolment is based on previously described diagnostic criteria for CIN, i.e. absolute neutrophil counts (ANC) below 1800/μl of blood for more than 6 months and no evidence of any underlying disease/condition associated with neutropenia following a defined clinical/laboratory investigation including bone marrow biopsy and karyotype. In all registered patients we performed targeted next generation sequencing (NGS) of myeloid genes for identification of clonal hemopoiesis (MiSeq, Illumina) and genotyping of the *DARC/ACKR1* gene for identification of the single nucleotide polymorphism (SNP) rs2814778 (-46T>C) associated with benign ethnic neutropenia.
Results: We present data from 200 adult CIN patients, 159 females and 41 males (79.5% and 20.5%, respectively), aged 19-90 years (median 60 years), registered from one center that accepts patients from all over Greece. Seven patients were non-Greek white Europeans and 193 were Greeks. The median time from the initial identification of neutropenia until last follow-up was 179 months (range 12-420 months) and the median time of follow-up was 133 months (range 12-396 months). The patients

had mean ANCs 1370±420/µL (median 1600, range 200-1700/µL), lymphocytes 1640±475/µL (median 1600, range 700-3700/µL), monocytes 336±134/µL (median 300, range 100-800/µL), platelets 221±48 x103/µl (median 219, range 150-336 x103/µl), haemoglobin 13.3±0.99 g/dL (median 13.25, range 10.6-16.5 g/dL) and MCV 88.15±5.76 fl (median 89, range 63.4-98.1 fl). Clonal hemopoiesis in NGS analysis was identified in 40 patients (20%) and these patients were further characterized as cases with clonal cytopenia of undetermined significance (CCUS). The most frequently mutated genes were DNMT3A and TET2 involving more than 50% of CCUS patients followed by BCOR/BCORL1, IDH1/2, ASXL1, SRSF2, TP53, WT1. Five patients (2.5%) were homozygous for the DARC/ACKR1 SNP rs2814778. Overall, five patients transformed into MDS/AML, four from the CCUS and one from the non-clonal group (P<0.0001) with a relative risk 20 for transformation in the presence of clonal disease. Nine patients developed a non-hematologic malignancy, three from the CCUS and six from the non-clonal group (non-significant difference). The patients had rare infections and only one patient presented a mild covid-19 infection so far.
Summary/Conclusion: This is the first study presenting longitudinal clinical/laboratory data and disease outcome in CIN. The coordinated collection of common data from CIN patients from different backgrounds under EuNet-INNOCHRON is anticipated to enrich further the knowledge on the natural history of this rare disease.

EP589 BCX9930, AN ORAL FACTOR D INHIBITOR, CONTROLS EXTRAVASCULAR HEMOLYSIS AND ALLEVIATES ASSOCIATED SYMPTOMS IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA INADEQUATELY CONTROLLED ON C5 INHIBITORS

A. Kulasekararaj [1,*], W. Füreder [2], S. Gandhi [1], M. Cornpropst [3], S. Dobo [3], M. Farmer [3], D. Kargl [3], W. P. Sheridan [3], M. Griffin [4], A. Risitano [5]

[1]Kings College Hospital NHS Foundation Trust, London, United Kingdom, [2]Medical University of Vienna, Vienna, Austria, [3]BioCryst Pharmaceuticals, Inc., Durham, United States, [4]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [5]AORN Moscati, Avellino, Italy

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare and potentially life-threatening disorder characterized by red blood cell (RBC) hemolysis, resulting from uncontrolled activity of complement leading to episodes of intravascular hemolysis (IVH), extravascular hemolysis (EVH), chronic hemolytic anemia, and thromboembolism. Administration of C5 inhibitors reduces IVH, but PNH RBCs become opsonized and susceptible to EVH. Complete normalization of hemoglobin (Hb) is only seen in a fraction of patients, while most continue to experience some degree of anemia and fatigue. BCX9930 is a potent, selective inhibitor of complement Factor D that blocks the initiation of the alternative pathway (AP) and has the potential to treat both IVH and EVH as an oral therapy.
Aims: To evaluate the safety, tolerability, and effectiveness of BCX9930 on EVH and residual IVH in PNH patients with an inadequate response to C5 inhibitors in an open-label, dose-ranging Study BCX9930-101 (NCT04330534).
Methods: Six patients receiving a C5 inhibitor with an inadequate response (received a transfusion within 3 months of screening or Hb < 10 g/dL) were enrolled. Oral BCX9930 was added to the C5 inhibitor for 28 days with an increase in BCX9930 dose on Day 15; treatment was with either 200mg BID escalated to 400mg BID (n= 2) or 400mg BID escalated to 500mg BID (n = 4). On Day 28, patients deriving benefit could continue BCX9930 in a long-term extension study.
Results: Two patients are receiving ravulizumab and 4 eculizumab (>900mg every 2 weeks in 3). At baseline, mean Hb was 8.9 g/dL, absolute reticulocyte count (ARC) was 196.3 x10^3/µL, and proportion of PNH Type II + III RBCs was 48%. Five patients received RBC transfusions (range 1-15) in the 3 months prior to screening. As of the last follow-up visit, all 6 patients have continued in the long-term study with a total duration of BCX9930 therapy of ≥58 days. Meaningful improvements across hemolysis biomarkers and fatigue scores were demonstrated. After the first week of dosing with 400mg BID, all 4 patients had a ≥ 1g/dL increase in Hb. As of the last treatment visit, the mean Hb in the absence of transfusions increased by 3.4 g/dL to a mean of 12.3 g/dL and mean ARC decreased to 86.4 x10^3/µL. Increased EVH control was further demonstrated by the increase in proportion of PNH Type II+III RBCs to a mean of 71%. One patient received 3 RBC transfusions during the treatment period, as compared to 15 transfusions in the 3 months prior to screening. No other patients have been transfused since initiating BCX9930. Self-reported fatigue (FACIT-fatigue total score) improved by a mean of 7.5 points, well above the minimal important difference (3 points). Five patients reported adverse events (AEs); the most common drug-related AEs were self-limited rash (3) and dizziness (2). No serious or Grade 3 or 4 AEs were reported and there were no trends in safety laboratory values
Summary/Conclusion: Oral BCX9930 at doses up to 500mg BID was safe and generally well-tolerated over at least 58 days in PNH patients with inadequate response to a C5 inhibitor. Following initiation of BCX9930, notable improvements were observed in Hb, ARC, abundance of PNH RBC, fatigue scores and RBC transfusion requirements. Both proximal AP inhibition of Factor D and demonstrated improvements in hemolysis support future evaluation of BCX9930 monotherapy for patients who are inadequately responding to C5 inhibitors.

EP590 PHARMACOKINETICS, PHARMACODYNAMICS, EFFICACY AND SAFETY OF RAVULIZUMAB IN CHILDREN AND ADOLESCENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: INTERIM ANALYSIS OF A PHASE 3, OPEN-LABEL STUDY

A. Kulagin [1], S. Chonat [2,*], A. Maschan [3], M. Bartels [4], J. Buechner [5], R. Punzalan [6], M. Richards [7], M. Ogawa [8], E. Hicks [8], J. Yu [8], A. Baruchel [9], A. G. Kulasekararaj [10]

Background: Paroxysmal nocturnal hemoglobinuria (PNH) typically manifests during adulthood, with pediatric patients accounting for ~14% of reported cases. Ravulizumab is a terminal complement component 5 (C5) inhibitor shown to have a similar efficacy and safety profile to eculizumab in adults with PNH, and a study in pediatric patients is ongoing.
Aims: To assess the pharmacokinetics (PK), pharmacodynamics (PD), efficacy and safety of ravulizumab in a pediatric population with PNH.
Methods: This ongoing phase 3, multicenter, single-arm, open-label study (NCT03406507) enrolled complement-inhibitor-naïve and eculizumab-experienced pediatric patients (aged < 18 years) with a diagnosis of PNH, at 9 sites in 6 countries. Naïve patients received a weight-based loading dose (LD) of ravulizumab on Day 1 followed by weight-based maintenance dose (MD) on Day 15, and then once every 8 weeks [LD (mg)/MD (mg)]: ≥ 30 to < 40 kg bodyweight [1200 mg/2700 mg]; ≥ 40 to < 60 kg bodyweight [2400/3000]; ≥ 60 to < 100 kg bodyweight [2700/3300]. For patients switching from eculizumab therapy, ravulizumab Day 1 was 2 weeks after the last eculizumab dose. All analyses were performed to the end of the primary evaluation period (Day 183). Primary endpoints included ravulizumab maximum and trough serum concentration (C_{max}, C_{trough}; at the end of dosing interval at steady state), accumulation ratio and change in free C5 concentration. Secondary endpoints included percentage change in lactate dehydrogenase (LDH) from baseline, transfusion avoidance (TA), breakthrough hemolysis (BTH) and hemoglobin stabilization (Hgb-S). Safety endpoints included incidence of treatment-emergent adverse events (TEAE) and serious adverse events (SAE).
Results: In total, 13 patients were enrolled, 12 (4 complement-inhibitor-naïve) were included in the interim analysis (1 patient did not complete Day 183 evaluation by database lock: 27 May 2020; **Table 1**). Ten (83.3%) patients were aged ≥ 12 years, with a median (range) age at first ravulizumab infusion of 15.0 (9–17) years. Steady-state therapeutic serum concentrations of ravulizumab were achieved immediately following the first dose and maintained throughout the primary evaluation period with no

evidence of accumulation (mean [SD] C_{max} and C_{trough} accumulation ratios of 1.1 [0.1] and 1.1 [0.2], respectively). Complete terminal complement inhibition was attained by the end of first ravulizumab infusion (defined as mean serum free C5 concentration < 0.5 µg/mL) and was sustained through Day 183 in all patients (**Table 1**). Mean (SD) percentage change in LDH was –42.1% (59.0) in complement-inhibitor-naïve patients and remained stable in eculizumab-experienced patients at +4.65% (44.7). Overall, 10 (83.3%) patients achieved TA, 8 (66.7%) achieved Hgb-S and no patients experienced BTH. TEAE were reported in 10 patients; the most frequent were abdominal pain and nasopharyngitis. No meningococcal infections, deaths or discontinuations due to TEAE were reported. Three patients had ≥ 1 SAE during the study and no SAE were assessed to be treatment-related.

Ravulizumab (10 mg/mL solution) loading dose on Day 1 and maintenance doses on Day 15 and q8w thereafter for patients weighing ≥ 20 kg, or q4w for patients weighing < 20 kg were administered by IV infusion. Data shaded grey are from complement-inhibitor-naïve patients.
[a]Lower limit of quantitation for free C5 = 0.0183 µg/mL. [b]Multiple LDH reference ranges are present depending on pediatric age and gender group: 100–220 U/L, 100–242 U/L, 100–275 U/L, 120–290 U/L and 140–280 U/L. [c]Day 183 samples were not analyzed at the central laboratory owing to internal Eurofins issue with process of registration samples; the samples were considered as missing. [d]At Day 183, the LDH level of patient 5 was greater than at baseline; however, the blood sample was reported to be hemolyzed and the patient did not have any new or worsening PNH signs or symptoms. [e]At Day 183; the LDH level of patient 11 was greater than at baseline; however, the blood sample was reported to be hemolyzed and the patient did not have any new or worsening PNH signs or symptoms.
BL, baseline; BLOQ, below limit of quantification; C5, complement component 5; C_{max}, max ravulizumab serum concentration; C_{trough}, trough ravulizumab serum concentration; D, day; F, female; IV, intravenous; LDH, lactate dehydrogenase; M, male; NA, not analyzed; NR, not reported; PNH, paroxysmal nocturnal hemoglobinuria.

Summary/Conclusion: These interim results are from the largest study of pediatric patients with PNH to date. In this rare population, ravulizumab was effective, well-tolerated, and provided immediate, complete, and sustained terminal complement inhibition irrespective of prior treatment with eculizumab. These PK, PD, efficacy and safety findings suggest that pediatric patients can be initiated on ravulizumab or switched from eculizumab to ravulizumab.

EP591 REAL - WORLD SCENARIO OF RESPONSE WITH LONG - TERM USE OF ANDROGENIC STEROIDS IN PATIENTS WITH ACQUIRED APLASTIC ANEMIA: REPORT FROM A TERTIARY CARE HOSPITAL IN WEST BENGAL, INDIA

A. Sen [1,*], T. K. Dolai [1]

[1]Hematology, NRSMCH, KOLKATA, India

Background: Aplastic anemia (AA) is a disease characterised by pancytopenia and it may be inherited or acquired (immune) in nature. Though the definitive treatment is allogeneic stem cell transplant, use of Anti Thymocyte Globulin (ATG), Cyclosporine (Cx) or TPO agonists as first line therapy have greatly improved the disease prognosis. Though androgenic steroids are used upfront in Inherited Bone marrow failure syndromes (IBMFS), sometimes they are also used in Acquired AA. The efficacy is lower than the first line agents (70%).
Aims: Though androgens are used commonly in patients who have failed first line therapy or as first-line in patients with logistic constraints, there is very little real-world data regarding the response outcomes with these drugs. The target of our study is to address this void.
Methods: This analysis was conducted among patients who attended NRS Medical College in West Bengal, India in the span of 1 year (1st January-31st December, 2020). Patients with AA, both Severe AA (SAA) and Non-SAA (NSAA) (according to the Camitta criteria), were considered and the patients who relapsed / did not respond to / could not be given first-line therapy, either due to logistic reasons or side effects (such as, rising creatinine or gum hypertrophy necessitating stoppage of cyclosporine), were included for the analysis (Table 1). Patients having features of IBMFS have been excluded from the analysis.
Second-line therapy was given with androgenic steroids such as, Stanozolol (St), Danazol (Da) or Oxymetholone (Ox), in addition to supportive care. The drug dosages were as follows: St 1 mg/kg/day; Da 10 mg/kg/day; Ox 2 mg/kg/day. First-line therapy comprised of ATG, Cx or Eltrombopag.
The improvement was assessed according to criteria in published literature, as follows: a) lesser requirement of transfusions; b) increase in haemoglobin (Hb) levels; c) increase in absolute neutrophil count (ANC); d) increase in platelet count
Results: Out of a total of 388 patients with Acquired AA, 108 required second-line therapy with ≥1 androgen (Table 1). Most of the patients were aged ≥ 40 years age (61.1%) and there was a male preponderance (1.5:1). Majority of patients had SAA (75.9%).
The most common cause for starting a patient on androgens was logistic, followed by starting the drug due to no response with frontline agents. Many patients had ≥1 reason for starting androgenic steroids. The most commonly used steroid was St, followed by Da and Ox. Many patients have received more than one type of steroid at different time periods, due to reasons ranging from cost to side effects (Table 1).
Overall response (OR), which included both Complete response (CR) and Partial response (PR), was noted in 47.2% patients (Table 1). The median time of OR was 2 years.

Number of patients with AA		388
Patients requiring second-line treatment with androgenic steroids (*n=108*) [Some patients received androgenic steroids due to more than one reason]	Relapsed after having responded to first-line therapy	14
	Did not respond to first-line therapy	45
	First-line therapy had to be stopped due to side effects	5
	Not given first-line drugs due to logistic reasons	67
Median age (range) in years		46.5 (8-78)
Number of patients ≤ 20 years age		13 (11.8%)
Number of patients 21-40 years age		29 (26.4%)
Number of patients ≥ 40 years age		66 (61.1%)
Sex (male: female)		1.5:1 (65:43)
Mean duration of AA from diagnosis (range) in years		4.4 (1-23)
Median duration of AA from diagnosis		3
Severe AA		82 (75.9%)
Non-Severe AA		26 (24.1%)
Baseline symptoms		Fever, transfusion requirement
First-line therapy		ATG, Cx, Eltrombopag
Median time after which androgenic steroids started (range) in years		1 (0-20)
Number of patients who received Stanozolol		89
Mean duration of Stanozolol use (range) in years		1.9 (0.1-6); 2 patients intermittent
Number of patients who received Danazol		26
Mean duration of Danazol use (range) in years		2.74 (0.25-6)
Number of patients who received Oxymetholone		4
Mean duration of Oxymetholone use (range) in years		1.75 (1-2)
Overall Response (CR+PR)		51 (47.2%)
Median time to attain response (range in years)		2 (0.25-10)
Continuing requirement for transfusions		57 (52.8%)

Table 1: Tabular representation of patients with Acquired AA, who received androgenic steroids as second line therapy. *11 patients received both Stanozolol and Danazol.* Abbrev: AA= Aplastic anemia, ATG= Anti Thymocyte Globulin, Cx= Cyclosporine, Hb= haemoglobin, CR= Complete response, PR= Partial response

Summary/Conclusion: Androgens are not considered as first line agents in Acquired AA, however 47.2% OR was seen in patients who had taken androgens for variable time periods. In this analysis, it was seen that the time required to attain OR was quite long, median time being 2 years. Thus, in situations where ATG/Cx/TPO agonists fail or cannot be used due to logistic reasons, androgens may be a good alternative. St or Da are the most commonly used agents and the superiority of one over the other cannot be decided. However, the choice of androgen used may depend on the expense or side effects. St is more expensive than Da and mainly used in IBMFS, while Da is preferred in male patients.

EP592 MANAGEMENT OF MENINGOCOCCAL DISEASE RISK IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) ON COMPLEMENT INHIBITORS: 18 YEARS' EXPERIENCE FROM THE UK NATIONAL PNH SERVICE IN LEEDS

L. Arnold [1,*], R. Burrow [2], K. Riley [1], T. Munir [1], R. Kelly [1], R. Jones [1], J. Gachev [1], B. Forrest [1], A. Pike [1], P. Muus [1], P. Hillmen [1], M. Griffin [1]

[1]Haematology, LTHT, Leeds, [2]Haematology, Public health England, Manchester, United Kingdom

Background: Eculizumab, treatment for Paroxysmal Nocturnal Hemoglobinuria (PNH) C5 inhibitors increase susceptibility to encapsulated microorganisms, (*Neisseria meningitidis)*. The PNH National service, has 18 years of experience. The risk of *N. meningitidis* is mitigated by vaccination, ciprofloxacin (500 mg bd) days 1-13 we moved to vaccination day one of complement inhibitor, and prophylaxis (penicillin / erythromycin). Since a case of sepsis with penicillin-resistant meningococci, patients also have course ciprofloxacin. Education, prompt action in case of fever and a 24 hour on-call service are equally important.

Aims: Until 2010 patients were revaccinated with MenACWY 3 yearly. Bexsero (MenB vaccine) vaccination added in 2015. In collaboration with Public Health England Meningococcal Reference Unit a program was developed to monitor titers after vaccination, to revaccinate if titers below protective levels. It is technically not possible to assay for meningoccal serogroup B antibody titers when on Eculizumab therapy.
Methods: Methods: Antibody titers were assayed following vaccination. Unprotective titers led to revaccination. We evaluate practice of 9 meningococcal infections in 8 patients. Present disease characteristics, serogroup and outcome, vaccination history and antibody status.
Results: Between 2002 and 2020, 324 patients commenced complement inhibitor treatment for PNH. 801 vaccinations with MenACWY were administered: median 2 vaccinations per patient (range 1 - 10). A total of 1,671 antibody titer assessments conducted in 294 patients, median of 4 tests per patient (range 1 - 15). Every test assessed antibodies against all four serogroups.
Titers were not assessed in 9% of patients (30), due to vaccination prior to change in practice or recent commencement.
Protective response after first vaccination was observed in 170 / 294 patients (57.8%) and a partial response (3 serotypes) in 51 /294 (17.3%). Revaccination of 51 partial responders resulted an additional 21 patients with a full response. Revaccination of 73 non-responders (antibodies to 0-2 serotypes) resulted in 32 more partial / full responses. 287 of 324 patients received MenB vaccinations: median 2 vaccinations per patient (range 1 - 4). 8 of 324 (2%) median age 22.5 years developed meningococcal sepsis (see table); patient 5 had 2 episodes. 3 of 5 cases with serogroup B infection were before serogroup B vaccination. 4 episodes in 3 patients were due to Y, C, W meningococci, in one the serogroup is unknown. All except patient 1 were compliant with antibiotic prophylaxis. Patient 7 died from meningococcemia, a delay in seeking medical attention may have contributed, (a penicillin resistant strain).
Results: Discussion:
The largest experience of managing meningococcal risk in complement inhibitor for PNH. Despite proactive management we had 9 cases of meningococcal sepsis,1 fatal infection. Recently practice of prompt treatment with ciprofloxacin if pyrexic on prophylaxis will prevent cases - patient 7 with a penicillin resistant strain. 3 patients had a meningococci sepsis serogroups C, W and Y;1 patient had no titers due to recent commencement on treatment, titres of 2 suggested protective immunity.

Table 1: Meningococcal infections from 2002-July 2020

Patient	Age	Eculizumab start date	Vaccination status with reference to the meningitis episode	*Neisseria meningitidis* diagnosed	Serogroup identified	Penicillin sensitivity	Fatal
1	40	Jun 2005	Before introduction of Men B vaccination*	Oct 2009	B	Sensitive	No
2	20	Aug 2008	Before introduction of Men B vaccination*	Oct 2008	B	Sensitive	No
3	20	Sep 2011	Before introduction of Men B vaccination*	Sep 2011	B	Sensitive	No
4	25	May 2016	Jun 2016 Full ACWY response	Jan 2017	Y	Sensitive	No
5	19 22	Mar 2016	Apr 2017 Partial (ACY) Mar 2020 Partial (ACY)	Sep 2017 May 2020	C NG	Sensitive Sensitive	No
6	23	Jan 2017**	Unavailable***	Mar 2017	W	NG	No
7	37	Jun 2013	Most recent Men B vaccination: Jan 2015	Sep 2019	B	Resistant	Yes
8	28	Dec 2017	Most recent Men B vaccination Feb 2018	Jan 2020	B	Sensitive	No

*meningococcal B vaccination was commenced in 2015

** commenced clinical trial with C5 inhibitor in Dec 2016, changed to eculizumab Jan 2017

*** Most recent MenACWY vaccination date Dec 2016 at start of C5 inhibitor clinical trial; no titers available prior to meningococcal event

NG: not known as PCR only confirmed

Summary/Conclusion: A full antibody response can be obtained on second vaccination in most if first one failed. If no response is achieved, then MenACWY vaccination is not likely to be successful. Current practice significantly mitigates risk of meningococcal disease; however, it is essential patients are vigilant for fever, seeking immediate medical attention stating their diagnosis of PNH on complement inhibitor therapy.

EP593 ELTROMBOPAG PLUS IMMUNOSUPPRESSIVE THERAPY VERSUS MATCHED SIBLING DONOR TRANSPLANTATION AS FIRST-LINE THERAPY FOR SEVERE APLASTIC ANEMIA – A META-ANALYSIS

J. Ji [1,*], Y. Yang [1], M. Chen [1], C. Yang [1], B. Han [1]

[1]*Peking Union Medical College Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Beijing, China*

Background: Eltrombopag (ELT) is a thrombopoietin agonist which has been recently applied with immunosuppressive therapy (IST) for untreated severe aplastic anemia (SAA) patients. This new combination therapy was reported to be effective, yet no study has compared ELT+IST with matched sibling donor bone marrow transplantation (MSD-BMT), the traditional first-line therapy for SAA.
Aims: This meta-analysis aimed to compare the efficacy and survival benefit of ELT+IST and MSD-BMT for newly-diagnosed SAA patients.
Methods: Databases of Pubmed, Embase, Cochrane Library and Web of Science were searched. Studies published in recent 10 years, with a topic of ELT+IST and/or MSD-BMT and a record of patient overall response (OR) rate/myeloid engraftment rate, 1, 2 and 2.5-year overall survival (OS) rate and causes of death were included. Patients were separated into ELT+IST group and MSD-BMT group for data analysis. Baseline characteristic-compatible subgroup were selected for further analysis. OR rate, OS rate, failure-free survival (FFS) rate and the proportion of adverse events (AE) were pooled and compared.
Results: 8 clinical trials or cohort studies with 1004 patients (113 patients receiving ELT+IST, and 891 receiving MSD-BMT) were selected. The pooled age of patients receiving ELT+IST was significantly older than that of MSD-BMT group (45.2±20.5 vs 21.6±15.6 years old, P=0.000). For ELT-IST group, the pooled OR rate was significantly lower (86% *vs* 94%, P=0.002), yet the 1, 2 and 2.5-year OS rate was significantly higher (99% to 99% *vs* 92% to 90% from 1 to 2.5-year OS, P<0.05). No significant difference was observed in 1 and 2-year FFS rate between 2 therapy groups. The major cause of death was infection for MSD-BMT, while no treatment-related death was recorded in ELT+IST group. The pooled relapse rate was 16%, and 8.4% for pooled clonal evolution rate for ELT+IST, while no record of relapse or clonal evolution was available for MSD-BMT. In the subgroup with compatible patient baseline characteristics (mean age: 33 years old), 92 patients were included in ELT+IST group and 213 patients were in MSD-BMT group. The pooled OR rate was lower (87% vs 95%, P=0.017), and the pooled 1, 2 and 2.5-year OS rate was higher (P<0.05) for ELT+IST. For ELT+IST, the relapse rate was 14%, and the clonal evolution rate was 7.6%, while there was no relevant data for MSD-BMT group.
Summary/Conclusion: ELT+IST had potential advantage in survival benefit but lower OR rate for newly-diagnosed SAA patients when compared with MSD-BMT during 2.5 years of follow-up. Treatment-related death and relapse/clonal evolution needed to be balanced when ELT+IST was considered for SAA patients.

EP594 SAFETY OF RAVULIZUMAB IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: STUDY 301/302 2-YEAR RESULTS

A. Kulasekararaj [1,*], M. Griffin [2], S. Langemeijer [3], K. Usuki [4], A. Kulagin [5], M. Ogawa [6], J. Yu [6], A. Mujeebuddin [6], J.-I. Nishimura [7], J. Wook Lee [8], R. Peffault de Latour [9]

[1]*Department of Haematological Medicine, King's College Hospital, National Institute for Health Research and Wellcome King's Clinical Research Facility and King's College London, London,* [2]*NHS Teaching Hospitals Leeds, Leeds, United Kingdom,* [3]*Radboudumc, Nijmegen, Netherlands,* [4]*NTT Medical Center Tokyo, Tokyo, Japan,* [5]*RM Gorbacheva Research Institute, Pavlov University, St Petersburg, Russian Federation,* [6]*Alexion Pharmaceuticals, Inc., Boston, MA, United States,* [7]*Osaka University Graduate School of Medicine, Suita, Osaka, Japan,* [8]*Department of Hematology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of,* [9]*Hôpital Saint-Louis AP-HP, Paris, France*

Background: Patients (pts) with paroxysmal nocturnal hemoglobinuria (PNH) often present with chronic intravascular hemolysis and clinical sequelae due to uncontrolled terminal complement activation, leading to an increased risk of thrombosis and death. In two phase 3 randomized trials of pts with PNH, ravulizumab (administered every 8 weeks; q8w) was shown to be non-inferior to eculizumab (every 2 weeks; q2w) for all efficacy endpoints with a similar safety profile and no unexpected safety signals. Each study had a 26-week randomized primary evaluation period followed by an extension period during which all pts received ravulizumab. Safety results from the 27 weeks–2-years extension period for both studies were analyzed.
Aims: Describe the 2-year safety profile of ravulizumab in pts with PNH from two phase 3 trials.
Methods: Clinical trials 301 (NCT02946463) and 302 (NCT03056040) were phase 3, randomized, open-label, noninferiority, multicenter studies of adult pts with confirmed diagnosis of PNH. Pts in study 301 were naïve to complement C5 inhibitor therapy, with lactate dehydrogenase (LDH) levels ≥ 1.5 × ULN and ≥ 1 sign or symptom of PNH at screening, and generally referred to as pts with high disease activity. Pts in study 302 had been stable on eculizumab treatment for ≥ 6 months prior to study entry, with LDH levels ≤ 1.5 × ULN at screening. Pts received weight-based dosing of ravulizumab q8w or the approved eculizumab dose (900 mg, q2w) for 26 weeks; eligible pts could continue on, or switch to, ravulizumab in

the extension period. The incidence of treatment-emergent adverse events (TEAEs), serious adverse events (SAEs), breakthrough hemolysis (BTH) and anti-drug antibody (ADA) status were assessed in the extension period.
Results: Patient demographics were similar across both studies. In total for combined studies, 434 pts received ravulizumab treatment in the extension period. Of these, 214 were complement C5 inhibitor-experienced having received eculizumab prior to switching to ravulizumab in the extension period. Total exposure for ravulizumab (27 weeks–2-years) was 662 patient-years for the studies. Ninety-eight pts (22.6%) reported treatment-related TEAEs, 10 pts (2.3%) reported treatment-related SAEs, and 3 pts (0.7%) had an SAE that led to study drug discontinuation (unrelated to treatment). Six pts (1.4%) had a major adverse vascular event (MAVE). The most commonly reported TEAEs (in ≥ 10% of pts) were upper respiratory tract infection, nasopharyngitis, headache and pyrexia, n (%): 80 (18.4); 70 (16.1); 56 (12.9); 44 (10.1), respectively (**Table 1**). The percentage of pts with BTH events in the 18-month follow-up extension periods were similar with 15 (6.2%) and 11 (5.6%) in pts naïve to complement C5 inhibitor therapy (study 301) and those with prior eculizumab use (study 302), respectively. Immunogenicity at 2 years was low across both studies, with treatment-emergent non-neutralizing ADA-positivity in 5 pts. Four deaths unrelated to treatment were reported during the extension period. Meningococcal infection was not observed up to the 2-year extension period; there was one fatal case of meningococcal sepsis in a patient at 2.2 years after receiving first dose of ravulizumab. More than 90% of pts in both studies continued ravulizumab treatment beyond the 2-year data cut of the extension periods.

Table 1 Safety outcomes from the combined 301 and 302 studies

	27 weeks – 2-year data cut (N = 434)	
Variable	**n (%)**	**Events (event rate)**
Total patient-years of exposure	-	**662.0**
Treatment emergent adverse events (TEAEs)		
Any TEAE*	391 (90.1)	2327 (351.5)
Related TEAEs	98 (22.6)	236 (35.6)
Unrelated TEAEs	381 (87.8)	2091 (315.8)
Grade 1	333 (76.7)	1347 (203.5)
Grade 2	280 (64.5)	794 (119.9)
Grade 3	100 (23.0)	159 (24.0)
Grade 4	19 (4.4)	25 (3.8)
Grade 5	2 (0.5)	2 (0.3)
TEAE considered as a MAVE	6 (1.4)[§]	8 (1.2)
Most common TEAEs in ≥ 10% of patients		
URTI	80 (18.4)	103 (15.6)
Nasopharyngitis	70 (16.1)	108 (16.3)
Headache	56 (12.9)	75 (11.3)
Pyrexia	44 (10.1)	52 (7.9)
Serious adverse events (SAEs), n (%)		
Any serious SAE	86 (19.8)	121 (18.3)
Related SAE	10 (2.3)	12 (1.8)
Unrelated SAE	80 (18.4)	109 (16.5)
SAE leading to study drug discontinuation	3 (0.7)[†]	3 (0.5)
Death	4 (0.9)[‡]	-

Rate = rate of AE adjusted by patient-years of exposure, defined as (number of events)/100 patient years. Grade 1 = mild, Grade 2 = moderate, Grade 3 = severe, Grade 4 = life-threatening, Grade 5 = fatal.
*TEAEs are AEs with a start data and start time on or after the date and time of the first infusion of study drug.
§Eight MAVEs were recorded: 1 patient had 2 events of pulmonary embolism, 1 patient had 2 events of cerebral infarction; the other MAVEs included thrombophlebitis, deep vein thrombosis, jugular vein thrombosis and peripheral artery thrombosis. Six events were considered to be unrelated to treatment and two events were unlikely related to treatment. None of these events led to change in dose.
†Three discontinuations were recorded: acute myeloid leukemia, myelodysplastic syndrome and lung adenocarcinoma.
‡Four deaths unrelated to study drug were reported: pulmonary sepsis, acute myeloid leukemia, lung adenocarcinoma and lung neoplasm malignant; the two deaths leading to study drug discontinuation were acute myeloid leukemia and lung adenocarcinoma.
AE, adverse event; MAVE, major adverse vascular event; SAE, serious adverse event, TEAE, treatment emergent adverse event; URTI, upper respiratory tract infection.

Summary/Conclusion: Ravulizumab was well tolerated in pts with PNH who were complement C5 inhibitor therapy naïve or experienced, with no new safety signals reported up to 2 years of treatment.

EP595 EFFECT OF PEGCETACOPLAN ON QUALITY OF LIFE IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: WEEK 48 OF PEGASUS PHASE 3 TRIAL COMPARING PEGCETACOPLAN TO ECULIZUMAB

A. Röth [1,*], B. Höchsmann [2], M. Griffin [3], C. M. de Castro [4], J. Szer [5], K. Usuki [6], J. Soret [7,8], M. Al-Adhami [9], C. Chen [9], S. P. Sarda [9], J. Panse [10]

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, acquired, life-threatening hematologic disease characterized by chronic complement-mediated red blood cell hemolysis. Current standard treatments for PNH are the C5 inhibitors eculizumab (ECU) or ravulizumab. Despite their proven efficacy in the control of intravascular hemolysis (IVH), up to 72% of patients experience persistent hemolysis leading to suboptimal hemoglobin (Hb) levels and 36% require transfusions despite ECU treatment which results in significant impact on quality of life (QoL), including persistent fatigue. Pegcetacoplan (PEG) is a C3 inhibitor that provides broad hemolysis control (including IVH and extravascular hemolysis) in patients with PNH.
Aims: This analysis evaluates QoL measures in the PEGASUS study (NCT03500549), a phase 3, open-label, randomized, active-comparator trial evaluating the efficacy and safety of PEG compared with ECU.
Methods: This study is an extension of the PEGASUS trial. PEGASUS enrolled patients ≥18 years of age with PNH and Hb levels <10.5 g/dL despite receiving treatment with ECU for ≥3 months. Patients entered a 4-week run-in period in which they received ECU plus twice-weekly PEG (1080 mg, administered subcutaneously) and were then randomized 1:1 to monotherapy with PEG or ECU for 16 weeks. Patients receiving ECU during the randomized controlled period entered another 4-week run-in period (ECU+PEG), before PEG monotherapy (groups: PEG-to-PEG and ECU-to-PEG). This was followed by an Open Label Period (OLP), in which all patients received pegcetacoplan monotherapy. The primary endpoint was change from baseline in Hb levels at Week 16, where PEG demonstrated superiority to ECU *(Hillmen P et al, EHA 2020)*. Secondary endpoints included the QoL measures by the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire-Core 30 Scale (EORTC QLQ-C30) and Linear Analog Scale Assessment (LASA). The EORTC QLQ-C30 contains 30 questions comprising 5 functional, 9 individual symptom, and one global health status/QoL item(s). The LASA consists of 3 sections asking to rate the perceived level of functioning (scale 0-100) and contains specific domains for activity level, ability to carry out daily activities, and overall QoL.
Results: PEGASUS enrolled 80 patients (Peg, n=41; ECU, n=39). Overall, mean baseline scores of the EORTC QLQ-C30 functional and symptom scales were similar between groups. At Week 16, patients in the PEG group typically scored better than ECU (ECU only to Week 16) patients on various scales of the EORTC QLQ-C30 (Figure A). After receiving PEG monotherapy for 28 weeks (OLP), both groups showed improvements in all functional scales (Figure A) and the global health status/QoL at Week 48 (Figure B) and as indicated by an increase in the score from baseline. Improvements in the fatigue (Figure B) and dyspnea scales were also observed in both groups at Week 48 as indicated by a reduction in the symptom score close to the population norms (fatigue general population norm: 24.1 [22.7], dyspnea general population norm: 10.9 [20.6]). Mean total LASA scores increased in the PEG-to-PEG group as compared to the ECU-to-PEG group to Week 16 and after 28 Weeks of open-label PEG monotherapy the mean score was comparable between both groups at Week 48 (Figure A).

A

All observed, mean (SD)	PEG-to-PEG n=41			ECU-to-PEG n=39

Financial difficulties	18.70 (26.93)	8.33 (16.67)	7.78 (16.80)	24.32 (37.39)	22.22 (33.81)	11.90 (22.62)
LASA						
Total LASA score	161.00 (67.99)	213.37 (69.36)	215.97 (67.14)	156.66 (61.27)	148.14 (65.26)	218.41 (60.11)

B

Summary/Conclusion: Although no statistical tests were performed on these QoL endpoints based on the trial protocol, substantial and clinically relevant improvements in QoL were consistently observed with PEG across both LASA and EORTC QLQ-C30 scores.

EP596 RISK OF SERIOUS INFECTIONS IN PATIENTS WITH OR WITHOUT PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: A REAL-WORLD MATCHED COHORT ANALYSIS

B. J. Patel [1], R. Ofori-Asenso [2,*], A. Shang [3], A. Surinach [4], A. Alexandrou [2], N. Balachandran [2], P. Katz [3], S. Sreckovic [3], J. Maciejewski [1]

[1]Department of Hematology and Medical Oncology, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, United States, [2]Roche Products Ltd, Welwyn Garden City, United Kingdom, [3]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [4]Genesis Research, Hoboken, NJ, United States

Background: Due to complement-associated defects and the use of C5 inhibitors, the risk of infection may be high in patients with paroxysmal nocturnal hemoglobinuria (PNH). However, there are only limited data on comparative rates of hospitalized serious infections (SI) in patients (pts) with PNH vs pts without PNH.
Aims: To compare the incidence rate (IR) of SI, including bacterial, viral, or opportunistic infections in pts with or without PNH in a real-world setting.
Methods: Using the IBM MarketScan Commercial Database, a cohort of pts with PNH was identified with confirmed diagnosis of PNH between Jan 1, 2000 and Dec 31, 2019 and ≥3 claims for PNH within 365 consecutive days. The earliest claim that satisfied this criterion was assigned as the index. A cohort of individuals with no evidence of PNH in the study period was randomly selected from the database and matched (without replacement) to the PNH cohort by age, sex, insurance type, region, enrollment length, HIV status, diabetes status, and chemotherapy status at a 1:3 ratio. In this analysis, cases and controls were followed up for ≥6 months. Cases of SI were identified via validated algorithms (Pawar 2019 [PMID: 30679153]; Dommasch 2019 [PMID: 31075163]; Khan 2020 [PMID: 30980714]). We limited our analysis to SI to reduce surveillance bias associated with assessing outpatient infections. The analysis used all infections with discharge diagnosis codes, and a sensitivity analysis was performed by restricting to only SI with primary discharge diagnosis code. The SI discharge dates were required to be separated by ≥28 days to reduce the risk of counting readmissions for same infection (Feldman 2017 [PMID: 27589220]). A sensitivity analysis was performed using ≥14 days. Mean cumulative function (MCF) was used to characterize the cumulative number of infections. A Poisson regression model was fitted to estimate the incidence rate ratio (IRR) and 95% CI. The hazard of first infection was compared between groups via Cox proportional hazards model. Subgroup analyses were performed for infection subtypes and for pts with PNH with or without aplastic anemia (AA).
Results: Overall, 1083 pts with PNH (200 [18.5%] with AA; 322 [29.7%] who received anti-C5 agents during follow-up) and 3249 control pts were identified. In all, 20.9% of pts with PNH and 4.7% of control pts experienced ≥1 SI during a follow-up of 3196.9 and 12,596.0 person-years, respectively. The IR of SI was 12.7 (95% CI: 11.5, 14.0) and 1.7 (95% CI: 1.5, 2.0) per 100 person-years for pts with PNH and control pts, respectively, translating into an IRR of 7.27 (95% CI: 6.17, 8.57). The overall IR for SI was not significantly different between PNH patients with or without AA. Subgroup analyses showed higher IR in pts with PNH compared with control pts across all infection subtypes (Fig. 1A) and sex and age groups (Fig. 1B). The hazard of first infection was higher in pts with PNH vs control pts (HR, 6.08; 95% CI: 4.95, 7.48). The MCFs suggested that for every 100 pts with PNH, there were 15, 26, and 57 excess SI compared with control pts within 1, 2, and 5 years, respectively. The IR did not change when the allowable gap between discharge dates was ≥14 days. The higher IR of SI in pts with PNH remained consistent when the analysis was restricted to only SI with primary discharge diagnosis status (IRR, 6.75; 95% CI: 5.16, 8.84).

Table: Incidence of SI in PNH patients versus control patients. A, By infection subtype. B, By sociodemographic group.

CI, confidence interval; IR, incidence rate; IRR, incidence rate ratio; RD, rate difference; SI, serious infection; URTI, upper respiratory tract infection; UTI, urinary tract infection.
[a] Per 100 person-years; [b] RD is the incidence rate difference (incidence rate in cases-controls) per 100 person-years.

Summary/Conclusion: This analysis revealed substantial burden of SI in pts with PNH compared with pts without PNH. Measures to minimize the risk of SI could improve health outcomes of pts with PNH and reduce infection-related healthcare costs.

EP597 REAL WORLD DATA OF PATIENTS WITH ACQUIRED PURE RED CELL APLASIA: A SINGLE INSTITUTION EXPERIENCE

M. L. Tung [1,*], P. S. Chia [1], W. Teo [1]

[1]Hematology-Oncology, National University Health Systems, Singapore, Singapore

Background: Pure red cell aplasia (PRCA) is a rare condition characterised by absent erythropoiesis within the bone marrow. The acquired form may present as a primary haematological disorder in the absence of other diseases and is classified as idiopathic PRCA. Occasionally, it can present secondary to other conditions and can be associated with various medications, viral infections, immune disorders, ABO-incompatible haematopoietic stem cell transplantation (HSCT) and malignancies such as thymomas.
Aims: This is a retrospective audit of all adult patients diagnosed with PRCA from 2010 to 2020 to evaluate underlying causes, treatment administered, time to response and survival outcomes.
Methods: A retrospective review of all the patients diagnosed with PRCA above the age of 18 at NUH from 2010 to 2020 was performed. Clinical data recorded include patient's age at diagnosis, gender, laboratory values at diagnosis, associated conditions, treatment administered, time to response and survival outcomes.
Results: A total of 31 patients were diagnosed with PRCA from our clinical database. There were 20 male and 11 female patients identified. Median age at diagnosis was 58 years (range: 27 – 83 years old). 11 patients were diagnosed with idiopathic PRCA and the rest were diagnosed with secondary PRCA (64.5%). Secondary PRCA was associated with conditions such as thymomas (n=3), autoimmune disease (n=3), drug-related (n=3), ABO-mismatched HSCT (n=7), haematological malignancies (n=2) and parvovirus-induced (n=1). Median haemoglobin at presentation was 6.1 g/dL (range: 3.3 – 12.3 g/dL) and median absolute reticulocyte count was 4.7 X 10^9/L (range: 1.7 – 27.8 X 10^9/L). 22 patients were started on immunosuppressive therapy (IST) and 87.5% achieved a complete response. 7 patients were unevaluable for treatment response due to patient's demise, lost to follow-up or short duration of follow-up. 1 patient was unable to tolerate IST and another patient subsequently lost response and now has refractory PRCA. 14 patients had sustained response to IST but only 14.3% were able to stop IST successfully without relapse. Amongst 4 patients with PRCA associated with thymomas, 2 were diagnosed post-thymectomy and all required adjuvant IST post-thymectomy for sustained response. A total of 26 patients were assessed for survival outcome. 21 patients were alive and 4 were deceased from underlying conditions such as end-stage renal failure (ESRF), relapsed acute leukaemia and infective complications. The cause of death for 1 patient was unknown but likely related to the underlying metastatic thymic carcinoma.

Summary/Conclusion: Given that PRCA is a rare diagnosis, the treatment initiated, associated response rates and long- term follow-up for evaluation of the sustainability of those responses are needed to help haematologists better manage these patients.

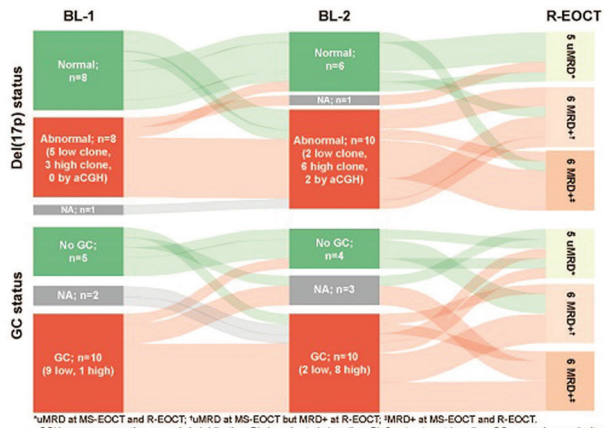
EP598 CLINICAL CHARACTERISTICS OF 512 ECULIZUMAB-NAIVE PAROXYSMAL NOCTURNAL HEMOGLOBINURIA PATIENTS IN CHINA: A SINGLE-CENTER OBSERVATIONAL STUDY

Y. Du [1,*], S. Hu [1], Y. Yang [2], C. Yang [1], M. Chen [1], B. Han [2]

[1]Hematology, [2]Peking Union Medical College Hospital, Beijing, China

Background: The characters update of patients with paroxysmal nocturnal hemoglobinuria (PNH) in China has not been well addressed. We retrospectively reviewed patients with complete data who visited Peking Union Medical College Hospital from 2009 to 2018 and had been followed up for more than 2 years.
Aims: To update the characters of patients with PNH in China.
Methods: Retrospectively analyzed 512 patients diagnosed with PNH in the past ten years from a single center in China.
Results: There were 512 patients, including 56.3% males and 43.8% females. The median age at disease onset was 33 (9~80) years. Classic PNH, bone marrow failure (BMF)/PNH and subclinical PNH accounted for 52.3%, 46.3% and 1. 6% of the patients, respectively. Most of the patients were at 21~40 years (50.6%) and 41~60 years (25.4%). The most common symptoms and positive lab findings were hemolytic and BMF related. Most of the patients had >50% of Flare- granulocytes. PNH clone size correlated with hematoglubinuria (R2=0.038, P=0.001), erectile dysfunction (R2=0.03, P=0.019), reticulocyte (R2=0.164, P<0.01) and LDH level (R2=0.268, P<0.001). Thrombosis events (TEs) occurred in 18.0% of patients. 88.8% were venous and 11.2% were arterial events. 77.2% of the patients had single-site thrombosis with the abdominal vein (44.8%) the most common site. 22.8% of patients experienced repeated or multiple-site thrombosis. Renal deficiency happened in 16.9% of patients. Patients with classic PNH had longer disease duration, bigger PNH clone size, higher LDH, TBil, DBil, AST, Scr, and blood cell count, lower ferritin compared with those with BMF/PNH. Although the rate of thrombosis was similar for patients with classic PNH (17.3%) and BMF/PNH (19.1%, P=0.66), patients with larger PNH clone and BMF/PNH had higher chance of renal impairment (P<0.05). Immunosuppressive agents, glucocorticoids were the most common treatments and only 39.1% of patients with thrombosis received anticoagulants. The chance of pregnancy was rare and the abortions were high for women in need of fertility. More evolution from BMF/PNH into classic PNH (26.2%) and less from classic PNH into AA/PNH (2.2%) and even less into malignancies were observed at a median of 93.5 (24~144) months follow-up. The major causes of deaths were thrombosis (29.6%), hemorrhage (18.5%) and infections (18.5%). Thrombosis (HR, 3.462; P =0.013) and renal deficiency (HR, 2.105; P =0.032) were the independent risk factors for overall survival (OS).
Summary/Conclusion: Although most PNH patients survived without complement inhibitors, more hemolytic features of PNH in China might be greatly improved with complement inhibitors in the future.

Chronic lymphocytic leukemia and related disorders - Biology & Translational Research



EP599 IMPACT OF UNFAVORABLE GENETICS ON MINIMAL RESIDUAL DISEASE (MRD) RESPONSE TO VENETOCLAX+RITUXIMAB RETREATMENT IN RELAPSED OR REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA (R/R CLL): PHASE 3 MURANO SUBSTUDY

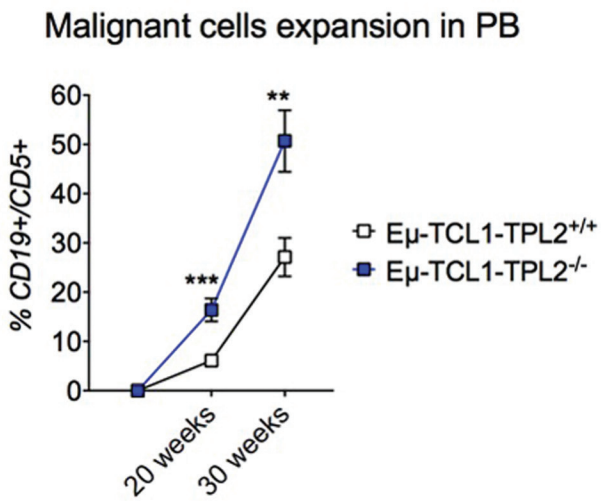
J. Qun Wu [1,*], J. F. Seymour [2], B. Eichhorst [3], P. Hillmen [4], T. Kipps [5], A. W. Langerak [6], C. Owen [7], J. Dubois [8], C. Mellink [8], A.-M. van der Kevie-Kersemaekers [8], B. Chyla [9], Y. Jiang [1], M. Boyer [10], M. Thadani Mulero [10], M. Lefebure [10], A. P. Kater [8]

[1]Genentech Inc., South San Francisco, United States, [2]Royal Melbourne Hospital, Peter MacCallum Cancer Centre and University of Melbourne, Melbourne, Australia, [3]University of Cologne, Department I of Internal Medicine and Center of Integrated Oncology Aachen, Bonn, Cologne, Dusseldorf; German CLL Study Group, Cologne, Germany, Cologne, Germany, [4]St. James's University Hospital, Leeds, United Kingdom, [5]UCSD Moores Cancer Center, San Diego, United States, [6]Erasmus MC, University Medical Center, Rotterdam, Netherlands, [7]University of Calgary, Calgary, Canada, [8]Dept of Hematology, Cancer Center Amsterdam, Amsterdam University Medical Centers, University of Amsterdam, Amsterdam, Netherlands, [9]AbbVie, North Chicago, United States, [10]Roche Products Limited, Welwyn Garden City, United Kingdom

Background: At the 5-yr update of the Phase 3 MURANO trial (NCT02005471), median (95% CI) progression-free survival (PFS) was 54 (48–57) mo with venetoclax-rituximab (VenR) or 17 (15–22) mo with bendamustine-rituximab (BR) treatment, while 36% of VenR-treated patients (pts) and 63% of BR-treated pts had received new anti-CLL therapy. A substudy from 2018 onward enrolled 34 R/R CLL pts who progressed after initial treatment to receive VenR as retreatment (n=25) or crossover from BR (n=9). We report on the VenR-treated pts who had progressive disease (median [range] PFS 46 [36–58] mo), were eligible for anti-CLL therapy, and were retreated with VenR.
Aims: Evaluate molecular profile changes from the MURANO main study baseline (BL-1) to the retreatment baseline (BL-2), describe the genetic features at BL-2 and assess their association with MRD response to VenR.
Methods: Pts on retreatment received VenR (Ven 400mg/d for 2 yrs + monthly R for the first 6 mo). Genomic complexity (GC; defined by copy number alterations [CNA]: 0–2 non-complex, 3–4 low, ≥5 high) was assessed by array comparative genomic hybridization (aCGH). Chromosomal abnormalities were analyzed by aCGH and fluorescence *in situ* hybridization (high clone ≥20%, low clone 7–<20%). Peripheral blood MRD was analyzed by allele-specific oligonucleotide PCR and/or flow cytometry, with a $<10^{-4}$ threshold for undetectable (u)MRD.
Results: At data cutoff (13 Oct 2020), 25 pts were retreated with VenR; median (range) follow-up 12.1 (2.5–21.2) mo, median (range) treatment-free interval 28.3 (12.4–38.1) mo. Unfavorable genetic characteristics were enriched from BL-1 to BL-2. At BL-2, 14/24 pts had del(17p), including 11 high clones, with 3 newly acquired and 4 who shifted from low to high clone. An increase in CNA from BL-1 to BL-2 was observed; median (range) was 3 (1–6) at BL-1 and 4 (1–15) at BL-2 (P<0.05). Overall, 11/20 pts had GC (8 with high GC) at BL-2, with either new chromosomal abnormalities or increased clone size in poor prognostic lesions such as 2p and 8q gain, and 7q, 8p, 11q and 18p loss.
Investigator-assessed objective response rate to VenR retreatment was 70% (14/20 evaluable pts; 50% [14/25] among intent-to-treat pts; 5 complete response, 9 partial response, 5 non-evaluable). Of 17 pts with available MRD data at the retreatment end of combination treatment (R-EOCT), 5 achieved uMRD and 12 were MRD+ (Figure). Sixteen pts had evaluable del(17p) results. Of 6 pts without del(17p) at BL-2, 4 attained uMRD at R-EOCT while all 10 with del(17p) at BL-2 were MRD+ at R-EOCT. Of these, 4/10 had new del(17p) from BL-1 or had evolved from del(17p) low clone to high clone. GC status was available for 14 pts. Of 4 pts without GC at BL-2, 2 attained uMRD at R-EOCT. Of 10 pts with GC at BL-2, 8 were MRD+ and 2 had uMRD at R-EOCT. Of the pts with GC at BL-2, 5/10 had new or increased GC from BL-1. Ten pts attained uMRD at main study EOCT; 4/10 re-attained uMRD at R-EOCT and 6/10 did not. Among the 6 who were unable to re-attain uMRD, 83% (5/6) had del(17p) at BL-2 (3/5 were newly evolved from BL-1) compared with 40% (2/5) at BL-1.

Figure. Increased del(17p) clonality and GC negatively impact MRD response at R-EOCT

*uMRD at MS-EOCT and R-EOCT; †uMRD at MS-EOCT but MRD+ at R-EOCT; ‡MRD+ at MS-EOCT and R-EOCT.
aCGH, array comparative genomic hybridization; BL-1, main study baseline; BL-2, retreatment baseline; GC, genomic complexity; MRD, minimal residual disease; MS-EOCT, main study end of combination treatment; NA, not available; R-EOCT, retreatment end of combination treatment; uMRD, undetectable minimal residual disease.



Summary/Conclusion: Pts who relapsed after initial VenR therapy were highly enriched for unfavorable characteristics at BL-2. We observed a genetic profile shift from BL-1 to BL-2, with greater GC as well as higher prevalence and increased clonality in del(17p). Increased prevalence of unfavorable genetic risk factors negatively impacted MRD response of retreatment pts at the R-EOCT. Deep initial response alongside favorable BL-2 characteristics predict attainment of uMRD with VenR retreatment.

EP600 TPL2 ABLATION ACCELERATES DISEASE DEVELOPMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA EU-TCL1 MOUSE MODEL

J. Bordini [1,*], E. Stagakis [2], M. Frenquelli [1], D. Vyrla [2], C. Lenzi [1], A. Campanella [3], A. G. Eliopoulos [2], P. Ghia [3]

[1]Division of Experimental Oncology, IRCCS Ospedale San Raffaele, Milan, Italy, [2]Department of Biology, Medical School, National & Kapodistrian University of Athens, Athens, Greece, [3]Division of Experimental Oncology-School of Medicine, Vita-Salute San Raffaele University, Milan, Italy

Background: Tumor progression locus 2 (TPL2; also known as MAP3K8) is a serine-threonine kinase that regulates innate/adaptive immunity and inflammation, through ERK activation and cytokines gene expression. Upon inflammatory signals, TPL2 modulates the expression of cytokines and chemokines that promote immune cell recruitment, differentiation, and activation, and in turn, the establishment of an inflammatory microenvironment. Increased TPL2 kinase activity is involved in inflammatory diseases and operates as a potent tumor promoter in most cancers, in association with known oncogenes. However, suppressed TPL2 expression has also been reported in some tumor types, such as lung cancer, and its ablation is associated with increased tumorigenesis in several experimental cancer models, being required for optimal p53 response to genotoxic stress. In line with the latter cases, we have observed, using gene expression datasets, that TPL2 expression is also lower in leukemic cells from patients with chronic lymphocytic leukemia (CLL) as compared to normal B cells, suggesting that TPL2 reduction might be also involved in the pathogenesis of this disease.
Aims: We aimed at investigating the *in vivo*effects of TPL2 ablation in the disease development of CLL, taking advantage of the Em-TCL1 mice, a validated animal model for CLL, and at focusing our attention on the molecular pathways affected by the absence of TPL2.
Methods: We crossed TPL2$^{-/-}$mice with Eμ-TCL1 mice to generate Eμ-TCL1-TPL2$^{-/-}$animals. We analyzed disease expansion by assessing the percentage of CD19^{+}CD5^{+}malignant cells in the peripheral blood (PB), spleen, and bone marrow (BM) using flow cytometry. Malignant cells were collected from the spleen, sorted by flow cytometry, and analyzed for gene expression using RNAseq. We validated the expression levels of selected genes by qRT-PCR.
Results: Eμ-TCL1-TPL2$^{+/+}$mice develop CLL-like disease with aging. Analysis of CD19^{+}CD5^{+}cells at 20 and 30 weeks of age showed increased malignant cell expansion in all relevant tissues. In particular, in the PB of Eμ-TCL1-TPL2$^{-/-}$mice we observed 16% malignant cells at 20 weeks and 51% at 30 weeks at variance with control Eμ-TCL1-TPL2$^{+/+}$mice where malignant cells were 6% and 27%, respectively ($p<0.01$) (Figure 1). In the absence of TPL2, disease expansion was also accelerated in the BM ($p<0.05$) and spleen ($p<0.01$) analyzed at the same time points.
Gene expression profiling of B cells purified from Eμ-TCL1-TPL2$^{-/-}$and Eμ-TCL1-TPL2$^{+/+}$mice showed upregulation of genes involved in cytokine/chemokine production and leukocyte activation in the former. Validation by qRT-PCR confirmed higher expression of genes implicated in CLL pathogenesis and tissue homing in the Eμ-TCL1-TPL2$^{-/-}$animals, including CCL4 ($p<0.05$), CCL3 ($p<0.05$), CCR5 ($p<0.01$), Zap70 ($p<0.05$) and BAFF ($p<0.01$). We also observed, in Eμ-TCL1-TPL2$^{-/-}$mice, downregulation of genes involved in cell death regulation, including pro-apoptotic factors such as NOXA ($p<0.01$), PUMA ($p<0.01$), GADD45 ($p<0.01$), and ATF-3 ($p<0.01$). The expression of all these genes was not altered in either Eμ-TCL1 or TPL2$^{-/-}$parental mice as compared to wild type mice.

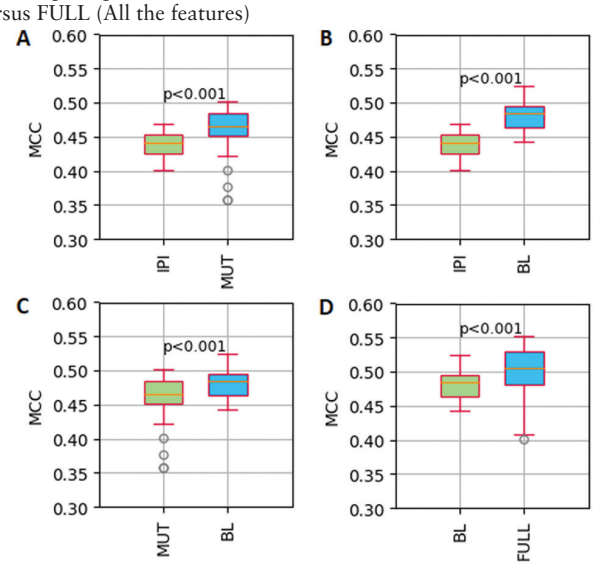
Summary/Conclusion: Ablation of TPL2 expression accelerate CLL development in Eμ-TCL1-TPL2$^{-/-}$mice. The absence of TPL2 leads to the inhibition of pro-apoptotic genes in malignant cells and the upregulation of genes with major pathogenetic roles in CLL, including tissue invasion and dissemination. Our data suggest that loss of TLP2 might synergistically contribute to disease development under pro-tumorigenic conditions.

EP601 LONG NON-CODING RNA LINC00525 PROMOTES PROLIFERATION AND INHIBITS APOPTOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA CELLS BY TARGETING MIR-338-3P/ WWP1 AXIS

C. Yang [1], H. Liu [2], L. Cao [2], Y. Miao [2], R. Huang [2], H. Zhu [2], X. Shi [2], W. Xu [2], J. Li [2], L. Fan [2,*]

[1]Jiangsu Province Hospital, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China, [2]Department of Hematology, Jiangsu Province Hospital, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Emerging evidences have indicated that long noncoding RNAs (lncRNAs) play essential roles in the development and progression of cancers. LncRNAs were aberrantly expressed in most hematological malignancies including leukemia, participating in tumor suppression or promoting oncogenesis and modulating key genes in different pathways. Dysregulation of LINC00525 has recently been reported in several types of cancers, and researches on the function of LINC00525 in cancers suggested that LINC00525 could act as an oncogene. But the functional involvement of LINC00525 has not been studied in chronic lymphocytic leukemia (CLL).
Aims: In order to explore the expression and biological function of LINC00525 in CLL.
Methods: In our study, CCK8 assays, cycle assays, apotosis experiments were used to identify biological effects of LINC00525 on CLL cells in vitro. The expression of LINC00525, microRNA-338-3p (miR-338-3p) were detected by qRT-PCR. Dual-luciferase reporter assay and RNA immunoprecipitation (RIP) assay were performed to show the interactions of LINC00525 and miR-338-3p. The bioinformatics methods were completed to find the target genes of miR-338-3p. And Dual-luciferase reporter assay and Western blot analysis were further used to confirm the target gene of miR-338-3p.
Results: We found that LINC00525 knockdown obviously suppressed CLL proliferation and increase apoptosis in vitro. Besides, silencing of LINC00525 significantly increased the expression of microRNA-338-3p (miR-338-3p), which could play a tumor suppressor role in CLL. Moreover, dual-luciferase reporter assay and RNA immunoprecipitation (RIP) assay revealed that LINC00525 exerted tumor-suppressive functions by binding directly to miR-338-3p, and there was a reciprocal inhibition between LINC00525 and miR-338-3p in the same RNA induced silencing complex (RISC). Furthermore, overexpression of LINC00525 enhanced the expression of suppression of the E3 ubiquitin ligase (E3) WWP1, which was identified as a downstream target gene of miR-338-3P. Thus, LINC00525 positively regulated WWP1 expression through sponging miR-338-3P, and acted as tumor suppressor in CLL.
Summary/Conclusion: LINC00525 promotes cell proliferation through LINC00525/miR-338-3p/ WWP1 axis in CLL.



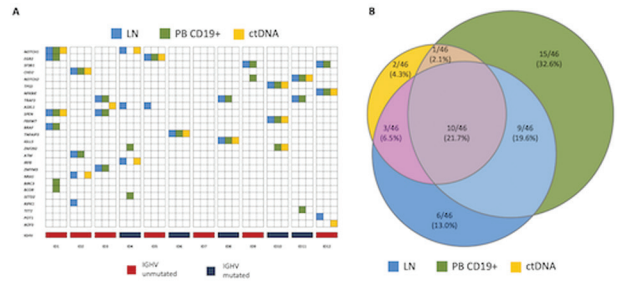
EP602 COMPARING MACHINE LEARNING-BASED PREDICTION OF TREATMENT IN CLL USING RECURRENT GENE MUTATIONS VERSUS (PARA)CLINICAL FEATURES

M. Parviz [1,*], C. Brieghel [1], R. Agius [1], C. U. Niemann [1]

[1]*Hematology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark*

Background: The international prognostic index for patients with chronic lymphocytic leukemia (CLL-IPI) is the current standard for prognostication. We previously improved the CLL-IPI by 1) using a Treatment and Infection Model (CLL-TIM) and 2) by the number of signaling pathways impaired by recurrent mutations. In this study, we compare the performance of Machine Learning models trained on CLL-IPI variables plus baseline (para)clinical variables with CLL-IPI plus recurrent mutations in patients with newly diagnosed CLL.
Aims: 1) Investigating the predictive performance of CLL-IPI variables, recurrent gene mutations, and (para)clinical variables for Treatment at time of CLL diagnosis.
2) Studying the impact of data-driven selection of the Machine Learning algorithm as well as the interaction between data variables and the algorithms.
Methods: In a cohort consisting of 314 patients with newly diagnosed CLL, CLL-IPI variables, recurrent gene mutations, and (para)clinical variables were extracted and used as features in a predictive framework in which a variety of Machine Learning algorithms (Linear SVM, AdaBoost, CatBoost, XGBoost, LightGBM, RandomForest, ExtraTrees, and Bagging) were used to predict CLL treatment as the outcome.
By using different combinations of feature sets, four models were defined as following:
1. CLL-IPI features only (IPI),
2. CLL-IPI features plus recurrent mutations (MUT),
3. CLL-IPI features plus (para)clinical baseline features (BL),
4. All the above features (FULL).

Patients were randomly split into a 60% train set and a 40% blinded validation set. The train set was further split 40 times into training set (75%) and test set (25%) to perform hypothesis testing, whereas the validation is still blinded. We here report the preliminary results on the train set.
Results: The preliminary results showed that adding either data on recurrent mutations (MUT) or (para)clinical baseline data (BL) improved the predictive performance significantly compared to the CLL-IPI only (Fig. 1A and 1B). Comparing the BL and MUT models, showed that adding baseline (para)clinical features (BL) predicted CLL treatment better than adding recurrent mutations (MUT) (Fig. 1C). As expected, including all the three feature sets (FULL) outperformed the BL model. For all four hypotheses, the *Bagging* algorithm achieved the best performance (Fig. 1D).
Fig. 1 illustrates the distribution of MCC (Mathew Correlation Coefficient) values of each model. **A**) IPI (CLL-IPI features) versus MUT (CLL-IPI plus recurrent mutations features), **B**) IPI versus BL (CLL-IPI features plus (para)clinical baseline features), **C**) MUT versus BL, **D**) BL versus FULL (All the features)



Summary/Conclusion: We here demonstrate that including data on recurrent mutations and (para)clinical features on top of CLL- IPI can improve the predictive performance in a Machine Learning model predicting CLL treatment. Furthermore, a data driven selection of the optimal Machine Learning algorithm improves the predictive power. Upon confirmation of these findings in a blinded internal validation set and in external cohorts, these data indicate that combined modelling of multidimensional OMICs and (para)clinical data can pave the way for truly personalized management of CLL.

EP603 MULTIREGIONAL SEQUENCING AND CIRCULATING TUMOR DNA ANALYSIS PROVIDE COMPLEMENTARY APPROACHES FOR COMPREHENSIVE DISEASE PROFILING OF SMALL LYMPHOCYTIC LYMPHOMA

R. Moia [1,*], C. Favini [1], V. Ferri [1], L. Terzi Di Bergamo [2], M. Schipani [1], G. Forestieri [2], S. Sagiraju [1], A. Andorno [3], S. Rasi [1], D. Talotta [1], W. Al Essa [1], R. Adhinaveni [1], A. Bruscaggin [2], V. Spina [2], L. De Paoli [1], G. Margiotta Casaluci [1], A. Patriarca [1], R. L. Boldorini [3], D. Rossi [2], G. Gaidano [1]

[1]*Division of Hematology, Department of Translational Medicine, Università del Piemonte Orientale, Novara, Italy,* [2]*Institute of Oncology Research and Oncology Institute of Southern Switzerland, Bellinzona, Switzerland,* [3]*Department of Pathology, Università del Piemonte Orientale, Novara, Italy*

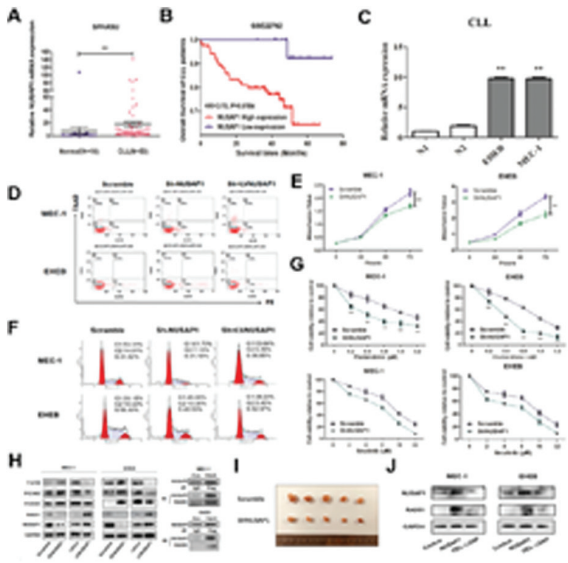
Background: Spatial heterogeneity is a hallmark of metastatic solid cancer, while it is less obvious in leukemic B-cell tumors that systemically involve secondary lymphoid organs and circulate in blood. Small lymphocytic lymphoma (SLL) is a model that can inform on whether spatial heterogeneity exists in leukemic B-cell tumors, as it is the sole entity that markedly involves both blood and lymph nodes in all cases. Circulating tumor DNA (ctDNA) recapitulates disease genetics in aggressive lymphomas but its role advantage multiregional sequencing of peripheral blood and lymph node biopsy is unexplored.
Aims: To dissect the genetics of different anatomical compartments in SLL with a multiregional sequencing and liquid biopsy approach.
Methods: Patients with SLL (n=12) were referred to our institution and provided with: i) tumour gDNA extracted from fresh frozen lymph node cells or formalin-fixed paraffin-embedded (FFPE) lymph node biopsies; ii) tumour gDNA extracted from sorted peripheral blood (PB) CD19+/CD5+ cells; iii) ctDNA from plasma; and iv) germline gDNA extracted from CD3+ T-cells and/or granulocytes for comparative purposes. The CAPP-Seq assay was used for the mutational profiling and comprised a panel of 124 genes relevant in B cell malignancies. Copy number variants (CNVs) were identified with the GATK4 CNV workflow.
Results: Overall, the analysis of the three SLL compartments analyzed (i.e. lymph node biopsy, circulating PB CD19+ cell compartment, and plasma ctDNA) identified a total of 46 mutations in genes known to be mutated in B cell malignancies. At least one mutation was found in 11 out of 12 (91.7%) patients with a median number of 3 mutations per patient (range 0-6). The most frequently mutated genes were *TRAF3* and *ASXL1* in 3/12 (25.0%) patients each, followed by *NOTCH1*, *EGR2*, and *SF3B1* in 2/12 (16.7%) patients each (Fig 1A). By comparing the representation of gene mutations in the different anatomical compartments investigated in SLL, 10/46 (21.7%) mutations were identified in all three compartments, whereas the remaining mutations were differently distributed among the three examined compartments. More precisely, 6/46 (13.0%) mutations were exclusive of the lymph node biopsy, 15/46 (32.6%) were exclusive of the circulating PB CD19+ cell compartment, and only a small fraction of mutations (2/46; 4.3%) were detectable uniquely in the plasma ctDNA (Fig 1B). Interestingly, from a translational perspective, a *BIRC3* mutation that may harbor potential predictive value, has been identified only in the circulating PB CD19+ cell compartment. In addition, a bioinformatic algorithm for CNVs analysis has been applied to 8 patients in order to identify potential additional differences between the lymph node biopsy and the circulating PB CD19+ cell compartment. This algorithm showed 100% concordance with FISH karyotype and allowed the detection of at least one CNVs difference in 3/8 patients (37.5%).

Summary/Conclusion: These results suggest that the multiregional sequencing of the different anatomical compartments of SLL is essential to gain a comprehensive view of the disease mutational landscape. Consistently, mutational analysis of the SLL lymph node biopsy should be coupled to analysis of the circulating PB CD19+ cell compartment, and eventually with ctDNA analysis. This observation may have clinical relevance when treatment tailoring is based on specific gene mutations used as molecular predictors that might be present in only one specific anatomical compartment of the disease.

EP604 CFOS/MIR-181A CIRCUITRY IS INVOLVED IN BCR SIGNALLING AND DEATH OF CLL CELLS.

A. Ramassone [1,*], M. M. Rachid [1], A. M. Di Marco [1], E. Grifa [1], J. N. George-William [1], F. Autore [2], A. Tommasso [2], I. Innocenti [2], L. Laurenti [2], A. Veronese [3], R. Visone [1]

[1]Department of Medicine, Dentistry and Biotechnology, "G. d'Annunzio" University, Chieti, [2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, [3] Center for Advanced Studies and Technology, "G. d'Annunzio" University, Chieti, Italy



Background: B-cell receptor (BCR) signalling plays a pathogenic role in Chronic Lymphocytic Leukemia (CLL); in CLL, there is constitutive activation of the BCR, and the CD40L-CD40 signalling is impaired. We have recently demonstrated that miR-181b is a downstream effector of B and activated T cells' interaction. Indeed, miR-181b is an effector of the CD40L-CD40 pathway, which induces death of CLL cells by increasing the cytotoxic activity of T cells versus the leukemic clone. We thus hypothesized that also miR-181a could stimulate this process. Considering the crosstalk between the CD40L-CD40 and the BCR pathway, we speculated the involvement of the miR-181a also in the BCR pathway.
Aims: Assess the involvement of miR-181a in BCR signalling pathway; evaluate the ability of miR-181a to induce the cytotoxic activity of T cells.
Methods: Since the BCR stimulation induces an heterogeneous response in the expression of miRNAs due to BCR stereotype, to assess the involvement of miR-181a in BCR signalling pathway, CLL cells were treated in vitro with Ibrutinib, a BCR inhibitor. The expression of the miR was then analysed in CLL samples from patients treated with Ibrutinib. To evaluate whether the transcription factor cFOS take part in BCR signalling, its expression was analysed after Ibrutinib treatment. To test whether the transcription factor cFOS regulates the miR-181a, the expression of the miR was analysed after overexpression or silencing of cFOS. To assess if the miR-181a could promote the cytotoxic activity of T cells, Cytotoxic T lymphocytes (CTLs) were generated by mixing CD40L-stimulated and miR-181a-overexpressed CLL cells with autologous T cells.
Results: We observed an increase in miR-181a expression after in vitro inhibition of BCR signalling; we observed the same effect also in vivo in most of CLL patients treated with Ibrutinib. The increased expression of miR-181a inversely correlated with the amount of White Blood Cells (WBC) and, specifically, it was higher in those patients for which the WBC decreased more than 50%. To explain a possible mechanism by which the expression of miR-181a increase, we focused on the transcription factor cFOS, which we already found involved in the transcriptional regulation of miR-181b in CLL; we found that cFOS expression decreased after Ibrutinib treatment in vitro and that overexpression of cFOS downregulated miR-181a, while its silencing increased the expression of the miR in CLL cell line.
Since the overexpression of miR-181a was associated with a reduction of the WBC in vivo, we sought to identify a mechanism by which the miR could affect cell survival. To this end, we focused on the IL10, whose downregulation through miR-181b increase the cytotoxic activity of CTL. We found that miR-181a overexpression downregulated the levels of IL10 after the CTL generation assay in half of the analysed patients, and this was associated with the increase in the percentage of CTL. Conversely, in those patients for which we did not observed a reduction of IL10, there were no effect on CTL amount. Previous studies demonstrated that the IL10 was upregulated by cFOS protein and that cFOS was a target of miR-181a. Considering that cFOS negatively regulates miR-181a, we suggest that the circuitry consisting of cFOS/miR-181a could play a role in BCR signalling and CLL cells death.
Summary/Conclusion: MiR-181a is upregulated by BCR signalling inhibition in vitro and in vivo. The overexpression of miR-181a promotes the generation of autologous cytotoxic T cell versus the leukemic clone through the downregulation of IL10.

EP605 NUSAP1 ENHANCES DRUG RESISTANCE BY BINDING TO RAD51 THROUGH DNA DAMAGE REPAIR PATHWAY IN CHRONIC LYMPHOCYTIC LEUKEMIA

Y. Han [1,2,*], Y. Zhang [1,2], X. Hu [1,2], H. Zhang [1,2], X. Sun [1,2], X. Zhang [1,2], X. Yun [1,2], X. Wang [1,2]

[1]Department of Hematology, Shandong Provincial Hospital, Cheeloo College of Medicine, Shandong University, [2]Department of Hematology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: Enhanced DNA damage repair effect is an important mechanism for drug-resistance in chronic lymphocytic leukemia (CLL). Previous studies reported that nucleolar and spindle associated protein 1 (NUSAP1) was involved in DNA damage repair process and played important roles in the development, progression, and metastasis in several types of cancer. However, its role and mechanism in the development of CLL are still unclear.
Aims: We aim to further explore the expression and exact role of NUSAP1 in CLL development, providing theoretical basis for new molecular markers and targeted therapy.
Methods: Expression levels of NUSAP1 mRNA and protein in CLL cell lines and patient specimens were detected by qRT-PCR and Western blot, and Kaplan-Meier survival curve and overall survival were analyzed by log-rank test. Peripheral blood samples from *de novo* CLL patients and healthy volunteers were collected with informed consents at the Department of Hematology in Shandong Provincial Hospital Affiliated to Shandong University (SPHASU). Microarray datasets GSE22762 were obtained from Gene Expression Omnibus. With altering NUSAP1 expression by lentivirus-transfected cells in vitro, the effects of NUSAP1 on cell proliferation, apoptosis and cycle were detected by CCK8, Annexin V-PE /7AAD staining and PI/RNase staining respectively.
Results: To study the role of NUSAP1, CLL specimens were chosen for qRT-PCR analysis. The expression level of NUSAP1 gene in samples of CLL patients was significantly increased than that of healthy donors ($P<0.05$) (Figure A). Besides, the results indicated that the overall survival (OS) of patients with highly expressed NUSAP1 was significantly worse than in patients with low expression with the statistical analysis database GSE22762 (Figure B). mRNA and protein expression levels of NUSAP1 were significantly higher in CLL cell lines than in PBMCs from healthy donors (Figure C). Moreover, the amounts of DNA fragmentation of the apoptotic cells were remarkably increased in shNUSAP1 transfection cells compared with the Scramble group (Figure D). Our findings indicated that NUSAP1 knockdown notably suppressed cell proliferation (Figure E). In addition, after downregulating NUSAP1, MEC-1 and EHEB cells were blocked in G0/G1 phase (Figure F). Treatment with fludarabine or ibrutinib in shNUSAP1 group showed enhanced cytotoxicity in CLL cells (Figure G). Suppression of NUSAP1 inhibited the action of proteins in DNA damage repair pathway (Figure H). Through COIP, NUSAP1 was identified to bind with RAD51 (Figure H). After CLL cells were subcutaneously injected into (SCID) beige mice for 45 days, tumor volumes were significantly reduced in mice treated with ShNUSAP1 cells compared to scramble group (Figure I). Compared with the NUSAP1 upregulated group, the NUSAP1-ΔSAP transfection group suppressed RAD51 expression as expected (Figure J). Hence, NUSAP1 participates in the DNA damage repair process and enhances the drug resistance in CLL.

Summary/Conclusion: Collectively, our findings demonstrate that NUSAP1 contributes to DNA damage repairing by binding with RAD51 and promoting stable proliferation of CLL cells both *in vitro and vivo*. Therefore, NUSAP1 is expected to be a potential target for the treatment of CLL with drug-resistance.

EP606 CLINICAL VALIDATION OF A NGS CAPTURE PANEL TO IDENTIFY MUTATIONS, COPY NUMBER ALTERATIONS AND CHROMOSOMAL REARRANGEMENTS IN MATURE B-CELL NEOPLASMS

A. Gomez Llonin [1,2,*], A. Puiggros [1,2], J. Rodríguez [3], L. Nonell [4], B. Rodriguez-Santiago [3], P. Rodriguez [3], H. Mattlin [3], M. I. Banchs [3], M. Salido [1,2], S. Beà [5], A. Background: At a research level, next-generation sequencing (NGS) techniques have provided a large amount of new information, sometimes with clinical implications. In mature B-cell neoplasms (MBCN) the main applications are focused on the identification of somatic variants, while there are limited applications including rearrangements and copy number alterations (CNAs), which are crucial in clinical practice.
Aims: Thus, we designed an NGS capture panel to analyze in a single assay all key genetic aberrations including single nucleotide variants (SNVs), indels, CNAs and chromosomal rearrangements.
Methods: A total of 173 samples from 170 patients diagnosed of different MBCN (55 DLBCL, 43 MZL, 37 CLL, 14 FL, 12 MCL, 5 BL, 4 HCL) were analyzed. DNA was extracted from peripheral blood (n=88), bone marrow (n=7) or other tissues (n=78). Samples were tested in two sequentially designed versions of a custom targeted panel (PV1 and PV2) (Roche Nimblegen) covering 4 rearrangement genes (*BCL2*, *BCL6*, *MYC* and *CCND1*), 35 frequently mutated genes, and 13 CNA regions (Figure). PV1 also included 9,111 SNPs to assess CNAs genomewide (size=4.6Mb). In PV2 the size was significantly reduced (1.4Mb), and the design for *BCL2* and *MYC* optimized. Sequencing was performed using Illumina NextSeq500. Data were analyzed for SNVs and small indels (MUTECT2), rearrangements (DELLY and Smoove) and CNAs (CopywriteR). Results were validated using different genetic techniques (chromosome banding analysis, FISH, genomic arrays, PCR, Sanger and other NGS panels).
Results: High sensitivity and specificity were achieved (Figure). Regarding mutations, variants with a mean coverage >110x, ≥10 supporting variant reads, and variant allele frequency ≥ 6.4% for PV1 and ≥ 4.2% for PV2 were considered. Besides 107 mutations identified in clinical practice (107/108, 99%), 461 variants affecting the cellular pathways typically described in MBCN were detected, of which 14.1% were classified as pathogenic and 38.7% as likely pathogenic. Regarding rearrangements, optimization of the PV2 design for *BCL2* and *MYC* allowed an improvement in sensitivity. Both panels identified the translocation partners in all patients [including 31% (20/65) in which the partner could not be identified by conventional techniques]. While *BCL2* and *CCND1* were always rearranged with IGH, 42% of *BCL6* rearrangements involved non-IG genes, which were highly variable. *MYC* was rearranged with IG genes in 72% of cases. In three cases, double rearrangements involving two different translocation partners were detected. Furthermore, a MCL was identified carrying a double rearrangement of *MYC* with chromosomes 4 and 11, besides *CCND1*-IGH rearrangement. Regarding CNAs, both panels were highly concordant in terms of size and location of the detected aberrations with those previously defined by genomic arrays. The NGS panels achieved a similar sensitivity than genomic arrays (cut off detection: 20-30% aberrant cells) but the removal of SNPs from PV2 compromised it (Figure).

Panel design						Sensitivity and specificity	
						PV1	PV2
Single nucleotide variants (SNVs) and indels		*TNFRSF14* *XPO1* *CARD11* *BIRC3* *TP53* *NOTCH2* *TNFAIP3* *NOTCH1* *MAP2K1*	*ARID1A* *MYD88* *EZH2* *CCND1* *CD79B* *CXCR4* *ARID1B* *TRAF2* *EP300*	*BCL10* *NSD2* *POT1* *MLL2* *CD79A* *SF381* *BRAF* *ATM* *CREBBP*	*ID3* *CCND3* *UBR5* *FOXO1* *KLF2* *CHD2* *MEF2B* *TCF3*	Sensitivity= 100% Specificity= 100%	Sensitivity= 97% Specificity= 100%

	Gains	2p12-2p16 Chr18	Chr3	8q24 (MYC)	Chr12		
Rearrangements		*BCL2*				Sensitivity= 70% Specificity= 100%	Sensitivity= 86% Specificity= 100%
		BCL6				Sensitivity= 100% Specificity= 100%	Sensitivity= 86% Specificity= 100%
		MYC				Sensitivity= 50% Specificity= 100%	Sensitivity= 75% Specificity= 100%
		CCND1				Sensitivity= 100% Specificity= 100%	Sensitivity= 100% Specificity= 100%

Figure. Summary of the target alterations analyzed in the NGS panels, as well as the sensitivity and specificity achieved in each of the designed versions (PV1 and PV2)

Summary/Conclusion: Our NGS panel allows a more comprehensive evaluation of the genomic landscape of MBCN patients in a single assay by (a) detecting the most important and recurrent mutations, translocations and CNAs with high sensitivity, (b) identifying rearrangement partners not detected by FISH and (c) identifying other clinically relevant genetic alterations not included in clinical guidelines. Although further studies are required to improve its performance, it could potentially be implemented in clinical practice.

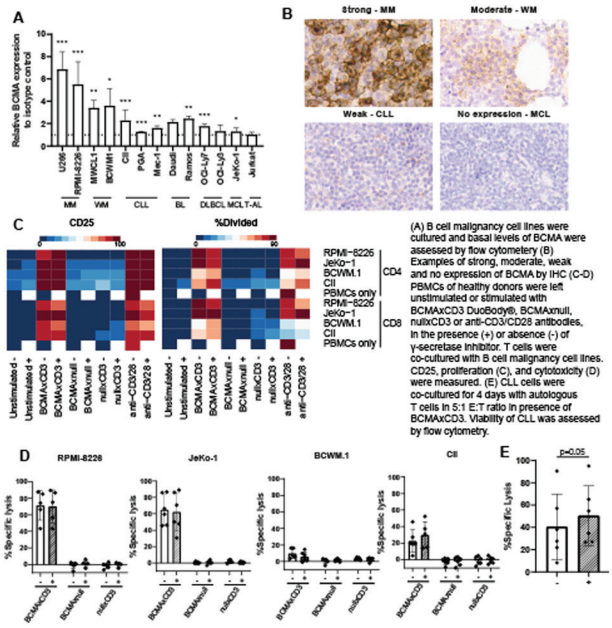
EP607 INFLUENCE OF THE STATE OF THE "TELOMERE-TELOMERASE" SYSTEM ON THE COURSE OF CHRONIC LYMPHOCYTIC LEUKEMIA

N. Isaeva [1,*], E. Fokina [2], I. Dokshina [3], J. Zmeeva [1]

[1]Laboratory of Cellular and Molecular Immunology, Federal State-Financed Scientific Institution «Kirov Research Institute of Hematology and Blood Transfusion under the Federal Medical Biological Agency, Kirov, [2]Department of support of scientific research, Federal State-Financed Scientific Institution «Kirov Research Institute of Hematology and Blood Transfusion under the Federal Medical Biological Agency, Киров, [3]Department of Hematology and Chemotherapy, Federal State-Financed Scientific Institution «Kirov Research Institute of Hematology and Blood Transfusion under the Federal Medical Biological Agency, Kirov, Russian Federation

Background: Chronic lymphocytic leukemia (CLL) is a prevalent lymphoproliferative disease characterized by a high heterogeneity of the course. The variability of CLL is directly related to the immunobiological characteristics of cell clones in each patient, differences in the survival of leukemia cells, their activation, proliferation and interaction with the microenvironment. Telomeres, which are located at the ends of chromosomes and represent nucleoprotein structures, serve as protection against "replicative aging" of cells during division. In tumor cells, genomic instability is associated with pronounced telomere dysfunction, at the same time critical telomere contraction and, ultimately, chromosome degradation with loss of cell viability are prevented by the activation of cellular telomerase.
Aims: To evaluate the influence of the length of telomeric fragments (LTF) of lymphocytes and telomerase activity in CLL on the nature of the disease course.
Methods: We examined 95 patients at the onset of CLL and 22 healthy individuals (comparison group), comparable in age and gender. The length of telomeric fragments in CD19-positive peripheral blood lymphocytes was determined using the multi-color flow cytometry method with the stage of fluorescent in situ hybridization ("FACS Canto II", Becton Dickinson). The activity of cellular telomerase was evaluated by the level of expression of the matrix RNA gene of the catalytic unit of the human telomerase reverse transcriptase (hTERT) enzyme, for which the content of complementary DNA in the reactions of reverse transcription and quantitative polymerase chain reaction was determined in the peripheral blood in real time («DT-96», DNA Technology). The significance of the differences in the parameters was

determined using the Mann-Whitney test. The time from the diagnosis of CLL to the start of specific treatment was calculated by the Kaplan-Meyer method.
Results: LTF in peripheral blood B-lymphocytes in patients was significantly shorter than in donors (3,7 [2,8; 4,6] kb vs. 6,8 [5,6; 8,7] kb, p < 0,01). In all patients with CLL, cellular hTERT was in an activated state. Reduction of LTF below 5,0 kb, corresponding to less than 1,5 standard deviations from the mean value in the comparison group, was found in 35,7 % of cases, moderate activation of hTERT (up to 15,2 copies per µl) - in 74,7 %, high activation (more than 15,2 copies per µl) - in 25,3 %. There were 4 groups of patients, depending on the levels of LTF and the degree of hTERT activation. Group I included 9 patients with shortened LTF and high hTERT activation, group II - with shortened LTF and moderate hTERT activation (n=25), group III - without a decrease in LTF with high hTERT activation (n=15), and group IV - without a decrease in LTF with moderate hTERT activation (n=46). The median duration of the time period from the diagnosis of CLL to the start of specific therapy in groups I, II, III and IV of patients was 4,0; 22,0; 30,0 and 36,0 months, respectively. The time interval before the start of therapy in patients of group I was significantly shorter than in other groups (p≤ 0,001). No statistical differences were found between groups II, III, and IV.
Summary/Conclusion: A significant influence of the state of the "telomer-telomerase" system on the nature of the CLL course was established. A decrease of LTF in B-lymphocytes, combined with a high activation of cellular telomerase, correlates with earlier initiation of therapy.



EP608 BCMA AS A TARGET FOR T-CELL REDIRECTING BISPECIFIC ANTIBODIES IN B-CELL LYMPHOMAS AND CLL

A. Martens [1,2,3,4,*], J. Rietveld [1,2], R. de Boer [1,2], F. Peters [1,2,3,4], A. Ngo [1], L. van Mil [1], K. de Heer [2,5], M. Spaargaren [3,6,7], C. van Noesel [6,7], E. Eldering [1,3,4,7], H. Adams [8], R. Verona [8], A. Kater [2,3,4,7]

[1]Experimental Immunology, [2]Department of Hematology, Amsterdam UMC, [3]Cancer Center Amsterdam, [4]Amsterdam Infection & Immunity Institute, Amsterdam, [5]Department of Hematology, Flevoziekenhuis, Almere, [6]Department of Pathology, Amsterdam UMC, [7]Lymphoma and Myeloma Center Amsterdam, Amsterdam, Netherlands, [8]Janssen Pharmaceutical Companies of Johnson & Johnson, Philadelphia, United States

Background: B-cell maturation antigen (BCMA) is highly expressed on normal and malignant cells and is a feasible target for multiple myeloma (MM) immunotherapy, which is currently clinically exploited with Teclistamab (Tec, BCMAxCD3 DuoBody®, JNJ-64007957; NCT03145181). BCMA is expressed on late stage B-cells, and whether BCMA can serve as immunotherapeutic target for earlier stage B-cell malignancies is currently unknown. Data regarding BCMA expression on B-cell malignancies are limited. Increased serum levels of soluble BCMA in chronic lymphocytic leukemia (CLL) and Waldenström macroglobulinemia (WM) have been observed, indicating that these B-cell malignancies do express BCMA which is subsequently cleaved off the membrane by γ-secretase (γ-sec).
Aims: We assessed BCMA expression on B-cell lymphoma cell lines and primary malignant cells and explored effects of T-cell activation and killing of B-NHL mediated by Tec *in vitro*.
Methods: B-NHL cell lines or CLL cells were cultured in presence or absence of γ-sec inhibitor. BCMA expression was assessed by flow cytometry or immunohistochemistry (IHC). To assess Tec function, cell lines or primary CLL were co-cultured with healthy donor (HD) T-cells in presence of Tec. Cytotoxicity, T-cell activation and cytokine production were assessed by flow cytometry.
Results: BCMA expression varied among different B-NHL cell lines while Jurkat (T-cell line) did not express BCMA. Highest BCMA expression was observed in MM cell lines (RPMI-8226 and U266), followed by WM (MWCL1 and BWCM.1), Burkitt lymphoma (BL, Daudi and Ramos), CLL (CII, PGA and Mec-1), diffuse large B-cell lymphoma (DLBCL, OCI-Ly3 and OCI-Ly7) and mantle cell lymphoma (MCL, JeKo-1) (Fig 1A). γ-sec inhibition increased BCMA expression, even when basal levels of BCMA were low, indicating active BCMA shedding. These data were corroborated in primary B-cell lymphoma by IHC and showed moderate levels in WM, and weak or undetectable expression in MCL, DLBCL and CLL (Fig 1B). BCMA membrane expression could be detected at low levels on primary CLL cells by flow cytometry and could be marginally increased by γ-sec treatment.

Next, potency of Tec against lymphoma cell lines was studied. Co-culture of HD T-cells with RPMI-8226, CII, BWCM.1 or JeKo-1 in the presence of Tec resulted in T-cell activation, proliferation and cytotoxicity (Fig 1C-D), independent of the level of BCMA expression. Response to Tec therefore seems to be dependent on a threshold BCMA expression level, but is likely also influenced by tumor intrinsic factors, since WM cell lines with high expression are not efficiently killed.
Efficacy of Tec on primary tumor cells was studied using CLL cells. Despite low BCMA levels, HD T-cells lysed CLL cells up to 40% in presence of Tec. Furthermore, Tec induced activation, degranulation and efficient cytotoxicity by CLL-derived T-cells upon coculture with autologous CLL cells (Fig 1E).

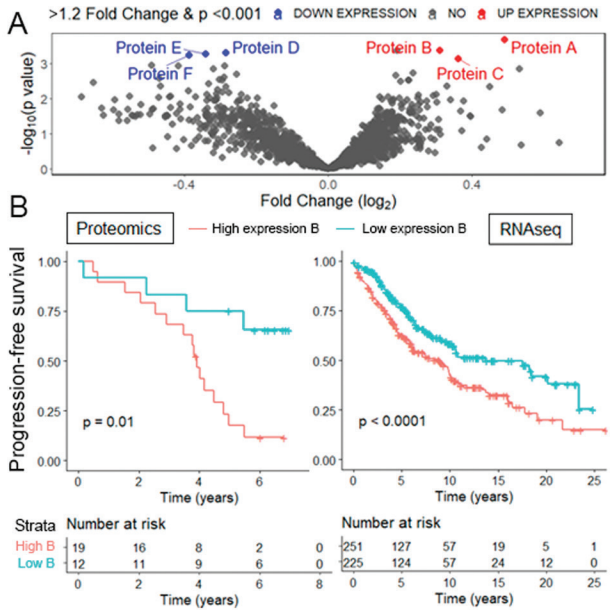
Summary/Conclusion: In conclusion, BCMA expression is variable on B-cell lines, which can be enhanced by γ-sec inhibition, and Tec induces cytotoxicity independent of BCMA expression levels. Despite low BCMA expression in primary CLL, Tec induced cytotoxicity and autologous T-cell activation. Further studies to understand the determinants of response to Tec will be required to identify which other diseases might be suitable targets for Tec treatment.

EP609 IN SILICO PREDICTION REVEALS PUTATIVE T-CELL CLASS I NEOEPITOPES WITHIN THE CLONOTYPIC BCR IG OF CLL PATIENTS

A. Vardi [1,2,*], A. Agathangelidis [2], S. Gkagkaridou [2], A.-L. Schaap-Johansen [3], M. Karypidou [2], A. Boukla [4], A. Fylaktou [4], N. Stavroyianni [1], M. Iskas [1], A. Anagnostopoulos [1], S. R. Hadrup [3], A. Chatzidimitriou [2,5], P. Marcatili [3], K. Stamatopoulos [2,5]

[1]Hematology Department & HCT Unit, G.Papanikolaou Hospital, [2]Institute of Applied Biosciences, Centre for Research and Technology Hellas, Thessaloniki, Greece, [3]Department of Health Technology, Technical University of Denmark, Lyngby, Denmark, [4]National Peripheral Histocompatibility Center, Department of Immunology, Hippokration Hospital, Thessaloniki, Greece, [5]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

Background: Chronic lymphocytic leukemia (CLL) is characterized by the existence of subsets of patients carrying stereotyped i.e. quasi-identical B-cell receptor immunoglobulins (BcR IG), strongly suggesting restricted antigenic selection. Data showing autonomous BcR signaling through homotypic interactions between BcR IG molecules, distinctive for each subset, suggest that the selecting epitopes may lie within the clonotypic BcR IG itself. Antigenic drive appears relevant also for T cells in CLL, where published evidence supports that CLL T cells are selected by restricted, subset-specific tumor antigens. That said, whether the antigens selecting CLL progenitors and T cells are the same remains obscure.



Aims: We performed *ad hoc* prediction of putative T-cell class I neoepitopes contained within the clonotypic BcR IGs of CLL patients, with an intended bias towards major stereotyped subsets.
Methods: We selected 27 patients to represent the full spectrum of CLL: (i) with mutated IGHV genes (M-CLL, n=5), (ii) with unmutated IGHV genes (U-CLL, n=5), (iii) assigned to major stereotyped subsets (subset #1, n=7; subset #2, n=5; subset #4, n=5). RT-PCR was performed for the heavy (H) and the light (K/L) IG chain using subgroup-specific leader primers for the IGHV/IGK/LV gene and universal primers annealing to the constant region (IGHG, IGHM, IGKC, IGLC), in order to produce a full-length V-(D)-J gene rearrangement sequence, plus the start of the constant domain. PCR products were subjected to direct double-strand Sanger sequencing with a quality-optimized protocol. The amino acid sequences were subsequently parsed in peptides and subjected to NetMHCpan. The rank score was calculated, considering the 4-digit HLA-A and -B typing for each patient separately. Only high-binding peptides (rank score <.5%) were selected. Exact matches to germline and/or proteome databases were excluded.
Results: Overall, 202 predicted neoepitopes were identified in 22/27 patients. All 22 patients had predicted $CD8^+$ T-cell epitopes within the heavy chain, and 19/22 also within the light chain. Half of the peptides (n=106, 52.5%) resulted from somatic hypermutations (SHMs) at the intersections of FR and CDR3 regions (FR1/CDR1, n=14; CDR1/FR2, n=28; FR2/CDR2, n=6; FR3/CDR3, n=17; CDR3/FR4, n=41). The remaining mostly involved the FR3 (n=52) and CDR3 (n=21). Overall, the majority of peptides involved (at least part of) the CDR3 (79/202, n=39.1%), which is particularly relevant given its small length (9-27 aa) within the full sequence (331-660 aa). There was no statistically significant difference in the rank score of peptides involving the CDR3 vs. all others. Peptide clustering revealed similar or identical predicted neoepitopes among different patients (17 clusters of two, 2 clusters of three, 1 cluster of four). Importantly, these clusters involved: (i) shared CDR3 patterns in patients assigned to the same subset, but also (ii) subset-specific recurrent SHMs in the IGHV gene, e.g. G to E SHM at position 28 in the CDR1 of subset #4, which was previously reported to be present in 114/265 (43%) subset #4 cases.
Summary/Conclusion: *Ad hoc* prediction with established bioinformatics algorithms identified a significant number of putative T-cell class I neoepitopes contained within the clonotypic BcR IG of CLL patients. Many of them culminate from subset-specific ('stereotypic') CDR3 patterns or recurrent SHMs, suggesting that the targeted SHM which shapes the CLL BcR IG repertoire may produce immunogenic $CD8^+$ T-cell epitopes. Their actual immunogenicity has to be tested in *ex vivo* studies, currently underway by our group.

EP610 SWATH-MS PROTEOMICS AS A NEW TOOL FOR DISCOVERING POTENTIAL DRUG TARGETS AND BIOMARKERS IN CHRONIC LYMPHOCYTIC LEUKEMIA

U. T. Khan [1,2,*], K. Clarke [3], G. L. Eagle [1], J. Zhuang [1], M. Oates [1], A. Phipps [4], P. Hillmen [5], F. Falciani [3], R. E. Jenkins [6], A. R. Pettitt [1,2]

[1]Molecular & Clinical Cancer Medicine, University of Liverpool, [2]Department of Haemato-Oncology, Clatterbridge Cancer Centre NHS Foundation Trust, [3]Computational Biology Facility, University of Liverpool, Liverpool, [4]Pharmaceutical Sciences, pRED, Welwyn Garden City, [5]Section of Experimental Haematology, Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, [6]Pharmacology and Therapeutics, University of Liverpool, Liverpool, United Kingdom

Background: Genomic and transcriptomic studies in chronic lymphocytic leukaemia (CLL) have significantly improved our understanding of disease biology and drug resistance mechanisms whilst simultaneously identifying new biomarkers. Despite the ability of such biomarkers to predict treatment response and survival, the prognostic/predictive information they provide is not absolute. Since disease phenotype is determined at the protein level and given the imperfect correlation between mRNA and protein expression, we hypothesised that a proteomic approach might shed new light on pathogenetic mechanisms and indicate potential drug targets and biomarkers.
Aims: Using SWATH-MS (Sequential Window Acquisition of All Theoretical Mass Spectra), the study aimed to elucidate differences in the pre-treatment CLL proteome that correlated with response to fludarabine-based chemo-immunotherapy defined by post-treatment minimal residual disease (MRD) status.
Methods: Pre-treatment cryopreserved peripheral blood mononuclear cells collected from patients as part of the ARCTIC and AdMIRe trials were lysed and protein extracted using published protocols. After trypsin digestion, the peptides were processed and mass spectrometry (Sciex TripleTOF 6600) performed. Data was normalized within DIA-NN software and proteins were identified (q<0.01) using our published CLL-specific SWATH library. Data was visualized in R and the inter-batch variation removed along with an outlier. Differential protein expression analysis was performed between MRD positive (MRD+, defined as ≥1 CLL cell in 10,000 leukocytes in the bone marrow) and negative (MRD-) groups measured three months after the end of treatment. Receiver operating characteristic (ROC) analysis was performed to split patients into low- and high-expression groups for each protein using thresholds that gave the optimum sensitivity and specificity. Functional analyses were performed using Ingenuity Pathway Analysis and Gene Set Enrichment Analysis tools.
Results: Thirty-two patients were included in the study. Bone marrow MRD data was available for 29 patients, of which 17 (59%) were MRD+ and 12 (41%) MRD-. The median age was 64 (IQR 59-68.5), with a male preponderance (75%). Of the 4696 proteins identified, 2357 were consistently detected and used for subsequent analysis. Using >1.2 fold change and p<0.001 cut-offs, six differentially expressed proteins were identified (proteins A-F; Fig. A). Unsupervised clustering and principal component analysis plots of the six proteins showed clustering of samples based on their MRD status. In univariate analysis, high expression of protein B along with a low expression of proteins D and E were associated with increased risk of progression or death (HR 4.17 [p=0.012], HR 2.75 [p=0.041] and HR 2.53 [p=0.046], respectively). The findings were corroborated using an external RNAseq dataset of 476 patients (The International Cancer Genome Consortium), which confirmed that protein B and its mRNA expression were associated with worse progression-free survival (PFS) in both datasets (p=0.01 and p<0.0001; Fig. B). Functional analyses of proteomic data revealed enrichment of pathways related to mTOR along with processes related to Golgi vesicle transport and protein localization to endoplasmic reticulum, suggesting a possible drug resistance mechanism.

Summary/Conclusion: Proteomic analysis using SWATH-MS provides a novel approach to elucidating pathogenetic mechanisms in CLL. In this study, protein B was identified as a potential drug target and biomarker for therapy response.

EP611 CHARACTERIZATION OF STAT5B MUTATIONS AND TCRB REPERTOIRE IN CD4+ T LARGE GRANULAR LYMPHOCYTE LEUKEMIA

Background: T-cell large granular lymphocyte leukemia (T-LGLL) is a rare lymphoproliferative disease whose etiology is still unknown. T-LGLL includes two subtypes of lymphoproliferation: the most frequent CD8+ T-LGLL (70% of cases) and the less common CD4+ T-LGLL (30% of cases). In the CD4+ variant, the leukemic T-LGLs express the CD4 determinant (either alone or together with CD8), the α/β T-cell receptor (TCR), and display a typical mature cytotoxic and activated/memory T-cell phenotype. Previously, in small series of cases, up to 55% of CD4+ T-LGLL patients have shown to be characterized by *STAT5B* mutations, at variance from CD8+ T-LGLL cases, who frequently harbor *STAT3* mutations and only seldom *STAT5B* mutations.
Aims: In this study, we collected the largest cohort of CD4+ T-LGLL (n=35) so far described at molecular level in the literature. We evaluated the presence of *STAT5B* mutations and their correlation with patients' clinical data. In addition, we characterized the clonal landscape, publicness, and structural similarities of TCRβ repertoire in CD4+ T-LGLL in comparison to healthy TCR repertoires.
Methods: CD4+ T-LGLL patients were enrolled from Hematology Units of 3 Academic Institutions, i.e., Padova (Italy; n=22), Helsinki (Finland; n=6), and Shinshu (Japan; n=7). Buffy coats from healthy controls (n=37) were supplied by the Finnish Red Cross Blood service (Helsinki, Finland). *STAT5B* deep amplicon sequencing was performed for each patient in LGL or PBMC using Illumina platform on MiSeq instrument. The evaluation of differential *STAT5B* transcriptional activities was measured through *STAT5B* luciferase reporter assay. TCRβ sequencing was obtained from genomic DNA (the same DNA used for amplicon sequencing) with Adaptive Biotechnologies' ImmunoSEQ assay.
Results: We observed 63% (23/35) of the patients harboring *STAT5B* mutations. In addition to the gain-of-function *STAT5B* mutations previously described in T-LGLL (*N642H, Y665F, Q706L, S715F*), we found 6 novel mutations (*Q220H, E433K, T628S, P658R, P702A, V712E*) located not only in hot spot regions but also in other gene domains. In 22% (5/23) of *STAT5B* mutated CD4+ T-LGLL cases, multiple *STAT5B* mutations were either coexisting in one clone or in distinct clones. On clinical grounds, patients with *STAT5B* mutations were distinguishable from *STAT5B* wild type patients for increased lymphocyte and LGL counts.
The deep sequencing of TCRβ repertoire was obtained on 27 patients. We demonstrated that as well as large LGL expansions, also the non-leukemic TCR repertoires exhibited higher clonality in CD4+ T-LGLL patients than in healthy controls. Considering clones with the size exceeding 5% of the repertoire, we identified 59 different clonotypes and 24% of them were also found among the non-expanded TCR repertoires of other CD4+ T-LGLL patients. In 44% of the patients, the LGL clonal expansion was characterized by TRBV06 (TCRVβ13.1) expression. Nevertheless, structural similarities among LGL clonotypes were infrequent and direct viral antigen matches were not identified.
Summary/Conclusion: *STAT5B* mutations are the hallmark of CD4+ T-LGLL and they associate with higher lymphocyte and LGL counts. Despite the gain-of-function nature of the mutations, patients rarely have any symptoms, and the disease is indolent. TCR repertoire of both leukemic and non-leukemic CD4+ T cells is more clonal than in healthy individuals and TRBV06 is overrepresented hinting towards an initial immune response to an antigen as a likely triggering event of LGL expansion.

EP612 AUTOPHAGY-RELATED GENETIC VARIANTS INFLUENCE THE RISK OF DEVELOPING CHRONIC LYMPHOCYTIC LEUKEMIA: A STUDY IN THE CONTEXT OF THE CRUCIAL CONSORTIUM

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia among adults in Western countries and remains as an incurable disease. Despite the information provided by genome-wide association studies (GWAS), the genetic component underlying CLL has not been completely unravelled and multiple susceptibility loci remain to be identified. An aberrant expression of autophagy-related genes has been associated with cancer development (1,2) and it has been observed that autophagy shapes anti-tumoral immune responses by acting at multiple levels including the promotion of signals to activate phagocytosis of tumour cells but also signals to induce MHC-class-I and -II presentation (3,4), T-and B-cell activation, development and maintenance (5).
Aims: Considering this background, we investigated whether autophagy-related variants might influence the risk of developing CLL.
Methods: We conducted a population-based case–control study including 1285 Caucasian CLL cases and 1386 healthy controls ascertained through the Consortium for Research in Chronic lymphocytIc LeukemiA (CRuCIAL). Sixteen single nucleotide polymorphisms (SNPs) within autophagy-related loci were selected on the basis of their previous associations with other haematological malignancy (at P<0.01 level) (6). Hardy–Weinberg equilibrium (HWE) was assessed in the control group (P>0.01) and the association between CLL risk and the autophagy-related SNPs was tested using unconditional logistic regression analysis. A P-value of 0.0010 (0.05/16/3 inheritance models) was set to be the multiple testing significance threshold. Functional characterization of the most interesting markers was tested using cytokine quantitative trait loci (cQTL) data after stimulation of peripheral blood mononuclear cells (PBMCs), whole blood or monocyte-derived macrophages (MDMs) from 408 healthy subjects from the Human Functional Genomics Project (HFGP) cohort with LPS, PHA, Pam3Cys, CpG and B. burgdorferi and E. coli, as experimental model for cytokine production capacity. We also analysed the correlation between selected SNPs with data on 91 annotated immune cell populations, 103 serum inflammatory proteins, 7 steroid hormones and autophagy flux.
Results: Selected SNPs were in HWE. Logistic regression analysis showed that the $ATG5_{rs12527992}$, $BIRC6_{rs12992095}$, $KLHDC7B_{rs140522}$, and $NAMPT_{rs62481378}$ SNPs were associated with CLL risk at P<0.05 level. The strongest association was found for the $KLHDC7B_{rs140522}$ SNP that remained significant after correction for multiple testing. Each copy of the $KLHDC7B_{rs140522A}$ allele increased the risk of CLL by 25% (OR=1.25, 95%CI 1.11-1.40, P=0.0001; Table 1). Furthermore, we

found an association for the $NAMPT_{rs62481378}$ SNP with an increased risk of CLL that remained marginally significant after multiple testing correction. Each copy of the $NAMPT_{rs62481378A}$ allele increased the risk of the disease by 36% (OR=1.36, 95%CI 1.10-1.67, *P*=0.0044; Table 1). Functional experiments trying to shed some light into the biological mechanisms underlying these associations have been conducted and statistical analyses are currently ongoing.

Table 1. Association of autophagy-related SNPs and CLL risk.

SNP_rsID	Gene	Risk allele	OR(95% CI)[§]	*P*

Abbreviations: SNP, single nucleotide polymorphism; OR, odds ratio.
[§] Logistic regression analysis assuming a log-additive model of inheritance.
Significant results in bold (P<0.05).

Summary/Conclusion: This study suggests that the *KLHDC7B* locus is involved in determining the risk of CLL and points to a modest effect of the *NAMPT* gene. Additional studies are warranted to establish the role of *ATG5* and *BIRC6* loci in modulating disease risk.

EP613 THE GUT MICROBIOME IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

T. Faitova [1,*], E. R. Svanberg [1], C. da Cunha-Bang [1], E. E. Ilett [2], M. Jørgensen [2], C. MacPherson [2], C. Utoft Niemman [1,3]

[1]Department of Haematology, [2]PERSIMUNE Centre of Excellence, Rigshospitalet, [3]Institute for Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark

Background: The human gut microbiome may impact both immune function and carcinogenesis. Previous studies have reported potential associations between gut microbiome constitution and both the incidence and progression of a wide array of cancers. The gut microbiota in patients with chronic lymphocytic leukemia (CLL) remains to be characterized.
Aims: Our research aims to investigate whether gut dysbiosis, i.e. the loss of "health-promoting" commensal gut microbes and/or the overgrowth of pathogenic bacteria, distinguishes patients with CLL from that of the background population.
Methods: Feces samples were collected, immediately fixated and frozen within 72 h; total genomic DNA was sequenced using Next Generation Sequencing (NGS). Control cohorts were selected from an array of previously published cohorts. Taxonomical profiling was done using an in-house bioinformatics pipeline. Data analysis was performed using standard Compositional Data Analysis (CoDA) methods.
Results: In total 10 CLL patients were included in the study. The control cohort included 124 healthy individuals. We observed that the gut microbiome alpha diversity in bacterial genera was reduced among the CLL patients (Figure 1A). Lower number of observed species (P = 0.006) and a lower diversity (Shannon index, P = 0.004; Inverse Simpson index, P = 0.0048) was observed in the CLL cohort versus healthy controls. Finally, the abundance of Bacteroidetes and Proteobacteria was increased while the abundance of Firmicutes was decreased in the CLL patients compared to healthy controls (Figure 1B).

Summary/Conclusion: Our data indicate that the microbiome in CLL patients is less diverse than that of the background population. The gut dysbiosis in CLL includes an increase in Proteobacteria and an increase abundance of other specific bacterial genera. Further investigations are crucial for our understanding of the interplay between the gut microbiome and CLL development. The aim of such studies should be to identify possible interventions modulating the microbiome to change the course of CLL and the adjoined immune dysfunction.
Figure 1. Comparison between the CLL cohort and control cohorts. A) Box plots of Observed number of genera, Chao 1, Shannon and Inverse Simpson indices in CLL cohort and a control cohort. Six controls were randomly sampled from each of the two control cohorts and pooled as CONTROLS. B) Relative abundance of four major bacterial phyla in microbiota in CLL cohort and a control cohort. All samples from each of the two control cohorts were pooled as CONTROLS. The P-values (adjusted for multiple testing with the Benjamini-Hochberg procedure) obtained upon Wilcoxon rank-sum tests are indicated.

EP614 EX VIVO DRUG SENSITIVITY IDENTIFIES COMBINATION TREATMENT WITH PI3K/BCL-2 INHIBITORS FOR MONOTHERAPY-REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

L. Karlsen [1,2,3], P. Athanasiadis [4,5], I. Murali [6], A. K. Hilli [7], K. Taskén [1,2,3], J. R. Brown [6,8], T. Aittokallio [4,5], G. E. Tjønnfjord [9], S. S. Skånland [1,2,*]

[1]Department of Cancer Immunology, Oslo University Hospital, [2]K. G. Jebsen centre of B-cell malignancies, [3]Institute of Clinical Medicine, University of Oslo, [4]Department of Cancer Genetics, Oslo University Hospital, [5]Oslo Centre for Biostatistics and Epidemiology (OCBE), University of Oslo, Oslo, Norway, [6]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, [7]Department of Medicine, Diakonhjemmet Hospital, Oslo, Norway, [8]Harvard Medical School, Boston, United States, [9]Department of Haematology, Oslo University Hospital, Oslo, Norway

Background: The phosphatidylinositol 3-kinase inhibitors (PI3Ki) idelalisib and duvelisib are approved for relapsed chronic lymphocytic leukemia (CLL). However, treatment intolerance and resistance remain clinical challenges. Strategies to overcome these challenges include targeting bypass mechanisms by using a different PI3Ki and combining different classes of targeted therapies. Direct drug testing on patient-derived primary cells may provide insights into patient-tailored therapeutic options.
Aims: The aims of this study were to (i) characterize the efficacy, selectivity, and synergy of 10 clinically relevant PI3Ki alone and in combination

with the B-cell lymphoma-2 (BCL-2) antagonist venetoclax in primary CLL cells, (ii) investigate whether signaling molecules can serve as early biomarkers for drug sensitivity, and (iii) identify clinically relevant treatment options for CLL patients who have failed on a PI3Ki monotherapy.
Methods: We performed high-throughput drug sensitivity screens with 72h drug treatment of primary cells from 18 CLL patients and 3 healthy blood donors. A phospho-flow cytometry assay was applied to study intracellular signaling changes in primary CLL cells after 30 min of drug treatment *ex vivo*.
Results: The pan-PI3Ki buparlisib, copanlisib and pictilisib were most active in 72h assays, with up to 97% reduction in cell viability at 10 000 nM. However, treatment with the p110d-selective PI3Ki umbralisib plus venetoclax showed more selective targeting of CLL cells compared to normal B cell and T cells than combinations involving a pan-PI3Ki. Interestingly, distinct changes in cell signaling induced by 30 min of drug treatment predicted cell viability in 72h assays. AKT (pS473) and S6-ribosomal protein (pS235/S236) correlated with drug sensitivity to p110d-selective PI3Ki plus venetoclax, while BTK (pY551) correlated with sensitivity to pan-PI3Ki. Samples from patients no longer responding to idelalisib *in vivo* (n=4) showed high sensitivity to pan-PI3Ki *ex vivo*. Drug sensitivity assessment of an ibrutinib (BTK inhibitor), idelalisib and venetoclax refractory CLL patient indicated combination of idelalisib and venetoclax as a promising therapeutic option. The patient was treated with the combination, and obtained a good clinical response. Unfortunately, the patient experienced unacceptable gastrointestinal adverse effects as she had with idelalisib monotherapy, and the treatment was stopped. Interestingly, the patient continued to show a strong *ex vivo* response to the pan-PI3K inhibitors buparlisib, copanlisib and pictilisib, suggesting that these therapies may be considered for CLL patients who relapse on currently available targeted therapies.
Summary/Conclusion: These data provide insights into efficacy, selectivity, and synergy of combinatorial strategies in CLL, and indicate a potential for signaling molecules as early biomarkers for patient stratification. *Ex vivo* drug sensitivity assessment of CLL cells from a patient who had failed on all available targeted therapies in Norway indicated combined PI3K/BCL-2 inhibition as an effective treatment option. This demonstrates that *ex vivo* drug sensitivity assessments can guide clinical decisions in CLL. We further showed that CLL cells from refractory patients remain sensitive to pan-PI3Ki *ex vivo*, suggesting pan-PI3Ki as potential treatment options to be explored for relapsing CLL patients.

EP615 THE IGLV3-21 LIGHT CHAIN ANALYSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

N. Bilous [1,*], I. Abramenko [1], Z. Martina [1], I. Dyagil [1], A. Chumak [1]

[1]*Research Center for Radiation Medicine, Kyiv, Ukraine*

Background: Unmutated (UM) immunoglobulin heavy chain variable region (IgHV) status or subset #2 stereotyped Ig receptor (IgHV3-21/IgLV3-21) expression is associated with poor prognosis in chronic lymphocytic leukemia (CLL). It is considered that the light chain also can affect CLL outcome. The IgLV3-21 light chain usage was shown to confer unfavourable prognosis irrespective of IgHV mutational status or subset #2 stereotyped receptor.
Aims: To analyse the presence of IgLV3-21 in CLL cohort and corelate it with clinical outcome and poor prognosis molecular markers.
Methods: A total of 166 CLL patients with available IgHV data and clinico-biological information were included in the study. All patients gave written informed consent. Patient characteristics were as follows: 72% males; median age: 57; Binet stages B or C: 55%; IgHV status: 73% IgHV-unmutated (more or equal 98% identity to germline, UM); 27% IgHV-mutated (less than 98% germline identity, M), recurrent mutations: *TP53*: 12.9% (13 of 101 cases), *NOTCH1*: 10.3% (15 of 145 cases); *SF3B1*: 18.3% (17 of 93 cases); major stereotyped subsets assigned using the ARResT/AssignSubsets tool: 20.5%, the most frequent: subset #1 (4.2 %), subset #2 (3.0%), subset #3 (2.4%), subset #6 (2.4%). In 115 patients the Ig light chain rearrangements were analysed by Sanger sequencing using BIOMED-2 protocol, in 51 patients the IgLV3-21 chain presence was tested with real-time PCR method and primer strategy developed by Stamatopoulos et al. [2018]. Time-to-first-treatment (TTFT) and overall survival (OS) were analyzed by Kaplan-Meier statistic.
Results: The IgLV3-21 light chain expression was found in 16 (9.6%) patients in studied group, among them 5 cases (31.3%) belonged to subset #2 (IgHV3-21/IgLV3-21). Non-subset #2 IgHV3-21 cases were not represented. Besides of stereotyped subset #2, only subset #5 was represented (one case). More than half of the IgLV3-21 expressing cases (9 of 16) were IgHV M, largely due to subset #2 cases, all of which were IgHV M. In accordance with previous studies a higher frequency of *SF3B1* mutations was seen in IgLV3-21 patients ($P = 0.061$), they were presented irrespective of subset #2 stereotyped Ig expression (subset #2: 50% and non-subset #2: 33.3%, $P = 0.548$). At that, *SF3B1* mutations did not affect significantly neither OS ($P = 0.525$), nor TTFT ($P = 0.831$). Patients with the IgLV3-21 chain demonstrated a significantly shorter median OS compared to IgHV M (70 vs. 277 months, $P = 0.005$), but comparable to IgHV UM cases (75 months, $P = 0.688$). Similarly, TTFT was shorter in IgLV3-21 compared to IgHV M cases, although did not reach statistical significance (15 vs. 33 months, $P = 0.161$), and did not differ significantly from IgHV UM cases (8 months, $P = 0.255$). Upon dividing IgLV3-21 group into subset #2, non-subset #2/IgHV M and IgHV UM, we did not find a significant difference regarding both OS ($P = 0.714$) and TTFT ($P = 0.259$).
Summary/Conclusion: Our results in line with previous publications suggest that the IgLV3-21 light chain expression identifies unfavourable CLL subgroup independent of the IgHV mutational status and is associated with presence of *SF3B1* mutations. Subsequent studies in a larger CLL cohort will clarify the significance of IgLV3-21 for risk stratification of patients.

EP616 ANALYSIS OF GENOMIC COMPLEXITY IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) USING OPTICAL GENOME MAPPING

Background: Complex karyotype (CK) is a predictor of poor prognosis in patients with chronic lymphocytic leukemia (CLL). CK is defined as the presence of ≥3 chromosomal aberrations in the same clone by chromosome banding analysis (CBA). However, recent studies have suggested that the best cut-off to predict an adverse outcome in CLL should be established at 5 abnormalities detected by either CBA or chromosomal microarrays (CMA) (Baliakas et al, 2019; Leeksma et al, 2021). Both methods are useful for risk stratification of CLL patients, but they are not equivalent due to limitations intrinsic to each technique (Ramos-Campoy et al, 2021). Optical genome mapping (OGM) is a novel method that relies on the imaging of long DNA molecules (>250 kb) labeled at specific sites. The unique pattern of labels throughout the genome allows to map the genomic location of every molecule and detect both balanced and unbalanced abnormalities with high resolution and sensitivity. This is as promising technology that overcomes most of the limitations of CBA and CMA.
Aims: 1. To compare the results obtained by OGM with previous CBA and CMA information. 2. To analyze the usefulness of OGM in the assessment of genomic complexity in CLL patients.
Methods: A total of 22 CLL patients were included, 12 carried CK by CBA and 10 were non-CK. Tumor DNA extracted from peripheral blood was analyzed by OGM (Bionano Genomics). Abnormalities found by OGM were compared with available CBA, FISH and CMA (12 CytoScan HD and 10 CytoScan 750K, ThermoFisher) results, and complexity detected by OGM in each group was assessed.
Results: OGM detection rate of previously known abnormalities was 93% (14/15) and 86% (119/138) in non-CK and CK groups, respectively.

Discordances were mainly small copy number alterations (CNAs) detected by CMA and subclonal aberrations in the karyotype expanded during CBA culture but represented in a minor proportion, also below CMA sensitivity. Size and coordinates of CNAs detected by OGM were highly concordant with those defined by CMA. Moreover, OGM provided additional structural information associated with some microarray CNAs or helped to identify unknown cytogenetic elements reported by CBA in 11/22 (50%) patients. Additional new abnormalities, including balanced rearrangements and CNAs, were found by OGM in both groups. The median number of abnormalities by OGM was 72 (range: 38-103) in non-CK and 120 (range: 50-249) in CK patients. They were highly enriched in insertions, duplications or deletions of unknown clinical significance displaying sizes smaller than CMA resolution (from only 3 to 100Kbp). When polymorphic variants and unbalanced abnormalities smaller than 100Kbp were filtered, CK group displayed significantly a more complex genome than non-CK patients [median 22 (6-77) vs 5 (2-8), P<0.01]. Globally, OGM detected a higher complexity, although a good correlation between the number of aberrations recorded by OGM and CBA or CMA was observed (r_p=0.831 and r_p=0.935, respectively) (Figure).

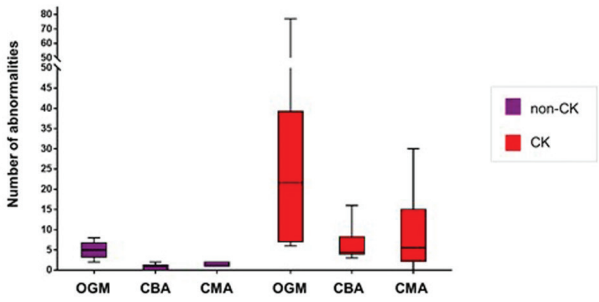

Figure. Total number of abnormalities detected by optical genome mapping (OGM, filtered data), chromosome banding analysis (CBA) and chromosomal microarrays (CMA) in non-CK and CK groups.

Summary/Conclusion: 1. OGM is a valuable tool to assess genomic complexity in CLL. It effectively detects the vast majority of the abnormalities defined by standard methods, allowing a comprehensive interpretation of some of the alterations; 2. Several additional abnormalities of unknown clinical significance are identified by OGM; 3. Further studies are required to define genomic complexity criteria by OGM and implement this technique in the routine management of CLL patients.

EP617 THE IDO-KYN-AHR PATHWAY PROMOTES CHRONIC LYMPHOCYTIC LEUKEMIA CELLS SURVIVAL AND MITIGATES THE APOPTOTIC EFFECT OF ABT-199

C. G. Atene [1,*], R. Maffei [2], S. Fiorcari [1], N. Mesini [1], P. Zucchini [1], S. Martinelli [1], L. Potenza [1], M. Luppi [1], R. Marasca [1]

[1]Department of Medical and Surgical Sciences, University of Modena and Reggio Emilia, [2]Department of Hematology and Oncology, A.O.U of Modena - Policlinico, Modena, Italy

Background: Chronic Lymphocytic Leukemia (CLL) accounts for about 30% of all adult leukemia and is common in Western countries. In the clinical treatment, although innumerable advances have been made, the disease is still incurable. To identify new treatment strategies it is necessary to take into account that leukemic cellsentertaina complex crosstalk with the surrounding tumor microenvironment (TME) and for this reason is important to consider a "double hit" therapeutic approaches.
The indoleamine 2,3-dioxygenase (IDO)-kynurenine (Kyn)-aryl hydrocarbon receptor (AhR) pathway is active in several types of human cancer, including hematologic malignancies, that pathologically exploit tryptophan (Trp) metabolism along the kynurenine pathway (KP) to promote growth and escape immune surveillance. IDO-derived kyn produced during cancer progression and inflammation have both autocrine and paracrine action and seem to be one of the pathways that link the leukemic cell and the TME.
Aims: We wondered to investigate the functional role of the KP and the effects of its inhibition in CLL.
Methods: Gene transcription and protein expression were evaluated by real time PCR and western blot. Enzymatic activity was assessed through ELISA. Survival was measured with annexinV/PIassay. Overexpression and silencing of target genes was obtained by nucleofection.
Results: Previously we have demonstrated that CLL cells expressed IDO at variable levels and we found that several TME stimuli were able to up-regulate IDO mRNA and protein. We have showed that IFNγ induced an active IDO protein through STAT1 signaling as assessed measuring Kyn production and Trp consumption by ELISA. Interestingly, when we up-regulated IDO in CLL cells they showed an increased survival. Same results were obtained treating cells with Kyn. We also observed that Kyn mediated AhR translocation from the cytoplasm to the nuclei, inducing its activation as assessed by up-regulation of CYP1A1, a known AhR target gene. Analyzing the anti-apoptotic proteins of the Bcl2 family after Kyn treatment, we found the induction of Mcl1, that was affected by adding CH-223191, an antagonist of AhR. Then we decided to silence AhR in CLL cells and we found that the survival of leukemic cells was compromised as they had reduced levels of Mcl1.We then analyzed to what extent KP-induced survival could affect ABT-199 sensitivity in CLL samples. Our results indicated that pre-treatment with Kynmitigated the effect of ABT-199, which produced less apoptosis, while the use of CH-223191 has been shown to have a synergistic effect in inducing apoptosis of leukemic cells.
Summary/Conclusion: Our data demonstrated that IDO-Kyn-AhR axis is active in CLL cells and promotes Mcl1 expression,sustaining the survival of leukemic cells. Our results indicated the KP as a new potential therapeutic target in the CLL microenvironment.

EP618 LNCRNA LANDSCAPE ANALYSIS IDENTIFIED LNCRNA LEF-AS1 AS AN ONCOGENE THAT UPREGULATES LEF1 AND PROMOTES SURVIVAL IN CHRONIC LYMPHOCYTIC LEUKEMIA

X. Du [1,2], H. Liu [1], C. Yang [1], X. Shi [1], L. Cao [1], X. Zhao [1], Y. Miao [1], H. Zhu [1], L. Wang [1], W. Xu [1], J. Li [1], L. Fan [1,*]

[1]Department of Hematology, Jiangsu Province Hospital, Nanjing, [2]Department of Hematology, Subei People's Hospital, Yangzhou, China

Background: Chronic lymphocytic leukemia (CLL) is a malignant disorder of mature B lymphocytes, and the precise pathogenesis is unknown at present.
Aims: This study set out to screen the differential expression profile of long non-coding RNA (lncRNA) by microarray and explore the underlying mechanism, biological function, and clinical significance of lncRNA in CLL cells.
Methods: We performed microarray detection to screen the differential expression profile of lncRNA and related experiments to explore the underlying mechanism, biological function, and clinical significance of the lncRNA of interest.
Results: Compared to the lncRNA expression profiles of the control group, we picked out lncRNA LEF1-AS1 for further exploration. By quantitative real-time polymerase chain reaction, we validated that primary CLL cells harbor higher lncRNA LEF1-AS1 levels than normal B cells. Expression of LEF1 on RNA and protein level elevated in the two cell lines with stable overexpression of LEF1-AS1. In the term of biological functions, proliferation rates increased, and apoptosis rates decreased in the LEF1-AS1 overexpressed cell lines, as well as a trend of shortened G0/G1 phase and prolonged G2/M phase in the cell cycle. In primary CLL cells, mRNA expression of LEF1 decreased after negatively regulating the expression of LEF1-AS1. RNA Binding Protein Immunoprecipitation and RNA pull-down demonstrated that LncRNA LEF1-AS1 and LEF1 protein could combine especially. However, we have not determined the prognostic significance of lncRNA LEF1-AS1 in CLL patients.
Summary/Conclusion: The thesis concludes that LEF1-AS1 may be a potential oncogenic lncRNA that regulates the expression of the target gene LEF1 by interacting with protein LEF1, which promotes proliferation and suppresses apoptosis of CLL cells.

EP619 DISCOVERY OF HBW-3-10: A POTENT, ORALLY ACTIVE, REVERSIBLE BRUTON'S TYROSINE KINASE (BTK) INHIBITOR WITH ANTITUMOR ACTIVITIES IN MICE

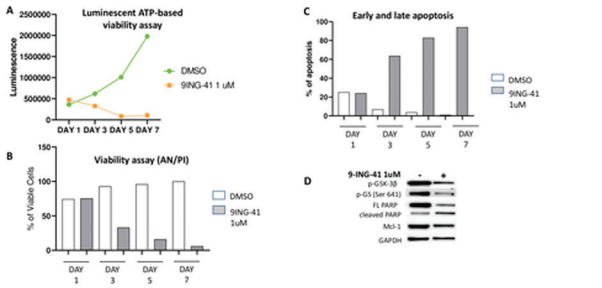
C. Yuan [1,*], Y. Li [1], G. Liu [1], C. Yue [1], N. Lee [1]

[1]Chengdu Hyperway Pharmaceuticals, Chengdu, China

Background: The first generation irreversible BTK inhibitor ibrutinib has been approved for the treatment of B cell-related diseases, including chronic lymphocytic leukemia (CLL), for several years. However, CLL patients who used ibrutinib may develop drug resistance due to acquired

mutations, in particular C481S in BTK that directly impacts the binding of ibrutinib. In recent years, efforts have been made to develop the second generation reversible BTK inhibitors that are effective against both wild-type and C481S mutated B-cell malignancies. LOXO-305 and ARQ-531 are two examples of the second generation reversible BTK inhibitors in advanced clinical trials for ibrutinib-resistant CLL.
Aims: Discovery of Potent, Orally Active, Reversible Bruton's Tyrosine Kinase (BTK) Inhibitors
Methods: New reversible BTK inhibitors were designed, synthesized and tested for enzymatic activities against wild-type and C481S-mutated BTK. Highly active compounds were confirmed for growth effects in diffuse large B-cell lymphoma derived TMD8 cells. Their microsomal stability and ADME properties were also assessed. Potent and bioavailable compounds were further evaluated for in vivo efficacy using a TMD8 xenograft tumor model in mice. A 14-day toxicity study in rats was performed to examine compound safety.
Results: As shown in the table, HBW-3-10 has greater potency and pharmacokinetic profile (rats, 10mg/kg PO) than ARQ-531. In a TMD8 mouse xenograft study, HBW-3-10, ARQ-531 and ibrutinib were compared directly, all dosed at 10mg/kg QD, and the resulting tumor growth inhibition rates (TGI) are 38.3%, 9.3% and 22.5%, respectively. Based on our data, HBW-3-10 is more efficacious than ARQ-531 and ibrutinib. In a 14-day preliminary toxicity experiment in rats, both HBW-3-10 and ARQ-531 were dosed 100mg/kg QD. Animals in ARQ531 group started showing signs of sickness on day 3, and all died on day 6 due toxicity; in contrast, no animal in HBW-3-10 group showed any sign of sickness or died during the entire course of study.

compound	BTK IC_{50} (nM)	BTKc481s IC_{50} (nM)	TMD8 IC_{50} (nM)	hERG (uM)	Cmax (ng/mL)	AUC $_{0-\infty}$ (ng·hr/mL)	$T_{1/2}$ (hr)
ARQ-531	4.1	2.2	82.2	3.53	2414	12963	4.0
HBW-3-10	2.8	1.6	13.9	9.88	25721	211031	3.4



Summary/Conclusion: We have discovered a novel second generation reversible BTK inhibitor HBW-3-10, that has a superior preclinical profile, efficacy and safety than other known ones. HBW-3-10 provides a valuable clinical candidate for treating Ibrutinib resistant CLL and beyond!

EP620 TARGETING CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) CELLS WITH THE GLYCOGEN SYNTHASE KINASE-3 BETA (GSK-3B)-SELECTIVE SMALL MOLECULE INHIBITOR, 9-ING-41

E. C. Silva Barcelos [1,*], S. Baldoni [1], F. M. Adamo [1], E. Dorillo [1], D. Sorcini [1], A. Stella [1], C. Rompietti [1], F. De Falco [1], E. Rosati [2], L. Cavalcante [3], F. J. Giles [3], P. Sportoletti [1]

[1]Hematology Section, University of Perugia, [2]Biosciences and Medical Embryology Section, University of Perugia, PERUGIA, Italy, [3]Actuate Therapeutics, Fort Worth, United States

Background: GSK-3β is a serine/threonine kinase that plays a role in several disease processes, including cancer. Aberrant overexpression of GSK-3β promotes survival in B cell lymphoma cells. By contrast, little is known about the role GSK-3β in CLL and its potential as a new therapeutic target. 9-ING-41 is a selective GSK-3β inhibitor with significant pre-clinical and clinical activity in advanced malignancies. Its modes of action include direct induction of apoptosis, reversal of chemoresistance, immune-modulation, and reversal of fibrosis. 9-ING-41 induces apoptosis in B lymphoma cell lines. We hypothesized that targeting GSK-3β with 9-ING-41 may be a new CLL treatment strategy via interference with tumor survival through novel pathways.
Aims: To explore the effects of single agent 9-ING-41 on viability and apoptosis in a preclinical in vitro model of CLL.
Methods: Experiments were conducted in the PGA1 CLL cell line. 9-ING-41 was obtained from Actuate Therapeutics, Inc. Cell viability/apoptosis were assessed using Celltiter-Glo assay and flow cytometry after Annexin V-APC/propidium iodide (PI) staining. Real-time PCR and western blotting were used to measure apoptotic markers.
Results: In PGA-1 cells, 1 μM 9-ING-41 concentration resulted in reduction of the phosphorylation levels of GSK-3β and its substrate glycogen synthase (GS) (Fig. 1D). Sensitivity to 9-ING-41 was evaluated using a luminescent *ATP-based viability* assay to measure the killing efficacy of the GSK3 inhibitor. Starting at day 3, 9-ING-41 caused a reduction in cell viability, with the highest impact on intracellular *ATP* concentration observed after 7 days of treatment (Fig. 1A). *Annexin V*/PI *labeling* further supports the anti-leukemic effects of 9-ING-41. The percentage of double negative viable PGA-1 cells decreased at day 3, 5 and 7 in the presence of 9-ING-41 compared to vehicle control (33.2% vs 92.3%, 16.1% vs 96% and 6.1% vs 99%, respectively; Fig. 1B). The cytotoxicity induced by 9-ING-41 was due to apoptosis, as indicated by a significantly increased percentage of Annexin V/PI apoptotic cells compared to vehicle. Early and late apoptosis increased at day 3, 5 and 7 treatment with 9-ING-41 compared to vehicle (63.9% vs 6.8%, 82.9% vs 3.8%, 94.2% vs 1%, respectively; Fig. 1C). 9-ING-41 treatment was associated with a 1.5-fold and 2.4-fold upregulation of the pro-apoptotic family members BAX and NOXA at the mRNA level (N=2; p<0.01). At day 3, *BCL2* anti-apoptotic expression *was 1.4-fold lower in* 9-ING-41 treated cells compared with the vehicle control. In vitro studies are ongoing to investigate the potential association of 9-ING-41 with the BCL2 inhibitor Venetoclax. The apoptotic effects of 9-ING-41 were further supported by the detection of increased degradation of PARP protein to its inactive fragment (Fig. 1D). Cleavage of PARP suggests caspase activation contributed to 9-ING-41 induced apoptosis of CLL cells. Treatment with 9-ING-41 resulted in increased active cleaved products of caspase-3, concurrent with a decrease in its pro-form (Fig. 1D). Additionally, 9-ING-41 treatment was associated with reduction of MCL-1 protein expression.

***In vitro* effects of 9-ING-41 in the PGA-1 cell line.** PGA-1 cells were treated with 1uM of 9-ING-41 at the indicated time points (1, 3, 5 and 7 days). (A) Luminescent cell viability assay. The orange and green points indicated PGA-1 cells treated with 9-ING-41 or DMSO control, respectively. PGA-1 cells were labeled with Annexin-V /PI and classified as (B) viable (Ann-/PI-) and (C) early (Ann+/PI-) and late apoptotic (Ann+/PI+). (D) Western blot analysis of PGA-1 cells treated with 9-ING-41 1uM. Protein bands of p-GSK-3β, p-GS (Ser 641), PARP (Full length-FL and Cleaved), Mcl-1 and GAPDH. Figure 1

Summary/Conclusion: Our study is the first to explore the relevance of 9-ING-41 as a therapeutic strategy in CLL. 9-ING-41 has significant single agent activity with the ability to induce apoptosis in a cell line-dependent manner. Targeting GSK-3β may expand therapeutic options for CLL patients. Ongoing work continues to assess combinations with approved targeted agents in order to overcome drug-induced resistance.

EP621 INFLUENCE OF POLYMORPHISMS OF CODON 72 OF TP53 IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

M.-A. Cabero-Becerra [1,*], J. Garcia-Vela [2], P. Sanchez-Godoy [3], A. Arias-Arias [4], J.-A. Garcia-Marco [5]

[1]Hematology, Hospital La Mancha Centro, Alcázar de San Juan, [2]Hematology, Hospital Universitario de Getafe, [3]Hematology, Hospital Universitario Severo Ochoa, Madrid, [4]Statistics, Hospital La Mancha Centro, Alcázar de San Juan, [5]Hematology Department, Molecular Cytogenetics Unit, Hospital Universitario Puerta de Hierro-Majadahonda and Instituto de Investigación Sanitaria Puerta de Hierro-Segovia de Arana, Madrid, Spain

Background: Predictors of a transformation of chronic lymphocytic leukemia (CLL) into Richter syndrome (RS) have not been yet established, although biomarkers that have been reported as associated with risk of DLBCL-type RS development include the mutational status of NOTCH1, TP53 abnormalities, and the use of subset 8 immunoglobulin genes (IGHV4-39). On the other hand, second malignancies are frequent complications in patients with CLL, and immune defects associated with this disease have been suggested as the main cause. The possibility was raised that some germline TP53 polymorphisms in healthy populations may also affect p53 function. Because of this, much research has been done on the ability of SNPs to cause alterations in p53 function in many types of cancer. One of the most studied polymorphisms is codon 72 (R72P), due to its potential effect on the risk of cancer.
Aims: In this study, we will analyze the relationship of the genotypes of the TP53 codon 72 polymorphisms in a large cohort of patients with

CLL, to demonstrate the association of codon 72 with the evolution of the disease.
Methods: 558 patients diagnosed with CLL were included from a group of hospitals for the study of chronic lymphoproliferative disorders, with clinical data at diagnosis, including immunophenotype, FISH, IgHV, and karyotype studies. RT-PCR and Sanger sequencing techniques analyzed the codon 72 Arg/Arg, Arg/Pro, and Pro/Pro genotypes of TP53.
Results: The Pro/Pro genotype was significantly associated with Binet stage B and C CLL, Richter transformation, and a shorter time to the first treatment. Besides, Pro/Pro and Arg/Arg genotypes was associated with a risk of have secondary neoplasms (p=0,016). Follow-up assessments showed secondary neoplasms in 19.7% (n=110) of the patients, with the tumors appearing in the bladder, skin, and colon (14.5% each), prostate (13.6%), and the lung (12.7%). During the study period, 335 patients died. Analyses of overall survival demonstrated that patients with the Pro/Pro genotype lived significantly less than those with the other genotypes (p=0,028) (Figure 1). In the subgroup of patients with RS, no significant differences were found, although a trend of lower survival was observed in patients with the Pro / Pro genotype, and that in turn, the patients with RS with Pro/Pro genotype have much shorter survival than those without RS. Finally, in the multivariate analysis, the Pro/Pro homozygous genotype at TP53 codon 72 was identified as an independent variable associated with a 1,728-fold increased risk of death (95% CI: 1.062-2.810; P = 0,028) in comparison with the Arg/Pro heterozygous genotype.

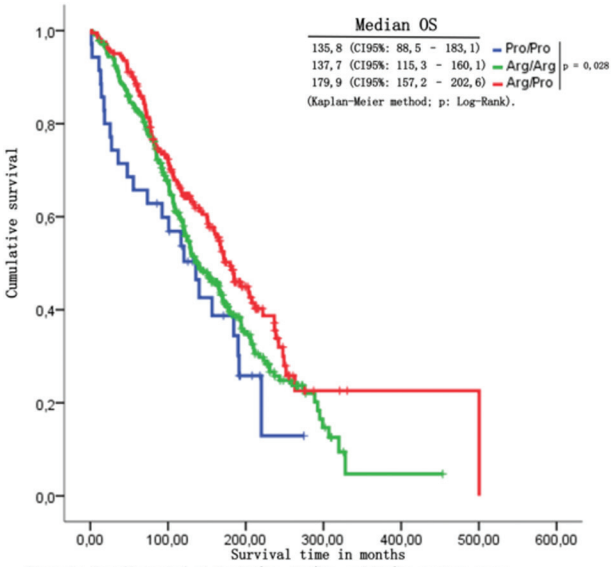


Figure 1a: Overall survival of the Arg/Arg, Arg/Pro, and Pro/Pro genotype groups.

Summary/Conclusion: Thus, we conclude that the Pro/Pro genotype of TP53 codon 72 has a potential role in the progression and mortality of CLL patients, and maybe it could be related to RS. In contrast, the Arg/Pro genotype was associated with a lower risk of secondary neoplasms than the homozygous genotypes.

EP622 CRISPR/CAS9 AND MRNA-BASED GENE EDITING AND EXPRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

A. Di Rita [1,2], F. Nardi [1,2], L. Pezzella [1,2], S. Ciofini [2], A. Gozzetti [2], M. Bocchia [2], A. Kabanova [1,*]

[1]*Toscana Life Sciences Foundation,* [2]*University of Siena, Siena, Italy*

Background: Robust and efficient protocols for gene editing and expression are highly needed in order to facilitate study of gene function in primary tumour cells from patients with chronic lymphocytic leukemia (CLL). CLL cells are notoriously prone to apoptosis when cultured *in vitro* and are for being hard-to-manipulate. This makes it challenging to modulate their endogenous gene expression or to induce expression of exogenous genes. Conventional methods based on plasmid/siRNA transfection or viral transduction are not efficient in CLL cells.
Aims: Hence, the development of optimized methods adapted to CLL cells gives an opportunity of developing screening platforms to assess function of multiple genes in assays *in vitro*.
Methods: In this work we set up conditions for CRISPR/Cas9-based gene knockout and mRNA-driven gene overexpression in B cells freshly isolated from peripheral blood of CLL patients. We also developed a platform for high-throughput *in vitro* production of mRNA encoding multiple genes allowing to scale up eventual screening assays.
Results: We show, on one hand, that it is possible to set up electroporation conditions that only marginally affect CLL cell viability. At such conditions, electroporating CLL cells with ribonucleoprotein complexes containing recombinant Cas9 nuclease and synthetic guides one can achieve >70-80% of homozygous knockout of a given. On the other hand, electroporation with *in vitro* transcribed mRNA allows to achieve >90% of electroporation efficiency and finely modulate gene expression levels in CLL cells. Gene overexpression persists for up to 4 days and longer allowing to perform long-term *in vitro* assays.
Summary/Conclusion: CRISPR/Cas9- and mRNA-based platforms for gene editing and expression are readily applicable to minimally manipulated primary CLL cells.

EP623 THE SIGNS OF NEGATIVE SELECTION IN IGHV FRAMEWORK REGIONS ARE ASSOCIATED WITH WORSE OVERALL SURVIVAL OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

I. Abramenko [1,*], N. Bilous [1], Z. Martina [1], I. Dyagil [1], A. Chumak [1]

[1]*Research Center for Radiation Medicine, Kyiv, Ukraine*

Background: The mutational status of the variable region of the immunoglobulin heavy chain (*IGHV*) genes remains the most significant prognostic factor in chronic lymphocytic leukemia (CLL) patients. Numerous studies confirmed an improved progression-free and overall survival (OS) for mutated (M) *IGHV* patients compared to unmutated (UM) patients. However, the groups of M and UM patients are also heterogeneous, and additional markers are used for a more accurate prognosis. There are some evidences that CLL is antigen-driven disease: gene-expression profile indicating activation of signaling pathways through the B-cell receptors (BCR), expression of similar BCRs (stereotyped cases), efficacy of drugs inhibiting BCR signaling, etc.
Aims: The aim of this work was to determine the prognostic value of the signs of antigen selection in *IGHV* sequences of CLL patients.
Methods: The study included 127 M *IGHV* CLL patients (88 men and 39 women aged 58.6±0.91 years). All patients gave written informed consent. The *IGHV* gene mutational status was assessed by a direct sequencing. BASELINe statistics was used to determine if antigen selection occurred (Uduman et al., 2011, 2014). Major stereotyped subsets were assigned using the ARResT/AssignSubsets tool. All analyzed sequences were presented in Genbank database. Mutations of *TP53* gene were analyzed in 88 patients by a direct sequencing and were revealed in three patients. OS was analyzed by Kaplan-Meier statistic.
Results: The distributions of replacement (R) and silent (S) mutations in the CDR (complementary determining region) and the FR (framework region) regions of M sequences were 75.7:24.3 and 61.1:38.9, correspondingly, and were in agreement with data of Rene et al. (2014). Using BASELINe statistics, we found that two sequences (1.6%) had signs of positive selection and 15 sequences (11.8%) had signs of negative selection in CDRs ($p<0.05$). The FR regions had signs of negative selection ($p<0.05$) in 37 (29.1%) cases. In other cases, the Σ statistic values were borderline ($p<0.1$) or insignificant ($p>0.1$). No associations of OS with signs of selection in CDRs were found. At the same time, OS was worse in CLL patients with signs of negative selection in FRs (group I, median of OS 111 months) compared to other M *IGHV* patients (group II, median of OS 202 months), p=0.027. Observed CLL patients of both groups were comparably by age (p=0.287), gender (p=0.488), Binet stage (p=0.37), *TP53* mutational status (p=0.781), and the expression of stereotyped BCRs (p=0.488). In comparison to group II, sequences of group I had higher numbers of S mutations in CDRs (1.94±0.23 vs 0.96±0.2; p=0.001) and in FRs (5.97±0.34 vs 2.73±0.19; p=0.001), slightly lower numbers of R mutations in FRs (4.7±0.39 vs 6.04±0.31; p=0.05), and significantly lower R to S ratio in FRs (41.1:58.8 vs 69.4:30.6; p=0.00001). Besides, the number of amino acid substitutions in codons 24-26, 80, 83, and 96 was significantly reduced (or absent) (p=0.00041, when comparing the total number). In multivariate analysis, which was carried out considering the recommendations of International CLL-IPI working group (2016), the following factors were predictive for OS of M CLL patients: clinical stage (Binet A vs Binet B-C), age (≤65 years vs >65 years), and negative selection in FRs (data of serum β2-microglobulin

concentration were missing; *TP53* mutations were detected in a small number of cases and had no prognostic value in our M *IGHV* group).
Summary/Conclusion: The obtained data suggest of possible impact of features of somatic hypermutation processes in CDRs and FRs of *IGHV* for CLL prognosis.

EP624 GENE EXPRESSION MODEL TO IDENTIFY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS WITH AN ULTRA-STABLE DISEASE. A CAMPUS CLL STUDY.

Anna, University of Ferrara, Ferrara, [10]Division of Hematology, Department of Translational Medicine, University of Eastern Piedmont, Novara, [11]Hematology, Department of Molecular Medicine, Sapienza University, Rome, Italy

Background: Chronic lymphocytic leukemia (CLL) shows an extremely heterogeneous clinical course. Among cases with a favorable immunogenetic profile (mutated immunoglobulin heavy chain variable region (IGHV) genes, absence of unfavorable FISH lesions), there are those with an ultra-stable (US) clinical course who do not progress for at least 10 years from diagnosis. In a previous study (Raponi et al, Ann Oncol 2018) we described the genetic landscape of US-CLL patients and suggested a predictive model, based on the expression of six genes, capable of identifying these cases at diagnosis.
Aims: To test the previously designed classifier model in an expanded multicenter cohort of cases, including US-CLL and patients that despite favorable immunogenetic features progressed and required treatment within 5 years from diagnosis (non-US-CLL), in the context of the Campus CLL group.
Methods: Sixty new patients (31 US-CLL and 29 non-US-CLL) were included. All showed a mutated IGHV status, normal FISH or del13q only. US-CLL showed a median follow-up of 15.3 years (range: 10-23), while non-US-CLL showed a median time to progression of 2 years (range: 0-4.9). Droplet digital PCR (ddPCR) was applied to quantify the expression of the 6 previously identified genes (*P2RX1, PLXND1, CPT1A, PRRC2C, GPM6A, SMCHD1*) (Raponi et al, Ann Oncol 2018). These 60 cases were pooled with the 79 of our previous study (total: 89 US-CLL and 50 non-US-CLL). The absolute expression values of each gene were used to refine the original decision tree model.
Results: The decision tree model was initially fit on a training dataset obtained by the resample with bootstrap of 139 patients (n=1390). The validation of the decision tree based model and self-consistency test were performed by k-fold cross validation (CV) method. The decision-tree is derived from the best predictive model in the R output, identifying 12 subgroups (nodes) and 5 associated factors (genes).
By applying the decision tree model to the original cohort of 139 patients and according to the absolute expression values of the 5 genes included in the final model (*GPM6A+P2RX1+PLXND1+PRRC2C+SMCHD1*), 127/139 (91.4%) were correctly classified and 12 (8.6%) were misclassified. In particular, all the 89 US-CLL were correctly predicted (sensitivity: 100%), as well as 38 out of 50 cases who developed a progressive disease were classified by the model as non-US-CLL (specificity: 76%). Overall, the positive and negative predictive values of the model were 88.1% and 100%, respectively.
Summary/Conclusion: Although for early stage and asymptomatic CLL patients 'watch and wait' remains the standard of care, early treatment intervention is a tempting investigational scenario in the era of novel drugs. Besides the impact on patients' counseling at diagnosis and subsequent monitoring, our approach could further refine the current prognostic algorithms of low-risk CLL (mutated IGHV and favorable FISH) by allowing to identify CLL patients who are very likely to remain stable for more than a decade and may never require treatment from those who may benefit from experimental early intervention.

EP625 SOMATIC HYPERMUTATION PROFILES IN STEREOTYPED IGHV4-34 RECEPTORS FROM SOUTH AMERICAN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

C. Stanganelli [1,*], D. Torres [2], C. Ortega [3], M. E. Márquez [3], V. Remedi [4], J. Cabrera [1], C. Mardaraz [5], C. Galvano [6], A. Krzywinski [6], C. Lang [7], L. Zanella [7], E. Agriello [7], R. Bezares [8], A. Pavlovsky [5], M. Pavlovsky [5], P. Oppezzo [3], I. Slavutsky [6]

Background: Chronic lymphocytic leukemia (CLL) is the most common mature B-cell neoplasm in the West. IGHV (immunoglobulin heavy-chain variable region) mutational status displays strong prognostic value. About 40% of CLL patients carry quasi-identical B-cell receptor (BCR) immunoglobulins that can be assigned to distinct stereotyped subsets. IGHV4-34 is one of the most frequently used genes in CLL patients and mostly of them display an indolent outcome.
Aims: We here study the mutational profile of CLL patients expressing IGHV4-34 focusing on the different stereotypes that are present in this rearrangement and their correlation with prognostic factors and activation-induced cytidine deaminase (AID) expression, one of the hallmarks of disease progression in CLL.
Methods: A multi-institutional cohort of 1444 unselected CLL patients from Argentina (891), Brazil (358), Uruguay (116) and Venezuela (79) were analyzed. RT-PCR and bidirectional sequencing were done. Cytogenetics and molecular cytogenetics analysis were performed. IGHV sequences with <98% homology with respect to the germline counterpart were considered as mutated (M), whereas those with ≥98% homology were classified as unmutated (U). Silent (S) and replacement (R) mutations were analyzed per VH FR and VH CDR subregions. ARResT/AssignSubsets and ARResT/Teiresias were employed in order to identify major and minor/novel subsets, respectively. The study was approved by the local Ethics Committees of each Institution. All individuals provided their informed consent.
Results: We identified 144 (10%) IGHV4-34 expressing cases (78 males; mean age: 65.6 years; Rai stages: 0: 60.6%, I-II: 31.1%, III-IV: 8.2%); 119 M, 35 of them with stereotyped BCR. Subset #4 was the most frequent (71.4% of cases) followed by subsets #16 (17.1%), #29 (8.6%), and #201 (2.9%), with different distribution among countries. R mutations were more represented in VH FR2, VH CDR1 and VH CDR2 in subset #16 compared to subsets #4, #29, and non-stereotyped (NST) IGHV4-34 M-CLL with significant differences in VH FR2 between subset #16 and the NST IGHV4-34 M-CLL (p=0.0001). Asymmetric distribution in R/S mutations ratio among different VH subregions with higher ratio in VH CDR2 for subset #29 and, in VH CDR1 and VH FR2 for subset #16 was found. Analysis of somatic hypermutation profile showed significant differences in G28>D/E between subsets #4 and #16 (p<0.0001) and in P45>S for subsets #4, #16, and #29 vs NST M-IGHV4-34 (p=0.048). In addition, differences in E55>Q for subset #4 vs #16 (p=0.0376) or subset #16 vs NST (p=0.0001) or across subsets (p=0.0001) and, in S64>I for subset #29 vs NST (p=0.0001) were also observed. S64T was absent in subsets #4 and #16. High frequency of disruption of the glycosylation motif in VH CDR2 region was always present. All stereotyped IGHV4-34 cases showed normal karyotypes. Deletion 13q14 single was present in 42.8% of stereotyped cases with a different distribution among subsets. A shorter time to first treatment was found in NST vs stereotyped M-IGHV4-34 patients (p=0.034). AID overexpression was evaluated in 26 IGHV4-34 patients, 8 of them display expression, only 2 stereotyped. The remaining patients expressing AID were NST and 5/6 (83%) showed a U-IGHV status.
Summary/Conclusion: Our results add new information supporting the importance of recurrent amino acid changes at particular positions, contributing to refine the molecular characterization of our cohort and, reinforcing the role of the genetic background and environmental factors in CLL patients.

EP626 NGS APPROACH FOR IGHV REARRANGEMENT ANALYSIS IN CLL PATIENTS WITH OLIGOCLONAL DISEASE

S. Dumpis [1], B. Biderman [2,*], E. Likold [2], A. Sudarikov [2]

[1]Dept. of Biological and Medical Physics, Moscow Institute of Physics and Technology, [2]Molecular Hematology Lab., National Research Center for Hematology, Moscow, Russian Federation

Background: Mutational status of the IGHV genes, IGHV gene family usage, and B-cell receptor stereotype are the key prognostic factors for CLL. However, the routinely used Sanger sequencing technique may fail for the cases with an expansion of more than one tumor B-cell clones, especially with rearranged genes of the same IGHV family (up to 4% CLL cases)
Aims: To evaluate the robustness of NGS technology for IGHV analysis in complicated CLL cases.
Methods: DNA samples from CLL patients (N=26) for whom we previously failed to obtain IGHV rearrangements data by Sanger sequencing included in the study. IGHV loci were PCR amplified as described in BIOMED-2 protocol and by Campbell et al. Sequencing libraries were prepared with Nextera XT kit (Illumina, USA) according to the manufacturer's recommendations and were analyzed with MiSeq Genome Analyzer (Illumina, USA). Sequencing data were processed via Mixcr software (Bolotin et al. https://github.com/milaboratory/mixcr). The mutational status and receptor stereotype were identified using IMGT and ARRest databases according to ERIC recommendations.
Results: In 20 cases two clonal rearrangements were identified; in 18 cases IGHV genes of the same family were used in both clones (IGHV3 for 14 patients and IGHV1 for 4). One patient had IGHV1-69 и IGHV7-4 genes rearrangements (these two families are usually amplified with the same primer). One more patient had IGHV1-69 and IGHV3-73. In 19 cases only one rearrangement was productive, and one patient had two productive IGHV rearrangements. Herewith the mutational status did not differ within the rearrangement pairs. Thus, we determined U-CLL for 16 patients and M-CLL for 4 patients. Besides, two patients with stereotyped receptor CLL#2 and one patient with CLL#1 were found in U-CLL group. Three patients were found with only one productive clonal rearrangement. The heterogeneity of Sanger sequencing in these cases was presumably related to an insufficient amount of tumor cells in the sample comparing with a high polyclonal background. Three patients had three clonal rearrangements. In two cases all rearrangements were productive (IGHV3 and IGHV4 families) and highly mutated. One of these patients had two malignancies - CLL and mantle cell lymphoma. Both these two cases were classified as M-CLL. The third case demonstrated the major productive rearrangement (91% clones) with unmutated IGHV3-53 gene and two small (<5%) unmutated clones with IGHV1-69 (productive) and IGHV3-74 (unproductive).
Summary/Conclusion: Using NGS approach we have shown that in the cases with two IGHV gene rearrangements from the same VH gene family, variants with IGHV3 family are the most common (77,7%). U-CLL variants were also prevalent. Though Sanger sequencing is still more suitable for routine IGHV gene analysis in CLL, a significant number of complicated cases might benefit from NGS technology, therefore, allow to obtain definite diagnosis and assign appropriate treatment.

EP627 SYSTEMATIC TRANSCRIPTOME ANALYSIS REVEALS DISTINCT COMPETING ENDOGENOUS RNA NETWORK IN CHRONIC LYMPHOCYTIC LEUKEMIA

Y. Zhang [1,*], X. Zhang [1], Y. Han [1], Z. Tian [1], X. Hu [1], X. Wang [1]

[1]Department of Hematology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: Increasing studies have identified that non-coding RNAs play critical roles in the initiation and progression of tumors via participating in competitive endogenous RNA (ceRNA) networks. However, the roles and functions of the ceRNA network in chronic lymphocytic leukemia (CLL) remain poorly understood.
Aims: The present study aims to explore the transcriptomatic profile and construct the distinct ceRNA network in CLL.
Methods: The expression profile of RNAS of CLL patients, CLL cell lines (MEC-1 and EHEB) and healthy group were obtained by the illumina sequencing. R software was used for functional enrichment analysis. The data in the genome microarray map GSE22762 was used for survival analysis. The lncRNA/circRNA-miRNA-mRNA ceRNA networks were visualized by Cytoscape 3.7.2. Four DEmRNAs and the circRNA hsa_circ_0007675/hsa-miR-185-3p/TCF7L1 axis were verified by Quantitative real-time PCR.
Results: In the present study, 57 differentially expressed- (DE-)mRNAs, 1391 DElncRNAs, 335 DEmiRNAs and 10013 DEcircRNAs were identified comparing CLL patients with healthy donors. Meanwhile, 482 mRNAs, 6085 lncRNAs, 302 miRNAs and 1847 circRNAs were explored differently expressed between CLL cell lines and healthy donors. GO and KEGG analysis results showed that these differentially expressed genes (DEGs) are related to the occurrence and development of tumors.The survival analyses showed that 16 DEGs (INIP, IL3RA, CHD1, NLRP12, IL20RB, B3GALT4, SIT1, ACOT8, AGFGR, PCLAF, C19orf18, SELENOS, OR7A17, PCDH7, HNRNPC, PHGDH) were significantly differentially expressed.
The ceRNA network were constructed by Cytoscape software. In total, 11 mRNA nodes, 19 miRNA nodes, 105 lncRNA nodes were identified as differentially expressed profiles between CLL patients and control. Meanwhile, a total of 256 DEcircRNAs, 19 DEmiRNAs, and 11 DEmRNAs were employed to construct the ceRNA network between CLL patients and control. We verified four DEGs (TCF7L1, TRIM34, SLC30A10, HOXD4) and the circRNA hsa_circ_0007675/hsa-miR-185-3p/TCF7L1 axis. Compared with normal people, the expression of these four genes and hsa_circ_0007675 in patient specimens were significantly increased whereas the expression of hsa-miR-185-3p was downregulated ($p<0.05$).
Summary/Conclusion: In this study, we identified the expression profile of RNAs in CLL patients and CLL cell lines. Functional enrichment analysis and survival analysis revealed the potential functions of DEGs. The ceRNA network we established can help to further understand the pathogenesis of CLL and provide potential prognostic markers and novel therapeutic targets.

EP628 CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL): HIGH-RISK DATA FROM AN IRISH POPULATION.

Atkinson [1,8], G. Le [1,11], A. Gillett [1,12], C. L. Bacon [1,12], A. M. McElligott [8,13], F. Quinn [12,14], E. Vandenberghe [1,12]

[1]Haematology, St. James's Hospital, [2]Haematology, Trinity St. James's Cancer Institute, [3]Cancer Molecular Diagnostics Laboratory, St. James's Hospital, Dublin, [4]Haematology, [5]Clinical Trials, Midlands Regional Hospital, Tullamore, [6]Haematology, University Hospital Limerick, [7]Haematology, University Hospital Llimerick, Limerick, [8]Haematology, Trinity St. James's Cancer Institute, [9]Data Management, St. James's Hospital, [10]Haematology, St. James's Hospital, [11]Haematology, Trinity St. James's Cancer Instituite, [12]Haematology, Trinity St James's Cancer Institute, [13]Haematology, Trinity Translational Medicine Institute, [14]Haematology, Cancer Molecular diagnostics Laboratory, Dublin, Ireland

Background: CLL is the most common B-lymphoid malignancy in the Caucasian population, principally affecting the elderly and displaying marked genetic and clinical heterogeneity. Targeted treatments have proved successful in extending the life-expectancy of those with ultra-high risk CLL. The poor outcomes of this subgroup have been mostly attributed to *TP53* mutations. However, *SF3B1* and *NOTCH1* gene mutations are also significant driver mutations contributing to this ultra-high-risk group.
Flow cytometry has enabled the identification of further high-risk subgroups through the detection of surface pro-tumour microenvironment modulators - including CD49d, CD62L and ROR1. The most prognostically significant is CD49d which is associated with bulky lymphadenopathy and shortened overall and treatment-free survivals. Blocking these surface modulators has proved promising in inducing CLL apoptosis and clinical trials in this area are ongoing.
The National Cancer Registry of Ireland (NCRI) collects cancer incidence data from hospital in-patient enquiry (HIPE) data and laboratory reports. However, there is a potential for national incidence figures to underestimate real-world data.
Aims: We have performed an in-depth study of consecutive newly diagnosed CLL patients captured directly from the flow cytometry laboratory and compared our incidence figures to registry data from the NCRI. Including a second cohort of previously diagnosed CLL patients who required therapy during the study time period, we performed extended immunophenotyping (CD62L, CD49d and ROR1) and mutational analysis of *TP53* and *NOTCH1* genes in order to characterize disease biology in a representative Irish population.

Methods:
Two patient groups were recruited from three institutions (St. James's Hospital, University Hospital Limerick and the Midlands Regional Hospital) from October 2017 - September 2018. Group 1 included consecutive patients with newly diagnosed CLL and group 2 included previously-diagnosed patients who required treatment during the study time period. Ethics approval was granted and written informed consent was sought for biobanking, immunophenotypic and molecular analysis (extended flow panel, *TP35* and *NOTCH1* mutational status). If consent was not provided, the patients were included for epidemiological purposes only.
Results: 148 patients were included: 111 newly-diagnosed (1) and 38 known cases of known CLL pre-treatment (2). An incidence of 5 per 100,000 (females) and 11 per 100,000 (males) was established. The median age was 67.5 years with 58 patients (39%) aged ≥ 70 years. The male to female ratio was 2.2:1. Immunophenotyping and mutational analysis of groups 1 and 2 revealed: CD62L (1-63.5%; 2- 64%), CD49d (1- 27.1%; 2- 34.6%), ROR1 (1- 85.9%; 2- 88.5%), mutated *TP53* (1- 9.2%; 2- 11.8%) and mutated *NOTCH1* (1- 9.4%; 2 16.7%). The association between CD49d expression and lymphadenopathy was demonstrated. In cases where expression levels fell between 10-30%; CD62L had two (11.7%) and CD49d had nine (90%) cases of bimodal distribution patterns.

Table: Baseline characteristics.

Demographic, clinical and molecular Characteristics	All patients N=148		Group 1 N=111		Group 2 N=37	
Men	102	68.9%	76	68.5%	26	70.3%
Women	46	31.1%	35	31.5%	11	29.7%
Median age at diagnosis (Years)	67.5 (29-91)	-	69 (41-91)	-	60 (29-79)	
Binet stage A	97/148	65.6%	94/111	84.7%	3/37	8.1%
Binet stage B	28/148	18.9%	14/111	12.6%	14/37	37.8%
Binet stage C	23/148	15.5%	3/111	2.7%	20/37	54.1%
TP53 mutated	12/121	9.9%	8/87	9.2%	4/34	11.8%
NOTCH 1 mutated	13/115	11.3%	8/85	9.4%	5/30	16.7%
ROR1 ≥ 30%	96/111	86.5%	73/85	85.9%	23/26	88.5%
ROR1<30%	15/111	13.5%	12/85	14.1%	3/26	11.5%
CD62L ≥ 30%	70/110	63.6%	54/85	63.5%	16/25	64.0%
CD62L<30%	40/110	36.3%	31/85	36.4%	9/25	36.0%
CD49d ≥ 30%	32/111	28.8%	23/85	27.1%	9/26	34.6%
CD49d <30%	79/111	71.2%	62/85	72.9%	17/26	65.3%

Summary/Conclusion: We have established in-depth epidemiological and molecular analysis of an Irish patient cohort in an effort to redress the paucity of published Irish data. We have established that our CLL cohort and biobank benchmarks from a clinical and laboratory perspective to other international cohorts. A longitudinal study of the patient cohort will establish whether CD49d expression ≥10% is prognostically useful and whether cases of CD62L with bimodal patterns of expression have clinical relevance.

EP629 INFLUENCE OF INFLAMMATORY CYTOKINES ON S100A PROTEINS EXPRESSION IN CLL PATIENTS

O. Mitrovic [1,*], M. Diklic [1], D. Antic [2,3], B. Mihaljevic [2,3], V. Vukovic [2], V. Otasevic [2], K. Tomic [2], V. Cokic [1]

[1]Institute for Medical Research, University of Belgrade, [2]Lymphoma Center, Clinic for Hematology, Clinical Center of Serbia, [3]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: S100A proteins possess a broad range of intra- and extracellular functions. The involvement of these proteins in inflammation-mediated responses is of particular interests, considering that inflammation represents one of the landmarks of malignancy. Processes such as inflammation and cellular stress trigger the release of S100A proteins to extracellular space, interacting with their receptors and activating numerous intracellular signaling pathways, for instance NF-κB and AP1. Through them, S100A proteins take part into regulation of some of the most essential cellular processes: cell differentiation, apoptosis, inflammation, proliferation, etc.
Aims: The aim of the study is to assess the role of inflammation in activation of S100A proteins via proliferation and inflammation related signaling pathways.
Methods: We observed 60 CLL patients' samples to isolate mononuclear cells (MNC) and CD19⁺ cells. MNC of CLL patients were treated with pro-inflammatory IL-6 and anti-inflammatory IL-10 cytokines, and inhibitors of JAK1/2, NF-κB and PI3K signaling pathways, to evaluate S100A4, S100A8, S100A9, S100A12 and NF-κB protein expression by immunoblotting. Also, we used immunocytochemistry to analyse the number of the S100As immunopositive MNC of CLL patients.
Results: S100A8 showed higher level of protein expression in MNC and CD19⁺ cells in comparison to healthy control. The number of immunopositive S100A4 ($p<0.05$) and S100A9 cells ($p<0.001$) was significantly decreased in CD19⁺ cells and MNC, respectively of CLL patients in comparison to healthy control. In addition, S100A4 and S100A9 proteins expression had statistically significant lower level of expression in MNC. Also, IL-6 stimulated expression of S100A8 and S100A4 in MNC of CLL, while the expression of latter one was prevented by NF-κB and JAK1/2 inhibitors. IL-10 reduced expression of S100A8 and S100A12 in MNC of CLL.
Summary/Conclusion: Pro-inflammatory IL-6 and anti-inflammatory IL-10 cytokines have opposite effect on inflammatory S100A8 protein in CLL, with a potential to be a prognostic marker.

EP630 RELEVANCE OF NRF2/KEAP1 AXIS IN CHRONIC LYMPHOCYTIC LEUKEMIA DEVELOPMENT

E. Gomes [1], J. Jorge [1,2,3,4], J. P. Carda [1,2,3,4,5], M. I. Costa [1], N. Magalhães [1,6], D. Roque [1,6], R. Alves [1,2,3,4], B. Lapa [1,2], S. Marini [5], S. Duarte [5], A. Pereira [2,3,7], A. C. Gonçalves [1,2,3,4], A. B. Sarmento-Ribeiro [1,2,3,4,5,*]

[1]Laboratory of Oncobiology and Haematology and University Clinic of Haematology, [2]Coimbra Institute for Clinical and Biomedical Research (iCBR) - Group of Environment, Genetics and Oncobiology (CIMAGO), Faculty of Medicine of University of Coimbra, [3]Center for Innovative Biomedicine and Biotechnology (CIBB), University of Coimbra, [4]Clinical Academic Center of Coimbra (CACC), [5]Clinical Haematology Department, Centro Hospitalar e Universitário de Coimbra (CHUC), [6]Chemistry Department, Faculty of Science and Technology, University of Coimbra, Coimbra, [7]Medicine Department, Hospital Distrital da Figueira da Foz, Figueira da Foz, Portugal

Background: Chronic lymphocytic leukemia (CLL) is characterized by the accumulation of long-lived resting clonal B lymphocytes in blood, bone marrow, and secondary lymphoid organs. Oxidative stress is known to be one of the mechanisms important in CLL development and progression. Specifically, NRF2/KEAP1 axis plays a crucial role in redox balance, inducing the expression of target genes, namely those related to antioxidant defenses.
Aims: The goal of this study was to clarify the relevance of NRF2/KEAP1 axis in CLL development, particularly through the evaluation of its target genes expression levels and their correlation with clinical and laboratory data, in order to identify potential new CLL diagnostic biomarkers.
Methods: We evaluated the expression levels of *NFE2L2*, *KEAP1*, *NFKB1*, *NQO1*, *HMOX1*, *GPX1*, *SQSTM1*, *TXNRD1*, *BCL2*, *GSTM1* and *HPRT* (endogenous control) genes in peripheral blood of 25 CLL patients and 30 healthy controls (CTL) using qPCR. Informed consent was obtained in accordance with the Helsinki Declarations. Mann-Whitney U and Kruskal-Wallis tests were used to assess the statistical significance between groups. Receiver operating characteristic (ROC) curves analysis was performed to analyze variables accuracy as diagnostic biomarkers. Patients were dichotomized according to the cut-off points obtained from the ROC curves constructed to predict death. All statistical analyses were two-sided and a $p<0.05$ was considered statistically significant.
Results: The 25 CLL patients studied were 13 males and 12 females with a median age of 73y, ranging between 48 and 83 years, and the 30 healthy controls, were 15 males and 15 females with a median age of 75 years, ranging between 54 and 99 years. At diagnosis, all CLL patients were Binet A (low risk). 24% of CLL patients presented low-risk cytogenetic abnormalities, 19% presented intermediate-risk, and 24% high-risk and 33% did not present any cytogenetic abnormalities. Our results showed, in CLL patients, an increase on gene expression levels of *NQO1* [CLL: m=0.161; interquartile range (IR)=0.283; CTL: m=0.023; IR=0.098; p=0.005] and *BCL2* [CLL: m=3,400; IR=6,353; CTL: m=0,434; IR=1,039; p<0,001) and a decrease of *NFKB1* (CLL: m=0,900; IR=0,690; p=0,014; CTL: m=1,752; IR=5,220; p=0,014) and *SQSTM1* (CLL: m=0,144; IR=0,395; CTL: m=0,880; IR=3,153; p<0,001), when compared to controls. None of the other evaluated genes showed significant differences between CLL patients and controls.

ROC analysis for these genes suggested that their expression levels might be possible diagnostic biomarkers for CLL *NQO1* (AUC:0,733; IC95%:0,593-0,873; cut-off>0,159; sensitivity=57%; specificity=85%; p=0,005); *BCL2* (AUC:0,882; IC95%:0,786-0,978; cut-off>0,532; sensitivity=91%; specificity=74%; p<0,001); *NFKB1* (AUC:0,695; IC95%:0,553-0,837; cut-off<1,030; sensitivity=64%; specificity=77%; p=0,014); *SQSTM1* (AUC:0,799; IC95%:0,676-0,921; cut-off<0,443; sensitivity=68%; specificity=87%; p<0,001)]. No correlation was found between gene expression levels and CLL patients' survival, as well as with other clinical and laboratory data.

Summary/Conclusion: The decrease of *NFKB1* and *SQSTM1* gene expression levels observed in our study confirms the importance of oxidative stress in CLL, and the increase of *BCL2* and *NQO1* reflect the ability of tumor cells to resist cell death. Furthermore, as these genes are target of the NRF2/KEAP1 axis, our study suggests the relevance of the NRF2/KEAP1 axis for CLL development, being the levels of *NFKB1*, *SQSTM1*, *BCL2* and *NQO1* genes potential new diagnostic biomarkers.

Background: Other malignancies occurring in patients with CLL are a well-known, but insufficiently investigated area, highlighting the need for further research.

Aims: To leverage the understanding of other malignancies in CLL, particularly regarding potential links to chemoimmunotherapy (CIT) and/or novel agents, as well as associations with relevant clinicobiological factors.

Methods: Data from consecutive sets of patients diagnosed with CLL between 2000-2016 were collected by affiliated members through ERIC and subjected to detailed statistical analysis. Collected variables included: demographics, stage at diagnosis, treatment, treatment response, death, cause of death, other malignancy (type, date of diagnosis, outcome), biomarker profiles.

Results: Overall, 13,808 patients from 64 centers were evaluated: 8,517 males, 5,291 females; median age: 66 (range, 27-92). At diagnosis, 74/16/10% of cases were classified as Binet stages A/B/C. Biomarker profiling (performed before frontline treatment): 1,055/6,310 cases (14.1%) with del(11q); 843/6,928 cases (10.8%) with *TP53* aberrations

[del(17p) and/or *TP53* mutation]; 3,127 (48%) and 3,390 (52%) cases with unmutated or mutated IGHV genes, respectively. With a median follow-up of 77 months (range, 49-199), 7,134/13,308 (53.6%) patients had received ≥1 line(s) of treatment (1: 59.3%, 2: 19.3%, 3: 11%, 4+: 10.4%). Therapies received (at any line) included only CIT/CIT+novel agents/only novel agents in 71.5/21.3/7.2% of cases, respectively. Frontline therapies were FCR (32.3% of cases), bendamustine+/-antiCD20 (10.7%), other CIT (mostly chlorambucil+antiCD20) (46.7%), BTKi+/-combinations (4.8%), idelalisib+/-combinations (0.5%), venetoclax+/-combinations (0.9%), various other regimens (4%). Within this series, 2,919/13,808 cases (21.1%) were reported with other malignancies besides CLL; cases with Richter's transformation (n=390/10,157, 3.8%) were not included in this count. CLL diagnosis preceded the other malignancy in 1,939 cases (14% of the cohort): of these, 317 and 1,622 cases developed other hematological or non-hematological malignant neoplasms, respectively. The great majority of the former concerned MDS/AML (31%) and other lymphoid malignancies (49%), excluding MGUS. The incidence of MDS/AML was significantly enriched in (i) patients with unmutated IGHV genes (p=0.05) or del(11q) (p=0.009); (ii) treated patients (p<0.001), particularly those receiving ≥3 treatment lines (p<0.01); and (iii) patients treated with FCR (p<0.001). FCR retained independence on multivariate analysis. Within the group of non-hematological malignant neoplasms, non-melanoma skin cancer (NMSC) accounted for 31% of cases; malignant neoplasms of the prostate, colon, breast, bronchus/lung and melanoma collectively accounted for 41.6% of cases. Several of these neoplasms were significantly more prevalent in untreated patients (p<0.01 for breast, prostate, colon), despite that the follow-up of treated vs untreated patients did not differ significantly. Only NMSC was significantly more prevalent (p=0.007) in treated patients.

Summary/Conclusion: We report strong associations between the development of other hematological malignancies, especially MDS/AML, and certain biological features as well as treatment for CLL, with a highly relevant risk for patients treated with CIT, particularly the FCR regimen. In contrast, the development of solid tumors appeared unaffected by treatment administration, prompting further investigation in specific patient subgroups that will be presented at the congress.

EP632 VENETOCLAX-OBINUTUZUMAB MODULATES CLONAL GROWTH: RESULTS OF A POPULATION-BASED MINIMAL RESIDUAL DISEASE MODEL FROM THE RANDOMIZED CLL14 STUDY

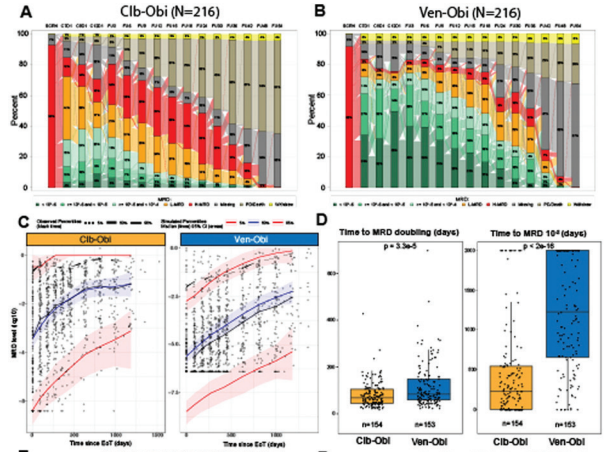
Background: The CLL14 study has established fixed-duration treatment of the Bcl-2 inhibitor venetoclax and the CD20 antibody obinutuzumab (Ven-Obi) for patients (pts) with previously untreated chronic lymphocytic leukemia (CLL). High rates of undetectable minimal residual disease (uMRD) have been observed with one year of treatment.



Aims: The aim of this report is to provide a population-based exploratory analysis of MRD growth dynamics after stopping Ven-Obi and chlorambucil-Obi (Clb) therapy and to compare growth trajectories between targeted treatment versus chemoimmunotherapy.

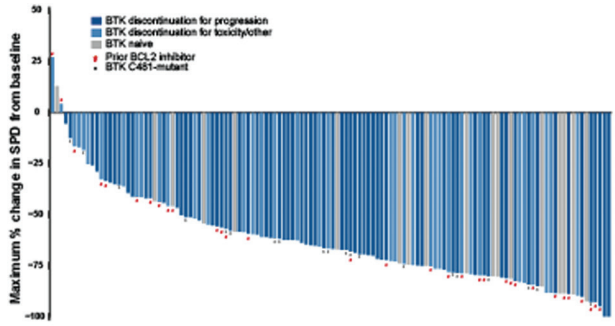
Methods: Pts were randomized 1:1 to receive 12 cycles of Ven with 6 cycles of Obi or 12 cycles of Clb with 6 cycles of Obi. MRD was analyzed by next-generation sequencing (Adaptive clonoSEQ Assay). Samples from peripheral blood (PB) are collected every 3-6 months. For the longitudinal analyses of MRD growth dynamics, a population-based logistic growth model with nonlinear mixed effects (NLME) approach was developed to estimate population and individual patient parameters. Cases with at least two measurable timepoints were included; data < LLOQ were incorporated by likelihood-based method. Prognostic markers were screened as covariates for impact on key model parameters based on statistical (Akaike information criterion) and graphical assessments. Statistical inference on MRD doubling time and time to reach 10^{-2} MRD level was derived for the stratified subgroups.

Results: Of 432 enrolled pts, 216 were assigned to receive Clb-Obi and 216 to Ven-Obi. At follow-up month 30, 7 (3.2%) pts in the Clb-Obi arm and 58 (26.9%) pts in the Ven-Obi arm had uMRD levels $<10^{-4}$ (Fig A,B). Based on the inclusion criteria for the population analysis, 154 pts from Clb-Obi arm and 153 pts from Ven-Obi arm were included. The model was well calibrated, and high concordance between observed and predicted values was confirmed (Fig C).

The median MRD level at EoT was significantly lower after Ven-Obi than after Clb-Obi ($10^{-6.00}$ vs $10^{-3.26}$, p<2e-16). Within the Ven-Obi arm, end of treatment MRD values did not differ between pts with low-risk and high-risk features, such as IGHV status ($10^{-5.79}$ for mutated IGHV vs $10^{-6.12}$ for unmutated IGHV) or *TP53* deletion/mutation ($10^{-5.38}$ for deletion/mutation vs $10^{-6.03}$ for non-deleted/mutated). The median MRD doubling time was significantly longer after Ven-Obi than Clb-Obi therapy (median days 84 versus 67 days, p = 3.3e-5)(Fig D). The median time from EoT to MRD level increase to 10^{-2} was also significantly longer after Ven-Obi therapy compared to Clb-Obi therapy (median 1225 days versus 227 days, p<2e-16)(Fig D).

Based on a covariate screening of 28 biological and clinical characteristics, the final model showed a significant impact on MRD growth dynamics by Ven-Obi treatment, high MRD levels at the start of treatment, high CLL-IPI, deletion11q, higher disease burden, response to treatment, and IGHV status (Fig E,F). Pts with *TP53* deletion/mutation also had higher growth, although statistical significance was not reached due to low number of pts. After adjusting all the covariates in the model, the effect of Ven-Obi treatment on MRD growth remained significant (Fig E,F).

Summary/Conclusion: This analysis establishes a robust, population-based model of MRD growth dynamics that allows description of growth trajectories and treatment effects after treatment cessation. In addition to more effective MRD eradication with Ven-Obi, our results demonstrate that MRD growth is modulated more efficiently by BCL2-targeting treatment in contrast to genotoxic chemoimmunotherapy.



EP633 PIRTOBRUTINIB (LOXO-305), A NEXT GENERATION, HIGHLY SELECTIVE, NON-COVALENT BTK INHIBITOR IN PREVIOUSLY TREATED CLL/SLL: RESULTS FROM THE PHASE 1/2 BRUIN STUDY

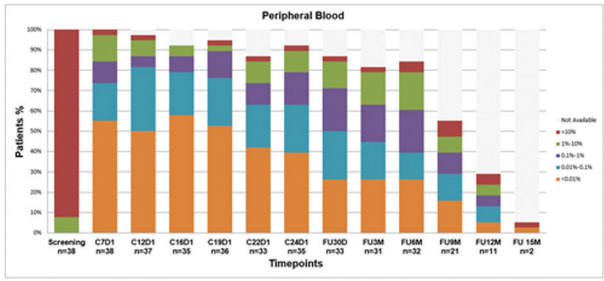
Background: Despite the marked efficacy of covalent BTK inhibitors (BTKi) in CLL/SLL, the development of resistance and discontinuation for adverse events can lead to treatment failure. Moreover, pharmacological liabilities of these agents such as low oral bioavailability or short half-life can lead to suboptimal BTK target coverage and ultimately result in acquired resistance in some patients (pts). To address these limitations, pirtobrutinib (LOXO-305), a highly selective, non-covalent BTKi that inhibits both WT and C481-mutated BTK with equal low nM potency was developed.
Aims: To evaluate safety and efficacy of pirtobrutinib in previously treated CLL/SLL.
Methods: BRUIN is a multicenter phase 1/2 trial (NCT03740529) enrolling pts with advanced B-cell malignancies who have received ≥2 prior therapies. Oral pirtobrutinib was dose escalated in a standard 3 + 3 design in 28-day cycles. The primary endpoint was MTD/RP2D identification. Efficacy evaluable pts included all dosed pts who underwent their first response evaluation or discontinued therapy. Safety was assessed in all pts (n=323). Response was assessed according to the iwCLL 2018 criteria, including PR with lymphocytosis (PR-L).
Results: As of 27 September 2020, 323 pts with B-cell malignancies (170 CLL/SLL, 61 MCL, 26 WM, and 66 other B-cell lymphomas) were treated on 7 dose levels (25-300mg QD). Among the 170 CLL/SLL pts, the median age was 69 (range 36-84) years. Median number of prior lines of therapies was 3 (range 1-11), 86% of CLL/SLL pts had received a prior BTKi, and 67% an anti-CD20 antibody, chemotherapy, and BTKi; 21% had received a PI3K inhibitor and 34% venetoclax. At enrollment, high risk features such as 17p deletion were present in 25% (20/81), TP53 mutation in 30% (27/91), and unmutated IGHV in 88% (71/81). Pirtobrutinib demonstrated high oral exposures, with doses ≥100mg QD exceeding the BTK IC90 for the entirety of the dosing interval. No DLTs occurred. Consistent with pirtobrutinib's selectivity, the only treatment-emergent adverse events regardless of attribution or grade seen in ≥10% of pts (n=323) were fatigue (20%), diarrhea (17%) and contusion (13%). Responses were observed at the first dose level of 25mg QD. A RP2D of 200mg QD was selected for future studies. At the efficacy cutoff date, 150 CLL/SLL pts remained on therapy and 139 were efficacy evaluable (121 BTKi-treated). Median follow-up was 6 months (range 0.6-17.8+) for efficacy evaluable pts. The ORR was 63% with 69 PRs, 19 PR-Ls, 45 SDs, 1 PD, and 5 discontinued prior to first response assessment (Figure). An additional 37 pts were ongoing and awaiting initial radiologic assessment. Responses deepened over time; among pts with at least 10 months of follow-up (n=29), the ORR was 86%. ORR was not influenced by the reason for prior BTKi discontinuation (i.e. progression vs intolerance), or other classes of prior therapy received (including a covalent BTK and a BCL2 inhibitor). Of the 88 responding pts, all except 5 remain on therapy (4 progressed, and 1 achieved a PR and electively discontinued). The longest followed responding pt continues on treatment for 17.8+ months.

Data cutoff date of 27 September 2020. Data for 13 CLL/SLL patients are not shown in the waterfall plot due to 4 having no target lesions identified at baseline, 5 with no/incomplete post-baseline lesion measurements, and 4 discontinued prior to first post-baseline disease assessment.

Summary/Conclusion: Pirtobrutinib demonstrated promising efficacy in CLL/SLL pts following multiple prior lines of therapy including a covalent BTKi and a BCL2 inhibitor. Importantly, the activity of pirtobrutinib was not restricted to pts with BTK C481 mutations. Pirtobrutinib was well tolerated and exhibited a wide therapeutic index.



EP634 MINIMAL RESIDUAL DISEASE-DRIVEN TREATMENT INTENSIFICATION WITH SEQUENTIAL ADDITION OF IBRUTINIB (IBR) TO VENETOCLAX (VEN) IN RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): THE IMPROVE STUDY

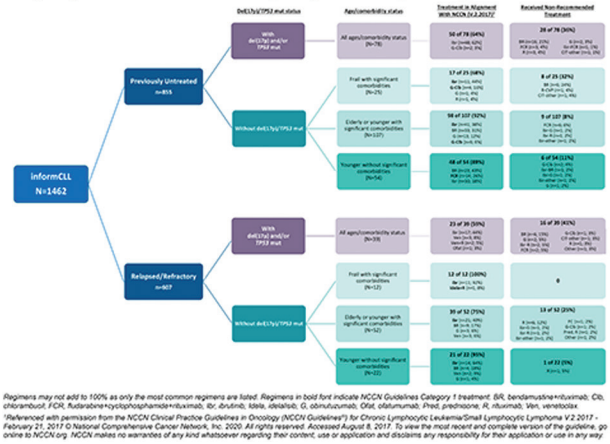
Città della Salute e della Scienza di Torino, Torino, [11]Division of Hematology, Azienda Ospedaliera SS Antonio e Biagio e Cesare Arrigo, Alessandria, [12]Institute of Hematology, Università Cattolica del Sacro Cuore-Policlinico A. Gemelli, Roma, [13]Division of Hematology, Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy

Background: Undetectable MRD (uMRD) has become an achievable endpoint for patients (pts) with CLL, in particular using the BCL2 inhibitor VEN allowing treatment discontinuation in a MRD-driven approach. uMRD can be reached in a proportion of pts with VEN mono, and in larger fraction in combination with the BTK inhibitor IBR. It remains to be established who can achieve best responses with single agent or combination strategies.
Aims: This phase 2 multicenter MRD-driven Italian study aims at discontinuing treatment upon reaching uMRD in pts with relapsed/refractory CLL treated with VEN mono or through the addition of IBR in pts who did not achieve uMRD with the single agent.
Methods: VEN mono (up to 400 mg/day as per label) was administered for 12 months. MRD in peripheral blood (PB) and bone marrow (BM) was evaluated using the ERIC 6-color flow panel. Pts with uMRD in both PB and BM at C12D1 discontinued VEN at C12D28. Pts with detectable MRD in PB and/or BM added IBR 420 mg/day from C13D1 and continued both drugs up to C24D28, uMRD, progression or toxicity (whichever first). After C24D28, pts with detectable MRD and still in response continued IBR alone. The primary endpoint was uMRD4 (<1 CLL cell in 10^4 leukocytes) in both PB and BM.
Results: 38 pts (recruited from Nov 2017 to Jul 2018) started VEN. Median number of prior therapies was 1 (range 1-4), 61% were previously treated with FC+/-R; 8/33 (24%) carried del(17p); 10/30 (33%) *TP53* mutations, and 24/30 (80%) unmutated IGHV. One pt discontinued treatment due to myelodysplasia (unrelated to VEN) and 1 pt

progressed on VEN mono before C12D1, 1 evaluation was missed due to COVID-19. As of 31 Jan 2021, overall response rate with VEN mono was 36/38 (95%), 19 CR and 17 PR. As per protocol, 17 pts (45%) with uMRD4 in PB and BM at C12D1 discontinued VEN at C12D28. 19 (55%) responsive cases with detectable MRD at C12D1 added IBR to VEN from C13D1. By combining IBR and VEN for a median of 7 months (range 3-10) 5/10 pts in PR improved their response to CR, 16/19 (84%) achieved uMRD4 in both PB and BM (Fig. 1), thus stopping both therapies. The remaining 3/19 continued IBR. After a median follow up of 30 months, median PFS has not been yet reached; 3 pts progressed without treatment need, 1 pt restarted VEN mono as per protocol, 2 pts developed Richter transformation. 11/33 pts (33%) who discontinued treatment in uMRD, after a median observation of 30 months remain uMRD (6 treated with VEN only). No cases of clinical and/or laboratory tumor lysis syndrome were reported in 39 pts (1 excluded from the efficacy analysis because of atypical phenotype). Adverse events were mild, with no discontinuations or dose reductions; with prolonged follow-up no new relevant toxicities occurred.

Summary/Conclusion: Our updated results demonstrated that a sequential MRD-guided approach is feasible and leads to an overall uMRD in 33/38 pts (87%) with either VEN mono or in combination with IBR. Interestingly, 84% of pts who did not achieve uMRD after VEN alone obtained uMRD after the addition of IBR and the remaining 3 patients who did not obtain uMRD even after the combination, could be selected for continuous IBR. Median PFS is not yet reached after 30 months of follow-up. This MRD-driven sequential approach allows to reach identical depth of response in each patient enrolled in the study using a personalized intensification avoiding unnecessary drug exposure, ultimately identifying the few pts that may benefit from continuous IBR. Time to clinical progression, response to VEN retreatment, and characteristics of pts with persistent MRD remain to be established.



EP635 REAL-WORLD APPLICATION OF NATIONAL COMPREHENSIVE CANCER NETWORK CLINICAL PRACTICE GUIDELINES IN ONCOLOGY (NCCN GUIDELINES®) FOR CLL/SLL FROM THE INFORMCLL REGISTRY

J. Barrientos [1,*], A. Mato [2], N. Ghosh [3], J. Sharman [4], M. Gutierrez [5], M. Naganuma [6], S. Upasani [6], D. Alagappan [7], Q. Huang [7], A. Young [6], D. Brander [8]

[1]Northwell Health Cancer Institute, Lake Success, [2]Memorial Sloan Kettering Cancer Center, New York, [3]Levine Cancer Institute, Charlotte, [4]Willamette Valley Cancer Institute & Research Center/US Oncology Research, Eugene, [5]Lymphoma Research Foundation, New York, [6]Pharmacyclics LLC, an AbbVie Company, Sunnyvale, [7]Janssen Scientific Affairs, LLC, Horsham, [8]Duke University Health System, Durham, United States

Background: NCCN Guidelines® provide recommendations on evolving standards of care to inform treatment (tx) decisions.
Aims: To understand the application of guidelines in routine clinical practice, we assessed how tx regimens in the informCLL registry (Mato *ASH* 2020) aligned with National Comprehensive Cancer Network (NCCN®)-recommended regimens for CLL/SLL.
Methods: informCLL enrolled patients (pts) ≥18 years (y) receiving approved CLL tx (10/2015–6/2019) and who provided informed consent. Pts were categorized by del(17p)/*TP53* mutation (mut) status, line of therapy, and age/comorbidity. Comorbidities were assessed using Charlson Comorbidity Index (CCI); significant comorbidities (SC) were defined as CCI ≥3 (Mato *Blood Adv* 2020). For pts without del(17p)/*TP53* mut, age/comorbidity groups were: (1) frail with SC (≥65 y + CCI ≥3), (2) elderly (≥65 y + CCI <3) or younger with SC (<65 y + CCI ≥3), (3) younger without SC (<65 y + CCI <3). For this analysis, NCCN Guidelines for CLL/SLL V.2.2017 were used given 74% enrollment in ≥2017.
Results: Of 1462 pts enrolled (previously untreated [1L], 58%; relapsed/refractory [R/R], 42%), community-based practices enrolled 93%. Median age was 71 y (range 34–95); median CCI was 1.0 (range 0–11) and 16% had CCI ≥3. 27% of pts (n=389) had del(17p)/*TP53* mut data available. Alignment with NCCN-recommended regimens was 59–64% for pts with del(17p)/*TP53* mut and 68–100% for pts without del(17p)/*TP53* mut. Most pts with del(17p)/*TP53* mut (1L, n=78; R/R, n=39) had Category (Cat) 2A ibrutinib (ibr) as recommended (1L, 62%; R/R, 44%), but a quarter had non-recommended chemoimmunotherapy (CIT) with bendamustine+rituximab (BR) or fludarabine+cyclophosphamide+R (FCR) (1L, 24%; R/R, 21%). In pts without del(17p)/*TP53* mut who were frail with SC (1L, n=25; R/R, n=12), 60% of 1L pts had Cat 1 ibr or obinutuzumab+chlorambucil, but 24% received BR, which was not recommended; all R/R pts had Cat 1 ibr or idelalisib+R. In pts without del(17p)/*TP53* mut who were elderly/younger with SC (1L, n=107; R/R, n=52), 69% of 1L and 58% R/R pts had Cat 1 ibr or Cat 2A BR. Of pts without del(17p)/*TP53* mut who were younger without SC (1L, n=54; R/R, n=22), 87% of 1L and 82% R/R pts had Cat 1 or 2A with CIT (BR or FCR), or ibr. Despite guideline recommendations for prognostic testing, a majority of pts (73%, n=1073) had no data available for del(17p)/*TP53* mut status. For these pts the most common tx regimens were ibr (44%), CIT (32%), and anti-CD20 monotherapy (14%).

Figure. Alignment with NCCN Guidelines for CLL/SLL in previously untreated and relapsed/refractory patients in informCLL

Regimens may not add to 100% as only the most common regimens are listed. Regimens in bold font indicate NCCN Guidelines Category 1 treatment. BR, bendamustine+rituximab; Clb, chlorambucil; FCR, fludarabine+cyclophosphamide+rituximab; Ibr, ibrutinib; Idela, idelalisib; O, obinutuzumab; Ofat, ofatumumab; Pred, prednisone; R, rituximab; Ven, venetoclax.

Summary/Conclusion: A third of pts with del(17p)/*TP53* mut, a high-risk population with poor outcomes after CIT, did not receive NCCN-recommended regimens. Most pts without del(17p)/*TP53* mut received recommended tx across age/comorbidity groups. A majority of pts in the registry lacked del(17p)/*TP53* mut data and therefore may have received suboptimal tx. These results underscore a need for awareness of NCCN Guidelines recommendations to better inform tx decisions, especially in the community setting. *References:* Referenced with permission from the NCCN Clinical Practice Guidelines in Oncology (NCCN Guidelines®) for Chronic Lymphocytic Leukemia/Small Lymphocytic Lymphoma V.2.2017 - February 21, 2017 © National Comprehensive Cancer Network, Inc. 2020. Background: Ibrutinib, a once-daily Bruton's tyrosine kinase inhibitor, is approved in the European Union and other regions for the treatment of adult patients with chronic lymphocytic leukemia (CLL); it is the only targeted therapy associated with both a significant progression-free survival (PFS) and overall survival (OS) benefit in multiple randomized phase 3 studies compared with established chemotherapy/chemoimmunotherapy regimens in patients with previously untreated CLL/small lymphocytic lymphoma (SLL).
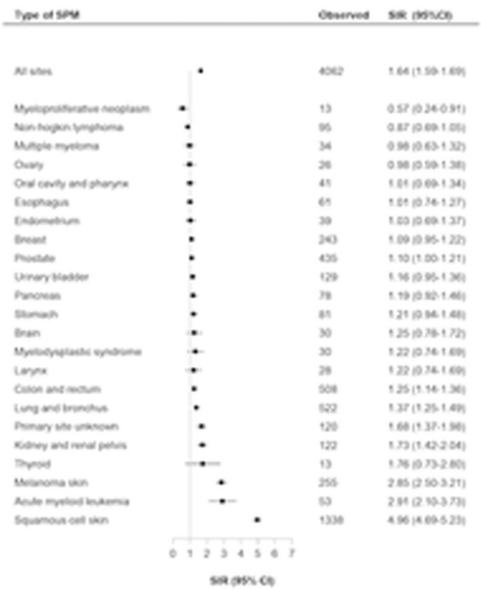
Aims: To report extended long-term follow-up data for first-line ibrutinib vs chlorambucil in older patients with CLL/SLL from the RESONATE-2 study.
Methods: The phase 3 RESONATE-2 study enrolled patients with previously untreated CLL/SLL who were aged ≥65 years and without del(17p) (N=269). Patients were randomly assigned in a 1:1 fashion to receive once-daily single-agent ibrutinib (420 mg) until disease progression or unacceptable toxicity (n=136) or chlorambucil (0.5–0.8 mg/kg) for up to 12 cycles (n=133). Long-term outcomes included PFS, OS, overall response rate (ORR), and safety. Responses were assessed by the investigator per 2008 iwCLL criteria.
Results: Overall, significant PFS benefit was sustained for patients treated with ibrutinib vs chlorambucil (hazard ratio [HR] 0.160 [95% confidence interval (CI) 0.111–0.230]) after up to 7 years of follow-up (median 74.9 months; range 0.1–86.8 months) (Figure). In addition to the overall population, PFS benefit with ibrutinib was observed in the subgroup of patients with high-risk genomic features, including unmutated IGHV (HR 0.109 [95% CI 0.063–0.189]) and del(11q) (HR 0.033 [95% CI 0.010–0.107]). At 6.5 years, 61% of patients treated with ibrutinib vs 9% of patients treated with chlorambucil remained progression-free. Ibrutinib treatment resulted in an OS rate of 78% at 6.5 years. The ORR for ibrutinib-treated patients was 92%, and the complete response (CR/CRi) rate rose to 34% at the current follow-up. For adverse events (AEs) of interest, ongoing rates remained low for grade ≥3 hypertension (year 5–6: 5%, n=4; year 6–7: 4%, n=3) and grade ≥3 atrial fibrillation (year 5–6: 1%, n=1; year 6–7: 1%, n=1); there were no grade ≥3 major hemorrhage events in years 5–7. Grade ≥3 AEs leading to dose reductions were observed in 1% (n=1) of patients in year 5–6 and 1% (n=1) of patients in year 6–7. For patients who had dose reductions due to any grade AEs (n=31 across years 0–8), 22/31 (71%) had resolution or improvement of the AE. Progressive disease was the primary reason for discontinuations in year 5–6 (5%, n=4) and year 6–7 (6%, n=4). AEs of any grade leading to discontinuations were observed in 3% (n=2) of patients in year 5–6 and none in year 6–7. With up to 7 years of follow-up, 47% of patients remain on single-agent ibrutinib.

Figure. Investigator-Assessed Progression-Free Survival.



Summary/Conclusion: With extended long-term follow-up from RESONATE-2, first-line treatment with ibrutinib demonstrated sustained PFS and OS benefit for patients with CLL/SLL, including patients with high-risk genomic features. Deepening of responses continued over time. Low rates of grade ≥3 AEs of interest were observed at up to 7 years of follow-up. Discontinuations and dose reductions due to AEs were rare, and most AEs leading to dose reduction resolved or improved. No new safety signals were observed, and ibrutinib continues to be well tolerated.

EP637 SECOND PRIMARY MALIGNANCIES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA: A NATIONWIDE, POPULATION-BASED STUDY IN THE NETHERLANDS

L. Van Der Straten [1,2,3,*], M.-D. Levin [2], M. A. Dinnessen [1], O. Visser [4], E. F. Posthuma [5,6], J. K. Doorduijn [7], A. W. Langerak [3], A. P. Kater [8], A. G. Dinmohamed [1,8,9,10]

[1]Research and Development, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [2]Internal Medicine, Albert Schweitzer hospital, Dordrecht, [3]Immunology, Erasmus MC, Rotterdam, [4]Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [5]Internal Medicine, Reinier de Graaf hospital, Delft, [6]Hematology, Leiden University Medical Center, Leiden, [7]Hematology, Erasmus MC Cancer Institute, Rotterdam, [8]Hematology, Amsterdam UMC, Lymphoma and Myeloma Center Amsterdam, Amsterdam, [9]Public Health, Erasmus MC, University of Rotterdam, Rotterdam, [10]Hematology, Amsterdam UMC, Vrije Universiteit Amsterdam, Amsterdam, Netherlands

Background: The longevity of patients with chronic lymphocytic leukemia (CLL) improved progressively over the past decades due to efficacious therapies in the upfront and relapsed/refractory setting. The downside of this improved longevity is the development of second primary malignancies (SPMs), which, in turn, may attribute to morbidity and excess mortality in CLL patients. Therefore, awareness of the magnitude of SPMs in CLL is essential for health-related planning and surveillance activities.
Aims: In this nationwide, population-based study, we assessed the risk of SPM development in CLL patients diagnosed in the Netherlands compared with the general Dutch population.
Methods: We selected all CLL patients diagnosed in the Netherlands between 1989-2018 from the Netherlands Cancer Registry. To counteract surveillance bias, an SPM was defined as a malignancy occurring at least six months after CLL diagnosis. Of note, transformations were regarded as the same entity as the primary tumor and basal cell carcinomas were excluded from the analysis since they were not registrated nationwide throughout the entire study period. CLL patients were followed from the date of diagnosis to SPM development, death, or end of follow-up (December 31, 2018, whichever occurred first). Standardized incidence ratios (SIRs)—with associated 95% confidence intervals (CIs)—were calculated using the exact Poisson method as the ratio of the observed malignancies in the CLL population and the expected malignancies in an age-, sex-, and period-matched group from the general population.
Results: A total of 23,622 CLL patients (61% males; median age 69 years) were included in this analysis, of whom 4,062 (17%) subsequently developed an SPM after a median follow-up time of 4 years (IQR:1-8 years). Overall, the risk of SPMs in CLL patients was 64% higher than in the general population (SIR 1.64; 95% CI: 1.59-1.69; Figure 1). The increased risk was observed both for solid (SIR 1.72; 95%CI 1.66-1.77) and hematological malignancies (SIR 1.24; 95%CI 1.11-1.37) with no sex-related differences. However, patients aged 18-60 were more at risk for the development of an SPM (SIR 1.88; 95%CI 1.76-2.01) as compared to patients aged above 60 years (SIR 1.58; 95%CI 1.52-1.63). The overall risk of solid SPMs was significantly heightened for the following sites (in order of increasing risk): skin (squamous cell and melanoma), kidney and renal, primary site unknown, lung, colon and rectum and prostate. As for hematological malignancies, the risk of developing acute myeloid leukemia (AML) was significantly increased compared to the general population. Conversely, myeloproliferative neoplasms were less frequently observed than in the general population (Figure 1).

Summary/Conclusion: In this nationwide, population-based study, we demonstrated that CLL patients have an increased risk of developing various SPMs compared to the general population. SPMs in CLL may originate from shared pathophysiological factors, environmental exposures, host characteristics, or some combination of the three. In addition, CLL-related therapy could have attributed to the development of an SPM, particularly in AML. Collectively, our study findings can be used in the communication between patient and physician about appropriate surveillance activities and interventions to counteract the increased morbidity and excess mortality associated with SPMs. The current study serves as a benchmark to assess how the spectrum of SPMs may alter in a contemporary era with chemo-free treatment options.

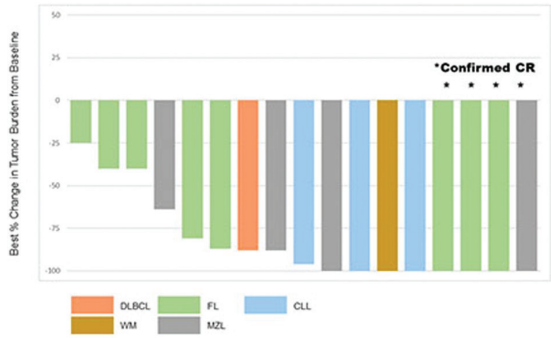
EP638 TG-1701, A SELECTIVE BRUTON TYROSINE KINASE (BTK) INHIBITOR, AS MONOTHERAPY AND IN COMBINATION WITH UBLITUXIMAB AND UMBRALISIB (U2) IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) AND LYMPHOMA

C. Cheah [1,*], W. Jurczak [2], M. Lasica [3], N. Wickham [4], T. Wróbel [5], J. Walewski [6], C. Yannakou [7], S. Cheung [8], K. Lewis [1], M. Długosz-Danecka [2], K. Giannopoulos [9], H. Miskin [10], J.-P. Tang [10], E. Normant [11], O. O'Connor [10], A. Ricart [10], C. Tam [3]

[1]Haematology, Linear Clinical Research, Nedlands, Australia, [2]Haematology, Maria Sklodowska-Curie National Research Institute of Oncology, Krakow, Poland, [3]Haematology, St. Vincent Hospital and University of Melbourne, Melbourne, [4]Haematology, Ashford Cancer Centre Research, Adelaide, Australia, [5]Haematology, Wroclaw Medical University, Wroclaw, [6]Haematology, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland, [7]Haematology, Epworth HealthCare, Melbourne, Australia, [8]Haematology, Ashford Cancer Centre Research, Adelaide, [9]Haematology, St John's Cancer Centre, Lublin, Poland, [10]TG Therapeutics, New York, United States, [11]Haematology, TG Therapeutics, New York, United States

Background: TG-1701 is a selective, covalent BTK inhibitor administered once daily (QD). Both the "U2" combination (anti-CD20 mAb ublituximab + the PI3Kδ-CK1ε inhibitor umbralisib) and BTK inhibition are highly active in treatment-naïve (TN) and relapsed/refractory (R/R) CLL, each having previously demonstrated superiority over standard chemoimmunotherapy. Herein we report the results of the dose escalation of TG-1701 monotherapy and TG-1701+U2.

Aims: The primary objectives of the study are to characterize the safety profile and define the recommended Ph 2 doses for the drugs alone and in combination.



Methods: Patients with R/R CLL, MCL and Waldenström's (WM) were enrolled in an ongoing Ph 1 study initially evaluating dose escalation (DE) of oral TG-1701 QD continuously administered in 28-day cycles (100, 200, 300, and 400 mg). After characterizing the safety profile of TG-1701 monotherapy, we implemented a parallel DE arm of TG-1701+U2. Select dose levels of TG-1701 monotherapy were expanded. All patients were treated until disease progression, unacceptable toxicity, or investigator/patient decision to withdraw.

Results: As of 03 February 2021, 123 patients were treated with TG-1701 as follows: 25 in the monotherapy DE arm, 61 in the 200 mg disease-specific cohorts (20 CLL [5 TN], 21 MCL [4 TN], 20 WM [8 TN]), 20 in the 300 mg CLL cohort (4 TN), and 17 in the 1701+U2 DE arm. The median # of prior therapies was 1 (range, 1 - 10). All patients were BTKi-naïve. All 123 patients were evaluable for safety. TG-1701 was well tolerated and the maximum tolerated dose (MTD) for monotherapy was not reached at 400 mg (demonstrating near 100% saturation of the BTK at all dose levels studied). Treatment emergent adverse events (TEAE) of clinical interest included atrial fibrillation (AF 4.0% of patients, G ≥3 in 1 case), G ≥3 hypertension (2.4%), and bleeding events (18.7%, all G1-2). No cases of ventricular tachyarrhythmia were reported. TEAEs leading to TG-1701 dose reduction occurred in 6.5% of patients. TEAEs leading to treatment discontinuation occurred in 1.6% of patients (AF, COVID-19). At the data cut-off, 119 patients were evaluable for response, including 40 in DE (Table). The median duration of response has not been reached among responders overall. The median follow-up (mFU range) was 15.9 mos (1.3 - 28.6+) in DE and 8.5 mos (1.4 -15.6+) in disease-specific cohorts. No complete responses (CR) were confirmed on TG-1701 monotherapy. The objective response rate (ORR) for 1701+U2 was 82.3% with a 23.5% CR rate. Best change from baseline in tumor burden in patients in the 1701+U2 combination arm is presented in the figure below.

Table. Response per investigator review by treatment group

	DE arm (N = 23)	200 mg CLL (N = 20)	200 mg MCL (N = 20)	200 mg WM (N = 20)	300 mg CLL (N = 19)	1701+U2 DE arm (N = 17)
ORR, %	56.5	95.0	60.0	95.0	100	82.3
CR, %	0	0	0	0	0	23.5
Very good PR, %	4.3			0		5.9
PR, %	47.8	95.0	60.0	70.0	100	52.9
Minor response, %	4.3			25.0		0
mFU mos	17.5	11.6	8.2	9.7	5.8	14.3

Best change from baseline in tumor burden in patients in the combination arm

Summary/Conclusion: TG-1701 exhibits an encouraging safety and efficacy profile. The combination of 1701+U2 has been well tolerated and dose escalation continues. The combination shows enhanced depth of response over TG-1701 monotherapy. Recruitment to this study (NCT03671590) continues.

EP639 ZANUBRUTINIB MONOTHERAPY IN PATIENTS WITH RELAPSED OR REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA: 34-MONTH FOLLOW-UP RESULTS

W. Xu [1,*], S. Yang [2], K. Zhou [3], L. Pan [4], Z. Li [5], J. Zhou [6], S. Gao [7], D. Zhou [8], J. Hu [9], R. Feng [10], H. Huang [11], T. Wang [5], M. Ji [12], H. Guo [12], J. Huang [12], W. Novotny [12], S. Feng [12], J. Li [1]

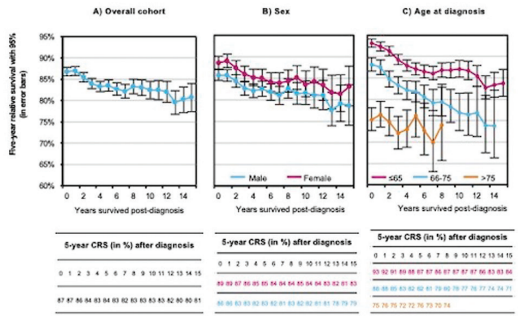
of Southern Medical University, Guangzhou, [11]The 1st Hospital of Soochow University, Suzhou, China, [12]BeiGene (Beijing) Co., Ltd., Beijing, China, BeiGene (Shanghai) Co., Ltd., Shanghai, China, and BeiGene USA, Inc., San Mateo, United States

Background: Zanubrutinib is a highly selective, potent, and irreversible Bruton's tyrosine kinase (BTK) inhibitor approved in China for the treatment of adult patients with relapsed/refractory (R/R) chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL). The previous publication of this study reported that zanubrutinib is highly active in R/R CLL/SLL, with a well-tolerated safety profile (*J Hematol Oncol.* 2020;13:48). We present here the long-term results of this study.
Aims: To evaluate the efficacy, safety, and tolerability of zanubrutinib in patients with R/R CLL/SLL.
Methods: In this single-arm, multicenter, phase 2 study (NCT03206918), patients with R/R CLL/SLL received oral zanubrutinib (160 mg twice a day) continuously until progressive disease (PD) or unacceptable toxicity. Efficacy endpoints including overall response rate (ORR), duration of response (DOR), and progression-free survival (PFS) were assessed by an independent review committee (IRC) per International Workshop on CLL guidelines (*Blood*. 2008;111:5446) or the Lugano Classification (*J Clin Oncol*. 2014;32:3059) for CLL and SLL, respectively.
Results: Ninety-one patients (82 with CLL; 9 with SLL) were enrolled from 11 sites in China. Median age was 61 years (range, 35-87). Most patients had ≥1 poor prognostic variable, including unmutated immunoglobulin heavy chain variable region gene *(IGHV*; 56.0%), del(17p) or TP53 mutation (24.2%), and del(11q) (22%).
With a median 33.9-mo follow-up period (range, 0.8-41.4), 31 patients (34.1%) discontinued treatment primarily due to progressive disease (PD) in 15 patients and adverse events (AEs), regardless of relation to study drug, in 14 patients. Most patients (66%) were still on zanubrutinib treatment. The efficacy data are presented in the **Table**. The overall response rate was generally consistent across all subgroups analyzed, including those with unfavorable prognostic factors. Patients with del(17p) and/or TP53 mutation and del(11q) achieved high response rates of 91% (95% CI, 70.8%>98.9%) and 100% (95% CI, 83.2%>100%), respectively.
The most commonly reported treatment-emergent adverse events (TEAEs) are listed in the **Table**. Most AEs regarding to lab abnormalities were with low CTCAE severity (grade 1-2) and without clinical consequences. Second primary malignancies were reported in 5 patients (2 gastric adenocarcinoma; 1 each of colon cancer, breast cancer, and rectal cancer). Only 1 patient reported atrial fibrillation (grade 2). TEAEs leading to death were reported in 6 patients (2 pneumonia; 1 each for cardiopulmonary failure, brain herniation, and multiple organ dysfunction syndrome; 1 with cardiac failure, pneumonia, and respiratory failure). TEAEs leading to dose modification were reported in 42 (46.2%) patients. Commonly reported TEAEs leading to treatment discontinuation included pneumonia (n=4) and hepatitis B (n=2).

Table.

Efficacy, n (%)	**N=91**	
CR	6 (6.6)	
PR	63 (69.2)	
PR-L	11 (12.1)	
SD	3 (3.3)	
PD	3 (3.3)	
Not evaluable[a]	2 (2.2)	
Discontinued before first assessment, n (%)	3 (3.3)	
Overall response rate (95% CI) (%)	87.9 (79.4, 93.8)	
Estimated progression/death event free rate at		
24 months (95% CI) (%)	80.5 (70.5, 87.4)	
36 months (95% CI) (%)	68.1 (56.6, 77.4)	
DOR event free rate at		
24 months (95% CI) (%)	83.4 (73.2, 90.0)	
36 months (95% CI) (%)	69.9 (57.0, 79.6)	
Common nonhematologic AEs (>30% any grade), n (%)	**Any Grade**	**Grade ≥3**
Upper respiratory tract infection	51 (56.0)	11 (12.1)
Hematuria	39 (42.9)	0
Pneumonia	34 (37.4)	22 (24.2)
Purpura	31 (34.1)	0
Hypokalemia	28 (30.8)	7 (7.7)
Common hematologic AEs,[b] n (%)		
Neutropenia	71 (78.0)	46(50.5)
Thrombocytopenia	48 (52.7)	15 (16.5)
Anemia	36 (39.6)	10 (11.0)

AE, adverse event; CR, complete response; DOR, duration of response; PD, progressive disease; PR, partial response; PR-L, partial response with lymphocytosis; SD, stable disease.
[a] 'Not evaluable' were due to missing anatomy imaging of 2 patients.
[b] Incidence of neutropenia, thrombocytopenia, and anemia were summarized based on group term.



Summary/Conclusion: Results with longer follow-up continue to show a high response rate. Deep and durable responses were achieved in all patient subgroups including patients with high-risk cytogenetics. Data support the tolerability of long-term zanubrutinib treatment in R/R CLL/SLL, with no new safety signals identified.

EP640 CONDITIONAL RELATIVE SURVIVAL AMONG PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA: A NATIONWIDE, POPULATION-BASED STUDY IN THE NETHERLANDS

L. Van Der Straten [1,2,3,*], M.-D. Levin [2], O. Visser [4], E. F. Posthuma [5,6], J. K. Doorduijn [7], A. W. Langerak [3], A. P. Kater [8], A. G. Dinmohammed [1,8,9,10]

[1]Research and Development, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [2]Internal Medicine, Albert Schweitzer hospital, Dordrecht, [3]Immunology, Erasmus MC, Rotterdam, [4]Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [5]Internal Medicine, Reinier The Graaf Hospital, Delft, [6]Hematology, Leiden University Medical Center, Leiden, [7]Hematology, Erasmus MC Cancer Institute, Rotterdam, [8]Hematology, University of Amsterdam, Lymphoma and Myeloma Center Amsterdam, Amsterdam, [9]Public Health, Erasmus MC, University of Rotterdam, Rotterdam, [10]Hematology, Amsterdam UMC, Vrije Universiteit Amsterdam, Amsterdam, Netherlands

Background: Therapeutic advances in chronic lymphocytic leukemia (CLL) across various therapy lines over the past decades significantly improved the outcomes of CLL patients at the population level. The greater longevity of CLL patients requires measures that capture the prognosis for long-term CLL survivors because survival estimates measured from diagnosis are no longer relevant. Conditional survival is an appropriate measure in this respect because it considers the survival likelihood of patients who have already survived several years post-diagnosis. At present, studies on conditional relative survival (CRS) in CLL have hitherto been lacking.
Aims: This nationwide, population-based study examined up-to-date estimates of 5-year relative survival (RS) at diagnosis and for each additional year survived up to 15 years post-diagnosis among CLL patients in the Netherlands.
Methods: We selected all CLL patients diagnosed in the Netherlands between 1989 and 2018—with survival follow-up through 2019—from the Netherlands Cancer Registry. We used RS to approximate the disease-specific survival. RS was calculated as the ratio of the observed patients' overall survival over the expected survival of an age-, sex- and period-matched group from the general population. We estimated RS using the hybrid approach to provide up-to-date survival estimates for patients diagnosed between 1989 and 2018 who were alive during the follow-up interval of 2008-2019. The survival estimates produced herein can be interpreted as the predicted survival probabilities of patients during 2008-2019. Five-year RS was stratified by sex and age at diagnosis (18-65, 66-75, and >75 years) and calculated up to fifteen years post-diagnosis. Differences in survival estimates were considered significant when the 95% confidence intervals (CIs) did not overlap
Results: A total of 22,840 CLL patients (61% males; median age, 69 years) were diagnosed in the Netherlands during 1989-2018, of whom 16,439 (72%) were at risk under the hybrid approach. Overall, 5-year RS was 87% (95% CI, 86%>88%) at diagnosis and gradually decreased over time, reaching 81% (95% CI, 77%>84%) at 15 years post-diagnosis (Figure 1A). This pattern was observed irrespective of sex, with no obvious sex differential in survival over time (Figure 1B). There was, however, an apparent age differential in 5-year RS at diagnosis, with corresponding estimates (95% CI) of 93% (92%>94%), 88% (87%>90%), and 75% (73%>79%) for patients across the three age groups, respectively (Figure 1C). Five-year RS decreased with each additional year survival post-diagnosis irrespective of age. As a result, the prognostic effect of age mainly persisted during the follow-up period.

Summary/Conclusion: CLL patients continue to experience considerable excess mortality in contemporary clinical practice—as compared to equivalent groups from the general population—despite surviving up to 15 years post-diagnosis. This finding might be explained by the indolent and largely incurable nature of CLL. As such, further progress is warranted to decrease excess mortality in CLL. Furthermore, our data underscore that excess mortality is more significant in elderly patients, especially among over 75-year-olds. Therefore, age above 75 might be considered in prognostic models such as the CLL-IPI to enhance prognostication. Collectively, CRS statistics may offer CLL patients and their physicians information to engage in dialogue about personal health-related planning and surveillance activities.

EP641 SYSTOLIC FUNCTION OF THE LEFT VENTRICULAR MYOCARDIAL IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA RECEIVING IBRUTINIB.

E. Emelina [1,*], G. Gendlin [1], I. Nikitin [1]

[1]Hospital Therapy №2, Pirogov Russian National Research Medical University, Moscow, Russian Federation

Background: The effect of anticancer drugs on the systolic function of the left ventricular (LV) myocardium determines the prognosis and survival of patients (pts). The systolic function of the LV myocardium in pts with chronic lymphocytic leukemia (CLL) treated with ibrutinib (Ib) has not been sufficiently studied.
Aims: Evaluate LV myocardial systolic function in pts with CLL receiving Ib.
Methods: We examined 227 pts with CLL in dynamics, receiving Ib, at the age of 66.0 (32.0-91.0) years, among which 144 men at the age of 66.0 (32.0-91.0) years and 83 women at the age 65.0 (39.0-83.0) years. We examined 116 pts before the start of Ib therapy and after 3-30 months, median 15.0 (10.0-21.0) months of Ib treatment. Other111 pts at the time of the first examination had already received Ib for 9.0 (6.0-14.0) months, they were also examined in dynamics: the interval between visits 1 and 2 was from 3 to 32 months, the median was 15.0 (10.0-23.5) months. All pts underwent echocardiography (Echo) with tissue Doppler at 2 follow-up visits. Indicators of LV systolic function were compared as dependent and independent values.
Results: In a longitudinal comparison, patients at visit 2 (n = 125) showed a decrease in the ejection fraction (EF) from 68.3 (63.4-72.7)% to 66.9 (62.4-70.9)% Simpson (p = 0.024). We separately analyzed changes in systolic function in pts with baseline EF greater than / equal to 60% (n = 112). In this pts group, there was also a decrease in EF from 69.5 (58.4-82.5)% to 67.2 (51.7-84.5)% according to Simpson (p = 0.004), which indicates a clear trend towards decrease in systolic function of the LV myocardium. When comparing Echo parameters as independent values in pts treated with Ib (n = 111) with pts before Ib treatment, an increase in the indexed end diastolic volume (iEDV) and the indexed end sistolic volume (iESV) was noted. Thus, in the pts group receiving Ib, iEDV was 55.1 (47.3-64.7) ml versus 49.8 (44.1-59.4) ml in patients before Ib treatment (p = 0.01), iESV in pts receiving Ib 17.7 (13.5-22.8) ml versus 15.8 (12.1-20.1) ml in pts before starting Ib treatment (p = 0.04). Probably, the tendency to dilatation of the LV chamber leads to a gradual decrease in LV systolic function and, under certain conditions, to a sharp decrease in EF. Thus, we encountered a sharp drop in EF in a 74-year-old patient who was added obinutuzumab to Ib. A previously stable patient after 4 injections of obinutuzumab developed heart failure with severe dyspnea at the level of functional class 3, a sharp decrease in EF from 58.1% to 35.2%, dilatation of the LV cavity - the end-diastolic volume increased from 119.7 ml to 165. 0 ml. Thus, it should be borne in mind that the combination of Ib with anticancer drugs affecting cardiomyocytes can lead to a sharp drop in EF with the development of severe heart failure.
Summary/Conclusion: In patients with CLL receiving ibrutinib, there is a tendency towards a decrease in systolic LV myocardial function. An increase in the LV cavity in patients with CLL, taking Ib, may be one of the reasons for a decrease in systolic LV myocardial function.The use of Ib with other antineoplastic drugs that affect the systolic function of the myocardium can lead to a sharp drop in the LV ejection fraction and the development of severe heart failure. Probably, in patients taking Ib, the vulnerability of myocardial systolic function and sensitivity to the effects of various agents on cardiomyocytes is formed.

EP642 PRELIMINARY RESULTS OF THE PHASE 2 STUDY OF ZANUBRUTINIB IN PATIENTS WITH PREVIOUSLY TREATED B-CELL MALIGNANCIES INTOLERANT TO IBRUTINIB AND/OR ACALABRUTINIB

M. Shadman [1,*], J. P. Sharman [2], M. Y. Levy [3], R. Porter [4], S. F. Zafar [5], J. M. Burke [6], A. Chaudhry [7], B. Freeman [8], J. Misleh [9], H. A. Yimer [10], J. L. Cultrera [11], T. H. Guthrie [12], E. Kingsley [13], S. S. Rao [14], D.-Y. Chen [15], X. Zhang [15], A. Idoine [15], A. Cohen [15], S. Feng [15], J. Huang [15], I. Flinn [16]

Sammons Cancer Center, Dallas, [4]SSM Health Dean Medical Group, Madison, [5]Florida Cancer Specialists & Research Institute, Fort Myers, [6]Rocky Mountain Cancer Centers, Aurora, [7]Summit Cancer Centers, Spokane, [8]Summit Medical Group, Florham Park, [9]Medical Oncology Hematology Consultants PA, Newark, [10]Texas Oncology-Tyler, Tyler, [11]Florida Cancer Specialists & Research Institute, Leesburg, [12]GenesisCare, Jacksonville, [13]Comprehensive Cancer Centers of Nevada, Las Vegas, [14]Alpha Med Physicians Group, Tinley Park, [15]BeiGene (Beijing) Co., Ltd., Beijing, China and BeiGene USA, Inc., San Mateo, [16]Sarah Cannon Research Institute/Tennessee Oncology, Nashville, United States

Background: Many patients with B-cell malignancies require continuous treatment with Bruton tyrosine kinase inhibitors (BTKi). Adverse events are a common reason for ibrutinib or acalabrutinib discontinuation. Early data from BGB-3111-215 showed zanubrutinib was well tolerated in patients with B-cell malignancies who were intolerant to either ibrutinib or acalabrutinib. Here we report preliminary results of the BGB-3111-215 trial, with a median follow-up of 4.2 months.
Aims: To assess the safety of zanubrutinib and recurrence of adverse events that led to prior BTKi intolerance.
Methods: Patients meeting protocol criteria for intolerance to ibrutinib, acalabrutinib, or both (without documented progressive disease) were given zanubrutinib monotherapy (160 mg twice daily or 320 mg once daily). Recurrence of adverse events that led to intolerance of prior BTKi and additional safety measures were assessed based on the Common Terminology Criteria for Adverse Events v5.0. Investigators determined responses using disease status at study entry as baseline and established disease criteria.
Results: As of November 1, 2020 (data cutoff), 44 patients (n=34 chronic lymphocytic leukemia/small lymphocytic lymphoma, n=6 Waldenström macroglobulinemia, n=2 mantle cell lymphoma, n=2 marginal zone lymphoma) were enrolled, received ≥1 dose of zanubrutinib, and analyzed for safety. The median age was 70.5 y (range, 49-91); median duration of treatment was 4.2 months (range, 0.1-12.6). The median number of prior regimens was 2 (range, 1-12). Regarding prior BTKi, 39 patients received ibrutinib only, 4 received ibrutinib and acalabrutinib, and 1 received acalabrutinib only. The median number of ibrutinib- or acalabrutinib-intolerant adverse events per patient was 2 (range, 1-5). 83% of ibrutinib and 78% of acalabrutinib intolerant events did not recur on zanubrutinib; **Table**. At data cutoff, 43 patients remained on treatment; 1 withdrew consent due to zanubrutinib-unrelated grade 3 syncope. Overall, 34 patients (77.3%) reported any adverse event; most commonly reported adverse events were myalgia (n=9; 20.5%), contusion (n=8; 18.2%), dizziness (n=7; 15.9%), fatigue (n=7; 15.9%), and cough (n=5; 11.4%). Grade ≥3 adverse events were reported in 6 patients (13.6%), serious adverse events in 1 patient (2.3%, febrile neutropenia and salmonella infection), adverse events requiring dose interruptions in 6 patients (13.6%), and adverse events leading to dose reduction in 2 patients (4.5%). No adverse events led to zanubrutinib discontinuation. No deaths were reported. All efficacy evaluable patients (26/26 [100%]) maintained (10 [38.5%]) or achieved deepening (16 [61.5%]) of their response.

Recurrence and Severity Change of Adverse Events Leading to Ibrutinib or Acalabrutinib Intolerance

	Adverse events leading to ibrutinib and acalabrutinib intolerance, N	Recurrence on zanubrutinib, n (%)		Severity change of recurrence on zanubrutinib, n (%)	
		No	Yes	Recurred at lower severity	Recurred at same severity
Ibrutinib	87	72 (82.8)	15 (17.2)	13 (86.7)	2 (13.3)
Acalabrutinib	9	7 (77.8)	2 (22.2)	1 (50.0)	1 (50.0)

Note: Multiple events of the same preferred term for a patient are counted once for the event per the worst grade experienced before and after enrollment.

Summary/Conclusion: Zanubrutinib provided an additional treatment option after intolerance to other BTKi, demonstrating tolerability and sustained or improved efficacy. Updated results will be presented.

EP643 A PHASE 1A/B DOSE ESCALATION STUDY OF THE MUTATION AGNOSTIC BTK/FLT3 INHIBITOR LUXEPTINIB (CG-806) IN PATIENTS WITH RELAPSED OR REFRACTORY B-CELL MALIGNANCIES

Background: Luxeptinib (CG-806) is a potent, non-covalent oral inhibitor designed to target BTK and FLT3. It suppresses BCR signaling pathways (through inhibition of LYN, SYK, BTK, AKT, ERK) in cell lines and primary CLL cells, kills malignant B-cells insensitive to ibrutinib or venetoclax at low nM concentrations, and shows enhanced activity in combination with venetoclax. Luxeptinib is currently being evaluated in a Phase 1a/b trial in patients with relapsed or refractory B-cell malignancies (NCT03893682).
Aims: Primary objectives are to assess the safety and tolerability of Luxeptinib and determine the recommended Phase 2 dose for future clinical trials in patients with R/R CLL/SLL or NHL. Key secondary objectives include elucidation of the pharmacokinetic (PK) and pharmacodynamic (PD) characteristics, and evidence of antitumor activity.
Methods: Luxeptinib is administered continuously as oral capsules BID in 28-day cycles, in ascending cohorts of 3 patients. Treatment emergent adverse events (TEAEs) and tumor responses are evaluated per disease specific guidelines.
Results: As of December 4, 2020, a total of 16 patients (age 65.8 ± 7.9 years, 9 CLL/SLL, 3 follicular lymphoma, 1 Richter's transformation lymphoma, 1 Waldenstrom's macroglobulinemia, 1 mantle cell lymphoma, 1 diffuse large B cell lymphoma) with a median of 3 prior systemic regimens (range of 1 - 12) have been treated with luxeptinib at doses of 150 mg (n=1), 300 mg (n=1), 450 mg (n=6), 600 mg (n=4) and 750 mg (n=4). The most common drug-related or possibly drug-related TEAEs included nausea in 6 (37.5%), vomiting in 5 (31.3%), diarrhea and neutropenia in 4 (25%) each, and fatigue in 3 (12.5%) patients. Drug related grade ≥ 3 TEAEs included neutropenia (n=3, 18.8%, no fevers were reported), thrombocytopenia, diarrhea, hypertension, and headache (n=1, 6.3% each). One patient, who had developed grade 2 hypertension during screening and prior to dosing on C1D1, experienced grade 4 hypertension after Luxeptinib treatment at 750 mg BID for 5 days. While this was considered a DLT per protocol, CG-806 plasma levels in this patient were lower than those observed in patients at this and lower dose levels. No drug-related hypertension has been observed in any other patient treated to date. The steady-state (C_{min}) plasma levels of luxeptinib in patients treated with ≥ 600 mg BID were generally in the 1-2µM range and were sustained over multiple cycles. PD analysis demonstrated that C_{min} of Luxeptinib in the plasma of patients treated with doses of 300 mg or higher significantly reduced levels of phosphorylated BTK, SYK, ERK and FLT3 in EOL-1 reporter cells in a plasma inhibitor activity assay, demonstrating multi-target engagement. All 3 CLL patients with elevated lymphocyte counts pre-treatment experienced on-target lymphocytosis upon initiation of luxeptinib therapy.
Summary/Conclusion: Luxeptinib has a favorable safety profile in patients treated with 150 mg to 600 mg BID over multiple cycles. A single DLT (grade 4 hypertension in one patient with pre-existing hypertension) led to expansion of the 750 mg dose level to 6 patients. Pharmacodynamic studies documented inhibition of SYK, BTK and ERK in the BCR signaling pathway. Enrollment of patients with R/R CLL/SLL and NHL at dose level 5 (750 mg) is ongoing and updated clinical data will be presented at the meeting.

EP644 TEN-YEAR FOLLOW-UP OF 415 CLL PATIENTS TREATED WITH FLUDARABINE CYCLOPHOSPHAMIDE-BASED CHEMOIMMUNOTHERAPY IN THE FRONTLINE ARCTIC AND ADMIRE TRIALS, A COMPREHENSIVE ASSESSMENT OF PROGNOSTIC FACTORS

D. Allsup [1,*], Z. Criag [2], D. Howard [2], D. Cairns [2], A. Hockaday [2], A. Bloor [3], Z. Soe [4], C. Pepper [5], S. Anna [6], T. Munir [4], A. Rawstron [7], P. Hillmen [8]

[1]*Centre for Atherothrombosis and Metabolic Disease, Hull York Medical School, Hull,* [2]*Clinical Trials Research Unit, University of Leeds, Leeds,* [3]*Haematology, The Christie NHS Foundation Trust, Manchester,* [4]*Haematology, St James Institute of Oncology, Leeds,* [5]*Clinical and Experimental Medicine, Brighton and Sussex Medical School, Brighton,* [6]*Department of Oncology, University of Oxford, Oxford,* [7]*Haematological Malignancy Diagnostic Service,* [8]*Haematology, St James University Hospital, Leeds, United Kingdom*

Background: ADMIRE and ARCTIC were phase II randomised controlled trials recruiting between July 2009-September 2012 comparing fludarabine, cyclophosphamide and rituximab (FCR) with or without mitoxantrone (FCMR) or the addition of mitoxantrone with low dose of rituximab (FCM-miniR).
Aims: To assess how pre-specified prognostic factors, minimal residual disease (MRD), toxicity and number of treatment cycles affect progression free survival (PFS) and overall survival (OS) in the combined ADMIRE/ARCTIC cohort.
Methods: ARCTIC/ADMIRE provided long-term data on 415 previously untreated CLL patients. Kaplan-Meier survival estimates, and Cox proportional hazards models assessed PFS and OS according to potential prognostic factors, toxicities and treatment cycles received. Penalised multivariable Cox regression identified the prognostic factors predictive of PFS and OS. Multiple imputation by chained equations was used to account for missing data.
Results: Median duration of follow-up is 84 months. There is no significant difference in the hazard ratios for PFS or OS between FCR and FCM-R and between FCR and FCM-miniR. Overall PFS is 65 months (95% confidence interval (CI) 56,72) and OS is 108 months (CI 101,not reached).
Univariable Cox regression analysis of PFS by pre-treatment prognostic factors revealed unmutated IGHV genes (UM-IGHV), 17p/11q deletion, TP53 mutations, CLL-IPI, %CD38+ cells, decreasing CD20 mean fluorescence intensity (MFI), %CD49d+ cells, CCR6 (MFI and %+ cells) and LAIR1 MFI to be associated with shortened PFS. A baseline multivariable penalised Cox regression analysis of PFS found UM-IGHV, CCR6, 17p/11q deletion, TP53 mutations, CD49d and SF3B1 mutations remained prognostic for PFS.
Similar univariable analysis of OS found increasing age, positive direct Coombs test, UM-IGHV, deletion 17p, TP53 mutations, CLL-IPI and %CD49d+ cells, and decreasing CCR6 MFI and LAIR1 MFI to be associated with shortened OS. Multivariable penalised Cox regression by pre-treatment factors found age, %CD49d+ cells, d17p, TP53 mutations and direct Coombs test remained prognostic for OS. Mutations in ATM, BIRC3, NOTCH1 and SF3B1 are not associated with shortened OS.
Detectable marrow MRD ($>10^{-4}$) 3 months after therapy completion is associated with inferior PFS and OS on univariable analysis. Incorporation of MRD into a prognostic multivariable model revealed that UM-IGHV, MRD, d17p/TP53 mutations and %CD49d+ cells are predictive of PFS. In the same model for OS age, MRD, %CD49d+ cells, d17p/TP53 mutations and direct coombs test are predictive of OS (Table 1).
Grade 3/4 infection-related toxicities are associated with inferior PFS and OS however the occurrence of other toxicities are not associated with inferior outcomes. Hypogammaglobulinemia is not associated with the probability of grade 3/4 infection or shortened PFS/OS. Participants who received 3 cycles or less of the prescribed 6 cycles for reasons other than progressive disease had inferior PFS and OS and more likely to have other poor prognostic features.

Table 1 | Multivariable penalised Cox regression model results for PFS and OS

	Progression-free survival			Overall survival		
	Coefficient (standard error)	Hazard ratio (95% CI)	Frequency variable selected from 42 imputed datasets^	Coefficient (standard error)	Hazard ratio (95% CI)	Frequency variable selected from 42 imputed datasets^
VH mutation status Unmutated vs. Mutated	0.328 (0.13)	1.39 (1.08 to 1.79)	42	N/A*		
3 month post-treatment marrow MRD status Positive vs. Negative	1.03 (0.12)	2.81 (2.22 to 3.56)	42	0.39 (0.18)	1.48 (1.04 to 2.1)	42
Standardised CD49d (% of positive cells)	0.0302 (0.0416)	1.03 (0.95 to 1.12)	31	0.0737 (0.0686)	1.08 (0.941 to 1.23)	36
Deletion 17p &/or mutated TP53 Yes vs. No	0.0862 (0.1)	1.09 (0.896 to 1.33)	20	0.098 (0.146)	1.1 (0.828 to 1.47)	24
Age at randomisation >65 years vs. ≤65 years	N/A*			0.129 (0.15)	1.14 (0.847 to 1.53)	42
Direct Coombs test Positive vs. Negative	N/A*			0.0496 (0.147)	1.05 (0.788 to 1.4)	24

* Variables marked as N/A were penalised and therefore not selected as prognostic for either PFS or OS in the multivariable penalised Cox model.
Other variables included in the model but selected in 5 or fewer imputed datasets in both the PFS and OS models are not presented.
^ Multiple imputation by chained equations (MICE) was used to account for missing data, with 42 imputed datasets generated. A penalised Cox regression model was run for each imputed dataset. Variables frequently selected from the imputed datasets by the penalised Cox model are considered to be more predictive of the outcome than those not selected or selected infrequently. Each variable selected contributes to predicting the outcome in combination with the other selected variables, even if it is not significantly associated with the outcome itself.

Summary/Conclusion: A multivariable analysis of prognostic factors and MRD reveals the key prognostic factors for shortened OS to be age, MRD, d17p/TP53 mutation and CD49d. Mutations in ATM, BIRC3, NOTCH1 and SF3B1 were not predictive of shortened OS and many other factors routinely assessed for CLL prognostication have little value. Patients discontinuing therapy early or who experience significant infection-related toxicity have inferior outcomes and should be considered high risk for early progression.

EP645 OUTCOME OF 100 TP53-DISRUPTED CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS TREATED FRONT-LINE WITH IBRUTINIB. A REAL-LIFE CAMPUS CLL STUDY.

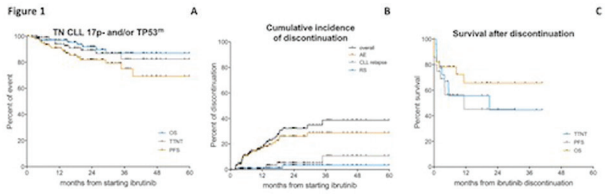
Background: Disruption of the TP53 gene, including 17p13 deletion (17p-) and/or *TP53* gene mutation (TP53m), is a negative prognostic biomarker in chronic lymphocytic leukemia (CLL) associated with genome complexity, early relapse and shorter survival after chemo-immunotherapy. Although the first-in class BTK inhibitor ibrutinib has proven to be highly active in CLL with unfavorable features, data on treatment-naive (TN) patients with TP53 abnormalities derive from almost 90 patients included in 5 clinical trials.



Aims: The aim of this study is to describe the efficacy and discontinuation rate of ibrutinib in TN CLL patients with TP53 disruption in the real-life setting.

Methods: Medical charts of CLL patients followed in 14 centers belonging to the Italian Campus CLL network were retrospectively reviewed to identify CLL with 17p- (cut-off 10%) and/or TP53m treated front-line with ibrutinib. The primary endpoint was the rate of discontinuation. Secondary endpoints were progression-free survival (PFS), time-to-next treatment (TTNT), overall survival (OS). Survival after ibrutinib discontinuation was also assessed. CLL diagnosis and response assessment were carried out according to the iwCLL 2018 guidelines. Adverse events were classified according to the CTCAE v5.0 grading. Statistical analyses were performed with Prism 7.

Results: One hundred TN CLL patients were recruited in this study. Fifty-one patients were male, the median age at the start of ibrutinib was 71 years (range 37-87), including 35 octogenarians, the median CIRS was 4 (range 0-13), 42 had a creatinine clearance <60ml/min. According to Rai's classification, 27 were in stage III and 18 in stage IV. □2-microglobulin was increased in 28 patients. Seventy-seven patients were IGHV unmutated, 33 displayed only 17p-, 22 only TP53m and 45 both 17p- and TP53m.

The overall response rate was 84%, including 10% of complete remissions (confirmed by bone marrow biopsy). After a median follow-up of 24 months, 13 patients relapsed, 10 required further therapy, 2 developed a Richter syndrome (RS) transformation and 8 died (4 infections, 1 melanoma, 1 RS, 1 sudden death). The median PFS, TTNT and OS have not been not reached. The 12, 24 and 36-month PFS was 91%, 82% and 75%, respectively. The 12, 24 and 36-month TTNT was 94%, 89% and 82%. The 12, 24 and 36-month OS was 96%, 92% and 87% (Fig. 1A). We observed that PFS was shorter in patients older than 75 years (2-yy PFS 69% vs 89%, p=0.04) and who did not respond (85% vs 66%, p=0.03).

Twenty-eight patients discontinued treatment, 20 due to adverse events (8 infections, 5 atrial fibrillations, 4 others and 3 deaths), 6 due to CLL progressions and 2 RS. After 12 and 24 months of treatment, the cumulative incidence of discontinuation for the whole cohort was 18% and 32%. In particular, it was 17% and 26% due to adverse events, 1% and 5% due to CLL relapse, 1% and 3% for RS (Fig. 1B). Patients who discontinued ibrutinib due to adverse events had a shorter PFS and OS (both p<0.0001). After a median observation of 14 months after ibrutinib discontinuation, the estimated median PFS and TTNT were 11 and 20 months, respectively (Fig. 1C). Overall, 22 infective events (9 grade □3), 8 atrial fibrillations, 8 minors but no major occurred.

Summary/Conclusion: We report the largest real-life study of ibrutinib in TN CLL patients with TP53 abnormalities, confirming the efficacy of ibrutinib in this subset of patients. Although ibrutinib discontinuation is not uncommon, only a few patients needed further treatment. Patients who stopped ibrutinib due to adverse had a shorter survival.

EP646 REAL-WORLD EFFICACY AND SAFETY OF VENETOCLAX IN CHRONIC LYMPHOCYTIC LEUKAEMIA – FIRST DATA FROM THE VERONE STUDY, IN PATIENTS WITH VENETOCLAX MONOTHERAPY

L. Ysebaert [1,*], X. Troussard [2], V. Levy [3], R. Le Calloch [4], R. Guièze [5], S. Leprêtre [6], A.-S. Michallet [7], V. Leblond [8], P. Feugier [9], M. Gjoklaj [10], A. Delmer [11]

[1]IUCT Oncopole, Toulouse, [2]CHU de Caen, Caen, [3]Hôpital Avicenne, Bobigny, [4]CH de Quimper, Quimper, [5]CHU Estaing, Clermont-Ferrand, [6]Centre Henri Becquerel, Rouen, [7]Cancer Research Center Lyon, Lyon, [8]Hôpital Pitié-Salpêtrière, Sorbonne Université, Paris, [9]Nancy University Hospital, Vandoeuvre-lès-Nancy, [10]Abbvie France, Rungis, [11]Reims University Hospital, Reims, France

Background: The efficacy and tolerability of venetoclax (V), a first-in-class selective oral B-cell lymphoma 2 (BCL-2) inhibitor, were shown in previous clinical trials for patients with chronic lymphocytic leukaemia (CLL). However, real-world data having assessed V in non-selected CLL patients are limited.

Aims: This French observational, prospective ongoing study aims to describe the effectiveness and tolerability of V in a real-life setting, and the V use in routine clinical practice.

Methods: This prospective non-interventional study is conducted in adult patients starting V for CLL (NCT03415035). This first analysis was performed in patients treated with V monotherapy, 16 months after the first inclusion in the study. The Overall Response Rate (ORR), and the Progression-Free Survival (PFS) were estimated at 1 year after V start in patients with at least one follow-up visit (evaluable population).

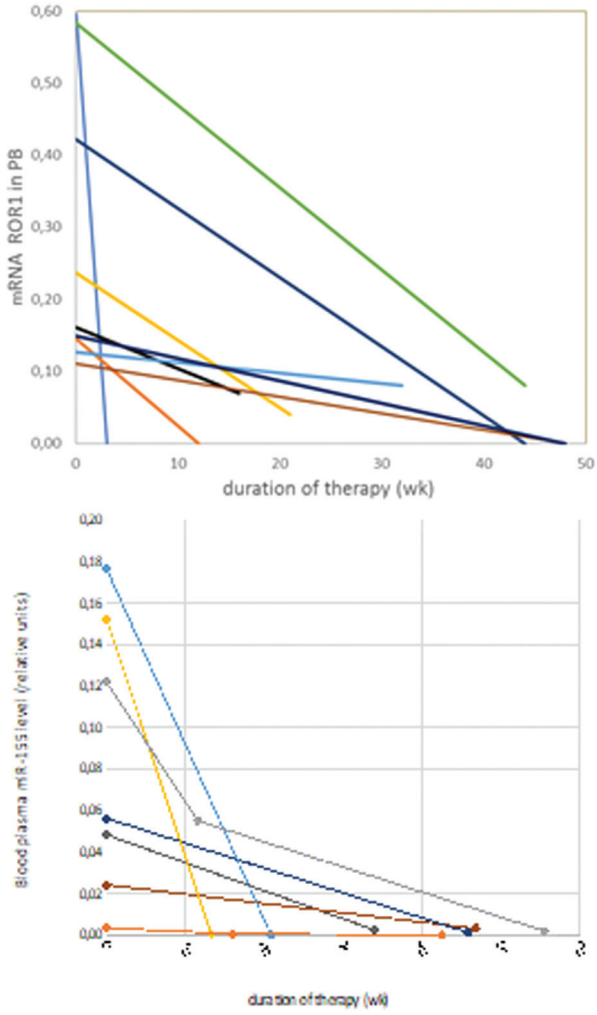
Results: From March 2018 to June 2020, 158 patients, included in 60 centres, started V monotherapy for CLL and were retained in the safety population, 153 met all the selection criteria (analysed population), and at date 62 entered the evaluable population. In the analysed population (n=153), baseline patient and CLL characteristics were as follows: mean age, 72.1±10.3 years; male, 69.3%; ECOG ≥2, 17.9%; ≥1 comorbidity, 86.9%; median CLL duration, 8.3 years (range: 0.1 - 29.4); prior CLL therapy, 96.7% (median number in pre-treated patients: 2, range 1 – 9; 1/2/≥3 prior treatment lines, 19,6%/31,8%/48,6%; including chemo-immuno-therapy 83.7%, B-cell receptor inhibitors 73.9%; Del(17p), 15.0%; *TP53* mutation, 12.4%.Prior to the first V intake, preventive measures were taken in most patients (hospitalisation 86.1%, hydration

86.7%, antihyperuricemic prophylaxis 72.8%, laboratory assessments 62.7%). The median duration of the ramp-up period was 5.0 weeks (range 1.0 – 23.9), and 72.8% reached the recommended daily dose of 400 mg at the moment of the analysis. In the 62 patients of the evaluable population, the 1-year ORR was 85.5% [95% CI 76.7% - 94.3%]. Considering the median follow-up of patients of 13.1 months, the 1-year estimate for PFS was 80.2% [95% CI 68.8% - 88.6%]. Overall, 81.0% of the 158 patients of the safety population experienced adverse events [AEs, mainly as neutropenia (43.0%) and diarrhoea (23.4%)], 58.2% ≥grade 3 AEs, 45.6% serious AEs (SAEs), and 19.6% V-related SAEs. Three patients experienced 4 fatal V-related AEs (deterioration of the general status, ascites, hepatic failure, and unknown cause at home). Over the ramp-up period, 16 patients (10.1%) experienced tumour lysis syndrome (assessed as serious in 3 patients, 1.9%; leading to treatment discontinuation in 4 patients, 2.5%).

Summary/Conclusion: Our first real-world data show that V monotherapy is effective in non-selected pre-treated CLL patients, with similar outcomes as compared to clinical trials. Early safety data are reassuring with few tumour lysis syndromes leading to treatment discontinuation during the ramp-up period. Further results are expected next year.

EP647 POTENTIAL CAPABILITIES OF MRNA ROR1 AND MIR-155 FOR MRD ASSESSMENT IN CLL

A. Gorbenko [1,2], M. Stolyar [1,*], V. Bakhtina [3], M. Mikhalev [4], I. Olkhovskiy [1,2]



[1]Department of Health, Krasnoyarsk branch of the National Research Center for Hematology, [2]Federal State Budgetary Scientific Institution Federal Research Center Krasnoyarsk Scientific Center of the Siberian Branch of the Russian Academy of Sciences, [3]Krasnoyarsk regional clinic Hospital, [4]Krasnoyarsk city Clinical Hospital № 7, Krasnoyarsk, Russian Federation

Background: The most used methods for assessing minimal residual disease (MRD) in CLL are based on flow cytometry or RQ-PCR with allele-specific oligonucleotide primers. Recently, the assessment of MRD by the level of specific extracellular DNA using the most sensitive ddPCR technologies, as well as NGS approaches, has been proposed. Blood mRNA and microRNA molecules can also be studied as probable informative biomarkers of MRD in CLL (Giudice I.D., et.al., 2019). The use of plasma nucleic acids promises to be more effective in assessing MRD because they can detect the presence of B-CLL cells in different compartments, including lymph nodes and bone marrow. A new flow cytometric method for assessing MRD status has been proposed based on analysis of the tumor-associated antigen ROR1 (CD160-ROR1 FCA) (Farren T.W., et. al., 2020). ROR1, a receptor transmembrane tyrosine kinase, is highly expressed by cells during embryonic development but is not found in adult tissues. Expression of antigen ROR1 has been found in patients with B-CLL cells and independent of anatomical niches, clinical B-CLL heterogeneity, or B-cell activation. Another knowledge onco-associated RNA in CLL is mir-155 (Stolyar M.A., et. al., 2020; Cui B., et. al., 2014).

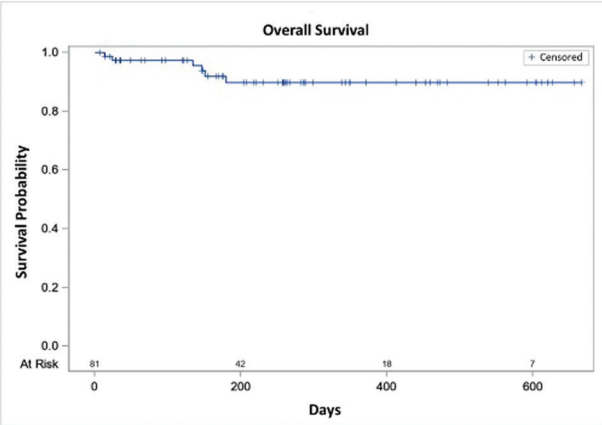
Aims: To investigate the usefulness of the combination of two ROR1 mRNA and miR-155 for evaluating the effectiveness of CLL therapy.

Methods: This study included blood samples from 37 B-CLL patients and 9 of it were observed before and during therapy of fludarabine, cyclophosphamide, rituximab combination. The control group consisted of 51 healthy donors. The expression level of ROR1 mRNA and miR-155 was determined by RT-PCR using Formula Gena Ltd kits. The results were statistically evaluated using the R- package.

Results: We did not find expression of mRNA ROR1 in venous blood and miR-155 in plasma of healthy donors. Overexpression of ROR1 (Me=0.16) was observed in 70% of our CLL patients before treatment. miR-155 level in this group was Me=0.05 relative units. Both RNAs were weakly dependent on the blood cells count or disease stage. Initially, increased ROR1 expression decreased in all patients during therapy (Figure). In most patients, the level of circulating miRNA-155 in the blood plasma also decreased (Figure). RNA dynamics correlated with clinical improvement. Further enhancement the analytical sensitivity of PCR for selected RNAs may be useful in developing new approaches to assessing MRD in CLL. It is important to note that for these tests there is no need for preliminary sequencing of allele-specific regions of immunoglobulin genes, as well as in expensive devices for NGS.

Dynamics of mRNA ROR1 and miR155 in venous blood samples after initiation of CLL therapy

Summary/Conclusion: The dynamics of mRNA ROR1 and miR-155 levels could be explored in the future as biomarkers of residual disease in CLL



EP648 SAFETY AND EFFECTIVENESS OF VENETOCLAX IN COMBINATION WITH RITUXIMAB IN ELDERLY PATIENTS WITH RELAPSED/REFRACTORY CLL TREATED UNDER REAL-LIFE CONDITIONS – DATA FROM THE OBSERVATIONAL STUDY VERVE

I. Schwaner [1,*], H. Hebart [2], C. Losem [3], T. Wolff [4], J. Huelsenbeck [5], B. Schmidt [6], D. Rossi [7], T. Nösslinger [8]

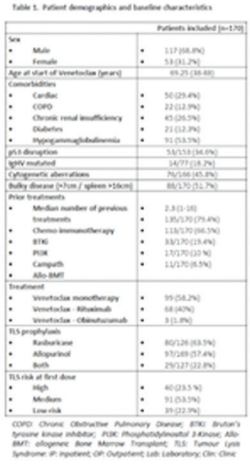
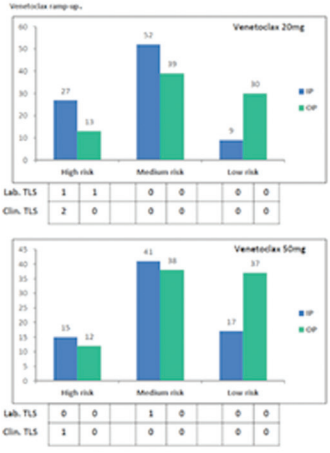
Research Bellinzona, Bellinzona, Switzerland, [8]3. Medizinische Abteilung für Hämatologie und Onkologie, Hanusch Krankenhaus, Wien, Wien, Austria

Background: In clinical trials, treatment of chronic lymphocytic leukaemia (CLL) with venetoclax (Ven) has shown promising efficacy and good tolerability. However, patients treated in clinical trial often represent a selected group not representative for patients treated in daily practice. Prospective real-world data on Ven usage are limited.
Aims: We conduct a prospective non-interventional observational study assessing effectiveness, safety, and quality of life in relapsed/refractory patients (RR) treated with Ven in Austria, Germany, and Switzerland. The population enrolled is representative for patients treated with Ven according to local label. This report focuses on patients treated with Ven in combination with rituximab (R).
Methods: Adult patients with CLL requiring therapy treated with Ven+R according to local label are eligible for the study. Patients' visits are scheduled at the physician's discretion and according to clinical practice. Study documentation is possible at baseline, weekly during ramp-up, monthly until the end of 6 months and 3-monthly afterwards up to a maximum of 3 years. Response assessment according to IwCLL criteria can be documented at the end of ramp-up, after 3, 12, and 24 months.
Results: On November 15th, 2020, 87 patients receiving Ven+R were enrolled, 81 had received at least one dose of Ven (= safety population), and for 65 treatment response had been documented at least once (=effectiveness population). Median age was 73 years, 75% of patients were male, 63% had at least one comorbidity, most commonly cardiovascular (46%), 59% received comedication. Patients were pre-treated with a median of 1 (range 1-10) line of therapy, e.g. chemo-immuno-therapy (CIT; 76%) or B-cell receptor inhibitors (33%). Del(17p), *TP53* mutation, and presence of unmutated *IGHV* had been diagnosed in 26%, 26%, and 41%, respectively (excl. missing data: 33%, 34%, 73%).
With a median observation time of 254 (range 1-667) days, 81% of patients experienced at least one AE, 46% experienced CTCAE grade 3/4 AEs, SAEs were reported in 30%. Grade 5 AEs were reported in two patients, tumour lysis syndrome (TLS) in 10 patients (12%). The median for progression-free survival (PFS) and overall survival (OS) has not been reached, the 12-month estimates were 88,1% (PFS) and 89,8% (OS). 6 cases of death were reported as not treatment related. At 12 months, an estimated 84,7% of patients remain on therapy. The reported best overall response at 12 months was 78,7% (CR+CRi 36,1%; PR: 42.6%). Remissions appeared to deepen with longer treatment duration.



Summary/Conclusion: Under real-world conditions, Ven+R is used in elderly patients. The treatment was well tolerated. Most patients receive Ven+R in second line of therapy after initial CIT. Patients present with high-risk features, e.g. del(17p); yet, the response rate was high. Despite the advanced age of the enrolled patient population, PFS and OS estimates are like those observed in the Ven+R pivotal phase III trial MURANO.



EP649 COMPARISON OF VENETOCLAX INPATIENT AND OUTPATIENT RAMP-UP STRATEGIES FOR CLL. UK MULTICENTRE RESTROSPECTIVE STUDY

R. Figueroa Mora [1,*], A. Rampotas [2], D. Halperin [3], J. Vidler [4], P. Gavin [5], M. Dungarwalla [6], P. Ferguson [7], N. Elmusharaf [8], M. Furtado [9], D. Melotti [10], S. Gohil [10], A. Schuh [11], P. Patten [4], B. Kennedy [3], T. Eyre [2], N. Martinez-Calle [1], T. Munir [12]

[1]Haematology, Nottingham University Hospitals NHS trust, Nottingham, [2]Haematology, Oxford University Hospital NHS Foundation Trust, Oxford, [3]Haematology, University Hospitals of Leicester NHS Trust, Leicester, [4]Haematology, King's College Hospital NHS Foundation Trust, London, [5]Haematology, University of Aberdeen, Scotland, [6]Haematology, Milton Keynes University Hospital NHS Foundation Trust, Milton Keynes, [7]Haematology, University Hospitals of North Midland NHS Trust, Stoke-on-Trent, [8]Haematology, University Hospital of Wales, Cardiff, [9]Haematology, Royal Cornwall Hospitals NHS Trust, Cornwall, [10]Haematology, University College of London Hospital NHS Foundation Trust, London, [11]Oncology, Oxford University Hospital NHS Foundation Trust, Oxford, [12]Haematology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Recommendations for venetoclax initiation in Chronic Lymphocytic Leukaemia (CLL) include inpatient admission during ramp-up dosing for patients at High-risk of Tumour Lysis Syndrome(TLS). Outpatient-based monitoring for high-risk TLS risk subgroup has been implemented in some centres. It is of interest to evaluate patterns of TLS monitoring and safety of this practice in the real world setting.
Aims: The primary objective is to evaluate TLS incidence CLL patients treated with venetoclax outpatient ramp-up in routine clinical practice. Secondary objectives are identifying the dose and time-point in which TLS occurs, management of TLS, TLS outcomes and impact on treatment delivery.
Methods: We performed aUK multi-centre, retrospective observational study, analysing consecutive adult CLL patients treated with venetoclax monotherapy or in combination with anti-CD20 monoclonal antibody (May/2016 to December/2020). Patients treated within clinical trials were excluded. Key outcomes were: Development of biochemical or clinical TLS after each venetoclax dose escalation, frequency of TLS between outpatient and inpatient ramp-up strategy, treatment delay/discontinuation after TLS events, frequency of rasburicase use for TLS treatment and TLS-related morbidity and mortality. Response rate using iwCLL criteria was collected.
Results: 170 patients from 11 UK centres were included. Patient's characteristics are shown in Table 1. 17p deletion and/or TP53 mutation was present in 34.5% (n=53), 51.7% had bulky disease (>7cm). 66.5% were previously Bruton Tyrosine Kinase inhibitor (BTKi) exposed. 99 patients (58.2%) had venetoclax monotherapy. All patients received TLS prophylaxis during the first steps of escalation, 63.2% with rasburicase. 23.5% (n=40) of patients had high TLS risk at initial ramp up. 127 high-TLS-risk dose escalations occurred, 52% (N=66) as inpatient. Overall, 7 TLS events were observed (3 clinical, 4 biochemical), 6/7 in the high-risk group (4.7% of high-risk escalations). 2/7 were outpatients at TLS onset and were admitted, 4/7 received emergency rasburicase and 1/7 required haemodialysis. There were no deaths or treatment discontinuations related to TLS, 6/7 patients had the next dose delayed. Most TLS events occurred at 20 and 50mg dose level and at the 6h post-dose timepoint (Fig. 2). 46 episodes of single laboratory abnormality were observed. Raised serum phosphate the most frequent (67.4%), 15.2% required admission and 17.4% patients had subsequent dose delayed for that reason. Complete and partial response rates were 45.9% and 39.1% respectively. All patients who experienced TLS episodes achieved some grade of response (CR or PR). CR rate in patients with isolated hyperphosphatemia was 80%.

Summary/Conclusion: Our real-word observational study revealed thathigh-risk patients could be managed as outpatients without a significant increase in TLS events or admission compared to impatient escalation. As previously described, TLS occurred predominantly at initial ramp up stages and early timepoints. We observed higher than expected proportion of inpatient ramp up medium and low risk patients. Despite low numbers, no deaths or discontinuations due to TLS were observed. Single laboratory abnormalities were frequently observed, mainly hyperphosphatemia, but only rarely translated into dose delays or TLS. Higher CR rates were positively associated with TLS and isolated hyperphosphatemia.

EP650 MOLTO, A MULTICENTER, OPEN LABEL, UNCONTROLLED, PHASE II CLINICAL TRIAL ON SAFETY AND EFFICACY OF VENETOCLAX, ATEZOLIZUMAB AND OBINUTUZUMAB IN RICHTER TRANSFORMATION OF CLL: SAFETY INTERIM ANALYSIS

A. M. Frustaci [1,*], A. Tedeschi [1], P. L. Zinzani [2], D. Pietrasanta [3], M. Coscia [4], T. Zenz [5], M. Motta [6], G. Gaidano [7], L. Scarfo [8], M. Deodato [1], G. Zamprogna [1], C. Vitale [4], R. Cairoli [1], D. Rossi [9], M. Montillo [1]

Seràgnoli," University of Bologna, Bologna, [3]Hematology, Azienda Ospedaliera SS Arrigo e Biagio e Cesare Arrigo, Alessandria, [4]Hematology, A.O.U. Città della Salute e della Scienza di Torino and Department of Molecular Biotechnology and Health Sciences, University of Torino, Torino, Italy, [5]Hematology, University Hospital Zürich and University of Zürich, Zürich, Switzerland, [6]Hematology, ASST Spedali Civili, Brescia, [7]Hematology, Department of Translational Medicine, University of Eastern Piedmont, [8]Hematology, Università Vita-Salute San Raffaele and IRCC Ospedale San Raffaele, Milano, Italy, [9]Hematology, Oncology Institute of Southern Switzerland; Institute of Oncology Research, Bellinzona, Switzerland

Background: Diffuse large B-cell (DLBCL) transformation from chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL), Richter Syndrome (RS), has poor prognosis. Venetoclax, Bcl-2 inhibitor, has shown activity in DLBCL-RS. Atezolizumab is a humanized monoclonal antibody (MoAb) targeting PD-L1 on tumor-infiltrating immune cells/tumor cells and prevents PD-1 receptor-B7.1 interaction. Obinutuzumab, antiCD-20 MoAb, presents greater antibody-dependent (AD) cellular cytotoxicity, AD cellular phagocytosis and direct cell death compared to rituximab. Preliminary data showed safety and activity of atezolizumab+/-obinutuzumab in heavily pretreated DLBCL.
Aims: MOLTO is a multicenter international phase II study (EUDRACT 2018-005028-40) evaluating safety and efficacy of venetoclax, atezolizumab, obinutuzumab combination in 28 RS.
Methods: Treatment consists of 35 cycles with obinutuzumab (1000 mg C1-8), atezolizumab (1200 mg C1-18) and venetoclax (400 mg/d C1-35), in untreated DLBCL-RS from CLL/SLL. Initial safety run phase consists of 9 pts receiving at least 3 courses. Enrollment would have been stopped in case of ≥3 non-infective/non-hematologic therapy-related G≥4 adverse events (AEs). Remaining pts received same treatment schedule of initial safety cohort.
Results: Enrollment started from October 2019. As none of the 9 pts of the safety run phase developed an infective and/or non-hematological G ≥4 AE, enrollment went on and, as of February 2021, a total of 14 pts received at least 1 cycle of therapy. In table 1 are shown pts characteristics. Overall, 110 cycles have been administered. Five serious AE (SAEs) were recorded in 4 pts: 1 fever of unknown origin (FUO) and 1 case of autoimmune encephalitis, both G3, resolved and not leading to treatment discontinuation, and 1 G5 pneumonia. The remaining 2 SAEs were related to hospitalization due to disease progression (PD). Twelve/14 pts (85.7%) developed at least 1 AE of any grade. Severe (G 3-5) hematological toxicity was recorded in 7 pts, while 5 pts (including 3 developing SAEs) experienced severe non-hematological toxicity. The most common hematological toxicity was thrombocytopenia: 20 episodes/110 courses (18.2%), 9 being G≥3. Other G≥3 hematologic toxicities included: 10% neutropenia and 0.9% anemia. Two severe non-hematological toxicities were recorded: 1 hyperamylasemia and 1 hypercalcemia. Seven pts (50%) experienced a grade 2 FUO and only 1 major infection was observed. Two were the AE of special interest: 1 autoimmune myositis and 1 autoimmune encephalitis both successfully managed with steroids. No G≥3 infusion related reactions (IRR) occurred and all G1/2 have been considered associated to obinutuzumab. Venetoclax ramp-up was successfully completed in all pts, in 2 cases accelerated dose-escalation (Koening et al. 2020) was performed due to rapidly PD. No laboratory or clinical tumor lysis syndrome (TLS) was recorded. Overall, 9 pts are still on treatment with a median time on study of 4.4 (range 1 - 16.7) m, only 1/5 pts discontinued treatment due to toxicity.

Table 1. Patients' characteristics

	Number (%)
Age Median (range)	69.5 yrs (range: 51-81)
Pts with age ≥65 years	11 (78.6)
Male/Female	6/8
N° of pts pretreated for CLL	9 (64.3)
Median number of prior CLL Tx (range)	1 (0-3)
N° of pts pretreated with BTKi	5 (35.7)
N° of pts pretreated with CIT	5 (35.7)
Bulky disease (≥ 5 cm)	11 (78.6)
Presence of del17p and/or *TP53mut*	6 (42.9)
Ann Arbor Stage	
I	1 (7.1)
II	2 (14.3)
III	6 (42.9)
IV	5 (35.7)

Summary/Conclusion: The combination venetoclax, obinutuzumab and atezolizumab was well tolerated even in elderly pts. In the absence of significative warning, Independent Data Monitoring Committee allowed the accomplishment of safety run phase. Obinutuzumab-atezolizumab combination did not result in an enhanced rate or severity of IRR. In this highly proliferating disease, venetoclax did not lead to TLS even when applying accelerated ramp-up. Accrual is ongoing, and updated results will be presented at the meeting.

Background: Given the multifactorial immune defect characterizing chronic lymphocytic leukemia (CLL), it appears conceivable that these patients have risk factors that increase their likelihood of complications and death from COVID-19.
Aims: To evaluate incidence and severity of COVID-19 cases in a well-defined cohort of patients with CLL receiving venetoclax-based combinations.
Methods: We administered a survey to a cohort of CLL treating hematologists from hematological centers in southern Italy. Participants were asked: a) to indicate whether they had offered a test for detection of COVID-19 infection (mainly nasopharyngeal swabs) only to CLL patients who reported symptoms or universally; b) to provide information on the incidence of COVID-19 infection and its severity; c) to specify reasons of possible treatment modifications. The survey was restricted to relapsed-refractory (R/R) CLL patients treated from Feb 1st to Dec 31th 2020 with time-limited venetoclax/rituximab (VR) combination as recommended by MURANO protocol (venetoclax for up to 2 years plus rituximab for the first 6 months), within their clinical practice.
Results: A specific questionnaire was sent to 30 CLL hematologists, but only 26 responded to all questions. We considered suitable for the present analysis the 24 questionnaires compiled by hematologists who declared to have treated at least one patient with VR combination in the observation period. Of those, 20.8% worked in academic hospitals. Overall, the survey allowed to collect data on 124 patients who were treated with VR combination. The median number of patients treated in each center was 5 (range,1-15).COVID-19 surveillance tests consisted of viral RNA reverse transcriptase PCR (RT-PCR) on nasopharyngeal swabs. Generally, a policy of universal SARS-CoV-2 testing to be performed on patients at different time-points of therapy was used. Most patients (83/124, 66.9%) were tested before beginning the ramp-up with venetoclax; moreover 66/124 (53.2%) were regularly tested before each rituximab infusion (Fig 1).Reasons for potential change of the schedule of treatment were also investigated. The survey revealed that adherence to treatment was relatively high (70.8%). Only 29.1% physicians modified the therapeutic program mainly because of grade 3 neutropenia. Changes consisted of transient interruption of venetoclax, reduction of doses, and delay of rituximab infusion.Only 2/124 patients (1.6%) had a symptomatic RT-PCR proven diagnosis of COVID-19 infection and required hospitalization. Both patients needed oxygen therapy and admission into an intensive care unit. Of those, 1 patient who was receiving VR combination at the time of COVID infection, eventually died. The second patient developed COVID-19 infection while receiving venetoclax monotherapy (after the VR combination period). He recovered from COVID-19 infection and after 21 days of treatment interruption, he was able to restart venetoclax.
Summary/Conclusion: Results of the present survey provide information, thus far lacking, on the use in real-world clinical practice of VR combination during the COVID19 pandemic in 2020. Current literature on the prevalence of COVID-19 infection in CLL, has some limitations (i.e., small size sample, heterogeneity of treatment, restriction to only the first pandemic wave); this survey, performed on a large number of CLL patients treated with VR combination only seems to provide additional information on safe management of CLL treatment during the COVID19 pandemic.

EP652 LEUKEMIA CUTIS IN CHRONIC LYMPHOCYTIC LEUKEMIA: A RETROSPECTIVE STUDY OF THE FRENCH INNOVATIVE LEUKEMIA ORGANIZATION (FILO)

Background: Cutaneous infiltration by leukemic cells with clinically identifiable skin lesions, also called leukemia cutis (LC), has seldom been reported in chronic lymphocytic leukemia (CLL). There is no available data on the genetic background of LC-CLL.
Aims: In this study we retrospectively analyzed the clinical, histopathological, and molecular features of 46 CLL patients with specific LC from centers of the FILO.
Methods: We collected clinical and biological data including cytogenetic aberrations assessed by FISH, karyotype, IGHV mutational status and amplicon-based next-generation sequencing of 13 CLL-associated mutated genes from peripheral CLL cells.
Results: We identified 46 cases of skin biopsy-proven LC-CLL. All patients had proven CLL prior to LC. Median time between skin manifestations and CLL was 5.4 years (1-18 years). Skin lesions were either diffuse (n=16), localized (n=13) or regional (n=9). Head and neck were the most common site (22 cases) with a high incidence of earlobe lesions (10/46 cases), while lesions on arms and legs, trunk and extremities were found in 17, 13, and 14 cases respectively. The most common skin manifestations were papulonodular (24/46 cases) and non-infiltrated erythematous lesions (n= 9). Plaques, vesicles, mosquito bite-like, rhinophyma-like, ulcerations or necrotic lesions were uncommon. Some infiltrates appeared at the sites of previous scars following herpes, mosquito bite or a plant wound in 4 patients.
A majority of cases were IGHV mutated (n=21/37, 57%). The IGHV4-34 gene ranked among the most frequent IGHV genes (8/37, 21.6%) as compared to usually 10% of CLL. Conventional karyotype was performed in 25 patients. It was normal in 8 cases (32%) and complex (>3 abnormalities) in 6 cases (25%). An intriguing finding was the unexpected high frequency of t(14;18) translocation in 6/25 patients (25%), while it usually occurs in < 5% of CLL. Among the 34 cases tested by FISH: trisomy 12 was frequent (10/34; 29%), while 13q, 11q and 17p deletions were found in 23%, 12% and 9% respectively. Molecular testing was performed in 38 patients: 13 patients harbored only one mutation (34%) while 11 patients had 2 to 5 mutations. The most frequently mutated genes were *NOTCH1/FBXW7* (34%), *TP53* (21%), *SF3B1* (13%) and *BIRC3* (13%).
Follow-up data were obtained for 34 patients. Skin lesions tended to occur in stage A and before any treatment: 20 patients (60%) had skin lesions before the first line of treatment while 14 (40%) had received at least 1 line of treatment before any skin manifestations. Six patients developed skin lesions later in the course of the disease. Thirty-one patients were treated: 13 patients received a fludarabine or bendamustine-based regimen, 5 chlorambucil based, 5 Ibrutinib, 4 polychemotherapy, 1 obinutuzumab, 2 venetoclax and 1 idelalisib. Treatment was initiated because of the presence of skin lesions in 15 patients. Systemic treatment led to a complete skin response in 74% (23/31) of patients. The 8 patients who did not experience a complete skin response (among which the 5 patients treated with chlorambucil) achieved a partial response of the systemic CLL disease as well.
Summary/Conclusion: In this large CLL-LC cohort, we did not find a specific clinical or biological profile associated with LC, nor any difference related to morphology or site of skin lesions. t(14;18) is enriched

and we are currently investigating its significance in this atypical clinical presentation of CLL. Our results suggest that CLL patients with cutaneous lesions are not associated with poor prognosis features and they respond well to CLL systemic treatment.

EP653 MANAGEMENT OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA AND ARTERIAL HYPERTENSION WHO ARE ON IBRUTINIB THERAPY.

E. Emelina [1,*], G. Gendlin [1], I. Nikitin [1]

[1]*Hospital Therapy №2, Pirogov Russian National Research Medical University, Moscow, Russian Federation*

Background: One of the possible cardiotoxic effects of ibrutinib (Ib) is the induction of arterial hypertension (AH). In addition, some patients (pts) who are assigned Ib already have hypertension. Poorly managed hypertension may have a direct impact on the prognosis and survival of pts with CLL receiving Ib.
Aims: To assess the manageability of hypertension and the effectiveness of antihypertensive therapy in pts with chronic lymphocytic leukemia (CLL), receiving Ib.
Methods: We conducted a prospective study for 56 months with the inclusion of 217 pts with CLL receiving AH-inducing Ib. In 116 (53.5%) pts AH was diagnosed before Ib therapy, in 24 (11.1%) pts AH occurred during Ib treatment. Out of 140 pts with AH: grade 1 - 15 pts (10.7%), grade 2 - 41 pts (29.3%), grade 3 - 84 pts (60%). Among pts with CLL and AH there were 86 men aged 67.0 (60.0-72.0) years and 59 women aged 67.0 (59.0-74.0) years.
As part of a comparative analysis, a 24-hour blood pressure monitor (24h-BPM) was carried out in dynamics against the background of antihypertensive therapy in three groups of pts: with CLL and AH receiving Ib (n=140) and pts with AH without cancer receiving AH treatment on an outpatient basis (n=159) and in a hospital (n=100). Pts did not have significant differences in age and sex composition. All pts received antihypertensive therapy, while the pts group with CLL and hypertension was under our distant controlled treatment. Combined antihypertensive therapy was required in 40.8% of patients with CLL and AH: a combination of 2 drugs - 54.9%, of 3 drugs - 33.3%, of 4 drugs - 9.8%. Pts in the comparison groups received antihypertensive therapy prescribed by the doctors of the hospital and polyclinics. Comparison of blood pressure (BP) indicators in dynamics according to 24h-BPM data in pts with CLL and AH receiving Ib was carried out, as well as comparison in the three indicated groups.
Results: During the observation period in pts with CLL and AH receiving Ib, we managed to achieve an effective decrease in blood pressure on our antihypertensive therapy: according to the control 24h-BPM, the 24-hour average systolic blood pressure (24-SBP) significantly decreased (p=0.009), 24-hour average diastolic blood pressure (24-DBP) (p=0.014), hypertensive time index (HTI) of SBP (p=0.006) and DBP (p=0.009) in waking period and in sleep period HTI of SBP (p=0.046) and DBP (p=0.008). When compared in 3 groups: pts with CLL and AH receiving Ib showed a more significant decrease in 24-SBP, 24-DBP (p=0.001) and HTI during wakefulness and sleep (p <0.0001) compared with pts in the population. Target blood pressure in the pts group with CLL and AH was achieved significantly more often than in the population (p <0.0001). In pts with CLL and AH on the background of antihypertensive therapy, significantly less pts with an unfavorable daily night picker profile (p=0.0003). Pts with CLL and AH, who received angiotensin-converting enzyme (ACE) inhibitors, had better overall survival, which was not observed with other antihypertensive drugs (p=0.001).
Summary/Conclusion: Despite the possible induction of hypertension by Ib, in pts with CLL treated with Ib, it is possible to achieve an effective reduction in blood pressure on antihypertensive therapy. To control AH 40.8% pts with CLL and AH, combination therapy with a predominance of two-component therapy is required. Pts with CLL and AH taking ACE inhibitors have higher overall survival rates compared to pts with CLL who did not receive this group of drugs.

EP654 EFFECTIVENESS AND SAFETY OF IBRUTINIB IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) AND MANTLE CELL LYMPHOMA (MCL) IN BELGIAN ROUTINE CLINICAL PRACTICE WITH A 3-YEAR FOLLOW-UP

A. Janssens [1,*], S. Snauwaert [2], D. Bron [3], Z. Berneman [4], F. Offner [5], C. Van Bogaert [6], B. De Beleyr [6], A. Smet [6], L. Nielsen [6], R. Wapenaar [7], M. André [8]

Background: The Belgian ibrutinib Real-World (RW) Data (BiRD) study is a multicenter, observational study of adults with a confirmed diagnosis of CLL, MCL, or Waldenström's macroglobulinemia (WM) eligible for reimbursed ibrutinib treatment at treatment initiation or participating in a Medical Need Program and switched to reimbursed treatment in Belgium. RW studies provide valuable insights into ibrutinib effectiveness and safety in routine clinical practice. Here we present updated results from the third interim analyses (IA) with a median follow-up of 34.3 months for the CLL cohort and 35.8 months for the MCL cohort.
Aims: To assess ibrutinib outcomes (primary: progression-free survival [PFS] and overall response rate [ORR]; secondary: included overall survival [OS] and safety) in RW patients (pts) with previously untreated or relapsed or refractory (R/R) CLL and R/R MCL in Belgium.
Methods: Data were collected both prospectively (pro) and retrospectively (ret). Total population results were adjusted for left truncation.
Results: Effectiveness results are presented in the Table.
In the CLL cohort, 221 pts (pro n=71; ret n=150) were included in the effectiveness population; 64.3% were male, median age at ibrutinib initiation was 72 (range, 38-90) years, median time from diagnosis to ibrutinib initiation was 5.8 years, 27.4% were previously untreated 59.1%, had del17p and/or *TP53* mutation, and 72.5% had no *IGHV* mutation. The median PFS for CLL was 38.3 months (51.5/not reached [NR] months in the pro/ret cohorts). ORR was 90.0% (complete response [CR] 16.7%, partial response [PR] 51.6%, PR with lymphocytosis 21.7%). Median OS was NR. Of the 226 pts in the CLL safety population, 96.9% had ≥1 treatment-emergent adverse event (TEAE) and 52.2% had ≥1 serious TEAE. TEAEs led to dose reduction, interruption, or discontinuation in 21.2%, 31.9%, and 26.5% of pts, respectively. TEAEs of interest in pts with CLL reported as % (% difference from second IA, after an additional 15.3 months of follow-up) were: major bleeding 4.9% (-0.4%); infection 66.4% (9.3%); hypertension 17.3% (5.1%); atrial fibrillation (AF) 10.6% (3.2%); arthralgia/myalgia 16.8% (4.1%); diarrhea 21.7% (3.2%). Median treatment duration for pts with CLL was 25.5 months (19.6/28.6 months pro/ret), and 135/226 pts (58.7%) remain on treatment.
In the MCL cohort, 76 pts (pro n=20; ret n=56) were included in the effectiveness population; 76.3% were male, median age at ibrutinib initiation was 74 (range, 47-88) years, and median time from diagnosis to ibrutinib initiation was 2.8 years. The median PFS for MCL was 18.6 months (21.5/26.8 months in the pro/ret cohorts). ORR was 93.4% (CR 39.5%, PR 53.9%). Median OS was 32.2 months. Of the 76 pts in the MCL safety population, all had ≥1 TEAE and 67.1% had ≥1 serious TEAE. TEAEs led to dose reduction, interruption, or discontinuation in 31.6%, 43.4%, and 26.3% of pts, respectively. TEAEs of interest in pts with MCL reported as % (% difference from second IA, after an additional 15.2 months of follow-up) were: major bleeding 7.9% (1.3%); infection 64.5% (6.6%); hypertension 6.6% (0%); AF 21.1% (4.0%); arthralgia/myalgia 11.8% (0%); diarrhea 35.5% (5.2%). Median treatment duration for pts with MCL was 24.7 months (22.8/25.3 months pro/ret), and 26/76 pts (34.2%) remain on treatment.

Table. Effectiveness results

	CLL			MCL		
	Pro	Ret	Total[a]	Pro	Ret	Total[a]
N	71	150	221	20	56	76
Overall median PFS, months (Q1-Q3)	51.5 (29.1-NR)	NR (15.7-NR)	38.3 (12.2-66.4)	21.5 (6.1-40.5)	26.8 (17.3-61.4)	18.6 (8.2-46.2)
36-month PFS rate, % (95% CI)	55.6 (38.5-69.7)	65.0 (55.5-73.0)	53.8 –[b]	29.7 (6.8-54.6)	40.7 (27.2-53.7)	31.4 –[b]
PFS: Mutated *IGHV*, months (Q1-Q3)	NE	49.9 (37.3-49.9)	49.9 (21.3-49.9)	NE	NE	NE
PFS: Unmutated *IGHV*, months (Q1-Q3)	NE	53.5 (31.6-NR)	53.5 (31.6-NR)	NE	NE	NE
PFS: Del17p and/or *TP53* mutation, months (Q1-Q3)	NE	49.7 (27.3-NR)	41.5 (21.3-NR)	NE	NE	NE
PFS: No del17p and *TP53* mutation, months (Q1-Q3)	NE	49.9 (31.3-NR)	49.9 (17.8-NR)	NE	NE	NE
POD24,[c] months (Q1-Q3)	NE	NE	NE	NE	NE	18.5 (7.2-27.1)
POD>24,[d] months (Q1-Q3)	NE	NE	NE	NE	NE	21.5 (16.8-NR)
Median OS, months (Q1-Q3)	NR (20.7-NR)	NR (38.3-NR)	NR (21.3-NR)	NR (16.6-NR)	43.2 (29.1-NR)	32.2 (13.1-NR)
36-month OS rate, % (95% CI)	60.6 (45.8-72.6)	76.3 (67.8-82.9)	62.9 –[b]	53.3 (29.4-72.4)	62.0 (47.4-73.6)	47.5 –[b]

CI, confidence interval; NE, not estimable; NR, not reached; OS, overall survival; PFS, progression-free survival; pro, prospective; ret, retrospective. [a]Total population adjusted for left truncation. [b]95% CI not calculated as analysis adjusted for left truncation. [c]PFS ≤24 months under the most recent prior line for MCL (n=19). [d]PFS >24 months under the most recent prior line for MCL (n=15).

Summary/Conclusion: Results over a median follow-up of 35+ months from the BiRD study confirm the sustained effectiveness of ibrutinib in both CLL and MCL. TEAEs were manageable in elderly patients with no new safety signals.

Chronic myeloid leukemia - Biology & Translational Research

EP655 NEUTROPHIL EXTRACELLULAR TRAPS ARE INCREASED IN CHRONIC MYELOID LEUKEMIA AND ARE DIFFERENTIALLY AFFECTED BY TYROSINE KINASE INHIBITORS

A. Telerman [1,*], G. Granot [1], A. Shacham-Abulafia [2,3], M. H. Ellis [3,4], O. Yarchovsky-Dolberg [3,4], P. Raanani [2,3], O. Wolach [2,3]

[1]Felsenstein Medical Research Center, Rabin Medical Center, [2]Institue of Hematology, Rabin Medical Center, Petah Tikva, [3]Sackler School of Medicine, Tel Aviv University, Tel Aviv, [4]Hematology Institute and Blood Bank, Meir Medical Center, Kfar Saba, Israel

Background: Chronic myeloid leukemia (CML) is a myeloproliferative neoplasm (MPN) driven by the BCR-ABL1 fusion gene. Atherothrombotic complications are increasingly reported with the use of certain tyrosine kinase inhibitors (TKI's). The mechanism underlying these complications is not fully understood but may involve off-target effects that promote vascular toxicity. In response to various stimuli, neutrophils can expel extracellular strands of decondensed DNA in complex with histones and additional proteins called neutrophil extracellular traps (NETs). These structures have the ability to ensnare and kill microbes but are also implicated in the pathogenesis of thrombosis.
Aims: Study NET formation in CML and evaluate a possible contribution of BCR-ABL1 and of TKI's to NET formation.
Methods: Neutrophils were isolated from CML patients (n=9) and from age and gender matched controls (n=9) by Percoll gradient. NETosis was evaluated by measuring the levels of accepted NETosis markers. NET formation was assessed by the NETosis Assay Kit (Cayman chemical) as well as by immunofluorescence (IF). Expression of citrullinated histon H3 (H3cit), an established marker of NETosis and of PAD4, an initiator of this process, was determined by Western blot and IF. CD11b expression and reactive oxygen species (ROS) production were analyzed by FACS and ELISA, respectively. Assessments were performed in resting and in PMA/ionomycin stimulated neutrophils and after *ex vivo* treatment with clinically relevant concentrations of imatinib (5.3 µM), ponatinib (0.17 µM) and dasatinib (0.22 µM). To validate our findings and further study the effect of BCR-ABL1 and TKIs on NETosis, we prepared BCR-ABL1 retroviral transduced HoxB8-immortalized mouse hematopoietic progenitors which differentiate into neutrophils *in vitro*.
Results: Neutrophils from patients with CML had a significant increase in NETs formation as assessed by morphology and by an increase in DNA-associated neutrophil elastase compared to normal neutrophils, at baseline ($p \leq 0.05$, $p \leq 0.03$, respectively) and after PMA stimulation ($p \leq 0.005$, $p \leq 0.002$, respectively). In accordance, H3cit and PAD4 expression (staining and WB) and ROS generation were also higher in CML samples compared to controls ($p \leq 0.04$). Ponatinib treatment of neutrophils from CML patients significantly augmented DNA-associated neutrophil elastase levels as compared to DMSO, imatinib and dasatinib treated neutrophils ($p \leq 0.05$ for all comparisons). Ponatinib treatment also led to increased ROS levels in CML neutrophils as compared to DMSO and imatinib ($p \leq 0.05$). Differentiated BCR-ABL1-transduced HoxB8 neutrophils stimulated with ionomycin demonstrated increased H3cit & PAD4 expression. These processes were significantly reduced by Cl-amidine, a PAD4 inhibitor. Ponatinib and nilotinib increased H3cit expression in HoxB8-BCR-ABL1 cells after stimulation with ionomycin. However, no significant difference was found in ROS generation of ionomycin stimulated HoxB8 neutrophils transduced with empty vector or with BCR-ABL1. Also, no difference was observed in ROS levels of HoxB8-BCR-ABL1 cells treated with the different TKIs.
Summary/Conclusion: Our findings support the hypothesis that CML is associated with increased NET formation which is further augmented by ponatinib, suggesting a possible role for NETs in promoting vascular toxicity in CML. In the BCR-ABL1/HOXB8 model, NETs formation is PAD4 dependent. Further studies are needed to assess the possible role of increased NETs formation in CML on the CVS associated with BCR-ABL1 and TKIs exposure.

EP656 PROFILES OF NK CELL SUBSETS ARE ASSOCIATED WITH SUCCESSFUL TYROSINE KINASE INHIBITOR DISCONTINUATION IN CHRONIC MYELOID LEUKEMIA AND CHANGE FOLLOWING INTERFERON TREATMENT

J. Kong [1], Y.-Z. Qin [1], X.-S. Zhao [1], Y. Hou [1], K.-Y. Liu [1], X.-J. Huang [1], H. Jiang [1,*]

[1]Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Recent studies have shown that approximately 50% of chronic myeloid leukemia (CML) patients receiving tyrosine kinase inhibitor (TKI) with a sustained deep molecular response (DMR) can acquire treatment free survival (TFR), meaning without molecular relapse (MR), and that prior interferon (IFN) treatment and relatively high natural killer (NK) cell levels at and after TKI discontinuation are associated with TFR. Moreover, we recently reported that post-TKI discontinuation IFN treatment could prevent MR.
Aims: To clarify the possible mechanism of TFR in CML patients, here we evaluated whether NK cells are associated with MR in patients with CML, and investigated the effects of post-TKI discontinuation IFN treatment on lymphocyte subsets.
Methods: Part of patients with CML in our previous study of INF-α post TKI discontinuation following a DMR were included in this patient population. After immunophenotyping, the associations between lymphocyte and NK cell subsets and MR after TKI discontinuation were analyzed in the subset of patients who did not receive IFN-α and the effects of IFN-α on these same cell subsets were evaluated in those who did.
Results: Thirty-four patients measuring blood lymphocyte subclasses were included in this study. The median follow-up time was 32 (13-67) months. After TKI treatment discontinuation, 12 patients with $0.0032\% < BCR\text{-}ABL1^{IS} \leq 0.1\%$ received IFN-α treatment, three (25%) of which experienced protocol-defined molecular relapse ($BCR\text{-}ABL1^{IS} > 0.1\%$); 22 patients did not receive IFN-α treatment, 9 of whom (37.5%) eventually experienced MR. In the 22 patients who did not receive IFN therapy, there were no significant differences in Tregs or NK cells at TKI discontinuation between the nonrelapsed and relapsed patients. At one month after TKI discontinuation, the nonrelapsed patients showed a significantly higher proportion and count of NK cells than the relapsed patients (median counts and ranges of 529/mm^3, 346-827 and 279/mm^3, 45-645), respectively) (p=0.016). In particular, the proportion and count of CD56dim NK cells were significantly higher in the nonrelapsed patients (median: 29.92% (range: 7.42%>48.59%) and median: 467/mm^3 (range: 200-955), respectively) than in the relapsed patients (median: 16.01% (range: 2.09%>31.46%) and median: 362/mm^3 (range: 58-438), respectively) (p=0.017 and p=0.079, respectively). In contrast, at one month after TKI discontinuation, the nonrelapsed patients showed significantly lower proportions and counts of CD4+ T cells and CD4+CD25+CD127low/- Tregs than the relapsed patients. In the 12 patients who received IFN-α treatment, the level of CD56bright NK cells was increased significantly after both 3 and 6 months of IFN-α treatment.
Summary/Conclusion: NK cells, especially cytotoxic CD56dim NK cells, are associated with MR after TKI discontinuation in CML patients.

Additionally, IFN-α treatment can gradually increase the level of CD56bright NK cells in CML patients.

EP657 TNF-MEDIATED CML CELL SURVIVAL RESISTS TKI TREATMENT AND THIS CAN BE TARGETED BY IKK2-INHIBITION

M. Bütow [1,*], T. Maié [2], T. Jaquet [1], I. G. Costa [2], N. Chatain [1], M. Crysandt [1], S. Koschmieder [1], W. Wagner [3], T. H. Brümmendorf [1], M. Schemionek-Reinders [1]

[1]Department of Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, Uniklinik RWTH Aachen, [2]Institute for Computational Genomics, Joint Research Center for Computational Biomedicine, RWTH Aachen University, [3]Helmholtz-Institute for Biomedical Engineering, Stem Cell Biology and Cellular Engineering, RWTH Aachen Faculty of Medicine, Aachen, Germany

Background: Treatment with tyrosine kinase inhibitors (TKIs) substantially improved the clinical outcome in CML. Although, the Bcr-Abl1-directed approach eliminates the majority of CML cells, TKIs often spare leukemic stem cells (LSCs). Interestingly, tumor necrosis factor (TNF) has been described to coordinate hematopoietic stem cell survival and a TKI persistent TNF signature in LSCs was identified. Elevated TNF plasma levels were observed in chronic phase (CP) and progressed CML and were significantly elevated in bone marrow and spleen in CML mouse models. Targeting the TNF-induced NFκB-signaling by overexpressing the inhibitory IκBα protein, impaired leukemogenesis in a retroviral model of Bcr-Abl1 driven disease.
Aims: Here, we aimed to complement TKI therapy by TNF pathway-directed treatment, to specifically target persisting CML cells in CP- and blast crisis (BC) CML.
Methods: Publicly available microarray data were analyzed for induction of TNF regulated pathways. 32D Bcr-Abl1, SCLtTA/Bcr-Abl1-BM, human K562 & KCL22 (imatinib-sensitive (S) and -resistant (R)) cells were evaluated using qRT-PCR, Western blot, annexin V & CFSE staining. CP-CML-CD34$^+$-cells and BC mononuclear cells (MNCs) were subjected to colony-forming unit (CFU) assays or annexin V + CFSE measurements upon treatment with the IKK2 small molecule inhibitor LY2409881 (LY) +/- nilotinib or DMSO as control, in the presence of TNF, IL1α or IL1β.
Results: Analysis of microarray data unveiled enrichment of TNF signaling molecules in the CD34$^+$CD38$^-$ compartment of CP-CML patient cells. 32D Bcr-Abl1 and primary murine SCLtTA Bcr-Abl1-BM cells exhibited enhanced TNF signaling compared to their Bcr-Abl1 negative counterparts. 32D Bcr-Abl1, KCL22 and K562 cells displayed no reduction in TNF signaling molecules upon TKI treatment, suggesting a Bcr-Abl1 kinase-independent persistence. The combination of nilotinib and LY reduced expression of IκBα and NFκB and abrogated their phosphorylation. This treatment reduced proliferation and induced apoptosis (fold change [fc]: 2.4; p<0.01) in KCL22 S cells. In primary CD34$^+$ CP-CML cells, we discovered diminished clonogenic potential compared to TKI alone (fc: 0.05; p<0.01). Replating revealed nilotinib to preserve cells with colony-forming ability, as previously reported. These LSCs were in turn targeted by IKK2 inhibition (fc: 0.17; p<0.01). Reduction of the clonogenic potential was accompanied by apoptosis induction upon combinatorial treatment compared to TKI alone (fc: 2.5; p<0.01), also in the non-dividing cell fraction (fc: 5.2; p<0.001). Gene set enrichment of microarray data comparing BC to CP patient cells displayed further upregulation of TNF signaling in BC-LSCs. Interestingly, IKK2 inhibition could bypass TKI resistance in KCL22 R cells by apoptosis induction (fc: 2.4; p<0.01). Also, in BC-CML MNCs, combined nilotinib and LY treatment significantly decreased self-renewal (fc: 0.1; p<0.01) and induced apoptosis (fc: 1.8; p<0.01). Furthermore, combinatorial treatment targeted persistent CML-CP LSCs in the presence of IL1α and IL1β (fc: 0.6 & 0.5; p<0.05), underlining the relevance of IKK2 inhibition as global approach to target the pro-leukemic inflammatory environment.
Summary/Conclusion: In conclusion, we demonstrate that elevated TNF signaling in CML patients persists during TKI treatment. By combining IKK2 inhibition with a Bcr-Abl1-directed TKI, we were able to target non-dividing CP-CML LSCs but also TKI resistant BC-CML cells. We suggest targeting of TNF-induced signaling as a promising approach to address TKI persistence and resistance in CP- and BC-CML.

EP658 AGE-RELATED DNA DAMAGE RESPONSE (DDR) IN HEMATOPOIETIC STEM CELLS FROM CHRONIC MYELOID LEUKAEMIA PATIENTS WHO ATTEMPTED TKI DISCONTINUATION.

C. Manfroni [1,*], G. Arosio [1], M. Villa [1], M. Mauri [1], G. Giudici [2], S. Bombelli [1], B. Manghisi [2], E. Inzoli [2], R. Perego [1], L. Mologni [1], C. Gambacorti-Passerini [1,2]

[1]University of Milano-Bicocca, [2]San Gerardo Hospital, monza, Italy

Background: Chronic Myeloid Leukemia (CML) is a myeloproliferative disease caused by the 9;22 chromosomal translocation which leads to the formation of the chimeric kinase BCR-ABL. The introduction of imatinib and other tyrosine kinase inhibitors (TKI) allowed excellent control of the disease in the majority of patients. In a number of patients, after a prolonged treatment, Ph+ cells become undetectable or below 10^{-4}, thus allowing a TKI discontinuation attempt. However, about half of CML patients experience a molecular relapse, which in 80% of cases occurs within 6 months from interruption, and need to resume treatment. There is currently no marker to predict the outcome of discontinuation.
Aims: Previous studies have shown that age can predict relapse after TKI discontinuation. We hypothesized that this may be linked to the DDR phenotype of leukemic stem cells (LSCs). We aimed to analyze the DDR status of LSCs, measured at diagnosis, in CML patients who attempted TKI discontinuation, and correlated it with treatment-free remission (TFR) duration.
Methods: CD26 has been proposed as a marker of CML LSCs. We sorted LSCs (CD45+CD34+CD38-CD26+) and normal HSCs (CD45+CD34+CD38-CD26-) from bone marrow samples obtained at diagnosis in 27 CP-CML patients who later discontinued TKI (imatinib, n=15; other TKIs, n=12). The analysis of DDR phenotype was performed by γH2AX immunofluorescence at confocal microscope. Clinical and molecular data were correlated with discontinuation outcome.
Results: CD26 staining correctly identified Ph+ cells within CD34+CD38- cells (Figure 1). We found that DDR in the CD34+CD38- population correlates with patients' age (p = 0.05) and that CD26+ LSCs present greater DDR compared to normal CD26- stem cells (117±48.9 vs 48.8±19.9; p<0.0001, Figure 1). A correlation was also found between DDR at diagnoses and the outcome of TKI discontinuation, which identifies patients in durable TFR as those with less DNA damage at onset (72.2±32.4 vs 107.6±18; p = 0.034). Another interesting finding of this study was the duration of molecular remission before the discontinuation: in fact, it was clear that the longer the duration of deep molecular remission, the lower the probability of relapse after the TKI discontinuation (p = 0.026).

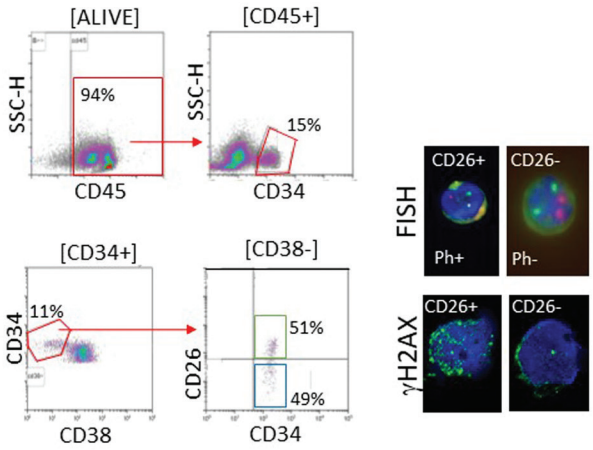

Figure 1. *Left*, FACS sorting protocol of CD45$^+$CD34$^+$CD38$^-$CD26$^+$ and CD45$^+$CD34$^+$CD38$^-$CD26$^-$ cells from a Ph$^+$CML patient sample. *Right*, representative images of BCR/ABL FISH and γH2AX analyses from isolated CD26$^+$ and CD26$^-$ cells are shown.

Summary/Conclusion: We identified DDR and duration of remission as potential biomarkers of relapse in CML patients after TKI discontinuation. Our data also indicate that CML LSCs possess a more pronounced DDR phenotype compared to normal HSCs. These results need to be validated in a larger cohort of patients.

EP659 ASSESSMENT OF LEUKEMIC STEM CELL CD26+ IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH DEEP MOLECULAR RESPONSE.

R. Bengio [1,*], M. Peña [2], F. Palacios [2], B. Moiraghi [3], P. Negri Aranguren [4], A. Enrico [5], R. Mariano [6], M. J. Toloza [7], I. Larripa [7]

[1]Clinica Hematologica, [2]Depto. Citometria, IIHEMA,Academia Nacional Medicina, [3]Servicio Hematologia, Hospital Ramos Mejia, Buenos Aires, [4]Hematologia y Hemoterapia, Instituto Privado de Hematologia y Hemoterapia, Parana, [5]Depto Hematologia, Hospital Italiano, La Plata, [6]Depto Hematologia, Hospital San Martin, Parana, [7]Lab. Genética Hematológica, IMEX, CONICET-Academia Nacional Medicina, Buenos Aires, Argentina

Background: Chronic Myeloid leukemia (CML) is a myeloproliferative neoplasm characterized by the reciprocal translocation t(9;22)(q34;q21) resulting in the *BCR-ABL1* fusion gene and the oncogenic protein P210 with constitutive tyrosine kinase activity. The study of this protein led to the development of tyrosine kinase inhibitors (TKI). It has been shown that patients with a deep and sustained molecular response could stop treatment. It is likely that relapse after TKI discontinuation is due to the persistence of Leukemic Stem Cell (LSC), which are transcriptionally quiescent. The expression of the enzyme dipeptidylpeptidase IV (CD26) is restricted to CD45+/CD34+/CD38- LSC in CML BCR/ABL1+, but is not found in other myeloid or lymphoid LSC. For this reason it is considered a novel specific biomarker of neoplastic cell in CML.
Aims: To detect the LSC (CD26+) in CML patients with different molecular responses (MR) and to assess if these cells remain in deep molecular response (DMR).
Methods: Peripheral blood samples from 174 CML patients (94 males and 80 females) were evaluated for detection of LSC by flow cytometry and quantitative PCR (qRT-PCR) for *BCR-ABL1* rearrangement. All individuals provided an informed consent, in accordance with our Institutional Ethics Committee. The analysis of both studies was carried out simultaneously on the same sample, during the follow up at different time points after diagnosis and under TKI treatment (Imatinib, Nilotinib, Dasatinib). Median age was 48 years old (range 18-82). The molecular responses in International Scale (IS) were: 6% (10/174) Null MR, 9% (15/174) Minimal MR, 16% (28/174) Minor MR, 27% (47/174) Major MR and 42% (74/174) DMR (BCR-ABL1 transcripts reduction ≥ 4 log, including $MR^{4.0}$, $RM^{4.5}$ and $RM^{5.0}$).
Flow cytometry studies were performed with 200 µl of whole blood stained with a panel of 8 antibodies: HLA-DR/CD45/CD38/CD26/CD34/CD117/CD123/CD3 using BD FACS Canto™ II flow cytometer. *BCR-ABL1* qRT-PCR was performed by Taqman method with the Molecular MD *One-Step* kit using a Rotor-Gene 6000 Q real-time thermal-cycler (QIAGEN).
Results: The immunophenotype and molecular response were analyzed in all 174 cases. It was observed that patients with good molecular response (≥3log BCR-ABL1 reduction) had a significantly lower percentage of cases with LSC compared to those who had <3log reduction (P<0.0074, RO: 2.7). The analysis of the 74 patients with DMR (40% (29/74) in $RM^{4.0}$, 55% (40/74) in $RM^{4.5}$ and 5% (4/74) in $RM^{5.0}$) showed that the LSC percentage was: 27% (8/29), 15% (6/41) and 0% (0/4) respectively. This suggests that the decrease in LSC could be related to deeper molecular responses.
Summary/Conclusion: Our results showed that CML patients with molecular response ≥3log BCR-ABL1 reduction were significantly associated with lower proportion of cases with persistence of LSC. When the LSC analysis was performed exclusively in cases with DMR, no significant differences were observed between $RM^{4.0}$, $RM^{4.5}$ and $RM^{5.0}$. However, we observed that the presence of LSC decreased as the depth of the molecular response increased.
Since the LSC is highly quiescent, it could be present even in cases with undetectable DMR. In our study LSC were not detected in 81% (60/74) of cases in DMR, while in the remaining 19% (14/74), CD26+ cells remain despite DMR. This new approach to the study of the LSC could be useful during the follow up of patients in DMR, especially if they would be included in clinical trials of treatment discontinuation.

EP660 EUTOS EXPERIENCE OF STANDARDISATION OF MOLECULAR MONITORING FOR CML (2016 – 2020). USE OF SECONDARY BCR-ABL1 REFERENCE MATERIALS FOR CONVERSION FACTOR VALIDATION AND ASSESSMENT OF MR4.5 DETECTION

H. White [1,*], M. Salmon [1], K. Machova Polakova [2], S. Saussele [3], A. Hochhaus [4], N. Cross [1]

[1]University of Southampton, Salisbury, United Kingdom, [2]Institute of Hematology and Blood Transfusion, Prague, Czech Republic, [3]Department of Haematology and Oncology, Mannheim, [4]University of Jena, Jena, Germany

Background: Monitoring of *BCR-ABL1* mRNA levels using RT-qPCR assays standardised to the International Scale (IS) is essential for management of CML patients, especially when cessation of tyrosine kinase inhibitor therapy is intended. Before the development of secondary reference materials, laboratories used an expensive sample exchange process with reference laboratories for IS calibration. Secondary cell-based reference panels are now available that are traceable to and replicate the WHO primary reference material with an additional standard to include MR4.5.
Aims: To develop and evaluate the use of lyophilised cell line panels to derive and monitor stability of laboratory specific conversion factors (CFs) and the ability of laboratories to measure MR4.5.
Methods: From 2016 – 2020 samples were distributed annually to EUTOS references labs who agreed to participate (2016 n= 49, 2017 n=48, 2018 n=50, 2019 n=49). The samples were: three HL60/K562 cell line lysates at approximately 10%, 0.1% and 0.0032%BCR-ABL IS, a cDNA sample with known *ABL1* and *BCR-ABL1* copy number and secondary reference material panels composed of five vials of lyophilised cells (HL60/K562; LYO panel) supplied by Novartis (2016 -2019) or Thermo Fisher Scientific (Acrometrix™, 2020). IS values for both panels were assigned by reference to the WHO primary reference material for both *ABL1* and *GUSB*. All samples tested by RT-qPCR following normal lab protocols. Anonymised control gene transcript copy numbers over a 4 week audit period for 50 local routine samples were also collected.
Results: CFs were determined using the secondary reference lyophilised cell line panels using the method described at https://www.nibsc.org/documents/ifu/09-138.pdf. The validity of lab CFs was determined annually using: Optimal (+/- 1.2 fold): Previous panel CF / New panel CF = 0.83 – 1.2; Satisfactory (+/- 1.6 fold): Previous panel CF / New panel CF = 0.63 – 1.58; Unvalidated: Previous panel CF / New panel CF <0.63 or >1.58. The validity of CFs for all rounds are shown in the Table.

ABL1	**2016/2017 (n=43)**	**2017/2018 (n=45)**	**2018/2019 (n=42)**	**2019/2020 (n=39)**
Reference Panel	LYO	LYO	LYO	Acrometrix
% Optimal	32.6	60.0	53.8	48.7
% Satisfactory	34.9	22.2	28.2	43.6
% Unvalidated	32.6	17.8	17.9	7.7
GUSB	**2016/2017 (n=11)**	**2017/2018 (n=12)**	**2018/2019 (n=12)**	**2019/2020 (n=13)**
Reference Panel	LYO	LYO	LYO	Acrometrix
% Optimal	9.1	25.0	41.7	46.2
% Satisfactory	27.3	41.7	50.0	7.7
% Unvalidated	63.6	33.3	8.3	46.2

To assess whether labs could detect MR4.5 data were analysed in six categories: median number of *CG* transcripts reported for cell line lysates, detection of *BCR-ABL1* in DMR cell line samples and MR4.5 reference panel samples, *CG* and *BCR-ABL1* transcript number per ul cDNA, %*BCR-ABL1*/*CG* for cDNA sample and quality of *CG* audit data. The scores for each category were weighted, and combined scores calculated. In all rounds

>95% of labs were assessed as being able to detect MR4.5 in all or most samples.
Summary/Conclusion: The % of labs with CFs validated as optimal or satisfactory increased from 67.5% (2016) to 92.3% (2020) and 36.4 (2016) to 53.9% (2020) for *ABL1* and *GUSB* respectively. The percentage of laboratories able to detect MR4.5 in most samples was high across all years with a median of 98%. The EUTOS molecular standardisation study indicates that secondary reference panels can be used effectively to obtain and validate IS CFs over time, validate MR4.5 detection and monitor additional aspects of quality assurance.

EP661 ANALYSIS OF MRNA AND DNA LEVEL OF ATYPICAL BCR-ABL1 TRANSCRIPTS IN CML PATIENTS OUTLINED AN ELIGIBILITY FOR TKI STOPPING

H. Zizkova [1], R. Vajnerova [1], A. Benesova [1], J. Koblihova [1], H. Klamova [1], D. Srbova [1], E. Motlova [1], C. Fava [2], J. Petiti [3], E. M. Gottardi [3], G. Saglio [2], K. Machova Polakova [1,*]

[1]Institute of Hematology and Blood Transfusion, Prague, Czech Republic, [2]Department of Clinical and Biological Sciences, University of Turin, [3]Laboratory of Medicine and Hematology, A.O.U. San Luigi Gonzaga, Turin, Italy

Background: Tyrosine kinase inhibitors (TKI) cessation in patients with chronic myeloid leukemia (CML) can be currently managed in clinical practice. However, only patients with major transcript types are eligible for TKI cessation according to European LeukemiaNet recommendation as BCR-ABL1 quantification for monitoring of measured residual disease (MRD) is standardized for e13a2/e14a2 transcripts only.
Aims: The collaborative EUTOS work aimed 1) to compare DNA and mRNA data measured by qPCR and ddPCR in CML patients with atypical BCR-ABL1 transcripts and 2) to evaluate DNA/mRNA pattern in the patients in deep molecular response (DMR) and their potential eligibility for TKI stopping.
Methods: Paired peripheral blood samples from 9 patients (e19a2=5; e13a3=2; e1a2=1; e6a2=1) with median follow-up 90 months (range 20-225 months) were measured by qPCR (n=223) and ddPCR (n=188). Four patients with e19a2, 1=e13a3 and 1=e6a2 responded to TKI with sustained DMR. Patient-specific genomic BCR-ABL1 fusions were characterized by NGS. The sensitivity of DNA and mRNA analysis varied between 10^{-4} – 10^{-5}. The deterministic model was applied to evaluate MRD pattern.
Results: The amount of mRNA and DNA BCR-ABL1$_{RelDG}$ (the quantity of BCR-ABL1 was determined in relation to the corresponding quantity in the diagnostic sample defined as 100%) highly correlated in samples collected from the start of TKI until achievement of DMR (defined as MRD at levels 10^{-4}-10^{-5}). Differences were found at DMR levels in 75/223 samples measured by qPCR and in 62/188 samples by ddPCR. Out of the 75 samples measured by qPCR, 60 samples were DNA quantifiable and mRNA POQR (positive outside of quantifiable range) or negative, 13 samples were DNA POQR and mRNA negative. Only 2 samples were quantifiable and POQR on mRNA and POQR and negative on DNA, respectively. By ddPCR, BCR-ABL1 was DNA quantifiable and mRNA POQR or negative in all 62 samples with discrepant levels.
A total of 203 samples were available for comparison of mRNA analysis by qPCR and ddPCR. Of these, 39 results were discordant at levels below 10^{-4}. Of these samples, 33 were quantifiable or POQR by ddPCR and were either POQR or negative by qPCR. Six samples were negative by ddPCR while positive by qPCR. DNA BCR-ABL1 levels were concordant by both techniques in 184 of 220 samples. Of the 36 discordant samples, 27 were BCR-ABL1 quantifiable by ddPCR, while POQR or negative by qPCR.
MRD pattern of the 6 patients in DMR was double negative in 1 patient with e19a2, DNA positive/RNA negative in 3 patients (e19a2, e13a3, e6a2) and double positive in 2 patients with e19a2.
Summary/Conclusion: The observed data on BCR-ABL1 atypical transcripts are highly similar to the published data with major BCR-ABL1. DNA and mRNA BCR-ABL1 quantity in CML patients with atypical transcripts were highly concordant at levels above 10^{-4}. The discrepancy was found at DMR levels, where majority of samples were DNA quantifiable or POQR, while POQR or negative on mRNA. ddPCR showed higher precision in DNA and mRNA detection/quantification compared to qPCR at DMR levels. According to the previously proposed traffic light stratification model of probability of treatment free remission (TFR) after TKI stop, 1 patient has high probability of TFR, 3 patients have intermediate probability and 2 patients have low probability of TFR.
We assume that TKI stopping protocols may be safe also for CML patients with atypical BCR-ABL1 transcripts, especially if precision of MRD monitoring is enhanced by using ddPCR and optionally by DNA analysis.
Support: EUTOS2018, MZCR 00023736

EP662 ANALYSIS OF MYELOID MUTATIONS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA AND THEIR ASSOCIATION WITH ADVERSE EVENTS AND RELAPSE AFTER DISCONTINUATION.

A. Segura Diaz [1,*], R. Stuckey [1], M. N. Sáez Perdomo [1], Y. Florido Ortega [1], J. F. López Rodriguez [1], S. Sánchez Sosa [1], J. D. González San Miguel [2], M. T. Gómez Casares [1], C. Bilbao Sieyro [1]

[1]H.U.Dr. Negrin de GC, [2]H.U. Insular de GC, LAS PALMAS, Spain

Background: Chronic myeloid leukemia (CML) is a myeloproliferative neoplasm characterized by the presence of the *BCR-ABL1* fusion gene and is treated using tyrosine kinase inhibitors (TKI). The development of new technologies such as next-generation sequencing (NGS) has led to major advances in the understanding of CML pathogenesis. Molecular studies are beginning to reveal genetic profiles associated with adverse events among patients with CML, including thrombotic events, resistance and/or intolerance to TKI and risk of progression. Moreover, the majority of studies on TKI discontinuation show that approximately half of patients maintain treatment-free remission (TFR), but the factors that determine this are yet to be elucidated.
Aims: Study the mutational profile of CML patients and its association with the development of adverse events and maintenance of TFR after TKI discontinuation.
Methods: We retrospectively analyzed 200 ng genomic DNA extracted from peripheral blood at diagnosis of 63 CML patients subsequently treated with TKI with a minimum follow-up of 3 years. NGS was performed with the MiSeq (Illumina) platform using the targeted panel Myeloid Solution™ (SOPHiA GENETICS). Only variants with VAF≥2%, MAF<1% and described as having a pathogenic or probably pathogenic effect were considered. Adverse events considered include thromboembolic or chronic ischemic events, progression to accelerated or blastic phase, and TKI resistance. With respect to TKI discontinuation, we considered relapse vs. no relapse, and late relapse (TFR maintained>6 months) vs early relapse (<6 months).
Results: Of the 63 patients, 32 (50.8%) were male; average age at diagnosis was 54 years. In 48 patients (76.2%) no mutation was detected; 15 (23.8%) presented ≥1 mutation, with an average allelic frequency (VAF) of 25.7%. The most frequently mutated genes were *ASXL1* (n=9) and *TET2* (n=3) (**Figure 1**). No association was found between the presence of mutation in the CHIP genes (*TET2*, *ASXL1*, *DNMT3A* or *JAK2*) and age.
Sixteen patients had a thrombotic event during follow-up (25.4%). No differences were found in the presence of CHIP mutations between patients with and without a thrombotic event (no event: 7/47, 14.9%; event: 4/16, 25%) or presence of any pathogenic mutation (no event: 10/47, 21.3%; event: 5/16, 31.3%).
Three patients (4.7%) developed TKI resistance; two of them carried pathogenic mutations. One patient presented two mutations in *ASXL1* (VAF 8-9%); the other in *WT1* (VAF 22%) and *KRAS* (VAF 24%), the latter patient was the only one in our series that advanced to blastic phase. Of the 24 patients who attempted TKI discontinuation, 17 (70.8%) maintained TFR for >6 months while 7 (29.2%) had early relapse. There was no difference between the patients who relapsed vs those who maintained TFR, or between early and late relapse in terms of myeloid mutations.

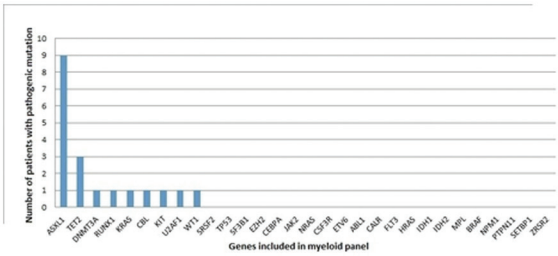

Figure 1. Pathogenic mutations detected in a series of 63 patients with CML.

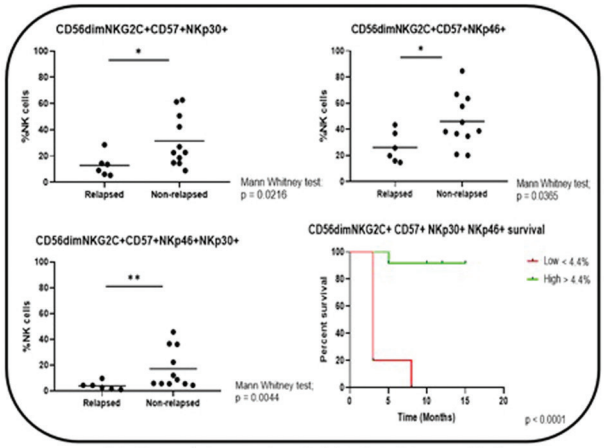

Summary/Conclusion: Less than a quarter of the CML patients analyzed presented pathogenic mutations. These results contrast with those observed in the BCR-ABL1-negative myeloproliferative neoplasms, of whom approximately 50% present mutations (besides the driver genes) and with a higher average VAF. Although patients with thrombotic events presented a higher incidence of myeloid mutations, these differences were not significant. Our results suggest that myeloid mutations are not predictive of TFR or relapse following TKI discontinuation. Larger series are needed to determine whether these mutations are associated with TKI resistance or blastic phase evolution.

EP663 COMPREHENSIVE IMMUNOPROFILE OF NK CELLS FROM CML PATIENTS IN TFR REVEALS A POSSIBLE ROLE OF MEMORY-LIKE NK CELLS

Ramos Mejia, [3]Fundaleu, [4]Servicio de Hematología, Hospital Posadas, [5]Servicio de Hematología, Instituto Alexander Fleming, Buenos Aires, [6]Servicio de Hematología, Hospital Italiano de Mendoza, Mendoza, [7]Servicio de Hematología, Hospital Italiano de Buenos Aires, Buenos Aires, [8]Servicio de Hematología, Hospital San Martin, Parana, Argentina

Background: Long-term survival of patients with chronic myeloid leukemia (CML) has significantly improved since the introduction of BCR-ABL1 tyrosine kinase inhibitors (TKIs). Several clinical trials show that approximately half of patients who achieve a sustained deep molecular response during TKI treatment maintain molecular remission after stopping TKIs. There is currently no biomarker that reliably predicts treatment free remission (TFR) in CML, but growing evidence remarks the importance of the immune system, especially of Natural Killer (NK) cells in this scenario.
Aims: Our aim is to discover a biomarker for TFR prediction by analyzing the conventional and adaptive phenotype of NK cells at the time of discontinuation and their relation to successful TKI cessation, and to assess any phenotypic changes throughout the months without treatment.
Methods: Fifty chronic phase CML patients who participated in the Argentina Stop Trial were recruited from 7 Argentinian centers. Peripheral blood samples were collected before TKI stopping and then at months 3, 12 and at any time when $MR^{3.0}$ was lost. Freshly isolated mononuclear cells were immunophenotyped by staining with CD3, CD16, CD25, CD56, CD57, CD158, NKp30, NKp44, NKp46, NKG2A, NKG2C, NKG2D and PD-1 antibodies and subpopulations of NK cells were analyzed by flow cytometry (BD FACS Canto™II). Molecular recurrence-free survival was estimated by the Kaplan–Meier method. Mann Whitney test, Wilcoxon test or paired T test were performed to compare variables between groups, where $p<0.05$ was considered statistically significant. Quantitative variables were dichotomized according to ROC curves. Survival curves were compared with log rank test.
Results: Forty-six patients were analyzed with a median follow-up of 15 months (range 12-21) and with an estimated molecular recurrence-free survival of 67.4% at 12 months. At the time of discontinuation, non-relapsing patients had significantly higher frequencies of NK subpopulations with cytomegalovirus-related memory features ($CD56^{dim}CD57^{+}NKG2C^{+}$), but higher expression of cytotoxicity markers $NKp30^{high}$ ($p=0.0216$) or $NKp46^{high}$ ($p=0.0365$). Most important, a higher coexpression of NKp30 and NKp46 on $CD56^{dim}CD57^{+}NKG2C^{+}$ subpopulation (defined as memory-like NK, ML-NK) showed a significant difference in survival when relapsed vs non-relapsed patients were compared (0% vs 92% at 12 months, log rank test, $p<0.0001$) (Fig. 1). After TKI discontinuation, a significant and sustained increase or decrease over time could be seen for 4 NK cells subpopulations expressing CD57, NKG2D, PD-1 and NKp44, while NKp30, CD158, $CD57^{+}CD16^{+}CD158^{+}$, and ML-NK subpopulations did not significantly change over the course of 12 months.

Note: These analysis were performed only in patients that were positive for cytomegalovirus determination (CMV+) and showed a memory-like subpopulation of NK cells characterized by the expression of NKG2C receptor of 8% or higher.

Summary/Conclusion: Our study is the first, to our knowledge, to describe this adaptive-like subpopulations of NK cells with enhanced cytotoxicity-related phenotype which could have a protecting role in patients who do not relapse. Moreover, the ML-NK phenotype was retained more efficiently in TFR patients off-therapy, suggesting that the restored immune control observed at the time of discontinuation is not an entirely TKI-mediated effect, which could be used as a predictive biomarker. The clinical impact of NK cells in patients who have discontinued TKIs is still controversial. To fully understand their role, we are planning to carry out functional studies

EP664 TARGETING THE LEUKEMIC STEM CELL NICHE BY PI3K INHIBITORS IN CHRONIC MYELOID LEUKEMIA TO OVERCOME LEUKEMIC STEM CELL RESISTANCE

Y. Filik [1,2,*], K. Bauer [1,2], E. Hadzijusufovic [1,2,3], W. R. Sperr [1,2], P. Valent [1,2]

[1]Ludwig Boltzmann Institute for Hematology and Oncology, [2]Department for Internal Medicine I, Division of Hematology and Hemostaseology, Medical University of Vienna, [3]Department/Hospital for Companion Animals and Horses, University Hospital for Small Animals, Internal Medicine Small Animals, University of Veterinary Medicine Vienna, Vienna, Austria

Background: Recent data suggest that the disease-related microenvironment (stem cell niche) is critically involved in drug resistance of leukemic stem cells (LSC) in chronic myeloid leukemia (CML). Attacking the stem cell niche in CML may thus be an effective approach to overcome LSC resistance. We have recently shown that osteoblasts induce substantial LSC resistance against tyrosine kinase inhibitors (TKI) in CML. We also found that several BCR-ABL1 TKI, like ponatinib or nilotinib, exert growth-inhibitory effects on endothelial cells.
Aims: In the current study, we screened for drugs that are able to suppress the growth and viability of osteoblasts and endothelial cells in the CML context.
Methods: Proliferation was analyzed by measuring ^{3}H-thymidine uptake in niche-related cells and apoptosis was measured by AnnexinV/DAPI-staining.
Results: We found that PI3K/mTOR blocker BEZ235 and pan-PI3K inhibitor copanlisib suppress growth and viability of primary osteoblasts (BEZ235 IC_{50}: 0.05 µM, copanlisib IC_{50}: 0.05 µM), the osteoblastic cell line

IBS: Imatinib binding site; IM: Imatinib; DA: Dasatinib; NI: Nilotinib; BMR: Best molecular response.
At study entry, all the pts. were in chronic phase, only Pt. 1 evolved to blast crisis independently of the change in TKI. Pts. 2 and 3 exhibited the same 35bp insertion variant, and achieved non optimal responses, while in pts 4, 5, 6 and 7 good MR were obtained: Pts. 4 and 7 achieved deep molecular responses to 2nd generation TKI (MR4.5). A synonymous variant was described in Pt 5 and showed a good molecular evolution despite any TKI treatment changeIBS: Imatinib binding site; IM: Imatinib; DA: Dasatinib; NI: Nilotinib; BMR: Best molecular response.

CAL-72 (BEZ235 IC_{50}: 0.5 µM; copanlisib IC_{50}: 1 µM), primary umbilical vein-derived endothelial cells (BEZ235 IC_{50}: 0.5 µM; copanlisib IC_{50}: 0.5 µM), and the endothelial cell line HMEC-1 (BEZ235 IC_{50}: 1 µM; copanlisib IC_{50}: 1 µM). Moreover, we found that BEZ235 and copanlisib cooperate with nilotinib and ponatinib in suppressing growth and viability of osteoblasts and endothelial cells. Finally, BEZ235 and copanlisib were found to overcome osteoblast-induced resistance of K562 cells, KU812 cells, and primary $CD34^+/CD38^-$ CML LSC against nilotinib and ponatinib.
Summary/Conclusion: Together our data suggest that targeting niche cells by BEZ235 and copanlisib is an effective approach to overcome niche-induced TKI resistance in CML.

EP665 RARE MUTATIONS IN BCR-ABL THE KINASE DOMAIN IN CRONIC MYELOID LEUKEMIA PATIENTS.

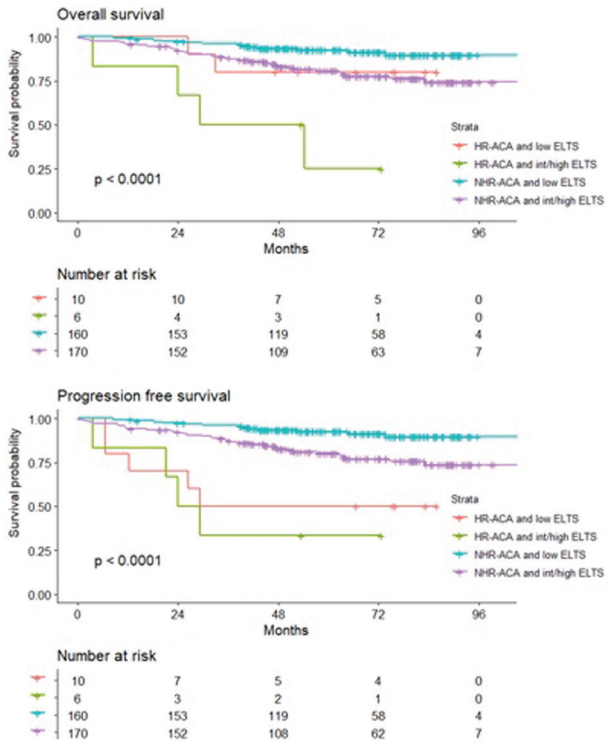
Background: BCR-ABL kinase domain (KD) mutations are the most frequent mechanism of tyrosine kinase inhibitor (TKI) resistance in chronic myeloid leukemia (CML) patients (pts.). Detection of specific mutations influences the choice of the second or subsequent TKI lines. Intensive efforts are focused on characterizing their biological and clinical significance.
Aims: To characterize rare p210 BCR-ABL KD variants revealed in an argentine multicentric study.
Methods: This prospective study screened a cohort of CML TKI resistant pts, from 40 centers, from June 2011 to August 2020. Mutational analysis was performed by direct sequencing of BCR-ABL KD, NCBI sequence reference ID: NM_005157.5 (Branford *et al*, 2002). Molecular response was defined upon fusion transcript level measured by Real Time quantitative PCR (Gabert *et al*, 2003) and expressed in international scale as IS%BCR-ABL (Cross *et al*, 2012).
Results: Mutation screening was performed in 271 CML resistant pts. BCR-ABL DK mutations were detected in 26.2% (71/271) pts: single and compound mutations in 96% (68/71) and 4% (3/71), respectively. The most frequent mutations identified were T315I 35% (25/71) and F317L 11% (8/71). Only 10% (7/71) pts. unveiled rare variants with unknown TKI sensitivity and are described in Table 1. A novel BCR-ABL KD mutation was revealed.
At study entry, all the pts. were in chronic phase, only Pt. 1 evolved to blast crisis independently of the change in TKI. Pts. 2 and 3 exhibited the same 35bp insertion variant, and achieved non optimal responses, while in pts 4, 5, 6 and 7 good MR were obtained: Pts. 4 and 7 achieved deep molecular responses to 2nd generation TKI (MR4.5). A synonymous variant was described in Pt 5 and showed a good molecular evolution despite any TKI treatment changeIBS: Imatinib binding site; IM: Imatinib; DA: Dasatinib; NI: Nilotinib; BMR: Best molecular response.
Summary/Conclusion: Detected insertions and deletions variants conducting to truncated proteins, alternative splicing and changes in the Imatinib binding site (IBS) may affect TKI binding to BCR-ABL KD. Variants in the C-terminal region as the missense mutation (c.1322C>T) might confer worse prognosis. Even though the 35bp insertion (c.1423_1424ins35) conferred resistance to Imatinib (IM) and Nilotinib (NI), a sustained suboptimal response was achieved with Dasatinib (DA) therapy. The novel variant (p.Glu308Gly) affects a highly conserved IBS region, probably causing the IM resistance in our patient; however a deep response to NI was achieved. It is important to report single experiences in the treatment and follow up of pts. with uncommon mutations in order to be able to have more data regarding its clinical course. Our study highlights the need for BCR-ABL KD sequence analysis to characterize mutations in therapy resistant CML pts with the aim of guiding targeted treatment.

Chronic myeloid leukemia - Clinical



EP666 NEGATIVE PROGNOSTIC IMPACT OF HIGH-RISK ADDITIONAL CYTOGENETIC ABNORMALITIES IN ADDITION TO THE ELTS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

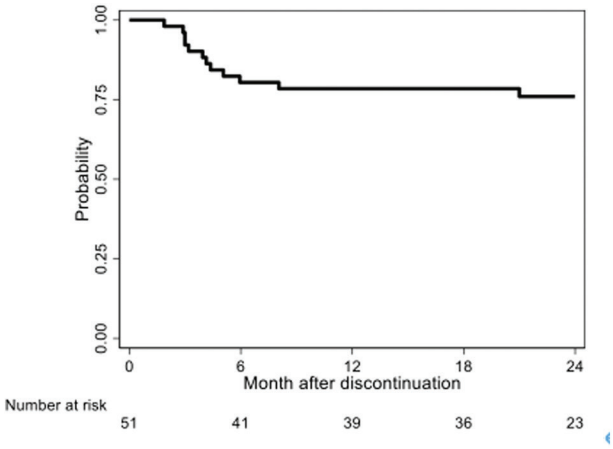
C. C. Kockerols [1,*], I. G. Geelen [1], M.-D. Levin [1], J. J. Janssen [2], H. B. Beverloo [3], A. G. Dinmohamed [4], M. Hoogendoorn [5], J. J. Cornelissen [6], P. E. Westerweel [1]

[1]Department of Hematology, Albert Schweitzer Hospital, Dordrecht, [2]Department of Hematology, Amsterdam University Medical Center, location VU Medical Center, Amsterdam, [3]Department of Clinical Genetics, Erasmus Medical Center, Rotterdam, [4]Department of Research and Development, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [5]Department of Hematology, Medical Center

Leeuwarden, Leeuwarden, [6]Department of Hematology, Erasmus Medical Center, Rotterdam, Netherlands

Background: The negative prognostic impact of high-risk additional cytogenetic abnormalities (HR-ACAs) in chronic myeloid leukemia (CML) is well established. Also, the EUTOS long-term survival score ELTS may be used to identify patients at increased risk for CML-related death during TKI therapy. However, it has not been investigated if HR-ACAs and higher ELTS are related and if a better prognostic prediction may be achieved when combining HR-ACAs and the ELTS.
Aims: The objectives were to assess the relation of HR-ACA with the ELTS at diagnosis and to evaluate the impact of HR-ACA in addition to ELTS on survival in a real-world CML patient population.
Methods: This retrospective analysis was performed using data derived from a real-world population-based registry of 480 Dutch CML patients diagnosed between 2008 and April 2013 (The PHAROS CML Registry combined with HemoBase) with a follow-up until February 2016. HR-ACAs were defined according to the stratification of Hehlmann *et al.* (Leukemia 2020): +8, +Ph, +19, +21, +17 (or i[17q]), 3q26.2, 11q23, –7/7q– and complex karyotypes (≥3 ACAs) in Ph-positive cells. Loss of the Y chromosome and other ACAs were classified as low-risk ACAs. Overall and progression-free survival (OS and PFS) analyses were performed using the Kaplan Meier method and the log-rank method to test for equality. PFS in chronic phase CML was measured from diagnosis to death or progression to AP/BC; patients in AP/BC at diagnosis were excluded from this analysis.
Results: Cytogenetic assessments were available for 415 (86.4%) patients, of whom 20 (4.8%) had HR-ACAs. Trisomy 8 and an additional Ph-chromosome were the most prevalent HR-ACA. HR-ACA had a significant negative prognostic impact on both OS (HR 3.24; 95% CI, 1.61-6.49; p = 0.001) and PFS (HR 4.76; 95% CI, 2.44-9.35; p < 0.001). Low-risk ACA in Ph-positive cells or clonal cytogenetic aberrations in Ph-negative cells (CCA/Ph-) had no prognostic impact. No significant difference in Sokal-score or ELTS was found in patients with *versus* without HR-ACA (p = 0.573 and p = 0.831). HR-ACA was confirmed as an independent prognostic factor in a cox-regression multivariable analysis with the ELTS at diagnosis and type of first-line TKI as covariables. In our subgroup analysis, patients with both HR-ACAs and an intermediate to high ELTS at diagnosis had a markedly reduced OS compared to patients without HR-ACA or with a low ELTS (figure: plot 1). In the PFS analysis, both HR-ACA subgroups had a significantly reduced survival probability compared to patients without HR-ACA (figure: plot 2).

Summary/Conclusion: These results confirm the negative prognostic impact of HR-ACA on newly diagnosed CML patients and support its implementation as an independent risk-variable in a new prognostic model, including both the presence HR-ACA and the ELTS at diagnosis. Furthermore, they provide a first validation of the ACA risk stratification proposed by Hehlmann *et al.* since our survival analysis clearly distinguishes HR-ACAs from low-risk ACA or CCA/Ph-. Patients with HR-ACA at diagnosis or int/high ELTS, and especially when in combination, may benefit from a more aggressive treatment approach with upfront 2GTKI, a more stringent response monitoring and an early consideration of allogeneic stem cell transplantation in case of inadequate treatment responses.



EP667 TREATMENT-FREE REMISSION IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE FOLLOWING FRONTLINE NILOTINIB: RESULTS FROM JALSG N-STOP216

N. Takahashi [1,*], I. Matsumura [2], Y. Minami [3], T. Ono [4], T. Hata [5], S. Ohtake [6], Y. Atsuta [7], M. Kurata [7], K. Fujimaki [8], T. Nagao [9], C. Nakaseko [10], N. Iriyama [11], T. Miyamoto [12], N. Asou [13], H. Kiyoi [14], Y. Miyazaki [5]

[1]Akita University School of Medicine, Akita, [2]Kindai University Faculty of Medicine, Osakasayama, [3]National Cancer Center Hospital East, Kashiwa, [4]Hamamatsu University Hospital, Hamamatsu, [5]Atomic Bomb Disease Institute, Nagasaki University Hospital, Nagasaki, [6]Kanazawa University, Kanazawa, [7]Japanese Data Center for Hematopoietic Cell Transplantation, Nagoya, [8]Fujisawa City Hospital, Fujisawa, [9]Tokyo Medical and Dental University, Tokyo, [10]International University of Health and Welfare, Narita, [11]Nihon University, Tokyo, [12]Kyushu University, Fukuoka, [13]International Medical Center, Saitama Medical University, Hidaka, [14]Nagoya University Graduate School of Medicine, Nagoya, Japan

Background: Previously reported results from JALSG CML212 (UMIN000007909), a multicentrer open-labeled prospective randomized controlled phase 3 study on de novo chronic myeloid leukemia in chronic phase (CML-CP), showed that cumulative achievement rates of $MR^{4.5}$ (*BCR-ABL1* ≤0.0032% on the International Scale [$BCR\text{-}ABL1^{IS}$]) by 18 months were 33.0% (75/227) (95% CI:27.0–39.6%) in the nilotinib (NIL) arm and 30.8% (70/227) (95% CI: 24.9–37.3%) in the dasatinib arm, with no significant difference.
Aims: JALSG N-STOP216 (UMIN000024984), the next planned study, will evaluate patients with sustained $MR^{4.5}$, for at least 2 years on frontline NIL for estimating the rate of treatment-free remission (TFR), which is a new treatment goal in CML-CP.
Methods: BCR-ABL-positive CML-CP patients with ≥3 years of frontline NIL and sustained $MR^{4.5}$ for more than 2 years were enrolled in this trial. Patients restarted NIL after loss of major molecular response (MMR; $BCR\text{-}ABL1^{IS}$ ≤0.1%). The data cutoff was December 14, 2020, by which point all patients had completed 12 months of TFR, restarted NIL, or discontinued the study. All patients provided informed consent.
Results: A total of 54 patients were registered from 23 institutes and 51 patients were analyzed as FAS and PPS. Median age of the patients was 53 years (28–79 years). The proportions of Sokal low-, intermediate-, and high-risk groups were 41.2%, 35.3%, and 23.5%, respectively. The proportions of EUTOS low- and high-risk groups were 88.2% and 11.8%, respectively. The median duration of NIL treatment was 53 months (36–129 months), and the median duration of MR4.5 ($BCR\text{-}ABL1^{IS}$ ≤0.0032%) was 31 months (24–104 months). The median time to achieved MMR was 183 days (81–1567 days). At 12 months, 39/51 patients remained in TFR (76.5%; 95% CI:62.5%–87.2%) and 12 patients (23.5%) lost MMR. Of 11 patients who restarted NIL, 10 (90.9%) regained MMR in 6 months (1 discontinued study without MMR because of AE). At 12 months, 37/51 patients remained in MR4.0 ($BCR\text{-}ABL1^{IS}$ ≤0.01%) (72.6%; 95% CI:58.3%–84.1%); 14 patients (27.5%) lost MR4.0, and 31/51 patients remained in MR4.5 (60.8%; 95% CI:46.1%–74.2%); 20 patients (39.2%) lost MR4.5. No patient experienced disease progression. There was 1 death (pancreas cancer). At 24 months, the treatment-free survival (TFS) rate was 75.9% (95% CI:61.5%–85.6%; Fig.1). As estimated using the Kaplan–Meier method, TFS did not differ among Sokal risk groups (low, int, and high; p=0.5651), EUTOS risk groups (low and high; p=0.5389), duration of NIL (<4 years and ≥ 4 years; p=0.8910), duration of MR4.5 (<30 months and ≥ 30

months; p=0.5852), or time of MMR (<183 days and ≥ 183 days; p=0.1789).

Summary/Conclusion: JALSG N-STOP216 provides prospective TFR data in Japanese patients with CML-CP who achieved sustained MR$^{4.5}$ on frontline NIL. After stopping NIL, 76.5% of patients remained in TFR at 12 months later. The results suggest that a higher proportion of patients with CML-CP who achieved sustained MR$^{4.5}$ on frontline NIL will remain progression free without treatment compared with that in previous TFR trials.

EP668 TREATMENT-FREE REMISSION IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE FOLLOWING FRONTLINE DASATINIB: RESULTS FROM JALSG D-STOP216

[1]Department of Hematology, National Cancer Center Hospital East, Kashiwa, [2]Kindai University Faculty of Medicine, Osakasayama, [3]Akita University School of Medicine, Akita, [4]Kanazawa University, Kanazawa, [5]Japanese Data Center for Hematopoietic Cell Transplantation, Nagoya, [6]The Jikei University Hospital, [7]Nihon University School of Medicine, Tokyo, [8]Kurashiki Central Hospital, Kurashiki, [9]Japanese Red Cross Nagoya Daiichi Hospital, Nagoya, [10]Chiba University Hospital, Chiba, [11]Aiiku Hospital, Sapporo, [12]Tokyo medical and dental university, Tokyo, [13]Hamamatsu University Hospital, Hamamatsu, [14]Fujisawa City Hospital, Fujisawa, [15]International University of Health and Welfare, Narita, [16]Kyushu University, Fukuoka, [17]International Medical Center, Saitama Medical University, Hidaka, [18]Nagoya University Graduate School of Medicine, Nagoya, [19]Nagasaki University Hospital, Nagasaki, Japan

Background: Previously reported results from JALSG CML212 (UMIN000007909), a multicenter open-labeled prospective randomized controlled phase 3 study on *de novo* chronic myeloid leukemia in chronic phase (CML-CP), showed that cumulative achievement rates of MR$^{4.5}$ (*BCR-ABL1* ≤0.0032% on the International Scale [*BCR-ABL1*^{IS}]) by 18 months were 33.0% (75/227) (95% CI:27.0–39.6%) in the nilotinib arm and 30.8% (70/227) (95% CI: 24.9–37.3%) in the dasatinib (DAS) arm, with no significant difference.
Aims: JALSG D-STOP216 (UMIN000024985), the next planned study, will evaluate patients with sustained MR$^{4.5}$, for at least 2 years on frontline DAS for estimating the rate of treatment-free remission (TFR), which is a new treatment goal in CML-CP.
Methods: BCR-ABL-positive CML-CP patients with ≥3 years of frontline DAS and sustained MR$^{4.5}$ for more than 2 years were enrolled in this trial. Patients restarted DAS after loss of major molecular response (MMR; *BCR-ABL1*^{IS} ≤0.1%). The data cutoff was December 14, 2020, by which point all patients had completed 12 months of TFR, restarted DAS, or discontinued the study. All patients provided informed consent.
Results: A total of 56 patients were registered from 25 institutes. Forty-nine of these patients were diagnosed with FAS and PPS[A1]. Median age of the patients was 52 years (24–80 years). Sokal low-, intermediate-, and high-risk group proportions were 40.8%, 44.9%, and 14.3%, respectively. EUTOS low- and high-risk group proportions were 91.8% and 8.2%, respectively. The median duration of DAS treatment was 51 months (36–129 months), and the median duration of MR$^{4.5}$ (*BCR-ABL1*^{IS} ≤0.0032%) was 30 months (24–64 months). The median time to achieve MMR was 178 days (83–1921 days). At 12 months, 29/49 patients remained in TFR (59.2%; 95% CI: 44.2%–73.0%), and 20 patients (40.8%) lost MMR. All the 22 patients (100%) who restarted DAS, regained MMR within 6 months. At 12 months, 27/49 patients remained in MR$^{4.0}$ (*BCR-ABL1*^{IS} ≤0.01%) (55.1%; 95% CI: 40.2%–69.3%), 22 patients (44.9%) lost MR$^{4.0}$, and among 25/49 patients that remained in MR$^{4.5}$ (51.0%; 95% CI: 36.3%–65.6%), 24 patients (49.0%) lost MR$^{4.5}$. No patients experienced disease progression or death for any reason. At 24 months, the treatment-free survival (TFS) rate was 59.2% (95% CI: 44.2%–71.4%; Fig.1). TFS did not differ among Sokal risk groups (low, int, and high; p=0.6300), EUTOS risk groups (low and high; p=0.4613), duration of DAS (<4 years and > ≥ 4 years; p=0.8522), duration of MR$^{4.5}$ (<30 and ≥ 30 months; p=0.8974), or time of MMR (<178 days and ≥ 178 days; p=0.1318).
Summary/Conclusion: JALSG D-STOP216 provides prospective TFR data in Japanese patients with CML-CP who achieved sustained MR$^{4.5}$ on frontline DAS. After stopping DAS, 59.2% of patients remained in TFR 12 months later. The results suggest that a higher proportion of patients with CML-CP who achieved sustained MR$^{4.5}$ on frontline DAS will remain progression free without treatment compared with that in previous TFR trials.

EP669 COMPARISON OF THE SOKAL AND EUTOS LONG-TERM SURVIVAL SCORES IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA RECEIVING TYROSINE KINASE INHIBITORS

X. Zhang [1,2,*], Y. Qin [1,2], Y. Lai [1,2], H. Shi [1,2], X. Huang [1,2], Q. Jiang [1,2]

[1]Peking University People's Hospital, [2]Peking University Institute of Hematology, Beijing, China

Background: There are limited studies comprehensively comparing the significance between Sokal and EUTOS long-term survival (ELTS) scores in patients with chronic-phase chronic myeloid leukemia (CML-CP) receiving tyrosine kinase inhibitor (TKI) therapy.
Aims: To compare the significance of the Sokal and ELTS scores in predicting the therapy responses and outcomes in CML-CP patients receiving front-line imatinib or the second generation (2G) TKI therapy.
Methods: Data from consecutive patients with newly-diagnosed CML-CP from January 2006 to August 2020 were reviewed. Propensity score matching (PSM) was performed to explore the impact of front-line TKI therapy choice in the CML-CP patients based on the Sokal or ELTS score.
Results: Data from 1559 CML-CP patients receiving front-line imatinib (n = 1331) or 2G TKI (n = 228) therapy were analyzed. In multivariate analyses, both the Sokal and ELTS scores could predict the probabilities of achieving complete cytogenetic response (CCyR) (ref. low-risk; Sokal: intermediate-risk, HR, 0.8 [0.7, 0.9], p = 0.005; high-risk, HR, 0.7 [0.6, 0.8], p < 0.001; ELTS: intermediate-risk, HR, 0.9 [0.7, 1.0], p = 0.080; high-risk, HR, 0.6 [0.5, 0.8], p < 0.001) and major molecular response (MMR) (ref. low-risk; Sokal: high-risk, HR, 0.8 [0.7, 1.0], p = 0.014; ELTS: intermediate-risk, HR, 0.8 [0.6, 0.9], p = 0.003; high-risk, HR, 0.6 [0.4, 0.8], p < 0.001) and failure-free survival (FFS) (ref. low-risk; Sokal: intermediate-risk, HR, 1.7 [1.3, 2.3], p = 0.001; high-risk, HR, 2.0 [1.5, 2.8], p < 0.001; ELTS: intermediate-risk, HR, 1.5 [1.2, 2.0], p = 0.003; high-risk, HR, 2.7 [1.9, 3.8], p < 0.001) and progression-free survival (PFS) (ref. low-risk; Sokal: intermediate-risk, HR, 2.1 [1.2, 3.5]; p = 0.006; ELTS: intermediate-risk, HR, 1.7 [1.0, 2.7]; p = 0.035; high-risk, HR, 3.9 [2.2, 6.7], p < 0.001) in all patients.

However, the ELTS score rather than the Sokal score was significantly-associated with the probabilities of achieving MR$^{4.5}$ (ref. low-risk; intermediate-risk, HR, 0.8 [0.6, 1.0], p = 0.046; high-risk, HR, 0.6 [0.4, 0.9], p = 0.026) and overall survival (OS) (ref. low-risk; intermediate-risk, HR, 1.8 [1.0, 3.2], p = 0.063; high-risk, HR, 5.0 [2.7, 9.1], p < 0.001). Similar findings were observed in those receiving front-line imatinib therapy. However, in those receiving front-line 2G TKI therapy, only the ELTS score could predict the probabilities of achieving CCyR, MMR, FFS and PFS, especially in the high-risk subgroup identified by the ELTS score who had lower probabilities of achieving CCyR (HR, 0.4 [0.2, 0.6], p < 0.001) and MMR (HR, 0.3 [0.1, 0.5], p < 0.001] and had inferior FFS (HR, 3.6 [1.8, 7.0], p < 0.001) and PFS (HR, 3.3 [1.2, 9.2], p = 0.022) than the low-risk subgroup. In the PSM analysis, although the intermediate-risk subgroup identified by both the Sokal (n = 267, 34.9%) and ELTS (n = 69, 31.5%) scores receiving front-line 2G-TKI therapy had higher 7-year probabilities of achieving CCyR (p < 0.001 and p < 0.001) and MMR (p = 0.003 and p < 0.001) and FFS (p = 0.012 and p = 0.004) than those receiving front-line imatinib therapy, the advantage for predicting the probability of PFS (p = 0.058) was only shown in those by the ELTS score.

Summary/Conclusion: Our findings provide evidence supporting the higher predictive performance of the ELTS score than the Sokal score in CML-CP patients receiving TKI therapy, especially front-line 2G TKI therapy. Patients identified as intermediate-risk by the ELTS score might benefit more from front-line 2G TKI therapy.

EP670 ASCIMINIB RESPONSES IN PONATINIB-PRETREATED PATIENTS WITH CHRONIC MYELOID LEUKEMIA

Background: Resistance or intolerance to second-generation tyrosine-kinase inhibitors (2GTKIs) is a rough issue in chronic myeloid leukemia (CML) patients. Asciminib, not yet commercially available, inhibits ABL kinase activity by a mechanism distinct to that of currently used TKIs and maintains activity against many resistant forms of BCR-ABL1. Recent data from phase I-III trials showed high response rates with a good safety profile in patients failing to 2GTKIs. However, no studies have specifically addressed response rates with asciminib in ponatinib-pretreated (PPT) patients.

Aims: To present data on responses to asciminib in PPT and non-PPT patients in the setting of clinical practice.

Methods: We gathered retrospective clinical data from 31 patients treated with asciminib after failure of several lines of TKI treatment. Eleven patients received ponatinib at some point for a median time of 18 months. A total of 29 patients were included in the efficacy analysis (2 patients were excluded due to short follow-up). We defined failure as either resistance (BCR-ABL1[15] increase despite optimal TKI dosing) or intolerance (unacceptable toxicity leading to TKI termination). Asciminib use was provided by Novartis under a managed-access program (MAP). Data was collected from October 2018 to June 2020 in 25 institutions from the Spanish CML Group (GELMC).

Results: The median time on asciminib for the entire cohort was 9 months (7 in the PPT group and 13 in the non-PPT group). Median time on previous TKI for the entire cohort was 77 months (56 vs 105 for PPT and non-PPT patients, respectively). Median previous TKI lines before asciminib were 4, with no differences for PPT and non-PPT groups. Switch to asciminib was due to resistance in 5/11 (45%) vs 3/20 (15%) for the PPT and non-PPT, respectively, and due to intolerance in 6/11 (55%) and 17/20 (85%) for PPT and non-PPT groups. The median dose of ponatinib was 45 mg in resistant patients and 15 mg in intolerant patients.

Responses rates according to asciminib indication and previous exposure to ponatinib are shown in table 1. The probabilities of maintaining or improving responses were 100%, 56% and 22% for complete cytogenetic response (CCyR), major molecular response (MMR) and MR4.5 respectively in non-PPT group versus 27%, 18% and 0% in PPT group, respectively. Probability of improving baseline responses were 78%, 47% and 22% for CCyR, MMR and MR4.5 respectively in non-PPT group versus 33%, 10% and 0% respectively observed in PPT patients.

Concerning baseline mutational status, 12 (39%) of the 31 patients displayed BCR-ABL1 mutations (only 1 with T315I), with a heterogeneous pattern and no clear association with outcome: 7 patients in the non-PPT group (35%) and 5 patients in the PPT group (45%).

In terms of tolerability, 10/17 (59%) in the non-PPT-intolerant subgroup displayed side effects; whereas in the PPT-intolerant subgroup 3/6 patients (50%) displayed side effects: grade 1 rash, grade 3 pancreatitis, and grade 4 thrombocytopenia, accordingly.

At the end of follow-up, 27 (87%) continued receiving asciminib, 2 suffered from progression to blast phase and 2 patients showed loss of efficacy; notably, these 4 patients were in the PPT group, whereas all non-PPT continued on asciminib.

Best response to asciminib in non-PPT vs PPT patients

	Resistant (n=8)		Intolerant (n=21*)		Total (n=29*)	
	Non-PPT (n=3)	PPT(n=5)	Non-PPT (n=15*)	PPT (n=6)	Non-PPT (n=18*)	PPT (n=11)
CHR[a]	3/3 (100%)	5/5 (100%)	15/15 (100%)	6/6 (100%)	18/18 (100%)	11/11 (100%)
CCyR[a]	2/3 (66%)	1/5 (20%)	14/15 (93%)	2/6 (33%)	18/18 (100%)	3/11 (27%)
MMR[a]	0/3 (0%)	1/5 (20%)	10/15 (67%)	1/6 (17%)	10/18 (56%)	2/11 (18%)
MR4.5[a]	0/3 (0%)	0/5 (0%)	4/15 (27%)	0/6 (0%)	4/18 (22%)	0/11 (0%)
Patients without respective response at baseline						
CCyR[b]	2/3 (66%)	1/5 (20%)	5/6 (85%)	2/4 (50%)	7/9 (78%)	3/9(33%)
MMR[b]	0/3 (0%)	0/5 (0%)	7/12 (58%)	1/5 (20%)	7/15 (47%)	1/10(10%)
MR4.5[b]	0/3 (0%)	0/5 (0%)	4/15 (27%)	0/6 (0%)	4/18 (22%)	0/11 (0%)

Table 1. Responses to asciminib in non-ponatinib-pretreated patients and ponatinib-pretreated patients subgroups. *PPT*: ponatinib-pretreated patients. *CHR*: complete hematological response, *CCyR*: complete cytogenetic response, *MMR*: major molecular response, *MR4.5*: detectable disease with BCR-ABL1^{IS} < 0.0032%. *Two patients were excluded from response analysis due to short follow-up. [a]Patients with CHR, CCyR, MMR, or MR4.5 at baseline were evaluable for hematologic, cytogenetic, or molecular response and were considered responders if they maintained their response. [b]Evaluable patients without a CCyR, MMR, or MR4.5 at baseline.

Summary/Conclusion: Asciminib constitutes a valid treatment option for patients failing 2GTKIs. However, our data suggest that response rates after ponatinib failure are poor, with these patients remaining a high risk group in which alternative treatments are needed.

EP671 OUTCOMES BEFORE AND AFTER DOSE REDUCTION IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA RECEIVING BOSUTINIB OR IMATINIB

M. W. Deininger [1,*], T. H. Brümmendorf [2], D. Milojkovic [3], F. Cervantes [4], F. Huguet [5], A. Viqueira [6], E. Leip [7], S. Purcell [8], J. E. Cortes [9]

[1]University of Utah Health Care, Salt Lake City, United States, [2]Universitätsklinikum RWTH Aachen, Aachen, Germany, [3]Hammersmith Hospital, London, United Kingdom, [4]Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain, [5]Institut Universitaire du Cancer, Toulouse, France, [6]Pfizer SLU, Madrid, Spain, [7]Pfizer Inc, Cambridge, United States, [8]Pfizer Ltd, London, United Kingdom, [9]Georgia Cancer Center, Augusta, United States

Background: Bosutinib is approved for patients with Philadelphia chromosome-positive chronic myeloid leukemia (CML), at a starting dose of 400 mg once daily (QD) in newly diagnosed patients in chronic phase (CP).
Aims: This analysis evaluated the impact dose reduction has on the outcomes of bosutinib and imatinib in patients with CP CML.
Methods: In the open-label BFORE trial, 536 patients with newly diagnosed CP CML were randomized to receive 400 mg QD bosutinib (N=268) or imatinib (N=268; 3 untreated). Dose could be reduced to 300 mg QD for toxicity. Following sponsor approval, dose reduction to bosutinib 200 mg QD was permitted for 4 weeks maximum; after this time, dose escalation or treatment discontinuation was required. Maintenance of response after dose reduction was defined as having a response >6 months after the first reduction. Database lock: June 12, 2020, 5 years after the last patient enrolled.
Results: In the bosutinib arm, dose reduction to 300 (without further reduction) or 200 mg QD was seen in 82 (31%) and 33 (12%) patients, and median time to dose reduction was 85 and 205 days. In the imatinib arm, 50 (19%) patients had a dose reduction to 300 mg QD, and median time to dose reduction was 92 days. Most common (≥2% of patients) treatment-emergent adverse events (TEAEs) leading to dose reduction were increased alanine aminotransferase (8%), thrombocytopenia (7%), diarrhea (7%), increased lipase (6%), increased aspartate aminotransferase (4%), nausea (4%), neutropenia (3%), rash (3%) and abdominal pain (2%) with bosutinib, and neutropenia (4%) with imatinib.
Of the patients who remained on 400 mg QD bosutinib (n=153) or imatinib (n=214), respectively, 120 (78%) and 139 (65%) achieved major molecular response (MMR). Among patients who had a bosutinib dose reduction to 300 mg QD, 51/82 (62%) had MMR >6 months after dose reduction: 14 (17%) maintained MMR before and after dose reduction and 37 (45%) achieved MMR for the first time after dose reduction. Seven (9%) patients had MMR before dose reduction but discontinued treatment before the next >6 months assessment. In the imatinib arm, 32/50 (64%) patients had MMR >6 months after dose reduction: 9 (18%) maintained MMR before and after dose reduction and 23 (46%) achieved MMR for the first time after dose reduction. One (2%) patient had MMR before dose reduction but discontinued treatment before the next >6 months assessment and 1 (2%) patient lost a previously attained MMR after dose reduction. Among patients who had a bosutinib dose reduction to 200 mg QD, 12/33 (36%) had MMR >6 months after dose reduction: 7 (21%) maintained MMR before and after dose reduction and 5 (15%) achieved MMR for the first time after dose reduction. Six (18%) patients had MMR before dose reduction but discontinued treatment before the next >6 months assessment. Similar trends were seen for complete cytogenetic response.
Summary/Conclusion: Management of TEAEs through bosutinib or imatinib dose reduction enabled patients to continue treatment, with a substantial number of patients achieving MMR for the first time after dose reduction.

EP672 SECOND-LINE BOSUTINIB FOR PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA: FINAL 10-YEAR RESULTS OF A PHASE 1/2 STUDY

C. Gambacorti-Passerini [1,*], T. H. Brümmendorf [2], Y. T. Goh [3], I. Dyagil [4], K. Pagnano [5], A. Batai [6], A. G. Turkina [7], E. Leip [8], S. Purcell [9], J. Leone [8], A. Viqueira [10], J. E. Cortes [11]

[1]University of Milano-Bicocca,, Monza, Italy, [2]Universitätsklinikum RWTH Aachen, Aachen, Germany, [3]Singapore General Hospital, Duke-NUS Medical School, Singapore, Singapore, [4]National Research Center for Radiation Medicine, Kiev, Ukraine, [5]Hematology and Hemotherapy Center, University of Campinas, Campinas, Brazil, [6]Joint St. Stephen and St. László Hospital, Budapest, Hungary, [7]National Research Center for Hematology, Moscow, Russian Federation, [8]Pfizer Inc, Cambridge, United States, [9]Pfizer Ltd, London, United Kingdom, [10]Pfizer SLU, Madrid, Spain, [11]Georgia Cancer Center, Augusta, United States

Background: Bosutinib is approved for patients with Philadelphia chromosome–positive (Ph+) chronic myeloid leukemia (CML) resistant/intolerant to prior therapy and newly diagnosed Ph+ chronic phase (CP) CML. In a phase 1/2 study, second-line bosutinib showed durable efficacy and manageable toxicity in patients with imatinib-resistant (IM-R) or imatinib-intolerant (IM-I) Ph+ CP CML.
Aims: The final efficacy and safety analysis of this phase 1/2 study and its extension study (NCT00261846 and NCT01903733) is presented.
Methods: Patients with Ph+ CP CML who received bosutinib starting at 500 mg/day after prior treatment with imatinib only were included. This analysis was based on ≥10 years of follow-up.
Results: 19% of patients were on treatment with bosutinib at year 10, and 13% were still receiving bosutinib at study completion after ≥10 years; 19% completed ≥10 years of follow-up. Median duration of treatment and follow-up were 26 and 54 months, respectively. Median (range) dose intensity was 436 (87–599) mg/day. The most common primary reasons for permanent treatment discontinuation were lack of efficacy (unsatisfactory response or disease progression; 27%) and adverse events (AEs; 26%). In patients with a valid baseline assessment, cumulative complete cytogenetic response (CCyR), major molecular response (MMR) and MR[4] rates were 50%, 42% and 37%, respectively (Table). Responses were durable, with estimated probabilities of maintaining CCyR, MMR and MR[4] >50% after ≥10 years (Table). At 10 years, cumulative incidence of on-treatment progression/death was 24% and Kaplan-Meier (K-M) overall survival 72% (Table). 55 deaths (IM-R: n=41; IM-I: n=14) occurred on study; causes of death were disease progression (n=30), AEs (n=16; none bosutinib-related), other (n=5) and unknown (n=4). Any grade treatment-emergent AEs (TEAEs) occurring in ≥40% of patients were diarrhea (86%), nausea (46%) and thrombocytopenia (42%). Pleural effusion, cardiac and vascular TEAEs occurred in 13%, 12% and 11% of patients, respectively. 28% of patients had AEs leading to permanent treatment discontinuation; the most common (≥2% of patients) were thrombocytopenia (6%), neutropenia (2%) and alanine aminotransferase increased (2%).

Outcome after ≥10 years[a]	IM-R N=195	IM-I N=89	Total N=284
Patients with CCyR, n/N	88/182	42/80	130/262
Cumulative CCyR rate, % (95% CI)	48 (41–56)	53 (41–64)	50 (43–46)
Probability of maintaining CCyR, % (95% CI)[b,c]	61 (49–73)	52 (32–73)	58 (48–69)
Patients with MMR, n/N	58/127	25/70	83/197
Cumulative MMR rate, % (95% CI)	46 (37–55)	36 (25–48)	42 (35–49)
Probability of maintaining MMR, % (95% CI)[b,c]	55 (39–70)	54 (15–93)	56 (41–71)
Patients with MR[4], n/N	50/127	23/70	73/197
Cumulative MR[4] rate, % (95% CI)	39 (31–48)	33 (22–45)	37 (30–44)
Probability of maintaining MR[4], % (95% CI)[b,c]	55 (38–73)	52 (8–96)	56 (39–72)
Cumulative incidence of on-treatment progression/death, % (95% CI)	29 (23–36)	14 (8–23)	24 (20–30)
Overall survival, % (95% CI)[b]	71 (63–79)	73 (60–87)	72 (64–79)

Molecular data not on International Scale and not available for patients in China, Russia, South Africa and India. CCyR imputed from MMR in extension study if valid cytogenetic assessment not available on a specific date.
[a]Outcomes reported after ≥10 years; few events (e.g., initial response, loss of response and death) occurred after year 10.
[b]K-M estimates.
[c]Among responders.

Summary/Conclusion: These 10-year data are consistent with prior results of durable efficacy and manageable toxicity with second-line bosutinib and support long-term bosutinib use in patients with CP CML after imatinib failure.

EP673 TREATMENT-FREE REMISSION IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH LOW-DOSE TKIS. A FEASIBLE OPTION ALSO IN THE REAL-LIFE SETTING?

A. Iurlo [1,*], S. Artuso [1], D. Cattaneo [1], E. Abruzzese [2], G. Binotto [3], M. Bocchia [4], M. Bonifacio [5], A. Gozzini [6], R. Latagliata [7], A. P. Leporace [8], L. Luciano [9], A. Moscati", Taranto, [11]Division of Hematology, San Bortolo Hospital, Vicenza, [12]Division of Hematology, AOU Città della Salute e della Scienza, Torino, [13]Division of Hematology, Dipartimento di Patologia Umana dell'Adulto e dell'Età Evolutiva, Policlinico G Martino, University of Messina, Messina, [14]Division of Hematology, Department of Molecular and Clinical Sciences, Polytechnic University of Marche, Ancona, [15]Division of Hematology and BMT, Department of Medical and Morphological Researches, University of Udine, Udine, [16]Department of Clinical and Biological Sciences, University of Torino, Torino, [17]Scientific Direction, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, [18]Division of Hematology, Department of Precision and Translational, Policlinico Umberto 1, Sapienza University, Rome, Italy

Background: Long-term use of TKIs may expose patients (pts) to significant adverse events (AEs) that may affect quality of life. In recent years, treatment-free remission (TFR) has become a new therapeutic goal and is considered feasible also by international expert guidelines. Most clinical trials have indeed demonstrated that this approach is safe in CML pts who have gained a sustained DMR during treatment at a standard dose. In the real-life practice, TKI dose reductions are often required to reduce AEs but their impact on the possibility of attempting a TFR is still a matter of debate.
Aims: To explore the attitude of Italian hematologists towards the prescription of TKIs at a reduced dose and its impact on TFR attempts in CML pts.
Methods: In September 2020 a questionnaire was sent to the 54 centers participating in the Campus CML. This interactive network connects Italian Hematology specialists active in the field of CML with the aim of sharing experiences and updates for the diagnosis and treatment of this disease, the identification and prevention of specific toxicities of the drugs used and also on possible future therapeutic approaches. The online survey consisted of questions regarding the use of reduced doses of TKIs in the clinical practice and the physicians' propensity to offer a TFR to these pts.
Results: The survey was completed by 45 centers (83%). All declared to have CML pts in treatment with low-dose TKIs (total number = 1.579). More in detail, this occurred in 22.4% of pts treated with imatinib, 24.2% with nilotinib, 34.0% with dasatinib, 70.3% with bosutinib and 74.5% with ponatinib. Dose reduction was due to AEs in most cases (70%), while only in the remaining pts TKIs were de-escalated after achieving molecular milestone. Most involved hematologists believed that reduced doses of TKIs should not influence TFR attempts; indeed, this approach was offered to 117 pts. The TKI most frequently used at reduced doses prior to a TFR attempt was imatinib (60 pts), followed by nilotinib (32 pts), dasatinib (22 pts) and, to a lesser extent, by ponatinib (2 pts) and bosutinib (1 patient). Before attempting TFR, 77 pts had received only one TKI, while 33 and 7 pts were, respectively, treated in second or later lines of therapy, with a median TKI duration of 121.8 months (range 16-221.9). At the time of TFR, all pts had already achieved a DMR, with a median treatment duration of 72 months. After a median follow-up from TKI discontinuation of 25 months (range 1.6-128.7), 88 pts (75.2%) were still in TFR. The median time to molecular recurrence (≥MMR) in the entire cohort was 3.9 months (range 1.6-29.6), and a MMR or a DMR was rapidly achieved in all cases after resuming TKI therapy (median time 5.8 months, range 1–25.8).
Summary/Conclusion: In this large series of real-life CML patient management in Italy, treatment with low-dose TKI represents an important reality and, as expected, bosutinib and ponatinib are the drugs more frequently used in this setting. While a third of Italian hematologists still has some uncertainties on the feasibility of attempting a TFR after using reduced doses of TKIs outside of clinical trials, TFR is most often considered a safe option also in the real-life practice in pts treated with TKIs at a reduced dose either because of AEs or due to an optimal response already achieved. Interestingly, only about 25% of our series experienced a molecular recurrence, less than reported in pts treated at a standard dose. Consequently, TFR was not impaired by low-dose TKI regimens. Updated results will be presented.

EP674 COVID-19 IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA: DISEASE OUTCOMES AND FIRST VACCINATION DATA IN RUSSIAN FEDERATION

E. Chelysheva [1,*], M. Gurianova [1], A. Petrova [1], O. Shukhov [1], A. Bykova [1], E. Lomaia [2], J. Vlasova [3], I. Nemchenko [1], N. Tsyba [1], O. Gavrilina [4], K. Zakurdaeva [5], A. Turkina [1]

[1]Scientific and Advisory Department of Chemotherapy of myeloproliferative neoplasms, National Research Center for Hematology, Moscow, [2]Scientific lab of clinical oncology and hematology, Almazov National medical research centre, [3]BMT department for adults, R.M. Gorbacheva Institute of Pediatric Oncology Hematology and Transplantation, I.P.Pavlov First St. Petersburg State Medical University, St.Petersburg, [4]National Research Center for Hematology, [5]RakFond, Moscow, Russian Federation

Background: Due to the challenge of COVID-19 pandemic the prognosis for patients (pts) with hematologic (hem) tumors, including chronic myeloid leukemia (CML), was difficult to make. With the data accumulation and vaccination start in early 2021, a view of the problem begins to change.
Aims: We aimed to describe the disease course of COVID-19, treatment and first vaccination data in pts with CML in Russian Federation.
Methods: A total of 113 CML pts were analyzed: 106 pts with lab-confirmed or suspected COVID-19 and 7 pts vaccinated against COVID-19. Registration of COVID-19 cases was done prospectively during in person or remote consultations from March 2020 till February 2021. The pts were participants of CHRONOS19, a nationwide observational cohort study of adult (≥18 y) pts with wide spectrum of hem diseases (NCT04422470). We performed a sub-analysis for CML and COVID-19 cohort with the data of 3 hem clinics regarding diagnostics, disease course, treatment and outcomes. Additionally, we evaluated the tolerability and first vaccination results in 7 CML pts (Sputnik V in civil vaccination).
Results: Case registration corresponded to incidence in the country with clear 2 "waves": 1st one in March-August (n=35) and 2nd starting from September 2020 (n=71) (fig1). COVID-19 was clinically and/or lab diagnosed and treated according to current national recommendations. CML was newly diagnosed during COVID-19 in 8(8%) pts, while 86(81%) were on treatment and 12(11%) were in treatment-free remission (TFR). One case was in pregnant pt. CML phases were chronic(CP)/accelerated/blast crisis in 95(89,6%), 6(5,4%) and 5(5%) pts respectively. Median (Me) age of pts was 52 years (range 22-75), 58(55%) were male. No CML therapy during COVID-19 was in 34 (32%) pts (interrupted or not started), therapy was held in 67 (63%), no data in 5 (5%). Disease course of COVID-19 was asymptomatic, mild, moderate and severe in 5 (5%), 59 (56%), 29(27%) and 13(12%) pts respectively. No therapy for COVID-19 was in 30 (28%) pts, symptomatic therapy (fever relief, anti-cough, decongestants, vitamins etc) - in 73 (69%) pts, antiviral drugs and antibiotics were used in 28 (26%) and 44 (42%) pts respectively. Anticoagulants, corticosteroids and IL-6 inhibitors were introduced mainly during 2nd wave while hydroxychloroquine was abandoned (fig.1). Hospitalization was in 33(31%) pts, oxygenation was applied in 12 (11%) pts. The outcomes were as follows: 101(95%) pts alive (98 recovered, 3 not yet), 4 (3,7%) pts died (2 due to COVID, 2 to CML progression), 1(1,3%) –no data. No COVID reinfection was detected so far. No factors connected with moderate/severe vs asymptomatic/mild COVID-19 were found when analyzing gender, CML phase, TFR, comorbidities, 1st and 2nd wave, except age≥52 years (p=0,039). A trend of mild disease was in pts taking TKI vs without TKI (p=0,065).
Seven CP CML pts with Me age 63 years (range 50-70) were vaccinated against COVID-19 since December 2020: 2 had the 1st shot and 5 pts completed vaccination. All 7 pts tolerated the procedure well, with no adverse effects. One pt was checked for antibodies 21 days after the 2nd shot and revealed a high level of anti-SARS-CoV-2 IgG with coefficient of positivity 6,2 (reference range 0-0,9).

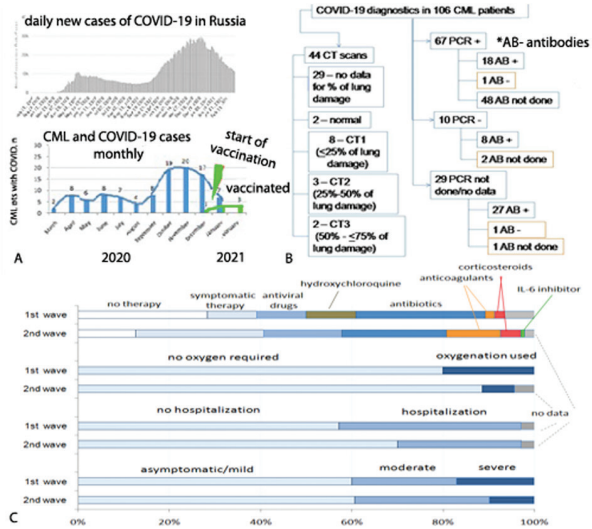

Figure 1. Incidence (A), diagnostics (B) and treatment (C) of COVID-19 in CML patients

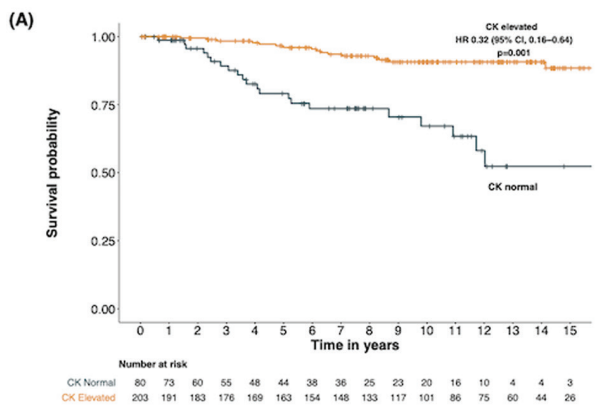
Summary/Conclusion: The incidence, disease course and COVID-19 dependent mortality rates in CML pts seem to be similar to common population. Older age is a factor of moderate/severe disease course. The

TKI impact on COVID-19 course and post-vaccination immunity in CML pts need to be studied.



EP675 ASSOCIATION OF CREATINE KINASE ELEVATION WITH CLINICAL OUTCOMES IN CHRONIC MYELOID LEUKEMIA

A. Bankar [1,*], J. Lipton [1]

[1]*Hematology, Princess Margaret Cancer Centre, Toronto, Canada*

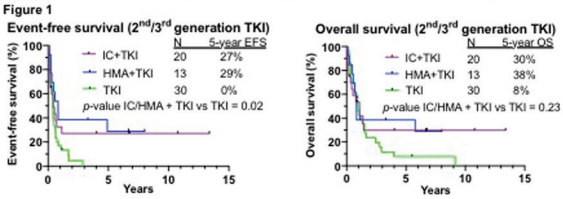
Background: Creatine kinase (CK) elevation is seen with tyrosine kinase inhibitor (TKI) treatment for Chronic Myeloid Leukemia (CML). Its correlation with musculoskeletal (MSK) symptoms and treatment outcomes in not well studied.
Aims: To measure the association CK elevation with overall (OS) and event-free survival (EFS) in patients with CML.
Methods: Retrospective, single-centre study on all newly diagnosed chronic phase CML patients from 2001 to 2017 seen and followed by senior author on study at Princess Margaret Cancer Centre, Toronto, Canada. Primary exposure was CK elevation after initiation of first line TKI, defined as two CK values above baseline within any 6 months period. Clinical variables were age, sex, cardiovascular risk factors (smoking, hypertension, diabetes mellitus, and hypercholesterolemia), sokal index and use of second line TKI. Primary outcome was OS, and secondary outcomes were EFS and cumulative incidence of CK elevation. The effect of covariates was measured as hazard ratio (HR, 95% CI) using cox proportional hazard models and compared with log rank test.
Results: Total 283 newly diagnosed CML patients were included. The median age was 49.8 years (18.0-82.0), 54.1% were male. The median follow-up was 8.8 years (IQR 4.4-12.7). The median baseline CK was 100 IU/L (10.0-1490). First line TKI were imatinib (78.1%), followed by dasatinib (11.0%), nilotinib (8.1%) and bosutinib (2.8%). 203 patients (72%) had CK elevation [76% (169/221) on imatinib, 54% (34/62) on second generation TKI (SG-TKI)]. The median time to CK elevation with imatinib was 1.0 years (IQR 0.8-1.3) compared to 1.2 years, (IQR 0.5-3.7) with SG-TKI. There was no difference in the cumulative incidence of CK elevation between imatinib (HR 0.92, 0.64-1.35) and SG-TKI. There was no difference in grade of CK elevation between different TKIs (anova, p=0.57). CK levels of patients with MSK symptoms were higher compared to those without (*t*-test, p=0.02). 3 patients on imatinib had rhabdomyolysis.
38 patients (13.4%) died during follow-up. Using CK elevation as time-dependent covariate, the Kaplan–Meier survival analysis showed that patients with CK elevation had a lower probability of death (7.8%, 16/203) compared to those with normal CK (27.5%, 22/80) (p<0.001). In multivariable Cox regression, the impact of CK elevation on OS remained unchanged: adjusted HRs for OS were 0.31 (0.16–0.60) for CK elevation; 3.39 (1.67–6.84) for intermediate sokal and 5.11 (1.95-13.4) for high sokal risk.
116 patients (41%) were considered for secondary outcome-EFS [98 discontinued treatment-46 suboptimal response or progression, 52-toxicity; 18 patients died without treatment related event]. Using CK elevation as time-dependent covariate, Kaplan–Meier survival function showed that patients with CK elevation had a lower probability of an event compared to those without CK elevation (p=0.003). In multivariable Cox regression, the impact of CK elevation on EFS remained unchanged: adjusted HR for EFS were 0.51 (0.33–0.79) for CK elevation. Other significant variables were intermediate and high sokal risk, SG-TKI (better EFS); higher comorbidities (worse EFS).

Overall survival in chronic myeloid leukemia patients according to CK elevation (n=283)

Summary/Conclusion: The cumulative incidence of CK elevation in CML patients on TKI is 72% with no difference between imatinib and SG- TKI. CK levels correlated with MSK symptoms but rhabdomyolysis was rare. CK elevation independently predicted better OS and EFS. These results inform clinicians on not discontinuing TKI based on laboratory elevation of CK alone.

EP676 FRONTLINE TREATMENT APPROACHES FOR CML IN MYELOID BLAST PHASE: A SINGLE-CENTER EXPERIENCE OVER 2 DECADES

K. Saxena [1,*], E. Jabbour [1], G. Issa [1], K. Sasaki [1], A. Maiti [1], F. Ravandi [1], N. Daver [1], T. Kadia [1], C. DiNardo [1], M. Konopleva [1], K. Chien [1], S. Pierce [1], H. Kantarjian [1], N. Short [1]



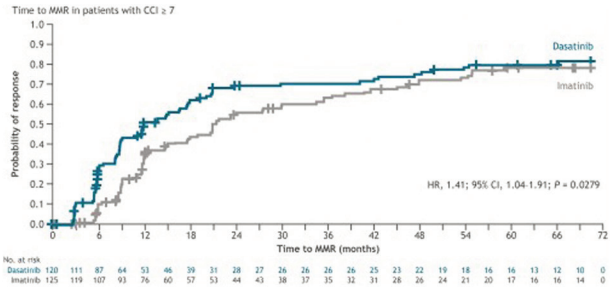
[1]*MD Anderson Cancer Center, Houston, United States*

Background: The natural course of untreated or TKI-resistant chronic myeloid leukemia (CML) is progression to a blast phase (BP), which may be myeloid (MBP) or lymphoid. Over the past 20 years, the advent of tyrosine kinase inhibitors (TKIs) against the BCR-ABL1 fusion protein has dramatically reduced the incidence of CML-BP. However, CML-BP still occurs in some patients, and outcomes remain exceedingly poor with no consensus frontline treatment approach.
Aims: We retrospectively evaluated the outcomes with different frontline treatment approaches in patients with CML-MBP who were treated at our institution over 2 decades.
Methods: Patients were included if they were diagnosed with CML-MBP as defined by ≥20% bone marrow myeloblasts (WHO criteria) between 2000-2019, with or without the presence of concomitant extramedullary (EM) disease, and received frontline therapy for CML-MBP. Patients with EM-only disease were excluded. Patients could have received prior therapy for CML in chronic phase (CP) or accelerated phase (AP) but no prior therapy for BP aside from hydroxyurea. Patients were divided into 4 frontline treatment approaches: 1) intensive chemotherapy (IC)+TKI, 2) hypomethylating agent (HMA)+TKI, 3) TKI alone, or 4) IC alone. We assessed morphologic/hematologic responses per AML IWG 2003 criteria and cytogenetic/molecular responses per CML ELN 2020 criteria. We assessed cumulative incidence of relapse (CIR), event-free survival (EFS), overall survival (OS), and the benefit of allogeneic stem cell transplantation (ASCT).
Results: 104 patients were identified who received frontline treatment for CML-MBP (IC+TKI, n=20; HMA+TKI, n=20; TKI alone, n=56; IC alone, n=8). Baseline patient characteristics are shown in Table 1. Patients who received IC+TKI were younger than other groups. The majority of patients in each group had received at least one prior TKI for treatment of CML CP/AP. A 2nd/3rd generation TKI was used for CML-MBP in 100% of patients treated with IC+TKI, 65% with HMA+TKI, and 54% with TKI alone.
Hematologic, cytogenetic and molecular response rates are shown in Table 1. Given similarities in outcomes between IC+TKI and HMA+TKI, these two groups were combined for analysis (IC/HMA+TKI, n=40). Compared to TKI alone, IC/HMA+TKI resulted in a higher CR/CRi rate (57.5% vs 33.9%, $p<0.05$), higher complete cytogenetic response (CCyR) rate (45% vs 10.7%, $p<0.001$), and led to more patients proceeding to ASCT (32.5% vs 10.7%, $p<0.01$). These superior outcomes with IC/HMA+TKI were observed despite a higher 60-day mortality with combination therapy compared to TKI alone (15% vs 1.8%, $p<0.05$).
With a median follow-up of 6.7 years, long-term outcomes were similar between the IC+TKI and HMA+TKI groups, and both were superior to TKI alone when all patients were considered as well as when analysis was limited to those treated with a 2nd/3rd generation TKI (Figure 1). When using a 2nd/ 3rd generation TKI, IC/HMA+TKI led to improved 5-year CIR (44% vs 86%, $p<0.05$), 5-year EFS (28% vs 0%, $p<0.05$), and 5-year OS (34% vs 8%, $p=0.23$) compared to TKI alone.
Landmark analysis was performed to assess the benefit of ASCT in patients who achieved an objective response (CR/CRi/MLFS). Median time to ASCT was 4.7 months, and long-term survival was superior for patients who proceeded to ASCT (58% vs 22%, $p=0.12$) compared to those who did not proceed to ASCT at the landmark timepoint.

Table 1

	N (%); Median [Range]			
	IC + TKI (N=20)	HMA + TKI (N=20)	TKI (N=56)	IC (N=8)
Age, years	47 [29-83]	56 [37-89]	57 [21-79]	56 [27-74]
De novo CML-MBP	5 (25%)	5 (25%)	3 (5.3%)	0
Year of treatment initiation for MBP	2013 [2007-2018]	2013 [2003-2019]	2004 [2000-2012]	2003 [2000-2003]
Prior TKI exposure for CML	14 (70%)	14 (70%)	32 (60%)	7 (87.5%)
BM blast %	37 [21-64]	40 [28-79]	49 [21-87]	30 (20-60)
Cytogenetic clonal evolution	12 (60%)	15 (75%)	42 (75%)	6 (75%)
Best Response				
CR/CRi	12 (60%)	11 (55%)	19 (33.9%)	1 (12.5%)
CR/CRi/MLFS	16 (80%)	14 (70%)	27 (48.2%)	1 (12.5%)
Time to best response, months	0.9 [0.7-6.9]	2.2 [0.8-5.5]	2.1 [0.6-16.3]	0.6 [0.6-0.6]
CCyR achieved	8 (40%)	10 (50%)	6 (10.7%)	0
Best molecular response				
MMR	3/17 (17.6%)	2/16 (12.5%)	1/47 (2.1%)	0
CMR	2/17 (11.8%)	1/16 (6.3%)	1/47 (2.1%)	0
Proceeded to SCT	7 (35%)	6 (30%)	6 (10.7%)	1 (12.5%)
60-day mortality	3 (15%)	3 (15%)	1 (1.8%)	3 (37.5%)
5-year outcomes				
EFS	27%	19%	5%	0%
OS	30%	28%	13%	0%
5-year outcomes with a 2nd/3rd generation TKI				
EFS	27%	29%	0%	N/A
OS	30%	38%	8%	N/A

Figure 1



Summary/Conclusion: Compared to patients treated with TKI alone for CML-MBP, treatment with IC+TKI or HMA+TKI leads to improved response rates, CIR, EFS, and OS, particularly for patients treated with a 2nd/3rd generation TKI.

EP677 EFFECT OF COMORBIDITIES ON PATIENT RESPONSES WITH FIRST-LINE DASATINIB VERSUS IMATINIB IN CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE: EXPLORATORY POST HOC ANALYSIS OF DASISION

M. Breccia [1,*], M. Mauro [2], E. Jabbour [3], G. Saglio [4], A. Jiménez-Velasco [5], P. le Coutre [6], I. DeGutis [7], W. Khan [7], O. Sy [7], R. Swanink [8], J. E. Cortes [9]

[1]"Sapienza" University, Rome, Italy, [2]Memorial Sloan-Kettering Cancer Center, New York, [3]The University of Texas MD Anderson Cancer Center, Houston, United States, [4]University of Turin, Turin, Italy, [5]Hospital Universitario Carlos Haya, Malaga, Spain, [6]Charité Universitätsmedizin Berlin, Berlin, Germany, [7]Bristol Myers Squibb, Princeton, United States, [8]Bristol Myers Squibb, Braine-l'Alleud, Belgium, [9]Georgia Cancer Center, Augusta University, Augusta, United States

Background: Tyrosine kinase inhibitors (TKIs) have dramatically improved the standard of care for patients (pts) with chronic myeloid leukemia in chronic phase (CML-CP). In the 5-y follow-up of the phase 3 DASISION study (NCT00481247), dasatinib (DAS) was associated with faster and deeper molecular responses than imatinib (IM) as first-line (1L) therapy for CML-CP. The NCCN guidelines recommend considering multiple factors independent of risk score when selecting TKI therapy, including the presence of comorbidities. Over 50% of pts with CML-CP have ≥1 comorbidity at diagnosis; as such, comorbidities may influence 1L treatment (Tx) choice for most pts.
Aims: Investigate the effect of comorbidities on response outcomes with DAS vs IM via an exploratory post hoc analysis of DASISION at 5-y follow-up.
Methods: DASISION was a multinational, open-label, phase 3 trial assessing DAS vs IM for newly diagnosed CML-CP. Pts were randomized to receive 100 mg DAS (n=259) or 400 mg IM (n=260) QD. Charlson Comorbidity Index (CCI) was retrospectively calculated for each pt at diagnosis. Efficacy and safety data were retrospectively stratified based on CCI score categories 2–4, 5–6, and ≥7 (higher scores indicate higher comorbidity burden). Rates of major molecular response (MMR) and $MR^{4.5}$ were compared between Tx arms using unstratified Cochran–Mantel–Haenszel tests. Time to MMR and $MR^{4.5}$ were evaluated using Kaplan–Meier method with HRs based on Cox proportional hazards models and *P* values from unstratified log-rank tests. CIs for median time to response were calculated using the Brookmeyer and Crowley method. *P* values are descriptive and unadjusted for multiple comparisons.
Results: In total, 14 (3%) pts had CCI 2–4 (DAS 7, IM 7), 260 (50%) had CCI 5–6 (DAS 132, IM 128), and 245 (47%) had CCI ≥7 (DAS 120, IM 125). Baseline characteristics were balanced between groups. Dose reductions of DAS and IM occurred in 14% vs 29% (CCI 2–4 group), 23% vs 12% (CCI 5–6 group) and 54% vs 22% (CCI ≥7 group) of pts, respectively. Responses were greater with DAS vs IM in the CCI 2–4 group (MMR: 85.7% vs 57.1%, *P*=0.2542; $MR^{4.5}$: 71.4% vs 14.3%, *P*=0.0374), and were significantly higher in the CCI 5–6 group (MMR: 81.1% vs 64.8%, *P*=0.0033; $MR^{4.5}$: 42.4% vs 29.7%, *P*=0.0329). Median time to MMR in the CCI 5–6 group was significantly shorter with DAS vs IM (15.0 vs 24.0 months; HR,1.64; *P*=0.0006). In the CCI ≥7 group, response rates were numerically higher (MMR: 70.8% vs 64.0%; $MR^{4.5}$: 45.0% vs 39.2%) and median time to MMR was significantly shorter with DAS vs IM (12.0 vs 21.4 months; HR, 1.41; *P*=0.0279; **Figure**). Rates of grade (gr) 3–4 Tx-related adverse events (TRAEs) were (DAS vs IM): 0% vs 14% (CCI 2–4); 8% vs 9% (CCI 5–6); 24% vs 13% (CCI ≥7). Gr 3–4 TRAEs leading to discontinuation did not occur in the CCI 2–4 group, and were reported with similar frequency with DAS and IM in CCI 5–6 and ≥7 groups. No deaths occurred in the CCI 2–4 group; a similar percentage of pts treated with DAS and IM died in the CCI 5–6 and ≥7 groups.

Summary/Conclusion: In this exploratory post hoc analysis, DAS was effective in all CCI groups, in line with previous findings, suggesting that comorbidities do not negatively affect TKI activity. Response rates were significantly higher with DAS than IM in pts with CCI 5–6, but comparable between Txs in pts with CCI ≥7. Time to response was significantly faster with DAS than IM in both the CCI 5–6 and ≥7 groups, while the frequency of gr 3–4 TRAEs leading to discontinuation was similar between Txs. These findings highlight the benefit of 1L Tx with DAS in pts with CML-CP and a high comorbidity burden.

EP678 HYDROXYUREA PRE-TREATMENT IN CHRONIC MYELOID LEUKEMIA PATIENTS: MORE HARM THAN GOOD?

C. C. Kockerols [1,*], I. G. Geelen [1], M.-D. Levin [1], J. J. Janssen [2], A. G. Dinmohamed [3], M. Hoogendoorn [4], J. J. Cornelissen [5], P. E. Westerweel [1]

[1]Department of Hematology, Albert Schweitzer Hospital, Dordrecht, [2]Department of Hematology, Amsterdam University Medical Center, location VU Medical Center, Amsterdam, [3]Department of Research and Development, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [4]Department of Hematology, Medical Center Leeuwarden, Leeuwarden, [5]Department of Hematology, Erasmus Medical Center, Rotterdam, Netherlands

Background: The current role of hydroxyurea (hydrea) as a treatment modality in chronic myeloid leukemia (CML) is limited. However, many clinicians still use it as a bridging therapy before starting treatment with tyrosine kinase inhibitors (TKI).
Aims: The objectives of this analysis were to evaluate the use of hydrea in clinical practice in the treatment of CML, and assess the benefits of hydrea pre-treatment on achieving early response milestones and disadvantages such as the occurrence of hematotoxicity during subsequent TKI therapy.
Methods: We performed a retrospective analysis on data from a real-world population-based Dutch registry (The PHAROS CML Registry combined with HemoBase) of newly diagnosed chronic phase CML patients between 2008 and April 2013. Patients were stratified based on having received pre-treatment with hydrea. All time-dependent analyses were performed using the cumulative incidence competing risk (CICR) method with death and progression considered as competing events. The start date of first-line TKI treatment was used as time-point zero in the time-dependent analyses.
Results: From a total of 432 evaluable patients, 194 (45%) patients had received hydrea pre-treatment. Hydrea-treated patients had a higher mean leukocyte count and more often reported presence of

hyperviscosity symptoms (3 *vs* 9%, p = 0.009), constitutional symptoms (36 *vs* 26%, p = 0.049), or symptomatic splenomegaly (26 *vs* 12%, p < 0.001) at diagnosis. However, the majority of hydrea-treated patients had no symptoms of hyperleukocytosis or splenomegaly (66%). Surprisingly, the hydrea-treated group had a significantly longer interval between diagnosis and start of first-line TKI treatment (22 *vs* 15 days, p = 0.002). Also, after the start of TKI therapy, hematotoxicity occurred more frequently in hydrea pre-treated patients (23 *vs* 11%, p < 0.001). There was no benefit observed of hydrea pretreatment for patients achieving a CHR at 1 or 3 months, nor for CCyR and MMR at the ELN-set response milestones during the first year of treatment. The proportion of patients achieving MMR at 12 months was significantly higher in the non-hydrea group (55% *vs* 43%, p = 0.05), however this difference was no longer significant when correcting for ELTS-score and type of first-line TKI in a cox-regression model.

Summary/Conclusion: Hydrea pre-treatment is used in nearly half of newly diagnosed CML patients, including many patients without a high leukemic load and/or symptom burden. We observed a significantly longer delay in starting first-line TKI treatment in hydrea-treated patients. Furthermore, hydrea pre-treatment was associated with a higher rate of hematotoxicity during first line TKI treatment and no apparent benefit in achieving the ELN-defined response milestones. Our data suggest an unneeded pre-treatment use of hydrea when a diagnosis of CML is under consideration and recommend restricting the use of hydrea pre-treatment to patients with clinically significant (symptomatic) hyperleukocytosis or symptomatic splenomegaly. More restrictive use of hydrea may shorten the delay of TKI treatment initiation at diagnosis and help limit hematotoxicity of TKI therapy.

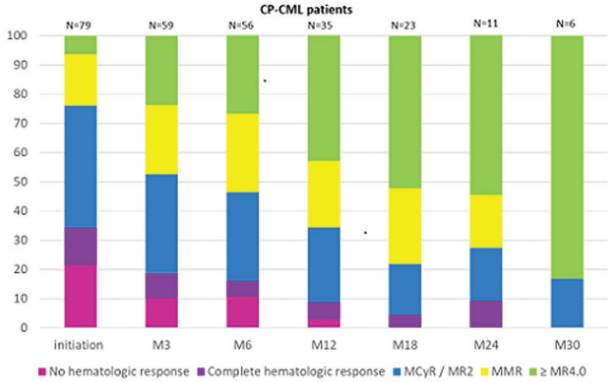
EP679 FRENCH REAL–LIFE OBSERVATIONAL STUDY "TOPASE" EVALUATING SAFETY AND EFFICACY OF PONATINIB CONFIRMS INDUCTION OF DEEP MOLECULAR RESPONSES IN 110 RESISTANT OR INTOLERANT CML PATIENTS

A. Guerci-Bresler [1], A. Turhan [2,*], P. Rousselot [3], G. Etienne [4], V. Coiteux [5], M. Berger [6], E. Cayssials [7], F. Huguet [8]

[1]Hematology, CHRU Brabois, NANCY, [2]Hematology, University Paris Saclay, Villejuif, [3]Hematology, CH Versailles, Versailles, [4]Hematology, Institut Bergonie, Bordeaux, [5]Hematology, CHRU Lille, Lille, [6]Hematology, CHU Estaing, Clermont-Ferrand, [7]Hematology, CHU Poitiers, Poitiers, [8]Hematology, Oncopole, Toulouse, France

Background: Ponatinib is a 3rd generation tyrosine kinase inhibitor (TKI) indicated in chronic phase (CP), accelerated phase (AP) and blast phase (BP) CML as well as in patients (pts) with T315I mutation.

Aims: TOPASE is an observational cohort, designed to evaluate, with a 2 to 4 years follow-up period, the efficacy and safety of ponatinib in routine clinical practice.



Methods: This interim analysis reports results from data of pts included in 42 CML French centers from February 2018 to December 2020.

Results: 110 pts were registered, 97 in CP and 13 in AP/BP; median age was 58.7 [20-90] years. Reason for prescription was resistance in 73% and intolerance in 26% of pts. Ponatinib was prescribed in 14 % of cases in second line and in 53% in third line of treatment. Last treatment administered prior to ponatinib was dasatinib (39%), bosutinib (24%), nilotinib (24%), imatinib (10%) and ABL001 (2%). Twenty seven of the 69 pts screened for mutations harbored a BCR-ABL mutation (T315I in 13). Thirty two per cent had an history of hypertension and 30% were treated for hypertension at inclusion. In CP-CML pts, ponatinib starting dose was 15mg/d in 37%, 30 mg/d in 43% and 45 mg/d in 20%. Respectively in each subgroup the percentage of intolerant pts were: 42, 24 and 10 %.Considering AP/BP pts, ponatinib initiating dose was 45 mg/d in 62%, 30 mg/d in 23% and 15 mg/d in 15% of pts. At the initiation of ponatinib, out of 93 CP-CML pts evaluable for response, 26% of pts were in MMR or beyond, 39% were in MCyR and/ or MR2, 14% were in CHR and 21% were not in CHR. Efficacy analysis was performed on all the 59 CP-CML pts with BCR-ABL1 > 0.1% at ponatinib start and with at least one evaluation under treatment, as defined in the protocol.After a median treatment duration of 10.7 months [0.4; 36.4], MMR was achieved in 30 pts (51%) (Table 1). Overall, the global responses in all evaluable patients showed a shift towards deeper responses up to 30 months (Table 2). In 37 pts (34%) [31 in CP and 6 in AP/BP] ponatinib was discontinued early after a median exposure of 5.8 months. Reasons for discontinuation were lack of response or progression (n=15), adverse event (n=14) or another reason (n=8). Treatment related adverse events (TRAE) were reported in 52% of pts (n=52) (serious = 11% [n=11]). Most common TRAE (all/serious) were hypertension (9/1), constipation (5/1), dry skin (5/0), lipase increase (4/0).Cardiovascular events (5/4) included acute coronary syndrome (1), angina pectoris (1), aortic insufficiency (1), atrial fibrillation (1), pericardial effusion (1) and cerebrovascular events (2/2) included ischemic stroke and cerebrovascular accident. Four pts died during follow-up: 1 from disease progression (pt included in AP/BP) and 3 from AE (1 general status alteration, 1 pancytopenia [pt included in AP/BP] and 1 from pulmonary embolism, the only AE considered as related to ponatinib). More complete data analysis on the incidence of TRAEs according to the dose of ponatinib are currently conducted and will be presented.

Table 1: Pts in CP and without MMR at ponatinib initiation who achieved MMR or above at least once on therapy according to initial daily dose of Ponatinib.

CP phase at initiation	Dose at initiation (mg/day)			
	15 mg (n=17)	30 mg (n= 28)	45 mg (n=14)	Total (n=59)
MMR (or above) at least once during follow-up	6 (35%)	17 (61%)	7 (50%)	30 (51%)

Figure 1:Therapeutic response during follow-up

Summary/Conclusion: Results from this real-world French cohort confirm the high efficiency of ponatinib in TKI-resistant and intolerant CML pts. Ponatinib induces deep molecular responses, with an acceptable safety profile. Vascular events rate seems low in this study, which is the largest prospective observational study on ponatinib use in Europe.

EP680 WITHDRAWAL SYNDROME AFTER TYROSINE KINASE INHIBITORS DISCONTINUATION IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

A. Petrova [1,*], E. Chelysheva [1], O. Shukhov [1], A. Bykova [1], M. Gurianova [1], I. Nemchenko [1], N. Tsyba [1], A. Turkina [1]

[1]National Research Center for Hematology, Moscow, Russian Federation

Background: Withdrawal syndrome (WS) - a musculoskeletal pain after discontinuation of tyrosine kinase inhibitors (TKI) in patients (pts) with chronic myeloid leukemia (CML) - was described in the treatment-free remission (TFR) studies with a weighted mean incidence of 27% [Chen et al, Front Oncol., 2019]. The pathophysiological mechanisms of WS and predisposing factors have not been well established.

Aims: To characterize the outcomes of WS and evaluate factors associated with WS in a large cohort of CML pts who discontinued TKI therapy.

Methods: WS was evaluated in prospective pts group (PG, n=109) and in retrospective group (RG, n=74). The key inclusion criteria: CML chronic phase, any TKI therapy ≥ 3 years, deep molecular response (DMR) duration ≥2 years in PG and ≥1 year in RG. DMR was defined as at least MR4 (BCR-ABL ≤ 0,01% IS). TKI were restarted in both groups in case of major MR (MMR, BCR-ABL>0,1% IS) loss. In 34 pregnant pts (24 and 10 in RG and PG accordingly) TKI were restarted in case of MR2 (BCR-ABL>1%) loss.

WS was defined as a musculoskeletal pain newly observed after TKI cessation or as a worsening of previously observed symptoms in pts with medical history of locomotion system diseases. WS was registered In PG every month (mo) during first 6 mo after TKI cessation, every 2 mo from 6 to 12 mo and every 3 mo thereafter. The data in RG were collected according to medical records.

Age, gender, Sokal score, duration and the type of TKI therapy, presence of locomotion system diseases and pregnancy were evaluated in pts with and without WS. Comparison was done with Mann–Whitney U-test and Chi-squared test. The survival without MMR loss was evaluated by Kaplan-Meier method.

Results: Median (Me) time of observation was 33 mo (range 1-136). MMR loss free survival at 36 mo was 49% and 43% in PG and RG respectively (p=0,96).
WS was observed in 49(27%) of 183 pts: 41(38%) in PG and 8(11%) in RG. WS was presented as arthralgia, myalgia, ossalgia or combination of symptoms in 37(76%), 17(35%), 4(8%) and 35(71%) pts. Newly observed and worsening symptoms were in 35(71%) and 14(29%) pts respectively. Me time to WS appearance was 2 mo (range 1-7). Me duration of WS was 5 mo (range 1-35). WS grade 1-2 was in 45(92%) pts, grade 3 in 4(8%) pts.
TKI therapy was resumed in 15(31%) of 49 pts with WS: in 13 pts with MMR loss, in 1 pt with 3rd grade WS symptoms and in 1 pt due to physician decision. WS was resolved in all 15 pts at 1-3 mo after TKI restart. Thirty-four (69%) pts with WS remained in TFR. WS completely resolved in 31 and gradually decreased up to 1st grade in 3 pts at the time of analysis.
WS was resolved spontaneously or with nonsteroidal anti-inflammatory drugs in 14(45%) and 17(55%) pts accordingly. Two of 17 pts also received glucocorticoids. The outcomes of WS are presented on figure 1. An older age (p<0,0001), longer duration of TKI therapy (p<0,0001) and the presence of locomotion system diseases (p=0,022) were observed in pts with WS (table 1). The development of WS was not registered in any of pregnant pts (p<0,001).

Figure 1.
Withdrawal syndrome outcomes in 49 CML patients

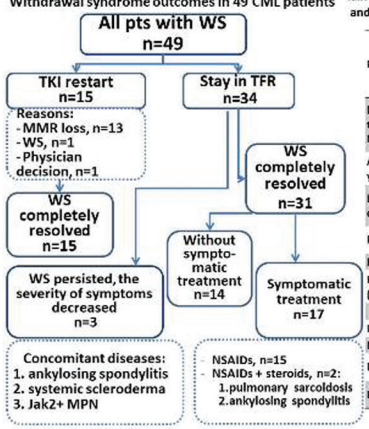


Table 1. Comparative analysis of patients with and without withdrawal syndrome (n = 183)

Parameters	Pts with WS n=49	Pts without WS n=134	P value
Duration of TKI treatment, Me (range), years	119 (40-218)	72 (6-181)	<0,0001
Age, Me (range), years	53 (24-80)	37 (21-86)	<0,0001
Locomotion system diseases, n (%)	18 (37)	27 (20)	0,022
Pregnancy, n (%)	0 (0)	34 (25)	<0,001
Female, n (%)	28 (57)	84 (63)	0,496
High Sokal risk, n (%)	3 (6)	19 (14)	0,188
TKI before discontinuation:			
Imatinib, n (%)	37 (76)	86 (64)	0,149
Nilotinib , n (%)	11 (22)	36 (27)	0,545
Dasatinib, n (%)	1 (2)	11 (8)	0,136
Bosutinib, n (%)	0 (0)	1 (1)	0,545

Summary/Conclusion: The rate of WS in the large CML cohort was 27%. We evaluate a higher WS incidence in PG compared to RG (38% vs 11%). The differences may be cause by methods of data collection: prospective observation probably allowed to more accurately identifying the presence of WS. On the other hand, there were more pregnant pts in RG, and we found for the first time that WS doesn't develop in pts with pregnancy. A longer period of TKI exposure, older age and the history of locomotion system diseases were associated with the development of the WS.

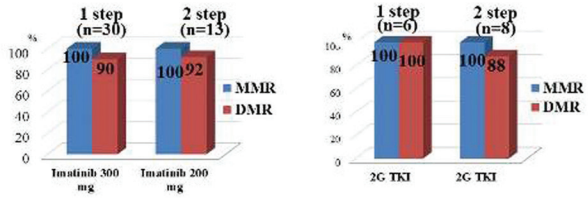
EP681 FIRST INTERIM RESULTS OF THE RUSSIAN PROSPECTIVE STUDY OF REDUCTION AND DISCONTINUATION TREATMENT OF TKI (READIT) IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH DEEP MOLECULAR RESPONSE

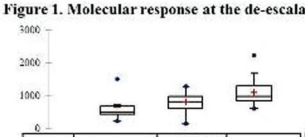
M. Gurianova [1,*], O. Shukhov [1], E. Chelysheva [1], A. Petrova [1], A. Bykova [1], I. Nemchenko [1], N. Tsyba [1], A. Abdullaev [2], A. Sudarikov [2], A. Nikiforova [3], S. Gorbacheva [3], D. Grebenkin [3], V. Kazey [3], A. Turkina [1]

[1]Department of Myeloproliferative Diseases, [2]Laboratory of Molecular Hematology, National Research Center for Hematology, [3]Head of Bioanalytical Department, Exacte Labs, Moscow, Russian Federation

Background: TKI dose reduction may be safely used for AE correction or prevention in pts with optimal response. The feasibility of TKI dose reduction as a step before treatment-free remission (TFR) phase has been confirmed in several trials. However, no unified scheme has been developed for each TKI. The connection of plasma blood TKI concentration with the AE and response preservation has not been studied.
Aims: To provide the first interim results of the «Study of REduction And DIscontinuation Treatment of TKI (READIT)» (NCT 04578847): evaluation of the response rates and first data of imatinib (IM) plasma blood concentrations after dose reduction.

Methods: Two consecutive phases are planned in the trial: 1) TKI dose reduction phase for at least 12 months (mo), 2) TFR observation (24 mo). The TKI dose reduction phase consists of two 6 mo steps: 1st step (300 mg for IM, 400 mg for nilotinib (NIL), 50 mg for dasatinib (DAS) and 300 mg for bosutinib (BOS)) and 2nd step (25 mg for DAS and 200 mg for IM, NIL and BOS) of TKI dose reduction. Inclusion criteria: adult CML in chronic phase (CP), TKI therapy ≥ 3 years, major molecular response (MMR, BCR-ABL1 ≤0,1%) ≥2 years and deep molecular response (DMR, BCR-ABL1 ≤0.01%) ≥1 year. Recruitment of patients in reduced doses was possible, provided that the duration of the current therapy is at least 6 mo. Treatment by TKI doses of previous step was resumed in case of confirmed MMR loss (BCR-ABL>0.1% in two samples).
Plasma blood concentration was measured for IM (24±2 hours (Cmin) and 4 hours (Cmax) after drug intake). We used the Mann-Whitney U-test for comparative analysis.
Results: A total of 70 CML pts were included from Dec.2019 till March 2021. The baseline characteristics: male 41%, Median (Me) age 56 years (range 23-74); Me TKI therapy duration 6,3 years (range 2.5-18.9); Me duration of MMR and DMR was 3,3 years (range 2-11,2) and 2 y (range 1-11,2), respectively. At baseline 46 (66%) pts received IM (39 pts-400 mg, 3 pts–300 mg, 4 pts–200 mg) and 24 (34%) pts - second-generation (2G) TKI: NIL - 13 pts (6 pts-800-600 mg, 6 pts-400 mg, 1 pt–200 mg), DAS- 6 pts (4 pts-100-70 mg, 2 pts–50 mg), BOS- 5 pts (1 pt–500 mg, 2 pts–300 mg, 2 pts–200 mg).
Thirty-six pts have completed 1st dose reduction step. Three pts on IM lost DMR (1 pt-after 3 mo, 2 pts-after 6 mo dose reduction), no cases of DMR loss in the 2G TKI group. Twenty-one pts completed 2nd step of dose reduction. Two pts lost DMR after 3 mo: 1 pt on IM and 1 pt on DAS. *(Fig.1)*. Of those 5 pts 4 were restored DMR at the same dose. There were no cases of confirmed loss of MMR during the dose reduction phase.
We analyzed the IM concentration in 98 plasma blood samples (Cmax-in 32, Cmin–in 66). There was a significant difference in Cmin of IM 400 mg, 300 mg and 200 mg (p=0.0019) and no difference in Cmax of IM 300 mg and 200 mg. (p=0.078) *(Fig.2)*.
No difference in IM concentration (Cmin and Cmax on 300 and 200 mg) was in 5 pts who lost DMR compared to pts without DMR loss. No significant difference IM 400 mg Cmin was in pts with and without AE (p=0.26).





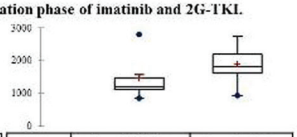


Figure 1. Molecular response at the de-escalation phase of imatinib and 2G-TKI.

	Cmin IM 200 mg (ng/ml)	Cmin IM 300 mg (ng/ml)	Cmin IM 400 mg (ng/ml)
No pts.	6	28	32
Min	232,8	150,5	621,7
Max	1515	1284	2231
Me	506,75	815,4	989,4

	Cmax IM 200 mg (ng/ml)	Cmax IM 300 mg (ng/ml)
No pts.	6	26
Min	852,8	927,1
Max	2800	3167
Me	1217	1810,5

Figure 2. Concentration (Cmin and Cmax) of IM 400 mg, 300 mg and 200 mg.

Summary/Conclusion: No MMR loss was detected during therapy with 1st and 2nd step of TKI dose reduction and about 90% of pts remained in DMR. This proves the safety of TKI treatment at reduced doses. The results will be updated within a longer follow-up in order to evaluate the impact of de-escalation phase on TFR rates. The role of different TKI concentrations will be studied.

EP682 A SURVEY OF HEALTHCARE PROFESSIONALS IN THE UNITED KINGDOM TO DESCRIBE CURRENT PATHWAYS AND MANAGEMENT PRACTICES IN CHRONIC MYELOID LEUKAEMIA: THE ADAPT CML SURVEY

M. Copland [1], K. Gibson [2], D. Milojkovic [3], N. C. Cross [4], B. Huntly [5], J. Billot [6], J. Ryan [2], A. Mead [7,*]

[1]Paul O'Gorman Leukaemia Research Centre, University of Glasgow, Gartnavel General Hospital, Glasgow, [2]Novartis Pharmaceuticals UK Ltd, [3]Hammersmith Hospital, Imperial

College Healthcare NHS Trust, London, [4]Faculty of Medicine, University of Southampton, Southampton, [5]Department of Haematology, and Wellcome Trust-MRC Cambridge Stem Cell Institute, University of Cambridge, Cambridge, [6]OPEN VIE, Marlow, [7]MRC Weatherall Institute of Molecular Medicine, NIHR Oxford Biomedical Research Centre Haematology Theme, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom

Background: A survey of healthcare professionals in the UK to describe current pathways and management practices in chronic myeloid leukaemia:the ADAPT CML survey.
Aims: To understand the current diagnosis (Dx), treatment (Tx) and management, including unmet need, landscape for UK patients (pts) with chronic phase chronic myeloid leukaemia (CML-CP).
Methods: We conducted a survey with 46 Haematology consultants (27 from district general hospitals [DGH]; 19 from tertiary centres [TC]). Structured interviews with Medical Science Liaisons from Novartis, were conducted between July and October 2020. Responses were descriptively analysed.
Results: Most (70%) respondents saw 5-10 newly diagnosed CML-CP pts per year (43%, 39%, 17% had a current total CML-CP pts population estimate of ≤50, >50 ≤100, and >100 respectively). All respondents stated they routinely use physical examination, white blood counts, platelet counts, haemoglobin counts and blood film in their CML diagnostic work-up, although only 89% used chromosome banding analysis (CBA). Information on cardiovascular (CV) risk most commonly captured routinely in pt notes prior to tyrosine kinase inhibitor (TKI) initiation were comorbidities (98%), smoking status (98%) and CV history (91%), while total cholesterol (61%) and blood glucose (52%) were less frequently captured. Only 32% used QRisk assessment. Sokal remained the most commonly used prognostic scoring tool (76%).
The median (interquartile range) estimated percentage of pts on different lines of treatment (LoT) at DGH were 1st line (1L): 66% (55%–75%); 2nd line (2L): 25% (20%–32.5%); 3rd line (3L): 10% (5%–10%). At TC, 1L: 57.5% (50%–61.5%); 2L: 30% (21.25%–30%); 3L: 16.5% (10%–20%). Regardless of LoT or reason for prior TKI discontinuation (intolerance [INT]/resistance [RES]), major molecular response was the main response goal in 1L, 2L and 3L. INT was the most cited reason for switching to 2L (67%) or 3L (54%) TKI, while switch to 4L was RES (80%). Impact on quality of life (QoL) (85%) and tolerability affecting compliance (80%) were the most cited definitions of TKI INT. The most commonly reported choice of TKI was imatinib (98%) for 1L, dasatinib (50%) or nilotinib (41%) for 2L and a 2nd generation TKI (39%), TKI based on mutation profile (37%), or bosutinib (22%) for 3L. Additional factors influencing TKI choice at each LoT (not mutually exclusive) are listed in Table 1. In the first and subsequent years of TKI use, all respondents reported frequent monitoring of response by RQ-PCR or cytogenetics (78% using BCR-ABL1 RQ-PCR only); in line with ELN recommendations.
Most respondents (70%) used ELN2020 to guide patient management. Increased frequency of monitoring (65%) and evaluation of compliance (65%) were the most cited actions following an ELN warning response. For pts with >1 warning response or a failure response, a switch in therapy (72%/93%, respectively) and mutation analysis (76%/89%, respectively) were the most cited actions taken. Most frequently cited unmet needs in CML per line were improving QoL (1L, 48%), TKI toxicity (2L, 63%) and RES to current options (3L,72%).

Table 1. Factors influencing choice of tyrosine kinase inhibitor by line of treatment

Factors that play a part in decision-making process when selecting a TKI for a patient with CML-CP [1]	Line of treatment (L), N (% [n=46])				
	1L	2L (after 1L INT)	2L (after 1L RES)	3L (after 2L INT)	3L (after 2L RES)
Efficacy	31 (67%)	31 (67%)	36 (78%)	29 (63%)	34 (74%)
Safety profile	32 (70%)	34 (74%)	32 (70%)	32 (70%)	25 (54%)
Tolerability	35 (76%)	39 (85%)	29 (63%)	37 (80%)	29 (63%)
Quality of life	22 (48%)	28 (61%)	23 (50%)	23 (50%)	17 (37%)
Dosing regimen	16 (35%)	20 (43%)	15 (33%)	12 (26%)	8 (17%)
Comorbidities	45 (98%)	41 (89%)	37 (80%)	39 (85%)	32 (70%)
Age	33 (72%)	22 (48%)	24 (52%)	23 (50%)	20 (43%)
CML progression risk score	28 (61%)	13 (28%)	16 (35%)	10 (22%)	10 (22%)
CV risk score	31 (67%)	30 (65%)	33 (72%)	24 (52%)	24 (52%)
Patient choice	19 (41%)	23 (50%)	16 (35%)	16 (35%)	12 (26%)
Cost	14 (30%)	2 (4%)	2 (4%)	2 (4%)	2 (4%)
Guidelines	27 (59%)	25 (54%)	25 (54%)	20 (43%)	20 (43%)
Aiming for TFR	24 (52%)	16 (35%)	9 (20%)	4 (9%)	2 (4%)
Standard local management choice	16 (35%)	8 (17%)	8 (17%)	6 (13%)	7 (15%)
Physician experience	13 (28%)	19 (41%)	18 (39%)	19 (41%)	19 (41%)
Mutational profiling/screening	0 (0%)	0 (0%)	5 (11%)	2 (4%)	5 (11%)
Other	1 (2%)	0 (0%)	0 (0%)	2 (4%)	2 (4%)

1 not mutually exclusive

Summary/Conclusion: The survey suggests TKI tolerability remains an unmet need in both 1L and 2L CML treatment while TKI resistance is more a concern in later lines. The survey also suggests management of CML in UK is broadly in line with ELN recommendations. However, it also highlights areas for improvement for optimal pt management including the need for well documented CV risk assessment, CBA in all diagnostic workup, mutation analysis in all warning/failure, and increased evaluation of TKI compliance.

EP683 TREATMENT ADHERENCE IN CHRONIC MYELOID LEUKEMIA PATIENTS

B. Sidi Mohamed El Amine [1,*], H. Asma [1], C. Malika [1], Z. Zahia [1], S. A. Nadjet [1]

[1]Hematology Department, Universitary hospital of Sidi Bel Abbés, Sidi Bel Abbes, Algeria

RECEIVING TYROSINE KINASE INHIBITORS

Background: Oral tyrosine kinase inhibitors (TKIs) are the standard of care for chronic myeloid leukemia (CML). TKIs are administered in an outpatient setting for an indefinite period which may negatively impact adherence. Non-adherence to TKIs is associated with disease progression.
Aims: This study was designed to determine the proportion of CML patients non-adherent to their TKIs regimen and their outcome. The secondary objective was to identify the influence of patient characteristics on TKIs adherence.
Methods: Cross-sectional retrospective chart and dispensing record reviews were performed to identify patients receiving a TKI (imatinib, nilotinib and dasatinib) from January 2012 to December 2018. Adherence was evaluated using the medication possession ratio.
Results: With a median follow-up of 72 months, 83 patients with CML were included in our study. 16 (19%) patients were considered non-adherent to treatment. At 18 months of treatment, a major molecular response (MMR) was obtained in 61 (73.5%) patients. The 5-year event-free survival (EFS) of adherent patients was better than those who did not adhere to TKIs: 86% vs 61% (p = 0.0039). The rate of MMR was higher in adherent patients: 89% vs 6% (p <0.0001). 7 (44%) of non-adherent patients had grade 3 or 4 TKIs toxicity (p <0.001), while a low level of education was found in 11 (69%, p = 0.01). After multivariate analysis, only the occurrence of severe side effects of TKIs was predictive of patient non-adherence.
Summary/Conclusion: Non-adherence to TKIs of patients with CML should always be considered as a cause of treatment failure. It requires a good therapeutic education of the patients, and a better management of TKIs side effects.

EP684 THE EFFECT OF BODY MASS INDEX ON EFFICACY AND SAFETY OF BOSUTINIB OR IMATINIB IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA

T. H. Brümmendorf [1,*], J. E. Cortes [2], L. Busque [3], C. Gambacorti-Passerini [4], L. Stenke [5], A. Viqueira [6], E. Leip [7], S. Purcell [8], M. W. Deininger [9]

[1]Universitätsklinikum RWTH Aachen, Aachen, Germany, [2]Georgia Cancer Center, Augusta, United States, [3]Université de Montréal, Montréal, Canada, [4]University of Milano-Bicocca, Monza, Italy, [5]Karolinska Institutet, Stockholm, Sweden, [6]Pfizer SLU, Madrid, Spain, [7]Pfizer Inc, Cambridge, United States, [8]Pfizer Ltd, London, United Kingdom, [9]University of Utah Health Care, Salt Lake City, United States

Background: Bosutinib is approved for the treatment of Philadelphia chromosome–positive (Ph+) chronic myeloid leukemia (CML) resistant/intolerant to prior therapy and newly diagnosed Ph+ chronic phase (CP) CML. Body mass index (BMI) was shown to influence treatment response with front-line dasatinib vs imatinib.
Aims: We report the efficacy and safety of bosutinib and imatinib by BMI in patients with newly diagnosed CP CML.
Methods: In the open-label BFORE trial (NCT02130557), patients were randomized to receive 400 mg once daily bosutinib or imatinib. Outcomes were assessed according to baseline BMI ≥25 or <25 kg/m^2. This post hoc analysis was based on the final 5-y analysis (database lock: June 12, 2020).
Results: In the bosutinib and imatinib arms, respectively, 149 (56.4%) vs 115 (43.6%) patients and 145 (54.3%) vs 122 (45.7%) patients had BMI ≥25 vs <25. In both the bosutinib and imatinib arms, median

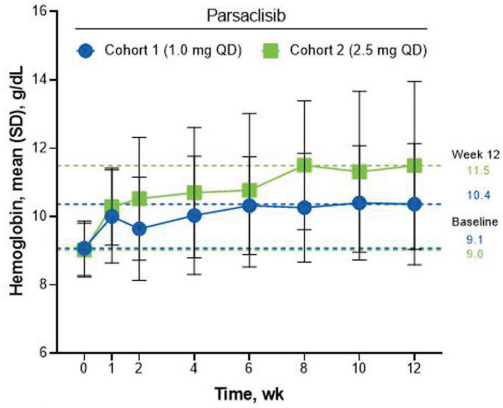
Treatment duration and time on study was 55 mo for patients with BMI ≥25 or <25; respective median dose intensity was 394 vs 393 mg/d and 400 vs 400 mg/d. Molecular response (MR) rates are shown in the table. Cumulative incidence of major MR was similar in patients with ≥25 vs <25 receiving bosutinib (HR 0.99; 95% CI 0.74–1.31) or imatinib (HR 1.09; 95% CI 0.81–1.47). Event-free survival and overall survival rates at 60 mo are shown in the table. Most common reasons for treatment discontinuation were adverse events (AEs) (bosutinib 28.2 vs 20.0%; imatinib 13.3 vs 10.7%) and lack of efficacy (bosutinib 5.4 vs 5.2%; imatinib 16.1 vs 19.8%). In patients with BMI ≥25 vs <25, dose reductions and interruptions due to treatment-emergent AEs (TEAEs) occurred in 43.6 % vs 46.2% and 66.4% vs 69.7% of patients with bosutinib and 24.5% vs 24.6% and 40.6% vs 50.8% with imatinib. Any grade TEAEs in ≥30% of patients with BMI ≥25 vs <25 were diarrhea (73.8 vs 73.1%), nausea (40.9 vs 31.9%), thrombocytopenia (30.9 vs 41.2%), increased alanine (37.6 vs 28.6%) and aspartate aminotransferase (30.2 vs 20.2%) with bosutinib and diarrhea (49.0 vs 29.5%), nausea (46.2 vs 37.7%), muscle spasms (33.6 vs 26.2%), neutropenia (14.7 vs 32.0%) and thrombocytopenia (10.5% vs 30.3%) with imatinib.

	Bosutinib			Imatinib		
	BMI ≥25 n=149	BMI <25 n=115	OR (95% CI)*	BMI ≥25 n=145	BMI <25 n=122	OR (95% CI)*
Cumulative rate by 60 mo, %						
MMR	73.2	74.8	0.84 (0.48–1.50)	66.2	68.1	1.18 (0.69–2.01)
MR[4]	57.0	59.1	0.89 (0.54–1.47)	49.7	46.7	1.06 (0.64–1.75)
MR[4,5]	45.6	50.4	0.76 (0.46–1.25)	39.3	33.6	1.30 (0.76–2.21)
			HR (95% CI)*			HR (95% CI)*
Cumulative incidence of on-treatment progression/death at 60 mo, %	5.4	8.7	0.69 (0.28–1.70)	1.4	18.9	0.07 (0.02–0.30)
Kaplan-Meier OS at 60 mo, %	97.1	91.9	0.36 (0.11–1.18)	98.5	90.0	0.17 (0.04–0.76)

Note: OR >1 and HR <1 favor BMI ≥25 kg/m².
* Adjusted for Sokal risk group and region as determined at randomization.
MMR=major molecular response; OS=overall survival

Summary/Conclusion: Efficacy of bosutinib was consistent in patients with BMI ≥25 or <25; however, with imatinib a low (vs high) BMI appeared to be associated with worse survival outcomes. Differences in certain TEAEs were observed between BMI subgroups in both treatment arms.

Enzymopathies, membranopathies and other anemias



EP685 EFFICACY AND SAFETY RESULTS FROM AN OPEN-LABEL PHASE 2 STUDY OF PARSACLISIB FOR THE TREATMENT OF AUTOIMMUNE HEMOLYTIC ANEMIA (AIHA)

W. Barcellini [1,*], I. Murakhovskaya [2], L. Terriou [3], F. Pane [4], A. Patriarca [5], K. Butler [6], S. Moran [6], S. Wei [6], U. Jäger [7]

[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [2]Albert Einstein College of Medicine/Montefiore Medical Center Bronx, New York, United States, [3]Univ. Lille, Inserm, CHU Lille, Centre de Référence des Maladies Autoimmunes Systémiques Rares du Nord et Nord-Ouest de France (CeRAINO), INFINITE – Institute for Translational Research in Inflammation, Lille, France, [4]University of Naples "Federico II", Naples, [5]University of Eastern Piedmont and AOU "Maggiore della Carità", Novara, Italy, [6]Incyte Corporation, Wilmington, United States, [7]Medical University of Vienna, Vienna, Austria

Background: There are no approved therapies for AIHA, a rare acquired condition caused by autoantibody-mediated decompensated destruction of red blood cells. The phosphatidylinositol 3-kinase δ inhibitor parsaclisib has shown efficacy in preclinical models of autoantibody-mediated diseases.
Aims: To describe preliminary 12-week efficacy and safety from an ongoing, multicenter, open-label phase 2 trial (NCT03538041) of parsaclisib in patients with primary AIHA.
Methods: Eligible patients were aged ≥18 years; had a diagnosis of warm AIHA (wAIHA), cold agglutinin disease (CAD), or mixed-type AIHA without an underlying lymphoproliferative malignancy; hemoglobin (Hgb) ≥7–≤10 g/dL; and failure of ≥1 standard therapy. Concomitant use of low-dose corticosteroids (≤20 mg/d prednisone equivalent) was permitted. After providing informed consent, patients received parsaclisib for 12 weeks at a starting oral dose of 1.0 mg once daily (QD; cohort 1) or 2.5 mg QD (cohort 2; enrolled after ≥6 patients with wAIHA in cohort 1 completed 6 weeks). Patients in cohort 1 could have their dose increased to 2.5 mg QD after 6 weeks if they had not achieved meaningful clinical response and/or required transfusions; those in cohort 2 could have dose reductions to 1.0 mg QD for tolerability. Patients achieving clinical benefit could continue to receive parsaclisib in an extension period. Primary endpoints were efficacy (proportion of patients with complete response [CR; Hgb ≥12 g/dL] or partial response [PR; Hgb 10–12 g/dL or ≥2 g/dL increase from baseline] at any visit from Week 6–12) and safety (treatment-emergent adverse events [TEAEs]).
Results: A total of 21 patients (cohort 1, n=10 [8 patients had a dose increase]; cohort 2, n=11) were enrolled and received parsaclisib; 17 patients (81%) completed 12 weeks of treatment. Mean (SD) age was 58.8 (16.6) years; 11 patients (52%) were female and 20 (95%) were White. Fourteen (67%), 4 (19%), and 3 (14%) patients had wAIHA, CAD, and mixed AIHA, respectively, and 6 (29%) had transfusions in the past year. Mean (SD) Hgb at baseline was 9.0 (0.8) g/dL and was similar between cohorts. Overall, 7 patients (33%) achieved CR (cohort 1, n=2 [20%]; cohort 2, n=5 [45%]) and 14 (67%) had PR (cohort 1, n=6 [60%]; cohort 2, n=8 [73%]) at any visit from Week 6 to 12. Dose-dependent increases from baseline in Hgb were observed over time, with cohort 2 (2.5 mg QD) achieving mean Hgb >10 g/dL by Week 2 (**Figure**). Other hemolytic markers including haptoglobin, reticulocytes, indirect bilirubin, and lactate dehydrogenase trended toward normalization. TEAEs occurred in 18 patients (86%). Five patients (24%) had grade ≥3 TEAEs, with only neutropenia occurring in >1 patient (n=2 [10%]). One patient (5%) had a serious TEAE (hemolytic anemia; deemed unrelated to treatment). Treatment-related AEs (TRAEs) were reported in 6 patients (29%); pruritic rash was the only TRAE occurring in >1 patient (n=2 [10%]), and neutropenia and thrombocytopenia were the only grade ≥3 TRAEs (n=1 [5%] each). TEAEs led to dose interruption in 4 patients (19%) and included neutropenia (n=2 [10%]), diarrhea (n=1 [5%]), and hepatotoxicity (n=1 [5%]; deemed unrelated to parsaclisib). One patient (5%) in cohort 1 discontinued parsaclisib due to a TEAE (thrombocytopenia). There were no fatal TEAEs.

Figure. Hemoglobin Levels at Each Study Visit

QD, once daily.
Dashed lines indicate mean hemoglobin (g/dL) at baseline and Week 12 for each cohort.

Summary/Conclusion: Parsaclisib was generally well tolerated, and treatment resulted in durable normalization of Hgb levels as early as Week 2. Parsaclisib has the potential to be an effective oral treatment for both wAvIHA and CAD and warrants further clinical investigation.

EP686 RARE ANEMIA DISORDERS EUROPEAN EPIDEMIOLOGICAL PLATFORM (RADEEP): DISTRIBUTION OF PATIENTS AFFECTED BY PYRUVATE KINASE DEFICIENCY IN EUROPE

M. D. M. Mañú Pereira [1,*], P. Bianchi [2], R. van Wijk [3], A. Glenthoj [4]

[1]Translational research in Rare Anaemia Disorders, Vall d'Hebrón Research Institute, Barcelona, Spain, [2]Hematology Unit, Pathophysiology of Anemias Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [3]Central Diagnostic Laboratory, University Medical Center Utrecht, Utrecht University,, Utrecht, Netherlands, [4]Danish Center for Hemoglobinopathies, Department of Hematology, Rigshospitalet, Copenhagen, Denmark

Background: Pyruvate kinase deficiency (PKD) is an ultra-rare chronic hereditary hemolytic anemia of variable severity, ranging from mild anemia to life-long transfusion dependence. Conventional treatment consisting of transfusions and splenectomy is challenged by clinical trials of PK activators (e.g. Mitapivat) and lentiviral gene therapy. Mild cases are often not monitored for long-term complications resulting from permanent haemolysis. In addition, lack of standardized diagnostic procedures combined with a low prevalence results in a significant number of undiagnosed or misdiagnosed patients. Consequently, this hampers access to proper treatment options for PKD patients in Europe.

Aims: The aim of this study was to assess the distribution of PKD patients in Europe in order to improve diagnosis and follow-up rates and to facilitate access to available treatment options by patients suffering from PKD.
Methods: The study was conducted through RADeep, which is endorsed by ERN-EuroBloodNet. Up to 145 centres dealing with RADs from 16 European countries were included in the study. Data on PKD patients in follow-up was requested, stratified by age range, adult and paediatric (<18) and by severity according to two main variables: splenectomy and regular transfusion, which was defined as >6 transfusions per year. Data on number of diagnosis in the last 25 years was requested only from diagnostic centres. Data was correlated to a country's total population (2020). Based on highest frequency, estimations were calculated for the expected number of PKD patients in all participating countries.
Results: Data on 499 PKD patients in follow-up and 611 diagnosed PKD patients retrieved from 84 medical centres from 15 European countries is shown on figure 1. Highest frequency for both PKD patients in follow-up and PKD diagnosis was found in Denmark, respectively 4,47 and 4,81 per million. This is in line with previous published data on PKD prevalence, with estimations ranging between 3,2 and 8,5 per million. Based on the PKD diagnosis frequency in Denmark, we calculated the expected number of PKD patients in the rest of participating countries. Results showed an expected number of PKD patients of 1.995, meaning that our study is covering on average 25% of PKD patients in follow-up and 31% of diagnosed PKD cases. Important differences on PKD patients in follow-up coverage are found among countries, from 63% in France to less than 25% in most of participating countries. Diagnostic coverage was highest in the Netherlands, France and Portugal. According to stratification of PKD patients based on severity, 267 adult patients were stratified as follows; 18% splenectomised on regular transfusion, 4% non-splenectomised on regular transfusion, 43% splenectomised on occasional or non-transfusion and 35% non-splenectomised on occasional or non-transfusion. Finally, % of PKD patients genotyped was found to be on average 90% and 86% for adults and pediatrics respectively (range 20-100%).

Figure 1. European distribution of PKD patients and estimations on expected number of PKD patients based on reference frequency

Summary/Conclusion: This study clearly shows the need to improve and standardize PKD patients' pathway at the national level across Europe in order to ensure adequate and timely diagnosis, and proper access to best treatment for any PKD patient. National recognition of centres of expertise for PKD for follow-up (i.e. France), centralized diagnosis (i.e. Netherlands) and/or existing registries (i.e. France, Netherlands, Denmark) dramatically improve disease coverage. Therefore, important efforts are needed in most other European countries to improve PKD diagnosis and follow-up rates.

EP687 FOSTAMATINIB FOR THE TREATMENT OF WARM ANTIBODY AUTOIMMUNE HEMOLYTIC ANEMIA (WAIHA): UPDATES FROM THE PHASE 2 AND PHASE 3 CLINICAL TRIALS

D. Kuter [1,*], S. Tong [2]

[1]Hematology Division, Massachusetts General Hospital, Boston, [2]Clinical Science, Rigel Pharmaceuticals, South San Francisco, United States

Background: Warm antibody autoimmune hemolytic anemia (wAIHA) currently has no approved treatment options and is a rare, potentially serious disorder. The disease is characterized by red blood cell (RBC) phagocytosis in macrophages via a spleen tyrosine kinase (SYK) dependent signaling pathway. Fostamatinib, a potent oral SYK inhibitor, prevents SYK-dependent platelet phagocytosis in immune thrombocytopenia (ITP) and is an approved treatment for ITP. Fostamatinib may also prevent SYK dependent RBC phagocytosis in wAIHA.
Aims: We conducted subgroup analyses of the phase 2, open-label study (NCT02612558) to better understand factors related to response to fostamatinib in patients with wAIHA. We also provide an update on the phase 3, randomized, double-blind, placebo-controlled, global study (NCT03764618) of fostamatinib for wAIHA including a Data Monitoring Committee (DMC) review of blinded data.
Methods: Both studies enrolled (or are enrolling) adult patients with a diagnosis of primary/secondary wAIHA (documented by a positive direct antiglobulin test); baseline hemoglobin level ≤10 g/dL. Exclusion Criteria include (but are not limited to): presence of other forms of AIHA; uncontrolled hypertension. Hemoglobin (Hgb) response was defined as Hgb ≥10 g/dL with a ≥2 g/dL increase from baseline without rescue therapy. The Phase 2 study treated patients for up to 24 weeks at 150 mg BID. The phase 3 study is currently enrolling patients. During the 24-week study, eligible patients are randomized 1:1 to received fostamatinib or placebo. Randomization is stratified by concomitant steroid use and severity of anemia at baseline. The starting dose of 100 mg BID is increased to 150 mg BID after 4 weeks if drug is tolerated. Two concurrent wAIHA therapies are permitted during the study. A steroid taper protocol is implemented in patients with a Hgb response, and rescue therapy is allowed as needed. Patients can rollover to an open-label extension study upon completion of the randomized phase.
Results: In the phase 2 studies, 44% (11/25) of patients had a Hgb Response by Week 24. In total, 48% responded as there was one late responder at Week 30 (12/25). Common adverse events (AEs) were diarrhea and hypertension. In a subgroup analysis, patients with secondary wAIHA (4/5 [80%]) appeared to respond better than patients with primary wAIHA (7/19 [37%]). Patients who received fostamatinib as second-line therapy (one prior wAIHA treatment) (6/9 [67%]) appeared to respond better than those who received fostamatinib as third-or-later-line therapy (>1 prior treatment) (5/15 [33%]). Female patients (8/14 [57%]) appeared to respond better than male patients (3/10 [30%]). Small sample sizes make it difficult to draw conclusions.
Patient enrollment in the phase 3 study began last year. The study will enroll approximately 90 patients at 103 sites in 22 countries. As of January 11, 2021, 62 of 99 sites are open to screening (subject to local COVID-19 regulations), and 64 of 90 patients (71%) have been randomized. The DMC Review of data in 43 patients is shown in the table below.

DMC Review of Blinded Data on 43 Patients from Phase 3 Study (as of July 14, 2020)	
Percent of patients who discontinued study	16%
Due to AEs	7%
Due to loss of response	2%
Subject decision	7%
Mean age (range), years	60 (28-87)
Female	63%
Median duration of wAIHA (range), years	2.7 (0.1-28.3)
Median number of unique prior AIHA therapies (range)	2 (1-9)
Percent of patients on glucocorticoids	91%
Percent of patients on daily concomitant steroid use	
<20 mg/day	70%
≥20 mg/day	30%
Median Hgb	8.6 g/dL
Percent of patients with baseline Hgb <9 g/dL	61%
Percent of patients with primary wAIHA	88%
All patients provided informed consent. Fostamatinib is investigational (off-label) in wAIHA.	

Summary/Conclusion: Fostamatinib markedly improved Hgb levels in 48% of 25 evaluable patients with wAIHA in phase 2 studies. The AEs observed in the phase 2 study are consistent with the fostamatinib safety database of >3500 patients across different diseases. The subgroup analyses in the phase 2 study were consistent with response rates in the larger ITP studies with regard to improved response rates with earlier line fostamatinib use. The results of the larger phase 3 study may help identify factors associated with better outcomes.

EP688 COMPLEX MODES OF INHERITANCE IN HEREDITARY RED BLOOD CELL DISORDERS: A CASE SERIES STUDY OF 155 PATIENTS

I. Andolfo [1,2], S. Martone [1,2], B. E. Rosato [1,2], R. Marra [1,2], A. Gambale [2,3], G. Forni [4], V. Pinto [4], M. Göransson [5], V. Papadopoulou [6], M. Gavillet [6], M. Elalfy [7], A. Panarelli [2], G. Tomaiuolo [2,8], A. Iolascon [1,2], R. Russo [1,2,*]

[1]Department of Molecular Medicine and Medical Biotechnology, University Federico II, [2]CEINGE - Biotecnologie Avanzate, [3]Department of Laboratory Medicine (DAIMedLab), UOC Medical Genetics, University Federico II, Napoli, [4]Centro della microcitemia e delle anemie congenite, Ospedale Galliera, Genoa, Italy, [5]Department of Paediatrics, The Queen Silvia Children's Hospital, Sahlgrenska University Hospital, Gothenburg, Sweden, [6]Service and Central Laboratory of Haematology, Department of Oncology and Department of Laboratory Medicine and Pathology, Lausanne University Hospital (CHUV), Lausanne, Switzerland, [7]Thalassemia Centre, Faculty of Medicine, Ain Shams University, Cairo, Egypt, [8]Department of Chemical Engineering, Materials and Industrial Production, University Federico II, Napoli, Italy

Background: Hereditary anemias are a heterogeneous group of conditions that are characterized by complex genotype-phenotype correlations. Based on clinical manifestations and morphological red blood cell (RBC) alterations, hereditary anemias can be broadly classified into four different subtypes: (i) disorders of hemoglobin synthesis, such as thalassemia and hemoglobinopathies; (ii) hypo-regenerative and hypo-productive anemias, such as Diamond-Blackfan anemia and congenital dyserythropoietic anemias; (iii) RBC membrane defects that are due to either alterations to the structural organization of the membranes, such as hereditary spherocytosis and hereditary elliptocytosis, or to alterations to membrane transport functions, such as hereditary stomatocytosis; and (iv) nonspherocytic hemolytic anemias, due to RBC enzyme defects.
Next-generation sequencing (NGS) has revolutionized the framework of the diagnosis of hereditary anemias by reducing both time and cost. Nevertheless, it remains a challenge to diagnose many hereditary anemia phenotypes according to phenotypic features and conventional diagnostic testing.
Aims: To identify complex modes of inheritance in hereditary red blood cell disorders by NGS analysis.
Methods: In this study, we evaluated a large case series of 155 consecutive patients with different of forms hereditary erythrocyte defects who were referred to the Medical Genetics Unit ('Federico II' University Hospital, Naples, Italy) from January 2018 to September 2020. All of the cases followed a diagnostic workflow based on a targeted-NGS panel of 86 genes known to be causative of hereditary RBC defects.
Results: We obtained an overall diagnostic yield of 83% of tested patients. Monogenic inheritance was seen for 67% (104/155), and multi-locus inheritance for 17% (26/155). *PIEZO1* and *SPTA1* were the most mutated loci among the other causative genes identified. The high frequencies of mutations in both of these genes were mainly related to their low genic intolerance, as suggested by the high values of the Residual Variation Intolerance Score percentiles for both genes. Accordingly, 18/26 patients with multi-locus inheritance showed dual molecular diagnosis of hereditary stomatocytosis (mainly dehydrated hereditary stomatocytosis type 1) and hereditary spherocytosis. These dual inheritance cases were characterized by analysis of their inheritance patterns, hematological indices, iron balance parameters, and hemolytic markers. Of note, dual inheritance patients were clinically indistinguishable from patients with hereditary spherocytosis. Additionally, their Osmoscan profiles were analyzed, which highlighted alterations of the ektacytometry curve of dual inheritance patients compared to both dehydrated hereditary stomatocytosis and hereditary spherocytosis.
Summary/Conclusion: One of the major advantages of the NGS approach is the identification of both polygenic conditions and modifier variants associated with causative mutations. Studies of Mendelian conditions have revealed the extent to which many rare diseases can be characterized by complex modes of inheritance, such as digenic inheritance and dual molecular diagnoses. Our findings expand the genotypic spectrum of red blood cell disorders and indicate that multi-locus inheritance should be considered for analysis and counseling of these patients. Of note, the genetic testing was crucial for diagnosis of patients with a complex mode of inheritance.

EP689 INHIBITION OF COMPLEMENT C1S WITH SUTIMLIMAB IN PATIENTS WITH COLD AGGLUTININ DISEASE (CAD): 1-YEAR INTERIM RESULTS OF THE PHASE 3 CARDINAL STUDY LONG-TERM FOLLOW-UP

A. Röth [1,*], W. Barcellini [2], S. D'Sa [3], Y. Miyakawa [4], C. M. Broome [5], M. Michel [6], D. J. Kuter [7], B. Jilma [8], T. H. A. Tvedt [9], I. Weitz [10], P. Patel [11], X. Jiang [11], C. Reuter [12], J. Su [12], F. Shafer [11], M. Lee [11], W. Hobbs [12], S. Berentsen [13]

Background: CAD is a rare chronic autoimmune hemolytic anemia characterized by classical complement pathway–mediated hemolysis (predominantly extravascular occurring in the liver), anemia, and fatigue. Sutimlimab (formerly BIVV009) is a first-in-class humanized monoclonal antibody and C1s inhibitor that selectively targets the classical complement pathway, while leaving the lectin and alternative pathways intact.
Aims: CARDINAL (NCT03347396) evaluated sutimlimab efficacy and safety in adults with CAD and a recent transfusion history. One-year interim results of the long-term follow-up are reported.
Methods: CARDINAL is a Phase 3, open-label, single-arm study with a 26-week treatment period (Part A) and ongoing extension (Part B) for 2 years after the last patient finishes Part A. Interim data are available for Part B (data cut: January 16, 2020). Adult patients with confirmed CAD diagnosis, baseline hemoglobin (Hb) ≤10 g/dL, and ≥1 blood transfusion in the past 6 months were enrolled after providing informed consent. Sutimlimab was administered intravenously on Days 0 and 7, then biweekly. Interim Part B analysis assessed long-term efficacy and safety of sutimlimab, and durability of response (including laboratory parameters and quality of life [QOL]). Efficacy endpoints were change from baseline in hemolytic markers and the Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue Scale. Descriptive statistics, frequency, or percentage were used to analyze outcomes.
Results: Overall, 24 patients enrolled and 22 finished Part A and entered Part B. Of enrolled patients, 62.5% were female; mean (standard deviation [SD]) age was 71.3 (8.2) years; mean (SD) number of transfusions <6 months before enrollment was 3.2 (4.0); 62.5% had received ≥1 targeted therapy in the last 5 years. Sutimlimab treatment led to rapid improvement in mean Hb level after the first dose; Hb remained >11 g/dL from Weeks 5 (Part A) to 53 (Part B; **Table**). Mean total bilirubin rapidly normalized by Week 3 and was maintained <20 µmol/L through Week 53. Mean FACIT-Fatigue scores rapidly increased by Week 1 and remained >40 points from Weeks 3 to 51; mean increase from baseline to Week 51 was 11.4, consistent with a clinically meaningful improvement. Improvements in Hb, bilirubin, and FACIT-Fatigue correlated with the normalization of C4 and near-complete inhibition of classical complement pathway activity (by Wieslab assay). Mean C1q levels were unaffected. Normalization of absolute

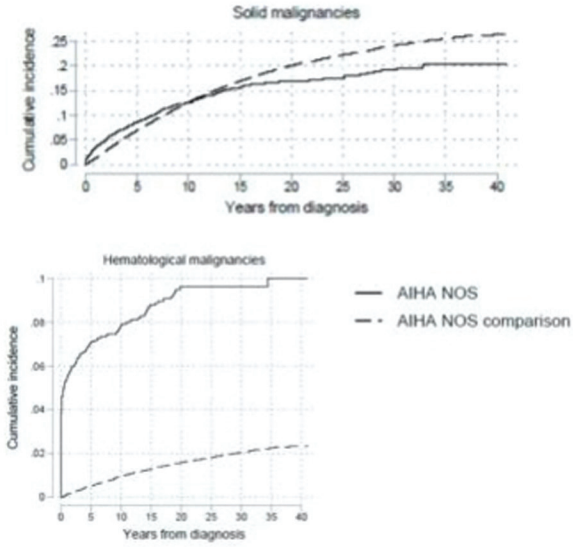
reticulocyte count from baseline to Week 3 was also observed, alongside normalized haptoglobin levels and reductions in lactate dehydrogenase. Of patients who entered Part B, 86.4% were transfusion-free from Weeks 26 to 53. From baseline to the data cutoff date, all 24 patients experienced ≥1 treatment-emergent adverse event (TEAE), with one serious TEAE (viral infection; treatment related). No meningococcal infections or TEAEs of meningitis were reported. One TEAE of device-related thrombosis (unrelated to sutimlimab) was reported in Part B; there were no other vascular thromboembolic TEAEs. No patients developed systemic lupus erythematosus.

Table. Long-term efficacy outcomes and laboratory parameters following sutimlimab treatment during the CARDINAL study

	Part A (N=24)				Part B (N=22)	
Hemolytic markers	Baseline		Week 26		Week 53	
	n	Mean (SD)	n	Mean (SD)	n	Mean (SD)
Hb, g/dL	24	8.6 (1.6)	20	11.3 (2.4)	16	11.8 (1.4)
Total bilirubin, µmol/L	21	53.3 (24.0)	17	18.7 (12.3)	19	16.9 (8.7)
LDH, U/L	24	438.1 (284.6)	20	332.9 (155.54)	21	367.2 (253.64)
Absolute reticulocytes, ×10⁹/L	22	138.3 (68.0)	17	87.0 (41.6)	15	87.2 (38.9)
Haptoglobin, g/dL	24	0.27 (0.28)	20	0.33 (0.34)	22	0.45 (0.49)
Complement parameters	Baseline		Week 25		Week 51*	
	n	Mean (SD)	n	Mean (SD)	n	Mean (SD)
Total C4, g/L	23	0.04 (0.07)	20	0.29 (0.07)	3	0.24 (0.19)
Classical complement pathway activity, %	24	19.8 (16.7)	21	3.0 (3.1)	21	3.2 (3.4)
C1q, ng/mL	24	84906.2 (35723.0)	21	77885.9 (26305.9)	21	63137.2 (20151.9)
QOL outcome	Baseline		Week 26		Week 51*	
	n	Mean (SD)	n	Mean (SD)	n	Mean (SD)
FACIT-Fatigue	22	32.5 (10.6)	17	42.5 (8.3)	18	44.3 (8.7)
Transfusions	Baseline to Week 5 n (%)		Weeks 5 to 26 n (%)		Weeks 27 to 53 n (%)	
Patients with 0 transfusions	19 (79.2)		17 (70.8)		19 (86.4)	

C4, complement protein 4; C1q, complement component 1q; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue; Hb, hemoglobin; LDH, lactate dehydrogenase; QOL, quality of life; SD, standard deviation.
*Last data collection.

Summary/Conclusion: Sutimlimab, a first-in-class selective anti-C1s classical complement pathway inhibitor, maintained Hb levels >11g/dL, sustained normalization of bilirubin, and continued to improve FACIT-Fatigue scores, with no newly identified safety concerns at 1 year. These results of the ongoing CARDINAL Part B long-term study demonstrate that continued upstream inhibition of the classical complement pathway with sutimlimab provides sustained and durable treatment effects in chronic CAD.



EP690 CANCER RISK IN PATIENTS WITH WARM AUTOIMMUNE HAEMOLYTIC ANAEMIA - A NATIONWIDE COHORT STUDY

S. Tranekaer [1,*], D. L. Hansen [1], H. Frederiksen [1]

[1]Department of Clinical research, The research unit of Haematology, Odense, Denmark

Background: Warm autoimmune haemolytic anaemia (wAIHA) is an acquired blood disorder characterized by antibodies directed against own RBCs. wAIHA is either primary or secondary due to cancers or other diseases. The presence of an underlying disease in wAIHA is associated with an overall reduced prognosis, compared with primary wAIHA. The association between wAIHA and some cancers, especially B-cell malignancies, have been established, but accurate risks are missing. To our knowledge, no studies have investigated the cumulative incidence of cancer following diagnosis of primary or secondary wAIHA.
Aims: The aim of this study is to evaluate the prevalence of any cancer amongst patients with wAIHA at time of diagnosis, compared with the general population, and whether patients with wAIHA have a higher incidence of cancer after wAIHA-diagnosis.
Methods: Patients with wAHIA diagnosed 1980-2016 were identified in the nationwide Danish Haemolysis Cohort. Each patient was age-sex-matched with up to 50 comparisons from the general population without haemolysis. Patients and comparisons were followed from index date, corresponding to date of wAIHA diagnosis or an assigned matched date for comparisons. We identified incident and prevalent cancer diagnoses using the Danish Cancer Registry. Patients and comparisons were followed until a cancer diagnosis, death, emigration or end of study, whichever came first. Any registered cancer diagnosis before index-date + 30 days were considered prevalent, thereafter, all cancer diagnoses were defined as incident cancer diagnosis. We present cumulative incidences (CIs) of cancer diagnoses after one year, five years, and ten years.
Results: We identified 2,700 patients with wAIHA and 133,730 sex and age-matched comparisons. Out of the 2,700 patients with wAIHA, 1,589 (58.9%) were primary wAIHA, and 1,111 (41.1%) patients were secondary wAIHA due to defined underlying diseases – most frequently haematological cancers. Women accounted for 56% of patients, and this uneven sex distribution were most prominent in primary wAIHA. Median age was 58.8 years for patients with primary wAIHA and 68.2 years for secondary wAIHA patients. The mean age at death for the patients diagnosed with primary wAIHA was 77.6 years, 75.0 years for patients diagnosed with secondary wAIHA, and 83.9 and 83.8 years in the respective comparison groups.
The CI of haematological cancer was higher for patients diagnosed with wAIHA vs. general population comparisons (Figure). For all haematological malignancies, except multiple myeloma, the CI remained higher in wAIHA vs. comparisons. For solid cancer the CI was higher the first 10 years following wAIHA diagnosis vs. comparisons, after time point incidences equalized (Figure).

Figure: The cumulative incidences of all solid and haematological cancers combined in patients diagnosed with wAIHA and comparisons

Summary/Conclusion: Patients diagnosed with wAIHA have a higher risk of developing malignancies after the wAIHA diagnosis. The increased risk for subsequent cancer development after wAIHA-diagnosis is most prominent for haematological malignancies.

EP691 BASELINE CHARACTERISTICS BY AGE OF A GLOBAL COHORT OF PATIENTS DIAGNOSED WITH PYRUVATE KINASE DEFICIENCY – A DESCRIPTIVE ANALYSIS FROM THE PEAK REGISTRY

P. Bianchi [1,*], E. J. van Beers [2], J.-L. Vives Corrons [3], B. Glader [4], A. Glenthøj [5], H. Kanno [6], K. H. M. Kuo [7], C. Lander [8], D. M. Layton [9], D. Pospíšilová [10], V. Viprakasit [11], J. Williams [12], Y. Yan [12], B. McGee [12], R. F. Grace [13]

[1]UOC Ematologia, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [2]Van Creveldkliniek, Department of Internal Medicine, University Medical Center Utrecht, Utrecht, Netherlands, [3]Institute for Leukaemia Research Josep Carreras ENERCA Coordinator, University of Barcelona, Barcelona, Spain, [4]Stanford University School of Medicine, Palo Alto, CA, United States, [5]Department of Hematology, Rigshospitalet, Copenhagen, Denmark, [6]Department of Transfusion Medicine and Cell Processing, Tokyo Women's Medical University, Tokyo, Japan, [7]Division of Hematology, University of Toronto, Toronto, Canada, [8]Metabolic Support UK, Wrexham, Wales, [9]Department of Haematology, Hammersmith Hospital, Imperial College Healthcare NHS Foundation Trust, London, United Kingdom, [10]Deparment of Pediatrics, Palacky University and University Hospital, Olomouc, Czech Republic, [11]Siriraj Hospital, Mahidol

University, Bangkok, Thailand, [12]Agios Pharmaceuticals, Inc, Cambridge, MA, [13]Dana-Farber/Boston Children's Cancer and Blood Disorder Center, Boston, MA, United States

Background: Pyruvate kinase (PK) deficiency is the most common hereditary red cell glycolytic enzyme defect leading to lifelong hemolytic anemia. Despite current supportive interventions, patients (pts) may develop serious complications, such as iron overload, regardless of their age or transfusion history. Information describing the real-world burden of disease among the pediatric population is limited.
Aims: This analysis aimed to characterize the clinical manifestations and disease management strategies for the pediatric cohort (<18 years [yrs]) and the adult cohort (≥18 yrs) with PK deficiency enrolled in the Peak Registry (NCT03481738).
Methods: The Peak Registry is an ongoing, global prospective and retrospective cohort study of adult and pediatric pts diagnosed with PK deficiency. Demographic, medical history, laboratory, and treatment data for this analysis were collected from eligible pts who enrolled in the Registry as of the latest data cut (24Mar2020). All analyses reported are descriptive and based on non-missing data as of the time of enrollment in the Registry. Continuous variables are summarized as means (SD) or medians (range), while categorical variables are summarized as counts and percentages.
Results: A total of 140 pts (56 pediatric and 84 adult) were included in this analysis. The mean age of participants at enrollment was 7.8 yrs (SD 4.6) for the pediatric cohort vs 37.4 yrs (SD 15.5) for adults. Hemoglobin levels (median [range]) were 8.4 g/dL (5.8–12.3) in the pediatric cohort and 9.5 g/dL (6.7–12.9) in adults. Ferritin levels (median [range]) in the pediatric cohort were 772 ng/mL (78–2499) and 404 ng/mL (19–2263) in adults. History of chelation therapy was 50.0% (0–5 yrs), 54.5% (6–11 yrs), and 63.6% (12–17 yrs) in pediatric subgroups and 30.6% in adults. The median age at splenectomy for pediatric and the adult groups were at 5 yrs (2–12 yrs) and 6 yrs (1–27 yrs), respectively. The higher frequency of splenectomy (0% [0–5 yrs], 52.2% [6–11 yrs], 61.5% [12–17 yrs]) with increasing age across pediatric cohorts matches a decreased frequency in those who were treated with regular transfusions (≥6 transfusions within 1 yr prior to enrollment), 46.7% (0–5 yrs), 14.3% (6–11 yrs), and 10.0% (12–17 yrs). The frequency of splenectomy and regular transfusions was similar between the 6–17 yrs old cohort (55.6% and 12.9%) and the adult cohort (51.3% and 9.4%).

Table:	Overall Population		Pediatric Subgroups

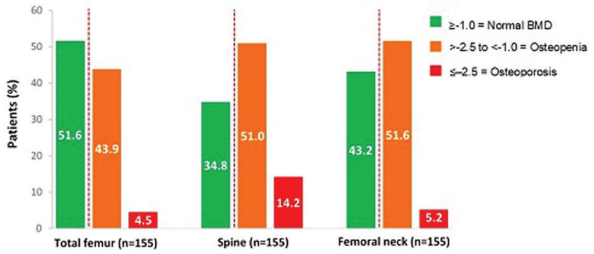
N represents number of patients with data available; *-1 age at diagnosis denotes presumably diagnosed in utero pt=patient; SD=standard deviation; yrs=year.

Summary/Conclusion: This analysis provides early insight into the disease manifestations experienced by pediatric pts with PK deficiency. Prior research has revealed that adult pts with PK deficiency experience a high disease burden. This analysis confirms that complications start early on, with pediatric pts experiencing significant anemia and treatment with transfusions and chelation before age 6. The timing of the decrease in regular transfusions matches the timepoint of an increased frequency of splenectomy, possibly reflecting the known impact of splenectomy on partially ameliorating the anemia in PK deficiency. However, despite the high rate of splenectomy in this cohort, many children and adults continue to have substantial anemia and disease burden. The Registry will continue to collect data in pts to better understand the clinical manifestations and complications of PK deficiency over time.



EP692 EARLY-ONSET OSTEOPENIA AND OSTEOPOROSIS IN PATIENTS WITH PYRUVATE KINASE DEFICIENCY

Background: Hereditary pyruvate kinase (PK) deficiency results in lifelong hemolytic anemia and several significant comorbidities, the epidemiology of which are not well characterized. Among these is reduced bone mineral density (BMD), which can result in premature osteopenia, osteoporosis, and fractures.
Aims: To better characterize the bone density abnormalities in patients (pts) with PK deficiency, this study evaluated pooled pre-treatment baseline data from 3 clinical trials involving pts with PK deficiency investigating mitapivat (AG-348), an allosteric activator of PK: DRIVE-PK (NCT02476916), ACTIVATE (NCT03548220), and ACTIVATE-T (NCT03559699). This is the first large PK deficiency cohort in which dual-energy x-ray absorptiometry (DXA) scores were systematically and consistently assessed.
Methods: DRIVE-PK is a completed phase 2, global, randomized, open-label study. ACTIVATE is an ongoing phase 3, global, randomized, double-blind, placebo-controlled study. ACTIVATE-T is an ongoing phase 3, global, open-label, single-arm study. In all 3 studies, pts ≥18 years (yrs) of age with a confirmed diagnosis of PK deficiency were eligible to participate. Pts were eligible to participate in DRIVE-PK and in ACTIVATE if they were not regularly transfused (DRIVE-PK: ≤3 units of red blood cells in the prior 12 months [mos]; no transfusions in the prior 4 mos; ACTIVATE: ≤4 transfusion episodes in the previous yr; no transfusions in the prior 3 mos) and in ACTIVATE-T if they were regularly transfused (≥6 transfusion episodes in the previous yr). BMD was measured using DXA at baseline; scans were obtained locally for all 3 studies. Scans were interpreted locally for DRIVE-PK and centrally for ACTIVATE and ACTIVATE-T. Osteopenia and osteoporosis were identified on DXA according to standard definitions, and prevalence of each was compared to prevalence ascertained via medical history.
Results: Of 159 pts evaluated (DRIVE-PK, n=52; ACTIVATE, n=80; ACTIVATE-T, n=27), median age was 34 yrs (range, 18–78) and majority were female (n=88; 55.3%). Of 155 pts who had baseline T-scores for total femur, spine, and femoral neck, 38 (24.5%) had a T-score of ≥–1.0 at all locations, indicating normal BMD; 91 (58.7%) had a T-score of >–2.5 to <–1.0 at 1 or more locations, indicating osteopenia; and 26 (16.8%) had a T-score of ≤–2.5 at 1 or more locations, indicating osteoporosis. The proportion of pts in each T-score range for each of the 3 locations is shown in the Figure. In contrast to the DXA scan findings, only 28 (17.6%) pts had a known medical history of osteopenia and 23 (14.5%) had a known medical history of osteoporosis. Taking together DXA scan results and medical history for all 159 pts, 85 (53.5%) had osteopenia and 33 (20.8%) had osteoporosis. Median age for pts with either osteopenia or osteoporosis (n=118) was 36 yrs (range, 18–78). Of these, 20 pts (16.9%) were regularly transfused and 98 pts (83.1%) were not regularly transfused.

Figure. Pooled T-scores at Baseline†

BMD: bone mineral density.
†Pooled population includes patients with PK deficiency from DRIVE-PK, ACTIVATE, and ACTIVATE-T trials.

Summary/Conclusion: In this large cohort, universal DXA scanning revealed that over three-quarters of adults with PK deficiency had osteopenia or osteoporosis, irrespective of transfusion requirements. Given the young median age of the cohort (34 yrs), these findings have considerable significance and implications for the screening and care of pts with PK deficiency throughout their adult lives. Early monitoring of these pts with DXA scans in order to ensure a prompt diagnosis of bone density abnormalities and indicated treatment may be warranted.

EP693 PHARMACOLOGIC INHIBITION OF PI3KΔ REDUCES AUTOANTIBODY FORMATION AND IS EFFICACIOUS IN A PRECLINICAL MODEL OF AUTOIMMUNE HEMOLYTIC ANEMIA

M. Scuron [1], B. Fay [1], R. Collins [1], L. Hall [1], A. Connell [1], N. Shin [1], M. Soloviev [1], D. Shuey [1], P. Smith [1,*]

[1]*Incyte Research Institute, Wilmington, United States*

Background: Autoimmune hemolytic anemia (AIHA) is a rare acquired disorder in which autoantibodies directed against red blood cell (RBC) membrane antigens lead to accelerated RBC destruction. The disease can be distinguished on the basis of the autoantibody class and thermal characteristics: warm AIHA (immunoglobulin [Ig]-G–mediated) and cold agglutinin disease (IgM-mediated). The mortality rate is approximately 11%, and there are currently no regulatory approved AIHA treatments. Phosphatidylinositol 3-kinases (PI3Ks) are divided into 3 classes (Class I, II, and III) according to their structure, regulation, and substrate specificity. The Class I PI3K delta isoform (PI3Kδ) has been implicated in autoimmune diseases associated with aberrant B-cell and antibody responses. Parsaclisib is an oral, small-molecule PI3Kδ selective inhibitor without known adverse off-target toxicities that is being clinically evaluated in AIHA and hematologic malignancies.
Aims: To evaluate the efficacious potential of small-molecule PI3Kδ inhibition in preclinical models of antibody-mediated immunity, including spontaneous AIHA.
Methods: The relevance of PI3Kδ inhibition on de novo antibody production was characterized in 2 preclinical mouse models. Intravenous 2,4,6-trinitrophenyl lipopolysaccharide (TNP-LPS) triggers a rapid antigen-specific, B-cell–mediated IgM response. In contrast, intraperitoneal injection of 2,4-dinitrophenyl-keyhole limpet hemocyanin (DNP-KLH) drives an antigen-specific, T-cell–dependent, B-cell–mediated IgG immunity. The interleukin-2 knockout (IL-2 KO) mice spontaneously develop a systemic autoimmune disease, dying from complications of AIHA mediated by autoantibodies. The pharmacologic effect of PI3Kδ inhibition was quantified using antigen-specific enzyme-linked immunosorbent assays, complete blood count, and flow cytometry.
Results: In vitro enzymatic selectivity screening revealed that parsaclisib potently inhibited the PI3Kδ kinase enzyme (50% inhibitory concentration [IC_{50}] = 1.1 ± 0.5 nM) with ~20,000-fold selectivity over the other PI3K family member enzymes. Oral prophylactic PI3Kδ inhibitor treatment dose-dependently reduced antigen-specific IgM and IgG antibody titers. The modulation of antigen-specific IgM and IgG responses following parsaclisib treatment was fully consistent with previously published data using TNP-LPS and DNP-KLH stimuli in PI3Kδ knockout mice. Selective pharmacologic inhibition of the PI3Kδ isoform ameliorated AIHA symptoms in the IL-2 KO mouse model, with disease modulation associated with the reduced presence of Ig-bound RBC. Hemoglobin and RBC levels were unaffected by PI3Kδ inhibition in healthy age-matched wild-type mice.
Summary/Conclusion: In preclinical models, PI3Kδ inhibition dose-dependently inhibited de novo IgM and IgG humoral responses and was highly efficacious in a spontaneous AIHA mouse model. These experimental data support the scientific rationale for clinically evaluating parsaclisib in AIHA (NCT03538041).

EP694 IMPACT OF OLIPUDASE ALFA ENZYME REPLACEMENT THERAPY ON PULMONARY, VISCERAL AND HEMATOLOGIC MANIFESTATIONS OF ACID SPHINGOMYELINASE DEFICIENCY: 1-YEAR RESULTS OF CLINICAL TRIALS IN CHILDREN AND ADULTS

Background: Acid sphingomyelinase deficiency (ASMD) is a rare, debilitating lysosomal storage disease with no approved treatment. Deficient ASM activity results in progressive pulmonary, hepatic, visceral, and hematologic dysfunction across a disease spectrum that includes central nervous system manifestations in the most severe patients. Disease awareness is low and diagnostic delays are common. It may fall to hematologists to evaluate and identify undiagnosed patients. Olipudase alfa (recombinant human ASM) is an enzyme replacement therapy in development for the non-central nervous system manifestations of ASMD.
Aims: Present safety and efficacy outcomes of 2 international clinical trials of dose-escalated olipudase alfa in children and adults with chronic ASMD.
Methods: ASCEND (NCT02004691/Sanofi Genzyme) is a Phase 2/3, multicenter, randomized, 52-week, double-blind, placebo-controlled trial in 36 adults with chronic ASMD randomized 1:1 to receive olipudase alfa or placebo. Independent primary efficacy endpoints were % change in % predicted lung carbon monoxide diffusing capacity (DL_{CO}) and % change in spleen volume (for the USA, combined with change in Splenomegaly Related Score [SRS]) at Week 52. ASCEND-Peds (NCT02292654/Sanofi Genzyme) is a Phase 1/2 multicenter, open-label trial evaluating olipudase alfa in 20 children with chronic ASMD. Primary objective was safety over 64 weeks. Efficacy outcomes at 52 weeks included change in spleen volume, DL_{CO}, and height Z-score. Both trials also evaluated changes in liver volume, platelet count, lipid profile, and biomarkers. Informed consent was obtained.
Results: In ASCEND (adult), least-square mean % change from baseline to Week 52 favored olipudase alfa over placebo for % predicted DL_{CO} (+22.0% vs. +3.0%, p=0.0004), spleen volume (-39.4% vs. +0.5%, p<0.0001), liver volume (-31.7% vs. -1.4%, p<0.0001), and platelets (+16.8% vs. +2.5%, p=0.019), with differences seen by Week 26. SRS decreased in both groups (-8.0 for olipudase vs. -9.3 for placebo at Week 52, p=0.70). Biomarker and lipid profiles improved in olipudase-alfa compared to placebo-treated patients. No patient had a

treatment-related serious adverse event or discontinued due to a treatment-emergent adverse event; 35/36 patients continue in an open-label extension.
In ASCEND-Peds (pediatric), splenomegaly and hepatomegaly improved in all patients at Week 52 (mean decrease ±SD: 49.2% ±9.7% and 40.6% ±9.4%, respectively, p<0.0001). Among 9 patients able to perform baseline DL_{CO} testing, mean % predicted DL_{CO} improved by 32.9% ±29.1% (relative change from baseline, p=0.0053). Platelet count improved by a mean ±SD of 34% ± 36% after 52 weeks of olipudase alfa (p=0.0003). Median height Z-score improved from -2.0 to -1.5 (p<0.0001). Biomarker and lipid profiles also improved. Treatment response was similar across age groups (<6 years, 6 to <12 years, 12 to <18 years). Eleven of 20 patients had infusion-associated reactions (mainly urticaria, pyrexia, and/or vomiting). Three patients had treatment-related serious adverse events: transient alanine aminotransferase increases in 1 patient, urticaria and rash in 1 patient, and anaphylactic reaction in 1 patient that was treated with a desensitization protocol. All patients completed the study and continue in an extension trial.
Summary/Conclusion: Olipudase alfa was well-tolerated in children and adults and, after 1 year of treatment, resulted in improved lung function, reductions in spleen and liver volumes, improved platelet counts and lipid profiles, reductions in disease biomarkers, and (in children) improved growth.

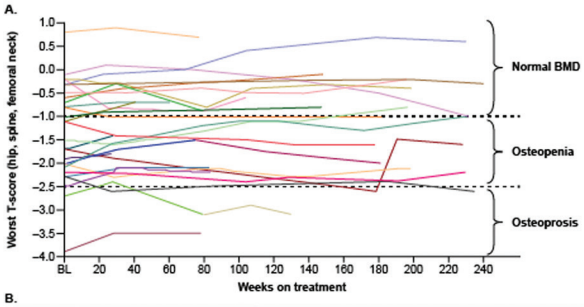
EP695 MITAPIVAT AMELIORATES RED CELL FEATURES AND DECREASES ANEMIA IN BAND 4.2-/- MICE, A MODEL OF HEREDITARY SPHEROCYTOSIS

A. Matte' [1,*], A. Recchiuti [2], E. Federti [1], C. Kung [3], A. B. Wilson [1], A. Pomilio [2], P. Kosinski [3], V. Riccardi [1], I. Iatcenko [1], L. Dang [3], A. Iolascon [4], R. Russo [4], C. Brugnara [5], A. Janin [6], C. Leboeuf [6], N. Mohandas [7], L. De Franceschi [1]

[1]Dept of Medicine, University of Verona, Verona, [2]University of Chieti, Chieti, Italy, [3]Agios Pharmaceuticals, Cambridge, United States, [4]Dept. of Molecular Medicine and Medical Biotechnology and CEINGE, University of Naples Federico II, Naples, Italy, [5]Dept of Laboratory Medicine, Boston Children's Hospital, Harvard Medical School, Boston, United States, [6]University Diderot of Paris, Paris, France, [7]Laboratory of Red Cell Physiology, New York Blood Center, New York, United States

Background: Hereditary spherocytosis (HS) is the most common cause of inherited red cell membranopathy, due to mutations in genes encoding membrane or cytoskeletal proteins, including band 3, ankyrin, spectrin or band 4.2. Loss of membrane cohesion results in surface area loss and generation of spherocytic red cells with decreased cellular deformability and reduced red cell survival due to splenic sequestration. A diagnostic test for HS is the incubated osmotic fragility implying a role for red cell ATP content in maintaining normal RBC function including membrane stability. Recently, relative PK deficiency has been observed in HS red cells (Andreas O et al. BJH 187: 386, 2019).
Aims: To understand whether the oral pyruvate kinase activator, mitapivat, by modulating ATP content, might have potential beneficial effects for HS RBCs in band $4.2^{-/-}$ mice, a well-established model of HS (Peters LL et al JCI 103: 1527, 1999).
Methods: Mitapivat was administrated to band $4.2^{-/-}$ mice at dosages of 100 mg/kg/day over 6 months. We analysed: hematologic parameters, red cell indices and osmotic fragility, markers of hemolysis, phagocytic index and iron homestasis.
Results: In band $4.2^{-/-}$ mice, Mitapivat resulted in (i) decreased anemia with reduced reticulocyte count (Hb 11.6±0.035 g/dL, n=17 *vs* 13.104±0.09 g/dL, n=9; P<0.05; retics: 11.4±0.1%, n=16 vs 7.6±0.2%, n=7 % P<0.05) and decreased hemolytic indices (LDH, total bilirubin) with decreased spleen weight/mouse weight ratio (8.41±0.08 vs 6.53±0.06, n=8 each group; P<0.05); (ii) reduction in the proportion of phosphatidylserine positive RBCs, measured with Annexin V binding (2.4±0.02% *vs* 1.5±0.06% n=5-6; P<0.05); (iii) reduction of naturally occurring antibody (NAb) bound to band $4.2^{-/-}$ RBC membrane; (iv) improvement of osmotic fragility. The decreased hemolysis was associated with reduction in serum erythropoietin (EPO: 1001.2±41.7 U/L vs 472 ± 12.5 U/L, n=7, P<0.05). We also documented *in vivo* reduction of erythrophagocytosis and *in vitro* decreased phagocytic index, supporting the improvement in HS red cell features by Mitapivat. The improvement of anemia in Mitapivat treated band $4.2^{-/-}$ mice was associated with decreased liver iron overload.
Summary/Conclusion: Our data indicate that Mitapivat ameliorates anemia of band $4.2^{-/-}$ mice, reduces chronic hemolysis and improves band $4.2^{-/-}$ mouse RBC features. Thus, Mitapivat might represent a potential therapy to be explored in patients with HS.

EP696 BONE MINERAL DENSITY IS STABLE IN ADULTS WITH PYRUVATE KINASE DEFICIENCY RECEIVING LONG-TERM TREATMENT WITH MITAPIVAT



H. Al-Samkari [1,*], E. J. van Beers [2], W. Barcellini [3], F. Galactéros [4], B. Glader [5], K. H. M. Kuo [6], D. M. Layton [7], Y. Ravindranath [8], H. Yaish [9], Y. Dong [10], F. Tai [10], P. Hawkins [10], V. Beynon [10], K. Gilroy [10], R. F. Grace [11]

[1]Division of Hematology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, [2]Van Creveldkliniek, Department of Internal Medicine, University Medical Center Utrecht, Utrecht, Netherlands, [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinic, Milan, Italy, [4]Unité des Maladies Génétiques du Globule Rouge, CHU Henri Mondor, Créteil, France, [5]Stanford University School of Medicine, Palo Alto, CA, United States, [6]Division of Hematology, University of Toronto, Toronto, Canada, [7]Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom, [8]Wayne State University School of Medicine, Children's Hospital of Michigan, Detroit, MI, [9]University of Utah, Salt Lake City, UT, [10]Agios Pharmaceuticals, Inc, Cambridge, MA, [11]Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA, United States

Background: Hereditary pyruvate kinase (PK) deficiency results in chronic hemolysis that can lead to reduced bone mineral density (BMD). A recent analysis of 159 patients (pts) with PK deficiency showed that >75% of adult pts had osteopenia or osteoporosis at a median age of 34 years (yrs). Mitapivat (AG-348) is an investigational, first-in-class, allosteric activator of PK that has been shown to improve hemoglobin and other hemolysis markers for up to 42 months (mos) in pts with PK deficiency. Mitapivat has mild aromatase inhibition effects; however, it is not clear whether this carries a negative impact on BMD in pts with PK deficiency. Conversely, reducing hemolysis through PKR activation with this agent may have a positive effect on BMD.
Aims: To report BMD over time in pts with PK deficiency receiving long-term treatment with mitapivat in the DRIVE-PK study.
Methods: DRIVE-PK (NCT02476916) is a phase 2, global, randomized, open-label, dose-ranging study in pts ≥18 yrs of age with a confirmed diagnosis of PK deficiency and not receiving regular transfusions (≤3 units of red blood cells ≤12 mos and no transfusions ≤4 mos). Pts were randomized 1:1 to 50 mg or 300 mg of mitapivat twice daily (BID) during a 24-week (wk) core period; eligible pts could enter an extension period to receive mitapivat for up to 8 yrs. Dose adjustments were permitted based on safety and efficacy; following an amendment, doses >25 mg BID were tapered to the lowest effective dose in the extension. BMD was measured using DXA scans at baseline (BL), every 6 mos through month 30, and then annually. DXA changes over time were assessed for pts receiving mitapivat >12 mos. Pts were classified as having normal BMD, osteopenia, or osteoporosis based on DXA T-scores.
Results: Of 52 participants in DRIVE-PK (median age 34 yrs [range, 18–61]), 31 (32% female) received mitapivat >12 mos and had on-treatment DXA monitoring for up to 56 mos. Of 30 pts who had BL T-scores for total hip, spine, and femoral neck, 12 (38.7%) had a T-score ≥–1.0 (normal BMD) at all locations, 13 (41.9%) had a worst T-score >–2.5 to <–1.0 (osteopenia) at 1 or more locations, and 5 (16.1%) had a worst T-score ≤–2.5 (osteoporosis) at 1 or more locations. As of the latest assessment during the extension period, 12 (38.7%), 11 (35.5%), and 5 (16.1%) of 31 pts had a T-score indicating normal BMD, osteopenia, and osteoporosis, respectively. None of the 12 pts with BMD in the normal range at BL showed worsening of BMD at latest assessment. Of 13 pts with a worst BL T-score of >–2.5 to <–1.0 at 1 or more location(s), 9 remained stable, 1 worsened, and 3 improved to a T-score of ≥–1.0, indicating normal BMD. Of 5 pts with a worst BL T-score of ≤–2.5 at 1 or more location(s), 4 remained stable and 1 improved to a T-score of >–2.5 to <–1.0 (Figure and Table). No fractures were reported during this study.

Figure. A. Individual longitudinal plot[a] of worst DXA T-score in pts treated with mitapivat for >12 mos[b,c]; B. Shift of worst DXA T-score category across hip, spine, or femoral neck from BL to last study assessment

A.

B.

Baseline		T-score at last assessment, n (%)		
Prior category[d]	n (%)	Normal BMD ≥-1.0	Osteopenia ≥-2.5 to <-1.0	Osteoporosis ≤-2.5
Normal BMD ≥-1.0	12 (38.7)	12 (38.7)	0	0
Osteopenia ≥-2.5 to <-1.0	13 (41.9)	3 (9.7)	9 (29.0)	1 (3.2)
Osteoporosis ≤-2.5	5 (16.1)	0	1 (3.2)	4 (12.9)

= stable = improved = worsened

[a]Each colored line represents an individual pt's longitudinal T-score results; [b]Safety Analysis Set: Pts who received mitapivat for >12 mos (365 Days); only pts with evaluable post-BL DXA T-score are included in the analysis; [c]Two pts are included who were treated for >12 mos, but only have evaluable post-BL T-score results up to 6 mos; one pt is included who has no evaluable T-score results from BL to 18 mos; [d]Safety Analysis Set: Subjects Who Received Mitapivat for >12 Months (365 Days); only patients with evaluable post-baseline DXA T-score are included in the analysis.
BL=baseline; BMD=bone mineral density; DXA=dual-energy X-ray absorptiometry; mos=months; pt=patient
Note: One patient did not have BL DXA, so the table shows results for 30/31.

Summary/Conclusion: DXA scanning revealed that BMD was largely stable over time in adult pts with PK deficiency receiving long-term treatment with mitapivat for up to 56 mos, despite a substantial degree of reduced BMD at BL. Therefore, mitapivat does not appear to promote progression of BMD abnormalities in these pts and could halt this process by decreasing hemolysis and ineffective erythropoiesis. Additional BMD data will be collected as part of this ongoing extension study.

EP697 WARM AUTOIMMUNE HEMOLYTIC ANEMIA IS ASSOCIATED WITH A REGULATORY T CELL DEFICIENCY AND A TH17 POLARIZATION

M. CIUDAD [1,2,*], S. OUANDJI [1], C. CLADIERE [1], T. GHESQUIERE [1], M. THEBAULT [1], F. MAURIER [3], T. MAILLET [4], M. SAMSON [1], P. SAAS [2], B. BONNOTTE [1], S. AUDIA [1]

[1]Department of Internal Medicine and Clinical Immunology, Referral centre for autoimmune cytopenia in adults (CeReCAI), Dijon University Hospital, [2]UMR1098, RIGHT Interactions Greffon-Hôte-Tumeur/Ingénierie Cellulaire et Génique, Université Bourgogne Franche-Comté, INSERM, EFS BFC, DIJON, [3]Department of Internal Medicine, Groupe Hospitalier UNEOS, METZ, [4]Service de Médecine Interne - Unité 11, Centre Hospitalier de Mâcon, Groupe Hospitalier Bourgogne Méridionale, MACON, France

Background: Warm autoimmune hemolytic anemia (wAIHA) is a rare acquired autoimmune disease mediated by antibodies targeting red blood cells. Until now, the involvement of T helper (Th) lymphocytes has been scarcely studied in humans, most of the conclusions being extrapolated from animal models. Although still debated, a skewing to a pro-inflammatory Th17 polarization seems to be associated with AIHA. On the other hand, a quantitative regulatory T cell (Treg) deficiency has been shown in one study, but their suppressive functions were not assessed. Importantly, the balance between the pro- and anti-inflammatory T cell responses has never been measured simultaneously.
Aims: Assuming that an imbalance between the pro- and the anti-inflammatory T cell responses could participate to AHAI pathogenesis, we quantified the different circulating helper T cell (Th) subsets, Tregs and assessed their functional capabilities and their transcriptomic profiles.
Methods: Newly diagnosed wAIHA patients (n=20) were compared to sex- and age-matched healthy donors (n=30). Cells were quantified at baseline by flow cytometry, and polarization was determined by intracellular cytokine staining after stimulation with PMA and ionomycin. Treg functions were evaluated by their capability to inhibit effector T cell proliferation. Cytokines were measured by luminex assays in culture supernatants and sera. RNA sequencing was performed on Treg isolated from 4 patients and 4 controls by fluorescence-activated cell sorting ($CD4^+CD25^{Hi}CD127^-$).
Results: AHAI patients have a decrease in circulating Treg ($CD4^+CD25^{Hi}Foxp3^+$, 3.20% *vs.* 4.45%, p=0.008), mostly affecting activated Treg ($CD4^+Foxp3^{hi}CD45RA^-$), known to arbor high suppressive capabilities. Moreover, Treg have a functional deficiency in AIHA, as shown by their lower ability to inhibit T cell proliferation (51% *vs.* 73%, p=0.03) associated to a trend to a lower inhibition of the secretion of pro-inflammatory cytokines (TNF-α, IFN-γ and IL-2) measured in coculture supernatants. Treg transcriptomic revealed an activated profile, as supported by an engagement in transcriptional and translational processes, an activation of TCR and IL-2 signaling, and an increased expression of CTLA-4 mRNA. Interestingly, TNF signaling pathway was also engaged, probably due to the increase in TNF-α in the sera of patients (2.29 *vs.* 1.24 pg/ml, p=0.002).
Although, Th polarization assessed by flow cytometry did not differ between patients and controls, the production of IL-17 by effector T cells measured in supernatants was higher during AHAI. Considering the Th17/Treg ratio, we observed an unbalance (0.023 *vs.* 0.01, p=0.01) of the pro-inflammatory over the anti-inflammatory T cell response during AIHA.
Summary/Conclusion: This work is the first to provide a concomitant evaluation of effector and regulatory T cells in human AIHA, showing an imbalance in the Th17/Treg ratio, associated with a quantitative and functional deficiency of Treg. Most interestingly, our results pointed out TNF-α as an interesting cytokine to target as its concentration is elevated in the sera and could participate to the inhibition of Treg functions.

EP698 SEVERE NEONATAL HAEMOLYTIC ANAEMIA AND SPHEROCYTIC-ELLYPTOCYTOSIS PHENOTYPE DUE TO THE INTERACTION OF THREE NOVEL SPTA1 MUTATIONS

J.-L. Vives-Corrons [1,*], E. Krishnevskaya [1], I. Hernandez [2]

[1]Red Cell Pathology and Hematopoietic Disorders (Rare Anemias Unit), Josep Carreras Institute for Leukaemia Research, Badalona (Barcelona), [2]Hematology Laboratory Department, Hospital Universitari Germans Trias i Pujol, Badalona(Barcelona), Spain

Background: RBC morphology is a key diagnostic feature for hereditary spherocytosis (HS) and hereditary elliptocytosis (HE). However, this phenotypic diagnosis may not be readily available in patients requiring frequent transfusions and does not predict disease course or severity. However, RBC deformability measured by osmotic gradient ektacytometry (OGE) allows a clear differentiation between HS and HE, where the truncated osmoscan curve reflects the inability of the already elliptical cells to deform further under shear stress. In Hereditary Pyropoikilocytosis (HPP), the RBCs appear to have a significantly decreased ability to maintain deformability in the face of hypotonicity and the classical trapezoidal profile of HE is less evident
Aims: We aim to demonstrate that in patients with HPP and SPTA1 variants, the implication of a canonical splicing site, may explain not only the marked defect of spectrin chains tetramerization and elliptocytosis, but also the weakness of skeleton attachment to the lipid bilayer and the loss of RBC membrane, microvesiculation and spherocytosis. As most of the SPTA1 gene variants described, so far, in patients with HE or HPP, only one or few nucleotides are affected, the resulting protein involvement could be variable, ranging from a slight clinical form (the most frequent) associated with moderate elliptocytosis to a more severe form (the rarest) leading to poikilocytosis, depending on the degree of tetramerization failure
Methods: The diagnosis of HHA was performed via a step-wise process including RBC morphology, Hb electrophoresis, and measurement of common RBC enzyme activities. RBC deformability and other rheological parameters were studied by OGE, using the osmoscan module of the Laser-assisted Optical Rotational Deformability Cell Analyser (LoRRca; MaxSis. RR Mechatronics) as previously described. The genetic diagnosis of membranopathies was performed by gene capture followed by t-NGS that includes a panel of 35 genes responsible for membranopathy hemoglobinopathy, enzymopathy and CDA. NGS and Whole exome sequencing (WES) have been performed using an Illumina HiSeq2000 device.
Results: Both patients studied here showed severe neonatal hemolytic anemia and jaundice, that required phototherapy and transfusion. One patient was a typical case of HPP splenectomized at the age of 30 years, and the other patient a newborn with a severe clinical form of HS. In both cases, the t-NGS study demonstrated a complex set of five variants

in the SPTA1 gene. Three of these variants were novel, two leading to abnormal splicing, and one to a microdeletion of chromosome 1, confirmed by WES, that removes the entire gene. In the patient with HPP, we have observed that, in addition to ellyptocytes and other bizarre forms, a high number of typical spherocytes are present. This effect is also demonstrated by the Osmoscan profile that is characteristic of HS, probably due to the masking of the HE trapezoid shape of the curve characteristic of ellyptocytes by the more severe rheological abnormalities of spherocytes.
Summary/Conclusion: Our study demonstrates that in HPP, associated with a high percentage of spherocytes and typical HS osmoscan profile, the interactions between both SPTA1 gene variants, in addition to the loss of shape recovery after elongation (ellyptocytes), a membrane instability leading to spherocytosis can also be observed, depending on the severity of tetramerization failure. This highlights the importance of molecular diagnostic in patients with no family history of RBC cytoskeleton disorders.

EP699 PYRUVATE KINASE DEFICIENCY IN THE RUSSIAN FEDERATION: AN OVERVIEW OF CLINICAL CHARACTERISTICS AND MOLECULAR DEFECTS.

E. Cherniak [1,*], S. Mann [1], N. Smetanina [1]

[1]Dmitry Rogachev National Research Center, Moscow, Russian Federation

Background: Non-spherocytic hemolytic anemia due to erythrocyte pyruvate kinase deficiency (PKD) is an autosomal recessive disorder associated with more than three hundred mutations in *PKLR* gene. PKD characterized by anemia, jaundice, and splenomegaly.
Until now we have no data on the incidence and prevalence of this disease in Russia. Due to the technical difficulties of conducting a study of erythrocyte pyruvate kinase activity, genetic research is currently the main method for diagnosing this disease in Russia.
Aims: The aim of our study was to create an overview of the PKD population in the Russian Federation.
Methods: We performed a retrospective analysis of data from 43 genetically confirmed cases of PKD. All patients had undergone at least one assessment at our center. The diagnosis was confirmed by next generation sequencing using the Hemolytic Anemia Panel, a 75-gene panel for inherited anemias. Clinical and genetic characteristics were collected from patient records.
Results: Forty-three patients were enrolled. The median age is 5 years old (4 month – 26 years old). The age at diagnosis varied between 4 month and 26 years. The ratio male: female was 1:1.53. At least once transfusion of erythrocyte suspension was required to 42 (97.67%) patients. The minimum age at the debut of transfusion dependence was the first day of life, the maximum – 4 years. Exchange blood transfusion was performed for 14 children, transfusion of packed red blood cells during the first year of life was noted for 40 children; 2 children underwent single transfusions on the background of infectious episodes at 3 and 4 years respectively. Clinically, 43 patients (100%) had an anemia, 29/37 (78,38%) had a splenomegaly and 132 (74,42%) had a jaundice. Iron overload, requiring the chelation therapy, was found in 11 (25.58%) patients. Splenectomy due to high transfusion dependence was performed in 10 patients: transfusion independence was achieved in 5 of them, for the rest cases – an increase of the interval between blood transfusions. Median of surgical intervention is 7 years 4 months, (min – max 1 year 4 months – 14 years 4 months).
The homozygous mutations in the *PKLR* gene were found in 11 patients (25.58%), compound heterozygous mutations in 32 patients (74.42%), 78.67% of them were missense mutations. 36 genotypes were described in 43 patients, among them were: c.1529G>A/c.1529G>A (n=4), c.1137_1139del/c.1456C>T (n=2), c.1079G>A/c.1529G> A (n=2), c.1130T>C/c.1456C>T (n=2), c. c.1174G>A/c.1456C> T (n=2), other genotypes occurred once. Two mutations were the most frequent: c.1529G>A (17.33%) and c.1456C>T (17.33%). Previously not described mutations were identified for 19 (44.19%) patients.
Summary/Conclusion: Patients with PKD are characterized by a predominance of severe course of the disease with early onset and transfusion dependence. PKD is rare for our country with a total number of 43 pediatric patients (2013-2021). The observed clinical and genetic heterogeneity in our cohort highlights the need for interdisciplinary approach and further studies.

EP700 MOLECULAR HETEROGENEITY OF GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD) DEFICIENCY IN PORTUGAL

L. Manco [1,*], C. Bento [1,2], L. Relvas [2], U. Kaminskaitė [1], M. Tabita [2], M. L. Ribeiro [1]

[1]CIAS-Dep. Life Sciences, University of Coimbra, [2]Dep. Haematology, Centro Hospitalar e Universitário de Coimbra (CHUC), Coimbra, Portugal

Background: Glucose-6-phosphate dehydrogenase (G6PD) deficiency is the most common enzyme defect in the world, affecting more than 350 million people. The *G6PD* gene is localized on the X chromosome (Xq28), spanning over 18 kb, and is composed of 13 exons and 12 introns. Until now, almost 400 allelic variants had been reported. The enzyme is responsible for the first step of the pentose phosphate pathway, in which NADPH is produced; hence G6PD is an essential enzyme in red blood cell for defence against oxidative stress. G6PD deficiency can cause neonatal hyperbilirubinemia and chronic haemolytic anaemia, however, most of the individuals are generally asymptomatic, only experiencing episodic acute haemolytic anaemia (AHA) in the contexts of oxidative stress, such as with certain drugs or infection. Patients with chronic nonspherocytic haemolytic anaemia (CNSHA), the severe type of G6PD deficiency, present mutations (Class I variants), most of them located in exons 10 or 11, that encode aminoacids located at the dimer interface, and severely affect protein stability.
Aims: To analyse the molecular heterogeneity of G6PD deficiency in Portugal.
Methods: A total of 143 Portuguese G6PD deficient patients (104 males, 36 heterozygous females and 3 homozygous females, without known black ancestry, had been enrolled in molecular diagnosis of G6PD deficiency at the Haematology Unit from CHUC, between 1994 and 2020. Individuals were mainly from Central Portugal, but also from Southern, Northern and Azores regions. Diagnostic was made based on the clinical history, hematologic data and demonstration of a reduced erythrocyte G6PD activity. Enzyme quantification was addressed by quantitative spectrophotometric enzymatic assay. Molecular study was made by PCR-RFLP analysis or by direct Sanger sequencing of all the exons and adjacent intronic regions of the *G6PD* gene.
Results: Twenty-one different *G6PD* pathogenic mutations were found. Among them, 20 were missense and one was an in-frame deletion of 18 nucleotides in exon 10 (G6PD Tondela). The three most frequent mutations belong to the G6PD A (376G) African background haplotype, namely G6PD A- (202G>A; 68Val>Met) (59.6%), G6PD Betica (968T>C; 323Leu>Pro) (12.3%) and G6PD Santamaria (542A>T; 181Asp>Val) (4.1%). Despite the African background haplotype, most hemizygous patients have non-African Y-chromosomal lineages. From the 18 rare mutations, the most common was G6PD Coimbra (592C>T; 198Arg>Cys), found in 4 chromosomes (2.74%). Four were described as class I G6PD mutations (Shinshu, Tondela, Covão do Lobo and Figueira da Foz). The other rare mutations present in 1, 2 or 3 individuals were: G6PD Vanua Lava, Taipei, Mediterranean, Azores, Mexico City, Seattle, Chatham, Mira d'Aire, Anadia, Canton, Kamiube, Flores and Kaiping. Five G6PD deficient hemizygous individuals (G6PD activity at about 80% in accordance with class III) have the silent mutation 1311C>T (437Tyr=) in combination with the IVS11+93C>T polymorphism, with no other mutation within *G6PD* gene. Six of the rare *G6PD* mutations were found for the first time in the Portuguese population (G6PD Tondela, Anadia, Flores, Azores, Covão do Lobo and Figueira da Foz).
Summary/Conclusion: This report confirms a wide genetic heterogeneity of G6PD deficiency in the Portuguese population.

EP701 SYMPTOMATIC BONE MARROW RECONVERSION: A COMMON FEATURE IN HEREDITARY SPHEROCYTOSIS?

C. Pochard [1,*], V. Azoury [1], R. Navarro [2], P. Mahe [2], M. Giansily Blaizot [2], C. Cyteval [3], A. M. Patricia [2]

[1]Hematology Biology, [2]Reference center for red cells disorders, [3]Radiology, CHU Montpellier, Montpellier, France

Background: Hereditary spherocytosis (HS) is a genetic disorder due to red cell membrane protein abnormalities, characterized by chronic and acute hemolytic anemia of variable degrees of severity. Extramedullary hematopoiesis is a rare complication, which has been reported in several single case reports. It is diagnosed through compressive complications or found incidentally at radiographic controls. Bone marrow reconversion, process in which the yellow marrow is transformed back to red marrow in adults, is observed in various pathological situations such as medullary infiltration by oncological blood diseases (lymphomas, leukemias, myelomas, myelofibrosis), in patients receiving hematopoietic growth factors or in thalassemia and sickle cell anemia. It is not known as a common complication in HS. Here we describe for the first time bone marrow reconversion in two unrelated HS patients complaining with disabling knee pain.
Aims: Study clinical manifestations and genetic characteristics of patients with bone marrow complications in our cohort of HS patients.
Methods: We retrospectively collected clinical and biological data from a total of 137 pediatric or adult HS patients (79 females/58 males; median age at diagnosis 12.4 years, (1day-63 years)) followed in our Center, including genetic analyses of genes implicated in red cell membrane disorders. We focused on bone marrow complications, especially extramedullary hematopoiesis and bone marrow reconversion, based on the available radiological data.
Results: We found no case of extramedullary hematopoiesis in this cohort. By contrast, 2 unrelated patients were diagnosed with bone marrow reconversion at the knees. The first one was a 24-years-old male who complained of knee pain during sports activities. MRI found an iliotibial band syndrome and a knee bone marrow reconversion. This led to the diagnosis of fully compensated hemolysis (Hb 137 g/l, reticulocytes: 381G/L), which was confirmed to be HS in our center, using pink test, EMA test and ektacytometry. NGS analyses showed that the patient bore a known *SPTB* frameshift mutation SPTB:p.Lys1337Serfs*3.
After this unusual presentation, a second patient, a 59-year-old woman diagnosed with HS at the age of 11, following the fortuitous discovery of anemia, consulted in our center for the follow up of her disorder. She also had fully compensated hemolysis (hb 123 g/L, reticulocytes 513 G/l). She was not a heavy smoker. She had been complaining of chronic knee pain for several months. Again, MRI, found a typical bilateral bone marrow reconversion, with decreased T1 signal intensity and STIR hyperintensity in tibial and femoral diaphysis bone marrow, respecting epiphyses (Figure). The patient bore a potentially pathogeneous splice mutation disrupting the splice branch point of intron 38 of the *ANK1* gene: ANK1: c.5097-.

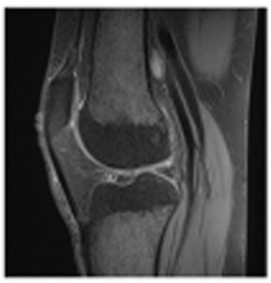


Figure 1A: Bone marrow STIR hyperintensity

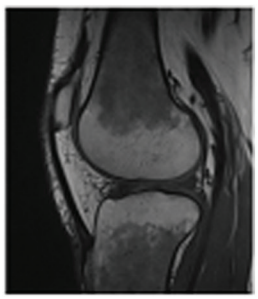

Figure 1B: Bone marrow T1 hypointensity

Summary/Conclusion: Unlike extramedullary hematopoiesis, bone marrow reconversion is an unrecognized bone marrow complication in HS. Extramedullary hematopoiesis is described in HS as mainly mediastinal, paravertebral, renal and splenic masses. Bone marrow reconversion found in 2 patients of this series should be searched more systematically in HS patients. It could be a common and underestimated process leading to chronic and disabling pain in HS patients. Apart from pain medication, the targeted management of this complication requires further investigations in non-anemic patients.

EP702 SOLUBLE CTLA-4 IN CHILDREN WITH IMMUNE CYTOPENIAS: RELATION TO DISEASE ACTIVITY

N. H. El-Sherif [1], S. Makkeyah [1,*], M. F. Hassan [2], M. Gamal [1]

[1]Pediatrics, [2]Clinical Pathology, Ain Shams University, Cairo, Egypt

Background: Cytotoxic T lymphocyte associated antigen-4 (CTLA-4) is a costimulatory receptor exhibiting a potent inhibitory signal on antigen-activated immune responses. A soluble form of CTLA-4 (sCTLA-4), resulting from an alternative splicing, has been identified and was found increased in several autoimmune diseases.
Aims: to evaluate serum levels of sCTLA-4 in different types of immune cytopenias and to determine its possible relation to the disease activity.
Methods: Serum levels of sCTLA-4 were assessed using enzyme linked immunosorbent assay in 47 children and adolescents with immune cytopenias and compared to 47 age- and sex-matched healthy controls.
Results: Among the 47 patients enrolled, 24 (51.1%) had chronic immune thrombocytopenia (ITP), 19 (40.4%) had autoimmune hemolytic anemia (AIHA), and 4(8.5%) patients with autoimmune lymphoproliferative disease (ALPS). sCTLA-4 levels were significantly higher in the sera of patients with immune cytopenias as compared to healthy controls ($p< 0.001$), however, levels were comparable between the different groups of immune cytopenias ($p=0.084$). Serum sCTLA-4 inversely correlated to the age at diagnosis, and hemoglobin level and ($p= 0.048$, and $p=0.039$ respectively), while it directly correlated with the disease duration ($p=0.023$) as well as markers of hemolysis including reticulocyte count, serum LDH and indirect bilirubin ($p=0.025$; $p=0.019$; $p=0.004$ respectively). Moreover, serum sCTLA-4 levels were significantly lower in patients with AIHA in remission compared to patients with active disease ($p=0.026$), however, this was not true among the ITP group ($p=0.523$).
Summary/Conclusion: Our results showed that Children with immune cytopenia exhibit significantly higher levels of circulating sCTLA-4 which correlated to the disease activity. The prognostic significance of the assessment of the circulating sCTLA-4 among patients with immune cytopenia and its use to tailor treatment regimen require additional studies.

EP703 IDENTIFICATION OF A WARM AUTOIMMUNE HEMOLYTIC ANEMIA (WAIHA) POPULATION USING PREDICTIVE ANALYTICS OF A KNOWN CLINICALLY PROFILED COHORT

K. R. McCrae [1,*], J. Beachell [2], T. Gooljarsingh [2], J. Gubitosa [3], G. K. Jones [3], M. L. Tjoa [2]

[1]Taussig Cancer Institute, Cleveland Clinic, Cleveland, [2]Janssen Global Services, LLC, [3]IPM AI, Cambridge, United States

Background: The disease burden of warm autoimmune hemolytic anemia (wAIHA), a rare disorder characterized by the destruction of red blood cells (RBCs) by pathogenic IgG autoantibodies, has not been well studied. At the time this claims database analysis was carried out a diagnostic code specific for wAIHA did not exist, which presented challenges in identifying patients with wAIHA.
Aims: Despite the absence of a diagnostic code specific for wAIHA we aimed to 1) identify a wAIHA cohort using a collection of diagnostic codes, 2) bisect severe versus non-severe wAIHA patients, 3) compare the frequency of comorbidities, anemia symptoms, treatments, diagnostic tests, and healthcare provider visits in these two groups, and 4) use a predictive model to validate clinical variables and prevalence estimates.
Methods: A de-identified, longitudinal, patient-level claims database of >300 million US patients was used for this study. Patients with wAIHA were identified based on a diagnosis code of "autoimmune hemolytic anemia" (AIHA), chronic use of steroids (≥ 30 days) in the last 36 months, and chronic use of non-steroidal immunosuppressants. Patients were classified as severe if claims related to transfusion, high frequency of blood testing, high frequency interactions with a hematologist, and/or ≥ 2 ER visits per year were observed in the 36-month period. Codes for anemia symptoms, comorbidities, treatments, and diagnostic tests were

grouped and analyzed within the most recent 12 months for each patient. Prevalence was estimated using Artificial Intelligence/Machine Learning (AI/ML) lookalike modeling, using known patients with wAIHA as the positive training class.
Results: A cohort of 1,548 patients with wAIHA was identified (n= 631 were classified as severe while n= 917 as non-severe). Median patient age was > 65 years, and patients were evenly distributed by gender. The rate of disease-relevant claims was disproportionately higher in the severe cohort versus the non-severe cohort. Over the 12-month study period, there was a 61% higher rate for anemia symptomatology codes and a 570 % higher rate for wAIHA specific testing and monitoring codes in the severe cohort. Primary hypertension, hyperlipidemia, gastro-esophageal reflux, and evidence of chemotherapy use were also present in wAIHA patients. All these conditions were observed more frequently in severe patients with the exception of lupus. Almost 44% of wAIHA claims for the full cohort were associated with hospital/emergency care - 48% for the severe group. AI/ML modeling predicted patients using claims variables for hemolytic anemia, other blood count abnormalities, and medical procedure claims commonly used for the diagnosis and management of wAIHA. The predictedpopulation supports reported US prevalence estimates of 30,000-49,000 patients.
Summary/Conclusion: We developed and validated a method for defining wAIHA patients using de-identified claims data based on AIHA ICD-10 codes and relevant treatments. We observed that while disease manifestations are generally the same in the severe and non-severe wAIHA cohorts, there is an increased rate of occurrence in the severe cohort during the same 12-month period. This increase was also associated with higher utilization of healthcare resources. The comorbidity of lupus was more commonly associated with non-severe wAIHA patients. This may indicate that patients with a known diagnosis (in this case lupus) who are more closely monitored are less likely to reach the level of severity that would categorize them as patients with severe wAIHA.

EP704 CLINICAL FEATURES AND TREATMENT RESPONSES IN PEDIATRIC PATIENTS WITH WARM ANTIBODY IMMUNE HEMOLYTIC ANEMIA

S. Çetinoğlu [1], Y. Oymak [2,*], F. Genel [3], Y. Ayhan [4], I. Odaman Al [2], N. Karakaya [5], T. H. Karapınar [6], S. Gözmen [2], R. C. Vergin [2]

[1]Pediatrics, Dr. Behcet Uz Children"s Hospital, İzmir, [2]Pediatric Hematology and Oncology, [3]Immunology, [4]Blood Bank, [5]Pediatric Hematolgy and Oncology, [6]Pediartic Hematology and Oncology, Dr. Behcet Uz Children's Hospital, Izmir, Turkey

Background: Autoimmun hemolytic anemia (AIHA) is characterized with autoantibodies that target normal red blood cell membrane antigens and induce cell lysis. Although there have been both pediatric and adult patients with AIHA, its presentation in childhood is relatively rare. Based on this, treatment responses and clinical findings of children with AIHA are very important.
Aims: In this study, we aimed to evaluate the treatment responses and clinical features of pediatric patients with AIHA who were followed up in our center.
Methods: This is a 12 years retrospective cohort study of warm AIHA case collected at Hematology and Oncology Clinic of Dr. Behcet Uz Children's Hospital. We included 39 patients aged between 1 month and 18 years. These patients' demographic characteristics, laboratory findings at diagnosis and treatment responses were recorded. Patients with underlying immunodeficiency or autoimmune disease were classified as secondary AIHA, and the other patients as idiopathic AIHA. Idiopathic and secondary autoimmune hemolytic anemia groups were compared in terms of recurrence. The patients groups according to first-line treatment selection were also compared in respect of recurrence.
Results: Thirty-nine patients with warm AIHA were collected 16 (41%) girls and 23 (59%) boys. The mean age at diagnosis was 5.1 ± 4.5 years and the mean follow-up period from diagnosis was 7.2 ± 5.9 years. Distrubition of the patients according to classification is seen table 1. Twelve (30.7%) patients reported consanguinity and viral etiology was detected in four (10.2%) patients. At the time of diagnosis, 6 patients received IVIG, 17 patients received steroid, 15 patients received IVIG + steroid combined therapy and only one patient didn't need treatment. Twenty-three (59%) of them required blood transfusions with a mean hemoglobin level of 5,40 ± 1,83 g/dl. The mean hemoglobin level of 16 (41%) patients who were not transfused at diagnosis was 7,67 ± 1,92 g/dl. According to response criteria 19 (48.7%) of the patients had complete response, 19 (48.7%) had partial response, and one patient (2.6%) was unresponsive. There weren't difference among the 3 groups of patients who were received IVIG, steroid or IVIG + steroid combined therapy in terms of recurrence during diagnosis (p = 0.128). There were 18 (46.2%) and 2 (5.1%) patients in the secondary and idiopathic AIHA groups who relapsed after treatment response at the time of diagnosis, respectively (p <0.001). During follow up additional therapies which include cyclosporine (n=7), mycophenolate mofetil (n=7), rituximab (n=3) sirolimus (n=2) and danazol (n=1) were applied. Four (10.2%) patients were splenectomised. Two patients (DOCK 8 deficiency and Digeorge syndrome) died.

Table 1. Distrubition of the patients according to warm antibody AIHA classification

	n (%)
Idiopathic	18 (46)
Secondary	21 (54)
1. Autoimmune disease	
• Evans syndrome	6 (15)
• Systemic lupus erythematosis	2 (5)
2. Immun deficiency	
• CTLA-4 haplo insufficiency	1 (2)
• Transient hypogammaglobulinemia of infants	1 (2)
• Digeorge syndorme	2 (5)
• DOCK-8 deficiency	2 (5)
• PNP deficiency	1 (2)
• Hypogammaglobulinemia	3 (8)
3. Autoimmune lymphoproliferative disease	3 (8)
Total	39 (100)

AIHA: Autoimmun hemolytic anemia, CTLA-4 : T lymphocyte associated protein 4, DOCK-8: Dedicator of cytokines 8, PNP: Purine nucleoside phosphorylase,

Summary/Conclusion: This study highlights heterogenity, severity and response rate of first line therapy in pediatric patients with warm AIHA. First line therapy with steroids is effective. However challenges in management of reccurent case remain unresolved. Thus the findings in this study may contributed to clinical features of recurrence in pediatric patients with warm reactive AIHA.

EP705 AUTOIMMUNE HEMOLYTIC ANEMIA ASSOCIATED WITH LYMPHOID MALIGNANCIES: REPORT FROM A FRENCH PROSPECTIVE REGISTER.

N. Grienay [1], M. Mounier [2], C. Rossi [3], O. Casasnovas [3], D. Caillot [3], M. Maynadié [2], B. Bonnotte [1], S. Audia [1,*]

[1]Internal Medicine and Clinical Immunology, Referral center for autoimmune cytopenia, [2]Register of hematological malignancies of Côte d'Or, [3]Hematology department, University Hospital of Dijon, Burgundy University, Dijon, France, Dijon, France

Background: The incidence of autoimmune hemolytic anemia (AIHA) is estimated between 1 to 3/100,000 person-years and is associated to another disease in half of the cases, mostly hematological malignancies. The accurate incidence of lymphoid malignancy (LM)-related AIHA remains elusive as previous data have been obtained from cohorts from tertiary centers, with possible selection bias.
Aims: Determination of the frequency, clinical characteristics, and evolution of LM-related AIHA based on prospective data collected in the register of hematological malignancies of Côte d'Or (RHEMCO), a population-based register recording all incident hematological malignancies occurring in a restricted geographical area of 532,886 inhabitants.
Methods: Patients included in RHEMCO between 01/01/1995 and 31/12/2015 were considered to calculate incidences. The medical records of AIHA patients referred to our tertiary hospital during the same periods were also considered for the clinical description and the

evolution of LM-related AIHA. AIHA was defined as regenerative (reticulocytes >120 G/L) anemia (hemoglobin <11 g/dL) with hemolysis (haptoglobin <0.3 g/L, elevated LDH, free bilirubin >14 µmol/L) and a positive direct antiglobulin test. Response was defined as hemoglobin >10 g/dL.

Results: Based on RHEMCO, the frequency of AIHA during LM was 0.77% (n=27/3499): 1.10% for chronic lymphoid leukemia (CLL), 0.67% for B cell lymphoma, 0.87% for T cell lymphoma and 0.36% for Hodgkin lymphoma (HL). The frequency of Evans' syndrome (ES) was 0.29% (n=10/3499): 0.44% for CLL, 0.24% for B cell lymphoma and 0.43% for T cell lymphoma.

From RHEMCO and medical records, 56 patients with secondary AIHA were identified among which 17 had ES. The median age at diagnosis was 74 [interquartile range (IQR): 54-92] years and 54% were male. For ES, the median age was 62 [IQR: 29-85] years and 76% were male. AHAI was associated with B cell lymphoma in 54%, CLL in 30.5%, T cell lymphoma in 13% and HL in 2.5%. ES was also mostly associated with low grade B cell lymphoma (47%) and CLL (41%). Anemia occurred after the diagnosis of LM in 38% of the cases with a median delay of 3 [IQR:0.5-18.4] years and 65% for ES, with a median delay of 5.1 [IQR:0.3-10.1] years. LM and AIHA were diagnosed simultaneously (≤ 3 months) in 49% of the cases for isolated AIHA and 29% for ES. Splenomegaly was observed in 63% of the cases. At AIHA diagnosis, the median hemoglobin level was 7.5 [IQR:3.5-12.3] g/dL. Warm antibodies represented 87% of the cases. Monoclonal gammopathy was detected in 47% of the cases and a circulating lymphocyte clone in 89%.

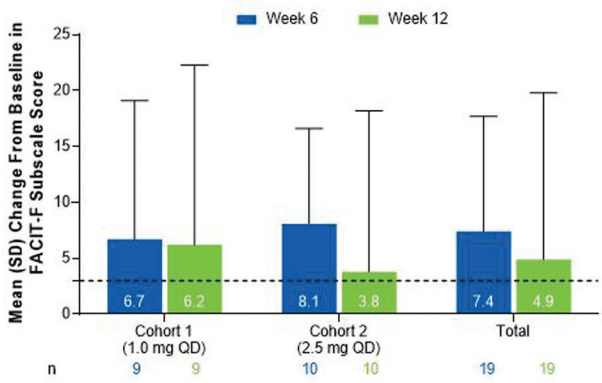
Patients with LM-related AIHA were treated in 97% of the cases, with medications dedicated to AIHA in 90% of the cases and specifically for LM in 67%. AIHA responded to steroids in 53% (n=17/32), to rituximab in 82% (n=14/17) and to splenectomy in 43% (n=3/7). After a median follow-up of 5.6 years, AIHA was considered in remission in 56%.

Summary/Conclusion: LM-related AIHA is rare, with an incidence of 0.063/100,000 person-years for CLL, 0.081/100,000 for B cell lymphoma and 0.01/100,000 for T cell lymphoma and HL. These incidences are close to the ones observed for LM-related ITP although ITP is considered 3 times more frequent than AIHA, highlighting the frequent secondary nature of AIHA. The diagnosis of AHAI was made simultaneously or after LM in almost 90% of the cases. Rituximab seems to be a treatment of choice in LM-related AIHA as shown by a response rate close to the one of primary AIHA.

EP706 FACIT-FATIGUE SUBSCALE OUTCOMES FROM AN ONGOING PHASE 2, OPEN-LABEL STUDY OF THE PHOSPHATIDYLINOSITOL 3-KINASE DELTA (PI3KΔ) INHIBITOR PARSACLISIB IN PATIENTS WITH AUTOIMMUNE HEMOLYTIC ANEMIA (AIHA)

F. Pane [1,*], I. Murakhovskaya [2], L. Terriou [3], W. Barcellini [4], A. Patriarca [5], K. Bibeau [6], K. Butler [6], S. Moran [6], S. Wei [6], U. Jäger [7]

[1]University of Naples "Federico II", Naples, Italy, [2]Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY, United States, [3]Univ. Lille, Inserm, CHU Lille, Centre de Référence des Maladies Autoimmunes Systémiques Rares du Nord et Nord-Ouest de France (CeRAINO), INFINITE – Institute for Translational Research in Inflammation, Lille, France, [4]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, [5]University of Eastern Piedmont and AOU "Maggiore della Carita", Novara, Italy, [6]Incyte Corporation, Wilmington, DE, United States, [7]Medical University of Vienna, Vienna, Austria



Background: AIHA is a rare acquired disorder resulting from decompensated autoantibody-mediated hemolysis of red blood cells. AIHA is characterized by low hemoglobin levels, which may lead to fatigue, one of the most common symptoms of AIHA. Fatigue has been associated with reduced overall quality of life (QoL) in anemia and other conditions, and a clinically meaningful reduction in anemia-related fatigue (ie, ≥3-point increase in the Functional Assessment of Chronic Illness Therapy–Fatigue subscale [FACIT-F]) may improve QoL. There are no approved treatments for AIHA. Aberrant signaling of PI3Kδ has been associated with autoimmunity. Parsaclisib is an orally administered selective PI3Kδ inhibitor that showed clinical antitumor activity in B-cell malignancies and ameliorated kidney and salivary gland pathology in autoantibody-mediated preclinical disease models of systemic lupus erythematosus and Sjögren's syndrome, respectively.

Aims: To describe FACIT-F outcomes from an ongoing, multicenter, open-label phase 2 study (NCT03538041) of parsaclisib for the treatment of patients with primary AIHA.

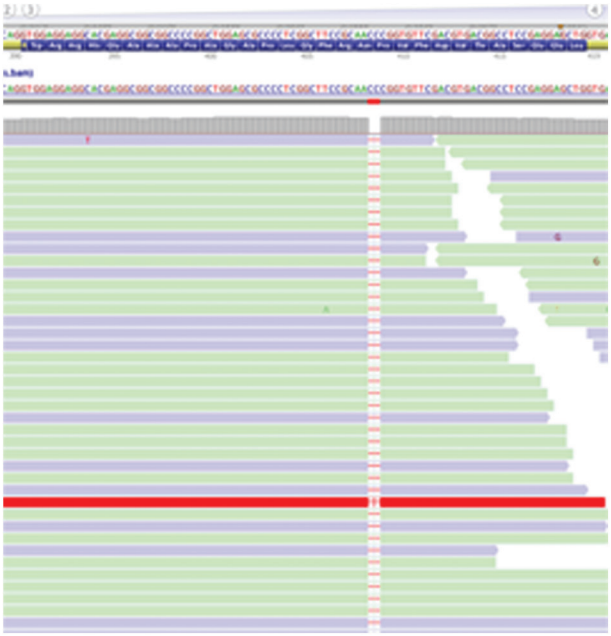
Methods: Eligible patients were aged ≥18 years; were diagnosed with primary warm AIHA (wAIHA), cold agglutinin disease (CAD), or mixed-type AIHA without an underlying lymphoproliferative malignancy or other autoimmune-related underlying conditions; had hemoglobin levels of ≥7–≤10 g/dL; and failed ≥1 prior treatment for AIHA. After informed consent was obtained, patients were enrolled into 1 of 2 successive cohorts and received parsaclisib for 12 weeks. In cohort 1, patients received parsaclisib 1.0 mg once daily (QD) with the option to have a dose increase (2.5 mg QD) at Week 6. In cohort 2, patients received parsaclisib 2.5 mg QD; a dose reduction to 1.0 mg QD was permitted for tolerability. Following completion of the initial 12-week treatment period, eligible patients achieving clinical benefit could continue into an open-label extension period. For the QoL assessment, patients responded to the FACIT-F subscale questionnaire at baseline, Week 6, and Week 12. An increase in FACIT-F score indicates less fatigue and better QoL.

Results: By the data cutoff date (October 12, 2020), 21 patients had enrolled (10 patients in cohort 1; 11 in cohort 2). The 2 cohorts were similar in age (median [range]: cohort 1, 62.0 [46–77] years; cohort 2, 60.0 [22–80] years), sex (male: cohort 1, 40%; cohort 2, 55%), AIHA subtype (wAIHA: cohort 1, 70%; cohort 2, 64%; CAD: cohort 1, 20%; cohort 2, 18%; mixed: cohort 1, 10%; cohort 2, 18%), baseline hemoglobin levels (mean [SD]: cohort 1, 9.1 [0.8] g/dL; cohort 2, 9.0 [0.8] g/dL), and baseline FACIT-F scores (mean [SD]: cohort 1, 32.6 [12.8]; cohort 2, 34.8 [11.7]). Both cohorts showed an increase in FACIT-F subscale score compared with baseline at Week 6 (mean [SD] change from baseline: cohort 1, 6.7 [12.4]; cohort 2, 8.1 [8.5]; total, 7.4 [10.3]) and Week 12 (mean [SD] change from baseline: cohort 1, 6.2 [16.1]; cohort 2, 3.8 [14.4]; total, 4.9 [14.9]; **Figure**). Mean (SD) percentage change from baseline in FACIT-F score was 40% (71.8) for all patients (cohort 1, 52% [100.7]; cohort 2, 29% [31.8]) at Week 6 and 35% (81.2) for all patients (cohort 1, 55% [111.2]; cohort 2, 17% [37.6]) at Week 12.

Figure. Change From Baseline in FACIT-F Subscale Score at Weeks 6 and 12

FACIT-F, Functional Assessment of Chronic Illness Therapy – Fatigue; QD, once daily.
Dashed line indicates a clinically meaningful improvement from baseline (≥3-point increase in FACIT-F score).

Summary/Conclusion: Parsaclisib treatment was associated with a clinically meaningful (ie, ≥3-point) improvement in fatigue-related QoL in patients with AIHA. This benefit was seen as early as Week 6 and persisted throughout the treatment period.



EP707 CLINICAL AND MOLECULAR CHARACTERISTICS OF IMERSLUND-GRÄSBECK SYNDROME: FIRST REPORT OF A NOVEL FRAMESHIFT VARIANT IN EXON 11 OF AMN GENE

M. Elshinawy [1,2,*]

[1]Pediatric Hematology, SULTAN QABOOS UNIVERSITY HOSPITAL, Muscat, Oman, [2]Pediatrics, Faculty of Medicine, Alexandria University, Alexandria, Egypt

Background: Imerslund-Gräsbeck syndrome (IGS) is a rare autosomal-recessive disorder characterized by selective vitamin B12 malabsorption, megaloblastic anemia, and proteinuria. The precise incidence of this disorder is unknown in the Middle East and Arab countries. The

disease is caused by a homozygous variant in either AMN or CUBN genes. In addition, some compound heterozygous variants are reported.
Aims: To report the clinical, laboratory and molecular data of patients diagnosed with IGS in Oman.
Methods: All data were retrospectively collected. Mutation analysis for all genes involved in vitamin B12/folic acid metabolism and megaloblastic anemia was conducted using next-generation sequencing (NGS).
Results: Three siblings (2 girls and a boy) have been diagnosed with the condition. They exhibit a phenotypic variability with different age of presentation and different spectrum of disease. All patients harbor a novel biallelic frameshift mutation in exon 11 of AMN gene (p.Pro409Glyfs*), which was not reported previously in the literature (Figure). Both parents are heterozygotes for the same variant. All patients responded well to vitamin B12 parenteral therapy, but proteinuria persisted.

Summary/Conclusion: In communities with high incidence of consanguinity, cases of early-onset vitamin B12 deficiency should be thoroughly investigated to explore the possibility of Imerslund-Gräsbeck syndrome and other vitamin B12–related hereditary disorders. Further local and regional studies are highly recommended.

EP708 USE OF AN NGS PANEL FOR DE DIAGNOSIS OF HEREDITARY HEMOLYTIC ANEMIAS

I. Zamanillo [1,*], S. Martin [2], X. Gutierrez [1], N. Lopez [1], R. Iñiguez [1], M. Poza [1], R. Ayala [1], J. Martinez-Lopez [1]

[1]Hematology, Hospital Universitario 12 de Octubre, Madrid, [2]Hematology, Hospital Regional Universitario de Málaga, Málaga, Spain

Background: Hereditary haemolytic anemias (HA) are a group of heterogeneous, low frequency entities characterized by the premature destruction of red blood cells (RBC). They are usually secondary to genetic mutations leading to alterations in hemoglobin or membrane structure and enzimatic production, as well as RBC differenciation and proliferation. In many cases, attaining an accurate diagnosis is complex due to overlapping clinical presentation, variable clinical expression and great variety of implicated genes.
The recent use of next generation sequencing (NGS) has led to an improvement in our understanding of these entities by widening the knowledge of genetic alterations involved, and has proved a useful tool for both diagnosis and genetic advice.
Aims: The aim of this study is to evaluate the results of an NGS panel for congenital anemias and medullary aplasia in a single center in Madrid, Spain.
Methods: A total of 39 patients were included in the study, 71% had clinical suspicion of HA and 28% had familiar history of hereditary anemia. We performed NGS (Ion Torrent S5XL System – Thermofisher Scientific) of a panel comprising 55 genes related to metabolic enzymes (AK1, ALDOA, BPGM, G6PD, GPI, GSS, HK1, NT5C3A, PFKFB1, PGK, PKLR, TPI1), membrane and cytoskeleton proteins (ANK1, EPB41, EPB42, EPB72, SLC4A1, SPTA1, SPTB, PIEZO1, PIGA, PIGT), ribosomic proteins (RPL11, RPL15, RPL5, RPS19, RPS26, SBDS), telomeric regulators (RTEL1,TERT, TERC, TINF2, DKC1), DNA repair (FANCA, FANCC, FANCG, LIG4), transcription factors (GATA1, GATA2, MECOM), globin chains (HBA1, HBA2, HBB) and other non-classifiable genes (ANKRD26, ATRX1, DNAJC21, SRP72, TRS2, HAX1, SAMD9, SAMDL9, ADAMTS13, ELANE, ERCC6L2, DDX41).
Results: The median age was 31 years; R(0-72), 59% were female. Mean hemoglobin was 12.5 g/dL and mean reticulocyte count was 100650/ml. Hemolysis paramethers were slightly elevated (mean LDH 244 U/L, mean bilirubin 1.73 mg/dL).
81% of the patients presented at least one genetic variant in the NGS study (median of 3 variants per patient). Among these, 71% presented pathogenic/likely pathogenic variants which were considered useful for the diagnosis, and 6 had variants of undetermined significance. Single Nucleotide Variation (SNV) were the most common, present in all patients with any variant. Insertions or deletions (indels) were additionally present in 20% of them.
Most of the variants were detected in genes associated with membrane and cytoskeleton (24; 58.5%), others non-classifiable (10; 24.4%), DNA repair (8; 19.5%), enzymatic genes (6; 14.6%), globin chains (5; 12.2%), telomeric genes and transcription factors (both 4; 9.8%) and ribosomic genes (3; 7.3%).
Genotype-phenotype correlation was variable in each group. Erytrocite membrane defects were confirmed in 70% of the patients with this clinical suspicion, but only 38% of the patients who were suspected of an alteration in globin chains had a proven genetic variant in these genes with a high percentage presenting alterations in membrane and cytoskeleton genes. Among the 5 patients with unknown HA, 3 had likely pathogenic variants in membrane and cytoskeleton genes and 2 in metabolic enzymes genes. 5 patients had pathogenic/likely pathogenic variants in various genes pertaining to more than one group, a situation with uncertain clinical significance.

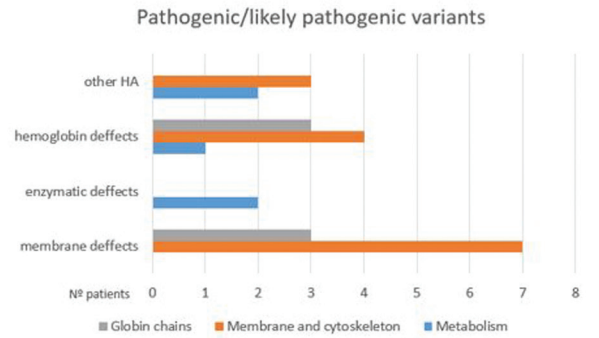


Figure 1. Correlation genotype-phenotype. Clinical suspicion (Y-axis) and gene affected in the NGS panel (color code).

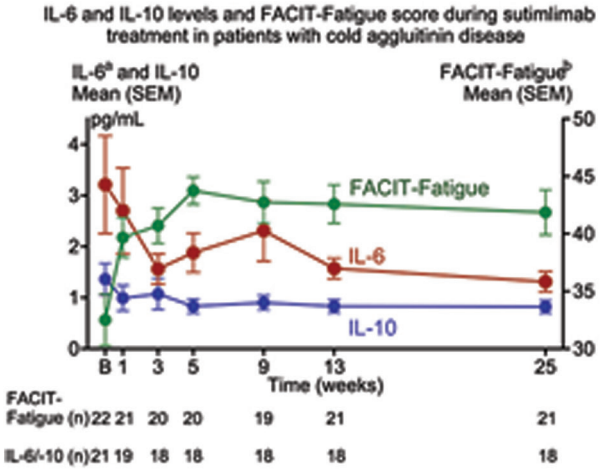
Summary/Conclusion: NGS is a useful tool for the diagnosis of hereditary hemolytic anemias. However, there are still a lot of unknowns in the genetic landscape that must be addressed to improve our understanding of these diseases.

EP709 INFLAMMATION AND FATIGUE IN PATIENTS WITH COLD AGGLUTININ DISEASE (CAD): ANALYSIS FROM THE PHASE 3 CARDINAL STUDY

I. C. Weitz [1,*], Y. Ueda [2], F. Shafer [3], J. Su [4], M. Foster [3], M. Storek [3], P. Patel [3]

[1]Keck School of Medicine of USC, Los Angeles, CA, United States, [2]Department of Hematology and Oncology, Osaka University Graduate School of Medicine, Osaka, Japan, [3]Sanofi, Cambridge, MA, United States, [4]Sanofi, Employee at time of study, Cambridge, MA, United States



Background: CAD is a rare and chronic autoimmune hemolytic anemia driven by activation of the classical complement pathway. Complement activation increases vascular inflammatory markers via generation of anaphylotoxin C3a- and C5a-mediated response of increased cytokine production (eg, interleukins [IL]-6 and IL-10) (Cofiell et al. *Blood*.

2015; Landsem et al. *Clin Exp Immunol*. 2013). In CAD, classical complement pathway activation and resulting chronic inflammation may contribute to patient fatigue beyond anemia. A chronic complement-mediated proinflammatory state exists in other hemolytic diseases such as paroxysmal nocturnal hemoglobinuria and atypical hemolytic uremic syndrome (Cofiell et al. *Blood*. 2015; Weitz et al. *Thromb Res*. 2012) with cytokine levels associated with fatigue (Weitz et al. *Thromb Res*. 2012; Montoya et al. *Proc Natl Acad Sci USA*. 2017); however, this association has not been formally studied in CAD. Sutimlimab (formerly BIVV009) is a first-in-class humanized immunoglobulin G4 monoclonal anti-C1s antibody that selectively inhibits the classical complement pathway. Here we summarize the results of an analysis of inflammatory cytokine expression and fatigue over the Part A 26-week treatment period of CARDINAL.

Aims: To assess key inflammatory cytokine IL-6 and IL-10 activity and their relation to fatigue in patients with CAD and the effect of treatment with sutimlimab.

Methods: Twenty-four patients with CAD and recent history of transfusion were enrolled in CARDINAL Part A and received intravenous sutimlimab on Days 0 and 7, then biweekly infusions (6.5 g dose for weight <75 kg [n=17]; 7.5 g dose for weight ≥75 kg [n=7]). Cytokine profiles (IL-6 and IL-10) and Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue scores were assessed from baseline to Weeks 1, 3, 5, 9, 13, and 25 as represented by the treatment assessment time point after initiating sutimlimab treatment. Summary statistics were reported at each time point.

Results: In CARDINAL Part A, baseline mean FACIT-Fatigue score (mean pg/mL [standard error of the mean (SEM)]) was 32.5 (2.3), which is comparable to fatigue severity in another complement-mediated hemolytic anemia, paroxysmal nocturnal hemoglobinuria (Schrezenmeier et al. *Haematologica*. 2014), and cancer (Escalente et al. *Cancer Med*. 2019). Sutimlimab treatment rapidly inhibited the classical complement pathway with a rapid improvement in mean FACIT-Fatigue score by Week 1 that was maintained through to the treatment assessment time point (**Figure**). Mean IL-6 level was 3.21 pg/mL at baseline, decreased as early as Week 1 (2.70 pg/mL) after starting sutimlimab treatment and was 1.31 pg/mL at Week 25 (**Figure**). A similar pattern of change was observed for IL-10, with the mean values of 1.36 pg/mL at baseline and 0.82 pg/mL at Week 25 (**Figure**). Decreased inflammation, as demonstrated by IL-6 and IL-10 activity, inversely correlated with FACIT-Fatigue score improvements over time.

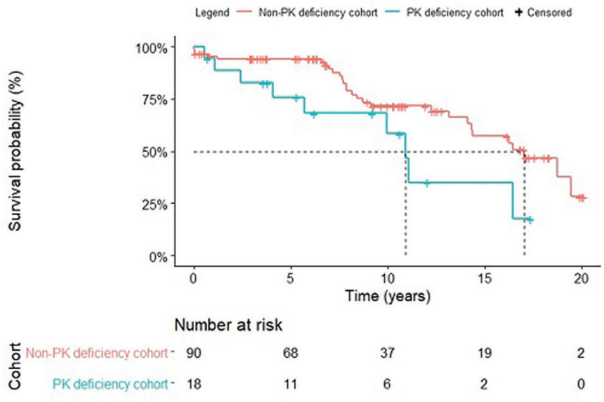
B, baseline; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue; IL, interleukin; SEM, standard error of the mean.
[a]Normal values for IL-6 were <3.2 pg/mL. [b]Increased FACIT-Fatigue reflects decreased fatigue and improved quality of life, and a clinically meaningful improvement in cold agglutinin disease is≥5 points.

Summary/Conclusion: Sutimlimab treatment in the CARDINAL Part A study was associated with rapid and steady decrease in IL-6 and IL-10 levels that coincided with clinically meaningful improvements in fatigue. These results suggest that, in addition to anemia, complement-mediated inflammation may contribute to fatigue manifestation in patients with CAD and improve with complement inhibition. Furthermore, they highlight the influence of classical complement pathway inhibition on inflammatory activity in CAD.

EP710 MORTALITY AMONG VETERANS WITH A DIAGNOSIS OF PYRUVATE KINASE DEFICIENCY: A REAL-WORLD STUDY USING US VETERANS HEALTH ADMINISTRATION DATA

E. Zagadailov [1,*], A. Boscoe [1], V. Garcia-Horton [2], S. Shi [3], S. Liu [4], L. Shi [4], D. Macaulay [2]

[1]Agios Pharmaceuticals, Inc., Cambridge, MA, [2]Analysis Group, Inc., New York, NY, United States, [3]Analysis Group, Inc., Montreal, QC, Canada, [4]School of Public Health and Tropical Medicine, Tulane University, New Orleans, LA, United States



Background: Pyruvate kinase (PK) deficiency is a rare, hereditary disease caused by autosomal recessive mutations in the *PKLR* gene, where a glycolytic defect causes reduced adenosine triphosphate levels, leading to hemolytic anemia. Serious complications such as osteoporosis, pulmonary hypertension, sepsis, iron overload, and liver cirrhosis are associated with the disease and its therapy. Treatment is supportive only, and comprises splenectomy, blood transfusions, iron chelation, and management of disease-related morbidity. Identifying PK deficiency in real-world data is challenging due to a lack of diagnosis codes and treatments that are specific to the disease. Hence, population-based studies of PK deficiency using claims or electronic health record databases are limited. In addition, data on mortality in this patient (pt) population are lacking and limited to a few individual case reports.

Aims: This study aimed to identify pts with a PK deficiency diagnosis as documented by physicians and to compare their mortality to an age- and gender-matched cohort of individuals without the disease.

Methods: Pts with ≥1 diagnosis code related to PK deficiency (ie, anemia due to disorders of glycolytic enzymes, other hemolytic anemias due to enzyme deficiency, or unspecified hereditary hemolytic anemia) from January 1995–July 2019 were selected from the US Veterans Health Administration (VHA) database. Inclusion criteria required physicians' notes to contain the words "pyruvate", "kinase", and "deficiency." A manual review of these notes was performed to identify pts with a physician-documented diagnosis of PK deficiency (PK deficiency cohort). The index date for this cohort was defined as the date of the first medical record with a diagnosis code related to PK deficiency. Each pt in this cohort was matched 1:5 by age at index, sex, and index year (yr) (±1 yr) to pts from the general VHA population with no diagnosis codes related to PK deficiency (non-PK deficiency cohort). The index date for the non-PK deficiency cohort was defined as a random visit date during their match's index yr. Survival time from the index date was compared between the PK deficiency cohort and their non-PK deficiency cohort matches using a univariate Cox proportional hazards model with robust standard error estimation.

Results: A total of 18 pts met inclusion criteria for the PK deficiency cohort and were matched to 90 individuals in the non-PK deficiency cohort. For both cohorts, mean age at index was 57 yrs, 94% were male, 83–85% were white, and mean Charlson Comorbidity Index score was 0.4–0.5 (no significant differences between cohorts). The median follow-up was 6 yrs for the PK deficiency cohort and 8 yrs for the non-PK deficiency cohort. During this period, 9 (50%) and 28 (31%) deaths were observed in the PK deficiency and non-PK deficiency cohorts, respectively. The median time to death was 10.9 yrs for the PK deficiency cohort and 17.1 yrs for the non-PK deficiency cohort (hazard ratio: 2.3; p=0.0306); the Kaplan–Meier curves for both cohorts are shown in the Figure. Ten yrs post-index, 42% and 28% of pts had died in the PK deficiency and non-PK deficiency cohorts, respectively.

Figure. Kaplan–Meier survival estimates for both cohorts

Summary/Conclusion: Results of this study suggest that pts with PK deficiency may be at an increased risk of mortality. Further research to understand cause of death in this population is warranted, as is the replication of this study using larger sample sizes and other real-world data sources that better represent females and the pediatric and adolescent PK deficiency age groups.

EP711 FEASIBILITY STUDY: USING DRIED BLOOD SPOTS AS A DNA SOURCE TO SCREEN FOR PYRUVATE KINASE CAUSING VARIANTS

J. Charlton [1], C. McGuire [1], R. Perera [1], C. Laas [2], C. Rakhit [1], D. Rees [3], B. Clark [1,4,*]

[1]Precision Medicine, King's College Hospital NHS Foundation Trust, [2]Red Cell Centre, Viapath at King's College Hospital, [3]Haematological Medicine, King's College Hospital NHS Foundation Trust, [4]Red Cell Biology, King's College London, London, United Kingdom

Background: Pyruvate kinase deficiency (PKD) is a genetic blood disorder typically caused by mutations in the *PKLR* gene, leading to low levels of pyruvate kinase enzyme, which is required by red blood cells to make energy. PKD is inherited in an autosomal recessive fashion but in some individuals only one pathogenic variant can be identified after sequencing gene exons. Patient genotypes have been associated with severity of disease, with patients carrying a non-missense mutation having a more severe presentation. Therefore, understanding the underlying genetic defect in individuals is important as it can inform patient management. On rare occasions, PKD can arise from pathogenic variants in the *KLF1* gene, a transcription factor that controls *PKLR* gene expression.
We have developed a small NGS panel to sequence the entire footprint of the *PKLR gene* and exons of *KLF1*. Bloodspots have also been investigated as a sample source. They do not need expensive packaging like liquid blood samples, and can be sent through the post. This small change could help countries refer samples for analysis if they do not have access to *PKLR* gene sequencing.
Aims: To develop a targeted NGS assay capable of using DNA from liquid blood samples and from bloodspots to detect all known types of genetic variants that cause PKD (SNVs, small indels and deletions).
To cover the entire footprint of the *PKLR* gene to detect deep intronic variants which may contribute to the phenotype.
Methods: Residual clinical samples were used as positive controls from patients previously diagnosed with PKD. These individuals had undergone Sanger sequencing of the *PKLR* gene as part of their diagnostic work up. Bloodspots were created from liquid blood samples and DNA extracted from both for comparison.
Qiagen Qiaseq was used to target and amplify genomic regions of interest in all samples. This uses unique molecular indices to label each amplicon enabling duplicate reads to be discarded and CNV detection possible. All genetic variation was assed using the ACMG guidelines.
Results: Comparing the sequence between the new method and the existing Sanger sequencing method there was 100% concordance in the genetic findings. A minimum of 10ng of input DNA is required for the new methodology which can be extracted from a bloodspot. Liquid blood and bloodspot samples from the same primary sample identified the same genetic variants, indicating that bloodspots are a suitable sample for diagnosis.
Sequencing 80 patient cases (mostly liquid blood), identified 73 different genetic variants in total (19 class 1, 7 class 2, 22 class 3, 11 class 4 and 14 class 5). Most of the common variants were present in all cases. Six of the class 3 variants warrant further investigation, four of these are deep intronic variants which may affect *PKLR* gene splicing. These have been identified in individuals with PKD but with only one known pathogenic variant identified to date.
Summary/Conclusion: Our data show that bloodspots are a good source of DNA and are suitable for clinical diagnosis. The assay and the bioinformatic pipeline is able to identify all variant types which are known to cause PKD. The approach to sequence the entire *PKLR* gene may be clinically beneficial, but it does identify more variants of unknown clinical significance compared to exon only sequencing. Functional studies are required in order to investigate these further, to build the knowledge base and to make this data clinically useful.

EP712 USEFULNESS OF NGS TECHNIQUES FOR PYRUVATE KINASA DEFICIENCY (PKD) DIAGNOSIS IN SPAIN

M. Morado [1,*], J. Martínez Nieto [2], R. del Orbe Barreto [3], F. A. González Fernández [2], B. Arrizabalaga [3], A. M. Villegas [2]

[1]Hematology, Hospital Universitario La Paz, [2]Hematology, Hospital Universitario Clinico San Carlos, Madrid, [3]Hematology, Hospital Universitario Cruces, Baracaldo, Spain

Background: PKD is the second most frequent enzymopathy and the first to produce chronic hemolytic anemia. Its prevalence is underestimated due to the low clinical suspicion, especially in mild cases, the low expressiveness of the peripheral blood smear and the limitations of enzymatic techniques. Next-generation sequencing techniques (NGS) allow simultaneous study of multiple causal genes in multiple patients, which provides the diagnosis of congenital hemolytic anemias.
Aims: During one year, all cases of undiagnosed chronic hemolytic anemias suspected to be PKD in Spain were remitted for NGS analysis.
Methods: DNA obtained from peripheral leukocytes was analyzed using a 40 genes panel covering congenital anemias at the Hematology Services of the Clínico San Carlos and Cruces University Hospitals. Ilumina platform (Truseq Custom Amplicon) was used. Pathogenic variants and those of uncertain significance were reported, using the GRCh37 / Hg19 genome as reference.
Results: Ninety-nine patients with congenital anemias from 23 national centers were analyzed. **PKD mutation was detected in 24 patients, 18 of them correctly suspected** of PKD (18/24, 75%), 3 of them were associated with a membranopathy, while 3 other suspected cases (12.5%) were finally diagnosed as hereditary membrane disorders, particularly xerocytosis (HX, 2 cases). Initial suspicion was different from PKD in 75 patients (18 membranopathies, 4 G6PD, 4 CDA and 49 with unknown origin). PKD explained **4% of the cases of undiagnosed anemias (2/49)** and was also detected in **two patients suspected of membranopathy (2/18),** interestingly with these two different diseases associated. It should be noted that **half (2/4) of the suspected cases of congenital dyserythropoietic anemia** (CDA) were eventually diagnosed as PKD. No cases of PKD were detected in patients suspected of G6PD deficiency.
Twenty-eight different gene variants were found in the 24 PKD confirmed cases. Six variants were constantly repeated in more than one patient, sometimes in combination: R486W (50% of patients), R337Q (17%), E241X (12.5%), R510Q (8%), I378X (8%), R559X (8%).
Summary/Conclusion: Our results confirms that NGS technique has become a powerful diagnostic tool, enabling a diagnoses in 78% of patients with congenital anemias in this study. Further, it allowed for the diagnoses of the majority of patients with clinical suspicion of PKD (75%), the detection of combined genetic alterations (in particular, 5 out of 24 PKD cases were combined with membranopathies), and the diagnosis of PKD in a high percentage of cases suspected of CDA (50%) or in a low percentage of unexplained anemias (4%). NGS also enabled the correct identification of two XH cases, initially suspected of PKD. The pathogenic variants detected in Spain are consistent with those previously reported, with the exception of the lower percentage of R510Q.

EP713 STUDY DESIGN OF A PHASE 2/3 RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY TO ASSESS THE EFFICACY AND SAFETY OF NIPOCALIMAB, AN FCRN ANTAGONIST, IN WARM AUTOIMMUNE HEMOLYTIC ANEMIA (WAIHA)

I. Murakhovskaya [1,*], B. Fattizzo [2], D. Cueto [3], M.-H. Jouvin [3]

[1]Montefiore Medical Center, Bronx, United States, [2]Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy, [3] Janssen Research & Development, LLC, Cambridge, United States

Background: Warm autoimmune hemolytic anemia (wAIHA) is characterized by the destruction of red blood cells (RBCs) by pathogenic autoantibodies which bind to RBCs and lead to their clearance in the spleen and liver. Patients with wAIHA can experience acute worsening of anemia, which can be a medical emergency, and have an increased risk of thromboembolic events and premature death. Nipocalimab is a fully human, aglycosylated, effectorless IgG1 monoclonal antibody that targets the IgG binding site on the neonatal Fc receptor (FcRn) with high affinity. FcRn, which is expressed in endothelial cells, is responsible for recycling IgG into the circulation and for the relatively long half-life of IgG antibodies compared to other Igs. It is expected that nipocalimab,

by inhibiting IgG binding to FcRn, will prevent IgG recycling and lower pathogenic IgG autoantibodies that cause many autoimmune diseases including warm autoimmune hemolytic anemia (wAIHA).
Nipocalimab has been studied in multiple phase 1 studies in healthy subjects and in a recently completed phase 2 study in subjects with Generalized Myasthenia Gravis (gMG). In the gMG phase 2 study, nipocalimab was generally well tolerated at doses from 5 mg/kg every 4 weeks to 60 mg/kg every 2 weeks. Treatment with nipocalimab was associated with rapid and durable total serum IgG and pathogenic IgG autoantibody reduction and meaningful clinical response. A statistically significant relationship between IgG autoantibody reduction and clinical benefit was observed. This study provided proof-of-concept evidence that lowering pathogenic IgG autoantibodies can ameliorate the autoimmune condition these antibodies cause.
Aims: To share the rationale and study design for an adaptive, phase 2/3 multicenter, randomized, double-blind, placebo-controlled study in patients with wAIHA whose aim is to evaluate the efficacy, safety, tolerability, PK, and PD of nipocalimab compared with placebo[1].
Methods: Male or female subjects ≥18 years of age who have been diagnosed with primary or secondary wAIHA and have not experienced a sufficient response or have not tolerated currently available treatments will be included in the study. Subjects with cold antibody AIHA, cold agglutinin syndrome, mixed type (i.e., warm and cold) AIHA, or paroxysmal cold hemoglobinuria will be excluded. Patients will be randomized 1:1:1 to receive nipocalimab at two different dose schedules or placebo. Following completion of 24 weeks of double-blind treatment, patients may enter an open-label extension period to receive nipocalimab.
Results: The following endpoints will be analyzed:
Primary endpoint:
Percentage of participants achieving durable response of improvement in hemoglobin (Hgb).
Main secondary endpoints:
Change from baseline in the total score from the Functional Assessment of Chronic Illness Therapy-Fatigue Scale at the end of the double-blind period.
Number of participants who attain normal lactate dehydrogenase, normal haptoglobin, and normal indirect bilirubin levels at a minimum of 3 consecutive visits after baseline.
Summary/Conclusion: A phase 2 study investigating nipocalimab in subjects with gMG provided proof of concept for a phase 2/3 interventional study with nipocalimab in subjects with wAIHA. This phase 2/3 study is currently enrolling in the USA and Europe.

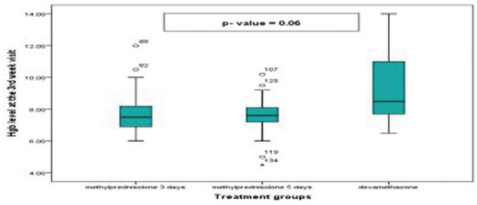
EP714 WARM AUTOIMMUNE HEMOLYTIC ANEMIA: A RETROSPECTIVE ANALYSIS OF 115 PATIENTS

B. Achouro [1,*], N. Seifeddine [1], E. Nihed [2], B. Emna [1], M. Wided [3], C. Amal [1], R. Haifa [1], B. Nesrine [1], K. Zahra [1], Z. Monia [1], B. Yosra [1], K. Abderrahim [1]

[1]Hematology, [2]Community Medecine, [3]Laboratory of hematology, Farhat Hached Hospital, Sousse, Tunisia



Background: Warm autoimmune hemolytic anemia (WAIHA) is a relatively rare hematologic disorder resulting from autoantibody directed against self-erythrocytes. There has been few studies about warm AIHA because of its low incidence.
Aims: We aimed to analyze 20-years' experience of WAIHA patients at a single referral center in Sousse. Clinical data, survival outcome of patients who were diagnosed with WAIHA were retrospectively analyzed.
Methods: This is a descriptive retrospective study. Data belonging to WAIHA in adult patients admitted in our department of hematology between January 2001 and December 2020 were analyzed.
Results: One hundred and fifteen patients (58.3% women) were included, the mean age at the time of wAIHA onset was 54 years (range 16-98), the mean hemoglobin level was 6.2 g/dL (range 2.1-10.9 g/dL). All the patients were direct antiglobulin test (DAT) positive (80 (69.6%) patients were IgG, 34 (29.6%) were IgG plus C3d, and only one was IgA DAT positive). wAIHA was considered "primary" for 53 patients (46%) and was associated with an underlying disorder in 62 (54%), including mainly lymphoproliferative diseases (31 patients) and connective tissue disease (25 patients). All patients received steroids at therapeutic dosages (corticosteroid 1 mg/Kg) as first line treatment (+/-chemotherapy for hematologic malignancy)). Hundred and one of them showed: complete response (68/59.1%) and partial response (33/28.7%). Thirty seven patients (32.2%) relapsed at least once and was retreated with corticosteroid in 15 patients because of anemic symptoms, or received cyclophosphamide in 12 patients, rituximab in only 4 patients and splenectomy in 6 patients. Twenty nine patients presented complication (11 cases of several infections, 3 cases of osteoporosis, 3 cases of thrombotic events, 9 cases of corticosteroid-induced diabetes, 3 cases of renal failure). After a median of follow-up of 44 months (1-188), 86 patients were in remission (eight in complete response, 60 in complete remission, 18 in partial remission), 11 patients were in relapse or refractory to a treatment and eighteen patients died (3 during poorly tolerated anemia, 4 due to infections, 1 related to metabolic acidosis for multiple myeloma, 1 ischemic stroke, and nine following a progression of hematologic malignancies or cancer).
Summary/Conclusion: This study indicates that secondary WAIHA are predominant. Oral corticosteroid is effective as first line therapy for warm AIHA, but several complication may arise. Despite a proven efficacy of rituximab as corticosteroid-sparing strategy, it is still little used as a second line therapy in our department for this immune disorders.

EP715 COMPARISON BETWEEN THE DIFFERENT REGIMENS AND PHARMACOLOGICAL FORMS OF CORTICOSTEROID AS FIRST-LINE THERAPY OF AUTOIMMUNE HEMOLYTIC ANEMIA (AIHA): RESULTS OF THE PROSPECTIVE OBSERVATIONAL COHORT.

G. Abdallah [1,*], E. A. S. Elbieh [1], M. F. M. Saleh [2], E. Abdelmonem [1], W. A. Abbas [2]

[1]clinical hematology unit, internal medicine, [2]internal medicine, Assiut university, Assiut, Egypt

Background: Autoimmune haemolytic anaemia (AIHA) is a critical health concern where myriad factors contribute to this autoimmune syndrome. There are no clear recommendations in the latest consensus of AIHA regard the different forms and regimens of corticosteroids in the treatment of the warm type.
Aims: we aim to compare the efficacy and safety of regimens started with intravenous corticosteroids and the regimen of prednisolone alone as first-line strategies for newly diagnosed adult warm AIHA.
Methods: The current study is a single-centre prospective cohort (NCT03269292, Clinical Trials.gov) conducted in a university-affiliated hospital (Assiut University Hospital, Assiut, Egypt). Subjects were enrolled if they have warm AIHA with positive direct antiglobulin (DAT) test either primary or secondary type and their age is more than 18 years. We excluded patients with previously treated AIHA and other types of immune haemolytic anaemia
The patients either administrated oral prednisolone 1mg/kg daily for 3 weeks or started therapy with one of three different regimens for the intravenous corticosteroid therapy: intravenous dexamethasone 40 mg daily for 4 days, Methylprednisolone 1 gram/day for 3 days, or Methylprednisolone 1 gram/day for 5 days then followed by oral prednisolone 1 mg/kg/day for the rest of the 3 weeks. Full clinical evaluation and CBC were done every 3 days for 3 weeks.
Results: 156 eligible newly diagnosed AIHA patients were recruited to the cohort and they receive corticosteroids as first line therapy.
The median hemoglobin level recorded at the baseline was significantly higher (p=0.001) in patients started the treatment with prednisolone orally (5.8g/dl) than patients started treatment with intravenous regimens (4.5g/dl). However, the median incremental increase of hemoglobin level from the baseline was significantly higher (p=0.003) in the patients started with intravenous regimens (3.1g/dl) than the other group (2g/dl). The analysis of the subgroups of patients started with intravenous regimens showed that no significant difference in the hemoglobin level at the baseline between the three treatment regimens (p=0.1). Although there was not any significant difference between these three groups regard the hemoglobin level at the end of the 3rd week but there was a trend to be higher in the dexamethasone group (figure 1).
There was not any significant difference between the regimens started with intravenous crticosteroids and the oral regimen alone as regard the frequency of the adverse events (p=0.3). The adverse events reported were either grade 1 or grade 2 and included hyperglycaemia, hypertensin, muscle weakness, hypokalaemia, abdominal pain and vomiting. They were not associated with long term sequalae or death.

Summary/Conclusion: In this study, we prove that regimens started with intravenous corticosteroids therapy are superior to oral regimen as they achieved higher levels of incremental increase in the hemoglobin levels from the baseline without increase of the incidence or increase the severity of the side effects. This is beneficial in cases of acute sever AIHA.

Gene therapy, cellular immunotherapy and vaccination - Biology & Translational Research

EP716 PHENOTYPIC, TRANSCRIPTIONAL AND FUNCTIONAL ANALYSIS OF CD19 CAR-T CELLS: SENESCENT/EXHAUSTED PHENOTYPE PREDICTS RESPONSE OF B CELL LYMPHATIC MALIGNANCIES

K. Beider [1,*], M. J. Besser [2], E. Jacoby [3], J. Schachter [2], V. Voevoda-Dimenshtein [1], E. Rosenberg [1], O. Ostrovsky [1], I. Danylesko [1], A. Shimoni [1], A. Avigdor [1], A. Nagler [1]

[1]Hematology Division, [2]Ella Institute of Immuno-Oncology, [3]Division of Pediatric Hematology and Oncology, The Edmond and Lily Safra Children's Hospital, Sheba Medical Center, Ramat Gan, Israel

Background: In spite of high rates of overall response following chimeric antigen receptor (CAR) T cell therapy its curative potential is jeopardized by exhaustion of the CAR T cells conceivably mediated by the immunosuppressive tumor microenvironment and excessive antigen exposure. However, cellular and molecular predictors of clinical response are not fully elucidated.
Aims: To identify phenotypic, transcriptional and cellular mediators of resistance to CAR T immune therapy.
Methods: We performed a broad immunophenotypic and transcriptomic analysis of the T cells from patients (pts) with relapsed/refractory B cell malignancies (n-39: NHL-28, ALL-5), and CLL-6) treated with locally produced CD19 CAR T cells in correlation with pts' day 28 clinical response. Intact CD3$^+$ T cells that were obtained from peripheral blood (PB) samples pre Flu/Cy lymphodepletion using negative magnetic sorting and the manufactured CAR T products were analyzed. The CD8$^+$ and CD4$^+$ T cells were individually assessed by a panel of 17 immune surface markers identifying different T cell subsets and underlying the T cell repertoire diversity. Transcriptional signature was assessed by NanoString technology.
Results: Phenotypic signature identified a higher proportion of exhausted CD57$^+$CD39$^+$ cytotoxic CD8$^+$ cells in CAR T products of non-responders (NR) in comparison to pts with complete response (CR). Furthermore, CD8$^+$ CAR T cells of NR pts were characterized by CD28 and IL-7R loss, and lower levels of CCR7. Expression of T cell checkpoint inhibitor PD1 was high in these exhausted CD8$^+$ cells. Importantly, higher proportion of exhausted cytotoxic CD8$^+$ cells was detected in PB of NR comparing to responders, suggesting the association of CAR T exhaustion with a dysfunctional phenotype of pts' T cells. In contrast, CD4$^+$ cells demonstrated low frequency of exhausted phenotype both in the PB as well as the CAR T product from both NR and CR pts, indicating that CD4$^+$ T cells are less prone to exhaustion compared to their CD8$^+$ counterparts, suggesting better persistence of CD4 CAR T cells following antigen exposure.
The transcriptional signature of the CAR T products overlaid with the phenotypic characterization. Higher levels of IL-7R, CD7, BATF3, IL15, FOS, MYC, CD69 and CD27 genes were detected in the CAR T cells of CR pts. In contrast, the CAR T cells of resistant pts were enriched with terminally exhausted population, upregulating CD57, TOX, EOMES, GZMB, GZMA, GZMH, CCL4 and LAG3 genes.
Finally, the functional capacity of the CAR T cells was evaluated in co-culture experiments with CD19$^+$ Raji cells. Stimulation with CD19$^+$ targets induced proliferation and cytokine secretion of the CAR T effectors. Importantly, reduced proliferation and reduced IL-2 secretion correlated with the exhaustion signature. Of note, CAR T cells with exhausted phenotype demonstrated killing capabilities comparable with the non-exhausted CAR cells. Similarly, CAR T cell degranulation, a prerequisite for target cell lysis did not differ as well. These data suggest that the in vitro cytolytic activity of exhausted CAR T cells may be preserved while their proliferation and cytokine production is clinically insufficient.

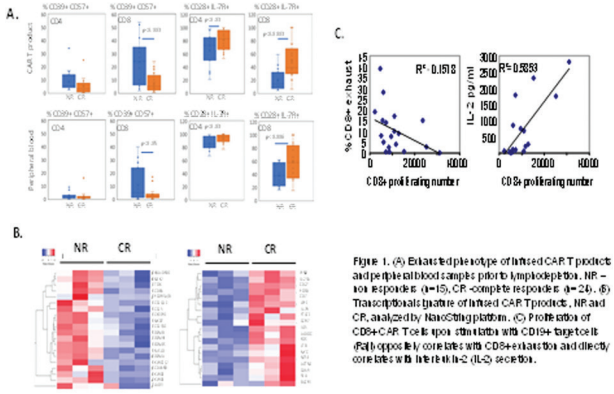


Figure 1. (A) Exhausted phenotype of infused CAR T products and peripheral blood samples prior to lymphodepletion. NR – non responders (n=15), CR -complete responders (n=24). (B) Transcriptional signature of infused CAR T products, NR and CR, analyzed by NanoString platform. (C) Proliferation of CD8+CAR T cells upon stimulation with CD19+ target cells (Pal) oppositely correlates with CD8+ exhaustion and directly correlates with interleukin-2 (IL-2) secretion.

Summary/Conclusion: Overall, these results reveal potential cellular and molecular mediators of resistance, identifying an enrichment of terminally exhausted CD8+ T cells as a main feature observed in PB and CAR T products of resistant patients. Delineating these mechanisms may guide future T cells engineering studies to enhance the efficacy and durability of CAR T therapy in B cell malignancies.

EP717 IMMUNE REGULATORY PROTEINS MODULATE FIBROSIS AND INFLAMMATION IN SCLERODERMATOUS GRAFT-VS-HOST DISEASE

L. Cui [1], C. De Souza [2], T. Lerbs [2], J. Poyser [3], M. Kooshesh [2], A. Saleem [2], K. Rieger [2], R. Brown [2], B. Kwong [4], S. Fernandez-Pol [2], S. Arai [5], J. Shizuru [3], A. M. Mueller [6], G. Wernig [1,*]

[1]Pathology, Institute for Stem Cell Biology and Regenerative Medicine, [2]Pathology, [3]Institute for Stem Cell Biology and Regenerative Medicine, [4]Dermatology, [5]Medicine, Stanford University, Stanford, United States, [6]Bone marrow transplant, University of Zurich, Zurich, Switzerland

Background: Chronic graft-vs-host disease (cGVHD) is an immune related disease condition that is incompletely understood. It coincides with transplantation of non-purified Hematopoietic Stem Cells (HSCs) in up to 70% of patients and represents a major obstacle to the success of allogeneic hematopoietic stem cell transplantation (HCT). Sclerodermatous GVHD (Scl GVHD) is a more severe form of cGVHD and is associated with poor prognosis and low sensitivity to immune suppression which is the current first line therapy.
Aims: We hypothesized that there exist a range of inflammatory cells delivering profibrotic signals. Such signals while initially performing tissue repair following transplant-related injury of the skin, can eventually perpetuate uncontrolled pathologic fibrosis. Therefore, we aimed at identifying downstream fibrotic gene expression signatures in fibroblasts associated with chronic inflammation.
Methods: In skin biopsies, we show that JUN and CD47 are key regulatory molecules overexpressed and activated in Scl cGVHD patients. Mechanistically, using ChIP-seq and ATAC-seq we describe JUNs role in altering the transcriptional landscape of IL6 and CD47. Finally, using novel and conventional mouse models that recapitulate clinical Scl cGVHD we show the effect of anti-CD47 and anti-IL6 antibodies as promising therapeutics for the treatment of inflammation and fibrosis in Scl cGVHD patients.
Results: 1. Our combined expression and signaling data confirm that JUN activation is tightly linked to a profibrotic and immune dampening signature in Scl cGVHD.
2. JUN deletion alters chromatin accessibility and nucleosome positioning of immune regulatory and fibrosis genes in human Scl cGVHD.
3. We demonstrate that JUN, CD47 and IL6 are upregulated in a novel mouse model of Scl cGVHD demonstrating progressive disease.
4. Finally we show that CD47 and IL6 blockade are an effective therapeutic strategy for the treatment of sclerosis in the skin related to Scl cGVHD in mice.
Summary/Conclusion: In summary, we describe a novel mechanism through which chronic inflammation perpetuates fibrosis via activation

of JUN, CD47, IL6, which result in a profibrotic signature in Scl cGVHD. Our findings are of particular interest, as these pathways have been implicated in tissue sclerosis in other contexts and indicate potential targets for therapeutic intervention using anti-CD47 and IL6R antibodies.

EP718 IMPROVED LEUKEMIA CLEARANCE AFTER ADOPTIVE TRANSFER OF NK CELLS ENGINEERED WITH THE BONE MARROW HOMING RECEPTOR CXCR4

M. Lambert [1], F. Segerberg [1,*], A. Andersson [1], R. Childs [2], M. Carlsten [1]

[1]Department of Medicine, Huddinge, Karolinska Institutet, Huddinge, Sweden, [2]Cellular and Molecular Therapeutics Branch, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, United States

Background: The overall survival in acute myeloid leukemia (AML) remains poor. New treatment options are needed. Early clinical trials have highlighted that adoptive transfer of natural killer (NK) cells can induce remission in patients with relapsed/refractory AML and high-risk myelodysplastic syndrome (MDS). Recent advances have now enabled investigators to explore the potential of genetically engineered NK cells to improve the efficacy.
Aims: The primary aim was to investigate whether *ex vivo* expanded human NK cells, engineered to overexpress the gain-of-function bone marrow (BM) homing receptor CXCR4^{R334X}, can be utilized for improved leukemia clearance *in vivo*. In addition, we further aimed to explore the role for the CXCR4/SDF-1α axis in NK cell BM homing by knocking out the CXCR4 gene.
Methods: A 4D-Nucleofector™ System (Lonza) was used to introduce CXCR4^{R334X}-coding mRNA, or RNP-complex for CRISPR/Cas9 mediated CXCR4 gene-knock-out (KO), into *ex vivo* expanded human NK cells. RNA transcript levels and cell surface expression of CXCR4 was determined by q-RT-PCR and flow cytometry staining respectively. KO efficacy was evaluated by ddPCR. CD107a degranulation experiments, and Calcein-AM-based killing assays, were used to evaluate the *in vitro* leukemia targeting potential post electroporation. *In vitro* migration was assessed by transwell migration assays whereas NSG-SGM3 mice were used to evaluate the *in vivo* migration capacity. To assess the *in vivo* anti-leukemic potential, NSG-SMG3 mice were inoculated intrabone with MOLM-14 cells prior to NK cell treatment.
Results: Here, we demonstrate that *ex vivo* expanded human NK cells, mRNA-transfected to overexpress the gain-of-function bone marrow (BM) homing chemokine receptor CXCR4^{R334X}, have a higher homing propensity for BM compartments *in vivo* leading to significantly improved leukemia rejection when adoptively infused into AML-bearing mice compared to control NK cells. Further, our data reveal that CXCR4^{R334X} mRNA-transfected NK cells more efficiently delayed leukemia spreading to non-tumor-inoculated BM compartments. Importantly, neither the CRISPR/Cas9 or the mRNA transfection approach used in this study affected the ability of NK cells to target AML cells.
Summary/Conclusion: Collectively, these data provide proof-of-concept that genetic engineering of human NK cells to promote homing to BM compartments is an independent modality that can be optimized to further enhance the efficacy of NK cell-based immunotherapy of myeloid leukemia.

EP719 HARNESSING EXHAUSTED, TUMOR-SPECIFIC T CELLS TO GENERATE A T-CELL RECEPTORS LIBRARY FOR ADOPTIVE T CELL THERAPY IN BLOOD MALIGNANCIES

F. Manfredi [1,*], L. Stasi [1], S. Buonanno [1], M. Noviello [1], S. Mastaglio [2], F. Ciceri [2], E. Ruggiero [1], C. Bonini [1]

[1]Experimental hematology, [2]Bone Marrow Transplant unit, IRCSS San Rafafele, Milan, Italy

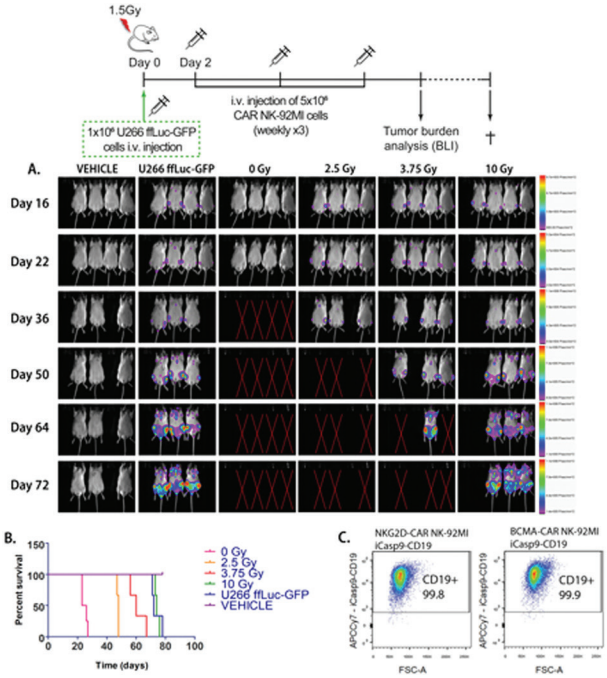
Background: Aggressive blood malignancies can benefit from the immune pressure imposed by allogeneic Hematopoietic Stem Cell Transplantation (allo-HSCT), able to eradicate cancer cells surviving chemo-radiotherapy. However, allo-HSCT may also mediate allo-reactions with potentially fatal outcomes. In order to boost HTSC efficacy while reducing toxicities, adoptive T cell therapy with genetically engineered T cells redirected against tumor antigens (ACT) is an appealing therapeutic candidate. However, ACT applicability in blood tumors is limited by the low number of known tumor-reactive T-Cell Receptors (TCRs).
Aims: We defined an experimental pipeline to isolate tumor-specific TCRs from allo-HSCT treated patients to widen the TCR repertoire for ACT by taking advantage of either multimers or inhibitory receptors surface markers expression.
Methods: Circulating Tumor-specific T cells in blood cancer patients who underwent allo-HSCT were phenotypically characterized, then purified and in vitro expanded by means of multimers directed toward immunodominant peptides of MAGE-A2, WT1, Survivin and hTERT tumor-associated antigens, restricted for HLA-A*0201 and HLA-A*2402 alleles. Tumor-Specific T cell TCR repertoire was studied by RNA sequencing.
Results: We successfully isolated and expanded markedly oligoclonal tumor-specific T-cell cultures from N=13/20 patients. Despite documented in vitro enrichment and expansion, cell cultures failed to lyse peptide-pulsed target cell lines during in vitro assays, suggesting that T cells were hypo-functional. To circumvent hypo-functionality, the dominant TCR from N=6 of those T-cell cultures was reconstructed and transferred into fit donor T cells which endogenous TCR have been previously knocked-down by means of CRISPR/Cas9 system. Newly engineered T cells proved able to specifically recognise and eliminate peptide-pulsed cell lines with different affinities in in vitro killing assays. A high-dimensional flow cytometry analysis performed on N=33 patients strengthened the hypothesis that tumor-specific T cells are hypo-functional ex vivo. Indeed, tumor-specific but not viral-specific T cells preferentially expressed multiple inhibitory receptors and showed an impaired differentiation program, with accumulation of stem cell-like memory T cells and terminal effectors. Interestingly, such phenotype was accentuated in those patients deemed to relapse after allo-HSCT. In order to take advantage such unique exhaustion signature, we exploited inhibitory receptors to segregate from three Acute Myeloid Leukemia patients a T cell fraction positive for multiple inhibitory receptors (IR+) and putatively enriched with tumor specificities. We then serially stimulated with autologous Leukemic-Antigen Presenting Cells (L-APCs) the IR+ and the control IR- fraction. In all the three tested patients, L-APCs promoted the occurrence of a dominant TCR clonotype in the IR+ but not in the IR- group. These dominant TCRs, when inserted into TCR-knocked-down donor T cells led to the generation of engineered T cells that efficiently lysed autologous leukemia in vitro while sparing healthy bone marrow cells.
Summary/Conclusion: Our data suggest the presence of circulating, though exhausted, tumor-specific T cells in patients after allo-HSCT. By exploiting multimers or the IR signature, we here provide a pipeline to isolate novel tumor-specific TCRs with different specificity, affinity and peptide sensitivity to be employed in ACT.

EP720 VALIDATION OF AN IL-1RAP CART-CELLS PRECLINICAL « GMP-LIKE » PRODUCTION PROCESS BEFORE AN UPCOMING FIRST IN HUMAN PHASE I CLINICAL TRIAL.

X. Roussel [1,2,*], M. Neto Da Rocha [1], C. Nicod [1], R. Trad [1], L. Bouquet [1], R. Hadebache [1], W. Warda [1], L. Bosdure [1], M. C. Laude [1], M. Guiot [1], C. Ferrand [1], M. Deschamps [1]

[1]EFS BFC, UMR1098, [2]Haematology, CHRU, BESANCON, France

Background: Use of Chimeric Antigen Receptor (CAR) T-cells have demonstrated excellent results in B-lymphoid malignancies. In myeloid malignancies, several other targets are investigated as the interleukin-1 receptor accessory protein (IL-1RAP). A limitation of CAR T-cells success is the persistence in patients over time without relapse. A central memory T-cells (T_{CM}) phenotype seems to be the best candidate for improving CAR T-cells efficiency.
Aims: The aim of this work is characterizing our preclinical "GMP-like" IL-1RAP CAR T-cells production, transferable for the clinic, in comparison to our experimental production.
Methods: Two arms were compared: CD4+/CD8+ cells were sorted from peripheral blood mononucleated cells of healthy donors on a ClinMACS Prodigy® device. Sorted CD4+/CD8+ cells were then activated by CD3/CD28 + IL-7/IL-15 before transduction, at day(D)1, using a IL-1RAP CAR lentiviral supernatant. In Comparison, for the experimental conditions, CD4+/CD8+ cells were activated using CD3/CD28 Beads + IL-2 before transduction at day 2. Cells were cultured for 9 days either in flask or in GMP approved device. Transduction efficiency was measure 4 days after the transduction by ΔCD19 reported gene labeling using flow cytometry. T-cells subsets phenotyping was perform on the fresh or thawed CAR T-cells final product (D9) and compared with untransduced T-cells (D0). Cytotoxicity was assessed by CD107a staining or IFNγ quantification by ELISA, after coculture with leukemic cell lines and IL-1RAP-coated recombinant protein. CAR T-cells metabolism was also assessed by Seahorse® analysis after IL-1RAP stimulation.



Results: Cells proliferation was similar between the two procedures of IL-1RAP CAR T-cells. However, the transduction efficiency was higher in the preclinical (64.6%±15.6%) than in the experimental process (45.6% ±10.4%). The CD4/CD8 ratio was maintained between D0 and D9 in the preclinical process in comparison to the experimental process (4.0±0.9, 4.0±1.9, and 1.7±0.7 respectively). At D9, the CAR T-cells product was mostly composed of stem cell-like memory T-cells (T_{SCM}) and T_{CM} in the preclinical GMP-like process in comparison with the experimental procedure (48.8%±0.8% and 30.9%±2.6% vs 30.1%±19,1% and 18.5%±6.5% respectively).
Better functionality was observed in the GMP-like process compare to the experimental one characterize by a higher CD107a positive CAR T-cells percentage, after coculturing against MonoMac-6 IL-1RAP tumor cell lines (34.1% ±9.8% vs 3.4% ±2.0% respectively, p=0.006%) or in presence of a IL-1RAP coated recombinant protein (55.7% ±4.6% vs 1.1% ±0.4% respectively, p<0.0001). These results were confirmed by IFNγ secretion quantitation (3708 pg/mL ±2176 pg/ml and 2535 pg/mL ± 1352 pg/mL respectively). Moreover, IL-1RAP coated recombinant protein stimulation show a basal glycolytic activation of CAR T-cells (fold rate at 2.0 ±0.2, p<0.001), but without difference of maximal glycolytic activity, suggesting a specific activation without exhaustion. Oxidative metabolism was similar with and without activation.
Summary/Conclusion: We have demonstrated that our IL-1RAP CAR T-cells preclinical GMP-like process meets standard requirements of production in term of T-cells subpopulation phenotype for anti-leukemia immunologic memory and cytotoxic functionality. It is ready for transfer in clean room in order to produce for AML patients in first in man phase I clinical trial.

EP721 EXPLORING A SAFE AND EFFECTIVE "OFF-THE-SHELF" CELL-BASED IMMUNOTHERAPY FOR THE TREATMENT OF MULTIPLE MYELOMA USING NON-IRRADIATED CAR NK-92MI CELLS

E. Maroto-Martín [1,*], J. Encinas [1], A. García-Ortiz [1], E. Castellano [1], L. Ugalde [2], R. Alonso [1], A. Leivas [1], M. L. Paciello [1], V. Garrido [1], B. Martín-Antonio [3], G. Suñe [3], T. Cedena [1], D. J. Powell Jr. [4], P. Río [2], J. Martinez-Lopez [1], A. Valeri [1]

[1]Hospital Universitario 12 de Octubre, CNIO, H12O-CNIO Hematological Malignancies Clinical Research Group, CIBERONC, [2]CIEMAT/CIBERER, Hematopoietic Innovative Therapies Division, IIS-FJD, Madrid, [3]Hospital Clinic de Barcelona/IDIBAPS, Department of Hematology, ICMHO, Barcelona, Spain, [4]University of Pennsylvania, Department of Pathology and Laboratory Medicine, Philadelphia, United States

Background: CAR-NK cells represent a safer approach than CAR- T cells. These ground-breaking CAR effectors exhibit some other immunological advantages, as they entail an 'off-the-shelf' strategy with no graft-versus-host disease. NK-92 is a universal, cheap and fast obtainable cellular therapy previously used in clinical trials. Although modest responses with these cells have been reported in Multiple Myeloma (MM), their cytotoxic potential can be enhanced by genetic modification. However, the products obtained so far offer some limitations and could be optimized in MM.
Aims: The aim of our study is to generate a risk-free and effective CAR NK-92MI immunotherapy for MM treatment.
Methods: NK-92MI cells were lentivirally transduced with a single second generation CAR, NKG2D-CAR or BCMA-CAR, both containing identical 4-1BB costimulatory domain, as well as dual BCMA-NKG2D CARs with different combinations of co-stimulators. CAR NK-92MI iCasp9-CD19 populations have been generated by retrovirus transduction with an SFG iCasp9.2A.ΔCD19 construct. All populations were purified by FACS sorting to obtain stable modified cell lines and vector copy number was measured by qPCR to ensure similar CAR expression. *In vitro* cytotoxicity assays were performed against an ensemble of MM cell lines with high and low expression of target ligands as well as a BCMA knock-out generated by CRISPR-Cas9 system: U266, $BCMA^{high}$ and $NKG2DL^{high}$; ARP-1, $BCMA^{dim}$ and $NKG2DL^{dim}$; XG-1, $BCMA^{high}$ and $NKG2DL^{low}$; $U266bcma^{KO}$, $BCMA^{KO}$ and $NKG2DL^{high}$. *In vivo*: $5x10^6$ CAR NK-92MI cell infusions were administered i.v. once a week for three weeks.
Results: We have demonstrated specificity, non-toxicity and higher *in vitro* antitumor activity of CAR NK-92MI cells compared to the parental cell line. Besides, we have noticed that the expression of both CARs in combination has not showed synergy, but a broadening of cytotoxic coverage against MM cell lines *in vitro* is remarked. *In vivo* MM orthotopic xenograft mouse model experiments have demonstrated that the irradiation dose used in the clinic completely abrogate the efficacy of this 'off-the-shelf' immunotherapy in our treatment schedule. Decreasing irradiation doses (2.5-3.75 Gy) has no impact on tumor elimination and leads to early NK-92MI-induced death in animals (Figure 1A-B). To settle these drawbacks, CAR NK-92 MI cells expressing suicide gene therapy have been generated (99.8% purity, Figure 1C) and it has been demonstrated that cells can be rapidly eliminated *in vitro* upon induction with Rimiducid (AP1903). This strategy will assure antitumor efficacy and safety of the immunotherapy, and all generated effectors displayed similar *in vitro* cytotoxic activity than their CAR NK-92MI counterparts. *In vivo* experiments are ongoing.

Summary/Conclusion: We have generated simple and combined stable CAR NK-92MI cells that improve the cytotoxic activity of the parental cell line. The co-expression of both CARs results in cytotoxic coverage against different MM targets. *In vivo*, these data show the futility of irradiation as an NK-92 CAR treatment strategy in our MM model and the further need of combinations with iCasp9 safety switch to ensure the safety and efficacy of the therapy.

EP722 CAR-TREG THERAPY FOR SYSTEMIC LUPUS ERYTHEMATOSUS

M. Doglio [1,*], M. Bonfanti-Lombardi [1], Z. Magnani [1], B. Camisa [1], M. Casucci [2], A. M. Manfredi [3], C. Bonini [1]

[1]Experimental Hematology Unit, [2]Innovative Immunotherapies, [3]Autoimmunity and vascular inflammation unit, San Raffaele Scientific Institute, Milan, Italy

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by an abnormal inflammatory response against nuclear antigens due to a loss of the immune tolerance with consequent damage to healthy organs. Auto-reactive B cells with autoantibody production and immune complex formation have a fundamental role in the pathogenesis of the disease. Regulatory T cells (Tregs) are a subset of T lymphocytes endowed with immune suppressive capabilities. Tregs control the activation of the immune system, preventing

unwanted inflammatory reactions and preserving the immune tolerance against self-antigens. An impaired Treg functionality is involved in SLE, where they do not manage to control the inflammatory response. Adoptive transfer of polyclonal Tregs has been employed to restore the immune tolerance in different autoimmune diseases, achieving unsatisfactory results due to a low frequency of antigen specific suppressive cells. Chimeric Antigen Receptors (CARs) are chimeric molecules capable of redirecting T cell specificity against target antigens, greatly enhancing T cell activity. CAR-Tregs proved effective in controlling the inflammation in pre-clinical mouse models of autoimmune diseases different from SLE.
Aims: The aim of the project is to employ the CAR technology to redirect and enhance Treg activity in order to exploit their immune suppressive capabilities to restore immune tolerance in Systemic Lupus Erythematosus.
Methods: We sorted CD4+CD25+ cells from peripheral blood of Healthy Donors using magnetic separation beads. Next, we expanded Tregs using anti-CD3/CD28 magnetic beads in the presence of IL-2 and rapamycin. Considering the role of B cells, we transduced CAR-Tregs with a Lentiviral Vector encoding for a second generation anti-CD19 CAR, constituted by the intracellular portion of both CD28 and CD3-zeta to provide a more physiological stimulation. GFP was employed as transduction marker. Starting from day +14 since the initial stimulation, we performed functional assays. Immune and suppression assays were evaluated with flow cytometry.
Results: We obtained a cell product highly enriched in Tregs and with a transduction efficiency of 50%. CAR-Tregs retained their immune suppressive capabilities and performed equal to untransduced Tregs in suppressing the proliferation of autologous lymphocytes upon polyclonal stimulation. Noticeably, CAR-Tregs, but not untransduced Tregs, suppressed autologous B cell proliferation, demonstrating an antigen-specific suppression capacity. When co-cultured with CD19+ tumor cells, CAR-Tregs did not display killing capacities, but rather an impressive proliferation activity. More strikingly, anti-CD19 CAR-Tregs suppressed conventional anti-CD19 CAR-T cell killing when co-cultured together in the presence of a CD19+ tumor cell line. Finally, we tested the immune suppressive capacities of anti-CD19 CAR-Tregs in a humanized mouse model of lupus. Engineered cells delayed the occurrence of leukopenia compare to untransduced regulatory lymphocytes.
Summary/Conclusion: In conclusion, we efficiently generated anti-CD19 CAR-Tregs and proved their efficacy both in vitro and in an in vivo humanized mouse model of lupus.

EP723 MONITORING COMMERCIAL ANTI-CD19 CAR T-CELL PRODUCT EXPANSION KINETICS: REAL-WORLD APPLICATIONS OF A NOVEL DROPLET DIGITAL PCR ASSAY AND OF MULTIPARAMETRIC FLOW CYTOMETRY

C. Monfrini [1,*], M. Magni [1], V. Aragona [1], C. Vella [1], L. Crippa [1,2], E. Fardella [1,2], A. Dodero [1], A. Chiappella [1], A. Guidetti [1,2], P. Corradini [1,2], C. Carniti [1]

[1]Hematology and Bone Marrow Transplantation Unit, Fondazione IRCCS Istituto Nazionale Tumori, [2]Università degli Studi di Milano, Milano, Italy

Background: Two CD19-directed CAR T-cell products (Tisagenlecleucel/Tisa-cel and Axicabtagene ciloleucel/Axi-cel) have been approved for refractory/relapsed (R/R) diffuse large B cell lymphoma (DLBCL) and primary mediastinal large B cell lymphoma (PMBCL) whereas Brexucabtagene autoleucel (Brexu-cel) has been used for R/R mantle cell lymphoma (MCL). Real-world data on commercial CAR T-cell product expansion kinetics are still limited and homogeneous standardized approaches are required to in vivo quantify CAR T cells.
Aims: To monitor and compare the expansion kinetics of commercial anti-CD19 CAR T-cell products using multiparametric flow cytometry (MFC) and a novel digital PCR method (ddPCR) we have developed.
Methods: We prospectively collected samples from 42 pts, [23 Axi-cel(15 DLBCL and 8 PMBCL), 18 Tisa-cel(18 DLBCL)] and 1 MCL patient receiving Brexu-cel at our Institution between Oct 2019 and Jan 2021. CAR T cells were monitored in peripheral blood (PB) on days 0,4,7,10,14,21,28 and monthly post-infusion by MFC using the CD19 CAR Detection Reagent (Miltenyi). A unique ddPCR primer-probe assay we have developed was used to quantify CAR vectors on genomic DNA extracted from PB, infusion bag-leftovers, bone marrow (BM) samples, tissue biopsies and circulating cell-free DNA (cfDNA).
Results: By MFC, 550 time-points of the 42 pts were analyzed. Median time to maximal expansion (Tmax) was identical for both products (10 days, range 7-28 days). At the point of maximal expansion (Cmax), there was no difference between pts receiving Axi-cel and Tisa-cel, with a mean of 76 cells/ul (range 1-442) vs a mean of 186 cells/ul (range 6-591) (p, ns). At this time point, CAR+ cells were more abundant among CD3+ cells in pts receiving Axi-cel (33.06% vs 15.58% for Tisa-cel, $p<0.05$). Complete response (CR) at 30 days from infusion (n=18) was associated with significantly more CAR+ cells at day 10 than non-CR (mean 146 vs 18 CAR+ cells/ul, $p<0.05$) and the magnitude of expansion in the first 30 days was higher in CR vs non-CR pts (mean area under the curve (AUC 0-30) = 1431.2 vs 584.3; $p<0.05$) irrespective of the product they received. For 16 pts (10 DLBCL, 5 PMBCL and 1 MCL) CAR T copy numbers were evaluated by ddPCR in 122 PB samples already analyzed by MFC. By transgene copy evaluation, similar kinetics of expansion were observed in all pts including the MCL patient receiving Brexu-cel. Consistent with MFC data, the median Tmax was 10 days (range 7-28 days), comparable values of transgene copies per mg of DNA were detected in PB samples from Axi-cel and Tisa-cel treated patients at the Tmax (mean $24x10^4$ copies/ug vs $13x10^4$ copies/ug, respectively) and the mean AUC 0-30 was significantly higher in CR vs non-CR pts (mean 115.9 vs 29.9;$p<0,05$). Collectively, a significant correlation between all MFC and ddPCR data was observed ($r=0.95$,$p<0,0001$ by Pearson Correlation). The ddPCR assay was then used to evaluate CAR T cells in samples for which MFC analysis was not suitable such as infusion bag-leftovers ($34x10^4$-$755x10^4$ copies/ug,n=13), cryo-preserved BM samples ($360-1x10^4$ copies/ug,n=3) tumor biopsies (0-864 copies/ug,n=3) and cfDNA ($0-9x10^4$ copies/ug,n=3).
Summary/Conclusion: Both MFC and ddPCR, allow the reproducible enumeration of commercial anti-CD19 CAR T-cells with concordant results. The ddPCR assay has the advantage over MFC to allow transgene copy evaluation in samples with limited cellularity and/or cryopreserved. In our cohort Axi-cel and Tisa-cel treated pts have similar expansion kinetics and CAR peak expansion was associated with clinical responses irrespectively of the product used.

EP724 SELECTION, EXPANSION, AND NEW PRETREATMENT OF HUMAN NATURAL KILLER CELLS WITH ANTI-CD38 MONOCLONAL ANTIBODY FOR EFFICIENT TREATMENT OF MULTIPLE MYELOMA.

Background: Though the outcome of patients with Multiple myeloma (MM) has significantly improved over the past decade, most of the patients eventually relapse, with a short progression-free survival period. Recent adoptive cellular immunotherapy is becoming a game-changer in cancer treatment after recent breathtaking outcomes in various clinical trials with chimeric antigen receptor T cells. Nevertheless, this novel therapy is not free from challenges such as affordability, tumor recurrence in heterogeneous tumors, and off-tumor toxicity. To overcome these roadblocks, we capitalize on the unique anti-tumor properties of Natural Killer (NK) cells to target MM in combination with approved

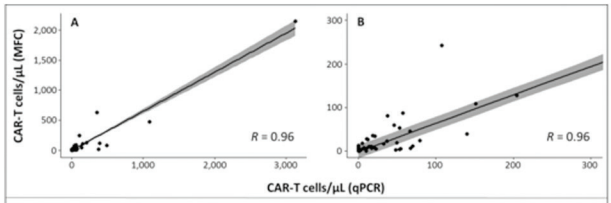
monoclonal antibody Daratumumab, applying CD16 polymorphism donor selection and straightforward new in vitro pretreatment to bypass undesired fratricide.
Aims: We propose to explore the feasibility of obtaining a clinically relevant amount of allogeneic NK cells derived from peripheral blood (PBNK) and assess their efficacy in combinatorial therapy with approved anti-CD38 monoclonal antibody Daratumumab to treat incurable MM.
Methods: PBNK cells were isolated from three healthy donors using NK cell isolation kit (Miltenyi). Phenotypic and functional analysis of PBNK cells was evaluated by flow cytometry with a defined panel of antibodies. Polymorphism analysis on FcγRIIIA-158 was performed by flow cytometry with the monoclonal antibody 3G8 clone and MEM-154 clone. Bioluminescence imaging was applied to assess the anti-tumor effectivity of PBNK cells alone, and in combination with Daratumumab, targeting the tumor cell lines RPMI and U266 labeled with the constitutive expression of Firefly Luciferase. In vivo studies were performed in mouse models of MM in four different groups: control group without treatment, single-agent treatment group with Daratumumab, single-agent treatment with PBNK cells, and combinatorial treatment group with Daratumumab and PBNK cells.
Results: We obtained a clinically relevant amount of PBNK cells (median of 14,050 million cells from a single donor) after five weeks of expansion in a GMP-grade feeder-free medium. In vitro studies confirmed the multi-tumor target capacity of expanded PBNK cells, achieving a maximum killing capacity in the fourth week of expansion. The increase in killing capacity may be explained, at least in part, by increased expression overtime of the activation receptor NKG2C. Combination of expanded PBNK cells with Daratumumab procures a synergistic therapeutic effect against MM, increasing more than 20% the therapeutic effect against CD-38 positive MM cell line after CD16 polymorphism donor selection and in vitro pretreatment of PBNK cells to avoid fratricide. Mice with human MM xenografts treated with this combination present tumor volumes 43-fold smaller than control ones.
Summary/Conclusion: Our in vitro and in vivo findings presented in this study demonstrate the feasibility of using allogeneic PBNK cells combined with Daratumumab for treating MM. Besides, CD16 polymorphism selection in PBNK cells and novel in vitro pretreatment to avoid fratricide procure a significant increase in the therapeutic effect against MM. Our results fully support and justify the continued development of allogeneic PBNK cells for the treatment of MM.

EP725 DETERMINANTS OF IN VIVO EXPANSION OF CD19 SPECIFIC CAR T-CELLS IN LARGE B-CELL LYMPHOMA: SINGLE CENTER IMMUNMONITORING RESULTS

V. Blumenberg [1,2,3,*], G. Busch [1,2], S. Baumann [1,2], D. Nixdorf [1,2], G. Hänel [1,2], L. Fröhlich [1,3], C. Schmidt [1], B. Tast [1,2], M. von Bergwelt [1,3], V. Bücklein [1,2], M. Subklewe [1,2,3]

[1]Department of Medicine III, University Hospital, LMU Munich, [2]Laboratory for Translational Cancer Immunology, Gene Center of the LMU Munich, Munich, [3]German Cancer Consortium (DKTK), German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: Pivotal trials of Axicabtagene-Ciloleucel (Axi-cel) and Tisagenlecleucel (Tisa-cel) for the treatment of relapsed and refractory (r/r) Diffuse Large B-Cell Lymphoma (DLBCL) demonstrated complete responses in 40%>58% of the patients with accompanied grade ≥3 adverse events in approximately 30% of the patients. Recently, others could associate high tumor volumne and low CAR T-cell expansion *in vivo* with poor treatment outcome. We hypothesize, that expansion of CAR T-cells and T cells in vivo depend on the composition and differentiation status of (CAR) T-cell subsets and that differential expansion of (CAR) T cell subsets determines response rate.
Aims: We performed a retrospective, single-center study in which we characterized potential determinants of CAR T-cell and T-cell expansion[MS1] and their association with treatment response at time of transfusion and 28 days thereafter: i) the distribution of CD4+ and CD8+ (CAR) T-cells subsets ii) the memory phenotype and immune checkpoint expression of (CAR) T-cells.
Methods: Patients with r/r DLBCL were treated with the CD19 specific CAR T-cell products Axi-cel or Tisa-cel at the LMU. Peripheral blood from 38 patients was collected before, during and after CAR T transfusion. Multi-parameter flow cytometry was done to detect CAR T-cells and assess marker for T-cell differentiation (CD3, CD4, CD8, CD45RA, CCR7) and immune checkpoints (PD-1, TIM-3, LAG-3). CAR T-cells were quantified based on a two step-staining approach with a biotinylated recombinant CD19 protein. Efficacy was evaluated through PET-CT scan three months and by CT scan six months after CAR T-cell transfusion and patients were categorized in Responder (complete remission) and Non-Responder (partial remission, stable or progressive disease).
Results: CAR T-cell expansion peaked between day 7 and 14 in the peripheral blood with a significantly higher expansion of CD8+ CAR T-cells compared to CD4+ CAR T-cells between day 4 and 28 (p=0.004-0.007). CAR T-cells were detectable in most patients until day 105 (sensitivity 1:1000). Responder (R) displayed a higher absolute number of CD8+ CAR T-cells over time after transfusion compared to Non-Responder (NR, p=0.02). CAR T-cells in R showed a higher frequency of an effector (p=0.004) and lower frequency of a central memory phenotype (p=0.002) compared to NR 28 days after CAR T-cell transfusion. Furthermore, assessment of immune checkpoints over time revealed a lower expression of PD-1 (p<0.0001), TIM-3 (p<0.0001), LAG-3 (p=0.001) on CAR T-cells in R compared to NR.
Summary/Conclusion: We have successfully established an Immunmonitoring platform for the assessment of CAR T-cell expansion and their immune phenotypes *in vivo* through flow cytometry. We observed relationships of CAR T-cell kinetics, memory subsets and immune checkpoint expression with efficacy. These findings might bear the potential to monitor treatment responses and prevent disease relapse together with other clinical variables.



EP726 MONITORING CAR-T CELL IN B-CELL LYMPHOMA PATIENTS THROUGH SINGLE CHAIN VARIABLE FRAGMENT QPCR

D. Carbonell [1,2,*], S. Monsalvo [1,2], M. Chicano [1,2], P. Muñíz [1,2], R. Bailén [1,2], G. Oarbeascoa [1,2], M. Bastos [1,2], N. Dorado [1,2], A. Pérez-Corral [1,2], J. Anguita [1,2], M. Kwon [1,2], J. L. Díez-Martín [1,2,3], I. Buño [1,2,4,5], C. Martínez-Laperche [1,2]

[1]Department of Hematology, Hospital General Universitario Gregorio Marañón, [2]Instituto de Investigación Sanitaria Gregorio Marañón, [3]Department of Medicine, [4]Department of Cell Biology, Complutense University of Madrid, [5]Genomics Unit, Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain

Background: CD19-targeted chimeric antigen receptor (CAR)-T cell is an approved cell therapy for the treatment of patients diagnosed with several subtypes of B cell lymphoma. Besides, monitoring CAR-T cell levels during follow-up is mandatory in order to ensure treatment success. Multiparametric flow cytometry (MFC) has proven to be an efficient method. However, improving follow-up with complementary approaches, such as qPCR could also be useful. CAR structure of both Tisagenlecleucel (Tisa-cel) (Kymriah®) and Axicabtagén Ciloleucel (Axi-cel) (Yescarta®) shares the FMC63 single chain variable fragment domain, which sequence is known, enabling their monitoring by qPCR.
Aims: To evaluate the utility of *FMC63*-specific qPCR for the detection of CAR-T cell levels during follow-up in patients treated with this therapy.
Methods: Twenty-nine patients diagnosed with a B-cell lymphoma who underwent CAR-T therapy with Axi-cel (8) and Tisa-cel (21) between June 2019 and January 2021 were included in this study. Peripheral blood (PB) samples were collected in EDTA tubes at days +7, +14, +30 and +90 (23, 24, 25 and 14 samples, respectively) from CAR-T administration, analyzing a total of 86 PB samples. In addition, nine tumor samples from eight patients were obtained from core needle biopsies. DNA was purified from PB samples using the *Maxwell 16 Blood DNA Purification Kit* (Promega, USA). Tumor samples were cut and disaggregated and DNA was purified using the QIAamp DNA Mini Kit (Qiagen). *FMC63*-specific qPCR was carried out in DNA samples, using primers and conditions previously described. For CAR-T quantification we first obtained the percentage of CAR-T cells through the ΔΔCt method (using a 100% CAR-T cell DNA sample) followed by a estimation of the absolute number of CAR-T cells from total cell count. MFC was performed on a DxFLEX cytometer (Beckman Coulter), using CD19 (20-291) protein-FITC (ACRO Biosystems). Quantitative variables were expressed as median and range. Comparison between

CAR-T cells detection by MFC and qPCR was analyzed using the Pearson correlation test.
Results: There was an optimal positive correlation between qPCR and MFC for the detection of CAR-T cells, demonstrating the usefulness of qPCR (Figure 1). Median number of CAR-T cells detected by qPCR was greater than those detected by MFC at days +7 and +14, as opposed to days +30 and +90 (Figure 1). This is probably because CAR-T cell contains a variable copy number of *FMC63* sequence and at the time of CAR-T expansion (days +7 and +14), these differences could be greater. At later stages, CAR-T cell percentage over the total number of cells is lower and the sensitivity of qPCR method is not comparable to MFC, which is able to analyze a greater number of cells. These facts may also explain the 22 samples in which CAR-T cells were detected by CMF and not by qPCR, since percentage of CAR-T in these samples was lower than 0.5% of total cells. (Figure 1). In respect of tumor samples, CAR-T cells were detected by qPCR in three out nine. Since fresh sample is not needed, qPCR demonstrates its superiority over MFC in terms of detection of CAR-T in tissue samples.

C

MFC \ qPCR	+	-
+	40	22
-	2	22

Days post CAR-T	Detected CAR-T cells/µL (median, range) qPCR	MFC
7	5 (0 - 351)	4 (0 - 627)
14	33 (0 - 3,128)	10 (0 - 2,147)
30	0 (0 - 1,085)	2 (0 - 476)
90	0 (0 - 494)	2 (0 - 76)

Figure 1. Correlation between multiparametric flow cytometry (MFC) and qPCR for CAR-T cell detection (Pearson correlation test). A. General overview of correlation. B. Zoom of samples with lower amount of CAR-T cells. C. CAR-T cells detected by microliter of peripheral blood by qPCR and multiparametric flow cytometry (MFC); positive and negative detection of CAR-T cells in patient samples through both methodologies.

Summary/Conclusion: Although qPCR is a reliable method for measuring CAR-T cell levels in patients undergoing this therapy, showing a good correlation with MFC, its sensitivity may not be sufficient at later stages of treatment. Approaches such as the application of qPCR in isolated T-cells or the use of digital PCR, could improve its usefulness in CAR-T cell monitoring.

EP727 CRISPR/CAS9 MEDIATED TCR EXCHANGE IN CORD BLOOD CD8+ T CELLS POTENTIALLY INCREASES GVL AND DECREASE GVHD

V. Lo Presti [1,*], E. Dunnebach [1], M. Plantinga [1], J. Kuball [1], J. J. Boelens [2], N. van Til [3], S. Nierkens [1]

[1]CTI - Center for Translational Immunology, UMC Utrecht, Utrecht, Netherlands, [2]MSKCC, New York, United States, [3]UMC Utrecht, Utrecht, Netherlands

Background: Hematopoietic cell transplantation (HCT) can potentially cure pediatric patients with acute myeloid leukemia (AML). However, a large proportion of transplanted patients eventually die due to relapse.
Aims: To improve overall survival, we propose a combined strategy based on the use of cord blood (CB) derived cells for cellular therapy and HCT.
Methods: We generated CB-CD8+ T cells expressing a recombinant T cell receptor (TCR) against Wilms tumor 1 (WT1) lacking endogenous TCR expression in order to avoid mispairing and competition. These cells were created through a highly efficient CRISPR-Cas9 multiplexing approach (up to 95% gene-editing efficiency) targeting the endogenous TCR alpha and beta chain. Next to this strategy, high lentiviral transduction efficiency resulted in high $WT1_{126}$-TCR expression levels with transduction enhancer LentiBOOST.
Results: By combining these approaches, we developed a tumor antigen-specific T cell product with robust expression of a $WT1_{126}$-specific TCR and very efficient elimination of endogenous TCR expression. TCR engineered T cells (TCR-T 2.0) show enhanced proliferation rate and cytokine production upon antigen recognition and express low levels of exhaustion markers (such as PD1, LAG3 and TIM3). Of note, TCR-T 2.0 show killing capacity when in coculture with AML blasts, but not in the presence of healthy cord-blood derived CD34+ hematopoietic stem cells.
Summary/Conclusion: Further drug product development could provide a potent off-the-shelf immune cell therapy approach to increase overall survival chances in pediatric relapse patients.

EP728 THE IMMUNOREGULATORY FUNCTIONS OF EXOSOME DERIVED FROM MESENCHYMAL STEM CELLS (MSCS) THAT GENETICALLY MODIFIED BY ADENO-ASSOCIATED VIRUS (AAV)

L. Liu [1,*], S. Feng [1], X. Pei [1]

[1]Hematopoietic Stem Cell Transplantation Center, National Clinical Research Center for Blood Diseases, State Key Laboratory of Experimental Hematology, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: There exist kinds of limitations of MSCs during its application, while exosome derived from MSCs has shown promising future.
Aims: To verify the effects and mechanisms of natural MSCs-exosome in treating acute GVHD in mice, then explore and establish a method for targeted modification of MSCs-exosome and verify the functions of the modified MSCs-exosome.
Methods: In different doses of MSCs-exosome groups and MSCs group, the weight loss of acute GVHD mice was observed, then the proliferation levels of activated T cells were measured through T cell activation experiment in vitro and OVA antigen specific T cell activation experiment in vivo. AAV2YF3 mutants carrying PD-L1 and PD-L1-ITGB1 was obtained after the construction of recombinant expression vectors and then was applied to infect human MSCs to modify their exosome. The immunoregulatory functions of the modified MSCs-exosome were measured with methods as above.
Results: 1) Mouse MSCs-exosome (300ug*3 times) and MSCs (1e6*3 times) effectively alleviated the weight loss of acute GVHD mice. 2) Compared with IL2, 10ug, 25ug and 50ug human MSCs-exosome inhibited the proliferation of activated T cells in vitro, respectively 86.01% (IL2), 40%, 39.61% and 42.84%; compared with PBS, 50ug, 100ug and 200ug mouse MSCs-exosome inhibited the proliferation of antigen-specifically activated OT-1 cells in vivo, respectively 42.6%, 33.1%, 14.2% and 10.6%. 3) After the infection of AAV2YF3 mutant carrying PD-L1 or PD-L1-ITGB1, the positive proportion of MSCs-exosome exceeds 40% and 60%, respectively. 4) Compared with the natural state, human MSCs-exosome modified by PD-L1 or PD-L1-ITGB1 showed better proliferation inhibitory effect in vivo, and increased the proportion of Treg cells in vitro.
Summary/Conclusion: MSCs-exosome exhibited similar immunomodulatory effects with MSCs. MSCs-exosome after PD-L1 and PD-L1-ITGB1 targeted modification effectively inhibited the proliferation of activated T cells and increased the proportion of Treg cells.

Gene therapy, cellular immunotherapy and vaccination - Clinical

EP729 CAR-T CELL IN DIFFUSE LARGE B-CELL AND PRIMARY MEDIASTINAL LYMPHOMAS IN REAL LIFE SETTING: A REPORT FROM THE PROSPECTIVE OBSERVATIONAL STUDY OF THE ITALIAN SOCIETY OF HEMATOLOGY.

Background: Relapsed/refractory (R/R) diffuse large B-cell (DLBCL) and primary mediastinal B-cell lymphoma (PMBCL) have a very poor prognosis with standard chemotherapy. The recently approved axicabtagene ciloleucel (axi-cel) and tisagenlecleucel (tisa-cel) are anti-CD19 chimeric antigen receptor T cells (CAR-T) that proved very effective in clinical trials and real-life setting. The Italian Society of Hematology (SIE) is conducting a prospective observational trial to evaluate safety and efficacy in patients (pts) treated with axi-cel and tisa-cel.
Aims: of the study are: 1. to register all DLBCL and PMBCL pts candidate to CAR-T in the Italian authorized centers; 2. to evaluate the intention to treat overall response rate (ORR, complete [CR] and partial response [PR]); 3. to evaluate duration of response (DOR), progression free survival (PFS) and overall survival (OS); 4. to evaluate safety in terms of cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS) and long-term cytopenia; 5. to evaluate different CAR-T products.
Methods: SIE designed a multicenter prospective observational study, approved by ethics committee of all centers. All pts treated since March 2019 to January 2021, were included into this national study.
Results: 126 pts were leukapheresed. Thirteen pts showed a rapid progression (10) or fatal infection (3) during the manufacturing and were not infused. The clinical characteristics of the 113 infused pts were: median age 53 years (19-70), male 64 (57%), stage III/IV 77 (68%), bulky disease 51 (45%); median number of prior lines was 3 (2-7); 33 patients (29%) failed a previous autologous stem cell transplantation and 81 (72%) were primary refractory. For histologies, 59 (52%) were DLBCL, 18 (16%) high-grade B-cell (HGBCL), 23 (20%) PMBCL, 13 (12%) transformed Follicular (tFL). Median lymphocyte count at the apheresis was 810/mm^3 (250-8900). Bridging therapy was delivered to 97 pts (86%). All pts received Flu-Cy lymphodepletion. Fifty-nine (52%) received axi-cel and 54 (48%) tisa-cel. Median follow-up time for infused pts was 6.9 months (IQR: 3.13-11.78). At 30-days after the infusion, all the 113 infused pts were evaluable for response: 45 (40%) CR, 35 (31%) PR, with and encouraging ORR of 71%. For the evaluable pts, DOR was 73% (95%CI:62-85) at 6-months and 58% (95%CI:44-77) at 12-months. In the whole series, 6 and 12-months PFS were 54% (95% CI:45-65) and 46% (95%CI:35-59); 6 and 12-months OS were 80% (95%CI:71-88) and 75% (95%CI:65-86), respectively. With the limitation of small number, 6-months PFS were 48% for DLBCL, 62% for HGBCL, 66% for PMBCL and 59% for tFL; 6-months OS by histotype were 78% for DLBCL, 80% for HGBCL, 80% for PMBCL and 92% for tFL. No differences between axi-cel and tisa-cel were reported in terms of OS and PFS. All grade CRS was observed in 87 (77%) of 113 pts, but only 6 (5%) were grade 3 or 4; ICANS was recorded in 31 (27%) patients, but only 11 (10%) were grade 3 or 4. Sixty-one (54%) pts received tocilizumab and 38 (34%) steroids. Cytopenia beyond 30 days was reported in 30 (27%) pts and 27 of them (24%) experienced viral or bacterial infections. No toxic deaths were recorded.
Summary/Conclusion: In the real-life, axi-cel and tisa-cel showed an ORR similar to those of the registrative trials, even if almost all pts underwent bridging therapy. The response rate is similar across histotypes and between products. CAR-T toxicity is manageable, relapse beyond 6 months is a rare event. Cytopenias as well as infections are an emerging problem in real-life setting.

EP730 CLINICAL OUTCOMES IN ADULTS WITH HEMOPHILIA B WITH AND WITHOUT PRE-EXISTING NEUTRALIZING ANTIBODIES TO AAV5: 6 MONTH DATA FROM THE PHASE 3 ETRANACOGENE DEZAPARVOVEC HOPE-B GENE THERAPY TRIAL

F. W. G. Leebeek [1,*], W. Miesbach [2], M. Recht [3], N. S. Key [4], S. Lattimore [3], G. Castaman [5], E. K. Sawyer [6,7], D. Cooper [6,7], V. Ferriera [6,7], S. W. Pipe [8]

[1]Erasmus MC, University Medical Center, Rotterdam, Netherlands, [2]University Hospital Frankfurt, Frankfurt, Germany, [3]Oregon Health & Science University, Portland, [4]University of North Carolina, Chapel Hill, United States, [5]Center for Bleeding Disorders and Coagulation, Careggi University Hospital, Florence, Italy, [6]uniQure BV, Amsterdam, Netherlands, [7]uniQure Inc, Lexington, [8]University of Michigan, Ann Arbor, United States

Background: Etranacogene dezaparvovec is an investigational gene therapy for hemophilia B (HB) comprising an adeno-associated virus serotype 5 (AAV5) vector containing a codon-optimized Padua variant human factor IX (FIX) transgene with a liver specific promoter. Preliminary data suggest that anti-AAV5 neutralizing antibodies (NAbs) may not preclude successful transduction with etranacogene dezaparvovec.
Aims: A Phase 3 trial (HOPE-B; NCT03569891) was established to assess efficacy and safety of a single dose of etranacogene dezaparvovec (2x10^{13}gc/kg). Adult males with HB (FIX≤2%) receiving routine FIX prophylaxis, with/without AAV5 NAbs, were enrolled into this open-label, single-dose, single-arm trial, following a ≥6 month lead-in. Co-primary endpoints; change in FIX activity (measured by one stage assay) at 26 and 52wks and 52wk annualized bleeding rate compared to lead-in.
Methods: Outcomes at 26wks are analyzed using descriptive statistics and a correlation analysis.
Results: 54 participants were dosed and completed 26wks of follow-up, 23 (42.6%) of whom had AAV5 Nabs at baseline (BL) with a median titer of 56.9 (max titer 3212; 1st-3rd quartile 23.3-282.5) and a distribution representative of the general population. One participant (titer 198) received a partial dose and was excluded from efficacy assessments. One participant (titer 3212) did not respond and remained on prophylaxis. All other participants (n=52) discontinued prophylaxis. No correlation of pre-existing NAbs with FIX activity was observed up to a titer of 678 (n=52, r=-0.28 [95% CI -0.51, 0.00], R^2=0.078). Mean FIX activity at 26 weeks was 32.7 IU/dl (min <2, max 90.4, 1st-3rd quartile 16.3-42.6, n=22) in participants with NAbs versus 41.3 IU/dl (min 8.4, max 97.1, 1st-3rd quartile 31.3-52.7, n=31) in those without.
No deaths and no inhibitors to FIX were reported.

Table 1. Most common adverse events reported among participants with and without AAV5 NAbs at baseline

Adverse event (n)	With AAv5 NAbs at baseline (n=23)	Without AAv5 NAbs at baseline (n=31)
Transient transaminitis requiring corticosteroids	2/23	7/31
Infusion-related reactions	5/23	2/31
Headache	2/23	5/31
Influenza-like illness	4/23	3/31

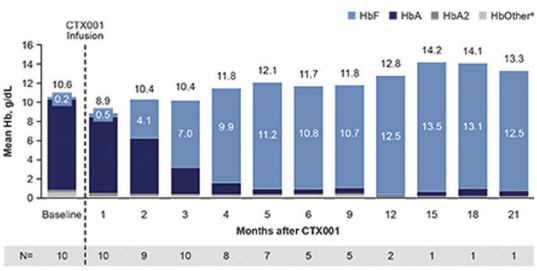
Summary/Conclusion: This study demonstrates successful treatment of participants with generally prevalent titers of pre-existing NAbs to AAV5 with etranacogene dezaparvovec, supporting broad eligibility for AAV5-based therapies.

EP731 IMMUNOTHERAPY USING A 3RD GENERATION CD20 TARGETED CAR T-CELL (MB-106) FOR TREATMENT OF B-CELL NON-HODGKIN LYMPHOMA (B-NHL) AND CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

M. Shadman [1,2,*], C. Yeung [1,2], M. Redman [1], S. Lee [1], D. Lee [1], S. Ra [1], A. Ramachandran [3], R. Lynch [1,2], S. Smith [1,2], C. Poh [2], A. Gopal [1,2], H. Warren [1,2], A. Chapuis [1,2], D. Green [1,2], J. Gauthier [1,2], R. Cassaday [1,2], H.-P. Kiem [1,2], C. Turtle [1,2], D. Maloney [1,2], B. Till [1,2]

[1]Fred Hutchinson Cancer Research Center, [2]University of Washington, Seattle, [3]Mustang Bio, Worcester, United States

Background: Immunotherapy with CD19 targeting CAR-T has become a standard treatment for patients (pts) with relapsed diffuse large cell lymphoma (DLBCL) and mantle cell lymphoma (MCL) and clinical trials have shown high efficacy in other B-NHLs. However, long-term remissions for the approved indications are ~40%, and toxicities including cytokine-release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) remain a challenge. CD20 is a proven target for treatment of B-NHLs/ CLL with demonstrated high clinical efficacy of unmodified, radiolabeled, and bispecific antibodies. CD20-targeted CAR-T represents a promising adoptive immunotherapy option that could be utilized to treat relapsed/refractory B-NHLs and CLL.
Aims: We present interim results of our ongoing phase I/II clinical trial investigating safety and efficacy CD20 CAR-T for high-risk B-NHLs and CLL (NCT03277729).
Methods: MB-106 is a fully human 3rd-generation CD20-targeted CAR-T with both 4-1BB and CD28 costimulatory domains. Lymphodepletion (LD) consists of cyclophosphamide (Cy) ± fludarabine (Flu). CAR-T cells are administered at one of 4 dose levels (DL): DL1: $3.3x10^5$, DL2: $1x10^6$, DL3: $3.3x10^6$, DL4: $1x10^7$ CAR T cells/kg. CAR-T is infused in the outpatient setting except for the first pt of each dose cohort (overnight observation). Pts with relapsed $CD20^+$ B-cell malignancies are eligible, including but not limited to DLBCL, follicular lymphoma (FL), MCL and CLL. Prior treatment with CD19 CAR-T is permitted. Treatment response is assessed on day 28. CRS and ICANS are graded per ASTCT consensus grading.
Results: The study underwent a major cell manufacturing modification after treating 7 pts with no objective responses as previously reported (Shadman, ASH 2020). This abstract includes pts who were treated under the modified process. Since December 2019, 12 pts (9 FL, 2 MCL, 1 CLL) were treated after LD with Cy-Flu. All DLs have been reached: DL0 (1 FL), DL1 (2 FL), DL2 (2 FL and 2 MCL), DL3 (3 FL, 1 CLL) and DL4 (1 FL), with no dose-liming toxicities. CRS occurred in 3 pts (25%): 2 pts with grade (Gr) 1 and 1 pt with Gr 2. Only 1 pt required tocilizumab and dexamethasone. No ICANS of any grade was observed. One pt developed Gr 3 neuropathic pain which, in the absence of other explanation, was attributed to the CAR-T. No pts had tumor lysis syndrome or Gr 3-4 infection. Clinical responses were observed at all dose levels. Overall response rate (ORR) was 92% (11/12) with a complete response (CR) rate of 58% (7/12). In FL pts (n=9), ORR and CR were 89% (8/9) and 67% (6/9), respectively. The CLL pt had a PET-negative CR and undetectable measurable residual disease in peripheral blood and bone marrow by flow cytometry (10^{-4}) (uMRD4) on day 28. Among pts who received DL3 (n=4) and DL4 (n=1), CR rate was 100% (5/5). All 7 pts who achieved a CR remain in remission at a median follow-up of 4 months (range 0 – 13 months). CAR-T expansion was robust, with median peak blood levels of CAR^+ T cells of 122 CAR^+ cells/µl (range 0.27-2024), corresponding to 19% (range 0.15 - 65%) of all $CD3^+$ cells.
Summary/Conclusion: The absence of significant toxicity at all dose levels, including no grade 3-4 CRS and no ICANS of any grade, suggests a highly favorable safety profile of MB-106 when compared to commercially available CAR-T cells targeting CD19. Treatment with MB-106 has also resulted in high ORR and CR rates with ongoing remissions in all patients who achieved a CR. Enrollment is currently ongoing and the data will be updated at the time of presentation.



EP733 CTX001 FOR TRANSFUSION-DEPENDENT B-THALASSEMIA: SAFETY AND EFFICACY RESULTS FROM THE ONGOING CLIMB THAL-111 STUDY OF AUTOLOGOUS CRISPR-CAS9-MODIFIED CD34+ HEMATOPOIETIC STEM AND PROGENITOR CELLS

F. Locatelli [1,*], S. Ailinca-Luchian [2], Y. Bobruff [2], M. D. Cappellini [3], S. Corbacioglu [4], J. Domm [5], J. Foell [4], J. de la Fuente [6], R. Handgretinger [7], T. W. Ho [2], W. [1]Ospedale Pediatrico Bambino Gesù Rome, Sapienza, University of Rome, Rome, Italy, [2]CRISPR Therapeutics, Cambridge, United States, [3]University of Milan, Milan, Italy, [4]University of Regensburg, Regensburg, Germany, [5]Sarah Cannon Center for Blood Cancer at The Children's Hospital at TriStar Centennial, Nashville, United States, [6]Imperial College Healthcare NHS Trust, St Mary's Hospital, London, United Kingdom, [7]Children's University Hospital, University of Tübingen, Tübingen, Germany, [8]Vertex Pharmaceuticals Incorporated, Boston, United States, [9]University of Athens, Athens, Greece, [10]BC Children's Hospital, University of British Columbia, Vancouver, Canada, [11]Joan and Sanford I Weill Medical College of Cornell University, New York, United States, [12]The Hospital for Sick Children/University of Toronto, Toronto, Canada

Background: Elevated levels of fetal hemoglobin (HbF) are associated with improved clinical outcomes in patients (pts) with transfusion-dependent β-thalassemia (TDT). CTX001™ is a novel cell therapy that uses non-viral, ex vivo CRISPR-Cas9 gene editing in autologous hematopoietic stem and progenitor cells (HSPCs) at the erythroid enhancer region of the *BCL11A* gene to reduce expression of BCL11A, a repressor of γ-globin, and reactivate HbF production. Early data from pts with TDT infused with CTX001 showed increased levels of total hemoglobin (Hb), HbF, and F-cell pancellularity over time. All pts ceased packed red blood cell (pRBC) transfusions within 2 months (mo) after CTX001 infusion and remained transfusion-free through the reported period. The safety profile was generally consistent with myeloablative conditioning.
Aims: Here, we present additional patient data and follow-up (f/u) from an interim data cut on 21 January 2021. Included in the data set are all pts with TDT enrolled in the CLIMB THAL-111 trial (NCT03655678) infused with CTX001 who had ≥3 mo of f/u available at the time of analysis (N=10).
Methods: Pts (aged 12 to 35 years) with TDT receiving pRBC transfusions of ≥100 mL/kg/year or ≥10 units/year over the previous 2 years were eligible. After mobilization with G-CSF (filgrastim) and plerixafor, peripheral $CD34^+$ HSPCs were collected by apheresis and edited using a specific single-guide RNA and Cas9 nuclease. Prior to CTX001 infusion on Day 1, pts received myeloablation with busulfan. Pts were monitored for stem cell engraftment and hematopoietic recovery, adverse events (AEs), total Hb and HbF production, percentage of F-cells, and pRBC transfusion requirements during f/u.
Results: Mean duration of f/u was 9.8 mo (range: 4.3–23.8). Four of 10 pts had genotypes associated with more severe disease: β0/β0, n=1; [IVS-I-110]/β0, n=2; and β+[IVS-I-110]/β+[IVS-I-110], n=1. At baseline, pts had mean (SD) total Hb and HbF levels of 10.6 (2.2) g/dL and 0.2 (0.2) g/dL, respectively, and had received a mean of 14.7 pRBC transfusions annually. Following CTX001 infusion, median neutrophil engraftment occurred on Day 30 (range: 19–39) and median platelet engraftment occurred on Day 38.5 (range: 29–52).
All 10 pts reported AEs; most were mild or moderate in severity and the post-CTX001 safety profile was generally consistent with busulfan myeloablation. As previously reported, 1 patient had 4 serious AEs (SAEs) that the principal investigator considered related or possibly related to CTX001: headache, hemophagocytic lymphohistiocytosis (HLH), acute respiratory distress syndrome, and idiopathic pneumonia syndrome, all in the context of HLH and all of which have resolved. No other pts had a CTX001-related SAE.
All pts demonstrated increases in total Hb and HbF (Figure), and F-cell pancellularity over time. Pts stopped pRBC transfusions within 2 mo after CTX001 infusion and were transfusion-free at the time of this analysis (up to 23.8 mo total f/u).

Figure. Mean Hb fractionation and total Hb in patients with TDT (N=10)

Hb, hemoglobin; HbA, adult hemoglobin; HbF, fetal hemoglobin; TDT, transfusion-dependent β-thalassemia
Mean HbF (g/dL) is indicated within the light blue bars and mean total Hb (g/dL) is shown above each bar
Number of patients (N) with data available at each time point is noted
*Hb adducts and other variants

Summary/Conclusion: The updated data reported here confirm previous reports showing CTX001 infusion increases total Hb and HbF with F-cell pancellularity in pts with TDT, and demonstrate the durability of this effect for up to 23.8 mo f/u. All 10 pts were transfusion-free within 2 mo after CTX001 infusion through the time of this analysis. The safety profile of CTX001 remained generally consistent with myeloablative conditioning and autologous hematopoietic stem cell transplantation. These results strongly support continued investigation of CTX001 as a potential functional cure for pts with TDT.
Submitted on behalf of the CLIMB THAL-111 Investigators.

EP734 FACTORS ASSOCIATED WITH PROGRESSION-FREE SURVIVAL (PFS) OF ADULT AND PEDIATRIC PATIENTS WITH RELAPSED / REFRACTORY B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH ARI-0001 CART19 THERAPY.

V. Ortiz Maldonado [1,*], S. Rives [2], A. Alonso-Saladrigues [2], M. Español-Rego [3], M. Montoro-Lorite [1], M. Castella [4], D. Benitez-Ribas [3], L. Magnano [1], E. Gine [1], M. Diaz-Beya [1], L. [1]Hematology, Hospital Clínic de Barcelona, [2]Hematology, Hospital Sant Joan de Deu, [3]Immunology, Hospital Clínic de Barcelona, [4]Banc de Sang iTeixits, [5]Apheresis Unit, Hospital Clínic de Barcelona, [6]Apheresis Unit, Banc de Sang iTeixits, [7]Medical Intensive Care Unit, Hospital Clínic de Barcelona, [8]Intensive Care Unit, Hospital Sant Joan de Deu, [9]Immunotherapy Platform Clínic-Sant Joan de Déu, Barcelona, Spain

Background: Prognosis of relapsed/refractory (R/R) B-cell acute lymphoid leukemia (ALL) is poor, particularly in patients relapsing after allogeneic hematopoietic cell transplantation (alloHCT). In this setting, several chimeric antigen receptor products targeting CD19 have been capable of achieving complete response (CR) rates of 70 to 85%. Nevertheless, a significant proportion of patients relapse despite having achieved a minimal residual disease (MRD) negative CR.
Aims: To identify factors associated with progression-free survival (PFS) in patients with R/R B-ALL treated with ARI-0001 (Academic CART19 cells).
Methods: We report the outcome of all patients with R/R B-ALL consecutively treated with ARI-0001 cells in two centers (adult and pediatric) from Jul 2017 to Dec 2020, including patients treated in the CART19-BE-01 trial and the consecutive compassionate use program. All patients signed informed consent and all protocols were approved by the Ethics Committees and the Spanish Medicines Agency. Lymphodepletion was performed with fludarabine (90 mg/m2) and cyclophosphamide (900 mg/m2), followed by the infusion of 0.1-5 x10^6 ARI-0001 cells/kg in a single or fractionated manner. We analyzed the impact on PFS of the following variables: age (+/- 18 yr and +/- 25 yr), prior treatment lines (+/- 4), prior immunotherapy (blinatumomab and inotuzumab), prior alloHCT, tumor burden (+/- 5% blasts at bone marrow), type of dosage (single vs fractionated dosing), and loss of B-cell aplasia (BCA). The statistical analysis was performed using Kaplan Meier / log rank test for all variables except for B-cell aplasia, which was introduced as a time-dependent covariate in a Cox regression.
Results: A total of 53 patients with R/R B-ALL received ARI-0001 cells. Median age at infusion was 30 years (3-68), including 10 pediatric patients (19%), and 55% were men. Patients had a median of 4 prior treatment lines (2-8), including blinatumomab 23% (12/53), inotuzumab 53% (28/53) and alloHCT 79% (42/53). All patients received lymphodepletion before receiving ARI-0001 cells. Treatment was fractionated in 72% of patients. The median PFS for the entire series was 13.5 months (95% CI: 7.14-not available), with a median follow-up for survivors of 19 months (range: 2-40 months). PFS at 12 and 24 months was 50.9% (95% CI: 38.4-67.4%) and 32.9% (95% CI: 20.6-52.6%), respectively. The median overall-survival (OS) for the entire series was 29.2 months (95% CI: 15-not available). OS at 12 and 24 months was 70.2% (95% CI: 58.1-84.8%) and 53.9% (95% CI: 40.5-71.8%), respectively. By univariate analysis, only two variables had an impact on PFS (table 1): tumor burden (+/- 5% of blasts at screening), with a PFS at 24 months of 52.5% (36.4-75.7%) vs. 10.7% (2.1-54.4%) and a hazard ratio (HR) of 2.14 (95% 1.04-4.42) for patients with 5% or more blasts at screening (p = 0.0386). On the other hand, loss of BCA had a HR of 4.41 (95% CI: 1.59-12.2), p = 0.0043. Both variables (tumor burden and loss of BCA) were also confirmed in the multivariate model, with a HR of 2.05 (1.004-4.17) for patients with 5% or more blasts at screening (p = 0.0484) and a HR of 4.32 (1.57-11.86) for patients with loss of BCA (p = 0.0045).

Factors associated with PFS	
Tumor burden	
PFS at 24 months <5% blasts	52.5% (36.4-75.7%)
PFS at 24 months ≥5% blasts	10.7% (2.1-54.4%)
Univariate Hazard ratio (≥5% blasts)	2.14 (95% CI: 1.04-4.42) (p = 0.0386)
Multivariate Hazard ratio (≥5% blasts)	2.05 (95% CI: 1.004-4.17) (p = 0.0484)
Loss of absolute B-cell aplasia	
Univariate Hazard ratio	4.41 (95% CI: 1.59-12.2) (p = 0.0043)
Multivariate Hazard ratio	4.32 (95% CI: 1.57-11.86) (p = 0.0045)

Summary/Conclusion: ARI-0001 therapy was able to achieve long term remissions in this population of R/R B-ALL patients across all patient subgroups. Nevertheless, patients referred for ARI-0001 cell therapy with 5% or more of bone marrow blasts and those who lost B-cell aplasia after ARI-0001 cell therapy had a shorter PFS.

EP736 CTX001 FOR SICKLE CELL DISEASE: SAFETY AND EFFICACY RESULTS FROM THE ONGOING CLIMB SCD-121 STUDY OF AUTOLOGOUS CRISPR-CAS9-MODIFIED CD34+ HEMATOPOIETIC STEM AND PROGENITOR CELLS

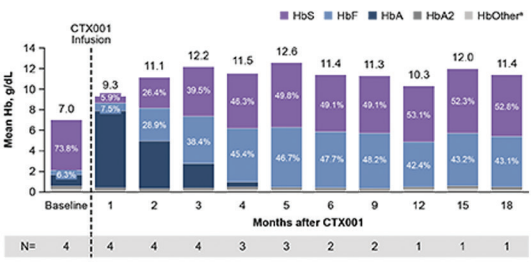
S. Grupp [1,*], N. Bloberger [2], C. Campbell [3], C. Carroll [4], J. S. Hankins [5], T. W. Ho [2], W. Hobbs [3], S. Imren [3], Y. Lu [3], M. Mapara [6], M. de Montalembert [7], L. Moritz [3], D. Rondelli [8], N. Shanbhag [3], A. Sharma [5], P. Sripakdeevong [2], M. H. Steinberg [9], H. Frangoul [4]

[1]Children's Hospital of Philadelphia, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, [2]CRISPR Therapeutics, Cambridge, [3]Vertex Pharmaceuticals Incorporated, Boston, [4]Sarah Cannon Center for Blood Cancer at The Children's Hospital at TriStar Centennial, Nashville, [5]St. Jude Children's Research Hospital, Memphis, [6]Columbia University, New York, United States, [7]Necker-Enfants Malades Hospital, Assistance Publique-Hôpitaux de Paris (AP-HP), University of Paris, Paris, France, [8]University of Illinois at Chicago, Chicago, [9]Boston University School of Medicine, Boston, United States

Background: Elevated levels of fetal hemoglobin (HbF) are associated with improved clinical outcomes in patients with sickle cell disease (SCD). CTX001™ is a novel cell therapy that uses non-viral, ex vivo CRISPR-Cas9 gene editing in autologous hematopoietic stem and progenitor cells at the erythroid enhancer region of the *BCL11A* gene to reduce expression of BCL11A, a repressor of γ-globin, and reactivate HbF production. Early data from patients with SCD infused with CTX001 showed increased levels of total hemoglobin (Hb), HbF, and

F-cell pancellularity over time. No vaso-occlusive crises (VOCs) were reported for any patient after CTX001 infusion. The safety profile was generally consistent with myeloablative conditioning.

Aims: Here, we present additional patient data and follow-up from an interim data cut on 28 January 2021. Included in the data set are all patients with SCD enrolled in the CLIMB SCD-121 trial (NCT03745287) infused with CTX001 who had at least 3 months of follow-up available at the time of analysis (N=4).



Methods: Patients (aged 12 to 35 years) with severe SCD, defined as ≥2 VOCs/year requiring medical care over the previous 2 years, were eligible. After mobilization with plerixafor, peripheral CD34+ hematopoietic stem and progenitor cells were collected by apheresis and edited using a specific single-guide RNA and Cas9 nuclease. Prior to CTX001 infusion on Day 1, patients received myeloablation with busulfan. Patients were monitored for stem cell engraftment and hematopoietic recovery, adverse events, total Hb and HbF production, hemolysis, percentage of F-cells, and VOCs during follow-up.

Results: Mean duration of follow-up was 10.1 months (range: 4.3 to 19.2). At baseline, patients had mean (SD) total Hb of 7.0 (1.6) g/dL and mean (SD) HbF of 6.3% (2.2%) of total Hb. Patients had a mean of 5.3 severe VOCs annually in the previous 2 years. Following CTX001 infusion, median neutrophil engraftment occurred on Day 25.5 (range: 17 to 30) and median platelet engraftment occurred on Day 31.5 (range: 30 to 40).

All 4 patients reported adverse events; most were mild or moderate in severity and the post-CTX001 safety profile was generally consistent with busulfan myeloablation. No serious adverse events considered by the principal investigator to be related or possibly related to CTX001 were reported.

All patients demonstrated increases in total Hb and HbF (Figure), as well as F-cell pancellularity over time. Mean %HbF rose to >30% by month 3 and all patients had %HbF >30% as of the last visit before data cut. No patients experienced VOCs during the time of this analysis (up to 19.2 months). Markers of hemolysis, including haptoglobin, lactate dehydrogenase, and total bilirubin, improved in all patients and normalized by month 6.

Figure. Mean Hb fractionation and total Hb in patients with SCD (N=4)

Hb, hemoglobin; HbA, adult hemoglobin; HbF, fetal hemoglobin; HbS, sickle hemoglobin; SCD, sickle cell disease
Mean %HbF and %HbS of total mean Hb at each visit is indicated within the bars and mean total Hb (g/dL) is shown above each bar
Number of patients (N) with data available at each time point is noted
*Hb adducts and other variants

Summary/Conclusion: The updated data presented here confirm previous reports showing CTX001 infusion increases total Hb and %HbF with F-cell pancellularity in patients with SCD, and demonstrate the durability of efficacy up to 19.2 months of follow-up. All 4 patients were free of VOCs from CTX001 infusion through the time of this analysis. The safety profile of CTX001 remained generally consistent with myeloablative conditioning and autologous hematopoietic stem cell transplantation. These results strongly support continued investigation of CTX001 as a potential functional cure for patients with SCD.

Submitted on behalf of the CLIMB SCD-121 Investigators.

EP737 REAL-WORLD TREATMENT WITH CAR T-CELL THERAPY OF UNITED STATES (US) PATIENTS WITH LARGE B CELL LYMPHOMA (LBCL)

A. Klink [1,*], K. Savill [1], D. Liassou [1], D. Chopra [1], J. Laney [1], A. Gajra [1]

[1]*Cardinal Health, Dublin, United States*

Background: The advent of chimeric antigen receptor (CAR) T-cell therapy has represented one of the most innovative therapeutic advances in oncology in recent years. Impressive clinical responses to CAR T-cell therapy observed in patients with relapsed and refractory B-cell lymphoid malignancies have led to the Food and Drug Administration (FDA) approval of four CAR T-cell therapies in the US since 2017. Axicabtagene ciloleucel (axi-cel) and tisagenlecleucel (tisa-cel) have now been on the US market for the treatment of patients with LBCL since 2017 and 2018, respectively, hence allowing for assessment of their use in real-world clinical practice.

Aims: This real-world claims-based study aimed to describe characteristics and treatment outcomes of patients with DLBCL treated with the CAR T-cell therapies tisa-cel or axi-cel.

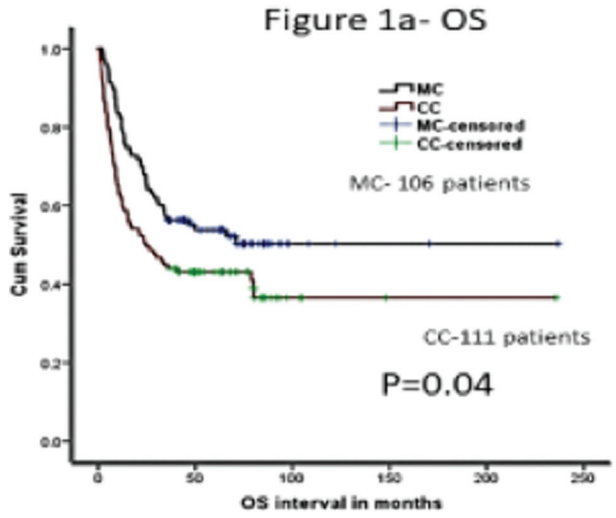
Methods: Patients with at least 1 claim for tisa-cel or axi-cel and a diagnosis code of DLBCL were identified from the Symphony Integrated Dataverse (IDV), a large US claims database containing linked longitudinal prescription, medical, and hospital claims. The IDV contains claims for 280 million active unique patients representing over 73% of specialty prescriptions, 58% of medical claims, and 30% of hospital claims volume in the US. Patient characteristics and treatment patterns were summarized using descriptive statistics.

Results: Among a total of 93 patients with DLBCL identified in this study, 58% (n=54) received axi-cel and 42% (n=39) received tisa-cel. The majority (n=60, 65%) of patients were male, and the median age at time of tisa-cel or axi-cel was 64 years (range, 20-78 years). Commercial insurance was the primary payer at the time of tisa-cel or axi-cel therapy for most patients with DLBCL included in the study (n=77, 83%). Patients with DLBCL treated with tisa-cel or axi-cel were distributed across each of the 4 US census regions. The majority (n=55, 59%) of patients received tisa-cel or axi-cel in the outpatient setting. Tisa-cel or axi-cel was received a median of 12.9 months following patients' initial diagnosis of DLBCL. Less than half (n=42, 45%) of patients received 2 or more lines of systemic therapy prior to tisa-cel or axi-cel and 17% (n=16) received systemic therapy after tisa-cel or axi-cel during a median follow-up period of 6.3 months.

Summary/Conclusion: In the first few years of market availability in the US, the CAR T therapies tisa-cel or axi-cel have been used to treat patients with LBCL outside of the clinical trial setting mostly in the outpatient setting. Findings from this real-world study suggest that patients may be receiving tisa-cel or axi-cel prior to the failure of prior lines of therapy. Despite short follow up, one in 6 patients appear to have relapsed disease based on need for additional systemic therapy. Updated follow-up and outcomes will be presented at time of congress. Further research is warranted to understand real-world clinical outcomes among patients treated with CAR T therapy outside the trial setting.

EP738 T CELL LINEAGE MIXED CHIMERISM IN ACUTE LEUKAEMIA/MDS- IS IT PROGNOSTIC - A SINGLE CENTRE RETROSPECTIVE STUDY

V. Sheth [1,*], V. Potter [2], H. Delavallade [2], S. Gandhi [2], A. Kulasekararaj [2], P. Krishnamurthy [2], V. Mehra [2], F. Dazzi [3], G. Mufti [2], A. Pagliuca [2], D. Mclornan [4], K. Raj [4]



[1]*Fred Hutchinson Cancer Research Center, Seattle, United States,* [2]*Kings College hospital, London, United Kingdom,* [3]*Kings College Hospital, Kings College Hospital,* [4]*Guys and St Thomas, London, United Kingdom*

Background: T-cell depletion, especially alemtuzumab, reduces the risk of graft-versus-host disease (GVHD) following allogeneic hematopoietic stem cell transplantation (HSCT) using unrelated donor peripheral stem cell graft (PBSC-matched/mismatched), but has been associated with an increased frequency of mixed t cell chimerism (MC) and subsequent relapse. In adult patients receiving alemtuzumab and having MC (T cell), early pre-emptive donor lymphocyte infusion (pDLI) has been safe and effective in reducing relapses, without increasing risk of graft vs host disease (GVHD). Among responders in paediatric cohort having lineage specific MC(CD34/33), pDLI could achieve outcomes nearly similar to patients having complete chimerism (CC). However, many patients having MC actually fail to receive timely pDLI, and their outcomes remain particularly dismal, which is not considered. Thus, we compared long term outcomes of patients with T cell MC (including patients not receiving pDLI) to patients having complete chimerism CC

Aims: Thus, we compared long term outcomes of patients with T cell MC (including patients not receiving pDLI) to patients having complete chimerism CC for overall survival, disease free survival and other outcomes

Methods: One-hundred six adult patients with CD3 MC after day 60, in patients undergoing HSCT for acute leukaemia/myelodysplastic syndrome (MDS) from an unrelated donor (UD), using alemtuzumab and predominantly PBSC grafts, between 2007-2016, were compared with 111 patients having CC. CD33 chimerism was >98%. In patients with

MC intention was to start pDLI (by day 100) after rapid withdrawal of immunosuppressants (chimerism <50%).
Results: Both groups were comparable for age, mismatches, graft source, and disease risk. MC group had more patients receiving reduced intensity (RIC) regimen (62% vs 52% in CC, p=0.15). The median follow-up was 33 (0.6-150 months). Fifty- three (56%) patients received pDLI. The median dose of pDLI was 1 x10^6/kg and median time to pDLI was 5 months from transplantation. Out of 56 patients, 36 patients (67%) had a response (RR) (85% achieving CC) and 17 (33%) patients had no response (NR). Fifty patients (44%) did not receive any pDLI (ND). pDLI was well tolerated with no difference in GVHD (p=0.65), infections (p=0.37) or NRM (P=0.37) between pDLI and ND. Overall survival (OS) was significantly better in MC group as compared to CC (52.4% vs 42%, p=0.04), mainly due to reduction in non- relapse mortality NRM (14% vs 26%, p=0.05) and all grade acute and chronic GVHD (38% vs 68%, p=0.001, and 37% vs 51%, p=0.025). Relapses and disease-free survival were comparable between the two groups (32% vs 38%, p=0.99 and 38.5% vs 45%, p=0.12, for CC and MC, respectively). After multivariate analysis, MC still had significantly better OS (p=0.02, HR-1.53, CI-1.0-2.2) and NRM (p=0.02, HR-2.44, CI-1.3-5.2, ref MC). Within MC group, response to pDLI was the only significant factor predicting OS, DFS and relapses with NR and ND having unfavourable outcomes as compared to RR (p=0.0001, HR=5.45, and p=0.001, HR-5.95, respectively).

Summary/Conclusion: In this large single centre study, we have shown that T cell MC in patients undergoing UD allografts with alemtuzumab is no longer an adverse prognostic factor, with timely initiation of pre-emptive pDLI, and their OS is in fact better than CC, mainly due to reduction in NRM and early onset aggressive GVHD. This strategy is safe and well tolerated. Response to pDLI is the main independent predictor of overall outcomes in patients with MC.

EP739 OBJECTIVE RESPONSE AT LOW DOSE IN THE FIRST-IN-HUMAN IMMUNICY-1 TRIAL EVALUATING NON-GENE EDITED ALLOGENEIC CYAD-211 ANTI-BCMA CAR-T PRODUCT IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA

S. Anguille [1,*], A. S. Al-Homsi [2], D. Deeren [3], T. Nishihori [4], N. Meuleman [5], M. Abdul-Hay [2], G. Morgan [2], J. Brayer [4], N. Braun [6], C. Lonez [6], E. Breman [6], M.-S. Dheur [6], E. Alcantar-Orozco [6], D. E. Gilham [6], A. Flament [7], F. F. Lehmann [6]

[1]University Hospital Antwerp (UZ Antwerp), Antwerp, Belgium, [2]New York University Langone Health, New York, United States, [3]AZ Delta, Roeselare, Belgium, [4]H. Lee Moffitt Cancer Center, Tampa, United States, [5]Institut Jules Bordet, Université Libre de Bruxelles (ULB), Brussels, [6]Celyad Oncology, Mont-Saint-Guibert, Belgium, [7]Celyad Oncology, Mont-Saint-Guibert, United States

CYAD-211 is administered after a non-myeloablative preconditioning chemotherapy consisting of cyclophosphamide (300mg/m^2/day) and fludarabine (30mg/m^2/day) for 3 days. Three CYAD-211 dose-levels (DLs; 30, 100 and 300x10^6 cells per infusion), are evaluated, according to a 3+3 design. The lowest DL was implemented as a safety-run for this first-in-human trial.

Background: Autologous chimeric antigen receptor (CAR) T-cells targeting B-cell maturation antigen (BCMA) have shown impressive objective response rates in patients with advanced multiple myeloma (MM).
CYAD-211 is a first-in-class, non-gene edited allogeneic anti-BCMA CAR T-cell product that uses an "all-in-one" vector approach to co-express, in addition to the CAR, a single optimized short hairpin RNA (shRNA) to down-regulate the expression of the T-cell receptor (TCR) CD3ζ subunit thus reducing the risk of graft-versus-host disease (GvHD). This non-gene editing technology does not permanently alter the genome integrity, therefore decreasing the potential safety risk associated with "off-target" genome modifications. Preclinical experiments demonstrated that persistence of allogeneic T-cells produced with shRNA technology is superior to cells engineered with gene-editing technologies.
Aims: The objective of the open-label Phase I IMMUNICY-1 (NCT04613557) trial is to evaluate the safety and clinical activity of a single infusion of CYAD-211 in relapsed or refractory MM patients.
Methods: A bank of clinical- grade CYAD-211 cells was generated through a single production run using a portion of a single donor apheresis. The bank generated >10^{10} CYAD-211 cells suitable for the entire dose escalation segment and expansion cohort of the trial.
Patients with relapsed or refractory MM with measurable disease as per the International Myeloma Working Group (IMWG) response criteria are eligible for the trial.
Results: As of the data cutoff of February 24, 2021, enrollment in the DL1 was completed (Table). Clinical activity evaluation was performed on Day (D) 22 and D36 for the first two patients with one confirmed partial response (PR) and one stable disease (SD). No dose-limiting toxicity nor Grade ≥ 3 treatment-related adverse events (AE) were reported. No immune effector cell-associated neurotoxicity syndrome (ICANS) nor GvHD were observed. One cytokine release syndrome (CRS) grade 1 was observed in the patient presenting the PR. CYAD-211 cells were detected by PCR-based method in the peripheral blood of the PR patient.

Clinical data from patients at DL1 as of 25-Feb-2021

Characteristics	Patient 1	Patient 2	Patient 3
Age (years)	57	72	78
Gender	M	F	M
ECOG PS	0	0	1
MM subtype	λ light chain	IgG, λ light chain	IgG, λ light chain
Time since diagnosis (years)	7	7.5	6.4
R-ISS Stage at diagnosis	I	II	II
mSMART risk	Standard	Intermediate	-
Extramedullary disease	N	N	N
Bone marrow plasma cells (%)	15	65	5
Prior lines of therapy (number)	4	4	2
Prior autologous transplant	Y	Y	N
AE of clinical interest			
CRS	Grade 1 (fever)	-	-
ICANS	-	-	-
GvHD	-	-	-
Infection	-	-	-
Best response	**PR**	**SD**	***Not available yet***

ECOG PS: Eastern Cooperative Oncology Group performance status; F: Female; Ig: Immunoglobulin; M: Male; mSMART: Mayo Stratification of Myeloma and Risk-Adapted Therapy; N: No; R-ISS: Revised International Staging System; Y: Yes

Summary/Conclusion: The IMMUNICY-1 clinical trial seeks to provide the proof-of-principle that single shRNA-mediated knockdown can generate safe and functional allogeneic CAR T-cells in humans. The observed clinical activity at such low DL of 30x10^6 cells is encouraging in the allogeneic setting. Clinical and cell kinetics data from the completed first DLs will be presented at the time of the congress.The early stages of this trial continue to support the development of allogeneic CAR T-cell therapy as a feasible approach that may overcome many of the hurdles associated with autologous CAR-T cells.

EP740 PRELIMINARY ANALYSIS OF A PHASE 1 STUDY OF NEXI-002 AUTOLOGOUS MULTI-AGENT-SPECIFIC CD8+ T CELLS FOR THE TREATMENT OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RRMM)

A. Kin [1,*], M. M. Htut [2], J. C. Varela [3], V. Edavana [4], S. Kim [4], L. Suarez [4], M. Oelke [5], D. Bednarik [4], R. D. Knight [6], M. M. Al Malki [2]

[1]Division of Oncology, Karmanos Center/Wayne State Universityte, Detroit, MI, [2]Hematology/Hematopoietic Cell Transplant, City of Hope National Medical Center,

Duarte, CA, [3]Marrow Transplant Program, Advent Health Blood and Marrow Program, Orlando, FL, [4]Pre-clinical Research, Neximmune, Inc, Gaithersburg, MD, United States, [5]Pre-clinical Research, Neximmune, Inc, Gaithersburg, MD, United Kingdom, [6]Clinical Research, Neximmune, Inc, Gaithersburg, MD, United States

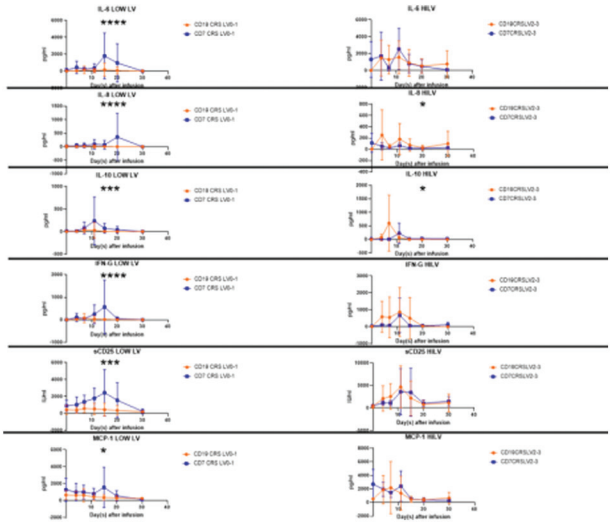
Background: MM is an incurable malignancy that occurs predominately in older patients and is characterized by the growth of malignant plasma cells in the bone marrow. The median age of patients at diagnosis is 69 years and MM accounts for approximately 17% of all hematologic cancers. Despite substantial advances in therapy, virtually all patients relapse, emphasizing the need for additional effective treatments.
Aims: To characterize the safety and preliminary efficacy of NEXI-002, an HLA-restricted adoptive non-genetically modified and autologous cell product. The NEXI-002 product contains CD8+ T-cell memory subtypes that combine tumor potency with the potential for long-term immune persistence.
Methods: First-In-Human open-label phase 1/2 clinical trial. Safety, activity and correlative exploratory endpoints are evaluated and followed in patients during the study. HLA 02:01 patients underwent leukapheresis and artificial antigen presenting cells (aAPCs) were employed to isolate and expand CD8+ T-cell clonotypes expressing T cell receptors specific for HLA-restricted peptides from the WT1, CD138, CS1, and NY-ESO antigens. After expansion, the NEXI-002 product consists of γδ and CD8+ lymphocytes that are infused into the patient.
Results: Three patients were treated with single infusions of 80 to 100 million cells of NEXI-002 following lymphodepleting chemotherapy (fludarabine 30 mg/m^2 and cyclophosphamide 300 mg/m^2 on Days -5 to -3). All three patients have completed the dose-limiting toxicity (DLT) period. No cytokine release syndrome, neurotoxicity, infusion-related reaction, or other NEXI-002-related serious adverse events were observed. At the time of analysis, correlative studies demonstrate the NEXI-002 product is comprised mostly of CD8+ antigen-specific T cells that include stem-like central memory, central memory, and effector T cells. The infused CD8+ antigen-specific T cells were detectable by multimer staining in peripheral blood and the product phenotype was maintained over time. Flow cytometry studies of cells stained for antigen specificity determined that infused NEXI-002 cells contain T cell clones that were undetectable in the peripheral blood of patients at baseline but were detected in blood and persist over the current 3-4 weeks of follow-up. A robust lymphocyte recovery occurred quickly after the infusion of NEXI-002, demonstrating CD3 (CD4/CD8) reconstitution following lymphodepletion chemotherapy.
Summary/Conclusion: Early results indicate that NEXI-002 infusion is safe and well tolerated and is capable of proliferation and persistence within peripheral blood. NEXI-002 may have the potential to provide clinical benefit for patients with RRMM. Due to these encouraging findings, the trial will be expanded to gain greater safety and activity experience with NEXI-002. Updated data will be available.

EP741 A 10 YEAR RETROSPECTIVE SERIES OF PERIPHERAL BLOOD STEM AND PROGENITOR CELL COLLECTION IN PEDIATRIC CANDIDATES FOR AUTOLOGOUS EX-VIVO GENE THERAPY

Cicalese [2,3], M. E. Bernardo [1,2,3], A. Aiuti [1,2,3]

[1]Vita-Salute San Raffaele University, [2]San Raffaele Telethon Institute for Gene Therapy (SR-Tiget), [3]Pediatric Immunohematology Unit and BMT Program, [4]Immunohematology and Transfusion Medicine Unit, [5]Hematology and Bone Marrow Transplantation Unit, IRCCS San Raffaele Scientific Institute, [6]AGC Biologics S.p.A., Milan, [7]Immunohematology and Transfusion Medicine Service, Fondazione IRCCS Policlinico S. Matteo, Pavia, [8]Department of Anesthesia and Critical Care, IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: Collection targets for autologous hematopoietic stem and progenitor cell (HSPC) gene therapy (GT) should ideally account for the cell manipulation process and for unmanipulated backup storage. Therefore higher amounts of HSPCs in comparison to conventional autologous and allogenic HSPC transplantation harvests are required.
While pediatric donors have historically undergone bone marrow (BM) harvest, HSPC mobilization and apheresis may be safer and more suitable for the purpose of autologous GT.
Aims: To analyze the safety and collection yields of peripheral blood stem and progenitor cells (PBSCs) collection in pediatric candidates for GT.
Methods: We retrospectively analyzed the mobilization and apheresis procedures of all consecutive pediatric (<18 years) patients treated at IRCCS Ospedale San Raffaele (OSR) between April 1st 2010 and March 31st 2020, candidate to GT for for adenosine deaminase deficiency (ADA-SCID), b-thalassemia, metachromatic leukodystrophy (MLD), mucopolysaccharidosis 1 Hurler (MPSIH), or Wiskott-Aldrich syndrome (WAS).
Results: We included 45 consecutive patients (ADA-SCID = 4, b-thalassemia = 7, MLD = 10, MPSIH = 8, WAS = 16), who underwent mobilization with lenograstim, with (n=41) or without (n = 4) plerixafor, and 1-3 cycles of leukapheresis. Median weight was 15.8 kg (range 7-54.1); median age was 3.7 years (0.4-14.4). Forty patients were enrolled upfront to mobilization and leukapheresis, for collection of both the drug product (DP) starting material and an unmanipulated backup, while five for potential or actual limitations of BM harvest. HSPCs were used as a starting material for the manufacture of the DP (n = 2), cryopreserved for backup (n = 2), or both (n = 41). We recorded 108 adverse events within 14 days following the last apheresis, mostly of grade 1-2 (87%).
Minimum collection targets were usually 7-13 x10^6 CD34$^+$/kg. Overall, patients collected a median of 37.0 x10^6 CD34$^+$ cells/kg (range of 3.3-63.8 x10^6); male gender, underlying disease (b-thalassemia) and lower drug dose were found to be positive predictors of yield. Only three patients among those that underwent mobilization upfront (n = 40) required an additional HSPC collection.
42/43 backups were >2 x 10^6 CD34+ cells/kg; 41/42 patients received a drug product dose in the reference infusion range (from 4 to 30.9 x10^6 CD34+ cells/kg), and all patients that received the drug product engrafted.
As compared to our historical cohort of BM harvests, mobilization and leukapheresis allowed the collection of a higher number of cells in a short period of time. Shorter duration of anesthesia – required to place a central venous catheter – lower fluctuations in intravascular volume and reduced pain are additional advantages of PBSC collection.
Summary/Conclusion: Mobilization and leukapheresis allow the collection of a large number of HSPCs, even in pediatric donors of low weight, with a favorable safety profile, satisfying GT requirements. Beyond GT, the collection of large number of HSPCs by mobilization and leukapheresis may overcome significant weight discrepancies between a pediatric donor and a familial HSCT recipient, and prospectively allow to implement HSPC selection strategies.



EP742 DIFFERENCES IN SERUM CYTOKINE LEVELS AND PEAK TIMES BETWEEN CD19 AND CD7 CAR-T TREATMENT

D. wang [1,*], L. qiu [1], X. li [1], X. xu [1], L. cui [1], S. fu [1], H. Wang [1]

[1]clinical laboratory, Hebei Yanda Ludaopei Hospital, Langfang, China

Background: In the past few years, Chimeric Antigen Recepter T-cell(CAR-T) immunotherapy played as a superstar treating acute lymphocytic leukemia(ALL). CD19 CAR-T has been widely used on refractory or relapse B-ALL patients with exciting outcomes. CD7 has been pointed out as a potential target for treating T-ALL. According to our unpublished data, the manifestation of patients treated with CD7 CAR-T is different from the patients treated with CD19 CAR-T. In this experiment, we tried to figure out the difference between CD19 CAR-T and CD7 CAR-T in serum cytokine levels and peak time for guiding clinical practice.
Aims: To figure out the differences in serum cytokine level and peak time between samples of CD19 CAR-T treated and CD7 CAR-T treated.
Methods: peripheral blood sample were collected from 86 patients treated with CD19 CAR-T and 10 patients treated with CD7 CAR-T. According to CRS severity grading, 79/86 were classified as CD19 CRS low grades (0-2 grade), 7/86 as CD19 CRS high grades (higher than 3 grade), and 7/10 as CD7 CRS low grades, 3/10 as CD7 CRS high grades. 24 cytokines QBplex microbeads kits for cytokine monitoring were bought from Beijing Quantobio Company. Cytokine samples were analyzed by flow cytometry on day0, 4, 7, 11, 15, 20, and 30 after CAR-T infusion. ScFV positive CAR-T cells and T cells percentage and counts were detected at the same time by flow cytometry.
Results: Two group had similar ScFV positive CAR-T cells with median peak percentage 53% in CD7 CAR-T and 57% in CD19 CAR-T group, and median counts in peak time were 1.55X10e8/L in CD7 group and 2X10e8/L in CD19 group. Firstly, most cytokines from patients treated

with CD7 CAR-T were obviously higher than those from the patients with CD19 CAR-T treatment in CRS low grades. Secondly, in CRS high grades, most of the cytokines were secreted and reached a peak value in both of CD7 and CD19 CAR-T group. On the other hand, the peak time was earlier in CD19 group than CD7 group. Many main cytokines reached peak value between day7 and day 10 in CD19 group, and in CD7 group were between day 11 and day 15, even on day 20 in some cases. Besides, in CRS low grades, the expression levels were fairly low in CD19 CAR-T group, but those were much higher in CD7 group. In most cases, there were clinical CRS manifestations corresponding to cytokine levels in CD7 group and none or mild symptoms in CD19 group. In other words, most patients treated with CD7 CAR-T had higher cytokine levels and showed more intense symptoms than patients with CD19 CAR-T, even with CRS low grade. Meanwhile, in many cases, side-effects showed up later in CD7 CAR-T group than that in CD19 CAR-T group which corresponding to later peak time in CD7 group.

Summary/Conclusion: Most cytokine levels were higher in CD7 CAR-T group than CD19 CAR-T cases in CRS low grade, and reached peak time later in CD7 group. Clinical symptoms showed corresponding to cytokine levels in most cases. Although different technique and activated cell number might result these, serum cytokines played an important role in CAR-T therapy and study.

EP743 INTENTION TO TREAT VERSUS MODIFIED INTENTION-TO-TREAT ANALYSIS IN BCMA AND CD-19 CHIMERIC ANTIGEN RECEPTOR TRIALS: A SYSTEMATIC REVIEW AND META-ANALYSIS

G. R. Mohyuddin [1,*], T. Atieh [1], N. Ahmed [1], D. Sborov [2], B. McClune [2], A.-O. Abdallah [1], A. Goodman [3], M. Aziz [4], I. Allen [5], V. Prasad [6]

[1]Kansas University Medical Centre, Fairway, [2]University of Utah, Salt Lake City, [3]University of California San Diego, San Diego, [4]University of Toledo, Toledo, [5]University of California, [6]University of California San Francisco, San Francisco, United States

Background: Chimeric antigen receptor T-cell therapy (CART) has revolutionized the treatment of hematological malignancies but is associated with logistical challenges. Current reporting of trials uses a modified intention-to-treat analysis (mITT) which may over-estimate efficacy and limit external validity.
Aims: We assessed what proportion of CD-19 and BCMA CART trials report the number of patients not receiving CART after being enrolled. We performed a meta-analysis of both the mITT and intention-to-treat (iTT) overall response rate (ORR) for CART.
Methods: Four databases were searched (Web of Science/MEDLINE/PubMed, Embase, and Cochrane Registry of Controlled Trials). All prospective clinical trials of CD-19 and BCMA-targeting CART enrolling two or greater patients from January 1st 2013 to November 1st 2020 were included. PRISMA guidelines were used for abstracting data and assessing the quality and validity of the data. Two independent reviewers verified the data and resolved any conflicts. Data was pooled using random effects model. The primary outcome was the proportion of trials reporting number of patients enrolled and those that actually received CART therapy. Secondary outcomes were calculated for trials that reported on the number of patients that dropped out of the study after enrollment and prior to CART administration. Secondary outcomes included ORR on an intention-to-treat analysis incorporating all enrolled patients.
Results: A total of 28 BCMA CART and 100 CD-19 CART trials were identified. Amongst 28 BCMA CART and 100 CD-19 CART trials, only 10 BCMA and 63 CD-19 trials clearly reported on how many patients were enrolled, and how many actually got CART. For this cohort of trials, the mITT ORR for BCMA CART was 78.0% (95% CI= 67.0-89.0%) and iTT ORR was 70.0% (95% CI=59.0-80.0%). For the CD-19 CART, the mITT and iTT ORR were 80.7% (95% CI= 77.0-84.3%) and 69.6% (95% CI=63.7-75.6%), respectively.
Amongst the 10 BCMA trials reporting on the number of patients enrolled but not receiving CART, a total of 395 patients were enrolled and received CART with results of their efficacy reported. An additional 46 patients did not receive CART after enrolling. For six of these patients, the reason for not receiving CART was rapid disease progression necessitating alternate therapy, however, for the remainder of the 40 patients (86.9%), the reasons were not reported.
Amongst the 63 CD-19 trials that reported on the total number of patients enrolled, 32 trials enrolled patients that did not subsequently receive CART, whereas in the other 31 studies all enrolled patients went on to receive CART. In these 63 studies, a total of 2559 patients were enrolled and received CART with efficacy results reported. An additional 286 patients did not receive CART after enrolling. The most common reasons listed were: not reported or other (80, 28%), death (49, 17%), difficulties with manufacturing CART (46, 16%), adverse events (17, 6%), progression of disease or disease-related complications (17, 6%), and infection (11, 4%).
Summary/Conclusion: Across BCMA and CD-19 CART trials, there is a difference of 8 – 11% in the overall response rate between modified and intention-to-treat analyses and a paucity of information regarding reasons why patients did not receive the intended study treatment.

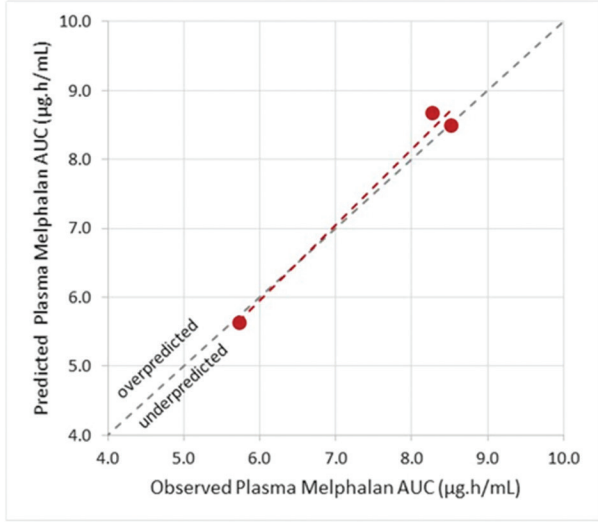
EP744 LONG TERM CYTOPENIA AND INFECTIONS IN PATIENTS TREATED WITH ANTI-CD19 CAR T-CELLS: AN ANALYSIS OF BONE MARROW AND CLINICAL RISK FACTORS

A. Guidetti [1,2,*], V. Marasco [1], A. Dodero [1], A. Chiappella [1], C. Oltolini [3], N. Rampi [1], F. Bagnoli [1], C. Carniti [1], P. Corradini [1,2]

[1]Hematology, Fondazione IRCCS Istituto Nazionale dei Tumori, [2]Oncology and Hemato-Oncology, Università degli Studi di Milano, [3]Clinic of Infectious Diseases, Division of Immunology, Transplantation and Infectious Diseases, IRCCS San Raffaele Scientific Institute, Milano, Italy

Background: Chimeric antigen receptor (CAR) T-cells therapy targeting CD19 is emerging as a promising treatment for patients affected by relapsed/refractory Diffuse Large B Cell Lymphoma (DLBCL) and Primary Mediastinal B Cell Lymphoma (PMBCL). Cytokine Release Syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) have been described as the most common toxicities in the first 14 days after CAR T-cells infusion. During follow-up, patients are often suffering from long-lasting cytopenia and infections, the causes of long-term toxicity have not yet been clearly explained.
Aims: To investigate the frequency of infections and cytopenia after CAR T-cells infusion and whether clinical characteristics, laboratory data and bone marrow (BM) function could be associated to the risk of long term toxicity
Methods: Consecutive patients receiving CAR T-cells at Fondazione IRCCS Istituto Nazionale dei Tumori in Milano between 2019 and 2020 with at least 3 months of follow-up were included in the study. Clinical and laboratory data were collected from electronic medical records; patients with persistent severe cytopenia (i.e. ANC < 1000/µl and/or PLT < 50000/µl) at 3 months of follow-up were investigated with BM biopsy, cytogenetic, FISH analysis and NGS studies.
Results: Forty-six patients receiving anti-CD19 CAR T-cells affected by DLBCL (n=34) and PMBCL (n=12) were included in this analysis. Median age was 49 years (range, 21-72) and median follow-up was 9 months (range, 1-21). Four patients died before 3 months of follow-up. All patients received anti Peumocystis jiroveci, antiviral and antifungal prophylaxis starting at lymphodepletion (LD) and continued until CD4 count > 200/µl. Overall in the first 3 months we observed 21 infectious events in 15/42 patients (33%), including bacterial (n=14), fungal (n=5) and viral (n=2) infections. CRS of any grade after CAR T-cells infusion,

the use of steroids and tocilizumab were significantly associated with an increased risk of infections at 3 months.
Severe cytopenia was observed in 11/42 (26%) of patients at 3 months and in 9/31 (29%) at 6 months. Neutropenia pre CAR T-cells infusion, a peak of ferritin > 5 times upper value (i.e > 1375 ng/ml) and female sex were significantly associated with a higher incidence of cytopenia at 3 months whereas neutropenia before LD was associated with cytopenia at 6 months
Three months after CAR T-cells BM examination was performed in 6/11 of patients with severe cytopenia and in 10 relapsed/refractory patients without cytopenia during work-up for a new treatment. In cytopenic patients, BM histologic examination showed dysmyelopoiesis (n=1), hypocellular marrow (n=3) and normal morphology (n=2), cytogenetic analysis was normal and FISH analysis for del5q and -7 were negative. NGS study was performed in 4 patients showing a clonal hematopoiesis of indeterminate potential (CHIP) due to DNMT3A mutations with a VAF of 2% and 9% in two of them. BM of 10 relapsed patients without cytopenia were histologically normal.
Summary/Conclusion: Three months after CAR T-cells infusion almost a third of patients experienced one or more infectious events and cytopenia was present in a quarter of patients. CRS and consequent treatment seemed to be factors predisposing to infections whereas cytopenia seemed to be associated to neutropenia pre CAR T-cells or high ferritin peak. At 3 months a limited occurrence of myelodysplastic features were observed in BM analyzed. A larger cohort of patients and a longer follow-up is required to confirm these data.



EP745 TOWARDS PATIENT-SPECIFIC DOSING OF MELPHALAN CONDITIONING FOR ARU-1801, A NOVEL GENE THERAPY FOR TREATMENT OF SICKLE CELL DISEASE

B. Johnson [1,*], T. Hoang [2], C. Lo [3], C. Little [3], J. McIntosh [3], M. Grimley [4]

[1]Sumitovant Biopharma, [2]Roivant Sciences, [3]Aruvant Sciences, New York, [4]Cincinnati Children's Hospital, Cincinnati, United States

Background: Sickle cell disease (SCD) is a severe genetic disease for which the only cure is allogeneic hematopoietic stem cell transplant (HSCT), but this procedure requires myeloablative conditioning (usually with busulfan) to allow donor cell engraftment at the risk of chemotherapy-related toxicities, including short-term (e.g. neutropenia, veno-occlusive disease) and long-term (e.g. ovarian failure, secondary leukemia) effects. Reduced-intensity conditioning (RIC) regimens may reduce toxicities, thus expanding access to gene therapy for SCD. ARU-1801 gene therapy (autologous CD34+ hematopoietic stem cells and progenitors [HSPCs] transduced with a lentiviral vector [LV] encoding a modified γ-globin^{G16D} gene) is being investigated with a melphalan RIC regimen (140 mg/m^2). We previously reported data on 3 patients; while two had stable engraftment, one patient had a gradual decline in VCN over time, potentially linked to sub-target melphalan exposure due to rapid clearance from renal hyperfiltration (GFR = 200 mL/min/1.73m2). Melphalan plasma exposure may be a key variable to efficacy of ARU-1801 gene therapy. Melphalan clearance is dependent on renal function and SCD is often associated with renal injury. Pharmacokinetic (PK) model-based dose adjustment may lead to reduced variability and optimized melphalan exposure.
Aims: To evaluate the potential of a model-based, individualized melphalan dosing strategy for ARU-1801 in SCD.
Methods: Three patients with SCD in the ongoing Phase 1/2 MOMENTUM study received a single IV dose of melphalan 140 mg/m^2 conditioning off-label prior to infusion of ARU-1801 gene therapy. PK samples were collected for 6 hours post-end of infusion (dried blood spots for first 2 subjects, plasma for third subject, assayed by direct ionization or liquid chromatography/mass spectroscopy, respectively). Blood-to-plasma ratio and hematocrit were used to convert data from blood PK samples to plasma concentration. Plasma PK parameters were determined using non-compartmental methods and the observed area under the plasma concentration-time curve (AUC) was compared to predicted values based on a population PK model of melphalan from 100 patients with multiple myeloma undergoing HSCT (Nath et al, BJCP 2010). Predicted AUCs were calculated based on melphalan dose and model-predicted plasma melphalan clearance, based on patient covariate values collected prior to melphalan infusion: fat-free-mass (FFM), hematocrit, and eGFR (based on Cystatin-C).
Results: Covariate values showed large variability across the 3 patients (2 female, FFM: 38.8 to 53.0 kg, BMI: 18.7 to 28.9 kg/m^2, hematocrit: 31.0 to 38.3, Cystatin-C eGFR 78 to 200 mL/min/1.73m^2). Preliminary geometric mean (and coefficient of variation) plasma melphalan AUC from 3 patients with SCD was 7.39 µg.h/mL (22.4%). The observed AUC agreed well with predicted values from the PK model, with r^2 = 0.98 (Figure 1). Notably, the model accurately predicted a low melphalan AUC in the patient with eGFR of 200 mL/min/1.73m^2 (predicted: 5.62, observed: 5.73 µg.h/mL).

Figure 1. Individual predicted vs observed melphalan AUC

Summary/Conclusion: Model-based predictions of melphalan AUC in patients with SCD appear to be accurate across a wide range of covariate values. These data suggest individualized melphalan dosing prior to ARU-1801 infusion may be feasible; additional data will be used to refine the PK model for patients with SCD. A simple melphalan dose adjustment algorithm based on few covariate values has the potential to reduce variability and optimize melphalan exposure, which may result in improved patient outcomes after treatment with ARU-1801.

EP746 FACILITY READINESS ASSESSMENT FOR CAR-T TREATMENT IN AUSTRALIA: NHL PERSPECTIVE

M. Sadhik [1], P. Bagul [1,*]

[1]R&DS, IQVIA, Bangalore, India

Background: Chimeric antigen receptor T-cell (CAR-T) therapies have demonstrated the potential to treat relapsed/refractory hematological malignancies[1]. First CAR-T therapy (Kymriah) was launched in 2017 and up to this day there are 3 approved therapies in the US for DLBCL, MCL and ALL.[2] Kymriah and Yescarta, both are approved in the US, EU, Japan, and Australia.[3-8] Despite having demonstrated strong efficacy data in clinical trials in multiple indications[3-8], the commercial pick-up of these drugs hasn't been great. As per some studies, there are two key challenges affecting the commercialization of CAR-Ts:[9]
- **complex manufacturing and supply chain** Reprogramming/CAR-T creation and expansion and Infusion
- **high-touch commercial model:** High cost to set up, certify, and scale sites
These challenges make it difficult for healthcare facilities to utilize CAR-T treatment for eligible patients. It is crucial to find out the facilities which has the potential infrastructure to make the treatment available. In this study, we have come up with solutions to address those challenges by identifying the eligible facilities and their referrals. The target of our study is Australia, as it has an untapped capacity to make the CAR-T treatment available for patients due to its improved healthcare system and high healthcare spending.
Aims: - Identify potential healthcare facilities which are eligible for CAR-T treatments and clinical research, using:
- Site/ Facility Identification;
- Accreditations for different CAR-T processes (leukapheresis, manufacturing, infusion)
Methods: Due to complexities involved in manufacturing and supply chain, having a centralized manufacturing facility becomes critical for CAR-T therapies. Many strategic decisions around marketing and clinical trials can be taken by identifying eligible healthcare facilities considering factors like capability to perform complex processes, patient potential,

and clinical trial experience. To achieve this objective of identifying key facilities, we have used a proprietary approach as explained below:
- Site Identification was performed using top down drug consumption approach to obtain Relapsed/refractory Non-Hodgkin's lymphoma (NHL) treating hospitals and their estimated patient potential
- A Referral network was established for the hospitals which have accreditations for all 3 processes, considering them the most eligible sites for treatment or clinical research

Results: There are a total of 82 hospitals in Australia, from which:
- Eight Hospitals are fully accredited for CAR-T and could potentially treat 17% of eligible R/R NHL patients;
- · 62% of hospitals are without any accreditation for CAR-T processes;
- · 28% of partially accredited (1 or 2 processes) hospitals could benefit from additional certification to grant them autonomy to perform CAR-T;
- · Around 18% of hospitals have experience in conducting CAR-T clinical trials

Summary/Conclusion: A limited number of hospitals in Australia are equipped with adequate facilities to process and provide the CAR-T treatment. Hospitals with 1 or 2 processes accreditation could benefit to further 50% of patients from additional certification to grant them autonomy to perform the treatment. Utilizing the referral network data, patients can be referred to fully accredited facilities expanding treatment access.

EP747 ANAKINRA PROPHYLAXIS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA RECEIVING ORVACABTAGENE AUTOLEUCEL (ORVA-CEL)

L. Costa [1,*], S. Mailankody [2], P. Shaughnessy [3], P. Hari [4], J. Kaufman [5], S. Larson [6], D. Dingli [7], K. Lee [8], K. Conte [9], T. DeVries [10], J. Piasecki [10], M. Li [9], R. Dubowy [9], M. Htut [11]

[1]University of Alabama Birmingham, Birmingham, AL, [2]Memorial Sloan Kettering Cancer Center, New York, NY, [3]Sarah Cannon Transplant and Cellular Therapy Program, Methodist Hospital, San Antonio, TX, [4]Medical College of Wisconsin, Milwaukee, WI, [5]Winship Cancer Institute of Emory University, Atlanta, GA, [6]UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA, [7]Mayo Clinic, Rochester, MN, [8]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [9]Bristol Myers Squibb, Princeton, NJ, [10]Bristol Myers Squibb, Seattle, WA, [11]City of Hope Comprehensive Cancer Center, Duarte, CA, United States

Background: Orva-cel is a B-cell maturation antigen (BCMA)-targeted chimeric antigen receptor (CAR) T cell therapy being evaluated in the phase 1/2 EVOLVE study (NCT03430011) in patients with relapsed/refractory multiple myeloma (RRMM) who had at least 3 prior lines of therapy. We previously reported safety and efficacy in the EVOLVE phase 1 study and established the recommended dose (RD) of orva-cel as 600×10^6 CAR$^+$ T cells (Mailankody S, et al. *J Clin Oncol*. 2020;38(suppl):abstr 8504).
Aims: Cytokine release syndrome (CRS), a dominant toxicity of CAR T cell therapy, is mediated in part by interleukin-1 (IL-1). Here, we report clinical outcomes of a cohort of phase 1 patients treated prophylactically with anakinra, an IL-1 signaling inhibitor, with the objective of assessing any reduction in the incidence of grade ≥2 CRS after orva-cel treatment at the RD.
Methods: Fourteen patients were enrolled sequentially for anakinra prophylaxis and treated with orva-cel at the RD. The non–anakinra prophylaxis control group comprised the remainder of the phase 1 patients receiving orva-cel at the RD (n = 19). The median follow-up (range) was 3.0 months (1.8–6.2) for the anakinra prophylaxis group and 8.8 months (5.3–12.2) for the non–anakinra prophylaxis group. Anakinra 100 mg was administered subcutaneously the night before orva-cel infusion, 3 hours before the infusion (Day 1), and every 24 hours on Days 2–5. Dosing was increased to every 12 hours if CRS developed. CRS was graded by Lee (2014) criteria. Tocilizumab and corticosteroids were used per protocol-specified treatment management guidelines.
Results: Disease characteristics and outcomes are shown in the **Table**. In the anakinra prophylaxis and non–anakinra prophylaxis groups, the median number of prior regimens was 6 and 5, and bridging therapy was used in 57% and 68% of patients, respectively. The total frequency of CRS was similar in the 2 groups, but with less grade 2 events in the anakinra prophylaxis patients (relative risk, 0.54 [95% CI, 0.21–1.38]). No grade ≥3 CRS was observed in either group. The incidence of neurological events (NEs), grade ≥3 infection, and macrophage activation syndrome/hemophagocytic lymphohistiocytosis (MAS/HLH) was similar. Tocilizumab and corticosteroid use was numerically lower with anakinra prophylaxis. Orva-cel expansion kinetics were similar in the 2 groups. All patients had a 2-month efficacy assessment, with an ORR of 100% in anakinra prophylaxis and 95% in non–anakinra prophylaxis patients.

Table. Disease characteristics and safety outcomes in the phase 1 EVOLVE study

	Anakinra prophylaxis, n = 14	Non–anakinra prophylaxis, n = 19
International staging system, %		
Stage I	43	47
Stage II	36	37
Stage III	21	16
Measurable serum and/or urine M-protein, %	93	74
LDH >ULN, %	21	0
CRS, %		
Grade 1	64	37
Grade 2	29	53
Grade ≥3	0	0
CRS time to onset, median (range), days	2 (1–11)	2 (1–2)
CRS duration, median (range), days	3 (2–8)	3 (1–7)
NEs, %		
Grade 1	7	5
Grade 2	7	5
Grade ≥3	7	0
Infection, %		
Grade 1	0	16
Grade 2	0	11
Grade ≥3	14	11
MAS/HLH, %		
Grade 1	0	5
Grade 2	7	0
Grade ≥3	0	5
Tocilizumab and/or corticosteroid use, %		
Any tocilizumab use	79	90
Multiple instances of tocilizumab use	29	37
Any corticosteroid use	43	63
Tocilizumab + corticosteroid use	43	63

LDH, lactate dehydrogenase; ULN, upper limit of normal.

Summary/Conclusion: In this nonrandomized evaluation of anakinra prophylaxis with orva-cel treatment, the incidence of grade ≥2 CRS was lower in patients receiving anakinra prophylaxis. The use of anakinra prophylaxis had no adverse effect on the incidence of NEs, infection, or MAS/HLH, nor on orva-cel expansion or disease response. These results warrant further study of anakinra prophylaxis in CAR T cell therapy.

EP748 A PROSPECTIVE PHASE I/IIA TRIAL TO EVALUATE THE SAFETY AND EFFICACY OF GTA002, AN OFF-THE-SHELF, EX VIVO-CULTURED ALLOGENEIC NK CELL PREPARATION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (WINK TRIAL)

J. Passweg [1,*], M. Heuser [2], W. Fiedler [3], T. Kerre [4], J. Maertens [5], A. van de Loosdrecht [6], A. M. Mueller [7], J.-H. Bourhis [8], K. Nowek [9], J. Spanholtz [9], V. Bonnamain [9], S. Winckels [9], A. Ganser [2]

[1]University Hospital Basel, Basel, Switzerland, [2]Hannover Medical School, Hannover, [3]Universitaetsklinikum Hamburg Eppendorf, Hamburg, Germany, [4]University Hospital Ghent, Ghent, [5]University Hospital Leuven, Leuven, Belgium, [6]Amsterdam University Medical Center, Amsterdam, Netherlands, [7]University Hospital Zurich, Zurich, Switzerland, [8]Institut Gustave Roussy, Villejuif, France, [9]Glycostem Therapeutics BV, Oss, Netherlands

Background: Although many patients with acute myeloid leukemia (AML) achieve morphological complete remission (CR) due to improved treatment modalities, the majority of them still relapse leading to poor long-term prognosis. These relapses are due to residual leukemic stem cells that can be identified as minimal/measurable residual disease (MRD), with MRD serving as a predictive factor for relapse and mortality. Elimination of MRD in patients having reached CR is seen as essential for optimal and persistent clinical responses.
Aims: A promising approach is the development of adoptive immunotherapies aimed at directly eradicating residual tumor cells using natural killer (NK) cells. NK cells can be applied clinically in an allogeneic setting, enabling the supply of high numbers of immune effector cells, which were not exposed to cytotoxic chemotherapeutics. A proprietary *ex vivo* expansion and differentiation method in a fully closed, automated manufacturing platform was developed to generate GTA002, an "off-the-shelf" (allogeneic), cryopreserved NK cell preparation, generated from CD34+ hematopoietic stem and progenitor cells derived from umbilical cord blood. The safety and tolerability of the product was demonstrated in a Phase I trial in elderly patients with AML (Dolstra et al. 2017).
Methods: We are currently conducting a prospective 2-stage, open-label, single arm, multicenter Phase I/IIa trial to evaluate the safety and efficacy of GTA002 in 33 adults with AML who are in CR with MRD and who are

not proceeding to allogeneic HSCT (ClinicalTrials.gov NCT04632316). After providing informed consent, patients enrolled in the clinical trial receive a lymphodepleting conditioning regimen consisting of cyclophosphamide and fludarabine followed by up to 3 NK cell infusions 4 days apart and will be followed up for 12 months. The dose escalation stage will assess the safety and tolerability of repeat NK cell infusions in a 3+3 design with 3 cohorts and a cumulative dose range of 325 to 3,000 x10^6 viable NK cells. The expansion stage will evaluate the safety, tolerability and efficacy of NK cell infusions in 24 additional subjects.
Results: Enrollment in the first cohort (one single NK cell infusion) started in December 2020. Preliminary safety data from the first cohort will be discussed at the meeting.
Summary/Conclusion: The overall objective of the trial is to evaluate whether GTA002 is safe and if it can eradicate MRD, thereby reducing the relapse risk and mortality in subjects with AML who are in CR with MRD and who do not proceed to allogeneic HSCT.

EP749 "MYTCELL": A SMARTPHONE APPLICATION GUIDES MANAGEMENT OF CAR T-CELL & BITE RELATED TOXICITIES

V. Blumenberg [1,2,3,*], L. Siegmund [1,2], L. Fröhlich [1,3], M. von Bergwelt [1,3], V. Bücklein [1,2], M. Subklewe [1,2,3]

[1]Department of Medicine III, University Hospital, LMU Munich, [2]Laboratory for Translational Cancer Immunology, Gene Center of the LMU Munich, Munich, [3]German Cancer Consortium (DKTK), German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: The Bispecific T-cell engager (BiTE) Blinatumomab and the CD19-specific Chimeric Antigen Receptor (CAR) T-cell products Axicabtagene-Ciloleucel and Tisagenlecleucel are approved Immunotherapies for relapsed and refractory B-cell neoplasms. However, they are accompanied by potentially lethal T-cell associated immune related adverse events that significantly differ from toxicities known from chemotherapy or even checkpoint blockade. Patients require comprehensive monitoring and a well educated interdisciplinary team of health care professionals.
Aims: To support the optimal management of these patients, we developed the interactive smartphone application "myTcell", which guides and educates physicians in the assessment and treatment of CAR & BiTE related toxicities.
Methods: We initiated a multi step content development process with an extensive literature research of toxicity guidelines consented by the ASTCT, EBMT and NCCN as well as of officially released drug information. Findings were translated into an information platform with diagnostic and therapeutic recommendations as well as algorithms for interactive toxicity grading tools. A prototype is currently being validated at three Geman treatment centers before becoming available in Europe. App development has been funded through educational grants by Celgene, Gilead Sciences and Novartis.
Results: "myTcell" guides disease and product specific in a step by step process through the clinical workflow of cell therapy including indication, leukapheresis, bridging therapy and application of CAR T cells and BiTEs. Upon entering relevant clinical data for grading of CRS, ICANS and HLH interactive tools display toxicity grade or likelihood of toxicity as well as grade-specific management recommendations. Further, "myTcell" assists with the diagnosis and treatment of so far underreported adverse events such as pancytopenia. Besides, "myTcell" includes an overview of the key literature and most recent publications in the field of CAR T-cells and BiTEs.
Summary/Conclusion: "myTcell" has the potential to become a highly usable smartphone app supporting the application of T-cell recruiting immunotherapies and the education of health care professionals. Thus, "myTcell" can increase guideline adherence, accelerate the broader and safer application of CARs and BiTEs and ultimately improve patient outcomes.

Hematopoiesis, stem cells and microenvironment

EP750 DIFFERENTIAL HEMATOPOIETIC SUPPORT ACROSS THE ADIPOCYTIC DIFFERENTIATION AXIS: PHARMACOLOGICAL MODULATION TO ACCELERATE HEMATOPOIETIC RECOVERY

F. Schyrr [1,2,*], V. Campos [1], B. von der Weid [1,2], R. Sarkis [1,2], A. Oggier [1], D. Banfi [3], G. Turcatti [3], O. Naveiras [1,2]

[1]Laboratory of Regenerative Hematopoiesis (Gr-Naveiras), Ecole Polytechnique Fédérale de Lausanne (EPFL), [2]Laboratory of Regenerative Hematopoiesis (Gr-Naveiras), Université de Lausanne (UNIL), [3]Biomolecular Screening Facility, Ecole Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland

Background: The hematopoietic stem cell (HSC) niche constitutes a complex bone marrow (BM) microenvironment that tightly controls HSC proliferation. Adipocytes have been shown to inhibit hematopoietic progenitor proliferation, but adiponectin-expressing cells are required for full HSC support and pre-adipocytes can efficiently support the growth of hematopoietic cells in culture. Given that specific bone marrow stromal cell (BMSC) subpopulations, preadipocytes, and adipocytes are part of the same differentiation axis, this apparently contradictory data suggests that the same precursor can generate cells with divergent hematopoietic-supportive capacity.
Aims: We thus hypothesized that pharmacological modulation of the adipocytic differentiation axis could inhibit bone marrow-derived adipocyte maturation and predict hematopoietic progenitor support.
Methods: To test this hypothesis, we performed devised high content phenotypic screening pipeline to identify modulators of adipocytic differentiation with increased hematopoietic support in the absence of exogenous cytokines. For *in vivo* validation of the screen, compounds were tested for their capacity to shorten aplasia post lethal irradiation and bone marrow transplantation. Specifically, the Prestwick Chemical Library of FDA-approved drugs, a library containing natural products and the library of chemicals generated from swiss academic laboratories were screened for their potential to prevent lipidation.
Results: After confirmation screen and dose-response determination, 49 inhibitors were selected. RNA-seq further classified compounds inhibiting adipocyte-specific gene expression as well as maintaining expression of hematopoiesis-supportive cytokines. Functional *in vitro* assays further identified a specific vitamin D analog as the strongest niche modulator, and transcriptome analysis revealed a CAR-like phenotype. *In vivo* administration significantly decreased both the adipocyte size and content of bones at day 18 post BM transplantation, increased platelet recovery and increased total number of CFU per leg.
Summary/Conclusion: Our pipeline allowed for the screening of more than 4000 compounds and identified a vitamin D derivative as a first candidate to induce a CAR-like phenotype and accelerate hematopoietic recovery in radio/chemotherapy-induced aplasia.

EP751 INTEGRATED SINGLE CELL ANALYSIS IDENTIFIES UNIQUE MOLECULAR AND FUNCTIONAL FEATURES OF EXTRAMEDULLARY HAEMATOPOIESIS IN HUMANS

N. Mende [1,*], H. Bastos [1], E. Laurenti [1]

[1]Haematology, Wellcome - MRC Cambridge Stem Cell Institute, Cambridge, United Kingdom

Background: In adults, most hematopoietic stem and progenitor cells (HSPCs) reside within the bone marrow (BM), giving rise to all mature blood cells. Yet at any given time, a small proportion of HSPCs circulates in peripheral blood (PB), and under severe stress and disease, also the spleen can significantly contribute to blood production. However, the cellular, molecular and functional composition of circulating and extramedullary HSPC pools remains unexplored.
Aims: Here I will discuss the single cell characterisation of the adult human HSPC pool found in the two main extramedullary haematopoietic tissues, spleen and PB, comparing and contrasting it to BM.
Methods: Using matched and unmatched samples from deceased and living donors, we profiled more than 115,000 single CD34+ HSPCs by scRNA-seq and/or CITE-Seq and 3,900 single phenotypic haematopoietic stem cells / multipotent progenitors (HSC/MPPs) in functional assays.
Results: We find largely distinct HSPC compositions in extramedullary tissues and BM. The topography of the hematopoietic hierarchy in BM supports continuous HSPC proliferation and blood production. In contrast, modelling active differentiation using scRNA-seq data and flow cytometry analysis detect few to no proliferating progenitor cells in extramedullary tissues. Together with a balance of early to late progenitors heavily shifted to early progenitors in spleen and PB, this indicates a cellular configuration in extramedullary tissues positioned for lineage-primed demand-adapted haematopoiesis. Importantly, the vast majority of HSC/MPPs in spleen and non-mobilised PB are molecularly distinct from those found in BM, differing in adhesion molecules and lineage priming properties. Finally, single cell functional assays demonstrate that steady-state non-mobilised PB is dominated by quiescent HSC-like cells functionally restricted to erythrocyte and megakaryocyte production. The functional bias of PB HSC/MPPs towards a largely erythro-megakaryocyte skewed lineage output becomes imbalanced with age and in haematological conditions.

Summary/Conclusion: In summary, the cellular and functional composition of HSPC circulating in PB is uniquely different from that of BM. We show that alterations in this composition faithfully report impairments of haematopoiesis. Our study thus identifies extramedullary cellular reservoirs for demand-adapted haematopoiesis and provides a framework of clinical relevance.

EP752 A STAT5B-CD9 AXIS DETERMINES SELF-RENEWAL IN HEMATOPOIETIC AND LEUKEMIC STEM CELLS

S. Kollmann [1], R. Grausenburger [1], T. Klampfl [1], P. Valent [2], G. Heller [3], V. Sexl [1,*], B. Maurer [1]

[1]Institute of Pharmacology and Toxicology, University of Veterinary Medicine Vienna, Austria, [2]Department of Medicine I, Division of Hematology and Hemostaseology, Comprehensive Cancer Center, [3]Department of Medicine I, Division of Oncology, Medical University of Vienna, Vienna, Austria

Background: Leukemic stem cells (LSCs) share characteristics of hematopoietic stem cells (HSCs) and represent the major therapeutic hurdle in leukemia patients. Many leukemic entities depend on an activated JAK/STAT signaling pathway, with STAT5 being critical in hematopoiesis and leukemia. As specific STAT5 inhibitors have not entered the clinics yet, alternative drug targets are needed. STAT5 is actually two distinct transcription factors, STAT5A and STAT5B which share more than 96% protein identity. It is widely believed that STAT5A and STAT5B are functionally redundant in the hematopoietic system. This dogma is challenged by the recent finding that activating STAT5 mutations in leukemia are restricted to *STAT5B*.
Aims: We aimed at understanding the distinct and individual roles of STAT5A and STAT5B in HSC and LSC self-renewal to identify downstream druggable targets.
Methods: We characterized the HSC compartment of mice lacking STAT5A or STAT5B via flow cytometry, single cell RNA-Seq and *in vitro* assays. We analysed *Stat5a*$^{-/-}$ or *Stat5b*$^{-/-}$ HSC and LSC potency in *in vivo* settings including serial transplantation and 5-FU treatment. We validated the potential downstream target CD9 in primary STAT5-dependent leukemia patient samples.
Results: We identified distinct functions for STAT5A and STAT5B in HSCs and in LSCs and define STAT5B as the driving force behind the maintenance and self-renewal of these cell types. We identify CD9 as a novel STAT5B target gene and show that the levels of CD9 correlate positively with STAT5 phosphorylation and negatively with the survival of STAT5-dependent leukemia patients. The elevated CD9 surface levels on LSCs render the cells particularly sensitive towards CD9-blocking, which we show to induce differentiation and apoptosis.
Summary/Conclusion: We suggest that CD9 may serve in prognosis and therapy of STAT5-dependent leukemia. We show that it is vital to consider STAT5A and STAT5B as distinct entities in normal and malignant hematopoiesis.

EP753 DENATONIUM AS BITTER TASTE RECEPTOR AGONIST AFFECTS THE CLONOGENIC CAPACITY AND DIFFERENTIATION OF HEMATOPOIETIC STEM CELLS

V. Pensato [1,*], A. Laginestra [2], P. Falvo [3], G. Mitola [3], E. De Marchi [4], S. Bruno [1], S. Mongiorgi [5], F. Bertolini [3], E. Adinolfi [4], M. Cavo [1,6], A. Curti [6], V. Salvestrini [7]

[1]Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, [2]Laboratory of Experimental Oncology, IRCCS Istituto Ortopedico Rizzoli, Bologna, [3]Laboratory of Hematology-Oncology and Hemo-Lympho Pathology Unit, European Institute of Oncology, Milano, [4]Department of Morphology, Surgery and Experimental Medicine, Section of Pathology, Oncology, and Experimental Biology, University of Ferrara, Ferrara, [5]Department of Biomedical and Neuromotor Sciences-DIBINEM, University of Bologna, [6]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Istituto di Ematologia "Seràgnoli, [7]Istituto di Ematologia "Seràgnoli", Bologna, Italy

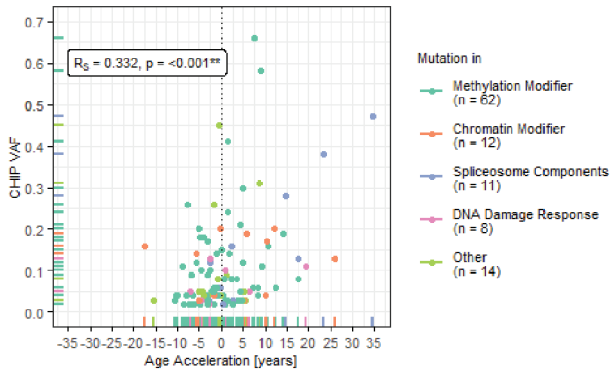
Background: The ability of cells to detect changes in the microenvironment is important in cell signaling and responsiveness to environmental fluctuations. There are a variety of receptor types through which cells respond to changes in their microenvironment including those for cytokines, hormones, mechanical tension, and there are thousands of different receptors expressed on any given cell type. Among these, the largest group belongs to the family of G protein-couple receptors (GPCRs). Bitter taste receptors (T2Rs) comprise 25 distinct members of the GPCR family. Initially described in the oral cavity, T2Rs are actually widely expressed in different tissues and the increasing amount of evidence about their extra-oral localization has suggested a wider function in sensing microenvironment, also in cancer settings. We recently reported that Acute Myeloid Leukemia cells express fully functional T2R subtypes which are involved in the regulation of leukemia cell functions.
Aims: In this study, for the first time, we investigate the activity of bitter taste agonist Denatonium on HSCs biology.
Methods: Highly purified cord blood-derived CD34^{+} cells were used for this study. T2R expression was analyzed by RealTimePCR and IF. We investigated molecular profiling by GEP assay, viability by colorimetric assay, apoptosis and HSC subset frequency by FACS analysis. In vitro assays for primitive hematopoietic cells (CFU-C, LTC-IC) were performed. For *in vivo* engraftment studies, NSG mice were used.
Results: In the present work, we show that HSCs expressed several T2R subtypes at molecular and protein levels. Stimulation of HSCs with a T2R agonist, Denatonium (DEN), induced intracellular Ca^{2+} concentration increase, thus demonstrating T2Rs functionality. GEP analysis identified a number of genes significantly modulated by DEN treatment. Specifically, genes involved in the stem cell population maintenance and regulation of cell-matrix adhesion are deregulated. Functional assays demonstrated that DEN exposure does not affect HSC viability and not induce apoptosis. Nevertheless, depending on the extent of stimulation, DEN modulates the frequency of stem cell progenitors in the culture. In particular, acute stimulation increases the frequency of lineage restricted progenitors (CLP, CMP, GMP) and their clonogenic capacity. On the other hand, chronic exposure to DEN supported the depletion of the more primitive stem cell compartment, reducing the frequency of the LTC-IC. These results are supported by *in vivo* experiments. NSG mice transplanted with DEN-treated HSC showed an increased engraftment in BM and spleen matched by an increased frequency of more differentiated progenitors.
Summary/Conclusion: Our results expand the observation of T2R expression to the hematological setting and shed light on a role of T2Rs in the extrinsic regulation of HSC functions. Moreover, our data may suggest a role for microenvironment "bitter" molecules in regulating normal hematopoiesis. Notably, many common drugs, such as antibiotics, chloroquine, haloperidol, procainamide, are bitter tasting and are thus effective ligands for T2Rs. For this reason, they could exhibit off-target effect in T2R expressing cells, including normal hematopoietic cells. Our results may have implications in understanding the off-target actions of diverse drugs.

EP754 CLONAL HAEMATOPOIESIS: USING LONGITUDINAL COHORT DATA TO STUDY THE AGEING HUMAN HAEMATOPOIETIC SYSTEM

K. Kirschner [1,*], M. Terradas Terradas [2], E. Latorre-Crespo [3], L. Schumacher [3], P. Alison [2], R. Neil [3], T. Chandra [3], I. Deary [3], S. Cox [3], S. Harris [3]

[1]Institute of Cancer Sciences, University of Glasgow/ CRUK Beatson Institute, [2]University of Glasgow, Glasgow, [3]University of Edinburgh, Edinburgh, United Kingdom

Background: Clonal haematopoiesis (CH) is apparent in the general population from age 60 with a steady increase to 18-20% over age 90 driven by somatic mutations in leukaemic driver genes, leading to reduced diversity of the blood pool. CH carries an increased risk for leukaemia.
Aims: We investigated CH in the Lothian Birth Cohort through targeted error-corrected sequencing of blood samples taken from aged participants every 3 years for 15 years.
Methods: *Study Cohorts*
The Lothian Birth Cohorts (LBCs) of 1921 and 1936 are two longitudinal studies of ageing. Participants have been followed up every ~3 years, each for five waves, from the age of 70 (LBC1936) and 79 (LBC1921). MPN patient material was derived from the Cambridge Stem Cell Bank.
Error corrected sequencing
Genomic variants were determined in 1,148 LBC participants with error corrected sequencing. CH variants were classified as per Jaiswal et al.
Results: We identified 73 participants with CH (6.2%). The gene-specific prevalence ranged between 1-37 cases with CH-variant allele frequencies ranging from 0.034-0.677. Mathematical modelling of the population dynamics of clones shows that, at old age, the commonly used threshold to diagnose CH can be reached as the result of neutral drift in synonymous mutations. This clinically implemented detection method therefore leads to a ~50% false discovery rate of fit mutations. Using our longitudinal data, we can better detect clones whose growth cannot be explained by neutral drift by considering the measured distribution of fluctuations of neutral mutations. This method allows us to uncover fitness-inducing mutations with high sensitivity as well as uncover highly fit variants before they achieve the threshold-based definition of CH.
Summary/Conclusion: Longitudinal data allow for more accurate modelling and detection of fitness effects of CH in an aged population.



EP755 CHIP CLONE SIZE CORRELATES WITH EPIGENETIC AGE ACCELERATION

J. D. Feldkamp [1,*], V. M. Vetter [2], C. M. Arends [1], T. J. L. Lang [1], L. Bullinger [1,3], F. Damm [1,3], I. Demuth [2,4], M. Frick [1,3]

[1]Division of Hematology, Oncology, and Tumor Immunology, [2]Lipid Clinic at the Interdisciplinary Metabolism Center, Charité - Universitätsmedizin Berlin, Berlin, [3]German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, [4]BCRT - Berlin Institute of Health Center for Regenerative Therapies, Charité - Universitätsmedizin Berlin, Berlin, Germany

Background: Clonal hematopoiesis of indeterminate potential (CHIP) occurs in the peripheral blood of approximately 20% of people > 60 years of age without history of hematologic disorders. CHIP is associated with age related conditions such as cardiovascular diseases and increased all-cause mortality. DNA-methylation at various CpG loci is known to reliably correlate with chronological age and mortality. Different epigenetic clocks have been developed based on these methylation sites and their potential to reflect biological age is a research topic of great interest.
Aims: Aim of the current study was to investigate the relationship between CHIP status, epigenetic age, and epigenetic age acceleration in 382 elderly individuals.
Methods: Epigenetic age was determined using DNA extracted from peripheral blood of elderly individuals (median 74.8; range 55-98 years) without hematologic malignancy and with previously determined CHIP status (Arends et al., Leukemia, 2018). Methylation fractions were determined using methylation-sensitive single nucleotide primer extension. DNA methylation age (DNAm age) was calculated using an adapted version of an 8-CpG clock (Vidal Bralo et al., Front Genet, 2016), implementing a previously established regression model from the Berlin Aging Study II cohort. Age acceleration (AA) was determined as the residual that results from DNAm age regression on chronological age. Intrinsic epigenetic age acceleration (IEAA) was determined likewise with regression on chronological age and blood cell counts.
Results: Median DNAm age was 76.15 (SD ± 9.67) years. As determined previously, 107 (28%) of the 382 individuals had evidence of CHIP with a median VAF of 6%. In line with previous publications, sex was significantly associated with AA (female -1.18 years; male 0.96 years; p = .007). When looking at all cases, CHIP was not significantly associated with epigenetic age acceleration (CHIP pos. 1.07 years; CHIP neg. -0.41 years; p = .201). On the contrary, presence of CHIP clones with large VAF (≥ 20%, n = 15) significantly correlated with increased AA when compared to CHIP negative individuals (contrast analysis following ANOVA, p = .022). Mean difference in AA between these groups was 6.04 years. To further analyze the impact of clone size and to account for the continuous character of VAF, a Spearman correlation was performed for AA and VAF of individuals with CHIP (n = 107). Here, we observed a significant, positive correlation between age acceleration and clone size (R_s = .332; p = <.001; Figure 1), which remained significant after adjustment for sex and chronological age (R_s = .326; p = <.001). Comparable results were obtained when correlating IEAA and CHIP clone size (n = 84; R_s = .411; p = <.001 after adjustment for sex and chronological age). When looking at individual functional groups of CHIP genes [methylation modifiers (*DNMT3A*, *TET2*), chromatin modifiers (*ASXL1*, *EZH2*), spliceosome components (*SF3B1, SRSF2, U2AF1, ZRSR2*), DNA damage response (*TP53, PPM1D*), other], no significant correlations could be observed with respect to age acceleration. However, small group sizes preclude final conclusions and warrant further investigation.

Figure 1: Spearman Correlation for VAF and Epigenetic Age Acceleration

Summary/Conclusion: In our study investigating the correlation of epigenetic age and CHIP, clone size was significantly associated with epigenetic age acceleration, indicating premature aging in this population. Though cause and consequence relations require further study, these results provide a new perspective on the critical role of CHIP clone size.

EP756 CHANGES IN BONE MARROW STROMAL MICROENVIRONMENT PROGENITOR CELLS IN PATIENTS WITH HEMOBLASTOSIS

N. Petinati [1,*], I. Shipounova [1], N. Sats [1], N. Drize [1], E. Fastova [2], O. Shukhov [3], E. Chelysheva [3], A. Magomedova [2], S. Kravchenko [2], A. Turkina [3], E. Parovichnikova [4], V. Savchenko [4]

[1]Physiology of hematopoiesis lab., [2]Intensive Hight dose chemotherapy of hemoblastosis, [3]Department of chemotherapy of myeloproliferative disorders, [4]Department of hemoblastosis chemotherapy, hematopoiesis depression and BMT, NATIONAL RESEARCH CENTER FOR HEMATOLOGY, Moscow, Russian Federation

Background: In patients with hemoblastosis, the stromal microenvironment of the bone marrow (BM) is changed, and there is convincing evidence supporting the role of multipotent mesenchymal stromal cells (MSCs) in the transformation of the bone marrow niche, which, as a result, promotes the survival of leukemic cells. MSCs regulate both normal and malignant hematopoiesis. The preservation of leukemia stem cells (LSC) in the body even after high-dose chemotherapy is the main difficulty in the treatment of hemoblastosis, which determines the development of relapses. Since LSCs are located in their niche and are regulated by various non-hematopoietic cells, including MSCs, studying the mechanisms of interaction between LSCs and MSCs can increase the effectiveness of treatment.
Aims: The aim of this work was to study general changes and differences in the characteristics of MSCs in patients with myeloid leukemia and patients with lymphoproliferative diseases.
Methods: The study included MSCs and colony-forming units fibroblast (CFU-F) obtained from the BM of 114 patients in the onset of the disease: 32 with AML (13 male and 20 female, age 39.2±2.3) 20-ALL (7 male and 13 female, age 26.4±1.9), 20-CML (11 male and 9 female, age 44.6±3.8) and 41-DLBCL (15 male and 26 female, age 54.9±2,0). MSCs and CFU-F from the BM of donors of appropriate age were used as control. All donors and patients signed informed consent. MSCs and CFU-F were cultured by standard methods. Relative expression level (REL) of several genes were investigated by real time PCR.
Results: The concentration of CFU-F in the BM of patients of all studied hemoblastosis at the onset of the disease is reduced in comparison with the values in donors of the corresponding age (Table). At the same time, concentration of CFU-F in the BM of ALL patients was most pronounced and reliably reduced by almost 4 times. A decrease in the concentration of these stromal progenitor cells may reflect systemic damage to the BM stroma. The revealed changes in DLBCL patients without bone marrow involvement indicate that there is not only a direct effect of leukemic cells on the stroma due to intercellular contacts, but also an indirect one, through factors secreted by the tumor. In patients with DLBCL total MSCs production is significantly higher than in donors. In other patients cumulative MSCs production does not differ from donors. In stromal cells of patients with hemoblastosis, there are both general changes associated with proliferation, differentiation and maintenance of hematopoiesis, as well as fundamental differences presented in Table. In all patients MSCs REL of *SPP1, ICAM1, TGFb1*, and *TGFb2* genes did not differ from donors' ones. In the MSCs of patients with leukemia, the REL of *IL6, JAG1, LIF* genes were increased, and REL of *IL8, SDF1* were not changed compared to the MSCs of the donors. MSCs from patients with acute leukemia were characterized by a decrease in *SOX9* and an increase in *CSF1, IL1b*, and *IL1bR1* expression. In MSCs of patients with myeloid leukemia, the *PPARG* and *PDGFRA* were increased. Gene expression in MSCs from DLBCL patients was significantly different from that in patients with leukemia.

Table. Concentration of CFU-F in bone marrow, total cellular production of MSCs, time to P0 and gene expression differences in patients with hemoblastosis and donors of the corresponding age.

REL of genes presented by the ratio to in MSCs of healthy donors. ↑-Higher than in donor MSCs, ↓ - lower than donor MSC

		AML	ALL	CML	DLBCL
CFU-F concentration per 106 BM cells	Patients	11,5±4,7	8,7±3,8*	15,8±4,2	11,5±2,1
	Healthy donors	22,3±2,7	30,6±3,4	21,7±2,4	18,3±4,9
Cumulative MSCs production for 4 passages, x106 cells	Patients	4,8±0,8	5,5±1,5	7,5±1,6	9,6±1,1*
	Healthy donors	5,2±0,4	8,8±1,2	5,2±0,5	7,2±1,1
Time to P0, days	Patients	17,6±0,6*	19,8±1,4*	17,7±0,8*	13,1±0,4
	Healthy donors	14,0±0,3	13,5±0,3	13,7±0,3	13,7±0,7

	CSF1	↑	↑	Normal	ND
	IL1B	↑	↑	Normal	ND
	IL1BR1	↑	↑	Normal	ND
HSC regulation	JAG1	↑	↑	↑	ND
	SDF1	↑	Normal	Normal	↑
	LIF	↑	↑	↑	ND
Differentiation	SOX9	↓	↓	Normal	Normal
	PPARG	↑	Normal	↑	Normal
Proliferation	FGF2	Normal	Normal	Normal	↑
	FGFR1	↑	Normal	Normal	↓
	FGFR2	Normal	Normal	↑	↑
	PDGFRA	↑	Normal	↑	ND
	PDGFRB	↑	Normal	Normal	Normal

*Significant differences between MSCs from the BM of healthy donors and patients at the onset of the disease, p<0.05

Summary/Conclusion: Altered functions of the stromal microenvironment in patients indicate its role in the maintenance and proliferation of tumor cells. The findings could pave the way for new therapies that target the altered stromal niche for hematopoietic cells.

EP757 PREVALENCE AND CLINICAL IMPACT OF CLONAL HEMATOPOIESIS OF INDETERMINATE POTENTIAL (CHIP) IN PATIENTS UNDERGOING HEART TRANSPLANTATION.

V. Panagiota [1,*], S. V. Rojas [2], N. M. Borchert [1], R. Gabdoulline [1], M. Verboom [3], E. C. Boyle [2], C. Schrimpf [2], C. Bara [2], M. Hallensleben [3], R. Blasczyk [3], F. Thol [1], A. Ganser [1], A. Haverich [2], M. Heuser [1]

[1]Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, [2]Department of Cardiothoracic, Transplantation, and Vascular Surgery, [3]Institute of Transfusion Medicine and Transplant Engineering, Hannover Medical School, Hannover, Germany

Background: Clonal hematopoiesis of indeterminate potential (CHIP) is driven by leukemia-associated somatic variants, primarily affecting the genes *DNMT3A, TET2, ASXL1 and JAK2* and rises steadily with age. While CHIP occurs among the healthy elderly population, CHIP is associated with several pathogenic states, including an elevated risk for hematologic neoplasms, ischemic stroke and overall mortality. Experimental evidence suggests that CHIP is a novel emerging causal cardiovascular risk factor that contributes to the development of atherosclerosis and cardiac dysfunction and exacerbates cardiovascular diseases. Recent studies report an association of CHIP with ischemic heart failure as well as degenerative aortic valve stenosis resulting in increased mortality.
Aims: The goal of our study is to characterize the prevalence and clinical impact of CHIP in patients undergoing heart transplantation.
Methods: We investigated 82 patients who underwent heart transplantation between 2013 and 2018 in the Department of Cardiac, Thoracic, Transplant and Vascular Surgery of Hannover Medical School, and for whom DNA from peripheral blood before heart transplantation and follow up information was available. The study was approved by the institutional review board of Hannover Medical School and written informed consent was obtained according to the Declaration of Helsinki. DNA from whole blood was evaluated for CHIP with a custom TruSight myeloid sequencing panel and next generation sequencing (NGS), including 46 entire genes or hotspots. Variants were validated by an established NGS-MRD method with a sensitivity of 0.02%.
Results: Of 82 patients with a median age of 55.5 years, 39 (47.6%) were diagnosed with a dilated cardiomyopathy (DCM), 24 (29.3%) with coronary artery disease (CAD), 7 (8.5%) with restrictive cardiomyopathy (RCM) and 12 (14.6%) with other heart diseases. Fifty-six patients were male (68.3%). Twelve of 82 (14.6%) patients carried CHIP-associated variants. The median variant allele frequency was 9.76% (range 3.06-32.7%). One of the 12 patients carried 3 and one patient carried 2 concurrent CHIP-associated variants. Mutations in *DNMT3A* were the most frequently detected and were observed in 6 of 12 patients (50%). The prevalence of CHIP in DCM, CAD, RCM and other patients was 25.5, 12.5, 0 and 9.1%, respectively (P=.46). CHIP carriers were numerically older compared to non-carriers (59 vs 53.5 years, P=0.4) and had numerically less cardiovascular risk factors (CVRFs) at the time of HTx (>1 CVRF 75% vs 90%, P=.16; >2 CVRFs 16.7 vs 35.7%, P=.09). All other investigated baseline characteristics (hemoglobin, platelet count, leukocytes, donor/recipient characteristics) for HTx did not differ between the groups. Day-90 mortality was 25% vs 5.7% in CHIP carriers vs non-carriers (P.27). CHIP carriers had a similar 2-year overall survival (OS) after HTx when compared to non-carriers (58% vs 73%, P=.33, HR 1.62, 95%CI 0.61-4.3, Figure). CHIP-associated variants had no impact on the risk of allograft rejection (77.1% vs 58.3%, P=.28) or malignancy development after HTx (11.4% vs 16.7%, P=.64) compared to CHIP non-carriers.

Figure

Summary/Conclusion: Acquired somatic mutations in the CHIP-driver genes occur with a prevalence of 14.6% in patients undergoing HTx. Patients with CHIP had fewer traditional cardiovascular risk factors, suggesting that CHIP may contribute to their cardiovascular risk. CHIP was associated with a higher early mortality rate but did not affect long-term survival in patients undergoing HTx.

EP758 KER-050, AN INHIBITOR OF TGF-B SUPERFAMILY SIGNALING, OBSERVED TO HAVE A RAPID, DYNAMIC, AND DURABLE EFFECT ON ERYTHROPOIESIS.

M. Feigenson [1,*], R. Nathan [1], C. Materna [1], A. Gudelsky [1], E. Lema [1], C. C. Tseng [1], F. M. Fisher [1], J. Seehra [1], J. L. Lachey [1]

[1]Keros Therapeutics, Lexington, United States

Background: Erythropoiesis, the multi-stage differentiation process of hematopoietic stem cells to red blood cells (RBCs), is a tightly regulated process required for adequate blood supply. Ineffective erythropoiesis causing anemia, such as in myelodysplastic syndromes (MDS) or myelofibrosis (MF), can result from defects at any stage in the pathway. However, current treatments target distinct stages of erythropoiesis, resulting in some patients being unresponsive to treatment; targeting multiple stages of erythropoiesis may provide a better treatment option. The TGF-β superfamily regulates erythropoiesis by maintaining a balance between progenitor quiescence and differentiation. KER-050, a modified ActRIIA ligand trap, is designed to promote erythropoiesis through inhibition of TGF-β ligands that signal though SMAD2/3, including activins and GDFs. In a Phase 1 clinical study, administration of KER-050 to healthy volunteers led to a robust, rapid, and sustained increase in RBCs and hemoglobin (HGB) as well as an increase in platelets, potentially suggesting a broader effect of KER-050 on hematopoiesis.
Aims: Determine the durability of effect and mechanism of action of KER-050 on erythropoiesis.

Methods: C57BL/6 male mice (12-week-old) were treated with a single dose of either vehicle or a research form of KER-050 (RKER-050). Peripheral blood was evaluated for reticulocytes (RET), RBCs, and HGB, and bone marrow (BM) erythroblasts were analyzed by flow cytometry, at multiple time points from 12 hours (hr) through day 51. Erythropoietin (Epo) levels were measured in serum.
Results: Treatment with RKER-050 resulted in rapid and sustained increases in RBCs and HGB, observed from 12hr through day 51. Within 12hr, RBCs (+8%) and HGB (+9%) were significantly increased. This response corresponded to a 20% reduction in BM proerythroblasts and erythroblasts (TER119+ cells) and a concomitant 18% increase (compared to vehicle) in circulating RETs, supporting that the maturation of these late-stage precursors contributed to the rapid RBC effect. Indeed, analysis of specific BM populations showed a general shift in the TER119+ cells from early to late erythroblast populations.
Within 48hr, the number of BM TER119+ cells increased by 37% compared to vehicle, demonstrating that precursor pools reduced at 12hr were quickly restored. In parallel, the initial increase in RETs observed at 12hr were transiently reduced (-15%), implying continued late-stage maturation of RETs to RBCs. This continued movement of earlier stage erythroid precursors into later stages of the pathway continued, with RET levels again replenished and TER119+ cells reduced by 48hr, likely supporting that the robust and sustained response in RBCs was due to administration of KER-050.
In addition to RKER-050 promoting differentiation of erythroid precursors to elicit its effect on RBCs, a RKER-050-mediated upregulation of Epo may also be contributing to the sustained increase in RBCs. Epo does not appear to play a role in the initial rapid RBC increase since Epo upregulation was not observed until day 4; however, Epo was increased from day 4 through day 37 which could indicate a role in sustaining the RKER-050-mediated increase in RET (+4%), RBCs (+8%), and HGB (+3%) to at least day 51.
Summary/Conclusion: In these studies, we observed that RKER-050 had a rapid and durable effect on erythropoiesis. The observed effects of RKER-050 on multiple stages of erythroblast maturation (both early- and late-stage) and increase in circulating EPO provide a strong rationale for investigating KER-050 as a treatment for ineffective hematopoiesis in MDS and MF.

EP759 CROSSTALK BETWEEN NITRIC OXIDE AND GLUCOCORTICOID RECEPTOR IS DISPENSABLE FOR INITIAL STRESS-INDUCED ERYTHROID PROGENITOR CELL EXPANSION

S. Momčilović [1,*], S. Vignjević Petrinović [1], D. Marković [2], M. Milošević [1], A. Jauković [3], I. Okić Đorđević [3], S. Mojsilović [3], D. Bugarski [3]

[1]Group for Neuroendocrinology, [2]Group of immunology, [3]Group for Hematology, Institute for Medical Research University of Belgrade, Belgrade, Serbia

Background: Nitric oxide (NO) is an ubiquitous signaling molecule that interacts with glucocortiocids in response to perturbed tissue homeostasis under hypoxic or inflammatory conditions. Using a mouse model of psychological stress, we have recently shown that chronic stress induces initial erythroid progenitor cell expansion by modulating the production of NO in the bone marrow. However, it remains unknown whether this stress-induced effect requires a NO-glucocorticoid receptor (GR) crosstalk.
Aims: This study was aimed to examine 1) a role of GR in initial stress-induced erythroid progenitor cell response and 2) a possible interaction between GR and NO in the bone marrow during chronic stress.
Methods: Adult male mice were subjected to 2h daily restraint stress for 7 consecutive days. The role of GR was assessed by subcutaneous administration of the GR antagonist mifepristone (RU486), 60 min prior to each restraint procedure. The number of bone marrow erythroid progenitors burst forming units-erythroid (BFU-E) and colony-forming unit-erythroid (CFU-E) was determined using colony assays. In order to examine a possible GR/NO interplay in the bone marrow during chronic stress, we used a blockade of NO biosynthesis, and mice were randomly assigned to following groups: (1) R - restraint group, exposed to daily restraint stress for 7 consecutive days; (2) L-NAME + R group, received a subcutaneous injection of L-NAME (non-selective nitric oxide synthase inhibitor) 30 min prior daily restraint; (3) L-NAME group, treated with L-NAME only; or (4) control group. To analyze GR activation, we assessed the nuclear translocation of GR by examining the level of GR expression in bone marrow nuclear cell fraction, using Western blot technique, and compared the protein expression levels among experimental groups. Plasma corticosterone levels were determined using a ^{125}I-coupled double antibody radioimmunoassay.
Results: Chronic stress induced a marked increase in the number of BFU-E (two-way ANOVA; $F(1,12)=29.996$; Bonferroni adjustment, $p<0.001$) and CFU-E (two-way ANOVA; $F(1,12)=28.946$; Bonferroni adjustment, $p<0.001$) progenitors in the bone marrow. Blockade of GR with RU486 prior to daily stress completely abolished the effect of repeated stress on both BFU-E (two-way ANOVA; $F(1,12)=27.301$; Bonferroni adjustment, $p<0.001$) and CFU-E cells (two-way ANOVA; $F(1,12)=28.168$; Bonferroni adjustment, $p<0.001$). Exposure to chronic stress significantly increased the expression of GR in bone marrow nuclear cell fraction (two-way ANOVA $F(1,12)=13.036$, $P<0.01$), and blockade of NO biosynthesis prior to each restraint did not alter stress-induced incresae in nuclear GR protein expression (two-way ANOVA; $F(1,12)=0.132$; $p>0.05$). In accordance, analysis of corticosterone levels among experimental groups revealed a highly significant difference in corticosterone concentration regarding the main effect for stress (two-way ANOVA; $F(1,12)=159.436$, $p<0.001$), while there was no significant main effect for the blockade of NO biosynthesis (two-way ANOVA; $F(1,12) =0.775$, $p>0.05$).
Summary/Conclusion: These findings suggest a crucial role for GR in the expansion of bone marrow erythroid progenitors under conditions of chronic stress. Although both GR and NO are required for stress-induced initial erythroid progenitor cell expansion, their interaction within bone marrow microenvironment is not essential for observed effect during chronic stress.

EP760 STUDY OF THE MACROPHAGE POLARISATION CONTINUUM WITH RELEVANCE TO COVID19

C. Severn [1,2,*], T. Oates [2], P. Moura [3], S. Cross [4], H. Baum [5], K. Heesom [2], M. Wilson [2], A. Toye [1,2]

[1]National Institute for Health Research Blood and Transplant Research Unit (NIHR BTRU) in Red Blood Cell Products, [2]School of Biochemistry, University of Bristol, Bristol, United Kingdom, [3]Center for Haematology and Regenerative Medicine, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [4]Wolfson Bioimaging Facility, Faculty of Biomedical Sciences, [5]Max Planck Bristol Centre for Minimal Biology, School of Chemistry, University of Bristol, Bristol, United Kingdom

Background: Macrophages are immune cells known for the detection and destruction of bacteria and viruses. In addition, macrophages are vital for a more generalised inflammatory response, providing cell-cell contacts and producing a cocktail of cytokines that stimulate a variety of other immunopathology's; including wound healing. Importantly, macrophages exhibit plasticity in their specific phenotypes, able to transiently convert between pro or anti-inflammatory subsets of cells along a continuum. For example, the pro-inflammatory M1 subset are heavily involved in immune modulation and the anti-inflammatory M2c subset is central to the erythroblastic island in the bone marrow.
Aims: The aim of our work was to further understand and characterise human macrophages and their polarity using a well characterised in vitro culture model. A multipronged approach of mass spectrometry, flow cytometry and a previously described2 imaging pipeline was utilised to interrogate the cell surface expression and behaviour of cultured cells.
Methods: We compared three populations against our control unstimulated macrophage (MØ) population, including the classically activated "inflammatory" M1 stimulated with interferon-g (IFNg) against the non-classically activated M2a macrophage subset stimulated with interleukin-4 (IL-4) and finally M2c macrophages stimulated with dexamethasone. The glucocorticoid dexamethasone was also applied as a treatment of the inflammatory M1 subset to better understand the specific effects of this steroid on macrophage polarisation to mimic anti-inflammatory steroid treatment for diseases such as COVID19.
Results: In doing this we demonstrate an increase in CD163 and CD206, markers synonymous with anti-inflammatory M2 macrophages when compared with untreated M1 macrophages. We detected specific alterations in cell surface markers and behaviour between the subsets of *in vitro*produced macrophages associated with the known phenotypes.
Summary/Conclusion: This provides a detailed dissection of the macrophage polarity continuum that is relevant to the macrophage field as a whole and to the current situation with COVID-19. This *ex vivo* method of recapitulating an aspect of the inflammatory response to disease has the prospect to be a test bed for future drugs and therapeutics.

EP761 NICHE HEALTH MAINTAINS SURVIVAL

C. Schreck [1,*], T. Landspersky [1], M. Sacma [2], F. Hettler [1], J. Riviere [1], J. S. Hecker [1], K. Götze [1], T. P. Yamaguchi [3], F. Bassermann [1], H. Geiger [2], R. A. J. Oostendorp [1]

[1]3. Medizinische Klinik Hämatologie und Onkologie, Klinikum rechts der Isar; Technische Universität München, München, [2]Institute of Molecular Medicine, Ulm University, Ulm, Germany, [3] Cancer and Developmental Biology Laboratory, Center for Cancer Research, National Cancer Institute-Frederick, Frederick, MD 21702, United States

Background: Life is stressful. Stressors like chronic infections or inflammation can alter both the composition and the function of hematopoietic niche cells, which affects blood cell formation.
Aims: We aim to identify cellular maintenance processes which ensure hematopoietic niche health upon stress.
Methods: For this purpose, we use mice in which the hematopoiesis maintenance factor *Wnt5a* is specifically deleted in Osterix+ mesenchymal progenitor and stem cells (MPSCs). These mice show normal steady state hematopoiesis, but progressive damage of hematopoietic stem cells upon stress.
Results: Mice lacking *Wnt5a* in MPSCs suffer from stress-related bone marrow failure and increased mortality. Niche cells devoid of *Wnt5a* show defective actin stress fiber orientation due to an elevated activity of the small Rho GTPase Cdc42. This results in incorrect positioning of autophagosomes and lysosomes, thus reducing autophagy and increasing oxidative stress. Strikingly, a short pharmacological intervention to attenuate elevated Cdc42 activation in vivo restored actin-anchored autophagy in MPSCs salvages hematopoiesis and as a consequence improves survival upon stress.
Summary/Conclusion: In summary, our study identifies *Wnt5a*, by affecting Cdc42 regulated actin stress fiber orientation and autophagy in niche cells, as a restriction factor for niche health upon stress. Our data further imply a critical role for autophagy in MPSCs for adequate support of hematopoiesis by the niche upon stress.

EP762 IMMUNE STATUS IN HEMATOLOGICAL CANCER PATIENTS AFTER COVID19

I. Kamaeva [1,*], I. Lysenko [1], N. Nikolaeva [1], A. Sagakyants [1], E. Bondarenko [1], O. Shulgina [1], E. Kapuza [1], T. Pushkareva [1], O. Kit [2], A. Velichko [1], Y. Gaysultanova [1]

[1]Hematology, [2]Abdominal surgery, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation

Background: Patients with immunosuppression, including those with hematologic cancers, are at greater risk of developing SARS-CoV infection. The virus is capable of infecting monocytes, macrophages and dendritic cells in order to promote the secretion of cytokines, and IL-6 can contribute to the excessive activation of the effects of the acquired immune system (usually lymphocytes) and innate immunity (neutrophils, monocytes, NK cells, etc.).
Aims: The purpose of the study was an assessment of the immune status of patients with hematological cancers after multi-course chemotherapy, therapy with anti-CD20+ antibodies and PCR-confirmed COVID19.
Methods: The study included 12 adult patients with lymphoproliferative diseases with a history of PCR-confirmed COVID-19. All patients underwent 4 to 6 chemotherapy cycles. The BD FACSCanto II flow cytometer with Becton Dickinson reagents were used to assess the immune status of patients. The research group consisted of patients with non-Hodgkin's large B-cell lymphomas. The blood plasma taken into a vacuum system with K2EDTA as an anticoagulant was used. The relative and absolute numbers of the main populations of T- and B-lymphocytes, the immunoregulatory index, and subpopulations of T-lymphocytes were assessed.
Results: Most patients showed a decrease in the relative number of lymphocytes, on average by 73%. The absolute and relative numbers of monocytes in half of the cases exceeded the norm or were similar to it. The immunoregulatory index in most cases (N=7) was decreased on average by 42%, compared to the norm. The absolute number of T-lymphocytes (CD3+) in 6 patients decreased on average by 42%±0.6. The population of T-helpers (CD3+CD4+) in 5 patients was reduced by an average of 44%±0.8. The number of double-positive (CD3+CD4+CD8+) T-lymphocytes in most cases (N=10) was reduced by 80%±0.8. At the same time, the number of double-negative (CD3+CD4-CD8-) T-lymphocytes increased by 177% in 7 patients. All patients showed a decrease in the B-cell immunity component. The relative number of B-lymphocytes (CD19+) was decreased on average by 78%, absolute number by 61%. The increase in all types of memory cells, both helper-inducer and cytotoxic populations, was registered.
Summary/Conclusion: Conclusions. Elevated numbers of various memory cells, together with a decrease in T-lymphocytes, could indicate the activation of the cellular adaptive immunity. A decrease in B-lymphocytes could indicate a decrease in the activity of the humoral component of adaptive immunity. The latter could also be a result of multi-course chemotherapy with anti-CD20+ monoclonal antibodies.

EP763 RING CHROMOSOMES IN HEMATOLOGICAL MALIGNANCIES

P. Diamantopoulou [1], D. Pantelia [1], M. I. Margariti [1], M. Kalomoiraki [1], C. Sambani [1], K. Manola [1,*]

[1]National Center for Scientific Research (NCSR) "Demokritos", ATHENS, Greece

Background: Ring chromosomes are uncommon and poorly investigated cytogenetic abnormalities in hematological malignancies.
Aims: The aim of the study was to shed light to the nature of ring chromosomes in bone marrow samples from patients with hematological malignancies and to identify the spectrum of chromosomal abnormalities in addition to ring chromosomes, by conventional and molecular cytogenetic analysis.
Methods: This study includes 40 patients with ring chromosomes identified among 28.821 patients with hematological malignancies from 1998 until 2019. The cytogenetic analysis was performed on 24h and 48h unstimulated bone marrow cultures using GTG-banding. Karyotypes were described according to the international system for human cytogenomic nomenclature (ISCN) 2016. Molecular cytogenetic analysis was performed by fluorescence in situ hybridization (FISH) using probes for the centromere of chromosomes (CEP) 1, 3, 7, 8, 9, 11 and for chromosomal regions 8q24.21 (MYC gene), 11q23 (MLL gene) and 17p13 (p53 gene) chosen each time according to karyotype and diagnosis. For each sample, 10 metaphases (mFISH) at least were analyzed.
Results: The frequency of ring chromosomes in hematological malignancies was ~ 0,14%. Among our patients with ring chromosomes, 48,5% had AML, 33,5% MDS, 6% MPD, 9% LPD and 3% ALL. The sex ratio was 1.1 (21 males/19 females) and the mean age was 67.6 years (range 12-91). Ring chromosomes were found as a sole abnormality in 2 patients (5%), with one more abnormality in 4 (10%) and in complex karyotypes in 34 patients (85%). The most frequent additional abnormality was marker chromosomes (51.2%), followed by -5/del(5q) (43,8%), -7/del(7q) (34,1%), -11 (26.8%), +8 (24.3%), -21 (19.5%), -17 (17.1%), -18 (14.6%). The nature of ring chromosomes was identified in 16 cases by mFISH and revealed: a) CEP 11 accompanied by MLL amplification in 9/16 (56.3%) all in complex karyotypes in AML or MDS cases. b) MYC amplification without CEP 8 in 2/16 (12.5%) as a sole abnormality. c) CEP 7 in 2/16 (12.5%) cases without additional abnormality in the karyotype except -7. d) CEP 1, 3 and 9 and TP53 gene in 1/16 (6.3%) each.
Summary/Conclusion: Ring chromosomes are very rare aberrations in hematological malignancies. They are observed mainly in AML and MDS, in elderly patients and in complex karyotypes. The most frequent additional abnormalities are marker chromosomes, -5/del(5q) and -7/del(7q). The most common origin of ring chromosome was that of chromosome 11, accompanied simultaneously by MLL amplification.

Hodgkin lymphoma - Clinical

EP764 CLINICAL OUTCOMES OF RELAPSED HODGKIN LYMPHOMA PATIENTS AFTER CONTEMPORARY FIRST-LINE TREATMENT: RESULTS FROM THE GERMAN HODGKIN STUDY GROUP

P. J. Bröckelmann [1,2,*], H. Müller [1,2], S. Gillessen [1,2], X. Yang [3], L. Koeppel [4], V. Pilz [4], P. Marinello [3], P. Kaskel [4], M. Raut [4], M. Fuchs [1,2], P. Borchmann [1,2], A. Engert [1,2], B. von Tresckow [5,6,7]

[3]Merck & Co., Inc., Kenilworth, NJ, United States, [4]MSD Sharp & Dohme GmbH, Haar, [5]Department of Hematology and Stem Cell Transplantation, West German Cancer Center, University Hospital Essen, University of Duisburg-Essen, Essen, [6]German Hodgkin Study Group (GHSG), Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf (CIO ABCD), University of Cologne, Cologne, [7]Cancer Center Cologne Essen (CCCE), Essen, Germany

Background: The relative benefit of targeted agents increasingly investigated and applied in relapsed or refractory Hodgkin lymphoma (rrHL) is difficult to estimate due to a lack of randomized trials.
Aims: This retrospective study thus aimed at evaluating disease characteristics, treatment patterns and associated outcomes at first occurrence of rrHL after contemporary first-line treatment.
Methods: We retrospectively identified patients with sufficiently documented first rrHL initially receiving standard of care 1st-line treatment in the GHSG HD13 (early-stage favorable), HD14 (early-stage unfavorable) and HD15 (advanced-stage) trials. We additionally evaluated rrHL patients enrolled in the placebo-controlled randomized GHSG HDR3i trial comparing conventional DHAP vs. everolimus + DHAP salvage therapy prior planned autologous stem-cell transplantation (ASCT). We assessed overall survival (OS) starting with date of 1st rrHL and ending with date of death for any reason and progression free survival (PFS) measured from date of rrHL to second rrHL or death from any reason. Patient, disease and treatment characteristics were analyzed with descriptive statistics and survival endpoints with Kaplan-Meier estimates.
Results: A total of 437 patients with first rrHL (HD13: n=87, HD14: n= 118, HD15: n=188, HDR3i: n=44) were identified. Of these, 402 patients with sufficient documentation and follow-up were assessed with a median age of 37.5 years (18.4-76.8). Time to relapse was ≤12 months in 49% and stage III/IV rrHL present in 52% of patients. High-dose chemotherapy and autologous stem-cell transplantation (ASCT) with and without consolidation was administered in 20% and 52% of patients, respectively. The remaining 111 patients (27%) did not receive ASCT mostly due to insufficient response to salvage chemotherapy, advanced age, localized disease or patients' preference. Overall, 10-year PFS and OS after first relapse were 48.2% (95% confidence interval CI: 42.0%>54.4%) and 59.3% (95%CI: 53.2%>65.4%), respectively (**Figure 1**). Patients unsuitable for ASCT had less favorable 10-year PFS (32.5%, 95%CI: 19.1%>45.9%) and OS (41.9%, 95%CI: 28.1%>55.6%). Significantly inferior PFS and OS was also observed in primary refractory patients (10-year PFS 36.0%, 95%CI: 24.2%>47.9%; 10-year OS 44.5%, 95%CI: 31.6%>56.6%) and those with stage IV disease at rrHL (10-year PFS 29.3%, 95%CI: 18.5%>40.9%; 10-year OS 39.6%, 95%CI: 27.9%>51.1%). Outcomes in these higher risk patients appeared more favorable with ASCT than without ASCT.

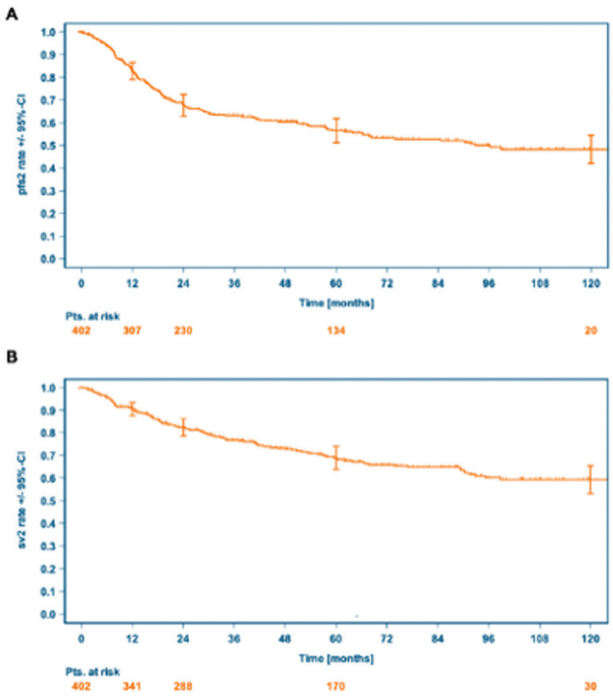

Figure 1 PFS (Panel A) and OS (B) after rrHL in patients treated in HD13, HD14, HD15 and HDR3i

Summary/Conclusion: Our analysis of relapse and treatment patterns after contemporary HL therapy provides a robust benchmark to evaluate novel therapeutic strategies in rrHL. We confirm the curative potential of current rrHL treatments including non-ASCT approaches and roughly 50% of rrHL patients do not experience a consecutive relapse after 2nd-line treatment.

EP765 MODIFICATION OF ESCALATED BEACOPP WITH DACARBAZINE SUBSTITUTION REDUCES TOXICITY WHILE MAINTAINING EFFICACY FOR THE TREATMENT OF ADVANCED-STAGE HODGKIN LYMPHOMA.

Background: In the treatment of advanced Hodgkin lymphoma, it is increasingly common practice to modify escalated BEACOPP (eBPP) by removing oral procarbazine and replacing it with intravenous dacarbazine (250mg/m2 D2-3) to reduce haematopoietic stem cell and gonadal toxicity. However, published data of the "escalated BEACOPDac (eBP-Dac)" regimen are very limited.
Aims: The aims are to compare efficacy and toxicity outcomes of patients treated with eBPDac versus eBPP.
Methods: This is a retrospective study of 147 patients from 16 centres in the UK, Ireland and France who were treated with eBPDac first line for advanced stage Hodgkin lymphoma. Outcomes were compared with 58 matched patients treated with eBPP at 4 UK centres. Most patients were treated as per HD15 or HD18 protocol. 28 patients in Paris and two in Truro followed the AHL2011 protocol with 2 courses of eBPDac given upfront and if iPET2 negative were deescalated to 4 cycles of ABVD.
Results: From 2009, 205 patients were treated first line with either eBPP (n=58) or eBPDac (n=147) with median follow-up 51.3 months and 22.9 months respectively. Patients were well matched with no significant differences in age (median: 23 y vs 27 y), sex, stage (stage 3/4: 81% vs 83%) and international prognostic score (IPS3+: 74% vs 65%).
51% of eBPDac patients received only 4 cycles (vs 12% of eBPP patients; p<0.001) reflecting publication of HD18 trial data. In total, 74% patients achieved iPET2 Deauville score ≤3 and 90% patients achieved PET negative remission by end of treatment. 77% of eBPDac patients achieved iPET2 Deauville ≤3 which was statistically similar to the eBPP cohort (67%; p=0.181) and matched the 76% iPET D2/3 reported in HD18. Of 205 patients, 202 are alive and 197 continue in first remission. Two eBPP patients have relapsed at 13 and 41 months and the latter died of refractory disease. One eBPDac patient had primary refractory disease, and three have relapsed at 2, 7 and 24 months. One 56-year-old eBPDac patient with high IPS died with bowel perforation during cycle 1 and one 34-year-old with alcoholic liver disease died 8 months after treatment while still in remission.
Toxicity was compared over the first 4 cycles. Mean day 8 (D8) ALT was similar between the two regimens. Mean D8 neutrophil count was lower in eBPDac than eBPP patients (1.81 vs 2.45; p=0.067; G-CSF given day 9), however it increased to 5.61 in eBPDac patients given GCSF from day 4. There is a trend toward fewer non-elective days of inpatient care

for eBPDac compared with eBPP (mean: 3.74 vs 5.83; p=0.118), and eBPDac patients received fewer red cell transfusions compared with eBPP patients (mean 1.93 units vs 4.16 units; p<0.001). Women aged < 35, who completed ≥4 cycles of eBPDac/eBPP had a similar rate of return of menstrual cycles (eBPP: 22/25; eBPDac: 29/29), although eBPDac patients appeared to restart menstruation earlier post chemotherapy (mean: 4.48 months vs 9.12 months, p=0.0026). However, this could also reflect the higher mean chemotherapy cycle number completed by the eBPP women (5.86 vs 4.60; p<0.001). The use of Goserelin to suppress ovulation varied between centres.

Baseline Characteristics	eBEACOPP N=58	eBEACOPDac N=147	p-value
Median Age (range)	23 (16-54)	27 (16-62)	U=4665, p=0.293

6	45 (78%)	39 (27%)	p=3.93E-10
7	1 (2%)	0	
On treatment	0	3	
iPET Deauville score 1-2	10 (21%)	39 (27%)	
3	22 (46%)	72 (50%)	
4	16 (33%)	32 (22%)	
5	0	1 (1%)	Fisher, p=0.181
≤3	32 (67%)	111 (77%)	
No iPET	10	3	
Mean day 8 ALT (cycles 1-4) [SD]	40.2 (±32.7)	46.5 (±31.5)	t(96)=1.17, p=0.244
Mean day 8 neutrophils (cycles 1-4) [SD]	2.45 (±1.45)	1.81 (±1.09)	t(87)=2.77, p=0.0067
Mean no. days non-elective admission (cycles 1-4) [SD]	5.83 (±7.40)	3.74 (±5.47)	U=2762, p=0.118
Mean no. red cell units transfused (cycles 1-4) [SD]	4.16 (±4.12)	1.93 (±2.89)	U=1996, p=2.52E-5
Median follow-up from diagnosis in months (range)	51.3 (5.0-127)	22.9 (0.89-47.0)	U=1053, p=2.2E-16
Mean no. months for return of menstrual period post-chemotherapy [SD]	9.12 (±5.73)	4.48 (±2.06)	t(24)=3.55, p=0.0016
Mean no. cycles completed by women <35 years of age [SD]	5.86 (±0.35)	4.60 (±0.93)	U=113, p=5.20E-6

Summary/Conclusion: Accepting the limitations of a retrospective study, we suggest that substituting dacarbazine for procarbazine is unlikely to compromise the efficacy of eBPP and may have some toxicity benefits. Despite a predominance of high risk advanced stage patients, with nearly 2 years median follow-up we have observed only 2 deaths and 4 progression events from 147 patients treated with eBPDac, suggesting this regimen is highly efficacious for the treatment of Hodgkin lymphoma.

EP766 LONG-TERM FOLLOW-UP AND BIOMARKER ANALYSES OF RELAPSED/REFRACTORY HODGKIN LYMPHOMA PATIENTS TREATED WITH BRENTUXIMAB VEDOTIN AND DHAP: THE HOVON/LLPC TRANSPLANT BRAVE STUDY

J. Driessen [1,*], M. J. Kersten [1], L. Visser [2], A. van den Berg [2], J. M. Zijlstra [3], S. H. Tonino [1], G. J. Zwezerijnen [4], R. Boellaard [4], P. J. Lugtenburg [5], M. Hutchings [6], M. Background: Patients with relapsed/refractory classical Hodgkin lymphoma (r/r cHL) generally have a poor prognosis. We have shown that brentuximab vedotin (BV) in combination with DHAP (dexamethasone, cytarabine, cisplatin) is highly effective with manageable toxicity. Here we present the long-term follow-up, including thymus and activation regulated chemokine (TARC) and metabolic tumor volume (MTV) analyses.

Aims: The aim was to find predictive biomarkers for r/r cHL patients treated with BV-DHAP and to evaluate the long-term follow-up.

Methods: Patients were treated with 3 cycles of BV-DHAP followed by autologous stem-cell transplant (ASCT). Serum was collected at baseline, after each cycle, and during follow-up. Soluble (s)TARC was measured by ELISA. Based on levels in healthy controls, a baseline sTARC <1000 pg/mL was considered not elevated. Immunohistochemical (IHC) staining was done for TARC on the lymph node biopsy at baseline. Baseline ^{18}F-FDG-PET-CT scans were analyzed quantitatively for MTV using a fixed threshold of standard uptake value (SUV) ≥4.0. Predictive value of biomarkers for time to progression (TTP) was assessed by calculating the area under the curve (AUC) of the receiver operating characteristics curve and log-rank survival analysis. For biomarker evaluation, patients who died without progression (n=2) were censored at time of death.

Results: Sixty-five patients, of whom 46% had primary refractory dis-

Summary/Conclusion: Treatment with BV-DHAP in r/r cHL patients shows a high 3-year PFS and OS. Serum sTARC correlates with baseline MTV and can be used as an early response marker already after 1 cycle of BV-DHAP. InterimPET status is predictive for post-ASCT TTP and sTARC can complement interimPET response evaluation. In addition, we have identified low TARC expression in HRS cells as a possible poor prognostic factor. Risk assessment using different biomarkers could help guide treatment decisions in an era with new targeted treatment options for r/r cHL.

EP767 IMPACT OF THE FIRST COVID-19 LOCKDOWN IN GERMANY ON THE RATE OF ACUTE INFECTIONS DURING INTENSIVE CHEMOTHERAPY FOR HODGKIN LYMPHOMA

A. S. Jacob [1,*], H. Goergen [1], M. Fuchs [1], S. Gillessen [1], S. Kreissl [1], A. Pluetschow [1], J. Momotow [1], V. Schaub [2], A. Huettmann [3], M. Haenel [4], A. Zimmermann [5], J. Dierlamm [6], J. Meissner [7], S. Mathas [8], S. Martin [9], A. Engert [1], C. Lehmann [10], P. Borchmann [1]

[1]German Hodgkin Study Group (GHSG) and Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Düsseldorf (CIO ABCD), University of Cologne, Cologne, [2]Department of Internal Medicine II, University Hospital of Tuebingen, Eberhard-Karls-University, Tuebingen, [3]Department of Hematology, University Hospital of Essen, Essen, [4]Department of Internal Medicine III, Clinic of Chemnitz, Hospital Kuechwald, Chemnitz, [5]Department III, University Hospital of Munich, Munich, [6]Department of Hematology / Oncology, University Hospital of Hamburg-Eppendorf, Hamburg, [7]Deparment V, University Hospital of Heidelberg, Heidelberg, [8]Department of Hematology, Oncology and Tumorimmunology, Charité Campus Benjamin Franklin, Berlin, [9]Department of Internal Medicine II, Hematology / Oncology, Robert-Bosch-Hospital, Stuttgart, [10]Department I of Internal Medicine, Center for Molecular Medicine Cologne (CMMC), German Center for Infection Research (DZIF), University of Cologne, Cologne, Germany

Background: Acute infections and fever under chemotherapy are an important cause for morbidity and mortality in hematologic malignancies such as Hodgkin lymphoma (HL). Prophylactic anti-infective concomitant medication is prescribed frequently. Another protective measure could be self-protection via social distancing and wearing facemasks. However, evidence on the effect of self-protection on infections during chemotherapy is currently not available.
Aims: We asked if the frequency of acute infections during chemotherapy for advanced-stage HL decreased when Corona Virus Disease 2019 (COVID-19) protection measures were in effect.
Methods: We analyzed the occurrence of infections during all documented eBEACOPP cycles that started between 01 March and 30 June of 2017-2020 among patients treated within the GHSG HD21 study in Germany. We compared cycles starting between March and June 2020 with cycles starting between March and June of 2017-2019 regarding infection rates and infection characteristics by logistic regression models and means of descriptive statistics.
Results: We analyzed 911 cycles of 313 adult patients treated with 4 to 6 cycles of eBEACOPP. We found a significant decrease in the frequency of infections during chemotherapy for HL during COVID-19 lockdown from 131 (19.6%) of 670 cycles in the years 2017-2019 to 30 (12.6%) of 239 cycles during COVID-19 lockdown (OR 0.574 (95% CI 0.354-0.930), P = 0.024). Correspondingly, 20 (24.1%) of 83 patients had an infection during the COVID-19 lockdown versus 99 (43.2%) of 229 patients in the years 2017-2019 (P = 0.0023). The strongest effect was observed for unspecified infections (unknown type of etiologic agent), occurring in 39 cycles (5.8%) during 2017-2019 in comparison to 5 cycles (2.1%) during COVID-19 lockdown. There was also a strong trend towards fewer minor infections: during the COVID-19 lockdown period there were 8 cycles (3.3%) with a minor infection compared to 66 cycles (9.9%) with an infection during the reference period.
Summary/Conclusion: The significant and relevant decrease observed in acute infections while receiving chemotherapy for HL during the COVID-19 lockdown demonstrates the potential of protective measures to shield patients from transmissible pathogens. We conclude that these measures may be recommended for cancer patients at risk for infections during chemotherapy.

EP768 THYMUS AND ACTIVATION-REGULATE CHEMOKINE (TARC) IS A RELIABLE TUMOR MARKER FOR BOTH DIAGNOSIS AND MONITORING CLASSICAL HODGKIN LYMPHOMA

S. Boldizsar [1,*], A. Masszi [1], B. Vince [1], Z. Molnar [1], J. Kovacs [1], B. Kapuvari [1], B. Deak [1], E. Szaleczky [1], E. Varady [1], A. Rosta [1], J. Rottek [1], T. Schneider [1], K. Kohalmy [1]

[1]National Institute of Oncology, Budapest, Hungary

Background: Classical Hodgkin lymphoma (cHL) accounts for 15% of all lymphoproliferative diseases, which is often presented with lymphadenopathy and B symptoms. The diagnosis of cHL is based on tissue sampling and histology, and the disease activity is monitored by serial PET/CT scans. cHL is considered to be highly curable, however substantial proportion of the patients suffer from refractory / relapsing disease. A reliable serum biomarker could support the management of these patients at the time of the diagnosis and later during the follow-up period. Thymus and Activation-Regulated Chemokine (TARC or CCL17) is highly expressed by Hodgkin and Reed-Sternberg cells and secreted into the serum, which raises the possibility to apply TARC as a tumor marker in cHL.
Aims: The aim of the study was to evaluate serum TARC as a reliable tumor marker in the course of treatment, and the follow up in patients with cHL.
Methods: Consecutive cases of cHL were enrolled in the study. In cohort 1 patients diagnosed between 2011 and 2018 were used to determine the cut off value of TARC. A second cohort of patients from 2019-2020 were used to validate the result. Serum TARC levels were determined with a quantitative sandwich enzyme immunoassay. Receiver Operating Characteristic (ROC) curve analysis was performed.
Results: In cohort 1, 613 patients diagnosed with cHL between 2011 and 2018 were enrolled. In 241 cases from this cohort, serum TARC concentrations were determined at baseline before therapy, as well. Receiver Operating Characteristic (ROC) curve analysis was performed for comparison with healthy controls (n=168). The cut-off value was found to be 637 pg/ml with 90.9% sensitivity and 98.2% specificity. During follow-ups measurements were carried out in 3 month intervals following diagnosis, and 6 month intervals after 3 years. The median serum TARC value was 14350 pg/ml in patients with active disease status. In cases with complete remission determined by PET/CT scans median TARC concentration was 401 pg/ml. ROC curve analysis of active versus complete remission groups showed 85.6% sensitivity and 93.7% specificity with a 936 pg/ml cut-off value. This result was used in the second half of the study: In cohort 2, 69 patients were enrolled who were consecutively diagnosed with cHL between 2019 and 2020. In this cohort 58 of 69 patients had TARC value above the cut off limit. In 2019 we treated 27 patients, and 23 of them had a positive TARC test result at baseline. At the end of the first line treatment 18 were in complete remission verified by PET/CT. More importantly all of these patient had a TARC value below 936 pg/ml.
Summary/Conclusion: Our results show that TARC is a robust and reliable tool in classical Hodgkin lymphoma both at diagnosis and for follow-up. The cut off values we found were similar to the previously published results. Measuring TARC can provide a sensitive method for treatment response assessment that can make the PET/CT based treatment protocols more effective.

EP769 BRENTUXIMAB VEDOTIN WITH CHEMOTHERAPY IN ADOLESCENTS AND YOUNG ADULTS (AYAS) WITH STAGE III OR IV HODGKIN LYMPHOMA: A SUBGROUP ANALYSIS FROM THE PHASE 3 ECHELON-1 STUDY

A. P. Grigg [1,*], A. S. LaCasce [2], N. L. Bartlett [3], D. J. Straus [4], K. J. Savage [5], P. L. Zinzani [6], G. P. Collins [7], M. A. Fanale [8], K. Fenton [8], C. Dong [9], H. H. Miao [9], H. E. Crosswell [10]

[1]Clinical Haematology, Austin Hopsital, Austin, VIC, Australia, [2]Dana-Farber Cancer Institute, Partners CancerCare, Boston, MA, [3]Siteman Cancer Center, Washington University School of Medicine, St. Louis, [4]Lymphoma Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, United States, [5]BC Cancer, Vancouver, Canada, [6]Institute of Hematology "L. e A. Seràgnoli", University of Bologna, Bologna, Italy, [7]Oxford University Hospitals, NHS Trust, Oxford, United Kingdom, [8]Seagen Inc., Bothell, WA, [9]Takeda Oncology, Cambridge, MA, [10]Bon Secours Hematology Oncology, Bon Secours, St. Francis Health System, Greenville, SC, United States

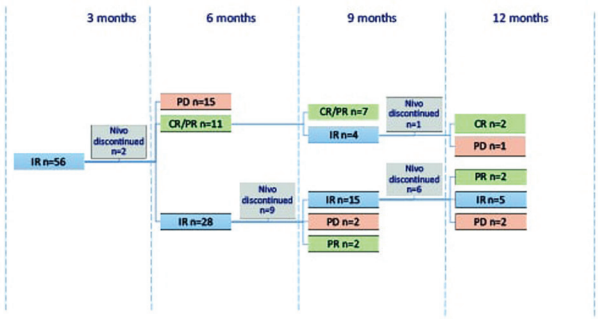
Background: Classical hodgkin lymphoma (cHL) is a rare disease that commonly occurs in adolescents and young adults (AYAs), typically defined as 15 to 39 years. Given their young age at presentation, key factors in treatment selection include not only a high cure rate, but minimal long-term toxicities. Brentuximab vedotin (Adcetris®; A) is a CD30-directed ADC approved in combination with doxorubicin, vinblastine, and dacarbazine chemotherapy (A+AVD) for adults with previously untreated stage III/IV cHL based on results from the phase 3 ECHELON-1 trial. Recent 5-year data demonstrated a significantly improved PFS per investigator (INV) vs doxorubicin, bleomycin, vinblastine, and dacarbazine (ABVD) (HR, 0.69; 95% CI, 0.54–0.9; P=0.003) (Straus 2020).
Aims: To describe key efficacy and safety results for AYA pts enrolled in ECHELON-1.
Methods: ECHELON-1 (N=1334) is a global, open-label, multicenter, randomized trial of pts with previously untreated stage III/IV cHL. A total of 771 AYAs (58%) received either A+AVD (n=396) or ABVD (n=375) with a PET scan after cycle 2 (PET2). An analysis of PFS (time from randomization to progression or death from any cause) per INV was conducted.
Results: These results refer to the AYA subset. After a median follow-up of 60.7 months (95% CI, 60.4-61.0), there was a 36% reduction in the risk of progression or death with A+AVD vs ABVD (HR 0.64; 95% CI, 0.45-0.92; P=0.013) with a 5-year PFS of 86.3% vs 79.4%, respectively, similar to the ITT population. The PFS benefit of A+AVD vs ABVD was independent of PET2 status; PET2 positivity (Deauville 4-5) was 6% and 8%, respectively.
On the A+AVD arm, 81 pts (20%) had at least one subsequent anticancer therapy (including radiotherapy) vs 96 pts (26%) on the ABVD arm; 26 pts (7%) received subsequent high dose chemotherapy and autologous stem cell transplant vs 32 pts (9%) on the A+AVD and ABVD arms, respectively.
Any-grade peripheral neuropathy (PN) occurred in 64% and 40% of pts on the A+AVD and ABVD arms, respectively. Resolution or improvement of PN occurred in 88-89% of pts on both arms. Ongoing PN was predominantly Grade 1 (62%) and Grade 2 (26%), with 8 pts (3% of

the total cohort) on the A+AVD arm and one pt (<1%) on the ABVD arm reporting ongoing Grade 3 PN. Seven pts (1.8%) and 5 pts (1.4%) on the A+AVD and ABVD arms, respectively, reported a secondary malignancy. Subsequent pregnancies were reported in female pts (44 A+AVD; 26 ABVD) and partners of male pts (31 A+AVD; 30 ABVD). No stillbirths were reported. All but one pt in each arm was <40.
Summary/Conclusion: Consistent with the ITT population, AYAs treated with A+AVD compared to ABVD had a durable PFS benefit at this significant 5-year milestone. No impact on the rate of secondary malignancies and a numerically greater number of pregnancies were observed, outcomes of interest to AYAs. Additionally, the majority of PN events improved or resolved over time. A+AVD should be considered a treatment option for AYAs with stage III/IV cHL.

EP770 BRENTUXIMAB VEDOTIN- CONTAINING REGIMENS FOR THE TREATMENT OF RELAPSED/REFRACTORY CLASSICAL HODGKIN LYMPHOMA IN CLINICAL PRACTICE: FOCUS ON SUBSEQUENT THERAPIES.

E. Borzenkova [1,*], N. Mikhaylova [1], K. Lepik [1], L. Fedorova [1], O. Smykova [1], A. Beinarovich [1], V. Baykov [1], N. Volkov [1], A. Kozlov [1], Y. Kuznetsov [1], E. Kondakova [1], E. Lepik [1], I. Moiseev [1], A. Kulagin [1]

[1]RM Gorbacheva Research Institute of Pediatric Oncology, Hematology and Transplantation, St. Petersburg, Russian Federation



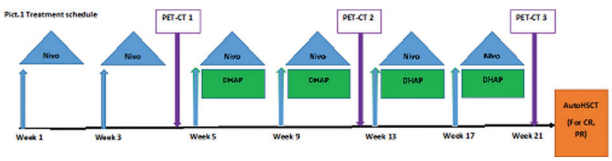
Background: Brentuximab vedotine (BV) has shown a high overall response rate in refractory/relapsed Hodgkin lymphoma (r/r cHL) with reported stable remissions achieved in pivotal clinical trial. However, only limited data is available regarding its role in role-term outcomes in real life clinical practice in light of recent treatment landscape shift due to the introduction of immune checkpoint inhibitors.
Aims: -
Methods: This retrospective analysis included patients with r/r cHL (n= 131) treated with BV – containing regimens in Pavlov University clinic from 2012 to 2020. Median age at BV- treatment was 28 year (range, 16-50). Seventy two percent of pts had advanced stages at BV- treatment. 61% of pts had primary refractory disease. ASCT was performed in 47,3% of patients prior BV- therapy. Median number of previous therapy lines was 4 (3-11). BV was used a monotherapy in 100 pts (76,3%) and in combination with bendamustine in 31 pts (23,6%). Median number of treatment cycles was 4 (range, 3-11). Dose of BV was 1,8mg/kg for all pts; dose of bendamustine was 90mg/m2 in day 1 and 2 of the 21 day cycle.
Results: At the time of analysis the median follow- up for alive pts (n=95) was 48,9 (3,0-104,6) months. Overall response rate was 61,0% (80 pts): CR in 38,9% (51 pts) and PR in 22,1% (29 pts). The duration of response for these pts was 11,1mo (1-101,4 months). Most of patients (93,1%, n=122) received additional therapy after BV-based treatment. The type of next therapy was BV-retreatment in 14,7% (18 pts), PD-1 inhibitors in 44,2% (54 pts), allogeneic stem cell transplantation (allo SCT) in 23,7% (29 pts), chemotherapy in 17,2% (21 pts). Overall, 58 pts were treated with anti PD-1 therapy at various time point after BV-based treatment.
The median overall survival (OS) was not reached and 5-year OS was 75,6%. The median progression free survival (PFS) was 6,0 mo (4,7-7,3 months) and 5- year PFS was 24,4%. At the moment of analysis, nine pts (6,8%) were in a remission after BV with no additional treatment.
Among factors significantly associated with favorable prognosis regarding the OS were PD-1 treatment after BV (5- year OS 89,7% vs 58,9%, p=<0,001) and consolidation by allo-SCT (5- year OS 82,8% vs 69,6%, p=0,049). Regarding PFS, the consolidation of remission by allo-SCT was significantly associated with favorable prognosis (5-year PFS 72,4% vs 10,8%, p=< 0,001)
Importantly, there was no benefit of combined regimens of BV+Bendamustine vs BV- monotherapy (5- year PFS of 30% vs 21,8%, p= 0,149), nor the overall response rate, p=0,881).
Summary/Conclusion: Brentuximab vedotin based regimens are highly active in inducing response in patients with r/r cHL with only modest potential achieve sustained remissions. There was no significant benefit of BV-benda combination regarding the PFS when compared to BVmonotherapy in the analyzed patient population. The outcomes of patients after BV treatment in the era of immunotherapy are more favorable than in registration studies, with significant advantage regarding OS in patients receiving anti-PD-1 treatment after BV failure. The alloHSCT represents an important approach for consolidation of response achieved with BV treatment, however the optimal strategy regarding the alloHSCT remains to be defined in prospective randomized trials.

EP771 OUTCOMES OF PATIENTS WITH INDETERMINATE RESPONSE DURING PD-1 INHIBITOR THERAPY FOR RELAPSED AND REFRACTORY CLASSICAL HODGKIN LYMPHOMA

L. Fedorova [1,*], D. Shmidt [1], K. Lepik [1], E. Kondakova [1], V. Baykov [1], I. Moiseev [1], N. Mikhailova [1], A. Kulagin [1]

[1]RM Gorbacheva Research Institute, Pavlov University, Saint Petersburg, Russian Federation

Background: Currently, the issue of adequate criteria for evaluation of response to immunotherapy of Hodgkin lymphoma is not resolved. LYmphoma Response to Immunomodulatory therapy Criteria (LYRIC) introduced a new concept of indeterminate response (IR). However, only a limited number of studies have evaluated the efficacy of PD-1 inhibitors using LYRIC criteria. Thus, the prognosis of patients who develop IR warrants further analysis.
Aims: To assess the response evolution and prognosis of patients with relapsed and refractory classical Hodgkin lymphoma (r/r cHL) who demonstrated IR during nivolumab (Nivo) therapy.
Methods: We retrospective reviewed data on 160 patients with r/r cHL treated with Nivo 3 mg/kg as part of the Russian Named Patient Program or 40 mg as part of a clinical trial (NCT03343665). Response was evaluated using PET-CT every 6 cycles (3 months).
The analysis identified 56 (35%) patients who achieved IR at first response evaluation according to LYRIC criteria after 3 months of therapy. Nivo dose was 3 mg/kg in 39 (70%) patients, 40 mg in 17 (30%) pts. There were 25 (45%) male and 31 (55%) female patients. Median age was 36 (23-64). Median time from diagnosis to Nivo was 33 (10-200) months. Thirty-nine (70%) patients were resistant to first-line chemotherapy. Prior to Nivo treatment brentuximab vedotin was administered in 24 (43%) patients and 15 (27%) patients underwent autologous HSCT. Stable disease (SD), partial response (PR) and progressive disease (PD) were in 1 (2%), 9 (16%) and 46 (82%) pts respectively. Extranodal disease was detected in 41 (73%) pts and B-symptoms in 37 (66%) pts. Median number of therapy lines was 4 (2-10).
Results: Two out of 56 pts discontinued Nivo at 3 months of therapy due to patient's decision. After 6 months of Nivo therapy 28 pts maintained IR, other variants of response are demonstrated in Picture 1. Nine patients with IR at 6 months discontinued Nivo due to discretion of the treating physician and continued different type of therapy. Among 19 pts with IR who continued Nivo therapy, at 9 months of treatment 15 pts retained IR. After 9 months of therapy Nivo was discontinued in 6 pts with IR due to discretion of the treating physician in 4 pts, secondary MDS in 1 pt and Named Patient Program closure in 1 pt. At 12 months of therapy 5 pts maintained IR, 2 pts transformed to PR and 2 pts to PD [Pic.1].
It is worth noting that biopsy was performed at the time of IR in 3 pts and tumor cells were found in all specimens.
Median follow-up was 36 (6-53) months. Three-year overall survival (OS) and progression-free survival (PFS) was 93% and 20%, respectively. Nivo dose was not associated with OS (p=0.76) or PFS (p=0.11). Disease status at the Nivo initiation was significantly associated with PFS (p=0.04), but not with OS. Extranodal disease presence was significantly associated with PFS (p<0.0001), but not with OS.



Summary/Conclusion: Patients with r/r cHL can maintain long-term stable clinical course during IR and Nivo therapy continuation despite the presence of tumor cells revealed in biopsy specimens. Thus, LYRIC criteria allow preventing early discontinuation of PD-1 inhibitor therapy in patients for which it could be potentially beneficial.

EP772 PRELIMINARY RESULTS OF THE COMBINATION OF NIVOLUMAB AND DHAP IN PATIENTS WITH RELAPSED OR REFRACTORY CLASSICAL HODGKIN LYMPHOMA (NIVO-DHAP) AS A SECOND-LINE THERAPY BEFORE AUTOLOGOUS HSCT

N. Mochkin [1,*], S. Vladislav [1], A. Mamedova [1], V. Melnichenko [1], E. Demina [1], V. Bogatyrev [1], A. Samoylova [1]

[1]Hematology&BMT, FSBI "NMSC n.a.N.I.Pirogov" Russian Ministry of Healthcare, Moscow, Russian Federation

Background: Immunotherapy with checkpoint inhibitors (anti-PD-1) is highly effective in relapsed/refractory (R/R) classical Hodgkin Lymphoma (cHL). Nivolumab, that was registered in Russia in december 2017, is widely used for this setting as a monotherapy. However, we have promising data about using Nivolumab in combination with different chemotherapy protocols as a bridge to autologous hematopoietic stem cell transplantation (autoHSCT), which remains the standard treatment for chemosensitive R/R cHL in the past decades.
Aims: To evaluate the safety and efficacy of Nivo-DHAP combination as a bridge to autoHSCT in patients with R/R cHL.
Methods: Study trial consisted of 2 cycles of Nivo as a monotherapy (fixed dose 240 mg every 14 days) with 4 subsequent cycles of Nivo-DHAP (fixed doses of Nivolumab 480 mg with standard doses of DHAP every 28 days). Response rate was assessed using PET-CT according to the Ligano and LYRIC criteria before Nivo-DHAP (PET-CT 1), after 2 cycles of Nivo-DHAP (PET-CT 2) and after 4 cycles of Nivo-DHAP (PET-CT 3). In case of chemosensitive disease at the end of the treatment, patients were proceeded to autoHSCT. Treatment schedule is represented at Picture 1. Cyclophosphamide+G-CSF, G-CSF alone or G-CSF+plerixafor were administered for stem cell mobilization. Safety assessment was carried out according to the toxicity criteria of the Common Terminology Criteria for Adverse Events (CTCAE) (v4.03). 20 patients treated from March 2020 until January 2021 were included in the preliminary analysis. All subjects provided written informed consent. Median age was 34 (21-55), male/female 12/8. 4 patients had more than 2 previous lines of therapy.
Results: The overall response rate was 75% (n=20, complete response (CR) 10%, partial response (PR) 65%, stabilization 20%, indeterminate response 5%) at PET-CT 1 (after 2 cycles of Nivo as a monotherapy). At PET-CT 2 (after 2 cycles of Nivo-DHAP) overall response rate reached 100% (n=20, CR 60%, PR 40%). At PET-CT 3 (after 4 cycles of Nivo-DHAP) it remains 100% (n=19, 1 patient is still on treatment). Hematological toxicity grade 3-4 was registered in 6 patients (30%), non-hematological toxicity were moderate (≤ grade 2): neurotoxicity – 3 (15%), nephrotoxicity – 2 (10%), skin toxicity – 1 (5%), endocrine disorders – 1(5%), infusion reactions – 1 (5%) patients respectively. Cytarabine and cisplatin doses were reduced in 5 patients (10-50% from baseline according to the standard approach). At the time of analysis, 13 patients underwent autoHSCT. In 2 patients stem cell mobilization failure was considered even with plerixafor administration.

Summary/Conclusion: Preliminary results of the combination of Nivolumab and DHAP showed high efficacy and relatively low toxicity in patients with R/R cHL before autoHSCT. We plan up to 40 patients in 2021 in order to obtain reliable data on the safety and efficacy of the regimen as well as to assess long-term survival and perform the retrospective comparative analysis with a group of patients who received the «traditional» DHAP without Nivolumab.

EP773 SUBCLINICAL COAGULATION DISORDERS IN NEWLY DIAGNOSED PATIENTS WITH HODGKIN LYMPHOMA (HL): A PHENOMENON RELATED TO THROMBOINFLAMMATION

C. Chatzidimitriou [1], M. Politou [2], P. Kotsi [3], I. Konstantinou [1], I. Assimakopoulos [1], M. Arapaki [1], M. Dimou [4], M. Dimopoulou [5], M. Siakantaris [5], M.-C. Kirtsoni [6], E. Variami [7], N.-A. Viniou [7], V. Komninaka [5], A. Liaskas [1], T. Giannikos [5], E.-F. Triantafyllou [5], M. Efstathopoulou [5], T. Iliakis [4], V. Pardalis [4], E. Plata [5], P. Tsaftaridis [5], P. Panagiotidis [6], K. Konstantopoulos [5], M. Angelopoulou [1], T. Vassilakopoulos [1,5,*]

[1]Department of Haematology and Bone Marrow Transplant Unit, National and Kapodistrian University of Athens, "Laikon" General Hospital, [2]Department of Transfusion Medicine, Aretaieion Hospital, School of Medicine,National and Kapodistrian University of Athens, Athens, [3]Department of Transfusion Medicine, University Hospital of Larissa, University of Thessaly, Larissa, [4]1st Propaedeutic Department of Internal Medicine, [5]Haematology and Bone Marrow Transplant Unit, National and Kapodistrian University of Athens, [6]1st Department of Propaedeutic and Internal Medicine, [7]1st Department of Internal Medicine, "Laikon" General Hospital, Athens, Greece

Background: Hodgkin lymphoma (HL) is characterized by an inflammatory syndrome, associated to advanced stages and B-symptoms and frequently manifested with increase in inflammation markers.
We observed in clinical practice, that HL patients frequently present at diagnosis with mild coagulation disorders, namely prolonged prothrombin time (PT) / INR and activated partial thromboplastin time (aPTT), which is not described as an established knowledge in textbooks.
Aims: We aimed to 1) analyze coagulation parameters [prothrombin time (PT), INR and activated partial thromboblastin time (aPTT)] in newly diagnosed HL patients in comparison to healthy individuals, 2) correlate them with clinical and laboratory parameters, and 3) investigate the possible underlying mechanisms.
Methods: Coagulation parameters (PT/INR, aPTT, fibrinogen, D-dimers) were determined and recorded in 80 consecutive patients with newly diagnosed HL before treatment initiation, compared to 225 healthy individuals and analyzed according to demographic data, clinical findings (histology, disease extent, IPS, B-symptoms) and laboratory parameters related to inflammation (hemoglobin, platelet and white blood cell count, ESR/CRP, albumin, α_2/γ-globulins, ferritin/haptoglobin). Coagulation factors (F)II, V, VII, X and TFPI were measured in plasma and serum with ELISA, respectively, in 35/80 patients.
Results: HL patients demonstrated increased median values of all parameters compared to controls: INR 1.12 vs 0.99 (p<0.001), aPTT 37.8 vs 33.9 (p<0.001) and fibrinogen 587.5 vs 303 (p<0.001). INR was elevated (>1.2) in 28.7% of patients, aPTT (>40 sec) in 32.9%, fibrinogen (>400 mg/dL) in 83.3% and D-Dimers (>0.5 μg/ml) in 54.4%. Elevated INR/PT, aPTT, and fibrinogen were observed more frequently in patients with advanced stages (IIB/III/V) and B-symptoms. INR and aPTT correlated strongly with all inflammation markers (Spearman's rho 0.25-0.53 and 0.26-0.38) except of leukocyte counts (and γ-globulins and ferritin for aPTT). Significantly increased levels of FII, FV and FX were observed in the majority of the patients (54.3%>88.6%), while FVII was found to be within normal limits and decreased in 1/35 patients. TFPI levels were also elevated in most cases (65.7%). A negative strong correlation between INR and FVII was noted (p<0.001). FII, FV, FX correlated with each other and with fibrinogen (p= 0.001-0.030), as well as with inflammation markers. No correlation was found between coagulation factor levels and clinical stage, B-symptoms or IPS, except the one of FX with high IPS (p=0.039).
Summary/Conclusion: Among HL patients 29-33% present with PT/INR and aPTT prolongation at diagnosis, which correlate with advanced stages, B-symptoms, and inflammation markers. This observation is of clinical importance because it prevents further unnecessary investigation. The observed negative correlation between INR and FVII, in combination with the increased levels of TFPI, suggests a possible role of TFPI in terms of excessive inhibition of TF/FVII complex. Notably, the increased levels of FII, FV, and FX correlate with inflammation markers. Taken together, the above data lead to the hypothesis that, prolonged PT/INR and aPTT are collateral findings related to disease activity and raised due to excessive activation of hemostasis in the context of thromboinflammation in HL. Similarly, the elevation of FII, FV, and FX is interpreted within thromboinflammation, which is seemingly in contrast

with the prolonged PT/aPTT, suggesting an underlying compensatory mechanism.

EP774 OUTCOME AND PROGNOSTIC FACTORS IN PATIENTS WITH ADVANCED HODGKIN LYMPHOMA WHO REMAIN PET/CT-POSITIVE AFTER 2 CYCLES OF ABVD: REAL-LIFE EXPERIENCE IN A MULTICENTER SETTING IN GREECE.

Background: Positive PET/CT after 2 cycles of ABVD (interim PET, iPET) has a strong adverse prognostic significance in patients with advanced Hodgkin lymphoma (HL), who continue treatment with ABVD. These patients could be successfully salvaged by treatment escalation to BEACOPP, but more "real-life" data are needed in order to predict their outcome.
Aims: The aim of this study is the evaluation of treatment strategies, patient outcome and potential prognostic factors in iPET positive (iPET+) patients in 15 hematological departments of Greece.
Methods: This is a retrospective study of 282 patients with advanced HL according to GHSG (stages III/IV or IIB with bulky mediastinal and/or extranodal disease), who received 2 cycles of ABVD and underwent PET/CT. iPET was evaluated according to the Deauville 5-point scale score (D5PSS) and scores 4 and 5 were considered positive (residual uptake >liver). In case of PET positivity, further treatment strategy (intensification to BEACOPP or not) was at the treating physician's discretion, as this study reflects every-day clinical practice. However, consistent strategies have been followed within the same Department. Radiotherapy was also at physician's discretion.
Results: iPET was negative in 77% and positive in 23% of patients respectively. 62 out of 65 iPET(+) patients were ≤60 years old and consisted the study population, as they were eligible for treatment intensification. Of these patients, 37 received intensified treatment: 36 with BEACOPP (of whom 31 received BEACOPP-escalated, 2 BEACOPP-14 and 3 BEACOPP-baseline) and 1 with ESHAP. 25 patients continued with ABVD due to individual Department's treatment strategy (n=18), or, in 7 patients, because of treating physician's decision or due to misclassification as D5PSS 3. The 5-year progression free survival (PFS) was 53% in the whole population of iPET(+) patients. It was 59% vs 41% for patients who received intensified treatment or continued with ABVD respectively (p=0.09). In Departments which did not follow the treatment intensification strategy the 5-year PFS was 32% for patients who continued with ABVD. Patients who remained iPET(+) with D5PSS 4 had 5-year PFS 60% vs 37% for patients with D5PSS 5 (p=0.13). Apart from patient's age, no other potential prognostic factor associated with disease extent or aggressiveness affected the outcome of iPET(+) patients. Surprisingly, patients <45 years old had inferior outcome in univariate analysis. In multivariate analysis, D5PSS 5 (vs 4) was an independent adverse prognostic factor for PFS (HR: 2.789, 95% CI: 1.049-7.416, p=0.04), whereas continuation with ABVD vs treatment intensification was of borderline significance (HR: 2.434, 95% CI: 0.934-6.340, p=0.069).
Summary/Conclusion: Our study provides "real-life" data confirming the adverse outcome of iPET(+) patients as well as the remarkable efficacy of treatment intensification with BEACOPP-escalated. Of note, the 5-year PFS almost reached 60% despite the fact that the study included patients with "strictly" advanced-stage disease, without admixing early stages with adverse characteristics. Conventional prognostic factors may be replaced by different scores of iPET positivity. However, larger studies are needed in order to confirm and extend these results in order to draw safe conclusions.

EP775 TREATMENT OF HODGKIN DISEASE IN RELAPSE AFTER 3 LINES INCLUDING BRENTUXIMAB WITH DOSE DENSE PROTOCOL PLUS LENALIDOMIDE

M. salamoon [1,*]

[1]medical oncology, al Bairouni university hospital, damascus, Syrian Arab Republic

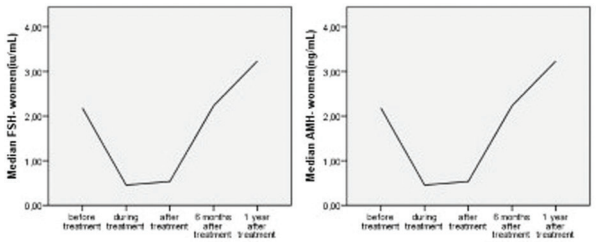
Background: Hodgkin disease, one of lymphoid malignancy that affects any age group with good results on standard chemotherapy. When relapse occurs, response rate decrease and survival becomes shorter. The introduction of anti-CD30 has improved results in relapsed patients; however, prognosis becomes very bad after further relapse.
Aims: to evaluate a new combination between dose-dense chemotherapy and lenalidomide in refractory Hodgkin lymphoma after at least 3 lines of chemotherapy and even after relapse on brentuximab
Methods: This is a prospective study conducted at Al Bairouni University Cancer Center in Damascus, Syria. We have included 75 patients with known HD in relapse after 3 lines of chemotherapy including Brentuximab. They received Cyclophosphamide 2gram/m^2 + Mesna uroprotection in day 1, Procarbazin 100mg/m^2 for 7 days, Gemcitabine 1000mg/m^2 on days 1 and 8, prednisolone 1mg/kg from day 1 through day 14 with G-csf support for 5 days from day 9 through day 13. Treatment is repeated every 21 days for 6 cycles. Lenalidomide at a dose of 10 mg daily was given upfront for 6 months.
Results: Complete response was documented in 52 patients (69.3%) and partial response in 12 patients (16%) while disease progressed in the remaining 11 patients. At 3 years of follow up, another 12 patients progressed with a progression free survival rate of 69.3% and 61 patients were found alive after 3 years with an overall survival rate of 81.3%. hematologic toxicities dominated the scene especially long term neutropenia and thrombocytopenia which decreased adherence to protocol to 85%. 10 out 75 patients received brentuximab as a 3rd line. 8 out of the 10 patients received brentuximab showed a complete response (p.value 0.05).among the 11 progressed patients, 6 had a pulmonary infiltration (p value 0.03)
Summary/Conclusion: In the light of good response rate and acceptable toxicity profile, we can recommend this combination as a 4th line treatment in relapsed HD patient and as a salvage in those candidates for peripheral stem cell transplant; however, larger number of patients is mandatory in order to generalize these results.

EP776 PET-STATUS AND PATIENTS WITH NEWLY HODGKIN LYMPHOMA (HL) PROGNOSIS: IS IT ALL THAT DEFINITIVE?

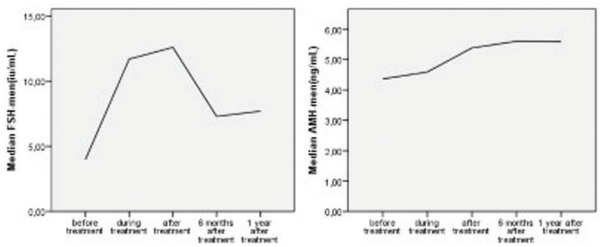
O. Novosad [1,*], I. Pastushenko [1], N. Shudrak [1], O. Gorbach [1], V. Kozlov [2], L. Mykhalska [3], O. Kindrakevych [3], M. Novikov [4], O. Karnabeda [5], V. Stratienko [6], O. Oliinichenko [7], Y. Kmetyuk [8], O. Karpova [8], A. Ashykhmin [9], T. Rudiuk [10], I. Kriachok [1]

[1]Oncohematology, National Cancer Institute, Kiev, [2]Hematology, Regional Clinical Hospital, Odessa, [3]Center of Hematology, Clinical Hospital "Feofaniya", [4]Diagnostic radiology, Oncology Hospital "LISOD", [5]Hospital of Oncology "Innovacia", Kiev,

[6]Hematology, Regional Clinical Hospital, Kherson, [7]Center of Nuclear Medicine, [8]Diagnostic radiology, Clinical Hospital "Feofaniya", [9]Radiology, National Cancer Institute, [10]Bogomolets National Medical University, Kiev, Ukraine



Background: Using PET in a metabolic response assessment has provided an opportunity of individualized treatment for patients with newly diagnosed HL. Current risk assessment systems cannot provide a reliable prediction of failure in an individual treatment. The main idea lying behind several PET protocol studies is identifying patients within a high-risk group and potential early relapse/refractory disease.
Aims: The primary endpoints were to assess a correlation between PET findings and response to therapy, type of regimen and clinical outcome, as well as whether there is a difference when patient treatment is intensified or not intensified depending on PET findings.
Methods: This sub-study was conducted in a scope of a broader prospective multicenter study on the predictive value of PET response assessment (205 patients with HL, up to 69 years of age). Patients received a treatment with ABVD or BEACOPP-14/esc or "switched-regimens" (ABVD+BEACOPP-esc/14, BEACOPP-esc/14+ABVD). Metabolic PET imaging was performed on routine protocols using Deauville criteria for response assessment.
Results: The ORR was 91.7%. The ORR for patients with stage I-II was 95.5% (106/111) vs 87.2% (82/94) for patients with stage III-IV.
In total, the disease progression occurred in 48.3% (15/31) of interim PET-positive (PET2+) patients and 11.5% (20/174) of interim PET-negative (PET2-) patients ($p<0.05$). We confirmed a significant difference between the 5-year event free survival (EFS) rate for patients with PET2+ vs PET2-. Thus, PET2- patients with early and advanced stages had an EFS level much higher than the PET2+ patient group (87% and 85% vs 55% and 15% respectively, Log-rank test, $p=0.0001$).
Using ABVD and "switched-regimens" for I-II-stage patients did not reveal a significant correlation to the 5-year EFS.However, a more intensified treatment for patients with stage III-IV of HL showed a significantly better level of EFS compared to the ABVD regimen, and it did not depend on PET2 status (Log-rank test, $p=0.0003$). Moreover, intermediate-risk group cohort (2B stage) tends to improve the EFS levels when the regimens was given BEACOPP-esc/14+ABVD vs ABVD+BEACOPP-esc/14 vs ABVD (80% vs 60% vs 55% respectively, $p=0.064$) and was independent of PET2 status.
End-of-treatment PET-negative (PET3-) status was found in 83.8% (130/155) of the study group patients and 16.1% (25/155) had the end-of-treatment PET-positive (PET3+), respectively ($p<0.05$). Using the Cox regression, we confirmed a significant correpatienlation between the EFS with PET3 status and ABVD regimen. 1-year EFS for this group of ts with PET3+ was worse than PET3-(15% vs 83% respectively, $p<0.0001$). Additionally, the combination of ABVD and radiotherapy for early stages has improved the EFS rate compared to sole ABVD treatment without radiation (86% compared 60%, $p=0.013$) based on PET3 status.
Summary/Conclusion: Our results of PET use with primary HL patients have demonstrated a high prognostic value of the interim and end-of-treatment PET. For intermediate-risk group and advanced stages in particular, the efficiency of treatment intensification improves regardless of their PET status.



EP777 EVALUATION OF GONADAL FUNCTION IN YOUNG MEN AND WOMEN DIAGNOSED WITH HODGKIN LYMPHOMA

A. Georgopoulou [1,*], A. Giannakou [1], T. Vassilakopoulos [1], K. Konstantopoulos [1], N. Georgopoulos [2], S. Kalantaridou [3], E. Lalou [1], K. Keramaris [1], E. Loukari [2], M. Arapaki [1], I. Konstantinou [1], M. Belia [1], C. Chatzidimitriou [1], A. Kopsaftopoulou [1], I. Mammali [1], D. Galopoulos [4], M. Angelopoulou [1]

[1]hematology and BMT department, laikon general hospital, ATHENS, [2]endocrinology department, university hospital of Patras, patras, [3]obstetrics and gynecology, areteion university hospital, [4]hematology and BMT, laikon general hospital, ATHENS, Greece

Background: ABVD or escBEACOPP chemotherapy +/- radiation is the treatment approach for patients with Hodgkin lymphoma (HL). As a result of treatment improvement, there are many long-term survivors, in whom treatment-related complications are recognized. Among these, gonadal insufficiency plays a fundamental role, with major psychological/social consequences. This is more prevalent in female patients, in whom collection and cryopreservation of oocytes or ovarian tissue are usually not applied in everyday clinical practice. Evidence-based data are scarce on this subject. Moreover, little is known about the kinetics of gonadal function and sex hormones during chemotherapy to safely guide contraceptive measures.
Aims: The aim of this study is the prospective evaluation of gonadal function in young men and women with hematological malignancies receiving chemotherapy. We here present the preliminary results on 45 patients with Hodgkin lymphoma.
Methods: This is a prospective study of gonadal function in HL patients, with an age limit of ≤40 years in women and ≤45 years in men. Hormonal measurements were performed at pre-specified time points: before treatment, during chemotherapy, at the end of chemotherapy and every six months for the following three years. The following hormones were measured: follicle-stimulating hormone (FSH), lutenizing hormone (LH), progesterone (PG), estradiol (E_2), anti-Mullerian hormone (AMH) in women and FSH, LH, testosterone, AMH and inhibin–β in men. The study included: 19 women [median age: 27 years, 19 ABVD] and 26 men [median age: 30 years, 26 ABVD]. FSH reflects gonadal function in both men (Sertoli cells) and women (increased levels indicate gonadal dysfunction). AMH is considered as the most sensitive biomarker for gonadal reserve in women (decreasing values correlate with ovarian insufficiency), but its exact role in men is not clarified. E2 and testosterone are the major sex hormones.
Results: Women: FSH values increased between the beginning and the end of treatment (median value: 4.35IU/mL, 7.7IU/mL, $p=0.001$). FSH increased from the beginning, peaking in the middle and remaining high until the end, without reaching normal levels six months after the end. Consistently with FSH, AMH showed a decrease during treatment: [median values: 1,92IU/mL (start), 0,18IU/mL (middle), $p=0.000$], maintained low levels through the rest of the treatment and slowly reached normal values six months later. Estradiol was not affected.
Men: Spermatogenesis, reflected by the increase of FSH, was affected: [median values: 3,7IU/mL (start), 11IU/mL (middle), 15IU/mL (end), fsh0-1 $p=0.000$, fsh0-2 $p=0,000$]. FSH increased during treatment, reaching a peak towards the end. FSH did not reach normal values after six months ($p=0,017$), but only after one year. Contrary to women, AMH values gradually increased during treatment: [median values: 4,13IU/mL (start), 4,28IU/mL (middle), 5,61IU/mL (end), $p=0.001$] and remained high until six months after the end of treatment. Most surprisingly, testosterone increased (start, middle, end: 430ng.dl, 534ng/dl, 596ng/dl, 0-1 $p=0,003$, 0-2 $p=0,002$ respectively).

Summary/Conclusion: Gonadal function in patients with HL is affected during chemotherapy in both sexes. In women, both FSH and AMH indicate gonadal dysfunction for at least 6 months after chemotherapy; AMH proved as a more sensitive marker compared to FSH. In men, gonadal function returned to baseline levels at one year after chemotherapy. However, in men, unexpectedly, AMH and testosterone significantly

increased during treatment, possibly reflecting destruction of Leydig cells.

EP778 ENDOCRINE DISORDERS IN HODGKIN LYMPHOMA SURVIVORS

M. Voytko [1,*], T. Pospelova [1], V. Klimontov [2], J. Shebunyaeva [1]

[1]Hematology, [2]endocrinology, Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: Current treatment options for Hodgkin's lymphoma are mostly effective, but may have a negative pronounced damaging effect on some organs. Long-term effects of antitumor therapy in HL survivors include secondary cancers, cardiovascular and pulmonary disorders, neurological complications, and endocrine and gonadal dysfunctions. Endocrine late effects with hormonal disturbances, could have many physical and social consequences for HL survivors.
Aims: To assess the prevalence and risk factors of endocrine disorders in HL survivors.
Methods: The study evaluated the functioning of the endocrine system in 160 patients with HL (55 male and 105 female) aged 18 to 65 years after chemoradiotherapy. The clinical examination included a biochemical analysis of blood, test of serum hormones (THS, T3, free T4, PTH, FSH, LH, free testosterone, DHEA-S, SHBG) by ELISA, BMD was assessed by dual-energy X-ray absorptiometry.
Results: The structure of endocrine pathology in patients with HL included primarily hypothyroidism (25%), hyperparathyroidism (15,6%) and hypogonadism (29% of male and 25.3% of female). Dysfunction of the hypothalamic-pituitary-thyroid axis occurred significantly more often in patients after combined chemoradiotherapy than in patients receiving chemotherapy only ($\chi 2=9,4$, p=0,002). We found that increased levels PTH was negatively correlated with BMD in the lumbar spine (r = -0,74, p = 0,00002) and in the femoral neck (r = -0,66, p = 0,0003). The men with HL had lower free testosterone than controls (p=0,04). However, LH and FSH levels in male with HL were elevated: p = 0,0004 and p = 0,04, respectively. Women of reproductive age with HL had higher levels of LH in the luteal phase (p = 0,05) and a higher levels of FSH in the follicular phase (p = 0,02) than controls.
Summary/Conclusion: The high prevalence of endocrine disorders in HL survivors demonstrates the necessity to develop screening programs for early treatment of endocrine pathology in patients with HL, as well as the participation of endocrinologists in the follow-up and treatment of this category of patients.

EP779 GERMAN EVIDENCE-BASED LIVING GUIDELINE ON DIAGNOSIS, THERAPY AND FOLLOW-UP OF ADULT PATIENTS WITH HODGKIN LYMPHOMA

A. Aldin [1,*], M. Follmann [2], P. Borchmann [3], C. Baues [4], S. Sasse [5], P. J. Bröckelmann [3], S. Kreissl [3], D. Eichenauer [3], J. Momotow [3], B. von Tresckow [3,6], S. Borchmann [3], A. Engert [3], N. Skoetz [1]

[1]Evidence-Based Oncology, Department I of Internal Medicine, Center for Integrated Oncology: Aachen Bonn Cologne Duesseldorf, Faculty of Medicine and University Hospital of Cologne, University of Cologne, Cologne, [2]German Guideline Program in Oncology, German Cancer Aid, Berlin, [3]German Hodgkin Study Group, Department I of Internal Medicine, Center for Integrated Oncology: Aachen Bonn Cologne Duesseldorf, Faculty of Medicine and University Hospital of Cologne, University of Cologne, [4]Department of Radiooncology, University Hospital of Cologne, Cologne, [5]Clinic for Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, RWTH Aachen University, Aachen, [6]Department of Hematology and Stem Cell Transplantation, West German Cancer Center, University Hospital Essen and University of Duisburg-Essen, Essen, Germany

Background: The German guideline for diagnosis, treatment and follow-up of adult patients with Hodgkin Lymphoma is an evidence-based guideline that is updated according to the living guideline principle. The guideline was first published in February 2013, and updated in June 2018. The second update (presented here) was published in October 2020; a third update will follow in 2021.
Aims: To keep recommendations on diagnosis, treatment and follow-up up-to-date and in line with new clinical research evidence.
Methods: The guideline was developed and updated jointly by a number of different national clinical and methodological experts. In March 2019, the systematic literature search was updated and conducted in MEDLINE, Embase und CENTRAL. After independent screening by methodological experts, the newly identified evidence was presented to the clinical working groups of the guideline. Subsequently, data was extracted from all studies that contributed to the clinical research questions of the guideline, and evaluated according to GRADE principles. Based on these results, new recommendations were derived and existing recommendations updated. All unmodified, updated and new recommendations were revised, discussed and voted on in a formal consensus process by a clinical expert panel from the participating professional societies. The guideline was funded by the German Cancer Aid (funding number 113332).
Results: The updated guideline entails 168 recommendations in total; thereof 29 updated and 13 new recommendations. The new recommendations concern patients in the intermediate stages, pregnant patients and rehabilitation measures. In patients with intermediate risk, a PET/CT-guided radiotherapy approach can be applied, if treated with two cycles of $BEACOPP_{escalated}$ followed by two cycles of ABVD ("2+2"). Thus, after chemotherapy with "2+2", an interim PET/CT scan shall be performed. Only those patients with a positive (Deauville-Score ≥4) interim PET/CT scan-result shall receive consolidation radiotherapy. For pregnant patients who are diagnosed in their first trimester of pregnancy, start of chemotherapy should be delayed until the beginning of the second trimester, if justifiable. For pregnant patients who are diagnosed in their second or third trimester, chemotherapy can be administered. Whether or not awaiting delivery is an option, shall be decided individually. If chemotherapy is administered, it should be stopped at the latest between the 35th and 37th week of pregnancy, or two weeks before delivery. Radiotherapy should be avoided during pregnancy. Patients who receive chemotherapy during pregnancy, can receive consolidation radiotherapy after delivery, but there should not be more than 12 weeks between completion of chemotherapy and start of radiation therapy. Prematurity, particularly before the 32nd week of pregnancy, should be avoided. Furthermore, pregnant patients shall undergo close obstetric monitoring, in addition to standard examinations. After therapy, all patients shall be offered medical rehabilitation to enable social reintegration and participation in work life.
Summary/Conclusion: Living guideline in the sense of a regular, standardized process in a defined time frame provides current recommendations for the treatment of different patient groups, which should be translated into daily clinical practice. As far as possible, guideline implementation will be monitored by recommendation-based quality indicators measured by cancer registries or certification systems.

EP780 TREATMENT OUTCOMES OF HODGKIN LYMPHOMA: PET GUIDED DE-ESCALATION IN REAL WORLD

S. Dasgupta [1,*], S. Dasgupta [1]

[1]Clinical Haematology, TATA MEDICAL CENTER, Kolkata, India

Background: Acceptance of de-escalating therapy in the REAL world has been slow due to the limited access and cost of PET scans.
Aims: To audit Hodgkin Lymphoma (HL) characteristics and 5-year outcomes in a single tertiary cancer center.
To study the outcomes of patients who underwent PET directed therapy compared to patients who received standard 6 cycles of ABVD therapy
Methods: 1396 lymphomas (>18 years) were entered in the *Onco-Collect* data base of patients receiving 1st line treatment from May 2011 to December 2017. Demography, Clinical features, staging, prognostic stratification, and first line treatment response and outcomes of 280 HL patients treated at a tertiary center have been analyzed. A PET directed approach was followed for patients receiving ABVD therapy. Early stage (1 and 2) patients received 4 or 6 cycles and in Late stage (3 and 4) received ABVD x 6 cycles or ABVD followed by AVD in patients who were in complete remission after 2 cycles.
Overall Response (OR) rates, and DFS were evaluated for patients receiving 1st line treatment, and these patients were followed till September 2020.
Results: HL formed 20% of the lymphoma cohort receiving 1st line treatment at our Institute. The median age was 37 years at presentation and age distribution was 53%, 39% and 8% respectively for <40 years, between 40 to 65 years and ≥ 65 years of age. Gender ratio for male to

female was 2.18:1. 41% Patients presented in early stage [I & II], and 58% in late stage [III &IV].
Most common protocol used was standard ABVD in 90% patients. The OR rate (CR +PR+ SD) was 89.2%, and the progression on treatment 6.8%. With a median follow-up of 48 months, the DFS is 79.36%. DFS for the patients above 65 years was 62% at 5 years and for those below 65 years was 76% (p=0.052). The 5-year DFS for stage 1, 2, 3 and 4 was 94.73%, 85.57%, 78.81% and 67.78% respectively (p=0.017). Patients with early-stage disease receiving 6 cycles (#55) had similar outcomes at 5 years compared to patients receiving 4 cycles +/- radiotherapy (#34). Outcomes for late-stage disease, after the omission of bleomycin after 2 cycles in patients achieving PET CR was comparable to patients receiving 6 cycles of ABVD
Summary/Conclusion: HL presents at a median age of 37 years in the adults ≥18 years and the bimodal peak is not seen in our population. The OR to treatment is nearly 90%, with CR in 76% patients. Our initial experience with de-escalation of therapy have yielded encouraging results in the REAL world setting. Long term outcomes for Stage 3 & 4, can be improved with chemotherapy escalation strategies or use of targeted molecules and immune therapy.

EP781 THE PROGNOSTIC VALUE OF PD-L1 AND PD-L2 LOCI ALTERATIONS IN PATIENTS WITH RELAPSED/REFRACTORY HODGKIN LYMPHOMA TREATED WITH NIVOLUMAB

L. Kirill [1,*], N. Elena [1], K. Yuriy [1], F. Liudmila [1], K. Elena [1], K. Andrey [1], B. Evgeniya [1], M. Ivan [1], B. Vadim [1], M. Natalia [1], G. Tatiana [1], M. Nikolay [1], I. Tatiana [1], K. Alexander [1]

[1]RM Gorbacheva Research Institute, Pavlov University, Saint-Petersburg, Russian Federation

Background: PD-1 inhibitors represent an effective option in the treatment of relapsed and refractory classical Hodgkin lymphoma (r/r cHL). The chromosomal alterations in 9p24.1 (PD-L1 and PD-L2) locus were shown to be a characteristic feature of malignant Reed-Sternberg (RS) cells, and considered as a potential predictive marker of immunotherapy efficiency in the limited number of reports.
Aims: The aim of the current study was to investigate the prevalence and the type of 9p24.1 alterations in severely the pretreated population of r/r cHL patients receiving nivolumab (nivo) during Russian named patient program, as well as to assess their influence on the efficiency of immunotherapy
Methods: This retrospective analysis included 46 patients with r/r cHL who were treated with nivo (26 female and 20 male). The median age was 30 (14-64). The histological types of cHL in this cohort were nodular sclerosis in 84,8% (n=39), mixed cellularity 8,7% (4), lymphocyte rich 4,3% (2), and lymphocyte depleted in 2,2% (1). An advanced disease at initial diagnosis was in 65,2 % (n= 30) of patients; 56,5% (n=26) of patients had primary resistant disease. The median number of previous lines of therapy was 5 (2-10). In 7 patients, the tumor biopsy was performed at the disease progression after immunotherapy with subsequent 9p24.1 locus analysis. Determination of the type of alteration in the biopsies was carried out according to the protocol presented in the previously published studies (Roemer MG, et.al. 2016).
Results: The alterations of the PD-L1 and PD-L2 loci were observed in all analyzed tumor specimens before and after nivo treatment. The type of alteration observed before immunotherapy was polysomy in 9% (n = 4), copy gain - in 69% (n = 32), amplification - in 22% (n = 10) of cases. The comparison of 9p24.1 alteration structure before and after immunotherapy showed an increase in the number of cases with 9p24.1 locus amplification (1/7 before vs. 4/7 after, p=0,14).
The analysis of the association of 9p24.1 alterations with the clinical outcomes was performed. There was a significant difference in progression-free survival among patients according to alteration type (p = 0.02): for 9p24.1 amplification, a 3-year PFS was 20% (95% CI 3.1- 47%) with median of 20.6 months (95% CI 6.6-35.6), for copy gain a 3-year PFS was 34% (95% CI 18-50%) with median PFS 23.8 months (95% CI 6.6- 35.6) and for polysomy, a 3-year PFS was 0% with a median PFS 7.2 months (95% CI 4.3-NE). However, the statistically significant influence of alteration type on best overall response was not observed (p = 0.2).
There was no significant dependences between alteration type and analyzed clinical factors, including initial disease stage (p = 0.86), the initial presence of B-symptoms (p = 0.78), and the primary refractory disease (p = 0.98). Despite the limited number of patients, a significant association (p = 0.03) of chromosomal alterations with the histological type of cHL was observed in the analyzed population: in all cases of 9p24.1 amplification, the nodular sclerosis type of cHL was confirmed during the histological investigation.
Summary/Conclusion: The polysomy of 9p24.1 may be considered as a negative prognostic factor regarding progression-free survival in a limited population of patients. The dynamics of 9p24.1 locus alterations before and after nivolumab therapy, as well as their association with the histological type of classical Hodgkin lymphoma were described.

Indolent and mantle-cell non-Hodgkin lymphoma - Clinical

EP782 IBRUTINIB PLUS RITUXIMAB (IR) VS PLACEBO PLUS RITUXIMAB (R) FOR WALDENSTROM'S MACROGLOBULINEMIA (WM): FINAL ANALYSIS AFTER FIVE YEARS OF FOLLOW-UP FROM THE RANDOMIZED PHASE 3 INNOVATE STUDY

Background: Ibrutinib is a once-daily Bruton's tyrosine kinase inhibitor approved as either a single agent or in combination with rituximab (R) for treatment of patients (pts) with WM across all lines of therapy. In the primary analysis of the phase 3 iNNOVATE™ study (NCT02165397; median follow-up 26.5 mo), IR demonstrated superior progression-free survival (PFS) vs placebo plus R in pts with WM.
Aims: We present results from the final analysis of the randomized arms of iNNOVATE.
Methods: Pts with confirmed symptomatic WM were randomized (75 pts per arm) to once-daily ibrutinib 420 mg or placebo plus R (375 mg/m^2/wk IV at weeks 1–4 and 17–20). Pts could receive first-line treatment or be previously treated; pts with prior R therapy had to have achieved at least a minor response (MR) to their last R-based regimen. Endpoints included PFS and response rates per Independent Review Committee, overall survival (OS), hemoglobin (Hgb) improvement, time to next treatment (TTNT), and safety. Change in serum IgM was also assessed.
Results: Pt characteristics were well balanced between arms. After a median follow-up of 50 mo (range 0.5+ to 63), median PFS had not been reached (NR; 95% CI 57.7 mo to not estimable) with IR vs 20.3 mo (95% CI 13.0–27.6) with R (hazard ratio [HR] 0.25 [0.15–0.42]; *P*<0.0001) (**Figure**); 54-mo PFS rates were 68% vs 25%. PFS benefit with IR vs R was independent of prior treatment status (HR [95% CI]: first-line, 0.32 [0.14–0.70]; previously treated, 0.22 [0.11–0.43]) or genotype (HR [95% CI]: MYD88^{L265P}/CXCR4^{WT},

0.18 [0.08–0.43]; MYD88^{L265P}/CXCR4^{WHIM}, 0.27 [0.12–0.62]; MYD88^{WT}/CXCR4^{WT}, 0.29 [0.07–1.19]). Improved PFS with IR was observed across prespecified subgroups, including age, serum IgM, Hgb, IPSSWM, and MYD88 mutation status. Major response rates (≥partial response) with IR increased and were sustained over time, reaching 76% vs 31% with R (P<0.0001); overall response rates (≥MR) were 92% vs 44% (P<0.0001). A greater proportion of pts achieved sustained Hgb improvement with IR vs R (77% vs 43%; P<0.0001). IgM decreased rapidly during the first year; maximum change was –33.5 g/L with IR (56 mo) vs –26.9 g/L with R (57 mo). Median OS was NR in either arm; 54-mo OS rates were 86% with IR vs 84% with R. Median TTNT was NR with IR and 18 mo with R; 87% of pts receiving IR and 29% receiving R had not received subsequent treatment at 54 mo. Thirty-five pts (47%) on R crossed over to single-agent ibrutinib after disease progression. The safety profile of IR was consistent with previous reports. The prevalence of grade ≥3 AEs of clinical interest with IR generally decreased over time. Of 12 pts with grade 3–4 atrial fibrillation, 9 (75%) remained on treatment; no other ibrutinib discontinuations due to common (≥10%) grade 3–4 AEs occurred. 88% of AEs that led to an ibrutinib dose reduction resolved following dose reduction. After study closure, 68 pts (45%) remained on treatment (32 in an extension study; 36 in a commercial setting).

Figure. PFS per IRC by treatment group

NE, not estimable.

Summary/Conclusion: With up to 5 years of follow-up, IR showed ongoing superiority across clinical outcomes in pts with WM regardless of genotype, prior treatment, and key pt characteristics. Similar patterns of response with IR were observed in pts receiving first-line treatment and in previously treated pts. No new safety signals were observed; IR maintained a manageable safety profile after an additional 24 months of follow-up.

EP783 PHASE 2 STUDY OF ZANUBRUTINIB IN PATIENTS WITH RELAPSED/REFRACTORY MARGINAL ZONE LYMPHOMA (MAGNOLIA STUDY)

Background: BCR signaling mediated through Bruton's tyrosine kinase (BTK) plays a critical role in the development and maintenance of marginal zone lymphoma (MZL). BTK inhibitors have established activity in relapsed/refractory (R/R) MZL with the phase 2 study of ibrutinib demonstrating an objective response rate (ORR) of 48% (Noy et al. *Blood*. 2017;129:2224-2232).

Zanubrutinib is a potent and highly specific next-generation BTK inhibitor designed with greater selectivity for BTK vs TEC- and EGFR-family kinases, which are thought to be related to off-target toxicities. Therapeutic activity of zanubrutinib was established in an early-phase study (BGB-3111-AU-003) of 20 patients (pts) with R/R MZL demonstrating an ORR of 80%, with a complete response (CR) rate of 15%, and partial response (PR) rate of 65% (Tedeschi et al. EHA 2020, abstract 2804).

Aims: To present initial efficacy and safety results in pts with R/R MZL enrolled in MAGNOLIA (BGB-3111-214).

Methods: MAGNOLIA is a phase 2, multicenter, single-arm study of adults with R/R MZL who had received ≥1 line of therapy including ≥1 CD20-directed regimen. All were treated with zanubrutinib 160 mg twice daily until disease progression or unacceptable toxicity. Use of long-term antiplatelet and anticoagulation agents was permitted. The primary end point was ORR determined by an independent review committee in accordance with the Lugano classification. Secondary end points include ORR by investigator assessment, duration of response (DOR), progression-free survival (PFS), and safety.

Results: As of January 11, 2021, 68 pts were enrolled and treated. Median age was 70 years (range, 37-95), with 28% aged ≥75 years. Subtypes included extranodal (mucosa-associated lymphoid tissue; 38%), nodal (38%), splenic (18%), and indeterminate (6%) MZL. Median number of prior therapies was 2 (range, 1-6) and 32% of pts had disease that was refractory to last therapy.

Median duration of drug exposure was 59.1 weeks (range, 3.7-84.1). Sixty-six pts were evaluable for efficacy. At a median study follow-up of 15.5 months (range, 1.6-21.7), investigator-assessed ORR (CR + PR) was 74% (CR 24%, PR 50%, stable disease 17%). Responses were observed in all subtypes, with an ORR of 68%, 84%, 75%, and 50% in extranodal, nodal, splenic, and indeterminate subtypes, respectively. CR rate was 36% for extranodal MZL, 20% for nodal, 8% for splenic, and 25% for indeterminate subtype. Median DOR and PFS were not reached; 15-month PFS was 68% and 12-month DOR was 81%. IRC review is ongoing.

Twenty-eight (41%) pts discontinued treatment: 20 due to disease progression, 1 withdrew consent, 3 required prohibited medications, 4 due to adverse events (AEs; 2 due to COVID-19 pneumonia, 1 due to pyrexia attributed to disease transformation, and 1 due to myocardial infarction [MI]). The most common (≥10%) treatment-emergent AEs reported were diarrhea (22%), bruising (21%), constipation (15%), pyrexia (13%), abdominal pain (12%), upper respiratory tract infection (12%), back pain (10%), and nausea (10%). Most AEs were grade 1 or 2. Neutropenia was the most common grade ≥3 AE (10%). Two pts

died from COVID-19 pneumonia and 1 pt with pre-existing coronary artery disease died from MI. No fatal AEs were considered related to zanubrutinib. All-grade AEs of interest included neutropenia (13%), thrombocytopenia (13%), atrial fibrillation/flutter (3%), and hypertension (3%). No major/serious hemorrhage was reported. No AEs led to dose reductions.

Table: Baseline Characteristics, Efficacy, and Safety Outcomes

	R/R MZL (N = 68)[a]
Baseline Characteristics	
Male sex, n (%)	36 (52.9)
ECOG PS 0-1, n (%)	63 (92.6)
Bone marrow involvement, n (%)	29 (42.6)
Efficacy (investigator assessment)	**(N = 66)[b]**
ORR, n (%) [95% CI]	49 (74.2) [61.99, 84.22]
Best response, n (%)	
CR	16 (24.2)
PR	33 (50.0)
SD[c]	11 (16.7)
PD	5 (7.6)
Discontinued study before first assessment	1 (1.5)
Time to response (months), median (range)	2.8 (1.7, 8.5)
Safety[d]	**(N = 68)[a]**
Any AE	65 (95.6)
Grade ≥3 AE, n (%)	26 (38.2)
Serious AE, n (%)	25 (36.8)

AE, adverse event; CR, complete response; ECOG PS, Eastern Cooperative Oncology Group performance status; MZL, marginal zone lymphoma; ORR, overall response rate; PD, progressive disease, PR, partial response; R/R, relapsed/refractory; SD, stable disease.
[a] Safety analysis set is defined as all patients who received at least one dose of study drug.
[b] Efficacy-evaluable set is defined as patients who received at least one dose of study drug and with centrally-confirmed diagnosis of MZL (2 patients were excluded due to MZL transformation to diffuse large B-cell lymphoma).
[c] Three patients with stable disease were continuing on study treatment.
[d] Treatment-emergent AEs including AEs that had an onset date or worsening of severity from baseline (pretreatment) on or after the first dose of study drug and up to 30 days after study drug discontinuation or initiation of a new anticancer therapy. Worsening of an event to Grade 5 beyond day 30 after last dose of study of a treatment-emergent adverse event is also considered a treatment-emergent adverse event (if it is prior to new anticancer therapy start).

Summary/Conclusion: Zanubrutinib demonstrated high response rates and durable disease control with a favorable safety profile in pts with R/R MZL.

EP784 PRELIMINARY CLINICAL DATA FROM A PHASE 1B STUDY OF MAVORIXAFOR AND IBRUTINIB IN PATIENTS WITH WALDENSTRÖM'S MACROGLOBULINEMIA WITH MYD88 AND CXCR4 MUTATIONS

S. Treon [1,2,*], C. Buske [3], S. Thomas [4], A. Branagan [5], M. Dimopoulos [6], J. J. Castillo [7,8], F. Garzon [9], W. Tang [9], R. Ronan [9], S. Seyffert [9], V. Garg [9], S. Ali [9], A. Taveras [9], A. Badarau [10], K. Zmajkovicova [10], S. Maier [10], B. Maierhofer [10], J. Matous [11]

[1]Bing Center for Waldenstrom's Macroglobulinemia Research, [2]Dana Farber Institute, Harvard Medical School, Boston, MA, United States, [3]Comprehensive Cancer Center and Institute of Experimental Cancer Researc, University of Ulm, Ulm, Germany, [4]Deparatment of Lymphoma/Myeloma, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, [5]Massacusettes General Hospital Cancer Center,, Boston, MA, United States, [6]Department of Clinical Therapeutics, National and Kapodistrian, University of Athens School of Medicine, Athens, Greece, [7]Bing Center for Waldenstrom's Macroglobulinemia, [8]Dana Farber Cancer Institute, Harvard Medical School, [9]X4 Pharmaceuticals, Boston, MA, United States, [10]X4 Pharmaceuticals, Vienna, Austria, [11]Colorado Blood Cancer Institute, Sarah Cannon Research Institute, Denver, CO, United States

Background: Waldenström macroglobulinemia (WM) is a rare B-cell lymphoproliferative disorder characterized by increased clonal IgM-secreting cells. Though other covalent and noncovalent BTK inhibitors (BTKi) are in development for WM, ibrutinib is the only BTKi approved by the FDA and EMA for WM. Most patients with WM (>90%) have somatic mutations in *MYD88*, and a subset (≤40%) also have WHIM-like activating mutations in *CXCR4* (*CXCR4*^{WHIM}). The presence of *CXCR4*^{WHIM} impacts response to BTKi in WM, as manifested by delayed response, inferior depth of response, and/or shorter progression-free survival. Inhibition of CXCR4 has been shown to sensitize *CXCR4*^{WHIM}-expressing cells to ibrutinib. Mavorixafor, an oral small-molecule antagonist of CXCR4, has been shown to inhibit CXCL12 binding and ERK hyperactivation for many *CXCR4* mutations in vitro.
Aims: This study examines the safety and efficacy of mavorixafor in combination with ibrutinib in patients with WM with *MYD88* and *CXCR4* mutations.
Methods: This phase 1b, open-label, multicenter, single-arm study (NCT04274738) examines intra-patient dosing, safety, pharmacokinetics (PK), and pharmacodynamics (PD) of mavorixafor in combination with ibrutinib. Eligibility includes age ≥18 years, clinicopathological WM diagnosis, consensus criteria indication for treatment, measurable disease, 0–3 prior therapies, confirmed *MYD88*^{L265P} and *CXCR4*^{WHIM} mutations, and ability to provide written informed consent. Patients are initiated on mavorixafor 200 mg and ibrutinib 420 mg, both oral and once-daily (QD). Mavorixafor escalation to 400 mg occurs after 28 days if no dose-limiting toxicities (DLTs) are observed and to 600 mg after 400 mg is deemed safe (<2/6 DLTs). Patients are followed for adverse events (AEs) and change from baseline in IgM, PK, and PD (peripheral white blood cell [WBC] counts).
Results: At data cutoff (January 22, 2021), 7 patients have enrolled; all continue on study. All 7 patients were escalated to 400 mg, with 6 remaining at 400 mg and 1 de-escalated to 200 mg (median exposure, 90 days). None have yet escalated to 600 mg. A total of 56 AEs were observed (84% grade 1 severity). Of 50 AEs with complete assessment for causal relationship to study drugs, 4 were deemed related to mavorixafor only, 7 to ibrutinib only, and 18 to the combination. A single patient experienced all events attributed to mavorixafor only (all grade ≤2 GI events). Only 1 DLT was observed, consisting of grade 3 hypertension with definitive attribution to ibrutinib and possible attribution to mavorixafor. No AEs led to study discontinuation, and no serious AEs were observed. Six out of 7 patients showed decrease in IgM after 1 cycle. Four patients were treated for ≥3 cycles; all had decrease in serum IgM, with 2 achieving a ≥50% decrease from baseline consistent with partial response after 3 cycles (median decrease, 51.0%; range, 4.4%–84.5%). Mavorixafor and ibrutinib exposures were consistent with previous reports, and combination treatment increased peripheral lymphocytes, neutrophils, and monocytes.
Summary/Conclusion: Our findings to date in patients with WM carrying both *MYD88* and *CXCR4* mutations show that mavorixafor in combination with ibrutinib is well tolerated at doses up to 400 mg QD. Mavorixafor and ibrutinib exposures were consistent with previous single-agent studies, suggesting no drug–drug interactions, and mavorixafor exposures tracked with increases in key WBC counts. Combination of mavorixafor with ibrutinib led to rapid and clinically meaningful decrease in IgM levels, suggesting that mavorixafor may sensitize *CXCR4*^{WHIM}-expressing cells to BTKi.

EP785 ROLE OF MAINTENANCE RITUXIMAB (MR) AFTER FIRST-LINE (1L) BENDAMUSTINE + RITUXIMAB (BR) OR R-CHOP IN PATIENTS (PTS) WITH MANTLE CELL LYMPHOMA (MCL) FROM A LARGE US REAL-WORLD (RW) COHORT

G. Salles [1,*], M. Wang [2], A. Kumar [1], K. Qi [3], K. Daly [4], L. Parisi [4], A. Zhu [4], P. Martin [5]

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX, [3]Janssen Research & Development, IHI RWE, Titusville, NJ, [4]Janssen Research & Development, Oncology, Raritan, NJ, [5]Weill Cornell Medicine, New York-Presbyterian Hospital, New York, NY, United States

Background: Maintenance with rituximab (MR) after 1L R-CHOP improved overall survival (OS) in both young and elderly pts with MCL in clinical trials. How MR is used in routine clinical practice and the benefits of MR after 1L BR are less defined.
Aims: To evaluate the RW patterns and outcomes of MR after 1L BR or R-CHOP in a large US MCL cohort.
Methods: This retrospective study included adult pts with MCL diagnosed Jan 2011-Nov 2020 in the nationwide Flatiron Health EHR-derived deidentified database. MR is defined in pts who received 1L induction combination with R, and R was continued as monotherapy for ≥28 days. Pt characteristics, treatment patterns, RW time to next treatment (rwTTNT, defined as start of 1L treatment to subsequent treatment

or death), and rwOS were evaluated for pts treated with 1L BR or R-CHOP±MR ("entire cohort"). Considering the potential for selection biases in the application of MR, analyses were also performed in pts who were alive and did not initiate subsequent treatment within 8 months of starting 1L BR or within 6 months of 1L R-CHOP ("MR-eligible cohort"). Multivariate analyses (MVA) were performed for rwTTNT/OS on the effects of MR adjusting for age, ECOG PS, LDH, WBC, and blastoid/pleomorphic and bulky disease status.

Results: Among 2946 pts with documented 1L MCL treatment, 86.3% were from community oncology setting. In the entire cohort, 854 pts received BR alone (median duration of treatment [mDOT]: 4.1 months), 368 received BR+MR (mDOT: 25.7 months), 365 received R-CHOP alone (mDOT: 3.5 months), and 147 received R-CHOP+MR (mDOT: 26.9 months). Median age of pts starting 1L BR±MR (72.8 years) was older than pts starting 1L R-CHOP±MR (66.4 years). A lower proportion of pts receiving BR+MR had high-risk MCL international prognostic index (MIPI; 26.0% vs 38.0%) and blastoid/pleomorphic MCL (4.9% vs 7.5%) vs BR alone. With estimated median follow-up of 39.8 months (range 0.03-117.1) for BR±MR and 61.0 months (range 0.03-115.0) for R-CHOP±MR, the 36-month rwTTNT rate was the highest with BR+MR (72%), followed by R-CHOP+MR (68%). Median rwTTNT was reached at 17.0 and 7.8 months for BR and R-CHOP alone, respectively.

In the MR-eligible cohort, 590 pts received BR alone (mDOT: 4.67 months), 365 received BR+MR (mDOT: 25.8 months), 207 received R-CHOP alone (mDOT: 4.0 months), and 145 received R-CHOP+MR (mDOT: 26.9 months). Disease characteristics of intermediate/high MIPI or blastoid/pleomorphic biology were similar among those treated with BR/R-CHOP only vs those with BR/R-CHOP+MR (Table). MVA showed that MR was independently associated with longer rwTTNT (hazard ratio [HR] 0.45; 95% confidence interval [CI], 0.38-0.53; p <0.001) and rwOS (HR 0.56; 95% CI, 0.45-0.7; p <0.001). With estimated median follow-up of 38.9 months (range 0.03-117.1) for BR±MR and 64.3 months (range 0.03-115.0) for R-CHOP±MR, the 36-month rwTTNT rate was 73% for BR+MR and 69% for R-CHOP+MR. Estimated median rwTTNT was reached at 36 and 21.5 months for BR and R-CHOP alone, respectively. The 36-month rwOS rate was 84% for BR+MR, 76% for BR alone, 89% for R-CHOP+MR, and 76% for R-CHOP alone.

Table. Baseline characteristics and clinical outcomes in the MR-eligible cohort

	MR-eligible cohort			
	BR N = 590	BR+MR N = 365	R-CHOP N = 207	R-CHOP+MR N = 145
Baseline characteristics				
Median age at LOT 1, years	73.2	71.9	66.4	67.7
Bulky disease, n/N (%)	82/577 (14.2)	63/362 (17.4)	31/203 (15.3)	20/142 (14.1)
ECOG PS ≥ 2, n/N (%)	34/307 (11.1)	14/181 (7.7)	5/66 (7.6)	3/69 (4.3)
MIPI intermediate risk, n/N (%)	65/156 (41.7)	47/100 (47.0)	18/35 (51.4)	19/37 (51.4)
MIPI high risk, n/N (%)	51/156 (32.7)	26/100 (26.0)	12/35 (34.3)	12/37 (32.0)
Blastoid/pleomorphic MCL, n (%)	29 (4.9)	18 (5.0)	23 (11.1)	12 (8.3)
Clinical outcomes				
36-month rwTTNT rate, % (95% CI)	50 (45-55)	73 (68-78)	37 (30-45)	69 (62-78)
36-month rwOS rate, % (95% CI)	76 (72-81)	84 (80-89)	76 (69-82)	89 (84-95)

LOT, line of therapy.

Summary/Conclusion: This is the largest RW cohort of pts with MCL who were treated with 1L BR or R-CHOP followed by MR. MR was associated with improved rwTTNT and rwOS. The best rwTTNT rate was seen with 1L BR+MR. The phase 3 SHINE study (NCT01776840) is evaluating the potential benefit of adding ibrutinib to BR with R maintenance in pts with previously untreated MCL.

EP786 KTE-X19 VERSUS STANDARD OF CARE FOR RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA PREVIOUSLY TREATED WITH BRUTON TYROSINE KINASE INHIBITORS: REAL-WORLD EVIDENCE FROM EUROPE

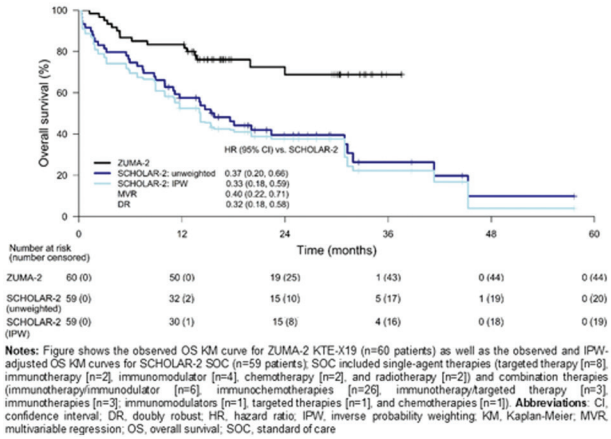
Background: Patients with mantle cell lymphoma (MCL) who progress after receiving a Bruton tyrosine kinase inhibitor (BTKi) have generally poor prognosis. KTE-X19, an autologous anti-CD19 chimeric antigen receptor T cell therapy, is being evaluated in patients with relapsed/refractory (R/R) MCL who received 1–5 prior therapies including a BTKi (phase II multicenter, single arm ZUMA-2 trial). Results for 60 efficacy-evaluable patients with ≥12 months of follow-up have been previously reported (Wang et al., ASH 2020, Abstract 1120). After a median follow-up of 17.5 months, the estimated overall survival (OS) rate at 15 months was 76%; median OS was not reached.



Aims: To estimate and compare effectiveness of treatment of R/R MCL post-BTKi with KTE-X19 versus active standard of care (SOC) in a real-world patient cohort in Europe, based on individual patient data.

Methods: The estimated clinical efficacy of KTE-X19 came from ZUMA-2, and real-world data on the effectiveness of SOC across Europe was collected in a retrospective, observational, multicenter chart review (SCHOLAR-2). An SOC cohort was constructed to closely match the patients enrolled in ZUMA-2 (patients with ECOG 0–1 and a minimum of 12-month potential follow-up from initiation of active therapy post-BTKi). A naïve (unadjusted) comparison was performed as a benchmark, followed by three separate comparisons using inverse probability weighting (IPW), multivariable regression (MVR), and doubly robust methods designed to adjust for imbalances in prognostic factors across the two non-randomized populations. Survival times were summarized using Kaplan-Meier curves. Cox proportional hazards models were used to estimate the effect of KTE-X19 relative to SOC with outcomes presented as hazard ratios (HRs) along with the 95% confidence intervals (CIs).

Results: Clinical data from 288 R/R MCL patients treated with a BTKi between July 2012–July 2018 were collected in SCHOLAR-2 across 24 centres in Denmark, France, Germany, Italy, Spain, Sweden, and the United Kingdom. The SOC cohort included 59 patients who received their first subsequent active treatment(s), referred to as SOC, prior to July 2019. Baseline characteristics were median age of 63 years, 73% male, 46%/54% ECOG 0/1, 82% stage III–IV disease, 36% with a prior autologous stem cell transplant (ASCT), and 95% with ≥2 prior lines of therapy. The median number of prior lines of therapy including BTKi was 3 (range: 1–6). Median duration on prior BTKi was 7.3 months, and the ORR to prior BTKi was 40%. In ZUMA-2, baseline characteristics were median age of 65 years, 85% male, 97% Stage III-IV, median of 3 prior lines of therapy, 43% prior ASCT, and median duration of 7 months on prior BTKi with ORR of 37%.

At a median follow-up of 27.6 months from initiation of SOC in SCHOLAR-2, the median OS was 15.7 (95% CI: 10.0–30.9) months; 15-month OS rate was 52%. Results of the naïve, unweighted, comparison showed that KTE-X19 was superior to SOC with an OS HR of 0.37 (95% CI: 0.20–0.66; p<0.001). The IPW-adjusted median OS in SCHOLAR-2 was 14.2 (95% CI: 8.8–30.9) months. With the IPW approach (base-case), the HR was 0.33 (95% CI: 0.18–0.59; p<0.001), consistent with the naïve analysis. The HR estimates were also consistent across sensitivity analyses using the MVR and doubly robust models (Figure 1).

Figure 1: Kaplan-Meier curves of overall survival in ZUMA-2 (KTE-X19) and SCHOLAR-2 (standard of care)

Notes: Figure shows the observed OS KM curve for ZUMA-2 KTE-X19 (n=60 patients) as well as the observed and IPW-adjusted OS KM curves for SCHOLAR-2 SOC (n=59 patients); SOC included single-agent therapies (targeted therapy [n=8], immunotherapy [n=2], immunomodulator [n=4], chemotherapy [n=2], and radiotherapy [n=2]) and combination therapies (immunotherapy/immunodulator [n=6], immunochemotherapies [n=26], immunotherapy/targeted therapy [n=3], immunotherapies [n=3]; immunomodulators [n=1], targeted therapies [n=1], and chemotherapies [n=1]). **Abbreviations**: CI, confidence interval; DR, doubly robust; HR, hazard ratio; IPW, inverse probability weighting; KM, Kaplan-Meier; MVR, multivariable regression; OS, overall survival; SOC, standard of care

Summary/Conclusion: This analysis suggests that KTE-X19 can improve survival over current active SOC in Europe for the treatment of R/R MCL in patients who have previously received BTKi therapy.

EP787 OUTCOMES WITH KTE-X19 IN PATIENTS WITH RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA IN ZUMA-2 WHO HAD PROGRESSION OF DISEASE WITHIN 24 MONTHS OF DIAGNOSIS

M. L. Wang, MD [1,*], J. Munoz, MD, MS, FACP [2], A. Goy, MD [3], F. L. Locke, MD [4], C. A. Jacobson, MD, MMSc [5], B. T. Hill, MD, PhD [6], J. M. Timmerman, MD [7], H. Holmes, MD, MBA, FACP [8], S. Background: KTE-X19 is an autologous anti-CD19 chimeric antigen receptor (CAR) T-cell therapy approved in the United States and European Union for the treatment of relapsed/refractory mantle cell lymphoma (MCL). In the ZUMA-2 study in which KTE-X19 was evaluated in relapsed/refractory MCL, the objective response rate at a median 17.5-month follow-up period was 92% (67% complete response rate; *Blood*. 2020;136[suppl, abstr]:20-22).
Aims: To report results in patients with or without progression of disease within 24 months of diagnosis (POD24), an indicator of poor outcomes (*Br J Haematol*. 2019;185:940-944).
Methods: Eligible patients with relapsed/refractory MCL underwent leukapheresis and conditioning chemotherapy followed by a single infusion of KTE-X19. Efficacy results are reported for the 60 treated patients with ≥1 year of follow-up (median, 17.5 months), and safety results are presented for all 68 treated patients.
Results: High-risk disease characteristics were common in patients with (n=33) and without POD24 (n=35), although patients with POD24 had higher tumor burden and lactate dehydrogenase levels, and more had blastoid-type MCL (Table). The objective response rate in patients with (n=28) and without POD24 (n=32) was 93% and 91%, with complete response rates of 61% and 72%, respectively. In patients with and without POD24, median progression-free survival was 11.3 months (range, 0.9–30.3) and 29.3 months (range, 0–35.9), respectively. Medians for duration of response and overall survival were not reached in either group.
Most common Grade ≥3 adverse events in patients with versus without POD24 were neutropenia (91% vs 80%), thrombocytopenia (61% vs 46%), and anemia (55% vs 51%); Grade ≥3 cytokine release syndrome and neurologic events occurred in 9% versus 20% and 27% versus 34%, respectively. There were no cases of Grade 5 cytokine release syndrome, KTE-X19–related secondary cancers, or replication-competent retrovirus in either group.
In patients with versus without POD24, median peak CAR T-cell levels and median area under the curve were 53.4 cells/mL (range, 0.2–2566) and 583.4 cells/mL (range, 1.8–27,743.6) versus 112.4 cells/mL (range, 0.2–2589) and 1588.3 cells/mL (range, 3.8–27,238.7), respectively; by 12 months, B cells were detectable in 8/11 (73%) vs 7/15 patients (47%) in ongoing response.

Table

Characteristics	With POD24 (n=33)	Without POD24 (n=35)
Median age, year	65	66
Median prior therapies, n	3	3
Received ≥3 prior therapies, %	88	74
Ibrutinib	85	86
Acalabrutinib	21	26
Ibrutinib and acalabrutinib	6	11
Auto-SCT	36	49
Disease stage III/IV, %	97	97
Extranodal disease, %	52	60
LDH ≥1.5×ULN, %	24	9
Intermediate-/high-risk MIPI, %	48	63
MCL morphology, %		
Classical	48	69
Pleomorphic	6	6
Blastoid	33	17
Median tumor burden (SPD), mm² (range)	2254.6 (260–14,390)	1380.2 (293–16,878)
Ki-67 proliferation index, %	(n=23)	(n=20)
≥50%	74	65
≥30%	83	81
TP53 status	(n=20)	(n=16)
Mutated, %	15	19

LDH, lactate dehydrogenase; MCL, mantle cell lymphoma; MIPI, Mantle Cell Lymphoma International Prognostic Index; POD24, progression of disease within 24 months of diagnosis; SCT, stem cell transplant; SPD, sum of product diameters; *TP53*, tumor protein 53 gene; ULN, upper limit of normal.

Summary/Conclusion: KTE-X19 provided a high complete response rate across all patients, with the medians for duration of response and overall survival not reached. Patients with POD24 had more aggressive high-risk disease characteristics (tumor burden, lactate dehydrogenase levels, and blastoid-type MCL) and generally lower CAR T-cell expansion and progression-free survival versus patients without POD24. Earlier intervention with CD19-directed CAR T-cell therapy may benefit patients with MCL with known high-risk factors.

EP788 EARLY SAFETY AND EFFICACY FINDINGS OF AUTO1 (CAT19), A FAST-OFF RATE CD19 CAR, IN RELAPSED / REFRACTORY INDOLENT B CELL LYMPHOMAS

Background: We have previously described AUTO1 (CAT19), a CD19 CAR with a fast off-rate CD19 binding domain, designed to reduce CAR T-cell immune toxicity and improve engraftment. Its clinical activity has been tested in r/r paediatric and adult B-ALL. Cumulatively, this data confirms the intended fucntion of the receptor, with low levels of CRS/ICANS and long-term engraftment of CAR T-cells observed in both patient groups. Recently, CAR therapy has been explored in indolent lymphomas such as follicluar (FL) and mantle cell lymphoma (MCL), but a high incidence of toxicity inluding Grade 3-4 ICANS has been reported.

Aims: We have initiated testing of AUTO1 (CAT19) in the setting of indolent B-cell lymphoma (NCT02935257).
Methods: Manufacturing: CAR T-cell products were generated using a semi-automated closed process from non-mobilised leucapheresate. **Study design:** subjects>/=16y underwent lymhpodepletion with fludarabine (30mg/m2 x3) and cyclophosphamide (60mg/kg x1) followed by a single CAR T-cell infusion of 200 x10^6 CD19 CAR T-cells. Study endpoints include feasibility of manufacture, grade 3-5 toxicity and remission rates at 1 and 3 months.
Results: As of 18 February 2021, we recruited 10 patients of median age 57 years (range 39-68y), 7 with FL and 3 with MCL. Patients had received a median of 3 prior lines (range 2-5) and all patients had stage III/IV disease at screening. Apheresis and product manufacture was successful in all 10 patients and 9 patients were infused: 7 with FL and 2 with MCL. Grade1 CRS was reported in 4/9 and Grade 2 CRS in 1/9. 1/9 developed MAS which resolved with anakinra/dexamethasone. No ICANS was observed on study. Excellent CAR engraftment was observed and 9/9 patients were in CMR by 18FDG PET-CT post-treatment. At a median of 3.1 months (range 1-5.6m), 8/9 patients are in ongoing remission. One patient died in CMR at month 5.6 of COVID-19.
Summary/Conclusion: AUTO1 (CAT19) has a tolerable safety profile in adult patients with r/r low grade B-cell lymphoma despite high disease burden. Early data shows 100% complete remission rates and excellent CAR engraftment/expansion. Additional patients, updated data and longer follow up will be presented.

EP789 ZANUBRUTINIB (ZANU) IN PATIENTS (PTS) WITH RELAPSED/REFRACTORY (R/R) MANTLE CELL LYMPHOMA (MCL): LONG-TERM EFFICACY AND SAFETY RESULTS FROM A PHASE 2 STUDY

Background: Zanu is a highly selective, potent and irreversible Bruton tyrosine kinase inhibitor approved in the United States and China for treatment of adult pts with R/R MCL. Phase 2 study results of zanu showing high activity in R/R MCL (median follow-up (mfu), 18.4 mo) were previously reported (*Clin Cancer Res*. 2020;26:4216). We present here long-term results of this study (mfu, 35.3 mo).
Aims: To evaluate the sustainability of efficacy and long-term safety of zanu in pts with R/R MCL.
Methods: In this single-arm, multicenter phase 2 study (NCT03206970), pts received oral zanu (160 mg twice a day) continuously until progressive disease (PD) or unacceptable toxicity. Response assessments per 2014 Lugano criteria were performed every 12 wk for 96 wk, and every 24 wk thereafter. ORR rate (investigator-assessed ≥ partial response), duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety were assessed.

Results: Eighty-six pts were enrolled at 13 centers in China. Median age was 60.5 y, and 83.7% had an intermediate-/high-risk Combined MCL International Prognostic Index score (MIPI-b). Most pts had advanced MCL (90.7% stage III/IV); 45.3% had bone marrow involvement, and 70.9% had extranodal disease. Bulky disease >10 cm and >5 cm was found in 8.1% and 43.0% of pts, respectively. Median number of prior lines of therapy was 2 (range, 1-4), and 52.3% of pts had refractory disease.
As of Sep 8, 2020, mfu was 35.3 mo (range, 0.3-41.6); 45.3% of pts were on zanu, and 54.7% had discontinued zanu primarily due to PD (43.0%) and adverse events (AEs; 9.3%). ORR was 83.7%,and 67 (77.9%) pts achieved complete response. Median DOR was not reached; 57.3% (95% CI, 44.9-67.9) of responders were estimated event (PD/death)-free at 30 mo. Median PFS was 33.0 mo (**Fig A**); response was generally consistent across all subgroups analyzed (MIPI-b, prior therapy, refractory status, etc). Median OS was not reached (**Fig B**).
The safety profile was largely unchanged vs that of the previous mfu. The most common (≥20%) treatment-emergent AEs (TEAEs) were decreased neutrophil count (46.5%), upper respiratory tract infection (38.4%), rash (36.0%), decreased white blood cell count (33.7%), and decreased platelet count (32.6%); most were grade (gr) 1/2 events. Gr ≥3 TEAEs (≥5%) were decreased neutrophil count (18.6%), pneumonia (12.8%), platelet count decreased, white blood cell count decreased (7.0% each), and anemia (5.8%). Most AEs occurred during the early stage of zanu treatment and very few new events were reported during this follow-up period. Four new pts had gr ≥3 TEAEs of any infections (18.6% total, 65.1% all gr), and no new pt had gr ≥3 TEAEs of hypertension (3.5% total, 16.3% all gr) or major hemorrhage (serious/gr ≥3 bleeding or all gr central nervous system bleeding; 3.5% total). No cases of atrial fibrillation/flutter, gr ≥3 cardiac AEs, second primary malignancies, or tumor lysis syndrome were reported throughout this study. No new TEAEs led to death (8.1% total), treatment discontinuation (9.3% total), or dose reduction (2.3% total); 3 new pts had dose interruption during this follow-up period (18.6% total).

Figure

Figure: (A) Progression-Free Survival **(B)** Overall Survival

Summary/Conclusion: These data continued to show the deep response with zanu in pts with R/R MCL that was generally consistent across all subgroups, including high-risk pts. The long-term follow-up show that sustained PFS was achieved with zanu treatment, and about half of pts remained progression free at 36 mo. The new TEAEs reported during the follow-up period were limited; there were no new safety concerns.

EP790 HIGH-RISK MANTLE CELL LYMPHOMA IN THE LYMA TRIAL: A LYSA STUDY.

Background: Around 5-10% of mantle cell lymphoma (MCL) patients are primary refractory to chemotherapy. They have an extremely dismal prognosis, similar to responsive patients that relapsed within 12 months. Despite better understanding of risk factors and evolving classifications, these scores could not predict all high-risk patients and were not designed to guide treatment strategy in newly diagnosed MCL.
Aims: We conducted an ancillary study in a prospective phase III trial randomizing observation versus Rituximab maintenance after R-DHAP followed by ASCT (NCI NCT00921414; LyMa Trial; Le Gouill et al, NEJM 2017). Herein, we report our study of high-risk MCL patients.
Methods: High-risk MCL patients were defined as being primary chemo-refractory or having relapsed within 12 months following randomization (Visco BJH 2018; Eskelund ICML 2019). Patient's characteristics at baseline, treatment at relapse and outcomes were assessed. Survivals of high-risk versus control MCL patients were compared.
Results: Among the 299 MCL patients included in the LyMa trial, 31 high-risk MCL patients were identified (10.4%). Their characteristics at baseline were similar to control patients (n=268), regarding age, performance status, Ann Arbor staging, presence of B symptoms (p = NS). High-risk patients had more often elevated LDH (65% vs. 38%, p=0.006), high-risk MIPI score (45% vs. 16%, p < 0.001), Ki-67 > 30% (71% vs. 31%, p < 0.001) and blastoid/pleomorphic histology (32% vs. 9%, p < 0.001). In multivariate analysis, high-risk MIPI score and Ki-67 > 30% were associated with high-risk MCL. There was no significant difference in terms of TP53 expression between high-risk and control MCL. Many high-risk MCL patients have been classified as low-risk at diagnosis, with 36% of them having a low-risk MIPI score, 68% having a classic histology and 29% having a Ki-67 ≤ 30%. High-risk patients had more often positive MRD pre-ASCT in blood (47.1% vs. 20.6%, p=0.029) but not in the BM (50% vs. 34.9%, p=0.26) and had more positive PET pre-ASCT (48% vs. 25.6%, p=0.032). Median OS was 17 months in high-risk MCL patients, compared to 68 months in late progressors ((95% CI, 12 to 26 months vs. 47 to not reached respectively, p < 0.001). At relapse, 11/31 (36%) had a CNS involvement. Salvage therapies consisted of chemotherapy in 26 patients (CHOP, MTX-AraC, bendamustine, VR-CAP), rituximab in 26, temsirolimus in five, lenalidomide and combination of ibrutinib and lenalidomide in two other patients, as second line therapy. Ibrutinib was also used in two other patients as third line. Overall response rate was 37%, with 27% of complete response. Seven patients received allogeneic stem cell transplantation, of whom four died, from toxicity in two and from lymphoma in two. Median PFS and OS were 19.2 months and not reached for responding patients compared to 3.2 and 8.2 months for stable/progressive disease respectively.
Summary/Conclusion: Known risk factors do not perfectly identify high-risk MCL patients at baseline. High-risk patients with early disease progression had an extremely dismal prognosis and should receive innovative strategies combined with systematic CNS prophylaxis as salvage therapy.

EP791 UPDATED OUTCOMES WITH AXICABTAGENE CILOLEUCEL (AXI-CEL) RETREATMENT IN PATIENTS WITH RELAPSED/REFRACTORY INDOLENT NON-HODGKIN LYMPHOMA IN ZUMA-5

J. C. Chavez, [1,*], C. A. Jacobson,[2], A. R. Sehgal, [3], S. S. Neelapu,[4], D. G. Maloney,[5], G. Salles,[6], B. M. William,[7], Y. Yang,[8], L. Goyal,[8], J. Chou,[8], V. Plaks,[8], M. P. Avanzi,[8]

[1]University of South Florida H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, [2]Dana-Farber Cancer Institute, Boston, MA, [3]UPMC Hillman Cancer Center, Pittsburgh, PA, [4]The University of Texas MD Anderson Cancer Center, Houston, TX, [5]Fred Hutchinson Cancer Research Center, Seattle, WA, [6]Memorial Sloan Kettering Cancer Center, New York City, NY, [7]The Ohio State University Comprehensive Cancer Center, Columbus, OH, [8]Kite, a Gilead Company, Santa Monica, CA, United States

Background: ZUMA-5 is a Phase 2 study of axi-cel anti-CD19 chimeric antigen receptor (CAR) T-cell therapy in patients with relapsed/refractory (R/R) indolent non-Hodgkin lymphoma (iNHL; follicular lymphoma [FL]; marginal zone lymphoma [MZL]). In the primary analysis, 11 patients (9 FL; 2 MZL) were retreated with axi-cel, achieving an overall response rate (ORR) of 100% (91% complete response [CR] rate) at a median follow-up of 2.3 months post-retreatment, with no Grade ≥3 cytokine release syndrome (CRS) or neurologic events (Chavez et al. ASH 2020. #2036).
Aims: To report updated clinical and translational outcomes with longer follow-up of axi-cel retreatment in patients with R/R iNHL in ZUMA-5.
Methods: Eligible adults with FL or MZL had R/R disease after ≥2 lines of therapy. Patients were considered for retreatment if they progressed after a response at month 3, had no evidence of CD19-negative relapse in biopsy, had no axi-cel–neutralizing antibodies, and had no Grade 4 CRS or neurologic events with first treatment. Retreatment was per investigator discretion. At both treatments, patients received axi-cel (2×10^6 CAR T cells/kg) after conditioning chemotherapy.
Results: As of 9/14/2020, 13 patients with iNHL (11 FL; 2 MZL) received axi-cel retreatment, with 2 patients retreated after the primary analysis. Before their first treatment, patients had median 4 prior lines of therapy; 85% had stage 3–4 disease; 82% had FLIPI of ≥3; 46% were POD24, and 77% had refractory disease.
Among the 13 retreated patients, 85% had a CR to first treatment. Median first duration of response (DOR) was 8.2 months. Detectable CD19 was confirmed in all evaluable biopsies from retreated patients at relapse, and median time from first treatment to retreatment was 10.6 months. Following retreatment, the ORR was 100% (77% CR rate). After a median follow-up of 11.4 months, the median DOR had not yet been reached; 46% of retreated patients had ongoing responses at data cutoff.
At first treatment, CRS occurred in 9 patients (5 Grade 1, 4 Grade 2); neurologic events occurred in 5 (3 Grade 1, 1 Grade 2, 1 Grade 3). At retreatment, CRS occurred in 8 patients (6 Grade 1, 2 Grade 2); neurologic events occurred in 4 (3 Grade 1, 1 Grade 2). Median peak levels of biomarkers typically associated with severe CRS and neurologic events were similar at retreatment and first treatment (IL-6, 7.7 vs 5.7 pg/mL; IL-2, 1.8 vs 0.9 pg/mL; IFN-γ, 62.9 vs 64.2 pg/mL).
In the 11 retreated patients with FL, tumor burden (median sum of product diameters [SPD]) was lower before retreatment vs first treatment (1416 vs 4770 mm^2). Engraftment index (CAR T-cell expansion relative to sum of product diameters) is an indirect proxy for effector:target ratio and a key covariate of response to axi-cel (Locke et al. *Blood Adv*. 2020). Although median peak CAR T-cell levels appeared lower at retreatment vs first treatment (5.2 vs 14.3 CAR+ cells/μL blood), engraftment index was similar (0.003 vs 0.005 cells/μL×mm^2).
Summary/Conclusion: Axi-cel retreatment achieved deep and durable responses, with an acceptable safety profile. Tumor CD19 positivity was maintained at relapse, and engraftment index was similar at both treatments, comparing favorably to previous reports in aggressive lymphomas (Locke et al. ASCO 2020. #8012). These data suggest axi-cel retreatment is a promising option for patients with R/R iNHL.

EP792 A PHASE IISTUDY OF A SELECTIVE PI3KΔ INHIBITOR YY-20394 IN PATIENTS WITH RELAPSED OR REFRACTORY FOLLICULAR LYMPHOMA.

Background: Although many new therapies are being investigated for patients with relapsed/recurrent (/r) follicular lymphomas (FL), effective treatment options are very limited.The oral highly selective PI3Kd inhibitor YY-20394, was previously evaluated in a Phase1 dose escalation study, and demonstrated an acceptable safety profile and notable efficacy. In this study, we report on the topline data from an ongoing Phase 2 study of YY-20394 under investigation in patients with relapsed or refractory FL with at least 2 prior systemic treatments.
Aims: To evaluate the efficacy and safety of YY-20394 in FL patients.
Methods: Informed consent was obtained for all patients of the study. YY-20394 was given 80mg orally once daily (QD) with 28 days cycle until disease progression, unacceptable toxicity or withdrawal from the study. Adverse events (AEs) were graded by NCI-CTCAE v5.0. Efficacy was assessed according to IRWG criteria by the Independent Review Committee (IRC).
Results: As of a data cut-off of February 22, 2021, the study was fully enrolled (93 patients) with 89 patients evaluable for efficacy. For the 93 r/r FL patients, the median age is 50.4 years (range 29-78); 61.3% (57/93) are male and 38.7% (36/93) are female and all are Asian. At baseline, the majority of patients had an ECOG performance status of 0 (55.9%, 52/93) or 1 (40.9%, 38/93) and were classified as Ann Arbor-Cotswolds stage III (21.5%, 20/93) or IV (73.1%, 68/93). Nearly all patients (98.9%, 92/93) had grade 1, 2, or 3a FL; only 1 out of 93 patients had transformed to grade 3b high-grade lymphoma. Patients had received a median of three lines of prior treatment regimens (range 2-20), with 34 patients (34.6%) having received four or more lines of prior treatment regimens. Thirty-three percent of patients (31 out of 93 patients) had refractory disease after their last treatment regimen. All patients had received prior rituximab and alkylating agents. Three patients (3.2%) had undergone HSCT.
For the 89 evaluable patients, efficacy was determined by IRC. Complete response (CR) were achieved in 11 patients (12.4%), partial response (PR) in 60 (67.4%), stable disease (SD) in 15 (16.1%), and progressive disease (PD) in 3 (3.2%), for an Overall response rate (ORR) of 79.8% (95% confidence interval [CI] 58.5-83.0%) and a disease control rate (DCR) of 96.6%. The median time to response (TTR) is 1.87 months (range 1.66-5.60 months). All the patients have had at least 6 months of follow-up. The median time to disease progression has not been determined yet because 50.5% (47 out of 93) patients are still receiving YY-20394 treatment, and nearly two thirds of the 93 patients had a treatment duration of > 6 months at the cut-off date. The treatment duration for 29 subjects were more than 300 days, with the longest treatment duration of 637 days to date.
Among all 93 enrolled patients with r/r FL in the phase II study, the most common nonhematologic TEAEs (all grades /grade≥3) were pneumonia (24.7%/17.2%), ALT elevation (17.2%/2.2%), hypertriglyceridemia (23.7%/3.2%), hyperglycemia (18.3%/2.2%), rash (14.0%/2.2%), diarrhea (15.1%/1.1%), pneumonitis (0%/5.4%). Gr≥3 hematologic TEAEs were neutropenia (14.0%), thrombocytopenia 1.1%),) and leukopenia (5.4%).
Summary/Conclusion: YY-20394 is well tolerated with a promising objective response rates in patients with relapsed or refractory follicular lymphoma. Clinical trial information: NCT04370405

EP793 PREVALENCE OF SECOND CANCER DURING LONG TERM FOLLOW-UP IN HAIRY CELL LEUKEMIA PATIENTS TREATED WITH CLADRIBINE: A THIRTY-YEAR EXPERIENCE

Gemelli IRCCS Sezione di Ematologia, Dipartimento di Scienze Radiologiche ed Ematologiche, Università Cattolica del Sacro Cuore, Rome, Italy

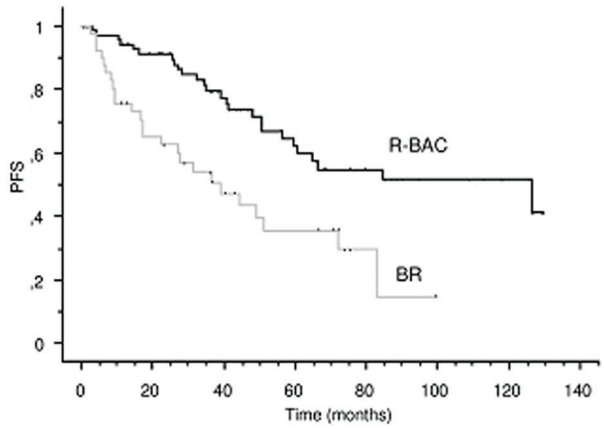
Background: Hairy cell leukemia (HCL) is a rare lymphoproliferative disease with an excellent prognosis after therapy with purine analogs. Conflicting results have been published concerning second cancer in these patients: several studies have showed an increase of second cancer during long term follow-up.
Aims: The aim of the study is to report on the prevalence of second cancer among HCL patients treated with cladribine (2CDA) in first line in the last 30 years.
Methods: We retrospectively reviewed data of patients treated with 2CDA between March 1991 and May 2019 at 18 Italian Hematological centers. All patients consented to the study.
Results: Among 553 patients reported, only 513 were evaluable because treated with 2CDA alone. M/F ratio was 4.5 with a median age of 54 years (range 24-88) and ECOG was 0 in 85% of cases. Twenty-seven (5%) patients were diagnosed with a previous cancer: no relapse was reported during follow-up.
At a median follow-up of 6.96 years (range 3.81-12.47), 19 second neoplasms were reported in 18 patients (3.5%), a percentage that is lower than what reported in the literature. No cases of relapse of a previous cancer were reported. Six patients had a cancer of urinary tract (4 prostate, 2 kidney, 1 bladder), 5 had a GI cancer (1 esofagus, 1 stomach, 3 colorectal), 4 had an hematological neoplasm (2 multiple myeloma, 1 mantle cell lymphoma and 1 diffuse large B cell lymphoma), 2 had breast cancer and 1 had lung cancer. Moreover, precancerous lesions were reported in 1.2% of patients: 4 presented with skin cancer (3 basocellular carcinoma and 1 dysplastic nevus), 1 with pleomorfic parotid adenoma and 1 with colorectal displastic adenoma. No therapy-related myeloid neoplasms were observed.

Surgical therapy alone was a curative option in 8 patients, while chemotherapy alone was reported in 5 cases. A combination of surgery and chemotherapy +/- hormone therapy was used in 5 cases.
Median OS of the population was not reached; 95.7%, 92.8% and 82.3% of patients are expected to be alive at 5, 10 and 15 years, respectively. Among 45 patients which died during follow-up, 6 cases (1.2%) were due to second cancer.
We compared our data with that reported by the Italian registries of cancer for the same period of observation. Among the general population, the cumulative standard incidence of cancer was 704.4 casesx100.000 inhabitants for males and 484.7 casesx100.000 inhabitants for females. In our population, the cumulative standard incidence of cancer other than HCL was 543.3 x 100,000 (IC 95%: 283.6-803.1) for males and 492.6 x 100,000 (IC 95%: 0.0-1099.0) for females. No statistically significant differences were identified between the two cohorts.
Summary/Conclusion: While 2CDA is greatly effective in treating HCL, the occurrence of second cancer is rare. The cumulative incidence of second neoplasms in our population did not significantly differ from that reported among the Italian population.

EP794 RISK FACTORS FOR POD24 IN PATIENTS WITH PREVIOUSLY UNTREATED FOLLICULAR LYMPHOMA: A SYSTEMATIC REVIEW AND META-ANALYSIS

T. Zhang [1,*], X. Wang [1], H. Zhang [1]

[1]*Department of Lymphoma, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*



Background: Follicular lymphoma (FL) is an indolent non-Hodgkin's lymphoma with heterogeneous outcomes. Progression of disease within 24 months (POD24) is strongly associated with poor outcome. Therefore, prediction of POD24 at diagnosis is essential to support the precision medicine treatment strategies making in clinical practice. However, risk factors associated with POD24 remain uncertain in FL patients.
Aims: To perform a systematic review and meta-analysis to identify the potential risk factors for POD24 in FL patients.
Methods: Comprehensive literature search in Embase, Medline and the Cochrane Library was performed from database inception to 1 September, 2020 to identify prognostic studies in patients with newly diagnosed grade 1-3a FL. The interested outcome was POD24. For studies not reporting POD24, we attempted to synthesize the association between risk factors and any progression within 24 months that defined by original studies. This study protocol has been registered on PROSPERO with registration number PROSPERO CRD42021231824.
Results: A total of 96 studies reporting 81 prognostic factors were included, among which 11 factors were eligible for meta-analysis. Results showed that elevated sIL-2R (HR 2.48; 95% CI, 1.74-3.54; p< 0.0001 [7 studies]), total metabolic tumor volume (TMTV) >510mL (HR 2.17; 95% CI, 1.60-2.95; p<0.0001, [5 studies]), elevated β2m (HR 4.14; 95% CI, 2.07-8.28; p<0.0001 [4 studies]), elevated LDH (HR 3.05; 95% CI, 1.63-5.71; p=0.0005, [4 studies]), grade 3a (HR 2.22; 95% CI, 1.31-3.74; p=0.0030, [3 studies]), lymphoma-associated macrophages (LAM)/ high -power field(HPF) ≥15 (HR =4.13; 95% CI, 1.92-8.88; p=0.0003, [2studies]), Vitamin D insufficiency (<20 ng/ml) (HR=2.66; 95% CI, 1.44-4.92; p=0.0020, [2studies]) were significantly associated with an increased risk of POD24. Absolute lymphocyte count (ALC)/Absolute monocyte count (AMC) ratio (cutoff:4.7), sex, and EZH2 mutation status, effector T-cell gene expression (two studies for each factor) were found not to be significantly associated with POD24.
Summary/Conclusion: To our knowledge, this is the first study that comprehensively analyses the risk factors associated with POD24 in FL patients. Results from this meta-analysis confirmed significant association between 7 factors and POD24. Our findings may contribute to the development of an optimized risk stratification model of FL POD24 in the future.

EP795 RITUXIMAB, BENDAMUSTINE, AND CYTARABINE (R-BAC) COMPARED WITH RITUXIMAB AND BENDAMUSTINE (BR) IN PREVIOUSLY UNTREATED ELDERLY PATIENTS WITH MANTLE CELL LYMPHOMA (BE-VE-BAC STUDY)

G. Bega [1,*], M. Riva [2], G. Scapinello [3], S. Finotto [4], R. Sartori [5], E. Lucchini [6], J. Olivieri [7], G. Guandalini [1], D. Facchinelli [2], M. C. Tisi [2], M. Basso [5], L. Ballotta [6], F. Piazza [8], I. Ferrarini [1], C. Visco [1]

[1]*Department of Medicine, Section of Hematology, University of Verona, Verona,* [2]*Cell Therapy and Hematology, San Bortolo Hospital, Vicenza,* [3]*Hematology and Clinical Immunology Unit, University of Padova,* [4]*Oncology 1 Unit, Department of Oncology, Istituto Oncologico Veneto IOV - IRCCS, Padova,* [5]*Onco Hematology Unit, Veneto Institute of Oncology IOV-IRCCS, Padua,* [6]*SC Ematologia, Azienda Sanitaria Universitaria Integrata Giuliano-Isontina, Trieste,* [7]*Hematology and SCT Unit, Università di Udine, Azienda Sanitaria-Universitaria Integrata Santa Maria Misericordia, Udine,* [8]*Hematology and Clinical Immunology Unit, Department of Medicine, University of Padua, Padova, Italy*

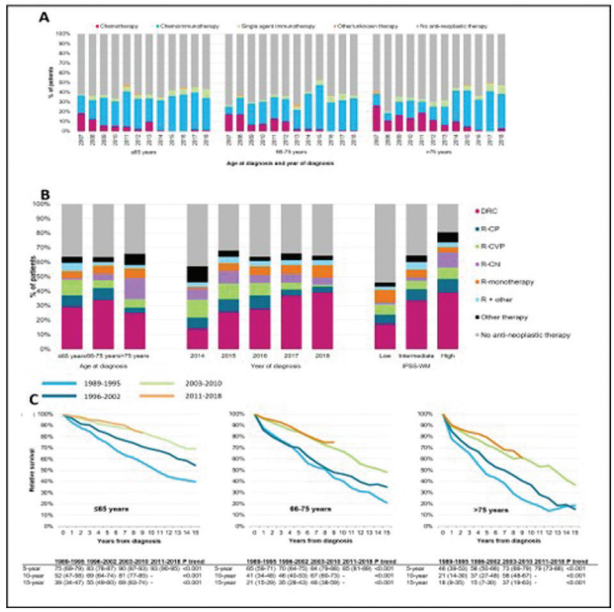
Background: Both rituximab plus bendamustine (BR), and rituximab, bendamustine, and cytarabine (R-BAC) are considered suitable induction therapies in elderly patients with mantle cell lymphoma (MCL), according to most recent ESMO and NCCN clinical practice guidelines. However, a direct comparison between the two regimens, either prospective or retrospective, has never been performed.
Aims: To compare the outcome and the safety features of patients with newly diagnosed MCL treated with BR or R-BAC between 2009 and 2020 in 7 Departments from north-east of Italy.
Methods: This is a multicenter retrospective observational study. The two regimens (BR and R-BAC) represented routinary induction regimens in the selected centers for patients with MCL not candidate to autologous transplant. Primary endpoint was 2-years progression-free survival (PFS). All patients treated with at least one cycle of either BR or R-BAC were included, provided they had a minimum follow-up of 12 months since start of treatment. Response was based on Lugano criteria. Due to the retrospective nature of the study, treatment assignement to one therapy instead of the other was based on local doctor decision. Inclusion bias were estimated by a propensity score stratified by gender, age, MCL morphology, and MIPI score.
Results: 137 patients with MCL with a median age of 72 years (range 53-90) were retrospectively analyzed. According to our propensity score calculation, the probability of receiving R-BAC was higher in younger patients (P<0.0001), but no other significant difference in the distribution of above mentioned prognostic variables was observed between the two groups. Therefore, we limited our survival analysis to patients with 80 years or less, which allowed us a fair comparison between the two groups (P=NS). This cohort included 115 patients (42 BR, 73 R-BAC) that represented the subjects for the present analysis. Of them, 76 (66%) were males, MIPI was elevated in 61%, 15% had blastoid or pleomorphic morphology, and median follow-up was 48 months (range 12-133). Patients treated with R-BAC achieved CR in 93% of cases, as compared with 55% for BR (P<0.0001). The 2-years PFS was 91%±3% and 63%±7% for R-BAC and BR, respectively (P=0.0007, Figure 1). Median overall survival (OS) was 125 months for R-BAC and 78 months for BR (P=0.07). MIPI score was the only predictive significant variable both in terms of PFS and OS. In terms of toxicity, R-BAC was associated with significantly more pronounced grade 3-4 thrombocytopenia than BR (32% versus 15%), although R-BAC doses were frequently reduced as compared to the original scheme.

Summary/Conclusion: The BE-ve-BAC study indicates that R-BAC, even when administered in the 2-days schedule or with attenuated dose, is associated with significantly prolonged PFS than BR in elderly patients with previously untreated MCL. As hypotesized hematological toxicity was significantly higher for the latter regimen as compared to BR. Further patients from more centers of our area are expected to be included, and long-term follow up of the R-BAC500

study is awaited to confirm our findings in an independent prospective setting.

EP796 PRIMARY THERAPY AND RELATIVE SURVIVAL IN PATIENTS WITH LYMPHOPLASMACYTIC LYMPHOMA/ WALDENSTRÖM'S MACROGLOBULINEMIA (LPL/WM): A POPULATION-BASED STUDY IN THE NETHERLANDS, 1989-2018

K. Amaador [1,*], M. J. Kersten [1], O. Visser [2], M. Brink [3], E. F. Posthuma [4,5], M. C. Minnema [6], J. M. Vos [7], A. G. Dinmohamed [3,7,8,9]



[1]Department of Hematology, Cancer Center Amsterdam, Amsterdam UMC, University of Amsterdam, Amsterdam, The Netherlands and LYMMCARE, [2]Department of Registration, [3]Department of Research and Development, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [4]Department of Internal Medicine, Reinier de Graaf Gasthuis, Delft, [5]Department of Hematology, Leiden University Medical Center, Leiden, [6]Department of Hematology, University Medical Center Utrecht, University Utrecht, Utrecht, [7]Department of Hematology, Amsterdam UMC, University of Amsterdam, Amsterdam, The Netherlands and LYMMCARE, [8]Department of Public Health, Erasmus MC, University Medical Center Rotterdam, Rotterdam, [9]Department of Hematology, Cancer Center Amsterdam, Amsterdam UMC, Vrije Universiteit Amsterdam, Amsterdam, Netherlands

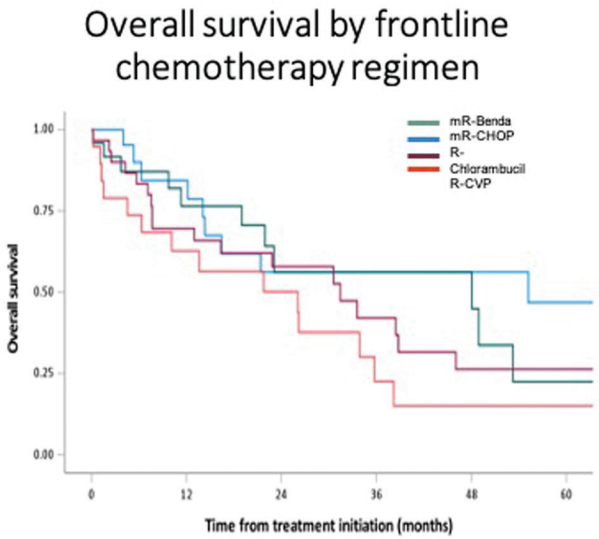
Background: LPL/WM is a rare lymphoproliferative malignancy. Although therapeutic advances have been made in LPL/WM over the past decades, it is unclear how these advances have impacted the population-level survival of LPL/WM patients, especially among contemporary diagnosed patients. This inconclusiveness relates to the lack of population-based studies in LPL/WM.

Aims: This nationwide, population-based study aimed to assess trends in first-line therapy and relative survival (RS) among LPL/WM patients diagnosed in the Netherlands during a 30-year period.

Methods: All LPL/WM patients diagnosed between 1989-2018—with survival follow-up through 2020—were selected from the Netherlands Cancer Registry (NCR). Data on primary therapy—that is, no anti-neoplastic therapy (i.e. watch-and-wait) and anti-neoplastic therapy (e.g. chemotherapy)—were available in the NCR. Information on the use of rituximab was available for patients diagnosed as from 2007. Patients were categorized into four periods (1989-1995, 1996-2002, 2003-2010 and 2011-2018), and three age groups (<65 (*n*=383), 66-75 (*n*=384) and >75 years (*n*=386)). Data on the exact anti-neoplastic therapy, asymptomatic/symptomatic disease, and IPSS risk group were available for patients diagnosed as from 2014. The exact anti-neoplastic regimens were presented for patients with symptomatic disease, stratified by year of diagnosis, the three abovementioned age groups, and IPSS risk group (i.e. low, intermediate, and high). RS was calculated to estimate disease-specific survival.

Results: A total of 6,232 LPL/WM patients (median age 70 years; 61% males) were included in the study. Due to the broader application of an initial watch-and-wait approach, treatment with anti-neoplastic agents at diagnosis gradually decreased over time, irrespective of age. The proportion of patients receiving upfront anti-neoplastic therapy was 41%, 38%, and 40% across the three age groups during 2011-2018. Data from 2007 onwards showed that the use of chemotherapy alone decreased over time, following an increased application of chemoimmunotherapy (Figure 1A). Symptomatic disease was present in 60% of patients diagnosed during 2014-2018. Detailed data on primary therapy among 960 symptomatic patients revealed that DRC was the most frequently applied therapeutic regimen across all age groups, of which its use increased from 14% to 39% between 2014 and 2018. Consequently, the use of R-C(V)P decreased between 2014 and 2018. The use of anti-neoplastic therapy increased with advancing IPSS risk group (Figure 1B). Five-year RS increased significantly across all age groups between the first and last calendar period. Specifically, 5-year RS (95% confidence intervals) was 75% (69%>79%), 65% (59%>71%), and 46% (39%>53%) in 1989-1995 across the three age groups, compared with 93% (90%>95%), 85% (81%>89%) and 79% (73%>86%) in 2011-2018 (Figure 1C).The age-stratified multivariable analysis of RS demonstrated that RS between 2003-2010 and 2011-2018 did not improve further.

Summary/Conclusion: The use of chemotherapy alone in LPL/WM is almost entirely abandoned in contemporary clinical practice in the Netherlands. The impressive survival improvement over time may be accounted for by the increased use of rituximab-containing therapy since its introduction in early-mid 2000. The lack of survival improvement in the post-rituximab era warrant longer follow-up of our post-rituximab cohort to assess the effects of recently introduced novel agents, and should bolster forthcoming studies across various therapy lines to further improve survival in LPL/WM.



EP797 TREATMENT PATTERNS AND OUTCOMES OF ELDERLY PATIENTS WITH MANTLE CELL LYMPHOMA UNFIT FOR STANDARD IMMUNOCHEMOTHERAPY: A UK AND IRELAND ANALYSIS

Background: Mantle Cell lymphoma (MCL) represents 3-10% of all non-Hodgkin B-cell lymphoma with a third of new diagnoses affecting patients (pts) aged >75 years. Although the treatment options for MCL have increased over the last years with the introduction of Bruton Kinase Inhibitors (BTKi), for older and unfit pts, treatment options are limited. Practice across the UK varies with regimens such as attenuated R-CHOP,

R-CVP, attenuated R-Bendamustine (R-B), R-Chlorambucil (R-CHL) used. Outcomes in this population are not fully characterised.
Aims: This study aims to identify treatment pattens and outcomes of the most commonly used attenuated and low intensity regimens used in pts with newly diagnosed MCL unfit for standard chemoimmunotherapy (i.e. full dose R-CHOP or R-B).
Methods: Data were retrospectively collected across 19 centres in the UK and Ireland between 1/1/2010 and 31/11/2020. All pts who were ineligible for standard regimens and had received at least 1 dose of an attenuated or low intensity regimen. Baseline characteristics, treatment characteristics and toxicity data were collected. Progression free survival (PFS) and overall survival (OS) were calculated using standard Kaplan-Meier analysis. Univariable and multivariable Cox regression analysis (MVA) was used to examine the associations between baseline factors, regimens, PFS and OS.
Results: 95 pts (attenuated RCHOP n=22, attenuated R-B n=24, R-CHL n=30, R-CVP, n=19) were analysed. Median age was 79 years (range:58-89) with baseline ECOG of 0, 1 and ≥2 for 22.1, 41.1% and 36.8% respectively. 50% were ≥80 years and median CIRS-G score was 6 (range:0-24). 93% had stage III-IV disease with 91% presenting with high MIPIb or MIPI score. 14.5% had blastoid morphology. Pts receiving R-CHL had higher age, with worse ECOG and along with those receiving R-CVP had greater CIRS-G than the other groups.
Overall response rate (ORR) for the whole cohort was 72% with a median duration of response (DoR) of 19.1 months (95% CI 12.9-25.4). Numerically higher ORR and DoR were observed in attenuated R-B and R-CHOP (83.3%, 33.8 months and 82%, 22 months). 60 pts progressed with 47 receiving further treatment including 36 receiving Ibrutinib.
Median PFS for all pts was 15 months (95% CI:8.7-21.2) and median OS was 31.4 months (95% CI:19.7-43.2). The median PFS and OS for attenuated R-CHOP pts was 16.7 months (95% CI 9.8-23.7) and 55.2 months (95% CI 1.9-108.4), attenuated R-B pts was 21.9 months (95% CI 0-46.3) and 48.1 months (95% CI 0-109.5), R-CVP pts was 7.4 months (95% CI 0.3-14.5) and 26.1 months (95% CI 2.7-49.4), and R-CHL pts was 12.0 months (95% CI 5.4-18.7) and 31.4 months (95% CI 17.9-45.0) respectively. By MVA, factors associated with an inferior PFS were bulk (>10cm) (HR:2.05, p=0.04) and blastoid morphology (HR:2.63, p=0.02). Higher treatment intensity (R-CHOP/R-B composite) provided a superior PFS compared with RCVP/R-CHL (MVA HR:0.48, p=0.01). Factors associated with inferior OS by MVA were age (HR:1.06), ECOG performance status (HR:2.50), blastoid morphology (HR:3.12) and POD24 status (HR:4.37).

Summary/Conclusion: Overall, PFS and OS following front-line dose attenuated immunochemotherapy is unsatisfactory. POD24 association with worse OS is now validated in elderly frail pts. Outcomes were generally poor, but attenuated R-CHOP or R-B may improve disease control compared to R-CVP or R-CHL. Clinical trials investigating novel agents such as BTK and BCL2 inhibitors in this specific clinical setting are warranted.

EP798 REAL-WORLD TREATMENT PATTERNS AND OUTCOMES OF 3455 PREVIOUSLY UNTREATED MANTLE CELL LYMPHOMA PATIENTS IN US ROUTINE CLINICAL PRACTICE

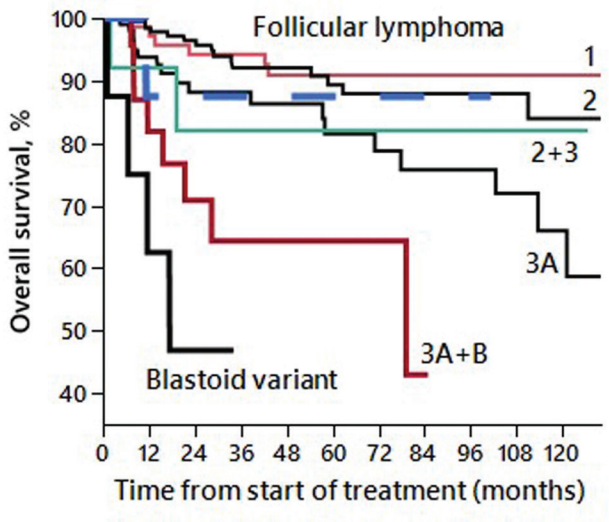
P. Martin [1,*], M. Wang [2], A. Kumar [3], K. Qi [4], K. Daly [5], L. Parisi [5], A. Zhu [5], G. Salles [3]

[1]Weill Cornell Medicine, New York-Presbyterian Hospital, New York, NY, [2]The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX, [3]Memorial Sloan Kettering Cancer Center, New York, NY, [4]Janssen Research & Development, IHI RWE, Titusville, NJ, [5]Janssen Research & Development, Oncology, Raritan, NJ, United States

Background: Mantle cell lymphoma (MCL) is a non-Hodgkin's lymphoma with heterogeneous biology and outcomes.
Aims: We characterized real-world (RW) treatment (tx) patterns and outcomes of patients (pts) with MCL to identify factors associated with outcomes in the US.
Methods: This retrospective study included adult pts with MCL diagnosed between January 2011 and November 2020 in the nationwide Flatiron Health EHR-derived deidentified database ("MCL-eligible"). Pt characteristics, tx patterns, RW time-to-next tx (rwTTNT, defined as start of first-line [1L] tx to subsequent tx or death), and RW overall survival (rwOS) were evaluated.
Results: 3455 pts were included, 85.3% from a community oncology setting. In 2946 (85.2%) pts with documented 1L MCL tx, median age was 69.5 years (range, 27.7-85.3); 9.5% had blastoid/pleomorphic MCL. 262 (39.6%) and 235 (35.6%) of 661 pts with available MCL international prognostic index had intermediate and high risk, respectively. 150/1253 pts (12.0%) with available Eastern Cooperative Oncology Group performance status (ECOG PS) had an ECOG PS ≥ 2. Chemoimmunotherapy was the most common 1L tx, including bendamustine plus rituximab (BR) in 1223 (41.5%), rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) in 512 (17.4%), and cytarabine (ara-C)-containing tx in 414 (14.1%). 667 pts received R maintenance (MR). In 1036 pts < 65 years, 243 pts received 1L stem cell transplant (SCT), mainly autologous. In 1L-treated pts, with a median follow-up of survivors of 45.3 months (range, 0.03-117.2), median rwTTNT was 24 months; 36-month rwOS was 67%. The Table shows tx received and outcomes by age and SCT status. Multivariate analyses showed age ≥ 65 years, ECOG PS ≥ 2, lactate dehydrogenase/upper limit of normal ≥ 1, white blood cell count ≥ 10 × 10^9/L, bulky disease (≥ 5 cm), and blastoid/pleomorphic morphology were associated with shorter rwTTNT and rwOS; MR was independently associated with longer rwTTNT and rwOS. In pts < 65 years who were alive and did not initiate subsequent tx within 6 months of 1L tx ("SCT-eligible"), 36-month rwTTNT and rwOS were similar between pts treated with versus without SCT: 65% versus 59% and 86% versus 85%, respectively.

Table. Tx and outcomes in 1L MCL

	Age < 65 years at 1L tx (n = 1036)		Age ≥ 65 years at 1L tx (n = 1910)	
	No SCT (n = 793)	Received SCT (n = 243)	No SCT (n = 1835)	Received SCT (n = 75)
1L tx received, n (%)				
Ara-C-containing	189 (23.8)	130 (53.5)	67 (3.7)	28 (37.3)
BR	244 (30.8)	42 (17.3)	914 (49.8)	23 (30.7)
R-CHOP	172 (21.7)	48 (19.8)	273 (14.9)	19 (25.3)
Pt outcome, % (95% confidence interval)				
36-month rwTTNT	40 (36-44)	63 (57-71)	37 (35-40)	63 (51-77)
36-month rwOS	75 (72-79)	86 (81-91)	61 (58-63)	82 (72-94)



Summary/Conclusion: In this large RW cohort of primarily community-based US practices, median 1L rwTTNT for pts with MCL was ~ 2 years. BR was the most commonly used 1L tx. SCT was uncommon even in pts < 65 years, suggesting RW considerations may influence SCT eligibility and availability. Additionally, SCT was not clearly associated with rwOS. As with other reports, older age and high-risk disease features were predictive of worse outcome in RW, while MR appeared to be associated with better outcomes. Outcomes across the board appear worse than prospective trials, suggesting a need to focus on developing tx that can be delivered effectively in the community setting.

EP799 COMBINATION OF EZH2 GENE MUTATION AND BCL2 GENE REARRANGEMENT AS AN INDICATOR OF FAVORABLE PROGNOSIS OF FOLLICULAR LYMPHOMA

E. Nesterova [1,*], N. Severina [2], B. Biderman [2], A. Sudarikov [2], T. Obuchova [3], A. Kovrigina [4], S. Kravchenko [1], E. Gemdzhian [5], V. Savchenko [6]

[1]Department of Highly Dose Chemotherapy of Hemoblastosis, [2]laboratory of Molecular Hematology, [3] laboratory of kariology, [4]Pathological anatomical department, [5]Biostatistics laboratory, [6]Bone marrow transplant department, National Research Center for Hematology, Moscow, Russian Federation

Background: Follicular lymphoma (FL) is the second most common B-cell non-Hodgkin's lymphoma, accounting for 25% of all newly diagnosed lymphomas in Russia. The clinical course of the disease is variable and associated with tumor morphology: the prognosis for grade 1-2 and 3A is better than for grade 3B and for transformation into aggressive lymphomas (Fig. 1). The variability of the clinical course is also observed among indolent FL (grade 1-2 and 3A). The variability of the disease can be explained by the pathogenetic mechanisms ("linear" and divergent pathways) of the development of the tumor cell, which are confirmed by the detected genetic markers. *EZH2* is an early marker of FL and its changes confirm the «linear" pathway of tumor cell development. Today the pathogenetic aspects of FL are not fully understood and the data are contradictory.
Aims: To determine the mutational status of the *EZH2* gene in patients with indolent FL, to compare the results obtained with the immunomorphological and cytogenetic characteristics of the tumor; to determine predictive value.
Methods: A prospective comparative search study conducted from January, 2020 to December, 2020 at the National Research Center for Hematology (Moscow) included 64 patients (35 men and 29 women, with a median age of 53 years) with newly diagnosed FL. All 64 biopsies taken before therapy administration were investigated for the mutational status of *EZH2* gene exon 16 (Sanger sequencing) and for the rearrangement of the *BCL2* gene (karyotyping and FISH). All patients received anthracycline-containing regimens with rituximab (R-CHOP / R-EPOCH). Molecular, immunomorphological and cytogenetic data were compared blindly with the outcome of immunochemotherapy treatment.
Results: Mutations of *EZH2* gene *(mutEZH2) were* detected in 10/64 (16%) of cases. In the *mutEZH2* group of patients grade 1-2 of FL was diagnosed in 4/10 cases, and grade 3A - in 6 out of 10 cases. Rearrangement of the *BCL2* was found in 1-2 grade group in 3/4 cases, in 3A grade - in 3/6 cases. Adverse events (early relapse/progression/death from progression were determined in 4/10 (40%) patients and only in cases with *EZH2* mutations and without *BCL2* gene rearrangement. There were no deaths in cases with both *EZH2* mutations and *BCL2* gene rearrangement.
Wild type *EZH2* gene status *(wtEZH2)* was shown for 54/64 (84%) cases. In this group grade 1-2 FL was diagnosed in 26/54 (48%) cases, and grade 3A – in 28/54 (52%). *BCL2* gene rearrangement was detected in 19/22 (86%) grade 1-2 FL cases, and in 14/25 (56%) grade 3A cases. Adverse events in the group without *EZH2* mutations were found in 20/54(37%), and were twice as common in the absence of *BCL2* gene rearrangement (16% versus 82% in grade 1-2, and 36% versus 100% in grade 3A). Deaths from progression were observed in 12/54 (22%) patients.

Summary/Conclusion: *EZH2* gene mutations were detected in 16% of cases and were found equally in grade 1-2 and 3A groups of FL patients. FL cases with both *EZH2* mutations and *BCL2* rearrangement are characterized by a long persistently recurrent course. FL cases with wild type EZH2 gene and without *BCL2* gene rearrangement are associated with a high risk of transformation into DLBCL and high mortality.

EP800 LENALIDOMIDE PLUS RITUXIMAB IN PATIENTS WITH RITUXIMAB-RESISTANT INDOLENT B-CELL AND MANTLE CELL LYMPHOMAS: 10-YEAR FOLLOW-UP

A. Gupta [1,*], S. Schuster [1], J. Svoboda [1], S. Nasta [1], E. Napier [1], K. Walsh [1], E. Chong [1]

[1]Lymphoma Program, Abramson Cancer Center, University of Pennsylvania, Philadelphia, United States

Background: Lenalidomide plus rituximab is now a standard-of-care option for indolent B-cell non-Hodgkin lymphomas (iNHL) and mantle cell lymphomas (MCL). We previously demonstrated the efficacy of combination lenalidomide and rituximab in patients (pts) with rituximab-refractory iNHL and MCL (Chong et al Clin Can Res 2015). We now report the longest experience to date with this regimen.
Aims: The aim of this retrospective review was to determine 5 and 10-yr outcomes for rituximab-resistant pts treated with lenalidomide and rituximab and to identify adverse events (AEs) leading to dose discontinuation.
Methods: We conducted an open-label phase II trial in pts with iNHL or MCL and rituximab resistance, defined as failure to respond to or progression of disease within 6 months of rituximab or a rituximab-containing regimen. Pts received lenalidomide 10 mg daily for 8 weeks, followed by 4 weekly doses of rituximab 375 mg/m^2 and continued lenalidomide maintenance until disease progression, toxicity or pt choice.
Results: 50 pts (30 FL, 14 MCL, 2 MZL, 4 SLL) were enrolled between 2008-2012. Median follow-up was 10.5 years (yr). Pts received a median of 3 prior therapies (range: 1–7). Progression free survival (PFS) for all pts at 5 and 10 yrs was 20.0% [95%CI 8-35] & 13% [95%CI 3-30%]; 5- and 10-yr response duration (RD) was 27% [95% CI 12-46] and 18% [95% CI 4-40], respectively; 5- and 10-yr overall survival (OS) was 58% [95%CI 43-70] and 45% [95%CI 30-58], respectively. 5-yr OS from the time pts were deemed rituximab-resistant was 64.0% and 10-yr OS 51.9%.
For pts with FL, 5- and 10-yr PFS were both 13%, and 5- and 10-yr OS were 60% and 40%. For MCL, 5- and 10-yr PFS were both 25% and 5- and 10-yr OS were 50% and 36%. At 10.5 yr follow-up, 4 pts (2 FL, 1 MCL, 1 MZL) remain in complete remission (CR), 3 of whom discontinued lenalidomide at 7.0-yr, 8.8-yr and 10.1-yr in CR. 1 pt with FL discontinued study in CR after 11.6-yr but continues on commercial lenalidomide at 5 mg daily.
The most common grade 1–2 AEs requiring dose reductions were neuropathy (n = 3) and diarrhea (n = 5), which all resolved with dose reduction. The most common grade 3–4 AEs requiring dose reductions were neutropenia (n = 6, 12%) and tumor flare (n = 3, 6%). Pts discontinued therapy due to toxicity at a median of 4.9 mo (range 0.3–25.7) from lenalidomide start due to grade 3–4 rash (n = 2), grade 2 abdominal pain (n = 1), and grade 3–4 thrombocytopenia (n = 2). Only 1 pt discontinued lenalidomide after >1 yr (25.7 mo); this was due to persistent diarrhea. The pt who developed grade 2 abdominal pain was retreated with lenalidomide without recurrence of pain and sustained a second CR for 5 yrs. 5 (10%) pts developed secondary cancers at a median of 15.5 mo (range: 0.8–50.5) from starting lenalidomide, including 2 hematological (acute myeloid leukemia, B-acute lymphoblastic leukemia) and 3 solid cancers (NSCLC, renal cell carcinoma, prostate cancer). Prior to enrollment, 4/5 of the pts with secondary cancers had received alkylating agents and 3/5 had received anthracyclines. Of all pts, 78% had previously received alkylating agents and 62% had received anthracyclines.

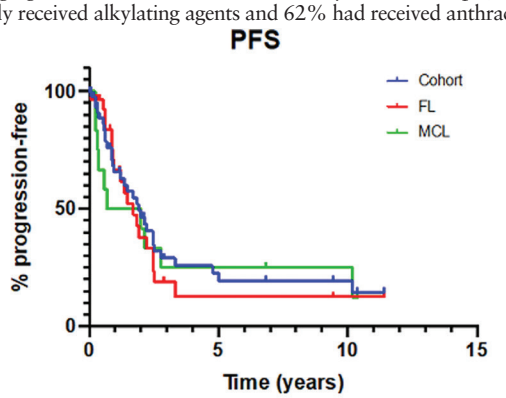


Figure 1:
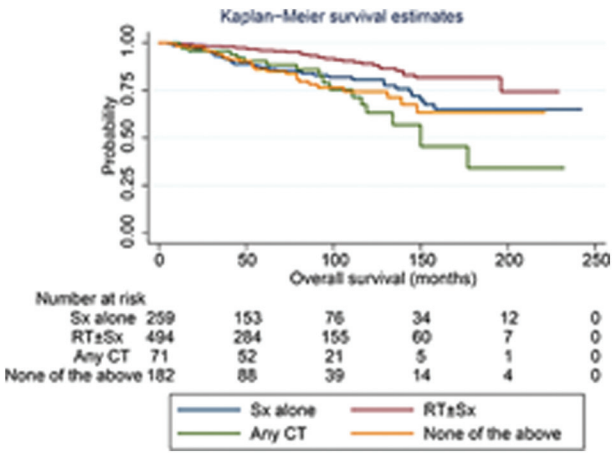
Progression free survival (PFS) for the entire cohort and for patients with follicular (FL) and mantle cell (MCL) lymphoma.



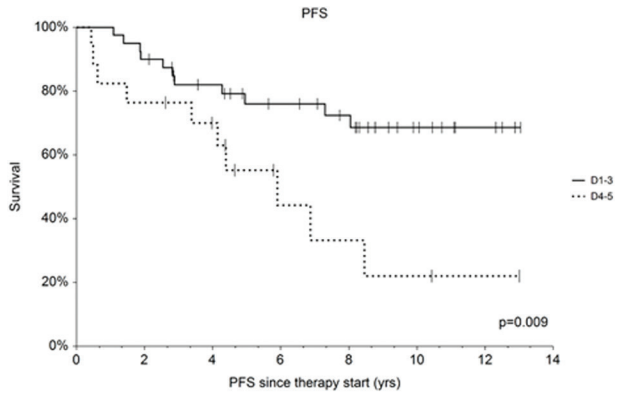
Summary/Conclusion: These data represent the longest reported outcomes for lenalidomide plus rituximab in iNHLs and MCL. We demonstrate durable responses and a manageable safety profile with rituximab plus low-dose lenalidomide.

EP801 EFFECTS OF CONVENTIONAL TREATMENTS ON EARLY-STAGE PRIMARY CUTANEOUS MARGINAL ZONE LYMPHOMA

H. Liu [1], L. Cao [1], C. Yang [1], Y. Miao [1], X. Du [1], R. Huang [1], H. Zhu [1], X. Shi [1], W. Xu [1], J. Li [1], L. Fan [1,*]

[1]*Department of Hematology, Jiangsu Province Hospital, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Background: Information on the outcomes and treatments of early-stage (I/II) primary cutaneous marginal zone lymphoma (PCMZL) is limited.
Aims: This study aims to identify the prognostic factors in early-stage PCMZL and compare long-term population-based survival outcomes of conventional approaches.
Methods: We extracted data on stage I/II PCMZL patients from the Surveillance Epidemiology and End Results (SEER) database and used the Kaplan-Meier plot, log-rank test, Cox regression, propensity score matching (PSM) analyses to explore the association of characteristics and therapeutic methods with survival.
Results: We identified 1,006 early-stage PCMZL cases between 1993 and 2016 in the SEER registry. Multivariate analysis indicated that age over 60 years at diagnosis, specific primary sites (i.e., face, scalp, neck, lower limb, and hip), diagnosis before 2005, and coexisting malignancy were unfavorable predictors for overall survival (OS), while radiotherapy (RT) with or without surgery (Sx) improved OS independently. Besides, we also noted that age over 60 years, diagnosis before 2005, and chemotherapy (CT) were adverse predictors for disease-specific survival (DSS). According to Cox regression and PSM analyses, RT improved the OS and DSS rates while CT reduced the OS and DSS rates. No data demonstrated a survival benefit with Sx in this study.



Summary/Conclusion: For early-stage PCMZL patients, RT can probably be an essential component for the initial therapy, and a combination with new treatment options, such as rituximab, could be considered in future studies. Sx has no survival benefit throughout this study but it is an available diagnostic workup. Systemic CT had inferior efficacy and is not recommended as an initial regimen for such an indolent tumor in an early stage.

EP802 EARLY INTERIM PET/CT PREDICTS THE OUTCOME IN HIGH-TUMOUR-BURDEN FOLLICULAR LYMPHOMA PATIENTS

V. Procházka [1,*], A. Kredátusová [1], V. Hanáčková [1], L. Henzlová [2], E. Buriánková [2], J. Ptáček [2], T. Papajík [1]

[1]*Dept. of Hemato-Oncology,* [2]*PET-imaging center, dept of Nuclear Medicine, University Hospital in Olomouc, OLOMOUC, Czech Republic*

Background: High-tumour-burden follicular lymphoma (HTB-FL) is a highly heterogeneous disease. About one-fifth of patients experience poor response to frontline therapy or early relapse within 24 months of treatment (POD24). Identification of early progression of the disease is still an unmet prognostic need. Use of positron-emission tomography/computed tomography (PET/CT) in the interim setting remains controversial.
Aims: To assess the impact of early metabolic assessment on early disease outcome
Methods: We analysed 124 previously untreated grade I-IIIA HTB-FL patients undergoing PET/CT at diagnosis and after immunochemotherapy, with 57 of them having early interim PET/CT scans within 14-21 days after the 2nd chemotherapy cycle. Imaging studies were conducted using the Siemens Biograph 16 HI-REZ (2008-2015) and Siemens mCT 40 (2015-2017) systems with the same image acquisition protocols at the same centre. Both PET/CT scanners were accredited by EARL, a European Association of Nuclear Medicine research initiative. Images were read by two independent experts blinded for patient outcome.
Results: The cohort consisted of 35 females and 22 males with a median age of 56 years, with advanced (CS III/IV) disease in 96.5%. The FLIPI/PRIMA-PI percentages were as follows: low 12%/31%, intermediate 44%/43% and high 44%/26%. All but one of the patients were treated with a rituximab-anthracycline-containing regimen (1 R-bendamustine) and 34 received rituximab maintenance. Forty-six patients (81%) achieved CR, seven (12%) achieved PR and four (7%) had stable disease or progressed on therapy. After a median follow-up of 8.4 years, twenty (35%) relapsed and eight died. Eight of them (14%) progressed/relapsed within 24 months of therapy. Interim PET-2 was assessed as negative (Deauville 1-3) in 40 (70%) and positive (D4-5) in 17 (30%) patients. End-of-induction PET scans were obtained in all but two patients (1 PD on therapy, 1 refusal), with 47 (85%) negative (D1-3) and eight (15%) positive (D4-5) results. Five-year PFS reached 55.2% and 79.2% (p=0.009) and 5-y OS 88.2% and 94.9% (p=0.017) in the D4-5 and D1-3 groups, respectively. Positive and negative predictive values were 58.8%/72.5% for PFS events and 29.4%/92.5% for death. The risk of a POD24 was 24% and 10% in the D1-3 and D4-5 groups, respectively.

Summary/Conclusion: Early interim PET/CT negativity is associated with a high negative predictive value for progression or lymphoma-related death. The risk of developing a POD24 event is reduced by 58% in the negative (D1-3) group. Interim PET/CT might be useful in identifying HTB-FL individuals at risk for immunochemotherapy failure. Larger analyses are needed to establish the role of interim PET in decision-making.

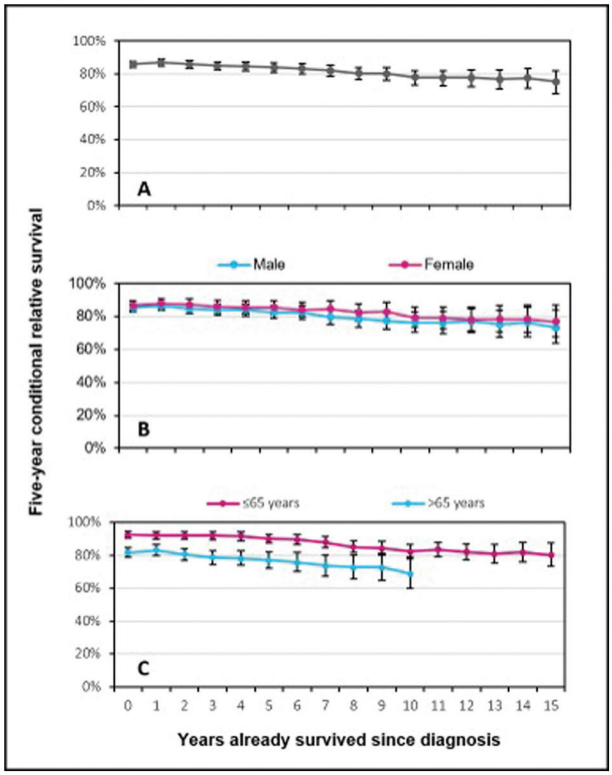
EP803 RISK OF SECOND PRIMARY MALIGNANCIES IN PATIENTS WITH FOLLICULAR LYMPHOMA: A POPULATION-BASED STUDY IN THE NETHERLANDS

M. Dinnessen [1,*], O. Visser [2], S. Tonino [3], E. Posthuma [4], N. Blijlevens [5], M. J. Kersten [3], P. Lugtenburg [6], A. Dinmohamed [1]

[1]*Department of Research,* [2]*Department of Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht,* [3]*Department of Hematology, Amsterdam UMC, Cancer Center Amsterdam, Amsterdam,* [4]*Department of Internal Medical, Reinier de Graaf Gasthuis, Delft,* [5]*Department of Hematology, Radboud UMC, Nijmegen,* [6]*Department of Hematology, ErasmusMC Cancer Institute, Rotterdam, Netherlands*

Background: Some population-based studies demonstrate that the improved longevity of patients with follicular lymphoma (FL) is offset

by an increased risk of a variety of second primary malignancies (SPMs) compared to the general population. Awareness about the incidence of SPMs in patients with FL is important to mitigate potential sequelae of SPMs.
Aims: To complement and extend on the sparse literature on SPM development in FL, this nationwide population-based study aimed to assess the risk to develop SPMs in patients with FL in the Netherlands diagnosed during a 30-year period.
Methods: We selected all patients diagnosed with FL grades 1-3B between 1989-2018 from the Netherlands Cancer Registry (NCR) and followed these patients until SPM development, death, or end of follow-up (December 31, 2018), whichever occurred first. Standardized incidence ratios (SIRs) for all SPMs combined—except for basal and squamous cell carcinomas—and specific subtypes of SPMs were calculated by dividing the number of observed malignancies by the expected number of malignancies in an age, sex, and period matched population from the NCR. Synchronous malignancies diagnosed within six months from FL diagnosis (n=248; 1.8% of the total FL population) were excluded to minimize detection bias. We assigned 95% confidence intervals (CIs) for the SIRs by assuming a Poisson distribution for the number of observed SPMs.
Results: We included 13,656 FL patients (median age, 62 years, 49% females) in this study, of whom 1,415 patients (10%) developed at least one SPM after a median follow-up of 5.2 years from diagnosis (interquartile range (IQR), 2.0-10.2 years) at a median age of 69 years (IQR, 62-75 years). Of the 1,415 patients, 550 patients (38%), 432 patients (31%), and 432 patients (31%) were diagnosed with an SPM at 0.5-5, 5-10, and 10-30 years from diagnosis. The cumulative incidence of SPMs was 7.3% (95% CI, 6.8-7.8%) and 14.9% (95% CI, 14.1-15.8%) at 5 and 10 years, respectively.
The risk of developing an SPM for patients with FL was statistically significantly elevated compared to the general population with a SIR of 1.27 (95% CI, 1.20-1.34; Figure 1), irrespective of sex. The increased risk was more pronounced among patients 18-60 years at diagnosis (SIR, 1.52; 95% CI, 1.40-1.64) compared to patients >60 years at diagnosis (SIR, 1.10; 95% CI, 1.02-1.18), possibly due to a higher baseline risk among patients 18-60 years. The excess risk of SPMs diminished, albeit it did not disappear, among patients diagnosed in the post-rituximab era (>2002) compared to patients diagnosed in the pre-rituximab era (SIR, 1.15; 95% CI, 1.07-1.24 and SIR, 1.38; 95% CI, 1.28-1.49, respectively). A significantly greater risk was observed for acute myeloid leukemia (7.85), and myelodysplastic syndrome (3.47), and solid tumors of the following sites: thyroid (3.58), lung and bronchus (1.63), primary site unknown (1.52), urinary bladder and renal pelvis (1.52), melanoma of the skin (1.49), and colon and rectum (1.18; Figure 1).



Summary/Conclusion: This nationwide, population-based study demonstrates that FL patients have a 1.27 times greater risk of SPMs than the general population that persists for patients diagnosed in the rituximab era. SPMs could reflect late sequelae of treatment or the effect of shared etiologic factors, environmental exposures, and host characteristics. Surveillance of SPMs among FL survivors can be considered in the survivorship care of these patients—particularly among patients aged 18-60 years at diagnosis—to prevent SPMs or reduce the impact of SPMs.

EP804 CONDITIONAL RELATIVE SURVIVAL IN LYMPHOPLASMACYTIC LYMPHOMA/WALDENSTRÖM'S MACROGLOBULINEMIA (LPL/WM): A POPULATION-BASED STUDY IN THE NETHERLANDS

K. Amaador [1,*], M. J. Kersten [1], O. Visser [2], E. F. Posthuma [3,4], M. C. Minnema [5], J. M. Vos [6], A. G. Dinmohamed [6,7,8,9]

[1]Department of Hematology, Cancer Center Amsterdam, Amsterdam UMC, University of Amsterdam, Amsterdam, The Netherlands and LYMMCARE, [2]Department of Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [3]Department of Internal Medicine, Reinier de Graaf Gasthuis, Delft, [4]Department of Hematology, Leiden University Medical Center, Leiden, [5]Department of Hematology, University Medical Center Utrecht, University Utrecht, Utrecht, [6]Department of Hematology, Amsterdam UMC, University of Amsterdam, Amsterdam, The Netherlands and LYMMCARE, [7]Department of Research and Development, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [8]Department of Public Health, Erasmus MC, University Medical Center Rotterdam, Rotterdam, [9]Department of Hematology, Cancer Center Amsterdam, Amsterdam UMC, Vrije Universiteit Amsterdam, Amsterdam, Netherlands

Background: Population-based studies in LPL/WM are limited. Nevertheless, these studies revealed that the introduction of rituximab improved the population-level survival of LPL/WM patients across all age groups. The improved survival necessitates measures that capture the prognosis for long-term LPL/WM survivors because survival estimates measured from diagnosis can be rather discouraging due to patients who die within the first years post-diagnosis. Conditional relative survival (CRS) is a concept that refers to the probability of survival—corrected for the life expectancy in the general population—after having survived from a specified time since diagnosis. Studies on CRS in LPL/WM lack to inform long-term LPL/WM survivors about their prognosis at a specified time since diagnosis.
Aims: This nationwide, population-based study examined up-to-date estimates of 5-year relative survival (RS) at diagnosis and for each year survived up to 15 years post-diagnosis among LPL/WM patients in the Netherlands.
Methods: All patients diagnosed with LPL/WM between 1989-2018—with follow-up for survival until December 31, 2019—were selected from the Netherlands Cancer Registry. RS was calculated to estimate disease-specific survival. RS is defined as the ratio of the observed to expected survival, of which the latter is matched to the patient by age, sex, and calendar year. We calculated 5-year RS at diagnosis and 5-year CRS for each additional year survived up to fifteen years after diagnosis, conditional on being alive at the beginning of that year. Up-to-date survival probabilities for patients diagnosed during 1989-2018 who were alive between the follow-up interval of 2008-2019, were generated using the hybrid approach. These survival probabilities can be interpreted as the predicted survival probabilities for patients diagnosed during 2008-2019. Survival statistics were computed for the overall cohort and according to sex and age at diagnosis (≤65 and >65). Survival differences between the point estimates were assessed by 95% CI overlap.
Results: A total of 6,234 LPL/WM patients (median age, 70 years; and 61% males) were diagnosed in the Netherlands during 1989-2018, of whom 4,296 (69%) were at risk under the hybrid approach. The overall 5-year RS measured from diagnosis was 86% (95% CI, 84%>88%) and gradually decreased with additional years survived to 75% (95% CI, 68%>82%) at 15 years post-diagnosis (Fig. A). This trend was emulated according to sex, with no sex differential in survival over time (Fig. B). However, there were significant differences in 5-year RS at diagnosis with increasing age, namely 93% (95% CI, 91%>95%), and 82% (95% CI, 79%>85%) across the age groups, respectively (Fig. C). Five-year CRS decreased with each additional year survived among patients aged ≤65 and >65 years at diagnosis. Consequently, the age-related survival gap persisted during the follow-up period.

Summary/Conclusion: This study highlights that contemporary diagnosed LPL/WM patients, as compared to the general population, continue to experience excess mortality regardless of having survived up to 15 years post-diagnosis. This gradual increase in excess mortality might result from the incurable nature of this disease characterized by multiple relapses throughout the disease course. CRS estimates offer LPL/WM patients information about their survival expectations with each year survived post-diagnosis and provides means to physicians to tailor surveillance and follow-up activities. Our study results touch upon the need for novel treatment strategies to reduce short- and long-term excess mortality in LPL/WM patients.

EP805 EFFICACY AND SAFETY OF ZANUBRUTINIB VERSUS RITUXIMAB-BASED CHEMOIMMUNOTHERAPY IN WALDENSTRÖM MACROGLOBULINEMIA: MATCHING-ADJUSTED INDIRECT COMPARISONS

J. Castillo [1,*], K. Yang [2], R. Liu [3], Y. Wang [4], A. Cohen [2], T. Zimmerman [2], Q. Zhao [5], X. Gao [3], B. Tang [2]

[1]Dana-Farber Cancer Institute, Boston, [2]Beigene, San Mateo, [3]Pharmerit-an Open Health Company, Bethesda, United States, [4]Beigene, [5]Pharmerit-an Open Health Company, Shanghai, China

Background: There is a lack of randomized trials directly comparing zanubrutinib with chemoimmunotherapy in Waldenström Macroglobulinemia (WM).
Aims: This study aimed to indirectly compare zanubrutinib with bendamustine-rituximab (BR) and with dexamethasone-rituximab-cyclophosphamide (DRC) separately through matching-adjusted indirect comparisons (MAIC).
Methods: MAIC were conducted to re-weight the individual data of 102 WM patients (83 relapsed/refractory [R/R] and 19 treatment-naïve [TN]) treated with zanubrutinib in the ASPEN trial (NCT03053440) so that the weighted average baseline characteristics of patients treated with zanubrutinib matched those of 71 R/R patients treated with BR, and 72 TN patients treated with DRC separately. Matching variables for MAIC with BR included age, prior lines of therapy, IgM concentration, International Prognostic Scoring System for WM score, and extramedullary disease (EMD); and for MAIC with DRC included age, platelet count, hemoglobin concentration, and EMD. Kaplan-Meier curves of progression-free survival (PFS) and overall survival (OS) of comparators were digitized to re-create patient-level data. Comparisons of survival and adverse event incidence between treatments were conducted using Cox proportional hazards models and modified Poisson models.
Results: Compared to DRC, zanubrutinib was associated with significantly longer PFS (hazard ratio [HR]: 0.39 [95% confidence interval 0.18-0.82] and 0.35 [0.14-0.86] pre- and post-matching, respectively) and insignificantly longer OS (HR: 0.56 [0.20-1.53] and 0.47 [0.14-1.62] pre- and post-matching, respectively), and insignificantly higher incidences of neutropenia (risk ratio [RR]: 1.63 [0.71-3.77] and 1.47 [0.58-3.74] pre- and post-matching, respectively). Compared to BR, zanubrutinib was associated with significantly longer PFS (HR: 0.32 [0.15-0.69] and 0.37 [0.15-0.91] pre- and post-matching, respectively), significantly longer OS (HR: 0.31 [0.12, 0.80] and 0.29 [0.10-0.85] pre- and post-matching, respectively), significantly lower incidences of neutropenia (RR: 0.45 [0.26-0.78] and 0.50 [0.27-0.91] pre- and post-matching, respectively) and insignificantly lower incidences of pneumonia (RR: 0.18 [0.02-1.55] and 0.26 [0.03-2.28] pre- and post-matching, respectively).

		MAIC of zanubrutinib vs DRC		MAIC of zanubrutinib vs BR	
Outcomes	Zanubrutinib pre-matching (N=102)	Zanubrutinib post-matching DRC (N= 53)	DRC (N=72)	Zanubrutinib post-matching BR (N=50)	BR (N=71)
PFS, 12-month rate, %	94	92	85	94	79
PFS, 24-month rate, %	85	90	68	81	59
OS, 12-month rate, %	97	95	92	98	87
OS, 24-month rate, %	90	94	85	88	77
Anaemia, %	5.0	4.2	NR	3.6	NR
Hypertension, %	5.9	3.1	4.2	9.5	NR
Neutropenia, %	15.8	14.3	9.7	17.5	35.2
Pneumonia, %	1.0	0.6	NR	1.5	5.6
Thrombocytopenia, %	5.9	4.4	0.0	5.2	NR

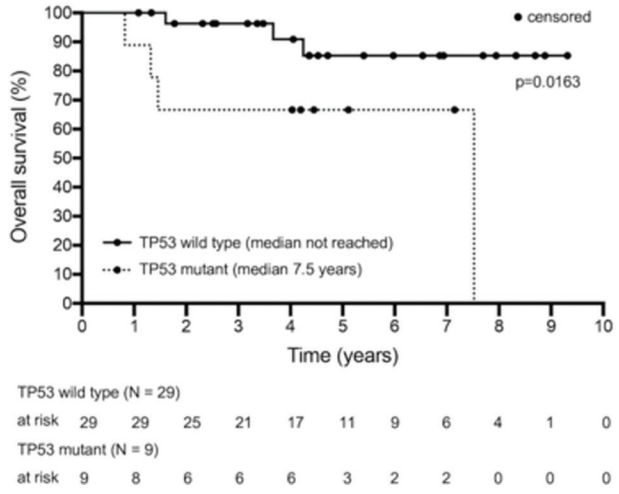
NR, not reported

Summary/Conclusion: Zanubrutinib demonstrated longer PFS than DRC, longer PFS and OS than BR in WM, and lower incidence of neutropenia before and after matching adjustment based on patient characteristics.

EP806 P53 IMMUNOHISTOCHEMISTRY DETECTS NON-PATHOGENIC MUTATIONS IN MANTLE CELL LYMPHOMA NECESSITATING TP53 NGS FOR CLINICAL DECISION MAKING

J. Nolan [1,*], C. Murphy [1], K. Dinneen [2], J. McHugh [3], H. Enright [3], B. Hennessy [4], E. El Hassadi [4], S. Kumar [4], J. Sargent [5], J. Quinn [6], L. Grogan [7], A. Fortune [8], M. Perera [9], B. Bird [10], D. O'Mahony [11], S. O'Reilly [11], D. O'Shea [12], E. Higgins [1], D. O'Brien [1], G. Lee [1], R. Flavin [2], F. Quinn [13], E. Vandenberghe [1]

[1]Haematology, [2]Histopathology, St James' Hospital, [3]Haematology, Tallaght University Hospital, Dublin, [4]Haematology, University Hospital Waterford, Waterford, [5]Haematology, Our Lady of Lourdes Hospital Drogheda, Drogheda, [6]Haematology, [7]Oncology, Beaumont Hospital, [8]Haematology, Mater Misericordiae University Hospital, Dublin, [9]Haematology, Midlands Regional Hospital, Tullamore, [10]Oncology, Bon Secours Hospital, [11]Oncology, [12]Haematology, Cork University Hospital, Cork, [13]Cancer Molecular Diagnostics, St James' Hospital, Dublin, Ireland



Background: Despite recent improvements in chemo-immunotherapy and novel therapies for mantle cell lymphoma (MCL), patients continue to experience heterogeneous clinical outcomes. Validated predictors of high-risk for adverse outcome include high-risk MCL International Prognostic Index (MIPI), Ki-67 ≥30% and blastic or pleomorphic histological variants. MCL harbouring pathogenic TP53 mutations treated on Nordic MCL2/MCL3 clinical trials have an inferior outcome, therefore detecting these mutations prior to treatment initiation may alter the treatment pathway utilising targeted therapy or a clinical trial. Missense TP53 mutations lead to accumulation of p53 within the cell, which is detectable by immunohistochemistry, whereas clinically relevant deletions or other TP53 mutations are only detected by Next Generation Sequencing (NGS).
Aims: We aimed to evaluate (1) the concordance of p53 immunohistochemistry and TP53 NGS in detecting high-risk missense TP53 mutations, (2) incidence of non-missense TP53 disruption in diagnostic specimens of MCL patients treated on the Nordic MCL2 protocol.
Methods: We identified patients treated between 2007-2019 on a modified Nordic MCL2 protocol (alternating Rituximab-CHOP/Rituximab-Cytarabine induction followed by BEAM-conditioned autologous stem cell transplantation). All patients undergoing HD-ASCT achieved VGPR/CR with induction therapy, as determined by Lugano criteria and were MRD negative. p53 expression by immunohistochemistry in diagnostic specimens was compared with NGS of TP53 and correlated

with clinical outcomes. Tumour sections with ≥30% of neoplastic cells staining positive for TP53 by IHC were defined as p53 positive as previously described. NGS called pathogenic TP53 mutations occurring at ≥5% VAF, with pathogenicity inferred from well-curated databases. All data is calculated from date of commencing Nordic protocol to date of censoring (death or end of study).

Results: 42 patients were treated with MCL2 between 2007-2019, of whom 38 had either DNA, tumour block or both available for TP53 mutation analysis. 34 (81%) patients were male and the median age was 59 years (range 37-67). 16 (41%) of patients had high-risk MIPI and 4 (9.5%) had non-classical MCL subtypes. Median overall survival (OS) was not reached and disease-free survival was 6.5 years. There was no transplant-related mortality. High-risk MIPI (p=0.078), Ki67≥30% (p=0.50), SOX11<10% (p=0.06) and non-classical MCL subtype (p=0.56) were not associated with inferior OS, likely due to the small cohort size.

Pathogenic TP53 mutations by NGS (6 cases) or p53 expression by IHC (4 cases) were detected in 9 patients (24%) and associated with inferior OS (p=0.0163) (Figure 1). Paired p53 IHC was unavailable for 5/6 TP53 mutated cases by NGS, however P53 was expressed in the remaining case. One of 4 P53 IHC positive cases lacked a corresponding NGS sample. Two P53 positive cases occurred in patients with NGS detectable mutations not classified as pathogenic: these patients remain in CR1 at 38 and 55 months from HD-ASCT respectively. There was 100% concordance between paired TP53 wild type cases and TP53 <30% by IHC (20 cases).

Figure 1. Overall survival

Summary/Conclusion: The presence of pathogenic TP53 was associated with adverse overall survival in this cohort. P53 IHC flagged two cases with TP53 mutations of uncertain significance by NGS. The implications of this finding must be explored in larger patient series, but suggest that IHC may not detect pathogenic TP53 mutations with sufficient accuracy to direct treatment pathways. All detected TP53 mutations were missense, reflecting the small study cohort.

EP807 OBINUTUZUMAB SHORT-DURATION INFUSION (SDI) IN PREVIOUSLY UNTREATED ADVANCED FOLLICULAR LYMPHOMA: RESULTS FROM THE END OF INDUCTION ANALYSIS OF THE PHASE IV GAZELLE STUDY

M. A. Canales [1,*], T. A. Buchholz [2], K. Izutsu [3], T. Ishikawa [4], L. M. Fogliatto [5], E. Vorozheikina [6], D. Klingbiel [7], S. Pokala [7], M. Tomiczek [7], J. Parreira [7], K. Hübel [8]

[1]Hospital Universitario La Paz, Madrid, Spain, [2]Scripps MD Anderson Cancer Center, San Diego, United States, [3]National Cancer Center Hospital, Tokyo, [4]Kobe City Medical Center, General Hospital, Hyogo, Japan, [5]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil, [6]IQVIA, Medical and Scientific Services, Moscow, Russian Federation, [7]F. Hoffmann-La Roche Ltd., Basel, Switzerland, [8]Uniklinik Köln, Köln, Germany

Background: Obinutuzumab (G)-chemotherapy (chemo) has demonstrated improved progression-free survival compared with rituximab (R)-chemo in previously untreated advanced follicular lymphoma (FL). G is currently administered by intravenous infusion over ~3–4 hours. A shorter duration of infusion in Cycle (C) 2 and subsequent cycles, as is standard practice with R, could improve convenience for patients (pts) and efficiency for infusion facilities.

Aims: We report the primary analysis of the prospective, open-label, multicenter, single-arm, Phase IV, GAZELLE study (NCT03817853), which evaluated the safety of G administered as a 90-minute (min) SDI from C2 onwards in pts with FL.

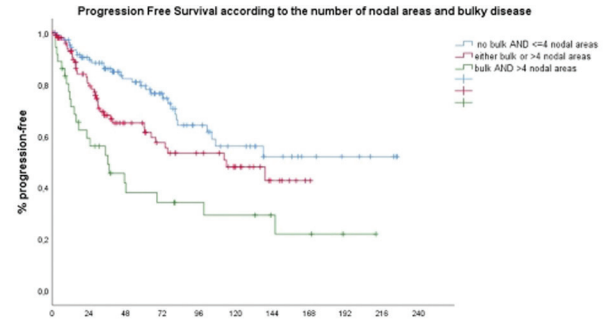
Methods: Pts with previously untreated FL who met Groupe d'Etude des Lymphomes Folliculaires (GELF) criteria received G (1000mg) intravenously on Day (D) 1, 8 and 15 of C1, and on D1 thereafter, plus chemo (bendamustine, CHOP or CVP) for 6–8 cycles. In C1, pts received G at the standard infusion rate. Pts without a Grade (Gr) ≥3 infusion-related reaction (IRR) in C1 were eligible to receive G as a 90-min SDI from C2. Pts with a Gr 3 IRR in C1 received the standard G infusion in C2, and were eligible for G SDI in subsequent cycles if no Gr ≥3 IRRs occurred. Pts with a second Gr 3/4 IRR discontinued G. At the end of induction (EOI), responding pts received maintenance G (1000mg) as SDI for 2 years or until disease progression (PD). The primary endpoint was incidence of Gr ≥3 IRRs during C2. IRRs were defined as any event occurring ≤24 hours from infusion judged to be related to treatment. Secondary endpoints included adverse events (AEs) and investigator-assessed overall response rate at EOI.

Results: As of December 3, 2020, 113 pts had received study treatment. Median age was 62.0 years, 50.4% were male, 61.9% had stage IV FL and 45.1% were classified as high-risk FLIPI. Of the 110 pts who were eligible for G SDI from C2, no pt experienced a Gr ≥3 IRR with SDI in C2 (**Table**). One pt experienced a Gr 3 IRR with SDI in C5, presenting hypertension. All other IRRs with SDI were Gr 1/2. No Gr 4/5 IRRs were reported. Other AEs were similar to those observed in previous studies. At the clinical cut-off date, 104 pts had a CT imaging-based response assessment at EOI and 9 pts had no response assessment; 76/113 (67.3%) pts had a complete response, 22 (19.5%) had a partial response, and six pts (5.8%) had PD.

Table. IRRs by cycle

	C1											
IRR, n (%)	C1 overall	D1	D2*	D8	D15	C2	C3	C4	C5	C6	C7	All cycles
All Gr	65/113 (57.5)	57/113 (50.4)	4/51 (7.8)	6/112 (5.4)	5/111 (4.5)	13/110 (11.8)	9/108 (8.3)	7/108 (6.5)	6/107 (5.6)	5/105 (4.8)	2/55 (3.6)	71/113 (62.8)
Gr ≥3	6/113 (5.3)	5/113 (4.4)	1/51 (2)	0	0	0	0	0	1/107 (0.9)	0	0	7/113 (6.2)

*timepoint applicable to pts treated with bendamustine



Summary/Conclusion: In GAZELLE, G SDI in C2 and beyond appeared to be safe. No Gr 3 IRRs were observed in C2 and only one Gr 3 IRR was reported in subsequent cycles. No new safety signals were reported and 67.3% of pts achieved a CR. These data suggest that the safety and efficacy profile of G SDI is comparable with the established profile of G in advanced FL.

EP808 EXAMINATION OF FOLLICULAR LYMPHOMA INTERNATIONAL PROGNOSTIC INDEX (FLIPI) SCORE FOR FOLLICULAR LYMPHOMA PATIENTS IN THE RITUXIMAB ERA OUTSIDE CLINICAL TRIALS

M. K. Angelopoulou [1,*], S. Diavati [1], T. Giannikos [1], P. Tsirkinidis [1], M. P. Siakantaris [1], P. Tsaftaridis [1], E. Plata [1], J. V. Asimakopoulos [1], E. Konstantinou [1], D. Giakoumi [2], G. A. Pangalis [2], K. Konstantopoulos [1], T. P. Vassilakopoulos [1]

[1]Hematology and BMT Department, Laikon General Hospital, [2]Department of Hematology, Psychikon Branch, Iatriko Athinon, [3]2nd Department of Propaedeutic Surgery, Laikon General Hospital, Athens, Greece

Background: FLIPI is the most frequently used prognostic tool even nowadays, although it was developed in the pre-Rituximab (R) era with overall survival (OS) as the endpoint. It has not been extensively studied, whether it can predict progression free survival (PFS) and if it still has a strong prognostic value for OS in R-treated patients, especially outside clinical trials.
Aims: To identify prognostic factors and examine the prognostic significance of FLIPI in a series of FL patients, treated in the R era outside clinical trials
Methods: 282 consecutive patients with FL diagnosed and treated between 2000 and 2020 from a single Unit were retrospectively studied. Several prognostic parameters were analyzed for OS, PFS and disease-specific survival (DSS).
Results: 112 patients (40%) were males with a median age of 56.7 years. 206 cases had histologic grade 1/2 (73%) and the remaining 76 (27%) grade 3A. The distribution of clinical stages was as follows: 71 (25%) stage 1, 35 (13%) stage 2, 42 (15%) stage 3, 132 (47%) stage 4; 12% had B symptoms, 21% elevated LDH, 25% bulky disease (>7cm), 7% had peripheral blood involvement and 41% had bone marrow involvement. 43% had >4 involved nodal areas. The most frequent treatment was R non-anthracycline chemotherapy, followed by RCHOP; 61% received maintenance after first line treatment. Median PFS was 114 months; 5- and 10-year PFS were 67.5% and 49%, respectively. For PFS, FLIPI score was not significant, whereas, bulky disease (p<0.0001) and number of nodal areas (p=0.018) were the only significant factors by univariate analysis; bulky disease remained significant by multivariate analysis (p<0.0001). A simple score based on nodal areas (0 points for ≤4 vs 1 point for >4) and bulky disease (0 points for no bulk vs 1 point for bulk) could stratify patients into three groups with a significantly different PFS (p<0.0001, figure). FLIPI score was prognostic for OS (p<0.0001) and DSS (P=0.004), but low- and intermediate risk groups had similar outcomes, especially for DSS. When low-and intermediate risk groups were grouped together (FLIPI 0-2) against high-risk (FLIPI 3-5), 5- and 10- year OS was 95% and 90.4% for FLIPI 0-2 vs 76% and 59% for FLIPI 3-5. 5- and 10- year DSS were both 96% for FLIPI 0-2 vs 90% and 76% for FLIPI 3-5. Considering the 5 parameters of FLIPI and bulky disease, by multivariate analysis, hemoglobin, age and bulky disease were the ones that were significant for OS, whereas, only bulky disease was significant for DSS.

	Group	Events/Cases	5-year PFS (%)	10-year PFS (%)
1 (0 points)	No bulk and ≤4 nodal areas	31/115	80	56
2 (1 point)	Either bulk or >4 nodal areas	39/106	65	48
3 (2 points)	Bulk and >4 nodal areas	23/36	38	29

Summary/Conclusion: In real world, outside clinical trials, with the observed improvement of survival of patients with FL in the R-era, FLIPI is still prognostic for OS, but may have limited predictive capacity for PFS. Bulky disease seems to be a potent marker for PFS, OS and DSS and should be further integrated and validated in easily applicable prognostic scores.

Infections in hematology (incl. supportive care/therapy)

EP809 IMMUNONOLOGICAL BIOMARKERS OF FATAL CORONAVIRUS DISEASE 2019 (COVID-19): A STUDY OF 513 PATIENTS INCLUDING HEMATOLOGICAL CASES

Background: Knowledge on the immunopathobiology of COVID-19 is rapidly increasing but most studies analyzed relatively small series of patients and immune features predictive of fatal outcome are unavailable for routine stratification. Furthermore, an increased risk of death in patients with hematological cancer infected by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has been identified, but it remains unknown if this is related to possible immunosuppression caused by cancer itself and cytotoxic treatment.
Aims: Characterize the immune response to SARS-CoV-2 in a large cohort of patients to identify high-risk immune biomarkers and evaluate the association between COVID-19 severity and immunosuppression in patients with hematological cancer.
Methods: Multidimensional flow cytometry was used to conduct holistic and unbiased analyses of 17 immune cell types on 780 peripheral blood samples obtained from 513 COVID-19 patients, 24 cases with non-SARS-CoV-2 infection and 36 age-matched healthy adults. 167 COVID-19 patients had 207 longitudinal samples collected over time. RNA sequencing on FACSorted cells and high-resolution flow cytometry were used to perform a deeper characterization of various myeloid and lymphoid subsets in 14 COVID-19 patients and 4 healthy adults.
Results: Immune profiles of COVID-19 patients were generally similar to those of age-matched patients with non-SARS-CoV-2 infection, but significantly different from those of age-matched healthy adults. When compared to the later, COVID-19 patients showed increased percentages of neutrophils, $CD4^{+}CD56^{+}$ T-cells, and plasmablasts, whereas levels of basophils, eosinophils, and non-classical monocytes, as well as double-negative, $CD8^{lo}CD56^{-}$, $CD8^{-/lo}CD56^{+}$ and $CD8^{hi}CD56^{-}$ T-cells, and B-cells were decreased. Both transcriptional and immunophenotypic data in myeloid and lymphoid subsets suggested an association between COVID-19 severity and neutrophil activation, as well as significantly reduced levels of specific adaptive immune cell types. Unsupervised clustering analysis of 513 patients revealed three immunotypes in response to SARS-CoV-2 infection. One of them, present in 14% of patients (n=74), was characterized by significantly lower percentages of all immune cell types except neutrophils and plasmablasts, and was significantly associated with more severe disease. Of note, 50% of COVID-19 patients with blood cancer displayed this immunotype. Accordingly, hematological patients showed a significantly higher frequency of admission into intensive care units (50% vs 5%, *P*<.001) and death (30% vs 4%, *P*<.001) than patients without tumor did. On multivariate analysis incorporating age and comorbidities, the frequency of B-cells and non-classical monocytes were independent prognostic factors for overall survival. Indeed, <1% B-cells in peripheral blood was most strongly associated with risk of death. Among patients with immune monitoring during follow-up, significant changes in the relative distribution of eight immune cell types, including basophils, $CD8^{lo}CD56^{-}$ T-cells, and B-cells, were observed from the first to last peripheral blood sample between patients who survived or died.

Summary/Conclusion: Our results accelerate our understanding of the immunopathobiology of COVID-19 and unveil an association between altered immune profiles in patients with hematological cancer and their poorer outcome. Reduced percentages of B-cells and non-classical monocytes are high-risk immune biomarkers that could be readily implemented in routine practice for risk-stratification of COVID-19.

EP810 PRESEPSIN AND RESPONSE TO ANTIBIOTIC THERAPY IN FEBRILE NEUTROPENIA OF ONCOHAEMATOLOGICAL PATIENTS

F. Vianello [1,*], L. Frison [1], A. C. Frigo [2], M. Arangio Febbo [1], F. Baratiri [1], F. D'amore [1], J. Ceccato [1], F. Cinetto [1], G. Semenzato [1], L. Trentin [1]

[1]Medicine, [2]Department of Cardiac, Thoracic and Vascular Sciences, University of Padova, Padova, Italy

Background: Febrile neutropenia (FN) is a potential life-threatening complication of the administration of chemotherapy in oncohematological patients. Only 20% of FN episodes have microbiologically-proven bacteremia. In most of cases, the therapeutic approach is based on the clinical picture and the laboratory evaluation of surrogate markers. More recently, soluble CD14 subtype, also known as presepsin (PS), has been proposed as a novel biomarker of microbial infection. Whether PS may have a role in predicting response to treatment is still unexplored.
Aims: We aimed to assess the kinetic of PS concentrations in a cohort of adult febrile neutropenia patients with haematological malignancies with particular interest to the time course in relation to the appropriateness of first-line empirical antimicrobial treatment.
Methods: From April 2018 to December 2019, consecutive patients admitted to our Unit for high dose chemotherapy alone or followed by autologous bone marrow stem cell transplantation were considered. Three categories were considered: *Sepsis*, *Bacteremia*, and *fever of unknown origin (FUO)*, As index tests, we considered PS, which was measured as follow: at patient admission; on the first day of chemotherapy (CT); at the onset of neutropenia (onset FN-); between 90 and 120 minutes from fever onset (onset FN+, before any broad-spectrum empirical antibiotic therapy); between 48 and 72 hours from the start of antibiotic therapy; between 24 and 48 hours from neutropenia resolution. Changes in presepsin concentration ([72 hours from empirical antibiotic - fever onset]/ fever onset) were categorised according to tertiles. The response to antibiotic therapy and the time to fever resolution according to tertiles of PS concentration were analysed considering in the model the factor tertile. The statistical significance was declared for p<0.05.
Results: 273 episodes (148 subjects, 80 males and 68 females) were eligible for this study. Reason for treatment was acute leukemia in 106 episodes, multiple myeloma in 68, lymphoma in 99. Autologous stem cell transplantation was performed in 68. In neutropenic patients with fever (FN+) or without fever (FN-), there was a statistically significant effect of the febrile status (p=0.0126), the time point considered (p<.0001) and their interaction (p=0.0006). At onset FN+ compared to FN- had higher levels (p<.0001, fold-change 1.82, 95% CI: 0.26 – 2.64; fig.1A). PS concentration was significantly higher in patients with documented bacterial infection (670 ng/L, [165–1267] ng/L than in those with negative cultures (358 ng/L, [105–1134] ng/L (p<0.0001, not shown). A statistically significant reduction was observed at 48-72 hours from antibiotic therapy (median 244 ng/L, range 89-721, p<0.0001; fig.1B). Patients with major reduction of presepsin concentrations from fever onset to antibiotic therapy, according to tertiles, tended to have received early appropriate antibiotic therapy (21/34, 61.7% in tertile 1, < -46%; 11/35, 31.4% in tertile 2, -45 to -17%; 5/35, 14.3% in tertile 3, -16% to +246%; p = 0.0009 for trend; fig.1C). Response to therapy probability was higher in tertiles 1 and 2 compared to tertile 3 ($OR_{1\ vs\ 3}$=3.5 and 95%CI: 1.0-12.4, p=0.0482; $OR_{2\ vs\ 3}$=9.7 95%CI: 2.2-42.5; fig.1D). A graded decrease in fever duration was observed across tertiles of changes for PS (trend *p*= 0.0004).

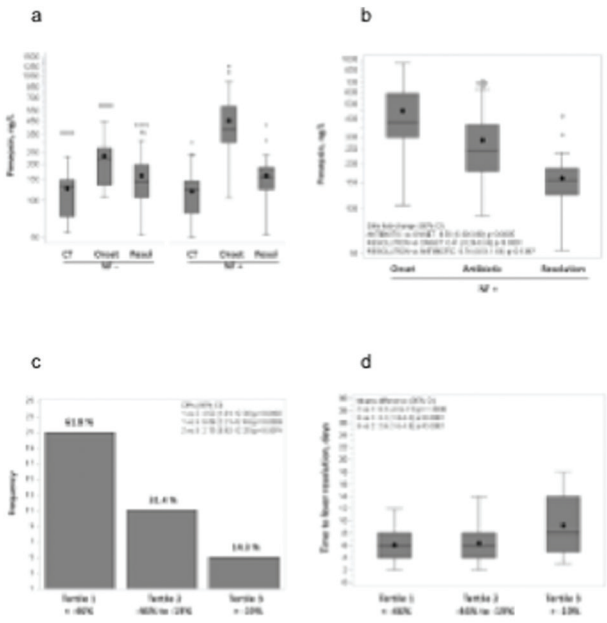

Figure 1

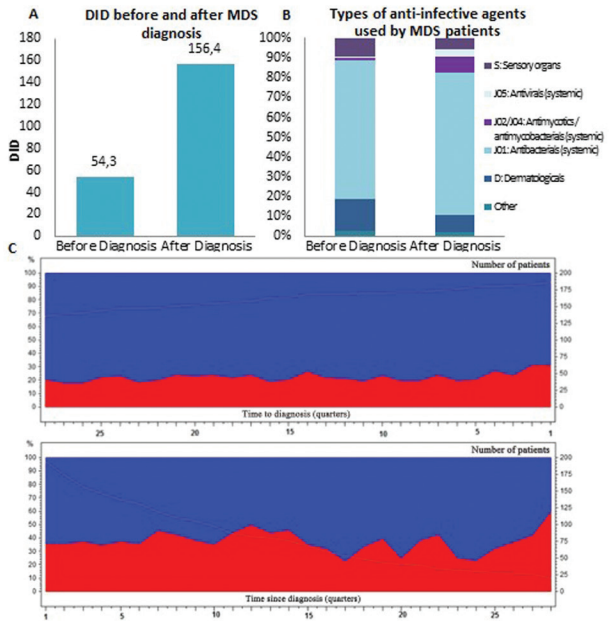
Summary/Conclusion: In conclusion, our study provides preliminary indications that PS has a role in monitoring appropriate antibiotic therapy in oncohematological patients with FN.

EP811 INCREASED USE OF ANTI-INFECTIVE AGENTS AFTER DIAGNOSIS OF MYELODYSPLASTIC SYNDROMES



J. Rozema [1,2,*], M. Hoogendoorn [3], R. Kibbelaar [4], A. van de Loosdrecht [5], N. Veeger [6,7], E. van Roon [1,2]

[1]Pharmacotherapy, Epidemiology and Economics, University of Groningen, Groningen, [2]Clinical Pharmacy & Pharmacology, [3]Internal Medicine, Medical Centre Leeuwarden, [4]Pathology Friesland, Leeuwarden, [5]Haematology, Amsterdam University Medical Centre, Location VUmc, Amsterdam, [6]Science Bureau, Medical Centre Leeuwarden, Leeuwarden, [7]Epidemiology, University Medical Centre Groningen, Groningen, Netherlands

Background: Infections in patients suffering from myelodysplastic syndromes (MDS) have a negative impact on quality of life, health care costs and are associated with mortality. Little is known about the burden of infections in MDS patients. Current estimates of infection rates are based on results from clinical trials or retrospective analyses that only reviewed hospital records. There are no population-based real-world studies that investigate the burden of infections by the use of anti-infective agents in MDS patients in first and second line care.
Aims: The primary objective of this study was to analyse the increase in susceptibility for infections in patients diagnosed with MDS. Therefore, the prescriptions of anti-infective agents in Dutch MDS patients, both before and after diagnosis of MDS, were collected. Dutch policies on prescribing anti-infective agents are strict and therefore are an accurate reflection of infection rates.
Methods: We performed an observational, population-based study using the HemoBase population registry, including all MDS patients diagnosed between 2005 and 2017 in Friesland, a Dutch province with circa 650.000 inhabitants (Rozema et al. (2021), accepted, Blood Advances). Informed consent was obtained. Community pharmacies provided information about the use of anti-infective agents from 10 years before MDS diagnosis to end of follow-up (Dec. 2020). These data were combined

with HemoBase registry data. Results were presented as prescriptions/year, treatment days/year or defined daily dose per 1000 patient days (DID). Descriptive analyses and Wilcoxon Signed Rank tests were performed using IBM SPSS version 24.

Results: A total of 292 MDS patients were identified, of whom in 201 patients (70%) information on prescribed anti-infective agents was obtained. The response rate was 91.4% for pharmacists and 56.5% for dispensing general practitioners. Patients received significantly more prescriptions/year after diagnosis (median 2.5; 95% CI: 2.1-3.0) than before diagnosis (median 0.8; 95% CI: 0.7-1.0; p<0.01). Likewise, the number of treatment days/year significantly increased (p<0.01) from a median of 7.7 (95% CI: 5.4-10.2) treatment days/year before diagnosis to 23.7 (95% CI: 16.8-31.0) after diagnosis. This corresponds to 54.3 DID (95% CI: 53.7-55.0) before diagnosis and 156.4 DID (95% CI: 154.6-158.2) after diagnosis (rate ratio: 2.9 (95% CI: 2.8-2.9); p<0.01, Fig. 1A). As shown in figure 1C, the prescriptions gradually increased over time. Patients with high-risk MDS did not seem to use more anti-infective agents than low-risk MDS patients (p=0.27). Before diagnosis, 26 patients (12.9%) were admitted to hospital due to an infection, compared to 78 patients (38.8%) after diagnosis; the rate ratio for an infection-related hospital admission was 3.0 (95% CI: 1.9-4.7). Patients mostly received antibacterial agents for systemic use (ATC group J01): 69.6% before diagnosis and 71.3% after diagnosis (Fig. 1B).

Summary/Conclusion: This study showed a significantly increased use of anti-infective agents in patients after diagnosis of MDS in both low-risk and high-risk MDS patients. After the diagnosis MDS, patients had a 3-fold higher risk for infections in an outpatient setting and a 3-fold higher chance for an infection-related hospital admission compared to before MDS diagnosis. To our knowledge, this is the first descriptive population-based study that provides an overall insight in prescribed anti-infective agents both in- and outside the clinical setting in a well-defined representative MDS patient cohort.

EP812 IMPACT OF THE CLINICAL MANAGEMENT OF HYPERTENSION, INFLAMMATION AND THROMBOSIS ON THE SURVIVAL OF HOSPITALIZED COVID-19 PATIENTS

P. Martínez-Botía [1], A. Acebes-Huerta [1,*], Á. Bernardo [2,3], A. Caro [1,4], B. Leoz [5,6], D. Martínez-Caballeira [1,4], C. Palomo-Antequera [7,8], I. Soto [1,4], L. Gutiérrez [1,9]

[1]Platelet Research Lab, Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), [2]Clinical Diagnosis Laboratory – Dept. of Hematology, Hospital Universitario Central de Asturias (HUCA), [3]Platelet Research Lab, ISPA, [4]Dept. of Hematology, Hemostasis Section, [5]Dept. of Intensive Medicine, Hospital Universitario Central de Asturias (HUCA), [6]Translational Microbiology Group, Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), [7]Dept. of Internal Medicine, Hospital Universitario Central de Asturias (HUCA), [8]Bone Metabolism, Vascular Metabolism and Chronic Inflammatory Diseases Group, Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), [9]Dept. of Medicine, University of Oviedo, Oviedo, Spain

Background: The coronavirus disease 2019 (COVID-19), caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) usually resolves with no further complications. However, in some patients, an unbalanced immune response and the occurrence of thrombotic events lead to severe clinical manifestations; with age, gender and comorbidities (namely, arterial hypertension [AHT] or diabetes) as acknowledged risk factors. The clinical management of these hospitalized patients is still a matter of debate, and the effectiveness of certain treatments (angiotensin-converting enzyme 2 inhibitors [ACE2-Is], angiotensin receptor blockers [ARBs], non-steroid anti-inflammatory drugs [NSAIDs], corticosteroids, and low molecular weight heparin [LMWH]) to handle said manifestations and comorbidities has been questioned.

Aims: In this study, we aim to assess the impact of the clinical management of arterial hypertension, inflammation and thrombosis on the survival of COVID-19 patients.

Methods: This observational retrospective study is composed of two Spanish cohorts, one from HM Hospitales and another from Hospital Universitario Central de Asturias, with 2035 and 72 laboratory-confirmed COVID-19 adult patients, respectively. The global analysis was performed in the HM cohort after stratification to study the impact of the different treatment arms, having as control group on each arm the respective untreated patients. The HUCA cohort was used as validation of the implementation of thromboprophylaxis in hospitalised patients. The primary end point was the time from hospital admission to discharge or death. Cox proportional-hazards regression, Kaplan-Meier survival curves and propensity score matching were employed, to further control for potential bias and the non-randomized treatment administration. Demographic variables (sex and age), comorbidities (diabetes and AHT), and treatment arms (when opportune) were included as co-variates. All analyses and figures were generated using R software (version 3.6.1).

Results: Cox regression identified age (older), sex (males) and AHT (but not diabetes) as risk variables in the HM cohort. Among the treatment arms of study, all treatment regimens, including LMWH alone or in combination with corticosteroids and anti-AHT drugs, conferred a significant advantage, as opposed to corticosteroids alone or in combination. Furthermore, the management of AHT with ACE2-Is or ARBs is not detrimental, as initially reported, and neither was the use of NSAIDs. On the contrary, our analysis shows that the use of corticosteroids, including dexamethasone, is not beneficial. Importantly, the therapeutic or prophylactic management of thrombosis in COVID-19 patients with LMWH, significantly improves the survival of hospitalized patients.

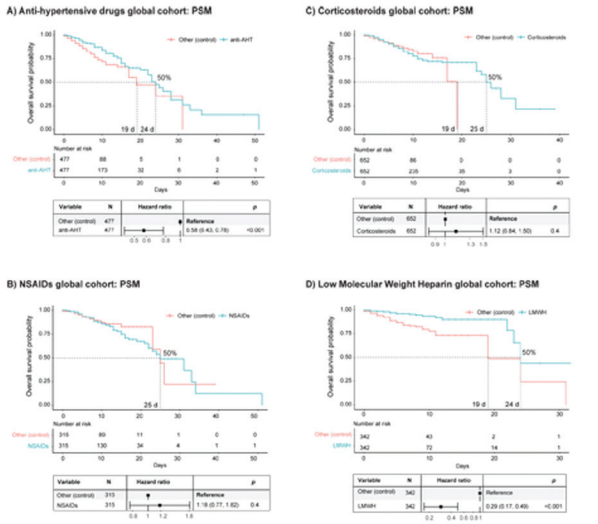


Figure 1. Impact of the different treatment arms on the survival of COVID-19 patients. Kaplan–Meier curves and forest plots obtained from Cox regression after propensity score matching (PSM) of COVID-19 patients treated or not with anti-AHT drugs (ACE2-Is and ARBs) **(A)**, NSAIDs **(B)**, corticosteroids **(C)** and LMWH **(D)**.

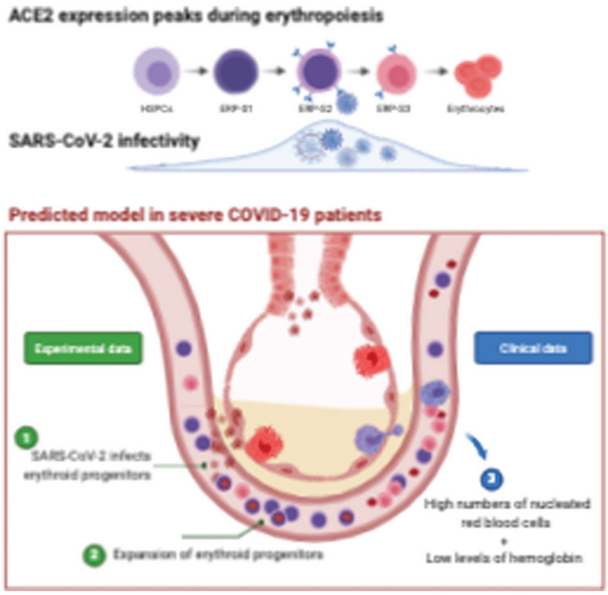

Summary/Conclusion: These results suggest cautiousness when administering corticosteroids for immunosuppression, and whether to limit said administration to the situations that require it (i.e., to facilitate pulmonary capacity as part of the general guidelines in patients with respiratory distress), but not as a protocolized guideline to treat hospitalized COVID-19 patients in general. In particular, dexamethasone may potentially be detrimental to patients in general wards (not critically ill and without respiratory distress). Additionally, they support the effectiveness of thrombosis prophylaxis with LMWH on COVID-19 patients as a first-line treatment, without the need to compromise the treatment of comorbidities.

EP813 HUMAN ERYTHROID PROGENITORS ARE DIRECTLY INFECTED BY SARS-COV-2: IMPLICATIONS FOR EMERGING ERYTHROPOIESIS IN SEVERE COVID19 PATIENTS

H. Huerga Encabo [1,*], W. Grey [1], M. Garcia-Albornoz [1], R. Ulfferts [2], H. Wood [1], I. Valle Aramburu [3], V. Papayannopoulos [3], R. Beale [2], D. Bonnet [1]

[1]Haematopoietic Stem Cell Laboratory, [2]Cell Biology of infection laboratory, [3]Antimicrobial defense laboratory, The Francis Crick Institute, London, United Kingdom

Background: An aberrant increase of erythroid progenitors in circulation have been reported in severe COVID-19 cases and correlates with severity and mortality. The infectivity of SARS-CoV-2 in HSPCs and more particularly in erythroid progenitors have not been characterized. In this report, we have studied HSPCs and different erythroid progenitor populations to assess if they can be infected by SARS-CoV-2.
Aims: Demonstrate that SARS-CoV-2 can infect erythroid progenitors and disrupt erythropoiesis causing the aberrant increase of nucleated red blood cells observed in severe COVID-19 patients.
Methods: Clinical data: A sample of 30 patients who were being treated for COVID-19 on intensive care units at King's College Hospital; **RNAseq data import and analysis of ACE2 expression:** RNAseq dataset was downloaded from GSE118537; **Isolation of mononuclear cells from human cord blood, bone marrow and peripheral blood; Flow cytometry analysis and cell sorting; mRNA quantification by RT-qPCR; Immunostaining, confocal microscopy and immunofluorescence quantification of ACE2 and TMPRSS2; SARS-CoV-2 production and infection; Colony-forming Unit (CFU) assay**
Results: - Patients treated for severe COVID-19 show a rapid and profound decline in hemoglobin following admission. Interestingly, this is associated with the appearance of circulating nucleated red cells.
- Publicly available datasets indicate that ACE2 and TMPRSS2 expression is scarce among hematopoietic cell types, and absent on human HSPCs. Progenitors of the erythroid lineage appear to be the only cell types expressing both ACE2 and TMPRSS2 among the cells present in the bone marrow (The Human Cell Atlas Bone Marrow Single-Cell Interactive Web Portal). Intrigued by this observation, we used detailed datasets of in vitro human erythropoiesis and we found that ACE2 expression peaks during erythropoiesis. Erythroid progenitors of Stage 1 (ERP-S1) can be defined as CD34+CD117+CD71+CD235a-, ERP-S2 as CD34-CD117+CD71+CD235a- and ERP-S3 as CD34-CD117-CD71+CD235a+.
- ERP-S2 cells are highly susceptible to SARS-CoV-2 infection. Importantly, our results showed that SARS-CoV-2 can infect and amplify its genome in erythroid progenitors of Stage 2 and Stage 3 but is not able to bind and infect HSPCs from the bone marrow.
- We also infected the erythroid progenitors from peripheral blood at lower MOI and we obtained similar results. After being in the presence of SARS-CoV-2, erythroid progenitors produce more colonies. We detected the virus in the colonies from ERP-S2, indicating that SARS-CoV-2 remains in ERP-S2 after 14 days of the initial infection.
Summary/Conclusion: We document here that intensive care COVID19 patients suffer a profound decline in hemoglobin levels but show an increase of circulating nucleated red cells, suggesting that SARS-CoV-2 infection either directly or indirectly induces stress erythropoiesis. Early erythroid progenitors, defined as $CD34^{-}CD117^{+}CD71^{+}CD235a^{-}$, show the highest levels of ACE2 and constitute the primary target cell to be infected during erythropoiesis. SARS-CoV-2 causes the expansion of colony formation by erythroid progenitors and can be detected in these cells after two weeks of the initial infection. Our findings constitute the first report of SARS-CoV-2 infectivity in erythroid progenitor cells and can contribute to understanding both the clinical symptoms of severe COVID19 patients and how the virus can spread through the circulation to produce local inflammation in tissues, including the bone marrow.

EP814 HUMORAL IMMUNITY RESPONSES AFTER VACCINATION FOR HEPATITIS B VIRUS IN AUTOGRAFTED PATIENTS: A SINGLE CENTER EXPERIENCE

N. Al Musailem [1,*], A. Al Shami [1], A. Estanislao [1], J. Bacal [1], M. Al Enazi [2], N. Al Mulhem [3], A. Bahrani [3], R. Attas [3], H. Al Hashmi [1], P. Kaloyannidis [1]

[1]Adult Hematology & Stem Cell Transplantation Department, [2]Family Medicine Department, [3]Department of Pathology and Laboratory Medicine, King Fahad Specialist Hospital, Dammam, Saudi Arabia

Background: Vaccination against hepatitis B virus (HBV) is highly recommended for hematopoietic stem cell transplantation (HSCT) recipients who have no protective antibody titers against the surface antigen (anti-HBs). The effectiveness of vaccination, reflecting the immune system functionality, represents a reliable marker for the qualitative immune reconstitution post HSCT. However, it is subjected to several factors (pre-immunization, HSCT type, conditioning regimen, graft source, etc.) thus complicating the drawing of secure conclusions as for the efficacy of vaccination programs post HSCT. With regard to autologous HSCT (AHSCT), the general aspect is that the immune system recovers soon after AHSCT therefore patients (pts) after a period of approximately 6 months post AHSCT are considered to be as immunocompetent as healthy individuals.
Aims: We evaluated the HBV vaccination responses in pts autografted for malignant diseases who had anti-Hbs titers <10 IU/ml both before AHSCT as well as the time of vaccination and were in remission and off chemotherapy post-transplant.
Methods: Twenty seven pts aged 51,6 (22-67) years (ys), autografted for lymphoma (n=19), multiple myeloma (n=9) and leukemia (n=1) were included in the study. The median CD34+ infused cells were $6{,}4\times10^{6}$/kg. The engraftment was successful and regarding the lymphocytes recovery, the median absolute count at +100 day was 1740 (450-4090)/mm^3. After a median of 4,3 (0,6–8,5) ys post AHSCT, the recombinant HBV vaccine Genevac-B® (Serum Institute of India Pvt. Ltd) was given monthly, in a 3 doses schedule (20 mg/injection). The median lymphocytes count during the vaccination period were 374/mm^3, 1643/mm^3, 628/mm^3, 844/mm^3, and 301/mm^3 for the B, CD3+, CD4+, CD8+ and NK cells respectively; all within normal ranges. We considered as effective response the presence of >10 IU/ml anti-HBs titers and the ultimate response rates of pts who successfully completed the 3 vaccine doses, were compared with an internal group of healthy individuals (control group) who were also vaccinated in our centre with the same product during the study period.
Results: After the 1st dose the response rate was 11% (3/27 pts), reaching to 81% (21/26 pts) after the 2nd and to 88% (23/26 pts) after the 3rd

dose. In univariate (student's T-test) and multivariate (logistic regression) analysis, no factor significantly affected the achievement of protective anti-HBV responses after vaccination completion, probably due to the size of our study group. The observed response rates after each dose were lower compared to the reported ones based on the reported product's efficacy profile (19%, 86% and 100% after the 1st, 2nd and 3rd dose respectively). In the direct comparative analysis with our control group, a strong trend for inferior responses was noticed for the autografted pts (88% vs 100%, p=0,07).
Summary/Conclusion: This study on a relatively homogenous group of pts is, to our knowledge, the only one that directly compares the HBV vaccine responses in autografted pts with healthy individuals who were vaccinated in the same area, similar period with the same product, thus providing an accurate comparative analysis. Although the intervention was offered late post AHSCT and pts had already adequate lymphocytes subpopulations counts at the time of vaccination, the response rates were lower compared to healthy individuals. Our results, in agreement with others, are indicative of a long lasting immune impairment post AHSCT highlighting the necessity of prolonged surveillance and intensified vaccination programs for autografted pts.

EP815 DETECTION OF SARS-COV-2 INFECTION PREVALENCE IN 474 HEMATOLOGIC PATIENTS UNDER THERAPY WITH A TRIPLE SCREENING PROCEDURE INCLUDING TRIAGE, MOLECULAR NASOPHARYNGEAL SWAB AND RAPID SEROLOGICAL TEST.

A. Candoni [1,*], G. Petruzzellis [2], S. Volpetti [1], G. Facchin [1], R. Stocchi [1], J. Olivieri [1], C. Marcon [1], A. Sperotto [1], V. Radici [1], R. Mullai [1], C. Comuzzi [1], F. Calabro' [1], R. Fanin [1]

[1]University Hospital of Udine- ASUFC, [2]Division of Hematology and SCT, Udine, Italy

Background: There are still limited epidemiological data regarding the efficacy and performance of screening procedures to detect the prevalence of SARS-CoV-2 infection (including symptomatic cases and asymptomatic carriers) in hematologic outpatients undergoing active anticancer therapy.
Aims: The primary endpoint of the study was to estimate the effective prevalence of SARS-CoV-2 infection (including silent and symptomatic cases) in consecutive and unselected hematologic outpatients under anticancer therapy.
Methods: Between May 1, 2020, and June 15, 2020 (under first wave of SARS-CoV-2 pandemic), 474 consecutive hematologic patients (pt) undergoing anticancer therapy, were evaluated and tested for SARS-CoV-2 with a combined screening procedure, including triage, molecular nasopharyngeal swab (NPS) and rapid serological immunoassay (for anti- SARS-CoV-2 IgG/IgM). The most frequent neoplasms was: lymphoma in 198 case, multiple myeloma in 103 cases, acute leukemia in 83 cases.
Results: Overall, 1263 SARS-CoV-2 NPS (median/pt=3 NPS, range 1-9) and 474 serological tests (one for each pt), were performed. At triage questionnaire, a total of 60 (13%) pt self-reported symptoms potentially COVID-19 related. The presence of symptoms (mainly fever > 37°C) was more frequent in pt with acute leukemia (23%), myelodysplastic syndromes (50%) and lymphomas (14%). SARS-CoV-2 NPS was positive in 0% of cases, but in 8 pt (1.7%) the specific serological test was positive (4/8 IgM and IgG positive and 4/8 only IgM positive). The prevalence of SARS-CoV-2 infection, in this tested neoplastic population, was 1.7% and, of the 60 cases who declared symptoms potentially COVID-19-related (positive triage), only 1/60 (1,6%) was found to be SARS-CoV-2 positive.
Summary/Conclusion: 1) This is a large study detecting the prevalence of SARS-CoV-2 infection (including asymptomatic cases) in oncohematologic pt receiving active therapy, during the first epidemic peak and under the restrictive lockdown measures, in one of the active areas of the SARS-CoV-2 circulation. Our findings suggest that a questionnaire-based triage system, even if accurate and important, has a low predictive value for the identification of cancer patients with SARS-CoV-2 infection since a differential diagnosis between tumor related symptoms (such as fever, cough or dyspnea) and COVID-19 related symptoms is always very difficult.
2) Lacking specific recommendations for the detection of asymptomatic SARS-CoV-2 infection carriers, a combined diagnostic screening (including triage +NPS +serological test) could be useful in detecting the right prevalence of SARS-Cov-2 infection in neoplastic pt populations including silent infection cases. This prevalence data can obviously be variable according to the territorial context, to the entity of the restrictive measures adopted and to the epidemic curve. Nevertheless, its knowledge is important to balance risks/benefits of oncologic treatments and to avoid, if the prevalence is low, the reduction of dose intensity or a selection of less intensive, but also less effective, anticancer therapies.

EP816 COVID-19 INFECTION IN MULTIPLE MYELOMA PATIENTS – CZECH EXPERIENCE

Background: COVID-19 disease caused by SARS-CoV-2 coronavirus has affected millions of people worldwide. The mortality of this infection varies with age and comorbidities up to more than 10% in very elderly population. The aim of our study was to determine the mortality rate and healthcare utilization among multiple myeloma patients and describe the potential risk factors for death.
Aims: The aim of our study was to determine the mortality rate and healthcare utilization among multiple myeloma patients and describe the potential risk factors for death.
Methods: We retrospectively analyzed entries in the Czech Registry of Monoclonal Gammopathies from patients who were infected with SARS-CoV-2 from March 2020 until January 2021. Demographic data, treatment patterns, comorbidities, symptoms of COVID-19, treatment modalities and healthcare utilization was compared in survivors and non-survivors.
Results: Overall, 158 patients with MM and COVID-19 with known outcome of the infection were identified. There were 72.8% (115/158) survivors and 27.2% (43/158) deceased patients. Both groups were balanced in gender, ECOG, M protein isotype, ISS stage and comorbidities. Non-survivors were significantly older (median 71.5 years vs 67.9 years, p=0.046). There were no differences between previous treatment lines in either group. Patients received median one prior line of therapy (range 0-6, p=0.994). 95% of patients were exposed to IMiDs (150/158), 89.9% to proteasome inhibitors (142/158) and 18.4% (29/158) to anti-CD38 antibody. Autologous stem cell transplantation was used in 36.7% (58/158) of patients. There were no differences in administered treatment in both groups. Inpatient treatment due to COVID-19 was required in 46.8% (74/158) of patients. Survivors hospitalization rate was 31.3% (36/115) and 88.4% (38/43) in non-survivors. In-hospital mortality was 51.4% (38/74). Non-survivors had more intensive care unit stays (4.3% vs 55.8%, p<0.0001) and needed more ventilation support (0.9 % vs 23.3%, p<0.0001). Mortality of patients who needed ICU was 82.8% (24/29 ICU stays) and 32.7% (16/49 ward stays) in patients who needed standard ward inpatient therapy. Mortality of patients needing artificial ventilation was 90.9% (1/11). Mortality of patients needing non-invasive ventilation or high flow nasal oxygen and 85.0% (17/20). Mortality of patients needing

low flow nasal oxygen was 50% (19/38). Table 1 shows results in detail.

Type of care	Survivors (n=115)	%	Non-survivors (n=43)	%	p value
Outpatient (N, %)	79	68.7	5	11.6	<0.0001
Hospitalized (N, %)	36	31.3	38	88.4	<0.0001
Standard ward (N, %)	33	28.7	16	37.2	0.4029
ICU (N, %)	5	4.3	24	55.8	< 0.0001
Length of stay (median, range)	11	(4-40)	10	(2-42)	0.4691
Oxygen support					
Without O2 (N, %)	85	73.9	5	11.6	< 0.0001
NIV / HFNO (N, %)	3	2.6	17	39.5	< 0.0001
ALV (N, %)	1	0.9	10	23.3	< 0.0001
Oxygen (low flow) (N, %)	19	16.5	19	44.2	0.0006
Symptoms of COVID-19					
Symptomatic (N, %)	76	66.1	39	90.7	0.0038
Fever (N, %)	49	42.6	29	67.4	0.0093

Treatment					
Convalescent plasma (N, %)	2	1.7	2	4.7	0.6397
Hydroxychloroquine (N, %)	0	0.0	1	2.3	0.6076
Remdesivir (N, %)	7	6.1	7	16.3	0.0907
Complications					
Bacterial superinfection (N, %)	11	9.6	15	34.9	0.0003
Relation to neutropenia (N, %)	0	0.0	3	7.0	0.0275
Thrombotic complications (N, %)	0	0.0	2	4.7	0.1265

ICU: intensive care unit, NIV: non-invasive ventilation, HFNO: high-flow nasal oxygen, ALV: artificial lung ventilation

Summary/Conclusion: The mortality of MM patients with COVID-19 was very high especially in patients in need of any type of ventilation support. Healthcare utilization was high with almost half of the infected myeloma patients needing inpatient treatment. No apparent risk factors in terms of disease status or previous treatment were identified.
Supported by MH CZ - DRO (UHHK, 00169906) and by the program PROGRES Q40/8.

EP817 EPIDEMIOLOGY AND MORTALITY IN BACTERAEMIA IN ADULT PATIENTS WITH HEMATOLOGIC MALIGNANCIES

B. Achouro [1,*], M. Manel [2], S. Nadia [1], A. Asma [3], E. Nihed [3], B. Emna [1], R. Haifa [1], B. Nesrine [1], K. Zahra [1], Z. Monia [1], B. Yosra [1], B. Jalel [1], K. Abderrahim [2]

[1]Hematology, [2]Microbiology, [3]Community Medecine, Farhat Hached Hospital, Sousse, Tunisia

Background: Patients with hematological malignancies have higher risk of acquiring infectious complications and bacterial bloodstream infections.
Aims: The aim of the study evaluated epidemiology, outcome and risk factors of mortality in *bacteraemia in adult patients with hematologic malignancies*.
Methods: In this retrospective study, all adult patients with hematologic malignancies who developed documented bacteraemia between January 2010 and December 2019 were evaluated. Risk factors with a P-value less than 0.20 were initially included in the binary logistic regression model to determine the independent risk factors for mortality Bloodstream infection in adult hematologic malignancies. Then the model was reduced by means of manual backward elimination. P values of 0.05 or less were considered statistically significant.
Results: Two hundred and thirty one bacteraemia episodes were identified in 174 patients. Acute myeloid leukaemia (AML) was the most common and accounted for 57.1% followed by acute lymphocytic leukaemia (ALL) for 31.2%. The bacteraemia occurred in 140 patients (60.6%) with uncontrolled/relapse or refractory disease (89 (38.5%) of them during induction chemotherapy). Neutropenia was observed in 207 episodes (89.6%), during more than 10 days in 172 episodes (74.5%) and more than 80% have severe neutropenia. Gram-negative and Gram-positive bacteria accounted for 179 (77.5%) and 52 (22.5%) of bacteraemias pathogens, consequently. In blood cultures; Klebsiella pneumonia, Escherichia coli and Staphylococcus aureus were detected in 34.6%, 17.3% and 15.6% of the samples, respectively. Fifty-eight of the bacteraemias pathogens were multi-drug resistant bacteria (25.1%). Thirty-five (15.2%) of the cultured Gram-negative bacterias were extended spectrum beta-lactamase (ESBL). Carbapenemase positive culture was in 25 episodes (10.8%) in Gram-negative bacteria cultures. During 90 (39%) episodes of bacteraemias, patients had sepsis related organ failure or organ dysfunction. Forty-seven died related to a bacteraemias (K. pneumoniae bacteraemias had the highest case-mortality (25 cases)). The independent risk Factors influencing mortality were: MASCC<21 (P: 0.039) and qSOFA>2 (P: $<10^{-3}$).
Summary/Conclusion: Our study shows that Gram-negative bacteria are predominant for this population. In our population, MASCC<21 and qSOFA>2 increase the mortality rate.

EP818 COVID-19 INFECTION IN PATIENTS WITH HEMATOLOGICAL DISEASES IN BRAZIL: CLINICAL CHARACTERISTICS AND PROGNOSTIC FACTORS

K. Tozatto Maio [1,*], L. Bassolli de Oliveira Alves [1], B. Del Guerra de Carvalho Moraes [1], M. Bellesso [1], A. Brandão [1], G. H. Hencklain Fonseca [1], A. Duran [1], J. Pereira [1], L. Mariano [1], E. Magalhães Rego [1], H. Higashino [1], S. Chevret [2], S. Figueiredo Costa [1], V. Rocha [1]

[1]Hospital das Clinicas da FMUSP, São Paulo, Brazil, [2]Université de Paris, Paris, France

Background: The COVID-19 pandemic had a high burden in Brazil. To date, data on mortality and prognostic factors of COVID-19 infection in Brazilian patients with hematological disorders are scarce.
Aims: To describe the characteristics and outcomes of patients with hematological disorders admitted to the hematological COVID care unit of a reference center in Brazil;to analyze the impact of prognostic factors on in-hospital mortality.
Methods: This prospective, single-center study,included 118 patients who have been admitted to the hematological COVID care unit of the Hospital das Clínicas da Faculdade de Medicina da USP, São Paulo, Brazil, from March to September 2020.All patients had >18 years,an underlying hematological disease and a moderate or severe COVID-19 infection.For analyses, patients were grouped in:(1)benign or no oncological treatment(n=43),(2) intensive chemotherapy,including induction protocols for acute leukemia and stem cell transplantation conditioning(n=44) or(3) intermediate chemotherapy,including lymphoma regimens,myeloma triple treatment or continuous treatment(n=31).The primary outcome was in-hospital mortality;secondary outcome was overall survival after admission in the COVID-19 unit.Univariate analysis(UVA) used odds ratio(OR) for baseline characteristics and ROC curve analysis for laboratory tests collected at admission.Multivariate analyses(MVA) were adjusted by age and hematological disease status group.The median follow-up and survival time after COVID-19-unit admission were estimated by Kaplan-Meier method.All statistical tests were two-sided;p-values<0.05 were considered significant.
Results: Median age was 58(19-90) years and 55% of patients were male. Most patients(83%)had hematological malignancies,-mainly non-Hodgkin lymphoma(29%) and multiple myeloma(19%). The most frequent benign disease was sickle cell disease(5%).12 patients had undergone hematopoietic stem cell transplantation (HSCT),4 allogeneic and 8 autologous.70% had at least one comorbidity, mostly arterial hypertension and diabetes mellitus. Thromboembolic events occurred in 9%. Median hospital stay in the COVID-19 unit was 12(1-63) days;54% needed intensive care and 41% mechanical ventilation.In-hospital mortality rate was 41%[95%CI 32-50];most deaths occurred in patients with malignancies.Median follow-up was 73(95%CI 61-81) and 54(95%CI 39-66) days after admission and discharge from the COVID-19 unit, respectively.UVA showed a risk of death increased by 25% every 10 years old.The risk of in-hospital death was 3-fold and 5-fold higher in groups 2 and 3 compared with group 1.MVA showed higher risk of death in patients from group 2(OR=11.1,95% CI 2.9-54.8) or group 3(OR=9.7,95%CI 2.4-47.5]),who had lactate dehydrogenase(LDH)>440 U/L(OR=16.8,95%CI 4.9-71.8),C-reactive protein(CRP)>100 mg/L(OR=4.1,95%CI 1.4-13.6) or platelet count<150x10e9/L(OR=3.7,95%CI 1.3-11.7), regardless of age(OR=1.2,95%CI 1.0-1.5).79% of in-hospital deaths were from COVID-19; others were mainly due to hematological disease.The

overall median survival time after admission was 92 days(95% CI 34-NA) and the 75-day survival probability was 51%(95%CI 41-60).25% of patients had hospital readmission,mostly due to other infections.
Summary/Conclusion: In line with other reports,patients with hematological diseases are at higher risk of mortality from COVID-19 infection,particularly in low and middle income countries.In our cohort, prognostic factors were status of disease,platelets count,LDH and CRP. These findings might help risk stratification and prioritization of vaccines in this setting.

EP819 CLINICAL OUTCOMES OF COVID-19 IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES TREATED IN THE COMMUNITY SETTING IN CROATIA

H. Holik [1,2,*], I. Krečak [3], I. Zekanović [4], I. Vučinić Ljubičić [1], V. Gverić-Krečak [3], M. Morić Perić [4], S. Kovačević [1], I. Čabraja [5], B. Coha [1]

[1]Department of Hematology and Oncology, General Hospital Dr. Josip Benčević, Slavonski Brod, [2] School of Medicine, University of Osijek Josip Juraj Strossmayer, Osijek, [3]Department of Internal medicine, General Hospital Šibenik, Šibenik, [4]Department of Internal medicine, General Hospital Zadar, Zadar, [5]Department of infectious diseases, General Hospital Dr. Josip Benčević, Slavonski Brod, Croatia

Background: The coronavirus infectious disease-19 (COVID-19) has caused a pandemic. Patients with hematological malignancies COVID-19 have worse clinical outcomes when compared to the general population; however, data regarding the outcomes of patients with hematological malignancies suffering from COVID-19 treated outside academic centers are scarce.
Aims: To analyze the clinical course of COVID-19 in patients with hematological malignancies treated in the community setting.
Methods: In this multicenter retrospective study patients suffering from hematological malignancies in whom COVID-19 was diagnosed from March 1, 2020, to February 16, 2021, were included from three community hospitals in Croatia (General Hospital "Dr. Josip Benčević", General Hospital Šibenik and General Hospital Zadar). These hospitals cover area of about 405 000 inhabitants that accounts 10% of total Croatian population.
Results: During the study period there were a total of 21 745 people diagnosed with COVID-19 in that area and 66 (0.3%) had malignant hematological disease; most of them were male (65.15%) with a median age of 70 years (20-92). The majority of the patients (56%) became infected with COVID-19 during the second wave (November and December 2020). Lymphoproliferative disorders were recorded in 41 (62%) patients and 25 (38%) had myeloproliferative disorders. Among lymphoproliferative disorders, 16 patients had chronic lymphocytic leukemia, 18 had non-Hodgkin's lymphomas and 7 multiple myeloma. In the myeloproliferative group, 14 patients had Ph-negative or Ph-positive chronic myeloproliferative neoplasms, 2 acute myeloid leukemia and 9 had myelodysplastic syndrome. The majority of patients with lymphoproliferative disorders were not in active treatment (54%) while 34% and 12% of patients acquired COVID-19 during the first- or later lines of treatment, respectively. A total of 45 (68%) patients needed hospitalization; the majority had lymphoproliferative disorders (64.4%). Among hospitalized patients, 42 (93.3%) patients had pneumonia and 38 (84.4%) needed oxygen therapy and 8 (17.7%) were treated in the intensive care unit (ICU). Four patients had thromboembolic complications and two had hemorrhages during hospitalization (a total of 13.3%). Out of 66 patients with COVID-19, 12 patients died (18.1%) and the total mortality rate of hospitalized patients was rather high (27%), with the majority of them suffering from lymphoproliferative disorders (75%).
Summary/Conclusion: The COVID-19 pandemic is strongly affecting patients with hematologic malignancies. These data gathered from a community setting demonstrated that patients with hematological malignancies suffering from COVID-19 have poor clinical outcomes with a high rate of pneumonia, frequent hospitalizations and a high mortality rate. More worrisome, patients with lymphoproliferative disorders were shown to have particularly poor outcomes; thus, future studies evaluating reasons for poor clinical outcomes in patients with COVID-19 and lymphoproliferative disorders are of utmost importance. Education, social distancing and development of new drugs against COVID-19 are important strategies to protect this highly vulnerable population.

EP820 INFECTION BY SARS-COV-2 IN HEMATOLOGIC PATIENTS: AN UNICENTRIC RETROSPECTIVE STUDY

F. Saraiva [1,*], H. Parreira [1], A. Rebelo [1], M. Lemos [1], S. Pereira [1], R. Brito [1], M. L. Fernandes [1], C. J. Saunders [1], I. Rocha [1], M. Fevereiro [1], M. Henrique [1], G. Ferreira [1], L. Carande Checa [1], P. Sousa Santos [1], P. Ribeiro [1]

[1]HSAC CHULC, Lisboa, Portugal

Background: The coronavirus disease 2019 (COVID-19) pandemic has imposed several constrains in the medical practice, especially in hematologic patients (pts) where a higher mortality rate is expected. In our center strict measures were implemented earlier, with the use of personal protective equipment, hand wash at all times, internal separated circuits, frequent prophylactic tests, teleconsultation and rapid isolation of positive cases. However, data is still limited and risk factors for increased susceptibility remain unclear.
Aims: Characterize our pts with COVID-19 regarding the type of hematologic disease, the respective treatment, infection severity and identification of any possible risk factors that may have impact in the outcome.
Methods: Pts with a positive quantitative RT-PCR from nasopharyngeal swab between 18/03/2020 and 02/02/2021 were identified. Epidemiologic, laboratory, and clinical characteristics were retrospectively collected. Chi-square and Mann-Whitney-U tests were performed to identify statistical differences between groups and logistic binary regression to assess predictive risk factors. Severity of illness was defined by level of care [ambulatory, general inpatient wards and intensive care unit (ICU)], need for respiratory support, incidence of thrombotic events, acute kidney injury and/or death. Active hematologic treatment was defined as therapy within 6 months of COVID-19 diagnosis.
Results: A total of 81 pts were identified, with a median age of 61 years (19-88), 52% were male, 63% had an ECOG PS 0 and 69% had at least one comorbidity (hypertension 36%, dyslipidemia 21%, cardiovascular disease 21%, diabetes mellitus 14% and pulmonary disease 11%). Regarding the hematologic disease, 83% had a neoplastic malignancy (non-Hodgkin lymphoma 30%, myeloproliferative neoplasms 16%, acute myeloid leukemia 11% and multiple myeloma 11%), 64% were in active treatment and 43% had active disease. Concerning the COVID-19 infection, 46% required hospital admission among which 65% needed respiratory support and 9% admitted to an ICU. Median overall survival (OS) was not reached (84% at 1 month) and the mortality rate was 17%, mainly in pts with active disease and neoplastic malignancy. Non-survival pts had a lower hemoglobin level (8,3g/dL vs 12g/dL; *p-value* 0,016), a higher CRP (218mg/L vs 22mg/L; *p-value* 0,041), acute renal failure (36% vs 6%; *p-value* 0,014), more need of respiratory support (71% vs 27%; *p-value* 0,004) and mechanical ventilation (21% vs 5%; *p-value* 0,022). There were no statistical differences regarding age, absolute lymphocyte count, platelet count and LDH. Regression analysis revealed hemoglobin level (*p-value* 0,026), CRP (*p-value* 0,05) and respiratory support (*p-value* 0,003) as predictive factors for death. In our pts there were no thrombotic events.
Summary/Conclusion: Nearly half of the pts were admitted to the hospital and discharged. In our analysis low hemoglobin level, high CRP and respiratory support were associated with poorer survival, however, given our small sample, these findings need to be confirmed. Contrary to most of the published results, the number of confirmed COVID-19 positive cases was surprisingly low, with only 81 cases in 11 months, with a mortality rate similar to the general population and lower than expected. We believe that implementing early and rigorous protective measures as well as create self-awareness may be the key to improve mortality rate in this highly susceptible population.

EP821 MEASUREMENT OF VARICELLA ZOSTER IGG ANTIBODY IN CHILDREN TREATED FOR ACUTE LYMPHOBLASTIC LEUKEMIA

M. Salama [1], M. Salama [1], H. Donia [2], Y. El Chazli [1,*]

[1]Pediatrics, [2]clinical pathology, Alexandria University, Alexandria, Egypt

Background: Children treated for acute lymphoblastic leukemia are at increased risk of severe infection with varicella zoster virus (VZV) that causes significant morbidity and mortality. Previous studies have reported the risk of disseminated infection in these patients, in the absence of prophylaxis to be approximately 50%. Hence the importance of identifying patients who have unprotective serum levels of Varicella antibodies as candidates for vaccine after completing their chemotherapy protocol.
Aims: Determine the level of varicella IgG antibody in children treated for acute lymphoblastic leukemia and assess the need for their vaccination after end of therapy.
Methods: A prospective study conducted on 2 groups, each consisting of 44 children treated for acute leukemia at the Pediatric Hematology and Oncology Unit of Alexandria University Children's Hospital. Children in group 1 were on maintenance chemotherapy and in remission ≥ 1 year, while group 2 have completed chemotherapy ≥ 6 months. The level of varicella IgG antibody was assessed by VZV IgG ELISA, it was considered positive (protective) above 0.77 u/ml.
Results: In group 1 (patients on maintenance chemotherapy) males were slightly more represented than females (61.4% vs 38.6%). The median age at the time of the study was 6 years. Most of the studied patients were B-ALL (86.4%) while only (13.6%) were T-ALL. Only 5 (11.4%) were varicella IgG positive, while the remaining 39 (88.6%) were negative with a median IgG titer of 0.07 u/ml. In group 2 (off-therapy patients), 56.8% of patients were males versus 43.2% females. The median age at the time of the study was 10 years, and the median duration since completion of chemotherapy was 24.5 months. Most of the studied patients were B-ALL (93.2%) while only 6.8% were T-ALL. Only 9 (20.5%) were Varicella IgG positive while the remaining 35 (79.5%) were negative with a median IgG titer of 0.12u/ml. In both groups, age of diagnosis, the gender, duration of chemotherapy, type of ALL, and intensity of the treatment protocol did not significantly affect the varicella antibody titer.
Summary/Conclusion: Varicella zoster vaccine should be given to all leukemic patients after completion of chemotherapy as the varicella IgG level was unprotective in the majority of children.

EP822 INVASIVE ASPERGILLOSIS IN HEMATOLOGICAL PATIENTS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN SINGLE-CENTER STUDY

Y. Rogacheva [1,*], V. Markelov [1], M. Popova [1], A. Volkova [1], I. Nikolaev [1], O. Pinegina [1], S. Ignatieva [2], T. Bogomolova [2], S. Bondarenko [1], N. Klimko [1,2], A. Kulagin [1]

[1]RM Gorbacheva Research Institute, Pavlov University, St. Petersburg, Russia, [2]I.I. Mechnikov North-Western State Medical University, Ministry of Health of Russia, Saint Petersburg, Russian Federation

Background: Invasive aspergillosis (IA) is dominant among fungal disease after allogeneic hematopoietic stem cell transplantation (allo-HSCT). The emergence of new immunosuppressive drugs, the expanding use of antifungal agents with activity against *Aspergillus spp*. on the one hand, and the improvement of treatment, prophylaxis and diagnostic methods on the other hand affect epidemiology and treatment efficacy of IA.
Aims: To estimate the epidemiology of IA in large cohort of allo-HSCT recipients during 1-year period after allo-HSCT in a retrospective single-center study.
Methods: We analyzed 556 patients underwent allo-HSCT from 2017 to 2019 years in CIC 725. Transplantation from related donor was performed in 109 (20%), from unrelated donor – 286 (50%), haploidentical donor – 161 (30%). The median age - 36 years (18-69), men – 48,7%. The median follow up time was 15,6 months. During the observation period, 40 patients with proven and probable IA were included into analysis. According to EORTC/MSG 2019 criteria 2 proven and 38 probable cases were diagnosed in adults with hematological malignances and non-malignant hematological diseases after allo-HSCT.
Results: Thirty-four (6%) patients had IA before HSCT and the only one patient had IA after allo-HSCT. Incidence of IA during 1-year period after allo-HSCT was 7,1% (40/556). IA more common diagnosed in patients with acute leukemia – 35% and lymphomas – 30%. Most of the patients at the moment of IA diagnosis received antifungal prophylaxis with fluconazole (65%) or posaconazole (17,5%). The main site of infection were lungs 95%, sinuses – 5%. The diagnosis of IA were proved by bronchoalveolar (BAL) or sinuses liquid culture in 32,5% cases, and the etiology were: *Aspergillus niger* – 6 (46%), *Aspergillus fumigatus* – 5 (38%), *Aspergillus spp*. – 2 (16%). The median day of IA onset was day +172 (35-315) after allo-HSCT. Factors significantly associated with higher incidence of IA were CMV-infection (p<0.0001) and acute graft versus host disease (p=0.0478), but not disease status, conditioning regimen, donor type or history of IA. Overall survival at 12 weeks for patients with IA was 85%.
Summary/Conclusion: Pre-existing IA had 6% of allo-HSCT recipients. Incidence of IA after allo-HSCT during 1-year period was 7,1% with the median day +172. The main site of infection were lungs, etiology – *Aspergillus niger*. Only CMV-infection and aGVHD were associated with higher risk of IA in post-transplant period. Overall survival at 12 weeks for patients with IA was 85%.

EP823 IMPACT OF ADEQUATE EMPIRICAL BROAD-SPECTRUM ANTIBIOTIC FOR BLOODSTREAM INFECTION IN PATIENTS UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A SINGLE CENTER EXPERIENCE

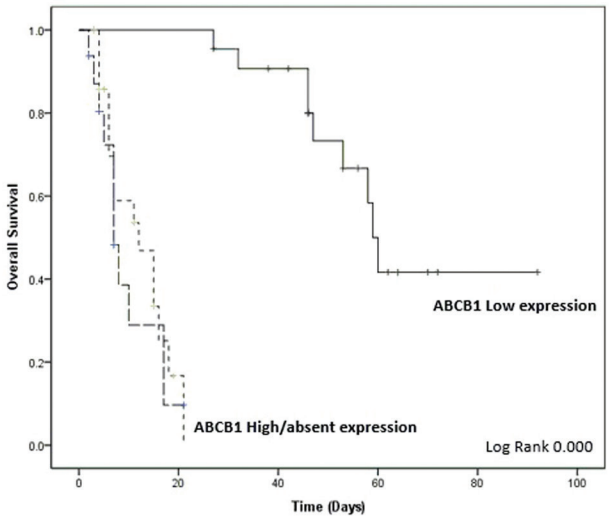
M. A. Rodriguez Gil [1,*], E. M. Gamez Jimenez [1], P. Gonzalez-Sierra [1], E. Lopez Fernandez [1], Z. Mesa Morales [1], A. Romero Aguilar [1], L. Moratalla Lopez [1], M. Jurado Chacon [1]

[1]Hematology, Hospital Universitario Virgen de las Nieves, Granada, Spain

Background: Patients undergoing allogeneic hematopoietic stem cell transplantation (allo-HSCT) are exposed to a wide range of severe complications. Bloodstream infection (BSI) is an emergency that occurs frequently and is one of the main causes of morbidity and mortality in these patients. Hence, the importance of knowing the principal microorganisms responsible for this complication and therefore, prescribing the most adequate broad-spectrum empirical antibiotic.
Aims: Our main objective is to describe episodes of BSI between days 0 to 100 in patients undergoing allo-HSCT in our center. Our secondary objectives are to analyze the role of prophylactic antibiotic therapy, the impact of inappropriate empirical antibiotic therapy on patients outcome and overall survival (OS) in patients suffering early BSI.
Methods: A one center retrospective study, with data obtained from the electronic clinical history, of the BSI in allo-HSCT in our center from 2015 to 2020. Statistical analysis has been performed with IBM SPSS.19 using appropriate tests for each case.
Results: Over the selected period, 154 patients underwent allo-HCST (follow-up median of 329 days), whose main characteristics are summarized on Table 1.
63 episodes of BSI were microbiologically identified in 50 patients (32.5% incidence). 12 patients (7.7%) died as a direct consequence of BSI. Having received allo-HCST, BSI occurred on day 11 (median) and day 51.7 (mean average), range of minimum and maximum values 0-100.
100 patients (64.9%) received prophylactic antibiotics, mostly quinolones (57.1%). 7.8% received early treatment with carbapenems. We were unable to establish a significant relationship between the incidence of BSI in patients who received prophylaxis and those who did not, (chi-square, p=0.7) nor for overall survival rate (logrank, p=0.4).
Gram negative bacilli were the most common group (37 BSI, 58.7%), mainly E. Coli (24 BSI, 38%), with 6 BSI caused by non-fermenting GNB (4 Pseudomonas aer., 6.3%). There were 21 cases of BSI (33%) caused by Gram positives (11 Staphylococcus spp - 7 S. epidermidis and 1 S. aureus -, 7 E. faecium, 1 E. faecalis, and 2 Strept. mitis) and 5 by anaerobic microorganisms.
The majority of BSI (60%) were treated empirically during the first hour with empirical antibiotic monotherapy (carbapenem in 66% of the cases). The empiric antibiotics used for 12 of the episodes of BSI (19%) were inadequate according to the microorganism's resistance profile, and 5 of them died as a direct consequence of the BSI (overall crude mortality rate due to BSI 7%, mortality rate directly related to inadequate antibiotic 41.6%).

There were statistically significant differences in overall survival (OS) between patients who suffered BSI during the first 100 days post HSCT and those who did not (log-rank-p<0,001).

Table 1. Characteristics of patients (n=154) undergoing allogeneic HSCT	
Gender	
- Male	90 (58,4%)
- Female	64 (41,6%)
Age (median), years	50 (15-70)
Hematologic Disease	
- Acute leukemia	51 (33,1%)
- Lymphoma	55 (35,7%)
- Myelodysplastic/myeloproliferative syndrome	38 (24,7%)
- Bone marrow failure	6 (3,9%)
- Multiple myeloma	4 (2,6%)
HSCT Conditioning	
- Reduced intensity	69 (44,8%)
- Myeloablative	62 (40.3%)
- Non-myeloablative	23 (14,9%)
HLA Matching	
- HLA-identical	112 (72,7%)
- HLA-mismatch	30 (19,5%)
- HLA-haploidentical	12 (7,8%)
Source of Stem Cells	
- Peripheral blood	147 (95,5%)
- Bone marrow	6 (3,9%)
- Umbilical cord	1 (0,6%)
Acute graft versus host disease	110 (71,4%)



Summary/Conclusion: BSI after HSCT remains a clinical challenge. In our center, one-third of patients develop this complication. Gram negative bacilli are the main germs involved, especially E. coli.
It is absolutely essential to know our environment's epidemiology and the presence of multi-resistant germs, so as to fit empirical treatment to clinical practice. The use of an inappropriate antibiotic can result in a significant mortality increase.
From our experience, the use of prophylactic antibiotics is not indispensable to decrease the incidence of BSI.
We found significant differences in OS between patients who suffered BSI and those who did not. It is necessary to conduct multivariate studies in order to confirm this hypothesis.

EP824 IMPACT OF THE ABCB1 DRUG RESISTANCE GENE ON COMPLICATIONS ASSOCIATED WITH COVID-19

C. Ramos [1,*], I. OLARTE [2], I. Mendoza [2], A. Martinez [1]

[1]HEMATOLOGY, [2]Hospital General de México, Hospital General de México, Mexico City, Mexico

Background: Overexpression of the ABCB1 gene has been associated with a poor prognosis in various hemato-oncological diseases due to resistance to different chemotherapy types. Usually, the gene expression is low, but drugs like steroids can stimulate it. The COVID-19 infection has affected much of the world, especially Latin America, where mortality is higher than expected, mostly due to hypertension, diabetes, and obesity. Since the beginning of the pandemic, different combinations (chloroquine, azithromycin, antivirals) have been used, some with a moderate benefit (Tocilizumab, convalescent plasma) but without establishing a group that could benefit. The ATP flow pump contributes to cell detoxification, including overdosing of drugs; some drugs are substrates of this pump and modify its operation
Aims: Describe the impact of ABCB1 drug resistance gene expression on mortality and ventilatory support in critically ill patients with COVID-19
Methods: Sixty-one patients (23 women and 38 men) were diagnosed with COVID-19 and included in the study. Mononuclear cells were isolated by Ficoll-Paque (GE Healthcare).RNA isolation was performed using Trizol ™ reagent (Invitrogen, Carlsbad, CA). The RNA obtained's concentration and purity was measured using Nanodrop ™ 2000 (Nanodrop Technologies, Wilmington, ME, USA). cDNA was synthesized from 1 µg of RNA using oligo (dT) and MML-V enzyme from Promega Biotech AB. The expression levels of the ABCB1 gene were determined by qPCR using the TaqMan ™ system (Hs01069047, Applied Biosystems, Inc. Foster City, CA, USA) and normalizing with the endogenous GUSB gene (Hs00939627) (Gene expression = 2 – ΔCT, where ΔCT = CT of the gene of interest - CT of the reference gene.) The expression levels were classified according to the known values in healthy donors.
Results: 61 patients diagnosed with COVID-19 with criteria for hospital care and supplemental oxygen. The majority were men (n = 36, 59%), obesity was the most frequent comorbidity (n = 28.45.9%), followed by diabetes (n = 22, 36.1%) and hypertension (n = 18, 29.5%). Treatment for COVID-19 included high-flow oxygen in combination with the best available therapy; 8.2% (n = 5) started with hydroxychloroquine, 44.3% (n = 27) were treated with metformin hydrochloride, 36.1% with azithromycin, 55.7% (n = 34) with atorvastatin and 95.2% (n = 58) with low molecular weight heparin. During the hospital period. 49.2% (n = 30) required ventilatory support. When analyzing the expression of ABCB1, 63.9% (n = 39) had a high or absent expression, 36.1% showed a low expression. Cases with high / absent expression showed a worse prognosis compared to low expression (Log Rank = 0.000). When comparing the different risk variables, the high / absent expression of ABCB1 was a significant risk factor for death (OR 3.08, [1.02-9.26], p = 0.045) and ventilatory support (OR 2.8, [0.98-8.5], p = 0.054). Other factors such as male gender (OR 2.54 [0.89-7.27], p = 0.081) and older age (OR 5.19, [1.48-18.2] p = 0.010) were associated with a poor prognosis. Diabetes had low impact (OR 1.11, [0.38-3.22], p=0838) on prognosis.

Overall survival according to the ABCB1 expression, low versus high/absent expression.

Summary/Conclusion: Similar to cancer treatment, the modification of the expression of the ABCB1 gene (high or absent) impacts the prognosis of patients with severe COVID-19 disease due to the overuse of drugs

EP825 A COMPARATIVE OUTCOME ANALYSIS OF COVID-19 VS INFLUENZA INFECTION IN PATIENTS WITH ACUTE LEUKEMIA

F. Modemann [1,*], C. Bokemeyer [1], W. Fiedler [1], S. Ghandili [1]

[1]Department of Oncology, Hematology and Bone marrow transplantation with Section Pneumology, University Medical Center Hamburg Eppendorf, Hamburg, Germany

Background: Patients with acute leukemia and concomitant SARS-CoV-2 infection suffer from a more severe course of their infection than patients without underlying disease including a higher admission rate to ICU and a higher death rate. Similar observations have been made for concomitant influenza infections.
Aims: The aim of this study is to compare the clinical courses of COVID-19 and seasonal influenza in patients with acute leukemia (AL). This could help to find evidence for certain therapy modifications in AL patients with COVID-19 based on long lasting experience in patients with AL and influenza.
Methods: This is a retrospective single center analysis including all patients with AL and concomitant influenza or SARS-CoV-2 infection who were treated in the department of oncology and hematology of

the University Medical Center Hamburg-Eppendorf, Germany, between February 2013 until now. Data of the clinical course were collected from the patient's electronic medical records. Statistical analysis was performed by using IBM SPSS Statistics, version 26.
Results: In the Influenza-group (n = 21), 71 % were male, the median age was 58 years (r: 20-81). 17 patients (81%) had acute myeloid leukemia (AML), four patients (19%) had acute lymphoblastic leukemia (ALL). 29% had newly diagnosed AL at influenza infection, 33% were in complete remission and 38% were under treatment due to refractory or relapsed disease. 95% were currently under chemotherapy treatment at diagnosis of influenza, 80% of them were treated with intensive chemotherapy. Median duration of aplasia was six days (r: 0-38), five patients had no aplasia during influenza infection. 18 patients were treated with Oseltamivir. 15 patients had an Influenza A with ten cases of H1N1, six patients had an Influenza B. The distribution in the COVID-19 group (n = 15) was similar: 73% were male, the median age was 59 years (r: 21-76). Nine patients (60%) had AML, six (40%) had ALL or acute lymphoblastic lymphoma. 27% had first diagnosis of AL, 27% were in complete remission, 46% had relapsed or refractory disease. All patients were under chemotherapy during SARS-CoV-2 positivity, 80% were treated with intensive chemotherapy protocols. Duration of aplasia during SARS-CoV-2 positivity was 0-36 days (median: 10 days), four patients had no aplasia. With 67% compared to 38% in the influenza group, we scored significantly more critical and severe courses in the COVID-19 group (p = 0.042, Mann Whitney U test) according to WHO-grading. We observed higher rates of pneumonia (93% vs. 67%) in COVID-19 patients with a rate of 40% of acute respiratory distress syndrome (ARDS) in the COVID-19 group compared to 19% of ARDS in the influenza-group. Rate of death due to COVID-19 after 90 days was 20% compared to influenza-associated deaths of 14%. Regardless of the type of infection (SARS-CoV-2 or influenza), we could show that a long aplasia duration is an adverse prognostic marker for 90-days mortality due to COVID-19 or influenza (p = 0.016, Mann Whitney U test).
Summary/Conclusion: Patients with acute leukemia and concomitant SARS-CoV-2 diagnosis present with more severe clinical courses than patients with concomitant influenza, even though the rates of ARDS and critical disease of patients with AL and influenza are high. Therapy regimes with expected long duration aplasia should be possibly avoided in both patient cohorts due to higher mortality in patients with late regeneration of the blood count.

EP826 RISK FACTORS AND OUTCOME OF SARS-COV-2 INFECTION IN HEMATOLOGIC PATIENTS – A SINGLE CENTER EXPERIENCE

M. Narancic [1,*], M. Mikulić [2], S. Basic-Kinda [2], J. Batinic [2,3], A. Ostojic [2], D. Dujmovic [2], B. Dreta [2], M. Vodanovic [2], L. Desnica [2], V. Rezo Vranjes [4], G. Pavlisa [3,5], Z. Peric [2,3], P. Roncevic [2], D. Pulanic [2,3], D. Sertic [2], I. Aurer [2,3]

[1]Hematology, General hospital Zadar, Zadar, [2]Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, [3]Medical School, University of Zagreb, [4]Department of Microbiology, [5]Department of Pulmology, University Hospital Centre Zagreb, Zagreb, Croatia

Background: Reports on outcomes of COVID-19 in hematologic patients vary.
Aims: To describe outcomes and risk factors of SARS-CoV2 infection in patients treated in a large university medical center.
Methods: We analyzed the outcomes of our patients diagnosed with COVID-19 between July 2020 and January 2021. The diagnosis was made by PCR from nasopharyngeal/oral swabs or bronchoalveolar lavage. Outcomes were classified as: recovered, persistently positive, died.
Results: We identified 116 patients. Median age was 59 years (range 20-92); 55% were male. 13% had no symptoms; 49% had mild disease with no need for oxygen therapy; 14% with moderately severe disease were treated with low flow oxygen therapy; 25% had severe COVID-19 with respiratory failure and/or septic shock. Except for seven palliative patients, severe cases were treated with noninvasive ventilation (3%), mechanical ventilation (13%) and ECMO (1%). 27% received no treatment for COVID-19; 38% were treated with antibiotics, corticosteroids and/or anticoagulant therapy; 34% received remdesivir, 6% in combination with convalescent plasma; 5% were treated with extracorporeal blood purification. 65 patients recovered (56%), 17 are still positive (15%) and 34 (29%) died.
All 4 untreated and 16 patients that were off treatment for more than 3 months recovered. The outcome of those on treatment is presented in Table 1. Allotransplanted patients had the worst outcome, 5 died, 3 are persistently positive and 1 recovered. Untransplanted patients with acute lymphoblastic and chronic myeloid leukemia fared best, 3 out of 3 in each group recovered. Treatment with anti-CD20 monoclonal antibodies (MoAbs) resulted in an increase in persistent positivity, frequently longer than 8 weeks. Of the 34 patients, 9 died, 12 have persistent infection and 13 recovered. There was no clear-cut correlation between outcome and other types of treatment within diagnostic groups.

TABLE 1 Outcome of patients on treatment

Diagnosis	No. of patients	Recovered	Persistently positive	Died
Allotransplanted	9	1	3	5
AML	11	6	1	4
ALL	3	3	0	0
MDS	5	3	0	2
CML	3	3	0	0
MPN JAK2+	3	1	0	2
Aggressive NHL	22	8	7	7
Indolent NHL	12	5	4	3
CLL	6	2	1	3
MM	20	10	2	8

Summary/Conclusion: COVID19 in hematologic patients, who are currently on treatment, follows a significantly worse course than in the general population or other cancer types. Allotransplanted patients have the highest mortality, while those treated with anti-CD20 MoAbs frequently have a persistent infection with dubious outcome.

EP827 ROLE OF ERYTHROPOIESIS STIMULATING AGENTS (ESAS) IN SUPPORTIVE CARE OF LOW-RISK MYELODYSPLASTIC SYNDROMES

C. Cerchione [1,*], F. Alfinito [2], P. Danise [3], A. E. Pareto [4], G. Musuraca [1], A. Lucchesi [1], M. B. Giannini [1], V. Di Battista [1], F. Pane [2], G. Martinelli [1]

[1]Hematology Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), [2]Hematology, AOU Federico II, Napoli, [3]Hematology, Pagani Hospital, Pagani (SA), [4]Hematology, San Giuliano, Giugliano (NA), Italy

Background: Erythropoiesis stimulating agents (ESAs) are the frontline treatment in low-risk anemic MDS patients and an employment of this therapy in the earlier stage of the disease can delay the need for RBC transfusion, hypothetically by slowing the disease course. It's matter of debate whether the clinical response is a result of proliferation and maturation of the dysplastic clone or stimulation of residual normal erythropoiesis by ESAs.
Aims: Macrocytosis is one of the cytological hallmarks of dyserithropoiesis in MDS: an analysis of the erythropoietic response to ESAs therapy in a cohort of anemic non trasfusion-dependent MDS patients, enrolled in a retrospective register, RECAMDS, subgroup of Italian register, was performed.
Methods: 183 patients, treated with standard-dose ESAs, have been retrospectively analyzed. Data analysis was performed, according to IWG 2006 criteria, at the baseline, after 3 and 6 months of continuous treatment, with a subanalysis of the patients according to WHO and R-IPSS risk stratification. ESAs were started at mean Hb concentration of 9.31 g/dl, mean serum EPO concentration: 51 mU/L, after a mean time from diagnosis of 6 months (r.1-118).
Results: ORR was 83.6% (153/183), no difference among WHO and IPSS subgroups was found: 132/183 (72.1%) achieved response after 3 months of treatment, while other 21/183 (11.2%) after 6 months. 19 patients with stable disease (non-responders, according to IWG criteria), in which treatment was continued, achieved response after 9 months. In the macrocytic-responders group 83.2% exhibits again macrocytosis after 3 months, while 16.8% become normocytic. In the normocytic-responders group 89.8% exhibits again normocytosis, while 10.2% become macrocytic: in these patients, after 3 months, there was a contemporary worsening in neutropenia and thrombocytopenia, with transfusion-dependence, regarded as first signs of progression of disease. Non-responders were 30/183 (16.3%): in the macrocytic

non-responders group 89% exhibit again macrocytosis after 3 months, while 11% become normocytic; in the normocytic group 76% exhibits again macrocytosis, while 24% become normocytic.

MDS PATIENTS	183
M	89 (49%)
F	94 (51%)
ERYTHROPOIESIS	
BASELINE HB (mean, g/dL)	9.31 g/dL (r. 7.1-11.3)
BASELINE SERUM EPO (mean, mU/mL)	51 mU/mL (r.3-84)
OVERALL RESPONSE RATIO	
RESPONDERS	153/183 (83.6%)
RESPONDERS AT 3 MONTHS	132/183 (72.1%)
RESPONDERS AT 6 MONTHS	21/183 (11.4%)
RESPONDERS AT 9 MONTHS (NON RESPONDERS IN IWG 2006)	19/183 (10.3%)
NON RESPONDERS	30/183 (16.3%)

Summary/Conclusion: These preliminary data can suggest that, in the majority of MDS patients responsive to ESAs, the increase of Hb concentration occurs mainly stimulating erythroid production in MDS clones; in the minority of patients probably it happens recruiting residual polyclonal erythropoiesis. It is interesting to note that stimulating effects of ESAs last even when the expression of dysplasia progresses.

EP828 THE ASSESSMENT OF IMPACT OF COVID-19 IN PATIENTS WITH ACUTE LEUKEMIA

V. Popov [1,*], M. Omer [1], L. Iliescu [2], M. Andreescu [1], D. Georgescu [1], F. Mihai [1], M. Popescu [1], C. Pirvu [2], A. Grigorie [2], A. Rus [2], M. D. Badoiu Niculae [2], O. Constantin [2], A. Badea [2], A. Calen [2], O. Patrinoiu [1], S. Ciortan [1], C. Despan [1], G. Ofiteru [1], S. Ion [1], M. Balea [1], H. Bumbea [3]

[1]Hematology, [2]Intensive Care Unit, Colentina Hospital Bucharest, [3]Hematology, Emergency University Hospital, Bucharest, Romania

Background: The severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) was first reported in Wuhan, China in December 2019 and represented the pathogen agent that induced COVID-19. The onset and evolution of COVID -19 is severe when is associated with another comorbidities. Patients with acute leukemia present high risk for severe form of COVID-19
Aims: The main objective was to evaluate the particularities of COVID-19 in patients with acute leukemia.
Methods: Our study was prospective and included 49 patients with acute leukemia (27 male median age 64 and 22 female median age 54,5) who also were SARS CoV2 positive between April 2020- February 2021 admitted in Hematology and Intensive Care Unit Departments of Colentina Clinical Hospital Bucharest. The diagnosis was established using molecular test for SARS-Cov2
Results: In the group was included 32 patients diagnosed with acute myeloid leukemia (AML), 9 patients with acute lymphoid leukemia (ALL), 6 patients with acut promyelocytic leukemia and 2 patients with acute bifenotypic leukemia. Severe form of COVID-19 with ICU addmission was diagnosed in 16 patients (32,17%), almost all of them (15 patients) had unfavourable evolution compared with non-ICU patients group with only 1 deceased patient, p<0.0001. The recent chemotherapy followed by severe aplasia was the main negative factor that impacted patient evolution (rho=0.508, p=0.0002), 13 patients admitted in ICU Department and 12 patients in non-ICU. Severe pneumonia (more than 30% lung field) was diagnosed in 17 patients with recent chemotherapy and 4 untreated patients. The type of leukemia or refractory status have not any impact of patient evolution. Antiviral therapy – Remdesivir rapidly introduced in patient's therapy was followed by favourable evolution.
Summary/Conclusion: Patients with acute leukemia are negatively impacted by intensive chemotherapy during COVID-19 evolution. The key for good prognosis of these patients during COVID-19 are rapid diagnosis and antiviral therapy at the onset of the disease.

EP829 TREATMENT WITH REMDESIVIR, DEXAMETHASONE AND CONVALESCENT PLASMA TRANSFUSION IS SAFE AND BENEFICIAL IN HOSPITALIZED COVID-19 PATIENTS WITH HEMATOLOGICAL MALIGNANCIES.

J. Barankiewicz [1,*], A. Salomon-Perzynski [1], M. Wysocki [1], S. Jurek [2], E. Lech-Maranda [1]

[1]Department of Hematology, [2]Department of Hemostasis Disorders and Internal Medicine, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: Adult patients (pts) with secondary immunodeficiency in the course of blood cancers are at risk of severe COVID-19 with an unprecedented 34% risk of death. So far, no standards have been established to manage pts with hematological malignancies (HM) infected with SARS-CoV-2. Rapid control of SARS-COV-2 infection and the prevention of its complicated course are essential for clinical management, especially in those pts who require urgent systemic anti-cancer therapy (SACT). The treatment with remdesivir, dexamethasone and convalescent plasma have been shown to be active in COVID-19 treatment.
Aims: Here we present our experience with the use of these agents in a difficult-to-treat population with various HM (in particular aggressive lymphomas, acute leukemias and progressive indolent lymphomas) whose SACT has been disrupted due to active SARS-CoV-2 infection.
Methods: The observational, single-centre study was conducted from 07 November 2020 to 26 February 2021. All pts were diagnosed with HM and active SARS-CoV-2 infection requiring hospitalization. The severity of COVID-19 was evaluated according to the World Health Organization (WHO) Clinical Progression Scale. The COVID-19 directed treatment included remdesivir (at the standard dose for 5 consecutive days), COVID-19 convalescent plasma transfusion and dexamethasone. All patients gave their written informed consent for the data collection, and ethical clearance was obtained from the Ethics Committee of the Institute of Hematology and Transfusion Medicine, Warsaw, Poland.
Results: At the time of analysis thirty-six pts were included. The median age at COVID-19 diagnosis was 58.5 years (23-86), with male predominance (21 men and 15 women). All pts were diagnosed with HM: 11 pts with acute myeloid leukemia (30.5%), 3 pts with acute lymphoblastic leukemia (8.3%), 6 pts with mantle cell lymphoma (16.7%), 5 pts with chronic lymphocytic leukemia (13.9%), 2 pts with chronic myeloid leukemia (5.5%) and 2 pts with myelodysplastic syndrome (5.5%). The COVID-19 was diagnosed before and during treatment for underlying HM in 5 and 30 pts, respectively. At the time of COVID-19 diagnosis, median WBC was 3.5 G/L (0.05-165), median ANC for myeloid and lymphoid disease were 0.19 G/L (0.0 – 6.3) and 2.3 G/L (0.7-27), respectively. The median serum concentration of hemoglobin and PLT count was 9.2 g/dL (5.4-14.3) and 91 (4-800), respectively. The maximum severity of COVID-19 according to the WHO score was as follows: 4, 5-6, ≥ 7 points in 36%, 42% and 22% of pts, respectively. All pts received remdesivir with dexamethasone. The convalescent plasma transfusion was applied to 21 pts (57%). There were no transfusion related adverse events. The median time of hospitalization was 19.5 days (4-59). In total, 8 pts (22%) died; 7 due to COVID-19 and 1 due to progressive HM. SACT was initiated in all COVID-19 survivors requiring treatment with the median time of 17 days (9-65).
Summary/Conclusion: Treatment with remdesivir, dexamethasone and COVID-19 convalescent plasma transfusion may improve outcomes of adult HM patients infected with SARS-CoV-2 and provide the benefit of early initiation of systemic anti-cancer therapy.

EP830 SLOW INFUSION OF ANTI-THYMOCYTE GLOBULIN SIGNIFICANTLY DECREASED THE INCIDENCE OF REACTIONS AND THE NEED FOR CRITICAL CARE SERVICES

M. Damlaj [1,2,3,4,*], S. Alkhraisat [1], A. Alghamdi [1], A. Alaskar [1], A. Alhejazi [1], H. Alsadi [1], A. S. Al Saleh [1], M. Qureishi [1], M. Ahmed [1], B. Alahmari [1], M. Alzahrani [1]

[1]King Abdulaziz Medical City, [2]King Saud bin Abdulaziz University for Health Sciences, [3]King Abdullah International Medical Research Center, [4]Saudi Society of Blood and Marrow Transplantation (SSBMT), Riyadh, Saudi Arabia

Background: Antithymocyte globulin (ATG) utilization in HSCT for prophylaxis of GvHD is increasing. ATG administration can be complicated by infusion reactions, sometimes severe leading to treatment interruption or discontinuation. At our center, two protocols have been used with different infusion times.
Aims: The aim from this analysis was twofold; to compare the incidence of reactions between the two infusion protocols and to identify factors associated with infusion reactions.
Methods: Following IRB approval, patients that underwent HSCT from 2011 to 2020 and received ATG were included. From 2011-2015, ATG was infused over 6 hours while from 2016-2020, ATG was infused over 24 hours split over 2 bags given at 12 hours each. All patients received pre-medications with acetaminophen 1000 mg, diphenhydramine 25 mg and hydrocortisone 50 mg with additional doses in case of reactions. All variables were retrospectively collected. Categorical and continuous variables were compared using chi-squared or Kruskal-Wallis, as appropriate. Logistic regression was used for multivariable analysis

incorporating variables with p values of ≤ 0.1 at the univariable stage as well as unbalanced factors between the groups. Specifically; age, gender, diagnosis, stem cell source, conditioning intensity and absolute lymphocyte count (ALC) prior to ATG.

Results: A. Baseline Characteristics: During the study period, a total of 74 patients received thymoglobulin ATG. The median age was 32 years (14-63) and 41 (55%) were males. Underlying diagnosis was malignant in 45 (61%) and non-malignant in the remaining 29 (39%). Myeloablative conditioning was used in 27 (36%) and 11 (15%) received TBI. Most donors (56, 76%) were matched related and 54 (73%) received peripheral blood stem cells (PBSC).

B. Stratification by Infusion Time: A total of 11 (15%) received ATG as short infusion while the remaining 63 (85%) received it via long infusion. The short infusion cohort was significantly younger with higher proportion of female patients (P = 0.041). PBSCs were used more commonly in the long infusion group (P = 0.035). NMA conditioning was significantly used more commonly in the short infusion cohort and accordingly, ALC at ATG infusion was significantly higher as well (P = 0.012 and 0.007, respectively). Other characteristics were similar between the two cohorts (Table 1).

C. Infusion Reactions: Patients receiving short infusion had a significantly higher number of any infusion reactions (P<0.0001) as well as moderate to severe reactions (P<0.0001). Activation of critical care response team (CCRT) and transfer to the intensive care unit (ICU) was significantly higher in the short infusion group (p<0.0001). Interruption or discontinuation of ATG infusion occurred significantly more frequently in the short infusion cohort (P = 0.0001 and < 0.0001, respectively). Time to neutrophil and platelet engraftment as well as incidence of cytomegalovirus reaction requiring pre-emptive therapy was similar in the two groups (Table 2). In multivariable analysis for infusion reactions, only ALC count was predictive with OR 5.9 (1.6-21.9; P = 0.0087) (Table 3).

Baseline characteristics stratified by ATG infusion time

Variable	Short Infusion (n = 11)	Long Infusion (n = 63)	P value
Age, median (range)	20 (14-53)	35 (14-63)	0.023
Female Gender, n (%)	8 (73)	25 (40)	0.041
Diagnosis, n (%)			0.075
Malignant Disease	4 (36)	41 (65)	
Non-Malignant disease	7 (64)	22 (35)	
ECOG, median (range)	1 (0-2)	0 (0-3)	0.39
Donor Type, n (%)			0.19
MRD	9 (82)	47 (75)	
MUD	1 (9)	10 (16)	
MMUD	1 (9)	0	
Haplo	0	3 (5)	
Auto	0	3 (5)	
Stem Cell Source, n (%)			0.035
PBSC	5 (45)	49 (78)	
BM	6 (55)	14 (22)	
Conditioning Intensity, n (%)			0.012
MAC	1 (9)	26 (41)	
RIC	1 (9)	15 (24)	
NMA	9 (82)	22 (35)	
TBI Used, n (%)	2 (18)	9 (14)	0.74
ALC, median (range)	0.9 (0.04-2.39)	0.17 (0-18.4)	0.007
ATG Dose, median (range)	5 (3-15)	5 (2.5-15)	0.21

Incidence of reactions stratified by ATG infusion time

Variable	Short Infusion (n = 11)	Long Infusion (n = 63)	P value
Any Reaction, n (%)	11 (100)	18 (29)	< 0.0001
Moderate-Severe Reaction, n (%)	6 (55)	1 (2)	< 0.0001
CCRT Activation, n (%)	5 (45)	1 (2)	< 0.0001
ICU Transfer, n (%)	3 (27)	0	< 0.0001
ATG Held, n (%)	7 (64)	8 (13)	0.0001
ATG Discontinued, n (%)	5 (45)	3 (5)	< 0.0001
Time to ANC Engraftment, median (range)	19 (12-26)	17 (8-26)	0.2
Time to Plt Engraftment, median (range)	15 (4-30)	14 (6-59)	0.66
CMV Reactivation Requiring Therapy, n (%)	4 (36)	28 (44)	0.61

Logistic regression univariable and multivariable analysis predicting infusion reactions

Characteristic	Univariable Analysis	Multivariable Analysis
Age > median	0.38 (0.15-1.01; 0.053)	0.4 (0.11-1.4; 0.16)
Female Gender	0.78 (0.3-2; 0.61)	1.4 (0.47-4.1; 0.54)
Malignancy Diagnosis	0.67 (0.26-1.76; 0.43)	3.3 (0.58-19; 0.17)
ECOG > 0	0.43 (0.16-1.14; 0.09)	0.4 (0.12-1.17; 0.09)
MAC vs. Other	0.68 (0.25-1.8; 0.44)	0.8 (0.18-3.1; 0.7)
TBI Used	1.35 (0.37-4.9; 0.64)	
PBSC vs BM	0.41 (0.14-1.16; 0.09)	0.8 (0.12-4.8; 0.78)
MRD vs. Other	1.14 (0.39-3.35; 0.8)	
ALC > median	4.3 (1.5-11.9; 0.0046)	**5.9 (1.6-21.9; 0.0087)**
Infusion > 2 days	1.35 (0.51-3.6; 0.55)	

Summary/Conclusion: Prolonging the ATG infusion time significantly decreased reactions leading to lower treatment interruption or discontinuation. Importantly, severe reactions or the need for critical care services was almost not seen in the long infusion group permitting smooth administration of the conditioning regimen. Reactions were also independently increased with higher ALC levels. These observations warrant further validation.

EP831 ANTIBIOTIC-RESISTANT GRAM-NEGATIVE BACTERIAL INFECTIONS IN PATIENTS WITH HEMATOLOGIC MALIGNANCY

B. Achouro [1,*], M. Manel [2], H. Zeineb [1], E. Nihel [3], A. Asma [1], B. Emna [1], R. Haifa [1], B. Nesrine [1], K. Zahra [1], Z. Monia [1], B. Yosra [1], B. Jalel [1], K. Abderrahim [1]

[1]Hematology, [2]Microbiology, [3]Community Medecine, Farhat Hached Hospital, Sousse, Tunisia

Background: Patients with hematologic malignancies are at high risk for infections caused by antibiotic resistant gram-negative bacteria.

Aims: This study aimed to evaluate the characteristics, antibiotic resistance patterns and prognosis of infections due to multidrug resistant (MDR) gram-negative bacteria in patients with hematologic malignancy.

Methods: Data were collected retrospectively and concerned all infections caused by MDR gram-negative in patients with hematologic malignancy from January 2010 and November 2019 in our department of hematology. Data analysis was initially performed using the univariate analysis (chi^2 and student test). Then, risk factors with a P<0.05 were included in the binary logistic regression model to determine the independent risk factors of mortality.

Results: In Total, 512 patients developed infections with 83 MDR gram-negative strains detected in 80 patients, most of them (68 patients) have an acute leukemia. The MDR gram-negative infection occurred in 58 patients with uncontrolled disease, and the majority of them occurred in the presence of severe neutropenia (62 episodes/74.7%). Bloodstream infection (BSI) (57episodes/68.7%) was the most common infection types. Klebsiella pneumonia was the most common Gram-negative isolates (44 episodes/53%). Complications occurred in 44 (53%) episodes. In 41 episodes, patients received an appropriate antibiotherapy. The isolated MDR gram-negative bacteria exhibited sensitivity to amikacin in 17%, imipenem in 32.5% (three isolates were resistant to colistin). Twenty-two patients died during gram-negative MDR infections. The independent risk factors influencing mortality was: qSOFA>=2. (p: 0.003) (table 1).

Summary/Conclusion: The burden of infections due to gram-negative MDR bacteria is considerably high in patients with hematologic malignancy, with Klebsiella pneumonia being the most predominant causative pathogen. Mortality in these immunocompromised patients remains high and more effort is needed to improve the prognosis of these individuals.

EP832 ARTERIAL AND VENOUS THROMBOTIC COMPLICATIONS IN HOSPITALIZED PATIENTS WITH COVID-19: EXPERIENCE FROM A MEXICO CITY HEALTH SYSTEM.

L. Simental-Legarda [1,*], M. Ramos-Arrieta [1], F. Pérez-Jacobo [2]

[1]Internal Medicine, [2]Hematology, Hospital Central Norte Pemex, Mexico City, Mexico

Background: Patients with acute respiratory infection due to COVID 19 have an increased risk of thromboembolic disease. Coagulation activation, endothelial dysfunction, platelet activation and impaired fibrinolysis have all been proposed as directly involved in its pathogenesis. In Latin America, data regarding the incidence of acute thrombotic complications (venous and arterial) is scarce.

Aims: The aim of this analysis is to describe characteristics and outcomes of patients with confirmed COVID-19 infection with acute arterial and venous thrombotic events attended during a 10-month period, at a referral hospital in Mexico City.

Methods: We included consecutive critical and non-critical adult patients, hospitalized at Hospital Central Norte Pemex in Mexico City, between April 1, 2020 and January 31, 2021. All patients tested positive for SARS- CoV-2 using RT- PCR from nasopharyngeal and oropharyngeal swabs. Thrombotic events were diagnosed during clinical care. Thrombotic events included both venous (deep vein thrombosis [DVT]; pulmonary embolism [PE]) and arterial (myocardial infarction [MI], ischemic stroke, and other arterial thrombosis). All patients received thromboprophylaxis prior; and treatment (anticoagulation; platelet antiaggregation; a combination of both or other therapeutic interventions) at the time of diagnosis according to international and local recommendations.

Continuous variables (age, leucocyte count with differentials, hemoglobin, D-dimer, ferritin, LDH, etc.) are presented as mean ± standard deviation, (or median and range as appropriate) and were compared using the student-t or Mann-Whitney U test. All data were analyzed using SPSS

version 21 statistics software. A p value <0.05 was considered statistically significant.
Results: We analyzed 1379 hospitalized patients with confirmed COVID-19 infection. Twenty-five patients received a diagnosis of acute thrombotic events (1.81%): 13 cases (52%) of venous thrombosis (DVT: 1 case (4%); PE: 12 cases (48%)), and 12 cases (48%) of arterial thrombosis (acute Stroke: 6 cases (24%); MI/ACS: 5 cases (20%); and one case of Mesenteric thrombosis (4%)). Baseline characteristics are summarized in table 1. The mean age of all patients with thrombotic events was 62.96 14.4 years; and were predominantly male (64%).
Patients with venous thromboembolic events presented with higher D-dimer levels at the time of admission compared to those who had arterial thrombosis (mean 1965.38 vs 663.92, P= 0.014). We also observed a trend to higher hemoglobin levels at the time of diagnosis in patients with arterial events compared to cases of venous thromboembolism (mean 15.83 vs 14.01, P= 0.063). Comparison of patient's characteristics between venous and arterial thrombosis is found in table 2.
The overall mortality of the group with thrombotic events was 28%. The main cause for death was respiratory failure due to acute respiratory distress syndrome (5 patients, 71%).

Table 1. Baseline characteristics, by thrombosis site

	DVT	PE	Stroke	MI/ACS
Events; n (%)	1 (4)	12 (48)	6 (24)	5 (20)
Age (years)	27	61(51-82)	75 (60-82)	66 (50-72)

Hemoglobin (g/dL)	14.88 ± 2.45	14.01 ± 2.48	15.83 ± 2.12	0.063
Platelets (x10^9/L)	213.62 ± 83.66	235.46 ± 56.13	189.96 ± 105.0133	0.180
Viral load	795978.48 ± 251488.9	1260541.45 ± 344691	2284959.2 ± 547299	0.388
D-dimer at time of admission (ng/ mL)	1424.72 ± 1363.3	1965.38 ± 1517.51	663.92 ± 762.86	0.014
Maximum D-dimer levels (ng/ mL)	2743.16 ± 1831.5	3238.08 ± 1686.62	2207.00 ± 1900.68	0.164
LDH (UI/L)	685.24 ± 912.7	873.39 ± 1187.89	460.58 ± 455.062	0.271
Ferritin (ng/dL)	959.90 ± 1194.8	979.84 ± 1377.05	938.29 ± 1022.25	0.933
SIC score	2 (0-4)	2 (0-3)	2 (0-4)	0.406
SOFA score	2 (0-6)	1 (0-4)	2 (0-6)	0.900

Summary/Conclusion: Our analysis shows a low venous thromboembolic rate compared with other groups, and similar to another series reported in our country. Interestingly, we observed a significant proportion of arterial thrombotic complications. However, this study has limitations. Venous thromboembolism may have been underdiagnosed because of limited imaging studies. Also, neurological or ischemic cardiac symptoms may have been underestimated in patients with severe COVID-19 infection. Changes in prophylactic anticoagulation strategies, as well as in clinical practice, could affect the incidence of thrombotic events.

EP833 ACUTE LEUKEMIA AND SARS-COV-2 INFECTION: SINGLE CENTRE EXPERIENCE

N. Pantic [1,*], M. Mitrovic [1,2], N. Sabljic [3], M. Vucic [4,5], Z. Bukumiric [6], M. Virijevic [2,3], Z. Pravdic [1], J. Rajic [7], M. Todorovic Balint [2,8], A. Vidovic [2,7], D. Tomin [2,3], N. Suvajdzic Vukovic [1,2]

[1]Department of mixed hematological diseases, Clinic of Hematology, University Clinical Center of Serbia, [2]Department of Internal Medicine, Faculty of Medicine, University of Belgrade, [3]Departmet of Acute leukemia 1, Clinic of Hematology, University Clinical Center of Serbia, Belgrade, [4]Department of Malignant Hematological Disorders, Clinic of Hematology and Clinical Immunology, Clinical Center Nis, [5]Medical Faculty, University of Nis, Nis, [6]Institute for Medical Statistics and Informatics, Faculty of Medicine, University of Belgrade, [7]Departmet of Acute leukemia 2, [8]Departmet of Bone Marrow Transplantation, Clinic of Hematology, University Clinical Center of Serbia, Belgrade, Serbia

Background: During the past one year different protocols addressing the treatment of acute leukemia (AL) during the coronavirus disease 2019 (COVID-19) outbreak have emerged. However, reliable data regarding this topic are still deficient, since only case series with heterogeneous patient population with different hematologic malignancies are available.
Aims: To determine clinical characteristics of COVID-19 and to assess risk factors for mortality in patients with AL.
Methods: This prospective study included 51 consecutive adult patients actively treated for AL, with verified SARS-CoV-2 infection treated at two Clinical Centres in Central Serbia. The study enrolled all symptomatic and asymptomatic patients regardless of severity of the infection. Baseline data including age, sex, body mass index, comorbidities, AL type, disease status (newly diagnosed, complete remission (CR), relapsed/refractory (RR)), treatment (intensive, low-intensity chemotherapy, supportive care), time since AL diagnosis, outcome, laboratory parameters at the onset of infection were collected. Moreover, dana regarding COVID-19 symptoms, disease severity, COVID-19-specific therapies and time to PCR negativity were collected. Methods of descriptive and analytical statistics were used.
Results: Most patients (80.4%) had acute myeloid leukemia (AML). At time of COVID-19 diagnosis 35.3% of patients were newly diagnosed with AL. Concurrent diagnosis of COVID-19 and AML was made in 5.89% patients, 23.5% were RR and 41.2% were in CR. Intensive chemotherapy was administered in 80.4% of our patients. At the time of COVID-19 diagnosis 29.4% patients had bone marrow aplasia. Intrahospital transmission was probable in 50.98% patients. Five patients who were initially asymptomatic andwith negative PCR test at the time of admission developed COVID19 symptoms within the first 48 hours. The most common symptoms of COVID-19 were fever (70.4%), fatigue (66.7%) and dyspnea (39.2%). Asymptomatic, mild to moderate, severe and critical COVID-19 was registered in 9.8%, 43.1%, 37.3% and 9.8% patients, respectively. Median time to PCR negativity was 18 days (range 10-50). Mortality for the entire cohort was 17/51 (29.4%). In all cases death was associated with COVID-19 pneumonia. Among COVID-19 symptoms dyspnea (OR 12.536 (95% CI: 3.106 – 50.597)), cephalgia (OR 5.36 (95% CI: 1.200 – 26.482) and fatigue (OR 5.921(95% CI: 1.168 – 30.019) were associated with higher mortality. Patients newly diagnosed with AL (OR 6.00 (95% CI 1.133 – 15.188) and patients with bone marrow aplasia (OR 4.148 (95% CI 1.133 – 15.188) had a significantly worse outcome in comparison with patients in CR. Additionally, pneumonia severity (OR 14.963 (95% CI 3.212 – 69.700) and need for oxygen therapy (OR 6.455 (95% CI 2.56 – 20.262) were associated with higher mortality risk. Among laboratory parameters lower platelet count (OR 0.985 (95% CI 0.973 – 0.996)), prolonged prothrombin time (OR 1.554 (95% CI 1.104 – 2.186)), higher ISTH DIC score (OR 2.122 (95% CI 1.258 – 3.576), C-reactive protein (OR 1.011 (95% CI 1.004 – 1018) and LDH (OR 1.001 (95% CI 1.000 – 1.003) were predictive for death.
Summary/Conclusion: Baring in mind high mortality rate, and rate of intrahospital transmission, rigorous isolation of AL patients, permanent symptoms monitoring and prompt testing should be prioritized. Careful risk-benefit assessment regarding the continuing of anticancer therapy is required in patients receiving palliative therapy and intensive induction therapy. Conversely, there is no reason to withhold therapy for the patients in CR.

EP834 THE PROFILE OF FEBRILE NEUTROPENIA IN HEMATOLOGY-ONCOLOGY UNIT; EXPERIENCE OF CHILDREN WELFARE TEACHING HOSPITAL, MEDICAL CITY

H. Ghali [1], F. Mahdi [2], M. Al-Jadiry [1], S. Faraj [3], A. Al-Darraji [2], R. Al-Saeed [2], A. Sabhan [2], S. Fadhil [2], S. AL-Hadad [1,*]

[1]Pediatric hematology/oncology, College of Medicine, University of Baghdad / Children Welfare Teaching Hospital, Medical City, [2]Pediatric hematology/oncology, Children Welfare Teaching Hospital, Medical City, [3]Pediatric hematology/oncology, College of Medicine, University of Wasit / Children Welfare Teaching Hospital, Medical City, Baghdad, Iraq

Background: Infections in pediatric cancer patients are the major reasons for morbidity and mortality. In cases of malignant diseases, fever may herald an upcoming life-threatening situation. This study tried to unleash few mysterious interrogation points about the nature of febrile neutropenic episodes in children.
Aims: To assess the overall and attributable mortality from febrile neutropenia and to evaluate the susceptibility pattern to antimicrobials in febrile neutropenia.
Methods: A prospective non-interventional observational study. All consecutive pediatric inpatients affected by haematological diseases or solid

tumours who were admitted at the pediatric oncology unit in Children Welfare Teaching Hospital / Medical City, with fever and neutropenia (Absolute Neutrophile count (ANC) <500/cmm) or developed fever and neutropenia during hospitalization were enrolled into the study until hospital discharge or death, started from September 1st 2019 till February 29th 2020. The total number of patients admitted to the pediatric oncology unit was 207 patients, with a total of 350 neutropenic episodes.
Results: The majority of reported underlying diagnoses belong to hematological malignancies in 236 patients (67.4%). Acute lymphoblastic leukemia was reported to be the most frequent in 197 episodes (56.3%), followed by acute myeloid leukemia in 39 episodes (11.1%), then neuroblastoma (6.3%), and brain tumors (5.1%). Forty percent of patients recalled or had shown respiratory symptoms. Abdominal complaints were reported in 178 patients (50.9%). Bleeding was recorded in 79 patients (22.6%). Mucositis was noted in 187 patients (53.4%), grade II being the most frequently notified in 83 patients (44.4%). Performance score according to Eastern cooperative oncology group showed that the majority have a score of II (48.4%). At time of admission, the mean WBC count 3,100 /cmm, and the mean ANC was 140 with a range of (0 – 500). Blood was withdrawn for culture and sensitivity at time of admission; Sixty-one episodes showed positive bacterial growth (18.2%), while 274 showed no growth (81.8%). The growth showed gram-positive bacteria in two-third of episodes (65.6%), while gram-negative was shown in one-third (34.4%). The majority of patients (84.0%) belong to high-risk febrile neutropenia, while fifty-six patients (16.0%) were low-risk patients. Out of the group, 46.4% were labelled as fever without origin as the final diagnosis, while 34.0% with a presumptive 'clinical infection' diagnosis. Microbiological diagnoses were reported in 68 patients; 61 blood, 2 skin, 2 sputum, 2 urine, and 1 ear. Out of the group, 21 patients (6.0%) died as a complication of febrile neutropenia. The mean duration of fever before admission for the deceased group was 9.1 days which was significantly longer than the duration for the alive group (mean duration 3.0 days). There was a significant statistical correlation between the fate of the patients and the following parameters: type of malignancy, phase of disease, and treatment lines.
Summary/Conclusion: Conclusion: Acute lymphoblastic leukemia was the most frequently encountered underlying malignancy, acute myeloid leukemia was associated with the worst outcome. The result of blood cultures was comparable to worldwide results. Gram positive organisms were the most commonly identified growth. High-risk febrile neutropenia was the commonest reported type, low-risk being lowest because of possible treatment outside the hospital on oral-based antibiotics. Finally, infection related mortality was high.

EP835 AUDIT OF CHEMOTHERAPY DISRUPTION DUE TO COVID19 PANDEMIC:

H. ahmad [1], A. ahmad [1,*], M. iqbal [1], L. carter [1], I. khan [1], H. hambleton [1], A. razzak [1]

[1]*Haematology, Queen's Hospital, Burton, United Kingdom*

PERSPECTIVE FROM A UK DISTRICT GENERAL HOSPITAL
Background: Patients with cancer undergoing systemic chemotherapy have been postulated to be at increased risk of mortality from COVID-19. Given this proposed risk, NICE issued COVID-19 rapid guidelines for safe delivery of systemic chemotherapy in March 2020. Based on this guidance local and regional guidelines were established.
Aims: The primary objective of this audit was to assess the impact of COVID-19 on patients undergoing systemic chemotherapy and their outcomes at Queen's Hospital Burton.
Methods: 115 patients undergoing active chemotherapy were identified using local records of chemotherapy administration. Retrospective data collection and analysis of these patients was undertaken from March 2020 to December 2020.
Results: Patients with a diagnosis of Myeloma (36%) who had a stable disease (42%) had treatment either delayed or suspended during the first wave. Bisphosphonate treatment in 12 out of 14 patients was stopped who already completed the anti-myeloma treatment. Similarly for lymphoma patients, maintenance immunotherapy with Rituximab (6) and Obinutuzumab (3) were suspended or stopped in all cases. Other patients with aggressive Lymphomas, CML, High risk MDS/AML and those with advanced CLL either continued with their treatment or new therapy was started as clinically appropriate.
In total, 31 patients had chemotherapy delayed or stopped completely. Only 2 patients on maintenance Rituximab had disease progression. COVID-19 was detected in 9 patients and sadly 4 patients passed away with COVID-19 related complications. Among these were 2 patients on Ruxolitinib, one on VMP lite and 1 on Zometa without chemotherapy at the time. Following the first wave of COVID-19, of the 31 patients 29 were re-commenced on chemotherapy. No patients on high dose chemotherapy had an increase in morbidity and mortality.
Summary/Conclusion: The impact of COVID-19 and systemic anticancer therapies is poorly described and based on limited small cohort studies. A few of these studies concluded that cancer patients are not only at risk to contract the virus but also at risk of developing more severe complications as compared with the general population. The UK CORONAVIRUS CANCER MONITORING PROJECT (UKCCMP), serving as a public health surveillance registry, concluded that cytotoxic chemotherapy within 4 weeks before confirmed COVID-19 is not a significant contributor to more severe disease, or a predictor of death from COVID-19, compared with cancer patients who have not received chemotherapy in that period. Again, this analysis was based on small data sets. Our audit also confirms the findings of UKCCMP and shows no significant increased risk in mortality in patients both on active chemotherapy and where chemotherapy was temporarily stopped. The overall risks and benefits of continuing or holding chemotherapy need to be discussed in details with patients. Withholding anti-cancer therapies may well present a greater individual risk of morbidity and mortality than COVID-19. Further studies are required to assess the impact of COVID-19 on morbidity and mortality, to better inform these discussions.
Whilst these factors become clearer, additional measures within our practice have aimed to ensure safe patient care in this new environment. These included telephonic and video consultations, home delivery of oral chemotherapy and blood monitoring at local GP surgeries to avoid hospital exposures.

EP836 COMPLICATION, ASSOCIATED WITH CATHETERISATION OF CENTRAL VEIN IN HEMATOLOGY PATIENTS

N. Romanenko [1,*], A. Alborov [1], S. Gritsayev [1], E. Yuriev [1], S. Voloshin [1], E. Shilova [1]

[1]*Clinical Hematology, Russian Research Institute of Hematology and Transfusiology, SAINT-PETERSBURG, Russian Federation*

Background: The central vascular access needs to provide a large volume of infusion therapy, a parenteral feeding, transfusions of the blood components in hematology patients (HP). However, the procedure of central vein catheterization (CVC) may lead to risks of serious complications.
Aims: To find out the incidence of individual complications associated with CVC in HP.
Methods: We studied the complications associated with procedure of CVC in HP (n=2856) for the period of above 17 years (2003-2020 years). Most procedures were performed by subclavian access (into the v. subclavia dextra – in 2346 (82.1%) cases and into v. subclavia sinistra – 502 (17.6%)), only 8 cases (0.3%) into v. jugularis interna. After each CVC procedure was done X-ray control. There were performed bacteriological analyses and identification of microbial pathogen in cases if we suspected an infectious complication.
Results: There were observed range of complications associated with CVC. The more frequently were found hemorrhagic complications: 1) hematoma – in 117 cases (4.1%), 2) puncture of an artery – in 79 (2.8%), and one case catheterization of arteria subclavian, 3) bleeding from the catheter passage area – in 54 (1.9%), 4) delayed bleeding (after 3-4 hours or more) – in 24 cases (0.8%), and 5) clinically significant lymphorrhea – in 41 cases (1.4%). The thrombotic complications included thrombophlebitis, infiltrate with thrombosis of subclavian vein and they were counted 74 cases (2.6%). Most of thrombotic complications were associated with different bacterial pathogens. More rarely we documented complications as pain, numbness, paresthesia of the upper limb were observed in 45 patients (1.6%), as well as weakness, allergic Quincke's edema, fainting or collapse associated with anesthesia were observed in 34 ones (1.2%). Among the dangerous clinically significant complications that required additional measures were pneumothorax (n=3; 0.11%) and pneumothorax with hemoptysis (n=2; 0.07%). The complications associated with bloodstream infection in the form of bacteremia or fungeremia, which were observed by bacteriological culture, were detected in 71 (2.5%) patients. Positive bacterial

cultures from venous blood were detected in 89 cases, and 12 blood probes of them had mixed infection (2 and rarely 3 bacterial pathogens). Analysis of the different microorganisms indicated the prevalence of Gram-positive pathogens – 61.8% (n=55): the most part was Coagulase-negative Staphylococcus – 50.6% (n=45), S. aureus – 9.0% (n=8), Enterococcus spp. – 1.1% (n=1) and Micrococcus spp. – 1.1% (n=1). Gram-negative microorganisms were detected in 30.4% (n=27) of cases: Escherichia coli – 15.7% (n=14) patients, Enterobacter spp. – 9.0% (n=8), Acinetobacter spp. – 1.1% (n=1), Pseudomonas aeruginosa – 2.3% (n=2), Neisseria spp. – 2.3% (n=2). Causative agents of fungal infections were found for 7.8% of patients (n=7). They included fungi of the genus Candida – 6.7% (C. albicans – 5.6% (n=5), C. crusei – 1.1% (n=1)) and Rhodotorula spp. – 1.1% (n=1).

Summary/Conclusion: we found the most of CVC's complications were associated with hemorrhagic as hematoma (4.1%), its rate depended on thrombocytopenia, coagulation disorders and technic of procedure in HP. Blood stream infections associated with CVC were caused by gram-positive microbes in more cases (coagulase-negative Staphylococcus), little less by gram-negative (Escherichia coli).

EP837 HEMATOLOGIC CHARACTERISTICS AND C-REACTIVE PROTEIN OF PATIENTS WITH SARS-COV 2 ADMITTED TO A UNIVERSITY HOSPITAL IN BRAZIL.

M. Dias [1,*], M. Morgado [1], R. Portugal [1]

[1]Hematology, UFRJ, Rio de janeiro, Brazil

Background: COVID-19 is a new infectious disease. The risk of death depends on previous comorbidities, but prothrombin time and low platelets count are also related to death.

Aims: In this study, risk factors for death on hospital admission were evaluated.

Methods: We included patients admitted to the Emergency Department of University Hospital Clementino Fraga Filho (HUCFF), Federal University of Rio de Janeiro (UFRJ), Brazil, from March to May/2020 with laboratory-confirmed Covid-19 infection. A confirmed case was defined by a positive result on a reverse-transcriptase–polymerase-chain-reaction assay of a specimen collected on a nasopharyngeal swab secretion. Admission results were collected through retrospective review of medical records. Death was the primary outcome. Data were expressed as median (range), or n/N (%); P values were calculated by Mann-Whitney or Fisher's exact test, as appropriate. A two-sided α of less than 0.05 was considered statistically significant.

Results:

We analysed 116 patients. The median age was 61 years (range 22-94), and most were male (55%). Ninety-nine (85%) had one or more chronic underlying diseases, mostly hypertension (69%). Ninety-six (83%) patients had pulmonary CT scan compatible with viral pneumonia on admission, 87% necessitated supplementary oxygen therapy, 38% needed mechanical ventilation, of which 71% died. Thirty-one (27%) patients died. Non-survivors were older (66 X 59 years; p=0.077), had a higher proportion of cardiopathy (45% X 13%; p=0.001), renal failure (36% X 9%; p=0.002) and diabetes (52% x 31%; p=0.050), and on hospital arrival, higher neutrophils counts (6.9 x 103/mm3 X 5.4x103/mm3; p=0,037), higher neutrophils / lymphocytes ratio (7.4 X 5.1; p=0.012), higher CRP (174.4 X 102.7; p=0.004) and higher LDH (478 X 376; p=0.009). Level of hemoglobin, white blood cells, RDW, platelet count, PT and APTT were similar in survivors and non-survivors. Most patients (97%) received any low molecular weight heparin (LMWH). All patients who died received LMWH.

Summary/Conclusion: That patients admitted with COVID-19 with respiratory symptoms who needed mechanical ventilation had a high mortality rate (71%). On admission, cardiopathy, renal failure and CRP level were independently predictive of death. Basic coagulation profile and blood counts (CBC) on admission were similar between alive and dead cases. Almost universal use of low molecular weight heparin precluded any further discussion on this subject.

EP838 GROWTH OF ANTIBIOTIC RESISTANCE IN THE HEMATOLOGY DEPARTMENT OF CENTRAL KAZAKHSTAN DURING THE COVID-19 PANDEMIC

L. Turgunova [1,*], A. Klodzinskiy [2], A. Lavrinenko [3], S. Kolesnichenko [3], N. Seidalin [2], A. Zinchenko [2]

[1]Department of Internal Diseases, Karaganda Medical University, [2]Hematology Department, Hematology Center LLP, [3]Shared Resource Laboratory, Karaganda Medical University, Karaganda, Kazakhstan

Background:

Infectious complications remain as a serious problem for hematological hospitals. Despite the fact that COVID-19 is a viral infection, the pandemic could have affected the development of antibiotic resistance. In Kazakhstan, at the beginning of 2020, the fear of bacterial complications, the emergence of available information about the possibility of using antibiotics in the treatment of patients with COVID 19 led to an increase in the consumption of antibacterial drugs, primarily azithromycin, ceftriaxone. This could negatively affect the selection and development of antibiotic-resistant microorganisms in the departments where patients are especially exposed to infectious agents. There are no data on monitoring of the etiological structure of bacterial pathogens and the level of antibiotic resistance during a pandemic among patients of hematology departments in Kazakhstan.

Aims:

To analyze the etiological structure and assess the level of resistance to antimicrobial drugs before and during a pandemic COVID 19.

Methods:

A retrospective analysis of the etiological structure and sensitivity to antimicrobial drugs of pathogens isolated from 108 patients in the hematology department of Karaganda for the period before the pandemic (from January 2019 to March 20, 2020) and 181 patients after the introduction of a lockdown due to the COVID 19 pandemic (from March 20, 2020 to

Table 1. Laboratory findings of patients infected with Sars-Cov-2.

Lab on arrival	Total (N=116) median (range)	Alive (N=85)	Dead (N=31)	P value	Reference values
Hemoglobin (g/dL)	13.3 (2.6-14.4)	13.4 (2.6-14.4)	12.3 (8.2-16.5	0.210	13.5-18.0 g/dL

LDH high (≥400 U/L)	52/110 (47)	34/82 (42)	18/28 (64)	**0.049**	-

PT: prothrombin time; INR: international normalized ratio; APTT: activated prothrombin time; CRP: C-reactive protein; LDH: lactic dehydrogenase

02/01/2021). The study included positive bacteriological cultures from 9 biotopes (blood, urine, sputum, catheters etc.). The bacteriological study was carried out by standard bacteriological methods with identification by time-of-flight mass spectrometry (Microflex-LT, Biotyper System, Bruker Daltonics, Germany), the determination and interpretation of sensitivity to antimicrobial drugs was carried out in accordance with the recommendations of CLSI M100-24. Statistical processing of the data obtained was carried out on an online platform for the analysis and exchange of antibiotic resistance data (AMRcloud, version: Beta, 01/27/2021).
Results:
The results of the study showed that in the structure of microorganisms isolated from patients of the hematology department for the entire period of the study, gram-negative flora prevailed. Significant differences in the structure of bacteria before and during the pandemic period were noted: increased *Pseudomonas aeurogenosa* strains from 29.7% to 55.3% (p = 0.022) and drastically decreased in the growth of *Enterococcus faecalis*, from 40.5% to 10.6% (p = 0.001). The appearance of *P. aeurogenosa* strains carbapenemase producers up to 30.4% (p = 0.01) during a pandemic was noted. Despite the fact that the ratio of gram-negative and gram-positive flora did not statistically change, after the lockdown the percentage of methicillin-resistant *Staphylococcus aureus* (MRSA) increased from 11.8% to 35%.
Summary/Conclusion:
During the COVID 19 pandemic, in non-infection departments, like hematology, the frequency of MRSA excretion increased by 3 times and a third of *Pseudomonas aeurogenosa* strains were resistant to carbapenems. Stricter infection control is needed, as well as monitoring the growth of opportunistic flora, which is often resistant to antibiotics and thus aggravates the condition of patients in the hematological compartments.

Iron metabolism, deficiency and overload

EP839 ALK2 IS A POTENTIAL THERAPEUTIC TARGET IN ANEMIA RESULTING FROM CHRONIC INFLAMMATION

T. Backus [1,*], N. Medeiros [1], C. Materna [1], F. Fisher [1], J. Lachey [1], J. Seehra [1]

[1]*Keros Therapeutics, Lexington MA, United States*

Background: Hepcidin, a master iron regulator that helps to maintain appropriate iron levels in circulation, is elevated in many diseases of chronic inflammation. Hepcidin is expressed, in part, in response to signaling through activation of the TGF-□□type-1 receptor ALK2 and acts to reduce iron export through ferroportin. We have previously demonstrated the effect of inhibiting ALK2 via either a small-molecule or biologic in iron refractory iron deficiency anemia (IRIDA), a genetic form of anemia that results from high hepcidin, in preclinical studies. In IRIDA, KTI-2338, a selective small molecule ALK2 inhibitor, decreased hepcidin and increased serum iron levels in an *in vivo* mouse model. Hepcidin is also increased in response to elevated IL-6 in chronic inflammation, resulting in secondary anemia of inflammation (AI) in chronic inflammatory diseases such as chronic kidney disease (CKD). Herein, we assessed the therapeutic potential of inhibiting ALK2 signaling on anemia arising from chronic inflammation and determined the effect of modulating BMP signaling in anemia resulting from IL6 and high hepcidin.
Aims: To characterize development of AI in a mouse model of chronic kidney disease (CKD) and to test the efficacy of ALK2 inhibition to increase circulating iron in this model.
Methods: To assess the role of ALK2 signaling in AI, we evaluated an adenine-induced model of CKD. Briefly, to induce CKD, C57BL/6 mice were dosed daily via PO administration with 50 mg/kg of adenine or vehicle. After 6 weeks of adenine administration, anemia was confirmed in subset of mice. Concomitantly, the remainder of CKD mice began dosing with either vehicle or KTI-2338 5 mg/kg PO daily while continuing to receive daily adenine for 10 days. The study was terminated at 52 days and hematology, serum hepcidin, and serum iron levels were assessed.
Results: 6 weeks of adenine administration led to iron deficiency anemia (37.6% decrease in serum iron) and was associated with increased circulating IL6 (2.42-fold) and hepcidin (3.49-fold). After 10 days of therapy, the vehicle treated group remained anemic with reduced circulating iron, red blood cell (RBC) count, hemoglobin (HGB) and hematocrit (HCT) compared to the controls not receiving adenine. In contrast, mice that were administered KTI-2338 had an increase in serum iron (2.09-fold) and improvements in RBC count, HGB and HCT compared to the vehicle cohort. Reticulocyte HGB content, a measure of the incorporation of iron into hemoglobin, normalized to baseline levels with KTI-2338 therapy. Given that reticulocytes are immature RBCs, the effect on reticulocyte HGB content is potentially predictive that RBC and HGB levels would also continue to increase over a longer time course.
Summary/Conclusion: We have characterized an established mouse model of chronic inflammatory disease, CKD, as a well-defined model of anemia of inflammation. This preclinical model recapitulates the high IL6 and hepcidin and decreased serum iron that characterizes clinical AI. In this proof-of-concept study, inhibition of ALK2 improved hematological markers of anemia, serum hepcidin, and serum iron levels in a mouse model of anemia of inflammation (AI) resulting from chronic kidney disease characterized by elevated IL6. Inhibition of BMP6 signaling alone can override iron deficiency anemias driven by inflammatory signaling, potentially substantiating that inhibitors targeting ALK2 may provide a viable therapeutic intervention for AI.

EP840 ADMINISTRATION OF ALK2 NEUTRALIZING ANTIBODIES TO CYNOMOLGUS MONKEYS LED TO A SUSTAINED DECREASE IN HEPCIDIN, INCREASE IN CIRCULATING IRON AND INCREASE IN ERYTHROCYTE HEMOGLOBIN

C. C. Tseng [1,*], T. A. Backus [1], N. M. Medeiros [1], D. Abramovich [1], F. M. Fisher [1], J. L. Lachey [1], J. S. Seehra [1]

[1]*Keros Therapeutics, Lexington, United States*

Background: Hepcidin is a key endocrine mediator of iron metabolism that regulates dietary iron uptake and iron levels in blood. Hepcidin is expressed in part in response to signaling through the ALK2 receptor, a type I TGF-β receptor activated by complexing with the ligand BMP6 and the co-receptor hemojuvelin. Hepcidin signals to peripheral tissues and binds to and activates the degradation of the iron exporter, ferroportin. Thus, when hepcidin is high, iron is sequestered within cells and functions to increase tissue iron levels and reduce serum iron availability. Elevated hepcidin is associated with states of iron deficiency anemia such as iron-refractory iron deficiency anemia (IRIDA) and anemia of inflammation. We have previously reported that inhibition of ALK2 with a novel specific monoclonal antibody (KTI-mAb2.0) can suppress hepcidin and increase serum iron in healthy mice and in mice with iron deficiency anemia. KTI-mAb2.0 and KTI-mAb2.1 are two fully human antibodies that have been observed to specifically bind to and neutralize ALK2.
Aims: To determine the pharmacokinetic and pharmacodynamic properties of KTI-mAb2.0 and KTI-mAb2.1 in cynomolgus monkeys, a preclinical model highly representative of human biology.
Methods: Ad libitum-fed, female cynomolgus monkeys ranging in age from 2-4 years old were randomly assigned to receive KTI-mAb2.0 or KTI-mAb2.1 administered as a single subcutaneous dose (3mg/kg). Serum was sampled intermittently over a 56-day period and assessed for drug exposure, hepcidin and iron content. At a subset of timepoints, blood was sampled and assessed for reticulocyte and red blood cell hemoglobin content (RET-Hgb and RBC-Hgb, respectively). Hematological data was combined across both therapeutic groups.
Results: KTI-mAb2.0 and KTI-mAb2.1 were rapidly absorbed and reached Cmax within 48 hr and had half-lives of 33.9 hr and 49.1 hr, respectively. Robust and profound effects on hepcidin and serum iron were observed with both antibodies. Within 6hr of administration, KTI-mAb2.0 or KTI-mAb2.1 reduced serum hepcidin by 55.6% and 50.3%, respectively. The peak effect was observed beginning after 48 hr with reductions of 77.2% in the KTI-mAb2.0 treated group, and 77.8% in the KTI-mAb2.1 group and continued through day 10 before returning to baseline by day 14. The reduction in hepcidin corresponded to increased circulating iron with maximal changes occurring within 24hr of antibody administration. A 63.3% and 54.2% increase in iron was achieved with KTI-mAb2.0 and KTI-mAb2.1, respectively. Similar to hepcidin, the response was sustained through 10 days, returning to baseline by day 14. RET-Hgb increased by 4.9% at 3 days post dose and remained elevated for 10 days. Increases in RBC-Hgb content were observed initially 35 days post dose and remained 4.2% higher at study termination at day 56.
Summary/Conclusion: Our data demonstrate that both KTI-mAb2.0 and KTI-mAb2.1 reduced serum hepcidin and increased circulating iron in non-human primates, a preclinical model highly representative of human biology. Furthermore, the mobilized iron resulted in increased RET-Hgb and RBC-Hgb. These results provide evidence that treatment with KTI-mAb2.0 and KTI-mAb2.1 may be a viable approach to treating anemias that arise from elevated hepcidin, such as IRIDA and anemia of inflammation.

EP841 DISC-B, A SELECTIVE MATRIPTASE-2 INHIBITOR, ELICITED ROBUST INCREASE IN HEPCIDIN-25 AND REDUCTION IN SERUM IRON IN CYNOMOLGUS MONKEYS

V. Hong [1,*], S. Nguyen [1], J. Giraldes [1], M. Beconi [1], S. Venkatraman [1]

[1]*Disc Medicine, Cambridge, United States*

Background: Hepcidin is known as the master regulator of systemic iron homeostasis with reduction in synthesis leading to the development of iron overload. Hepcidin gene expression is negatively modulated by matriptase-2 (MT-2), a liver-specific type II transmembrane serine protease. MT-2 cleaves hemojuvelin (HJV), leading to the extracellular release of soluble HJV (sHJV) fragments and suppression of hepcidin expression. Therefore, inhibition of MT-2 represents a potential therapeutic strategy for diseases caused by inappropriately low hepcidin leading to iron overload or where therapeutic iron restriction may be used to control excessive erythrocytosis. DISC-B is a potent (MT-2 Ki =15 nM) and selective small molecule MT-2 inhibitor.
Aims: 1. To examine the dose-dependency of acute treatment of DISC-B on the key PD markers (hepcidin-25, sHJV, serum iron) in cynomolgus monkeys.
2. To determine the time to maximum decrease in serum iron upon multiple dosing.
3. To evaluate the effect of chronic treatment on key hematologic parameters.
Methods: A cross-over study was conducted in male cynomolgus monkeys (2-4-year-old; N=6). Animals were administered a single subcutaneous (SC) dose of DISC-B at 5, 15, 50 mg/kg or vehicle control, followed by administration of DISC-B once a day for 7 consecutive days; the washout period in between treatments was 2 weeks. For the single-dose treatments, blood samples were collected 48-hr prior to treatment (baseline) and at various time points after dosing. For the multiple dose part of the study, blood samples were collected 48-hr prior to dosing (baseline) and at various time points after the 1st and the 7th dose. All blood samples were processed to serum and sHJV, hepcidin-25, serum iron and total iron binding capacity (TIBC) were quantified. In addition, for the multiple dose part of the study, reticulocyte hemoglobin was determined at baseline and on Day 7. TSAT was calculated as the ratio of serum iron/TIBC x 100.
Results: Treatment of DISC-B resulted in a dose-dependent increase in hepcidin-25 with a maximum of 5-fold. Maximum serum iron percent reduction from baseline was 10%, 25%, and 50% for 5, 15, and 50 mg/kg, respectively. The magnitude of hepcidin-25 modulation was similar at 15 and 50 mg/kg dose. However, the serum iron reduction was higher with the 50 mg/kg group and responses were more consistent across different animals. Therefore, we selected the 15 mg/kg dose group to determine if the effect on serum iron would increase with subsequent days of dosing. After 7 days of treatment with DISC-B at 15 mg/kg serum iron decreased from 25% on day 1 to 45% at day 7 (~2-fold). The hepcidin-25 increase over baseline was comparable on day 1 and day 7. Importantly, all animals showed a reduction in CHr with a mean reduction of 1.3 pg (± 0.6) on day 7 compared to their baseline levels, suggesting the induction of iron-restricted erythropoiesis.
Summary/Conclusion: DISC-B modulates serum hepcidin-25 levels and iron homeostasis in cynomolgus monkeys in a dose-dependent manner. The consistent increase in hepcidin-25 and the increasing reduction in serum iron after 7 doses of DISC-B suggest that prolonged inhibition of MT-2 can lead to sustained, therapeutically relevant reduction in serum iron. Our data demonstrate that MT-2 can be successfully inhibited by a selective small molecule to increase hepcidin and decrease serum iron.

EP842 ALK2 INHIBITION, A NOVEL THERAPEUTIC APPROACH TO IRON OVERLOAD.

F. Fisher [1,*], T. Backus [1], N. Madeiros [1], E. Lema [1], C. Tseng [1], J. Lachey [1], J. Seehra [1]

[1]*Keros Therapeutics, Lexington, United States*

Background: Iron overload is a condition whereby excess iron is stored in peripheral tissues and can be caused by genetic mutations, or introduced via blood transfusions, hemolysis or diet. Excess deposition of iron in liver, heart and endocrine organs leads to toxicity and loss of function. Hepcidin, a key endocrine regulator of iron metabolism, mediates dietary iron uptake and iron levels in blood. Hepcidin circulates to tissues and binds to and activates the degradation of the iron exporter, ferroportin. Thus, when hepcidin is high, iron is sequestered within cells resulting in increased tissue iron levels and reduced serum iron availability. Likewise, when hepcidin expression is suppressed, ferroportin-mediated iron efflux results in the mobilization of iron out of tissues. Hepcidin is expressed, at least in part, in response to signaling through the ALK2 receptor, a type I TGF-β receptor, and inhibition of ALK2 results in reduced hepcidin expression and increased serum iron. We have shown in pre-clinical and clinical studies that ALK2 inhibition suppressed hepcidin expression. Indeed, we have previously reported in a Phase 1 clinical trial that inhibition of ALK2 with KER-047, a small molecule ALK2 kinase inhibitor, elicited rapid, robust and sustained dose-related increases in serum iron that were associated with decreases in hepcidin. The potential of ALK2 inhibition to aid export of iron from tissues may increase the available therapeutic modalities for the treatment of iron overload.
Aims: To test the efficacy of modulating ALK2 activity to regulate hepcidin and mobilize hepatic iron in an inducible model of iron overload.
Methods: To induce iron overload, CD1 mice were dosed QD via IP administration with 100mg/kg of iron dextran or vehicle. Post 20 days of iron loading, a subgroup of mice was used to confirm iron overload. The remaining iron loaded mice were dosed QD with either KTI-2338, a small molecule selective ALK2 kinase inhibitor (5 mg/kg) or vehicle. Iron dextran administration continued throughout. Mice were sacrificed 16hr post the 1st dose (16hr) and 12hr post the 3rd dose (63hr) of KTI-2338 and livers dissected and weighed. Non-heme tissue iron was extracted via acid hydrolysis and iron levels determined using the bathophenanthroline disulfonate method.
Results: Iron overload was confirmed in the mice dosed with iron dextran (ID-Veh) with a substantial 30-fold increase in hepatic iron compared to mice not receiving iron (Veh-Veh) (Veh-Veh: 648.4±36.01mg/g v ID-Veh: 19291±513.7mg/g, p<0.0001). No differences were observed in hepatic iron at 16hr post dose. By 63hr of KTI-2338 dosing, significant reductions in liver non-heme iron content was observed, resulting in a 62% decrease compared to vehicle treated mice (63hr ID-Veh: 25162±974.5mg/g v 63hr ID-2338: 9559±339.2mg/g, p<0.0001).
Summary/Conclusion: In this proof-of-concept study, ALK2 inhibition in a state of severe iron overload led to rapid and marked reductions in liver iron. In the clinic, chelation therapy is used to remove excess iron from circulation; however, due to the efficiency of iron cycling, this procedure can be ineffective or require a lengthy therapeutic regimen. We hypothesize that in conditions with iron overload, ALK2 inhibition may potentially be used to export excess iron from the liver, allowing for more effective chelation therapy. Future studies will assess the efficacy of KTI-2338 to reduce ectopic iron in sensitive tissues such as the heart and determine if this can be combined with chelation to rescue the pathologies of iron overload.

EP843 ANEMIA AND IRON METABOLISM IN PATIENTS WITH SARS-COV-2 INFECTION: THE ROLE OF INFLAMMATION AND HYPOXIA.

D. Maira [1,*], L. Duca [1], E. Di Pierro [1], D. Consonni [1], G. Grasselli [2], M. Proietti [2], R. Lombardi [2], L. Valenti [2], M. D. Cappellini [1], I. Motta [2]

[1]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico,* [2]*Università degli Studi di Milano, Milan, Italy*

Background: Coronavirus Disease (COVID-19) could be considered as a human model of marked inflammation combined with severe hypoxia. In this setting, both erythropoiesis and iron metabolism appear to be profoundly affected by inflammatory and hypoxic stimuli, which act in the opposite direction. In patients with SARS-CoV-2 infection, Hb levels tend to be relatively high even in the context of severe disease and marked inflammation. A better understanding of erythropoiesis and iron metabolism in COVID-19 could contribute to elucidate the relationship between hypoxia and inflammation on erythropoietic control.
Aims: To investigate the prevalence of anemia, the alterations of iron homeostasis,and the relationship between inflammation,hypoxia and erythropoiesis in a cohort of COVID-19 patients admitted both to medical wards and intensive care unit (ICU).
Methods: We retrospectively analyzed data of 303 patients with COVID-19 (178 subjects admitted to medical wards and 125 subjects admitted to the ICU). Biochemical parameters were collected on admission (T0), after 7 days of hospitalization (T1) and at discharge/death (T2).
Results: The median age of the patients was 62 years (53-71) and 72% were males. ICU patients had lower mean Hb levels compared to non-ICU patients (11.3±1.8 vs 12.8±1.8 g/dL at T0, 10.2±1.6 vs 12.2±1.9 g/

dL at T1, 10±1.4 vs 12±1.7 g/dL at T2; p<0.001). Mean Hb concentration did not fall under 12 g/dl in the non-ICU group and under 10 g/dl in the ICU group during hospitalization. Hb decreased by approximately 1 g/dl in both cohorts during the first 7 days of hospitalization, then remained stable until discharge. ICU patients also showed increased inflammatory markers and ferritin levels (1401 vs 839 mcg/l at T0, p<0.001; 913 vs 832 mcg/L at T1, p ns; 764 vs 651 mcg/L at T2, p ns). There were no significant differences in other iron parameters between groups. Hypoxia was a prominent feature of ICU patients (P/F ratio 91 vs 224, p<0.001).
Patients who were anemic on admission maintained relatively constant Hb concentrations from T0 to T2 (10.8 g/dL at T0, 10.2 g/dL at T1 and 10.4 g/dL at T2), thus remaining in a range of mild to moderate anemia. Conversely, the non-anemic group displayed a greater reduction of Hb levels (13.7 g/dl at T0, 12.7 g/dl at T1, 12 g/dl at T2). Anemic subjects were more hypoxic than non-anemic patients (P/F 151 vs 292 at T0, p<0.001) and showed significantly higher levels of CRP (10.8 vs 6.6 mg/dL), IL-6 (60.3 vs 47.7 ng/L) and leukocyte count (7290 vs 6130 x109/L). Ferritin was higher in anemic patients at T0 and T1 (1220 vs 926 mcg/L and 852 vs 896 mcg/L, p ns), decreasing more at T2 (655 vs 763 mcg/L, p ns).
Median hepcidin levels, which were available for a limited subset of non-ICU patients, were elevated during the whole period: 233 ng/mL at T0, 95 ng/mL at T1 and 60 ng/mL at T2.
Summary/Conclusion: In patients with SARS-CoV-2 infection, two main factors influence erythropoiesis and iron homeostasis: systemic inflammation and profound hypoxia. Markedly high ferritin and hepcidin levels reflect a strong inflammatory response. However, COVID-19 patients tend to have disproportionately high Hb levels in the contest of the inflammatory milieu. The absolute reduction in Hb levels is more prominent in patients who displayed normal Hb on admission. Conversely, anemic and profoundly hypoxic subjects show constant mean Hb levels over time. Thus, we can hypothesize that the erythropoietic drive provided by hypoxia could counterbalance the effect of inflammation on hepcidin regulation, preventing Hb levels from falling dramatically during hospitalization.

EP844 ERYTHROFERRONE, THE MEDIATOR BETWEEN ERYTHROPOISESIS, HEPCIDIN AND IRON METABOLISM, DURING ALLOGENIEC HEMATOPOIETIC STEM CELLS TRANSPLANT.

M. Pirotte [1,*], M. Fillet [2], L. Seidel [3], A. Jaspers [1], B. Frederic [1], Y. Beguin [1]

[1]Department of Hematology, [2]Laboratory for the Analysis of Medicines, [3]Department of Biostatistics and Medico-economic, University of Liège, Liège, Belgium

Background: Hematopoietic cell transplantation (HCT) is associated with important changes in erythropoiesis and alterations of iron metabolism. Production of hepcidin, the regulator of iron metabolism, is increased in iron overload or inflammation and decreased with iron deficiency or activated erythropoiesis. Erythroferrone (ERFE) has been recently identified as the erythroid regulator of hepcidin.
Aims: We investigated erythropoiesis and iron metabolism after before and up to 180 days after allogeneic HCT in 70 patients randomized between erythropoietin (EPO) treatment or no EPO. We investigated serially serum levels of CRP (marker of inflammation); soluble transferrin receptor (sTfR, quantitative measure of erythropoietic activity); serum iron and transferrin saturation (Tsat; iron availability for erythropoiesis) and ferritin (iron stores); hepcidin (regulator of iron metabolism); and ERFE (erythroid regulator of hepcidin). We also sought to identify biological and clinical factors associated with serum hepcidin and ERFE levels.
Methods: Serum hepcidin was measured by a liquid chromatography/tandem mass spectrometry method and serum erythroferrone by a specific ELISA kit (Intrinsic Lifesciences, The Bio Iron Company, USA), while the other parameters were measured by routine methods. A generalized linear mixed model (GLMM) was used to compare their evolution with respect to time and treatment arm. Univariate and multivariate linear regression models were used to identify biological and clinical factors (age, sex, diagnosis, disease risk index, HCT-CI, conditioning, donor type, graft type, ABO, red blood cell and platelet transfusions, CMV status, Graft-versus-Host Disease, infections and EPO treatment) associated with hepcidin and serum ERFE levels at different times after transplantation.
Results: Serum ERFE correlated overall with sTfR (p<0.0001), reticulocytes (p<0.0001) and inversely with hepcidin (p=0.0095). Serum ERFE paralleled sTfR levels, with a drop during conditioning followed by recovery during engraftment. Inversely, hepcidin peaked during conditioning and decreased during engraftment (Figure 1). ERFE and hepcidin levels were not significantly different between the control and EPO arms. Multivariate analyses showed that during conditioning and engraftment and at day 100 (R^2=0.17 to 0.61, p<0.001), the major determinant of ERFE was erythropoietic activity (sTfR or reticulocytes or serum Epo). Pretransplant hepcidin was associated (R^2=0.52, p<0.0001) with previous RBC transfusions (p=0.02) and serum ferritin (p=0.001). In the course of transplantation (day 0 to day 180), the major determinants of hepcidin levels (R^2 0.35 to 0.60, p<0.0001) were iron status (ferritin at all time points (all p<0.0001) and Tsat at day 56 (p=0.0003)) and erythropoietic activity (sTfR or reticulocytes or ERFE (p ranging from 0.05 to 0.0001)), while inflammation and clinical parameters had no detectable influence. Indeed, hepcidin levels remained significantly higher in patients with high compared to low pretransplant ferritin (p<0.0001).

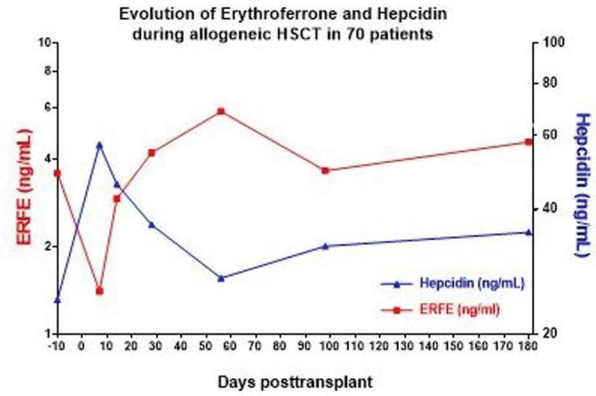

Figure 1

Summary/Conclusion: The evolution of ERFE, hepcidin and other parameters of iron status and erythropoietic activity after allogeneic HCT with or without EPO therapy confirms the strong impact of ERFE on hepcidin production and supports the erythropoietic origin of ERFE.

EP845 EFFICACY OF IRON SUPPLEMENTS GIVEN ON ALTERNATE DAYS VERSUS CONSECUTIVE DAYS IN THE TREATMENT OF IRON DEFICIENCY ANEMIA IN WOMEN OF REPRODUCTIVE AGE: NON-INFERIORITY, RANDOMIZED CONTROLLED TRIAL

S. Trithiphen [1,*], N. Uaprasert [1]

[1]Medicine, King Chulalongkorn Memorial Hospital, Bangkok, Thailand

Background: The consecutive-day split dosing of iron supplements is the most common treatment of iron deficiency anemia (IDA) in clinical practice. Although recent ferrokinetic studies in iron-deficient young women demonstrated greater iron absorption with alternate-day single dosing compared to conventional twice-daily split dosing, there have been no studies evaluating long-term efficacy between these two schemes in treatment of IDA in reproductive-aged women.
Aims: This open-label, non-inferiority, randomized controlled trial (TCTR20200614001) primarily aims to evaluate efficacy and safety between alternate-day single dosing of iron supplements versus consecutive-day split dosing in reproductive-aged women with IDA.
Methods: Women aged 18-50 years were eligible for enrollment. IDA was defined by serum ferritin levels (sF) <30 µg/L. Patients randomized in alternate-day dosing were given single doses of ferrous sulfate 400 mg on alternate days, while patients in consecutive-day dosing were given ferrous sulfate 200 mg twice daily. The primary outcome was the proportion of patients with ≥ 2 g/dL hemoglobin (Hb) increase at day 30 (D30) post-treatment. The secondary outcomes were the proportion of patients with ≥ 1 g Hb increase at D30; Hb and sF at D30 and D90; and incidence of adverse events.
Results: Of 37 in preliminary analysis, 19 and 18 were randomized to alternate-day dosing and consecutive-day dosing, respectively. There were no statistical differences in pretreatment Hb (8.15 vs. 8.67 g/dL, *P*

= 0.288) and sF (5.42 vs. 7.29 µg/L, *P* = 0.175) between alternate-day dosing and consecutive-day dosing, respectively. At D30, the proportions of patients with ≥ 2 g/dL Hb increase were 63.2% vs 61.1% (absolute difference 2.1%; 95% confidence interval [95%CI] -28.7% to 3.3%, *P* = 0.14 for non-inferiority), while the proportions of patients with ≥ 1 g/dL Hb increase were 100% vs 83.3% (absolute difference 16.7%; 95%CI -0.16% to 38.6%, *P* = 0.002, for non-inferiority) in alternate-day dosing and consecutive-day dosing, respectively. There were no statistical differences in Hb (D30; 10.35 vs. 11.12 g/dL, *P* = 0.135, and D90; 12.02 vs. 12.32 g/dL, *P* = 0.603) and sF (D30; 39.36 vs. 47.33 µg/L, *P* = 0.349, and D90; 38.53 vs. 48.70 µg/L, *P* = 0.349) between alternate-day dosing and consecutive-day dosing at D30 and D90 post-treatment, respectively. Gastrointestinal disturbances were reported of 26.3% in alternate-day dosing vs. of 31.3% in consecutive-day dosing, *P* = 0.748)

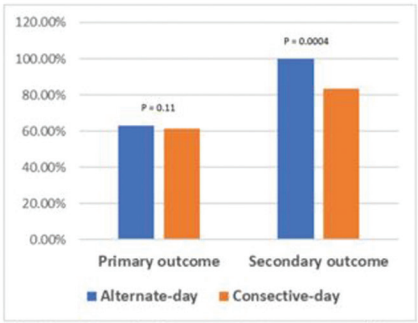

Figure: Proportions of patients with ≥ 2 g/dL Hb increase at day 30 post-treatment (primary outcome) and with ≥ 1 g/dL Hb increase at day 30 post-treatment (secondary outcome); p-value for non-inferiority of relative risk

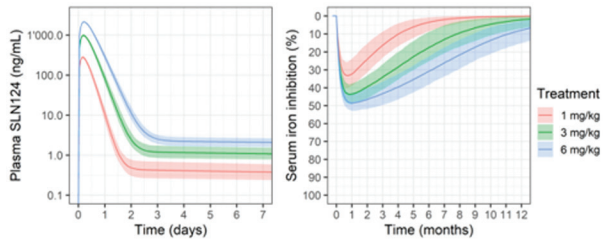
Summary/Conclusion: Alternate-day single dosing of iron supplements may be an alternative treatment for IDA, especially in patients who do not require a rapid correction of anemia. This trial is actively enrolling.



EP846 NON-CLINICAL SAFETY OF SLN124, A GALNAC CONJUGATED 19-MER DOUBLE-STRANDED SIRNA TARGETING TMPRSS6 FACILITATING EVALUATION IN CLINICAL STUDIES

M. Aleku [1], S. Chivers [2,*], H. Gille [3,4], M. Machacek [5], P. Schulthess [5], N. Roeder [1], D. Rider [1]

[1]Silence Therapeutics GmbH, Berlin, Germany, [2]Integrated Biologix GmbH, Basel, Switzerland, [3]IASON consulting, Niederzier, [4]BioNTech SE, Mainz, Germany, [5]LYO-X GmbH, Allschwil, Switzerland

Background: Hepcidin, the central regulator of systemic iron homeostasis, is synthesized predominantly in hepatocytes, and dysregulation of its production leads to a variety of life-limiting iron disorders. SLN124 is a liver-targeted N-Acetylgalactosamine (GalNAc)-conjugated siRNA which works by increasing hepcidin by silencing its repressor TMPRSS6. SLN124 is pharmacologically active in the mouse & cynomolgus monkey.
Aims: The primary objective was to evaluate the non-clinical safety and PK/PD of SLN124 in relevant toxicology species (mouse & cynomolgus monkey) to enable evaluation of SLN124 in the clinic.
Methods: In vitro serum stability (mouse, monkey & human) and metabolism (human S9 fraction/lysosomes and plasma) was evaluated. Potential genotoxicity was determined in in vitro micronucleus and mammalian cell gene mutation assays. Cytokine release was evaluated in vitro in whole blood assays (human & monkey) and in vivo (mouse & monkey). Potential immunogenicity was assessed in vivo in rabbits using LPH-conjugated SLN124. Biodistribution was considered in the mouse, following subcutaneous dosing at 10 mg/kg over 21 days. In vivo, SLN124 was evaluated in mouse & monkey repeat dose studies, the longest duration study was 13-weeks in both species, with a 12-week recovery period. Mice & monkeys were dosed subcutaneously at 0, 10, 30 & 83 mg/kg Q2Wx6 with weekly dosing for the last 2 doses. Population PK/PD modelling & simulation of the mouse and cynomolgus monkey SLN124 PK/PD was used to estimate an appropriate clinical starting dose and dose range.
Results: SLN124 is stable in serum, plasma and human S9 fraction/lysosomes. SLN124 was neither clastogenic nor mutagenic in the completed in vitro genotoxicity studies. No cytokine release was noted in the human whole blood assay or in vivo in the mouse & monkey. As rabbit immunisation did not result in any antibody generation, SLN124 does not pose an immunogenicity risk. SLN124 showed a typical GalNAc siRNA distribution pattern, with significant levels in the mouse liver and kidney only (peak levels noted after 6 hrs, with 25% remaining in the liver after 7 days with 6% by day 21). In the 13-week repeat dose studies, SLN124 was clinically well tolerated in the mouse & monkey, with expected non-adverse changes in the liver (reversible hepatocyte degeneration/regeneration in the mouse & basophilic granules in Kupffer cells in the monkey), kidney (reversible minor increased kidney weight and renal tubular basophilia/vacuolation in the mouse) and lymph nodes (vacuolated macrophages in the monkey). The NOAEL was ≥83 mg/kg for both the mouse & monkey (highest dose tested). Population PK/PD modelling of the observed SLN124 exposure in plasma & serum iron levels in the mouse and/or monkey was used to predict human exposure and serum iron inhibition in the clinic. At 1 mg/kg (~30 fold below the human equivalent dose of the monkey NOAEL), the model predicts a maximum 34% reduction in serum iron levels (Figure 1).

Figure 1 - Predicted SLN124 plasma concentrations and serum iron inhibition of median (line), 5th and 95th percentile (area) of 500 simulated typical 70 kg human individuals using the standard error of the parameter estimates for uncertainty after single subcutaneous SLN124 doses 1, 3, 6 mg/kg

Summary/Conclusion: The non-clinical safety profile of SLN124 is consistent with the known GalNAc siRNA safety profile and supportive of clinical entry, with PK/PD modelling supporting 1 mg/kg as an appropriate safe starting dose. Two clinical studies are underway: NCT04559971 in healthy volunteers and NCT04718844 in non-transfusion dependent b-thalassaemia and VL and LR-MDS patients.

EP847 PRE-TRANSPLANT HYPERFERRITINEMIA CANNOT PREDICT TRANSPLANT OUTCOMES IN HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANT FOR SEVERE APLASTIC ANEMIA

F. Lin [1,*], L. Xu [1], Y. Zuo [1], Y. Zhang [1], Y. Cheng [1], T. Han [1], X. Mo [1], P. Suo [2], Y. Sun [1], F. Tang [1], F. Wang [1], C. Yan [1], Y. Chen [1], W. Han [1], J. Wang [1], Y. Wang [1], X. Zhang [1], K. Liu [1], X. Huang [1]

[1]Peking University Institute of Hematology, Peking University People's Hospital, [2]Peking University Institute of Hematology, Peking University People's Hospital,, Beijing, China

Background: Many patients with hematologic diseases are heavily transfused and have elevated levels of serum ferritin. Pre-transplant Hyperferritinemia has proved its association with adverse outcomes in hematopoietic stem cell transplant (HSCT) for various diseases, but data on haploidentical HSCT (haplo-HSCT) and severe aplastic anemia (SAA) is absent.
Aims: To determine the impact of hyperferritinemia on outcomes in haplo-HSCT for SAA patients.
Methods: We retrospectively analyzed outcomes of 250 SAA patients who received haplo-HSCT between 2010 and 2018, stratified by pre-transplant status of hyperferritinemia.
Results: The cumulative incidences of neutrophil engraftment at 28 days (95.16 ± 0.25% vs 90.63 ± 0.69%, p = 0.950) and platelet engraftment at 100 days (88.17 ± 0.45% vs 89.06 ± 0.47%, p = 0.105) in the two groups were similar. Hyperferritinemia independently increased the risk of grade II-IV acute graft versus host disease (aGvHD) (HR = 2.065, 95% CI 1.139-3.741, p = 0.017), while it had no impact on grade III-IV aGvHD and chronic GvHD. The risk of transplant-related mortality (TRM) at 100 days (6.45 ± 1.80% versus 9.38 ± 3.64%, p=0.413) and 1 year post-transplant (11.44 ± 2.35 % versus 10.96 ± 3.91%, p = 0.973) were not increased in patients with hyperferritinemia. The 3-year overall survival (85.23 ± 2.81% versus 89.04 ±3.91%, p = 0.648) and failure-free survival (83.32% ± 2.91% versus 82.75 ± 4.73%, p = 0.725) were also comparable between patients with and without hyperferritinemia.
Summary/Conclusion: Pre-transplant hyperferritinemia cannot predict transplant outcomes in haplo-HSCT for SAA, and transplant should not be postponed due to high levels of SF in SAA patients. The results should be confirmed in further studies.

EP848 CHANGES IN ERYTHROPOIESIS IN MALARIA-INDUCED ANEMIA

R. Gozzelino [1,*], A. Pêgo [1], I. Lima [1], J. T. da Silva Barros [1], G. Martins [1]

[1]*Chronic Diseases Research Center (CEDOC)/NMS, NOVA Medical School, Lisboa, Portugal*

Background: Severe malarial anemia (SMA) is a disease developed in the course of *Plasmodium* infection, which is often associated with increased rates of malaria-related morbidity and mortality. Despite high levels of erythropoietin (EPO), the occurrence of ineffective erythropoiesis is one of the main features of SMA. To gain new insights into the pathogenesis of malaria infection, changes in erythropoiesis associated with single or multiple infections with *Plasmodium chabaudi chabaudi* were investigated as well as the contribution of the immune system to the development of SMA.
Aims: Previous studies demonstrated that during anemia, proinflammatory cytokines suppress erythropoiesis by promoting iron sequestration through the hepatic hepcidin production. We confirmed that a similar response is presented in our SMA model by analyzing immune activation and the expression of iron metabolism associated genes. These data also showed that iron sensors expression levels, such as transferrin receptor 2 (*Tfr2*) and the hemochromatosis gene (*HFE*), are strictly associated with the disease severity. The extent of an immune response activation upon the exposure to this parasitic infection was also linked to the degree of induced SMA, with T cells playing a major role.
Methods: Flow cytometry analyses were used to show the bone marrow and spleen response during the infection.
Results: The results obtained demonstrated that malaria infection significantly alters the erythropoietic process through the dynamic interaction between inflammation and iron metabolism.
In order to regulate the erythropoietic response in malaria, the spleen increases erythrocyte production and compensate the loss of an appropriate bone marrow erythropoiesis during the infection. This directly correlates with parasite load.
Summary/Conclusion: In conclusion, malaria infection significantly alters the erythropoietic process through the dynamic interaction between inflammation and iron metabolism.

EP849 RELATIONSHIP OF PRE-TRANSPLANT IRON STATUS TO OUTCOMES POST KIDNEY TRANSPLANTATION: A RETROSPECTIVE COHORT

J. J. Simpauco [1,*], L. Bonifacio [1]

[1]*Internal Medicine, National Kidney and Transplant Institute, Quezon City, Philippines*

Background: One of the most important aspects in the care of CKD patients is addressing anemia. Treatment includes iron replacement and blood transfusion which can lead to hemosiderosis. Abnormal iron balance, whether iron deficiency or iron overload is associated with increased mortality in CKD patients. Prospective cohorts showed increased mortality in kidney transplant patients with high post-transplant ferritin levels however no literature regarding the relationship of pre-transplant ferritin status has been published yet.
Aims: To determine the relationship of pre-transplant ferritin and transferrin saturation levels to outcomes post-transplant including overall survival, graft survival and renal function and incidence of hospitalizations.
Methods: The study design is a retrospective cohort. The subjects were 124 post-transplant patients divided into two groups (high ferritin vs. normal ferritin). Demographic data such as age, gender, transferrin saturation, etiology of CKD, duration and mode of renal replacement therapy, type of graft donor and history of blood transfusions were recorded. The outcomes investigated were: (1) Creatinine clearance at one- and three-years post-transplant (2) number of hospitalizations, (3) biopsy-proven graft rejection, (4) need for dialysis and (5) all-cause mortality. The statistical analyses used were univariate and bivariate analyses (chi-square) and multivariate analysis using multiple logistic regression (factor analysis and MANOVA).
Results: Demographic and clinical background for both arms were not significantly different (p >0.05). Patients with high ferritin were more likely to also have high transferrin saturation. (p 0.003). There was significant association between ferritin status pre-transplant and number of hospitalizations post-transplant (p 0.003) which can represent higher morbidity in this subset. No significant difference in terms of one- and three-year renal function, incidence of biopsy-proven graft rejection, need for dialysis post-transplantation or all-cause mortality was elicited between the two groups.

Table 2 Bivariate analysis of different outcomes post kidney transplantation in relation to ferritin levels pre-transplantation

			Normal Ferritin Group	High Ferritin Group	P value
1.	Kidney Function at Year 1	eGFR >60	37	51	0.220
		eGFR <60	15	17	
		Mean eGFR	75.12 (SD 23.6)	77.54 (SD 22.8)	
2.	Kidney Function at Year 3	eGFR >60	43	51	0.134
		eGFR <60	9	17	
		Mean eGFR	72.65 (SD 24.1)	76.98 (SD 23.7)	
3.	Number of hospitalizations		1.29	2.35	**0.003**
4.	Biopsy proven rejection		4	2	0.279
5.	Need for dialysis post-transplant		0	1	0.581
6.	All-cause mortality		1	5	0.198

Summary/Conclusion: There is a strong association between pre-transplant hyperferritinemia and number of hospitalizations after renal transplantations, and therefore a good predictor of morbidity especially infection-related complications.There is no difference in mortality and graft function between renal transplant patients with high and normal pre-transplant ferritin levels. Pre-transplant ferritin and transferrin saturation levels in this group may not be a good predictor for mortality.

EP850 TMPRSS6 POLYMORPHISMS AND A RISK OF IRON DEFICIENCY ANEMIA IN SCHOOL-AGED CHILDREN

R. Udomponglukkana [1,*], N. Sirachainan [2], A. Chuansumrit [2], W. Sasanakul [2], L. Mahaklan [2]

[1]*Ramathibodi Hospital, Mahidol University, Bangkok, Thailand,* [2]*Pediatrics, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand*

Background: In Thailand, the prevalence of iron deficiency anemia (IDA) in children is around 10-16%. Common etiologies of IDA include inadequate iron intake and chronic blood loss. Other than those, mutations in *TMPRSS6* gene have been reported. The *TMPRSS6* gene regulates hepcidin expression by encoding Matriptase-2, an enzyme which cleaves a cofactor promoting hepcidin transcription. With mutations to such gene, the patient has an elevated hepcidin level despite the iron deficiency status and is described as having iron refractory IDA (IRIDA). Several studies show that the *TMPRSS6* gene polymorphisms, for example rs855791 (p.V736A) and rs2235324 (p.K253E), associate with lower iron status. Whether these single nucleotide polymorphisms are associated with an increased risk of developing IDA in our population especially in children is an enticing question.
Aims:
1. To identify the prevalence of *TMPRSS6* gene polymorphism (p.V736A) in the study population
2. To identify the association between the *TMPRSS6* polymorphism (p.V736A) and the risk of iron deficiency anemia in Thai children

Methods: A total of 415 students aged between 9-15 years, from 3 schools were all included in this study. Their blood was taken for complete blood count, iron study and hepcidin assay. Directed by the results, they were then classified into normal, iron depletion (ID) and IDA groups, according to World Health Organization's definition. For DNA study, the DNA containing the p.V736A (c.T2321C) polymorphism was amplified by polymerase chain reaction (PCR) and identified by restriction fragment length polymorphism (RFLP) in all participants. Chi-square test was used to determine the difference in iron status with respect to genotypes (TT, CT and TT). Logistic regression analysis was used to determine its association with serum iron, ferritin and hepcidin levels.
Results: The T allele frequency in this population was 0.6. The percentage of TT genotype was highest in IDA group (48%) compared to ID (36.6%) and normal group (31.9%) although there were no significant differences, *p*-value= 0.226. The TT genotype had significantly lower serum iron when compared to the CT genotype (serum iron mean difference -7.9 [SE 3.2] mmol/L, *p*-value = 0.043 whereas it was not significant when compared to the CC genotype (mean difference -7.4 [SE 4.8] mmol/L, *p*-value = 0.354). There were also no significant differences of hepcidin and ferritin levels among genotypes.
Summary/Conclusion: The TT polymorphism of c.T2321C is common among Thai children with IDA and associates with a lower level of serum iron when compared to the other genotypes. Other polymorphisms of the *TMPRSS6* gene will be further studied to determine additional effects of combined polymorphisms to the iron status.

Lymphoma Biology & Translational Research

EP851 DISSECTION OF MANTLE CELL LYMPHOMA BONE MARROW B LYMPHOCYTES ON THE SINGLE-CELL LEVEL WITH FOCUS ON CLINICAL MARKERS AND SOXC FAMILY MEMBERS

S. V. Hansen [1,*], M. H. Hansen [1], O. Cédile [1,2], M. B. Møller [1], J. Haaber [1], N. Abildgaard [1], C. G. Nyvold [1,2]

[1]Haematology-Pathology Research Laboratory, Research Unit for Haematology and Research Unit for Pathology, University of Southern Denmark and Odense University Hospital, [2]OPEN, Odense Patient data Explorative Network, Odense University Hospital, Odense, Denmark

Background: Mantle cell lymphoma (MCL) is an often rapidly progressing accumulation of lymphocytes with generalized lymphadenopathy, and common involvement of peripheral blood and bone marrow (BM). Translocation t(11;14), leading to overexpression of cyclin D1 (CCND1), is one of the primary events in MCL development.
Aims: Here, we investigate the transcriptome of MCL cells from eight BM samples to provide insight into the complex and diverse molecular architecture of MCL at the single-cell expression level.
Methods: Transcriptome analysis was performed on viable $CD19^+$ cells sorted from diagnostic cryopreserved BM cells of eight MCL patients. All patients had nodal and BM involvement, were positive for CCND1 and SOX11 and displayed an otherwise heterogeneous clinical presentation. A concentration of 1400 cells/µl were used for single-cell mRNA sequencing (ScRNA-seq) using the 10x Chromium System and Illumina NovaSeq 6000. Data analysis was performed with Cell Ranger (10x Genomics) and R (Seurat 3.2).
Results: ScRNA-seq revealed transcriptional inter-tumor heterogeneity across the MCL patients. Expression analysis identified distinct subsets of non-malignant pre-pro B/pro-B cells with similar expression profiles across patients. MCL cells showed enrichment of genes involved in key pathways associated with B cell malignancies, such as PI3K/AKT/mTOR and NFκB.
Generally, the cell populations were transcriptionally defined as $CD20^+CD45^+CD5^{low/-}CD19^{low/-}CD23^{low/-}CD27^{low/-}$. While the light chain restriction was in overall concordant with the clinical laboratory analyses, we found a median of 9.5% (0.1–24.4%) of the light chain expressing cells that were both κ and λ positive. Also, on the single-cell transcription level, we demonstrated that CD23 was present in a subset of the $SOX11^+$ MCL cells (1.45–9.29%), supporting previous findings that some MCLs are CD23+, although this marker is frequently used to differentiate chronic lymphocytic leukemia from MCL. While 85% of all $SOX11^+$ cells were positive for IgM (35–98%) and 17% for IgD (1–43%), all patients had SOX11+ cells expressing IgA (2–47%) and IgG (1–15%), and patient 1–6 had a small $CD27^+SOX11^+$ fraction, suggesting that some of the MCL cells may be antigen-experienced although expected to originate from naïve B cells. While all patients displayed SOX11 and CCND1 expression in concordance to the clinical laboratory results, only 35% of the total single-cell cohort were marked SOX11+, and of the SOX11 positive cells 70.6% (44.59–81.47%) co-expressed CCND1 at a detectable level. Additionally, 4.49% of all cells expressed SOX4, a marker of more immature B cells, and 3.07% of these cells were $SOX11^+$. Not surprisingly, the expression levels of the classical MCL markers such as e.g. SOX11, CCND1, CD5, CD19 and CD20 were highly correlated ($p=0.02$, $\rho=0.99$), even though CD19 and to a larger degree CD5 were only detectable in a subset of cells.
We found that a blastoid MCL case (patient 1) was marked by a subset of cells expressing both SOX11 and SOX4 together with a presentation of protocadherin FAT1, which was exclusively expressed in this patient (20% of SOX11+ cells). FAT1 is a specific marker in acute lymphoblastic leukemia, and SOX4 plays a central role in survival of malignant lymphoblasts, thus these markers, posed for further investigation, may help establish differentiation state and possibly prognosis.
Summary/Conclusion: Our study demonstrates inter-tumor heterogeneity of MCL, characterizes MCL-specific expression profiles and provides insight into clinical markers at the single-cell transcription level.

EP852 WHOLE-GENOME CRISPR LIBRARY SCREENS IDENTIFY CD48 AS AN ESSENTIAL MOLECULE IN ADULT T-CELL LEUKEMIA/LYMPHOMA FOR DEFINING SUSCEPTIBILITY TO NATURAL KILLER CELL-MEDIATED CYTOTOXICITY

M. Chiba [1,*], J. Shimono [1], T. Ishio [1], H. Goto [1], S. Hashino [2], T. Teshima [1], M. Nakagawa [1]

[1]Department of Hematology, Hokkaido University Graduate School of Medicine, [2]Health Care Center, Hokkaido University, Sapporo, Japan

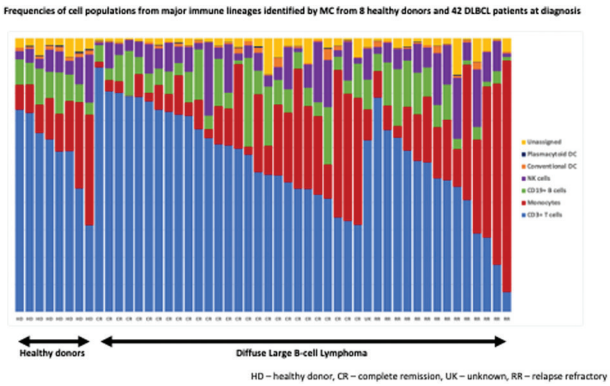
Background: Adult T-cell lymphoma/leukemia (ATLL) is a mature T-cell neoplasm and its prognosis is poor. Human T-cell leukemia virus type 1 (HTLV-1) is the causative retrovirus of ATL and it infects infants' CD4 positive T cell through breast feeding. A fraction of the HTLV-1 infected individuals develops ATLL after more than 50 years. During the long latency period genetic alterations and aberrant gene expression accumulate extensively in ATLL cells. In particular, ATLL has high frequency of somatic mutations, genomic losses and epigenetic silencing in human leukocyte antigen (HLA)-A, HLA-B and β2 microglobulin, highlighting immune escape from T-cells as a hallmark of ATLL. In theory this "missing self" increases susceptibility to natural killer (NK) cell-mediated killing but it remains unknown how ATLL cells evade NK cell-mediated immunosurveillance. In fact, activation of NK cells is controlled by signal integration from multiple stimulatory and inhibitory receptors on their cell surface so that functional elucidation for the key mechanism by which ATLL cells evade NK-mediated immune surveillance remains challenging.
Aims: The aim of this study was to identify ATLL cell-intrinsic molecules which play essential roles for immune evasion from NK cell-mediated cytotoxicity against ATLL.
Methods: Two Cas9-expressing ATLL cell lines were lentivirally transduced with the human clustered regularly interspaced short palindromic repeat (CRISPR) Brunello pooled library (Addgene #73178) of 76,441 single-guide RNAs targeting 19,114 protein-coding genes, selected by puromycin, cultivated for 2 weeks enough to have genes fully inactivated by sgRNAs. The cells were co-cultured with human YT1 NK cells at 1:2 of effector:target ratio for 24-48 hours. Mogamulizumab, anti-human CCR4 monoclonal antibody, was added to the effector/target cell mixture, which enabled us to evaluate the responsible genes for both direct NK cytotoxicity and mogamulizumab-mediated antibody dependent cellular cytotoxicity (ADCC). Resistance genes were those for which the corresponding sgRNAs were enriched in the screening cell pool relative to the cell pool without screening. MAGeCK algorithm was used to rank target genes enriched in the screening.
Results: Twenty genes were overlapped between top-ranked 500 genes in two ATLL cell lines. As a proof of concept, CCR4 was identified as the best overlapped gene, confirming the reliability of our screening. One of the other overlapped genes was CD48, which is a signaling lymphocyte activation molecule (SLAM) family cell surface receptor and is an activating NK cell receptor by ligating 2B4 receptor on NK cells. Through further analysis, the ability of CD48 knockout ATLL cells for evading NK cell-mediated direct cytotoxicity was confirmed by using not only a NK cell line but also human primary NK cells with reduced interferon gamma induction and degranulation. Notably, we found that primary ATLL cells reduced their CD48 mRNA expression along with aggressiveness of clinical subtypes.
Summary/Conclusion: Our findings indicated that CD48 is an essential molecule in ATLL for defining susceptibility to NK cell-mediated cytotoxicity. Thus this study improved our current understanding of the mechanisms for immune evasion in ATLL and provides a rationale for evaluation of CD48 as a biomarker for NK cell-based immunotherapies in the future.

EP853 COMPREHENSIVE CHARACTERIZATION OF THE MUTATIONAL LANDSCAPE IN EPSTEIN-BARR VIRUS-POSITIVE DIFFUSE LARGE B-CELL LYMPHOMA BY WHOLE-GENOME AND TARGETED AMPLICON-BASED SEQUENCING

H. M. Witte [1,*], J. Ketzer [2], T. Dr Rausch [3], V. Dr Benes [3], J. Dr Zimmermann [3], J. Dr Gebauer [4], H. Prof Dr Merz [5], V. Dr Bernard [5], L. Dr Harder [6], K. M. Sc. Ratjen [6], S. Dr Gesk [6], W. Dr Peter [7], J. Busch [7], P. Trojok [7], N. Prof Dr von Bubnoff [2],

H. Dr Biersack [2], A. C. Prof Dr Feller [5], A. Dr Künstner [8], H. Prof Dr Busch [8], N. PD Dr Gebauer [2]

[1]Hematology and Oncology, German Federal Armed Forces Hospital Ulm, Ulm, [2]Hematology and Oncology, University Hospital Schleswig-Holstein Campus Lübeck, Lübeck, [3]European Molecular Biology Laboratory (EMBL), Genomics Core Facility, Heidelberg, [4]Department of Internal Medicine I, University Hospital Schleswig-Holstein Campus Lübeck, [5]Hämatopathologie Lübeck, Reference Centre for Lymph Node Pathology and Hematopathology, Lübeck, [6]Institut für Tumorgenetik Nord, Kiel, [7]HLA Typing Laboratory, Stefan-Morsch-Foundation, Birkenfeld, [8]Medical Systems Biology Group, University of Lübeck, Lübeck, Germany



Background: The current World Health Organization (WHO) classification outlines the Epstein–Barr virus (EBV)-associated diffuse large B-cell lymphoma not otherwise specified (DLBCL NOS) as a distinct entity while its comprehensive genomic characterization remains fragmentary.
Aims: The substantial aim of the present study was to compile an extensive genomic landscape of EBV+ DLBCL (NOS).
Methods: In the current study, the genomic landscape of 47 cases of this rare entity has been characterized by whole-genome sequencing (WGS), targeted amplicon sequencing (tNGS) and fluorescence *in-situ* hybridization (FISH).
Results: Genomic data from WGS detected an accumulation of mutations with impact on WNT signalling (*FRAT1*, *SFRP5*), the nuclear factor κB (NFκB) pathway (*CSNK2A2*, *CARD10*), IL-6/JAK/STAT (*SOCS1/3*, *STAT3*) and alterations affecting immunological response like interferon-related signalling. Moreover, upon WGS-analysis there were several structural aberrations including 6q-deletions in 5/8 cases which underwent subsequent validation by FISH (14/32 cases). Present data reveal a distinctive genomic profile from EBV-negative DLBCL. Frequent typical DLBCL mutations could be identified in *ARID1A* (45%), *KMT2A/D* (32/30%), *ANKRD11* (32%), *NOTCH2* (32%) as well as EBV+ DLBCL (NOS) exclusive mutations in *CCR6* (15%), *DAPK1* (15%), *TNFRSF21* (13%), *CCR7* (11%) and *YY1* (6%).
Summary/Conclusion: We delineate the mutational landscape of EBV+ DLBCL (NOS) and comprehensively explore its pathobiological origin detecting several exclusive oncogenic drivers distinctive from other aggressive B-cell lymphoma subtypes. Moreover, we find deletions on chromosome 6 to be a highly recurrent cytogenetic feature of this rare entity. Current genomic findings contribute to the particular specification of the molecular taxonomy for aggressive B-cell lymphomas harbouring the potential to guide future treatment strategies.

EP854 DISEASE AND OUTCOME ASSOCIATED IMMUNE SIGNATURES AT DIAGNOSIS IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL)

E. Truelove [1,*], J. Taylor [1], F. Seymour [1], A. Clear [1], M. Calaminici [1], J. Gribben [1]

[1]Barts Cancer Institute, London, United Kingdom

Background: Treatment failure after RCHOP is associated with poor outcome in DLBCL. Peripheral blood (PB) absolute monocyte (AMC) and lymphocyte (ALC) counts at diagnosis can predict outcome, but the mechanism is unknown.
Aims: To characterise and functionally define the PB immune compartment in DLBCL.
Methods: Full blood counts (FBC) from 116 healthy donors and 146 previously untreated DLBCL patients were assessed. Twenty cytokines were measured in duplicate in serum from healthy donors (HD, n=11) and DLBCL patients at diagnosis (n=64) using the mesoscale discovery electrochemiluminescence platform. Peripheral blood mononuclear cells (PBMCs) from HD (n=8) and DLBCL patients (n=42) were analysed by mass cytometry (MC) to phenotype immune cell populations in depth. An intracellular cytokine staining MC protocol was applied to a subset of these PBMC samples for functional assessment. A standard HD control sample was acquired with each MC batch. Normalised data were analysed using the OMIQ platform.
Results: The median AMC was higher and ALC lower in DLBCL ($p<0.0001$). The AMC / ALC prognostic score defined 3 groups with distinct outcome in DLBCL ($p<0.0001$). Eight of 20 cytokines analysed were elevated in DLBCL, with 5 of these cytokines (CCL3, TNF, IL1RA, IL6 and IL10, $p<0.05$) significantly higher at diagnosis in patients who subsequently had relapse/refractory disease post RCHOP (R/R) compared to those with maintained complete remission (CR). Cytokine levels were independent of cell of origin (COO) except for IL1RA which was elevated in non-GCB.
Gated immune populations identified by MC were assessed for significant differential abundance with edgeR (FDR<0.05). Intermediate and non-classical monocytes were higher in DLBCL, whereas CD4 effector memory (EM1) and CD8 central memory (CM) were higher in HD. Within DLBCL samples, non-classical monocytes and CD8 effector memory (EM3) were more abundant in patients with subsequent R/R disease. FlowSOM clustering followed by edgeR analysis revealed 3 monocyte clusters at diagnosis associated with disease relapse. The most differentiating cluster consisted of classical monocytes with a suppressor phenotype ($CD14^{hi}$, $HLA\text{-}DR^{lo}$) and expression of CD163 and CD184. The most differentiating T cell cluster associated with subsequent relapse had a CD8 EM3 phenotype. These findings were independent of COO.
Functional analysis revealed constitutive over production of CCL3 and IL6 in DLBCL, predominantly by CD14+ monocytes ($p=0.0025$). Stimulation with LPS demonstrated blunted cytokine production responses in DLBCL, most pronounced in cases that relapsed. Stimulation with PMA/inomycin demonstrated no evidence of PB T cell exhaustion, with hypersensitivity of TNF and IL2 production in DLBCL, predominantly by CD4 T cells. Activated granzyme B / perforin positive NK cells were increased in DLBCL.

Summary/Conclusion: We find distinct immune cell and cytokine signatures associated with DLBCL and with outcome following RCHOP. Specifically, we identify cytokine overproduction in DLBCL, the main PB source being CD14+ monocytes, suggesting a non-cell autonomous role for PB cytokine production in DLBCL. We identify immune populations by manual gating and FlowSOM clustering with differential abundance in DLBCL and in those cases that subsequently relapsed, reflecting immune dysfunction associated with disease and outcome. Our data provide an explanation for the prognostic nature of the AMC /ALC, support the challenge to identify biomarkers and provide insight into steps that may be required to overcome the immune defects in RCHOP refractory DLBCL.

EP855 ROLE OF PROTEIN KINASES CK1 ALPHA AND CK2 IN CHRONIC ACTIVE BCR-DEPENDENT SIGNALING NETWORK IN MANTLE CELL LYMPHOMA: EFFECTS ON BTK-DIRECTED THERAPY.

S. Manni [1,2,*], Z. Spinello [1,2], A. Fregnani [1,2], A. Arjomand [1,2], L. Quotti Tubi [1,2], A. Visentin [1,2], L. Trentin [1,2], G. Semenzato [1,2], F. Piazza [1,2]

[1]University of Padova, Department of Medicine, [2]Veneto Institute of Molecular Medicine, VIMM, Padova, Italy

Background: Mantle cell Lymphoma (MCL) is a B cell tumor, characterized by frequent relapses. Chronic activation of multiple signaling pathways, including BTK, PI3K/AKT and NF-κB are of pathogenic importance in MCL. New drugs targeting the B Cell Receptor (BCR) dependent signaling pathways, such as ibrutinib, acalabrutinib, zanubrutinb and other BTK inhibitors, have been proved therapeutically efficient in MCL, but the disease remains uncurable. To this regard, there is an urgent need to discover novel druggable targets. We and others

demonstrated that two Ser-Thr kinases, namely protein kinases CK1α and CK2, are essential kinases for the survival of multiple myeloma (MM) cell, acute myeloid leukemias, lymphomas and other hematological malignancies, regulating pivotal survival signaling events. We therefore sought to investigate a potential role of these kinases in MCL downstream the BCR signalling

Aims: In the present study we analyzed the role of CK1α and CK2, in the regulation of chronic active, BCR dependent signaling pathways in MCL, such as NF-κB, BTK and AKT, and the potential of their inhibition in association with the BTK inhibitor ibrutinib, to effectively reduce MCL cell growth and clonal expansion.

Methods: CK1α and CK2 expression and BCR signaling components were analyzed in MCL cells from patients, MCL cell lines and controls by western blot (WB). CK1α or CK2 silencing was obtained through the generation of anti-CK1α or anti CK2 shRNA IPTG-inducible MCL cell clones. CK1 or CK2 chemical inhibition was obtained with D4476 (CK1i) or CX-4945 (CK2i). Cell survival/apoptosis and proliferation were investigated with an array of standard techniques and the therapeutic interaction between drugs was analyzed through the Chou-Thalalay combination index method. CK2 knock down *in vivo* was obtained in xenograft NOD SCID mouse models.

Results: CK1α and CK2 are overexpressed in MCL cells compared to healthy B lymphocytes. CK1 or CK2 chemical inhibition with D4476 or CX-4945 respectively, caused, a reduction in the activating phosphorylation of S536 p65/RelA and S473 AKT, important signaling events downstream the BCR. CK1α or CK2 were shown to sustain MCL cell growth and proliferation, since their chemical inhibition or gene silencing caused MCL cell apoptosis and cell cycle arrest. We discover a novel, unanticipated potential role of these two kinases in regulating BTK function, since their chemical inhibition or silencing with RNAi, caused a reduction in the activating phosphorylation of BTK on Y223. We confirmed these results also in an *in vivo* xenograft mouse model of CK2 knockdown. As a result, a striking cytotoxic effect on MCL cells was obtained through the combination of CK1α or CK2 inactivation with ibrutinib, as demonstrated by increased apoptotic Annexin V positive cells, PARP cleavage, reduction in pro-survival protein expression such as Mcl1 and pro-caspase 3. CK1i or CK2i acted synergically with ibrutinib, since the calculated combination index between the drugs (according to the Chou-Talalay methods) resulted less than 1,

Summary/Conclusion: Our findings suggest that CK1α and CK2 are fundamental kinases for MCL growth, regulating chronic active BCR-linked survival signaling cascades. Our data also indicate that these kinases could antagonize ibrutinib -induced apoptosis. Therefore, CK1α and CK2 could be rational therapeutic targets for the treatment of MCL, particularly those aggressive, ibrutinib-resistant forms.

EP856 HIGH RISK AGGRESSIVE B-CELL LYMPHOMA ON THE LIQUID BIOPSY

L. Meriranta [1,2,*], A. Alkodsi [1], A. Pasanen [1,2], M. Lepistö [3], Y. N. Blaker [4], J. Jørgensen [5], P. Mapar [3,6], M. Björkholm [7], M. Jerkeman [8], H. Holte [4], E. Pitkänen [3,6], P. Ellonen [3], S. Leppä [1,2]

[1]Applied Tumor Genomics Research Program, University of Helsinki, [2]Department of Oncology, Helsinki University Hospital Comprehensive Cancer Centre, [3]Institute for Molecular Medicine Finland, Helsinki, Finland, [4]Department of Oncology, Oslo University Hospital, Oslo, Norway, [5]Department of Hematology, Aarhus University Hospital, Aarhus, Denmark, [6]HiLIFE & Applied Tumor Genomics Research Program, University of Helsinki, Helsinki, Finland, [7]Department of Medicine, Karoliska Institutet, Stockholm, [8]Department of Oncology, Lund University, Lund, Sweden

Background: Inadequate molecular recognition of high-risk diffuse large B-cell lymphoma (DLBCL) hampers the discovery of novel treatments for the patients with poor outcome. Clinical significance and prognostic impact of circulating tumor DNA (ctDNA) warrants establishment in prospectively collected samples from homogeneous patient populations.

Aims: We aimed to delineate molecular determinants of outcome within the ctDNA of the patients with aggressive B-cell lymphoma.

Methods: We applied whole-genome and targeted duplex DNA sequencing to serially sampled plasma cell-free DNA of 101 patients less than 65 years with high-risk (aaIPI 2-3 and/or site-specific risk factors for central nervous system (CNS) progression) aggressive B-cell lymphoma. The patients were treated in a Nordic Lymphoma Group phase II trial with dose-dense immunochemotherapy and early CNS prophylaxis (Leppä et al., Blood Advances 4(9):1906-1915, 2020).

Results: We found that the patients with high pretreatment ctDNA burden (log hGE/ml) were at high risk of relapse and early death from lymphoma. In contrast, non-lymphoma related treatment failures were mainly seen in the patients with low to moderate ctDNA levels. High ctDNA burden overcame the conventional measures of high tumor burden and other high-risk features including double-hit lymphomas, revealing that additional clinically meaningful heterogeneity exists within the established clinical and biological risk factors.

Treatment refractoriness exhibited diverging ctDNA kinetics during therapy, whereas late molecular responses, and end-of-treatment negativity for minimal residual disease characterized cured patients. As a proof-of-concept, we show that advanced ctDNA tools based on hypermutation patterns and fragmentome disparities can complement prediction of progression at the end of therapy, and provide tools to clinical challenges, including false residual PET positivity.

Lastly, we analyzed the potential of non-invasive ctDNA interrogation for somatic drivers, hypermutation signatures and variant haplotypes to offer novel translational information for diagnostics and understanding of treatment-refractoriness in patients with aggressive B-cell lymphoma. Genomic dissection of pretreatment ctDNA revealed a strong association between *TP53*-loss and high ctDNA burden – a duo that in the context of high-risk biology rendered lymphomas refractory to frontline treatment. In contrast, subclonal *MYC* lesions that were not detectable at diagnosis were positively selected at late relapses following complete responses to the initial therapy. We further identified that the limitations of tissue biopsies can culminate in diagnosis-changing discoveries in plasma ctDNA, including progression-driving transformation to high-grade B-cell lymphoma.

Summary/Conclusion: Our integrative approach with prospectively collected serial plasma samples reveals that quantitative, mutational and fragmentome features of ctDNA can be utilized as novel diagnostic and prognostic tools in aggressive B-cell lymphomas.

EP857 DDX3X LOSS IS ASSOCIATED WITH AGGRESSIVE PHENOTYPES IN NON-HODGKIN'S LYMPHOMAS

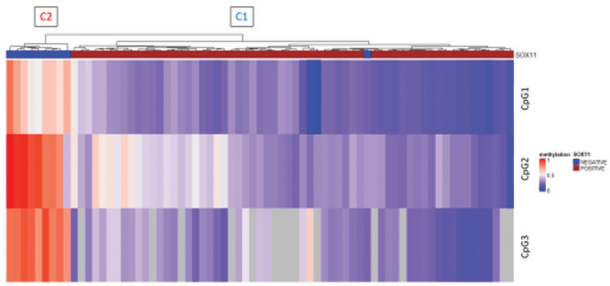
Background: Non-Hodgkin's lymphoma (NHL) is a diverse group of haematolymphoid malignancies, encompassing the more common diffuse large B-cell lymphoma (DLBCL) to the rarer T-cell lymphomas such as cutaneous T-cell lymphoma (CTCL). Several groups have performed comprehensive genomic analysis of various subtypes of NHL including DLBCL using whole exome sequencing (WES) and identified frequent occurrence of mutation in the *DEAD box helicase 3, X-linked* (*DDX3X*) gene. DDX3X is an RNA helicase and, depending on tumour type, plays a tumour suppressive or oncogenic role in cancer. However, its role in NHL remains unclear.

Aims: - To examine the mutational status of DDX3X in NHLs.
- To determine the molecular effects of DDX3X loss in cells derived from NHLs.



- To define functional involvements of DDX3X in NHLs.
Methods: We performed exome sequencing to identify genomic aberrations in *DDX3X* gene in DLBCL patients. Next, we generated CRISPR variants/ shRNA knockdown models of NHL cells line to mimic DDX3X mutation/loss. We determined the molecular effects of DDX3X loss by performing RNAseq analysis and immunoblot assay. We performed MTS and Annexin V/PI-based cell viability assays, BrdU proliferation assay, impedance-based metastasis assay and checkerboard assay to understand the functional involvement of DDX3X loss in NHLs.
Results: Targeted sequencing of *DDX3X* hotspots on exons 8-15 in a cohort of 158 unselected DLBCL subjects showed *DDX3X* mutations in 5 cases; whereas whole exome sequencing identified *DDX3X* mutations in 4 out of 9 patients with relapsed/refractory DLBCL treated with R-CHOP (rituximab + cyclophosphamide/ doxorubicin/vincristine/ prednisone). DLBCL patients (n=223) with *DDX3X* mutations had worse 5-year overall survival (22%) compared to patients with wild-type *DDX3X* (72%, p=0.021). Using NHL cell lines, we showed that the expression of mutant DDX3X-R475C or DDX3X knockdown caused significant up-regulation of cyclin-D1 and increased phosphorylation of oncogenic STAT3, Akt and p42/44. We demonstrated that DDX3X loss enhances proliferation and metastasis in DDX3X R475C-mutant/depleted NHL cells. DDX3X loss increased resistance to doxorubicin and histone deacetylase targeting drugs in DLBCL and CTCL cells, respectively. Importantly, B- and T-cell lineage DDX3X-depleted cells remained sensitive to STAT3 inhibition.
Summary/Conclusion: In conclusion, our data suggest that loss-of-function mutations in *DDX3X* are important molecular determinants of disease aggressiveness and treatment response in NHL. These data will help improve risk stratification of NHL may identify new therapeutic options for a subgroup of patients with poor prognosis.

EP858 A SIMPLE EPIGENETIC SIGNATURE DEFINES TWO BIOLOGIC GROUPS OF MANTLE CELL LYMPHOMA

M. Bühler [1,2,*], M. Kulis [1], M. Duran-Ferrer [1], G. Clot [1], F. Nadeu [1,3], A. Navarro [1,3], C. López [1,3], E. Giné [1,3], S. Beà [1,3], E. Campo [1,3], J. I. Martín-Subero [1]

[1]IDIBAPS, Hospital Clínic Barcelona, Barcelona, Spain, [2]Department of Pathology and Molecular Pathology, University Hospital Zurich, Zurich, Switzerland, [3]CIBERONC, Centro de Investigación Biomédica en Red de Cáncer, Madrid, Spain

Background: Mantle cell lymphoma (MCL) is a mature B cell lymphoma with a generally poor prognosis. However, in the past decade a subset of MCL with more indolent clinical course and predominant leukemic disease, termed leukemic non-nodal MCL (nnMCL), has been identified. It is important to confidently diagnose the two MCL subtypes in order to tailor treatment decisions based on their remarkably different clinical course. Current strategies in the differential diagnosis between nnMCL and conventional MCL (cMCL) include SOX11 expression and a gene expression signature (L-MCL16, Clot G et al., *Blood* 2018), but both methods present limitations which pose difficulties in clinical practice (e.g. low or partial expression of SOX11, L-MCL16 designed for peripheral blood samples). The epigenetic characterization of MCL (Queirós AC et al., *Cancer Cell* 2016 and Nadeu F et al., *Blood* 2020) identified two disease subtypes (C1 and C2), which mostly represent cMCL and nnMCL respectively. Furthermore, a *SOX11* distal enhancer region was discovered, which is *de novo* demethylated in SOX11 positive MCL.
Aims: Our study aims to translate the epigenetic subtypes of MCL into a simple assay, which can be easily implemented in clinical practice and universally applied to all types of clinical samples. Secondly, we aim to analyze the impact of the epigenetic disease subtype on clinical outcome in an extended series of cases. Lastly, we aim to characterize the DNA methylation profile of regulatory regions of *SOX11* to better understand the relationship between its expression and the C1 and C2 MCL subtypes.
Methods: We identified a 3 CpG signature (Duran-Ferrer M et al., *Nature Cancer* 2020) that accurately subclassifies MCL into C1 and C2 MCL. To overcome limitations of previous methodologies, we designed pyrosequencing assays that can be applied to any type of clinical sample, including frozen and formalin-fixed paraffin-embedded (FFPE) tissues, as well as peripheral blood samples. Extracted DNA was bisulfite converted, amplified by PCR and pyrosequenced for quantitative methylation analysis. Benchmarking experiments for validation of the assays were performed assessing technical reproducibility and methylation level comparison between different source of samples from the same patient (frozen, FFPE, peripheral blood).
Results: Benchmarking experiments show an excellent technical reproducibility and high correlation between different sample types of the same patient. The exploratory study shows a clear separation in two groups, which correspond to C1 and C2 MCL (Figure). C1 MCL show SOX11 positivity by immunohistochemistry, except for one single cases of pleomorphic MCL. All SOX11 expressing MCL show a consistent demethylation in the *SOX11* distal enhancer and promoter region, whereas a majority of SOX11 negative cases have high methylation levels in one of the regulatory regions, indicating that the DNA methylation status of *SOX11* regulatory regions might represent a *bona fide* surrogate of its expression status.

Summary/Conclusion: Our study highlights the stability and applicability of a methylation signature to classify MCL subtypes. Analysis of the methylation signature in an extended series of cases is currently ongoing and will allow us to determine the prognostic significance of the epigenetic subtype of MCL. This epigenetic signature applicable to any type of clinical samples may represent a novel and accurate tool for the differential diagnosis of cMCL and nnMCL in clinical routine.

EP859 EZH2 INHIBITOR TAZEMETOSTAT DEMONSTRATES ACTIVITY IN PRECLINICAL MODELS OF BRUTON'S TYROSINE KINASE INHIBITOR-RESISTANT MANTLE CELL LYMPHOMA

J. Keats [1], A. Lee [1], V. Estanek [1], J. Cunniff [1], W. Chen [1], R. Mehovic [1], I. Shegani [1], C. Markwood [1], C. Tang [1], D. T. Dransfield [1], J. L. Kutok [1], V. Gibaja [1], A. Raimondi [1,*]

[1]Research, Epizyme, Inc., Cambridge, United States

Background: Tazemetostat (EZM6438) is a potent, orally bioavailable small molecule inhibitor of EZH2, the enzymatic subunit of the polycomb repressive complex 2, which has been approved for treatment of epithelioid sarcoma and relapsed/refractory follicular lymphoma. EZH2 has been shown to play a key role in B-cell maturation and multiple B-cell malignancies are dependent on EZH2 for survival. Mantle cell lymphoma (MCL) is a rare subtype of mature B cell non-Hodgkin lymphoma characterized by the t(11;14)(q13;q32) translocation leading to overexpression of cyclin D1, which plays a significant role in tumor cell proliferation via cell cycle dysregulation, chromosomal instability and epigenetic regulation. This disease most often presents at an advanced stage and while most of the patients respond to frontline therapy (including Bruton's Tyrosine Kinase (BTK) inhibitors) they eventually relapse. The rate of intrinsic and acquired resistance results in a high unmet medical need.
Aims: Investigate if tazemetostat, as monotherapy or in combination with standard of care (SOCs) or emerging therapies, could offer therapeutic benefit to the BTK inhibitor-resistant MCL population.
Methods: *In vitro* 14-day proliferation assays assessed the activity of tazemetostat in MCL cell lines. *In vitro* proliferation assays in a panel of MCL cell lines evaluated the combinatorial potential of tazemetostat and SOCs or emerging therapies by pre-treating cells with tazemetostat for 7 days followed by co-treatment for 7 days with tazemetostat and combination partners. *In vitro* 10-day assays evaluated the *ex vivo* effect of tazemetostat on tumor B-cell proliferation from MCL patient samples. MCL cell line murine xenograft study assessed tumor growth delay in response to treatment with tazemetostat, BTK inhibitor zanubrutinib and their combination. ELISA assessed the intratumoral levels of H3K27me3.

Results: We demonstrated that tazemetostat synergized with zanubrutinib and resensitized a subset of cell lines that were intrinsically resistant to BTK inhibitors. *In vivo* studies in the MCL MINO cell line-derived murine xenograft model confirmed these findings, showing a significant tumor growth delay in response to combination treatment of tazemetostat and zanubrutinib compared to the single agent treatments with concomitant decrease in intratumoral levels of H3K27me3. To understand if tazemetostat could offer therapeutic benefit in the BTK inhibitor-acquired resistant MCL population, we generated *in vitro* MCL models of acquired resistance to the BTK inhibitors ibrutinib and zanubrutinib. These cell lines retained the *in vitro* sensitivity to tazemetostat observed in the parental cell line, suggesting tazemetostat as a potential therapeutic option in the setting of acquired resistance to BTK inhibitor. In addition, synergy was observed in *in vitro* combination studies with tazemetostat and lenalidomide, glucocorticoid receptor agonists and venetoclax in these cell line models. Lastly, we showed that tazemetostat induced anti-proliferative effects in samples derived from MCL patients that were relapsed or refractory to one or more current standard of care agents, including the BTK inhibitor ibrutinib. Subsequent studies aim to identify the mechanisms of growth inhibition driven by tazemetostat in MCL models, sensitive and resistant to BTK inhibitors.
Summary/Conclusion: Our data suggest that tazemetostat treatment (alone or in combination with a BTK inhibitor, SOCs or emerging therapies) could be a therapeutic option in the treatment of the MCL patient population that is relapsed/refractory to BTK inhibitor therapy.

EP860 NEXT GENERATION SEQUENCING PROVIDES NOVEL MOLECULAR MARKERS FOR MINIMAL RESIDUAL DISEASE MONITORING IN FOLLICULAR LYMPHOMA: BIOLOGICAL RESULTS FROM FONDAZIONE ITALIANA LINFOMI (FIL) FOLL12 TRIAL

Background: Despite immunochemotherapy provides durable responses in follicular lymphoma (FL) patients, the majority of them eventually relapse. Minimal residual disease (MRD) analysis, based on the detection of Bcl-2/IGH rearrangement by highly sensitive polymerase-chain reaction (PCR), is a standardized approach, able to early identify patients at risk of disease recurrence. Nevertheless, this tool has some limitations, including a 40% failure of marker identification. Next-generation sequencing (NGS) is going to overcome these issues, possibly increasing the number of patients eligible for MRD.
Aims: To screen by NGS a cohort of 120 FL who failed Bcl-2/IGH marker identification by standardized EuroMRD PCR, enrolled in the FIL "FOLL12" prospective clinical trial (EudraCT: 2012-003170-60), in order to identify new markers for MRD tracking during the follow-up (FU). First results of marker identification are here described, while complete MRD results will be presented elsewhere.
Methods: Advanced FL received upfront R-CHOP or BR, followed by a combined PET/MRD response-based post-induction therapy vs conventional maintenance with rituximab. Bone marrow (BM) samples were centralized at the Italian Network laboratories for MRD analysis. Baseline molecular evaluation was available for 615/628 cases who achieved PET negativity at end of induction. 270 of them (44%) lacked a conventional Bcl-2/IGH marker. Therefore, 163 (60%) were selected for BM lymphoma infiltration (median 25%, 1-90%), of whom 120 (74%) had available samples for analysis. Baseline gDNA was screened by IGH-NGS using EuroClonality-NGS framework region 1 (FR1) primers; IGH clonotypes identification was done by ARReST/Interrogate. In parallel, targeted locus amplification (TLA) on the IGH enhancer was used to identify novel Bcl-2/IGH rearrangements in a preliminary cohort of 15 patients. Finally, to test the reliability of newly identified markers, we generated patient-specific primers and carried out MRD analysis by ASO qPCR following EuroMRD guidelines in three cases.
Results: 111/120 (93%) sequenced samples passed the quality control (>10000 raw reads). A clonotype (>5% of IGH-VDJ annotated reads) was identified in 56% (63/111): 61 monoclonal and 2 biclonal, 54 productive and 9 unproductive IGH rearrangements (Figure 1). Moreover, in 8/15 (53%) patients screened by TLA a novel Bcl-2/IGH rearrangement was found; interestingly, TLA was able to identify a marker in 2 out of 5 cases failed by IGH-NGS. Finally, the reliability of these markers for MRD detection was preliminary assessed in three patients by ASO qPCR (targeting one Bcl2/IGH and two IGH rearrangements). The assays reached high level of sensitivity (from 1E-04 to 5E-05) and MRD kinetics in FU well described patients' outcome.

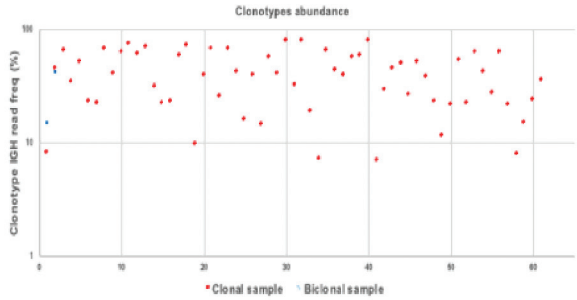

Figure 1.
Clonotypes identification in baseline BM of "no marker" patients by EuroClonality IGH-based NGS approach.

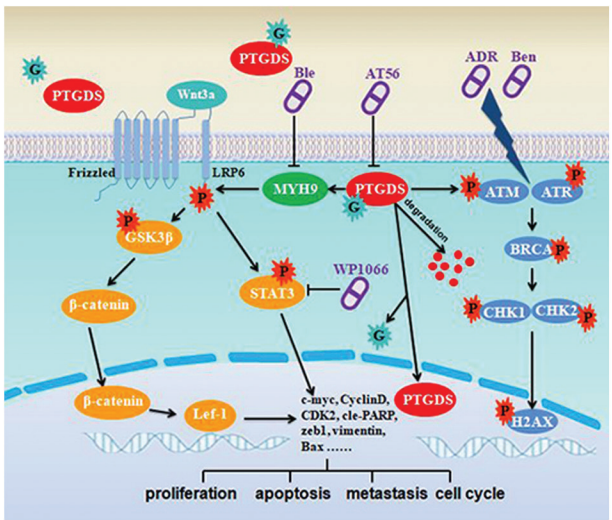
Summary/Conclusion: Preliminary data on wide NGS-based marker screening in FL patients lacking a conventional MRD marker in a clinical trial suggested that: 1) EuroClonality-NGS IGH approach was able to provide a new marker in more than half of the patients with BM infiltration; 2) TLA approach showed similar success rates in a small patients group (further experiments are ongoing); 3) the two techniques are not alternative and should rather be considered as complementary; 4) the new markers allowed to perform a "proof of concept" MRD monitoring by ASO qPCR, according to the strict EuroMRD rules. These data are highly promising to provide a MRD marker in the majority of FL patients: next steps of the present project will evaluate MRD by NGS in FU samples and assess its clinical impact.

EP861 PRMT5 INHIBITION RESTARTS A PRO-APOPTOTIC PROGRAM AND CREATES VULNERABILITY TO COMBINATION TREATMENT WITH BCL-2 INHIBITOR VENETOCLAX IN MANTLE CELL LYMPHOMA

F. Brown [1,*], I. Hwang [2], S. Sloan [1], C. Hinterschied [1], J. Helmig-Mason [1], M. Long [1], Y. Youssef [1], W. Chan [1], A. Prouty [1], J. Chung [1], Y. Zhang [3], K. Vaddi [3], S. Chen-Kiang [2], M. DiLiberto [2], O. Elemento [4], L. Sehgal [1], L. Alinari [1], P. Scherle [3], R. Lapalombella [1], J. Paik [2], R. Baiocchi [1]

[1]Internal Medicine, Division of Hematology, The Ohio State University, Columbus, [2]Pathology and Laboratory Medicine, Weil Cornell Medicine, New York, [3]Prelude Therapeutics, Wilmington, [4]Physiology and Biophysics, Weil Cornell Medicine, New York, United States

Background: Mantle cell lymphoma (MCL) is an incurable B cell malignancy comprising 3-6% of non-Hodgkin lymphomas diagnosed annually. MCL is associated with a poor prognosis due to emergence of resistance to immuno-chemotherapy and targeted agents. Due to the late median age of diagnosis, aggressive chemotherapy and stem cell transplantation are often not realistic options. The average overall survival of patients with MCL is 4-6 years and for the majority of patients who



progress on targeted agents like ibrutinib, survival remains at a dismal 3-8 months. There is a major unmet need to identify new therapeutic approaches that are well tolerated by elderly patients to improve treatment outcomes and quality of life.
Our group has identified the type II protein arginine methyltransferase enzyme, PRMT5, to be dysregulated in MCL and to promote growth and survival by supporting cell cycle progression, survival, and drug resistance. While we have demonstrated that novel SAM-competitive PRMT5 inhibitors provide potent anti-tumor activity in aggressive preclinical models, we have seen resistance and relapse.
With PRMT5i we have seen a decrease in AKT activity which in turn releases FOXO1 from a phosphorylated, inactive form. Performing ChIP seq on FOXO1 resulted in over 800 target genes likely to be regulated by this transcription factor. Among these genes, pro-apoptotic BCL2 family proteins were seen as a potential indicators of a change of pro-apoptotic threshold with PRMT5i. This prompted us to pursue co-inhibition of PRMT5 and BCL as a synergistic treatment in MCL.
Aims: To validate PRMT5 and BCL2 inhibition as a synergistic combination strategy in in vitro and in vivo models of MCL.
To confirm the role of FOXO1 and the BCL2 family proteins in any seen synergy.
Methods: Nine MCL cell lines were treated with PRMT5 inhibitor PRT382, at their IC50 at day nine and collected on day six. Immunoblots and rtPCR were used to look at changes in protein and transcript levels. Cells were treated alone and in combination with venetoclax. Synergy was calculated with an MTS read out on day nine and analyzed with Combenefit. shRNA clones were generated with a lentiviral transfection and viability was measured with annexin V/PI flow cytometry. Two murine paitient derived xenograft models, PDX.AA.MCL and PDX.IR.96069 were engrafted via tail vein in NSG mice. Disease burden was monitored weekly via flow cytometry.
Results: Eight of the nine MCL reached an IC50 of <1uM after nine days of PRT382 treatment. Collected samples showed an upregulation of BAX, BAK1, BBC3, and BMF in at least one cell line on a transcript and protein level. BAX was found to be the most ubiquitously upregulated. While only four cell lines were found to be sensitive to venetoclax treatment, seven showed synergy when treated with both drugs. Cell death was confirmed to be intrinsic and synergy was found to be dependent on BAX expression. Combination treatment with well-tolerated doses of PRT382 and venetoclax in the MCL *in vivo* models showed synergistic anti-tumor activity without evidence of toxicity. Both PDX models showed an extension of life with combination treatment (P<0.001) and delayed disease progression (P<0.05).
Summary/Conclusion: This preclinical data provides mechanistic rationale while demonstrating therapeutic synergy and lack of toxicity in this preclinical study and justifies further consideration of this combination strategy targeting PRMT5 and BCL2 in MCL in the clinical setting.

EP862 TARGETING GLYCOPROTEIN PTGDS INHIBITS THE PROGRESSION OF DIFFUSE LARGE B-CELL LYMPHOMA THROUGH MYH9-WNT-B-CATENIN/STAT3 AXIS

S. Hu [1,2,*], X. Zhou [1,2], S. Ren [1,2], Y. Cai [1,2], J. Liu [1,2], Y. Han [1,2], Y. Zhao [1,2], J. Yang [1,2], X. Wang [1,2]

[1]hematology, Shandong Provincial Hospital Affiliated to Shandong University, [2]hematology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: Glycoprotein prostaglandin D2 Synthase (PTGDS) is a member of lipocalin superfamily and plays a dual role in catalyzing the conversion of PGH2 to PGD2 and transporting lipophilic substances. AT56 is a selective inhibitor of PTGDS. PTGDS has been involved in several cellular processes including cancer, yet its role in carcinogenesis is contradictory.
Aims: Herein, we aim to investigate the functional significance of PTGDS in DLBCL and propose a novel therapeutic strategy for DLBCL.
Methods: Peripheral blood mononuclear cells were obtained from healthy volunteers. Lymph node biopsies from 53 DLBCL patients and 28 reactive hyperplasia cases were collected with informed consents. $CD19^+$ B cells were purified by $CD19^+$ magnetic microbeads. Expression level of PTGDS was detected by western blotting and ELISA. Lentivirus vectors were transfected to stably knockdown or overexpress PTGDS. CoIP and mass spectrometry were performed to investigate molecular mechanism. Point mutations were created to verify glycosylation sites. BALB/c nude mice were subcutaneously injected with DLBCL cells and mice were imaged using *In-Vivo* small animal imaging system. $p < 0.05$ was considered statistically significant.
Results: Upregulation of PTGDS mRNA in DLBCL was identified based on Oncomine database. The expression level of PTGDS protein was high in DLBCL tissues and serum, which was associated with poor prognosis. High expression of PTGDS protein was also confirmed in DLBCL cells. PTGDS overexpression and rhPTGDS were found to promote cell proliferation. PTGDS knockdown significantly restrained cell proliferation, promoted cell cycle arrest and cell apoptosis. AT56 suppressed cell proliferation, induced G0/G1 phase arrest and increased cell apoptosis in a dose- and time-dependent manner. AT56 also enhanced sensitivity to Bendamustine and Adriamycin. Besides, *in vivo* studies indicated PTGDS knockdown and AT56 exerted anti-tumor effect in DLBCL.
CoIP and mass spectrometry indicated PTGDS interacted with oncogenic factor, MYH9. PTGDS inhibition reduced expression of MYH9 and inhibited activation of Wnt-β-catenin/STAT3 pathway. Moreover, Wnt3a rescued the inhibitory effect of AT56 on malignant behaviors, including cell proliferation, cell cycle arrest and cell apoptosis. Besides, the role of AT56 on Wnt pathway could be reversed by Wnt3a. The proliferation inhibition and apoptosis induction caused by AT56 were enhanced by WP1066 while WP1066 reversed proliferation promotion caused by PTGDS overexpression. The enhanced proliferation by PTGDS overexpression was restored by Blebbistatin and it restored the activation of Wnt-β-catenin/STAT3 pathway caused by PTGDS overexpression.
We confirmed the N-glycoprotein of PTGDS protein in Asn 51 and Asn78 via point mutation and the abnormal glycosylation resulted in nuclear translocation, prolonged half time and enhanced oncogenic role.

Summary/Conclusion: Our investigations identified for the first time the oncogenic role of PTGDS in DLBCL tumorigenesis. Expression of PTGDS was upregulated and associated with prognosis of DLBCL patients. Besides, *in vitro* and *in vivo* studies indicated that PTGDS knockdown and AT56 treatment exerted anti-tumor effect through regulating through MYH9-Wnt-β-catenin/STAT3 axis. This study suggests that PTGDS could be a potential molecular target for DLBCL treatment and highlights the potential role of AT56 as a novel therapeutic strategy for DLBCL.

EP863 A CIRCULAR RNA EXPRESSION SIGNATURE PREDICTS DISMAL OUTCOME IN MANTLE CELL LYMPHOMA: A STUDY OF YOUNGER PATIENTS FROM THE NORDIC MCL2 AND MCL3 CLINICAL TRIALS

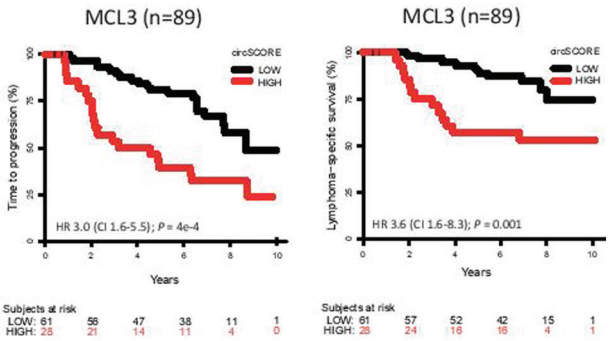
Aarhus University, Aarhus, Denmark, [6]Department of Immunotechnology, Lund University, Lund, Sweden, [7]Department of Oncology, Oslo University Hospital, Radiumhospitalet, Oslo, Norway, [8]Department of Hematology, Helsinki University Hospital, Helsinki, Finland, [9]Division of Oncology, Lund University, Lund, Sweden, [10]Department of Molecular Biology and Genetics, [11]Department of Biomedicine, Aarhus University, Aarhus, Denmark



Background: The outcome for patients with Mantle Cell Lymphoma (MCL) has markedly improved after introduction of cytarabine-containing chemoimmunotherapy followed by autologous stem cell transplant (ASCT). Despite the improved survival, a continuous relapse pattern, even beyond ten years, is observed and consequently a strong need for prognostic biomarkers to support clinical decision making, persists.

Circular RNAs (circRNAs) are endogenous non-coding RNA molecules with tissue and disease specific expression patterns, that serve gene-regulatory functions in cells, and might be implicated in carcinogenesis. Because circRNAs are highly stable with much longer half-lives than mRNAs they are promising for use as biomarkers in cancer. We have previously shown that circRNAs can be accurately quantified in samples from patients with B cell malignancies using the nanostring nCounter technology *(Dahl et al., Lab. Invest. 2018)*. Thus, a potential for a seamless implementation of a circRNA based biomarker into clinical practice, exists.

Aims: We aimed to perform a genome-wide profiling of circRNA expression patterns in MCL and to examine the prognostic potential of selected circRNAs in MCL using diagnostic samples from patients enrolled in the MCL2 and MCL3 clinical trials, amounting to a total of 163 younger patients, all treated with chemoimmunotherapy and ASCT.

Methods: We performed RNA-sequencing and bioinformatic identification of circRNAs in an exploratory cohort of 14 newly diagnosed patients with MCL and six healthy controls. 40 circRNAs were selected for quantification with nanostring using RNA samples from diagnostic tumor tissues of patients from the MCL2/MCL3 trials. We then assessed the prognostic potential of these circRNAs with the least absolute shrinkage and selection operator (LASSO) selecting the most predictive circRNAs for time to progression (TTP) in MCL2 (n=74), which served as the training cohort. Nine circRNAs were identified, the expression levels and regression coefficients of which were used to calculate a risk score (circSCORE) for each patient, stratifying them into two groups, separated by a cut-off value. CircSCORE was also calculated for each patient in the independent validation cohort MCL3 (n=89), thereby stratifying these patients into a circSCORE high risk and a circSCORE low risk group, as well.

Results: We detected 2 962 unique circRNAs in MCL and found that expression levels were, in general, inversely correlated with the proliferation marker Ki67. In MCL2, circSCORE separated patients into a high risk group (n=29, 39%) and a low risk group (n=45, 61%) with remarkable difference in TTP. Interestingly, we confirmed the predictive impact of circSCORE for both TTP (HR 3.0;P < 0.001;Figure) and lymphoma-specific survival (LSS) (HR 3.6;P < 0.01;Figure) in the similarly treated, independent cohort MCL3. As patients in the circSCORE high risk group more frequently displayed other high risk features compared to patients in the circSCORE low risk group, we assessed whether circSCORE was an independent prognostic factor in MCL3. Even when adjusting for Ki67, blastoid morphology, MIPI and presence of *TP53* mutations, circSCORE maintained prognostic impact for both TTP (HR 3.2; P = 0.01), and LSS (HR 4.6; P = 0.02), and only MIPI high risk and presence of *TP53* mutations also had prognostic effect in these models.

Summary/Conclusion: With this study, we are the first to perform a genome-wide profiling of circRNA expression in MCL, and we show that circSCORE is a novel prognostic biomarker highly predictive of outcome in younger patients treated with chemoimmunotherapy and ASCT.

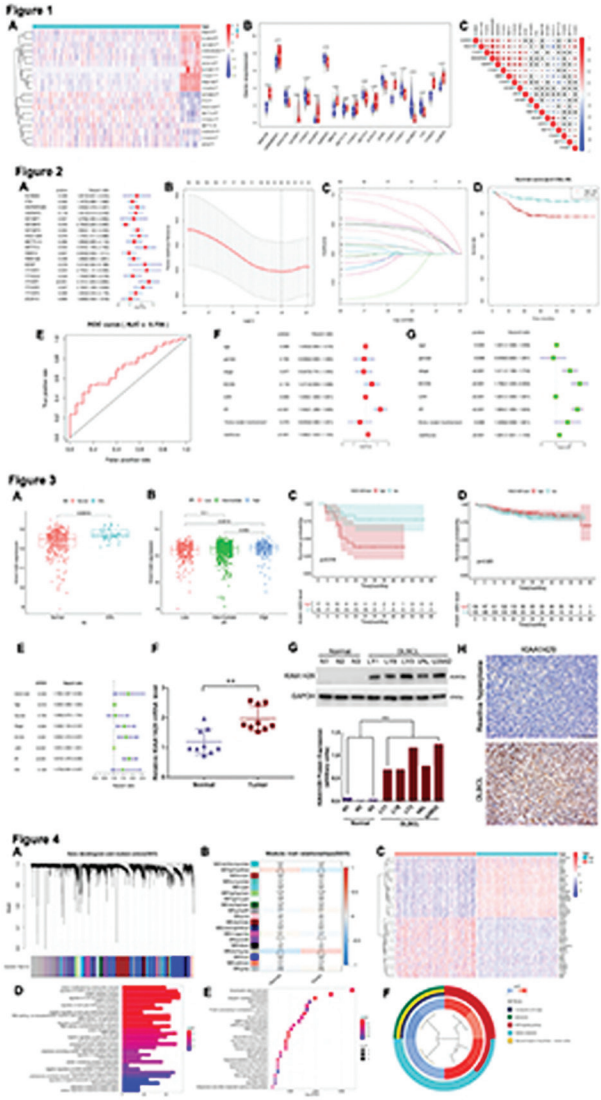
EP864 IDENTIFICATION OF M6A METHYLTRANSFERASE KIAA1429 AS A POTENTIAL TARGET IN DIFFUSE LARGE B-CELL LYMPHOMA

X. Chen [1,2,*], X. Zhou [1,2], S. Ren [1,2], T. Lu [1,2], M. Ding [1,2], Y. Cai [1,2], S. Hu [1,2], Y. Zhao [1,2], Y. Han [1,2], X. Wang [1,2]

[1]Department of Hematology, Shandong Provincial Hospital Affiliated to Shandong University, [2]Department of Hematology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: N^6-methyladenosine (m^{6}A) is the most abundant form of internal modifications in eukaryotic cells. m^{6}A methylation is dynamically modulated by diverse types of regulators, including methyltransferases ('writers'), RNA binding proteins ('readers'), and demethylases ('erasers'). Growing evidence has shown that m^{6}A methylation plays essential role in the development and progression of multiple cancers. However, the functions of m^{6}A methylation in diffuse large B-cell lymphoma (DLBCL) remains undefined.

Aims: In the study, we aimed to identify novel prognostic biomarker by m^{6}A methylation regulators and explore its underlying mechanism in DLBCL.



Methods: The available expression data and the clinical information of DLBCL samples and normal samples were extracted from three databases. The expression level of the m^{6}A methylation regulators was analyzed and the LASSO Cox regression was employed to calculate risk score. Kaplan-Meier survival analysis, univariate and multivariate Cox regression analyses, and ROC curve analysis were conducted. GO and KEGG enrichement were applied to explore the potential function. The lymph node biopsies of DLBCL patients and reactive hyperplasia cases were collected with informed consent to detect the expression of KIAA1429.

Results: We firstly assessed the expression of m^{6}A methylation regulators in DLBCL and found that most of them were dysregulated (p<0.001; Figure 1A-B). Subsequently, we discovered that the proportion of diverse m^{6}A RNA methylation regulators was weakly to strongly relevant (p<0.05; Figure 1C).

The univariate Cox regression analysis indicated that six genes were high-risk and were significantly associated with OS (p<0.05, HR>1; Figure 2A), including KIAA1429 (p=0.043, HR=1.743). Six genes were selected based on the minimum criteria of LASSO Cox regression to establish the risk signature (Figure 2B-C). The high-risk group had a significantly shorter OS in DLBCL patients (p<0.001; Figure 2D). Furthermore, ROC curve, univariate, and multivariate Cox regression analyses showed that high m^{6}A risk score acted as an independent indicator in DLBCL patients (p<0.001; Figure 2E-G).

KIAA1429 was found to be significantly associated with the IPI and DHL (p<0.05; Figure 3A-B). High expression of KIAA1429 resulted in a negative correlation with OS in DHL patients (p=0.018; Figure 3C). However, no significant difference was found in the OS of non-DHL patients (Figure 3D). Univariate analyses indicated that KIAA1429 was an independent indicator in DLBCL patients (p=0.04; Figure 3E). Enhanced expression levels of KIAA1429 mRNA and protein were verified in DLBCL cell lines (Figure 3F-G). Additionally, samples from DLBCL patients also showed significantly

high expression of KIAA1429 compared to the reactive hyperplasia group (Figure 3H).
WGCNA was used to investigate the underlying mechanism of KIAA1429 (Figure 4A-B). A significant association between KIAA1429 expression and its module genes was identified (Figure 4C). GO and KEGG enrichment illuminated that KIAA1429 may act as a potential prognostic biomarker by regulating the mRNA processing and MAPK signaling pathways (Figure 4D-F)

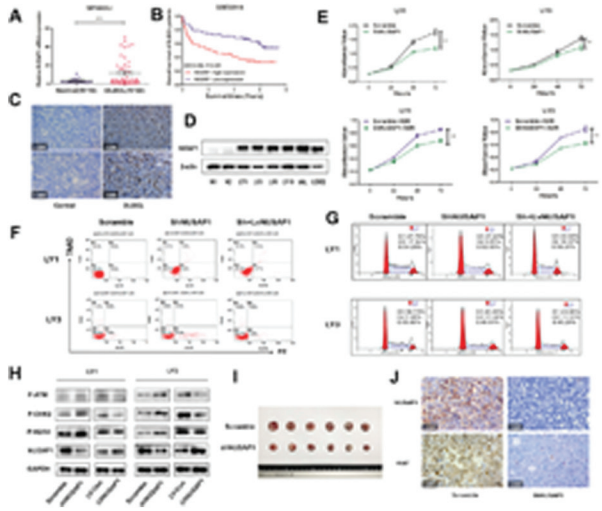
Summary/Conclusion: In summary, we identified for the first time that m^{6}A methylation regulators were dysregulated in DLBCL. More importantly, our study demonstrated the prognostic value of KIAA1429 in DHL patients. Further investigations on the mechanism of KIAA1429 in DLBCL may assist clinicians in achieving individualized treatment for this patient population.

EP865 PLK4 INHIBITION BY CFI-400945 ENHANCES DOXORUBICIN SENSITIVITY IN DIFFUSE LARGE B-CELL LYMPHOMA

Y. Zhao [1,*], X. Zhou [1,2], J. Yang [1], J. Liu [1], Y. Cai [1], S. Ren [1], S. Hu [1], X. Wang [1,2]

[1]Deparment of Hematology, Shandong Provincial Hospital, Cheeloo College of Medicine, Shandong University, [2]Deparment of Hematology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, Shandong, China

Background: Polo-like kinase 4 (PLK4) has been suggested as a tumor promoter role in solid malignancies. Elevated PLK4 expression was associated with progressed grade, inferior survival and reduced chemosensitivity, highlighting as an adverse prognosis indicator and a potential target for cancer therapy. CFI-400945 was the first orally available potent PLK4 inhibitor. The antineoplastic effects of CFI-400945 have been reported in many cancers and this inhibitor has entered phase I/II clinical trials in advanced solid tumors. However, the role of PLK4 in DLBCL is still unclear. Whether CFI-400945 has therapeutic potential in DLBCL remained undefined.
Aims: We aim to investigate the biological role of PLK4 and the antitumor effects of CFI-400945 in DLBCL.
Methods: Analysis of public database and clinical specimens was used to validate PLK4 expression and evaluate its clinical significance. Cell proliferation and apoptosis was assessed by CCK8 and flow cytometry analysis. Knockdown of PLK4 with shRNA was used to evaluate the effect of PLK4 expression on CFI-400945 potency. The effectiveness of the CFI-400945 as a single agent and in combination with doxorubicin in DLBCL cells was evaluated in vitro and in vivo studies.
Results: PLK4 expression was up-regulated at both transcriptional and translational levels in DLBCL cells. High levels of PLK4 expression predicted inferior prognosis in the patients receiving CHOP-based treatment. We then evaluated the antitumor effects of PLK4 inhibition by CFI-400945. The results demonstrated that treatment of PLK4 inhibitor induced a decrease in cell proliferation, an increase in cell apoptosis and a block at the G2-M transition in a dose-dependent manner. Furthermore, we found that the antineoplastic effects of CFI-400945 in DLBCL cell lines were due to the increased DNA damage, as observed by increased accumulation of γH2AX through phosphorylation of CHK1/CHK2. Since PLK4 inhibition affects DNA damage, we next aimed to explore the effects of PLK4 expression on sensitivity of DNA damage-inducing drugs (e.g., doxorubicin). Knockdown of PLK4 improved the anti-tumor effects of doxorubicin in DLBCL cells. PLK4 inhibition resulted in increased doxorubicin-induced DNA damage. Moreover, a combined treatment of CFI-400945 and doxorubicin was associated with promising antiproliferative effects in DLBCL cells. We then investigated the synergistic anti-tumor effects of the combined treatment in vivo. Mice treated with CFI-400945 and doxorubicin had significantly lower tumor burden after 21 days compared with those treated with vehicle or doxorubicin alone.
Summary/Conclusion: The present study suggests that PLK4 is a potential therapeutic target of DLBCL. The levels of PLK4 may serve as a determinant of doxorubicin sensitivity and a predictive biomarker of the patients with DLBCL. Inhibition of PLK4 by CFI-400945 represents a promising strategy for DLBCL, with potential for combination treatment with doxorubicin-involved therapy.



EP866 SUPPRESSION OF NUSAP1 INHIBITS CELL PROLIFERATION IN DIFFUSE LARGE B-CELL LYMPHOMA THROUGH DNA DAMAGE REPAIR PATHWAY

Y. Han [1,2,*], X. Zhou [1,2], J. Yang [1,2], J. Liu [1,2], S. Hu [1,2], S. Ren [1,2], Y. Zhao [1,2], X. Wang [1,2]

[1]Department of Hematology, Department of Hematology, Shandong Provincial Hospital, Cheeloo College of Medicine, Shandong University, [2]Department of Hematology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: Diffuse large B cell lymphoma (DLBCL) is the most common non-Hodgkin's lymphoma (NHL) with high heterogeneity. Previous studies have identified that NUSAP1 plays an important role in the occurrence and progress of multiple tumors. Whereas, no research has been reported regarding the role of NUSAP1 in DLBCL.
Aims: Herein, we aim to further explore the expression and exact role of NUSAP1 in DLBCL development, and provide theoretical basis for new molecular markers and targeted therapy.
Methods: Peripheral blood samples from *de novo* DLBCL patients and healthy volunteers were collected with informed consents at the Department of Hematology in Shandong Provincial Hospital Affiliated to Shandong University (SPHASU). Kaplan-Meier survival curves with log-rank test of overall survival (OS) were analyzed. Immunohistochemistry staining (IHC) was performed to assess NUSAP1 expression in specimens. Expression levels of NUSAP1 mRNA and protein were detected by quantitative RT-PCR and western blotting. The DLBCL cells were transfected by lentiviral shRNA and vectors to stably silence and up-regulate NUSAP1. Effects of doxorubicin on cell viabilities were assessed by cell counting kit-8. Besides, apoptosis and cell cycle were respectively

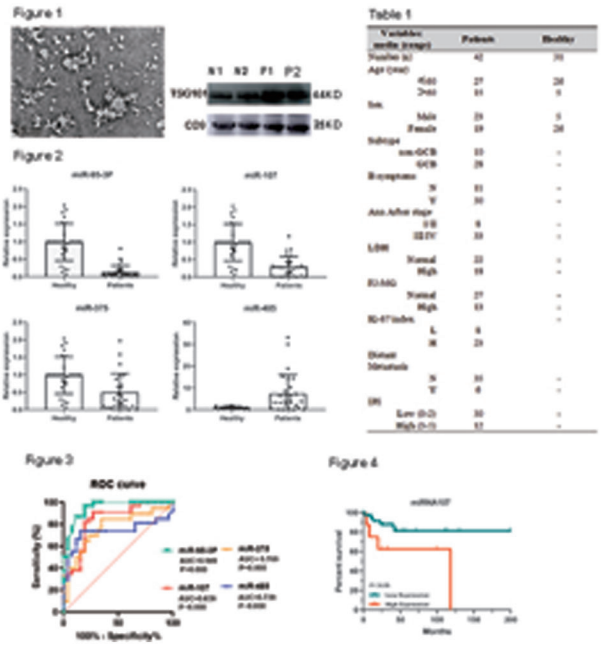
detected by annexin V-PE/7AAD and PI/RNase staining via flow cytometry. Invasion ability was analyzed by transwell assay. ShNUSAP1 cells and Scramble cells were subcutaneously injected to SCID-Beige mice to establish xenograft models.
Results: According to clinical specimens and bioinformatics analysis, the expression level of NUSAP1 gene in samples of DLBCL patients was significantly increased than that of healthy donors (P<0.05) (Figure A). Besides, patients with high expression of NUSAP1 was related to shorter overall survival (HR=0.456, P<0.01), indicating poor prognosis (Figure B). Stronger positivity of NUSAP1 was markedly observed in DLBCL lymph nodes than reactive hyperplasia group, which was associated with Ann Arbor stage of DLBCL patients (Figure C). Compared with normal B cells, the protein level of NUSAP1 were up-regulated in DLBCL cell lines (Figure D). After transfected with lentivirus, the proliferation rate of NUSAP1 knockdown group was lower than that of the control group, while the overexpression group was faster than control (Figure E). Through flow cytometry, silencing of NUSAP1 led to increased apoptotic rates of LY1 and LY3 cells (Figure F). Along with the recovery of NUSAP1 expression level, apoptosis rates were improved again. With the addition of doxorubicin at 100nM, interference of NUSAP1 could increase the sensitivity of cells to doxorubicin (Figure E). NUSAP1 intervention induced obvious cell cycle arrest in G1 phase of LY1 and LY3 cell lines, with concomitant reduction of cell proportion in S phase (Figure G). Surppression of NUSAP1 inhibited the action of DNA damage repair pathway (Figure H). We found that tumor growth was significantly suppressed by inhibiting NUSAP1 in xenograft models (Figure I). IHC for NUSAP1 and Ki67 on tumor sections showed that tumors derived from shNUSAP1 cells exhibited significantly lower levels of Ki67 compared to control group (Figure J).

Summary/Conclusion: Collectively, NUSAP1 contributes to tumor growth both in vivo and vitro through DNA damage repair pathway, which providing a new direction for prognosis assessment and targeted therapy of DLBCL.

EP867 TIGIT EXPRESSION AND ITS SCORING SYSTEM IN CLASSIC HODGKIN LYMPHOMA: A NOVEL THERAPEUTIC TARGET?

O. Annibali [1,*], A. Bianchi [2], A. Grifoni [3], V. Tomarchio [1], M. A. Tafuri [1], M. Verri [2], G. Avvisati [1], A. Crescenzi [2]

[1]Unit of Hematology, Stem Cell Transplantation, Transfusion Medicine and Cellular Therapy, Department of Medicine,, [2]UNIVERSITÀ CAMPUS BIO-MEDICO ROMA, Roma, Italy, [3]La Jolla Institute for Allergy and Immunology, La Jolla, United States



Background: Clinical use of immune-checkpoints inhibitors (anti PD-1/PD-L1) resulted very effective for the treatment of relapsed/refractory classic Hodgkin Lymphoma (CHL). Recently, T cell Ig and ITIM domains (TIGIT) has been recognized as an immune checkpoint receptor able to negatively regulate T cell functions.
Aims: Herein, we investigated the expression of TIGIT in CHL microenvironment in order to find a potential new target for inhibitor therapy.
Methods: TIGIT, PD-1 and PD-L1 expression was evaluated in 34 consecutive patients with CHL. In agreement with the evaluation model for immunohistochemical expression of PD-L1 in tumors, we proposed a scoring system for TIGIT immunohistochemistry in CHL; moreover, we compared TIGIT results with PD-1 and PD-L1 expression to obtain a complete assessment of the immunomodulation of Hodgkin lymphoma microenvironment.
Results: TIGIT expression in T lymphocytes surrounding Hodgkin Reed-Sternberg (HRS) cells was observed in 19/34 patients (56%), of which 11 (58%) had advanced stages. In 16/19 (84%) cases, TIGIT+ peritumoral T lymphocytes showed also PD-1 expression. All 15 TIGIT- patients had PD-L1 expression in HRS cells (100%) while among 19 TIGIT+ patients, 11 (58%) were PD-L1+ and 8 (42%) were PD-L1-. Using a new scoring system for TIGIT immunoreactivity, all TIGIT+ cases with higher score (4/19) were PD-L1-. Our results confirm co-expression of TIGIT and PD-1 in peritumoral T lymphocytes. Of relevance, we demonstrated a mutually exclusive expression of TIGIT and PD-L1 using new TIGIT scoring system able to identify this immunocheckpoints' modulation.
Summary/Conclusion: In conclusion, our preliminary results in Hodgkin lymphoma, demonstrated a mutually exclusive expression of TIGIT in peritumoral lymphocytes and PD-L1 in HRS cells, with an overlap in cases with low level of TIGIT reactivity. The new TIGIT scoring system is able to identify such modulation of these immunocheckpoints. These results pave the way to new therapeutic strategies for relapsed/refractory CHL

EP868 SERUM EXOSOMAL MICRORNAS AS NOVEL NON-INVASIVE BIOMARKERS FOR DIFFUSE LARGE B-CELL LYMPHOMA

J. Liu [1,*], X. Zhou [1], Y. Cai [1], S. Hu [1], T. Lu [1], S. Ren [1], X. Wang [1]

[1]Shandong Provincial Hospital Affiliated to Shandong University, Jinan, China

Background: Diffuse large B-cell lymphoma (DLBCL) is an aggressive malignant lymphoma with high heterogeneity, which bring great difficulties to precise diagnosis and prognosis. Circulation exosomal miRNAs have emerging as complementary biomarkers and exserted as new opportunities to develop non-invasive tests for early diagnosis or follow-up of disease. Accumulating evidence suggested that miR-107 played a critical role in suppressing tumorigenesis. However, the significance of exosomal miR-107 in DLBCL is still not well understood.
Aims: The aim of this study is to explore the serum exosomal microRNAs to be novel biomarkers as well as therapeutic targets for DLBCL.
Methods: Differentially expressed microRNAs (DEMs) involved in DLBCL progression were screened from Gene Expression Omnibus (GEO) database (GSE117063 and GSE29493). Serum-derived exosomes were isolated by Qiagen ExoEasy Maxi Kit. Transmission electron microscopy (TEM) and Western blot were performed to examine the exosomal characteristics. Quantitative real-time PCR (qRT-PCR) was applied to determine the serum exosomal expression levels of microRNAs from 42 DLBCL patients and 31 normal samples. Kaplan-Meier analysis, and ROC working curve analyses were performed to assess the diagnostic and prognostic values of exosomal miRNAs in DLBCL patients.
Results: A total of 14 DEMs in DLBCL were identified from the GSE117063 and GSE29493 datasets. Serum-derived exosomes were isolated from 42 patients and 31 healthy volunteers, and the characteristics of patients were subscribed in Table 1. TEM and western blot for Tsg101 and CD9 are consistent with previous description of exosomes (Figure 1). Among the identified DEMs,3 down-regulated miRNAs (miR-95-3P, miR-107, miR-375) and 1 up-regulated miRNA (miR-485) were verified to be significantly differently expressed in DLBCL patients (Figure2). ROC curve analyses revealed that these serum exosomal miRNAs, miR-95-3p, miR-107, miR-375, and miR-485, acted as potential biomarkers for DLBCL, with the AUC of were 0.94, 0.839, 0.769 and 0.739, respectively (Figure 3). In addition, Kaplan-Meier analysis of the TCGA database indicated that compared to the control group, DLBCL patients with low-expression of miR-107 presented worse prognosis (Figure 4), suggesting that miR-107 may be a prognostic factor for DLBCL.

Summary/Conclusion: In this study, we demonstrate for the first time that serum exosomal miRNAs, such as miRNA-107, could be applied as non-invasive novel diagnostic and prognostic biomarker in DLBCL. With further research we expect that miR-107 to be a promising therapeutic target for DLBCL.

EP869 DISCOVERY AND PRECLINICAL PROPERTIES OF JNJ-64264681, A POTENT AND SELECTIVE COVALENT BTK INHIBITOR FOR THE TREATMENT OF B CELL MALIGNANCIES

U. Philippar [1,*], N. Rao [2], H. Rui [3], M. Tichenor [4], M. Gaudiano [1], M. Bekkers [1], I. Cornelissen [1], K. Packman [2], S. Balasubramanian [4], J. Gerecitano [2], J. Bussolari [2], J. Venable [4]

[1]Janssen Research & Development, Beerse, Belgium, [2]Janssen Research & Development, Spring House, United States, [3]Janssen Research & Development, Shanghai, China, [4]Janssen Research & Development, San Diego, United States

Background: Bruton's tyrosine kinase (BTK), a member of the Tec family of tyrosine kinases, plays a critical role in B-cell activation and oncogenic signaling via the B cell receptor. BTK inhibitors have been widely studied in B-cell hematologic malignancies and 3 inhibitors, including the first-in-class BTK inhibitor ibrutinib, are currently approved. While BTK inhibitors have been paradigm-changing in Chronic lymphocytic leukemia, Mantle cell lymphoma, and Waldenstroms macroglobulinemia, combination therapies with other agents may be required to reach optimal response rates and cures in other histologies (eg, Diffuse large B-cell lymphoma [DLBCL]).
Aims: Describe the discovery and preclinical properties of a novel, highly selective, small-molecule covalent BTK inhibitor, JNJ-64264681, designed to enable combination therapies.
Methods: The covalent inhibitor potency was determined by k_{inact}/K_I ratios. Inhibition of B-cell activation was assessed in mouse primary cells. The proportion of free and modified BTK was determined in a covalent adduct assay. Dose response of BTK occupancy was assessed in Ramos B cells. A quantitative mechanistic model simulated and used human B cell BTK occupancy to estimate covalent binding. Target engagement and pharmacokinetics/pharmacodynamics studies were conducted in rats and tumor-bearing mice. The effect of JNJ-64264681 on cancer cell proliferation was assessed in B cell lymphoma cell lines, and tumor growth inhibition was studied in cell line and lymphoma patient-derived xenograft mouse models (OCI-Ly10, LY2298).
Results: JNJ-64264681 was developed to obtain high selectivity and ideal physicochemical properties. A series of optimizations resulted in improved microsomal stability, high pH 2 solubility, measurable pH 7 solubility, and double-digit nM potency in rat and human whole blood. Cocrystallization of JNJ-64264681 with BTK confirmed covalent bond formation with Cys481, and in line with this, the adduct was resistant to denaturation. JNJ-64264681 was highly selective against a diverse panel of receptors, enzymes, ion channels, and human kinases. BTK occupancy was dose proportional in vivo, and full occupancy was maintained even after plasma drug levels decreased. JNJ-64264681 showed potent antiproliferative activity (IC_{50} <100 nM) in CD79b-mutant activated B cell (ABC)-DLBCL cell lines, but not in cell lines which are independent of NF-κB signaling for survival, highlighting its selectivity. Treatment with JNJ-64264681 led to potent in vivo BTK occupancy, inhibition of specific cytokines and tumor growth inhibition in a CD79b-mutant ABC-DLBCL xenograft model. Furthermore, JNJ-64264681 showed significant tumor growth inhibition in the ABC-DLBCL-like LY2298 patient-derived xenograft model. Similarly, treatment with the combination of JNJ-64264681 and the MALT1 inhibitor JNJ-67856633 resulted in increased tumor growth inhibition compared with single agents and tumor regression in both CD79b mutant mouse lymphoma models.
Summary/Conclusion: The preclinical results confirm that JNJ-64264681 is a highly selective and potent BTK inhibitor and provide proof-of-concept for human trials in patients with B cell malignancies driven by the classical NF-κB pathway. JNJ-64264681 is currently in human clinical trials (NCT04210219 and NCT04657224) as single agent to establish dose and pharmacokinetics and to evaluate efficacy in combination with the first-in-class MALT1 inhibitor JNJ-67856633.

EP870 ANALYSIS OF EZH2 MUTATIONS IN SOLID AND LIQUID BIOPSY AND ITS ROLE AS PREDICTIVE MARKER FOR CHEMOTHERAPY IN PATIENTS WITH FOLLICULAR LYMPHOMA

L. Sanz-Villanueva [1,2], F. Díaz Crespo [3], R. Martín Rojas [2], D. Carbonell [1,2], M. Chicano [1,2], J. Suárez-González [1,4], P. Muñiz [1,2], J. Menarguez [2,3], M. Kwon [1,2], J. L. Diez Martín [1,2,5], I. Buño [1,2,4,6], C. Martínez-Laperche [1,2], M. Bastos Oreiro [1,2,*]

[1]Gregorio Marañón Health Research Institute (liSGM), [2]Department of Hematology, [3]Pathology Department, [4]Genomics Unit, Gregorio Marañón General University Hospital, [5]Department of Medicine, [6]Department of Cellular Biology, School of Medicine, Complutense University of Madrid, Madrid, Spain

Background: *EZH2* encodes the catalytic subunit of Polycomb repressor complex (PCR2) and mediates methylation of Lys27 residue of histone H3 (H3K27). Missense mutations in *EZH2* lead to decreased transcriptional function of genes involved in cell cycle regulation and plasma cell differentiation, which contributes to oncogenic transformation. *EZH2* have been detected to be mutated in near 20% of follicular lymphomas (FL) and this gene is included in the risk model m7-FL International Prognostic Index (m7-FLIPI). Furthermore, *EZH2* inhibitors appear as a new treatment option in FL.
Aims: We aimed to analyse retrospectively the frequency of mutations in *EZH2* at diagnosis in tissue and circulating cell free DNA (cfDNA) in patients with FL and assess the patient's response to therapy, depending on the *EZH2* mutation status.
Methods: We included 179 consecutive patients diagnosed with FL from 2002 to 2019. Thirty-seven patients were excluded due to insufficient DNA quantity or quality. Of the 142 analysed patients, 49 had cfDNA sample at diagnosis. DNA was extracted from solid biopsies using Maxwell(R) 16 FFPE Plus LEV DNA Purification Kit (Promega). We obtained cfDNA from plasma samples, using QIAamp® Circulating Nucleic Acid (Qiagen). RT-qPCR reactions were performed in ctDNA using PrimeTime Mini LNA probe for *EZH2* Y646. Sanger sequencing were used in tumor DNA for detection of mutations in exon 16 (Y646) and 18 (A682 and A692). Clinical characteristics, therapy and outcome were collected. Data analysis including descriptive statistics and Fisher's exact test was performed using IBM SPSS Statistics 26 (IBM, USA).
Results: Of the 142 patients analysed in tissue, 41 (29%) presented mutations in *EZH2*. These mutations were found in 46% of grade 3B FL and 27% of grades 1, 2 and 3A FL (Table 1). Y646 mutations in cfDNA were detected in 5/49 (10%) with *EZH2* mutated in tumor and stage III-IV FL. Clinical and biological characteristics according to *EZH2* mutation status in tumor were compared in patients with lower-grade FL (Table 1) and high grade 3B (data not shown). No statistical differences were found in lower grade-FL. Instead, patients with grade 3B and mutated *EZH2* had statistically higher FLIPI risk (80% vs 0%; p=0.048). Overall survival (OS) of total cohort and according to therapy received and *EZH2* mutation status were compared and there were no statistically

significant differences. In terms of progression free survival (PFS), our results shown that mutated *EZH2* patients treated with R-bendamustine were significantly associated with inferior PFS (p=0.013) (Figure 1a), unlike R-CHOP treated patients (p=0.15) (Figure 1b).

Table 1. Clinical characteristics and first-line therapy in patients with grade 1, 2 and 3A FL.

	N	Total (n=129)	Mutated *EZH2* in FFPE (n=35)	Unmutated *EZH2* in FFPE (n=94)	p-value
Clinical characteristics at diagnosis, n (%)					
Age at diagnosis, mean (range)	129	62 (15-90)	64 (41-90)	62 (15-89)	0.435
Sex					
Female	129	72 (56)	22 (63)	50 (53)	0.426
Male		57 (44)	13 (37)	44 (47)	
Histology					
Grade 1, 2	123	81 (66)	25 (74)	56 (63)	0.296
Grade 3A		42 (34)	9 (26)	33 (37)	
Stage					
I-II	123	38 (30)	7 (21)	31 (33)	0.196
III-IV		90 (70)	27 (79)	63 (67)

High		33 (28)	12 (35)	21 (25)	
First-line therapy, n (%)					
Treated	111	111 (86)	29 (83)	82 (87)	0.573
Watchful waiting	18	18 (14)	6 (17)	12 (13)	
R-bendamustine	30	30 (23)	7 (20)	23 (24)	
R-CHOP	57	57 (44)	18 (51)	39 (41)	
R-CVP, Rituximab and Radiotherapy	24	24 (20)	4 (11)	20 (21)	

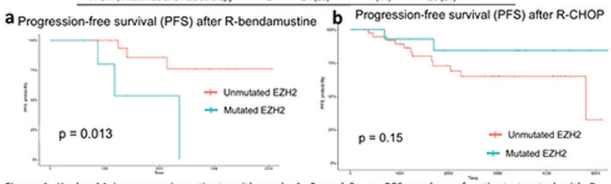

Figure 1. Kaplan-Meier curves in patients with grade 1, 2, and 3a. **a.** PFS on days of patients treated with R-bendamustine therapy; **b.** PFS on days of patients treated with R-CHOP therapy. PFS Progression-free survival.

Summary/Conclusion: The frequency of *EZH2* mutations in our total cohort is similar to previously reported. Mutations were more frequent in high grade FL patients. Low grade FL patients mutated at diagnosis, receiving R-bendamustine were associated with inferior PFS. The mutational status of these patients at diagnosis could be useful to guide treatment. In patients with stage III-IV, liquid biopsy may be used at diagnosis to guide on the selection of therapy, as *EZH2* mutations are detectable in advanced stage FL.

EP871 MELPHALAN FLUFENAMIDE IS A HIGHLY POTENT ANTI-NEOPLASTIC AGENT IN HIGH RISK DLBCL MODELS

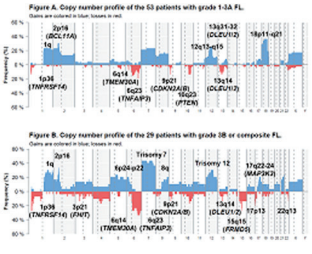
K. Byrgazov [1,*], V. Rraklli [1], M. Färnegårdh [1], F. Lehmann [1], A. Slipicevic [1]

[1]*Research, Oncopeptides AB, Stockhom, Sweden*

Background: Diffuse large B cell lymphoma (DLBCL) is a frequent aggressive lymphoid neoplasm. Standard protocol consisting of rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone (R-CHOP) has improved remission and survival rates in patients with DLBCL. Nevertheless, 30% of patients do not respond to the therapy with R-CHOP or relapse resulting in relapsed/refractory (R/R) disease. Currently, there are several protocols for the treatment of R/R-DLBCL including a combination of rituximab and bendamustine. However, survival rates in patients with R/R-DLBCL remain dismal and require improvement through introduction of novel drugs and combinations. Melphalan flufenamide (melflufen) is a novel peptide-drug conjugate that rapidly delivers cytotoxic alkylating payload inside tumor cells. This process is potentiated by aminopeptidases highly expressed in cancer cells. Therefore, prognostic significance of aminopeptidases in DLBCL and potency of melflufen were investigated in this study.
Aims: First, assess prognostic significance of aminopeptidase gene expression in DLBCL. Second, evaluate potency of melflufen in the models of high risk DLBCL.
Methods: Expression levels of aminopeptidase genes in patient samples was assessed using publicly available RNA-sequencing data (GSE125966). The prognostic significance of highly expressed aminopeptidase genes was further evaluated in R-CHOP-treated patients (N=692) with available gene expression and censored survival data (GSE31312, GSE83731). Three ABC (SU-DHL-2, U2932, NU-DUL-1) and nine GCB DLBCL (SU-DHL-4/5/8/10/16, DoHH2, DB, Toledo, RC-K8) cell lines were profiled for drug sensitivity to melflufen and standard of care (SoC) drugs doxorubicin and bendamustine using an assay quantifying living cells. The results were confirmed in vivo.
Results: Several aminopeptidase genes (*ERAP1, ERAP2, LAP3, LNPEP, LTA4H, METAP1, METAP2, NPEPPS, RNPEP, XPNPEP1, XPNPEP3*) showed high expression in DLBCL patient samples. Among these genes high expression of *LNPEP* (37.0 vs 50.4 month, HR 0.73, 95% CI 0.61-0.88, p<0.0001) and *LAP3* (37.4 vs 49.2 month, HR0.76, 95% CI 0.63-0.91, p=0.0005) conferred inferior survival of DLBCL patients. Aminopeptidase-potentiated peptide-drug conjugate melflufen showed a superior cytotoxicity to doxorubicin and bendamustine in all cell lines tested (Wilcoxon paired test p<0.0001). Interestingly, TP53 status of DLBCL cells did not significantly affect the cytotoxicity of melflufen.
Summary/Conclusion: Our results showed high expression of several aminopeptidase genes in DLBCL. Moreover, elevated expression of *LNPEP* and *LAP3* conferred significantly shorter survival in DLBCL patients. A novel peptide-drug conjugate melflufen potentiated by aminopeptidases showed a superior cytotoxicity to SoC drugs doxorubicin and bendamustine in a panel of eleven DLBCL cell lines. Low expression or mutations in *TP53* gene status of cell lines did not show a major effect on melflufen's cytotoxicity. Thus, melflufen may be suitable for treatment of high risk DLBCL.

EP872 GENOMEWIDE COPY NUMBER ANALYSIS OF GRADE 1-3A, 3B, AND COMPOSITE FOLLICULAR LYMPHOMA

P. Mozas [1,*], C. López [2], M. Grau [2], S. Valle [2], A. Navarro [2], F. Nadeu [2], B. González-Farré [1], A. Rivas-Delgado [1], A. Rivero [1], J.-G. Correa [1], G. Frigola [1], O. Balagué [1], E. Giné [1], J. Delgado [1], N. Villamor [1], P. Pérez-Galán [1], L. Magnano [1], E. Campo [1], S. Beà [1], A. López-Guillermo [1]



[1]*Hospital Clínic de Barcelona,* [2]*IDIBAPS, BARCELONA, Spain*

Background: Grade 3B follicular lymphoma (FL3B) and composite FL (FL with a component of diffuse large B-cell lymphoma, DLBCL) exhibit specific biological and clinical features. Thus, gene expression profiling studies have suggested that FL3B is intimately related to FL3A, while FL3B/DLBCL would be closer to DLBCL. However, data concerning copy number alterations (CNA) of these histologies are scarce.
Aims: To characterize the copy number profile of FL3B and composite FL, and to compare it with that of FL123A.
Methods: We selected 29 patients with FL3B (n=11) or composite FL (n=18), as well as a control group of 53 patients with grades 1-3A FL. Composite cases were further subclassified into FL123A/DLBCL (C123A, n=10) and FL3B/DLBCL (C3B, n=8). All biopsies were reviewed by at least two hematopathologists. Minimal common CNA regions were defined separately for FL123A and FL3B/C123A/C3B cases. DNA was extracted from diagnostic formalin-fixed, paraffin embedded lymph node biopsies. CNA were assessed using the OncoScan CNV Assay (Thermofisher). The *BCL2* rearrangement was analyzed by FISH and/or PCR. Non-parametric statistics were used for comparisons of categorical and quantitative variables.
Results: Baseline features of the patients and CNA of the samples are detailed in the *Table*. *BCL2* rearrangement was more frequent in FL123A (87%) than in FL3B (64%) or composite FL cases (56%, *P*=0.02). We detected CNA in 78/82 samples (95%). Although no significant differences were found in the total number of CNA among groups, the number of gains was higher in FL3B (median, 5) and composite FL (median, 6) compared to FL123A cases (median, 2; *P*=0.02). The most frequent CNA among the 82 samples were 1q gain (n=22, 27%), trisomy 7 (n=21, 26%), and 1p36 copy-neutral loss of heterozygosity (n=20, 24%).
Figure A shows the CNA profile of FL123A, and *Figure B* that of FL3B and composite FL. Several CNA showed a different distribution among FL123A, FL3B, and composite FL cases. Of note, losses of 6q13-q15

Table. Baseline features and CNA data of the patients.

	FL123A (n=53)	FL3B (n=11)	Composite FL (n=18)	*P*
Age, median (range)	57 (26–79)	66 (42–82)	68 (27–89)	0.046
Female sex, n (%)	29 (55)	6 (55)	8 (44)	NS
BCL2 rearrangement, n (%)	39 (87)	7 (64)	10 (56)	0.02
Stage III-IV, n (%)	39 (74)	9 (82)	15 (83)	NS
High-risk FLIPI score, n (%)	13 (26)	3 (27)	7 (41)	NS
Overall survival, % at 10 y (95% CI)	79 (68–91)	76 (51–100)	64 (44–93)	0.02
Total CNA, median (range)	6 (0–27)	11 (1–13)	10 (0–26)	NS
Gains, median (range)	2 (0–14)	5 (2–10)	6 (0–15)	0.02
Losses, median (range)	2 (0–18)	3 (1–9)	4 (0–13)	NS
CN-LOH, median (range)	1 (0–13)	1 (0–7)	2 (0–3)	NS
6p24-p22 gain, n (%)	3 (6)	4 (36)	1 (6)	0.02
6q14 loss (TNFAIP3), n (%)	8 (15)	6 (55)	5 (6)	0.005
6q23 loss (TNFAIP3), n (%)	10 (19)	6 (55)	3 (17)	0.04
9p gain (*MYC*), n (%)	2 (4)	1 (9)	4 (22)	0.04
15q15 loss (*RMD5*), n (%)	0	2 (18)	5 (28)	<0.001
17p13 loss, n (%)	1 (2)	2 (18)	4 (22)	0.01
Trisomy 5, n (%)	1 (2)	4 (36)	1 (6)	0.002
Trisomy 7, n (%)	11 (21)	5 (46)	5 (28)	NS
Trisomy 20, n (%)	0	0	3 (17)	0.01
Trisomy 21, n (%)	3 (6)	0	5 (28)	0.03

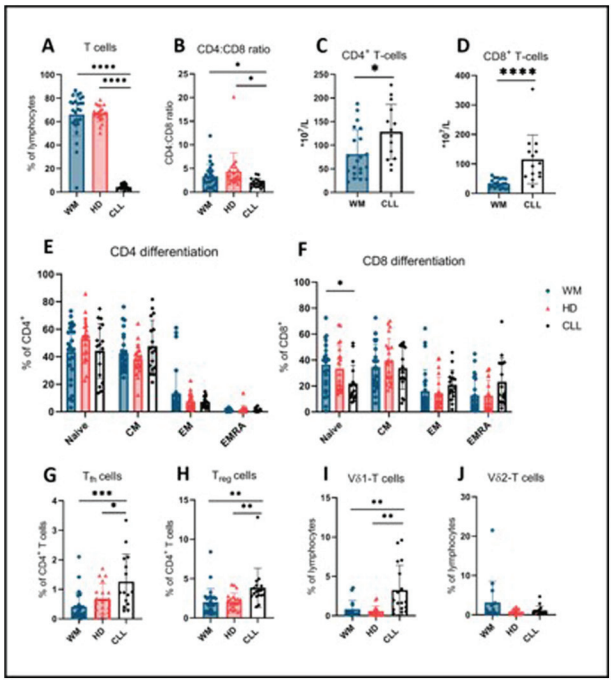
FLIPI, Follicular Lymphoma International Prognostic Index; y, year; CI, confidence interval; CNA, copy number alterations; CN-LOH, copy-neutral loss of heterozygosity; NS, not statistically significant.

(*TMEM30A*) and 6q23-q15 (*TNFAIP3*) were more frequent in FL3B cases (n=6, 55%). We then compared composite FL cases according to the FL component (FL123A vs FL3B) and found no significant differences, with the exception of trisomy 12, which was observed in four C3B and none of the C123A cases (*P*=0.02).

Summary/Conclusion: In this CNA analysis of 29 FL3B/C123A/C3B and 53 FL123A samples, 1q gain and trisomy 7 were the most frequent abnormalities. FL123A cases had a lower number of gains, and several alterations showed a differential distribution among histological subgroups. Further studies, including targeted NGS, are under way to deepen the understanding of these specific FL subtypes.

EP873 T-CELL SUBSET COMPOSITION AND FUNCTIONALITY IN PATIENTS WITH WALDENSTRÖM'S MACROGLOBULINEMIA.

K. Amaador [1,*], A. W. Martens [1,2], R. de Boer [2], J. M. Rietveld [2], E. Eldering [2,3], M. J. Kersten [1,3], A. P. Kater [1,3], J. M. Vos [1,3], S. H. Tonino [1,3]



[1]Department of Hematology, Cancer Center Amsterdam, Amsterdam UMC, University of Amsterdam, [2]Department of Experimental Immunology, Amsterdam Infection & Immunity Institute, Amsterdam UMC, [3]Lymphoma and Myeloma Center Amsterdam (LYMMCARE), Amsterdam, Netherlands

Background: Waldenström's macroglobulinemia (WM) is an incurable low-grade B-cell Non-Hodgkin lymphoma characterized by bone marrow infiltration with lymphoplasmacytic cells, and presence of an IgM M-protein. WM resembles chronic lymphocytic leukemia (CLL) with regard to biologic and clinical characteristics. The emergence of novel autologous T-cell directed therapies has prompted deeper understanding of the immune microenvironment. In CLL, extensive abnormalities in T-cell subset distribution and function have been described. These alterations may contribute to disappointing responses to T-cell directed immunotherapies. Novel autologous T-cell directed immunotherapy may improve the outlook for WM patients. However, studies evaluating T-cell functionality in WM are lacking.

Aims: We performed a systematic evaluation of peripheral blood (PB) T-cell subset composition and function in the of WM patients.

Methods: PB samples were collected from treatment-naive, relapsed and symptomatic WM patients, HCs and treatment-naïve CLL patients. Lymphocyte phenotyping was performed and differences in functionality were assessed by determining the potential of T-cells to degranulate and produce cytokines upon stimulation for 4h with phorbol myristate acetate/ionomycin. Furthermore, cytotoxic potential of the T-cells was assessed via engagement of blinatumomab (CD3xCD19 bi-specific T-cell engager), that re-directs T-cells via CD3 to kill CD19+ tumor cells. Correlations between percentages of the various T-cell subsets, cytokine production, cytotoxic capacity and various markers of disease activity were performed for treatment-naïve WM and pretreated WM separately.

Results: A total of 16 treatment-naïve WM patients, 10 pretreated symptomatic WM patients, 21 age-matched HCs and 17 treatment-naïve CLL patients were included in this study. In WM patients, the following cell types had counts similar to HCs: T-cells (relative), CD4$^+$ T-cells (relative), absolute CD4$^+$ and CD8$^+$ T-cells, T_{fh} cells, T_{reg} cells, and Vδ1/ Vδ2 T-cells (relative). This is in contrast to CLL patients, in which T-cell numbers (relative) were decreased, absolute CD4+ and CD8+ T-cells were increased compared to HCs, T_{fh}, T_{reg}, and Vδ1 T-cell numbers were increased as expected. CD4$^+$ and CD8$^+$ T-cell differentiation was also normal in WM as opposed to CLL in which a known skewing towards terminal differentiation in the CD8$^+$ T-cell population was observed. No difference in Vδ2 T-cell count was observed between all three groups (Figure 1). No significant differences were found in cytokine production and degranulation between CD4$^+$ and CD8$^+$ T-cells from WM patients in comparison with HCs, in contrast to CLL in which decreased amounts of TNF-α and increased expression of CD107a were found. The cytotoxic potential of WM-derived T-cells was intact and similar to HC-derived cells, while CLL-derived T-cells have an impaired cytotoxic response to blinatumomab.

Summary/Conclusion: These data represent the first systematic evaluation of the T-cell compartment in WM patients. The qualitative and quantitative changes in the immune system seen in CLL are not found in WM; T-cell numbers, distribution and functionality seem mostly preserved even in pretreated patients with a high disease burden. These findings are encouraging for the application of T-cell targeted immune therapies in WM, especially for the management of relapsed/refractory WM.

EP874 BERBERINE EXERTS IMMUNOREGULATING FUNCTION IN DIFFUSE LARGE B-CELL LYMPHOMA VIA DOWNREGULATING CD47 EXPRESSION

S. Ren [1,*], X. Zhou [1,2], Y. Cai [1], S. Hu [1], J. Liu [1], Y. Zhao [1], M. Ding [1], X. Chen [1], L. Zhan [1], X. Wang [1,2]

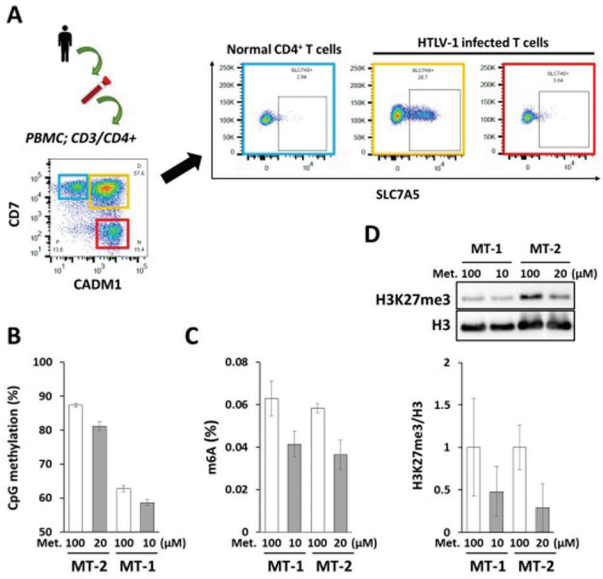
[1]Hematology, Shandong Provincial Hospital Affiliated to Shandong University, [2]Hematology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: CD47 expresses widely in human tissue and overexpresses in several malignance cells. The interaction between CD47 overexpressing on tumor cells and sSIRPα on macrophages triggers an inhibitory signal cascade that suppresses the phagocytosis function. Berberine is a quaternary amine isoquinoline alkaloid which was traditionally used in intestinal infection and found to have broad anti-tumor activities in several tumors in recent years. However, the function and mechanism of berberine in immunoregulation targeting CD47 is undefined.

Aims: To investigate the functional significance of CD47 in diffuse large B-cell lymphoma (DLBCL) progression and propose an adjuvant agent for DLBCL treatment.

Methods: Paraffin imbedding tissue sections of 55 newly diagnosed DLBCL patients and 40 reactive hyperplasia (RHL) patients were obtained after informed consents. CD47 expression was analyzed in DLBCL tissue sections and DLBCL cell lines. CD47 level was analyzed after berberine treatment, and related regulatory pathway was explored. The immunoregulating function of berberine were proved in co-culture experiment *in vitro*. A tumor bearing mice model was established to investigate the immunoregulating function of berberine *in vivo*.

Results: Firstly, we analyzed the CD47 expression in tissue sections form DLBCL and RHL patients. Compared to RHL, CD47 was overexpressed in DLBCL tissues (30/55 vs 11/40, p=0.009, **Figure 1A**). CD47 positive expression was correlation with higher DLBCL subtype (p=0.007) and Kaplan-Meier analysis showed that patients with positive CD47



expression had a bad OS (**Figure 1B**). Furthermore, aberrantly increased expression of CD47 was also detected in some DLBCL cell lines (**Figure 1C**).
Then DLBCL cells were treated with berberine and the results revealed that CD47 was downregulated by berberine at a time-dependent manner (**Figure 2A**). In the aspect of regulatory signal pathway, CD47 was modulated by berberine at the transcriptional level (**Figure 2B**). Then, inhibitor of c-myc, a transcriptional factor of CD47, were applied to LY1 cells. The results showed that inhibition of c-myc by 10058-F4 could suppress CD47 expression (**Figure 2C, left**). The expression level of c-myc was also decreased after berberine treatment (**Figure 2C, middle**). Moreover, overexpression of c-myc resulted in the increased expression of CD47 and rescued berberine-induced downregulation of CD47 (**Figure 2C, right**). Engulfment of LY1 cells by macrophage was improved when LY1 cells were pretreated with berberine for 48 hours (**Figure 2D**). And tumor growth was inhibited by berberine in the tumor-bearing mice model with decreased expression of CD47 and increased infiltrated macrophages (**Figure 2E**). Moreover, berberine enhanced the efficacy of anti-CD47 antibody and rituximab (**Figure 2F**).
Summary/Conclusion: Our results highlighted that CD47 was a significant feature and played an anti-phagocytosis function in DLBCL progression. We provided evidence for the first time that berberine exerts immunoregulation function in DLBCL via modulating c-myc/CD47 axis and enhance the efficacy of anti-CD47 antibody and rituximab, which provided novel insights into the treatment in DLBCL.

EP875 ABERRANT EPIGENETIC REGULATION THROUGH METABOLIC REPROGRAMMING IN ATL LEUKEMOGENESIS

T. Watanabe [1,*], Y. Yamamoto [1], K. Kamachi [1,2], Y. Kurahashi [1,3], N. Yoshida [1,2], H. Ureshino [1,2], Y. Fukuda-Kurahashi [1,3], H. Nakamura [4], E. Sueoka [5], S. Kimura [1,2]

[1]Drug Discovery and Biomedical Sciences, [2]Division of Hematology, Respiratory Medicine and Oncology, Department of Internal Medicine, Faculty of Medicine, Saga University, Saga, [3]OHARA Pharmaceutical Co., Ltd., Shiga, [4]Department of Transfusion Medicine, Saga University Hospital, [5]Department of Clinical Laboratory Medicine, Faculty of Medicine, Saga University, Saga, Japan

Background: Adult T-cell leukemia/ lymphoma (ATL) is derived from mature T-cells transformed by human T-cell lymphotropic virus type 1 (HTLV-1). Following HTLV-1 infection, it takes decades for carriers to develop ATL. HTLV-1–infected T-cells undergo multi-step leukemogenesis, with accumulation of genetic and epigenetic abnormalities. Trimethylation at histone H3Lys27 (H3K27me3) catalyzed by polycomb-repressive complex 2 accumulates aberrantly in HTLV-1-infected T-cells and its accumulation correlates with ATL development and progression.
We recently identified common differentially hypermethylated positions that are specific to HTLV-1-infected T-cells using comprehensive DNA methylation analysis. The accumulation of DNA methylation at these sites correlated strongly with ATL development and progression (*Blood* 2020, 136: 871-884). OR-2100, which we developed as a novel decitabine prodrug with enhanced oral bioavailability, suppressed tumor cell growth and global DNA hypomethylation. Taken together, epigenetic abnormalities, especially hypermethylation of DNA and histone H3Lys27, are functionally important for ATL leukemogenesis and represent effective therapeutic targets.
Aims: Here, we aimed to understand how these epigenetic abnormalities accumulate in HTLV-1-infected cells during multi-step carcinogenesis.
Methods: HTLV-1-infected cell lines were cultured in RPMI-1640 medium containing 100 μM methionine. We also prepared modified RPMI-1640 medium with a reduced concentration of methionine. DNA methylation at long interspersed nuclear element-1 (LINE-1), which is a surrogate marker for global DNA methylation status, was determined by bisulfite pyrosequencing. N^6-methyladenosine (m6A) in mRNA (m6A RNA methylation) was quantified by ELISA.
Results: Recently, the epigenetic reprogramming that drives T cell differentiation and proliferation was shown to be regulated by the incorporation of extracellular methionine through the amino acid transporter SLC7A5, the expression of which is induced by activation of the T-cell receptor (TCR) signaling pathway. Since several negative regulators of the TCR pathway are silenced by promoter hypermethylation in HTLV-1-infected cells, we hypothesized that epigenetic abnormalities are maintained through sustained SLC7A5-mediated incorporation of methionine in ATL cells.
As expected, we found that *SLC7A5* gene expression was higher in HTLV-1-infected T-cells than in normal T-cells using the gene expression datasets GSE55851 and GSE33615. Flow cytometric analysis of SLC7A5 protein expression in peripheral blood mononuclear cells from ATL patients revealed SLC7A5 expression in HTLV-1-infected cells from one of 10 ATL patients (Fig. A). Two HTLV-1-infected cell lines, MT-2 and MT-4, also expressed high levels of SLC7A5 protein. Methionine restriction suppressed the growth of HTLV-1-infected cell lines. As expected, DNA and RNA hypomethylation was induced by methionine restriction (Fig. B, C). A decrease in H3K27me3 and protein arginine methylation was also confirmed by western blot analysis (Fig. D). To understand better the epigenetic responses to methionine restriction, we are performing multi-omics analysis using transcriptome, DNA methylome, histone methylome and metabolome data.

Summary/Conclusion: Based on these results, we think that the epigenetic state of some HTLV-1-infected cells is regulated by methionine metabolism. Targeting methionine incorporation or metabolism to change epigenetic reprogramming could constitute a novel therapeutic strategy for the treatment of ATL.

EP876 XENOGRAFT MODELLING OF DRIVING MOLECULAR EVENTS IN BURKITT LYMPHOMA

M. Singh [1], H. Blair [1], N. Bell [1], C. Steel [2], K. Uppal [2], S. Green [2], S. Nakjang [3], A. Iliasova [1], M. Zaka [4], V. Rand [4], C. Bacon [1], O. Heidenreich [5], J. Vormoor [5], S. Bomken [1,*]

[1]Translational and Clinical Research Institute, [2]Newcastle University, Newcastle, United Kingdom, [3]Bioinformatics Support Unit, Newcastle University, Newcastle, [4]School of Health and Life Sciences, Teesside University, Middlesbrough, United Kingdom, [5]Prinses Maxima Centre, Utrecht, Netherlands

Background: The genomic landscape of Burkitt lymphoma has largely been defined, but the clonal complexity and key molecular events driving disease development and/or relapse remain to be determined. In part this relates to the relative lack of patient samples, especially following relapse, and the limited number of representative experimental models.
Aims: To develop a novel approach to the modelling and study of sporadic Burkitt lymphoma biology we developed orthotopic patient-derived xenograft models. The aim is that such models can be used both to study the molecular drivers of disease development/relapse and for pre-clinical testing of new treatment approaches.
Methods: Samples from newly presenting or relapsed patients were collected and cryopreserved with informed consent for animal research. Thawed cells were injected into NSG (NOD.Cg-Prkdc^{scid} Il2rg^{tm1Wjl}/SzJ, Jackson Laboratory) or Rag2$^{-/-}$γc$^{-/-}$ (C;129S4-Rag2$^{tm1.1Flv}$ Il2rg$^{tm1.1Flv}$/J, Jackson Laboratory). Tumour bearing animals were killed and serial

transplantation performed. Parallel samples were taken for cytogenetic and molecular analysis.
Immunohistochemistry and cytogenetic analysis were performed within an NHS diagnostic laboratory setting. RNA and DNA were isolated and subjected to mRNA or exome sequencing using Illumina Novoseq or NextSeq platforms. Species specific transcripts were identified and murine reads removed using Disambiguate before further analysis. Exome data were analysed using GATK4.
Results: Viable cells from multiple sources (tumour, pleural effusion, bone marrow) were successfully cryopreserved and showed good viability. Patient material from all samples engrafted within 30-48 days. Serial transplantation across three (n=3) or four (n=1) generations was successful in all samples.
Immunohistochemical/cytogenetic analysis were consistent with the original pathological diagnoses. Transcriptomic analysis identified a metagene expression pattern consistent with published Burkitt lymphoma patient data, as distinct from diffuse large B cell lymphoma, confirming the representative nature of the models at this level.
Exome sequencing identified several mutations previously described to be recurrent in sporadic Burkitt lymphoma, including in the genes *MYC*, *TP53*, *ARID1A*, *RHOA* and *ID3*. Multiple pathogenic mutations in *ID3* were identified in each of three seperate patient samples and analysis of variant allelic frequency across sequential xenograft generations demonstrated differential fitness within the subclonal populations.
Summary/Conclusion: Patient-derived xenograft models of Burkitt lymphoma are feasible and representative of the original disease, despite cryopreservation. Molecular analysis of these models provides an alternative approach to the study of drivers of disease progression and may be used to track clonal evolution in response to therapy.

EP877 CHN1 IS A NOVEL PROGNOSTIC MARKER FOR DIFFUSE LARGE B-CELL LYMPHOMA

J. Sun [1,2], X. Zhu [3], Y. Zhao [3], Q. Zhou [3], R. Qi [3], H. Liu [1,2,*]

[1]Graduate School of Peking Union Medical College, [2]Hematology, [3]The Key Laboratory of Geriatrics, Beijing Hospital, Beijing, China

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common B-cell malignancy. Thirty to forty percent of DLBCL patients still experience relapse or develop refractory disease even with standard immunochemotherapy, leading to a poor prognosis. Currently, although several gene-based classification methods can be used to predict the prognosis of DLBCL, some patients are still unable to be classified.
Aims: This study was performed to identify a novel prognostic biomarker for DLBCL.
Methods: A total of 1,850 B-cell non-Hodgkin lymphoma (B-NHL) patients in 8 independent datasets with microarray gene expression profiles were retrieved from the Gene Expression Omnibus (GEO) database and Lymphoma/Leukemia Molecular Profiling Project (LLMPP). The candidate genes were selected through three filters in a strict pipeline. Survival analysis was performed in two independent datasets of patients with both gene expression data and clinical information. Gene set enrichment analysis (GSEA) and the CIBERSORT algorithm were used to explore the biological functions of the genes.
Results: We identified 6 candidate genes associated with the clinical outcome of DLBCL patients: *CHN1*, *CD3D*, *CLU*, *ICOS*, *KLRB1* and *LAT*. Unlike the other five genes, *CHN1* has not been previously reported to be implicated in lymphoma. We also observed that *CHN1* had prognostic significance in important clinical subgroups; in particular, high *CHN1* expression was significantly related to good outcomes in DLBCL patients with the germinal center B-cell-like (GCB) subtype, stage III-IV, or an International Prognostic Index (IPI) score > 2. Multivariate Cox regression analysis of the two datasets showed that *CHN1* was an independent prognostic factor for DLBCL. Additionally, GSEA and CIBERSORT indicated that *CHN1* was correlated with cell adhesion and T cell immune infiltration.
Summary/Conclusion: Our data indicate for the first time that *CHN1* is associated with the prognosis of DLBCL and suggest its potential utility as a prognostic marker in DLBCL.

EP878 CCL2-CCR2 AXIS SIGNALING PROMOTES DIFFUSE LARGE B-CELL LYMPHOMA CELL SURVIVAL AND INVASION

L. Yan-Li [1,*]

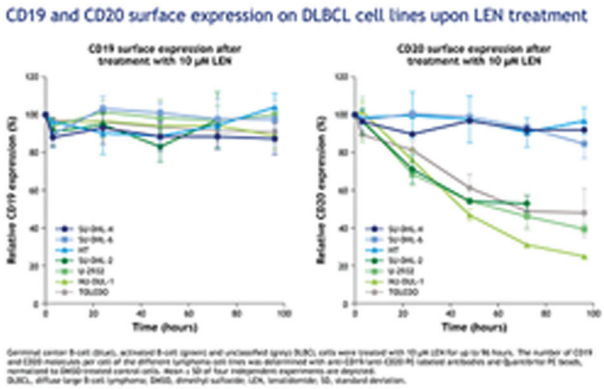
[1]Pathology, Anhui Medical University The First Affiliated Hospital of Anhui Medical University, Hefei, Anhui, China

Background: Diffuse large B cell lymphoma (DLBCL) incidence rates have increased year by year, a part of them have poor clinical outcomes, but the underlying mechanism involved is still unclear. Chemokines have been thought to play an important role in occurrence and development of tumors, but they are poorly studied in DLBCL. CC-Chemokine Ligand 2 (CCL2), the most representative of the CC chemokine family members, through binding to its high affinity receptor, CC chemokine receptor 2 (CCR2), has be regarded to involve in tumor growth, angiogenesis, epithelial mesenchymal transition, metastasis and immune escape etc. in recent years, but the role and mechanism in DLBCL has not been reported yet. Our preliminary study showed high expression of CCL2 or CCR2 was correlated with clinicopathological characteristics, and an adverse prognostic factor for overall survival (OS) and progression-free survival (PFS) of DLBCL patients.
Aims: The purpose of this study is to investigate the role of CCL2-CCR2 axis signaling in DLBCL by in vitro experiment.
Methods: CCL2 and CCR2 expression were analyzed in human DLBCL cell lines and normal B lymphocytes by Western blot (WB) and qPCR. CCL2 and CCR2 genes were silenced by lentivirus infection. The proliferation, migration, apoptosis and signaling pathway were detected by CCK8, transwell, flow cytometry (FC) and WB, respectively.
Results: CCL2 and CCR2 were expressed in all human DLBCL cell lines (SUDHL-2, SUDHL-4, SUDHL-6, OCI-Ly8 and OCI-Ly10). Blockade of CCL2-CCR2 axis signaling with lentivirus infection, CCL2 neutralizing antibody or CCR2 antagonist inhibited tumor cell proliferation, migration and anti-apoptosis ability. The CCL2-CCR2 axis involved in the proliferation and migration of DLBCL cells by activating PI3K/Akt signaling pathway, and induced apoptosis through activation of P38MARK signaling pathway.
Summary/Conclusion: Our study demonstrates that CCL2/CCR2 axis signaling plays an important role in the development of DLBCL by stimulating cell proliferation, migration and anti-apoptosis. The inhibition of CCL2 or CCR2 may, therefore, be a potential target for anticancer therapy in DLBCL.

EP879 LENALIDOMIDE-INDUCED EFFECTS ON CELL SURFACE EXPRESSION OF CD19 AND CD20 IN DLBCL CELL LINES AND FUNCTIONAL IMPACT ON ANTIBODY-MEDIATED CYTOTOXICITY

M. Patra-Kneuer [1,*], C. Augsberger [1], A. Polzer [1], C. Ginzel [1], K. Landgraf [1], S. Steidl [1], C. Heitmüller [1], J. Schanzer [1], J. Endell [1]

[1]MorphoSys AG, Planegg, Germany



Background: Lenalidomide (LEN) is an immunomodulatory drug with direct cytotoxic effects on tumor cells and stimulating effects on T and natural killer (NK) cells, making it an attractive combination partner for antibody therapies. However, clinical studies evaluating the addition of LEN to anti-CD20 based therapies compared to the current first-line standard of care (R-CHOP) for patients with diffuse large B-cell lymphoma (DLBCL) showed discordant results (ECOG-ACRIN trial 1412; ROBUST study). Recently, the combination of LEN with the anti-CD19 antibody tafasitamab has shown clinically meaningful efficacy in patients with relapsed or refractory DLBCL (L-MIND study).
Aims: We aimed to investigate whether LEN treatment affects antigen levels of CD19 and CD20 on DLBCL cell lines from different subtypes and whether potential target antigen modulation has an influence on antibody-dependent cellular cytotoxicity (ADCC) and phagocytosis (ADCP).
Methods: CD19 and CD20 surface expression was analyzed in 7 DLBCL cell lines (3 activated B-cell, ABC; 3 germinal center B-cell, GCB; 1 unclassified) after incubation with 1/10 µM LEN for 24–96 hours (h). For ADCP assays, DLBCL target cells were pretreated with 10 µM LEN or dimethyl sulfoxide (DMSO) for 96 h and then incubated with macrophages at an effector to target (E:T) ratio of 2:1 and 10 nM tafasitamab or rituximab (RTX) for 3 h. For ADCC assays,

DLBCL target cells were pretreated with 10 µM LEN or DMSO for 72 h and then incubated with NK cells at E:T ratios of 0.3:1 or 1:1 for 2 h in the presence of 1 nM tafasitamab, RTX or obinutuzumab (OBI). Antigen expression, ADCC activity, and ADCP activity were assessed by flow cytometry.

Results: While CD19 expression on lymphoma cells was unaffected by LEN treatment, CD20 expression was significantly reduced by 47–75% in all cell lines from the ABC and unclassified DLBCL subtype (SU-DHL-2, U-2932, NU-DUL-1 and TOLEDO; Figure). CD20 surface expression of the tested GCB lines was not affected by LEN treatment.

In ADCP assays, decreased CD20 levels were associated with significantly diminished phagocytosis rates mediated by RTX in 3/7 cell lines (% relative reduction in phagocytosis: 37, 23, and 21 in SU-DHL-2, U-2932, and TOLEDO cells, respectively). In contrast, no or negligible reduction of RTX-mediated phagocytosis by LEN was observed in the remaining 4/7 cell lines. ADCP activity of the CD19-targeting antibody tafasitamab remained unchanged in all tested cell lines.

Significant reductions in target cell killing were also observed in ADCC assays with 2/3 LEN-treated lymphoma cell lines for RTX (% relative reduction in ADCC: 14 and 16 in SU-DHL-2 and U-2932 cells, respectively) and for the glyco-engineered antibody OBI (% relative reduction in ADCC: 13 and 22 in SU-DHL-2 and U-2932 cells respectively). By contrast, RTX-/OBI-mediated cytotoxicity was not reduced by LEN in the GCB cell line SU-DHL-4. ADCC activity of tafasitamab against all 3 tumor cell lines was not decreased by LEN pretreatment.

Summary/Conclusion: LEN treatment decreased surface expression of CD20 but not CD19 in all tested ABC and unclassified DLBCL cell lines. Rates of ADCC and ADCP with CD20 antibodies were reduced in 3/4 of these cell lines, but this was not observed with tafasitamab. These findings suggest that antigen expression levels could have an impact on combination therapies with LEN in certain DLBCL subtypes and support the rationale for combining tafasitamab with LEN, independent of cell of origin.

EP880 LOW PERCENTAGE OF T-LYMPHOCYTES IN FOLLICULAR LYMPHOMA LYMPH NODE BIOPSIES, MEASURED BY FLOW CYTOMETRY, IS ASSOCIATED WITH INFERIOR PROGRESSION FREE SURVIVAL.

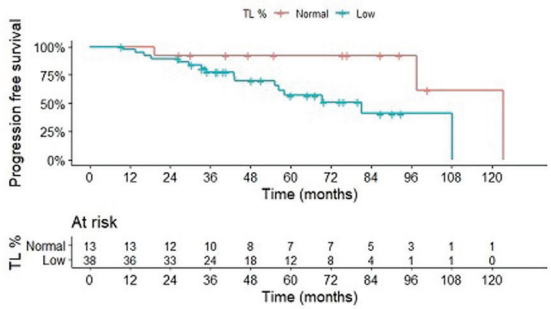
L. Korin [1,*], S. Cranco [1], M. L. Fuente [1], E. Babuin [1], A. Vitriu [1], P. Ochoa [1], A. Vijnovich Baron [2], F. Diaz Couselo [3], A. Novoa [4], M. B. Venegas [4], P. Tempra [4], N. Tartas [1], M. D. R. Custidiano [1], M. C. Foncuberta [1], J. C. Sanchez Avalos [1]

[1]Hematology, Instituto Alexander Fleming, [2]Pathology, Cepacit, [3]Internal Medicine, [4]Flow Cytometry, Instituto Alexander Fleming, Buenos Aires, Argentina

Lymph node TL % was able to further stratify clinical outcome in pts with low risk FLIPI-2. 75th percentile PFS for the low risk subgroup was estimated at 55.3 months but could improve to up to 97.4 months if normal TL % was detected, p:0.032. The same trend was observed in FLIPI-1 low risk pts (estimated 75th percentile of 55.3 months for the whole low risk category and of 29.6 and 97.4 months for the low and normal TL % subgroups, respectively; p:0.064).

Background: Several studies have suggested that tumor microenvironment (TME) could play an important role in lymphomagenesis and tumor progression in non-Hodgkin lymphoma. Gene-expression signatures derived from nonmalignant cells in the tumors, that predict survival, were identified in follicular lymphoma (FL). However, these molecular tools are not widely available and TME variables that could be easily translated into clinically relevant prognostic biomarkers are still missing in FL.

Aims: To determine the prognostic impact on survival of the percentage (%) of T lymphocytes (TL), measured by flow cytometry (FC), in tissue biopsies of FL patients (pts) at diagnosis and to evaluate whether these variables can provide additional information when superimposed on the FLIPI.



Methods: We selected pts with grade I-IIIa FL and available tissue biopsy FC data at the time of diagnosis who received treatment at our institution between 2007 and 2018. Clinical information was collected from medical records.

FC analysis was performed with 8-color FC panels according to international Euroflow protocols. % of lymph node TL by FC was compared to the normal values determined by Battaglia et al (Immunology 2003), and analyzed as an ordinal variable in 3 categories: low, normal and high. Progression free survival (PFS) was estimated with Kaplan-Meier method. The comparison between variables was performed with log-rank test and Cox proportional hazards model.

Results: 60 pts were included in this retrospective study. Median age was 57.5 years. 75% had stage III-IV disease. 28.3% of pts were stratified as high risk according to FLIPI-1 and only 13.3% with FLIPI-2 and PRIMA-PI. 23.3% were treated with Rituximab monotherapy and the remaining with Rituximab + CHOP, CVP or bendamustine. Complete response rate was 91.7%. 46 pts (76.6%) received Rituximab maintenance. POD24 was observed in 5 pts. Median PFS was estimated in 97.4 months. Only 3 pts died in our cohort with a median follow up time of 5.7 years.

A low % of TL in lymph nodes was associated with inferior PFS (hazard ratio 4.66, 95% confidence interval 1.02-21.21, p:0.046, figure 1). Median PFS in pts with normal lymph node TL % was 123.3 months compared to only 81 months in the low TL risk subgroup (p:0.05). There was also a trend towards worse outcomes in pts with high lymph node TL although not statistically significant (hazard ratio 11.17, 95% confidence interval 0.91-136, p:0.058).

Figure 1: Kaplan-Meier estimates of progression free survival in follicular lymphoma according to normal vs low T-lymphocyte percentage in lymph node biopsies

Summary/Conclusion: Low TL percentage in lymph nodes of pts with FL was associated with inferior outcomes in our cohort. First line therapies including an immunomodulatory agent such as lenalidomide could constitute an interesting strategy to restore a favorable immune microenvironment in this setting. Furthermore, the percentage of TL was able to provide additional prognostic information when combined with low risk FLIPI, identifying a subgroup with truly indolent behavior with 75% showing no evidence of relapse in more than 8 years. Data obtained from FC is easily acquired and should be taken into consideration when studying TME in FL.

EP881 PROGNOSTIC ROLE OF CD30 FROM A RETROSPECTIVE REVIEW OF 295 PATIENTS WITH ANGIOIMMUNOBLASTIC T CELL LYMPHOMA

J. Parrish [1,*], S. Premji [1], M. Khan [2], A. Elias [2], L. Malpica [2], R. Nair [2], D. Chihara [2], R. Miranda [3], J. Xu [3], F. Vega [2], S. Srour [4], S. Iyer [2]

[1]Internal Medicine, Baylor College of Medicine, [2]Department of Lymphoma/Myeloma, [3]Dept of Hematopathology, [4]Department of Stem Cell Transplant and Cellular Therapy, University of Texas MD Anderson, Houston, United States

Background: Angioimmunoblastic T cell lymphoma (AITL) is an aggressive malignancy with poor response to conventional chemotherapy. AITL is a subcategory of peripheral T cell lymphomas. Despite the approval of CD30 directed antibody drug conjugate- Brentuximab vedotin (BV), the prognostic role of CD30 in AITL is unknown.
Aims: The main aim of this study was to study the prognostic significance of CD30 expression in AITLThe main aim of the single institution retrospective study was to elucidate the prognostic implications of CD30 in AITL.
Methods: We analyzed patients newly diagnosed with AITL at our institution between 2000 and 2020. Along with CD30 receptor testing, variables such as date of diagnosis included age, gender, stage, LDH level, platelets, hemoglobin, bone marrow involvement, and EBV receptor positivity were collected. Treatment and progression data including response to frontline therapy, presence of consolidation stem cell transplant (SCT), and usage of brentuximab-based treatment. Endpoints were progression free survival (PFS) and OS; Univariate (UVA) and multivariate (MVA) Cox proportional hazard models were used to determine the significance of variables at diagnosis on PFS and OS.
Results: Out of the 295 individuals diagnosed with AITL,129 patients with CD30 testing who had response and survival data were included. This group had a median age of 65 (range 29-83) years and male predominance (51%) were identified. Table 1 summarizes patient and disease characteristics. Median follow up time was 40 (range 2-137) months, with three-year PFS and OS of 48% and 23% respectively. Sixty-seven individuals died within the first three years of the study. The 3-year OS is 46% in CD30+ individuals, and 55% in those who are CD30- (p=0.578). PFS is 20% in CD30+ individuals, and 29% in those who are CD30- (p-0.675). The variables included in Table 1 were assessed using UVA. Achieving Complete remission (CR) following frontline therapy (p=<0.0001) and consolidation with SCT (p=0.0428) were significantly associated with improved PFS. For OS, age <65 (p=0.0129), female gender (p=0.0437), and SCT (p=0.0003) were statistically associated with improved survival. CD30 and variables with p-value <0.15 were included in MVA. For PFS, achieving CR to frontline therapy (reference, complete remission), (HR 2.987, 95% CI: 1.524-5.855, p=0.0014) and consolidation with SCT (reference, SCT) (HR 2.036, 95% CI: 1.208-3.432, p=0.0076) were associated with better PFS. For OS, age >65 (HR 3.131, 95%CI: 1.545-6.344, p=0.0015), BM involvement (HR 2.134, 95% CI: 1.151-3.956, p=0.0161), incomplete remission (HR 2.208, 95% CI: 1-4.876, p=0.0499), male gender (HR 0.367, 95% CI: 0.199-0.678, p=0.0014), no SCT (HR 4.085, 95% CI: 2.119-7.872, p=<0.0001) and positive CD30 (reference, positive CD30) (HR 0.322, 95% CI: 0.158-0.656, p=0.0018) were associated with inferior OS.

Table 1		
Demographics	CD30 Positive (n=97)	CD30 Negative (n=32)
Median Age (range in years)	63 (29-83)	67 (42-83)
<65	53 (55%)	12 (38%)
>65	44 (45%)	20 (62%)
Gender (n=129)		
Female	53 (55%)	10 (31%)
Male	44 (45%)	22 (69%)
Stage (n=109)		
I-II	2 (2%)	3 (11%)
III-IV	79 (98%)	25 (89%)
LDH (n=72)		
Normal	25 (42%)	5 (38%)
High	34 (58%)	8 (62%)
Platelets (n=75)		
>=150 k	48 (80%)	9 (60%)
< 150 k	12 (20%)	6 (40%)
Anemia (n=76)		
Yes	31 (51%)	10 (67%)
No	30 (49%)	5 (33%)
Bone marrow involvement (n=117)		
Yes	31 (35%)	13 (46%)
No	58 (65%)	15 (54%)
EBER (n=122)		
Positive	71 (78%)	20 (65%)
Negative	20 (22%)	11 (35%)
Disease status (n=78)		
Complete response	75 (82%)	24 (83%)
Not in remission	17 (18%)	5 (17%)
Consolidation Stem cell transplant (n=115)		
Yes	48 (56%)	14 (48%)
No	38 (44%)	15 (52%)
Brentuximab-based treatment		
Yes	16 (20%)	0
No	64 (80%)	0

Summary/Conclusion: Age <65, achieving CR to induction treatment, and upfront SCT proved to be strong predictors of improved OS. In our cohort, only 20% of our patients received BV; nevertheless, unlike previous studies, individuals with CD30 positivity did not trend towards better OS. Therefore, additional work on CD30 biology in AITL is warranted.

EP882 EXPRESSION AND CLINICAL SIGNIFICANCE OF STING IN T- AND NK-CELL NON HODGKIN LYMPHOMAS

I. Xagoraris [1,*], P. Farrajota Neves da Silva [1], E. Drakos [2], S.-B. Ng [3], L. J. Medeiros [4], A. Österborg [1], G. Rassidakis [1]

[1]Department of Oncology-Pathology, Karolinska Institute, Stockholm, Sweden, [2]Department of Pathology, University of Crete Medical School, Heraklion Crete, Greece, [3]Department of Pathology, National University Hospital of Singapore, Singapore, Singapore, [4]Department of Hematopathology, University of Texas M.D. Anderson Cancer Center, Houston TX, United States

Background: The mechanisms of anti-tumor immune responses are currently under intense investigation in the era of immunotherapy. Cytosolic DNA of either endogenous or exogenous origin is sensed by the cGAS-STING pathway. Cyclic GMP-AMP (cGAMP) synthase (cGAS) is a cytosolic DNA sensor that activates anti-tumor immune responses through production of the second messenger cGAMP, which activates the adaptor protein STING. The latter then activates the transcription factors IRF3 and NF-κB via TBK1 and IKK kinases, respectively, inducing the expression of certain interferons (IFNs), such as IFN-alpha and IFN-beta, along with cytokines, which lead to cytotoxic T-cell mediated tumor cell killing. The expression patterns of STING protein in neoplastic cells of non Hodgkin lymphomas (NHL) is unknown to date.
Aims: To investigate the expression patterns and clinical significance of STING in T- and NK-cell lymphomas.
Methods: In the present study, we investigated STING expression and activation in 15 lymphoma cell lines by Western blot analysis using whole cell lysates and by immunohistochemistry (IHC) on formalin-fixed, paraffin-embedded cell blocks. The *in vitro* panel included four cell lines of ALK+ anaplastic large cell lymphoma (ALK+ ALCL) (Karpas 299, DEL, SUPM2, L-82), two of ALK- anaplastic large cell lymphoma (ALK- ALCL) (Mac1, Mac2a), one of Sezary syndrome (Hut78), and one of T-acute lymphoblastic leukemia (Jurkat), as well as eight B-cell lymphoma cell lines for comparison. In addition, STING protein expression was assessed in well-characterized cohorts of patients with T-cell NHLs using diagnostic biopsies obtained prior to treatment, immunohistochemical methods and a well validated monoclonal antibody. The T-cell NHL group (n=126) included 38 ALK+ ALCL, 36 ALK- ALCL, 17 other peripheral T-cell lymphomas (PTCLs) and 35 extranodal NK/ T-cell lymphomas of nasal type (NK/T-Nasal).
Results: High STING expression and activation assessed by Western blot analysis was found in all ALK+ and ALK- ALCL cell lines, as compared to Hut78 and Jurkat cells. Mac2a cells derived from a later stage of ALK- ALCL expressed higher levels of STING than Mac1 cells, which are derived from the same patient as Mac2a but at an earlier stage of disease. By contrast, the B-cell lymphoma cell lines were all negative or expressed very low levels of STING protein. Using a 10% cut-off for positivity, STING was differentially expressed among T-cell NHLs (Table 1, p<0.01, chi-square test) with ALK+ ALCL showing the highest frequency of STING-positive tumors. STING expression did not correlate with any clinical parameters including age, gender, Ann Arbor

stage, IPI score, LDH levels, B-symptoms, anemia, and others. STING expression in the lymphoma cells showed a statistical trend towards inferior overall survival in the ALK- ALCL group but not in other PTCL subtypes.

Table 1. STING expression in T- and NK-cell non Hodgkin lymphomas

Lymphoma type	Number of patients	STING-positive (n, %)	P-value
T-cell NHL	126	87 (69)	p<0.01
ALK+ ALCL	38	36 (95)	
ALK- ALCL	36	24 (67)	
Other PTCL	17	8 (47)	
T/NK nasal type	35	19 (54)	

Summary/Conclusion: STING is commonly and differentially expressed among T- and NK-cell NHL types and, therefore, pharmacologic modulation of cGAS-STING pathway activity may have therapeutic implications in T-cell malignancies.

EP883 SERUM MIR-22 AS NOVEL NON-INVASIVE PREDICTOR OF CLINICAL OUTCOME AND RESPONSE TO THERAPY IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

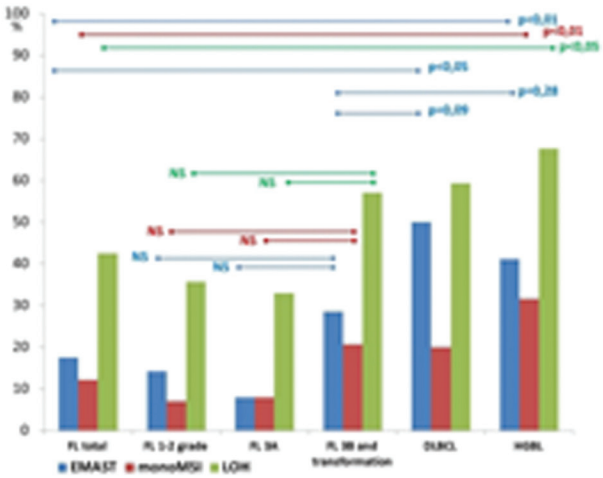
F. Marchesi [1,*], G. Regazzo [1], F. Palombi [1], E. Tremante [1], F. Bertoni [2], I. Terrenato [1], M. Marino [1], S. Vaccarini [3], M. Cantonetti [3], O. Annibali [4], V. Tomarchio [4], E. Papa [1], A. Mengarelli [1], M. G. Rizzo [1]

[1]IRCCS Regina Elena National Cancer Institute, Rome, Italy, [2]Institute of Oncology Research, Faculty of Biomedical Sciences, Oncology Institute of Southern Switzerland (IOSI), Bellinzona, Switzerland, [3]Tor Vergata University, [4]Campus Bio-Medico University, Rome, Italy

Background: Diffuse large B-cell lymphoma (DLBCL) is a clinically and genetically heterogeneous neoplasm with aggressive clinical course. The first-line treatment is chemoimmunotherapy with R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone), however up to 40% of patients are refractory to treatment and have a poor clinical outcome. The available prognostic tools are not able to identify all the patients refractory to R-CHOP. Liquid biopsies, introduced with the benefit of being non-invasive, facilitate serial sampling and dynamic patients monitoring. MiRNAs, small non-coding RNAs frequently deregulated in cancer, are present in body fluids in a highly stable form, making them interesting candidates as biomarkers. In this regard, we have previously performed a pilot study on serum miRNAs profile in DLBCL patients, and found that serum miR-22-3p was significantly correlated with PFS.
Aims: In order to validate the value of circulating miR-22 as reliable non-invasive biomarker and investigate is biological function in DLBCL, we pursued the following aims: a) to analyze serum miR-22 in an independent validation cohort of DLBCL patients; b) to compare miR-22 expression in serum and matched tumor samples and c) to asses its functional role in DLBCL pathogenesis and response to R-CHOP treatment.
Methods: Multicentre prospective study on de novo DLBCL patients (n=42) uniformly treated with R-CHOP. miR-22 expression profile was evaluated by qRT-PCR in serum samples and in matched tissue samples. Survival analysis was performed by Kaplan–Meier method. miR-22 levels were further analysed by qRT-PCR in six DLBCL cell lines and related conditioned culture medium. Sensitivity to R-CHOP treatment for each cell line was evaluated determining R-CHOP IC50 by cytotoxicity MTT assays after 72h hours of treatment. HBL1 DLBCL cell line was transfected with miR-22 mimic by electroporation, 24h hours post transfection cells were plated and vital cells were counted at 24h, 48h and 72h hours.
Results: a). Our data show that patients with baseline higher serum miR-22 levels had a significant worse clinical outcome in terms of 2-year progression free survival (p = 0.015). When considering all enrolled patients (training + validation cohorts: 78 patients) serum miR-22 was differentially expressed in refractory patients compared to responders (p=0.047). b) The comparison results of miR-22 expression in serum and paired tumour samples indicate a significant and inverse correlation (Spearman's Rho= -0.469, p=0.010). c) Assessing miR-22 expression in extracellular (conditioned medium) and intracellular fraction of DLBCL cell lines we observe that the value of extracellular to intracellular ratio of miR-22 levels is directly correlated with the cell resistance (IC50 of R-CHOP) to R-CHOP treatment (Spearman's Rho = 0.928; value = 0.008). Moreover, a decreased proliferation rate was found upon miR-22 overexpression in HBL1 cells (a cell line with low miR-22 basal expression).
Summary/Conclusion: Altogether the results of our study suggest that miR-22 may represent a prognostic and predictive biomarker in DLBCL, and may be involved in lymphoma pathogenesis and in mechanisms of response to treatment.

EP884 TUMOR MICROSATELLITE ANALYSIS IN B-CELL LYMPHOMAS

S. Kseniia [1,*], S. Kravchenko [1], E. Nikulina [1], A. Misurina [1], N. Risinskaya [1], A. Magomedova [1], A. Sudarikov [1]



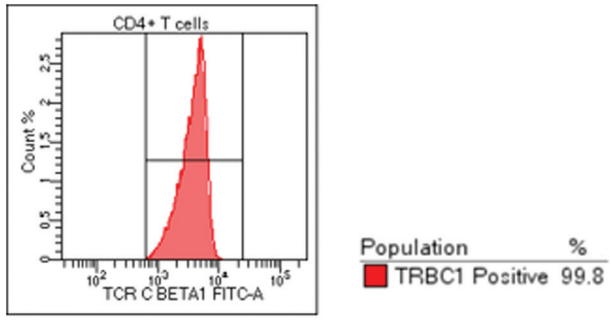
[1]National Research Center for Hematology, Moscow, Russian Federation (Russia), Moscow, Russian Federation

Background: Identification of patients with an unfavorable course of B-cell lymphomas could be difficult at the disease onset. The existing risk stratification models are based mainly on the patient somatic status and disease clinical features. The evidence suggests that it is necessary to search for new markers that would reflect the pathogenesis and behavior of the particular tumor.
DNA repair system functions to preserve the original sequence. The role of mismatch repair system (MMR) deficiency and the resulting microsatellite repeats instability (MSI) has been proven for solid tumors, in particular, colorectal cancer. As B-cell tumors are characterized by high genetic plasticity we suggest that their pathogenesis may also involve changes in the repair system.
Aims: To analyze microsatellite changes associated with repair system deficiency in patients with aggressive and indolent B-cell lymphomas.
Methods: Thirty-five diffuse large B-cell lymphoma (DLBCL) patients, 38 high-grade B-cell lymphoma (HGBL) patients, and 84 follicular lymphoma (FL) patients were included. There were 28 1-2 grade FL patients,

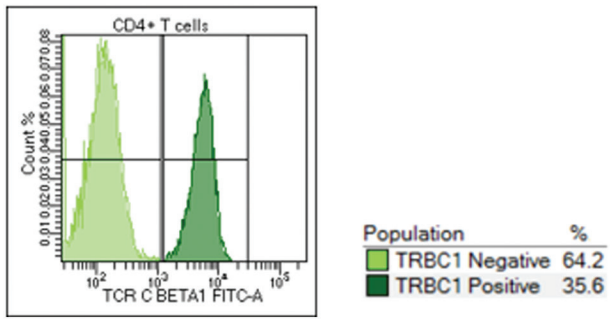
Figure1. The frequency of EMAST, monoMSI, and LOH in B-cell lymphoma groups and the results of pairwise comparison in the χ^2 test.

	FL total	FL 1-2 grade	FL 3A grade	FL 3B and transform ation	DLBCL	HGBL
EMAST	14*/80** (17,5%)	4/28 (14,3%)	2/24 (8%)	8/28 (28,6%)	16/32 (50%)	13/31 (41,2%)
monoMSI	10/82 (12,2%)	2/28 (7,1%)	2/25 (8%)	6/29 (20,7%)	7/35 (20%)	12/38 (31,6%)
LOH	34/80 (42,5%)	10/28 (35,7%)	2/24 (33%)	16/28 (57,1%)	19/32 (59,4%)	21/31 (67,7%)

*number of positive cases
**number of cases with a valid study result



25 3A grade FL patients, and 31 patients with type 3B FL and the transformation of FL into large-cell lymphoma in the latter group. All patients gave their voluntary consent to participate in the study. Microsatellite instability was studied using COrDIS Plus and COrDIS MSI kits (Gordiz Ltd, Russia) in tumor tissue and in peripheral blood cells as a control sample. Amplification was performed using thermal cycler DNAEngine (BioRad, USA). The subsequent fragment analysis was performed on the genetic analyzer Nanofor-05 (Sintol Ltd, Russia).
Results: The detected changes in the microsatellite profile were classified as follows: EMAST (elevated microsatellite alterations at selected tetranucleotide repeats) – the appearance of a new allele of tetranucleotide loci; LOH (loss of heterozygosity) – allelic imbalance; monoMSI – aberrations of mononucleotide markers that could not be differentiated between LOH and instability. Data on these genetic alterations frequencies and results of $\chi 2$ test are shown in Figure 1.
In general, DLBCL and HGBL are more likely to have microsatellite aberrations, especially EMAST, than FL. Microsatellite aberrations frequencies in DLBCL and HGBL groups were comparative. Within the general group of FL, differences were observed between indolent (1-2 and 3A grades) and aggressive FL (3B and FL transformation), but they did not reach statistical significance. However, EMAST, monoMSI, and LOH frequencies in transformed FL are seemed higher than in indolent FL.
The aggressive FL group is intermediate between DLBCL and HGBL and indolent FL. It is important to note that the histological transformation of FL does not accumulate a significant number of microsatellite aberrations in the genome, not like aggressive B-cell lymphomas de novo. This indicates that microsatellite repeats instability is mostly the tumor feature at its early development stages and is not acquired during tumor progression.
Summary/Conclusion: Microsatellite instability is common in B-cell lymphomas. EMAST, monoMSI, and LOH distribution have no nosological specificity. These genetic alterations are more peculiar to aggressive lymphomas de novo. The lack of statistical significance in pairwise comparison does not allow considering microsatellite analysis as a differential diagnosis tool. However, the probable prognostic significance of EMAST, monoMSI, or LOH could be reached while expanding the cohort of patients and conducting additional survival analysis.



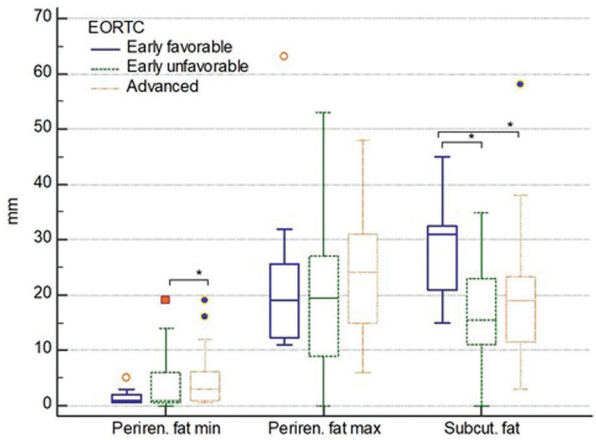
EP885 RELIABLE DETECTION OF T-CELL CLONALITY BY FLOW CYTOMETRY IN MATURE T-CELL NEOPLASMS USING TCR B CONSTANT REGION 1 (TRBC1): A COMPARISON WITH PCR BASED CLONALITY TESTING.

D. Waldron [1,*], D. O Brien [1], L. Smyth [1], F. Quinn [2], E. Vandenberghe [1]

[1]Haematology Department, [2]CMD Department, St. James's Hospital, Dublin, Ireland

Background: T-cell lymphomas are a pathologically and clinically complex group of heterogenous disorders. Often the interpretation of flow cytometry patterns may present challenges. Identification of an antibody specific for the TCR β constant region 1 (TRBC1) proposes to identify T-cell clonality and distinguish pathological T cells from normal T cells.
Aims: The aim of this project was to validate the diagnostic abilities of TRBCB1 antibody when used in conjunction with an existing T-cell antibody panel.
Our aim was to use a control group of patient samples and assess TRBC1 expression on both CD4+ and CD8+ T cells separately, and calculate the ratio of TRBC1 positive and negative αβ T cells.
30 cases submitted for an investigation of a T -cell lymphoproliferative disorder were then assessed for TCBC1 expression.
We report here on our experience with the TRBC1 antibody, from validation to real-life experience by direct comparison of TRBC1 expression with molecular clonality testing.
Methods: 10 normal peripheral blood samples were utilised to determine the normal biological range of TRBC1 on T cells. 30 consecutive patient samples submitted for investigation of a lymphoproliferative disorder were evaluated in a blind fashion independent of molecular analysis findings. Assessment of T-cell antigens including CD2/CD3/CD4/CD5/CD7/CD8/CD16/CD26/CD45/CD56/TCR αβ/TCR γδ along with TRBC1 were completed. Results were then compared to TCR gene rearrangement patterns by PCR.
Results: All normal control cases displayed a polytypic pattern of TRBC1 expression, with an average ratio of TRBC1 positive to TRBC1 negative expression of 1:2. Of the 30 consecutive cases evaluated, 7 cases were polytypic for TRBC1 and 22 cases were monotypic for TRBC1 expression. Direct comparison with molecular analysis demonstrated that no sample identified with monotypic (restricted) expression of TRBC1 was reported as polyclonal by PCR. A concordance rate of 95% (21/22 cases) between a clonal TCR gene rearrangement PCR result and a monotypic TRBC1 expression was calculated.

Summary/Conclusion: We have found the anti-TCR C Beta 1 antibody to be of high diagnostic value for assessment of clonality in patients with a suspected T cell neoplasm when used in conjunction with our existing diagnostic panel.
Incorporation of the TRBC1 antibody as part of the evaluation of a suspected T-cell neoplasm improves the identification of clonal T cells by flow cytometry and correlates well with molecular methods.
The importance of implementing a gating strategy directed at the abnormal population of T cells cannot be overstated.
This antibody is designed to detect clonal abnormalities in the constant region of the Beta chain of the TCR, therefore, it is not applicable for the assessment of normal γδ T cells or γδ T cell neoplasms.
To conclude, our results prove that this antibody improves the identification of clonal T cells by flow cytometry and is amenable to integration into a busy flow cytometry laboratory. By recognising the pitfalls and remaining mindful of the importance of gating strategies in the execution of this assay we find the TRBC1 antibody represents an excellent addition to the investigation of T-lymphoproliferative disorders by flow cytometry.



EP886 DIFFERENT ABDOMINAL FAT COMPARTMENTS DIFFERENTLY REFLECT ON PROGNOSIS IN CLASSICAL HODGKIN LYMPHOMA PATIENTS

M. Lucijanic [1,*], R. Huzjan Korunic [2], M. Ivic [1], A. Fazlic Dzankic [3], R. Kusec [1], V. Pejsa [1]

[1]Hematology, [2]Radiology, University hospital Dubrava, Zagreb, [3]Hematology, General Hospital Sisak, Sisak, Croatia

Background: There are conflicting data how obesity might affect outcomes in patients with classical Hodgkin lymphoma (cHL). Computed tomography (CT) scans done at the time of cHL staging offer a unique opportunity to assess different body fat compartments and their potential prognostic associations without exposing these patients to additional unnecessary procedures.
Aims: We aimed to assess subcutaneous and visceral abdominal fat measurements in patients with cHL at the time of diagnosis and to investigate their clinical associations.
Methods: We retrospectively analyzed 82 newly diagnosed cHL patients from our center with available CT scans prior to receiving specific therapy and with available clinical data. Patients were treated with either

ABVD or eBEACOPP chemotherapy regimens and subsequent radiotherapy per physicians' decision. Perirenal fat was chosen as a measurement of visceral fat and its thickness was assessed as the largest and the smallest distance from kidney outline to the inner limit of abdominal wall at the transversal level of the renal vein. Subcutaneous fat thickness was assessed as the largest distance between the skin and outer limit of the muscular abdominal wall at the transversal level of the umbilicus.
Results: Median age was 36 years, majority of patients were males [46/82 (56.1%)]. The most common histological subtype was nodular sclerosis [61/82 (74.4%)]. A total of 11/82 (13.4%) patients were classified as early favorable, 38/82 (46.3%) as early unfavorable and 33/82 (40.2%) as advanced disease by EORTC system. All three abdominal fat thickness measurements (minimal and maximal perirenal and subcutaneous fat thickness) correlated positively together, showed moderate positive correlation with BMI (Rho 0.54 to 0.57; P<0.05) and weak positive correlation with total psoas muscle area at the L3 level (Rho 0.24 to 0.33; P<0.05).
Patients with more advanced EORTC disease stage were significantly more likely to have higher minimal perirenal fat thickness but lower subcutaneous fat thickness (P<0.05 for both analyses) as shown in Figure 1. Similarly, minimal perirenal fat thickness was significantly positively correlated with the IPS (Rho=0.34, P=0.002), whereas subcutaneous fat thickness was significantly negatively correlated with the IPS (Rho=-0.27, P=0.013). No significant associations of BMI with EORTC stages nor IPS were present (P>0.05).
Higher minimal (HR=8.4; P<0.001) and maximal perirenal fat thickness (HR=3.15; P=0.049), but lower subcutaneous fat thickness (HR=3.57; P=0.033) were associated with inferior overall survival in univariate analyses. In addition, lower subcutaneous fat thickness (HR=4.45; P=0.005) was also associated with shorter time to disease progression. There was no association of BMI with neither survival nor time to progression.
Associations of perirenal and subcutaneous fat thickness were further analyzed in the multivariate models adjusted for age, gender, Ann Arbor stage and IPS. Both minimal perirenal fat thickness >2 mm (HR=49.2; P=0.019), subcutaneous fat thickness ≤22 mm (HR=45.7; P=0.038) and IPS (HR=2.44; P=0.025) remained significantly associated with inferior overall survival. Subcutaneous fat ≤22 mm (HR=14.4; P=0.013) and older age (HR=1.04; P=0.043) remained independently associated with shorter time to disease progression.

Summary/Conclusion: Excess body fat might differently affect outcomes in patients with cHL depending on its distribution. Distinction between different abdominal adipose tissue compartments is necessary to better understand relationship between obesity, cachexia and prognosis in patients with cHL.

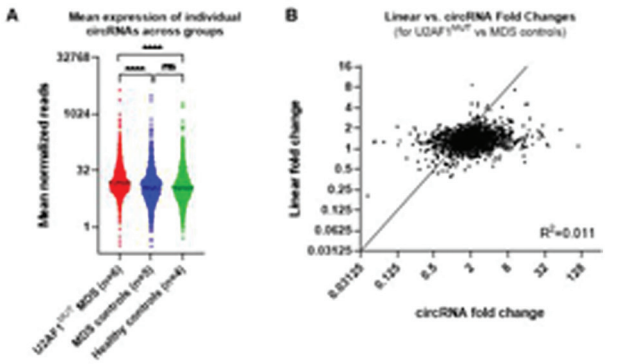
EP887 TRITON X-114 AND AMINE-BASED WASH STRATEGY REDUCES LPS TO FDA-LIMIT AND ACHIEVES PURER, MORE POTENT RECOMBINANT IMMUNOTOXIN.

R. George [1,2,*], F. Gsottberger [1], A. Ammon [1], K. Wendland [1], L. Mellenthin [1], A. Mackensen [1], F. Müller [1]

[1]Hematology and Oncology, Universityhospital Erlangen, [2]Friedrich-Alexander-University of Erlangen-Nurnberg, Erlangen, Germany

Background: Recombinant immunotoxins (rIT) are fusion proteins of a targeting moiety and pseudomonas exotoxin (PE). They arrest protein synthesis in eukaryotes by ADP-ribosylation of elongation factor 2 (eEF2) leading to target cell death. The CD22 targeted immunotoxin Moxetumomab pasudotox (Moxe) was approved for the treatment of relapsed/refractory hairy cell leukemia. Because immunotoxins stop eukaryotic protein expression, they are expressed in *E. coli*. However, proteins expressed in *E. coli* are contaminated by endotoxin (also called lipopolysaccharides (LPS)). LPS binds to toll-like receptors, inducing up to life-threatening systemic inflammation in mammals. Therefore, FDA-approved LPS-limit for therapeutics as well as for substances used in immunological studies in animals are as low as 0.05 EU/mg.
Aims: We aimed to establish a broadly applicable protein purification method to reduce LPS below FDA approved limits without altering stability or function of the protein.
Methods: Immunotoxins were expressed in *E. coli*, refolded, and purified using standard protocol by three column chromatography. To reduce LPS, an on column Triton X-114 wash, amine based spin columns, or the combination of the two was tested. LPS levels were measured by LAL-assay, protein quality control was done by SDS-PAGE analysis. Immunotoxins were tested extensively *in vitro* for ADP-ribosylation, cytotoxicity, thermal stability, and binding affinity. *In vivo* efficacy was determined in a systemic xenograft model.
Results: Moxe produced by standard method was contaminated by 2.7 EU/mg LPS. The on column Triton X-114 wash did not reduce LPS contamination by itself and spin-columns reduced LPS to 0.40 EU/mg. When combined, LPS was reduced by 120-fold to 0.02 EU/mg compared to standard method. Immunotoxins purified by the combination were purer by 9% which we found to be a result of the Triton X-114 on-column wash. Furthermore, *in vitro* cytotoxicity was enhanced up to 2.4-fold which was not explained by increased enzymatic ADP-ribosylation activity or improved protein stability, but by an enhanced binding affinity to CD22 on the cell surface. LPS-reduced protein maintained *in vivo* efficacy. Additionally, LPS was reduced below FDA-limits for other antibody formats (dsFv and Fab), for distinct PE variants and for antibodies against distinct targets.
Summary/Conclusion: Only Triton X-114 on-column wash combined with amine-residue-based spin columns reliably reduced LPS contamination below FDA-approved limits. Resulting immunotoxins were purer and more potent. With some modifications, the method may be applicable for any chromatography-based purification processes and may be run entirely on column.

Myelodysplastic syndromes - Biology & Translational Research



EP888 IMPLICATIONS OF THE SPLICEOSOME MUTATION U2AF1 FOR THE EXPRESSION OF CIRCULAR RNA

E. Wedge [1,2,3,*], T. Birkballe Hansen [4], C. Côme [2,3], J. Kjems [5], K. Grønbæk [1,2,3], L. Sommer Kristensen [6]

[1]Department of Hematology, Copenhagen University Hospital, [2]Biotech Research and Innovation Center (BRIC), [3]The Danish Stem Cell Center (Danstem), Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, [4]Department of Molecular Biology and Genetics, [5]Interdisciplinary Nanoscience Center (iNANO), [6]Department of Biomedicine, Aarhus University, Aarhus, Denmark

Background: Spliceosome mutations are common in myelodysplastic syndromes (MDS), but their role in cancer biogenesis and progression is not fully understood. *U2AF1* mutation is associated with a poor prognosis. This splicing factor is responsible for recognition of the 3' splice site, a process which is altered by the two commonly found hotspot mutations at residues S34 and Q157. Circular RNAs are produced when backsplicing events occur, in competition with linear mRNA splicing. CircRNAs have been implicated in numerous cancers and immune processes.
Aims: To explore the impact of *U2AF1* mutation on circRNA expression in MDS.
Methods: We analyzed RNAseq data from a transgenic mouse model with doxycycline-inducible $U2AF1^{S34F}$/$U2AF1^{WT}$ expression.[1] In addition, we generated total RNAseq data from FACS sorted CD34+ bone marrow cells from patients with MDS with *U2AF1* mutation (3 S34 mutations, 3 Q157 mutations), along with 5 matched MDS controls without spliceosome mutations and 4 healthy controls. CircRNAs were identified using the pipelines CIRI2 and find_circ, with detection by both pipelines required. CircRNA counts were normalized using DESeq2 including linear mRNA expression. DESeq2 was also used to generate adjusted p values.

Results: CircRNA expression was predominantly upregulated with the induction of *U2AF1*^{S34F} mutation in mice (p<0.0001, Wilcoxon test). The correlation between fold changes in circular and linear RNA expression (from corresponding splice sites) was low (R^2 =0.005) indicating that altered circRNA expression was independent to changes in linear expression. In MDS patients, circRNA expression was significantly higher in those with *U2AF1* mutations than matched controls (Figure A, p<0.0001, Wilcoxon test), whilst there was no significant difference between the MDS controls and the healthy controls. Again, changes in circRNA expression were independent to changes in linear expression (Figure B, R^2=0.011). Seven specific circRNAs were significantly upregulated (p_{adj}<0.05 and fold change >2) in patients with *U2AF1* mutation vs MDS controls. Literature searching revealed that two of these circRNAs (circZNF609 and circCSNK1G3) have previously been linked to cancer (hepatic cell carcinoma and renal cell carcinoma, respectively).[2,3] Global circRNA expression levels did not differ between patients with S34 and those with Q157 mutations (p=0.374, Wilcoxon test), but the patterns of expression were found to be distinct, indicated by separation of the two mutations on unsupervised cluster analysis.

Summary/Conclusion: We found both in a murine model and in MDS patients that *U2AF1* mutations lead to an increase in circRNA expression. Furthermore, distinct circRNA expression profiles were seen for mutations at the S34 and Q157 loci. Further investigation of the biological mechanism by which *U2AF1* mutation supports backsplicing, and profiling of a larger cohort of MDS patients, is merited.

L'Hospitalet de Llobregat, Llobregat, [19]Hematology, Hospital Universitario Santa Lucía, Cartagena, [20]Hematology, Hospital Fundación Jiménez Díaz, Madrid, [21]Hospital Vall d'Hebron, Barcelona, [22]Hospital Morales Meseguer,CRH-IMIB, Murcia, [23]Hospital Universitario y Politecnico La Fe, CIBERONC, Valencia, [24]Hospital Universitario Cruces, Barakaldo, [25]Hospital Clínico Universitario de Salamanca, Salamanca, [26]Hospital Germans Trias i Pujol, Badalona, [27]Hospital Virgen de las Nieves, Granada, Spain

Background: In myelodysplastic syndromes(MDS) in young adults without previous organic dysfunction, the role that germline variants play in its pathogenesis remains to be defined. In fact, the WHO 2017 classification only includes alterations in a single gene, *DDX41*, in this subgroup of patients. In order to provide knowledge in this group of patients, where these findings could impact allogeneic hematopoietic stem cell transplantation (allo-HSCT) strategies.
Aims: We proposed an exhaustive clinical analysis, favoured by the prospective nature of the study in a Spanish multicentre cohort of patients with data from paired tumor-germinal exome sequencing.
Methods: Prospective cohort study (2014-2020) of 168 patients from 20 Spanish Group of Myelodysplastic Syndrome (GESMD) centers with a *de novo* diagnosis of MDS between 16-60 years old, without prior organ dysfunction. Collection of 107 clinical variables in relation to family and personal history, diagnosis, treatment, HSCT and disease evolution. Whole exome sequencing(WES) was performed in paired tumor-germline samples with 100x average depth, 150 million reads per sample, and >95% Q30[a]. WES libraries were prepared using SureSelectXT Target Enrichment System for Illumina Version B.2 and sequenced on a HiSeq4000-NovaSeq6000-Illumina platform. The analysis of the variants was carried out by means of an in-house pipeline: filtering out intronic, synonymous and those variants with MAF>1%. The germline variants were categorized according to ACMG criteria.
Results: The median age at diagnosis was 49 years old(16-60) with the following WHO 2017 diagnoses: 13.6% MDS-unilineage dysplasia(UD), 11.1% MDS-ring sideroblasts(RS), 32.1% MDS-multilineage dysplasia(MD), 27,1% MDS-excess blasts(EB), 5.6% MDS-isolated deletion-5q(del-5q), 2.5% MDS-unclassifiable(U), 8% chronic myelomonocytic leukemia(CMML). We found germline variants which categorized as pathogenic(P), likely pathogenic(LP) or uncertain significance(VUS) in 82%(n=139) of 168 patients. The frequency of patients with germline variants according to the gene function/pathway were 36%(n=62) DNA damage response, 2%(n=4) telomere function maintenance, 10%(n=18) hematopoiesis regulators, 4.8%(n=8) ribosome function, 11.9%(n=20) immune response,and 32.7%(n=55)others. *DDX41*(n=3) and *SAMD9L*(n=1), recurrently implicated in the predisposition to myeloid neoplasia without extra-hemopoietic clinical features, were only present in 4 cases in our cohort. Patients with germline

TABLE 1. Clinical-genetic characteristics of the study cohort and comparisons between different groups based on the presence or absence of germline variants (VUS + LP + P according to ACMG).

VARIABLE	GLOBAL COHORT (N=168)	(A) With germline variant (GV) (n=139)	(B) With GV of DNA damage response (n=62)	(C) Without GV (n=29)	(D) Without GV of DNA damage response (n=106)	P (A vs C)	P (B vs C)	P (B vs D)

variants(P and/or LP and/or VUS) in DNA repair genes(Table1) showed a lower age(49 vs 53 years old; p=0.032), a higher frequency of family history of MDS/acute myeloid leukemia(AML), and less probability of concomitant myelofibrosis; together with a statistical tendency to present family history of oncologic neoplasia, when compared with those cases without germline alteration. In the overall cohort, the presence of germline variants in DNA repair genes was correlated with superior risk to progression to AML and worse survival. These findings remain statistically significant even when applying a multivariate analysis with IPSS-R dichotomized (≤3.5 vs >3.5).

Summary/Conclusion: Young adult patients diagnosed with MDS *de novo*, without having presented any previous organ dysfunction, show a germline profile enriched in variants affecting genes of the DNA repair pathways. This subgroup presents subtle but relevant clinical differences that would support its specific pathogenicity, adding clinical information to the prediction data *in silico*.

EP890 MOLECULAR AND CYTOGENETIC CHARACTERIZATION OF MYELODYSPLASTIC SYNDROMES IN CELL-FREE DNA

N. Garcia-Gisbert [1,2,*], B. Merchán [1,3], S. García-Ávila [1,3], M. Salido [4,5], C. Fernández-Rodríguez [1,5], L. Fernández-Ibarrondo [1,2], L. Camacho [1,5], J. Gibert [1], M. Lafuente [1,2], R. Longarón [1,5], B. Espinet [4,5], M. Andrade-Campos [1,3], L. Arenillas [4,5], X. Calvo [4,5], C. Besses [1], A. Salar [1,3], B. Bellosillo [1,2,5]

[1]Applied Clinical Research in Hematological Malignancies, IMIM-Hospital del Mar, [2]Universitat Pompeu Fabra, [3]Department of Hematology, Hospital del Mar, [4]Translational Research on Hematological Neoplasms, IMIM-Hospital del Mar, [5]Department of Pathology, Hospital del Mar, Barcelona, Spain

Background: Molecular studies and conventional cytogenetics are essential for patients with myelodysplastic syndromes (MDS) to establish a correct diagnosis and to optimize their prognosis and management. Routinely, these analyses are performed in bone marrow (BM) samples, especially cytogenetics as it is difficult to obtain metaphases in peripheral blood (PB) samples. Analysis of cell-free DNA (cfDNA), also known as liquid biopsy, has been reported as a reliable approach for detecting molecular abnormalities in MDS. However, there is limited information about cytogenetic alteration analysis in cfDNA from MDS patients.

Aims: To analyze the molecular and cytogenetic abnormalities of cfDNA using next generation sequencing (NGS) in patients with MDS.

Methods: BM aspirates and PB samples were collected from 57 newly diagnosed or treatment-naïve patients with MDS: 1 MDS-SLD, 33 MDS-MLD, 3 MDS-RS-SLD, 10 MDS-RS-MLD, 2 MDS-del(5q), 5 MDS-BE-1, 1 MDS-BE-2 and 2 MDS-U. PB samples from 33 healthy controls were also studied. Molecular characterization was performed in paired samples of BM DNA and cfDNA by NGS in all patients. Libraries were prepared using a custom panel including 48 myeloid-associated genes and genomic regions localized at the most frequently altered chromosomes in MDS (QIAseq Custom DNA Panels, Qiagen) and sequenced using Illumina technology with a 3000x minimum coverage. 14/57 (24.6%) presented cytogenetic/FISH alterations at the time of diagnosis, 2 of them with alterations not covered by the panel (+14, del(9q)). Copy number variant (CNV) analysis was performed by NGS to detect cytogenetic alterations in both cfDNA and BM, and confirmed by chromosomal microarrays (CMA) in BM DNA (CytoScan/OncoScan, ThermoFisher).

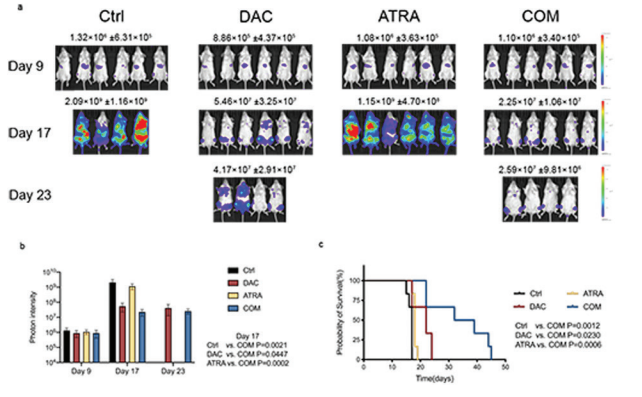
Results: We obtained a median amount of total cfDNA of 60.1 ng/ml in MDS patients that was significantly higher than that obtained from healthy controls (median 5.16 ng/ml) (p<0.001, Mann-Whitney). Sequencing of BM DNA and cfDNA showed a comparable mutational profile (153/161 mutations, 95.0% concordance). The most frequently mutated genes were *TET2* (47.4%), *SF3B1* (29.8%), *ASXL1* (21.1%), *SRSF2* (19.3%), *DNMT3A* (15.8%), *ZRSR2* (14.0%) and *U2AF1* (12.3%). A strong correlation was observed between the VAF of BM and cfDNA (r=0.787, p<0.001, Spearman). There were 7 discordant mutations: 3 were only detected in cfDNA and 4 were only detected in BM. These 7 discordant mutations presented a lower variant allele frequency (VAF) (median 7.41%, range 2.86–25.53%) when compared to the VAF observed in cfDNA in the whole cohort (median 31.44%, range 0.74–98.28%).

CNV analysis by NGS showed cytogenetic alterations in 9/57 MDS patients in both BM DNA and cfDNA. 8/12 (73%) cases with altered karyotype/FISH were detected by NGS, and the remaining were identified in few metaphases (2 cases presented +8 and 1 case +4) and in one case a del(5q) only detected by FISH. Interestingly, in a patient without analyzable metaphases in the karyotype, del(20q) was found by NGS and was confirmed by CMA. Overall, CMA and NGS were highly concordant to detect chromosomal aberrations although they do not reach the detection achieved by karyotype/FISH. However, all the cytogenetic aberrations detected by NGS in BM DNA were also detected in cfDNA (100% concordance).

Summary/Conclusion: The analysis of cfDNA allows the characterization of the molecular abnormalities in patients with MDS. Cytogenetic alterations were detectable in most cases by NGS in both BM DNA and cfDNA although with a lower detection rate than karyotype/FISH.

EP891 ALL-TRANS RETINOIC ACID ENHANCES THE CYTOTOXIC EFFECT OF DECITABINE ON MYELODYSPLASTIC SYNDROMES VIA ACTIVATING RARA-NRF2 COMPLEX

L. Wang [1,*], X. Zhou [1], X. Ye [1], L. Ye [1], C. Mei [1], Y. Ren [1], L. Ma [1], G. Xu [1], W. Xu [1], H. Tong [1]



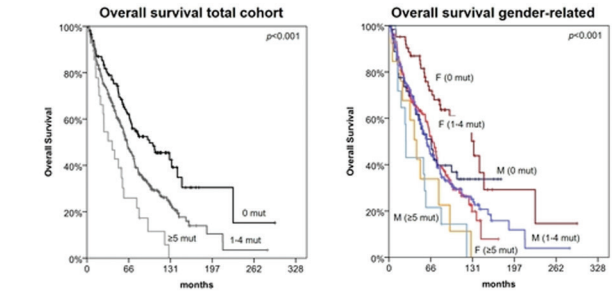
[1]department of hematology, The first affiliated hospital Zhejiang university school of medicine, Hangzhou, China

Background: Decitabine (DAC) is used as first-line therapy in patients with higher-risk (HR) myelodysplastic syndromes (MDS). However, the clinical outcomes of patients treated with DAC as monotherapy were far from satisfactory with overall response rate (ORR) of 33%>55.4% and overall survival (OS) of 17.7-22 months. Some clinical researches reported that the addition of ATRA to DAC increased response rate and prolonged survival of MDS and elderly acute myeloid leukemia (AML) patients. Therefore, the effect and mechanisms of combination therapy with DAC and ATRA have been studied.

Aims: Conducting the study to investigate the efficacy and mechanisms of DAC combined with ATRA on HR MDS both *in vitro* and *in vivo*.

Methods: The combination effects of DAC and ATRA were studied via MDS cell lines and primary cells from newly diagnosed MDS and AML patients. The underlying molecular mechanisms were investigated through MDS cell lines. The MOLM-13-luciferase xenograft murine model was used to verify the enhanced cytotoxic effect of combined drugs.

Results: The current study indicated that the strategy combining DAC and ATRA synergistically induced apoptosis of MDS-L and MOLM-13 cells *in vitro*, and inhibited the viability of primary cells from MDS and AML patients. The combination treatment significantly decreased leukemia burden and prolonged survival of the MOLM-13-luciferase xenograft murine model. Mechanistically, treatment on MDS-L and MOLM-13 cells with DAC as a single agent activated nuclear factor erythroid-2 related factor 2 (Nrf2) signaling pathway. Nrf2 pathway, the master regulator of cellular redox equilibrium, is widely reported to mediate resistance to chemotherapy, demethylation therapy, and target therapy in various tumors. Once activated, Nrf2 leads to the downstream antioxidant response, restrains cellular reactive oxygen species (ROS) accumulation, attenuates ROS-dependent cytotoxicity, thus conferring resistance to DAC. In the current study, the apoptosis of MDS-L and MOLM-13 cells induced by single DAC and combined with ATRA can be reversed by pretreatment with the ROS scavenger N-acetylcysteine (NAC), indicating that the cytotoxicity induced by both monotherapy and combination therapy were ROS dependent. Co-treatment with DAC and ATRA activated the RARα-Nrf2 complex in the nucleus, and reduced binding of HDAC1 to the functional complex, which prevented Nrf2 from being activated by DAC alone, promoted ROS accumulation and enhanced ROS-dependent cytotoxicity, thus overcoming the resistance of MDS cells to DAC.



Summary/Conclusion: The interaction between DAC and ARTA exerts collaborative cytotoxicity in MDS cells. Therefore, the regimen combining DAC and ATRA in higher-risk MDS holds potential for clinical application and deserves further explorations.

EP892 LESS CAN BE MORE – GENDER-RELATED MUTATIONAL LANDSCAPE AND OUTCOME IN MYELODYSPLASTIC SYNDROME

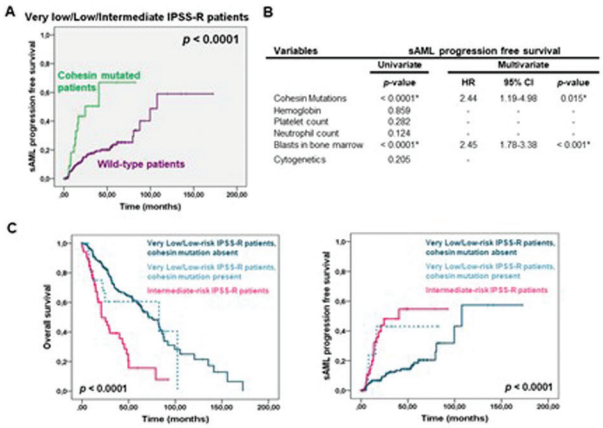
M. Meggendorfer [1,*], W. Walter [1], C. Haferlach [1], W. Kern [1], T. Haferlach [1]

[1]MLL Munich Leukemia Laboratory, Munich, Germany

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal stem cell neoplasms associated with cytopenias. Diagnosis is based on peripheral blood count, bone marrow morphology and cytogenetics. In addition to cytogenetics, which allows risk stratification of patients, multiple recurrent mutations have been identified in recent years. For some diseases, a gender-dependent prevalence of mutations and their impact on outcome have been described, but a systematic evaluation of the mutational landscape and its impact on the prognosis of patients in relation to their gender in MDS is still lacking.
Aims: To compare the molecular genetic landscape and identify potential different outcomes between female and male patients with MDS.
Methods: The cohort comprised 588 patients (234 female and 354 male) with a median age of 72, diagnosed as MDS by cytomorphology and cytogenetics following WHO classification. All patients were previously investigated by next generation deep sequencing (Haferlach et al, Leukemia 2014) and WGS. All data were analyzed for 4 virtual gene panels, the 12 genes as given in the MDS NCCN guidelines with a incidence >5% (Version 2.2020), the 34 gene panel summarized in McClure et al. (J Mol Diag 2018), the 723 cosmic cancer gene census (CCGC, v91) panel and finally the exome.
Results: A gender-specific analysis of the MDS subtypes confirmed the already known female predominance in MDS with isolated del(5q) (73% vs 27%; p<0.001), while all other MDS subtypes showed no gender differences. Additionally, female patients showed higher platelet counts than their male counterparts (mean 227,229/µl vs. 180,950/µl; p=0.001). There were no gender-related differences in age, karyotype or IPSS-R score. However, in non del(5q) subtypes female showed predominantly a normal karyotype (79% vs. 67%; p=0.002). Addressing individual gene mutations showed that female patients were more often mutated in *DNMT3A* (40/234, 17% vs. 24/354, 7%; p<0.001), while males were more often mutated in *TET2* (119/354, 34% vs. 58/234, 25%; p=0.027). Interestingly, *ZRSR2* mutations (on chr. X) occurred nearly exclusively in male patients (39/354, 11% in male vs. 1/234, 0% in female; p<0.001). Overall the median number of mutations was slightly higher in male patients and the absence of mutations in the myeloid specific gene panels was more pronounced in female patients (NCCN gene panel: 63/234, 27% vs. 55/354, 16%; p=0.001; McClure gene panel: 52/234, 22% vs. 44/354, 12%; p=0.002). The differences in mutation detection rates disappeared with the larger CCGC panel and the exome. In the following, we aimed to investigate whether the higher number of mutations in males also had an impact on patient outcome. While age and karyotype showed prognostic impact in both groups, gender *per se* did not affect the outcome. However, looking at gender-dependent survival, a prognostic impact becomes apparent by subdividing the myeloid gene panels into groups with no, 1-4, and ≥5 mutations per patient. Surprisingly, men showed no difference in survival between the two groups with no and less than 5 mutations, whereas this was statistically significant in women (figure, NCCN gene panel). This difference decreases with increasing panel size and number of mutations.**Summary/Conclusion:** Between female and male MDS patients differences in prevalence and mutational landscape occur. The number of mutations within a small panel of 12 recurrently mutated genes show prognostic impact that is predominant in female patients and should therefore be considered for risk stratification.

	months (n, cases)
0 mutation	98 months (n=117)
1-4 mutations	63 months (n=442)
≥5 mutations	40 months (n=28)

Female (F) months (n, cases)	Male (M) months (n, cases)
133 months (n=62)	66 months (n=55)
68 months (n=158)	60 months (n=284)
43 months (n=13)	27 months (n=15)



EP893 COHESIN MUTATIONS ARE ASSOCIATED WITH A POOR PROGNOSIS PHENOTYPE AND A WORSE CLINICAL OUTCOME IN LOW-RISK MYELODYSPLASTIC SYNDROMES PATIENTS

M. Martín Izquierdo [1,*], F. López Cadenas [2], J. Sánchez del Real [3], A. Hernández Sánchez [2], J. M. Hernández Sánchez [1], K. Janusz [4], M. Díez Campelo [2], M. Tormo [5], M. Megido [6], C. Olivier [7], A. Madinaveitia Ochoa [8], J. Dávila [9], M. Sierra [10], M. Vargas [11], S. Santos Mínguez [1], C. Miguel García [1], R. Benito [1], J. M. Hernández Rivas [1,2], F. Ramos [3], M. Abáigar [1]

Background: Mutations in cohesin genes have been described as novel mutations occurring in 10-15% of myelodysplastic syndromes (MDS), suggesting that the cohesin complex presents an important pathway in the MDS pathogenesis. However, the clinical impact of cohesin mutations is still undetermined.
Aims: Molecular and clinical characterization of MDS patients harboring cohesin mutations: genetic background, disease phenotype, clinical outcome and prognostic impact of integration of these mutations with conventional risk factors.
Methods: A cohort of 421 patients diagnosed with MDS was analyzed by targeted deep sequencing using an Illumina® custom panel of 117 myeloid-related genes, including cohesin genes: *STAG1*, *STAG2*, *SMC1A*, *SMC3*, *RAD21* and *CTCF*.
Results: The median age at diagnosis was 74.7 years (range 29.4-92.2); 59% were male. According to the WHO 2017 classification most of the patients had MDS with multilineage dysplasia with or without ring sideroblasts (MDS-RS-MLD and MDS-MLD, 45.5%), followed by MDS with excess blasts (MDS-EB2, 16% and MDS-EB1, 14.6%). Regarding IPSS-R, the majority of patients had very low (27%) and low (44%) risk, with 85% of the series having normal karyotype or clonal alterations of very good or good risk. The median follow-up was 2.3 years (range 0.01-15.6) and during this time 49% of patients died and 30% progressed to acute myeloid leukemia (AML).
The NGS study identified 54 mutations in cohesin genes in 50 patients (11.9%), being most of them loss of function type and *STAG2* (36/50) and *SMC3* (7/50) the most frequently mutated genes. Regarding the molecular landscape of patients with cohesin mutations: mutated patients presented a significantly higher number of mutations (p<0.0001) and displayed a specific mutational profile with a strong co-occurrence between cohesin and splicing mutations (p<0.0001) and Ras pathway alterations (p=0.001).
Regarding the clinical characterization, mutations in cohesin genes were associated with **MDS-EB-1/2** subtypes (p<0.0001), **intermediate and high-risk IPSS-R** categories (p=0.001) and **intermediate cytogenetic risk** (p=0.001), especially with trisomy 8 (p<0.0001). Moreover, patients with cohesin mutations displayed a **poor prognosis disease phenotype**, characterized by lower platelet, neutrophil and leucocyte count in blood (p=0.004, p=0.003 and p=0.037, respectively), a higher number of blasts in bone marrow (p=0.0003) and a **higher rate of progression** to sAML (p<0.0001).
Regarding the influence on clinical outcome, cohesin-mutated patients showed a **shorter overall survival** (OS: 3.1 *vs.* 5.2 years, p=0.052) and **a shorter time to sAML progression** (LFS: 1.4 *vs.* 8.3 years, p<0.0001). Noteworthy, this adverse impact was observed mainly in very low, low and intermediate-risk IPSS-R patients regarding LFS (multivariate analysis: HR 2.4, 95% CI 1.2-5.0; p=0.015).

To further study the negative impact of cohesin mutations, we assessed their **prognostic value on the IPSS-R stratification**. Of note, the OS and LFS of very low/low-risk patients who harbored cohesin mutations were statistically significant shorter than those without these mutations, but nearly identical to intermediate-risk patients.

Summary/Conclusion: Patients harboring cohesin mutations displayed a specific mutational profile, a poor prognosis disease phenotype and a worse clinical outcome, characterized by a higher rate and a shorter time to sAML progression. In addition, the incorporation of cohesin mutational data into current IPSS-R classification improved the prognostic stratification of very low and low-risk patients.

EP894 SINGLE-CELL RNA SEQUENCING TO EXPLORE THE ABNORMAL DIFFERENTIATION OF HEMATOPOIETIC STEM AND PROGENITOR CELLS IN MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA

Y. Liu [1,*], H. Niu [1], H. Wang [1], R. Fu [1], Z. Shao [1]

[1]*Hematology, General Hospital, Tianjin Medical University, Tianjin, China*

Background: Myelodysplastic syndrome (MDS) and acute myeloid leukemia(AML) are both myeloid neoplasms with obvious heterogeneity. The biological mechanisms of clonal proliferation, abnormal differentiation of hematopoietic stem and progenitor cells(HSPC)are largely unknown. Single-cell RNA sequencing (scRNA-seq) can reveal the specific information of individual cells, which is of great significance for revealing the heterogeneity and exploring the mechanism of MDS and AML.
Aims: To explore the mechanism of clonal proliferation and delayed differentiation of HSPC in patients with MDS and AML at single-cell level.
Methods: 5 MDS patients (2 with low-risk MDS[LR-MDS] and 3 with high-risk MDS[HR-MDS]), 2 AML patients were recruited. All the patients have signed the informed consent. Lineage-negative (Lin^-) hematopoietic cells from bone marrow(BM) were sorted by immunomagnetic beads, then scRNA-seq and bioinformatics analysis were given. The scRNA-seq data of BM mononuclear cells from 17 healthy donors (HDs) were downloaded from Gene Expression Omnibus (GEO) database, and the data of Lin^- cells were selected manually as control. According to the gene-set enrichment analysis, ribosomal genes and mitochondrial genes were selected for further confirmation by Quantitative Real-time polymerase chain reaction (qPCR) in $CD34^+$ cells from BM, and the correlations between gene expression and clinical characteristics were analyzed.
Results: The gene expression patterns in patients with MDS and AML were significantly different from HDs, and they were also significantly heterogeneous among patients. The proportion of hematopoietic stem cells(HSC) and multipotent progenitors(MPP) in MDS and AML was higher than that in HDs, while the proportion of erythroid precursors and lymphoid progenitors was significantly lower than that in HDs(Figure A,B).
Further analysis of HSC and MPP showed that the differential expression genes of MDS compared to HDs were similar to those of AML compared to HDs, so MDS and AML were put together to compare with HDs. Down-regulation of ribosomal genes and the up-regulation of mitochondrial genes were the most significant. Enriched up-regulated gene sets included abnormal mitochondrial metabolism, oxidative respiratory chain defects and neutrophil degranulation in HSC and MPP of MDS and AML patients, while down-regulated gene sets were enriched in ribosome, translation, metabolism of proteins(Figure C,D).

The mRNA expression of ribosomal and mitochondrial genes in BM $CD34^+$ cells by qPCR was consistent with the data of scRNA-seq. The expression of MT-CYB mRNA in LR-MDS(n=10), HR-MDS(n=14), AML(n=26) was significantly higher than that in the control group(patients with iron-deficiency anemia[IDA], n=16) ($P<0.05$), and the expression of MT-CO1 mRNA got similar results ($P<0.05$). (Figure E,F). The expression of RPL31 mRNA in LR-MDS(n=14), HR-MDS(n=24), AML(n=25) was lower than that in the control group(patients with IDA, n=22) ($P<0.01$), and positively correlated with hemoglobin (HB) ($r=0.377$, $P=0.020$)and platelet (PLT) ($r=0.367$, $P=0.023$). (Figure G-I).

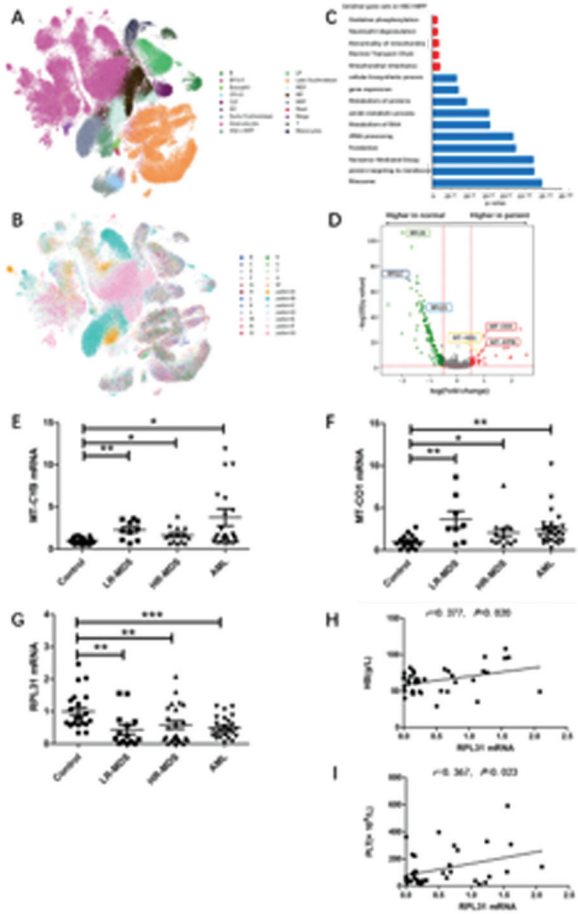

Figure A,B. UMAP of scRNA-seq data displaying Lin^- hematopoietic cells from 17 healthy donors(HDs) , 5 MDS and 2 AML patients. **A.** Display of clusters. **B.** Display of samples. **C.** Enriched gene sets in HSC and MPP. Red: up-regulated in MDS and AML, blue: down-regulated in MDS and AML. **D.** Volcano map of differential expression genes of HSC and MPP. **E,F.** MT-CYB, MT-CO1 mRNA in BM $CD34^+$ cells by qPCR in control, LR-MDS, HR-MDS, AML. **G-I.** RPL31 mRNA in BM $CD34^+$ cells by qPCR in control, LR-MDS, HR-MDS, AML and its correlation with HB and PLT in MDS patients. HSC: hematopoietic stem cells; MPP: multipotent progenitors; BM: bone marrow; LR-MDS: low-risk MDS; HR-MDS: high-risk MDS.

Summary/Conclusion: In patients with MDS and AML, dysfunction of ribosome and translation, abnormal mitochondrial metabolism and oxidative respiratory chain in HSPC, may be related to the incidence and development of MDS and AML.

EP895 LNCRNA PCSK1N-202 PROMOTES CD34+CELL PROLIFERATION VIA PIM2/HIF-1A IN MYELODYSPLASTIC SYNDROMES

Z. Liu [1,*], M. Tian [1], R. Fu [1]

[1]*Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China*

Background: Myelodysplastic syndromes (MDS) are characterized by malignant clonal hematopoietic stem cells with high-risk of progression to acute myeloid leukemia (AML). Pim-2 is a serine/threonine protein kinase that is elevated in various types of cancer and plays essential roles in the regulation of signal transduction cascades, which promote cell survival and cell proliferation. Our previous study revealed that pim-2 was highly expressed in CD34+ cells derived from the bone marrow of patients with MDS/AML. The expression of Pim-2 induces elevated expression of HIF1-α by decreasing the expression of IDH1, resulting in acceleration of CD34+ cell proliferation.
Long non-coding RNAs (lncRNAs) represent the majority of cellular transcripts and play pivotal roles in hematopoiesis. However, the functions of lncRNA on hematopoietic stem cells malignant clone remains largely unknown.
Aims: Here we investigate the profile of lncRNA derived from the bone marrow $CD34^{+}$cells in MDS patients and AML secondary to MDS (sAML) patients. And we focused on the lncRNA which could regulate pim2
Methods: The profile of lncRNAs in bone marrow CD34+ cells from MDS patients and sAML patients was detected by high throughput RNA-seq technology. The biological function and signal pathway of the target genes of differentially lncRNAs were analyzed by GO and KEGG cluster analysis. RT-PCR were used to detected the lncRNA and pim2. The SKM-1cell line was used in the study. The lentiviral vector(sh-RNA) were transfected into SKM-1 to interfere the lncRNA. CCK8 was performed to measure the proliferation rate of SKM-1 transfected with the lentiviral vector. 7-AAD/PI was used to analyze the apoptosis of SKM-1.
Results: In sAML, we found 1173 lncRNAs (648 upregulated/525 downregulated) and 326 mRNAs (125 upregulated/201 downregulated) significantly deregulated compared to those in MDS patients (|logFC| > 1, p value < 0.05). Overall, the KEGG enriched processes were mainly related to four mechanisms: metabolic pathways, phagosome, metabolism of xenobiotics by cytochrome P450, glycine, serine and threonine metabolism, glycosphingolipid biosynthesis - lacto and neolacto series, fatty acid degradation, cGMP-PKG signaling pathway. GO term analysis showed the mainly related lncRNAs function on cellular metabolic process, organic cyclic compound metabolic process, nucleobase-containing compound metabolic process and etc. Of these, lncRNA PCSK1N-202 may targeted-regulate the pim2 mRNA. RT-PCR showed that PCSK1N-202 was upregulated in AML and MDA patients. And PCSK1N-202 was positive related with pim2. The SKM-1 transfected with LV-sh- PCSK1N-202 induced the decline of pim2 followed with decreased cell proliferation rate, and increased cell apoptosis.

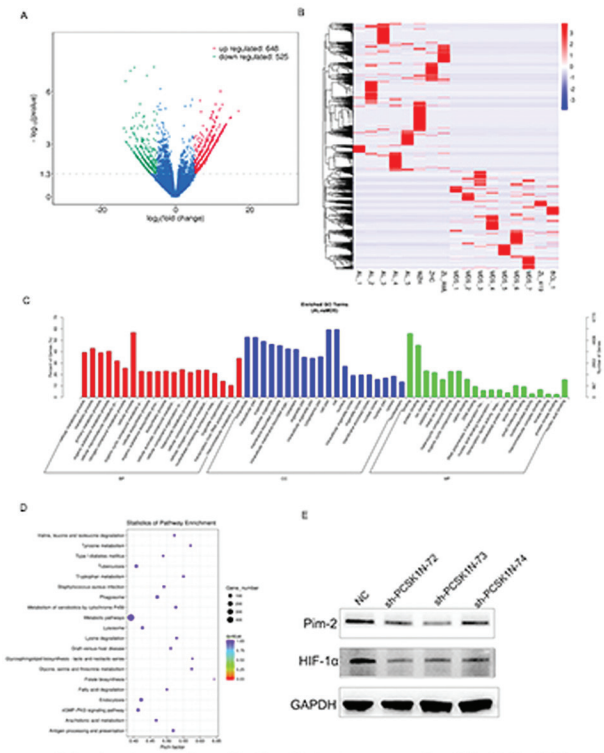

Fig A and B The volcanoplot and heatCluster of the differential lncRNAs in sAML, compared to MDS. Cand D. GO and KEGG terms of the differential lncRNAs. E. The interference of PCSK1N induced the downregulation of pim2 and HIF-1α

Summary/Conclusion: We reported novel information on specific lncRNAs contributing to AML transformation of MDS, and proposed cellular processes associated with these lncRNAs. Of the lncRNAs, the upregulation of PCSK1N-202 transcript might promotes CD34+cell proliferation via pim2/HIF-1α in myelodysplastic syndromes.

EP896 CLONAL HEMATOPOIESIS IS COMMON IN HIP ARTHROPLASTY PATIENTS AND ASSOCIATES WITH AUTOIMMUNE DISEASE AND LOWER HEMOGLOBIN LEVELS

Background: Clonal hematopoiesis (CH) is a common age-related condition predisposing to blood cancer and cardiovascular disease (CVD). Murine models demonstrate CH-mediated altered immune function and proinflammation. Low-grade inflammation has been implicated in the pathogenesis of osteoarthritis (OA), the main indication for total hip arthroplasty (THA). THA-derived hip bones serve as a major source of 'healthy' hematopoietic cells in experimental hematology.
Aims: We prospectively investigated frequency and clinical associations of CH in 200 patients without known hematologic disease undergoing THA for OA.
Methods: BM samples were collected from 200 patients without known hematologic disease undergoing THA for OA between 07/2017 and 08/2020 after written informed consent. The study was approved by the respective ethics committees in accordance with the Declaration of Helsinki. Targeted sequencing of 68 genes recurrently mutated in hematologic malignancies identified variants with a VAF threshold of ≥1%. For correlative analyses of clinical parameters, only variants fulfilling the current CHIP definition (clonal hematopoiesis of indeterminate potential, defined as somatic variants with allele frequencies [VAF] ≥2%) were included. Statistical analysis was performed with GraphPad Prism v6.0 and R v3.6.3.
Results: Prevalence of CH was 50.0%, including 77 patients with CHIP, and 23 patients harboring CH with lower mutation burden (VAF 1-2%). CH became progressively more frequent with age (Figure 1A). Most commonly mutated genes were *DNMT3A* (29.5%), *TET2* (15.0%) and *ASXL1* (3.5%). Most patients (n=56) had 1 mutation, 32 harbored 2 variants, and 10 carried 3 mutations, while two patients harbored 4 or 5 mutations, respectively. Number of variants per individual correlated with age (p=0.031), whereas VAF (median 2.7%, range 1.0-32.7%) did not (p=0.73). CHIP significantly correlated with older age (median, 74.0 years [y] with CHIP *vs.* 68.5 y without, respectively; p<0.00010), lower hemoglobin levels (median, 12.7 g/dL *vs.* 13.7 g/dL; p=0.0020) and higher MCV (median, 91.8 fl *vs.* 89.0 fl; p=0.0076). Of note, 66.7% of the patients with anemia had detectable mutations with VAF≥2% (who would thus be classified as clonal cytopenia of uncertain significance [CCUS]), whereas prevalence of CHIP was lower in patients with normal hemoglobin levels (32.7%, p=0.0014). Furthermore, we observed an enrichment of *SF3B1* and *TP53* mutations in anemic patients compared to those with normal blood counts (p=0.020). CHIP carriers were more likely to have CVD (p=0.0080), as previously reported, and present/prior malignancy (p=0.029). Strikingly, CHIP also associated with presence of autoimmune disease (AID, p=0.034), comprising diverse autoimmune disorders. Multivariate analysis with adjustment for age and sex confirmed significant associations between CHIP and older age (p=0.025), lower hemoglobin levels (p=0.0078), and AID (p=0.0081), but not with CVD or malignancy (Figure 1B).

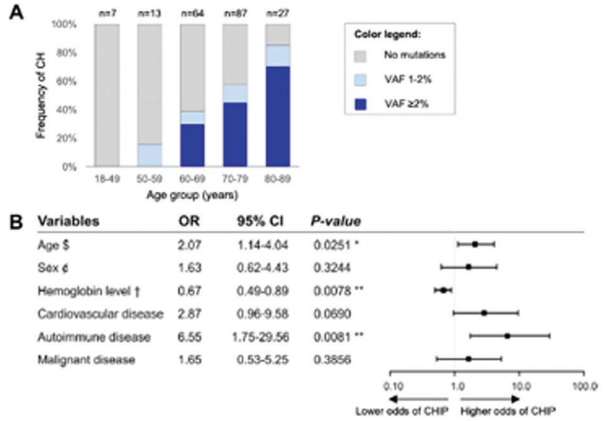

Figure 1. Frequency and clinical correlates of CH/CHIP in patients undergoing THA.
(A) Frequency of CH among different age groups.
(B) Multivariate analysis. $ per 10 years increase. ¢ fermale versus male. † per 1g/dL increase.

Summary/Conclusion: Prevalence of CH in our prospectively enrolled cohort of older adults undergoing THA for OA is considerably higher than previously reported in healthy individuals or specific patient groups, such as those with ischemic heart failure or CVD. Together, these findings underscore the association between CH and inflammatory diseases. Our results have considerable relevance for management of patients with OA, AID and anemia, and question the use of hip bone-derived cells as 'healthy' experimental controls.

EP897 THE CAR VIRUS RECEPTOR MEDIATES MATURATION AND MIGRATION IN ERYTHROID PRECURSOR CELLS AND IS DOWNREGULATED IN MDS

K. Bauer [1,*], S. Machherndl-Spandl [2], L. Kazianka [1], S. Gültekin [1], S. Suessner [3], J. Proell [3], J. Lauf [4], G. Hoermann [1], G. Eisenwort [1], N. Häfner [5], M. Background: Myelodysplastic syndromes (MDS) are myeloid neoplasms presenting with dysplasia in the bone marrow (BM) and peripheral cytopenia. Most patients present with erythroid hyperplasia in the BM and anemia.
Aims: We screened for genes that are expressed abnormally in erythroid progenitor cells (EryPC) and contribute to the pathogenesis of MDS.
Methods: In mRNA array- and flow cytometry staining experiments, we found that the Coxsackie-Adenovirus receptor (CAR) is markedly downregulated in $CD45^{low}/CD105^{+}$ EryPC in MDS patients compared to control EryPC.
Results: CAR was also down-regulated in EryPC in patients with acute myeloid leukemia with BM dysplasia. Correspondingly, the erythroblast cell lines HEL, K562, and KU812 stained negative for CAR. Lentiviral transduction of the full-length *CAR* gene into these cells resulted in an increased expression of early erythroid antigens, including CD36, CD71, and glycophorin A. In addition, *CAR*-transduction resulted in an increased migration against a serum protein gradient, whereas transfection of truncated *CAR*-variants did not induce erythroid antigens or migration. Furthermore, we found that conditional knock-out of *Car* in hematopoietic cells in C57BL/6 mice results in anemia, an accumulation of erythroid cells in the BM, erythroid dysplasia and impaired migration of murine EryPC against a serum protein gradient. Decreased CAR expression on EryPC was found to correlate with high-risk MDS and decreased survival.
Summary/Conclusion: Together, CAR is a functionally relevant marker that is down-regulated on EryPC in MDS and is of prognostic significance. Decreased CAR expression may contribute to the maturation defect and altered migration of EryPC and thus their pathologic accumulation in the BM in MDS.

EP898 UNCLASSIFIABLE MYELODYSPLASTIC SYNDROME DEFINED BY A CYTOGENETIC ABNORMALITY: A REAL-LIFE STUDY.

Background: Unclassifiable myelodysplastic syndrome defined by a cytogenetic abnormality (MDS-U-C) is a rare, poorly characterized entity that encompasses patients with at least one cytopenia, no marked dysplasia and a karyotype with one or more abnormalities considered to be presumptive criteria for MDS. Many cytopenia are still referred to as idiopathic cytopenia of undetermined significance (ICUS) because the cytological and cytogenetic diagnostic criteria for MDS are not met. Thanks to next generation sequencing (NGS) techniques, the discovery of somatic mutations in over 30% of patients with ICUS has prompted the definition of the entity "clonal cytopenia of undetermined significance"(CCUS). At present, these somatic abnormalities are not included in the WHO's diagnostic classification of MDS.
Aims: The aim of this study was to determine the clinical, laboratory and genetic characteristics of patients with cytopenia and cytogenetic abnormalities (regardless of whether or not the latter are listed by the WHO as presumptive) but no significant dysplasia. The ultimate objective was therefore to diagnose MDS-U-C more reliably in real life.
Methods: We performed a retrospective study of 64 patients diagnosed between 2011 and 2019 in nine French centres. The main inclusion criteria were cytopenia, at least one cytogenetic abnormality and the absence of marked dysplasia. Bone marrow smears were examined independently by three cytologists. Karyotypes were reviewed by members of the *Groupe Francophone de Cytogénétique Hématologique*. NGS was used to screen patients for a targeted panel of 58 genes frequently altered in MDS.

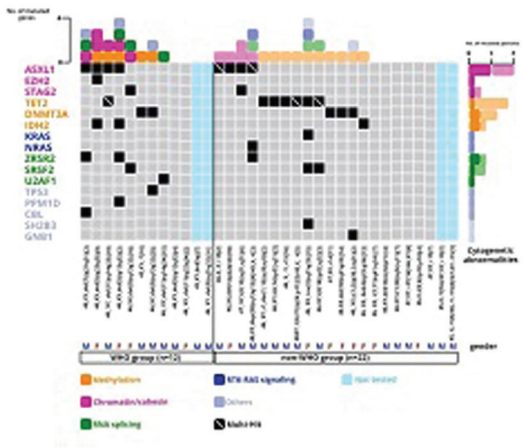

Figure 1: The genetic spectrum of cases of cytopenia with cytogenetic abnormalities

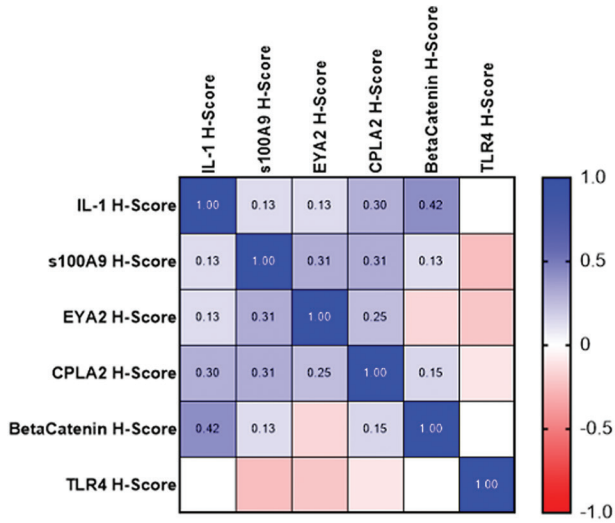
Each column represents a patient having had a molecular analysis (left: WHO-group, n =12; right: non-WHO group, n=22), and each row corresponds to a particular gene. Black and grey squares indicate mutated and non-mutated genes, respectively. Genes labelled as "multi-hit" contain more than one mutation. The plot at the top shows the number of mutated genes in each patient. The mutations are color-coded according to the legend below the grid. The plot on the right shows the number of patients with a mutation for each gene, by group (high opacity: WHO-group; low opacity: non-WHO group). The sex of each patient is specified below the grid.



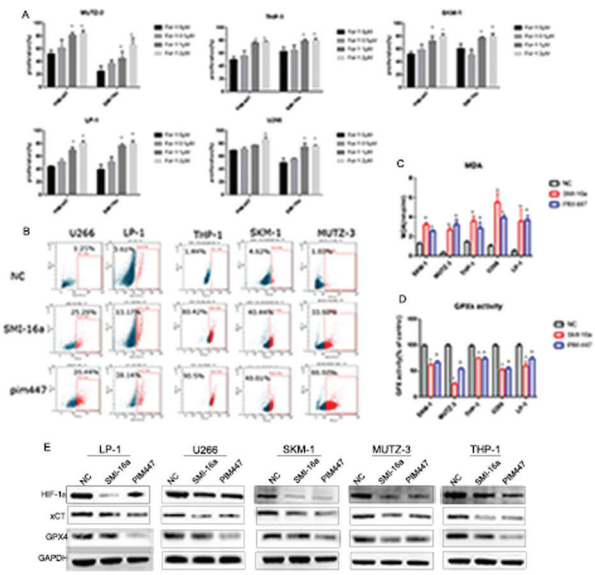
Results: The centralized cytology review led to 30 of the 64 patients being reclassified as having MDS; this relatively high proportion reflects the poor specificity of dysplastic features. We then divided the remaining 34 dysplasia-free patients into two groups: the "WHO group" comprising 12 individuals with a presumptive cytogenetic abnormality (including del(5q) (n=4), del(11q) (n=3), del(9q) (n=3), del(7q) (n=1) and -7 (n=1); median age: 74.3) and the "non-WHO group" comprising 22 individuals with non-recurrent abnormalities (except for trisomy 15 (n=5); median age: 76.7). The proportion of patients with one or more somatic mutations was 80% in the WHO group (mean number per patient: 2.4) and 70% in the non-WHO group (mean: 1.4) (p=0.11). The frequency of *ASXL1* mutations was higher in the WHO group (40% vs. 20 % in the non-WHO group; p=0.38), whereas the frequency of *TET2* mutations was higher in the non-WHO group (30% vs 10% in the WHO group; p=0.37) (Figure 1). The number and type of mutations in the WHO group were similar to those seen in patients with MDS, who harboured a median of 2 or 3 driver mutations (predominantly in *TET2, DNMT3A* and *ASXL1*). Although the same genes were involved in the non-WHO group, the mutation burden was lower than in MDS but higher than in clonal haematopoiesis of indeterminate potential (CHIP). With a median follow-up time of 10.4 months, the WHO group appeared to have a worse prognosis: 25% of these patients progressed to high-grade MDS (vs.4.5% in the non-WHO group; p=0.11).
Summary/Conclusion: Our present results confirmed that MDS-U-C is rare and is difficult to diagnose. Even though patients meeting all the criteria for MDS-U-C (i.e. the WHO group) seemed to progress more often to high-risk MDS and harboured a greater number of deleterious mutations (e.g. mutations in *ASXL1*), "non-WHO" patients must not be neglected; the latter require close monitoring and should perhaps be classified as cases of CCUS.

EP899 USING TISSUE MICROARRAY TO DETECT INFLAMMASOME SIGNALING COMPONENTS THAT CONTRIBUTE TO THE PATHOGENESIS OF MYELODYSPLASTIC SYNDROME

T. Kurian [1,*], K. McGraw [2], S. Bridgelall [2], R. Sharma [2], J. Lancet [2], R. Komrokji [2], S. Yun [2], L. Zhang [2]

[1]Moffitt Cancer Center & University of South Florida, [2]Moffitt Cancer Center, Tampa, United States

Background: Myelodysplastic syndromes (MDS) are characterized by aberrant maturation, ineffective hematopoiesis, cytopenia, and progression to acute myeloid leukemia. MDS pathogenesis is multifactorial and potentially linked to constitutive innate immune stimulation converging upon the NLRP3 inflammasome to induce pyroptosis, a caspase-1 dependent cell death. lnflammasome assembly is initiated by both cell-extrinsic stimuli including S100A9, the TLR4 and CD33 ligand, and cell-intrinsic danger signals licensing caspase-1 which activates IL-1b and beta-catenin resulting in cell death and cellular proliferation leading to maturation and differentiation blocks. Further, EYA2 has been suggested to be an inflammasome activator, whereas cPLA2 has been suggested to be an inhibitor.
Aims: The purpose of this study is to determine whether immunohistochemistry (IHC) may be utilized to assess expression of inflammasome components.
Methods: An IRB protocol was approved prior to initiating this study. We retrospectively identified 43 low risk MDS patients. A tissue microarray (TMA) was constructed utilizing MDS bone marrow biopsy samples (2-3 representative cores per sample). IL-1, S100A9, EYA2, cPLA2, beta-catenin, and TLR4 expression were assessed by IHC after validation of each antibody. IHC expression was scored independently by two hematopathologists by calculating scores (product of staining intensity x percent expression). IHC expression was compared using Spearman correlation estimate. Demographic and clinical data were collected and correlated with IHC expression using Kruskal-Wallis test, Spearman correlation, and Logrank test.
Results: Patients were median 72 years of age, 67% men and included 47% MDS-MLD, 35% MDS-RS, 14% MDS-SLD, 2% MDS del5q and 2% MDS-U. IL-1 expression correlated with beta-catenin expression, r = 0.42, 95% Cl 0.115 to 0.658 (p = 0.007). There was a trend towards significance between IL-1 and cPLA2, r = 0.30 (p = 0.067); S100A9 and CPLA2, r = 0.31 (p = 0.052); and S100A9 and EYA2, r = 0.31 (p = 0.057). See figure for correlation between antigen expression scores. Percentage EYA2 expression correlated with blast count, r = 0.425 (p = 0.008). The IHC expression of these antigens did not correlate with WHO MDS subclassification, IPSS, R-IPSS, disease progression, or survival ($p < 0.05$).



Summary/Conclusion: IHC staining of inflammasome activators using TMA may allow better characterization of molecular pathways contributing the MDS pathogenesis. A correlation was seen between expression of antigens known to be increased downstream of NLRP3 inflammasome activation. Furthermore, increased expression of EYA2 correlated with blast count. A future study will compare expression patterns between normal, low risk MDS and high risk MDS samples and correlate these findings with clinical outcome data to further elucidate the pathogenesis of MDS and identify potential targetable markers for novel therapeutic strategies.

EP900 PIM INHIBITORS INDUCE THE FERROPTOSIS VIA HIF1A/GPX4 PATHWAY IN HEMATOLOGICAL MALIGNANT CELLS

M. Tian [1], Z. Liu [1], R. Fu [1,*]

[1]Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China

Background: Ferroptosis, a form of regulated cell death (RCD) that involves iron accumulation and lipid peroxidation, is remarkably distinguishable from other forms of RCD, including necroptosis, apoptosis, and unregulated necrosis, in terms of its biochemistry, morphology, and genetics. Ferroptosis has been declared to be involved in many diseases, especially kinds of cancers. These studies provide useful evidence for the treatment of cancers. The Proviral Integration site for Moloney murine leukemia virus (PIM) kinases were reported to increased in several cancers, such as AML (acute myeloid leukemia) and MM (multiple myeloma). Nowadays the pim inhibitors are undergoing clinical trials. However, the mechanism of the pim inhibitors on tumor cells is still unclear.
Aims: The study aims to investigate whether the pim inhibitors can induce the ferroptosis in hematological malignant cells and what the mechanism is.
Methods: The cell lines SKM-1, MUTZ-3, THP-1, U266 and LP-1 treated with pim inhibitors (SMI-16a and Pim-447). CCK-8 assay was used to examine the cell proliferation following treated with drugs. The MDA (malondialdehyde) and GPXs were detected with biochemical method. FCM (flow cytometry method)was used to detected the ROS(reactive oxygen species). RT-qPCR was used to detected the relative expression level of mRNA involved. The related proteins were detected by western blot.
Results: The two pim inhibitors could decrease the proliferation of these cell lines significantly (Fig.1). And the inhibition effect treated for 48h was more obvious than 24h.The growth-inhibitory effect of pim inhibitors could be partially reversed by ferrostatin-1(ferroptosis inhibitors) (Fig.2). Then we analyzed the intracellular ROS level of the cells treated with SMI-16a and Pim-447 (Fig.2). SMI -16a and Pim-447 could increase the ROS level. The MDA level increased and the GPXs activity decreased following the treatment of SMI-16a and Pim-447(Fig.2). These results revealed that SMI-16a and Pim-447 induce ferroptosis in these cell lines. In order to investigate what the mechanism is, we preformed the western blot to examine the related proteins. The results showed that HIF-1αand xCT declined, which induced the GPX4 decreased(Fig.3).

Summary/Conclusion: Our study provides significant evidence to confirm the occurrence of ferroptosis in hematological malignant cells treated with pim inhibitors, and demonstrates that inhibition of ferroptosis was through HIF-1α/GPX4 pathway. These findings reveal a new form of cell death in the treatment of pim inhibitors.

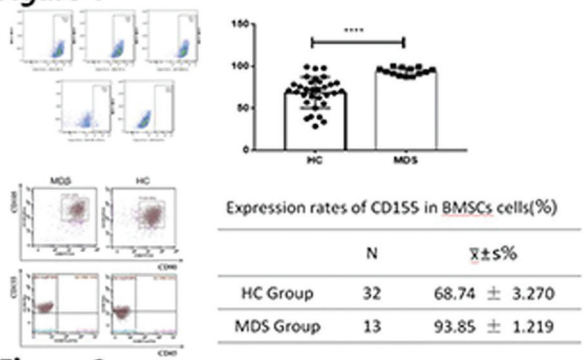
EP901 BMSCS REGULATE THE FUNCTION OF NK CELL BY CD155/TIGIT/CD226 PATHWAY IN MDS PATIENTS

R. Fu [1], Y. Guo [1], Z. Liu [1,*], H. Liu [1]

[1]Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China

Background: Myelodysplastic syndromes (MDS) are characterized by dysplastic bone marrow, ineffective hematopoiesis and high-risk transformation to acute myeloid leukemia (AML).It has been clearly addressed that the BM microenvironment plays an important role in malignant hematopoiesis, but the mechanism leading to MDS-associated immune is still unknown.
Aims: To analyzed the immune status of MDS patients, evaluated its impact on prognosis, and tried to study the specific mechanism of how mesenchymal stromal cells (MSCs) affecting immunity.
Methods: The study included 84 healthy controls and 84 inpatients with primary MDS, 22 patients with AML.We collected flow cytometry(FCM) reports and clinical data, including patient's sex, age, peripheral blood trilineage at initial diagnosis, number of bone marrow blast cells, karyotype analysis, etc. All MDS patients were stratified by IPSS-R for disease risk. 1. Statistical analysis of lymphocyte subset counts and cytokines in peripheral blood of different types of patients and healthy controls. 2. Correlation analysis between hemoglobin, platelets,neutrophil, blast cells, cytogenetics and lymphocyte counts was performed.3.We generated MSCs in BM samples from MDS patients and HCs.The expression of CD155 in MSCs and TIGIT/CD226 in lymphocytes were detected by FCM.
Results: 1.Percentage counts of NK cells in the HC group(19.94,95%CI 17.86-22.02, P<0.001)were significantly higher than other groups.The higher-risk group of MDS(11.51,95%CI 9.34-13.68) was obviously lower than the lower-risk group(16.91,95%CI 13.85-19,97)(P=0.006),close to the AML group(9.77,95%CI 6.33-13.20).Meanwhile, the level of IFN-Y in serum which is secreted mainly by NK cells was also the highest in the HC group(5.50,95%CI 3.74-7.26), followed by the MDS group and the lowest in the AML group(2.64,95%CI 1.91-3.37).Moerover,the higher-risk group(3.26,95%CI 2.45-4.07) was significantly lower than the lower-risk group(4.80,95%CI 3.66-5.95).In addition, CD8+ T cells and CD19+ cells had similar results as NK cells, but there was no significant difference with CD3+ cells and CD4+ T cells.2.Significantly higher level of NK cells percentage counts were found in patients with hemoglobin ≥ 100 ×1012/L compared to patients with lower hemoglobin(23.23,95%CI 17.26-29.21 and 15.77,95%CI 13.00-18.55,P=0.010). While the levels of NK cells were higher in patients with blast cells≤5% than in those with higher blast cells. (19.51,95%CI 16.09-22.93 and 14.65,95%CI 11.55-17.74,P=0.027). Patients with better karyotypes also had higher NK levels than those with poorer karyotypes(22.75,95%CI 19.47-22.03 and16.26,95%CI 11.36-21.15,P=0.060).No significant difference was found between NK cell levels with regard to platelet and neutrophil counts.CD8+ T cells behaved similarly to NK cells. 3.The expression of CD155 on the surface of BMSCs was significantly higher in the MDS group than that in the HC group(P=0.001, Figure1). Moreover,MDS patients had higher expression of TIGIT(P=0.012) and lower expression of CD226(P=0.001,Figure2B) on the surface of NK cells in bone marrow than that in HCs.And CD8+ T cells also have similar results as NK cells.We analyzed the correlation between TIGIT of NK cells and CD155 of BMSCs, and found that they were negatively correlated (P=0.0297), while CD226 was positively correlated with CD155 (P=0.0706, Figure 2C).

Figure 1



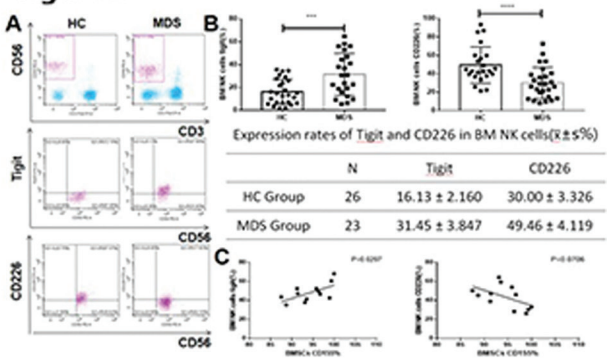


Figure 2

Summary/Conclusion: The decreased immune function in MDS patients is associated with prognosis.BMSCs are responsible for inducing an immune-suppressive microenvironment in MDS through CD155/TIGIT/CD226 pathway, the underlying mechanism remains to be further study.

EP902 PHARMACOLOGIC INHIBITORS OF CDK4/CDK6 EXERT ANTI-NEOPLASTIC EFFECTS ON CMML CELLS AND SYNERGIZE WITH THE MULTI-KINASE INHIBITOR PONATINIB IN NEOPLASTIC MONOCYTES

M. V. John [1,*], M. Schneeweiß-Gleixner [1,2,3], G. Eisenwort [1,2], B. Peter [1,2], D. Berger [2], G. Stefanzl [1,2], W. R. Sperr [1,2], P. Valent [1,2], K. V. Gleixner [1,2]

[1]Department of Internal Medicine I, Division of Hematology and Hemostaseology, [2]Ludwig Boltzmann Institute for Hematology and Oncology, [3]Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Medical University of Vienna, Vienna, Austria

Background: In chronic myelomonocytic leukemia (CMML), therapeutic options include hematopoietic stem cell transplantation, chemotherapy, demethylating agents and hydroxyurea (HU), which is used for palliative cytoreduction. Despite these approaches, progression to secondary acute myeloid leukemia (sAML) is frequently seen and the prognosis is poor. No targeted therapies are available in CMML. CDK4 and CDK6 serve as major drug targets in applied oncology. However, the effects of CDK4/CDK6 inhibitors have not been analyzed in CMML contexts so far.
Aims: We examined the anti-neoplastic effects of HU, which has been described to counteract CDK4/CDK6-expression in leukemic cells, and the specific CDK4/CDK6 inhibitors palbociclib, ribociclib and abemaciclib on primary CMML cells and various monoblastic cell lines. We also aimed to define cooperative anti-neoplastic effects of CDK4/CDK6-targeting drugs and the multi-kinase inhibitor ponatinib.

Methods: Primary leukemic cells of the bone marrow were obtained from 11 patients: 8 with CMML, 3 with sAML following CMML. We also analyzed the monoblastic cell lines THP-1, MONO-MAC-6 (MM6) and U937. Cell proliferation was determined by ^{3}H-thymidine uptake. Apoptosis and cell cycle distribution were quantified by flow cytometry. CDK4 and CDK6 mRNA were quantified by qPCR and protein expression and phosphorylation by Western blot analysis.
Results: Both HU and the CDK4/CDK6 inhibitors tested were found to disrupt the CDK4/CDK6-pathway in THP-1 and MM6 cells. Whereas HU decreased CDK4 and CDK6 mRNA- and protein expression, palbociclib, ribociclib and abemaciclib suppressed the expression and phosphorylation of RB1, the main target of CDK4/CDK6. HU was found to inhibit proliferation in all cell lines (IC_{50}: THP-1: 25-50 µM; MM6: 100-150 µM; U937: 500-750 µM) and in all primary cell samples tested (IC_{50}: 50-250 µM). Moreover, the CDK4/CDK6 inhibitors palbociclib, ribociclib and abemaciclib blocked cell proliferation in all cell lines (IC_{50}: 0.5–10 µM) and all primary cell samples examined (IC_{50}: 0.01–0.5 µM). Antiproliferative effects were accompanied by cell cycle arrest and induction of apoptosis. We next searched for suitable combination partners for CDK4/CDK6 inhibitors and identified ponatinib, a broad-spectrum multi-kinase inhibitor. Ponatinib was found to inhibit proliferation in all monoblastic cell lines (IC_{50}: 0.05-2.5 µM) and in primary leukemic cells (IC_{50}: 0.01-2.5 µM). The drug combinations HU+ponatinib, palbociclib+ponatinib, ribociclib+ponatinib and abemaciclib+ponatinib resulted in strong synergistic anti-proliferative effects in THP-1, MM6 and primary cells isolated from 2 CMML patients. Interestingly, the combinations HU+palbociclib, HU+ribociclib, and HU+abemaciclib also resulted in synergistic growth inhibition, a phenomenon, that can be best explained by different drug target interaction profiles. Finally, we were able to demonstrate, that the triple combination `HU+palbociclib+ponatinib´ exerts superior growth-inhibitory effects in THP-1 cells compared to all 2-drug combinations tested.
Summary/Conclusion: HU and specific CDK4/CDK6-targeting drugs inhibit the proliferation of CMML cells and synergize with ponatinib in producing growth-arrest. Targeting CDK4/CDK6 may be an interesting therapeutic approach in CMML. The clinical value of this observation remains to be tested in forthcoming studies.

EP903 THE PIVOTAL ROLE OF WEE1 AND PARP-1 IN MYELODYSPLASTIC SYNDROME (MDS): A NEW STRATEGY FOR THE TARGETED THERAPY OF MDS

S. Okabe [1,*], Y. Tanaka [1], A. Gotoh [1]

[1]*Department of Hematology, Tokyo Medical University, Tokyo, Japan*

Background: Myelodysplastic syndrome (MDS) is the clonal myeloid neoplasm which is characterized by blood cytopenia and an increased risk of transformation to acute myelogenous leukemia (AML). About 30 to 40% of MDS patients develop AML and these patients are chemoresistance. Moreover, iron overload (IOL) often begins to develop in patients with MDS through repeated blood transfusion. Because the outcome of MDS is poor, alternative therapeutic strategies are required to improve the survival of MDS patients.
Aims: The inhibition of the DNA damage response pathway including Poly (ADP-ribose) polymerase 1 (PARP-1) in the treatment of cancer has recently approved in clinically. Wee1 is also an oncogenic nuclear kinase, which regulate the cell cycle as a crucial G2/M checkpoint. Because overexpression of Wee1 can be observed in various cancer types, Wee1 inhibitor could suppress MDS and AML cells in combination with PARP-1 inhibitor.
Methods: In this study, we investigated whether Wee1 was involved in MDS progress. We also investigated the efficacy of Wee1 inhibitor, MK-1775 and PARP1 inhibitor, talazoparib by using MDS and AML cell line, SKM-1, MDS-L, U937, THP-1, MV4;11 and osteoblastic cell line, MC3T3-E1.
Results: We first investigated the relationship between Wee1 expression and MDS patients by microarray gene expression data from the online Gene Expression Omnibus (GEO). Wee1 expression was increased in AML transformed cells and AML cells compared to refractory anemia with excess blasts cells (GSE14468). In contrast, PARP-1 expression was not changed. We next evaluated the effect of MK-1775 or talazoparib on proliferation of MDS and AML cell lines. 72 h treatment of MDS and AML cells were inhibited by MK-1775 or talazoparib in a dose dependent manner. Cellular cytotoxicity and caspase 3/7 activity was also increased. We next investigated the relationship between MK-1775 and talazoparib. We found that cotreatment with MK-1775 and talazoparib showed superior effect than single drug treatment. We found that cellular cytotoxicity, caspase 3/7 activity, intracellular reactive oxygen species (ROS) and beta-galactosidase staining positive cells were also increased after MK-1775 and talazoparib treatment. Cotreatment with MK-1775 and talazoparib reduced colony formation. Cell cycle analysis showed significant cell population in sub G1 and induced apoptosis. The study of gene expression profiling of cells revealed that the expression of anti-apoptotic genes such as *BCL11A* and *BCL2* were reduced. We also found γ-H2AX was increased and BCL2 was reduced after MK-1775 and talazoparib treatment by immunoblot analysis. The change of mitochondrial transmembrane potential is one of the early intracellular events to occur following induction of apoptosis. Mitochondrial membrane potential was changed after MK-1775 and talazoparib treatment. Wee1 shRNA transfected cells reduced cellular proliferation. Cell cycle analysis showed G2/M arrest. We found that sensitivity of talazoparib was increased and induced apoptosis in Wee1 shRNA transfected cells. We next examined IOL by using osteoblastic cell line, MC3T3-E1. The cellular proliferation was reduced by ferric ammonium citrate (FAC) in a dose dependent manner. Intracellular ROS was increased. Talazoparib treatment protected FAC mediated cell death.
Summary/Conclusion: Targeting a combination of DNA damage and cell cycle checkpoints enhances therapeutic efficacy, and is proposed as a novel strategy for high-risk MDS and AML. It also provides promising clinical relevance as a therapeutic candidate for MDS patients.

EP904 AZACITIDINE SEQUENCED WITH RIGOSERTIB DOWNREGULATES NEGATIVE REGULATORS OF HEMATOPOIESIS INCLUDING MULTIPLE MAPK PATHWAYS IMPACTING STEMNESS/DIFFERENTIATION OF MDS-L CELLS WITH CLINICAL IMPLICATIONS

R. Rai [1,*], F. Patel [1], S. Melana [1], J. Feld [1], S. C. Navada [1], R. Odchimar-Reissig [1], E. P. Demakos [1], S. Fruchtman [2], E. P. Reddy [1], L. R. Silverman [1]

[1]*Icahn School Of Medicine, Mount Sinai, New York,* [2]*Onconova Therapeutics, Newton, United States*

Background: Myelodysplastic Syndrome (MDS) is characterized by ineffective clonal hematopoiesis and bone marrow failure (BMF). Azacitidine (AZA), a hypomethylating agent is the standard of care for treatment of higher-risk MDS patients either alone or in combination with newer therapeutic options [Silverman LR, Cancer Medicine 2017]. Responses to AZA alone occur in 50% of pts with significant improvement in hematopoiesis [Fenaux et al Lancet Oncol 2009]. AZA improves overall survival of pts, yet despite this, 100% of pts ultimately fail treatment. AZA combined with Rigosertib (RIGO), a novel agent that downregulates the Ras pathway inhibits Ras/Raf signaling [Athuluri-Divakar SK, *et al.* Cell, 2016], yields a response rate of 54% in pts who were HMA failures [Navada SC, *et al.* EHA 2019]. Chronic activation of the MAPK pathway can activate inflammatory pathways suppressing hematopoietic function (Ramalingham Nat Comm 2020). Thus, understanding the mechanism of resistance and identification of targets which can reverse HMA failure and improve hematopoiesis in MDS pts is critical.
Aims: To assess the effects of modulation of the Ras pathway combined with a hypomethylating agent specifically on MAPK signaling, the stemness and differentiation of the MDS-L cell line.
Methods: We investigated the differential protein expression in response to different treatment (AZA, RIGO alone and sequential combinations RIGO/AZA; AZA/RIGO) *in vitro* in MDS-L cell line by Reverse Phase Protein Array (RPPA). Further, we also studied the functional role of these treatments on differentiation in MDS cells by growing cells on semi-solid media as well as by flow cytometry using various stem cell and differentiation markers (CD34, CD38, CD45, CD123).
Results: RPPA analysis indicated discrete responses to treatment in MDS-L cells. The response was prominent with differential expression of 43 proteins specifically in MDS-L cells treated with the sequenced combination of RIGO/AZA that include PIK3R1, AKT1, mTOR, p38 MAPK, PTEN, RPS6KA1 (Fold change (FC) < -2). All of these proteins are downregulated which suggests inhibition of PI3K, mTOR and MAPK signaling. Proteins belonging to metabolic pathways, including ACC1 and ACLY, were found to be downregulated, whereas proteins related to mitochondrial function and oxidative phosphorylation (OXPHOS) were upregulated (FC > 1.5/< -1.5) in cells treated with RIGO/AZA.In addition, we found that MDS-L cells represented both CD34+CD38+ and CD34+CD38- populations. AZA increases the percentage of CD34+CD38+, indicative of differentiation, whereas RIGO alone increased the percentage of CD34+CD38- cells, representing a primitive stem cell population. Based on the combination of differentiation markers, we observed that RIGO alone, and sequenced combination RIGO/AZA, impacts different progenitors such as granulocyte-macrophage progenitor (GMP), megakaryocyte erythroid progenitor (MEP), and multipotent progenitor (MPP). RIGO/AZA treatment showed a decrease in GMP, while the % of MEP was increased, as compared to other treatments.

Summary/Conclusion: In addition to inhibition of the PI3/AKT/mTOR and MAPK pathway, the RIGO/AZA combination impacts metabolic and differentiation pathways of MDS-L cells. RIGO alone appears to promote maintenance of a primitive stem cell population in a less differentiated state, while the RIGO/AZA sequenced combination appears to encourage cells to enter a cycling stage. Further studies are underway to determine the effect of metabolic changes on differentiation and maintenance of hematopoietic stem cells.

EP905 PHENOTYPIC AND GENETIC FEATURES OF MYELODYSPLASTIC SYNDROME (MDS) BONE MARROW (BM) DERIVED MESENCHYMAL STROMAL CELLS (MSC) FOR DISEASE PROGNOSIS AND THERAPY

Z. Poon [1,2,*], H. Than [1,2], X. Fan [1,2], A. Cheung [1,2], W. Hwang [1,2,3]

[1]Hematology, Singapore General Hospital, [2]Duke-NUS Medical School, [3]National Cancer Centre, Singapore, Singapore

Background: Current strategies for MDS prognosis and therapy are primarily based on features of the hematopoietic system, but there is also a growing appreciation for the role that MDS-MSCs play in the development of the disease. The mechanisms by which MSCs contribute to different stages of MDS are not well understood but it is clear that there is a change in MSC biology during the course of MDS that may reflect the extent of progression or offer therapeutic opportunities for targeting the microenvironment.
To study this possibility, we retrospectively analyzed MSC samples from patients, focusing on how their characteristics change with risk classification and more importantly, with time to disease transformation. Our analysis identified gene cluster expression changes in patients that rapidly progressed to secondary leukemia and suggests targetable elements in MDS-MSCs that may help with slowing progression.
Aims: We aim to demonstrate that MDS-MSCs provide meaningful information that helps with disease prognosis and also highlight potential opportunities for targeting these MDS microenvironmental cells for therapy.
Methods: We investigated 34 MDS-BM samples with defined clinical outcomes. MSCs were derived from MDS-BM and cultured up to passage 3 for experiments. RNAseq, karyotyping, differentiation, immunophenotyping, secretome, co-culture LTC-IC assays were performed, and their results compared to discover changes related to disease progression. We also investigated the use of hypomethylating agents and MSC differentiation modulators as potential therapy for the MDS microenvironment *in vitro* or with pre-clinical animal models.
Results: RNAseq, secretome and functional assays show that certain unique characteristics group MDS-MSCs from patients with rapidly transforming disease better than other donor samples. These include gene and protein expression associated with changes in metabolism, hematopoietic support, angiogenesis, inflammation and ECM remodeling. Specifically, MDS-MSCs from rapidly transforming disease secreted elevated levels of macrophage inhibitory factor (MIF), pentraxin-3 (PTX3), VEGFa and reduced levels of SDF-1a. RNAseq analysis showed a cluster of >3000 genes separating samples from patients that transformed <2 years vs >5 years and implicated pathways in metabolism, ECM remodeling and angiogenesis. Finally, functional assays conducted on MDS-MSCs showed that >5 year survivors were more responsive to hypomethylating therapy and differentiation modulators as potential treatment for these stroma cells in reversing their dysplastic phenotype.
Summary/Conclusion: Analysis of MDS-MSCs may complement existing hematopoietic-based approaches for improving disease prognosis and may offer synergistic ways to slow disease progression.

EP906 PREVALENCE OF UBA1 MUTATIONS IN MDS/CMML PATIENTS WITH SYSTEMIC INFLAMMATORY AND AUTO-IMMUNE DISEASE

L.-P. Zhao [1,*], B. Schell [2], M. Sébert [1], M. Boy [3], P. Lemaire [2], S. Matis [2], L. Larcher [2], C. Chauvel [2], M. B. Dhouaieb [2], V. Bisio [3], C. Preudhomme [4], A. Marceau-Renaut [4], R. Itzykson [1], A. Mekinian [5], O. Fain [5], A. Toubert [3], P. Fenaux [1], N. Dulphy [3], E. Clappier [2], L. Adès [1]

[1]Department of Hematology, [2]Laboratory of Hematology, Assistance Publique des Hôpitaux de Paris, [3]Institut de Recherche Saint-Louis, INSERM, PARIS, [4]Laboratory of Hematology, Centre Hospitalier Universitaire Lille, Lille, [5]Internal medicine department, Assistance Publique des Hôpitaux de Paris, PARIS, France

Background: Systemic inflammatory and auto-immune diseases (SIAD), often including relapsing polychondritis (RP), are observed in 25% of patients with MDS or CMML, although the causal relationship is unclear. We previously reported in 85 MDS/CMML patients with SIAD (Zhao *et al*, Leukemia 2021) that *TET2*, *IDH1/2* and *SRSF2* mutations were more frequent in those patients compared to a control cohort of MDS/CMML patients without SIAD, and correlated with naïve/memory T cell imbalance and defects in immune checkpoint receptors expression. Recently, somatic mutations in the *UBA1* gene were described, defining a novel disease called VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome (Beck *et al*, NEJM 2020). 24% of the patients with VEXAS syndrome were reported to have MDS, and 60% had a previous diagnosis of RP.
Aims: To explore the prevalence of *UBA1* mutations in patients diagnosed with MDS/CMML and SIAD
Methods: From our cohort of 85 patients with MDS/CMML and SIAD, all male patients (n=45) for whom material was available (n=33) were analyzed for the presence of *UBA1* mutations. DNA was obtained from peripheral blood or bone marrow mononuclear cells and Sanger sequencing of exons 2 and 3 as well as exon-intron junctions was performed.
Results: The 33 patients with SIAD included 6 MDS with excess blasts, 21 MDS without excess blasts and 6 CMML. 3 of them had *UBA1* mutations. All 3 patients had MDS without excess of blasts, and no CMML patient had *UBA1* mutation. Review of their bone marrow smears showed numerous vacuoles in myeloid and erythroid precursors, which were however not specific of *UBA1* mutated cases of MDS. Patients #1 and #2 had normal karyotype while patient #3 had 9q deletion (**Table 1**). Mutations in *UBA1* affected methionine-41 in patient #2 and patient #3 as reported by Beck *et al*, while patient #1 had a newly described mutation of a splice site predicted to have similar consequence on UBA1 protein (Bourbon *et al*. Blood 2021). Patient #3 had also somatic mutations in *DNMT3A* and *TP53* (VAF 11% and 2%, respectively), while no other mutation was detected in patients #1 and #2 in our next-generation sequencing panel including 80 genes involved in myeloid malignancies.

3 patients in our MDS/CMML SIAD cohort had relapsing polychondritis, and 2 of them (patients #1 and #2) had *UBA1* mutations. The last patient with *UBA1* mutation (#3) had giant cell arteritis (GCA) (out of 7 GCA diagnosis in our SIAD cohort). All 3 patients with *UBA1* mutation had steroid refractory SIAD and were heavily treated with other immunosuppressive therapies including methotrexate, azathioprine or cytokine targeting agents. Patients #1 and #3 received azacytidine (AZA) for their SIAD, based on our previous experience (Fraison *et al*. Leukemia Research

Table 1: Patients main SIAD and hematological characteristics

Variables	Patient #1	Patient #2	Patient #3
Age at MDS/CMML diagnosis	74	78	66
Sexe	Male	Male	Male
SIAD features	relapsing polychondritis, Sweet syndrome	relapsing polychondritis, Hashimoto	giant cell arteritis
Hematological diagnosis	MDS SLD	MDS MLD	MDS SLD
Karyotype	normal	normal	Del 9q
Mutations in myeloid genes NGS	none	none	*DNMT3A* (VAF 11%), *TP53* (VAF 2%)
***UBA1* mutation**	c.118-1G>C	c.T122C:p.Met41 Thr	c.A121G:p.Met41Val
IPSS-R category	low	high	high

Values are presented as median [interquartile range] or number (%). MDS: Myelodysplastic Syndromes; CMML: Chronic Myelomonocytic Leukemia; SIAD: Systemic and Inflammatory Autoimmune Disease; SLD: Single Lineage Dysplasia; MLD: Multilineage Dysplasia; IPSS-R: Revised International Prognosis Scoring System;

2016), with a partial response allowing dose reduction of steroids. At last follow up, none of the 3 patients with *UBA1* mutation had MDS progression, and patient #2 died from a stroke 2.4 years after MDS diagnosis.

Summary/Conclusion: Our retrospective study represents the first assessment of *UBA1* mutation among patients with myeloid malignancies associated with SIAD. The low prevalence of *UBA1* mutations in our cohort suggests that other pathophysiological mechanisms may drive inflammation in a majority of MDS/CMML patients with associated SIAD, including mutations in epigenetic regulators *TET2/IDH* and *SRSF2* as we previously proposed.

EP907 MESENCHYMAL STROMAL CELLS AS A POTENTIAL THERAPEUTIC TOOL IN ENHANCING RESIDUAL HEALTHY HAEMATOPOIESIS IN LOW-RISK MDS PATIENTS

T. Jiménez Solas [1,*], S. Muntión Olave [1], F. López Cadenas [1], M. Martín Izquierdo [2], T. González Martínez [2], K. Janusz [3], T. Ezponda Itoiz [4], A. Vilas Zornoza [4], A. [1]Hematology, Hospital Universitario de Salamanca - IBSAL, [2]Cytogenetics, Hospital Universitario de Salamanca - CIC, Salamanca, [3]Hematology, Hospital Universitario Reina Sofía - UCO, Córdoba, [4]Oncology, Centro de Investigación Médica Aplicada (CIMA) - Universidad de Navarra, [5]Hematology, Clínica Universidad de Navarra, Pamplona, [6]Hematology, Hospital Vall d'Hebron, Barcelona, Spain

Background: Mesenchymal stromal cells (MSC) play a key role in the pathophysiology of MDS. Thus, MSC in MDS patients are abnormal and characterised by poor hematopoietic support capacity and their dysfunction contributes to the expansion of the malignant clone.
Aims: Considering the involvement of MSC in the pathophysiology of MDS, we aimed to study whether healthy MSC might have therapeutic potential in the positive regulation of residual healthy hematopoiesis in low-risk MDS patients.
Methods: Bone marrow (BM) samples from MDS patients (n=21), all from the low-risk MDS-DM category [WHO 2017] (IPSS: low/int-1 risk and IPSS-R: very low to intermediate) of new diagnosis and not exposed to haematological treatment, as well as from healthy donors (HD) (n=13), were analysed. Mononuclear cells (MNC) and MSC were isolated and expanded according to standard methodology up to 3rd-4th pass.
A short-term co-culture model was established in transwell (MNC:MSC ratio of 3:1, for 48h) with different cell combinations:
- Control MDS-MNC (basal MNC, not co-cultured).
- Control HD-MNC (basal MNC, not co-cultured)
- Group 1.1 - MDS-MSC co-cultured MDS-MNC
- Group 1.2 - MDS-MSC co-cultured HD-MNC
- Group 2.1 - HD-MSC co-cultured MDS-MNC
- Group 2.2 - HD-MSC co-cultured HD-MNC
- Group 3 - MDS-MSC co-cultured Mix-MNC (MDS+HD)
- Group 4 - HD-MSC co-cultured Mix-MNC (MDS+HD)

After 48h of culture, MNC from each group were collected and clonogenic assays were performed, from 5000 MNC seeded on semi-solid methylcellulose medium with EPO, at 37°C and 5% CO_2. After 14 days of incubation, CFU-erythroid (CFU-E) and CFU-granulomonocytic (CFU-GM) were counted (CFU/5000 MNC).
Results: In basal state (without co-culture with MSC) MDS-MNC showed a deficient formation of CFU-E and CFU-GM compared to HD-MNC, as well as an imbalance between the number of CFU and clusters, which translates into defective hematopoiesis in MDS patients (not shown).
To determine the effect of the addition of MSC on MNC of MDS patients (groups 1.1 and 2.1), we analysed the ratio between CFU formed by MDS-MNC co-cultured with MSC (MDS or HD) versus basal MDS-MNC (not co-cultured). We observed that the addition of HD-MSC trends to increase erythroid colony formation (Fig. 1-A) and that CFU-granulomonocytic were significantly enhanced by addition of MSC (Fig. 1-B).
In an environment simulating the diseased condition (groups 3 and 4), with mixed MDS and HD MNC (residual hematopoiesis), a significant recovery of hematopoietic capacity occurs with the addition of MSC,
Summary/Conclusion: Taken together, our results suggest that HD-MSC enhances MNC clonogenic capacity, especially when co-cultured with mixed MDS and HD MNC. Considering that this situation mimics what happens in lower-risk MDS patients, where often normal and dysplastic hemopoiesis coexists, HD-MSC could be a potential therapy to rescue residual healthy hematopoiesis and improve hematopoietic potential in these patients.

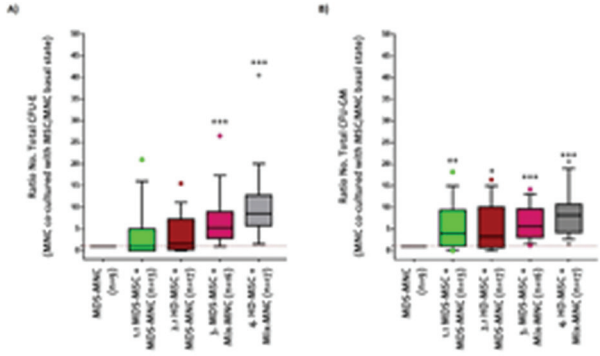

Figure 1. Ratio between CFU formed from MDS-MNC co-cultured with MDS-MSC or HD-MSC (as indicated in each study group) and CFU formed from basal state MNC-SMD (not co-cultured), in methylcellulose medium supplemented with EPO. **A)** CFU-E ratio, **B)** CFU-GM ratio. Data expressed as median ± range of the n indicated in each case. Mann-Whitney U test: * = p < 0.05; ** = p < 0.01; *** = p < 0.001; ns = not significant.

EP908 SIMPLE FLOW CYTOMETRY IMMUNOPHENOTYPING APPROACH PREDICTS THE DEVELOPMENT OF MYELOID NEOPLASMS IN PATIENTS WITH CCUS

D. Jevremovic [1,*], A. Nanaa [2], S. Geyer [3], A. Al-Kali [2], P. Nguyen [1]

[1]Laboratory Medicine and Pathology, [2]Division of Hematology, [3]Quantitative Health Sciences, Mayo Clinic, Rochester, United States

Background: Myeloid neoplasms (MN) are diagnosed by a combination of clinical, morphologic and genetic findings. Aberrant immunophenotype of myeloid cells by flow cytometry immunophenotyping (FCIP) is frequently associated with MN. However, by itself FCIP is insufficient for establishing the diagnosis of MN due to (I) lack of specificity and (II) marked variability in appraches by different laboratories. We have previously shown that abnormalities of CD13/HLA-DR expression on CD34-positive blasts could be a sensitive and specific method for a simple assessment of myeloid dysmaturation.
Aims: To determine whether a simple immunophenotyping approach using aberrant expression of CD2, CD7 and CD56 on myeloid blasts, and qualitatively abnormal FCIP patterns on CD13/HLA-DR and CD13/CD16 plots could predict development of MN in a subpopulation of patients with clonal cytopenia of undetermined significance (CCUS).
Methods: Bone marrow aspirates were analyzed using 2 8-color FCIP tubes (see table below). A total of 500,000 events were collected per tube, using BD Canto II instruments. The data were analyzed using Kaluza software. CD34+CD45dim blasts were evaluated for the aberrant expression of CD2, CD7 and CD56 (cut-offs 10%, 30%, and 10%, respectively, were established previously by adding 2 SD to the mean of the expression in the normal cohort. In addition, CD34-positive blasts were evaluated for the aberrant expression pattern of CD13/HLA-DR, as previously described [AJCP (2014) 142:292]. Aberrancies of granulocyte maturation were evaluated on the CD13/CD16 plot.
Relevant clinical and laboratory data, including CBC and the presence of genetic abnormalities, were extracted from the electronic medical record. Statistical analysis was done using R statistical software.
Results: Out of 86 patients with CCUS, 21 developed MN over the follow-up time period (median follow-up 28 months). FCIP abnormalities detected at diagnosis of CCUS were predictive of the future developmen of MN, with the most significant abnormalities being: (I) aberrant expression of CD7 on CD34-positive myeloid blasts (p=0.014, HR 3.74), (II) aberrant pattern of CD13/HLA-DR expression on CD34-positive myeloid blasts (p=0.019, HR 2.59), and (III) presence of multiple (>1) FCIP abnormalities (p=0.003, HR 1.90).

	FITC	PE	PercP Cy5.5	Pe-Cy7	APC	APC-H7	V450	V500
Tube 1	HLA-DR	CD13	CD34	CD33	CD117	CD16	CD15	CD45
Tube 2	CD2	CD7	CD34	CD56	CD36	CD64	CD38	CD45

Summary/Conclusion: A simple FCIP approach, which includes assessment of CD13/HLA-DR pattern on CD34-positive myeloid blasts, can be useful in predicting the development of MN in CCUS patients.

Myelodysplastic syndromes - Clinical

EP909 VENETOCLAX AND AZACITIDINE COMBINATION IN CHEMOTHERAPY INELIGIBLE PATIENTS WITH THERAPY-RELATED MYELOID NEOPLASMS, ANTECEDENT MYELODYSPLASTIC SYNDROMES OR MYELODYSPLASTIC/ MYELOPROLIFERATIVE NEOPLASMS

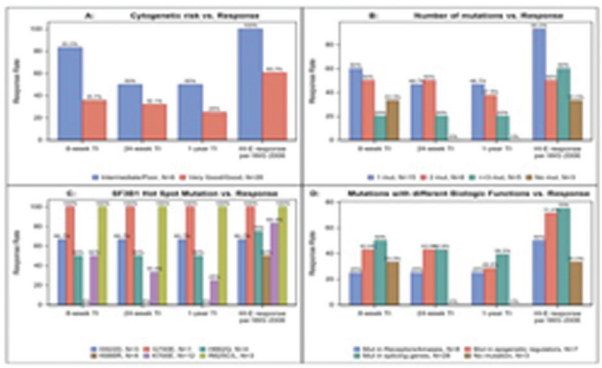
Background: Patients (pts) with therapy-related myeloid neoplasms (tMN), antecedent myelodysplastic syndrome, or antecedent myelodysplastic/myeloproliferative neoplasms (A-MDS/MPN) may have poor outcomes due to age and adverse genetic/karyotypic features. In the VIALE-A study, pts with tMN and A-MDS/MPN unfit for intensive chemotherapy treated with venetoclax (Ven) and azacitidine (Aza) demonstrated superior response rates and overall survival (OS) than Aza alone.
Aims: We describe the efficacy and safety of Ven+Aza among pts with tMN and A-MDS/MPN.
Methods: Data were pooled from pts enrolled in VIALE-A (NCT02993523) comparing pts who received Ven+Aza or placebo (Pbo)+Aza and a prior phase 1b study (NCT02203773) where pts received Ven+Aza. Enrolled pts were ≥18 years, treatment-naïve with no prior exposure to hypomethylating agents, and ineligible for intensive chemotherapy. Pts on Ven+Aza received Ven 400 mg orally (days 1–28) and Aza (75 mg/m^2; days 1-7/28-day cycle). Composite complete remission rate (CRc; complete remission [CR] + CR with incomplete hematologic recovery [CRi]), duration of response (DoR), and OS were assessed. Disease assessments were per modified International Working Group response criteria for AML.
Results: In this pooled analysis, tMN was observed in (Ven+Aza/Pbo+Aza) 31/9 and A-MDS/MPN in 59/26 pts. Poor-risk cytogenetics were observed in 18 (58%)/6 (67%) with tMN (5 or 5q deletion [del]: 4/1; 7 or 7q del: 6/1; complex [≥ 3 clonal abnormalities]: 10/ 4), and 19 (32%)/13 (50%) with A-MDS/MPN (5 or 5q del: 10/ 5; 7 or 7q del: 6/ 1; complex: 14/ 9). *TP53* mutation was observed in 5 /3 pts with tMN and 8/0 pts with A-MDS/MPN. Pts with tMN received a median (Ven+Aza/Pbo+Aza) of 5/4 cycles of treatment. CRc was achieved in19 (61%)/1 (11%). The mDoR was not reached (NR) (95% CI: 17.8, NR)/8.5 (NR, NR) months. The mOS was 16.4 (95% CI: 4.1, NR)/11.3 (0.6, 17.5) months. Pts with A-MDS/MPN received a median (Ven+Aza/Pbo+Aza) of 9/5 cycles of treatment. CRc was achieved by 39 (66%)/7 (27%) pts with mDoR of 17.3 (95% CI: 9.6, NR)/5.8 (1.1, NR) mos. The mOS was 15.9 (95% CI: 11.5, NR)/10.1 (4.7, 14.5) mos. Common grade≥3 adverse events (Ven+Aza/Pbo+Aza) were febrile neutropenia (tMN: 39%/11% and A-MDS/MPN: 36%/12%) neutropenia (tMN: 29%/33%; A-MDS/MPN: 39%31%), and thrombocytopenia (tMN: 32%/33%; A-MDS/MPN: 39%/62%).
Summary/Conclusion: Ven+Aza compared to Aza monotherapy resulted in higher CRc rates with longer DoR and median OS among treatment-naïve pts with tMN and A-MDS/MPN ineligible for intensive chemotherapy. The safety profile was similar to overall pts with the Ven+Aza combination. Outcomes by cytogenetic and molecular risk-groups will be presented.



EP910 EFFICACY OF IMETELSTAT IS INDEPENDENT OF MOLECULAR SUBTYPES IN HEAVILY TRANSFUSED NON-DEL(5Q) LOWER RISK MDS (LR-MDS) RELAPSED/REFRACTORY (R/R) TO ERYTHROPOIESIS STIMULATING AGENTS (ESA)

Background: IMerge (MDS3001, NCT02598661) is a Phase 2/3 global study of imetelstat, a first-in-class telomerase inhibitor, for red blood cell (RBC) transfusion dependent (TD) non-del(5q) patients (pts) with ESA-R/R LR-MDS. Phase 2 results indicated that imetelstat achieved durable transfusion independence (TI) with a manageable safety profile (Steensma ASH 2018; Fenaux EHA 2019; Steensma JCO 2020). With a median follow-up of 24 months for Phase 2, 42%, 32% and 29% of 38 pts achieved ≥8-week (w), ≥24-w and 1-year (y) TI, respectively (Platzbecker EHA 2020).
Aims: To evaluate clinical efficacy of imetelstat in molecularly defined subtypes based on cytogenetic and mutation profiles.
Methods: At screening, bone marrow aspirates were used for cytogenetic analysis by karyotyping. Peripheral blood samples were collected to analyze mutations by next-generation sequencing using the Illumina TruSight Myeloid Panel of 54 genes. Correlation analyses between molecular profiles and clinical efficacy, including TI ≥8-w, ≥24-w, ≥1-y, and hematologic improvement-erythroid (HI-E) response per International Working Group 2006 guidelines, were performed for pts in the Phase 2 part of IMerge study.
Results: Of 34/38 pts with baseline cytogenetic results, 28 (82.4%) pts had very good/good and 6 (17.6%) pts had intermediate (int)/poor cytogenetic risk (n=3 trisomy 8, n=1 for del(7q), inv(3)/t(3q) and complex karyotype). Though pts with int/poor risk had higher TI and HI-E response rates compared with pts with very good/good risk pts, no statistically significant difference was observed: 83.3% (5/6) vs 35.7% (10/28) had ≥8-w TI; 50% (3/6) vs 32.1% (9/28) had ≥24-w TI; and 50% (3/6) vs 25% (7/28) had ≥1-y TI; 100% (6/6) of pts with int/poor risk group vs 60.7% (17/28) achieved HI-E response (Fig. A).
Of 31/38 pts with baseline mutation data, 28 (90.3%) pts had at least one mutation, among which 15 (53.6%), 8 (28.6%) and 5 (17.9%) pts had 1, 2 and ≥3 mutations, respectively. The ≥8-w TI rate was 60%, 50% and 20% respectively, ≥1-y TI rate was 46.7%, 37.5% and 20% respectively, and HI-E response rate was 93.3%, 50% and 60%, respectively (Fig. B). Three pts (9.7%) had no mutation detected, of which 1 pt had 8-w TI and HI-E response. The most frequently mutated gene was SF3B1 (87.1%, n=27), consistent with the predominance of ring sideroblast phenotypes (n=23); followed by DNMT3A (19.4%), KIT (16.1%) and RUNX1 (6.4%), all coexisting with SF3B1 mutation. Among pts with SF3B1 mutation, hot spot mutations were detected: 3 (11.1%) E622D, 3 (11.1%) R625C/L, 4 (14.8%) H662Q, 4 (14.8%) K666R, 12 (44.4%) K700E and 1 (3.7%%) G740E, respectively. Durable TI was observed in pts with these hot spot mutations except K666R, and HI-E response was seen in pts with all hot spot mutations (Fig. C). Analysis of clinical responses across the mutation defined subgroups on genes involved in different biological functions, including splicing process, epigenetic regulation, or receptors/kinases, were performed and ≥8-w TI was 50.0%, 42.9% and 25.0%; ≥24-w TI was 42.9%, 42.9% and 25.0%; ≥1-y TI was 39.3%, 28.6% and 25.0%, and HI-E responses were 75.0%, 71.4% and 50.0%, respectively (Fig. D).
Summary/Conclusion: Imetelstat demonstrated clinical efficacy across different molecularly defined subgroups including in pts with poor prognosis in heavily transfused LR-MDS ESA-R/R, who have limited treatment options. Phase 3 of IMerge, a placebo-controlled trial of imetelstat, is ongoing to further confirm the efficacy, safety, and biomarker results.

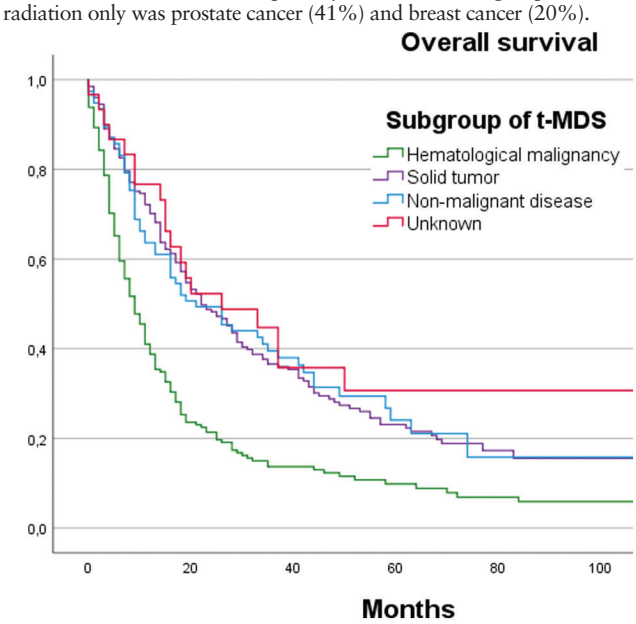
EP911 A MACHINE LEARNING APPROACH TO PREDICTING RISK OF MYELODYSPLASTIC SYNDROME

A. Radhachandran [1,*], A. Garikipati [1], Z. Iqbal [1], A. Siefkas [1], G. Barnes [1], J. Hoffman [1], Q. Mao [1], R. Das [1]

[1]Dascena, Inc., Houston, United States

Background: Myelodysplastic syndrome (MDS) is an underdiagnosed preleukemic condition mainly affecting patients over the age of sixty. In approximately one-third of patients, MDS evolves into acute myeloid leukemia (AML), which is highly aggressive and can be fatal. Accurate and early MDS diagnosis can allow physicians to monitor patients and provide early treatment, which may delay advancement of MDS and improve quality of life in many patient populations. However, MDS is often unrecognized by primary care physicians and is difficult to distinguish from other causes of bone marrow failures, cytopenias, and other clonal stem cell disorders.
Aims: The purpose of this study is to develop a machine learning algorithm (MLA) for the prediction of MDS one year prior to clinical diagnosis of the disease.
Methods: Retrospective analysis was performed on 790,470 patients over the age of 45 using electronic health records (EHR) drawn from over 700 healthcare sites across the US between 2001 and 2019. Two models, including a gradient boosted decision tree model (XGBoost) and a logistic regression model, were trained to predict onset of MDS using vital signs, lab results and demographics information from up to 2 years of patient EHR data. The models did not require blast percentage and cytogenetics as inputs. Retrospective predictions were made 1 year prior to MDS diagnosis as determined by International Classification of Diseases (ICD) codes. Performance was assessed with regard to area under the receiver operating characteristic curve (AUROC) and a SHAPley analysis of feature importance.
Results: On a hold-out test set, the XGBoost model achieved an AUROC value of 0.87 when tested for prediction of MDS one year prior to MDS diagnosis, at a sensitivity of 0.70, and specificity of 0.88. Age, hematocrit, red blood cell count, and peripheral oxygen saturation were found to be the most important features for MDS prediction. The XGBoost model was compared against a logistic regression model. The logistic regression achieved an AUROC of 0.77, at a sensitivity of 0.75 and specificity of 0.79. Receiver operating characteristic (ROC) curves and comparison of AUROC of the XGBoost (XGB) and logistic regression (LR) models are shown in figure below.



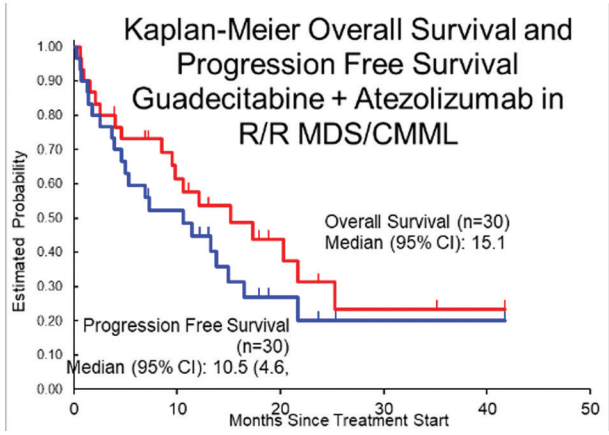
Summary/Conclusion: Machine learning methods can be used to accurately predict MDS one year prior to diagnosis using current standard procedures. The algorithm only utilized readily available EHR data, without requiring blast percentages or cytogenetics. In clinical practice, use of such a tool may allow for early diagnosis of MDS and more appropriate treatment admini stration.

EP912 THERAPY-RELATED MDS; A WIDE DEFINITION THAT NEEDS NARROWING

D. Berggren [1,*], M. Jädersten [2], S. Lehmann [1], E. Ejerblad [1]

[1]Department of Medical Sciences, Uppsala University, Uppsala, [2]Center for Hematology and Regenerative Medicine, Department of Medicine Huddinge, Karolinska Institutet and Karolinska University Hospital and PO Hematology, Stockholm, Sweden

Background: MDS patients with a history of chemotherapy and/or radiation therapy for a malignant or non-malignant disease are considered to have therapy-related MDS (t-MDS). This group is generally described to constitute 15-20% of all MDS cases and to have more adverse prognostic factors such as transfusion dependency and high risk cytogenetics. They also have shorter survival and are often treated aggressively if possible. For t-MDS patients only treated with radiation, the data is conflicting
Aims: The aims of this study were to characterize t-MDS in a population-based setting, to compare clinical characteristics and outcomes between t-MDS and de novo MDS (d-MDS), and between subgroups of t-MDS.
Methods: All patients aged 16 years or older diagnosed with MDS and MDS/MPN 2009-2017 and reported to the nationwide Swedish MDS-register were included (n= 3379). All patients treated with chemotherapy and/or radiation prior to the diagnosis of MDS were considered to have t-MDS.
Data on previous cancer diagnoses was obtained from the Swedish Cancer Registry and data on non-malignant diseases from the National Patient Register. In cases with multiple malignant diseases preceding MDS, the most likely one was chosen based on latency time and treatment traditions. Information was obtained from the Swedish Cause of Death Register up to November 20, 2019 to calculate overall survival (OS).
To assess the distribution of baseline patient characteristics, chi-squared test and Wilcoxon rank sum test was used. OS was analysed using the Kaplan–Meier approach with log-rank test used to compare OS.
Results: The median survival of the 14% (n=486) of patients classified as t-MDS was shorter compared to d-MDS, 16 vs 28 months (p=0.000). As a group, patients with t-MDS had more high risk cytogenetics, more transfusion dependency and a higher IPSS-R score compared to d-MDS. Patients previously treated with both chemotherapy and radiation and chemotherapy alone had a shorter median survival as compared to those treated with radiation only, 10 and 14 vs 32 months, respectively (p=0.000). Patients with a previous non-malignant disease or a previous solid tumour had a longer survival compared to patients with a previous hematological malignancy, 21 and 22 vs 9 months, respectively (p=0.000). To have the primary malignancy as an underlying cause of death was more common in patients with a previous hematological malignancy (43%) compared to patients with a previous solid malignancy (17%).
In the group of t-MDS patients previously treated with radiation only, known prognostic factors such as IPSS-R score, cytogenetics and transfusion dependency had a significantly lower risk profile compared to other groups of t-MDS. The most common primary condition in the group treated with radiation only was prostate cancer (41%) and breast cancer (20%).



Summary/Conclusion: Using Swedish register data we have characterized a large cohort of t-MDS. These patients have a significantly shorter survival as compared to d-MDS, but the survival difference is highly heterogeneous among subgroups. Patients previously treated with radiation only, have clinical characteristics and survival comparable to d-MDS and we question if these should be considered t-MDS. Patients with a previous hematological malignancy have a dismal prognosis, in part because of mortality associated with the primary condition.

EP913 RESULTS OF A PHASE I/II CLINICAL TRIAL COMBINING GUADECITABINE WITH ATEZOLIZUMAB IN PATIENTS WITH RELAPSED OR REFRACTORY MYELODYSPLASTIC SYNDROME (MDS) OR CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML)

C. L. OConnell [1,*], M. R. Baer [2], V. H. Duong [3], A. Emadi [3], I. Syed [4], G. Yaghmour [1], A. D. Ørskov [5], P. Kropf [6], D. Tsao-Wei [4], J.-P. Issa [7], K. Grønbæk [5]

[1]Internal Medicine, USC, Keck School of Medicine, Los Angeles, [2]Internal Medicine, University of Maryland, Baltimore, Maryland, [3]Internal Medicine, University of Maryland, Baltimore, [4]Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, United States, [5]Haematology, Rigshospitalet / Copenhagen University Hospital, Copenhagen, Denmark, [6]Transplantation & Cellular Therapy, Novant Health, Charlotte, [7]Coriell Institute for Medical Research, Camden, United States

Background: Median overall survival after failure of hypomethylating agents (HMAs) for patients with myelodysplastic syndrome (MDS) is 5-6 months. Preclinical and clinical data suggest that myeloblasts express PDL-1 and that HMAs induce T-cell PD-1 expression, which may promote resistance or relapse despite effective demethylation.
Aims: To determine the safety profile, efficacy and impact on overall survival of atezolizumab (atezo), a PDL-1 inhibitor, in combination with the decitabine and deoxyguanosine dinucleotide guadecitabine (guaD), for patients with MDS and CMML treated after failure of an approved HMA.
Methods: We conducted a Phase I/II clinical trial for adult patients with relapsed or refractory, intermediate (3+) or high-risk MDS by the revised international scoring system (IPSS-R), or CMML, after failure of a standard HMA. The primary endpoint of Phase I was to determine a safe dose of guaD in combination with a fixed dose of atezo. A 3x3 dose escalation design for guaD was used, beginning with 30mg/m2 (Dose level -1) SC days 1-5 with atezo 840mg IV days 8 and 22 of a 28-day cycle. Escalation to the recommended dose of guaD, 60 mg/m2 (Dose level 1), was allowed if no dose-limiting toxicities (DLTs) were observed at Dose level -1. If no DLTs were observed at Dose level 1, 3 additional patients were treated to confirm safety. Phase II was planned to include 30 patients treated at Dose level 1, with the primary endpoint of efficacy measured by overall response rate (ORR), based on the 2006 IWG Response Criteria for MDS. Overall survival (OS) was a secondary endpoint.
Results: Between June 2017 and October 2020, 33 patients from 4 centers enrolled in the study. Median age was 73 (54-85) years, 22 (67%) were male, 11 (33%) had IPSS-R intermediate-risk and 20 (64%) had high- or very high risk MDS, 2 had CMML, and two-thirds were refractory to their prior HMA. No DLTs occurred in 3 patients treated at Dose level -1. No DLTs were seen among 6 patients treated at Dose level 1, so 24 additional patients were treated. The most common grade 4 toxicities at Dose level 1, regardless of attribution, were thrombocytopenia in 11 (36.7%), neutropenia in 10 (33.3%), and anemia in 5 (16.7%) patients. There were 4 grade 3 events considered autoimmune and attributed to atezolizumab – 2 encephalitis and 2 pneumonitis. Four deaths occurred while on therapy, including 1 patient with sepsis and brainstem herniation after lumbar puncture; 11 patients came off treatment due to disease progression, 3 due to clinical deterioration, 2 at their own request, 4 at physician's discretion, and 5 patients due to unacceptable toxicity. A median of 5 cycles (1-21) were administered and median follow-up is 25.3 (3.9-41.7) months with 4 patients still on treatment. ORR is 30% (CI 16-41%), with 2 CR (6%), 4 marrow CR (12%), 1 PR and 3 (9%) Hematologic Improvement. Median overall survival is 15.1 (8.5, 21.6) months among the 30 patients treated at Dose level 1, 17.3 (8.5, 27.3) months among those refractory to prior HMA and 10.5 (4.4, 21.6) months in patients who responded and then relapsed after prior HMA (p=0.58). There was a trend for better survival among females, 21.6 (10.5, 41.7+) vs 12.1 (2.5, 20.3) months (p=0.068).

Summary/Conclusion: In this phase I/II trial of patients with higher risk, predominantly HMA-refractory MDS, guadecitabine with atezolizumab yielded modest IWG responses, but overall survival appears better than predicted for this patient population, particularly among women. Ongoing correlative work will investigate immunologic characteristics of long-term survivors.

EP914 ASXL1 MUTATIONS PREDICT A POOR RESPONSE TO DARBEPOETIN ALFA IN ANEMIC PATIENTS WITH LOW-RISK MDS: A MULTICENTER, PHASE II STUDY

M. Ichikawa [1,*], Y. Morita [2], H. Hanamoto [3], Y. Nannya [4], H. Shibayama [5], Y. Maeda [6], T. Hata [7], T. Miyamoto [8], H. Kawabata [9], K. Takeuchi [10], H. Tanaka [11], J. Kishimoto [12], S. Miyano [11], I. Matsumura [2], S. Ogawa [4], K. Akashi [8], Y. Kanakura [13], K. Mitani [1]

Background: Myelodysplastic syndromes (MDS) develop and progress as a result of accumulation of genetic mutations.
Aims: This multicenter, open-label, phase II study examined impact of gene mutations on the effect of darbepoetin alfa (DA) for anemia. Death within 1 year and progression to acute myeloid leukemia (AML) were also examined.
Methods: DA ≤240 μg was administered once weekly for 16 weeks to DA-naive, low-risk MDS (low or Intermediate-1 [Int-1] risk defined by the International Prognostic Scoring System [IPSS] risk classification) patients with anemia. DNA was extracted from the peripheral blood of patients, and presence of previously reported high-frequency gene mutations in MDS (*SF3B1*, *TET2*, *SRSF2*, *ASXL1*, *DNMT3A*, etc.) was analyzed by next-generation sequencing. Primary endpoint was association between frequently observed mutated genes and therapeutic effect of DA (IWG criteria 2006 (HIE)) at 16 weeks. A secondary endpoint was survival analysis results for death and progression to AML within

one year after 16 weeks of treatment. For AML, progression to AML and subsequent death were stated as events, and the patients without confirmed progression to AML were censored at the date of last known survival. For overall survival, death from any cause was considered an event, and for the survival cases, the study was terminated at the date of last known survival.
For the primary endpoint, relative risk and 95% confidence intervals (CI) were calculated using Wilson's score method; statistical significance was assessed using Pearson's chi-square test. Multivariate analysis was performed by adding baseline erythropoietin (EPO) levels (low: <91.8, high: 91.8+ [mIU/mL]) to the explanatory variables, and odds ratio was calculated using logistic regression model. Survival curve was estimated using Kaplan-Meier method and median survival time (MST) was calculated using Brookmeyer and Crowley method.
Results: Of the 85 patients enrolled between August 2016 and May 2019, 6 patients (4 were judged ineligible and 2 discontinued the study prior to the start of treatment) were excluded, and 79 subjects were included in the analysis. Of 79 subjects, 52 (65.8%) were male (median age 77.0 [29-90] years). IPSS risk was low in 27 (36.7%) and Int-1 in 50 (63.3%) subjects. The frequently mutated genes (≥10%) were *SF3B1* (24, 30.4%), *TET2* (20, 25.3%), *SRSF2* (10 cases, 12.7%), *ASXL1* (9, 11.4%), and *DNMT3A* (8, 10.1%). Overall response rate was 70.9%. Univariate logistic regression analaysis did not show any significant association between these mutations and therapeutic efficacy of DA. The same results were obtained when the analysis was limited to red blood cell transfusion-dependent subjects (n=15). After adjusting against baseline EPO values, mutations of *ASXL1* gene were associated with significantly worse response (odds ratio 0.180 [0.035-0.928], p = 0.040). Twenty-three deaths (29.1%) were observed, and the median survival time (95% CI) from the start of treatment to confirmed AML or death was 41.3 months (30.6 months - Not reached). Fifty-eight patients completed the 16 weeks of treatment without progression to AML. For these 58 patients, median survival time (95% CI) from the completion of 16 weeks of treatment was not reached (30.9 months – not reached) and the rate of survival without progression to AML within one year was 83.5% (70.7 – 91.1 %).
Summary/Conclusion: The results of this exploratory study suggest that the presence of *ASXL1* gene mutations may result in poor response to the anemic treatment with DA in low-risk MDS.

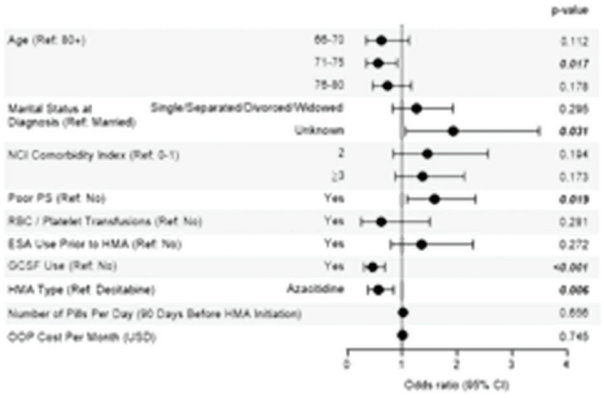
EP915 BENEFIT OF CONTINUING LUSPATERCEPT THERAPY IN PATIENTS WITH LOWER-RISK MYELODYSPLASTIC SYNDROMES WHO DID NOT ACHIEVE RED BLOOD CELL TRANSFUSION INDEPENDENCE BY WEEK 25 IN THE MEDALIST STUDY

U. Germing [1,*], P. Fenaux [2], U. Platzbecker [3], R. Buckstein [4], V. Santini [5], M. Díez-Campelo [6], D. Tang [7], R. Ito [7], S. Fabre [7], E. Mantovani [7], G. Zhang [7], X. Ha [7], D. Miteva [7], C. Hughes [7], W. Khan [7], R. S. Komrokji [8], G. Garcia-Manero [9]

[1]University Hospital of Düsseldorf, Düsseldorf, Germany, [2]Service d'Hématologie Séniors, Hôpital Saint-Louis, Université Paris 7, Paris, France, [3]Medical Clinic and Policlinic 1, Hematology and Cellular Therapy, University Hospital Leipzig, Leipzig, Germany, [4]Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada, [5]MDS Unit, Azienda Ospedaliero Universitaria Careggi, University of Florence, Florence, Italy, [6]Hematology Department, Institute of Biomedical Research of Salamanca, University Hospital of Salamanca, Salamanca, Spain, [7]Bristol Myers Squibb, Princeton, NJ, [8]Moffitt Cancer Center, Tampa, FL, [9]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: MEDALIST (NCT02631070) is an ongoing, randomized, placebo-controlled phase 3 trial evaluating the efficacy and safety of luspatercept, the first and only erythroid maturation agent, in patients with anemia due to lower-risk myelodysplastic syndromes (LR-MDS) with ring sideroblasts. A greater proportion of patients receiving luspatercept than placebo achieved the primary endpoint of red blood cell transfusion independence (RBC-TI) for ≥8 weeks during Weeks 1–24 (Fenaux P, et al. *N Engl J Med* 2020;382:140-151). However, for patients not achieving the primary endpoint during the first 24 weeks, the value of continuing luspatercept treatment is not yet well understood.
Aims: To evaluate the clinical benefit of continuing luspatercept treatment beyond 24 weeks in patients not achieving the RBC-TI primary endpoint during the first 24 weeks of the MEDALIST study.
Methods: Eligible patients were aged ≥18 years; were refractory, intolerant, or unlikely to respond to erythropoiesis-stimulating agents; and required regular RBC transfusions (≥2 units/8 weeks) in the 16 weeks prior to randomization. Overall, 229 patients were randomized 2:1 to receive either luspatercept (n=153) or placebo (n=76) every 3 weeks through the clinical assessment visit at Week 25, defined as 24 calendar weeks after the first dose, regardless of dose delays. Patients who did not achieve RBC-TI for ≥8 weeks on luspatercept by Week 25 but continued treatment were included in this analysis; the data cutoff was July 1, 2019. For this analysis, transfusion burden, serum ferritin (SF) levels, and hematologic improvement-erythroid (HI-E) response were assessed every 24 weeks. HI-E response was defined as a reduction in RBC transfusions of ≥4 units/8 weeks (for patients with baseline RBC transfusion burden of ≥4 units/8 weeks) or as an increase in hemoglobin level of ≥1.5 g/dL over 8 weeks (for patients with baseline RBC transfusion burden of <4 units/8 weeks).
Results: Of the patients receiving luspatercept, 68 did not meet the primary endpoint during the first 24 weeks and continued treatment. During Weeks 25–48, 16.2% (n=11/68) of these patients achieved RBC-TI for ≥8 weeks for the first time, and a mean change from baseline of –1.3 RBC units transfused was achieved in 36 pts. 44.1% (n=30/68) of patients who did not meet the primary endpoint achieved any degree of reduction in SF levels from baseline during Weeks 25–48, while 17.9% (n=7/39) shifted from a SF level ≥1,000 µg/L at baseline to <1,000 µg/L. During Weeks 1–48, 60.3% (n=41/68) of patients who did not meet the primary endpoint achieved ≥50% reduction in RBC transfusion burden for ≥8 weeks from baseline and 47.1% (n=32/68) achieved HI-E response. Over the entire treatment period up to the data cutoff, 60.3% (n=41/68) achieved ≥50% reduction in transfusion burden for ≥8 weeks from baseline, 22.1% (n=15/68) achieved RBC-TI for ≥8 weeks, and 48.5% (n=33/68) achieved HI-E response.
Summary/Conclusion: A considerable proportion of patients with LR-MDS in the MEDALIST study who did not achieve the primary endpoint, but continued to receive luspatercept beyond 24 weeks of treatment, experienced a broad range of clinical improvements, including reduced transfusion burden, reduced SF levels, and even TI.

EP916 PREDICTORS OF HYPOMETHYLATING AGENT DISCONTINUATION AMONG PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES



A. Zeidan [1,*], N. Joshi [2], H. Kale [2], W.-J. Wang [2], S. Corman [2], K. Hill [3], T. Salimi [3], R. Epstein [4]

[1]Yale University and Yale Cancer Center, New Haven, CT, [2]Pharmerit - an OPEN Health Company, Bethesda, MD, [3]Taiho Oncology, Inc., Princeton, NJ, [4]Epstein Health LLC, Woodcliff Lake, NJ, United States

Background: Real-world studies have shown that persistence with intravenous (IV) and subcutaneous (SC) hypomethylating agents (HMAs) among patients with higher-risk myelodysplastic syndromes (MDS) is poor, with over one-third of treated patients receiving <4 cycles or having a ≥90-day gap in therapy, despite recommendations for at least 4-6 cycles to elicit response in the absence of progression/unacceptable toxicity. Survival outcomes have also been shown to be worse, and direct medical costs higher, among HMA non-persistent versus persistent patients.
Aims: To explore factors associated with early discontinuation of HMA therapy among patients with higher-risk MDS in the real-world setting.
Methods: This was a retrospective cohort study among patients from the 2010-2016 SEER-Medicare linked database with a diagnosis of refractory anaemia with excess blasts (RAEB; a surrogate for higher-risk MDS) from 2011-2015. Included patients had to have received HMA therapy and have ≥12 months' continuous follow-up after diagnosis. Discontinuation was defined as stopping HMA therapy before 4 cycles. Multivariable logistic regression was used to assess predictors of HMA discontinuation.
Results: In total, 664 patients with RAEB and treated with HMAs were included. Overall, 193 patients (29%) discontinued before receiving 4

cycles of therapy; of these, 91 (47%) discontinued after 1 cycle, 57 (30%) after 2 cycles, and 45 (23%) after 3 cycles. Compared with patients continuing for ≥4 cycles, patients discontinuing before 4 cycles were generally older (mean age 79.1 vs 77.3 years; p<0.001) and more likely to be single/separated/divorced/widowed (35% vs 30%; p=0.024), have more comorbidities (National Cancer Institute [NCI] Comorbidity Index ≥3, 36% vs 26%; p=0.004), and have poor performance status (PS) (55% vs 40%; p<0.001). These trends were most pronounced among patients discontinuing HMA therapy after only 1 cycle vs ≥4 cycles (mean age, 79.2 vs 77.3 years; single/separated/divorced/widowed, 39% vs 30%; NCI Comorbidity Index ≥3, 41% vs 26%; poor PS, 63% vs 40%; p<0.05 for all comparisons). In multivariable analysis, age 71-75 vs ≥80 years (odds ratio [OR] 0.556, p=0.017) and poor PS (OR 1.585, p=0.019) remained significant predictors of HMA discontinuation. Among treatment-related factors, the most statistically significant association with HMA discontinuation was observed for granulocyte colony-stimulating factor (GCSF) use (OR 0.453, p<0.001). Number of pills/day in the 90 days before HMA initiation was not a predictor of HMA discontinuation (OR 1.009, p=0.656) (Figure).

Figure: Multivariable logistic regression analysis of predictors of early HMA discontinuation

In addition to the variables shown, the model controlled for gender, race/ethnicity, census location, and urban location. CI, confidence interval; ESA, erythropoiesis-stimulating agent; GCSF, granulocyte colony stimulating factor; HMA, hypomethylating agent; NCI, National Cancer Institute; OOP, out-of-pocket; PS, performance status; RBC, red blood cell; USD, US dollars.

Summary/Conclusion: In this real-world study, almost one-third of RAEB patients treated with IV/SC HMAs discontinued before 4 cycles, with almost half of these patients discontinuing after only 1 cycle. Predictors of HMA discontinuation included older age and poor PS. Novel therapeutic approaches and interventions are needed to improve persistence with HMA therapy, particularly among these higher-risk groups. Further research is also warranted to fully elucidate the reasons for early discontinuation in this population.

EP917 UPDATED SAFETY AND EFFICACY OF VENETOCLAX IN COMBINATION WITH AZACITIDINE FOR THE TREATMENT OF PATIENTS WITH TREATMENT-NAÏVE HIGHER-RISK MYELODYSPLASTIC SYNDROMES: PHASE 1B RESULTS

A. Wei [1,*], J. Garcia [2], U. Borate [3], C. Y. Fong [4], M. Baer [5], D. Nowak [6], P. Peterlin [7], J. Jurcic [8], M. Jacoby [9], U. Platzbecker [10], O. Odenike [11], I. Cunningham [12], Y. Zhou [13], D. Hoffman [13], L. Hogdal [13], K. Naqvi [14], S. Kye [13], G. Garcia-Manero [15]

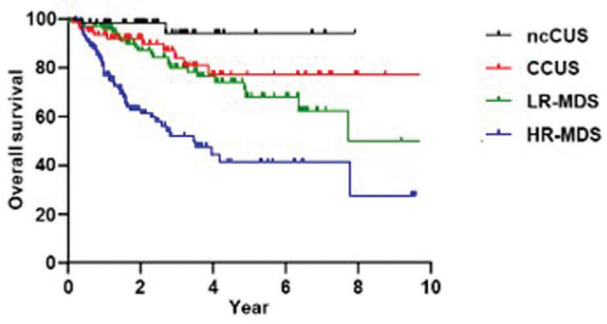
Background: Hypomethylating agents (HMA) are the current standard of care for patients (pts) with higher-risk myelodysplastic syndromes (HR-MDS) who are ineligible for allogeneic hematopoietic stem cell transplantation (HSCT). However, overall response rates (ORRs) remain suboptimal in pts receiving azacitidine (Aza), and their expected median overall survival (OS) is less than 2 years. Venetoclax (Ven) is a selective, potent, oral BCL-2 inhibitor, which has demonstrated synergy with HMAs in preclinical and clinical studies of myeloid malignancies.
Aims: We report updated safety and efficacy in pts treated in an ongoing phase 1b study (NCT02942290) evaluating Ven+Aza for treatment-naïve HR-MDS.
Methods: Pts (≥18 years) with International Prognostic Scoring System (IPSS) intermediate-2 or high-risk MDS, bone marrow (BM) blasts <20% at baseline and ECOG ≤2 performance status were enrolled. Aza 75 mg/m^2 was administered on Days (d) 1–7 of each 28-d cycle. Ven was initially given at a dose of 400 mg or 800 mg daily in 28-d cycles. Due to poor tolerance among pts with MDS, the study was amended to examine feasibility of several dose cohorts (100, 200 and 400 mg x 14 d each 28d cycle). Primary objectives were to assess the Ven+Aza safety profile and to establish the RP2D. Key secondary objectives included assessment of ORR and OS. Safety and efficacy analyses were carried out on all pts who received ≥1 dose of study drug and efficacy endpoints evaluated per IWG 2006 response criteria. Neutropenia included neutropenia, febrile neutropenia, neutrophil count decreased, neutropenic sepsis/infection, agranulocytosis. Thrombocytopenia included thrombocytopenia and platelet count decreased. Baseline mutational status was evaluated on BM aspirate samples using the Archer VariantPlex Myeloid panel.
Results: At data cutoff Dec 15, 2020, 78 pts had received Ven+Aza (51 pts received Ven at the RP2D of 400 mg x 14 d), with a median follow-up time of 23 mos (range 0.1–44.2). Median age was 70 years (range 26–87); 72% male; and 90% had excess BM blasts (>5 to ≤10%, n=21; >10 to ≤20%, n=49). Grade 3/4 neutropenia (59%) or thrombocytopenia (33%) were present at baseline. All pts experienced ≥1 treatment-emergent adverse event (TEAE), the most common being neutropenia (83%), nausea (55%), and constipation (54%). Grade 3/4 TEAEs were experienced by 96% of pts, with neutropenia (82%), febrile neutropenia (49%), and thrombocytopenia (42%) being the most common. Neutropenia (49%), including febrile neutropenia (45%), was the most common serious TEAE. The 30-day mortality rate after first dose was 1%. The intention-to-treat ORR was 80%, including complete remission (CR) in 40% and marrow CR (mCR) in 40% (42% of pts with mCR also had hematologic improvement; no partial remissions were recorded. For 31 pts with CR, median time to CR was 2.6 mos (range 1.2–19.6) and median duration of response was 13.8 mos (95% CI 8.9,–). Post-baseline transfusion independence rate (defined as no transfusion ≥8 weeks), for pts who were transfusion-dependent for RBC and/or platelets at baseline, was 46.5%. Median OS of the study population was 28.2 mos (95% CI 17.7, –). Median OS for 31 pts achieving CR was 28.6 mos (95% CI 27.5, –). 23% of the study population moved on to post-study allogeneic HSCT (incl. BM and peripheral blood stem cell).

Summary of efficacy	**n (% of N=78)**
Overall Response Rate (CR + mCR + PR)	62 (80)
CR	31 (40)
mCR	31 (40)
mCR + hematologic improvement[a] n/N (%)	13/31 (42)
Transfusion Independence Rate[b] n/N (%) [95% confidence interval]	20/43 (46.5) [31.2, 62.3]
	Months [95% confidence interval]
Median Overall Survival	28.2 [17.7, not estimable]
Median Overall Survival for CR	28.6 [27.5, not estimable]
Median Duration of Response for CR	13.8 [8.9, not estimable]

[a]Hematologic improvement (HI) includes pts who are eligible for HI evaluations and achieved neutrophil, erythroid, or platelet responses.
[b]For patients who were transfusion-dependent on RBC or platelet at baseline.
CR, complete remission; mCR, marrow complete remission; PR, partial remission



Summary/Conclusion: The combination of Ven+Aza was associated with a rapid and durable response, promising efficacy including remission rates and OS, and an acceptable safety profile for pts with HR-MDS. Additional correlation with disease risk features, including TP53 mutations, will be presented.

EP918 SIMILAR SURVIVAL AND GENETIC FEATURES BETWEEN CLONAL CYTOPENIA OF UNDETERMINED SIGNIFICANCE AND LOWER-RISK MYELODYSPLASTIC SYNDROME

E.-J. Choi [1,*], Y.-U. Cho [2], J.-H. Park [1], H.-S. Park [1], J.-H. Lee [1], K.-H. Lee [1], S.-H. Hwang [2], S. Jang [2], C.-J. Park [2], J.-H. Lee [1]

[1]Department of Hematology, [2]Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: Idiopathic cytopenia of undetermined significance (ICUS) is characterized by a persistent and clinically significant cytopenias which does not meet the diagnostic criteria for myelodysplastic syndrome (MDS). In some patients with ICUS, disease evolution to MDS or acute myeloid leukemia after variable periods of time was observed in several studies. However, the incidence and predictive factors of progression as well as management guidelines for ICUS patients are not well established.
Aims: We aimed to identify the clinical and genetic characteristics of ICUS in comparison with lower-risk MDS for understanding the pathophysiologic features and providing guidance for treating physicians.
Methods: We performed targeted deep sequencing including 61 myeloid neoplasm-related genes with a MiSeqDx sequencer (Illumina) using bone marrow (BM) samples obtained from the patients with ICUS (n=139) and MDS (n=226) between May 2009 and December 2019. The cut-off level of variant allele frequency (VAF) was set to 2.0% of mutant allele reads. Cloncal cytopenia of undetermined significance (CCUS) was defined as ICUS with ≥ 2% VAF of mutations and lower-risk MDS was defined as MDS with revised international prognostic scoring system ≤3.5.
Results: When we compared the overall survival (OS) of the patients according to the disease subtypes, OS of CCUS (77.0% at 5-year) was significantly better than that of higher-risk MDS (41.0%, *P*<.001) and worse than non-clonal ICUS (94.1%, *P*=.050), but it was similar to the OS of lower-risk MDS (67.9%, *P*=.363). Next, we compared the clinical and mutational features between CCUS (n=78) and lower-risk MDS (n=99). As shown in Table, there was no significant difference of patient characteristics between two groups except for higher hemoglobin level (10.5 vs. 9.0 g/dL, *P*=.008) in CCUS than lower-risk MDS, and the rate of red blood cell transfusion dependency was not different (*P*=.738). The median number of mutated genes of CCUS and lower-risk MDS were 1 (range, 0-4) and 1 (range, 0-6) (*P*=.651), and the median mutation numbers were 1 (range, 0-5) in CCUS and 2 (range, 0-7) in lower-risk MDS, respectively (*P*=.711). The mutational profiles of 61 genes were also similar between CCUS and lower-risk MDS except for *SF3B1* (2.6% in CCUS and 18.2% in lower-risk MDS; *P*=.001) and *STAT3* (5.1% in CCUS and 0% in lower-risk MDS; *P*=.023). Overall, 11 of 78 CCUS and 24 of 99 MDS died, and the causes of death were not different between two groups (*P*=.861).

Summary/Conclusion: In our study, CCUS and lower-risk MDS showed similar OS which was significantly better than higher-risk MDS and worse than non-clonal ICUS. The clinical and mutational characteristics were also similar except for the degree of anemia and the *SF3B1* and *STAT3* mutation. Our findings suggest that the patients with CCUS may be regarded and treated as the lower-risk MDS despite a lack of significant dysplasia or MDS-associated definitive chromosomal abnormality.

EP919 CHARACTERISTICS AND OUTCOMES OF MYELODYSPLASTIC SYNDROMES (MDS) WITH ISOLATED THROMBOCYTOPENIA: A RETROSPECTIVE, NATIONAL, COHORT STUDY

Background: Ordinarily, patients with MDS present with anemia and other cytopenias. Rarely, MDS may present with thrombocytopenia as an isolated abnormality (MDS-IT). There have been few systematic studies on MDS-IT and data regarding its prognosis are conflicting. Previous studies have defined MDS-IT based on the IPSS i.e. hemoglobin ≥10 g/dL, neutrophil count (ANC) ≥1.8×10⁹/L, and platelet count (PLT) <100×10⁹/L. However, these thresholds were developed for prognostic—not diagnostic—purposes which means that mild anemia and/or neutropenia might be present concomitantly with "isolated" thrombocytopenia.
Aims: We investigated the characteristics, overall survival (OS), and leukemia-free survival (LFS) of patients with MDS-IT. In this study, thrombocytopenia was defined as PLT<150×10⁹/L.
Methods: We identified patients who had PLT<150×10⁹/L, Hb>13 g/dL (men) or >12 g/dL (women), ANC≥1.8×10⁹/L, and monocytes <1.0×10⁹/L, registered in the Hellenic National Registry of Myelodysplastic and Hypoplastic Syndromes which includes 2792 patients diagnosed with MDS (analysis cut-off date; July 7, 2016). Patients were stratified into 4 subgroups: subgroup 1 had PLT 149-100×10⁹/L; subgroup 2, 99-50×10⁹/L; subgroup 3, <50×10⁹/L; and subgroup 4, <25×10⁹/L.
Results: A total of 77 patients (45 men; 32 women) with MDS-IT were identified (2.9% of total MDS cohort). Median PLT was 87×10⁹/L (range, 12-145×10⁹/L). Twenty-two patients (28.6%) were classified in subgroup 1; 38 (49.4%) in subgroup 2; 11 (14.3%) in subgroup 3; and 6 (7.8%) in subgroup 4. Median hemoglobin was 13.6 g/dL, and white-cell count 4.6×10⁹/L. The proportion of bone-marrow blasts ranged from 0-9% (median, 2%). Median follow-up was 51.0 months (range, 41.6-60.4), during which 15 (19.5%) patients died. AML developed in 9 patients with MDS-IT (11.7%). IPSS-R score was ≤3.5 in 73.5% and 83.1% had favorable cytogenetics. Morphological classification was consistent with refractory cytopenia with multilineage dysplasia in 70.7%. Unilineage dysplasia was seen in only 10.7%. On subgroup comparisons, we noted no significant differences in age, sex, IPSS-R,

blast percentage, cytogenetic pattern, and histological features (WHO type; cellularity; myelofibrosis). Median OS was 109 months (95% CI 103-115) and LFS 108 months (101-115). On subgroup comparisons, we noted no significant between-group difference in OS (P=0.891) and LFS (P=0.871). As compared with the total MDS cohort, patients with MDS-IT presented at younger age (64.7 vs. 72.4 years, P<0.001). Importantly, MDS-IT was characterized by superior survival rates as compared with the total MDS cohort, even after adjusting for age, cytogenetics, IPSS-R, and platelets (P=0.013 for OS and P=0.017 for LFS). There were, however, no differences in the top causes of death: infection was the commonest cause followed by disease progression and cardiovascular disease. Major bleeding comprised 10.3% of deaths in MDS-IT vs. 12.7% in total MDS registry (P=0.217).

Summary/Conclusion: In this large cohort study, one of the world's largest cohorts of MDS-IT, we show that MDS-IT is associated with multilineage dysplasia and lower-risk IPSS-R score. Interestingly, the degree of thrombocytopenia did not seem to correlate with mortality in MDS-IT. The finding that MDS-IT is associated with better survival outcomes as compared with other MDS is important and has major implications for the management of this disorder.

EP920 LUSPATERCEPT REDUCES RED BLOOD CELL TRANSFUSIONS IN PATIENTS WITH LOWER-RISK MYELODYSPLASTIC SYNDROMES REGARDLESS OF BASELINE TRANSFUSION BURDEN IN THE MEDALIST STUDY

G. Garcia-Manero [1,*], P. Fenaux [2], U. Platzbecker [3], R. Buckstein [4], V. Santini [5], M. Díez-Campelo [6], D. Tang [7], R. Ito [7], S. Fabre [7], E. Mantovani [7], R. Zoffoli [8], D. Miteva [7], C. Hughes [7], W. Khan [7], R. S. Komrokji [9], U. Germing [10]

[1]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX, United States, [2]Service d'Hématologie Séniors, Hôpital Saint-Louis, Université Paris 7, Paris, France, [3]Medical Clinic and Policlinic 1, Hematology and Cellular Therapy, University Hospital Leipzig, Leipzig, Germany, [4]Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada, [5]MDS Unit, Azienda Ospedaliero Universitaria Careggi, University of Florence, Florence, Italy, [6]Hematology Department, Institute of Biomedical Research of Salamanca, University Hospital of Salamanca, Salamanca, Spain, [7]Bristol Myers Squibb, Princeton, NJ, United States, [8]Bristol Myers Squibb, Braine-l'Alleud, Belgium, [9]Moffitt Cancer Center, Tampa, FL, United States, [10]University Hospital of Düsseldorf, Düsseldorf, Germany

Background: MEDALIST (NCT02631070) is an ongoing, randomized, phase 3 trial evaluating the efficacy and safety of luspatercept, the first and only erythroid maturation agent, which reduced red blood cell (RBC) transfusion burden (TB) and led to significant rates of transfusion independence (TI) in patients (pts) with anemia due to lower-risk myelodysplastic syndromes (LR-MDS) with ring sideroblasts (Fenaux P, et al. *N Engl J Med* 2020;382:140–151). TI is associated with improved prognosis in pts with MDS. The effect of luspatercept treatment on red blood cell transfusion (RBCT) units and visits in pts with different baseline TB warrants further investigation.

Aims: To evaluate the effect of luspatercept on the cumulative number of RBCT units and visits in pts with LR-MDS according to their baseline TB levels in the MEDALIST study.

Methods: Eligible pts were ≥18 years old; were refractory, intolerant, or unlikely to respond to erythropoiesis-stimulating agents; and required regular RBC transfusions (≥2 units/8 weeks [wks]) in the 16 wks prior to randomization. Overall, 229 pts were randomized 2:1 to receive either luspatercept (n=153) or placebo (n=76) every 3 wks through the clinical assessment visit at Wk 25, defined as 24 calendar wks after the first dose, regardless of dose delays. Pts experiencing clinical benefit continued treatment beyond 24 wks. The data cutoff for this analysis was July 1, 2019. Cumulative mean number of RBCT units and visits were estimated using the Nelson-Aalen nonparametric estimator with robust variance estimate for each treatment group. Luspatercept responders were defined as pts achieving RBC-TI for ≥8 wks during wks 1–24. At baseline, pts with <6 RBCT units/8 wks were defined as low TB (LTB) and pts with ≥6 RBCT units/8 wks were defined as high TB (HTB).

Results: Similar proportions of pts in the luspatercept and placebo groups were LTB and HTB at baseline; 56.9% (n=87/153) in luspatercept vs 56.6% (n=43/76) in placebo were LTB, whereas 43.1% (n=66/153) vs 43.4% (n=33/76) were HTB, respectively. Regardless of baseline TB, pts receiving luspatercept had lower mean cumulative RBCT units and visits at 24 wks relative to placebo. Mean cumulative RBCT units (95% confidence interval [CI]) in LTB pts was 6.8 (5.6–8.4) in the luspatercept group (n=81/87) vs 13.2 (11.5–15.2) in the placebo group (n=38/43); and for HTB pts, was 17.2 (15.1–19.6) in the luspatercept group (n=47/66) vs 24.2 (21.3–27.4) in the placebo group (n=30/33). Mean cumulative RBCT visits (95% CI) in LTB pts was 4.0 (3.3–4.8) in the luspatercept group (n=81/87) vs 7.2 (6.3–8.3) in the placebo group (n=38/43); and for HTB pts, was 9.4 (8.3–10.7) in the luspatercept group (n=47/66) vs 12.5 (11.0–14.2) in the placebo group (n=30/33). Luspatercept responders continued to show additional reductions in RBCT units and visits beyond 24 wks through 144 wks, relative to non-responders in both LTB and HTB groups (Table).

Table. Mean cumulative RBCT units and visits in luspatercept responders and non-responders

	RBCT units (95% CI)		RBCT visits (95% CI)	
Patients with LTB	Responders[a] (N=52)	Non-responders (N=35)	Responders[a] (N=52)	Non-responders (N=35)
At 24 wks	2.7 (2.0–3.7) n=49	13.0 (11.4–14.9) n=32	1.7 (1.2–2.2) n=49	7.5 (6.5–8.6) n=32
At 48 wks	4.7 (3.5–6.3) n=43	22.8 (20.1–25.8) n=15	2.8 (2.1–3.7) n=43	13.1 (11.8–14.6) n=15
At 144 wks	15.2 (11.5–20.0) n=5	57.1 (50.5–64.6) n=1	9.3 (7.2–12.2) n=5	33.4 (28.8–38.9) n=1
	RBCT units (95% CI)		RBCT visits (95% CI)	
Patients with HTB	Responders[a] (N=6)	Non-responders (N=60)	Responders[a] (N=6)	Non-responders (N=60)
At 24 wks	3.7 (1.8–7.4) n=6	18.9 (16.9–21.1) n=41	2.0 (1.0–4.0) n=6	10.3 (9.2–11.5) n=41
At 48 wks	9.3 (3.5–25.0) n=6	34.7 (29.6–40.7) n=21	5.0 (1.8–13.5) n=6	18.5 (16.1–21.2) n=21
At 144 wks	26.1 (8.3–81.9) n=1	85.6 (70.1–104.5) n=1	15.5 (5.2–46.3) n=1	47.0 (39.1–56.5) n=1

[a]Luspatercept responders were defined as patients achieving RBC-TI for ≥8 wks during wks 1–24.
CI, confidence interval; HTB, high transfusion burden; LTB, low transfusion burden; RBCT, red blood cell transfusion; RBC-TI, RBC transfusion independence; wks, weeks.

Summary/Conclusion: In the MEDALIST trial, luspatercept reduced cumulative RBCT units and visits relative to placebo over the first 24-wk period in pts with LR-MDS regardless of their baseline TB level. Luspatercept responders showed additional benefits in RBCT unit and visit reduction relative to non-responders beyond 24 wks.

EP921 FLOW-CYTOMETRIC ASSESSMENT OF BONE MARROW MICROENVIRONMENT IN LOW-RISK MYELODYSPLASTIC SYNDROMES

J. A. Giannotta [1,*], B. Fattizzo [2], L. Cro [3], M. Barbieri [3], G. V. Levati [2], E. Trombetta [3], W. Barcellini [1]

[1]Hematology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, [2]Oncohematology, University of Study, [3]Flow Cytometry Service, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Low-risk myelodysplastic syndromes (LR-MDS) are a very heterogeneous group of diseases, ranging from mild forms, deserving follow-up only, to life-threatening cytopenias with frequent complications. There is growing interest on the immunologic proinflammatory bone marrow (BM) microenvironment of LR-MDS that may be of pathogenic but even of therapeutic relevance, since novel drugs targeting several cytokine patterns are under study.

Aims: To evaluate BM microenvironment of LR-MDS and its relationship with disease features, somatic mutations, and response to recombinant EPO (rEPO).

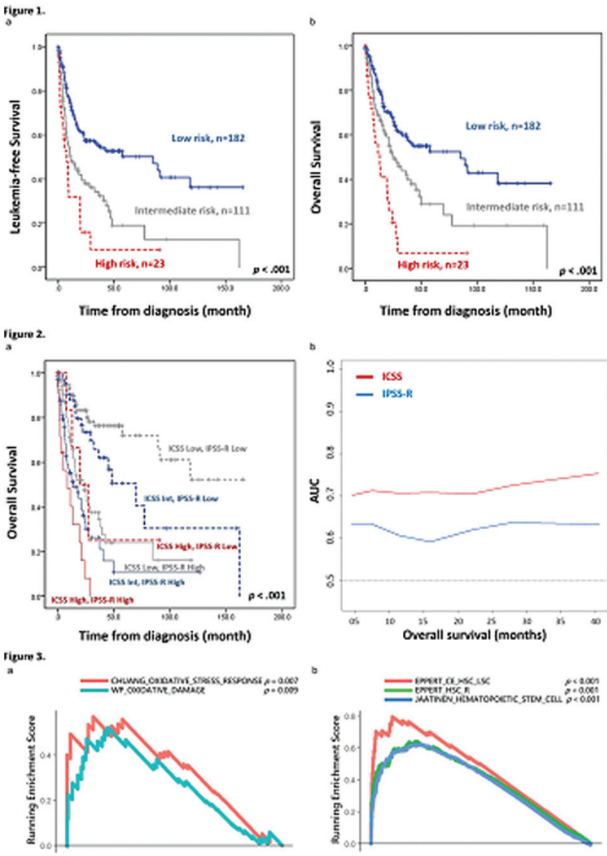
Methods: BM multiparameter flow cytometry (MFC) of patients with LR-MDS according to the revised international prognostic scoring system (IPSS-R) followed at a tertiary hematologic center have been retrospectively evaluated by 2 MFC experts. The proportions of the various lymphocyte populations (T, B, and NK cells), monocytes, and mastocytes have been evaluated using monoclonal antibodies directed against CD3, CD10, CD14, CD16, CD19, CD34, CD45, CD56, CD117, and HLA-DR.

Results: 136 LR-MDS patients (48 multiple- and 38 single lineage dysplasia M-/SLD, 37 ring sideroblasts RS, 5 with 5q deletion, 5 MDS/myeloproliferative neoplasm overlap, and 2 excess of blasts type 1), 60% males and with a median age of 73.6 years (36-90.6), have been studied. Table 1 shows mean percentages of total lymphocytes, T-, B-, and NK-cells divided according to WHO type: MDS-RS showed significantly lower

B cells and monocytes compared to patients with MDS-SLD (p=0.008 and p=0.03, respectively) and MDS-MLD (p=0.01 for B-cells). Elderly patients showed higher mastocyte levels (1.88±1.3% in >65 years vs 1.2±0.7% in younger patients, p=0.05). Concerning cytopenias, patients with Hb<10g/dL showed lower monocytes (3.4±2.2 vs 4.45±3%, p=0.02) compared to not anemic patients; those with PLT<100x10^9/L showed lower T-cells (67.2±15.4 vs 72.4±10.3%, p=0.02) and higher B-cells (14.2±11.5 vs 10.5±6.5%, p=0.02) compared to those with higher PLT; and subjects with neutrophils <1x10^9/L displayed higher mastocytes (2.5±2 vs 1.6±1%, p=0.004) and monocytes (5.5±4.08 vs 3.7±2.3%, p=0.004), as compared to those with higher values. Hypocellular patients showed increased total lymphocytes (20±9.3 vs 13±7.5%, p<0.0001) and NK-cells (21±17 vs 16.6±8%), and decreased mastocytes (1.2±1 vs 1.8±1.2%, p=0.03) compared to normo/hypercellular cases. Concerning somatic mutations, present in 27 out of 35 patients tested, the presence of ≥3 mutations was associated with increased total lymphocytes (22.4±14 vs 10.8±3.7%, p<0.001). Mutations of DNA methylation genes were related to lower T cells (69±11 vs 76±9%, p=0.04) and higher NK (18±8 vs 14±7%); mutated chromatin and transcription factor genes were associated with higher total lymphocytes (25±14 vs 11±6%, p=0.001 and 22.5±16.5 vs 12.3±6.8%, p=0.02, respectively). Mutations in *TP53* or *PHF6* were associated with increased T cells (83±0.7 vs 73±10%, p<0.001), mastocytes (2.4±1.4 vs 1.7±0.7, p<0.01), and monocytes (7.5±5 vs 3.8±2.3%, p=0.05), and decreased NK (7±1.4 vs 16±8, p<0.001). Regarding therapy, patients responding to rEPO showed reduced T cells (69±14 vs 76±10, p=0.05) and increased B cells (13±11 vs 7.5±5%, p=0.01).

Table 1: bone marrow microenvironment cells in low risk myelodysplastic syndromes (LR-MDS) according to WHO classification.
Values are given as mean ± standard deviation.

WHO category	Lymphocytes	T-cells	B-cells	NK-cells	Mastocytes	Monocytes
All patients	14.7±8	71±12	11.5±8	17.2±10	1.8±1.3	4±2.7
MDS-SLD	13.9±6	69.9±10	12.8±6	16.9±10	1.7±1	4.4±2.5
MDS-MLD	15.3±9	70.4±13	12.7±8	16.7±9	1.8±1.4	3.8±3
MDS-RS	12.4±8	71.9±13	8.8±7	19.1±13	1.7±1.7	3.7±7
5q-	17±6	78.6±5	7.7±2	13.8±7	1.5±1	3.8±1.4
MDS/MPN	14.3±12	78.2±6	6.2±2	15.6±6	2.3±0.7	9.5±6
MDS-EB1	21±14	52±28	34.5±30	13.5±11	4.2±5	2.4±1.3



Summary/Conclusion: Different types of LR-MDS show variable levels of BM lymphocyte, mastocyte and monocyte percentages. BM microenvironment characteristics correlate with cellularity and peculiar molecular alterations. Patients with greater T-cell infiltrate display higher frequency of disrupting mutations (i.e. *TP53*) and lower response to rEPO.

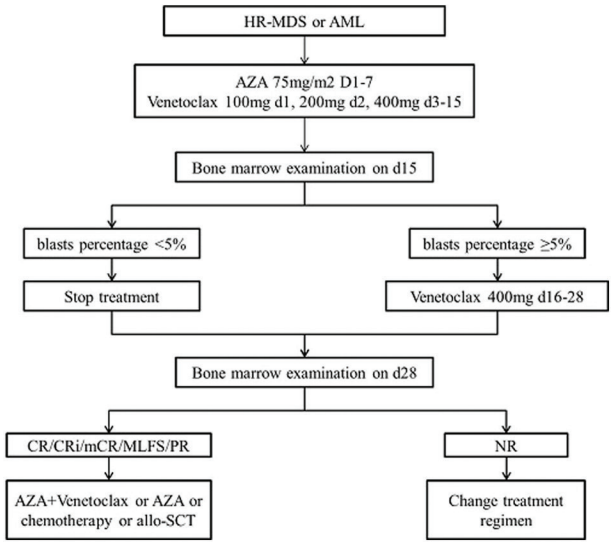
EP922 A CIBERSORTX-BASED IMMUNE-CELL SCORING SYSTEM COULD INDEPENDENTLY PREDICT PROGNOSIS OF MYELODYSPLASTIC SYNDROME PATIENTS

Y.-H. Wang [1,*], H.-A. Hou [1], C.-C. Lin [2], Y.-Y. Kuo [3], C.-Y. Yao [2], C.-L. Hsu [4], M.-H. Tseng [1], C.-H. Tsai [1], Y.-L. Peng [1], C.-J. Kao [1], W.-C. Chou [2], H.-F. Tien [1]

[1]Internal Medicine, [2]Laboratory, National Taiwan University Hospital, [3]Tai-Cheng Stem Cell Therapy Center, National Taiwan University, [4]Medical Research, National Taiwan University Hospital, Taipei, Taiwan, Republic of China

Background: Myelodysplastic syndromes (MDSs) are hematopoietic stem cell disorders with features of dysplasia in hematopoietic cells, ineffective hematopoiesis, and an increased risk of leukemia transformation. The revised international prognostic scoring system (IPSS-R) has been widely used to risk-stratify MDS patients and guide treatment strategies. Nevertheless, the prognosis of patients may vary greatly, even in the same risk group. Recent evidences dictate the central role of the bone marrow (BM) microenvironment, infiltrating immune cells, and relevant inflammatory pathways in the pathogenesis of MDS. However, the prognostic significance of immune cells in the BM of MDS patients remains unclear.
Aims: This study was aimed to investigate the clinical significance of BM-infiltrating immune cells in MDS patients and to construct an immune cell scoring system for better risk-stratification of these patients.
Methods: We recruited 316 primary MDS patients diagnosed at the National Taiwan University Hospital (1997-2019) who had adequate cryopreserved BM samples for RNA sequencing. We adopted TruSight myeloid sequencing panel and HiSeq platform to analyze the gene alterations of 54 myeloid-neoplasm relevant genes. The purified RNA was used to construct gene expression libraries with the Illumina Stranded mRNA Library Prep Kit and then sequenced on the Illumina NextSeq 500 platform. CIBERSORTx, a Next-generation of CIBERSORT (*C*ell type *I*dentification *B*y Estimating *R*elative *S*ubsets *O*f known *R*NA *T*ranscripts), which can quantify the relative expression of cell type-specific signatures in bulk tumors without doing cell sorting, was employed to estimate the relative cell fractions of 22 subtypes of immune cells that are intensely involved in innate and adaptive immunity.
Results: We applied univariate Cox regression analysis to examine the prognostic impact of 22 immune cell subtypes on the overall survival (OS) of MDS patients. A higher percentage of macrophages M0 was significantly correlated with better survival, whereas higher fractions of macrophages M2 and eosinophils, two cell types whose infiltration in tumors were correlated with prognosis, were associated with inferior survival. An immune-cell scoring system (ICSS) was constructed based on the fractions of M0, M2, and eosinophils, which could well divide MDS patients into three risk groups with distinct clinical outcomes. ICSS high-risk group, defined as having lower M0, higher M2, and higher eosinophils, had the worst leukemia-free survival (LFS) and OS among the three risk groups in the total cohort as well as in subgroups of patients with higher- or lower-risk IPSS-R (Figure 1, 2a). The prognostic significance was then confirmed in an independent validation cohort. Furthermore, ICSS high-risk group more frequently harbored mutations in *NPM1*, *TP53*, and *WT1*, but less commonly, *SF3B1* mutation. Time-dependent ROC curves revealed that ICSS could be complementary to IPSS-R in prognostication (Figure 2b). More importantly, multivariable analysis proved that the immune-cell score was an independent predictor of clinical outcomes in MDS patients. Bioinformatic analysis revealed that high-risk ICSS was significantly correlated with the oxidative stress and leukemic stem cell signatures (Figure 3).

Summary/Conclusion: In conclusion, we show that besides clinical features and genetic alterations, immune cells in the BM microenvironment also significantly impact LFS and OS in MDS patients. The ICSS is a



concise yet powerful risk-stratification system that can be incorporated into IPSS-R to refine the risk-stratification of MDS patients.

EP923 VENETOCLAX COMBINED WITH AZACITIDINE IN THE TREATMENT OF RELAPSED/REFRACTORY HIGH-RISK MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA: A RETROSPECTIVE SINGLE-CENTER STUDY

C. Mei [1], L. Ye [2], Y. Ren [2], X. Zhou [2], L. Ma [2], G. Xu [2], L. Wang [2], L. Jian [1], H. Tong [2,*]

[1]The first affiliated hospital Zhejiang university school of medicine, Hangzhou, China, [2]department of hematology, The first affiliated hospital Zhejiang university school of medicine, Hangzhou, China

Background: The treatment of patients with refractory and/or relapsed (R/R) high-risk myelodysplastic syndrome (HR-MDS) or acute myeloid leukemia (AML) remains a daunting clinical challenge. Venetoclax is a selective BCL-2 inhibitor, which combined with hypomethylating agents (HMA), has shown high response rates in unfit and previously untreated AML.
Aims: We performed a retrospective study of patients with R/R HR-MDS and AML receiving combination azacytidine (AZA) plus venetoclax (VEN) in order to determine their efficacy and toxicity in this context.
Methods: Venetoclax was recommended at a daily dose of 100 mg with a 3-day ramp to target dose of 400 mg for 28 days (VEN-28d) but was stopped on day 15 if bone marrow examination on day 15 showed residual blasts percentage was below 5% (VEN-15d). Azacitidine was administered 75 mg/m^2 subcutaneously daily on days 1 to 7 of each 28-day cycle. The treatment decision tree was depicted in Figure 1.
Results: We have included a total of 35 patients with R/R MDS, R/R AML, or denovo AML. Among them 17 patients were R/R MDS, 10 patients were R/R AML, and 8 patients were denovo AML. The overall response rate (ORR) and was 58.8 % in R/R MDS and 50% in R/R AML respectively, the complete remission (CR) rate was 29.4% in R/R MDS and 10% in R/R AML respectively. And the ORR was 71.4% in 14 R/R MDS and 10 R/R AML who stopped VEN on day 15, among them the CR rate was 35.7% in R/R MDS and 14.3% in R/R AML. The median OS was significantly different among the three groups (not reached in R/R MDS and denove AML vs. 5 months with 95% CI of 3.4-6.5 months in the R/R AML, p = 0.002). The most common treatment-emergent adverse events were peripheral blood cytopenias and infectious complications.

Summary/Conclusion: Our study showed that the real-world experience of treating patients with R/R MDS and AML with AZA plus VEN, which have high response rates but with a high frequency of myelosuppression. Of note, the dose reductions of venetoclax did not affect response and survival in our analysis. These data of combination AZA plus VEN in R/R AML and MDS warrant further prospective evaluation in clinical trials.

EP924 UPDATED OVERALL SURVIVAL OF ELTANEXOR FOR THE TREATMENT OF PATIENTS WITH HYPOMETHYLATING AGENT REFRACTORY MYELODYSPLASTIC SYNDROME

S. Lee [1,*], S. Mohan [2], J. Knupp [3], K. Chamoun [3], X. Bai [3], X. Ma [3], J. Shah [3], M. Kauffman [3], S. Shacham [3], B. Bhatnagar [4]

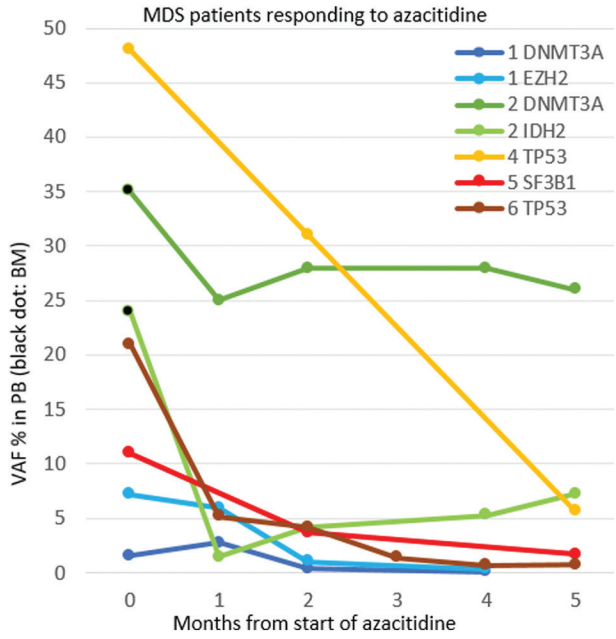
[1]Weill Cornell Medicine, New York, New York, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Karyopharm Therapeutics, Newton, MA, [4]The Ohio State University-James Cancer Hospital and Solove Research Institute, Columbus, OH, United States

Background: Patients (pts) with myelodysplastic syndrome (MDS) refractory to hypomethylating agents (HMAs) have limited therapeutic options and a dismal prognosis with a median overall survival (mOS) of 4-6 months. Eltanexor (ELTA) is a second-generation, oral, selective inhibitor of nuclear export (SINE) compound that showed anti-tumor activity and lower brain penetration compared to selinexor (SEL) in nonclinical models. It was hypothesized that ELTA could be dosed more frequently than SEL with a lower incidence of centrally mediated nausea. Early results from a phase 1/2 study of ELTA in pts with HMA refractory MDS demonstrated marrow complete responses (mCRs) and stable disease (SD); side effects were primarily low-grade, dose-dependent, and reversible (Lee ASH 2019).
Aims: In this abstract, we provide a subgroup analysis of and update on mOS in the efficacy evaluable population.
Methods: This phase 1/2 study (NCT02649790) evaluated single-agent oral ELTA in pts with higher-risk MDS, ie, high-risk or intermediate-2 MDS by International Prognostic Scoring System (IPSS) and 5%>19% myeloblasts. Of 20 pts enrolled, 15 pts were evaluable for efficacy and constitute the population studied in this analysis. Two doses of ELTA were evaluated: 10 mg (n=5) or 20 mg (n=15) every day for 5 days per week of a 28-day cycle.
Results: As of 1 Feb 2021, the 15 pts evaluable for efficacy (median age 76 years; range 62-89) had a median of 2 prior treatment regimens (range 1-4); 14 pts (93%) had higher-risk MDS including 9 pts (60%) high risk and 5 pts (33%) int-2. Similarly, using the global MD Anderson Cancer Center (MDACC) risk prognosis model (Kantarjian 2008), 14 pts (93%) had higher-risk MDS with 2 pts (13%) high risk and 12 pts (80%) int-2. Of the 20 enrolled patients, 7 (35%) had mCR and 5 (25%) had SD for a total disease control (mCR+SD) rate of 60%. Of the 15 pts evaluable for efficacy, 7 (47%) had mCR and 5 (33%) had SD. In the 10-mg cohort (n=5), all pts derived clinical benefit with 3 pts (60%) reaching mCR and 2 pts (40%) SD. In the 20-mg cohort (n=10), 4 pts (40%) had mCR and 3 (30%) had SD. Four pts had hematologic improvement (HI) and became transfusion independent for at least 8 weeks including 2 pts with tri-lineage HI. OS for pts who reached mCR (n=7) was significantly longer than for pts who did not reach mCR (n=8): median 11.86 vs 8.67 months (mo) (hazard ratio [HR]=0.27, p=0.05), and significantly longer than OS for pts with PD (n=3, mOS=3.15 mo, HR=0.23, p=0.04). Pts with disease control (n=12) had numerically longer mOS than pts with PD (9.86 vs 3.15 mo, HR=0.38, p=0.09). Pts with HI had a mOS of 10.58 months.
Summary/Conclusion: Single-agent oral ELTA was active in pts with high-risk, HMA-refractory MDS. Pts with mCR had significantly longer mOS than pts without mCR or with PD. Given the limited prognostic power of IPSS in HMA refractory pts, the MDACC model was also applied here for improved risk assessment. Further evaluation of ELTA in MDS as a single agent and in combination with other agents is ongoing.

EP925 EARLY DECREASE IN VARIANT ALLELE FREQUENCY IN PERIPHERAL BLOOD WITH DROPLET DIGITAL PCR IN MYELODYSPLASTIC SYNDROME (MDS) PATIENTS RESPONDING TO AZACITIDINE

J. Illman [1,*], S. Kytölä [2], M. Myllymäki [3], F. Ebeling [3]

[1]Department of internal medicine, Porvoo Hospital, Helsinki and Uusimaa Hospital District (HUS), Porvoo, [2]Laboratory of Genetics, HUS Diagnostic Center, Helsinki University Hospital and Helsinki University, [3]Department of Hematology, Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland



Background: Treatment response evaluation in MDS relies on serial assessment of peripheral blood (PB) counts, bone marrow (BM) morphology, and cytogenetics (IWG2006; Cheson et al, Blood 2006). BM

sampling is invasive, whereas biomarkers of response measured in PB could provide a less invasive alternative for monitoring treatment responses. Most MDS and CMML patients carry somatic driver mutations, that can be detected in PB. Consistent reductions in PB variant allele frequencies (VAFs) have been detected during decitabine therapy for MDS (Duncavage et al, Blood 2017), suggesting that detection of clonal dynamics in PB may be used as an early predictor of therapy response.

Aims: We evaluated whether changes in mutational load, using high sensitivity mutation-specific droplet digital PCR (ddPCR) of PB samples, could be used as an early sign of treatment response in MDS/CMML.

Methods: Patients were recruited between 1/2016-5/2018 at Helsinki University Hospital. All patients signed an informed consent. Serial PB samples were collected before treatment and during routine visits. Pre-treatment samples were analyzed with an in-house NGS myeloid panel of 45 genes. Mutation-specific ddPCR were designed, and on-treatment samples were analyzed with the QX200 Droplet Digital PCR system.

Results: The results of the first ten patients are reported here. Seven MDS patients were treated with azacitidine (AZA), one with lenalidomide (LEN), one CMML patient was treated with hydroxyurea (HU) and one with both HU and AZA. Median age at treatment initiation was 68 years (range 48-81). The median follow-up was 11 months (range 4-33). Altogether 17 myeloid driver mutations were found in the NGS and 15 of these (4 *SF3B1*, 2 *DNMT3A*, 2 *TP53*, 2 *IDH2*, 2 *EZH2*, 2 *NRAS, U2AF1*) were analyzed with ddPCR at 4-13 timepoints (median 7,5/patient). For one mutation in *SRFS2* there was not an available probe. For a mutation in *NF1* the analyses are pending. Using IWG2006 response criteria, seven patients responded to treatment (two CR, three mCR, two HI) and three patients had stable disease (SD). All responding (CR, mCR, HI) MDS-patients (n=6) had a decrease in VAF with a mean relative decrease of 71 % (range 20-94) from pretreatment to samples collected after the second AZA (n=5, figure) or LEN cycle (n=1). The decrease in VAF was detected 28-251 (median 43) days before the IWG2006-response was verified. Patient 2 in the figure had a *DNMT3A*-mutation that decreased only slightly (35% (BM) to 25 %), whilst the *IDH2* seemed to decrease rapidly after the first AZA-cycle, from 24% (BM) to 1,5 %, suggesting that the *DNMT3A*-mutation may reflect a pre-malignant clone. Two MDS cases with SD had mutations in *SF3B1*, one with stable VAF and the other with VAF-decrease (24 % to 11 %). One CMML-patient had a mCR-response at 10 months after HU and AZA; *NRAS* VAF decreased only from 46 % to 35 % and *IDH2* from 46 % to 36 %. The second CMML case had SD and reduction in *NRAS* from 45 % to 33% and *U2AF1* from 46 % to 32 %. Five patients lost their response during treatment. One patient in HI, had an increase from 5,7% to 20 % in *TP53* 55 days before progression. One patient in CR had an increase from 0,12 % to 25 % in *SF3B1* 49 days before progression. Another CR patient had an increase in *TP53* from 1,4 % to 4,9 % at progression. Two SD patients had moderate VAF-increases at progression; one in *SF3B1* from 18 % to 34 %, another in *NRAS* from 33 % to 43 % and *U2AF1* from 32 % to 42 %.

Summary/Conclusion: Detection of peripheral blood clonal dynamics using ddPCR may serve as a non-invasive tool for early response evaluation during azacitidine treatment in MDS.

EP926 COMPARISON OF DOSE MODIFICATION STRATEGIES TO ADDRESS EXPECTED HEMATOLOGIC TOXICITIES IN TREATMENT-NAÏVE HIGHER-RISK (HR) MDS PATIENTS TREATED WITH VENETOCLAX + AZACITIDINE

U. Platzbecker [1,*], J. S. Garcia [2], A. H. Wei [3], U. Borate [4], C. Y. Fong [5], M. R. Baer [6], D. Nowak [7], P. Peterlin [8], J. Jurcic [9], M. A. Jacoby [10], O. Odenike [11], I. Cunningham [12], Y. Zhou [13], D. Hoffman [13], K. Naqvi [14], S. Kye [13], G. Garcia-Manero [15]

[1]Medical Clinic and Policlinic 1, Hematology and Cellular therapy, University Hospital, Leipzig, Germany, [2]Dana-Farber Cancer Institute, Boston, United States, [3]Alfred Hospital and Monash University, Melbourne, Australia, [4]Knight Cancer Institute, Oregon Health and Science University, Portland, United States, [5]Olivia Newton John Cancer Research Institute, Austin Health, Melbourne, Australia, [6]Greenebaum Comprehensive Cancer Center, University of Maryland School of Medicine, Baltimore, United States, [7]Medical Faculty Mannheim of the Heidelberg University, Mannheim, Germany, [8]Nantes University Hospital, Nantes, France, [9]Myelodysplastic Syndromes Center, Columbia University Medical Center, Columbia University, New York, [10]Siteman Cancer Center at Barnes-Jewish Hospital and Washington University School of Medicine, St Louis, [11]University of Chicago Medicine and Comprehensive Cancer Center, Chicago, United States, [12]Concord Repatriation General Hospital, University of Sydney, Sydney, Australia, [13]AbbVie Inc., North Chicago, [14]Genentech Inc., South San Francisco, [15]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Venetoclax (Ven) is a selective, potent BCL-2 inhibitor. Ven + azacitidine (Aza) were associated with a combined complete remission (CR)/marrow CR (mCR) rate of 79% in a phase 1b study of patients (pts) with HR-MDS (NCT02942290).

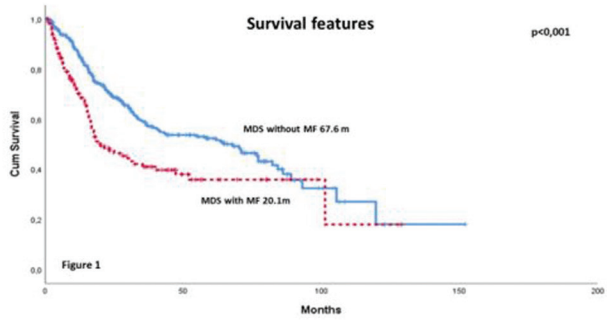
Aims: We compared two different dose modification strategies to manage expected hematologic toxicities in two safety expansion cohorts with similar follow-up periods.

Methods: Pts (≥18 yrs) diagnosed with treatment-naïve IPSS intermediate-2 or high-risk MDS with ECOG ≤2 were enrolled. Aza 75 mg/m^2 (i.v. or sub-Q, daily) was administered for 7 days (d) and Ven was administered at 400 mg for 14d in each 28d cycle. In both cohorts, dose modification during Cycle 1 was not recommended; dose modifications in subsequent cycles were prescribed for adverse events. In Safety Expansion Cohort 1 (SE1), either Aza or Ven were initially reduced according to investigator's choice for significant neutrophil or platelet toxicity. Dose reductions per protocol were 33% for Aza and 50% for Ven (for 14d each cycle). In subsequent cycles, Ven duration could be shortened to 9d of each cycle. In Safety Expansion Cohort 2 (SE2), dose modification guidelines recommended stepwise reductions, first in Aza dose (first to 50 mg/m^2, then 36 mg/m^2) and subsequently in Ven duration to 7d of each cycle (Ven 400 mg). The impact of each dose modification strategy on safety and efficacy in SE1 *vs* SE2 was compared. Worsening of treatment-emergent adverse events (TEAE) grades from baseline (BL) was analyzed by cycle. Responses were evaluated using IWG 2006 criteria. Analyses included all pts who received ≥1 dose of study drug.

Results: We compared 22 pts in SE1 and 21 pts in SE2 with median (range) follow-up of 7.5 (1.0–8.9) and 7.9 (1.8–10.1) mos, respectively. A similar frequency of ≥G3 hematologic TEAEs (approximate %) were reported in SE1 and SE2, respectively, including anemia (14% and 33%), febrile neutropenia (46% and 48%), leukopenia (36% and 19%), neutropenia (55% and 48%) and thrombocytopenia (32% and 38%). Infections (59% and 38%) were more frequent in SE1 than SE2. In a longitudinal analysis, there were more TEAE grade increases from BL to Cycle 1 in SE2 vs SE1. This could be as accounted by pts in SE1 and SE2 having unbalanced susceptibility to AEs at BL, as SE1 and SE2 pts received identical Aza + Ven doses in Cycle 1. Response rates were identical: 86% of pts in both SE1 and SE2 had CR or mCR. For pts with mCR, hematologic improvement occurred in 50% of SE1 and 46% of SE2 pts.

Table. Any Grade Hematologic TEAEs and Infections (>20%)

%	SE1 n=22	SE2 n=21
Infections	59	38
Neutropenia	55	48
Febrile neutropenia	46	48
Thrombocytopenia	36	48
Leukopenia	36	19
Anemia	14	48



Summary/Conclusion: No obvious hematologic differences were observed when reducing Aza before Ven (SE2) in MDS compared to investigator's choice (SE1). Both approaches had a similar acceptable safety profile without compromising efficacy for pts with HR-MDS.

EP927 PROGNOSTIC IMPACT OF BONE MARROW FIBROSIS IN PRIMARY MYELODYSPLASTIC SYNDROMES

M. F. Russo [1,*], C. Belli [2], A. Enrico [3], J. Arbelbide [4], M. Narbaitz [5], M. De Dios Soler [6], H. Garcia Rivello [4], C. Martin [3], M. Iastrebner [7], J. Gonzalez [8], M. Rosenhain [9], G. Alfonso [10], L. Kornblihtt [11], A. Perusini [4], A. L. Basquiera [12], C. Lazzarino [1]

[1]HIGA Dr. Diego Paroissien, Buenos Aires, [2]Laboratorio de Genética hematológica, Instituto de Medicina Experimental (IMEX-CONICET)/ Academia Nacional de Medicina, Ciudad Autónoma de Buenos Aires, [3]Hospital Italiano de La Plata, La Plata, [4]Hospital Italiano de Buenos Aires, [5]Academia Nacional de Medicina, [6]Hospital Curie, [7]Sanatorio Sagrado Corazón, [8]Hospital Durand, [9]Hospital Tornú, Ciudad Autónoma de Buenos Aires, [10]Hospital Posadas, Buenos Aires, [11]Hospital de Clínicas, Ciudad Autónoma de Buenos Aires, [12]Hospital Privado de Córdoba, Córdoba, Argentina

Background: Myelofibrosis (MF) is observed in 10-20% of patients with myelodysplastic syndrome (MDS). The presence of MF≥2 according to the European Myelofibrosis Network (EUMNET 2005) has been recognized as an adverse histological finding associated with an aggressive course including early bone marrow failure, shortened survival and leukemic evolution. According to a previous survey performed by our group, the bone marrow biopsy is the most available complemental study in our media. Therefore improving the knowledge of variables related with MF and their prognostic role in patients with MDS is highly desirable.
Aims: To examine the influence of the presence of any degree of myelofibrosis (MF≥1) in overall survival (0S) in an Argentine MDS cohort and its association with clinical and histopathologic variables such as percentage of blasts, bone marrow cellularity, atypical erythroid localization and dysplastic megakaryocytes.
Methods: We identified 468 MDS patients from a multicentric retrospective database of 706 patients who were included in the Argentinian Registry of MDS from 2007 to 2017, with recorded evaluation of MF in the bone marrow biopsy. Statistical analysis included Kaplan-Meier and log rank test, Cox proportional hazard and Logistic regression.
Results: From the selected cohort, 32.7% had MF≥1, 25.8% (n=121) with MF-1, 5.7% (n=27) with MF-2 and 1% (n=5) had MF-3. When analyzing the characteristics of the population, we observe that the median age of these patients was 70 years old (Interquartile range 60-78) being 66.1% >65 years old and 55.8% were males. At the time of diagnosis we observe: median hemoglobin 9.0g/dL, platelet counts 121.500/mL and neutrophils 1.800/µL; 25.7% poor karyotypes and 26.7% IPSS-R>3.5.
The median overall survival (OS) of the MF≥1 subgroup was 20.1 months (95% CI 10.1-30.0, p<0.001) versus MF-0 subgroup with 67.6 months (95%CI 45.1-90.3, p<0.001, *Figure 1*). Cox regression analysis revealed that MF≥1 (HR 1.46, 95% CI 1.06-2.03, p=0.020), *performance status* >2 (HR 2.07, 95% CI 1.44-2.96, p<0.001), hemoglobin level <10gr/dL (HR 1.64, 95% CI 1.16-2.32, p=0.005), platelet count <100.000/µL (HR 1.94, 95% CI 1.42-2.65, p<0.001), poor karyotypes (HR 1.86, 95% CI 1.32-2.63, p<0.001), bone marrow blasts ˃5% (HR 2.94, 95% CI 2.06-4.20, p<0.001) and Charlson Comorbidity Index >3 (HR 2.17, 95% CI 1.48-3.19, p<0.001) were independently associated with a reduced OS.
Regarding the association between MF≥1 and clinical and histopathologic features; this subgroup presented hemoglobin level <10gr/dL (p=0.003), ferritin level >1000mg/dL (p=0.004), increased bone marrow cellularity (p<0.001), atypical erythroid localization (p=0.002) and dysplastic megakaryocytes (p=0.006). Among these parameters, ferritin level (OR 3.41; p=0.006) and the atypical erythroid localization (0R 2.65; p=0.004) were significantly associated with the presence of MF≥1.

Summary/Conclusion: Our results highlight the presence of any grade of myelofibrosis in MDS as an independent adverse prognostic factor for survival in MDS. MF≥1 was also significantly associated with higher ferritin level and erythroid abnormalities in bone marrow.

EP928 DOSE SELECTION OF PEVONEDISTAT + AZACITIDINE IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES/CHRONIC MYELOMONOCYTIC LEUKEMIA AND ACUTE MYELOID LEUKEMIA: A MODEL-BASED ANALYSIS

X. Zhou [1,*], D. Mould [2], D. Zhao [1], M. Sekeres [3], L. Adès [4], R. Swords [5], H. Handa [6], R. Fram [1], D. Faller [1], O. Tsukurov [1], N. Gupta [1]

[1]Millennium Pharmaceuticals, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, [2]Projections Research Inc, Phoenixville, [3]Sylvester Comprehensive Cancer Center, Miami, United States, [4]University of Paris, and INSERM U944, Paris, France, [5]OHSU Knight Cancer Institute, Portland, United States, [6]National University Corporation, Maebashi, Japan

Background: Pevonedistat (PEV) combined with azacitidine (AZA) has demonstrated promising efficacy and a similar safety profile to that of AZA alone with no added myelosuppression, following evaluation in patients with higher-risk myelodysplastic syndromes (MDS)/chronic myelomonocytic leukemia (CMML) and acute myeloid leukemia (AML).
Aims: The objective of this pooled analysis was to assess the impact of PEV exposure on efficacy and safety.
Methods: The PEV exposure–efficacy analyses were conducted with data from NCT02610777, including overall survival (OS), complete response (CR), CR+partial response (PR) and event-free survival (EFS), in patients with higher-risk MDS/CMML who received PEV+AZA. The PEV exposure–safety analyses used pooled data from three studies (NCT01814826, NCT02782468 and NCT02610777), including ≥ grade 3 treatment-emergent adverse event (TEAE3), ≥ grade 3 neutropenia (NEU3), febrile neutropenia (FN), ≥ grade 3 aspartate aminotransferase elevation, ≥ grade 3 thrombocytopenia and ≥ grade 3 alanine aminotransferase elevation, in patients with higher-risk MDS/CMML and AML who received PEV+AZA. The exposure metrics for each patient were sourced from a previously developed population pharmacokinetic model using pooled data from eight phase 1/2 studies. Logistic regression was conducted to estimate PEV exposure–safety relationships for the toxicity endpoints, exposure–CR and exposure–CR+PR. The following covariates were assessed: age, sex, race, disease type and baseline Eastern Cooperate Oncology Group Performance Status (ECOG PS) score. The PEV exposure–survival for higher-risk MDS/CMML was assessed using Cox proportional-hazards models, with the

following potential covariates: age, sex, disease type, baseline ECOG PS score and Revised International Prognostic Scoring System score (IPSS-R).
Results: In total, the exposure–efficacy analyses included 41 patients (median age, 74 years; male, 76%; Caucasian, 90%; median IPSS-R, 5.5), and the exposure–safety analyses included 135 patients (median age, 74 years; male, 64%; Caucasian, 82%). Following a starting dose of 20 mg/m^2, there was a consistent clinical benefit in terms of OS, EFS, CR or CR+PR across the range of PEV exposures. Furthermore, PEV exposure was significantly related to the incidence of FN (p = 0.02), NEU3 (p = 0.003) and TEAE3 (p = 0.02), supporting PEV dose reductions for patients experiencing treatment-related adverse events.
Summary/Conclusion: These exposure–efficacy and exposure–safety results support a favorable benefit–risk profile of PEV 20 mg/m^2 on days 1, 3 and 5 in combination with AZA 75 mg/m^2 for 7 days in 28-day cycles. The study demonstrates consistent clinical benefit across ranges of PEV exposure following a starting dose of 20 mg/m^2 and supports PEV dose reductions for patients with treatment-related adverse events.

EP929 CLINICAL FEATURES OF MYELOID NEOPLASMS WITH DDX41 MUTATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

Z. Wan [1,*], B. Han [1]

[1]*hematology, Peking Union Medical College Hospital, Beijing, China*

Background: The World Health Organization has included myeloid neoplasms with germline predisposition into its classification since 2016. Especially, *DDX41* mutation is clinically unique due to its late onset compared with other germline lesions, such as *CEBPA* and *GATA2*.
Aims: This study was aimed to report the clinical features of *DDX41*-mutated myeloid neoplasms and describe phenotypes of different diagnosed entities utilizing both study- and individual- level data.
Methods: "*DDX41*" was searched in PubMed and Web of science between 2015/01/01 and 2020/12/31, with additional manual searching and individual-patient data seeking. Both study- and individual- level data were utilized to present the clinical features of the whole population and patients in different subgroups.
Results: 7 articles with 177 patients were finally included. Patients harboring mutated *DDX41* contributed to 3.1% [95%CI 2.7-3.6%] of myeloid neoplasms, with 81.3% [95%CI 69.6-90.7%] males and mean diagnosed age of 65.6 years [95%CI 62.9-68.3]. *DDX41*-mutattions were most common in patients with myelodysplastic syndromes (MDS) with excess blast-1/2 (38.7%) and acute myelocytic leukemia (AML, 36.8%). 76.9% [95%CI 59.9-90.2%] of patients carrying *DDX41*-mutattions had normal karyotype. 75.1% [95%CI 53.1-91.7%] patients had germline and 76.3% [95%CI 59.6-89.6%] patients had somatic *DDX41* variants. *ASXL1* and *TP53* were the top frequent concomitant somatic mutations. The pooled overall response rate for hypomethylating agents was 71.0% [95%CI 54.1-85.4] and all the patients with AML achieved complete remission at the first course. The median overall survival was between 32 months to not reached. Familial cases had younger age (p=0.0001), more germline p.D140fs variant (OR=2.88 [95%CI 1.09-7.76], p=0.021) and better response to treatment compared with sporadic cases.
Summary/Conclusion: Myeloid neoplasms carrying *DDX41*-mutations were mainly older, male, MDS EB-1/2 and AML patients. They had better response to the treatment and possible longer survival. Familial cases were diagnosed earlier and had more favorable response to treatment than sporadic cases.

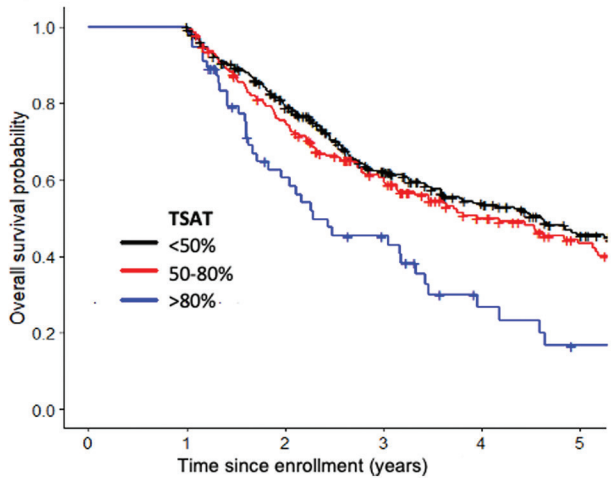
EP930 QUANTIFYING THE HEALTHCARE RESOURCE USE AND CLINICAL OUTCOMES OF PATIENTS WITH MYELODYSPLASTIC SYNDROME WITH RINGED SIDEROBLASTS IN ENGLAND

J. Farrell [1,*], A. Farrer [2], L. Maher [3], M. Chevli [3]

[1]*HEOR, Bristol Myers Squibb, Uxbridge,* [2]*HealthIQ, London,* [3]*Bristol Myers Squibb, Uxbridge, United Kingdom*

Background: Myelodysplastic syndromes (MDS) are characterized by cytopenias, ineffective haematopoiesis, and a risk of progression to acute myeloid leukaemia (AML). MDS with ring sideroblasts (MDS-RS) is a subtype of MDS, constituting ¬ 3-10% of all cases of MDS, in which excess iron accumulates in the mitochondria of the erythroid precursors.. The main clinical issues are severe anaemia, chronic blood transfusion requirement, and the subsequent risk of iron overload.
The Hospital Episodes Statistics (HES) database in England contains universal coverage of secondary care data from NHS hospitals, covering three main patient groups: 1) inpatient patient care; 2) Outpatient appointments and attendances (OP); and 3) Emergency Room (ER) visits with approximately 17 million episodes recorded each year.
Aims: To describe patients diagnosed with MDS-RS in England. In terms of demographics and clinical characteristics and to quantify the associated healthcare resource use (HCRU) and tariffs for this patient cohort including inpatient, day case, outpatient, and A&E care.
Methods: All data within an observation period between 01 January 2015- 31 December 2019, to include baseline characteristics for patients with ICD10 diagnosis code of D461 (MDS) were extracted from HES and presented as crude counts. Descriptive statistics including frequency and percentage were calculated as categorical variables; whereas, mean, median and interquartile range (IQR) were calculated for continuous variables. Length of follow-up was calculated as the total number of days between diagnosis date (index date) and end of study period. Tariffs were derived based on case mix; a method of classifying patient care based on expected clinical resource use for the provision of that care.
Results: Overall 914 patients (mean age at inclusion 76 years [youngest; 20, oldest; 96]; 40.26% female) were identified. During a mean observation period of 24.62 months (IQR 28.65) 103 (11.27%) patients experienced a disorder of iron metabolism, 278 (30.42%) suffered from sepsis and 235 (25.71%) from heart failure.
52 (2.62%) patients had no inpatient admissions. For those who had ≥1 event, the mean number of inpatient blood transfusion events per-patient-per-year was 15.93 (IQR 12.68), the mean number of outpatient blood transfusion events per-patient-per-year was 3.55 (IQR 1.55), 443 patients (51.39%) had ≥12 visits per year.
Overall HCRU is split by inpatient and outpatient care and ER attendance. In the inpatient setting there were a mean of 19.2 admissions per-patient-per-year, of which 99.11% were elective (resulting in a mean of 15.79 bed days per-patient-per-year). In the outpatient setting there were a mean of 4.08 appointments per-patient-per-year. There were a mean of 2.54 ER visits per-patient-per-year.
Overall tariff costs to the health service per-patient-per-year were £19,047 (inpatient tariff £10,389, outpatient tariff £579, transfusion £7,686, ER visits £393).
Summary/Conclusion: The results of this database analysis offer insights into the real-world management of patients with MDS-RS in England and the HCRU with its management. A burden on patients and the healthcare system has been identified due to the frequent hospitalisations and secondary care visits. This highlights the need for novel treatment options in the management of MDS-RS.

EP931 HIGH TRANSFERRIN SATURATION PREDICTS INFERIOR CLINICAL OUTCOMES IN PATIENTS WITH MDS



J. Teichman [1,*], M. Geddes [2], N. Zhu [3], M.-M. Keating [4], M. Sabloff [5], G. Christou [5], B. Leber [6], D. Khalaf [7], E. St-Hilaire [8], N. Finn [8], A. Shamy [9], K. Yee [1], J. [1]*Hematology, University of Toronto, Toronto,* [2]*Hematology, University of Calgary, Calgary,* [3]*Hematology, University of Alberta, Edmonton,* [4]*Hematology, Dalhousie University, Halifax,* [5]*Hematology, University of Ottawa, Ottawa,* [6]*Pathology,* [7]*Oncology, McMaster University, Hamilton,* [8]*Oncology, Universite Sherbrooke, Sherbrooke,* [9]*Hematology,* [10]*McGill University, Montreal,* [11]*University of British Columbia, Vancouver,* [12]*University of Saskatchewan, Saskatoon,* [13]*University of Manitoba, Winnipeg,* [14]*University of Toronto,* [15]*Statistics,* [16]*Sunnybrook Health Sciences Centre, Toronto,* [17]*Hematology, University of British Columbia, Vancouver, Canada*

Background: Iron overload (IO) reflected by increased ferritin level is associated with increased mortality in patients with myelodysplastic syndromes (MDS). However, ferritin is an imperfect metric of true IO. Elevated levels of oxidatively damaging non-transferrin bound iron and labile plasma iron correlate with transferrin saturation (TSAT) >70% and >80% respectively, but are not readily measurable.

Aims: We aimed to describe trends in TSAT in transfusion dependent MDS and to determine its relation to ferritin level and clinical outcomes.
Methods: Patients enrolled in the Canadian MDS registry from January 2008 to June 2019 were evaluated. Mean values of ferritin and TSAT were calculated at six-month intervals, and general linear mixed model analysis was used. Transfusion density was calculated at landmark year 1 and defined as the median number of units transfused per month since the onset of transfusion dependence (TD), with TD-low and TD-high defined as above or below the median. Survival was evaluated by TSAT category (<50%, 50-80%, >80%), and ferritin (≤500ug/L, 501-800ug/L, >800ug/L) using the mean values from enrolment onwards.
Results: 718 patients were included. Median age was 74 years. 12%, 31%, 29%, 15% and 13% were IPSS-R very low, low, intermediate, high and very high, respectively. With a median follow up of 2.1 years, actuarial overall survival (OS) was 2.4 years. 17% developed AML and 61% have died. AML, MDS progression, infection, cardiac events, and bleeding accounted for 26%, 20%, 19%, 9.6% and 6.34% of known causes of death, respectively. Mean TSAT increased with incremental ferritin categories, however TSAT and ferritin were only moderately correlated over time (r=0.63, p < 0.0001). Among all patients, ferritin increased from enrolment up to 42 months (p<0.0001), while TSAT remained stable over time (p=0.094). In TD patients, there was a significant increase in TSAT over time (p=0.0063). Median transfusion density was 2.7 units/month by landmark year 1. Higher TSAT and ferritin were both associated with inferior 5-year OS, PFS and LFS (Figure 1). In patients with ferritin >1000ng/mL, stratifying by TSAT category showed a trend toward OS. Higher transfusion density was also associated with inferior 5-year OS. In TD patients, TSAT category predicted cardiac death-free survival (DFS) (p= 0.0011), while ferritin category predicted infectious death. In univariate analysis, age, IPSS-R, blast percentage, ECOG, frailty score, Charlson Comorbidity Index, iron chelation (Y/N), transfusion density, TSAT category and ferritin category were significantly associated with inferior OS. In multivariate analysis, TSAT >80% (HR 1.58 95%CI 1.13-2.21) and high-TD (HR 1.90 vs. low-TD 95%CI 1.39-2.60) remained significant for OS (R^2 30.35%).

Figure 1.

Summary/Conclusion: Among a cohort of predominantly low-intermediate risk MDS patients, TSAT correlated moderately with serum ferritin. TSAT >80%, ferritin >800 ug/mL and high transfusion density were each associated with inferior survival. TSAT may be an indicator of the degree of oxidative stress present, and is readily measurable in a clinical setting. The relationship between elevated TSAT and reduced cardiac DFS warrants further study.

EP932 CIRCULATING MICRORNA MIR-99B AND MIR-125A IN MYELODYSPLASTIC SYNDROME-NONINVASIVE DIAGNOSTIC AND PROGNOSTIC BIOMARKERS

I. Mandac Smoljanovic [1,*], M. M. Kardum Paro [1], M. Vibor [1], D. Radic Kristo [1], M. Milosevic [2], S. Ostojic Kolonic [1]

[1]Clinical Hospital Merkur, [2]School of Medicine, Zagreb, Croatia

Background: Myelodysplastic syndrome (MDS) is a group of heterogeneous clonal hematologic disorders of hematopoietic stem cells, followed by ineffective hematopoiesis of one or more cell lines with the onset of consequent cytopenia with an increased risk of progression to acute myeloid leukemia. According to the World Health Organization classification, the diagnosis of MDS is based on morphological, clinical, cytogenetic, immunophenotypic and biological criteria.
In everyday clinical practice, the diagnosis of MDS is based on invasive cytomorphological analysis of peripheral blood and bone marrow cells, determination of blast percent, type and degree of dysplasia, presence of ring sideroblasts, and cytogenetic analysis of bone marrow cells.
Micro Messenger Ribonucleic Acids (miRNAs) are short, non-coding molecules of 18 to 25 nucleotides in length that play an important role in regulating cell development and metabolism, their differentiation and proliferation, regulation of the cell cycle and cell death. Tumor cells release miRNAs into the circulation (plasma, serum) where they remain relatively stable. Although their discovery allowed linking of disease and miRNA gene expression, a precondition for their clinical application was the determination of gene expression by real-time quantitative polymerase chain reaction with satisfactory efficacy and specificity. In the literature, gene expression of miRNAs has been linked to the diagnosis, classification and progression of various diseases.
Many studies have been conducted so far about the molecular mechanisms and epigenetic pathways in MDS and their prognostic and therapeutic significance, but few studies have analyzed the importance of miRNAs in MDS.
Aims: The aim of this study was to examine the level of change of gene expression of specific mRNAs (miR-125a, miR-99b, miR-126, miR-125b, miR-let-7a) in plasma of healthy volunteers and subjects diagnosed with MDS.
Methods: Gene expressions of miRNAs were determined at the Clinical Institute of Medical Biochemistry and Laboratory Medicine, Merkur University Hospital, accredited according to EN ISO 15189:2012, in plasma samples of 20 healthy volunteers and 41 MDS patients diagnosed at the Institute of Hematology of the Clinic for Internal Diseases of Merkur University Hospital, Reference Center of the Ministry of Health of the Republic of Croatia for Diagnosis and Treatment of MDS.
Results: A significant difference was found between the study group and healthy control in miR-99b level, where at normalized values relative to miR-126, an increased level in subjects compared to control was observed 4,521 times (P = 0.004).
There was negative correlation between miR-125a(rho=-0,326; P=0,038), RBC count and hemoglobin level (rho=-0,381; P=0,014).
miR-99b showed statistically significant positive correlation with WBC count (rho=0,310; P=0,048).
Summary/Conclusion: MiR-99b and 125a could serve as diagnostic and prognostic noninvasive biomarkers in MDS.
The results of the study suggest that gene expression of miRs (125a, 125b, 99b, let7a) could be regulated by the same mechanism and may be clinically relevant in subjects with MDS.

EP933 THE R-IPSS DOES NOT SEEM TO ACCURATELY PREDICT FATAL EVENTS IN MYELODYSPLASTIC SYNDROME PATIENTS WITH AUTOIMMUNE DISEASES

T. Brunet [1], F. Roy-Peau [1], M. Martin [1], M. P. Gallego-Hernanz [2], E. Cayssials [2], X. Leleu [2], J. M. Torregrosa-Díaz [2,*]

[1]Internal Medicine department, [2]Hematology-Oncology and celular therapy, University Hospital of Poitiers, Poitiers, France

Background: Myelodysplastic syndromes (MDS) are clonal hemopathies with a heterogeneous spectrum of presentation and a variable risk of transformation into acute myeloblastic leukemia (AML). Autoimmune diseases (AID) are present in 10 to 30% of cases, with unclear prognostic significance in this context. To date, the role of the R-IPSS in the context of an AID after an SMD has not yet been established.
Aims: To test the R-IPSS as a predictor as a predictor score of death/AML progression in MDS patients with AID. Secondary objectives were to study the association between the R-IPSS and the occurrence of an AID and the impact of AIDs on overall survival and leukemia-free survival (LFS).

Methods: We retrospectively collected data from primary MDS adult patients followed-up in the University Hospital of Poitiers between January 2010 and December 2019. Immunosuppressive therapy secondary-MDS were excluded. The date of onset and type of AID, as established by the standard criteria were collected. Simultaneous diagnoses of MDS and AID were considered if established in a 3-month interval from the MDS one. Left-censored patients (AID diagnosis before SMD) were dropped for the final survival analysis. A multistate cox model was performed with AID as an intermediate state. Baseline hazards proportionality for transitions to fatal events was tested by graph methods and checking the Schoenfeld residuals.
Results: AIDs were identified in 22 of 212 MDS patients (10.4%). MDS-AID patients were equally sex-distributed (p=0.45). Associated AIDs were as specified in table 1. At the time of SMD diagnosis, 54.2% of patients had general signs and 13% had cutaneous and/or joint signs. No association between AID and WHO MDS-subtypes was observed. We found a trend-significant benefic effect of low-risk R-IPSS (<3.5 points) on the development of an AID (HR 0.44; 95%CI 0.2-1.2; p=0.1). In this setting, skin symptoms were the only associated factor in our cohort (HR 6.7; 95%CI 2.7-16.4; p<0.001). Fifteen of 22 MDS-AID patients suffered from death/AML progression. As expected, R-IPSS was a good predictor for the combined endpoint of death and AML progression in the whole MDS cohort. However, once patients develop an AID, R-IPSS did not associate with fatal events (HR 3.5; 95%CI 0.5-24.1; p=0.2). In this setting, only the presence of cutaneous and general symptoms were associated with death/AML.

Autoimmune disease	n(%)
Rhizomelic Pseudopolyarthritis	1
Lupus	1
Hashimoto Tyroidite	1
Pyoderma gangrenosum	1
Dermatomiositis	1
Sweet's syndrome	5
Dysimmunity with anti-Ro52 positive anticorps	1
Lymphocytic colitis	1
Autoimmune hemolytic anemia	2
Horton's disease	1
Vascularitis NOS	2
Leukocytoclastic vasculitis	1
Sarcoidosis	1
Necrotizing cutaneous vasculitis	1
Sclerodermia	1
Chronic inflammatory demyelinating polyradiculoneuritis	1

Summary/Conclusion: The association of MDS to AIDs is of clinical heterogeneous expression. It tends to occur in low-risk MDS and does not seem to impact overall survival in our cohort.
The R-IPSS score (trend significantly) predicts the development of an AID (with an excess of risk for low-risk patients in our cohort) but once the autoimmune disease developed, it does not predicts accurately fatal events (AML and death). This finding lets us hypothesize the bigger role of AIDs severity than MDS factors in the mortality of MDS-AID.

EP934 IMPACT OF TRANSFORMATION TO ACUTE MYELOID LEUKEMIA (AML) ON OVERALL SURVIVAL (OS) AMONG PATIENTS (PTS) WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN THE UNITED STATES OF AMERICA (USA)

V. Kota [1,*], A. Ogbonnaya [2], E. Farrelly [2], B. Schroader [2], F. Kristo [3], A. Raju [2], M. Dalal [3]

[1]Georgia Cancer Center at Augusta University, Augusta, [2]Xcenda LLC, Palm Harbor, [3]Millennium Pharmaceuticals, Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States

Background: MDS is a clonal blood stem cell disorder characterized by dysplasia and ineffective hematopoiesis leading to cytopenias and risk of transformation to AML. *Post hoc* analyses of a randomized phase 2 trial (NCT02610777) that compared pevonedistat + azacitidine (AZA) versus AZA alone, demonstrated that transformation to AML was associated with deterioration of quality of life (6/12 pts and 7/12 pts reported worsening of physical functioning and fatigue, respectively).[1] Furthermore, OS was longer (median, 27.7 months [mths]) in pts who did not transform to AML [n=53] vs 13.6 mths in pts who did [n=14]; hazard ratio (HR), 0.289; p=0.0002).[2]
Aims: This retrospective study assessed the impact of AML transformation on OS in pts with HR-MDS receiving first-line therapy (1LT).
Methods: Pts with HR-MDS (≥18 years old) who initiated 1LT between Jan 1, 2008, and Jun 30, 2019, were identified from a large USA electronic medical record (EMR) database. Owing to lack of complete cytogenetics in the EMR, HR-MDS was defined based on International Classification of Diseases (ICD) coding for HR-MDS (≥1 ICD-9/-10 codes: 238.73, D46.2[0-2]) or an adapted HR-MDS algorithm based on the Revised International Prognostic Scoring System classification (intermediate or higher risk). Pts were followed from the start of HR-MDS 1LT until death, loss to follow-up or study end. Probability of transformation to AML following HR-MDS 1LT was assessed using Kaplan–Meier analysis. To account for differential follow-up time between pts who transformed to AML and pts who did not, a landmark analysis was conducted. The landmark time of 6 mths was chosen based on the guideline-recommended minimal duration of MDS treatment (6 cycles) and the median time to transformation (5.9 mths) among pts treated with AZA who transformed to AML (n=9/14) from the aforementioned study.[2] In the landmark analysis, AML status (transformed to AML or not) was defined in the 6 mths following 1LT initiation in pts with ≥6 mths of follow-up. Cox proportional-hazards model was used to assess the impact of AML on OS from the landmark. To further validate the association between transformation to AML and OS, a time-varying Cox proportional-hazards model was considered, such that AML status was included as a time-varying variable. Both Cox models involved adjustments for baseline differences between pts with HR-MDS who transformed to AML and those who did not.
Results: 874 pts with HR-MDS were identified. Mean age was 71.9 years, and 43% had a Charlson comorbidity index of ≥2. Hypomethylating agents were the most common 1LT, with 62% of pts receiving AZA and 20% receiving decitabine. Median follow-up was 11.2 mths. In pts treated with 1LT, the rate of transformation to AML was 26.9% at 1 year and 39.4% at 2 years. The unadjusted landmark analysis showed shorter OS in pts who transformed to AML than in pts who did not (**Table**). These results were also consistent in subgroup of pts treated with AZA. Multivariable Cox proportional-hazard analysis also showed that transformation to AML was associated with worse survival. Pts who transformed to AML had a higher risk of death than pts who did not after adjusting for baseline differences in the 6-mth landmark analysis (HR, 1.82; 95% confidence interval [CI]: 1.18–2.81) and in the adjusted time-varying analysis at 1 year (HR, 2.85; 95% CI: 2.19–3.72).

Table: 6-month landmark analysis results.

Parameter	Pts who transformed to AML	Pts who did not transform to AML
Overall population	**n=76**	**n=543**
Median OS, months	9.7	15.4
KM survival rate 6 months after landmark, %	62.5	74.2
	p=0.006	
Azacitidine subgroup	**n=42**	**n=343**
Median OS, months	9.1	15.4
KM survival rate 6 months after landmark, %	63.9	74.6
	p=0.029	

KM, Kaplan–Meier; OS, overall survival; pts, patients; AML, acute myeloid leukemia.

Presented at the 62nd American Society of Hematology Annual Meeting and Exposition, December 5–8, 2020, virtual.
2. Sekeres MA *et al.* Efficacy and Safety of Pevonedistat Plus Azacitidine Vs Azacitidine Alone in Higher-Risk Myelodysplastic Syndromes (MDS) from Study P-2001 (NCT02610777) [abstract 653]. Presented at 62nd American Society of Hematology Annual Meeting and Exposition, December 5–8, 2020, virtual.

Summary/Conclusion: Among treated pts with HR-MDS, transformation to AML was associated with inferior OS. These results highlight the importance of delaying transformation to AML as a treatment goal.

EP935 CHANGES IN THE CONCENTRATION OF TUMOR NECROSIS FACTOR TNF-□ IN BLOOD SERUM AND THE LEVEL OF CD33+ SUBSTRATE CELLS IN THE BONE MARROW OF PATIENTS WITH MYELODYSPLASTIC SYNDROME.

H. Starodub [1], V. Kubarova [1,*], N. Goryainova [1], N. Tretiak [1], B. Kuiavovych [1], O. Basova [1]

[1]*Государственное учреждение «Институт гематологии и трансфузиологии НАМН Украины», Киев, Ukraine*

Background: Myelodysplastic syndrome (MDS) belongs to a clinically, morphologically, genetically heterogeneous group of diseases characterized by clonality and arising from mutations in the hematopoietic progenitor cell, moreover, the disease has a progressively unfavorable course and a high probability of transformation into acute leukemia.
CD33+ expression is known to occur mainly on myeloid progenitor and hematopoietic stem cells and maturing granulocytes. At the same time, CD33+ has been shown to constitutionally inhibit the production of proinflammatory cytokines such as IL-1 and TNF-a. There are isolated pieces of evidence of increased cytokine secretion and cytokine-induced hematopoietic cell proliferation with decreased CD33+ expression.
Aims: The study aimed to establish the relationship between TNF-a and CD33+ cells in the bone marrow of patients with MDS RAEB I depending on the level of response to Lenalidomide therapy.
Methods: The object of the study was 25 patients with MDS RAEB I aged 36 to 81 years (mean age 58 years). The diagnosis was made based on clinical data and mandatory laboratory tests. Verification of the diagnosis of MDS RAEB I was carried out in accordance with the WHO criteria for myeloid neoplasms and acute leukemias, 2008. The duration of the disease at the time of inclusion of patients in the examination varied from 4 to 9 months. All patients included in the study corresponded to the functional state of ECOG-1 ECOG-2.
The immunophenotypic profile of tumor cells was established by flow laser cytometry. Determination of TNF-a concentration was performed by enzyme-linked immunosorbent assay using standard kits using an enzyme-linked immunosorbent assay "MultiScan EX" at a wavelength of 430 nm. The control was the plasma of healthy individuals. Student's test was used for statistical processing of the received data.
Results: Analysis of the obtained data shows an increase in the number of CD33+ cells in the bone marrow of patients with MDS RAEB I 1.4 times before treatment 13.9±1.7%, with an improvement of 19.8±1.3% (p<0, 05). The level of TNF-a with improvement decreased to 8.9±0.3 pg /ml at the pre-treatment rate of 11.3±0.5 pg/ml (7.9±0.5 pg/ml healthy individuals). In the group of 11 people (40.7%) with stabilization of the disease, the indicators of CD33+ and TNF-a remained at the pre-therapeutic level. Progression of the pathological process occurred in 33.3% (9 people) with reduced CD33+ cells in the bone marrow to 9.5±0.5%, which is 1.5 times lower than in patients before treatment and 2.08 times less, than in the period of improvement (19.8±1.3%). At the same time, there was an increase in the concentration of TNF-a in 1.4 times, compared with the improvement group (12.9±0.2 pg / ml and 8.9±0.3 pg / ml), respectively (p <0.05). The level of TNF-a in the groups before treatment and in the period of stabilization of the process did not differ significantly.
Summary/Conclusion: Thus there is an inverse relationship between TNF-a and CD33+ in different responses to treatment with Lenalidomide in patients with MDS RAEB I.

Background: The BOSTON study, a phase 3, randomized, open label clinical trial, has shown a clinical benefit of selinexor combined with bortezomib and dexamethasone (XVd) in patients with multiple myeloma. Selinexor acts by inhibiting the nuclear export protein XPO1, however, XPO1 expression does not correlate with response and the biological mechanisms underlying treatment response remain unclear. Additionally, while the overall response rate for XVd in the BOSTON study was 76.4%, there are currently no known genomic biomarkers to help guide treatment recommendations.
Aims: In this study, we characterized genomic and transcriptomic correlates of response to selinexor and identified potential biomarkers for clinical use.
Methods: We performed RNA sequencing on CD138+ cells from 100 patients who participated in the BOSTON study. We performed differential expression, followed by pathway analysis, to compare patients with long and short progression-free survival (PFS) in the XVd arm of the BOSTON dataset. Using the differentially expressed genes, we calculated GSVA (Gene Set Variation Analysis) scores and performed time-to-event univariate Cox proportional hazard models and log-rank testing to identify a novel gene expression signature that predicts PFS in the BOSTON dataset. We validated our signature using transcriptomic data from 64 patients from STORM, a clinical trial of selinexor combined with dexamethasone in patients with penta-refractory multiple myeloma.
Results: Through gene expression analysis, we identified a cluster of patients who are more likely to experience longer PFS with XVd as opposed to Vd (log rank p = 0.012, Fig 1A-B). We found that patients within the XVd arm in this cluster tend to be younger (wilcoxon p = 0.0029). Within this cluster of responders, we identified a total of 198 unique genes associated with longer PFS in the XVd arm (FDR < 0.05) that were not significantly associated with PFS in the Vd group. Furthermore, pathway analysis revealed increased interferon signaling, Myc deactivation, and proteasome downregulation in patients with longer PFS in this cluster (FDR < 0.05, Fig 1B). We identified a GSVA-based expression signature consisting of five genes, *ASTN1*, *REC114*, *CIART*, *RPL23AP65*, and *NPHS1*, that were downregulated in XVd patients with PFS > 300 days (Fig 1C). Using this signature, we accurately distinguished patients with long term PFS in the XVd arm of the BOSTON study (Cox proportional hazard model, FDR=0.003, hazard ratio=6.7, Fig 1D). Three of these five genes, *ASTN1*, *NPHS1*, and *RPL23AP65*, were also downregulated in patients that had better depth of response, defined as very good partial response (VGPR) or better. This signature validated successfully in the STORM study (Cox proportional hazard model, p=0.0095, hazard ratio=2, Fig 1D).

Figure 1. *Expression-based clusters identify patients likely to see longer PFS from XVd as opposed to Vd*

Summary/Conclusion: We report a novel, prognostic biomarker signature for selinexor, bortezomib and dexamethasone response in patients with multiple myeloma. We have validated our findings in the STORM cohort and are currently validating our findings in additional, independent cohorts of multiple myeloma patients treated with selinexor. This signature has important clinical relevance as it could identify patients most likely to benefit from treatment with selinexor-based therapy.

EP937 DEVELOPMENT OF NEXT-GENERATION ANTITUMOR ANTIBODIES ARMED WITH BRIDGING-BITE TO ADVANCE ANTI-MYELOMA IMMUNOTHERAPY

T. Konishi [1,*], T. Ochi [1,2], M. Maruta [1], K. Tanimoto [1], T. Saitou [3], T. Imamura [3], M. Yasukawa [2,4], K. Takenaka [1]

[1]Department of Hematology, Clinical Immunology, and Infectious Diseases, Ehime University Graduate School of Medicine, [2]Division of Immune Regulation, Proteo-Science Center, Ehime University Graduate School of Medicine, [3]Department of Molecular Medicine for Pathogenesis, Ehime University Graduate School of Medicine, Shitsukawa, Toon, Ehime, [4]Ehime Prefectural University of Health Sciences, 543, Takoda, Tobe-cho, Iyo-gun, Ehime, Japan

Background: Immunotherapy using monoclonal antibodies (mAbs) has improved clinical outcomes of patients with multiple myeloma (MM). Nevertheless, the prognosis of relapsed/refractory MM (RRMM) patients still remains poor probably due to the heterogeneity of myeloma cells, highlighting the need for the development of novel therapeutic approaches. Recently, new antibody-based modalities have been developed, and tested in clinical trials for RRMM. Bispecific T-cell engager (BiTE) which can induce antitumor T-cell responses has a potential to treat RRMM. In contrast, some issues would be raised to improve advantages of this modality. First, BiTE lacks an Fc domain which needs to induce NK-cell responses. Second, BiTE is continuously administered to induce sufficient antitumor effects because of its low molecular weight. Third, BiTE can target an antigen expressed by tumor cells, suggesting the weakness against heterogenous tumors. To overcome these obstacles, we have developed a novel BiTE-based modality, Bridging-BiTE (B-BiTE), which endows a series of clinically available mAbs with both NK-cell and T-cell activation capacity.
Aims: In this study, we have investigated the efficacy, universality, and safety of a mAb armed with B-BiTE for the treatment of MM.
Methods: B-BiTE, which encodes a single chain fragment variable (scFv) specific for an Fc domain and an scFv specific for the CD3ε, was designed. B-BiTE was mixed with a mAb at the molar ratio of 1:1 to generate B-BiTE/mAb complex. Proliferation and cytokine production by human peripheral blood T cells/NK cells for target cells in the presence of B-BiTE/mAb was measured by flow cytometry. Their cytotoxicity against target cells was assessed by ^{51}Cr-release assays. Five-week-old NOG mice were inoculated with MM1S myeloma cells. Then, antitumor effects and overall survivals of mice treated with a mAb alone or B-BiTE/mAb were compared.
Results: Using the CD20-specific mAb, Rituximab as a model, we have demonstrated that B-BiTE/Rituximab successfully bound to both CD20$^+$ tumor cells and human T cells, and activated human peripheral blood T cells as well as NK cells against tumor cells *in vitro*. Therefore, we applied B-BiTE to the CD38-specific mAb, Daratumumab (Dar) and the SLAMF7-specific mAb, Elotuzumab (Elo) to target myeloma cells. Human peripheral blood CD8$^+$ and CD4$^+$ T cells proliferated, and produced multiple cytokines against both CD38$^+$SLAMF7$^-$ and CD38$^-$SLAMF7$^+$ myeloma cells in the presence of B-BiTE/Dar and B-BiTE/Elo without increasing the frequency of regulatory T cells. Moreover, their antitumor cytotoxicity induced by B-BiTE/Dar and B-BiTE/Elo was enhanced when compared with that mediated by Dar/Elo alone *in vitro* and *in vivo*. Importantly, human peripheral blood T cells and NK cells obtained from patients with myeloma cooperatively responded to their own myeloma cells in the presence of B-BiTE/mAb. Furthermore, in the presence of polyclonal immunoglobulin, B-BiTE/mAb activated T cells/NK cells for myeloma cells, but did not induce any reactivity to normal cells.
Summary/Conclusion: B-BiTE can be a new modality to easily generate stable, safe, and effective bispecific antibodies from clinically available mAbs. This modality can allow us to prepare a panel of next-generation antibodies which induce both T-cell and NK-cell responses, resulting in further advancement of immunotherapy for RRMM.

EP938 ISB 1342: A FIRST-IN-CLASS CD38 T CELL ENGAGER FOR THE TREATMENT OF RELAPSED REFRACTORY MULTIPLE MYELOMA

M. Perro [1,*], B. Pouleau [1], C. Estoppey [1], C. Stutz [1], A. Croset [1], A. Laurendon [1], T. Monnet [1], M. Pluess [1], C. Ries-Fecourt [1], J. Macoin [1], R. Turrini [1], P. Suere [1], E. Nallet [1], M. Mbow [1], A. Drake [1], M.-A. Doucey [1], S. Blein [1]

[1]Oncology, Ichnos Sciences, Epalinges, Switzerland

Background: ISB 1342 is a bispecific antibody heterodimer based on the Ichnos proprietary Bispecific Engagement by Antibodies based on T cell receptor (BEAT®) platform. ISB 1342 is a first-in-class CD38 T cell engager under investigation in subjects with relapsed multiple myeloma refractory to proteasome inhibitors (PIs), immunomodulators (IMiDs) and daratumumab (study ISB 1342-101).
Aims: The aim of this study is to assess on target specificity and potency of ISB 1342 in vitro and in vivo.
Methods: ISB 1342 was engineered with a single chain variable fragment (scFv) arm that specifically recognizes a cluster of differentiation (CD)3-epsilon (CD3ε) and a fragment antigen binding (Fab) arm which specifically recognizes CD38 and does not compete with daratumumab. By co-engaging CD3ε on T cells and CD38 on tumor cells, ISB 1342 redirects T cells to kill CD38-expressing tumor cells. This mechanism of action is differentiated from existing monospecific CD38 targeting therapies and was designed to overcome resistance to daratumumab in multiple myeloma
Results: *In vitro*, ISB 1342 killed a large range of CD38-expressing tumor cell lines (EC50:12 to 90 pM) with 8 to 239-fold superior efficacy than daratumumab. ISB 1342 was also able to efficiently kill CD38 low-intermediate-expressing tumor cells that were poorly killed by daratumumab. ISB 1342 retained the potency to kill CD38 low-intermediate-expressing tumor cells when used in sequential or concomitant combination with daratumumab. In addition, the presence of soluble CD38 or glucocorticoid did not impact ISB 1342 killing potency. ISB 1342 was constructed with a double LALA mutation that dampens the binding to Fcγ receptors and C1q. Consistently, ISB 1342 showed only residual Fc-mediated effector functions and its mechanism of tumor cell killing critically relies on the engagement and the activation of T lymphocytes. ISB 1342 showed a favorable on target specificity profile *in vitro* and was unable to activate T cells in the absence of CD38 positive target cells. Further, ISB 1342-induced tumor cell killing was not associated with a detectable T cell fratricide *in vitro*. Finally, the potency of ISB 1342 was assessed *in vivo* in a therapeutic model of a subcutaneously established Daudi tumor co-xenografted with human PBMCs. In marked contrast to daratumumab, which induced only a partial tumor control, ISB 1342 induced complete tumor eradication when injected intravenously weekly at 0.5 mg/kg. As anticipated, the ISB 1342 control molecule (ISB 1342_13DU) made of an irrelevant CD38 binder failed to control tumor growth. The release of the Granzyme A and B, TNF-alpha and CXCL-10 in the tumor micro-environment one week post-treatment was strongly and significantly increased by ISB 1342 but not by daratumumab and ISB 1342_13DU; this represents a correlate of anti-tumor immunity associated with ISB 1342 efficacy *in vivo*.
Summary/Conclusion: Hence the higher potency of ISB 1342 relative to daratumumab supports the ongoing clinical development in multiple myeloma patients.

EP939 A NOVEL ONCOLYTIC LENTIVIRAL VECTOR FOR THE TARGETED AND THERAPEUTIC IFNB- EXPRESSION IN MULTIPLE MYELOMA

E. Kalafati [1,*], E. Drakopoulou [1], T. Bagratuni [2], E. Terpos [2], E. Tsempera [1], M. K. Angelopoulou [3], E. Verhoeyen [4,5], F.-L. Cosset [4], K. Konstantopoulos [3], E. Papanikolaou [6], N. Anagnou [1,6]

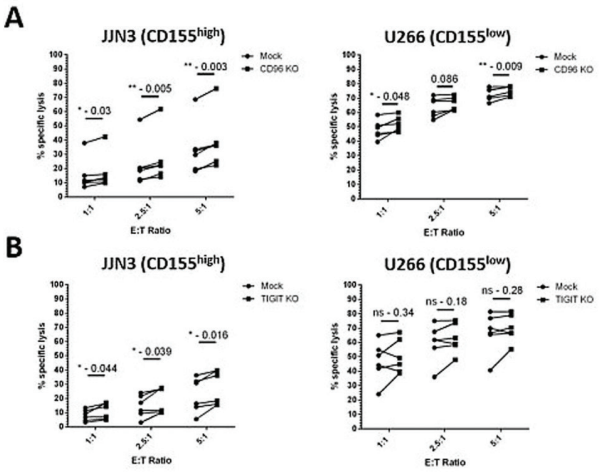
Background: Multiple myeloma (MM) is a plasma cell malignancy that remains incurable for most patients and, thus, new therapies are urgently needed. Oncolytic viruses are a promising new class of therapeutics that provide tumor-targeted therapy. In the context of developing a novel therapeutic approach for MM, we generated an IFNβ-expressing lentiviral vector (LV), pseudotyped with the measles virus HF glycoproteins that target myeloma cells through the binding to CD46 and SLAM receptors.
Aims: The purpose of this study was to assess the therapeutic efficacy of IFNβ/HF *in vitro* in H929 and JJN3 myeloma cell lines, as well as in primary cells from MM patients on first-diagnosis.
Methods: Production of IFNβ/HF and control GFP/HF LVs was carried out by transient co-transfection of HEK-293T cells. Vector titration and vector copy number per cell (VCN/cell) were determined by flow cytometry and qPCR, respectively. Cell survival and cytotoxicity were evaluated using Trypan blue exclusion and CCK-8 colorimetry assays, respectively. Apoptosis was estimated by Annexin V/7-AAD staining. The expression of apoptotic gene expression was determined by qPCR and Human Apoptosis Antibody Array, at mRNA and protein level, respectively. IFNβ secreted by IFNβ/HF-transduced cells was determined by ELISA, while its paracrine mechanism of action was evaluated by the Transwell® co-culture assay. Cell cycle analysis was performed with flow cytometry and propidium iodide. Lastly, serum neutralizing antibody activity was evaluated by flow cytometry on JJN3 cells transduced with GFP/HF LV, previously incubated with MM and normal donors' serum.
Results: IFNβ/HF LV exhibited a mean transduction efficiency of 29.5% (H929) and 23.1% (JJN3) and a mean VCN/cell of 1.6 and 1.2, respectively. Moreover, IFNβ/HF-transduction at MOI of 1, led to a dramatic 90.6% and 95.2% reduction of cell survival in H929 ($p=0.01$) and JJN3 ($p=0.04$) cells, respectively. Regarding apoptotic cells in H929 and JJN3 cells, a marked 90.3% ($p\leq0.001$) and 74.1% ($p\leq0.001$) increase was observed. Notably, the increase of Caspases 3 and 9 as well as of HtrA/Omi and Endo G proteins, both at the RNA and protein level, highlights the crucial role of the intrinsic apoptotic pathway as well as the caspase-independent pathway in the IFNβ-induced apoptosis. Moreover, a great reduction in the expression of the anti-apoptotic genes Bcl-2 and Bcl-xl was observed in IFNβ-transduced H929 and JJN3 cells. After Transwell® co-culture, IFNβ secreted by the transduced cells, was capable of significantly decreasing the viability of *untransduced* cells while the percentage of untransduced apoptotic cells surpassed 30% for both H929 ($p=0.004$) and JJN3 ($p=0.01$) cells. Furthermore, IFNβ/HF efficiently transduced primary cells (MOI=10) from patients with MM, decreasing cell survival up to 49.8% ($p=0.0089$), with a 51.8% increase of apoptosis ($p=0.01$) and induction of cell cycle arrest at a mean VCN/cell of 3.6. Finally, it was showed that the barrier of pre-existing immunity can be overcome using a higher MOI of 20, a positive outcome for its *in vivo* administration in patients vaccinated against measles virus.
Summary/Conclusion: Overall, the results of our study demonstrate that the IFNβ/HF LV can efficiently target and kill myeloma cells, providing evidence about the molecular mechanisms involved in cell death. Thus, our findings suggest that IFNβ/HF is a promising therapeutic candidate as a selective antitumor agent for the treatment of MM.

EP940 LONG-ACTING STARCH NANOPARTICLE DRUG DELIVERY SYSTEM TO TREAT MULTIPLE MYELOMA

S. Vuoti [1,*], M. Saari [2], K. Reinikainen [2], K. Narasimha [2]

[1]Clinical Pharmaceutical Chemistry, University Of Jyväskylä, Jyväskylän yliopisto, [2]Research and Development, Chembrain LTD, Kauhava, Finland



Background: Nanoparticle delivery systems offer a new approach to increase the effectiveness of treatment and decrease side effects in normal tissues by delivering drugs to the target tissue. Nanoparticle delivery systems have the potential to improve multiple myeloma treatment by increasing specificity and efficacy for example by improving localized concentration in the bone marrow and reducing adverse systemic effects. Furthermore, since orally administered drugs require strict patient compliance, some patient populations can benefit from intermittent dosing and sustained drug release properties. Bone is an advantageous microenvironment for tumor growth in multiple myeloma. Targeting tumor cells within the bone marrow remains a complex challenge due to issues with bone penetration and resistance in the tumor microenvironment.
Aims: Starch is one of the most abundant biomass materials in nature, and is non-toxic, biodegradable, edible, and relatively inexpensive material. The aim of the study was to develop a starch nanoparticle matrix for bone-targeted drug delivery and controlled release of the encapsulated drug for long-acting drug formulations.
Methods: We have previously patented a method for preparing starch nanoparticles (WO2015144983A1) using mechanical high-pressure homogenization at decreased temperatures. The chosen drug pomalidomide was encapsulated inside the starch nanoparticle matrix in situ during the fluidization process. Bone-targeting was achieved by modifying the matrix with alendronic acid. The efficacy of the starch nanoparticle formulations were studied in vitro and in vivo using mouse xenograft models.
Results: In vivo biodistribution of pomalidomide encapsulated with the modified starch nanoparticles showed increased retention and accumulation in the bone microenvironment. A significantly longer survival and decrease in tumor burden was shown when comparing the nanoparticle-delivered pomalidomide with standard oral dosing. Bone strength and volume was additionally improved. Even up to Q3W dosing was achievable using the starch nanoparticle encapsulated pomalidomide.
Summary/Conclusion: The starch nanoparticles offer a simple setup of a bio-based, non-toxic matrix for preparing drug nanoparticles without the use of any toxic chemicals. The present study demonstrates that the modified starch nanoparticles maintained a long-acting therapeutic concentration of pomalidomide and decreased tumor burden in the mouse models. Bone microenvironment targeting was achieved by modifying the nanoparticles in situ. The maximum drug loading capacity of the starch nanoparticle formulations was in the range required for a potential human dosing scheme. The presented method is clinically relevant and holds potential to decrease tumor growth in multiple myeloma.

EP941 KNOCKOUT OF CD96 OR TIGIT USING CRISPR/CAS9 ENHANCES NK INDUCED CYTOTOXICITY AND CYTOKINE PRO DUCTION IN THE PRESENCE OF CD155 EXPRESSING MYELOMA CELLS

J. Daly [1,*], M. Gurney [1], M. O'Dwyer [1]

[1]*Medicine, National University of Ireland, Galway, Galway, Ireland*

Background: Natural Killer (NK) cells are cytotoxic lymphocytes with an innate ability to recognize and destroy malignantly transformed cells. Using an array of activating and inhibitory receptors, cells are screened by NK cells and a net stimulus determines whether the target cell is released or destroyed. CD96 (TACTILE) is an inhibitory receptor expressed by NK cells, and ligand binding studies have shown that CD96 competes with the co-activating receptor DNAM-1 (CD226) for the shared ligand CD155. Blocking CD96 using a monoclonal antibody can reduce metastasis of solid tumours in mouse models. However in human NK cells conflicting data has shown CD96 to be both an activating and inhibitory receptor. Here, we identify CD96 as a human NK cell inhibitory receptor in Multiple Myeloma (MM), with CRISPR/Cas9-mediated KO of CD96 enhancing NK cell cytotoxicity and cytokine release. We conducted these experiments in parallel with CRISPR/Cas9-mediated KO of TIGIT in NK cells, as TIGIT has been documented as an inhibitory receptor, also binding CD155.
Aims: Using CRISPR/Cas9, target and knockout CD96 and TIGIT in expanded primary NK cells (epNK) and study the effect of KO on NK cell cytotoxicity and cytokine release when co-cultured with $CD155^{positive}$ MM cell lines JJN3 and U266
Methods: NK cells were isolated from fresh blood supplied by consenting healthy donors and expanded using NK Macs Medium. NK cells were incubated with either a multi-guide sgRNA-Cas9 complex (KO) or electroporation buffer (Mock) and electroporated using the MaxCyte GT. NK cells were cultured to allow for complete KO. Mock and KO NK cells were co-cultured with JJN3 or U266 MM cell lines at several E:T ratios. MM cell death was measured using the ZOMBIE fixable viability dye. $4x10^5$ Mock and KO NK cells were cultured at a 1:1 E:T ratio with JJN3 and U266 MM cell lines. The supernatant was used to test for the presence of TNF-α and IFN-γ using specific ELISA kits.
Results: Expression of CD155 was observed on a panel of MM cell lines. CD96 and TIGIT expression was observed on epNK cells (CD96:95%±1.45, TIGIT:27.55%±2.8). JJN3 were classed as $CD155^{high}$ and U266 as $CD155^{low}$. Using CRISPR/Cas9, over 90% and 75% KO was observed for CD96 and TIGIT ($p<0.0001$). Enhancements in cytotoxicity were observed by CD96 and TIGIT KO NK cells, compared to Mock controls. Particularly, the strongest enhancements were against the $CD155^{high}$ JJN3 MM cells (Fig.1). While TIGIT KO did not enhance secretion of TNF-α, CD96 KO resulted in a strong increase in TNF-α secretion when CD96 KO NK cells were co-cultured with U266 ($p=0.0011$), no observable change was observed with JJN3. TIGIT KO NK cells secreted significantly more IFN-γ when co-cultured with JJN3 (ns) and U266 ($p=0.0094$), while CD96 KO NK cells secreted more IFN-γ than when co-cultured with both JJN3 (ns) and U266 ($p=0.0012$). NK cells isolated from MM patient bone marrow aspirates were observed to have higher proportion of CD96 positive cells (45.8%±2.75) than NK cells from healthy peripheral blood (24%.16±3.1, $p=0.0043$).

Summary/Conclusion: This study identifies CD96 conclusively as an inhibitory receptor on human NK cells, regulating cytotoxicity and cytokine release which are enhanced upon KO using CRISPR/Cas9. Elevated CD96 expression on NK cells from MM patient bone marrow aspirates suggests that the tumour microenvironment may exaggerate the CD96/CD155 axis to promote immune-evasion of NK cells. In carrying out this research, we also present efficient genetic manipulation of NK cells to eliminate inhibitory receptor expression as a promising approach for personalised cancer treatments.

EP942 INDUCTION OF ELOTUZUMAB'S ADCC ACTIVITY BY TH1-LIKE GAMMA DELTA T CELLS TOWARDS OSTEOCLASTS AS WELL AS MYELOMA CELLS

T. Harada [1,*], Y. Inoue [1], H. Tenshin [2], A. Oda [1], M. Oura [1], K. Sogabe [1], R. Sumitani [3], S. Fujii [3], S. Nakamura [4], H. Miki [5], K. Kagawa [3], M. Hiasa [2], J. Teramachi [6], M. Abe [1]

[1]*Department of Hematology, Endocrinology and Metabolism,* [2]*Department of Orthodontics and Dentofacial Orthopedics, Tokushima University Graduate School of Biomedical Sciences,* [3]*Department of Hematology, Tokushima University Hospital,* [4]*Department of Community Medicine and Medical Science, Tokushima University Graduate School of Biomedical Sciences,* [5]*Division of Transfusion Medicine and Cell Therapy, Tokushima University Hospital, Tokushima,* [6]*Department of Oral Function and Anatomy, Graduate School of Medicine Dentistry and Pharmaceutical Sciences, Okayama, Japan*

Background: Antibody-dependent cellular toxicity (ADCC) is among predominant MOAs of anti-CD38 and anti-SLAMF7 therapeutic monoclonal antibodies (mAbs), which is augmented with IMiDs, lenalidomide (LEN) and pomalidomide (POM). However, effector function of immune cells is attenuated and exhausted in patients with MM, especially after repeated relapses or elderly frail patients, which hampers clinical efficacy of these therapeutic mAbs. To overcome this issue, we have been studying the utilization of γδ T cells for MM treatment. Human γδ T cells are important effectors in the first-line defense against infection and tumors, and we reported that such expanded γδ T cells effectively target and impair not only MM cells but also osteoclasts (OCs) (Cui, et al. IJH 2011) and that LEN and POM are able to activate and expand Th1-like γδ T cells and enhance their cytotoxic activity against MM cells in combination with recombinant phosphoantigens as well as zoledronic acid (Harada et al. Leukemia 2017).
Aims: The present study was undertaken to explore the effects of anti-CD38 and anti-SLAMF7 therapeutic mAbs on cytotoxic activity of the expanded human Th1-like γδ T cells against OCs and MM cells.
Methods: Th1-like γδ T cells were expanded from peripheral blood mononuclear cells (PBMCs) *ex vivo* by aminobisphosphonates in combination with IL-2. OCs were induced from PBMCs or isolated monocytes using M-CSF plus RANK ligand. The suface markes and protein expression were detected by flow cytometry and Western blotting.
Results: The expanded Th1-like γδ T cells highly expressed CD16, FcγRIIIa, together with perforin and granzymeB as well as the cytotoxicity-associated costimulatory molecules NKG2D and DNAX accessory molecule-1 (DNAM-1; CD226), similar to NK cells. The expanded Th1-like γδ T cells exerted direct cytotoxic activity towards OCs as well as MM cells. Addition of the anti-SLAMF7 mAb elotuzumab (ELO) further increased the cytotoxic activity of Th1-like γδ T cells against SLAMF7-expressing MM.1S and OPM-2 cells but not RPMI 8226 cells with marginal SLAMF7 expression, indicating induction of ADCC activity by Th1-like γδ T cells in combination with ELO. Induction of ADCC activity by Th1-like γδ T cells was much more potent with ELO compared to anti-CD38 therapeutic mAbs, daratumumab and isatuximab, suggesting suitability of Th1-like γδ T cells for ADCC induction with ELO. Interestingly, cytotoxic activity of Th1-like γδ T cells against OCs was also augmented in combination with ELO, although ELO alone did not show any cytotoxic activity against OCs, indicating the emergence of ELO's ADCC with Th1-like γδ T cells towards OCs. SLAMF7 expression was induced and robustly upregulated during osteoclastic differentiation from monocytes with M-CSF and RANK ligand, and ELO could target preOCs as well as OCs. MM cells interact with OCs to form vicious cycle between MM cell growth and osteoclastogenesis (Abe, et al. Blood 2004); however, ELO markedly potentiated

the γδ T cell-induced cell death against both MM cells and OCs in their cocultures.
Summary/Conclusion: These results collectively demonstrate that SLAMF7 is highly expressed in both MM cells and OCs, and that OCs as well as MM cells are susceptible to ELO's ADCC with Th1-like γδ T cells. Further study is warranted on ELO's ADCC activity for ambient cells in MM bone marrow and effective revitalization and expansion of Th1-like γδ T cells to make the better use of ELO's ADCC activity.

EP943 PROGRESSION AND DISSEMINATION OF EXPERIMENTAL MULTIPLE MYELOMA IS ASSOCIATED WITH LOSS OF INNATE AND ADAPTIVE IMMUNE-MEDIATED TUMOR CONTROL

Z. Kellermayer [1,*], N. Papazian [1], M. M. E. De Jong [1], C. Fokkema [1], S. Tahri [1], C. Den Hollander [1], P. Sonneveld [1], T. Cupedo [1]

[1]*Hematology, Erasmus MC, Rotterdam, Netherlands*

Background: Multiple myeloma is an incurable plasma cell malignancy and identifying mechanisms driving disease progression is crucial for future development of novel therapies. Immune-mediated control of tumor progression is an important factor in many malignancies, yet the cells and signals that constitute an effective anti-myeloma immune response are incompletely defined.
Aims: To identify immune-related mechanisms of disease progression in experimental multiple myeloma.
Methods: Intravenous transfer of 10^6 5TGM1-GFP murine myeloma cells into KaLwRij mice leads to myeloma development in 3 weeks. In contrast, C57BL/6 mice are reported to be resistant to myeloma development. We used both mouse strains and monitored tumor development through serum M-protein levels. Bone marrow and spleen were harvested to analyze the immune microenvironment and determine tumor dissemination with flow cytometry and histology.
Results: Myeloma was defined by >5% tumor cells in BM, presence of tumor cells in the spleen and detection of M-protein >2 mg/ml. In KaLwRij mice, myeloma developed in 100% (14/14) of mice while C57BL/6 mice did not develop myeloma based on these criteria. Interestingly, 65% (9/14) of C57BL/6 mice presented with myeloma cells in the bone marrow, but with significantly lower tumor load (M-protein 1.1 mg/ml vs. 5.8 mg/ml) compared to KaLwRij mice. This low tumor burden remained stable and was confined to the bone marrow, without any splenic involvement, suggestive of active tumor restraint. To identify the mechanism of successful immunological containment of myeloma cells, we compared the cytotoxic immune response in C57BL/6 and KaLwRij mice. In both murine strains, NK cell activation was apparent, with upregulation of early activation markers such as CD69 in response to tumor presence. In contrast, while activation was accompanied by an increase in NK cell numbers in the C57BL/6 mice, this expansion was absent from KaLwRij mice. Similarly, $CD8^+$ T cell activation and an increase in number of $CD11b^+$ recently activated $CD8^+$ T cells was present in C57BL/6 mice, yet absent from KaLwRij mice.
These data suggest a combined innate and adaptive immune-mediated control of multiple myeloma in C57BL/6 mice. To determine the stability of this immune-mediated control of multiple myeloma we followed C57BL/6 mice injected with 5TGM1 myeloma cells over time while monitoring tumor load through serum M protein. At 6 weeks post injection, 71% (5/7) of the C57BL/6 mice with low tumor load at 3 weeks had developed progressive disease, with serum M protein levels > 2 mg/ml and >5% myeloma cells in the bone marrow. Reassessing cytotoxic immune responses in myeloma-bearing C57BL/6 mice revealed a stark decline in absolute numbers of activated NK cells, very similar to the phenotype in KaLwRij mice. Interestingly, loss of $CD8^+$ T cells was seen in about half (2/5) of the C57BL/6 mice and was associated with loss of bone marrow-containment and the appearance of myeloma cells in the spleen.
Summary/Conclusion: Failure to mount adequate anti-myeloma immune responses is one of the drivers of disease development in KaLwRij mice. Transfer of 5TGM1 myeloma cells in C57BL/6 mice leads to tumor control via expansion of innate and adaptive immune cells. With time, immune-mediated restraint of multiple myeloma fails, exemplified by loss of NK cell and $CD8^+$T cell expansion, culminating in tumor outgrowth and systemic dissemination. This model will allow generation of novel insights into the mechanisms of immune escape by multiple myeloma cells.

EP944 SEA-BCMA, AN ENHANCED ANTIBODY FOR MULTIPLE MYELOMA, COMBINES EFFECTIVELY WITH MULTIPLE THERAPEUTIC MODALITIES

C. Yu [1], K. Klussman [1], M. Anderson [1], C. Henderson [1], S. Hengel [1], M. Ryan [1], H. Van Epps [1,*]

[1]*Seagen, Inc, Bothell, United States*

Background: Despite newly emerging therapies, significant unmet need remains in Multiple Myeloma (MM). Patients require multiple lines of therapy and ultimately succumb to disease. Therapies that are active, but well tolerated are crucial for these patients. Therapeutic antibodies have transformed the MM treatment paradigm, allowing patients to achieve deeper responses with minimal added toxicity, particularly in the therapeutic combination setting. SEA-BCMA is an investigational humanized nonfucosylated IgG1 antibody targeting BCMA, which shows preclinical evidence of encouraging activity and tolerability[1]. Preclinical studies show SEA-BCMA elicits anti-tumor activity through three mechanisms of action: (1) increased binding to FcγRIII through SEA technology leading to enhanced antibody dependent cellular cytotoxicity; (2) engagement of antibody dependent cellular phagocytosis; (3) blockade of the proliferative signals from BCMA ligand binding.
Aims: Here we show the preclinical combination of SEA-BCMA with therapeutics relevant to MM and BCMA targeting
Methods: We tested in vitro and in vivo combinations of SEA-BCMA with daratumumab, IMiDs, ADCs, and gammasecretase inhibitors.
Results: SEA-BCMA combines effectively with daratumumab in preclinical MM tumor xenograft models, creating an opportunity for a well-tolerated, antibody-based combination regimen. We also show increased anti-MM activity when SEA-BCMA is combined with standard of care IMiDs. In addition, SEA-BCMA combines effectively with antibody-drug conjugates in preclinical MM tumor xenografts leading to improved anti-tumor activity and prolonged survival in mice. Lastly, we evaluated SEA-BCMA in combination with gamma secretase inhibitors (GSIs), which block membrane cleavage of BCMA leading to increased membrane BCMA and decreased soluble BCMA[2]. We show here that GSI treatment enhances the SEA-BCMA activity by increasing Fcγ receptor activation and subsequent effector function.
Summary/Conclusion: In summary, SEA-BCMA shows preclinical evidence of combinability with multiple agents. SEA-BCMA is currently enrolling in a Phase 1 clinical trial for relapsed / refractory multiple myeloma (NCT03582033), and ongoing preclinical work supports potential combination strategies for future clinical investigation.

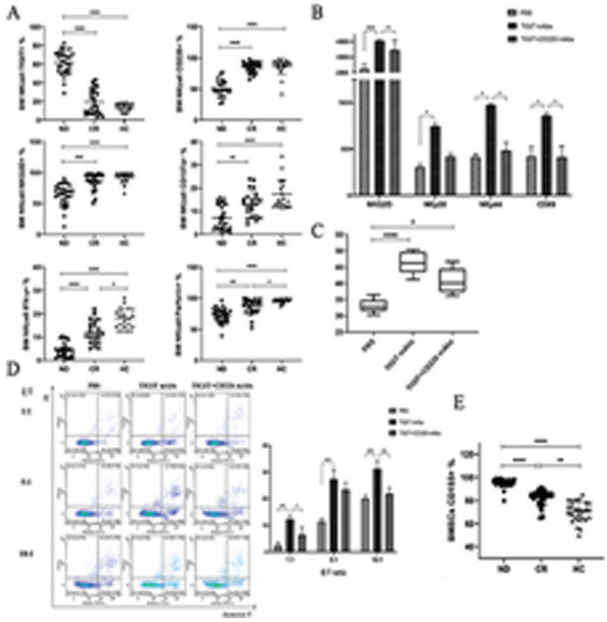
EP945 MELFLUFEN RAPIDLY ACCUMULATES WITHIN TUMOR CELLS AND DISTRIBUTES AN ALKYLATING PAYLOAD TO THE NUCLEUS AND MITOCHONDRIA

S. Haney [1], K. Flanagan [2,*], M. Varney [1], J. Williams [1], V. Rraklli [2], F. Lehmann [2], A. Slipicevic [2], S. Holstein [1]

[1]*University of Nebraska Medical Center, Nebraska, Omaha, NE, United States,* [2]*Oncopeptides AB, Stockholm, Sweden*

Background: Melphalan flufenamide (melflufen) is a novel peptide–drug conjugate that rapidly delivers a cytotoxic alkylating agent into tumor cells. High lipophilicity of melflufen allows for increased cellular uptake, and once inside the cell, aminopeptidases hydrolyze melflufen leading to entrapment and increased concentration of cytotoxic alkylating agents. Previous studies demonstrated that treatment of myeloma cells with melflufen results in significantly higher intracellular concentrations and cytotoxicity than melphalan. In addition to increased intracellular concentration, the increased lipophilicity of melflufen has the potential to contribute to altered intracellular distribution and distinct mechanisms of action.
Aims: The subcellular localization of melflufen and melphalan could have consequences regarding unique mechanisms of action and overcoming resistance mechanisms. Therefore, understanding the subcellular localization patterns of melflufen and melphalan, and the specific effects within organelles, will provide insight into the activity of these agents in myeloma and other tumor cells.



Methods: Using radiolabeled melflufen and melphalan, we directly examined the uptake of melflufen compared to melphalan within the cytosol of the cell, as well as within the nucleus, mitochondria, lysosomes and endoplasmic reticulum (ER). Furthermore, we assessed the effects of melflufen with regard to inducing mitochondrial DNA damage as well as effects on mitochondrial reactive oxygen species, mitochondrial specific gene expression and membrane potential to assess mitochondrial function in response to melflufen and melphalan treatment.
Results: We confirmed the increased cellular uptake of melflufen into the cytosol of myeloma cells, and further established that unlike melphalan, melflufen rapidly accumulated within the nucleus, where DNA alkylators are expected to function. Additionally, we determined that melflufen, but not melphalan, localized significantly within lysosomes, ER, and importantly, mitochondria where resulting effects on mitochondrial stress were analyzed. We also examined mitochondrial expression of specific aminopeptidases with potential to hydrolyze melflufen to deliver the alkylating payload within the mitochondria. Finally, expression of mitochondrial specific gene transcripts was analyzed for effects unique to melflufen treatment resulting from melflufen accumulation.
Summary/Conclusion: The increased lipophilicity of melflufen functions not only to increase tumor cell intracellular exposure, but also redistributes the alkylating payload within the cell which may have implications for additional mechanisms of action, and contribute to overcoming resistance mechanisms.

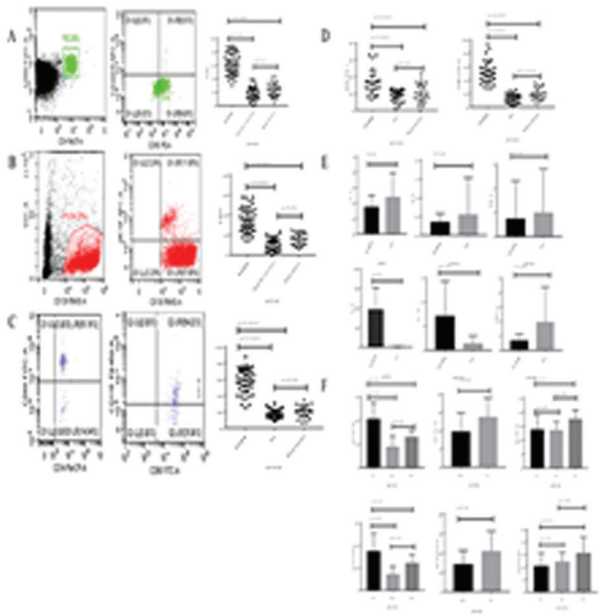
EP946 STUDY OF BONE MARROW MESENCHYMAL STEM CELLS REGULATING NK CELLS FUNCTION THROUGH TIGIT/CD226 IN PATIENTS WITH MULTIPLE MYELOMA

R. Fu [1], L. Deng [1], J. Zhang [1], Z. Liu [1,*], H. Liu [1]

[1]*Tianjin Medical University General Hospital, Tianjin, China*

Background: Bone marrow microenvironment plays a significant supporting role in the proliferation, differentiation, migration, survival and drug resistance of myeloma cells.
Aims: To detect the expression of the co-inhibitory receptor TIGIT and the co-stimulatory receptor CD226 on the surface of natural killer cells (NK cells) in multiple myeloma (MM) patients, and changes in the immune phenotypes and killing function of NK cells. Furthermore, to explore the underlying mechanism of bone marrow mesenchymal stem cells (BMSCs) regulating NK cells function through TIGIT/CD226 in patients with MM.
Methods: 1. The expressions of TIGIT, CD226, activated molecules NKG2D and CD107a and functional molecules IFN-γ and Perforin on the NK cells in bone marrow or peripheral blood were detedted by FCM. 2. BMSCs and NK cells were co-cultured at a ratio of 1:4 in vitro, which was grouped according to different monoclonal antibodies (mAbs) added. After co-cultured, the changes in the expression of NKG2D, NKp30, NKp44 and CD69 of NK cells and IFN-γ concentration were examined by FCM. 3. NK cells and U266 were co-cultured with different E:T ratio and the apoptosis of U266 was detected to evaluate the killing function of NK cells by FCM. 4. The expressions of CD155 on BMSCs and CD138+CD38+cells in the bone marrow were detected by FCM. The correlations between CD155 expression on BMSCs and the production of IFN-γ and Perforin in bone marrow NK cells, as well as clinical characteristics were analyzed.
Results: 1. In bone marrow, expression of TIGIT was significantly higher in patients with NDMM than those in patients with CR and HC (both P values <0.01). CD226 was significantly lower in NDMM patients than those in patients with CR and HC (both P values <0.01). NK cell surface activated molecules NKG2D and CD107a, and functional molecules IFN-γ and Perforin were significantly decreased in NDMM (Fig. A). In peripheral blood, TIGIT, CD226 and above immune phenotype expression levels were basically consistent with the trend in bone marrow. 2. In co-culture experiments of BMSCs and NK cells, only added anti-TIGIT mAbs, compared to both added anti-TIGIT and CD226 mAbs, the immune phenotypes of NK cells significantly increased (Fig. B). And the concentration of IFN-γ in the co-culture supernatants also increased (Fig. C). 3. After co-cultured with BMSCs, NK cells were co-cultured again with U266 in vitro, the apoptosis level of U266 in TIGIT mAbs group increased than those in TIGIT+ CD226 mAbs group at different E: T ratio (Fig. D). 4. The expression of CD155, the ligand of TIGIT and CD226, increased notably on the surface of BMSCs in MM patients(P<0.01) (Fig. E). 5. The expression of CD155 on BMSCs was negatively correlated with the production of IFN-γ and perforin in bone marrow NK cells with NDMM patients. And it has correlation with clinical characteristics including β2-MG, LDH, ALB, Hb, ISS stage and R-ISS stage in patients with MM.

Summary/Conclusion: 1. BMSCs may regulate NK cells through TIGIT/CD226. High expression of TIGIT on NK cells may mediate the inhibitory effect of BMSCs in MM patients. Blocking TIGIT could restore NK cells activation and killing function. 2. CD155, a common ligand of TIGIT and CD226, was overexpressed on BMSCs in NDMM patients. And it has correlation with NK cells function and clinical characteristics, indicating that CD155 maybe involved in the regulation of NK cells function by BMSCs.



EP947 TUMOR ASSOCIATED MACROPHAGES INHIBIT CD8+T CELLS IMMUNE RESPONSES VIA PD-1/PD-L1 PATHWAY IN MULTIPLE MYELOMA

R. Fu [1], J. Zhang [1], Z. Liu [1,*], H. Liu [1]

[1]*Tianjin Medical University General Hospital, Tianjin, China*

Background: Tumor-associated macrophages (TAMs) arise from in situ maturation of recruited circulating monocytes and constitue a significant part of myeloma tumor microenvironment. TAMs maybe contribute to the immune escape of multiple myeloma (MM).
Aims: Our study detected the expression of TAMs, CSF1R on macrophages and CSF1 on myeloma cells in bone marrow, and PD-1 on CD8 + T cells and PD-L1 on TAMs.
Methods: March 2020 to January 2021, 53 newly diagnosed MM patients, 33 remission MM (VGPR and above) patients and 28 healthy controls were selected as observation objects. The expression of TAMs, CSF1R on macrophages and CSF1 on myeloma cells, PD-1 on CD8 + T cells and PD-L1 on TAMswere detected by flow cytometry. Bone marrow mononuclear cells from newly diagnosed MM patients were extracted and cultured into TAMs, and then cocultured with CD8 + T cells to detect the expression of perforin and granzyme B.
Results: 1. The expression of TAMs in NDMM group was significantly higher than remission group (P<0.001) and healthy control group (P<0.05)(Figure A). 2. The expression of CSF1 on CD138+ cells in the NDMM group was higher than the remission group (P<0.0001) and the healthy control group (P<0.05), the difference was statistically significant (Figure B). 3. The expression of CSF1R on macrophages in NDMM group was higher than the remission group (P<0.0001)and healthy control group, and there was no statistical significance between remission group and healthy control group(Figure C). 4. The expression of PD-1 on CD8+ T cells in the NDMM group was significantly higher than that in the remission group (P<0.05) and the healthy control group, but there was no significant difference between the remission group and the healthy control group (P>0.05).The expression of PDL-1 on TAMs in the NDMM group was higher than that in remission group(P<0.01)

and healthy control group (P<0.05) (Figure D). 5. The expression of cytokines in the supernatants of TAMs cultured with mononuclear cells extracted from bone marrow. IL-6 and IL-10 in the NDMM group was significantly higher than that in the healthy control group (both P<0.05). TNF-α in the NDMM group was significantly lower than that in the healthy control group (P<0.05)(Figure E). 6. The expression of functional molecules was detected after coculture of TAMs and CD8+ T cells. CD8+ T cells cultured alone were defined as group A (perforin: 17.82 ±1.887%, granzyme B: 29.82±3.882%). TAMs+CD8+ T cells cocultured alone as group B (perforin: 9.622±056%, granzyme B: 14.91±1.711%). TAMs+CD8+ T cells and PD-1 inhibitor cocultured as group C (perforin: 13.61±1.258%, granzyme B: 20.97±2.5%). TAMs, CSF1R inhibitor and CD8+ T cells were cocultured as group D (perforin: 13.37±0.789%, granzyme B: 25.37±2.297%). TAMs, CSF1R inhibitor, CD8+ T cells and PD-1 inhibitor were cocultured as group E (perforin: 17.42±0.806%, granzyme B: 34.47±3.486%). There were significant differences among three groups of A, B and D (P < 0.05), and between two groups of B and C (both P<0.05), and the difference among the three groups of C, D and E was statistically significant (P<0.05)(Figure F).

Summary/Conclusion: CSF1 combined with CSF1R on the surface of macrophages, recruits macrophages to tumor areas, and promotes the formation of TAMs. TAMs can express PDL-1, bind to PD-1 on the surface of CD8 + T cells, inhibit the function of CTL, and participate in MM immune escape.

EP948 COEXISTENCE OF MYELODYSPLASTIC SYNDROMES (MDS) AND MULTIPLE MYELOMA (MM)

L. Pavlistova [1,2,*], A. Berkova [1,2], L. Lizcova [1], K. Svobodova [1], L. Hodanova [1], D. Vidlakova [1], S. Izakova [1], A. Jonasova [2], I. Spicka [2], J. Straub [2], K. Michalova [1], Z. Zemanova [1]

[1]Center of Oncocytogenomics, Institute of Medical Bichemistry and Laboratory Diagnostics, [2]1st Medical Department, General University Hospital and First Faculty of Medicine, Charles University in Prague, Prague 2, Czech Republic

Background: Myelodysplastic syndromes (MDS) have been described as a complication of chemotherapy with alkylating agents in patients treated for multiple myeloma (MM). However, there are also reports on the extremely rare coincidence of MDS and MM in the absence of preceding chemotherapy or together at the time of diagnosis. The exact causes of the uncommon co-occurrence of *de novo* MM and MDS are not known and therefore further studies are needed. Recurrent chromosomal aberrations are well characterized in both diagnoses and cytogenomic examination is part of the prognostic stratification of patients with MM and MDS as well. In MM, the most common findings are translocations involving the *IgH* gene (14q32), monosomy 13/del(13q), gain of 1q21, and deletion of the *TP53* gene (17p13). In MDS, these are mainly del(5q), monosomy 7/del(7q), trisomy 8 and del(20q). It can be assumed that cases of two distinct clones underlying MDS and MM may often be underdiagnosed.
Aims: The aim of the study was to perform a retrospective analysis of cytogenomic findings in a sufficiently large group of patients with MM, to identify cases with the independent cell clones bearing MM and MDS specific chromosomal aberrations and to assess its frequency and effects on patient survival.
Methods: In the 2004-2020 we examined the karyotype of 1415 patients with MM using a combination of cytogenomic methods. Conventional cytogenetic analysis was performed on bone marrow cells cultivated for 24 hours without stimulation. The presence of the most common MM aberrations in immunofluorescently labeled plasma cells was studied using the cIg-FISH method with locus specific DNA probes for detection of: *IgH* translocations, deletion of *TP53* gene, deletion 13q/monosomy 13 and loss/gain of 1p32/1q21 (Abbott Vysis, Kreatech, MetaSystems). The clonality of aberrations characteristic for MDS was confirmed using I-FISH on the whole bone marrow. Complex karyotypes were analyzed with the mFISH/mBAND method (MetaSystems).
Results: We detected a total of 13 patients with the simultaneous occurrence of independent clones with MM and MDS aberrations (5 males, 8 females with median age 66 years). Using the cIg-FISH method, we proved MM aberrations in 11 of them, in 2 remaining patients no aberrations were detected by specific panel. In nine cases, a myeloid cell clone was detected at repeated cytogenetic examination after the MM therapy [1x del(20q), 2x del(5q), 1x trisomy 8, 1x del(11q), 4x complex karyotype]. The median time to occurrence of myeloid clone was 40.5 months (range 3.5 to 169 months). The malignant MM clone persisted with the onset of secondary MDS in 5/9 cases. In addition, we identified four previously untreated MM patients with clonal aberrations characteristic of MDS at the first cytogenetic examination [2x del(20q), 1x del(7q), 1x del(5q) and trisomy 8]. Eight of 13 patients died 0.3 to 19 months from the occurrence of MDS cell clone (median 7 months).
Summary/Conclusion: We report nine cases of secondary MDS after MM therapy and four untreated patients with rare coincidence of MM and primary MDS. In this study, the finding of MDS specific aberrations was associated with a worsened prognosis. Therefore, especially in longer-treated patients with MM, it is necessary to take into account the risk of the onset of secondary myeloid disease and to focus on these aberrations in cytogenomic analysis.
Supported by RVO-VFN64165 and ProgresQ28/LF1.

EP949 CLINICAL AND PHENOTYPIC FEATURES OF EXTRAMEDULLARY DISEASE IN MULTIPLE MYELOMA PATIENTS: THE POSSIBLE LACK OF CD38 EXPRESSION.

F. Accardi [1,*], L. Notarfranchi [1], C. Mancini [2], E. Martella [1], N. Campanini [2], B. Dalla Palma [1], S. Bonomini [3], G. Sammarelli [1], V. Marchica [1], D. Toscani [1], P. Storti [1], F. Costa [1], J. Burroughs Garcia [1], L. Craviotto [1], N. Giuliani [1]

[1]Department of Medicine and Surgery, University of Parma, [2]Pathology Unit, [3]U.O. Ematologia e CTMO, Azienda Ospedaliero-Universitaria di Parma, Parma, Italy

Background: Extramedullary disease (EMD) is a clinical manifestation of multiple myeloma (MM), characterized by a plasma cell (PC) proliferation outside of the bone marrow (BM). The expression modulation of adhesion molecules, including CD44 and CD56, involved in BM homing, supports clonal PCs migration through the bloodstream. CD38 is a multifunctional transmembrane glycoprotein, expressed by PCs, which also plays a role as adhesion molecule. CD38 is considered a hallmark of MM cells and a therapeutic target for anti-CD38 antibody-based approach, however, CD38 expression profile by extramedullary PCs is still unknown.
Aims: To analyze the clinical and cytogenetic features of EMD patients (pts) with a comparative analysis of phenotypic differences, including CD56, CD44 and CD38 between BM PCs and EMD PCs in order to disclose antigenic changes related to the EMD onset.
Methods: We investigated 22 pts (median age 67 years, range 47 – 76), affected by MM (n°20) and primary PC leukemia (n°2) with a biopsy-proven soft tissue EMD. Clinical data included the type of disease, age at the time of diagnosis and at the time of EMD, myeloma type, ISS stage, cytogenetic abnormalities. The immunostaining from BM and EMD biopsies were scored using a semiquantitative evaluation of the percentage of CD56, CD44 and CD38, on MM cells on a 5-tiered scale (score 0, < 5% positive tumor cells; score 1, 5% to 24% positive tumor

cells; score 2, 25% to 49% positive tumor cells; score 3, 50% to 75% positive tumor cells; score 4, > 75% positive tumor cells).
Results: Three pts presented EMD at diagnosis while 19 pts presented EMD at relapse. The median time to EMD appearance during the relapse phase was 29 months (range 9-201 months). The most frequent MM subtype was light chain MM (41%) followed by IgG and IgA. 35% of the pts presented a high stage (ISS III) and a median LDH value above the normal limit. Overall 15 of 18 (88%) pts with available FISH, showed two or more cytogenetic alterations suggesting a high clonal heterogeneity. The most frequent cytogenetic aberration reported was amp(1q21) (72%), followed by del(13q) (65%), del(1p32) (47%), and hyperdiploidy (24%). Overall, 12 of 22 (55%) pts with EMD developed multiple plasmacytomas. The most common site was soft tissue (muscle, subcutaneous fat) and liver/spleen which represents 42%, of the total EMD followed by lymph nodes (15%). In 41% of the pts, the EMD relapse was dissociated from BM relapse that showed polyclonal plasmacytosis. CD56 showed a high score (3-4) in 5 of 22 (23%) EMD samples and was absent in 14 of 22 (64%) pts. 3 out 13 patients with discordant CD56 expression (18%) showed a strong down-regulation of CD56 in the EMD samples compared to BM. CD44 showed a high score (3-4) in 16 of 20 (80%) EMD samples and was absent in 2 of 20 (10%). Four pts with discordant CD44 expression (27%) showed an up-regulation of CD44 in the EMD samples compared to BM. CD38 had a high immunohistochemical score (3-4) in 16 of 19 BM samples (84%) and in two pts was negative. CD38 was absent (score 0) in 3 of 22 (14%) EMD samples and showed a low score (1-2) in 4 of 22 (16%) patients. Discordant CD38 expression was observed in 26% of samples with a down-regulation of CD38 in the EMD samples compared to BM.
Summary/Conclusion: Our data indicate that discordant expression of CD56, CD44 and CD38 may occur in EMD lesions compared to BM. The possible lack of CD38 expression in EMD was highlighted for the first time and it should be considered for its therapeutic impact.

EP950 INTEGRATIVE APPROACH TO FIND PREDICTIVE MARKERS OF RESPONSE TO DARATUMUMAB IN MULTIPLE MYELOMA

C. Pochard [1,*], H. Charles [1], L. Gabellier [1], L. Fornero [1], N. Robert [2], G. Requirand [2], G. Cartron [1], C. Bret [3], J. Moreaux [2], L. Vincent [1]

[1]Hematology, [2]Laboratory for Monitoring Innovative Therapies, [3]Biological Hematology, CHU Montpellier, Montpellier, France

Background: In newly diagnosed as well as in relapsed/refractory multiple myeloma, the anti CD38 monoclonal antibody daratumumab (Dara) has become essential in the therapeutic arsenal. Unfortunately, a subset of patients is not responding to Dara, or is progressing quickly after initiation of therapy. Different characteristics of the disease can be studied to predict and try to understand those response profiles. In addition to clinical markers, we looked at karyotypic and genomic parameters. We have also used plasma cell phenotyping with multiparametric flow cytometry (MFC) on CD200, CD117, CD56, CD38, CD45 and CD27. In particular, CD200 has been shown to be an independent pejorative prognostic factor for progression-free survival in myeloma patients and could play an important role in immunosuppression and regulation of anti-tumor activity.
Aims: Find clinical, karyotypic, genomic or phenotypic predictive markers of response to daratumumab in multiple myeloma.
Methods: We retrospectively included 97 multiple myeloma patients treated with Dara at Montpellier University Hospital. Standard clinical and therapeutic data were collected for all patients. Transcriptomic data were available in 68% of patients, and cytogenetic data in 47.5% of patients. All the patients had MFC data available before treatment with Dara. We collected the expression of CD200, CD117, CD27, CD45, CD56 and the mean fluorescence intensity of CD38 at diagnosis. Patients who obtained at least a partial response were considered as responders.
Results: The median age at Dara start was 68 years, and 59.8% of patients were responders versus 39.2% non-responders. The majority of patients were treated in monotherapy (48.5%). The Dara was given in combination with lenalidomide in 23.7% of patients, with bortezomib in 15.5%, with pomalidomide in 5.2% and with both lenalidomide and bortezomib in 3.1%. The median number of prior lines of therapy was 3 [0-7]. As expected, response to Dara was significantly associated with longer PFS (P<0.0001) and OS (P<0.0001). Within the various clinical and therapeutic data, the only significant parameter associate to the presence of response in multivariate analysis was the use of Dara in combination (P=0.03). Of note, complex karyotype was significantly associated with the absence of response to Dara, but only in univariate analysis (probably due to small number of events: 7 patients with complex karyotype). Comparing gene expression profiling (GEP) data of responder (n=24) versus non-responder patients (n=12) using GSEA revealed a significant enrichment in inflammatory response genes, genes encoding extracellular matrix and polycomb PRC2 as well as H3K27me3 target genes. Finally, Maxstat analysis of CD200 expression found that an expression of this protein in more than 95% of plasma cells was significantly associated with the absence of response to Dara (Figure). Similarly, expression of CD27 and CD45 were significantly associated with poor response to Dara. We did not find any significant correlation between Dara response and CD117 expression, CD56 expression nor CD38 mean fluorescence intensity (all patients were CD38 positive).

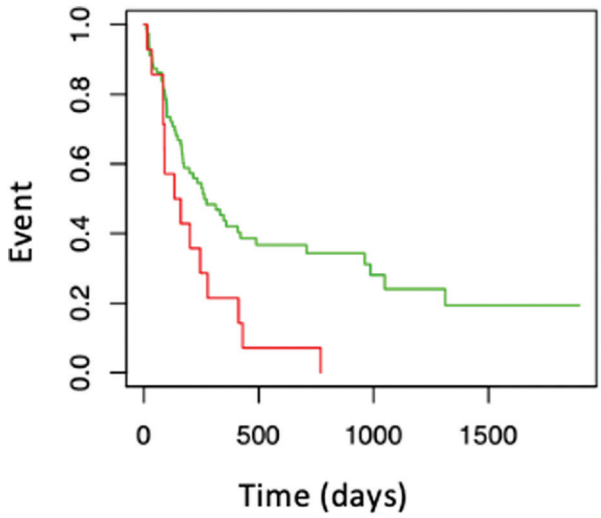


Figure 1: Expression of CD200 according to the response to daratumumab, in red: CD200 > 95%, and in green:CD200 ≤ 95%. P=0.008

Summary/Conclusion: Overall, our data seem to show that low expression of the checkpoint inhibitor CD200 and enrichment in inflammatory response genes expression is associated with good response to Dara. Further work is ongoing to understand the underlying mechanisms and to determine whether phenotypic or gene expression data could be used as predictive markers of response to Dara.

EP951 ALKBH5 PROMOTES THE PATHOGENESIS OF MULTIPLE MYELOMA THROUGH REGULATING LNCRNA SNHG15

Y. Lan [1], Y. Hua [1], T. Yao [1], L. Tingting [1], W. Qiuling [1,*]

[1]Institute of Hematology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, wuhan, China

Background: Our previous results indicated that the demethylase of RNA N-6 methylation (m6A) modification, ALKBH5, played an oncogenic role in multiple myeloma via modulating HIPPO pathway(the results have not yet been published). While latest researches have also showed m6A modification on non-coding RNAs. Besides, the interaction between m6A RNA and histone modifications have arouse the researchers' interest. Here we find that ALKBH5 demethylases the long non-coding RNA (lncRNA)-small nucleolar RNA host gene 15 (SNHG15) and positively regulates its expression. Further experiments also disclose that ALKBH5 may alter the H3K36me3 level and promotes the pathogenesis

of multiple myeloma through regulating lncRNA SNHG15 m6A and RNA expression.
Aims: We aim to further display the potential epigenetic mechanisms between ALKBH5, ncRNA and histone modification involved in the progression of MM
Methods: The expression of SNHG15 and SETD2 were detected by RT-qPCR and western blot. ALKBH5-siRNA lentivirus and NC were transfected into MM cells to knockdown ALKBH5 gene. SNHG15-siRNA lentivirus, SNHG15-cNDA lentivirus and NC were transfected into MM cells to knockdown and knockin SNHG15 gene. MeRIP-seq was previously accomplished (the results have not yet been published). CCK8 assays were performed to determine the proliferation of myeloma cells. Flow cytometry assays were performed to determine the apoptosis of myeloma cells. Transwell assays were performed to determine the migration of myeloma cells.
Results: 1. MeRIP-qPCR reveals that the m6A level of lncRNA SNHG15 is increased after ALKBH5 knockdown. RT-qPCR finds that the expression of lncRNA SNHG15 is increased and decreased after ALKBH5 knockin and knockdown. 2. Through overexpressing lncRNA SNHG15 in MM PMI8226 ALKBH5$^-$ cells, we established the in vitro compensated model (marked control, ALKBH5$^-$ and ALKBH5$^-$SNHG15$^+$ group). CCK8 assays show that lncRNA SNHG15 rescues the inhibited cell proliferation caused by ALKBH5 knockdown. Transwell assays display that lncRNA SNHG15 compensates the suppressed cell migration caused by ALKBH5 knockdown. And flow cytometry assays show that the rate of cell apoptosis in ALKBH5$^-$SNHG15$^+$ group RPMI8226 cells is lower in ALKBH5$^-$ group RPMI8226 cells. 3. RT-qPCR shows that lncRNA SNHG15 is upregulated in primary MM cells (cells from the bone marrow of MM patients sorted by CD138 antibody beads) and MM cell lines (RPMI8226, NCL- H929,U266, MM1R, MM1S and ARH-77 cells). After downregulation of lncRNA SNHG15 by SNHG15-siRNA lentivirus in RPMI8226 cells, the proliferation of SNHG15$^-$ group PMI8226 cells is decreased. 4. Western blot analysis reveals the expression changes of histone H3K36me3 methyltransferase SETD2 among control, ALKBH5$^-$, ALKBH5$^-$SNHG15$^+$ group MM RPMI8226 cells.
Summary/Conclusion: The RNA m6A demethylase ALKBH5 acts on lncRNA SNHG15 in multiple myeloma and positively regulates its expression. The overexpression of SNHG15 in ALKBH5$^-$ cells rescued the inhibited cell proliferation, the suppressed cell migration, and the accelerated cell apoptosis caused by ALKBH5 knockdown. LncRNA SNHG15 was highly expressed in CD138 + plasma cells from MM Patients and MM cell lines. LncRNA SNHG15 positively regulates MM cells proliferation. ALKBH5 regulates histone modification through lncRNA SNHG15.

EP952 INTESTINAL MICROBIOTA AS A PROGNOSTIC BIOMARKER IN MULTIPLE MYELOMA

A. García [1,*], M. L. Morales [1], P. Justo [1], M. Nieto [1], C. Cuéllar [1], J. Sánchez-Pina [1], J. Martínez-López# [1], M. Linares# [1,2]

[1]Translational Hematology, Fundación Investigación Biomédica Hospital 12 de Octubre, [2]Department of Biochemistry and Molecular Biology, Universidad Complutense de Madrid, Madrid, Spain

Background: There is an increasing evidence that the gut microbiota exerts an influence on the immune system, inflammatory mechanisms, and the tumor microenvironment. The presence of these microorganisms and their activity could have an impact on immune cells and the bone marrow, playing an important role in the origin and development of multiple myeloma (MM).
Aims: In this work we explore which microorganisms of the intestinal microbiota could be imbalanced in monoclonal gammopathies and their possible role in the development of multiple myeloma.
Methods: 22 stool samples from patients with monoclonal gammopathy of undetermined significance (MGUS) (n = 8), and multiple myeloma at diagnosis (MM) (n = 9) and in complete remission (CR) (n = 5, 3 of them paired with their diagnostic samples). Furthermore, healthy patients (n = 5) whose median age and gender ratio were similar to that of the patients were included as controls. After the extraction of the microbial DNA with the Qiagen AllPrep® PowerFecal® DNA / RNA kit, the ribosomal subunit of the bacterial 16S gene was sequenced using the Quick-16S ™ NGS Library Prep Kit (Zymo Research) for library generation. After sequencing on the Illumina® MiSeq ™, bioinformatic analysis and quantification of absolute abundance were carried out.
Results: The absolute abundance of bacterial 16 rRNA was decreased in patients with gammopathies (1A). The abundance levels of Saccharibacteria and Betaproteobacteria classes was increased in patients with MGUS and MM. Moreover, there was a significant increase in MM compared to MGUS patients in the Betaproteobacteria class and the *Lachnoclostridium sp32445* specie. By contrast, the abundance of the specie *Intestinibacter barletti* was higher in MGUS compared to MM patients (Fig. 1B). When comparing the paired samples, it was observed that an increase in the microorganisms of Fibrobacteria class and Prevotellaceae family upon reaching complete remission, contrary to *Bacteroides doreii* specie, which was increased at the diagnosis moment (1C).

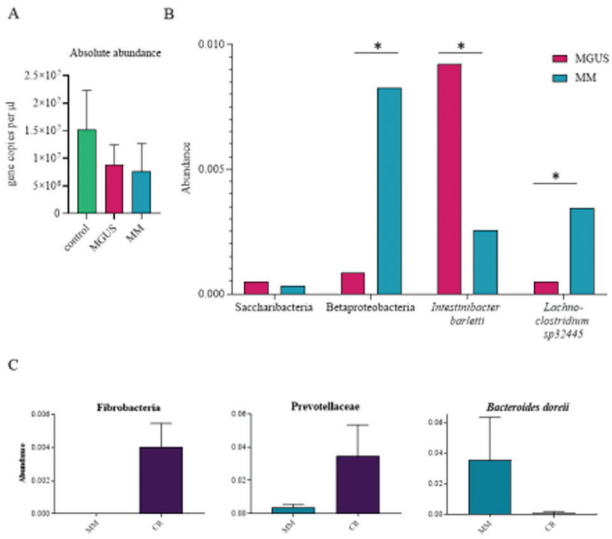

Figura 1. (A) Absolute abundance of bacterial 16S rRNA in control, monoclonal gammopathy of undetermined significance (MGUS) and multiple myeloma (MM) patients. **(B)** Abundance levels of Betaproteobacteria and Sacharibacteria classes and *Intestinibacter barletti* y *Lacnoclostridium sp32445* species in control, MGUS and MM patients. **(C)** Abundance levels of Fibrobacteria class, Prevotellacea family and *Bacteroides dorei* specie in paired in MM at diagnosis and at complete remission in paired patients.

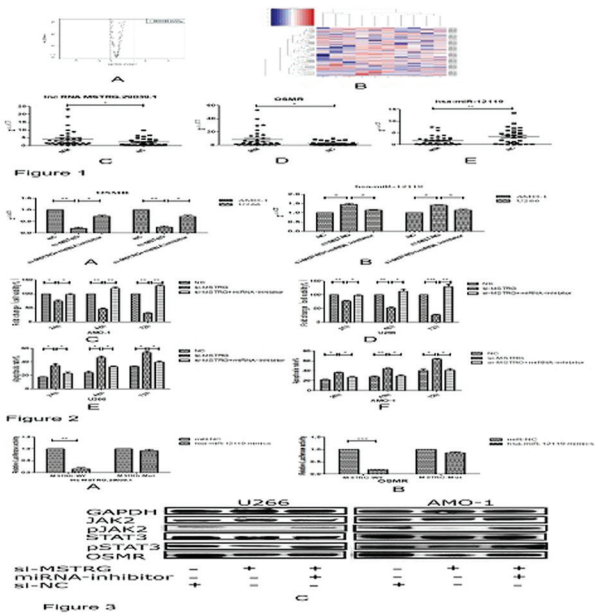
Summary/Conclusion: The level of abundance of the microorganisms studied shows differences between the groups of MGUS and MM patients at diagnosis compared to controls, as well as in MM patients between at diagnosis and at RC moments. This study suggests that the analysis of the intestinal microbiota in patients with monoclonal gammopathies could be of prognostic utility.



EP953 LNCRNA MSTRG.29039.1 PROMOTES PROLIFERATION BY SPONGING HSA-MIR-12119 VIA JAK2/STAT3 PATHWAY IN MULTIPLE MYELOMA

R. Fu [1], M. Han [1], Z. Liu [1,*], H. Liu [1]

[1]Tianjin Medical University General Hospital, Tianjin, China

Background: lncRNA is involved in the occurrence, development, metastasis and drug resistance of tumors, and involves a variety of biological functions. In addition, miRNA can regulate proliferation, migration, and even regulate epigenetics to promote the development of MM. However, the mechanism of ncRNA involved in MM is still unclear, and there are many unknown ncRNAs to be explored. Recently, there are more and more researches on the pathogenesis of various tumors with competitive endogenous RNA (ceRNA). ceRNA refers to transcripts that have a common miRNA binding site (MRE) and regulate each other at the post-transcriptional level,which could be used as a potential targeted drug to inhibit tumors. However, how ceRNA plays a role in multiple myeloma (MM) and the mechanism of action of specific ceRNA in the occurrence and development of MM is not fully clear.
Aims: This research aims to discover unknown ncRNAs in MM through high-throughput sequencing, and to study the mechanism and role of ceRNA involved in the pathogenesis of MM for the development of novel molecular markers and potential new targeted drugs.

Methods: In this study, the differentially expressed lncRNA and its target genes were analyzed to predict the lncRNA-miRNA-mRNA interaction pathway though high-throughput sequencing from 8 MM patients and 2 healthy controls. After verifying differential lncRNA and target genes by RT-PCR, lncRNA MSTRG.29039.1 was screened out. We knocked down the expression of MSTRG.29039.1 in MM cell lines by siRNA, detected proliferation by CCK8 as well as apoptosis level by FCM. Besides, we knocked down the miRNA for rescue experiment. The role of OSMR pathway JAK2/STAT3 was verified by Western blot.
Results: 262 new lncRNAs were screened by RNA sequencing with statistical differences, 203 were up-regulated and 59 were down-regulated, revealing the characteristics of 63 target genes that were highly expressed in 8 MM patients(Figure1.A B). According to the function and novelty of the target genes and the expression of lncRNA in MM, we screened out lncRNA MSTRG.29039.1, and verified that it and its target gene OSMR were highly expressed in MM(Figure1. C D), while the miRNA hsa-miR-12119 was low level in MM(Figure1.E). After knockdown of MSTRG.29039.1 in AMO-1 and U266 MM cell lines, the expression of OSMR was decreased, and the expression of hsa-miR-12119 was up-regulated, which can also promote cell apoptosis and inhibit proliferation. Then,we knocked down hsa-miR-12119 as well as knocked down MSTRG.29039.1 and found that apoptosis was reduced and cell proliferation increased(Figure2.A-F). We further found that MSTRG.29039.1 and OSMR have a common miRNA binding site, and the direct binding relationship was verified by dual-luciferase reporter assay system(Figure3.A-B). Thus, MSTRG.29039.1 can spangy miRNA to counteract the inhibitory effect of miRNA on OSMR. We found that OSMR regulates cell proliferation and apoptosis through the JAK2/STAT3 pathway by Western blot(Figure3.C).

Summary/Conclusion: Knockdown of MSTRG.29039.1 could reduce the expression of OSMR to promote apoptosis and inhibit cell proliferation though JAK2/STAT3 pathway, while knockdown of hsa-miR-12119 at the same time could counteract the above phenomenon. This can be a molecular marker and potential therapeutic target for MM.

EP954 DYSREGULATED EXOSOMAL MICRORNA EXPRESSION IN BONE MARROW MICROENVIRONMENT OF MULTIPLE MYELOMA, EXTRAMEDULLARY MULTIPLE MYELOMA AND PLASMA CELL LEUKEMIA

J. Gregorová [1,*], M. Žárská [1], M. Vlachová [1], L. Radová [2], L. Brožová [3], J. Jarkovský [3], R. Bezděková [4], L. Říhová [4], M. Almáši [4], M. Štork [5], L. Pour [5], J. Minařík [6], R. Hájek [7], S. Ševčíková [1,4]

[1]Department of Pathophysiology, [2]Ceitec, [3]Institute od Biostatistics and Analyses, Masaryk University, [4]Department of clinical hematology, [5]Department of Internal Medicine, University Hospital Brno, Brno, [6]Department od Hemato-Oncology, University Hospital Olomouc, Olomouc, [7]Department of Hematooncology, University Hospital Ostrava, Ostrava, Czech Republic

Background: Multiple myeloma (MM) is a heterogeneous plasma cell (PC) malignancy. These malignant PC are dependent on the bone marrow (BM) microenvironment. However, a subclone of PCs can escape the BM microenvironment and infiltrate soft tissues and organs in the so-called extramedullary myeloma (EM). This subclone may also escape to peripheral blood; if there are more than 20% of circulating PC (cPC), the disease is reclassified as plasma cell leukemia (PCL).
All cells of the BM microenvironment release exosomes. Exosomes are small membranous vesicles that originate from internal multivesicular bodies; they are found in all body fluids, including peripheral blood, breast milk, etc. Exosomes are important in intercellular communication, and they have been implicated in disease relapse, resistance to chemotherapy and many other processes important for tumorigenesis. They contain proteins and nucleic acids, such as microRNAs (miRNAs) - short non-coding RNA molecules that are involved in many physiological and pathological processes.
Aims: The aim of this work was to analyze expression of exosomal miRNAs in BM plasma samples of MM, EM and PCL patients.
Methods: Exosomes were isolated using qEV columns. MiRNAs were isolated from exosomes using qEV original Size Exclusion Columns, following miRNA isolation using miRNeasy Micro Kit. For next generation sequencing (NGS), 8 MM, 7 EM and 8 PCL samples were used. Results from NGS were validated on 40 MM, 25 EM and 21 PCL samples by RT-qPCR using Taqman Advanced MiRNA Assays.
Results: NGS analysis showed 1128 different miRNAs that were present in analyzed samples. Out of these, 239 miRNAs were found in at least 8 samples and had more than 1 read per million; thus, they were included in subsequent analysis. Out of these miRNAs, there are 6 miRNAs (miR-140-3p, miR-584-5p, miR-744-5p, miR-223-3p, miR-191-5p and miR-151a-3p) ($p<0.05$) that are significantly dysregulated between MM, EM and PCL patients. Furthermore, 11 miRNAs ($p<0.05$) were significantly dysregulated between MM and EM patients, 4 miRNAs ($p<0.10$) between MM and PCL patients and 7 miRNAs ($p<0.05$) between PCL and MM patients. After validation, we performed ROC analysis for sensitivity and specificity of these miRNAs.
Summary/Conclusion: Using NGS, we showed that they are differentially expressed exosomal miRNAs between MM, EM and PCL patients suggesting their role in pathogenesis of individual diseases.

EP955 LACK OF CD56 AS A POOR PROGNOSTIC MARKER IN PATIENTS WITH MULTIPLE MYELOMA

E. Koumpis [1,*], T. Malea [1], I. Tassi [1], K. Papathanasiou [1], I. Papakonstantinou [1], A. Serpanou [1], E. Tsolas [1], E. Kapsali [1], A. Papoudou-Bai [2], E. Hatzimichael [1]

[1]Department of Haematology, [2]Department of Pathology, Faculty of Medicine, School of Health Sciences, University of Ioannina, Ioannina, Greece

Background: CD56 or neural cell adhesion molecule (NCAM) is a membrane glycoprotein expressed on neural cells, muscle tissues and myeloma cells. Expression of CD56 has been studied in patients with multiple myeloma (MM), however with controversial results.
Aims: The scope of this study was to examine the expression of CD56 and investigate its association with clinicopathologic parameters.
Methods: We retrospectively collected and analyzed data from 109 patients with MM diagnosed over the last decade (January 2010 to June 2020). We assessed the expression of CD56 in bone marrow biopsies with immunohistochemistry and investigated its association with a variety of clinicopathological parameters. For the statistical analysis χ^2 test and Mann-Whitney U test were used to compare categorical and continues valuables in $CD56^+$ and $CD56^-$ patients, respectively. Statistical analysis was performed using SPSS 21.0 for Windows (SPSS, Chicago, IL).
Results: We assessed 109 patients with MM; Based on the expression of CD56 the patient population was divided to $CD56^+$patients and $CD56^-$ patients; Sixty-eight patients were CD56+ and 41 patients were CD56-. The median age at diagnosis of MM was 70 years in CD56+ patients and 72 years in CD56- patients (p=0.7). Lack of CD56 expression was associated with unfavorable prognostic parameters such as elevated lactate dehydrogenase (LDH) and β2-microglobulin levels, advanced stage in International Staging System (ISS) and clonal bone marrow plasma cell percentage ≥ 60%, while the expression of CD56 was associated with good differentiation of neoplastic plasma cells. The clinical and

biological parameters of the patients at the time of diagnosis of MM are presented in Table 1.

Characteristic	CD56 +	CD56 -	p-value (χ^2)
Age of diagnosis >65	47/68 (69,1%)	26/41 (63.4%)	0.69
Hemoglobin<10 g/dl	12/68 (17,6%)	12/41 (29.3%)	0.24
eGFR<40 mL/min/1.73m²	14/68 (20,6%)	10/41 (24.4%)	0.82
Increased LDH	16/68 (23.5%)	21/41 (51.2%)	0.006
Serum Ca^{2+} >11 mg/dL	10/67 (14,9%)	8/41 (19.5%)	0.72
β2-microglobulin (>5.5 mg/L)	9/63 (14,3%)	15/40 (37.5%)	0.013
Bone lytic lesions	37/65 (56.9%)	19/37 (51.4%)	0.74
Stage III (ISS)	10/63 (15.9%)	14/40 (35%)	0.046
SPEP M protein	48/66 (72.7%)	31/41 (75.6%)	0.92
Bence Jones Protein	26/48 (54.2%)	15/31 (48.4%)	0.79
Clonal bone marrow plasma cell infiltration >60%	26/68 (38.2%)	27/41 (65.9%)	0.009
Mature type neoplastic plasma cells	50/68 (73.5%)	21/40 (52.5%)	0.044

Table 1: Clinical and biological characteristics of patients with newly diagnosed multiple myeloma and their association with the expression of CD56. e-GFR: estimated Glomerular Filtration Rate, LDH: lactate dehydrogenase, SPEP: Serum protein electrophoresis

Summary/Conclusion: Our study confirmed that CD56 is a possible marker of poor prognosis in patients with MM. The measurement of expression of CD56 via either immunohistochemistry or flow cytometry is simple and cheap, and it could be incorporated in future prognostic or predictive scores. Prospective studies are needed in order to evaluate the role of expression of CD56 as a predictive biomarker in the era of novel regimens.

EP956 TRANSCRIPTOMIC ANALYSIS IDENTIFIED GENE CO-EXPRESSION AND CORRELATION WITH MULTIPLE MYELOMA PROGRESSION.

O. Adebayo [1,2,*], L. Boise [3], J. W. Lillard [4]

[1]Morehouse School of Medicine, Atlanta, GA, Morehouse School of Medicine, Atlanta, GA, Atlanta, [2]Windship cancer institute, [3]Medical Oncology Department, Emory University School of Medicine, Atlanta, GA 30322, USA, [4]Microbiology, Biochemistry and Immunology, Morehouse School of Medicine,Atlanta, GA 30310, Atlanta,, United States

Background: There is a gap in our understanding of the molecular mechanisms behind the chemoresistance seen in early multiple myeloma (MM) patients who receive standard treatment (i.e. Lenalidomide/revlimid, Bortezomib/velcade, and Dexamethasone (RVD)). The reason for the relatively high percentage of patients that progress after early RVD treatment is unknown. Therefore, the identification of clinically relevant clusters of co-expressed genes or biomarkers for MM progression in patients on RVD treatment would help identify novel mechanisms, drug targets, and prognostic markers.
Aims: Aim 1 will establish the clinical significance of BDKRB1, and associated genes co-expressed during MM progression.
Aim 2 will determine the molecular mechanisms by which bradykinin-BDKRB1 signaling affects MM cell growth and chemoresistance.
Methods: In this project, we employed a transcriptomic analysis approach to identify hub genes that correlate with MM progression and RVD chemoresistance. One of the most significantly expressed hub genes identified was the bradykinin receptor B1 (BDKRB1) gene, a G protein-coupled receptor. BDKRB1-signaling has been demonstrated in cell adhesion, signal transduction, and calcium flux, all of which can promote MM progression. The specific role of BDKRB1 in MM is undefined; therefore, an understanding of the molecular mechanisms mediated by BDKRB1 interactions in MM patients is urgently needed. To this end, we investigated the gene expression profiles and their correlation with MM clinical outcomes, using a novel weighted gene network co-expression analysis (WGCNA) method.
Results: WGCNA constructed 21 modules using the MMRF COMMpass dataset (n = 175) based on gene co-expression correlations between RVD treatment and age at diagnosis and/or death. The grey60 module contained BDKRB1 and 247 other upregulated co-expressed genes, which were significantly and positively correlated (p < 9.7E-07, R^2 =0.38) with MM progression following initial RVD treatment. The top biological processes associated with this module include the G protein-coupled receptor protein signaling pathway, calcium influx, inflammatory response, regulation of growth, and biological adhesion. Notably, gene expression driven by NF-Kβ is known to be activated by the bradykinin-BDKRB1 signaling axis, which significantly correlates with the lethal molecular subset of MM, MM proliferation and patient survival. The receiver operator characteristic (ROC) curve analysis predicted BDKRB1 as a statistically significant biomarker for MM progression (*p-values=0.00016*).
Summary/Conclusion: Our preliminary studies showed BDKRB1-signaling networks are significantly co-expressed and associated with MM progression. This is the first study to identify BDKRB1-associated gene networks and analyze their potential impact on MM progression. BDKRB1 is highly expressed in African Americans. AA is known to be 3 to 4-fold more likely to develop MM. Hence, the completion of my projects may shed new light on the impact of bradykinin-BDKRB1 signaling in MM progression, and RVD chemoresistance, and MM health disparities

EP957 THE ADIPONECTIN RECEPTOR AGONIST, ADIPORON, EXERTS ANTIPROLIFERATIVE AND PRO-APOPTOTIC EFFECTS THROUGH THE REGULATION OF ADIPORS/AMPK/ACC PATHWAY ON HUMAN MULTIPLE MYELOMA CELLS

J. Zhang [1,2,*], Y.-J. Wang [1,2], X.-T. Su [1,2], Y.-Q. Han# [1,2]

[1]Hematology department, The Affiliated Hospital of Inner Mongolia Medical University, Hohhot, [2]National Clinical Research Center for Hematologic Diseases, the First Affiliated Hospital of Soochow University, Soochow, China

Background: Multiple myeloma (MM) represents approximately 10 % of all blood tumors, which is characterized by abnormally uncontrolled clonal expansion of malignant plasma cells within the bone marrow. Despite advances in multimodal treatment regiments, it remains an incurable and fatal malignancy. Obesity has been implicated as a risk factor in multiple myeloma, but the specific biologic mechanisms have not yet been fully elucidated. As is reported, obesity might in part mediate its effects on myeloma cells via interaction with adipokines. Adiponectin is one of the most abundant and well-understood adipokines, and has been implicated as a protective character in the development of MM, according to its potent role in insulin-sensitizing, anti-lipotoxic, anti-apoptotic and anti-inflammatory properties. Hypoadiponectin was correlated with an increased risk in MM and in vitro study has confirmed that adiponectin could induce anti-proliferation and pro-apoptosis in MM cells, suggesting a promising therapeutic target in MM. However, the complex quaternary structure and rapid turnover may add to the difficulty in converting adiponectin to an applicable drug form, which pose a limitation in the use of adiponectin. AdipoRon was capable of binding and activating both adiponectin receptor 1(AdipoR1) and adiponectin receptor 2(AdipoR2) at a low micromolar concentration. Nevertheless, there is little data focusing on the roles of AdipoRon in MM cells.
Aims: To investigate the effects of AdipoRon on MM cells and the potential functional and molecular mechanisms.
Methods: We use the small-molecule agonist, AdipoRon, to treat the two MM cell lines: U266 and RPMI8226. The cell proliferation was detected by CCK-8. The early apoptosis and cell cycle were analyzed by flow cytometry. A real-time quantitative(RT-PCR) and western blot were used to determine the transcript and protein levels of potential signaling pathways.
Results: The western blot assay showed that both AdipoR1 and AdipoR2 were available in the two cell lines. The CCK-8 test indicated that AdipoRon significantly reduced the proliferation of MM cells with an increase concentration at a certain range. Moreover, at the same concentration, AdipoRon gradually suppressed the proliferation of MM cells with prolongation of exposure time. Flow cytometry results showed both the U266 and RPMI8226 cells were arrested in the G0/G1 phase and with fewer cells present in the S phase. Additionally, AdipoRon promoted apoptosis in the U266 and RPMI8226 cells, with up-regulation of cleaved-PARP and cleaved-Caspase-3. Molecular analysis further demonstrated that the phosphorylation of AMPK was strengthened gradually in AdipoRon-treated MM cells over time, while the phosphorylation of ACC decreased. Moreover, we found that CPT1A and ACC2 were up-regulated in AdipoRon-treated U266 cells.

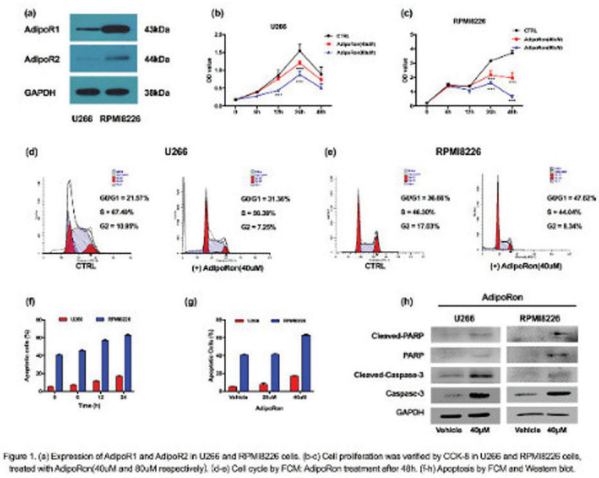


Figure 1. (a) Expression of AdipoR1 and AdipoR2 in U266 and RPMI8226 cells. (b-c) Cell proliferation was verified by CCK-8 in U266 and RPMI8226 cells, treated with AdipoRon(40uM and 80uM respectively). (d-e) Cell cycle by FCM: AdipoRon treatment after 48h. (f-h) Apoptosis by FCM and Western blot.

Summary/Conclusion: Our results demonstrated that the adiponectin receptor agonist, AdipoRon, suppressed the proliferation, induced apoptosis and cell arrest in U266 and RPMI8226 cells in a time- and dose-manner, possibly via regulation of AMPK/ACC pathway. Additionally, the abnormal up-regulation of metabolism-related gene ACC2 and CPT1A suggested that an imbalance of energy metabolism might participated in the regulation of AdipoRon on MM cells.

EP958 DECIPHERING CLINICAL IMPLICATION OF DYSREGULATED SERUM MICRORNAS IN NEWLY DIAGNOSED MULTIPLE MYELOMA: A RESULT OF COMPREHENSIVE MICRORNA PROFILING BY DEEP SEQUENCING

H. Sriram [1,2,*], T. Khanka [1,2], S. Ghoghale [1,2], N. Deshpande [1,2], S. Shah [3], S. Sharma [3], A. Chatterjee [3], G. Chatterjee [1,2], P. Amare [2,4], N. Inamdar [2,5], A. Gokarn [2,6], S. [1]Hematopathology Laboratory, Tata Memorial Centre, [2]Homi Bhabha National Institute, [3]HaystackAnalytics, [4]Laboratory of Cytogenetics, [5]Department of Biochemistry, [6]Department of Medical Oncology, [7]Cell and Tumor Biology Group, Tata Memorial Centre, Mumbai, India

Background: Multiple myeloma (MM) is an incurable plasma cell (PC) malignancy with genetic heterogeneity and variable therapeutic outcome. Despite the availability of several prognostic markers, treatment failure remains an unpredictable challenge in MM. Recent studies have identified serum/plasma-microRNA as a clinically relevant biomarker in many malignancies, including MM. The prognostic impact of serum miRNAs has been studied in MM. However, its role in the prediction of therapeutic response is still unknown. We studied serum-microRNA profiling by deep-sequencing in newly diagnosed-MM (NDMM) and evaluated its clinical utility.
Aims: To study the expression profile of plasma/serum microRNAs and identify clinically relevant dysregulated microRNAs.
Methods: The study cohort included **65-NDMM** (age range, 27-74; median-54 years) treated with Bortezomib-based therapy and could not be treated with autologous stem cell transplant due to various reasons as well as **10 age-matched controls**. Serum/plasma microRNAs profiling was performed by **deep sequencing** on BGISEQ-500 platform in diagnostic samples. The **initial therapeutic response** was monitored at the end of 4 and 8 cycles of Bortezomib-based therapy. The standard prognostication, including ISS staging, cytogenetics, and clonal-PCs assessment in bone marrow samples by flow cytometry, was performed.
Results: RNA-seq data analysis identified a total of 1098 microRNA. **Differential expression analysis** revealed 37 microRNA dysregulated in MM (fold change≥2, p-adjusted<0.05), greater majority being up-regulated (31/37). 14/37 have been previously reported in MM pathogenesis. Top dysregulated microRNAs (Log_2 fold change≥4, p-adjusted<0.05) included hsa-miR-92b-5p/hsa-miR-4775/hsa-miR-642a-5p/hsa-miR-103a-2-5p/hsa-miR-296-5p/hsa-miR-4665-5p/hsa-miR-4772-3p/hsa-miR-214-3p/hsa-miR-370-5p/hsa-miR-185-3p/hsa-miR-769-5p/hsa-miR-365a-3p/hsa-miR-365b-3p/hsa-miR-6843-3p. Among them, **hsa-miR-629-3p** was found significantly associated with **poor initial therapeutic response**. Additionally, hsa-miR-103a-2-5p, hsa-miR-296-5p, hsa-miR-4772-3p, hsa-let-7i-3p, hsa-miR-148a-3p and hsa-miR-328-3p are significantly associated with an increased (>95%) clonal PCs; hsa-miR-103a-2-5p, hsa-miR-625-3p, hsa-miR-342-3p, hsa-miR-532-3p and hsa-miR-625-3p demonstrated significant association with the ISS-stage-I and III. We also found a strong association of hsa-miR-103a-2-5p, hsa-miR-199a-3p and hsa-miR-204-5p with chromosome 17p deletion.
Summary/Conclusion: We have identified **37 dysregulated serum-microRNA** specific to and targeting functionally relevant pathways in MM, including p53-mediated signaling and proteasome-mediated processes. We, for the first-time report an association of hsa-miR-629-3p upregulation with poor initial response to Bortezomib-based therapy. We also report unique miRNAs associated with patients with high tumor burden MM (clonal-PC>95%). Thus, in addition to **prognostication and risk stratification,** our data demonstrated the value of serum microRNAs in **predicting initial response** to Bortezomib-based treatment in NDMM.

EP959 THE CLINICAL UTILITY OF A PLASMA MIRNA SIGNATURE IN MULTIPLE MYELOMA BONE DISEASE

A.-M. Papanota [1,*], P.-I. Tsiakanikas [2], C. K. Kontos [2], P. Malandrakis [1], C. Liacos [1], I. Ntanasis-Stathopoulos [1], N. Kanellias [1], M. Gavriatopoulou [1], E. Kastritis [1], M. Avgeris [2], M.-A. Dimopoulos [1], A. Scorilas [2], E. Terpos [1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, [2]Department of Biochemistry and Molecular Biology, Faculty of Biology, National and Kapodistrian University of Athens, Athens, Greece

Background: Multiple myeloma bone disease (MMBD) affects approximately 80% of newly diagnosed multiple myeloma (MM) patients and is associated with poor quality of life and worse survival. The pathophysiology of MMBD is complex and results from deregulation of bone remodeling. MicroRNAs (miRNAs) are small non-coding RNAs that regulate gene expression at post-transcriptional and/or translational level. miRNAs are implicated in the regulation of key physiological processes, including bone remodeling. However, little is known about their implication in MMBD.
Aims: The purpose of the current study was the evaluation of an established panel of 19 miRNAs associated with bone disease in osteoporosis of different etiology, in MMBD.
Methods: Small RNAs were isolated from blood plasma samples of 64 newly diagnosed MM cases, i.e. 37 patients with and 27 without osteolytic lesions, assessed via whole-body low-dose computed tomography. After RNA polyadenylation and first-strand cDNA synthesis, 19 miRNAs (let-7b-5p, miR-17-5p, miR-19b-3p, miR-29b-3p, miR-31-5p, miR-127-3p, miR-133b, miR-141-3p, miR-143-3p, miR-144-5p, miR-152-3p, miR-188-5p, miR-203a, miR-214-3p, miR-320a, miR-335-5p, miR-375, miR-550a-3p, miR-582-5p) were quantified by means of real-time qPCR, using LNA-enhanced forward and reverse primers as well as miGreen for detection. Spike-in control RNAs were used for normalization of miRNA levels. Last, biostatistical analysis was performed.
Results: Significantly lower levels of miR-143-3p (p=0.022), miR-17-5p (p=0.023), miR-214-3p (p=0.003), and miR-335-5p (p=0.018) were observed in MM patients with osteolytic lesions, compared to MM patients without osteolytic lesions. Receiver operating characteristic (ROC) curve analysis showed that each of the aforementioned miRNAs can accurately distinguish MM patients with MMBD from MM patients without MMBD: miR-17-5p (AUC=0.67; p=0.023), miR-143-3p (AUC=0.68; p=0.022), miR-214-3p (AUC=0.74; p=0.003), and miR-335-5p (AUC=0.69; p=0.018). In order to obtain a miRNA signature with higher discriminatory ability regarding MMBD, we built multivariate logistic regression models combining the levels of multiple miRNAs, selected among miR-17-5p, miR-143-3p, miR-214-3p, and miR-335-5p. The best predictive model resulted from the combination of these 4 miRNAs (function: $F=0.66 \times log(miR\text{-}335\text{-}5p) - 0.90 \times log(miR\text{-}17\text{-}5p) - 0.44 \times log(miR\text{-}143\text{-}3p)$

–1.67 x log(miR-143-3p) + 5.378. The evaluation of the proposed model using ROC analysis showed its significantly increased performance to successfully detect the presence of osteolytic bone disease in MM patients (AUC=0.80; p=0.001). Furthermore, a cutoff value of F_c=0.40, corresponds to increased diagnostic sensitivity of the described model (sensitivity: 96%, specificity: 53%), while a cutoff value of F_c=0.77 corresponds to increased diagnostic specificity (sensitivity: 48%, specificity: 94%).

Summary/Conclusion: Our study proposes a diagnostic model consisting of 4 miRNAs (miR-17-5p, miR-143-3p, miR-214-3p, and miR-335-5p) which and predict the occurrence of osteolytic lesions in MM patients. The suggested miRNA signature could be a useful tool able to guide therapeutic decision making, especially in ambiguous cases.

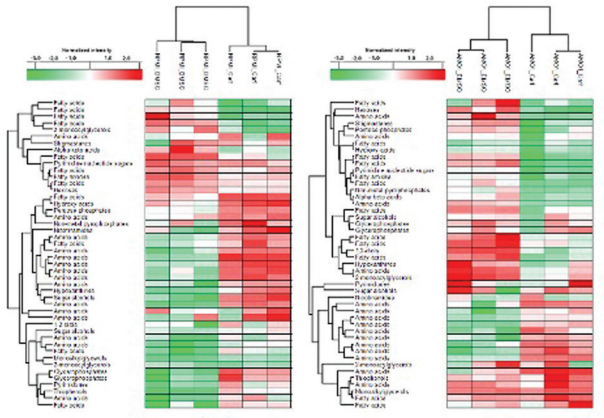
Acknowledgement: This research is co-financed by Greece and the European Union (European Social Fund - ESF) through the Operational Programme «Human Resources Development, Education and Lifelong Learning 2014-2020» in the context of the project "*Study of the expression of small non-coding RNAs in multiple myeloma and their correlation with bone disease.*"(MIS 5047940).

EP960 METABOLIC ADAPTATIONS IN CARFILZOMIB-RESISTANT MULTIPLE MYELOMA CELLS - A PILOT STUDY

D. Dytfeld [1,*], L. Magdalena [2], A. Bolomsky [3], T. Kubicki [1], M. Jarmuż-Szymczak [4], M. Kostrzewska-Poczekaj [4], K. Bednarek [4], L. Gil [1], H. Ludwig [3]

[1]Hematology, Poznan University of Medical Sciences, [2]Institute of Bioorganic Chemistry Polish Academy of Sciences, Poznań, Poland, [3]Center for Oncology and Hematology, Wilhelminen Cancer Research Institute, Vienna, Austria, [4]Institute of Human Genetics Polish Academy of Sciences, Poznań, Poland

Background: Multiple myeloma remains incurable mostly due to acquired resistance. Understanding the mechanisms of resistance would allow to create an algorithm for selecting optimal therapies and pave the road to new treatments.



Aims: Since proteomic and genomic analysis of myeloma cells did not reveal therapeutically relevant findings, we applied metabolomics to analyze biological alterations that allow for acquisition of resistance to carfilzomib – widely used proteasome inhibitor.

Methods: GC-MS-based comparative metabolomics was applied to compare the primary carfilzomib sensitive myeloma cell lines AMO1 and RPMI (RPMI 8226) with their carfilzomib resistant progenies generated by prolonged carfilzomib exposure. Cells were lysed, fractionated metabolite extracts were derivatized and submitted to GC/MS analysis performed with Agilent 7890A GCxGC (Agilent Technologies) combined with Pegasus 4D TOF-MS (Leco). MS data were normalized to total ion current (TIC) and analyzed using Perseus and MetaboAnalyst. The significance was estimated by the two-sample T-test and one-way ANOVA with FDR correction. Multivariate analyses were carried out by untargeted principal component analysis (PCA) and hierarchical clustering. Differentially accumulated metabolites (DAMs) were subjected to the MetaboAnalyst and Ingenuity Pathway Analysis software to determine canonical pathways, biological functions and upstream regulators.

Results: PCA revealed significant differences between sensitive and resistant progenies. 24 and 34 DAMs were identified in AMO1- and RPMI-resistant (Fig. 1) cells respectively, as compared to primary cells, 16 DAMs were common for both comparisons. The top-ranked canonical pathways included: aminoacyl-tRNA biosynthesis, amino acid's metabolism and biosynthesis of unsaturated fatty acids.

The analysis of functions of DAMs revealed overrepresented categories associated with oxidation of glucose-6-phosphate (p 1.6E-08 for AMO1, 1.84E-08 for RPMI) and accumulation of lipids (p 1.39E-05 for AMO1, 5.97E-08 for RPMI) - the oxidation of glucose-6-phosphate was activated (z-score 2.86 for RPMI and 2.00 for AMO1), while accumulation of lipids was inhibited in resistant cells (z-scores -2.37 for AMOA1, -1.91 for RPMI).

Network analysis of DAMs in AMO1 revealed that PML transcription regulator was predicted to be the top positive regulator, while ARNT (Aryl hydrocarbon receptor nuclear translocator) and D-glucose were predicted to be the negative regulators in resistant cells (p 4.49E-05 and 9.46E-06, z-scores: 2 and 2.23). The DAMs negatively regulated by ARNT and D-glucose and positively regulated by PML belonged to processes related to lipids accumulation, acylglycerol and pyruvic acid, molecules down-regulated in AMO1 resistant cells. Downregulation of these compounds induces an oxidation of glucose-6-phosphate in resistant cells. In RPMI, UCP1 (Uncoupling protein 1) transporter was identified as the positive upstream regulator of observed differences in resistant cells and functionally connected to lipid accumulation and D-glucose level. It might suggest that increased level of this regulator can lead to observed inhibition of lipids accumulation.

Summary/Conclusion: We successfully applied metabolomics to assess biological alterations in myeloma resistant cells. Our results are in line with previous studies underlining the role of glucose and fatty acids metabolism in acquired resistance in myeloma. Confirmation of results in clinical setting is needed for potential development of new drugs targeting disrupted metabolic pathways to overcome resistance.

EP961 SINGLE CELL MULTI-OMIC ANALYSIS AND IMMUNE CELL TYPE PROFILING OF MULTIPLE MYELOMA WITH T(4;14).

S. de Mel [1,*], J. Scolnick [2], X. Huo [3], C. Soekojo [1], F. Song [1], M. Ooi [1], W. J. Chng [4]

[1]Haematology, Oncology, National University Cancer Institute, National University Health System, [2]Physiology, national university of singapore, [3]Proteona Pte Ltd, [4]Medicine, Yong Loo Lin School Of Medicine, national university of singapore, singapore, Singapore

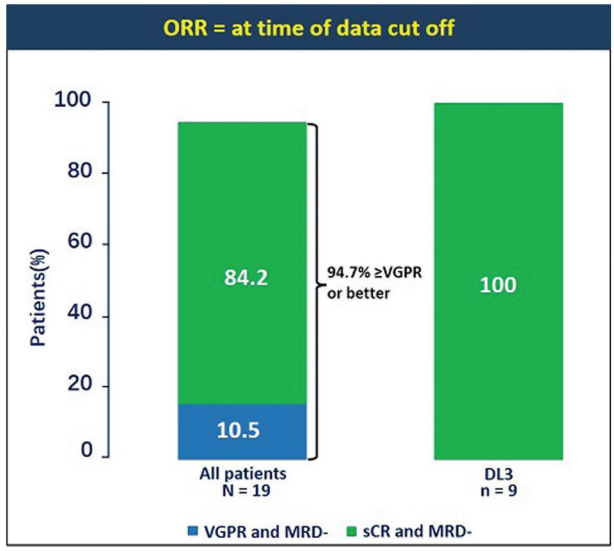
Background: Multiple Myeloma (MM) is an incurable plasma cell (PC) malignancy and high risk (HR) MM remains an unmet clinical need. Translocation 4;14 occurs in 15% of MM and is associated with an adverse prognosis. A deeper understanding of the biology and immune micro-environment of t(4;14) MM is necessary for the development of effective targeted therapies.

Aims: Here we utilized Proteona's ESCAPE™ single cell multi-omics platform to study a cohort of patients with t(4;14) MM with the goal of better understanding the biology underlying this high risk patient cohort.

Methods: Diagnostic bone marrow (BM) samples from 14 patients with t(4;14) MM were analysed using the ESCAPE™ platform from Proteona which simultaneously measures gene and cell surface protein expression in single cells. Cryopreserved BM samples were stained with 65 DNA barcoded antibodies and subsequently sorted on CD138 expression. The CD138 positive and negative fractions were recombined at a known ratio for analysis using the 10x Genomics 3' RNAseq kit. Resulting data were analyzed with Seurat and MapCell.

Results: The patients had a median age of 63 years. All received novel agent based induction. Median progression free and overall survival (PFS and OS) were 22 and 34 months respectively. MMSET was overexpressed in all PCs while FGFR3 expression could be categorized into zero cells expressing FGFR3, low expression (<10% of cells expressing FGFR3) or high expression (>80% of cells expressing FGFR3). We also found heterogeneity in the expression of cancer

testis antigens (CTA) such as FA133A and CTAG2 between PC clusters across samples.
Variation in the immune microenvironment of the BM was seen across all patient samples with no correlation between cell types and PFS or OS. However, an analysis of BM samples at diagnosis and relapse in one patient showed a shift in the ratio of T cells to CD14 monocytes with a ratio of 5.7 at diagnosis compared to 0.6 at relapse. Further analysis of PCs in this patient found 8 PC populations, each containing variable numbers of cells from both the diagnostic and relapse samples. This suggests that all populations present at relapse were also present at diagnosis, although at variable proportions. Increased expression of RCAN3 (associated with cereblon depletion) was detected at relapse.
Summary/Conclusion: We present the first application of single cell multi-omics immune profiling in high risk MM. The heterogeneity in expression of CTA has implications for the application of immunotherapies, while the upregulation of RCAN3 may explain failure of immunomodulatory therapy. Our small sample size may explain the lack of correlation between gene or protein expression with clinical outcomes. We propose that t(4;14) MM is a genomically and immunologically heterogeneous disease. Single cell analysis of larger cohorts is required to build on our findings.



Myeloma and other monoclonal gammopathies - Clinical

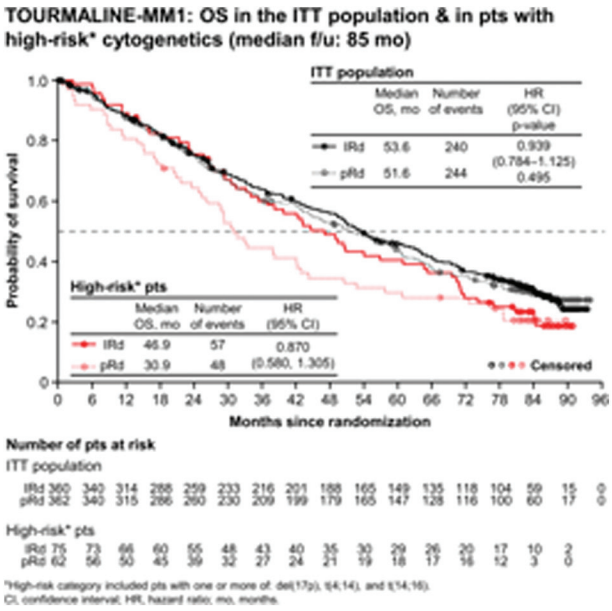
EP962 LONG-TERM FOLLOW-UP RESULTS OF A MULTICENTER FIRST-IN-HUMAN STUDY OF THE DUAL BCMA/CD19 TARGETED FAST CAR-T GC012F FOR PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

J. Du [1,*], H. Jiang [1], B. Dong [2], L. Gao [3], L. Liu [4], J. Ge [5], A. He [6], L. Li [1], J. Lu [1], X. Chen [2], Y. Zhao [7], Y. Han [7], Y. Chen [7], C. Han [7], X. Ye [7], H. Zhang [7], L. Shen [7], J. Liu [7], M. Sersch [7], W. Fu [1]

[1]Changzheng Hospital, Shanghai, [2]Xijing hospital, Xian, [3]The Second Affiliated Hospital of Army Medical University, Chongqing, [4]Tangdu hospital, Air Force Medical University, Xian, [5]The first affiliated hospital of anhui medical university, Hefei, [6]The Second Affiliated Hospital of Xian Jiaotong University, Xian, [7]Gracell Biotechnologies Ltd, Shanghai, China

Background: The dual CAR-T GC012F - developed on the novel FasT CAR-T platform, targeting both B cell maturation antigen (BCMA) and CD19, was designed to improve depth of response and overall efficacy for CAR-T as therapy for Multiple Myeloma.
Aims: Here we present updated data for the single-arm multicenter phase 1 study (NCT04236011; NCT04182581) including additional pts treated.
Methods: From October 2019 to July 2020, 19 heavily pretreated Relapsed/Refractory Multiple Myeloma (RRMM) pts (age 27-71) with a median of 5 prior lines (range 2-9) received a single infusion of GC012F. 94.7% (18/19) were high risk (HR; defined by mSMART), 5 pts had extramedullary disease, 1 pt presented with plasma cell leukemia, and 15/19 were refractory to last therapy. 4/19 pts had received prior anti-CD38, 18/19 pts prior IMiD. 18/19 pts were refractory to PI, 17 pts to IMiD, 3 pts being primary refractory. After lymphodepletion over 2-3 days (30 mg/m2/d, 300mg/ m^2/d Flu/Cy) CAR-T cells were administered as single infusion at 3 dose levels:1x10^5/kg (DL1) n=1, 2x10^5/kg (DL2) n=9 and 3x10^5/kg (DL3) n=9.
Results: As of Jan 12th 2021 cut-off, 19 pts were evaluated for response. Overall response rate (ORR) was 94.7% - all responses were VGPR or better (94.7% - 16/18 sCR, 2/18 VGPR) with all pts (19/19) being Minimal Residual Disease negative (MRD$^-$) by flow cytometry (10^{-4};10^{-6}) - earliest response d28 post infusion. 100% of pts achieved a reduction of paraprotein, 18/19 a 100% reduction. Best response was MRD$^-$sCR in 16/19 pts (84.2%). In DL3 (n=9) 4 additional pts were response evaluable for 6 mth follow-up: 100% (9/9) of pts achieved MRD$^-$sCR as best response, 87.5% (7/8) of response evaluable pts maintained MRD$^-$sCR at a landmark analysis at 6 mths. At data cut off, the median time to follow up was 13.8 mths (6.1-16.4) – with the median duration of response not yet reached. Cytokine Release Syndrome (CRS) and ICANs were graded by ASBMT criteria: grade 1-2 n=16 (84.2%), grade 3 n=2 (10.5%). Median duration of CRS was 4d (1-8d). No grade 4/5 CRS or Immunce effector cell-associated Neurotoxicity syndrome (ICANS) were observed. 2 deaths occurred on study and were assessed as not related to therapy – one reported previously; one patient was diagnosed with pseudomonas pneumonia on Day 52, refused life-saving treatment and passed. CAR-T median T_{max} was 10d (range 8-14d), median peak copy number (C_{max}) was 127548 (16,011-374,346) copies /ug DNA with a long duration of persistence of up to 60 weeks at time of data cut-off. Patients continue to be monitored for safety and efficacy.

Summary/Conclusion: BCMA-CD19 dual FasT CAR-T GC012F showed early, deep and durable responses with a high ORR (94.7%; VGPR or better) including a high MRD negative sCR rate (DL3=100%, n=9) in high risk RRMM pts including those refractory to anti-CD38, PI and IMIDs with a favorable safety profile consistent with previous findings. BCMA-CD19 dual FasT CAR-T GC012F may present a new treatment approach for patients with RRMM including those with high-risk features refractory to standard of care.



EP963 FINAL ANALYSIS OF THE PHASE 3 TOURMALINE-MM1 STUDY INVESTIGATING IXAZOMIB + LENALIDOMIDE-DEXAMETHASONE (IRD) VS PLACEBO-RD (PRD) IN RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA (RRMM) PATIENTS (PTS)

Background: Despite an increasing number of treatment options for RRMM, there remains a need for efficacious & tolerable therapies for pts who are refractory to treatment or continue to relapse. Proteasome inhibitors (PIs) are a backbone of therapy, but parenteral PIs may be limited by treatment burden & the need for clinic/hospital visits. The first oral PI, ixazomib, is approved in combination with Rd (IRd) for the treatment of MM pts who have received ≥1 prior lines of therapy. Approval was based on the double-blind, placebo-controlled, phase 3

TOURMALINE-MM1 study (Moreau NEJM 2016), which demonstrated a statistically significant improvement in progression-free survival (PFS) with IRd vs pRd (median PFS 20.6 vs 14.7 mo, HR 0.74, p=0.01). With limited additional toxicity vs pRd, all-oral IRd is an important option for RRMM pts.
Aims: To report final analyses for overall survival (OS) in the intent-to-treat (ITT) population (a key secondary endpoint) & subgroups of interest.
Methods: Randomization to IRd (n=360) or pRd (n=362) was stratified by number of prior therapies (1 vs 2/3), PI exposure, & International Staging System (ISS) disease stage (I/II vs III). Treatment continued until disease progression/unacceptable toxicity.
Results: At data cutoff (9/28/2020), median follow-up (f/u) was ~7 y (85 mo). Pts had received a median of 18 (range 1–99) & 16 (1–100) cycles of IRd & pRd, respectively. Overall, 32% of pts were alive at last OS f/u; 4% in each arm were still on treatment. Median OS with IRd vs pRd (ITT population) was 53.6 vs 51.6 mo (HR 0.939, p=0.495, Figure); this favorable trend was not statistically significant, but occurred in the context of the longest OS (both arms) reported to date in phase 3 Rd studies in RRMM. OS benefit with IRd vs pRd (lower HRs) was seen in predefined subgroups with adverse-risk characteristics including: refractory to any (HR 0.794) or last (HR 0.742) treatment line; age >65–75 y (HR 0.757); ISS stage III (HR 0.779); 2/3 prior therapies (HR 0.845); high-risk cytogenetics [≥1 of del(17p), t(4:14), t(14;16) (HR 0.870, Figure), & 1q21 amplification (HR 0.862)]. OS benefit was also seen in pts with standard-risk cytogenetics (HR 0.875). Imbalances in subsequent therapy in both arms may have led to inconsistencies in OS benefit for IRd pts. While 72% of IRd & 70% of pRd pts received ≥1 subsequent anticancer therapy, pRd pts began this therapy earlier than IRd pts. Of IRd vs pRd pts receiving ≥1 subsequent therapy, 25 vs 34% received daratumumab, 72 vs 77% received PIs (57 vs 62% bortezomib, 27 vs 33% carfilzomib), & 4 vs 10% had an autologous stem cell transplant. Most pts (IRd 92%, pRd 85%) remained blinded at time of next treatment, and while similar proportions of blinded pts received a PI or non-PI next-line therapy in both arms, unblinding strongly influenced next-line therapy decisions. OS benefit was reduced in pts who received a PI immediately after progression on IRd vs pts who received a PI after pRd. No new/additional safety concerns were evident during the 7-y f/u period, & the rate of new primary malignancies was similar in both arms (IRd 10%, pRd 12%).

Summary/Conclusion: At this final analysis of TOURMALINE-MM1, median OS with IRd & pRd were the longest reported to date in phase 3 Rd studies in RRMM. Although OS benefit with IRd vs pRd was not statistically significant in the ITT population, greater OS benefit was seen in subgroups with adverse prognostic factors, including high-risk cytogenetics. OS interpretation was confounded by imbalances in subsequent therapies, including extensive use of PIs & novel monoclonal antibodies.

EP964 UPDATED CARTITUDE-1 RESULTS OF CILTACABTAGENE AUTOLEUCEL, A B-CELL MATURATION ANTIGEN–DIRECTED CHIMERIC ANTIGEN RECEPTOR T CELL THERAPY, IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

S. Usmani [1,*], J. Berdeja [2], D. Madduri [3], A. Jakubowiak [4], M. Agha [5], A. Cohen [6], P. Hari [7], T.-M. Yeh [8], Y. Olyslager [9], A. Banerjee [10], C. Jackson [8], A. Allred [10], E. Zudaire [10], W. Deraedt [9], X. Wu [11], M. Carrasco-Alfonso [11], M. Akram [11], Y. Lin [12], T. Martin [13], S. Jagannath [3]

Background: Ciltacabtagene autoleucel (cilta-cel; JNJ-68284528) is a chimeric antigen receptor T (CAR-T) cell therapy with two B-cell maturation antigen–targeting single-domain antibodies. CARTITUDE-1 (NCT03548207) is a phase 1b/2 study conducted to evaluate cilta-cel in patients with relapsed/refractory multiple myeloma (R/R MM).
Aims: We report updated CARTITUDE-1 results in patients with a longer duration (median 12.4 months) of follow-up.
Methods: All patients provided informed consent. Eligible patients had MM, had received ≥3 prior regimens or were double refractory to a proteasome inhibitor (PI) and immunomodulatory drug (IMiD), and had received a PI, IMiD, and anti-CD38 antibody. Bridging therapy was permitted after apheresis. Patients received a single cilta-cel infusion (target dose: 0.75×10^6 CAR+ viable T cells/kg; range $0.5–1.0\times10^6$) 5–7 days after lymphodepletion with 300 mg/m^2 cyclophosphamide and 30 mg/m^2 fludarabine daily for 3 days. The primary objectives of the study were to characterize the safety of cilta-cel, confirm the recommended phase 2 dose (RP2D; phase 1b), and evaluate efficacy (phase 2). Cytokine release syndrome (CRS) was graded by Lee *et al* (Blood 2014) and neurotoxicity by Common Terminology Criteria for Adverse Events (CTCAE), v5.0 (in phase 1b). CRS and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded by American Society for Transplantation and Cellular Therapy (ASTCT) criteria (in phase 2). In this analysis, Lee *et al* and CTCAE v5.0 were mapped to ASTCT for CRS and ICANS, respectively.
Results: As of Sept 1, 2020, a total of 97 patients with a median of 6 prior lines of therapy received cilta-cel. The overall response rate per independent review committee (primary endpoint) was 97% (95% CI, 91–99), with 67% of patients achieving stringent complete response. The median time to first response was 1 month (range, 1–9), and median time to complete response or better was 2 months (range, 1–15). Responses deepened over time, and the median duration of response was not reached. Of 57 patients who were evaluable for minimal residual disease (MRD) assessment, 93% were MRD-negative at 10^{-5}. The 12-month progression-free survival (PFS) and overall survival rates were 77% (95% CI, 66–84) and 89% (95% CI, 80–94), respectively; the median PFS was not reached. Grade 3/4 hematologic adverse events (AEs) that occurred in ≥20% of patients included neutropenia (95%), anemia (68%), leukopenia (61%), thrombocytopenia (60%), and lymphopenia (50%). CRS occurred in 95% of patients (4% were grade 3/4), with median time to onset of 7 days (range, 1–12) and median duration of 4 days (range, 1–14, excluding 1 patient with duration of 97 days). CRS resolved in all patients except one with grade 5 CRS/haemophagocytic lymphohistiocytosis. CAR-T cell neurotoxicity occurred in 21% of patients (10% were grade ≥3). A total of 14 patients died during the study after cilta-cel infusion: no deaths occurred within the first 30 days, 2 deaths occurred within 100 days; and 12 deaths occurred more than 100 days post infusion, of which 5 were from disease progression, and 4 from treatment-related AEs.
Summary/Conclusion: A single infusion of cilta-cel yielded early, deep, and durable responses in heavily pretreated patients with MM, with a manageable safety profile at the RP2D. Investigation of cilta-cel in other

MM populations in earlier lines of therapy and in outpatient settings is under investigation.

EP965 FCRH5 TARGET EXPRESSION IN PATIENTS WITH RELAPSED REFRACTORY MULTIPLE MYELOMA (RRMM) TREATED WITH CEVOSTAMAB IN AN ONGOING PHASE I DOSE ESCALATION STUDY

T. Sumiyoshi [1,*], R. Nakamura [1], S. Lear [1], D. Wilson [1], V. Choeurng [2], A. Vaze [3], S. Trudel [4], A. Spencer [5], A. D Cohen [6], R. Fonseca [7], B. M Fine [8], M. Li [8], J. Cooper [8], S. J Harrison [9]

[1]Oncology Biomarker Early Development, [2]Oncology Biostatistics Early Development, [3]Early Development Safety, Genentech, Inc., South San Francisco, CA, United States, [4]Princess Margaret Cancer Centre and University of Toronto, Toronto, ON, Canada, [5]Alfred Health-Monash University, Melbourne, VIC, Australia, [6]Abramson Cancer Center and University of Pennsylvania, Philadelphia, PA, [7]Mayo Clinic in Arizona, Phoenix, AZ, [8]Oncology Early Clinical Development, Genentech, Inc., South San Francisco, CA, United States, [9]Peter MacCallum Cancer Centre and Royal Melbourne Hospital, Melbourne, VIC, Australia

Background: Fc receptor-homolog 5 (FcRH5), an immunoglobulin (Ig) domain-containing type I membrane protein, is expressed exclusively in the B-cell lineage; and has been identified as a desirable target for the treatment of MM [1]. The humanized IgG-based T-cell-engaging bispecific antibody cevostamab (anti-FcRH5xCD3; BFCR4350A) binds to the most membrane-proximal domain of FcRH5 on myeloma cells and to cluster of differentiation 3 (CD3) on T cells resulting in efficient immunological synapse formation and potent T-cell-directed killing of myeloma cells. Cevostamab showed promising activity and manageable toxicity as monotherapy in the GO39775 Phase 1 dose escalation study (NCT03275103) enrolling RRMM patients (pts) [2].
Aims: To analyse pre-treatment FcRH5 target expression by response to therapy and pts baseline characteristics (prior therapy, cytogenetic risk status), in the cevostamab Phase I study.
Methods: Bone marrow aspirates (BMA) were collected prior to receiving cevostamab treatment. FcRH5 cell surface expression on myeloma cells was assessed using flow cytometry and the levels of expression (reported as molecules of equivalent soluble fluorochrome [MESF]) were compared between pts by prior therapy and stratified by cytogenetic risk status (determined by FISH). The clinical cut-off date (CCOD) used for the current analyses was August 18, 2020.
Results: As of CCOD, 53 pts (median age: 62.0 years [range: 33–80]) had enrolled in the study. Median number of prior lines of therapy was 6 (range: 2–15). Prior treatments included proteasome inhibitors (PIs), 100% (94.1% refractory); immunomodulatory drugs (IMiDs), 100% (98.0% refractory); anti-CD38 mAbs, 81% (92% refractory); and 86% of pts received autologous stem cell transplant. Overall, 72% of pts were triple-class refractory (≥1 PI, ≥1 IMiD, and ≥1 anti-CD38 mAb), and 94% of pts were refractory to their last therapy. In pts who received ≥3.6mg/20mg doses, the ORR was 53% (18/34); response was consistent in pts with exposure to prior daratumumab and anti-BCMA agents. FcRH5 expression was detected on myeloma cells in all pts with adequate BMA samples for biomarker evaluation (n=44). Prior therapy and the number of lines of treatment did not appear to affect FcRH5 expression. Of the pts with evaluable samples for cytogenetics (n=28), 25 pts were high risk [HR; 1q21, t(4;14), t(4,16) or del(17p)] and 3 standard risk (SR). Baseline FcRH5 expression stratified by cytogenetic risk showed a trend towards higher expression in pts with HR cytogenetics; median (min, max) MESF was 6329 (352, 44409) in HR and 2591 (766, 4560) in SR. Expression levels were consistent in HR pts with 1q21 vs no 1q21, t(4,14) vs no t(4,14) and d(17p) vs no d(17p). No clear correlations were observed between response to cevostamab and baseline expression levels of FcRH5.
Summary/Conclusion: Response to cevostamab was observed irrespective of FcRH5 expression levels in pts with RRMM assessed to date. Prior therapy did not affect the expression levels of FcRH5. There was a trend towards higher expression levels in pts with high-risk cytogenetics. These data further confirm FcRH5 as a promising target for MM therapeutics.

EP966 EFFECTS OF SELINEXOR ON PREVIOUSLY TREATED MULTIPLE MYELOMA (MM) WITH RAS-MUTATIONS

C. Walker [1,*], S. Li [2], Y. Chai [1], J. Shah [1], S. Shacham [1], S. Lentzsch [2], Y. Landesman [1]

[1]Karyopharm Therapeutics, Inc., Newton, [2]College of Physicians and Surgeons of Columbia University, New York, United States

Background: Activating mutations of the RAS genes *NRAS*, *KRAS*, and *HRAS* (*RAS*^{mut}) occur in up to 50% of MM and portend poor survival and high recurrence rates. MM cells with *RAS*^{mut} are susceptible to inhibition of germinal center kinase (GCK), resulting in IKAROS degradation independent of cereblon (CRBN). Selinexor is a selective inhibitor of nuclear export (SINE) compound that can induce IKAROS degradation through CRBN-independent pathways to overcome immunomodulatory drug resistance. We explored the benefit of selinexor treatment for pts with *RAS*^{mut} MM.
Aims: To evaluate the effect of NRAS, KRAS or HRAS mutations on outcomes in MM pts treated with a selinexor regimen.
Methods: In the randomized BOSTON study, pts with MM after 1-3 therapies received weekly XVd or twice weekly Vd. In the single-arm STORM study, pts with penta-treated, triple class refractory MM were treated with twice weekly Xd. Both treatment regimens are now FDA approved. Mutations were assessed post-hoc by exome sequencing of 119 and 52 pts from BOSTON and STORM, respectively. Pts were considered *RAS*^{mut} if their MM had *NRAS*, *KRAS* or *HRAS* mutations in codons 12, 13 or 61.
Results: There were 54 pts (45%) with *RAS*^{mut} in BOSTON (XVd=26, Vd=28), and 17 (33%) in STORM (all receiving Xd). In BOSTON, pts with *RAS*^{mut} MM treated with XVd had significantly longer progression-free survival (PFS) than those treated with Vd (median [med]=12.9 vs 6.7 months [mo], hazard ratio [HR]=0.48 [95% CI 0.24-0.97], p=0.039). For pts treated with Vd, those with *RAS*^{mut} had significantly shorter overall survival (OS) compared to *RAS*$^{wild\text{-}type\ (WT)}$ (med=16.8 mo vs not reached [NR], HR=2.87 [95% CI 1.03-7.99], p=0.035). PFS trended shorter in *RAS*^{mut} (med=6.74 vs 9.82 mo, HR=1.64 [95% CI 0.88-3.07], p=0.122). In contrast, amongst pts on XVd, there was no difference in survival between *RAS*^{mut} and *RAS*^{WT} pts (PFS: med=12.8 vs 12.9 mo, HR=1.08 [95% CI 0.52-2.26], p=0.83; OS: med=NR vs NR, HR=0.94 [95% CI 0.36-2.45], p=0.91). In STORM, pts with *RAS*^{mut} had shorter OS compared to *RAS*^{wt} pts (med=6.1 vs NR, HR=2.51 [95% CI 1.22-5.19], p=0.010). Preliminary studies to explore the mechanisms of action related to *RAS*^{mut} MM sensitivity to XVd demonstrated that selinexor treatment in vitro leads to downregulation of GCK.

	PFS		OS	
	p-value	HR (95% CI)	p-value	HR (95% CI)
BOSTON *RAS*^{mut} XVd vs Vd	0.039	0.48 (0.24-0.97)	0.22	0.57 (0.23, 1.41)
BOSTON XVd arm *RAS*^{mut} vs *RAS*^{WT}	0.83	1.08 (0.52, 2.26)	0.91	0.94 (0.36, 2.45)
BOSTON Vd arm *RAS*^{mut} vs *RAS*^{WT}	0.12	1.64 (0.88, 3.07)	0.035	2.87 (1.03, 7.99)
STORM (Xd) *RAS*^{mut} vs *RAS*^{WT}	0.28	1.58 (0.69, 3.63)	0.010	2.51 (1.22, 5.19)

Summary/Conclusion: Despite typically having the worst outcomes, pts with *RAS*^{mut} MM had a similar benefit from XVd as *RAS*^{WT} MM, showing that the XVd combination can overcome traditionally poor prognostic *RAS*^{mut}. Mechanistically, selinexor induced down regulation of GCK and enhanced killing of *RAS*^{mut} MM cells. With a manageable safety profile, the XVd regimen could provide a viable treatment option to improve PFS and OS in pts with MM with RAS mutations.

EP967 MODULATION OF SOLUBLE B-CELL MATURATION ANTIGEN LEVELS BY TECLISTAMAB AND TALQUETAMAB IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA

S. Girgis [1,*], S. X. Wang Lin [1], K. Pillarisetti [1], R. Verona [1], D. Vieyra [1], T. Casneuf [2], D. Fink [1], X. Miao [1], Y. Chen [1], T. Stephenson [1], A. Banerjee [1], B. Hilder [1], J. Russell [1], J. Smit [1], J. Goldberg [1]

[1]Janssen Research & Development, LLC, Spring House, United States, [2]Janssen Research & Development, LLC, Beerse, Belgium

Background: B-cell maturation antigen (BCMA, CD269), a single transmembrane protein that is selectively expressed in the B-cell lineage, is a validated target for multiple myeloma (MM). BCMA can exists as both a surface protein and as a free soluble form (sBCMA). γ-secretase activity at the transmembrane domain leads to a shed BCMA protein fragment of approximately 6 kilodalton that can exist as free circulating sBCMA in blood. Teclistamab, a BCMA x CD3 bispecific antibody, and talquetamab, a GPRC5D x CD3 bispecific antibody, were developed to recruit $CD3^+$ T cells to $BCMA^+$ or $GPRC5D^+$ MM cells, respectively.
Aims: The objective of this study was to evaluate sBCMA levels in response to treatment with teclistamab or talquetamab in patients with relapsed and/or refractory MM.
Methods: Serum samples from patients with relapsed and/or refractory MM enrolled in the teclistamab and talquetamab phase 1 studies (64007957MMY1001 and 64407564MMY1001, respectively) were collected (at various timepoints between baseline and cycle 4 or end of treatment) and analyzed for sBCMA by an electrochemiluminescence ligand binding assay. Soluble BCMA data were quantitatively analyzed in reference to the patient's tumor burden and response, as well as to pharmacokinetic data. All patients enrolled in the phase 1 studies provided written informed consent.
Results: Teclistamab and talquetamab modulated levels of sBCMA in patients with high (≥ 50%) and low (< 50%) frequency of tumor plasma cells (TPCs), as well as in high and low risk cytogenetic groups. In cycle 3, the majority of the responders had reductions in sBCMA compared to baseline: 88% (50 out of 57) for teclistamab and 98% (49 out of 50) for talquetamab. In contrast, non-responders (patients who had progressive disease, stable disease, or minimal response) seemed to show an increase in sBCMA compared to baseline: 80% (33 out of 41) for teclistamab and 49% (24 out of 49) for talquetamab. Patients with deep responses tended to have a higher magnitude of sBCMA reduction compared to others. Based on the few patients who initially responded to teclistamab or talquetamab but then relapsed, sBCMA seemed to have an initial reduction followed by an increase in the levels. Soluble BCMA correlated with % bone marrow TPCs. The majority of patients with plasmacytoma (limited data were available) seemed to have high sBCMA, suggesting that sBCMA could be a comprehensive marker for tumor burden. Preliminary teclistamab population pharmacokinetic analysis showed that sBCMA did not appear to impact teclistamab exposure, suggesting that sBCMA was not acting as a sink for teclistamab.
Summary/Conclusion: Teclistamab and talquetamab induced changes in sBCMA levels that correlated with clinical activity, further supporting clinical development of these bispecific antibodies. Lastly, the findings provide support for sBCMA as a potential surrogate marker of myeloma tumor burden, and as a valuable marker for response in patients with MM.

EP968 SUBGROUP ANALYSIS ON RESPONSE TO INDUCTION THERAPY WITH BORTEZOMIB, LENALIDOMIDE AND DEXAMETHASONE WITH OR WITHOUT ELOTUZUMAB FOR NEWLY-DIAGNOSED, TRANSPLANT-ELIGIBLE MULTIPLE MYLEOMA

Background: Quadruplet treatment regimens including a proteasome inhibitor, immunomodulating agent and a monoclonal antibody are playing an emerging role in front-line treatment of multiple myeloma (MM). Recently, a randomized phase II trial (SWOG-1211, Usmani SZ et al., Lancet Haematology, 2021) comparing lenalidomide, bortezomib and dexamethasone (RVD) with or without the anti-SLAMF7 monoclonal antibody (moAb) elotuzumab (Elo) found no significant differences in response rates, progression-free survival (PFS) nor overall survival (OS) in high-risk newly diagnosed patients with high-risk MM.
Aims: We aimed to compare available response rates after induction therapy with RVD vs. Elo-RVD according to high-risk subgroups from our randomized phase III HD6 trial (NCT 02495922).
Methods: The German-speaking Myeloma Multicenter Group (GMMG) HD6 trial is a randomized multicenter phase III treatment protocol including 559 and 555 newly diagnosed transplantation-eligible MM patients in the intention-to-treat (ITT) and safety population, respectively. Induction therapy consisted of four 21-day cycles of RVD (arms A1+A2, n=280) or Elo-RVD (arms B1+B2, n=279). Exploratory analyses on response rates (very good partial response or better, ≥VGPR) according to predefined subgroups comparing RVD vs. Elo-RVD induction therapy will be presented.
Results: Median patient age was 59 (27-70) years at trial inclusion. Revised International Staging System (R-ISS), ISS stages, adverse cytogenetics (at least one of the following: del17p13, t(4;14), t(14;16) and the proportion of patients with renal impairment (either serum creatinine >2 mg/dl or glomerular filtration rate <40 ml/min) were equally distributed among the RVD and Elo-RVD groups. Revised ISS stages I / II / III were noted in 29.9% / 59.3% / 10.9% of patients in the RVD cohort vs. 28.1% / 58.1% / 13.8% in the Elo-RVD group. At least four cycles of preplanned RVD or Elo-RVD induction therapy were completed by 264 (94.3%) and 258 (92.5%) patients. The overall response rates (ORR, ≥PR) after the fourth cycle of induction therapy were 85.6% in the RVD group and 82.4% in the Elo-RVD group (Fisher p=0.53). Deep responses (very good partial response rates or better, ≥VGPR) were reached by 54.0% in the RVD group vs. 58.3% in the Elo-RVD group (Fisher p=0.22). The rates of ≥VGPR between RVD and Elo-RVD were significantly different in patients with R-ISS stage II (50.8% vs. 64.5%, Fisher p=0.03; odds ratio [OR]=1.83, 95% confidence interval [95% CI]: 1.09-3.07, Wald p=0.02). Borderline significant results were observed for patients with normal renal function (52.9% vs. 59.8%, Fisher p=0.07; OR=1.40, 95% CI: 0.98-2.01, Wald p=0.06). No differences were observed in other prognostically important subgroups such as in patients with renal impairment at baseline, with or without adverse cytogenetics, good (0-1) or poor (>1) World Health Organization (WHO) performance status or R-ISS stages I and III. Further analyses on toxicities and dose intensities of RVD vs. Elo-RVD are planned.
Summary/Conclusion: Addition of Elo to RVD improves the rate of deep responses (≥VGPR) post induction therapy in patients with R-ISS stage II, prognostically a rather heterogenous group of MM. Further subgroups that benefit from Elo-RVD vs. RVD regarding response post induction therapy could not be identified. However, benefit by the addition of monoclonal antibodies often becomes obvious during further treatment course (Moreau P et al., The Lancet, 2019). Final results for the primary endpoint of the HD6 trial (PFS) will be reported in late 2021.

EP969 DARATUMUMAB PLUS CYCLOPHOSPHAMIDE, BORTEZOMIB, AND DEXAMETHASONE INDUCTION THERAPY IN MULTIPLE MYELOMA FOLLOWED BY DARATUMUMAB MAINTENANCE: END-OF-STUDY RESULTS FROM LYRA

R. Rifkin [1,*], J. Melear [2], E. Faber [3], W. Bensinger [4], J. Burke [5], M. Narang [6], D. Stevens [7], K. Gray [8], Y. Lutska [8], P. Bobba [8], K. Qi [9], M. Qi [10], T. Lin [8], H. Yimer [11]

[1]US Oncology Research, Rocky Mountain Cancer Centers, Denver, [2]Texas Oncology, Austin, [3]Oncology Hematology Care, Inc., Cincinnati, [4]Swedish Cancer

Institute, Seattle, [5]US Oncology Research, Rocky Mountain Cancer Centers, Aurora, [6]US Oncology Research, Maryland Oncology Hematology, Columbia, [7]Norton Health Care, Louisville, [8]Janssen Scientific Affairs, LLC, Horsham, [9]Janssen Research & Development, LLC, Titusville, [10]Janssen Research & Development, LLC, Spring House, [11]US Oncology Research, Texas Oncology – Tyler, Tyler, United States

Background: The safety and efficacy of daratumumab (DARA) plus cyclophosphamide, bortezomib, and dexamethasone (CyBorD) as an immunomodulatory drug-sparing regimen in newly-diagnosed patients with multiple myeloma (NDMM) and relapsed MM (RMM) were demonstrated in a primary analysis of LYRA, a phase 2, single-arm, community practice-based study (NCT02951819). An updated analysis of the study further showed that responses deepened with DARA maintenance therapy.

Aims: To report the final end-of-study analysis of LYRA.

Methods: Adult patients (aged ≥18 years) from the United States with MM (International Myeloma Working Group criteria) and no more than 1 prior line of therapy received 4–8 induction cycles of DARA plus CyBorD (oral cyclophosphamide 300 mg/m^2 once weekly [QW]; subcutaneous bortezomib 1.5 mg/m^2 on Days [D] 1, 8, and 15; oral or intravenous (IV) dexamethasone 40 mg QW every 28 days; DARA IV, 8 mg/kg on D1 and D2 of cycle [C] 1, 16 mg/kg QW on C1D8–C2, 16 mg/kg Q2W in C3–C6, and 16 mg/kg Q4W in C7–C8). Written informed consent was obtained from all patients. Following induction, eligible patients were allowed to receive autologous stem cell transplantation (ASCT). Patients received ≤12 maintenance cycles of DARA 16 mg/kg IV Q4W and were then followed up for ≤36 months after induction.

Results: Of 101 patients (NDMM, 87; RMM, 14), 36% had high-risk cytogenetics. Patients with NDMM received a median of 6 induction cycles; those with RMM received 8. Of 87 patients with NDMM, 39 (44.8%) received ASCT and 63 (72.4%) completed 12 months of maintenance therapy. Of 14 patients with RMM, 1 (7.1%) received ASCT and 7 (50.0%) completed 12 months of maintenance therapy. A higher proportion of patients with NDMM who received ASCT achieved very good partial response or better (≥VGPR; 82.1%) and complete response or better (≥CR; 48.7%) vs patients who did not receive ASCT (70.2% and 29.8%, respectively; Table). For patients with NDMM, median progression-free survival (PFS) and overall survival (OS) were not reached (median follow up, 35.7 months). Estimated 3-year PFS rates were 69.3% for patients with NDMM who received ASCT and 72.6% for those who did not; estimated 3-year OS rates were 94.9% and 84.3%, respectively. Efficacy outcomes for patients with RMM are reported in Table. Overall, 62.0% of patients experienced grade 3/4 treatment-emergent adverse events (TEAEs), and neutropenia (14.0%) was most common (≥10%). Serious TEAEs were observed in 33.0% of patients, and pneumonia (4.0%) and pulmonary embolism (3.0%) were most common. TEAEs leading to death occurred in 2.0% of patients (all unrelated to study treatment). Nearly half of patients (56.0%) experienced infusion-related reactions; most were mild (4.0% had grade 3/4 events).

	NDMM who received ASCT (n=39)	NDMM who did not receive ASCT (n=47)	RMM (n=14)
ORR, %	97.4	83.0	85.7
sCR	23.1	17.0	28.6
≥CR	48.7	29.8	64.3
≥VGPR	82.1	70.2	71.4
	(n=39)	(n=48)	(n=14)
Estimated 3-year PFS, % (95% CI)	69.3 (43.0-85.3)	72.6 (54.0-84.7)	31.7 (5.6-63.4)
Estimated 3-year OS, % (95% CI)	94.9 (81.0-98.7)	84.3 (69.8-92.2)	50.0 (22.9-72.2)
ORR, overall response rate; sCR, stringent complete response			

Summary/Conclusion: In patients with NDMM or RMM, induction with DARA plus CyBorD followed by DARA alone as maintenance therapy resulted in durable and deep responses, with a 3-year PFS rate of 70%, regardless of ASCT status. No new safety concerns were identified with longer follow up.

EP970 ANCHOR (OP-104): MELFLUFEN PLUS DEXAMETHASONE AND BORTEZOMIB IN RELAPSED/REFRACTORY MULTIPLE MYELOMA—OPTIMAL DOSE AND UPDATED EFFICACY AND SAFETY RESULTS

R. Hájek [1,*], L. Pour [2], M. Granell [3], V. Maisnar [4], P. G. Richardson [5], S. Norin [6], M. Sydvander [6], J. Obermüller [6], E. M. Ocio [7]

[1]Department of Hemato-oncology, University Hospital Ostrava, Ostrava, [2]University Hospital Brno, Brno, Czech Republic, [3]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [4]Fourth Department of Medicine - Hematology, FN and LF UK Hradec Králové, Hradec Králové, Czech Republic, [5]Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, [6]Oncopeptides AB, Stockholm, Sweden, [7]University Hospital Marqués de Valdecilla (IDIVAL), University of Cantabria, Santander, Spain

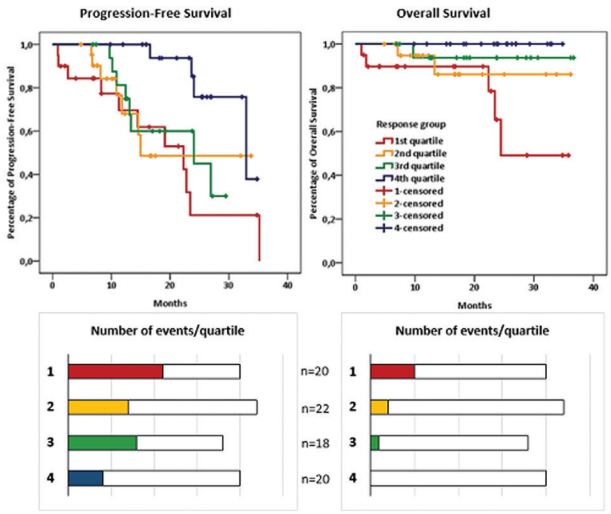
Background: The development of resistance to standard treatments for relapsed/refractory multiple myeloma (RRMM) highlights the need for novel therapies. Melphalan flufenamide (melflufen) is a first-in-class peptide-drug conjugate (PDC) that leverages aminopeptidases and thereby delivers and rapidly releases alkylating agents inside tumor cells. Melflufen plus dexamethasone showed clinical activity and an acceptable safety profile in RRMM in the phase 2 HORIZON study (Richardson PG, et al. *J Clin Oncol*. 2020 Dec 9 [Epub]).

Aims: To provide an update of the phase 1 dose-finding part of the bortezomib arm of the phase 1/2a ANCHOR study of melflufen plus dexamethasone in combination with bortezomib or daratumumab in patients with RRMM (NCT03481556).

Methods: Eligible patients with RRMM were refractory to (or intolerant of) a prior IMiD, with 1-4 prior lines of therapy. Prior treatment with a proteasome inhibitor (PI) was allowed, but patients could not be refractory to PIs in the last line of therapy. Melflufen (30, 40, or 20 mg intravenously; day 1 of each 28-day cycle) was administered with bortezomib (1.3 mg/m^2 subcutaneous; days 1, 4, 8, and 11) plus oral dexamethasone (20 mg on days 1, 4, 8, and 11 and 40 mg on days 15 and 22; dexamethasone dose reduced for patients aged ≥ 75 years). The primary objective in phase 1 was to determine the optimal phase 2 dose of melflufen for this combination.

Results: As of the data cutoff date (October 19, 2020), 13 patients received melflufen (30 mg, n = 6; 40 mg, n = 7) plus dexamethasone and bortezomib. In the 30-mg and 40-mg cohorts, respectively, the median age was 78.5 years (range, 70-82) and 70.0 years (range, 61-76); the median prior lines of therapy was 3.5 (range, 2-4) and 2.0 (range, 1-4); 33% and 50% of evaluable patients had high-risk cytogenetics; 83% and 71% were refractory to the last line of therapy; 100% and 86% received a prior PI; and 33% and 14% were refractory to PIs. In the 30-mg and 40-mg cohorts, respectively, the median treatment duration was 6.5 months (range, 1.4-29.0) and 8.7 months (range, 2.1-19.6); 4 patients (67%) and 4 patients (57%) were still on treatment; and 2 patients and 3 patients discontinued study treatment. Reasons for discontinuation included progressive disease (PD; n=1) and other (n=1) in the 30-mg cohort and adverse event (AE; n=1), lack of efficacy (n=1), and PD (n=1) in the 40-mg cohort. The confirmed overall response rate in the 30-mg and 40-mg cohorts, respectively, was 50% (1 very good partial response [VGPR] and 2 partial response [PR]) and 71% (1 complete response, 3 VGPR, and 1 PR). The most common grade 3/4 treatment-related AEs (TRAEs) were thrombocytopenia (30 mg, 50%; 40 mg, 100%) and neutropenia (30 mg, 33%; 40 mg, 71%); grade 3/4 nonhematologic TRAEs were infrequent. Three patients discontinued study treatment due to treatment-emergent AEs (30 mg, cardiac failure chronic [n=1] and osteolysis [n=1]; 40 mg, thrombocytopenia [n=1]). Serious TRAEs occurred in 2 patients (33%) in the 30-mg cohort (neutropenia and pneumonia [n=1], syncope [n=1]) and 1 patient (14%) in the 40-mg cohort (thrombocytopenia and neutropenia). No dose-limiting toxicities occurred at either dose level. A fatal AE occurred in 1 patient in the 30-mg cohort (cardiac failure chronic; considered unrelated to study treatment).

Summary/Conclusion: ANCHOR determined that the optimal dose of melflufen is 30 mg and results showed clinical activity in heavily pretreated patients with RRMM and poor prognostic factors. Recruitment in phase 2 is ongoing; updated data will be presented.



EP971 TIME TO BEST RESPONSE CORRELATES WITH OUTCOME IN THE RANDOMIZED COMPARISON BETWEEN KRD AND KTD FOLLOWED BY K MAINTENANCE OR OBSERVATION (AGMT-MM02 TRIAL)

Background: Rapid induction of remission is a favorable prognostic factor in several cancers (Hodgkin's and aggressive lymphomas). In multiple myeloma, only few data are available on response kinetics and outcome.
Aims: Here, we evaluated the association between time to best response in patients with transplant non-eligible, newly diagnosed multiple myeloma (TNE NDMM) enrolled in a randomized phase II study comparing KRd with KTd for induction and K with observation for maintenance therapy.
Methods: At time of data-cut (July 9, 2020), 91 patients were randomized and 80 patients with TNE NDMM received at least one cycle (=per protocol group) and have been analyzed so far in this still ongoing study. Median age was 75 years, ISS stage I/II/III: 21 (26.3%)/26 (32.5%)/33 (41.2%), ECOG stage 0/1: 40 (50%)/40 (50%). Patients were randomized for 9 cycles of KRd or KTd. After end of induction, those with SD or better were randomized to K maintenance (day 1 and 15) for 12 cycles or observation. MRD was assessed by NGF with a sensitivity of 10^{-6} in patients with ≥VGPR. To investigate whether time to best response influences survival, patients were assigned into quartiles. Response rates were evaluated by descriptive statistics, survival estimates calculated according to Kaplan-Meier and survival curves compared using the log-rank test. Fisher test was used for comparison of individual groups.
Results: Median follow-up was 19.2 months. As the trial is still ongoing, response rates and survival data are given for both arms combined. Twenty-seven patients (33.8%) achieved CR, 33 patients (41.3%) VGPR, and 14 patients PR (17.5%). Six patients (7.5%) showed only minor or no response [MR: 3 (3.7%), SD: 2 (2.5%), PD: 1 (1.2%)]. Eleven patients discontinued therapy within the first cycle due to investigator decision [4 (4.4%)], patient's decision [3 (3.3%)], development of AE/unacceptable toxicity [2 (2.2%)], and death or other reason [1 each (1.1%)], respectively. Eighteen of 40 patients (45%) tested were found to be MRD negative. The time to best response varied between 26 and 675 days. Quartile 1: 20 patients, days 26-42 days, quartile 2: 22 patients (43-112 days), quartile 3: 18 patients (113-253 days), quartile 4: 20 patients (254-675 days). The proportion of patients with progression or death declined from quartile 1 (55%) to quartile 2 (31.8%) and quartile 4 (20%). Only quartile 3 showed a rise up to 44.4% compared to quartile 2. Median progression-free survival was similar for patients of quartiles 1-3 (1: 22.3, 2: 15.0, 3: 24.0 months, p=0.645) but was significantly longer in those of quartile 4 (33.0 months, p=0.024, Fig. 1). Similar findings were observed for overall survival. There was a steady decrease in the proportion of death from quartile 1-4 (Fig. 1) and survival curves were similar for quartile 1-3 (p=0.143), but significantly superior for those of quartile 4 (p=0.019). Additional evaluations regarding high-risk cytogenetics, MRD negativity, depth of response or age did not reveal statistically significant differences, but showed tendencies that early responders include a higher proportion of patients with high-risk cytogenetics (presence of t(4;14) and/or del(17p)), MRD positivity and higher age. Updated results will be presented.

Figure 1: Progression-free survival and overall survival according to quartiles of time to best response. Number of events/quartile are shown separately.

Summary/Conclusion: In conclusion, our data show that slow response kinetics are associated with prolonged progression-free and overall survival in patients randomized to either KRd or KTd induction therapy followed by one year of carfilzomib maintenance or observation.

EP972 CILTACABTAGENE AUTOLEUCEL FOR TRIPLE-CLASS EXPOSED MULTIPLE MYELOMA: ADJUSTED COMPARISON OF CARTITUDE-1 OUTCOMES VERSUS REAL WORLD CLINICAL PRACTICE OBSERVED IN GERMAN REGISTRY

[1]Internal Medicine V and National Center for Tumor Diseases (NCT), University Clinic Heidelberg, Heidelberg, Germany, [2]Medical College of Wisconsin, Milwaukee, [3]University of Pittsburgh School of Medicine, Pittsburgh, United States, [4]Janssen Pharmaceutica NV, Beerse, Belgium, [5]Janssen-Cilag SpA, Cologno Monzese, Italy, [6]Cilag GmbH International, Zug, Switzerland, [7]Janssen EMEA Medical Affairs, Beirut, Lebanon, [8]Janssen Sciences Ireland UC, Dublin, Ireland, [9]Janssen R&D, Raritan, [10]Legend Biotech USA, Piscataway, United States, [11]OncologyInformationService O.I.s), Freiburg, Germany, [12]Mount Sinai Medical Center, New York, United States

Background: Patients with relapsed/refractory multiple myeloma (RRMM) who are triple-class exposed to immunomodulatory drugs (IMiDs), proteasome inhibitors (PIs) and anti-CD38 monoclonal antibodies (MoABs) have few treatment options available and poor outcomes (Gandhi et al., Leukemia, 2019). Ciltacabtagene autoleucel (cilta-cel), a chimeric antigen receptor T-cell (CAR-T) therapy, is studied in CARTITUDE-1, an open-label, single arm phase 1b/2 clinical trial assessing safety and efficacy of cilta-cel in adult patients with triple-class exposed RRMM. In absence of a comparator arm in CARTITUDE-1, comparison of trial outcomes versus an external cohort of similar patients allows to quantify clinical benefits relative to treatments used in current clinical practice.
Aims: To compare overall survival (OS) and time to next treatment (TTNT) in triple-class exposed patients with RRMM treated with cilta-cel vs. therapies as currently used in real world clinical practice (RWCP).
Methods: Individual patient data (IPD) for baseline risk factors and outcomes on OS/TTNT were available for cilta-cel patients from CARTITUDE-1 (September 2020) and for triple-class exposed RRMM patients treated with RWCP therapies from a German registry (OIs). This

registry includes around 3,400 RRMM patients captured from a representative sample of 108 centers collected between January 2016 and March 2020. Patients with ECOG score 0 or 1 and ≥ 3 prior therapy lines, who received at least 1 subsequent active MM therapy after becoming triple-class exposed were selected from the registry. Hazard ratios (HR) with 95% confidence intervals (CI) for cilta-cel vs. RWCP were estimated for OS and TTNT using IPW weighted (Li et al., FJAjoe, 2019; Austin et al., PCJSim, 2016) and multivariable Cox proportional hazards regression models, adjusting for differences in commonly available baseline characteristics. Patients with multiple treatment lines initiated after fulfilling the inclusion criteria, contributed multiple times to the analyses, with line of therapy and its follow-up (observations) as unit of analysis and baseline information defined specific at initiation of each treatment line. Correlation of observations within patients was corrected using robust standard errors.
Results: Patients enrolled in CARTITUDE-1 (113 patients) and observations from RWCP (258 observations from 192 patients) were used for comparison. Cilta-cel patients had more advanced disease in terms of higher refractoriness, shorter time to progression on most recent prior line, higher number of prior lines, and shorter average duration of prior lines. RWCP included more patients with R-ISS stage III and ECOG score 1. Overlap weights analyses led to well-balanced cohorts and HR estimates for OS (HR 0.18, 95% CI 0.09-0.38) and TTNT (HR 0.19, 95% CI 0.09-0.39) were statistically significant in favor of cilta-cel. Multivariable regression analyses including baseline characteristics as covariates showed similar results confirming findings using IPW.
Summary/Conclusion: Comparative analyses using PLD, adjusting for differences in patient characteristics between both cohorts, shows that cilta-cel patients had significantly longer OS and TTNT compared to patients treated with therapies used in current clinical practice in Germany. These findings highlight cilta-cel's potential as an effective treatment option to address currently unmet treatment needs in triple-class exposed patients with RRMM.

EP973 MELFLUFEN PLUS DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA EXPOSED AND/OR REFRACTORY TO PRIOR ALKYLATORS – A POOLED ANALYSIS OF THE O-12-M1 AND HORIZON STUDIES

Sammons Cancer Center, Dallas, [17]The Oncology Institute of Hope and Innovation, Glendale, [18]Division of Hematology-Oncology, Department of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, United States, [19]Oncopeptides AB, Stockholm, Sweden

Background: Therapies for multiple myeloma (MM) combine multiple drug classes including IMiDs, proteasome inhibitors, monoclonal antibodies, alkylators, histone deacetylase inhibitors, XPO1 inhibitors, and anti-B cell maturation antigen therapies (Legarda et al. *Cancer.* 2020;12:3576). Despite advances in therapy, outcomes remain poor for patients with relapsed/refractory MM (RRMM). Melphalan flufenamide (melflufen) is a first-in-class peptide-drug conjugate (PDC) that leverages aminopeptidases and thereby rapidly delivers and releases alkylating agents inside tumor cells. Melflufen has a mechanism of action (MOA) distinct from other alkylating agents (Slipicevic et al. AACR 2020. Abs. 1843). In the O-12-M1 (NCT01897714) and HORIZON (OP-106; NCT02963493) studies, melflufen plus dexamethasone showed meaningful efficacy and a clinically manageable safety profile in patients with RRMM (Richardson et al. *Lancet Haematol.* 2020;7:5; Richardson et al. *J Clin Oncol.* 2020;Dec 9 [Epub]).
Aims: To examine the clinical activity of melflufen in patients from the O-12-M1 (phase 2 only) and HORIZON studies who were exposed to alkylators in prior lines of therapy (LoTs).
Methods: Patients in the phase 2 portion of the O-12-M1 study and HORIZON had RRMM with ≥2 prior LoTs and received melflufen 40 mg plus dexamethasone 40 mg (20 mg if aged ≥75 years). Both studies had a primary endpoint of overall response rate (ORR); secondary endpoints included progression-free survival (PFS), overall survival (OS), and safety. Data from the 2 studies were pooled and analyzed according to prior exposure and refractory status to alkylators before study entry. Refractory status to prior alkylator therapy was defined as failure to achieve a minimal response or progression while on therapy, or within 60 days of last dose of alkylator therapy.
Results: A total of 202 patients were included in the analysis (HORIZON: n=157; O-12-M1: n=45); of these, 24 (12%) had not been exposed to an alkylator and 178 (88%) had been exposed to alkylators in ≥1 prior LoT (see **Table** for prior alkylator exposure/refractory status). Patients without prior exposure to an alkylator had the best response to therapy (ORR, 50.0% [95% CI, 29.1-70.9]; PFS, 7.1 months [95% CI, 3.7-9.0]). However, meaningful responses were also seen among patients exposed and refractory to prior alkylators (**Table**). PFS and OS were better or similar to that in the overall population in patients exposed to an alkylator in ≥1 prior LoT but not refractory and in patients exposed to an alkylator in 1 prior LoT and refractory, respectively. PFS and OS were shortest when both exposed and refractory to an alkylator in ≥2 prior LoTs; this group had more patients refractory to an alkylator in their last LoT (61%) and 82% were refractory to an alkylator within 12 months of study entry. Results should be interpreted with caution due to limited patient numbers. Grade 3/4 adverse events (AEs) were similar among patients exposed to prior alkylators (O-12-M1: 85%; HORIZON: 89%) and the overall population (O-12-M1: 84%; HORIZON: 89%). The most common AEs were hematologic but were mostly reversible and clinically manageable. Nonhematologic AEs were infrequent and primarily grade 1/2.

Table. Efficacy by Exposure and/or Refractoriness to Prior Alkylator Therapy

Patients	n	ORR, % (95% CI)	PFS, Median (95% CI), mo	OS, Median (95% CI), mo
Total	202	29.7 (23.5-36.5)	4.4 (3.7-5.1)	13.6 (11.2-17.6)
No prior alkylator exposure	24	50.0 (29.1-70.9)	7.1 (3.7-9.0)	22.4 (9.6-NE)
Exposed to alkylator in ≥1 prior LoT	178	27.0 (20.6-34.1)	4.2 (3.7-4.9)	11.8 (10.0-16.5)
Exposed in ≥1 prior LoT, not refractory	62	33.9 (22.3-47.0)	5.3 (4.2-7.9)	21.1 (17.2-33.2)
Exposed in 1 prior LoT and refractory	43	23.3 (11.8-38.6)	4.6 (3.0-6.5)	11.6 (7.7-18.9)
Exposed in ≥ 2 prior LoT, refractory in 1 LoT	40	35.0 (20.6-51.7)	3.7 (2.4-4.9)	10.1 (5.3-13.9)
Exposed and refractory in ≥2 prior LoTs	33	9.1 (1.9-24.3)	3.1 (1.7-4.0)	7.2 (4.8-13.6)

LoT, line of therapy; NE, not estimable.

Summary/Conclusion: Melflufen in combination with dexamethasone showed meaningful efficacy in heavily pretreated patients with RRMM including those exposed and/or refractory to prior alkylators and is in line with pre-clinical studies showing that melflufen has an MOA distinct from that of other alkylating agents.

EP974 EFFICACY AND SAFETY OF SELINEXOR, BORTEZOMIB, AND DEXAMETHASONE BASED ON REFRACTORY STATUS TO LENALIDOMIDE IN PATIENTS WITH PREVIOUSLY TREATED MULTIPLE MYELOMA: A POST-HOC ANALYSIS OF THE BOSTON STUDY

Background: Lenalidomide (LEN) is typically a frontline therapy for newly diagnosed MM. Patients (pts) with MM refractory to LEN are less likely to respond to other IMiDs and represent a signification area of unmet medical need. In the ITT population of the BOSTON study, selinexor, bortezomib, and dexamethasone (XVd) was associated with significant improvements in median progression-free survival (PFS), overall response rate (ORR), and rates of peripheral neuropathy, with trends in overall survival (OS) favoring XVd.
Aims: This study aimed to evaluate if PFS, overall response rate (ORR), time to next treatment (TTNT) and tolerability were influenced by prior treatment with LEN when comparing XVd with Vd.
Methods: The BOSTON trial (NCT03110562) is a Phase 3 randomized, controlled, open-label study of once weekly XVd vs twice weekly bortezomib and dexamethasone (Vd) in pts with MM and 1-3 prior therapies. We performed post-hoc analyses on two different subgroups to compare outcomes based on refractory status to LEN and immunomodulatory drug (IMiD) therapy.
Results: Amongst the 402 pts in BOSTON, 160 had MM refractory to any IMiD (XVd=74, Vd=86). Of those, 106 were documented to be refractory to LEN (XVd=53, Vd=53) and 296 were not refractory to LEN (XVd=142, Vd=154). Baseline characteristics were generally well balanced between subgroups. In these subgroups based on refractory status to IMiD or LEN, median PFS was significantly longer in the XVd arm as compared to Vd (IMiD refractory: 13.9 vs. 8.4 months (mo), p=0.005; LEN refractory: 10.2 vs. 7.1 mo, p=0.012; not LEN refractory, 15.4 vs 9.6 mo, p=0.014). Significant increases in TTNT were observed with XVd treatment in pts with MM that was: IMiD refractory (14.8 vs. 10.2 mo, p=0.003), LEN refractory (13.0 vs. 7.6 mo, p=0.015), and LEN not refractory (19.1 vs 12.9 mo, p=0.005). ORR was improved with XVd compared to Vd regardless of refractory status (IMiD refractory: 68.9% vs 55.8%, p=0.045; LEN refractory: 67.9% vs. 47.2%, p=0.016; and LEN not refractory: 79.6% vs 67.5%, p=0.010). The most common treatment-emergent AEs for the XVd/Vd arms for all subgroups were thrombocytopenia (66.2/30.6%; 71.7/40.4%; 55.6/22.4%), nausea (48.6/11.8%; 50.9/11.5%; 50.0/9.2%) and fatigue (40.5/20.0%; 45.3/21.2%; 40.8/17.1%) for IMiD, LEN, and not LEN refractory, respectively. Incidence of PN AEs of any grade were reduced with XVd compared to Vd: IMiD refractory: 27% vs. 42.4%; LEN refractory: 30.2% vs 36.5%; LEN not refractory: 33.1% vs 50.7%.
Summary/Conclusion: In pts with previously treated MM, PFS, ORR, and TTNT were significantly improved regardless of documented refractory status to LEN or to any IMiD. These analyses support the use of the XVd combination for pts with disease refractory to LEN and likely to any IMiD.

EP975 SUBGROUP ANALYSIS: EFFICACY AND SAFETY OF ORAL PANOBINOSTAT IN COMBINATION WITH SC BORTEZOMIB AND ORAL DEXAMETHASONE IN RELAPSED OR RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS > 75 YEARS OF AGE

Background: Panobinostat (Pano), a pan-histone deacetylase inhibitor, is approved for the treatment of relapsed or relapsed/refractory multiple myeloma (RRMM) in combination with BTZ and dex (FVd) in patients who received ≥2 prior lines of therapy, including BTZ and an IMiD. The pivotal phase 3 PANORAMA 1 trial, which used IV BTZ, demonstrated significant PFS benefit with FVd compared with placebo-Vd; however, AEs were more frequent. The randomized phase 2 PANORAMA 3 study was conducted to optimize FVd by comparing three varying regimens and by incorporating SC BTZ. This study demonstrated that 20 mg TIW provides favorable outcomes, more durable responses, and a favorable AE profile compared to those seen in PANORAMA 1. Here we present data indicating that response outcomes and AE rates in the subset of patients >75 in PANORAMA 3 were similar to those of the general trial population and to those of patients ≤75 years of age.
Aims: To evaluate the overall response rate (ORR; IMWG 2011 criteria) after up to 8 treatment cycles by Independent Review Committee assessment. Secondary endpoints included in this abstract are duration of response (DOR) and safety.
Methods: PANORAMA 3 (NCT02654990) was a randomized, open-label, international, multicenter phase 2 study. Eligible patients were ≥18 years old with 1–4 prior lines of therapy, including an IMiD. Patients primarily refractory to BTZ were excluded. Patients were randomized 1:1:1 to Pano 20 mg TIW (d 1, 3, 5, 8, 10, 12), Pano 20 mg BIW (d 1, 4, 8, 11), or Pano 10 mg TIW (d 1, 3, 5, 8, 10, 12), all administered in 21-day cycles. Randomization was stratified by age at screening (≤75 vs >75 years). For Cycles 1–4, patients ≤75 years old received SC BTZ 1.3mg/m(2) BIW (d 1, 4, 8, 11) and oral dex 20mg d 1, 2, 4, 5, 8, 9, 11, 12. Patients aged ≤75 years from cycle 5 onwards, and patients > 75 years for all cycles, received BTZ 1.3 mg/m(2) weekly (d1 and 8) and dex 20mg on d 1, 2, 8, and 9.
Results: In total, 248 patients were randomized and 241 patients received treatment. Of the patients who received treatment, 211 patients were ≤75 years of age and 30 patients were >75 years of age. In the overall patient population, across the 3 arms, the ORR after 8 cycles was 62.2%, and the median duration of response for the 20mg TIW arm, across all age groups, was 22 months. Median DOR in patients >75 years of age for each specific treatment arm could not be calculated and will be presented subsequently. Across the general study population, treatment-related Grade ≥3 AEs were reported in 78%, 72%, and 54% of patients in the 20 TIW, 20 BIW, and 10 TIW arms respectively; serious AEs were reported in 54%, 48%, and 44% of patients respectively; and discontinuations due to AEs occurred in 29.5%, 28%, and 15% of patients respectively. See Table 1 for response rates and Table 2 for adverse events for patients ≤75 and >75 years of age.

Table 1

Response Rates	Patients ≤75 Years of Age n=216			Patients >75 Years of Age n=32		
	20mg TIW N=72	20mg BIW N=73	10mg TIW N=71	20mg TIW n=10	20mg BIW n=10	10mg TIW n=12
ORR for up to 8 cycles	62.5%	68.4%	54.9%	60%	40%	25%

Table 2

Adverse Events	Patients ≤75 Years of Age n=211			Patients >75 Years of Age n=30		
	20mg TIW n=69	20mg BIW n=73	10mg TIW n=69	20mg TIW n=9	20mg BIW n=10	10mg TIW n=11
Serious AEs, all Grades	53.6	49.3	44.9	55.6	40	36.4
Serious AEs ≥ Grade 3 (%)	49.3	45.2	40.6	44	20	36.4
Diarrhea ≥ Grade 3 (%)	11.6	11	5.8	11.1	0	0
Thrombocytopenia ≥ Grade 3 (%)	40.6	32.9	26.1	55.6	20	9.1
Serious Infections ≥ Grade 3 (%)	24.6	23.3	21.7	11.1	0	36.4

Summary/Conclusion: In PANORAMA 3, SC BTZ improved the tolerability of FVd relative to that seen with IV BTZ in PANORAMA 1. Across the entire patient population, the most durable and deepest responses were observed in the 20 mg TIW arm, which yielded a median DOR of 22 months. In PANORAMA 3, the efficacy outcomes seen in the subset of patients >75 years of age were similar to those of the general study population and to those of the group ≤75. Importantly, in patients >75 years of age, rates of high-grade AEs, including diarrhea, were similar to those seen in the general study population and to those seen in the group ≤75.

EP976 SURVIVAL AMONG OLDER PATIENTS WITH PREVIOUSLY TREATED MULTIPLE MYELOMA TREATED WITH SELINEXOR, BORTEZOMIB, AND DEXAMETHASONE (XVD) IN THE BOSTON STUDY

Background: Multiple myeloma (MM) typically affects older patients (pts) who are more vulnerable to toxicity with anti-MM treatments. These pts have significant morbidities resulting in a need for dose modifications or alternative suboptimal treatment options. Significant improvements were observed in the BOSTON study with XVd vs Vd in progression-free survival (PFS), overall response rate (ORR) and rates of peripheral neuropathy (PN); median overall survival (OS) trended in favor of XVd.
Aims: Here we report survival outcomes in the BOSTON study population based on age.
Methods: The phase 3 randomized BOSTON trial (NCT03110562) is a controlled, open-label study of once weekly XVd vs. twice weekly standard Vd in pts with MM and 1-3 prior treatment regimens. We performed post-hoc analyses to compare survival benefits in pts ≥65 vs <65 years of age.
Results: The BOSTON study enrolled a total of 402 pts between June 2017 and February 2019 who were randomized into XVd or Vd arms. The numbers of pts treated with XVd or Vd who were ≥65 were 109/132 and 86/75 who were <65, respectively. Baseline characteristics were similar by age although pts ≥65 years were less likely to have received ASCT than those <65 years (48.4% vs. 25.3%). Median PFS was prolonged with XVd compared with Vd across both age groups: ≥65 (HR, 0.55 [95% CI, 0.37-0.83] P=0.002) and <65, (HR, 0. 74 [95% CI, 0.49-1.11], P=0.07). Vd was associated with a lower ORR (64.4%) than treatment with XVd (76.1%) (OR, 1.77 [95% CI, 1.00-3.11], P=0.024) in pts ≥65, while the ORR in those <65 was 76.7% with XVd and 58.7% (OR, 2.33 [95% CI, 1.18-4.59], P=0.007) with Vd. As of Jan 2021, the median OS for the overall population was not reached for both arms (HR=0.86; p=0.193), with 61 and 75 deaths in the XVd and Vd arms, respectively. Median OS was not reached in pts ≥65 with XVd and was 28.6 months with Vd (HR=0.60; 95% CI, 0.38-0.94; p=0.012), while OS was similar for pts <65 (p=0.926). Pts ≥65 had a lower incidence of death on XVd as compared to Vd (29 vs 56) and there were 32 deaths with XVd and 19 with Vd in pts <65. Grade ≥3 treatment emergent adverse events (AEs) were not observed more often in older compared to younger pts. Amongst pts ≥65, PN of any grade was lower with XVd (32.1%) compared to Vd (46.5%); (OR 0.57 [95% CI 0.34-0.97], p=0.017), including a lower incidence of grade ≥3 PN (XVd 4.6% vs. Vd 11.6%). Pts <65 followed a similar trend of PN AEs of any grade: XVd, 32.6%; Vd, 48.0% (OR 0.42 [95% CI 0.21-0.82], p=0.006).
Summary/Conclusion: In an older patient population with a poor prognosis, XVd was associated with a significant survival benefit, improved PFS and ORR with reduced PN, and requires relatively short and infrequent clinic visits. XVd may be a simple, effective regimen for pts with previously treated MM including those ≥65 years of age.

EP977 COMPARISON OF OUTCOMES WITH CILTACABTAGENE AUTOLEUCEL (CILTA-CEL) IN CARTITUDE-1 VERSUS STANDARD OF CARE IN TRIPLE-CLASS EXPOSED MULTIPLE MYELOMA PATIENTS IN CLINICAL TRIALS OF DARATUMUMAB

K. Weisel [1,*], T. Martin [2], A. Krishnan [3], S. Jagannath [4], K. Qi [5], A. Londhe [6], M. Mehra [7], S. Nair [8], J. Diels [7], M. Vogel [7], J. M. Schecter [9], A. Banerjee [10], S. Valluri [7], J. G. Berdeja [11], T. Nesheiwat [12], A. Garrett [12], S. Z. Usmani [13], K. Yong [14]

Background: Triple-class exposed relapsed/refractory multiple myeloma (RRMM) patients (ie, those exposed to a proteasome inhibitor [PI], immunomodulatory drug [IMiD], and an anti-CD38 monoclonal antibody) tend to relapse, leading to progressively worse outcomes, including shorter progression-free survival (PFS) with each subsequent relapse. CARTITUDE-1 (NCT03548207) is a single-arm, phase 1b/2 study evaluating the efficacy and safety of cilta-cel, a chimeric antigen receptor T-cell therapy with 2 B-cell maturation antigen-targeting single-domain antibodies, in heavily pretreated patients with RRMM. The CARTITUDE-1 study enrolled patients who received ≥3 prior lines of therapy [LOT] or were double refractory to a PI and IMiD, received a PI, IMiD, and anti-CD38 antibody, had an Eastern Cooperative Oncology Group performance status score of ≤1, and documented disease progression ≤12 months after the last LOT.
Aims: To compare efficacy outcomes in triple-class exposed RRMM patients treated with cilta-cel from CARTITUDE-1 (N=97) versus standard of care (SOC) in a cohort of patients who participated in global daratumumab clinical trials.
Methods: Triple-class exposed patients with RRMM who met CARTITUDE-1 eligibility criteria were identified from the follow-up data from 3 global trials of the anti-CD38 monoclonal antibody, daratumumab: POLLUX (phase 3 study of daratumumab-lenalidomide-dexamethasone vs lenalidomide-dexamethasone; NCT02076009), CASTOR (phase 3 study of daratumumab-bortezomib-dexamethasone vs bortezomib-dexamethasone; NCT02136134), and EQUULEUS (phase 1b study of daratumumab plus standard MM regimens; NCT01998971). In these trials, patients were followed for overall response, PFS, and overall survival (OS) on subsequent treatments (per physician's choice) after discontinuation of the study treatment. These trial data were used to identify an SOC patient cohort who met CARTITUDE-1 (Sept 2020 data cutoff) eligibility criteria, including organ function. Outcomes were compared between the cilta-cel and SOC cohorts, adjusting for unbalanced prognostic baseline covariates, using inverse probability of treatment weighting (IPTW) propensity scores with logistic regression for overall response rate (ORR), and Cox models for PFS and OS to estimate the average treatment effect in the CARTITUDE-1 population. Sensitivity analyses were performed using multivariate Cox regression models and propensity score matching.
Results: In all, 267 triple-class exposed patients with RRMM from the European Union (70.0%), North America (14.2%), Asia/Pacific (12.7%), and other regions (3.0%) met the inclusion criteria. Baseline characteristics were similar between the 2 cohorts after propensity score weighting (Table). Treatment regimens in the SOC cohort primarily included pomalidomide (26%), cyclophosphamide (26%), lenalidomide (20%), bortezomib (20%), carfilzomib (17%), and thalidomide (10%). Patients had significantly improved ORR, PFS, and OS with cilta-cel

(N=97) versus SOC (N=267) (table). Cilta-cel treatment benefit was robust across the sensitivity analyses.

	CARTITUDE-1 (N=97)	SOC Cohort Observed (N=267)	SOC Cohort IPTW-Adjusted
Baseline characteristic, %			
Age <65 years	64	42	53
<6 years since MM diagnosis	46	45	47
High-risk cytogenetics*	24	15	15
ISS stage III	14	10	15
Prior LOT >4	66	31	67
Time to progression on last LOT (≤4 months)	50	30	58
Triple-class refractory† and quad-drug refractory	45	82	47
Penta-drug refractory‡	42	13	37
Outcomes			
ORR, % OR (95% CI)§	97	43.1 41.41 (15.05, 171.45)¶	43.2 41.11 (14.04, 176.02)¶
PFS, HR (95% CI)		HR 0.24 (0.16, 0.35)¶	HR 0.19, (0.11, 0.32)¶
OS, HR (95% CI)		HR 0.30 (0.17, 0.52)¶	HR 0.23 (0.12, 0.43)¶

*del17p, t(14;16), t(4;14); †≥1 PI, ≥1 IMiD, and 1 anti-CD38 antibody; ‡≥2 PI, ≥2 IMiD, and 1 anti-CD38 antibody; §CARTITUDE-1 vs SOC cohort; ¶P <0.0001.

CI, confidence interval; HR, hazard ratio; IMiD, immunomodulatory drug; IPTW, inverse probability of treatment weighting; ISS, international staging system; LOT, line of therapy; MM, multiple myeloma; OR, odds ratio; ORR, overall response rate; PI, proteasome inhibitor; SOC, standard of care.

Summary/Conclusion: Cilta-cel shows significantly better efficacy outcomes over SOC in patients previously treated with a PI, IMiD, and daratumumab, highlighting its potential as an effective treatment option in triple-class exposed patients with RRMM.

EP978 MATCHING ADJUSTED INDIRECT COMPARISON OF CILTACABTAGENE AUTOLEUCEL VERSUS BELANTAMAB MAFODOTIN IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM) TREATED WITH ≥3 LINES OF PRIOR THERAPY

K. Weisel [1,*], A. Krishnan [2], K. Yong [3], J. M. Schecter [4], M. Vogel [5], C. C. Jackson [4], W. Deraedt [6], H. Tian [4], T.-M. Yeh [4], A. Banerjee [7], M. J. Carrasco-Alfonso [8], X. Wu [8], T. Nesheiwat [8], S. Van Sanden [5], J. Diels [5], S. Valluri [5], S. Z. Usmani [9], J. G. Berdeja [10], S. Jagannath [11], T. Martin [12]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Judy and Bernard Briskin Center for Multiple Myeloma Research, City of Hope, Duarte, United States, [3]University College Hospital, London, United Kingdom, [4]Janssen R&D, [5]Janssen Global Services, LLC, Raritan, United States, [6]Janssen R&D, Beerse, Belgium, [7]Janssen R&D, Spring House, [8]Legend Biotech USA, Inc, Piscataway, [9]Levine Cancer Institute-Atrium Health, Charlotte, [10]Sarah Cannon Research Institute, Nashville, [11]Mount Sinai Medical Center, New York, [12]UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, United States

Background: Ciltacabtagene autoleucel (cilta-cel; JNJ-68284528) is a chimeric antigen receptor (CAR) T-cell therapy with two BCMA–targeting, single-domain antibodies designed to confer avidity. In the phase 1b/2 CARTITUDE-1 single arm study (NCT03548207), a single infusion of cilta-cel yielded early, deep, and durable responses with a manageable safety profile in heavily pretreated triple-class exposed (to immunomodulatory drugs [IMiDs], proteasome inhibitors [PIs], and anti-CD38 antibodies) RRMM patients. In the absence of head-to-head trials, matched adjusted comparison methods may be helpful to compare the relative efficacy of different treatment regimens. A systematic literature review using PRISMA guidelines identified belantamab mafodotin as a potential BCMA-targeting non-CAR T-cell comparator in the triple-class exposed RRMM patient population.
Aims: To compare efficacy outcomes for cilta-cel from the CARTITUDE-1 study to the approved 2.5 mg/kg (every 3 weeks) dose of belantamab mafodotin from the DREAMM-2 trial (NCT03525678).
Methods: CARTITUDE-1 included triple class exposed patients who received ≥3 prior lines of therapy or were double refractory to an IMiD and PI, had ECOG score of ≤1, and disease progression ≤12 months after the last line of therapy. Unanchored matching-adjusted indirect treatment comparisons (MAIC) were performed based on individual patient-level data from 97 infused patients in CARTITUDE-1 and published aggregate-level data from DREAMM-2 (N=97). Patients from CARTITUDE-1 (N=85) who matched the eligibility criteria for DREAMM-2 (≥ triple-class refractory and refractory to last line of treatment) were included in the analysis. Individual patient data for time-to-event outcomes from DREAMM-2 were simulated based on the published Kaplan-Meier curves. Matching of CARTITUDE-1 patients to the DREAMM-2 population was based on propensity score weighting methods, using available prognostic factors identified from the literature and based on clinical expertise. Outcomes included overall response rate (ORR), complete response or better (≥CR), progression free survival (PFS), and overall survival (OS). For ORR and ≥CR, the relative effects of cilta-cel versus belantamab mafodotin were quantified using an odds ratio (OR) and 95% confidence interval (CI) derived from a weighted logistic regression analysis, while time to event endpoints were analyzed using a weighted Cox proportional hazards model. A similar comparative analysis was performed including all enrolled patients from CARTITUDE-1.
Results: Cilta-cel was associated with significantly higher ORR and ≥CR, and improved PFS and OS compared with belantamab mafodotin in a population matched to DREAMM-2 (Table). Similarly, higher efficacy was associated with cilta-cel in the comparative analysis which included all patients enrolled in CARTITUDE-1.

Outcome*	Cilta-cel vs. belantamab mafodotin 2.5 mg/kg
ORR, OR (95% CI)	270.65 (74.64, 981.41)†
≥CR, OR (95% CI)	59.17 (15.17, 230.76)†
PFS, HR (95% CI)	0.21 (0.11, 0.40)†
OS, HR (95% CI)	0.22 (0.10, 0.46)†

*Patient populations from CARTITUDE-1 (N=85, ≥ triple-class refractory and refractory to last line of treatment) and DREAMM-2 (N=97) were matched on refractory status, cytogenetic risk, EMD, and ISS; †P<0.0001.
CR, complete response; CI, confidence interval; EMD, extramedullary disease; HR, hazard ratio; ISS, international staging system; OR, odds ratio; OS, overall survival; PFS, progression-free survival.

Summary/Conclusion: These analyses demonstrated improved efficacy with cilta-cel versus belantamab mafodotin for ORR, ≥CR, PFS, and OS, highlighting its potential in patients with triple-class exposed RRMM.

EP979 FIRST-LINE THERAPY WITH LENALIDOMIDE AND DEXAMETHASONE IN TRANSPLANT-INELIGIBLE PATIENTS WITH MULTIPLE MYELOMA: FINAL RESULTS OF THE OBSERVATIONAL STUDY FIRST-NIS

H. Nückel [1,*], T. Behlendorf [2], H. Schulz [3], M. Schulze [4], U. Söling [5], D. Bürkle [6], M. Koenigsmann [7], T. Medinger [8], T. Dechow [9], C. Vannier [8], B. Niemeier [10], B. Schmidt [11], J. Rauh [12], K. Potthoff [8]

[1]Hämatologisch-onkologische Schwerpunktpraxis, Bochum, [2]Gemeinschaftspraxis für Innere Medizin, Hämatologie, Onkologie, Gastroenterologie, Halle (Saale), [3]Praxis Internistischer Onkologie und Hämatologie (PIOH), 'Frechen, [4]Praxis und Tagesklinik für Hämatologie/Onkologie, Zittau, [5]Hämato-Onkologisches Zentrum Kassel MVZ GmbH, Kassel, [6]Zentrum Ambulante Onkologie, Schorndorf, [7]MediProjekt GbR, Hannover, [8]iOMEDICO AG, Freiburg, [9]Studienzentrum Onkologie Ravensburg, Ravensburg, [10]iOMEDICO AG, iOMEDICO AG, Freiburg, [11]Hämato-Onkologische Überörtliche Gemeinschaftspraxis, München, [12]GIM - Gemeinschaftspraxis Innere Medizin, Witten, Germany

Background: Lenalidomide plus low-dose dexamethasone (Rd) is an established standard of care for transplant-ineligible patients (pts) with newly diagnosed multiple myeloma (NDMM) of all ages. Approval was based on the results of the pivotal phase III FIRST trial showing a significantly prolonged progression-free (PFS) and overall survival (OS) in pts treated with Rd compared with melphalan-prednisone-thalidomide (MPT) (Facon et al., Blood 2018). Since MM is a diagnosis of advanced age and only 35% of pts were age older than 75 years in the FIRST trial, the results are difficult to extrapolate to a real-world (RW) setting. Besides, RW data of this commonly used regimen are still scarce.
Aims: The focus of the final analysis part one of the FIRST-NIS is to evaluate effectiveness and safety of first-line Rd therapy in NDMM pts in a RW setting.
Methods: The prospective, multicenter, non-interventional, observational FIRST-NIS study collected data on 172 MM pts receiving Rd first-line therapy from 41 sites across Germany. Primary objective was to evaluate effectiveness of Rd assessed by 24-month PFS rate (PFS24). Secondary endpoints included OS, PFS, objective response rate (ORR), duration of response, quality of life (QoL) and safety. Descriptive statistics were used to analyze the data. Time-to-event analyses were performed using the Kaplan-Meier method. Final survival analysis will be performed 60 months after last patient in (LPI) in 2023 (final analysis part two).
Results: Of 172 pts enrolled, 164 pts qualified for effectiveness and 168 pts for safety analyses. Baseline characteristics of all pts and pts stratified

by age (≤75, >75 years) are presented in Table 1. With a median follow-up of 18.7 months at data base cut (4th November 2020), PFS24 rate was 48.0% for the total cohort, 65.5% for pts ≤75 years and 40.1% for pts >75 years. The median PFS was 22.9 months for all pts, 31.5 months for pts ≤75 years and 19.3 months for pts >75 years. The ORR was 59.1% in all pts, 70.8% in pts ≤75 years and 54.3% in pts >75 years. In total, 98.2% of pts developed adverse events (AEs). Grade 3/4 AEs were detected in 63.1% of pts, of which the most common were anemia (8.3%), thrombocytopenia (4.8%), dyspnea (4.8%) and pneumonia (4.8%).

Table 1: Baseline characteristics

Yes	12 (7.3)	3 (6.3)	9 (7.8)
No	97 (59.1)	28 (58.3)	69 (59.5)
Unknown	52 (31.7)	17 (35.4)	35 (30.2)
Missing	3 (1.8)	0 (0.0)	3 (2.6)

Summary/Conclusion: Although the FIRST-NIS represents an elderly RW pts population with approximately 70% of pts aged >75 years, the results revealed a favorable risk-benefit profile for Rd in NDMM pts. In elderly pts >75 years, however, PFS results were lower compared to younger pts ≤75 years. Reasons might be the higher rates of advanced-stage disease and renal impairment observed in the elderly pts. Overall, the Rd combination seems to be a reasonable and orally available treatment option also for elderly pts with NDMM in the RW setting.

EP980 ISATUXIMAB PLUS CARFILZOMIB AND DEXAMETHASONE VERSUS CARFILZOMIB AND DEXAMETHASONE IN ELDERLY PATIENTS WITH RELAPSED MULTIPLE MYELOMA: IKEMA SUBGROUP ANALYSIS

Background: A prespecified interim efficacy analysis of the Phase 3 IKEMA study (NCT03275285) demonstrated that isatuximab (Isa) plus carfilzomib (K) and dexamethasone (d) (Isa-Kd) significantly improved progression-free survival (PFS) compared with Kd in patients (pts) with relapsed multiple myeloma (RMM) (HR 0.531; 99% CI, 0.318–0.889; *P*=0.0007), with a clinically meaningful increase in minimal residual disease negativity (MRD-) (29.6% vs 13.0%) and complete response (CR) (39.7% vs 27.6%) rates, and a manageable safety profile.
Aims: This subgroup analysis of IKEMA examined efficacy and safety in pts aged <70 and ≥70 years.
Methods: Pts with 1–3 prior lines of therapy were randomized 3:2 to receive Isa-Kd (n=179) or Kd (n=123). The primary end point was PFS, as assessed by an independent response committee. We compared outcomes in pts <70 vs ≥70 years; division into different or additional age groups resulted in smaller sample sizes.
Results: Of the 302 randomized pts, 71.5% were aged <70 years (Isa-Kd: 70.9%; Kd: 72.4%) and 28.5% were aged ≥70 years (Isa-Kd: 29.1%; Kd: 27.6%). Consistent with the significant improvement of PFS in the overall population, the addition of Isa to Kd resulted in improved PFS independently of age (Table). The CR, ≥very good partial response (VGPR), and MRD- rates were higher with Isa-Kd vs Kd. Within the Isa-Kd arm, CR rate and ≥VGPR rate were similar in elderly and younger pts. MRD- was observed in 32.3% of younger pts and 23.1% of elderly pts with Isa-Kd. In both arms, Grade ≥3 and serious treatment-emergent adverse events (TEAEs) were more frequently reported in elderly pts vs pts <70 years old (Table). For both age groups, the incidence of Grade ≥3 TEAEs was higher whereas the incidence of serious TEAEs was similar between Isa-Kd and Kd. In the elderly subgroup, 3 (5.9%) pts receiving Isa-Kd and 1 (2.9%) receiving Kd had fatal TEAEs (Isa-Kd, infection; Kd, general health deterioration due to progressive disease). The most common Grade ≥3 TEAEs in pts aged <70 and ≥70 years treated with Isa-Kd vs Kd were hypertension (18.3% vs 17.0% [<70 years] and 25.5% vs 26.5% [≥70 years]) and pneumonia (14.3% vs 9.1% [<70 years] and 21.6% vs 20.6% [≥70 years]).

	<70 Years		≥70 Years	
	Isa-Kd (n=127)	Kd (n=89)	Isa-Kd (n=52)	Kd (n=34)
PFS HR (95% CI)	0.609 (0.384–0.968)		0.364 (0.176–0.751)	
CR, %	40.2	29.2	38.5	23.5
≥VGPR, %	72.4	56.2	73.1	55.9
MRD-, %	32.3	13.5	23.1	11.8
Grade ≥3 TEAEs, %*	71.4	63.6	90.2	76.5
Serious TEAEs, %*	54.0	52.3	72.5	70.6
Fatal TEAEs, %*	2.4	3.4	5.9	2.9
TEAEs leading to definitive discontinuation, %*	7.1	10.2	11.8	23.5

*n=126; n=88; n=51; n=34

Summary/Conclusion: The addition of Isa to Kd improved PFS and quality of response in elderly pts, with a manageable safety profile, consistent with the benefit observed in the overall IKEMA study population. Isa-Kd provides a potential new treatment option for elderly pts with RMM.

EP981 ISATUXIMAB PLUS CARFILZOMIB AND DEXAMETHASONE IN RELAPSED MULTIPLE MYELOMA PATIENTS WITH HIGH-RISK CYTOGENETICS: IKEMA SUBGROUP ANALYSIS

of Hematology, Bologna University School of Medicine, Bologna, Italy, [13]Sanofi R&D, Vitry-Sur-Seine, [14]Sanofi R&D, Chilly-Mazarin, France, [15]Sanofi, Cambridge, United States, [16]Department of Haematology, University College Hospital, London, United Kingdom

Background: A prespecified interim efficacy analysis of the Phase 3 IKEMA study (NCT03275285) demonstrated that isatuximab (Isa) plus carfilzomib (K) and dexamethasone (d) (Isa-Kd) significantly improved progression-free survival (PFS) compared with Kd in patients (pts) with relapsed multiple myeloma (RMM) (HR 0.531; 99% CI, 0.318–0.889; *P*=0.0007), with a clinically meaningful increase in minimal residual disease negativity (MRD-) (29.6% vs 13.0%) and complete response (CR) (39.7% vs 27.6%) rates, and a manageable safety profile.
Aims: This subgroup analysis of IKEMA examined efficacy and safety in pts with high-risk cytogenetics [t(4;14), del(17p), and t(14;16)] and/or gain(1q21).
Methods: Pts with 1–3 prior lines of therapy were randomized 3:2 to receive Isa-Kd (n=179) or Kd (n=123). High-risk cytogenetics was assessed by central laboratory analysis and defined as ≥1 of the following: del(17p): 50% cutoff; t(4;14) or t(14;16): 30% cutoff. Assessment of gain(1q21) was prespecified as ≥3 copies: 30% cutoff.
Results: Of the randomized pts, 23.5% (Isa-Kd) and 25.2% (Kd) had ≥1 high-risk cytogenetic abnormality (CA); 26.3% (Isa-Kd) and 25.2% (Kd) had isolated gain(1q21). The addition of Isa to Kd improved PFS for pts with ≥1 high-risk CA and standard-risk pts (Table); pts with t(4;14) (HR 0.549; 95% CI, 0.232–1.301) had a more pronounced treatment effect than pts with del(17p) (HR 0.837; 95% CI, 0.281–2.496). A clear PFS benefit with Isa-Kd was also seen for pts with isolated gain(1q21) and gain(1q21) combined with other high-risk CA (Table). The trend toward improved CR, ≥very good partial response (VGPR), and MRD- rates with the addition of Isa was more pronounced in pts with gain(1q21) than in pts with high-risk CA alone. Grade ≥3 treatment-emergent adverse events (TEAEs) were more common with Isa-Kd vs Kd, but the incidence of serious and fatal TEAEs was similar with both arms for high-risk pts (Table).

%	High-Risk		Standard Risk		Isolated Gain(1q21)		Gain(1q21) + High-Risk CA	
	Isa-Kd n=42	Kd n=31	Isa-Kd n=114	Kd n=77	Isa-Kd n=47	Kd n=31	Isa-Kd n=25	Kd n=19
PFS HR vs Kd (95% CI)	0.724 (0.361–1.451)		0.440 (0.266–0.728)		0.462 (0.219–0.972)		0.678 (0.299–1.537)	
CR	23.8	22.6	46.5	26.0	46.8	22.6	32.0	26.3
≥VGPR	57.1	54.8	78.9	54.5	80.9	51.6	64.0	52.6
MRD-	21.4	22.6	36.0	11.7	36.2	9.7	28.0	21.1
Grade ≥3 TEAEs	85.7	63.3	76.1	76.6	78.3	67.7	88.0	66.7
Serious TEAEs	64.3	66.7	57.5	59.7	63.0	51.6	60.0	66.7
Fatal TEAEs	0	0	4.4	5.2	6.5	3.2	0	0
TEAEs leading to definitive discontinuation	4.8	10.0	9.7	18.2	10.9	19.4	0	0

Summary/Conclusion: The addition of Isa to Kd improved PFS in pts with high-risk CA and disease response in pts with gain(1q21) isolated or combined with high-risk CA, with a manageable safety profile, consistent with the benefit observed in the overall IKEMA population. Isa-Kd is a potential new treatment option for the difficult-to-treat subgroup of pts with RMM and high-risk cytogenetics.

EP982 CARFILZOMIB, DEXAMETHASONE, AND DARATUMUMAB (KDD) VS KD IN RELAPSED/REFRACTORY MULTIPLE MYELOMA: ANALYSIS OF TIME TO NEXT TREATMENT, TIME TO PROGRESSION, AND PROGRESSION-FREE SURVIVAL FOR NEXT THERAPY

S. Z. Usmani [1,*], M. Beksac [2], A. Jakubowiak [3], B. Ding [4], I. McFadden [4], A. Yusuf [4], O. Landgren [5]

[1]Levine Cancer Institute/Atrium Health, Charlotte, United States, [2]Ankara University, Ankara, Turkey, [3]University of Chicago Medical Center, Chicago, [4]Amgen Inc., Thousand Oaks, [5]Sylvester Comprehensive Cancer Center, University of Miami, Miami, United States

Background: Lenalidomide (Len)- and bortezomib-based treatments are standard frontline therapies for multiple myeloma (MM). Many patients discontinue these drugs due to progression or toxicity, resulting in a need for bortezomib- and len-sparing treatment combinations for relapsed or refractory (RR) patients. After approximately 27 months of median follow-up in the phase 3, randomized CANDOR study, median progression-free survival was 29 months in patients treated with carfilzomib, dexamethasone, and daratumumab (KdD) vs 15 months in patients treated with carfilzomib and dexamethasone (Kd) (hazard ratio [HR]: 0.59; 95% confidence interval [CI]: 0.45–0.78) (Dimopoulos et al., *Blood* 2020).
Aims: To compare time to next treatment (TTNT), time to progression (TTP), and time to second objective disease progression (PFS2) in patients treated with KdD vs Kd in the CANDOR study.
Methods: The study design of CANDOR (NCT03158688) has been previously published (Dimopoulos et al., *Lancet* 2020). This post hoc analysis used a planned interim readout from CANDOR (data cutoff: June 15, 2020). TTNT was defined as the time from randomization to initiation of subsequent MM treatments. Patients who did not move on to a next treatment were censored. TTP was defined as the time from randomization to disease progression as assessed by a validated computer algorithm (Onyx Response Computer Algorithm). PFS2 was defined as the time from randomization to second disease progression or death, whichever occurred first. Since the date of the second disease progression was not collected in CANDOR, for patients who had progressive disease (PD), the start date of the next line of therapy was used as a surrogate for the PFS2 event; for patients who had not had a PD, the start date of the third line of therapy was used as a surrogate for the PFS2 event. TTNT, TTP, and PFS2 were compared between KdD and Kd arms using a stratified log-rank test and HRs were estimated by a stratified Cox proportional hazards model with stratification factors of International Staging System stage (1 or 2 vs 3), prior proteasome inhibitor (PI) exposure, and number of prior lines of therapy.
Results: Patients treated with KdD had longer TTNT compared with patients treated with Kd (HR: 0.473; 95% CI: 0.354–0.633), with median TTNT for patients in the KdD arm not estimable (NE) (95% CI: 30–NE) vs 18 months (95% CI: 14–25) in the Kd arm. Treatment with KdD improved TTP compared with Kd treatment (HR: 0.497; 95% CI: 0.370–0.667); median TTP was NE (95% CI: 28–NE) in the KdD arm vs 16 months (95% CI: 12–22) in the Kd arm. Median PFS2 was NE (95% CI: NE–NE) in the KdD arm vs 33 months (95% CI: 33–NE) in the Kd arm (HR: 0.729; 95% CI: 0.526–1.012). The observed improvements in TTNT, TTP, and PFS2 for KdD vs Kd-treated patients were consistent regardless of prior lines of therapy, prior PI exposure, prior len exposure, and len-refractoriness (Figure).

Figure. Subgroup analysis of (A) TTNT, (B) TTP, and (C) PFS2.

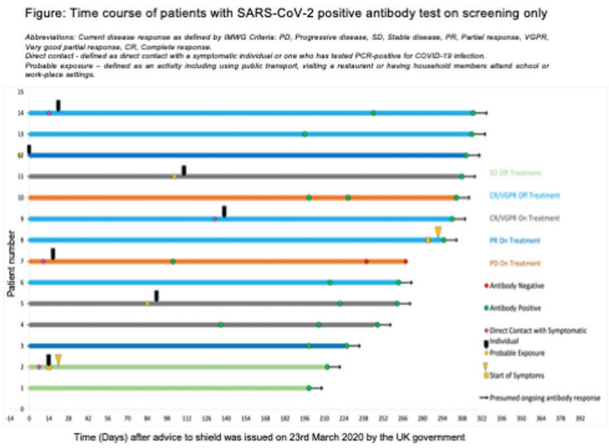
Refractory to len	30/99	NE	25/55	NE		0.620 (0.360–1.067)

0 1 2

CI, confidence interval; len, lenalidomide; Kd, carfilzomib and dexamethasone; KdD, carfilzomib, dexamethasone, and daratumumab; mo, months; NE, not estimable; PFS2, time to second objective disease progression; PI, proteasome inhibitor; TTNT, time to next treatment; TTP, time to progression.



Summary/Conclusion: Patients receiving KdD vs Kd had improvements in time to their next treatment, time to disease progression, and time to second disease progression or death following subsequent therapies. These data confirm and expand upon previously reported results of CANDOR, indicating the robust efficacy benefit of KdD across clinically relevant subgroups, including in those exposed and/or refractory to len. These findings reinforce the clinical value of KdD as an emerging standard of care in the management of RRMM for patients with 1–3 prior lines of therapy.

EP983 DEVELOPMENT OF ANTIBODY RESPONSE TO SARS-COV-2 FOLLOWING ASYMPTOMATIC INFECTION IN PATIENTS WITH PLASMA CELL DISORDERS ON IMMUNOMODULATORY THERAPY

W. Y. Chan [1,2,*], E. Sanchez [3], S. Chavda [1,2], C. Lecat [1,2], L. Ainley [1,2], K. Xu [1], B. Wisniowski [1], S. Mahmood [1], X. Papanikolaou [1], C. Kyriakou [1], J. Sive [1], A. Wechalekar [1], R. Popat [1], N. Rabin [1], L. Lee [1,2], E. Nastouli [3], K. Yong [1,2]

[1]Haematology, University College London Hospitals NHS Foundation Trust, [2]Research Department of Haematology, UCL Cancer Institute, [3]Clinical Virology, University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: Plasma cell disorder (PCD) patients are extremely vulnerable to SARS-CoV-2 infection due to disease-related impaired humoral and cellular immunity as well as the receipt of immunosuppressive therapy. Reported mortality in a large cohort of patients with plasma cell disorders is 33%. The roll out of the COVID-19 vaccine is welcomed in this population, however there is concern of suboptimal antibody responses, from previous experience with the influenza vaccine. There is urgent need to understand the humoral response to SARS-CoV-2 infection in these patients, in the context of systemic anti-cancer therapy (SACT).
Aims: We aimed to investigate the presence of SARS-CoV-2 antibodies in a cohort of PCD patients, the relationship with symptomatic infection, PCD characteristics and receipt of SACT.
Methods: SARS-CoV-2 antibody screening with the Elecsys Anti-SARS-CoV-2 assay (Roche Diagnostics, Basel, Switzerland), a semi-quantitative assay of IgG and IgM against the nucleocapsid (N) antigen was introduced for PCD patients at our institution in July 2020. Clinical information was retrieved from the medical records. Patients with unexpected positive antibody tests were asked about possible past contacts and exposure to SARS-CoV-2.
Results: We report on a six-month period of routine SARS-CoV-2 antibody screening. Two-hundred and forty-three PCD patients had one antibody test, 106 had serial samples. Total seroprevalence was 10.7% (26/243), of which 12 were patients with known PCR-swab positive COVID-19 disease. In a separate but overlapping cohort, 41 patients have had PCR confirmed COVID-19 disease; 20 of these patients were tested, and 12 (60%) had seroconverted. Median time to testing from positive PCR test in the antibody positive patients was 86.5 days (range 22-256) and in antibody negative patients, 30.5 days (range 5-176 days). No PCD or COVID-19 disease factors were found to influence the likelihood of mounting an antibody response after PCR-confirmed COVID-19 disease in these 20 patients. In our screened cohort, 14 (6.3%) patients were unexpectedly antibody positive. Their clinical course is summarised in the included figure. The majority 85.7% (12/14) of patients described no COVID-19 symptoms. Seven (50%) patients were on SACT (including ixazomib, pomalidomide, lenalidomide and dexamethasone combinations) throughout the period from possible exposure to positive antibody test, with no interruption to their ongoing oral immunomodulatory treatment. Ten antibody positive patients had serial positive results at median 45 days (range 21-119) apart, demonstrating persistence, but some decline in titre over time.

Summary/Conclusion: Our seroprevalence of 10.7% is lower but not dissimilar to that reported in the London population over a similar time period reflecting shielding behaviours in our patients but also the challenges of protecting them during high SARS-CoV-2 incidence in the community. Nevertheless, PCD patients retain the ability to seroconvert, even with asymptomatic COVID-19 disease and while on immunomodulatory therapy. Seroconversion rates following symptomatic infection appear lower however, with evidence of delay compared to the general population. These data support the advice for COVID-19 vaccination to be offered to all PCD patients although the suboptimal humoral response calls for close antibody monitoring of all vaccinated PCD patients and timely booster doses.

EP984 CHARACTERISTICS OF NEUROTOXICITY ASSOCIATED WITH IDECABTAGENE VICLEUCEL (IDE-CEL, BB2121) IN PATIENTS WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA IN THE PIVOTAL PHASE 2 KARMMA STUDY

S. Manier [1,*], A. Kansagra [2], L. D. Anderson, Jr [2], J. Berdeja [3], S. Jagannath [4], Y. Lin [5], S. Lonial [6], N. Shah [7], N. Raje [8], D. Siegel [9], A. Oriol [10], A. Truppel-Hartmann [11], E. Rowe [12], P. Patel [12], A. Agarwal [12], T. B. Campbell [12], P. Rodriguez-Otero [13], N. Munshi [14]

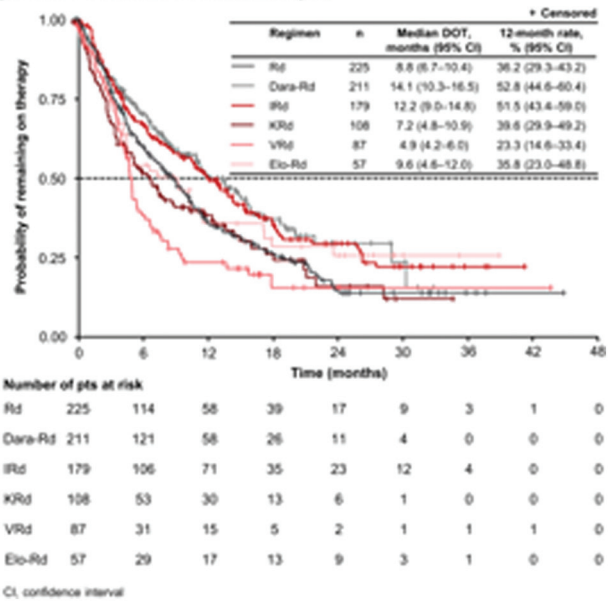
Background: Idecabtagene vicleucel (ide-cel, bb2121), a BCMA-directed CAR T cell therapy, showed promising efficacy in patients with relapsed and refractory multiple myeloma (RRMM) in the KarMMa study with an overall response rate (ORR) of 73% and a complete response rate (CRR) of 33% across the target dose range of 150–450 × 10^6 CAR+ T cells (Munshi NC, et al. *N Engl J Med* 2021;384:705-716). CAR T cell therapies have been associated with potentially severe adverse events, including cytokine release syndrome (CRS) and neurotoxicity (NT). Improved understanding of these adverse events may allow for better management of such toxicities.
Aims: To examine associations of NT with patient and disease characteristics, describe patient management, and evaluate the impact of NT on outcomes in the KarMMa study.
Methods: Patients enrolled in the KarMMa study had received ≥3 prior regimens, including an immunomodulatory agent, a proteasome inhibitor, and an anti-CD38 antibody, and were refractory to their last regimen per IMWG criteria (NCT03361748). Ide-cel target doses of 150, 300, or 450 × 10^6 CAR+ T cells were given after 3 d of lymphodepletion with cyclophosphamide (300 mg/m^2/d) and fludarabine (30 mg/m^2/d) followed by 2 d of rest. Endpoints included ORR (primary), CRR (key secondary), duration of response (DOR), progression-free survival, and safety. Investigator-identified NT events were captured under the single preferred term of neurotoxicity and graded according to NCI CTCAE v4.03. Events were managed with corticosteroids, anakinra, and tocilizumab as needed.
Results: Of 128 patients treated with ide-cel, NT was reported in 23 (18%); 12 patients (9%) had maximum grade 1 NT, 7 (5%) had grade 2, and 4 (3%) had grade 3. No grade 4 or 5 NT occurred. Most baseline characteristics were similar in patients with and without NT, including R-ISS disease stage III (22% and 15%), high-risk cytogenetics (39% and 34%), and extramedullary disease (35% and 40%); exceptions were high tumor burden (65% and 48%) and sex (48% and 62% men). NT (any grade/grade 3) occurred in 0%/0%, 17%/1%, and 20%/6% of patients at target doses of 150, 300, and 450 × 10^6 CAR+ T cells. Median time to onset was similar regardless of grade, and there were no late-onset events (**Table**). NT was managed with corticosteroids in 10 patients (43%), tocilizumab in 3 (13%), and anakinra in 1 (4%). Median (range) time to first use of corticosteroids was 2 d (1–6). ORR and DOR were similar in patients with and without NT (**Table**). All NT occurred in the proximity of CRS events with the start date of NT events either overlapping with or occurring within 1 wk of the start of a CRS event.

NT events	Grade 1 (n=12)	Grade 2 (n=7)	Grade 3 (n=4)	Any grade (n=23)
Time to onset, median (range), d	2 (1–10)	2 (1–4)	3 (1–4)	2 (1–10)
No. of events	13	7	4	24
Duration/event, n (%)				
1–5 d	9 (69)	3 (43)	1 (25)	13 (54)
6–10 d	4 (31)	2 (29)	0	6 (25)
>10 d	0	1 (14)	3 (75)	4 (17)
Ongoing	0	1 (14)	0	1 (4)
Median (range), d[a]	3 (1–9)	6 (1–26)	14 (2–22)	3 (1–26)
Corticosteroids, n (%)	2 (17)	4 (57)	4 (100)	10 (43)
Tocilizumab, n (%)	1 (8)	0	2 (50)	3 (13)
Anakinra, n (%)	0	0	1 (25)	1 (4)
Efficacy	**No NT (n=105)**		**NT, any grade (n=23)**	
Response, % (95% CI)				
ORR	73 (64.9–81.8)		74 (56.0–91.9)	
CRR	35 (26.1–44.4)		22 (4.9–38.6)	
PFS, median (95% CI), mo	8.9 (5.7–11.9)		6.1 (3.0–11.1)	
DOR, median (95% CI), mo[b]	11.0 (8.0–11.3)		10.0 (4.0–NE)	
OS, median (95% CI), mo	19.4 (18.0–NE)		NE (12.3–NE)	

Data cutoff: 14 Jan 2020. NE, not estimable; OS, overall survival; PFS, progression-free survival
[a]Ongoing NT excluded. [b]Among responders.

Summary/Conclusion: NT occurred early in the KarMMa study, was generally of short duration, and was mostly grade 1/2 with no grade ≥4 events. All NT was proximal to CRS. Patients with NT had a favorable ORR after ide-cel treatment. These results continue to demonstrate the durable efficacy and tolerability of ide-cel in patients with RRMM.



EP985 REAL-WORLD DURATION OF TREATMENT (DOT) WITH LENALIDOMIDE-DEXAMETHASONE (RD)-BASED REGIMENS IN PATIENTS (PTS) WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM): OUTCOMES FROM THE GLOBAL INSIGHT MM STUDY

Background: Daratumumab (Dara), ixazomib (I), carfilzomib (K), bortezomib (V), and elotuzumab (Elo) plus Rd, as well as Rd alone, are among the standards of care for RRMM treatment. In phase 3 RRMM trials, these regimens have been given as long-term/continuous therapy, with median DOTs ranging from 10.1 to 34.3 months. Longer DOT is associated with improved outcomes; however, the lengthy DOTs seen in clinical trials do not always translate to the real-world setting due to multiple pt- and treatment-related factors, emphasizing the importance of real-world data collection to aid in treatment decisions.
Aims: To estimate DOT with Rd-based regimens in RRMM pts in the global, prospective, observational INSIGHT MM study (NCT02761187).
Methods: From July 2016 to June 2019, INSIGHT MM enrolled 4307 pts from 15 countries, including 1939 pts with ≥2 prior lines of therapy (LOT). Prospective follow-up of ≥2 years/pt is ongoing. DOT was defined as time from Rd-based treatment initiation within a LOT (index regimen) to time of discontinuation of index regimen. Kaplan-Meier analyses were used to determine DOT for each Rd-based regimen reported, overall, and by LOT and region (Europe+Israel [EUR]; North America [NA]). Exposure to prior therapies and reasons for treatment discontinuation were also examined.
Results: In total, 821 pts received 867 Rd-based LOT for RRMM (225 Rd, 211 Dara-Rd, 179 IRd, 108 KRd, 87 VRd, and 57 Elo-Rd; pts could be included more than once if they received an Rd-based treatment in >1 LOT), including 464/262/150 in 2nd/3rd/≥4th line (134/70/24 Rd, 115/58/39 Dara-Rd, 58/82/40 IRd, 67/25/18 KRd, 57/16/15 VRd, and 33/11/14 Elo-Rd; 9 pts received the same regimen >once). Overall, median DOT was longest with Dara-Rd and IRd (14.1 and 12.2 months); the proportions of pts in treatment at 12 months (12-month DOT rate) were 52.8% and 51.5%, respectively (Figure). Analysis by region showed higher 12-month DOT rates in EUR vs NA with Dara-Rd (57.1 vs 43.7%), IRd (55.3 vs 34.2%), and KRd (41.0 vs 30.7%), a lower rate in EUR with VRd (11.0 vs 30.7%), and similar rates with Rd (40.8 vs 40.0%) and Elo-Rd (37.0 vs 33.6%). These rates were not analyzed in Latin America and Asia-Pacific regions due to small pt numbers. Among 2nd/3rd/≥4th-line pts, 12-month DOT rates with Dara-Rd were 58.8%/56.1%/31.1%; with IRd, 49.8%/56.6%/47.4%; with KRd, 41.3%/44.3%/35.3%; with Elo-Rd, 40.8%/30.0%/27.7%; with Rd, 36.8%/36.2%/28.1%; and with VRd, 25.0%/40.0%/0%. Most regimens received immediately prior to Rd-based treatment were V-based (n=504, 58.1%). Overall, common prior regimens received included VCd (20.6%), VRd (10.3%), VTd (9.1%), Vd (8.9%), Rd (6.6%), and VMP (5.9%), used primarily as 1st and 2nd line. Prior therapies were more diverse in pts receiving Rd-based treatment beyond 3rd vs in earlier lines. Overall, 555/867 (64.0%) of the reported LOT were in R-naïve pts and 312 (36.0%) were in pts exposed to R in any line prior to Rd-based treatment. At data cutoff, 530/867 (61.1%) Rd-based individual LOT had been discontinued; overall reasons for discontinuation (multiple reasons could be provided per LOT) included relapse in 224 pts (42.3% of 530), adverse events in 78 (14.7%), death in 33 (6.2%), and other reasons in 207 (39.1%).

Figure. Kaplan Meier analysis of DOT by index regimen in RRMM patients treated with Rd-based therapies

Summary/Conclusion: DOT with Rd-based treatment in the real-world setting of INSIGHT MM generally appeared shorter than in clinical trials. The longest DOTs were seen in 2nd and 3rd LOT with Dara-Rd and IRd. Thirty six percent of the reported LOT were in pts who received R in any prior line, while the most common therapies immediately prior to Rd-based therapy were V-based.

EP986 ISATUXIMAB PLUS CARFILZOMIB AND DEXAMETHASONE IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA ACCORDING TO PRIOR LINES OF TREATMENT AND REFRACTORY STATUS: IKEMA SUBGROUP ANALYSIS

Background: Patients (pts) with multiple myeloma (MM) often relapse and become refractory to successive lines of therapy, warranting better treatment options. The Phase 3 IKEMA study (NCT03275285) demonstrated that isatuximab (Isa) plus carfilzomib and dexamethasone (Kd) significantly improved progression-free survival (PFS) compared with Kd in pts with relapsed MM (RMM) (HR 0.53; 99% CI 0.32–0.89; *P*=0.0007).
Aims: Evaluate the efficacy and/or safety of Isa-Kd by number of prior lines of therapy (1 vs >1) and refractoriness to lenalidomide (Len) or bortezomib (Bor).
Methods: Pts were randomized (3:2) to Isa-Kd (n=179) or Kd (n=123). Isa (10 mg/kg IV) was given weekly for 4 weeks, then every 2 weeks. K (20 mg/m^2 days 1-2, then 56 mg/m^2) was given twice-weekly 3 of 4 weeks, and d (20 mg) twice-weekly. The primary endpoint was PFS; key secondary endpoints were very good partial response or better (≥VGPR), minimum residual disease negativity (MRD-), and complete response (CR) rates.
Results: Of the 302 randomized pts, 44.7% had 1 prior line, 55.3% had >1 prior line, 32.8% were Len-refractory, and 30.1% were Bor-refractory. PFS was improved with Isa-Kd vs Kd in pts who received 1 prior line and >1 prior line, as well as in pts refractory to Len, Len at last regimen, Bor, or Bor at last regimen (Table). The addition of Isa to Kd improved depth of response (≥VGPR, MRD-, and CR rates) in all subpopulations analyzed by prior treatment. Grade ≥3 treatment-emergent adverse events (TEAEs) were generally similar between the prior line subgroups (77.2% [Isa-Kd] vs 64.8% [Kd], 1 prior line; 76.5% [Isa-Kd] vs 69.1% [Kd], >1 prior line) and the overall safety population (76.8% [Isa-Kd] vs 67.2% [Kd]). Serious AEs were 62.0% vs 48.1% in the 1 prior line subgroup, and 57.1% vs 64.7% in the >1 prior line subgroup; TEAEs leading to discontinuations were 8.9% vs 11.1%, 1 prior line and 8.2% vs 16.2%, >1 prior line.

		n		PFS, HR (95% CI)	≥VGPR,%		MRD-, %		CR, %	
		Isa-Kd	Kd	-	Isa-Kd	Kd	Isa-Kd	Kd	Isa-Kd	Kd
Overall		179	123	0.53 (0.32-0.89)*	72.6	56.1	29.6	13.0	39.7	27.6
Number of prior lines as per randomization	1	80	55	0.59 (0.31-1.12)	75.0	61.8	33.8	18.2	41.3	36.4
	>1	99	68	0.48 (0.29-0.78)	70.7	51.5	26.3	8.8	38.4	20.6
Refractory to Len	Yes	57	42	0.60 (0.34-1.1)	66.7	35.7	24.6	9.5	38.6	11.9
Refractory to Len at last regimen	Yes	36	31	0.69 (0.35-1.39)	72.2	38.7	27.8	9.7	47.2	12.9
Refractory to Bor	Yes	52	39	0.62 (0.33-1.16)	55.8	51.3	17.3	10.3	28.8	17.9
Refractory to Bor at last regimen	Yes	32	23	0.38 (0.16-0.92)	62.5	47.8	25.0	8.7	31.3	17.4

*99% CI

Summary/Conclusion: The addition of Isa to Kd improved PFS and depth of response, irrespective of prior lines of therapy or refractory status, consistent with the benefit observed in the overall IKEMA study population. Isa-Kd had a manageable safety profile regardless of number of prior lines. Isa-Kd is a potential new treatment option for pretreated pts with RMM.

EP987 A PROSPECTIVE, NON-INTERVENTIONAL, MULTINATIONAL STUDY OF REAL-LIFE STANDARD OF CARE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA WITH ≥3 PRIOR LINES OF THERAPY: INTERIM DATA FROM LOCOMMOTION

Background: Despite advances in medical treatments that have improved patient survival, multiple myeloma (MM) remains an incurable disease. Most patients with MM eventually progress through standard drug classes of proteasome inhibitors (PIs), immunomodulatory drugs (IMiDs), anti-CD38 monoclonal antibodies (mAbs), and others. There are currently no prospective data on real-world standard of care in patients who progress after PIs, IMiDs, and anti-CD38 mAbs.
Aims: To describe the interim results from LocoMMotion (NCT04035226), the first prospective study on the efficacy and safety of real-life standard of care in patients with relapsed/refractory MM.
Methods: Between August 2019 and October 2020, eligible patients who were aged ≥18 years and had a diagnosis of MM were enrolled in 75 sites across 9 European countries and the US. Patients were included if they had received 3 or more prior lines of therapy or were double-refractory to a PI and IMiD, had measurable disease at screening, received at least a PI, an IMiD, and anti-CD38 mAb with documented progressive disease since their last line of therapy, and had an Eastern Cooperative Oncology Group performance status (ECOG PS) score of 0 or 1. All patients provided informed consent prior to enrollment in the study. Responses were assessed per International Myeloma Working Group response criteria. The overall response rate (ORR) of real-life current standard of care (primary objective of the study) was assessed by a Response Review Committee. Secondary objectives of the study included additional efficacy and safety evaluation of real-life standard of care.
Results: The data cut-off was November 4, 2020 for the first interim analysis of 225 patients (203 [90.2%] from Europe and 22 [9.8%] from the US) with a median follow-up of 3.7 months (range: 0–12.7). The median age was 68 years (range: 41–89), 124 (55.1%) patients were male, 162 (72.0%) had a baseline ECOG PS score of 1, and median time since initial MM diagnosis was 6.0 years (range: 0.3–22.8). Patients had received a median of 4.0 (range: 2–13) prior lines of therapy; all patients were triple-class exposed, 166 (73.8%) were triple-class refractory, and 208 (92.4%) were refractory to their last line of therapy. The ORR with real-life standard of care salvage therapy was 20.1% (95% CI: 15.0–26.0) in the response-evaluable population (n=219). Treatment-emergent adverse events (TEAEs) were reported in 148 (65.8%) patients, 95 (42.2%) were grade 3 or higher. The most common grade ≥3 TEAEs were anemia, thrombocytopenia, and neutropenia. Fifteen deaths (6.7%) occurred due to TEAEs during the study. Treatment is ongoing in 121 (53.8%) patients.
Summary/Conclusion: The interim results of this first, prospective study of real-life standard of care treatment demonstrate that heavily pretreated, triple-class exposed patients with relapsed/refractory MM continue to progress after multiple lines of therapy and have poor outcomes. Therefore, new treatments with novel mechanisms of action are needed for this patient population.

EP988 POMALIDOMIDE, BORTEZOMIB, AND DEXAMETHASONE AFTER 1 PRIOR LINE OF THERAPY IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA: A SAFETY SUBANALYSIS OF THE PHASE 3 OPTIMISMM TRIAL

Citta Della Salute e della Scienza di Torino, Torino, Italy, [13]Department of Hematology, Medical University of Lodz, Copernicus Memorial Hospital, Ciolkowskiego 2, Poland, [14]Celgene International Sàrl, a Bristol-Myers Squibb Company, Boudry, Switzerland, [15]Bristol Myers Squibb, Princeton, [16]Department of Medical Oncology, Jerome Lipper Multiple Myeloma Center, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

Background: Patients (pts) with newly diagnosed multiple myeloma (MM) are routinely treated with lenalidomide (LEN) until disease progression. Thus, at the time of first relapse, many pts will have LEN-refractory disease. These pts need proven effective therapies that not only help achieve disease control but also have a manageable safety profile. Pts with relapsed or refractory MM (RRMM) who were treated with pomalidomide (POM), bortezomib (BORT), and dexamethasone (DEX; PVd) at first relapse in OPTIMISMM (phase 3, NT01734928) had a significantly improved median PFS (20.7 vs 11.6 mo; HR, 0.54; 95% CI, 0.36-0.82; *P* = .0027) vs Vd; all pts were previously treated with LEN, and 57% were LEN refractory (Richardson PG, et al. *Lancet Oncol* 2019;20:781-794). Adverse events reported with PVd in the overall population were consistent with the individual safety profiles for POM, BORT, and DEX.

Aims: To report a safety analysis of treatment-emergent adverse events (TEAEs) in the events of interest (EOI) category for PVd vs Vd administered at first relapse in OPTIMISMM.

Methods: In 21-day cycles, pts received PVd or Vd (1:1). POM 4 mg/d was given on d 1-14 (PVd arm only); BORT 1.3 mg/m^2 was given on d 1, 4, 8, and 11 of cycle 1-8 and d 1 and 8 of cycle 9+; and DEX 20 mg/d (10 mg/d for pts aged > 75 yr) was given on the days of and after BORT. Key eligibility criteria included ≥ 2 cycles of prior LEN; LEN-refractory pts were allowed. Adverse events were graded according to the NCI CTCAE (version 4.0) and were summarized by system organ class and preferred term. All pts provided informed consent.

Results: 226 of 559 pts (40%) in OPTIMISMM had 1 prior line of therapy (LOT) and 221 (PVd, n=111; Vd, n=110) were included in the safety analysis population (all pts who received ≥1 dose of study drug). Baseline characteristics were generally well balanced between Tx arms. All pts had prior LEN Tx and 57% (126/221) were LEN refractory; 59% (131/221) had prior BORT Tx. Median duration of treatment was longer in the PVd vs Vd arm: 47.4 wk (4.7-147.0) vs 27.1 wk (0.4-162.0). Grade (Gr) 3/4 TEAEs EOI occurred in 57.5% of pts (PVd, 69.4%; Vd, 45.5%; **Table**). Overall, the most common Gr 3/4 TEAEs EOI were neutropenia (24.4%), infections and infestations (22.2%), and thrombocytopenia (20.4%). Gr 3/4 TEAEs EOI more common in the PVd vs Vd arm included neutropenia (36.9% vs 11.8%), infections and infestations (28.8% vs 15.5%), and peripheral neuropathy (11.7% vs 4.5%). Onset of neutropenia was mostly in the first 3 cycles and primarily Gr 3/4. Onset of infections and infestations commonly occurred during cycles 1-9 and were mostly Gr 1/2. Onset of peripheral neuropathy commonly occurred in the first 6 cycles; instances were mostly Gr 1/2. See table for median time to onset and duration of selected TEAE EOIs. TEAE EOIs were mainly managed with dose reductions and interruptions (**Table**). POM discontinuations due to ≥1 TEAE EOI of any grade were low (9.0%). In the PVd arm, 62% (31/50) of pts with any-grade neutropenia received G-CSF support. No pt discontinued POM due to neutropenia. Infections and infestations were the primary cause of PVd dose interruptions (54.1%). Peripheral neuropathy was the most common TEAE EOI leading to dose reduction (32.4%) and drug discontinuation (16.2%) with PVd.

Table. Summary of incidence, time to onset, duration, and dose modifications for TEAE EOIs

TEAE EOI	Grade 3/4 TEAE EOI, n (%)[a]		Grade 3/4 TEAE EOI, incidence rate per 100 person-years[b]		Median time to onset of any-grade TEAE EOI/median duration, d	
	PVd (n = 111)	Vd (n = 110)	PVd (n = 111)	Vd (n = 110)	PVd	Vd
≥ 1 Specified event	77 (69.4)	50 (45.5)	-	-	-	-
Neutropenia	41 (36.9)	13 (11.8)	46.25	18.14	23.1/ 8.0 (n=50)	46.0/ 5.0 (n=21)
Thrombocytopenia	22 (19.8)	23 (20.9)	21.30	32.96	11.0/ 15.0 (n=31)	30.4/ 14.0 (n=32)
Infections and infestations	32 (28.8)	17 (15.5)	32.91	23.71	63.9/ 12.0 (n=91)	57.5/ 12.0 (n=74)
Peripheral neuropathy	13 (11.7)	5 (4.5)	11.31	6.39	42.1/ 19.0 (n=69)	53.9/ 22.5 (n=52)
Summary of dose modifications						
	Any drug dose reduction due to TEAE EOI, n (%)		Any drug dose interruption due to TEAE EOI, n (%)		Any drug discontinuation due to TEAE EOI, n (%)	
	PVd (n = 111)	Vd (n = 110)	PVd (n = 111)	Vd (n = 110)	PVd (n = 111)	Vd (n = 110)
≥ 1 TEAE EOI leading to dose modification of any drug	65 (58.6)	43 (39.1)	88 (79.3)	60 (54.5)	24 (21.6)	17 (15.5)
Neutropenia	13 (11.7)	1 (0.9)	22 (19.8)	2 (1.8)	0	0
Thrombocytopenia	12 (10.8)	6 (5.5)	11 (9.9)	13 (11.8)	1 (0.9)	1 (0.9)
Infections and infestations	8 (7.2)	4 (3.6)	60 (54.1)	40 (36.4)	4 (3.6)	1 (0.9)
Peripheral neuropathy	36 (32.4)	29 (26.4)	24 (21.6)	18 (16.4)	18 (16.2)	11 (10.0)
Somnolence, including dizziness and confusion	8 (7.2)	1 (0.9)	8 (7.2)	3 (2.7)	1 (0.9)	1 (0.9)

[a]Occurring in >10% of pts in either treatment arm. [b]Incidence rate per 100 person-years was calculated as 100 × n/T, where n equals the number pts with the selected AE and T equals the total person-years.

Summary/Conclusion: The safety profile for PVd at first relapse in pts with MM is consistent with that in previous reports. TEAEs EOI generally occurred in early cycles of treatment and could be managed with dose modifications or appropriate treatment for infections.

EP989 SURVIVAL AND OUTCOMES OF NEWLY-DIAGNOSED MULTIPLE MYELOMA PATIENTS STRATIFIED BY TRANSPLANT STATUS DIAGNOSED BETWEEN 2007-2018: REAL-WORLD ANALYSIS FROM THE CANADIAN MYELOMA RESEARCH GROUP DATABASE

H. Mian [1,*], D. Reece [2], E. Masih-Khan [2], A. McCurdy [3], E. G. Atenafu [4], V. Jimenez-Zepeda [5], K. Song [6], M. Louzada [7], R. LeBlanc [8], M. Sebag [9], D. White [10], J. Stakiw [11], A. Reiman [12], R. Kotb [13], M. Aslam [14], E. Gul [4], C. P. Venner [15]

[1]McMaster University, Hamilton, [2]Princess Margaret Cancer Centre, Toronto, [3]The Ottawa Hospital, Ottawa, [4]Canadian Myeloma Research Group, Toronto, [5]Tom Baker Cancer Centre, Calgary, [6]Vancouver General Hospital, Vancouver, [7]London Regional Cancer Centre, London, [8]University of Montreal, [9]McGill University Health Centre, Montreal, [10]Dalhousie University, Halifax, [11]Saskatoon Cancer Centre, Saskatoon, [12]Saint John Regional Hospital, Saint John, [13]Cancer Centre Manitoba, Winnipeg, [14]Allan Blair Cancer Centre, Regina, [15]University of Alberta, Edmonton, Canada

Background: Considerable progress has been made in therapeutic options for multiple myeloma (MM). However, data confirming translation of these successes into routine clinical settings, as well as outcomes from large data sets spanning multiple lines of therapy, are limited. Understanding such real-world data can provide key insights into knowledge and clinical gaps which could be targeted for future optimization. The Canadian Myeloma Research Group Database (CMRG-DB) is a prospectively maintained disease-specific database with >7500 patients from 15 academic sites across Canada with legacy data from 2007.

Aims: The aim was to provide high-level outcomes for all patients within the database, stratified by frontline autologous stem cell status (ASCT), in order to: 1) evaluate the rates of early mortality (<6 months and <1 year); 2) understand the trends in overall survival (OS) over time; and 3) evaluate OS by line of treatment.

Methods: All patients in the database diagnosed with MM from 2007-2018 who received therapy for active MM were included in this analysis. Rates of early mortality (<6 months and <1 year) were summarized for

the cohort stratified by the use of frontline ASCT. Patients were analyzed by period of treatment in 3-year increments beginning in 2007 and by line of therapy. OS was measured from the time of therapy initiation to death or last follow-up and was analyzed using the Kaplan-Meier method.
Results: We identified 5154 patients meeting the study entry criteria. Of these, 3030 patients (58.79%) received an upfront ASCT and 2124 (41.21%) did not. At diagnosis, the median age for the entire cohort was 64 years (range 26-98) and 58.6% were males. The presenting features of anemia, lytic bone disease, renal failure and hypercalcemia were noted in 57.6%, 46.5%, 18.7% and 12.4% of patients, respectively. A total of 28.3%, 36.3% and 35.4% had ISS stage I, II and III disease, respectively. High-risk cytogenetics by FISH [t(4;14), t (14;16) and 17p deletion] were present in 33% of patients.
The 6-month and 1-year mortality rates were 0.2% and 2.0% for ASCT patients and higher at 7.8% and 13.8% for non-ASCT patients. The median OS was 125.3 months and 54.3 months for those that did and did not receive frontline ASCT, respectively. OS increased over time among the ASCT cohort with a clear change after 2013 (Figure 1A). Improvements were also noted among the non-ASCT cohort after 2010 (Figure 1B). When the cohort was stratified by line of treatment, OS decreased from 1st - to 3rd - line, with a notable drop in OS noted in 4th line and beyond among both the ASCT and non-ASCT cohorts (Figure 1C and 1D). Further details regarding the spectrum of regimens at each line will be provided.
Summary/Conclusion: The CMRG-DB is one of the largest prospectively maintained real-world MM data sets. Advancements in outcomes are notable, coinciding with the widespread adoptions of novel agents in frontline therapy (~2010) and routine lenalidomide maintenance (~2013) in Canada. Most of the improvement has been in lines 1-3 after which survival remains relatively short. Although notable gains have been made for ASCT patients with low rates of early mortality and improvements in OS, outcomes for non-ASCT patients lag and are targets for future optimization. The database serves as a useful tool to measure the impact of novel treatment approaches as they are introduced in routine clinical use, especially in advanced disease which continues to represent an area of unmet need.

EP990 COMPARISON OF CILTACABTAGENE AUTOLEUCEL VERSUS CONVENTIONAL TREATMENT IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

L. Costa [1,*], Y. Lin [2], T. Martin [3], S. Chhabra [4], S. Usmani [5], S. Jagannath [6], N. Callander [7], J. Berdeja [8], Y. Kang [9], R. Vij [10], H. Tian [11], S. Valluri [12], J. Marino [13], C. Jackson [11], A. Banerjee [13], A. Kansagra [14], J. Schecter [11], S. Kumar [2], P. Hari [4]

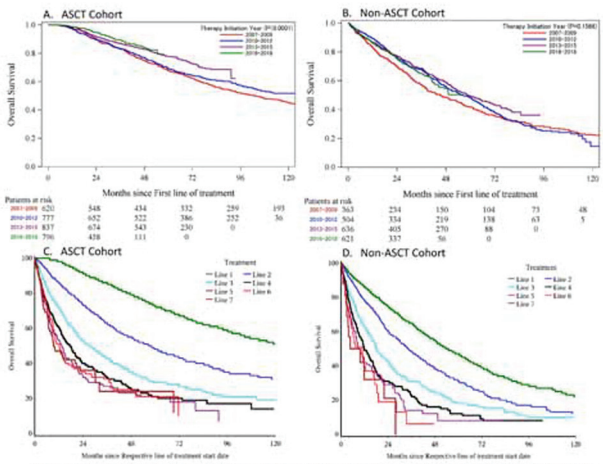

Figure 1: Overall survival by A) year of therapy initiation, ASCT cohort B) year of therapy initiation, non-ASCT Cohort C) line of treatment, ASCT cohort D) line of treatment, Non-ASCT cohort

Background: Ciltacabtagene autoleucel (cilta-cel; JNJ-68284528) is a chimeric antigen receptor T (CAR-T) cell therapy with two B-cell maturation antigen-targeting single-domain antibodies designed to confer avidity. CARTITUDE-1 (NCT03548207) is a single arm, phase 1b/2 study conducted to evaluate cilta-cel therapy in US patients with relapsed/refractory multiple myeloma (RRMM). Patients in CARTITUDE-1 were refractory to both an immunomodulatory imide drug (IMiD) and proteasome inhibitor (PI) or had received ≥3 prior lines of therapy and previous exposure to anti-CD38 monoclonal antibody (MoAb). While recent reports of cilta-cel efficacy were encouraging, it is unknown how they compare with similar patients receiving conventional (non CAR-T) treatment.
Aims: To compare the efficacy of cilta-cel versus conventional treatment in patients with RRMM.
