WITH EVERY CELL IN THEIR BEING

Patients give their all. So do we.

Within each and every patient lies the potential to create a living cell therapy. We are deeply committed to advancing cell therapy—by pursuing scientific breakthroughs, pioneering a pipeline of innovative constructs, and utilizing novel manufacturing.

Advancing Cell Therapy

BMS invests in Europe with new cell therapy manufacturing site planned in the Netherlands.

As part of Bristol Myers Squibb's continuing commitment, we are expanding global manufacturing capacity to bring treatments to more patients faster. Stay tuned as the new site progresses.

Author Information

The Abstract Book of the 26th Congress of the European Hematology Association, EHA2021 Virtual Congress, is published as a supplement of *HemaSphere* and available online at www.hemaspherejournal.com.

HemaSphere is an open access journal powered by the European Hematology Association and dedicated to support hematology patient care, research, and education worldwide.

Please read our instructions and guidelines for preparing and submitting articles.
Manuscripts must be submitted online at http://www.editorialmanager.com/hemasphere.

Article Processing Charges (APC)

Article types	EHA members	Non-members
Tier 1: Original articles, review articles, guidelines, & controversies	50%**	€1,080* equivalent ($1,200)
Tier 2: Letters, case reports, editorials, & perspectives	50%**	€540* equivalent ($600)
Tier 3: Comments, HemaTopics	Free	Free
All invited manuscripts*** (Invited review articles, invited guidelines, invited editorials, and invited perspectives)	Free	Free

*USD/EUR equivalent rate of 1.110, please note that all payments will be in USD.
**2021 Promotional Discounts on APCs: 50% discount for EHA members (first and last author of a manuscript) at the time of submission
***APCs for all contributions on *invitation* by the Editors will be waived.

EUROPEAN HEMATOLOGY ASSOCIATION

ABOUT EHA

EHA is a non-governmental and not-for-profit membership organization that is guided by its mission to promote excellence in patient care, research, and education in hematology.
In pursuing this mission, EHA acts exclusively in the interest of hematology as well as its practitioners, and is bound by core values of independence, integrity, and transparency.

EHA is an open networking organization - we celebrate collaboration and the sharing of knowledge and experience, assisting hematologists to achieve excellence not only in Europe, but also around the world.

EUROPEAN HEMATOLOGY ASSOCIATION

WOULD YOU LIKE TO BE PART OF THE EHA COMMUNITY?

Support our mission

Help EHA promote excellence in patient care, research, and education in hematology.
Join your fellow hematologists worldwide and enjoy membership benefits for both professional and personal development within the field of hematology.

Become a member*

Full Membership	€155/year
Junior Membership	€20/year
Health Care Affiliated Professional Membership	€90/year
Emeritus Membership	€90/year

* 50% mid-year proration

Membership benefits

- Discount on article publication charges for the journal *HemaSphere*
- Eligibility for EHA Congress travel grants
- Access to EHA Membership Directory
- Nomination and voting rights
- Unlimited access to the EHA Campus, the new learning platform
- Discount on EHA Congress and other EHA meetings
- Access to the Curriculum Passport online
- Subscription to EHA newsletters

For more information, please visit ehaweb.org

EHA | POWERED BY YOU!

Word of welcome

On behalf of the EHA Board and the Scientific Program Committee, we are pleased to present to you this year's Abstract Program.

The Scientific Program Committee has compiled an exciting program of oral and e-poster presentations out of more than 1800 abstracts that were submitted. While the number of abstracts is lower compared to other years, the quality is as high as ever and represents all fields of Hematology. The abstracts with the highest scores will be presented during the Presidential Symposium on Friday, June 11 (16:00 – 17:30 CEST), which will be one of the highlights of the Virtual Congress.

The oral presentations and e-posters will be released on the platform as of Friday, June 11 at 9:00 CEST. They will be available for all attendees to be viewed on-demand and to get updated on a broad range of topics and research areas. Although we will not physically meet this year, we aim to give maximum exposure to scientific work and allow for direct interaction between the authors and Congress delegates. Therefore, do not miss the unique opportunity to discuss and ask questions during the Live Q&A Sessions on the Thematic Days from June 13-17.

Supporting the next generation is an important task of EHA and this year we are awarding close to 100 participation grants to junior members who are presenting an abstract. During the Presidential Symposium, we are also awarding the YoungEHA Best Abstract Awards to trainees in with diverse backgrounds and at different stages in their career. Their names and the names of the participation grant winners can be found on the next pages.

The Late-Breaking Abstract Program is designed to provide an opportunity for investigators to submit abstracts with novel data that were not available at the time of the regular abstract submission deadline. Only a small selection of abstracts with the most ground-breaking results have been selected for presentation during the Late-Breaking Oral Session on Saturday, June 12 from 16:00 – 17:30 CEST.

All abstracts are available on the EHA Library and the Virtual Congress platform.

On behalf of the EHA Board, the committees, and all of the people involved in this year's Abstract Program, we trust you will enjoy reading this book and the research presented.

Prof Ruud Delwel

Chair, Scientific Program Committee of the EHA2021 Virtual Congress

Participation grant winners

For this Congress, **92** participation grants have been awarded to junior members of EHA, based on the mean score of their abstracts. EHA congratulates the following participation grant awardees:

Abdallah G, *Egypt*
Abdel-Aziz M, *Egypt*
Accardi F, *Italy*

YoungEHA Best Abstract Awards

One of the primary missions of the European Hematology Association is to support young hematology clinicians and researchers. For the fifth year after launching in 2017, we are proud to announce the YoungEHA Best Abstract Awards for 2021. These are awarded to the highest-ranking abstracts in the following four categories: Clinicians or medical students training for a PhD degree, PhD research students, postdoctoral fellows, and clinical hematology trainees. We are honored that these outstanding YoungEHA trainees will be presenting during the EHA Congress - they are the future of hematology!

Constellation PHARMACEUTICALS

Connecting stellar science with patient needs in hematology and oncology

Constellation Pharmaceuticals is a clinical-stage biopharmaceutical company with over 12 years of discovery and development history in epigenetics and cancer biology. Our clinical and research teams are deeply invested in a scientific approach to developing therapies that address serious unmet medical needs in patients with cancer.

Constellation's drug candidates, all of which were discovered internally, are products of our expertise both in gene targeting and in diseases where gene regulation and control matter.

We believe science has the potential to change lives.

Presidential Session

Presidential Symposium	S100 – S104	p. 1

Oral Sessions

ALL - Signaling and beyond	S105 – S109	p. 4
ALL - Novel subgroups and agents	S110 – S114	p. 6
ALL - CAR-T: Alternative targets and age groups	S115 – S119	p. 9
AML epigenetic and transcriptional control	S120 – S124	p. 12
AML mechanisms of resistance	S125 – S129	p. 14
AML classification	S130 – S134	p. 17
Developments in AML therapy	S135 – S139	p. 20
New biological and translational insights in CLL	S140 – S144	p. 23
Clinical trials with targeted therapies in CLL	S145 – S149	p. 26
Response, resistance and treatment-free remission in CML	S150 – S154	p. 29
Population based studies in myeloid disorders	S155 – S159	p. 32
Correlating mutations with phenotype in MDS	S160 – S164	p. 35
Novel targets in MDS	S165 – S169	p. 38
New directions in aplastic anemia and PNH	S170 – S174	p. 40
Basic and translational myeloma research	S175 – S179	p. 43
New treatment strategies for newly diagnosed multiple myeloma	S180 – S184	p. 45
New diagnostic and therapeutic approaches in multiple myeloma and AL amyloidosis	S185 – S189	p. 48
T cell re-directing therapies in relapsed/refractory multiple myeloma	S190 – S194	p. 51
New pathways and molecular mechanisms in MPN	S195 – S199	p. 54
Novel therapies and targets in MPN	S200 – S204	p. 56
Hodgkin lymphoma - Clinical	S205 – S209	p. 59
Indolent & mantle cell lymphoma - Clinical	S210 – S214	p. 62
Aggressive lymphoma - CAR-T & transplant	S215 – S219	p. 64
Aggressive lymphoma - Combination therapies	S220 – S224	p. 67
Lymphoma - Translational research	S225 – S229	p. 70
Stem cell transplantation - Preclinical/experimental	S230 – S234	p. 73
Stem cell transplantation - GvHD	S235 – S239	p. 75
Stem cell transplantation - Clinical	S240 – S244	p. 78
Stem cell biology and microenvironment	S245 – S249	p. 81
Cellular immunotherapy and gene therapy - Experimental	S250 – S254	p. 83
Cellular immunotherapy and gene therapy - Clinical	S255 – S259	p. 85
Changing the scene on sickle cell disease	S260 – S264	p. 88
Changing the scene on thalassemias	S265 – S269	p. 90
Changing the scene on congenital anemias	S270 – S274	p. 93
Focus on iron metabolism	S275 – S279	p. 95
Fungal, bacterial and viral infections in hematology	S280 – S284	p. 98
COVID-19 impact on hematology: How it started - How it's going	S285 – S289	p. 101
Transfusion medicine	S290 – S294	p. 104
ITP: from bench to bedside	S295 – S299	p. 106
Dilemmas in coagulation and thrombosis	S300 – S304	p. 109

Background: Hereditary Hemochromatosis (HH) is a common genetic disease of systemic iron overload caused by decreased activity of the hepcidin/ferroportin regulatory axis. The most common form of HH is caused by homozygosity for the HFE p.C282Y mutation, while rarer, juvenile subtypes can be caused by mutations in transferrin receptor 2, hemojuvelin, hepcidin or the hepcidin receptor ferroportin. Some patients with inherited hemochromatosis-like phenotypes do not carry mutations in these genes known to be involved in iron homeostasis.
We have recently diagnosed iron overload in 3 patients with epileptic encephalopathy. The clinical picture included normal red blood cell parameters, increased serum transferrin saturation, elevated liver iron and decreased serum hepcidin levels. Exome sequencing excluded mutations in known HH-associated genes and identified novel germline mutations in the phosphatidylinositol glycan class A (*PIGA*) gene. Somatic and germline pathogenic *PIGA* mutations are observed in patients with Paroxysmal nocturnal haemoglobinuria (PNH) and PIGA deficiency, respectively. PIGA is a protein involved in the first step of GPI anchor biosynthesis, which is important for the dynamics and cell membrane attachment of proteins.
Aims: GPI-anchored proteins involved in iron metabolism include HJV and ceruloplasmin. We therefore hypothesized that the iron overload observed in our patients was caused by failure in GPI-anchorage of these proteins. Impaired HJV surface expression would impair iron sensing and result in low hepcidin expression and increased iron uptake while altered ceruloplasmin levels may contribute to enhanced cellular iron retention.
Methods: We performed CRISPR/Cas12a-mediated knockout of *PIGA* in the hepatocytic cell line Hep3B. The expression of key players in iron homeostasis was analysed in WT and *PIGA* KO clones by gene and protein expression analysis. Rescue experiments were performed in *PIGA* KO clones by simultaneously overexpressing HJV and PIGA from constructs that either coded for PIGA WT protein or carried the mutations identified in our patients.
Results: PIGA mRNA transcript and protein were inactivated in the *PIGA* KO clones in comparison with clones that underwent the same CRISPR/Cas12a-mediated procedure but in which *PIGA* was not ablated (*PIGA* WT). Protein analysis detected decreased/absent levels of GPI-anchored proteins, such as CD59, Ceruloplasmin and HJV. We show that WT cells respond with increased hepcidin mRNA expression when HJV is overexpressed, while *PIGA* KO cells fail to do so. Simultaneous overexpression of HJV and a PIGA WT construct rescued hepcidin expression in *PIGA* KO cells to similar levels like WT but hepcidin remained significantly lower when the PIGA mutants L344P, R77Q, L110del and R412* were overexpressed.
Summary/Conclusion: We have discovered that GPI-anchoring of HJV is crucial for its function in regulating hepcidin. The results demonstrate that PIGA mutations are responsible for a novel form of juvenile hemochromatosis.

S101 THE BEYOND STUDY: RESULTS OF A PHASE 2, DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED MULTICENTER STUDY OF LUSPATERCEPT IN ADULT PATIENTS WITH NON-TRANSFUSION DEPENDENT BETA-THALASSEMIA

Background: β-thalassemia is an inherited hemoglobinopathy characterized by ineffective erythropoiesis and impaired red blood cell (RBC) maturation. Patients (pts) with non-transfusion dependent (NTD) β-thalassemia develop chronic anemia and other serious complications affecting survival and quality of life (QoL). Luspatercept, a first-in-class erythroid maturation agent approved by the EMA for treatment of anemia in adults with transfusion-dependent β-thalassemia, may have potential clinical benefit for NTD pts.
Aims: We report results of BEYOND, a phase 2, double-blind, randomized, multicenter study to determine the efficacy and safety of luspatercept vs placebo (PBO) in adults with NTD β-thalassemia (NCT03342404).
Methods: Eligible pts provided informed consent, were ≥18 years with β-thalassemia or hemoglobin (Hb) E/β-thalassemia and received ≤5 RBC units in the 24 weeks (wks) prior to randomization, with mean baseline Hb ≤10.0 g/dL. Pts were randomized 2:1 to receive luspatercept 1 mg/kg (titration up to 1.25 mg/kg) or PBO subcutaneously every 3 wks for ≥48 wks. Pts in both arms continued to receive best supportive care, including sporadic RBC transfusions and iron chelation therapy.
The primary endpoint was achievement of ≥1.0 g/dL mean Hb increase from baseline over a continuous 12-wk interval from Wks 13–24 in the absence of RBC transfusions. Secondary endpoints included proportion of pts who remained transfusion free over Wks 1–24, who achieved mean Hb increase of ≥1.5 g/dL from baseline to Wks 13–24, and mean change in NTD β-thalassemia pt-reported outcome tiredness and weakness (NTDT-PRO T/W) domain scores (higher scores reflect worse QoL).
Results: 145 pts were randomized: 96 received luspatercept and 49 received PBO. Median age was 40.0 years (range 18.0–71.0); 41.7% were male. Baseline median Hb was 8.2 g/dL (range 5.3–10.1); median NTDT-PRO T/W score was 4.3 (range 0–9.5). 20 (13.8%) pts received RBC transfusions (max 5 units) in the 24 wks prior to treatment.
74 of 96 (77.1%) pts in the luspatercept arm achieved the primary endpoint vs 0 of 49 PBO pts (P<0.0001; Fig. A). The primary endpoint was achieved by 40 of 55 (72.7%) luspatercept pts with mean baseline Hb

<8.5 g/dL (vs 0 PBO; *P*<0.0001), and 34 of 41 (82.9%) with mean baseline Hb ≥8.5 g/dL (vs 0 PBO; *P*<0.0001).
At Wks 13–24, 50 of 96 (52.1%) pts in the luspatercept arm achieved mean Hb increase of ≥1.5 g/dL compared to baseline vs 0 PBO (*P*<0.0001; Fig. A). 89.6% of pts in the luspatercept arm remained transfusion free at Wks 1–24 vs 67.3% PBO pts (*P*=0.0013). Change from baseline in NTDT-PRO T/W scores in luspatercept vs PBO arms were –0.92 vs –0.47 (least squares mean difference [LSMD] –0.48, *P*=0.0924) at Wks 13–24 and –1.00 vs –0.16 (LSMD –0.79, *P*=0.051) at Wks 37–48, respectively. Similar changes were also observed in the subset of luspatercept pts with mean baseline Hb <8.5 g/dL (LSMD at Wks 13–24 luspatercept vs PBO –0.73, *P*=0.0433). Improvement in NTDT-PRO T/W scores correlated with Hb increase (Fig. B).
Treatment-emergent adverse events (≥1, grade ≥3) were reported in 27 (28.1%) and 12 (24.5%) pts in luspatercept and PBO arms. Malignant events were only reported in the PBO arm, affecting 2 (4.1%) pts (diffuse large B-cell lymphoma, hepatocellular carcinoma). No thromboembolic or thrombophlebitis events were reported in either .arm.

Figure. (A) Change in mean Hb and (B) change in NTDT-PRO T/W scores vs change in Hb in pts treated with luspatercept and placebo.

Summary/Conclusion: Treatment with luspatercept resulted in significant improvements of anemia, as measured by Hb levels, vs PBO in adults with NTD β-thalassemia. Changes in NTDT-PRO T/W correlated with increases in Hb. Luspatercept was well tolerated in this pt population.

S102 HEMATOPOIETIC STEM CELL-GENE THERAPY FOR MUCOPOLYSACCHARIDOSIS TYPE I, HURLER: EVIDENCE OF EXTENSIVE METABOLIC CORRECTION AND EARLY CLINICAL RESPONSE

M. E. Bernardo [1,2,*], B. Gentner [3], F. Tucci 1, F. Fumagalli [1], F. Ciotti [1], M. Sarzana [1], G. Consiglieri [1], C. Filisetti [1], S. Pontesilli [3], C. Baldoli [3], S. Darin [1], S. Miglietta [3], E. Zonari [3], R. Parini [1], G. La Marca [4], F. Ciceri [3], L. Naldini [3], A. Aiuti [1]

[1]San Raffaele-Telethon Institute for Gene Therapy (SR-TIGET), Pediatric Immunohematology, Ospedale San Raffaele, [2]Vita-Salute" San Raffaele University, [3]Ospedale San Raffaele, Milano, [4]Ospedale Meyer, Firenze, Italy

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the standard of care for mucopolysaccharidosis type I Hurler (MPS-IH) patients showing high overall survival rates and high rate of full donor chimerism when patients are treated at young age and cord blood (CB) hematopoietic stem cells (HSC) are employed. In allo-HSCT, engrafted donor-derived cells constitute a stable endogenous source of the enzyme that can be distributed systemically. However, skeletal abnormalities persist and progress over time severely affecting patient's quality of life together with progressive neurocognitive deterioration.
Aims: Here we report the results of a first-in-human phase I/II clinical trial (NCT03488394) of 8 MPSIH patients treated with autologous HSC genetically modified to overexpress human IDUA and followed-up for a maximum of 2 years (median 12 months).
Methods: Patients (6 M, 2 F; median age at treatment 24 months) lacked a non-heterozygous-HLA-matched CB donor and displayed an IQ/DQ>70. Seven out of 8 patients received enzyme replacement therapy before gene therapy (GT) and 5 of them had a positive anti-IDUA IgG titer at baseline. A high number of autologous HSCs was collected by leukapheresis following mobilization and were transduced with a clinical-grade lentiviral vector encoding human *IDUA* cDNA. Primary endpoint of efficacy was IDUA activity in dried blood spot up to supraphysiologic levels at 1y post-GT. Treatment impact on nervous system and bone was assessed by biochemical, clinical and radiologic parameters.
Results: Median cell dose was 20.7 CD34+/Kg with a median transduction efficiency above 80% and a median vector copy number (VCN) per cell of 2.2 in the drug products. All patients had rapid hematologic recovery, with median neutrophil engraftment on day +20.5 and short thrombocytopenia limited to grade 3 in most patients. The 5 patients that tested positive for IDUA antibodies before GT cleared them within 3 months after GT. Adverse events were generally mild and comparable to those seen with autologous-HSCT, with the exception of one patient who experienced an acute allergic reaction on day+12 which promptly resolved. Gene-marked cells appeared in the bone marrow and peripheral blood in all patients as early as day+30 after GT and were accompanied by achievement of blood IDUA activity to supraphysiological levels in all patients, maintained at 12 months follow-up. All patients had a steep decline in urinary heparan sulfate (HS) and dermatan sulfate (DS) reaching normal or near-normal values by 1 year after treatment. Importantly, undetectable cerebrospinal fluid (CSF) IDUA activity at baseline became detectable by month 3 in all subjects and further increased by month 6 suggesting central enzyme expression, likely provided by local engraftment of microglia-like cells derived from transduced HSC. HS and DS levels in the CSF decreased post-GT suggesting central metabolic correction. With a median follow-up of 12 months, patients show stable cognitive and language performances, stable motor skills corresponding to continued motor development, improved joint stiffness and growth according to expected height percentiles of normal subjects. Brain and spine MRI showed improvements in some of the typical disease features at 1-year follow-up.
Summary/Conclusion: These results suggest that GT accomplishes extensive metabolic correction of peripheral and central compartments and promising preliminary clinical outcomes together with a favorable safety profile, highlighting the therapeutic potential of HSC-GT for the treatment of MPSIH.

S103 PAZOPANIB FOR SEVERE BLEEDING AND TRANSFUSION-DEPENDENT ANEMIA IN HEREDITARY HEMORRHAGIC TELANGIECTASIA

J. Parambil [1], J. Gossage [2], K. McCrae [3], T. Woodard [4], K. N. Menon [5], K. Timmerman [1], D. Pederson [1], D. Sprecher [6], H. Al-Samkari [7,8,*]

[1]Respiratory Institute, Cleveland Clinic, Cleveland, [2]Pulmonary and Critical Care, Augusta University, Augusta, [3]Hematology, Taussig Cancer Institute, [4]Head and Neck Institute, [5]Digestive Diseases Institute, Cleveland Clinic, Cleveland, [6]Cure HHT, Monkton, [7]Hematology, Massachusetts General Hospital, [8]Harvard Medical School, Boston, United States

Background: Hereditary hemorrhagic telangiectasia (HHT) is a rare angiogenic and bleeding disorder causing chronic gastrointestinal bleeding, epistaxis, and severe anemia. Pazopanib is an oral multi-kinase angiogenesis inhibitor with promise to treat bleeding in HHT. There are currently no FDA-approved agents to treat bleeding in HHT.
Aims: To evaluate the safety and effectiveness of low-dose oral pazopanib for severe HHT-associated bleeding.
Methods: We analyzed outcomes of HHT patients with severe bleeding and RBC transfusion dependence (per Gale criteria, ≥2 units pRBCs/month for ≥3 months) treated on a predefined institutional pazopanib treatment pathway for ≥12 months. This predefined institutional pathway outlined the eligibility, dosing, visit schedule, laboratory and adverse event monitoring, and endpoints of treatment and their assessment prior to initiation of pazopanib treatment. The primary endpoint was achievement of transfusion independence per Gale criteria (≥3 months RBC transfusion-free). Secondary endpoints included hemoglobin, epistaxis severity score, RBC transfusion and iron infusion requirements, number

of local hemostatic procedures, ferritin and transferrin saturation, compared using paired and repeated measures means tests.
Results: *Patients and Treatment*. 13 transfusion-dependent HHT patients with severe epistaxis and/or gastrointestinal bleeding received pazopanib [median (range) dose 100 (25-300) mg daily)] for a median of 22 months. Patient median (range) age was 66 (53-78) years and 6 (46%) were female. 12 patients (92%) were on medical disability due to severe chronic bleeding and anemia and 5 (38%) had been recommended to pursue palliative care as all available therapeutic options had been exhausted. 8 patients (62%) had previously failed systemic bevacizumab (either primary non-response or secondary loss of response). No patient had a complicating additional etiology of anemia or had received hormonal, antifibrinolytic, or erythropoiesis-stimulating agents in the 6 months prior to or at any point during pazopanib treatment.
Effectiveness. All patients achieved RBC transfusion independence. Compared with pretreatment, pazopanib increased mean hemoglobin by 4.8 (95% CI, 3.6-5.9) g/dL (7.8 vs. 12.7 g/dL, $P<0.0001$) and decreased mean epistaxis severity score by 4.77 (3.11-6.44) points (7.20 vs. 2.43 points, $P<0.0001$) after 12 months of treatment. Freedom from anemia (Hgb>11) was observed in 92% of patients at 12 months. Compared with 3 months pretreatment, RBC transfusions decreased by 93% (median of 16.0 vs. 0.0 units, $P<0.0001$) and elemental iron infused decreased by 92% (median of 4500 vs. 0 milligrams, $P=0.005$) during the first 3 months of treatment; improvements were maintained over time (**FIGURE**). Median ferritin increased 91 ng/mL (31 vs. 122 ng/mL, $P=0.0007$) and median transferrin saturation increased 14% (9% vs. 23%, $P=0.0002$). The number of required hemostatic procedures decreased 90% (median of 4 vs. 0, $P=0.0002$).
Safety. Pazopanib was well-tolerated: hypertension (31%), lymphocytopenia (23%), and fatigue (23%) were the most common adverse events (none were serious). No patient developed LFT abnormalities, venous or arterial thromboembolism, proteinuria or QTc prolongation during treatment. There were no fatal adverse events.

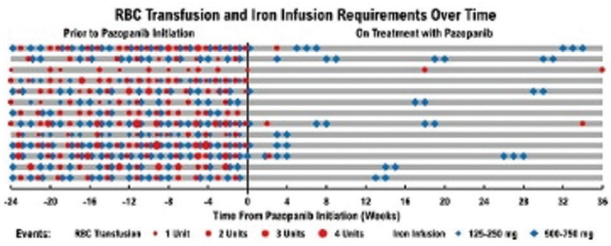

Figure. Swimmer plot detailing timeline of red cell transfusion and iron infusion events for each patient during the 24 months prior to pazopanib initiation and 36 weeks following its initiation. Each "lane" on the plot is representative of a patient over time. Each red circle is a red cell transfusion event and each blue diamond is an iron infusion event (the larger the circle or diamond, the more units of red cells or milligrams of elemental iron infused during that event). Red cell transfusion and iron infusion requirements decreased dramatically after starting pazopanib in all patients.

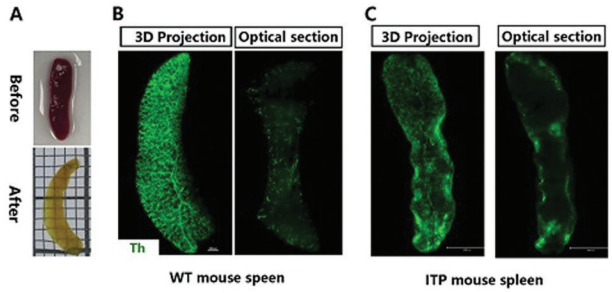

Summary/Conclusion: Pazopanib was safe and effective to manage severe bleeding in HHT, durably liberating all patients from transfusion dependence and normalizing hematologic parameters at doses much lower (median 100 mg daily) than the dose used to treat malignancies (800 mg daily).

S104 A B2 ADRENERGIC RECEPTOR AGONIST CORRECTS DYSREGULATED POLARIZATION OF T HELPER CELLS IN PRIMARY IMMUNE THROMBOCYTOPENIA

G. Zhang [1], F. Liu [1], Y. Su [1], Y. He [1], X. Zhu [1], H. Fu [1], X. Zhao [1], X. Zhao [1], Y. Chang [1], X. Zhang [1,*]

[1]*Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China*

Background: Accumulating evidence has begun to reveal that the nervous system can directly modulate the polarization of Th cells. Indeed, the β2-adrenergic receptor (β2-AR) has been described as the primary adrenergic receptor expressed in immune cells. Emerging studies have reinforced the therapeutic effects of β2-AR agonists in autoimmune diseases by modulating Th cell polarization and enhancing Treg cell function. Immune thrombocytopenia (ITP) is an acquired thrombocytopenia and involves complicated upstream immune dysregulation in which T-cell subsets are supposed to take centre stage. Th cells skewed towards Th1 and Th17 subsets are associated with antiplatelet autoantibody production. Conventional ITP therapies, such as high-dose dexamethasone, RTX and eltrombopag, restore the immune imbalance of Th cells to control levels, resulting in clinical improvement. Therefore, we focused on the role of β2-AR signalling in immune cell development and pathways during ITP.
Aims: To explore the regulation of the sympathetic nervous system on T cell polarization of immune thrombocytopenia (ITP) and describe the 3D distribution of sympathetic nerves in the spleen of active ITP model. Furthermore, to explore the treatment mechanisms of beta2-adrenergic receptor (β2-AR) agonists on ITP models, and provide potential new treatment methods for ITP.
Methods: The active ITP mouse model was established as previously reported (Blood 2010; Blood 2015). We determined the 3D distribution of neural innervations in the ITP mouse spleen by iDisco. For the depletion of sympathetic nerves, the mice were intraperitoneally injected with 150 mg/kg of 6-OHDA (Sigma) dissolved in 0.01% ascorbic acid/saline. Peripheral blood mononuclear cells were isolated from ITP patients and healthy control subjects. The expression of β2-AR and Th cell subsets was assessed by flow cytometry.
Results: Sympathectomized ITP (Syx-ITP) mice experienced a significantly longer platelet recovery time and lower overall survival than nonsympathectomized ITP (non Syx-ITP) mice. mRNA-seq results revealed that syx-ITP mouse CD4+ T cells expressed more Th1-related genes, while non-syx-ITP mice expressed more Th2- and Treg-associated genes. As mentioned above, the beta2-adrenergic receptor (β2-AR) has been described as the primary adrenergic receptor expressed in immune cells. Nonsyx and syx ITP mice both received i.p. injections of terbutaline. Both of these groups exhibited improved platelet counts, and the immune imbalance of Th cells in the spleen returned to control levels. The 3D procedure showed panicle-shaped sympathetic architecture in the ITP mouse spleen parenchyma (Figure 1). Next, we analysed the expression of β2-AR by flow cytometry. The density of β2-AR on CD4 T cells was significantly reduced in patients with ITP. To evaluate whether a β2-AR agonist affects CD4 T-cell polarization, we detected the proportions of T-cell subsets by flow cytometry in ITP patients and healthy controls with or without terbutaline treatment. Terbutaline inhibited the differentiation of Th1 cells but induced the differentiation of Th2 and T regulatory (Treg) cells in ITP patients. However, the percentage of Th17 cells was not affected by terbutaline treatment.

Summary/Conclusion: Impaired sympathetic innervation of the spleen and bone marrow plays a role in the pathogenesis of ITP. Terbutaline treatment corrects the dysregulated polarization of T helper cells during T-cell differentiation, suggesting a potential novel therapeutic approach for patients with ITP.

ALL - Signaling and beyond

S105 DYSREGULATION OF CHROMATIN MODIFIERS DRIVES LINEAGE SWITCH IN MLL-R ACUTE LEUKEMIA

R. Tirtakusuma [1,2], K. Szoltysek [1,3,*], P. Milne [1], V. V. Grinev [4], H. Blair [1], S. Nakjang [1], A. Ptasinska [5], S. Assi [5], C. Meyer [6], R. Marschalek [6], J. Allan [1], J. Vormoor [3], C. Bonifer [5], S. Bomken [1], O. Heidenreich [1,3]

[1]Newcastle University, Newcastle upon Tyne, United Kingdom, [2]Vall d'Hebron Institute of Oncology, Cellex Center, Barcelona, Spain, [3]Prinses Maxima Centrum, Utrecht, Netherlands, [4]Belarusian State University, Minsk, Belarus, [5]University of Birmingham, Birmingham, United Kingdom, [6]Goethe-University, Frankfurt/Main, Germany

Background: Rearrangements of the *MLL* gene (also known as *KMT2A*) occur in both acute lymphoblastic (ALL) and myeloid leukemia (AML), with the lineage choice being dependent on the *MLL* fusion partner. The *MLL/AF4* fusion is associated with pro-B lymphoid phenotype and defines high-risk ALL subtype across all age groups. Interestingly, MLLr leukemias can convert from a lymphoid CD19+ to myeloid CD19-negative phenotype, leading to antigen escape and resistance to epitope-directed therapies such as CAR-T cell or BiTE (*e.g.* blinatumomab) approaches.
Aims: Here we aimed to identify the molecular basis of lineage promiscuity in MLL/AF4 acute leukemia and cellular plasticity during lineage commitment decisions in the cell of origin of relapse.
Methods: We investigated a cohort of two mixed-phenotype (MPALs) and 10 matched diagnosis/relapse samples from lineage switched acute leukemia patients (LSALs). All samples were subjected to next generation sequencing to identify lineage switch-associated changes in (i) mutational profiles, (ii) Ig rearrangements, (iii) transcriptomic pattern and (iv) chromatin accessibility. To identify cellular origins of lineage switch relapse, hematopoietic stem/progenitor cells (HSPCs), precursors and mature cells were examined for the presence of *MLL/AF4* fusion gene and composition of pre-selected mutations. Putative drivers of lineage switch were functionally validated *in vitro*, both with MLL/AF4-positive cell lines, human CD34+ cord blood model (Lin et al., 2016) and MLL/AF4-positive PDX cells.
Results: Sorted MPAL populations and LSAL matched pair samples showed identical fusion breakpoints in each patient proving a common clonal origin of lymphoid presentation and myeloid relapse, and arguing against *de novo* or treatment-related secondary leukemias. We observed BCR rearrangements typical for the pro-B stage in all lymphoid cells. Myeloid cells either shared the same, had different clones or no V(D)J rearrangement at all, proving that lineage switch can emerge from leukemic subpopulations of different maturation stage. Lack of V(D)J rearrangement in the myeloid fraction was associated with presence of the *MLL/AF4* fusion in an HSPCs compartment suggesting a very immature cell of origin in these cases. Comparative transcriptomic analyses between lymphoid and myeloid populations revealed changes in surface marker expression (*e.g.* CD19, CD33) and increased expression of genes controlling myeloid differentiation. DNase-seq results linked observed transcriptional changes to altered genome-wide chromatin accessibility, associated with loss of occupancy of lymphoid TFs binding motifs (*e.g.* EBF1) and gain of motifs bound by myeloid C/EBPs. Furthermore, lineage switch cases concurred with mutation, transcriptional downregulation or missplicing of *CHD4*, gene encoding the central helicase subunit of the NuRD complex. Perturbation of *CHD4* by shRNA lead to the conversion of lymphoid to myeloid programmes in both *MLL/AF*-positive ALL and preleukaemic cell models, as exemplified by loss of CD19 and gain of CD33 surface markers.
Summary/Conclusion: This study shows that lineage switch in MLLr ALL can occur at multiple levels and is associated with transcriptional reprogramming including altered splicing. We propose epigenomic and spliceosome regulators as targets for future investigations and potential therapeutic approaches.

S106 IL7R MUTATIONAL ACTIVATION CAN INITIATE PH-LIKE AND PAX5 P80R PRECURSOR B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

A. Almeida [1], J. L. Neto [1], A. Cachucho [1], M. Euzébio [1], X. Meng [2], R. Kim [3], M. Fernandes [1], B. Raposo [1], M. L. Oliveira [1], D. Ribeiro [1], R. Fragoso [1], P. P. Zenatti [4], J. Background: Interleukin-7 (IL-7) and IL-7 receptor α (encoded by *IL7R*) are essential for normal lymphoid development. *IL7R* gain-of-function mutations were identified in acute lymphoblastic leukemia (ALL) and *IL7R* is a bona fide lymphoid oncogene.
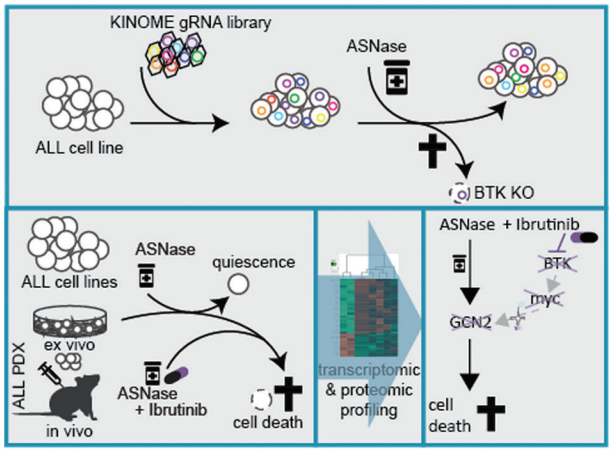
Aims: To determine whether *IL7R* gain-of-function mutations alone can initiate leukemia.
Methods: We generated conditional *Il7r*^{flCPT} knock-in animals that were characterized for disruption of lymphoid development. We analyzed immunophenotype by FACS, transcriptome by RNAseq, and proteome by LC-MS. Tumor mutational profiling was performed by WES. Further methodologies included Sanger sequencing, qRT-PCR, immunoblotting, immunohistochemistry, drug treatment, self-renewal transplant experiments, viral transduction of BM precursors, and cell sorting.
Results: We show that physiological levels of expression of mutant *IL7R* in lymphoid precursors lead to a pre-leukemia stage in which B-cell precursors display self-renewal ability. This is followed by the development of highly penetrant precursor B-ALL that resembles PAX5 P80R or Ph-like human leukemia. Leukemia establishment associates with transcriptional upregulation of oncogenes such as *Myc* or *Bcl2*, downregulation of tumor suppressors such as *Ikzf1* or *Arid2*, and mutations in *Pax5* (precisely P80R) or in signaling genes, such as *Kras, Flt3l, Limk1 or Cdc42bpb*. Transduction of hematopoietic precursors with a *Kras* mutant and subsequent transplantation to lethally irradiated recipient mice shows that Kras upregulates IL7R expression and cooperates in providing a selective advantage to IL-7R mutant-expressing B-cell precursors. In agreement, leukemia establishment associates with striking IL-7R signaling upregulation. This is reflected in the activation of key downstream targets, such as STAT5, MYC and mTOR. Importantly, leukemia cell viability relies on the maintenance of high IL-7R-mediated signaling, as shown by inhibition of JAK1, STAT5 or PI3K/mTOR signaling. To further demonstrate the importance of high IL-7R signaling levels in promoting leukemogenesis, we generated homozygous *IL7R* mutant animals, which display maximal signaling. We find that they display fully-penetrant early leukemia onset. Interestingly, we identify 2 transcriptional subgroups in mouse Ph-like tumors and provide evidence of their existence in human Ph-like ALL. One of the mouse Ph-like ALL subgroups is transcriptionally-enriched in antifolate resistance and JAK-STAT signaling pathways and presents mutations in regulators of chromatin remodeling and transcription, whereas the other shows enrichment for Wnt and Hippo signaling pathways and displays *Cdkn2a* deletions, *Kras* mutations and *Gins2* gains. Finally, we sought to identify therapeutic vulnerabilities in IL-7R-driven B-ALL. Because *IL7R* mutant leukemias exhibit clear upregulation of mTOR signaling, we administered the clinical-grade dual PI3K and mTOR inhibitor dactolisib and show it has a striking impact on the frequency of leukemia cells in the blood, significantly prolonging mouse survival. To identify novel targeted agents against mutant *IL7R* dependence, we performed a chemical screen on Ba/F3 cells ectopically expressing mutant IL-7Rα. We demonstrate that 2 distinct new generation sphingosine kinase inhibitors are effective against mutant *IL7R* mouse B-ALLs both in vitro and in vivo. Importantly, we validated our findings in *IL7R* mutant primary human B-ALLs.
Summary/Conclusion: Our studies provide a novel, powerful in vivo resource to explore the pathophysiology and therapeutic vulnerabilities of B-ALL, and demonstrate for the first time that *IL7R* can initiate this malignancy.



S107 BRUTON'S TYROSINE KINASE INHIBITION SENSITIZES ACUTE LYMPHOBLASTIC LEUKEMIA TO ASPARAGINASE BY INTERFERING WITH THE AMINO ACID RESPONSE - A ROLE FOR C-MYC

M. Butler [1,*], D. van Ingen Schenau [1], J. Yu [1], S. Jenni [2], M. P. Dobay [2], R. Hagelaar [1], B. M. T. Vervoort [1], T. M. Tee [1],

F. W. Hoff [3], J. P. Meijerink [1], S. Kornblau [4], B. Bornhauser [2], J. -P. Bourquin [2], R. P. Kuiper [1], L. T. van der Meer [1], F. N. van Leeuwen [1]

[1]Research, Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands, [2]Pediatric Oncology, Children's Research Centre, Zurich, Switzerland, [3]Pediatric Oncology/Hematology, Beatrix Children's Hospital University Medical Center Groningen, Groningen, Netherlands, [4]Leukemia and Department of Stem Cell Transplantation and Cellular Therapy, MD Anderson Cancer Center, Houston, United States

Background: Amino acid depletion agents, such as Asparaginase (ASNase), are attractive anti-cancer therapies as they do not produce long term toxicities associated with DNA damage. ASNase therapy has been a mainstay of Acute Lymphoblastic Leukemia (ALL) protocols for decades and acts by depleting asparagine from the blood, leading to an intracellular shortage of this amino acid. In contrast to most other cells, lymphocytes and leukemic blasts are dependent on the exogenous supply of asparagine, and as a result, exposure to this drug leads to a cessation of growth and cell death. However, suboptimal depletion of asparagine, as is the case in sanctuary sites such as the bone marrow and the CNS, will allow the leukemic cells to enter a reversible state of cellular quiescence rather than to undergo apoptosis, enhancing the chance of relapse.
Aims: To further optimize ASNase therapies in leukemia, and to broaden its use to other tumor types, a detailed understanding of the cell intrinsic and extrinsic factors that affect the opposing cellular responses to ASNase is needed. We hypothesized that by sensitizing the response to asparaginase, improved survival could be combined with reduced treatment related toxicities.
Methods: We employed a CRISPR/Cas9-based screen to identify actionable signaling intermediates that improve the response to ASNase. The results were validated using targeted knockouts and by using small-molecule inhibitors. We used both ALL cell lines and ALL- patient derived xenografts (ex vivo and in vivo) for these functional validations. Moreover, transcriptomic and proteomics profiling was performed to gain mechanistically insights.
Results: As expected, we identified genes known to be involved in the cellular response to amino acid starvation (GCN2 and TRIB3) to modulate the sensitivity to asparaginase treatment. Since pharmacological targeting of these kinases is expected to lead to treatment related toxicities, we focused on kinases that show a more hematopoietic restricted expression pattern.
Genetic inactivation of Bruton Tyrosine Kinase (BTK) and pharmacological inhibition using different FDA approved BTK inhibitors (Ibrutinib, Evobrutinib, ARQ531) strongly potentiated asparaginase induced apoptosis in a variety of ALL cell lines models. Moreover, we tested the effect of combination treatment in 38 different patient-derived xenografts (PDX) samples, mostly representing high risk leukemia cases and covering a wide variety of ALL subtypes. We observed ex-vivo synergism between ASNase and Ibrutinib in approximately 90% of the PDX models tested. In addition, leukemia formation in mouse PDX models was significantly delayed by the combination treatment.
Using transcriptomic and proteomic profiling, we could demonstrate that BTK inhibition effectively interferes with the ASNase induced amino acid stress response in these cells, a mechanism involving suppression of c-Myc function. As a result of the reduced c-Myc induced proteotoxic stress, GCN2 kinase, a critical regulator of the amino acid response (AAR) pathway, is suppressed. This prevents leukemic cells to adapt to amino acid deprivation, leading to the induction of cell death.

Summary/Conclusion: In conclusion, Ibrutinib or related BTK inhibitors may be used to enhance the clinical efficacy of asparaginase in ALL. Such a combination treatment may not only improve response to therapy but also reduce the need for genotoxic agents associated with long term toxicities.

S108 EHMT2/G9A DRIVES THE EPIGENETIC REGULATION OF GLUCOSE METABOLISM IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

A. Montanaro [1,*], E. Cerretani [1], S. Kitara [2], M. Marchesini [1], C. Rompietti [3], L. Pagliaro [1], A. Gherli [1], B. Lorusso [1], M. L. Minchillo [1], R. La Starza [3], C. Mecucci [3], Y. Xiong [4], J. Jin [4], F. Quaini [1], B. Knoechel [2], P. Sportoletti [3], K. Stegmaier [2], G. Roti [1]

[1]Department of Medicine and Surgery, University of Parma, Parma, Italy, [2]Department of Pediatric Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, [3]Department of Medicine, Hematology and Clinical Immunology, University of Perugia, Perugia, Italy, [4]Departments of Pharmacological Sciences and Oncological Sciences, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, Mount Sinai Center for Therapeutics Discovery, New York, United States

Background: The identification of genes involved in DNA methylation and post-translational histone modifications in hematologic malignancies offers an opportunity for novel therapeutic intervention, geared towards reversing or modulating epigenetic events underpinning these diseases. In fact, in acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS) methylation patterns are altered by mutations in *TET2*, *IDH1*, *IDH2*, *DNMT3A*, and *WT1* genes and matched therapies have demonstrated promising clinical activity. In T-cell acute lymphoblastic leukemia (T-ALL) the epigenetic driven approaches are not yet well validated, especially in the relapsed/refractory (R/R) setting.
Aims: In this project, we sought to identify druggable epigenetic dependencies in T-ALL to anticipate potential synergistic interventions in R/R T-ALL.
Methods: We leveraged the results of a chemical and an epigenome-centered shRNA screen to identify chromatin modifier dependencies in T-ALL. We prioritized the conserved protein lysine H3K9me2-1 methyltransferase, G9a/*EHMT2*based on the effect of targeted inhibition on cell viability and the preferential expression in leukemia vs. normal bone marrow. We described the phenotypic consequences of G9a loss due to small molecule inhibition or genetic suppression. The preponderance of results pointed to a role of G9a in the control of effectors of glycogen metabolism. We confirmed this as follows:1) functionally by glycolytic fluxes and mitochondrial dysfunction analysis, 2) transcriptionally by overlapping a geneset in which we suppressed G9a using small molecules or CRISPR/Cas9, with curated transcription factor GEO signatures to identify common denominators of G9a signaling. Finally, we validated our hypothesis in 3D scaffolds and orthotopic xenograft T-ALL models.
Results: We identified *EHMT2* as a transcriptional dependency in T-ALL by the intersection of a shRNA and chemical screens both focused on epigenetic modifiers. Competitive and non-competitive G9a inhibitors, BIX01294, UNC0638 and UNC0642, or genetic G9a suppression decreases T-ALL proliferation drifting the cells into a late apoptotic stage. At the same conditions, the level of H3K9me2 selectively decreases compared to other epigenetic markers, suggesting the on-target effect of the observed phenotype. G9a deprived T-ALL cells present with an increased number of autophagic vacuoles containing glycogen. Interestingly glycogen accumulation is sustained by the inactivation of Glycogen Synthase Kinase 3 (GSK-3) in multiple G9a null T-ALL cell lines. We next asked whether G9a alters glucose metabolism and demonstrated a reduction of oxygen consumption upon G9a inhibitors treatment suggesting that G9a alters the balance between glycolysis and glycogenesis. Consistently the lack of glucose, secondary to 2-deoxy-d-glucose (2-DG) treatment rescues the formation of autophagosomes upon G9a treatment. Transcriptional enrichment analysis of *EHMT2* loss showed that the metabolic sensor *SESN2* is repressed upon G9a modulation, and in turn, loss of *SESN2* recapitulates the effect seen with G9a inhibition. Finally, we demonstrated that UNC0642 impairs leukemia growth both in 3D scaffold T-ALL from clinical samples and in a T-ALL xenograft orthotopic model where the loss of H3K9me2 parallels the antileukemia effect seen with this drug.
Summary/Conclusion: In conclusion, we identified G9a as an epigenetic vulnerability in T-ALL. Corollary to this, we described a role of G9a in

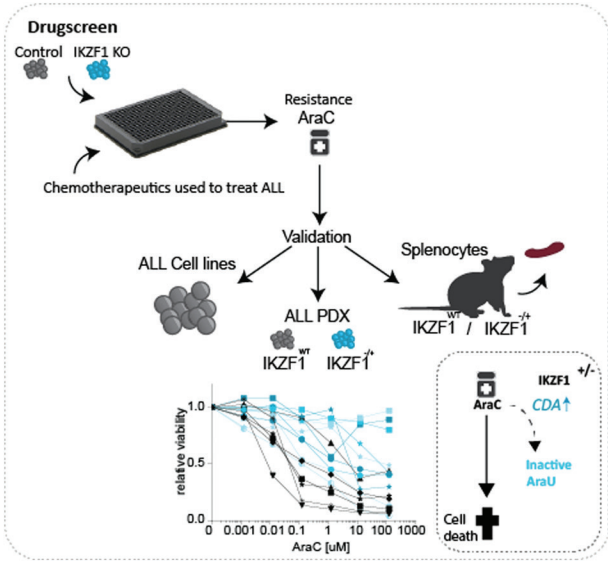
the control of a metabolic circuitry with SESN2 and GSK-3 as downstream effectors of an autophagic cell death.

S109 INDUCIBLE RNA INTERFERENCE IN PATIENTS´ ACUTE LEUKEMIA PDX MODELS IN VIVO TO IDENTIFY AND VALIDATE THERAPEUTIC TARGETS

M. Carlet [1,*], K. Völse [1], M. Becker [1], T. Herold [2], J. Irmela [1]

[1]Research Unit Apoptosis in Hematopoietic Stem Cells, Helmholtz Zentrum München, [2]University Hospital, LMU Munich, Munich, Germany

Background: Only a small proportion of oncology drugs pass early clinical evaluation and receive approval. To improve prediction, preclinical model systems are required, which faithfully mimic the complex *in vivo* situation of cancer patients, such as patient-derived xenograft (PDX) models. To molecularly mimic anti-leukemia treatment in PDX models, inducible systems are required to evaluate targets independently from confounding biological processes that never occur in patients, such as cell transplantation and homing.
Aims: We aimed at developing inducible RNA interference (RNAi) in PDX models of acute leukemias (AL) *in vivo* to identify and validate vulnerabilities as therapeutic targets.
Methods: We established for the first time a Cre-ER^{T2} based inducible RNAi-mediated gene silencing system in PDX. A total of 7 PDX samples, established from patients with heterogenous AL, were genetically modified to express recombinant Cre-ER^{T2} using lentiviruses. The shRNA cassette was flanked by two different pairs of loxP sites and was expressed in the opposite direction so that shRNA expression was initiated by treatment of mice with Tamoxifen, inducing Cre-mediated inversion and deletion (Stern et al. PNAS 2008). In fluorochrome-guided, competitive *in vivo* trials, with control and gene-of-interest cells in the same animal, the methods was tested for its sensitivity and specificity to validate therapeutic targets.
Results: PDX cells were transplanted and grown in mice until tumors were established and knockdown was induced by feeding mice with Tamoxifen. Using the novel technique, we could prove that the tumor-maintaining potency of the MLL-AF4 fusion protein is restricted to PDX samples carrying the rearrangement, demonstrating specificity of the technique. Induction of knockdown of MCL1 in established PDX tumors induced different intensities of growth disadvantages between individual samples, ranging from weak to strong phenotypes. We demonstrate that MCL1 silencing in acute lymphoblastic (ALL) and myeloid (AML) leukemia PDX models can predict response to pharmacological MCL1 inhibitors *in vivo*, proofing the high sensitivity of the inducible RNAi system. Finally, we demonstrate that inducible knockdown of DUX4 in PDX samples carrying the recently described DUX4-IGH translocation diminishes tumor growth *in vivo*. Transcriptome analysis revealed a reversal of the gene expression signature associated with the DUX4 subtype in PDX models *in vivo* and was used to identify novel therapeutic targets in PDX carrying the DUX4-IGH translocation.
Summary/Conclusion: We developed a highly sensitive and specific inducible knockdown technique in PDX models which enables individualized functional genomics in established tumors *in vivo*. Our molecular approach closely mimics the clinical situation and complements an important step in the evaluation chain of drug development and precision oncology.



ALL - Novel subgroups and agents

S110 LOSS OF IKZF1 CONTRIBUTES TO CYTARABINE RESISTANCE IN B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

B. Vervoort [1,*], M. Butler [1], D. van Ingen Schenau [1], R. Marke [2], B. Bornhauser [3], J.-P. Bourquin [3], L. van der Meer [1], F. van Leeuwen [1]

[1]Research, Prinses Maxima Centrum, Utrecht, [2]Research, Radboud UMC, Nijmegen, Netherlands, [3]Research, University Children's Hospital Zurich, Zurich, Switzerland

Background: Deletions and mutations affecting lymphoid transcription factor *IKZF1* occur in about 10-15% of patients with B cell precursor acute lymphoblastic leukemia (BCP-ALL) and predict a poor outcome. We have shown previously that loss of IKZF1 function compromises the therapeutic efficacy of glucocorticoids (GCs). Here, we investigated whether loss of IKZF1 function also affects therapy response to other chemotherapeutic agents used in the treatment of ALL.
Aims: To further optimize antimetabolite therapies for IKZF1 deleted leukemia to prevent relapse and therapy resistance.
Methods: We performed a drug screen including all chemotherapeutic agents used in the treatment of ALL. The results were validated using targeted knockouts, shRNA mediated knockdowns as well as a chemical induced breakdown of IKAROS. These assays were performed on ALL cell lines as well as murine splenocytes and ALL- patient derived xenografts.
Results: We observed that CRISPR/CAS9-mediated loss of *IKZF1* in SEM pre-B ALL cells markedly reduced the cellular response to the pyrimidine analogue cytarabine (AraC) relative to *IKZF1* wild type cells. The same drug resistance profile was observed upon shRNA-mediated knockdown of IKZF1 as well as in B-cells isolated from 8 to 14 weeks-old *Ikzf1*$^{+/-}$ mice. We confirmed these findings by *ex vivo* profiling of patient-derived xenografts (PDX), where we observed that *IKZF1*-deleted cases (n=10) were significantly (area under the curve (AUC) 78.690) more resistant to AraC than those wild type for *IKZF1* (n=6) (AUC 26.447). Loss of IKZF1 can also chemically be mimicked by the cereblon-E3 ligase Iberdomide, which specifically targets and breaks down members of the Ikaros protein family. Indeed, we observed that PDX wildtype for IKZF1, developed resistance to AraC in response to this drug. The metabolic enzyme cytidine deaminase (CDA) is an important determinant of AraC therapy response, both in ALL and acute myeloid leukemia (AML). Consistent with these findings, we observed that IKZF1 loss increases the expression of CDA in BCP-ALL cell lines as well as mouse primary B cells and PDX models. In addition, treatment of *IKZF1*$^{+/-}$ cells using pharmacological inhibitors of CDA, restored pyrimidine analogue sensitivity to control levels.

Summary/Conclusion: Together, these results demonstrate that loss of *IKZF1* confers resistance to AraC, both in experimental models and in patient-derived cells. We are currently performing CRISPR/CAS9 based reverse genetics screens to identify genes/pathways that enhance response to AraC or other antimetabolites. We expect that this approach will allow us to identify (hematopoietic cell-specific) pathways that can be targeted to sensitize responses to AraC in *IKZF1* deleted ALL and possibly AML. Preclinical validations of these findings, using representative PDX models, will guide the development of more effective antimetabolite therapies for this high-risk patient group.

S111 REDEFINING LOW RISK HIGH HYPERDIPLOIDY IN PAEDIATRIC ACUTE LYMPHOBLASTIC LEUKAEMIA

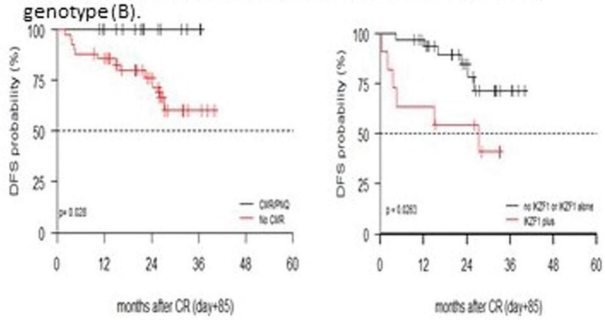
A. Moorman [1,*], A. Enshaei [1], A. Vora [2], C. Harrison [1], J. Moppett [3]

[1]Translational and Clinical Research Institute, Newcastle Univeristy Centre for Cancer, Newcastle upon Tyne, [2]Department of Haematology, Great Ormond Street Hospital, London, [3]Department of Haematology, Bristol Royal Hospital for Children, Bristol, United Kingdom

Background: High hyperdiploidy (HeH) with a modal number of 51 to 67 chromosomes occurs in ~30% of B-cell precursor acute lymphoblastic leukaemia (ALL). Although strongly associated with good outcome, relapses do occur and its prevalence means that HeH accounts for up to 25% of all relapses. No consensus exists regarding risk factors in this subgroup.
Aims: The objective of this study was to comprehensively evaluate all relevant risk factors to define a very low risk subgroup within HeH which could be used prospectively to define patients eligible for treatment de-escalation.
Methods: Analysis was performed using the UKALL97/99 (n=456, discovery) and UKALL2003 (n=725, validation) cohorts with median follow-up times of 10.6 and 9.4 years, respectively. Event-free survival (EFS), relapse rate (RR) and overall survival (OS) rates were calculated at 10 years and compared using univariate and multivariate analyses Cox regression models. To determine the optimal number of chromosomes needed to predict outcome, we used area under ROC curve, general linear model and targeted projection pursuit. We measured C-index, Mallows' Cp for each combination for selecting the fittest model. Multivariate analysis, general linear model, network analysis and coefficient of the risk model determined the optimal combination of chromosomes for predicting outcome and Bayesian information criterion with forward stepwise criteria for model selection.
Results: HeH karyotypes gain between 5 and 19 chromosomes so analysing all possible combinations and permutations of trisomies was impossible. Hence, we calculated the optimum number of chromosomes required to maximise prediction. Using the discovery cohort, we generated all possible combinations of one to six trisomies and found that four chromosomes produced the maximum prediction power. Multivariate Cox modelling defined chromosomes 5, 17, 18 and 20 as the optimal prognostic set. Using these four chromosomes, we developed and validated good risk (GR) and poor risk HeH profiles. The GR profile comprised patients with (a) +17 and +18 together or (b) either +17 or +18 but not +5 or +20. The poor risk (PR) comprised all other HeH cases. The size of the risk groups were similar in the validation and discovery cohorts: GR 80-82%, PR 18-20%. There was no correlation between HeH risk group and age, sex, white cell count or end of induction MRD. Patients with a HeH-PR profile had an increased RR in both cohorts: hazard ratio 2.50 (95% CI 1.51-4.14) & 3.80 (2.14-6.75), both p<0.001; which was independent of MRD. Threshold analysis revealed 0.03% to be the optimal MRD threshold and the RR for HeH-GR cases by MRD</≥0.03% was 4%/8% compared with 11%/27% for HeH-PR cases. The excellent outcome of HeH-GR patients was observed among the patients who received the least intensive therapy. Whereas the outcome of HeH-PR patients akin to that associated with intermediate risk cytogenetics (Table). Although smaller than a standard HeH subgroup, the HeH-GR group had a better outcome. In addition, it outperformed TT in terms of group size and prediction accuracy (Table).

	All HeH cases	HeH-PR	HeH-GR	Triple trisomy (+4,+10,+17)
	n (%)	n (%)	n (%)	n (%)
Number of cases	725	146	579	299
Proportion of HeH cases	100%	20%	80%	41%
NCI risk group				
Standard	550 (76)	107 (73)	443 (77)	229 (77)
High	175 (24)	39 (27)	136 (23)	70 (23)
End of induction MRD				
<0.03%	462 (73)	85 (70)	377 (74)	187 (73)
≥0.03%	170 (27)	37 (30)	133 (26)	68 (27)
Relapse				
No	670 (93)	122 (85)	548 (96)	284 (97)
Yes	47 (7)	22 (15)	25 (4)	10 (3)
Outcome at 10 years (95% CI)				
Relapse risk	7% (5-9)	16% (10-23)	5% (3-7)	4% (2-7)
Event Free survival	90% (87-92)	81% (73-86)	92% (90-94)	92% (88-94)
Overall survival	94% (92-95)	86% (79-91)	96% (94-97)	96% (93-97)
Prediction Accuracy				
C-index	-	0.64		0.60
Area under the curve	-	0.64		0.61

Summary/Conclusion: The UKALL-HeH profile defines two distinct HeH risk groups. Patients with a UKALL-HeH GR profile have an excellent outcome and represent low risk subgroup of HeH which could be considered for treatment de-escalation.



S112 UPDATED RESULTS OF THE GIMEMA LAL2116, D-ALBA TRIAL, FOR NEWLY DIAGNOSED ADULTS WITH PH+ ALL

S. Chiaretti [1,*], R. Bassan [2], A. Vitale [1], L. Elia [1], M. Messina [3], P. Viero [4], M. Annunziata [5], M. Lunghi [6], F. Fabbiano [7], M. Bonifacio [8], N. Fracchiolla [9], P. Di Bartolomeo [10], L. Gorreo Renzulli [3], M. S. De Propris [1], M. Vignetti [3], A. Guarini [11], A. Rambaldi [12], R. Foà [1]

[1]Translational and Precision Medicine, Sapienza University, Rome, [2]Ospedale dell'Angelo - Mestre, Venice, [3]GIMEMA Foundation, Rome, [4]Ospedale dell'Angelo, Mestre, Venice, [5]Cardarelli Hopsital, Naples, [6]AOU Maggiore della Carità, Novara, [7]Ospedale Villa Sofia-cervello, Palermo, [8]Medicine, Verona University, Verona, [9]IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, [10]Ospedale Civile, Pescara, [11]Molecular Medicine, Sapienza University, Rome, [12]Azienda Socio-Sanitaria Territoriale Papa Giovanni XXIII, Bergamo, Italy

Background: Outcome of Ph+ ALL has dramatically changed since the advent of tyrosine kinase inhibitors (TKIs). To further improve the outcome of this subset of patients, we designed an induction/consolidationchemo-free trial (GIMEMA LAL2116, D-ALBA) based on the administration of dasatinib plussteroids followed by at least two cycles of blinatumomab (maximum 5) and central nervous system (CNS) prophylaxis. Post-consolidation treatment was left at the investigator's choice. The first results at a median follow-up of 18 months have been recently published (Foà et al, NEJM2020): after the 2nd cycle of blinatumomab, a molecular response was achieved in 60% of the cases, which increased further after additional cycles of blinatumomab, translating into an overall survival (OS) and disease-free survival (DFS) of 95% and 88%, respectively.
Aims: To provide an updated follow-up of the study
Methods: After the primary endpoint, patients were followed for 12 months; data on subsequent treatment and survival are being collected in the ancillary study GIMEMA LAL2217.
Results: As reported, 63 patients were enrolled (median age 54 years, 24-82; no age limit); the median follow-up is 27.2 months (0.9-45.2). In line with previous data, molecular responses were recorded in the majority of patients also at the subsequent follow-ups (range 73%>89%). Overall, 3 additional relapses were observed (total: 9): 4 hematologic, 4 at the CNS and 1 nodal; the median time to relapse was 4.4 months (1.9-25.8). Three additional deaths in complete hematologic remission (CHR) were recorded (total: 6). Of the 58 patients who started blinatumomab, 29 were allografted: 9 from a sibling, 13 from an unrelated donor, 6 from a haploidentical donor and 1 from a cord blood (6 transplants were carried out in 2nd CHR). Before transplant, 8 patients received 2 and 3 cycles of blinatumomab, respectively, 5 4 cycles and 6 5 cycles (2 patient were allografted after the 1 cycle). Five deaths occurred, 2 in patients transplanted in 2nd CHR.
29 continued treatment with a TKI: 21 with dasatinib (85% after receiving all the 5 cycles of blinatumomab), 3 switched to imatinib due to intolerance (all after 5 cycles of blinatumomab) and 5 switched to ponatinib for a molecular increase or medical decision (66% received all 5 cycles of blinatumomab).
In the updated follow-up, 24 months OS is 87.8% and DFS is 79.8%. DFS was better in patients achieving a molecular response upon induction/consolidation than in those who did not (100% vs 75.9%, p=0.028, Fig 1A). Furthermore, we confirmed the inferior DFS for patients carrying an *IKZF1*-plus genotype compared to that of cases with no *IKZF1* deletions or with *IKZF1* deletions alone (84.5% vs 54.5%, p=0.026, Fig 1B).

Fig 1. DFS according to molecular response (A) and *IKZF1* plus genotype (B).

Summary/Conclusion: In the updated analysis of the D-ALBA trial, we confirm the very favorable outcome previously reported, as well as the deleterious prognostic impact of the *IKZF1*-plus genotype and the low transplant-related mortality rate. Among the few relapses, we observed a rather high incidence of CNS involvement. In the upcoming trial for newly diagnosed adult Ph+ ALL, CNS prophylaxis will be increased.

S113 INTERIM RESULTS OF A PHASE II STUDY OF BLINATUMOMAB PLUS PONATINIB FOR PHILADELPHIA CHROMOSOME-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

N. Short [1,*], H. Kantarjian [1], M. Konopleva [1], N. Jain [1], X. Huang [1], F. Ravandi [1], W. Wierda [1], G. Borthakur [1], K. Sasaki [1], G. Issa [1], Y. Alvarado [1], N. Pemmaraju [1], G. Garcia-Manero [1], J. Thankachan [1], R. Garris [1], E. Jabbour [1]

[1]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Ponatinib and blinatumomab both produce high rates of molecular remission in Philadelphia chromosome-positive (Ph+) acute lymphoblastic leukemia (ALL). The combination of these two agents may lead to deep and durable responses, thereby reducing the need for allogeneic hematopoietic stem cell transplant (HSCT).
Aims: We evaluated the efficacy and safety of a chemotherapy-free combination of blinatumomab and ponatinib in patients with newly diagnosed (ND) or relapsed/refractory (R/R) Ph+ ALL. For patients with ND Ph+ ALL, the primary endpoint was the complete molecular response (CMR) rate, defined as absence of a quantifiable PCR transcript for *BCR-ABL1*. For patients with R/R Ph+ ALL, the primary endpoint was the overall response rate (defined as the composite of CR/CRi). Secondary endpoints included safety measures, event-free survival (EFS) and overall survival (OS).
Methods: This is a single-arm phase 2 study in adults with ND or R/R Ph+ ALL. Patients were required to have a performance status of ≤2, total bilirubin ≤2x the upper limit of normal (ULN), and alanine aminotransferase and aspartate aminotransferase ≤3x the ULN. Patients with uncontrolled cardiovascular disease or clinically significant central nervous system comorbidities were excluded. Patients received up to 5 cycles of blinatumomab as a continuous infusion at standard doses. Ponatinib 30mg daily was given during cycle 1. Ponatinib was decreased to 15mg daily once CMR was achieved. After completion of blinatumomab, ponatinib was continued for at least 5 years in responding patients. Twelve doses of prophylactic intrathecal chemotherapy were administered.
Results: Between February 2018 and February 2021, 28 patients were treated (19 ND and 9 R/R). The median age for the entire cohort was 59 years (range, 25-83 years); 62 years (range, 34-83 years) and 36 years (range, 25-61 years) in the ND and R/R cohorts, respectively. *BCR-ABL1* transcripts were p190 in 69% of patients in the ND cohort and 100% in the R/R cohort. 44% of patients in the R/R cohort were in salvage 2 or beyond. Overall, 95% of patients responded; the CR/CRi rate was 100% in the ND cohort and 88% in the R/R cohort. No early death within 4 weeks were observed. 86% of responding patients achieved CMR (87% in the ND cohort and 86% in the R/R cohort). The median time to CMR was 1 month (range, 1-13 months). None of the patients in the ND cohort underwent HSCT; 4 patients (44%) in the R/R cohort underwent subsequent HSCT. With a median follow-up of 14 months, the estimated 1-year OS rate was 94% and the EFS rate was 81% for the entire study cohort. In the ND cohort, no patients have relapsed or died, and the 1-year OS and EFS rates were both 100%. In the R/R cohort, 1-year OS and EFS rates were 88% and 55%, respectively. The treatment was well-tolerated, and most side effects were grade 1-2. No patient has discontinued ponatinib due to toxicity. One patient discontinued blinatumomab due to recurrent grade 2 tremor.
Summary/Conclusion: The chemotherapy-free combination of ponatinib and blinatumomab shows encouraging safety and efficacy in Ph+ ALL, with high rates of CMR and durable remissions, particularly when used in the frontline setting. All ND patients remain in remission without HSCT, suggesting that this regimen may obviate the need for HSCT in this setting.

S114 PRELIMINARY RESULTS OF THE GIMEMA LAL2317 SEQUENTIAL CHEMOTHERAPY-BLINATUMOMAB FRONT-LINE TRIAL FOR NEWLY DIAGNOSED ADULT PH-NEGATIVE B-LINEAGE ALL PATIENTS

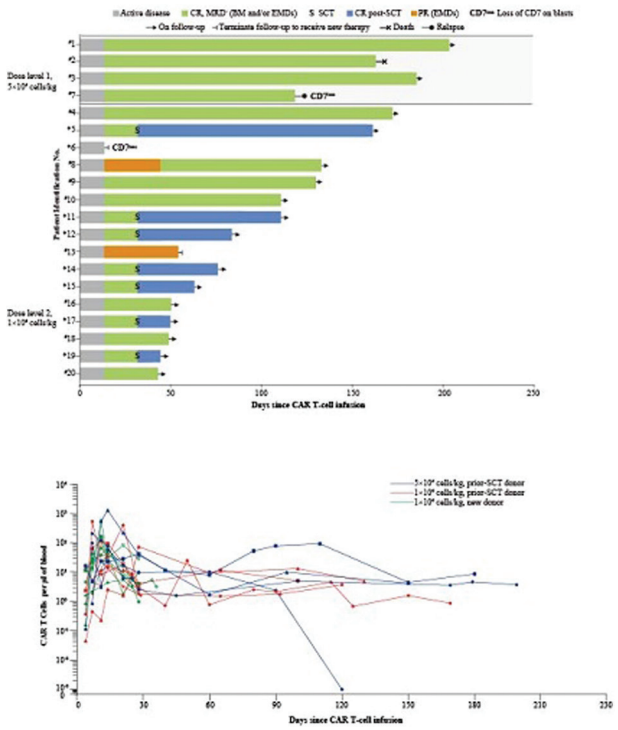
Background: The outcome of adult patients with Ph-negative acute lymphoblastic leukemia (ALL) has improved with survival rates nowadays in the range of 50% and greater, particularly for minimal residual disease (MRD) responsive subjects. To optimize the rate of MRD response and improve survival, in the GIMEMA LAL2317 trial two doses of the bispecific monoclonal antibody blinatumomab were added to chemotherapy. The study was designed for adult patients with B-lineage Ph-ALL aged 18-65.
Aims: To evaluate the efficacy of blinatumomab in increasing the early MRD negativity rate. MRD was measured by RQ-PCR with a cut-off for negativity set at <10-4.
Methods: The trial was based on the same chemotherapy backbone of GIMEMA LAL1913 (EHA 2018, #919) with two blinatumomab cycles given sequentially after early consolidation cycle 3 (high-dose methotrexate and Ara-C) and late consolidation cycle 6, respectively. While conversion to MRD negativity following blinatumomab 1 was the primary objective, the drug was intentionally given to all study patients regardless of MRD being assessable or not. Patients were stratified for risk-oriented therapy: very high risk (VHR, for early switch to allo-SCT) with a WBC count >100 x 10^9/l and/or highly adverse cytogenetics/genetics (the Ph-like signature was routinely investigated but did not enter into the risk model); high risk (HR) with >30 x 10^9/l WBC, a pro-B phenotype, or a late complete remission (CR); and standard risk (SR) with no risk factors. HR and SR patients were allocated to allo-SCT only when found to be MRD-85 positive at weeks 10-22. The sample size was calculated at 149 patients, with at least MRD-evaluable patients necessary to collect evidence for an improved blinatumomab-related response.
Results: Patients' recruitment closed in June 2020. 149 patients were enrolled and 146 are evaluable; 78 were male (54%), the median age was 41 years (range 18-65, 18% >55 years). Thirty-nine patients (48%) were VHR/HR, with 8.5% *KMT2A*+ and 28% expressing the Ph-like signature. A hematological CR was achieved in 131 patients (90.4%), 7 were resistant, 7 died early and 1 was not evaluable. Regarding the primary study endpoint, i.e. the MRD clearance after blinatumomab course 1, 85 patients with paired MRD samples were evaluable. After early consolidation, 73% of these patients were MRD-negative (<10^{-4}). This increased to 96% after the first blinatumomab administration (P=0.018), with a conversion rate from MRD positivity to MRD negativity of 87% (20/23 patients). Blinatumomab was also capable of eradicating MRD in Ph-like patients: 10/25 evaluable patients were MRD-positive after early consolidation and all became MRD-negative. With a median follow-up of 10 months (range 0.5-27.4), the 12-month overall and disease-free survival (OS, DFS) rates are 83.8% and 71.6%, respectively. Favorable prognostic factors were age <56 years (OS 65.4% in >55 years, 88% 41-55 years, 91% in 18-40 years, P<0.001 vs age >55) and week 10 MRD negativity (OS 94%, P=0.0073; DFS 88%, P=0.0036). Fifteen relapses occurred, translating into a 12-month relapse incidence of 11%, with no difference in blinatumomab-treated patients, whether MRD-positive, negative or unknown.
Summary/Conclusion: This preliminary analysis highlights the efficacy of blinatumomab added to chemotherapy in increasing MRD negativity (<10-4) in CD19+ B-lineage Ph-ALL, with the primary study endpoint fully achieved. This effect appears to translate into a lower early relapse rate and appears detectable in all risk subsets.



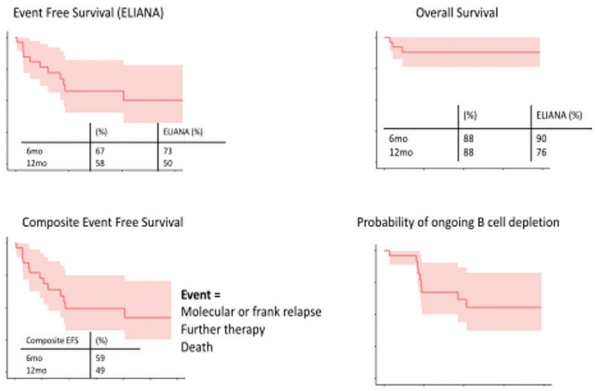
ALL - CAR-T: Alternative targets and age groups

S115 DONOR-DERIVED CD7 CAR T CELLS FOR T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

J. Pan [1,2,*], Y. Tan [3], B. Deng [4], Z. Ling [1], W. Song [1], J. Xu [2], J. Duan [2], Z. Wang [2], A. H. Chang [5], X. Feng [3]

[1]Department of Hematology, [2]Beijing Boren Hospital, Beijing, [3]National Clinical Research Center for Blood Diseases, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, [4]Cytology Laboratory, Beijing Boren Hospital, Beijing, [5]Clinical Translational Research Center, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China

Background: Despite the success of chimeric antigen receptor T cell therapy in B cell malignances, there is currently no proved CAR T treatment for T cell neoplasms. We provide first evidence support the use of donor derived CAR T cells in T cell leukemia.
Aims: To assess the safety, tolerability, pharmacokinetic profile, and anti-tumor activity of donor-derived CD7 CAR T cells in patients with r/r T-ALL.
Methods: In this phase 1 trial, CD7 CAR T cells were manufactured with T cells from prior SCT prior to a single infusion at doses of 5 × 105 or 1 × 106 (± 30%) cells per kilogram of body weight. donors, or from new donors who were HLA-matched or haploidentical, via leukopheresis and transduced with a lentiviral vector which carries a CD7 CAR construct. The primary endpoint was safety. Short-term efficacy was also assessed.
Results: Results of 20 enrolled patients who received infusion are reported. Of 20 patients, 12 received previous HSCT-donor derived CAR T cells and 8 received fresh haplo-identical donor derived CAR T cells and plan to received transplantation as consolidation after remission.Adverse events included grade 3-4 hematologic toxicity in all (100%), grade 3-4 and grade 1-2 cytokine release syndrome in 2 (10%) and in 18 (90%), grade 1 neurotoxicity in 3 (15%), grade 1-2 graft-versus-host disease in 12 (60%), and grade 1 viral activation in 3 (15%) patients. Nineteen (95%) patients had a response, including 18 (90%) with complete remission and 1 (5%) with partial remission. Of 19 responders, 7 were bridged to SCT and remained minimal residual disease (MRD)-negative until last visit; 12 were followed up at a medium of 4.4 months, among whom 9 remained MRD-negative, 1 had a relapse, 1 discontinued for other treatment, and 1 died of pulmonary fungal infection at 5.5 months. CAR cells mostly persisted beyond 3 months. Patient CD7-positive healthy T cells were depleted, while CD7-negative T cells increased.



Summary/Conclusion: We report the initial toxicity profile and anti-leukemia activity of a donor-derived CD7-targeted cellular immunotherapy for patients with relapsed or refractory T-ALL. (Funded by the National Key R&D program; ChiCTR.org number, ChiCTR2000034762.)

S116 OUTCOMES OF CHILDREN AGED UNDER 3 YEARS TREATED WITH TISAGENLECLEUCEL FOR B-ALL

Background: The pivotal ELIANA study defined outcomes for tisagenlecleucel in children and young adults with B-ALL aged 3 to 25 years. However, outcomes in children younger than 3 years, including those with infant ALL have not been fully documented.
Aims: To define outcomes of tisagenlecleucel therapy in children less than three years of age for B-ALL
Methods: Retrospective, standardised data collection was undertaken for all patients assessed for tisagenlecleucel for B-ALL aged under 3 years at the point of screening from centres represented in the I-BFM Resistant Disease Committee. Survival outcomes were assessed using Kaplan-Meier estimates. These included overall survival (OS, interval to death from any cause); event- free survival (EFS) as defined in the ELIANA study (interval to death, morphological disease relapse, or treatment failure by day 30, with censoring of patients receiving further therapy) as well as a stricter composite EFS (events included treatment failure, interval to death, molecular or morphological relapse or further therapy). Median follow up was calculated by a reverse Kaplan-Meier method
Results: 30 patients from 15 centres were screened and eligible. 3 patients were not infused due to: manufacturing failure (n=2), disease progression (n=1), giving a 90% feasibility rate. One patient had not reached the 1 month disease assessment, leaving 26 evaluable for disease outcomes and 27 for toxicity. 24 of 30 patients (80%) had MLL rearranged ALL, most had high risk features: 21 (70%) had had a prior stem cell transplant (SCT).
Two patients failed to respond, giving a CR/CRi rate of 24/26 (92%), all were MRD negative. The median follow-up was 15.5 months. EFS and overall survival OS are shown in Figure 1. OS at 6 and 12 months was 88%. EFS as per ELIANA criteria was 67% and 58% at 6 and 12 months respectively. Using the more stringent composite EFS, the 6 and 12 month EFS were 59%, and 49%. Of 27 patients infused, 10 (37%) received further therapy including 3 given maintenance therapy for poor CAR T cell persistence, 2 receiving chemotherapy for relapse and 5 (19%) who received allogeneic SCT: for relapse (n=2), B cell recovery (n=2), or as a planned procedure (n=1). For patients relapsing following CR (n=6/27 (22%) infused) there were 2/6 (33%) CD19- relapses.
Severe (grade ≥3) CRS, neurotoxicity, or cytopenia after day 30 post infusion occurred in 2/22 (10%), 1/22 (5%), and 8/22 (36%) respectively. 17/22 (77)% of the cohort developed hypogammaglobulinaemia. The 6 and 12 month probabilities of ongoing B cell depletion were 82% and 68%.

Summary/Conclusion: This cohort with predominantly MLL-rearranged leukaemia, represents the largest series of children aged under 3 treated with tisagenlecleucel. Median age at infusion was 17 months. It was feasible to leucapheresе and manufacture a product in 90%. The MRD negative CR/CRi response, 6 and 12 month EFS, and OS rates were equivalent to those of patients on the ELIANA study (median age 11 years). The toxicity profile i.e. rates of severe CRS, neurotoxicity and cytopenias were broadly similar, as were rates of hypogammaglobulinemia and infection. The rates of relapse and CD19- relapses were also similar to real-world data from the US, France and UK.
This was a cohort of very high-risk patients with predominantly infant ALL, traditionally a disease entity with very poor outcomes. The remarkably good EFS and OS documented strongly support use of tisagenlecleucel in the youngest children, even in the setting of very high-risk infant ALL.

S117 PHASE 2 RESULTS OF THE ZUMA-3 STUDY EVALUATING KTE-X19, AN ANTI-CD19 CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY, IN ADULT PATIENTS WITH RELAPSED/REFRACTORY B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

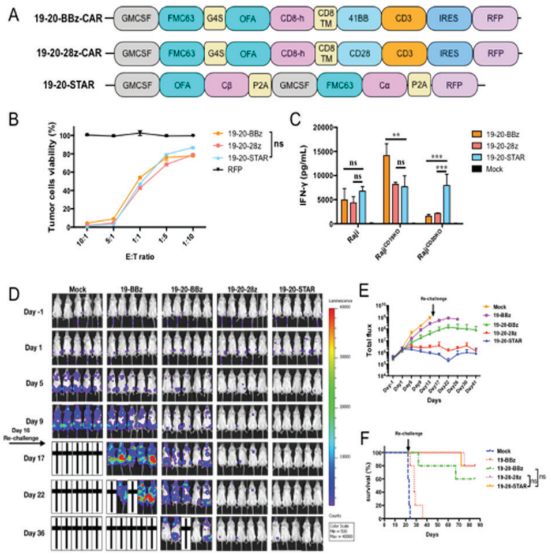
Background: ZUMA-3 is a Phase 1/2 multicenter study evaluating KTE-X19, an autologous anti-CD19 chimeric antigen receptor (CAR) T-cell therapy, in adult patients with relapsed/refractory B-cell acute lymphoblastic leukemia (R/R B-ALL). Phase 1 efficacy results at the recommended Phase 2 dose (1×10^6 CAR T cells/kg) were encouraging (Shah et al. *J Clin Oncol*. 2019;37[suppl, abstr]:7006).
Aims: To present the pivotal Phase 2 results of ZUMA-3.
Methods: Eligible adults had R/R B-ALL, >5% bone marrow blasts by local evaluation, and Eastern Cooperative Oncology Group performance status of 0–1. Patients received a single infusion of KTE-X19 after conditioning chemotherapy. The primary endpoint was the overall complete remission (CR) rate (CR + CR with incomplete hematologic recovery [CRi]) by central review. Key secondary endpoints were duration of remission, relapse-free survival, overall survival, measurable residual disease negativity rate by flow cytometry, and safety. Data are reported in all treated patients.
Results: As of 9/2020, 55 of 71 enrolled patients received KTE-X19, with a median follow-up of 16.4 months (range, 10.3–22.1). Adverse events (n=8) and ineligibility (n=4) were the most common reasons enrolled patients did not receive KTE-X19 infusion. Median age was 40 years (range, 19–84); median bone marrow blasts at screening were 65% (range, 5–100); and 47% of patients had ≥3 prior therapies, with 45%, 22%, and 42% having previously received blinatumomab, inotuzumab ozogamicin, or allogeneic stem cell transplant, respectively.
The CR + CRi rate was 71% (95% CI, 57–82; 56% CR, 15% CRi); 31% of responders had ongoing responses. Medians (95% CI) for duration of remission, relapse-free survival, and overall survival were 12.8 months (8.7–not estimable), 11.6 months (2.7–15.5), and 18.2 months (15.9–not estimable), respectively. In responders, medians (95% CI) for relapse-free survival and overall survival were 14.2 months (11.6–not estimable) and not reached (16.2–not estimable). The measurable residual disease negativity rate was 97% among patients with CR + CRi. Among 25 patients with prior blinatumomab treatment, the CR + CRi rate was 60%. Ten patients (18%) received subsequent allogeneic stem cell transplant at a median of 98 days post–KTE-X19 infusion. Median duration of remission remained unchanged when not censoring for allogeneic stem cell transplant.
Grade ≥3 adverse events occurred in 95% of patients, most commonly anemia (49%) and neutropenia (49% [febrile 13%]). Grade ≥3 cytokine release syndrome (per Lee et al. [*Blood*. 2014;124:188-195]) and neurologic events occurred in 24% and 25% of patients, respectively, and were generally reversible. Two Grade 5 KTE-X19–related events occurred (brain herniation, n=1; septic shock, n=1). Median times to onset of cytokine release syndrome and neurologic events were 5 days and 9 days, with median durations of 7.5 days and 7 days, respectively. Median peak CAR T-cell levels (cells/µL) were 40.5 (range, 1.3–1533.4) in patients with CR and 0 in nonresponders. CAR T cells were undetectable by 9 months in ongoing responders.
Summary/Conclusion: After a median follow-up of 16.4 months, KTE-X19 demonstrated compelling clinical benefit in heavily pretreated adults with R/R B-ALL, with the median overall survival not yet reached for responding patients and a manageable safety profile.



S118 A NOVEL CD19/CD20 DUAL SYNTHETIC T-CELL RECEPTOR AND ANTIGEN RECEPTOR (STAR) T CELL THERAPY FOR REFRACTORY AND RELAPSED (R/R) B CELL ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL)

J. Yang [1,2], J. Wang [3], X. Zhang [1], J. Li [1,2], L. Yu [3], Z. Zhou [3], L. Jia [3], Y. Liu [3], H. Zheng [4], X. Lin [3], P. Lu [1,2,*]

[1]Beijing Lu Daopei Institute of Hematology, Beijing, [2]Hebei Yanda Lu Daopei Hospital, Langfang, [3]Department of Basic Medical Sciences and Institute for Immunology, Tsinghua University School of Medicine, [4]China Immunotech (Beijing) Biotechnology Co. Ltd., Beijing, China

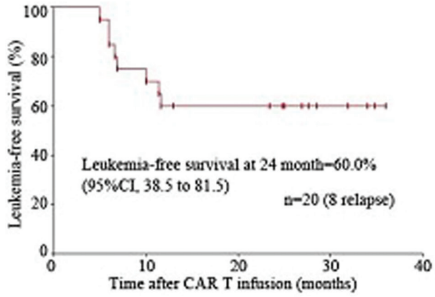
Background: While Chimeric Antigen Receptor (CAR)-T cell approach has proved to be effective to treat hematopoietic malignancies, its therapeutic potential, the safety, antigen escape and the duration of remission can be further improved. We developed a TCR complex-based CAR called Synthetic TCR and Antigen Receptor (STAR). STAR consists of two protein modules, each containing an antibody light or heavy chain variable region and the T-Cell Receptor (TCR) a or b chain constant region fused to the OX-40 co-stimulatory domain.
Aims: We report pre-clinical and phase I clinical data on an anti-CD19/CD20 (dual) STAR-T cell therapy (www.clinicaltrials.gov, NCT04260945) in patients with R/R B-ALL.
Methods: We constructed a novel, double-chain chimeric receptor STAR (Fig.1A). Peripheral blood (PB) mononuclear cells were obtained from healthy donors and patients for the pre-clinical and clinical studies, respectively. T-cells were transduced with the dual STAR lentiviral vector and a leukemia xenograft mouse model was used to assess the anti-tumor activity of the dual STAR-T. Ten R/R patients with either CD19+ or CD19/CD20+ B-ALL were enrolled (median age of 23 years [11-55]). Patients received a conditioning regimen of intravenous fludarabine and cyclophosphamide followed by STAR-T infusion. Patients that achieved complete remission (CR) had the option to proceed to allogeneic hematopoietic stem cell transplantation (allo-HSCT) or not.
Results: In preclinical studies, the dual STAR-T had comparable killing ability to both CD19/CD20-BBz (4-1BB) and CD19/CD20-28z (CD28) CAR-T (Fig. 1B) in Raji cell, and comparatively higher IFN-γ production in Raji^{CD20KO} cell(Fig.1C). In a leukemia xenograft mouse model, dual STAR-T resulted in more potent anti-leukemia activity when compared with CD19/CD20 CAR-T in 28z group (Fig.1D and 1E) or to the CD19 CAR-T group (19-BBz Fig. 1F).

The median observation time in the phase I trial was 194 days (14-276). The median pre-treatment bone marrow blast level was 7.0% (0.5%>53%). Except for 1 manufacturing failure, 9/10 patients received a single infusion of dual STAR-T at a median dose of 1×10^6/kg (6 of 1×10^6/kg and 3 of 2×10^6/kg). The median transduction efficacy was 47.7% (32.6%>58.8%). Two weeks post dual STAR-T therapy, 8/9 (88.9%) patients achieved minimal residual disease (MRD)-negative CR. One patient who failed to response had central nervous system leukemia. After CR was achieved, 6/8 patients pursued allo-HSCT. Post allo-HSCT, 1 had MRD-positive relapse at 3 months and 1 died of infection on day 73. The remaining 4 were still in CR after a median observation time of 258 days (179-276) post-transplant. Of the 2 patients who did not undergo allo-HSCT, one patient became MRD-positive on day 30 and another one relapsed 218 days post-STAR-T therapy. Cytokine release syndrome occurred in 7/9 (77.8%) patients, all of which were grade I. Three patients developed neurotoxicity (2 with grade I and 1 with grade III). We saw a high *in vivo* proliferation and persistence regardless of the infused STAR-T dose. The median peak level was reached on day 10 (7-14 days) with 6.35×10^5 copies number/ug PB genomic DNA.

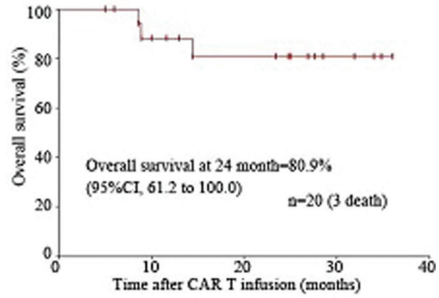
Summary/Conclusion: This study demonstrates the superiority of dual STAR-T in its anti-tumor potency compared to conventional CAR-T in an animal model. The CD19/CD20 STAR-T demonstrated technical feasibility and the ability to achieve a high CR with low toxicity in a phase I study of R/R B-ALL. Longer-term observation of these patients and larger patient studies are warranted. Given that is a TCR complex-based CAR, we see a potential for future development for solid tumor.

S119 LONG-TERM FOLLOW-UP OF SEQUENTIAL CD19-22 CAR T-CELL THERAY IN 20 CHILDREN WITH REFRACTORY OR RELAPSED B-ALL

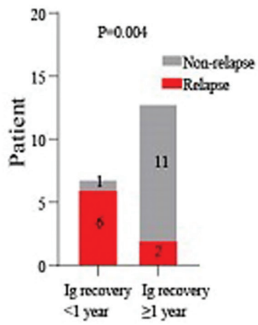
J. Pan [1], K. Tang [2,*], B. Deng [3], Z. Ling [1], W. Song [1], A. H. Chang [4]



[1]Department of Hematology, Beijing Boren Hospital, [2]State Key Laboratory of Experimental Hematology, Beijing Boren Hospital, [3]Cytology Laboratory, Beijing Boren Hospital, Beijing, [4]Clinical Translational Research Center, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China



Background: Despite high response rates induced by CD19 chimeric antigen receptor (CAR) T-cell therapy in refractory or relapsed B-cell acute lymphoblastic leukemia (r/r B-ALL), a majority of patients relapsed due to either target antigen loss or insufficient CAR T-cell persistence in long-term follow up. Here, we report updated results from a phase 1 trial, demonstrating long-term outcome of pediatric patients with r/r B-ALL after sequential CD19-22 CAR T-cell therapy.

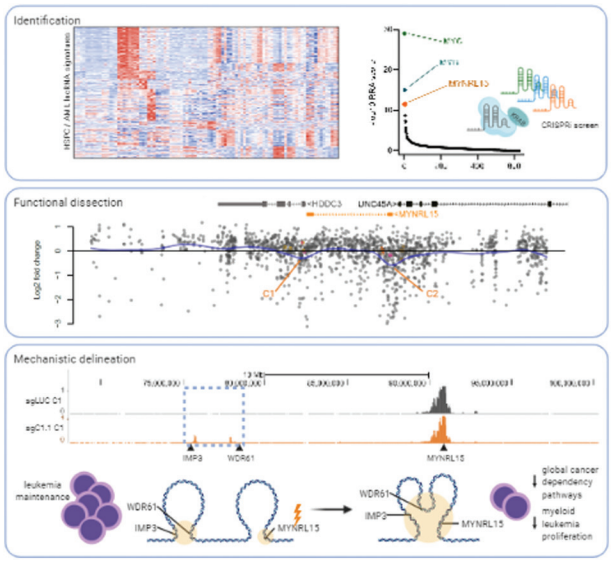


Aims: To evaluate long-term outcome of sequential CD19-22 CAR T-cell therapy in 20 r/r B-ALL children without post-CAR stem cell transplantation.

Methods: Between August, 2017 and February, 2021, consecutive 20 pediatric patients (pts) with r/r B-ALL received sequential CD19-22 CAR T-cell therapy in Beijing Boren Hospital. There were 13 males and 7 females, with a median age of 6 (range, 1 to 15) years. Fourteen pts relapsed and 6 pts had refractory minimal residual disease by flow cytometry (FCM-MRD$^+$) after previous chemotherapies. The previous median treatment time were 19 (range, 3 to 95) months in relapsed pts and 19.5 (range, 4 to 47) in FCM-MRD$^+$ pts. Severn pts had extramedullary diseases (EMDs), including 4 with exclusive EMDs. The median marrow blasts were 19.94% (range, 0.16%>93.18%) by FCM. Chromosome aberration and gene mutations were commonly observed including *TP53* mutation. All pts expressed CD19 and CD22 on blasts. CD19 or CD22 CAR lentiviral vector comprised ScFvs fragments derived from a murine anti-CD19 antibody or a humanized anti-CD22 antibody, and 4-1BB co-stimulatory and CD3z signaling domains. CAR T cells manufacture from PBMCs commenced since leukapheresis and was completed within 7-8 days, and protocols of 19 and 22 CAR T cell manufacturing were the same. CD19 and CD22 CAR T cells were infused with a median interval of 1.7 (range, 1.1 to 5.2) months. The median dose of infused 19 CAR T cells (cycle 1) was 10 (range, 3.3 to 42.8) × 10^5/kg and CD22 CAR T cells (cycle 2) was 10 (range, 0.25 to 47.4) × 10^5/kg (P=0.813). The 19 and 22 CAR T cell expansion and cytokine release syndrome (CRS) were monitored after infusion. The BM status and EMDs firstly evaluated on day 30 after CD19 CAR T cell infusion (cycle 1). Long term follow-up was carried out since infusion of 22-CART cells (cycle 2), at a median follow up time of 27.3 (range, 9.8 to 36) months.

Results: Median peak expansion of CD19 and CD22 CART cells were 9.84% (range, 0.19% to 68.7%) and 23.9% (range, 0.30 to 85.20%) among CD3$^+$ T cells respectively. All 20 pts achieved CR/CRi, FCM-MRD$^-$ and resolution of EMDs after cycle 1. CRS occurred in 18/20 (90.0%) pts in cycle 1 and 16/20 (80.0%) in cycle 2. Grade 1 neurotoxicity occurred in 3/20 (15%) pts in cycle 1 and 3/20 (15%) in cycle 2. Only 1 pt had grade 3 neurotoxicity in cycle 1 but he fully recovered after interventions. At a median follow-up time of 27.3 (range, 9.8 to 36) months, 8 pts relapsed and 3 of them died. Two (25%) of the 8 relapsed pts had CD19 antigen loss. The 8 relapsed patients included 6 out of 7 patients (85.7%) who had early Ig recovery (within 1 year), and 2 out of the 13 (15.3%) pts who had late Ig recovery (beyond 1 year) (P=0.004), suggesting that long-term disease free survival were associated with longer duration of CAR T cell persistence. 2-year LFS and OS was 60% (95%CI, 38.5-81.5%) and 80.9% (95%CI, 61.2-100.0%) respectively.

Summary/Conclusion: Sequential CD19-22 CAR T cell therapy can achieve promising long-term outcome with a 2-year LFS of 60% in pediatric patient with r/r B-ALL without post-CAR transplantation. Early Ig recovery has high risk of relapse.



AML epigenetic and transcriptional control

S120 NONCODING REGULATORY LOCUS MYNRL15 MODULATES CHROMATIN ARCHITECTURE AND REPRESENTS A NOVEL MYELOID LEUKEMIA DEPENDENCY

M. Ng [1,*], L. Verboon [1], R. Bhayadia [1], H. Issa [1], L. Gack [1], E. Regenyi [2], A. Kovacsovics [2], V. Amstislavskiy [2], A. Schwarzer [3], M. -L. Yaspo [2], D. Heckl [1], J. -H. Klusmann [1]

[1]Pediatric Hematology & Oncology, Martin Luther University Halle-Wittenberg, Halle (Saale), [2]Department of Vertebrate Genomics, Max Planck Institute for Molecular Genetics, Berlin, [3]Institute of Experimental Hematology, Hannover Medical School, Hannover, Germany

Background: The noncoding genome presents a largely untapped source of new biological insights, including tens of thousands of long noncoding RNA (lncRNA) loci. While emerging evidence implicate lncRNAs as important regulators of normal and malignant hematopoiesis, the vast majority lack functional characterization.
Aims: We aimed to identify and characterize lncRNAs that contribute to acute myeloid leukemia (AML) pathophysiology.
Methods: We screened lncRNA signatures from hematopoietic stem and progenitor cells (HSPC) and pediatric AML patient samples in six myeloid leukemia cell lines using CRISPR interference (CRISPRi). Leveraging low- and high-throughput CRISPR/Cas9-based strategies, we carried out in-depth functional dissection of the top candidate *in vitro* and *in vivo*, and defined its molecular mechanism through transcriptome and chromatin interaction profiling.
Results: To identify novel AML vulnerabilities, we performed a targeted CRISPRi screen of HSPC/AML lncRNAs (619 genes, 2009 sgRNAs) and marked *MYNRL15* – *m*yeloid leukemia *n*oncoding *r*egulatory *l*ocus on chromosome *15* – as a dependency in myeloid leukemia cells of diverse genetic backgrounds. Interestingly, *cis* and *trans* perturbation approaches revealed both the *MYNRL15* transcript and its flanking protein-coding genes to be dispensable. High density CRISPR tiling of a 15kb area surrounding *MYNRL15* (1671 sgRNAs) instead uncovered two candidate *cis*-regulatory DNA elements in the locus, which drive the *MYNRL15* perturbation phenotype. To determine the molecular basis of *MYNRL15* dependence, we performed RNA sequencing, and established *MYNRL15*'s involvement in maintaining key cancer dependency pathways (e.g. cell cycle, ribosome, spliceosome). Further, *MYNRL15* perturbation associated with coordinated dysregulation of several chromosome 15 neighbourhoods, and formation of a long-range chromatin interaction between the locus and the base of a distal loop, as detected via next-generation Capture-C. Integrative analysis of this chromatin conformation and transcriptome data, combined with a small CRISPR/Cas9 knockout screen of genes from the gained interaction region (31 genes, 178 sgRNAs), pinpointed two potent cancer dependency genes that are located in the region and down-regulated following *MYNRL15* perturbation: namely, *WDR61* and *IMP3*. Individual knockout of both genes robustly depleted myeloid leukemia cells, recapitulating the *MYNRL15* perturbation phenotype and positioning *WDR61* and *IMP3* as its regulatory targets. Importantly, in primary cells, *MYNRL15* perturbation eradicated AML blasts while sparing 50-60% of CD34$^+$ HSPCs *in vitro*, and reduced patient-derived AML xenografts up to 10-fold *in vivo*, indicating a potential therapeutic window. Remarkably, an exploration of external AML patient cohorts revealed hundreds of noncoding loci with similar features as *MYNRL15*, nearly half of which associated with cytogenetics and/or survival. Such loci may embody new class of noncoding regulatory regions with profound implications for AML and cancer pathophysiology, as exemplified by *MYNRL15*.

Summary/Conclusion: This work highlights the wealth of biologically and clinically relevant information that can be gained from studying noncoding regions, and the power of CRISPR/Cas9 systems for interrogating complex genomic loci. Leveraging these concepts, we describe the novel noncoding regulatory locus *MYNRL15*, and, through its detailed functional and molecular dissection, provide evidence for pan-myeloid leukemia vulnerabilities found at noncoding loci involved in chromatin architecture.

S121 HUMAN ENDOGENOUS RETROVIRUSES CHARACTERIZE THE DIFFERENT SUBPOPULATIONS OF NORMAL AND LEUKEMIC CELLS AND REPRESENT A SOURCE OF EPITOPES FOR CANCER IMMUNOTHERAPY IN ACUTE MYELOID LEUKEMIA

V. Alcazer [1,2,*], B. Paola [1], L. Tonon [3], E. Michel [4], V. Mutez [4], N. Chuvin [4], Y. Estornes [4], A. Viari [3], K. Metzeler [5,6], W. Hiddemann [6], A. Batcha [7], T. Herold [6], C. Caux [1], S. Depil [1,4,8]

Background: Human endogenous retroviruses (HERVs) represent 8% of the human genome. To date, HERVs expression and their immune impact have never been extensively studied in Acute Myeloid Leukemia (AML).
Aims: The aims of the study were to provide a thorough quantification of HERVs expression in AML, to assess their ability to classify normal and leukemic cells (including leukemia stem cells (LSC)) and to identify relevant CD8$^+$ T cell epitopes among AML-specific HERVs.
Methods: Using a custom pipeline based on Telescope (Bendall et al., 2019), we quantified the expression of 14,968 HERVs loci in several RNA-seq and ATAC-seq datasets from sorted normal and leukemic bone marrow cells (n=81 RNA and n=122 ATAC samples) and bulk bone marrow samples from AML patient at diagnosis (n=788 samples from 4 independent international cohorts). HERVs were also quantified in 42 different normal tissues from the Genotype-Tissue Expression database for AML-specific HERVs definition (>1000 samples). For epitope validation, bone marrow infiltrating lymphocytes (MILs) were cultured during 14 days in RPMI with 8% human serum and high-doses IL2 (6000 UI/mL). Specific CD8$^+$ T cells against the selected peptides were stained using dextramer at day 14.
Results: Unsupervised hierarchical clustering based on the top 20% most variable HERVs showed a robust classification of normal hematopoietic cell types with a cluster purity of 77.6% (versus 65.3% with

a gene-based approach). Clustering of samples based on active HERVs regions (defined by peaks surrounding HERVs regions +/- 1000bp in ATAC-seq data) further improved the clustering, reaching 88.3% cluster purity (Figure 1A). Adding AML samples with the same classification approach showed a clustering of AML cells with their cell-of-origin. Differential peak-count analysis showed a distinct open-chromatin profile at HERVs regions between leukemic cells and normal bone marrow cells.

We then explored HERVs expression in the 4 independent AML RNA-seq datasets. Unsupervised hierarchical clustering based on the most variable HERVs defined 9 clusters (Figure 1B) that presented distinct cancer hallmark profiles (assessed by single sample gene-set variation analysis) and that were associated with significant overall survival differences (Figure 1C), regardless of established prognosis factors such as age, ELN2017 and white blood count in a multivariate Cox model.

To further demonstrate the value of HERVs as pertinent biomarkers, we established a LSC signature based on HERVs correlated with the previously published LSC17 score in the 4 independent bulk datasets. The resulting 47-HERVs LSC signature allowed separation of LSCs versus all the other cell populations in the independent sorted-cells validation set (Figure 1D).

Finally, 262 HLA-A*02 CD8$^+$ T cell epitopes were predicted among AML-specific HERVs identified by differential HERVs expression between AML and normal tissues. Among the top scoring peptide according to their tumor abundance, eight peptides (P1, P2, P4, P6, P15, P16, P18 and P20) were selected for biological validation. MILs from AML patients at diagnosis were then screened for specific CD8$^+$ T cells using dextramer, showing spontaneous responses against P1 in all patients and against P4, P6, P15 or P16 in some patients (n=10 patients).

Summary/Conclusion: HERV retrotranscriptome characterizes normal and leukemic cell subpopulations, including LSCs, and defines new AML subtypes of different prognosis. Moreover, HERVs represent an important reservoir of non-conventional T cell epitopes relevant for cancer immunotherapy.

S122 ISOFORM-SPECIFIC AND SIGNALING-DEPENDENT PROPAGATION OF ACUTE MYELOID LEUKEMIA BY WILMS TUMOR 1

C. Bonifer [1,*], S. Potluri [2], S. A. Assi [1], P. S. Chin [1], D. J. Coleman [3], O. Heidenreich [4], P. N. Cockerill [1]

[1]Institute of Cancer and Genomic Sciences, [2]University of Birmingham, Institute of Cancer and Genomic Science, University of Birmingham, [3]nstitute of Cancer and Genomic Sciences, Iniversity of Birmingham, Birmingham, United Kingdom, [4]Prinses Máxima Centrum for Pediatric Oncology, Prinses Máxima Centrum for Pediatric Oncology, Utrecht, Netherlands

Background: Acute myeloid leukemia (AML) is caused by recurrent mutations in members of the gene regulatory machinery controlling hematopoietic progenitor cell growth and differentiation. We have demonstrated each AML-subtype displays a specific gene regulatory network (GRN) with transcription factors (TFs) forming differently connected network nodes and regulating sub-type specifically expressed target genes. Our analyses showed that each AML sub-type establishes its own cellular identity distinct from that of normal cells. We showed that some TFs forming prominent network nodes within an AML-subtype specific GRN are required for the maintenance of their own sub-type but not others (Assi et al., 2019, Nature Genetics). Moreover, they are not essential for the growth of normal cells, highlighting an increased dependency of cancer GRNs on specific pathways which could be exploited for therapeutic purposes. Importantly, our analysis found TF families forming network nodes in more than one AML sub-type. One such network node is formed by the Zn^{++}-finger transcription factor and tumour suppressor Wilms Tumor 1 (WT1).

Aims: WT1 is mutated in about 10% and overexpressed in 90% AML patients conferring a poor prognosis. However, little is known about how WT1 drives a more aggressive AML and why it is upregulated. It is unclear how WT1 mutant proteins alter cellular phenotypes, whether WT1 is an essential factor for leukemic maintenance, how it cooperates with other oncogenes and which target genes are bound by it, and whether the binding pattern and the impact on gene expression differs between isoforms. Here we addressed these questions at the global level by studying the role of WT1 in two major AML sub-types, t(8;21) and FLT3-ITD.

Methods: To answer these questions, we used the culture of cell lines and primary cells from patients to perturb the expression of WT1 by knockdown, the activation of the endogenous gene by CRSPR activation and by the expression of different WT1 isoforms, followed by the analysis of leukaemic growth together with genome-wide analyses of gene expression, chromatin accessibility and chromatin immunoprecipitation assays

Results: Our most important results are (i) that WT1 is essential for leukaemogenesis in a xenograft model of AML, (ii) that it is an important component of AML maintenance of multiple subtypes of AML but not in normal cells, (iii) that it acts in an isoform-specific fashion, (iv) that specific mutants and isoforms drive increased growth, iv) that overexpression of the endogenous gene causes aberrant growth thus linking its expression to increased fitness, (vi) that increased expression is linked to oncogenic signaling and, most importantly, (vi) that its binding within chromatin changes the expression of many different genes, but in an AML sub-type-specific fashion. We also show that WT1 regulates differential splicing in an isoform-specific fashion, indicating that this protein regulates AML maintenance at multiple levels.

Summary/Conclusion: Our work shows that the transcription factor WT1 forms a major node in the rewired mutation-specific gene regulatory networks of multiple AML sub-types. For two main AML subtypes we demonstrate that different WT1 isoforms exhibit different gene-specific patterns of binding, and support contrasting biological activities, including enhanced proliferation and directing differential splicing. We also show that *WT1* responds to oncogenic signaling and is part of a sub-type specific signaling-responsive transcription factor hub that controls AML growth. WT1 therefore plays a central and wide-spread role in AML biology.

S123 MYC SUPER-ENHANCER HIJACKING BY EVI1 IN LEUKEMIA IS CTCF DEPENDENT

[1]Hematology, Erasmus MC, [2]Oncode Institute, [3]Clinical Genetics, Erasmus MC, Rotterdam, Netherlands, [4]German Cancer Research Center, [5]Internal Medicine V, Heidelberg University Hospital, Heidelberg, [6]Munich Leukemia Laboratory, Munich, Germany

Background: Chromosomal rearrangements are a frequent cause of oncogene deregulation in human malignancies. In acute myeloid leukemia (AML) with inv(3)/t(3;3) rearrangements a *GATA2* enhancer at 3q21 is hijacked by *EVI1* at 3q26, causing *EVI1* overexpression and *GATA2* haploinsufficiency (Groschel et al, Cell 2014). Besides inv(3)/t(3;3), many other AML cases with 3q26 rearrangements and *EVI1* overexpression have been reported, including t(2;3), t(3;7), t(3;6) and t(3;8). It has been suggested that *EVI1* overexpression in all 3q26-rearranged AML is induced by the repositioning of an enhancer to the *EVI1* promoter (Ottema et al., Blood 2020), but a common mechanism remains to be elucidated.

Aims: In this study we aimed to investigate how enhancer-promoter interactions drive oncogenic *EVI1* expression in 3q26-rearranged leukemias. AML with t(3;8)(q26;q24), hereafter referred to as t(3;8) AML,

was used as a model of such leukemias. In this AML subgroup, a region containing a *MYC* super-enhancer (*MYC* SE) is translocated to the vicinity of *EVI1*.
Methods: We generated a patient-based t(3;8) AML cell line to study the transcriptional activation of *EVI1* by the *MYC* SE. First, we introduced e*GFP* in frame with a T2A self-cleavage site downstream of *EVI1* in K562 cells. Next, we generated a t(3;8) *in vitro* using CRISPR-Cas9 targeted at breakpoints detected in a t(3;8) AML patient. To investigate which *MYC* SE modules drive oncogenic *EVI1* transcription in t(3;8) AML, we designed sgRNAs to sequentially delete these individual enhancer modules. The effects of these deletions were measured by flow cytometry, followed by 4C-seq and ChIP-seq.
Results: We showed that *MYC* SE is translocated to *EVI1* in t(3;8) AML patients, resulting in promoter activation and *EVI1* overexpression. Further supporting this notion, introduction of t(3;8) in K562 *EVI1-eGFP* also led to *EVI1* overexpression. 4C-seq revealed specific interaction between the *EVI1* promoter and *MYC* SE in t(3;8) cells, which was not found in the parental K562 line. This was accompanied by increased activity of the *EVI1* promoter, as shown by H3K27ac and H3K9ac ChIP-seq.
The *MYC* SE is a cluster of individual enhancer modules that may recruit different sets of transcription factors. Upon sequential deletion of these modules by CRISPR-Cas9, only the deletion of one specific module caused loss of *EVI1* expression and partial loss of enhancer-promoter looping. ChIP-seq revealed binding of early hematopoietic regulators to this module in CD34+ hematopoietic stem and progenitor cells (HSPCs). This module also contained a CTCF binding site in convergent orientation with a CTCF binding site at the *EVI1* promoter. Targeting either of these CTCF binding sites resulted in loss of enhancer-promoter interaction and strong downregulation of *EVI1* expression.
In t(3;8) and other 3q26-rearranged AMLs, the translocations preserved the CTCF binding site upstream of *EVI1* and relocated an enhancer normally active in HSPCs. These commonalities suggest a shared mechanism for *EVI1* activation in all 3q26-rearranged leukemias, whereby an active hematopoietic enhancer is hijacked by a CTCF-mediated loop with the *EVI1* promoter.
Summary/Conclusion: Here we demonstrate that the *MYC* SE hyperactivates *EVI1* expression in t(3;8) AML. One specific *MYC* SE module binding early hematopoietic transcriptional regulators is critical for *EVI1* expression and promoter-enhancer looping. We propose a common mechanism by which *EVI1* uses a CTCF-bound enhancer-docking site to hijack enhancers active in early hematopoiesis.

S124 TET3 PROMOTES GROWTH AND EPIGENETICALLY REGULATES GLUCOSE METABOLISM AND LEUKEMIC STEM CELL ASSOCIATED PATHWAYS IN ACUTE MYELOID LEUKEMIA

A. J. Pulikkottil [1], S. Bamezai [1,*], F. Mohr [1], K. Feder [1], N. Vegi [1], U. Kohlhofer [2], L. Quintanilla-Martinez [2], K. Döhner [3], H. Döhner [3], A. Sinha [4], M. Feuring-Buske [3], C. Buske [1], V. P.S. Rawat [3]

[1]Insitute for Experimental Cancer Research, University Hospital Ulm, Ulm, [2]Institute of Pathology, University Hospital of Tübingen, Tübingen, [3]Department of Internal Medicine III, University Hospital Ulm, Ulm, Germany, [4]Basepair, New York, United States

Background: Metabolic studies in acute myeloid leukemia (AML) demonstrate that altered glucose metabolism signatures and overexpression of several glycolytic enzymes is a hallmark of the disease and critical for its progression. However, the reasons for aberrant expression of glucose metabolic genes is poorly understood. The TET family (TET1-3) of dioxygenase enzymes regulate active gene expression via establishment of 5-hydroxymethylcytosine (5hmC) epigenetic marks and are deeply embedded in the pathobiology of AML. Recent studies demonstrate that *TET3* is required for normal human erythropoiesis. But the functional role of TET3 in human AML remains uninvestigated.
Aims: To investigate the functional role of TET3 in AML biology, its associated 5hmC marks and gene regulation in AML
Methods: Expression in patients and healthy cells were analyzed by qRT-PCR, TET3 expression was depleted by using shRNA or sgRNA, and impact on AML growth was tested by performing in vitro and in vivo assays. Impact on global gene expression and 5hmC marks was analyzed by next generation sequencing.
Results: We report that the epigenetic factor *TET3* is overexpressed in the majority of human AML patients and functionally validated human leukemic stem cells (LSCs) compared to their normal counterparts. In line with its high expression, the TET3 promoter is enriched for euchromatic histone marks such as H3K4me3 and lacks the repressive mark H3K27me3 in AML cell lines and murine MLL-AF9 (MA9) c-kit+ LSCs. TET3 knockdown (KD) or knockout (KO) in AML cell lines and MA9 c-kit+ LSCs suppressed their clonogenic potential *in vitro* and resulted in severely reduced leukemic engraftment in vivo. The overexpression of wild type TET3 or the form lacking DNA binding, TET3$^{\Delta CXXC}$, augmented growth of AML cells and skewed normal myeloid-erythroid differentiation program of healthy human CD34^{+} cord blood derived hematopoietic stem progenitors (HSPCs) in vitro. *TET3* KD in NB-4 cells caused differential regulation of 1,409 genes. GSEA revealed the downregulation of the LSC signature, STAT5 signaling and glucose metabolism pathways. Factors central to glucose metabolism and glucose transport were downregulated, such as enzymes *HK1-2*, *ENO2*, which also positively correlated with *TET3* expression in AML patients. Conversely, overexpression of TET3 in healthy HSPCs upregulated the expression of glycolysis, STAT5A and AML associated genes. CellRadar analysis showed that TET3 maintained the expression of early myeloid progenitor associated gene signature in AML cells and suppressed the expression of mature myeloid lineage associated gene signature in AML and healthy HSPCs. TET3 depletion in NB-4 cells resulted in a global reduction of 5hmC marks in Hydroxymethylated DNA immunoprecipitation-sequencing (hMe-DIP-Seq) analysis. Several critical glucose metabolism genes exhibited loss of 5hmC marks. Our own and published ChIP-seq data sets demonstrated that glucose metabolism genes are enriched for 5hmC marks and TET3 binding sites in AML cells. Finally, TET3 depleted or overexpressing AML cells showed reduced or increased ability to metabolize glucose to glucose-6-phosphate. TET3 depletion rendered AML cells highly sensitive to the glycolysis inhibitor 2-Deoxy-D-glucose (2-DG) or an STAT5 inhibitor (STAT5i). Combination therapy of 2-DG and STAT5i antagonized murine AML MLL-AF9 LSC and human AML cell growth.
Summary/Conclusion: In this study, we uncover the growth-promoting role of TET3 in AML and describe a close link between TET3 induced 5hmC epigenetic marks, glycolysis and the STAT5 pathway.

AML mechanisms of resistance

S125 RELEASE OF INTERFERON-GAMMA BY AML CELLS REMODELS BONE MARROW IMMUNE MICROENVIRONMENT BY INDUCING REGULATORY T CELLS

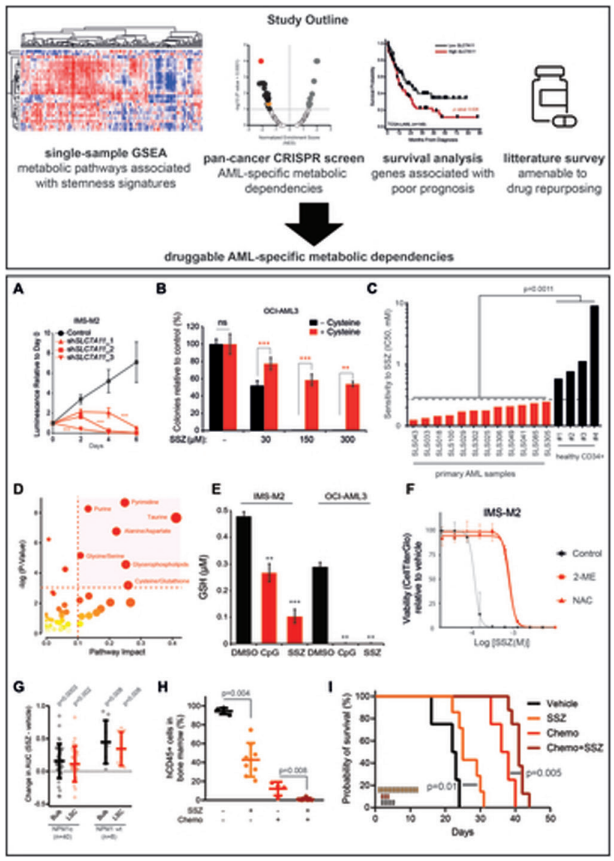
Background: For a long time, acute myeloid leukemia (AML) onset and progression were considered exclusively due to critical mutations in hematopoietic stem cells. Recently, it comes out that additional cellular components of the stroma and immune bone marrow (BM) microenvironment play a supportive role. AML cells can provide their signals able to create their permissive niche through the microenvironment modulation. Among those signals, interferon (IFN)-γ has a prominent role in conferring immuno-suppressive capacity to mesenchymal stromal cells (MSCs), primary elements of the BM niche harnessing the AML immune-tolerant microenvironment. In this AML-protecting scenario, T regulatory cells (Tregs) play a pivotal role. Although it is known that the AML microenvironment favors Treg expansion, the mechanisms underlying their induction in the AML BM microenvironment are poorly elucidated.
Aims: We aimed at investigating the role of AML-produced IFN-γ in initiating microenvironmental modifications in favor of AML expansion.
Methods: We isolated AML cells and generated MSCs from AML patient BM. Gene expression profile (GEP) (AML, N=61; healthy donors, HDs



N=7) and NanoString analysis (AML, N=24) on BM-derived cells were also done. Next, we set up MSC/AML cell co-culture experiments and we investigated gene expression in MSCs and AML cells before and after co-cultures. We also set up a murine model in which the IFN-γ-expressing C1498 AML cells were knockdown for the *ifng* gene by RNA interference and inoculated intra-bone in mice. BM infiltrate was analyzed in mice and AML patients.
Results: We found that AML patients variably express and release IFN-γ allowing us to stratify them according to *IFNG* expression and cytokine production. Genome-wide and immune-targeted GEP revealed that AML patients with high *IFNG* level hold an inflammatory/immune-modulating gene signature distinct from AML patients with lower *IFNG* level, including the up-regulation of IFN-γ-stimulated genes (e.g. indoleamine 2,3-dioxygenase (IDO)1 and Nitric Oxide synthase (NOS)-2), which are known to regulate immune-tolerance. *In vitro*, AML cells with higher IFN-γ cytokine production subverted the transcriptome of MSCs by inducing IFN-γ-dependent genes related to Treg recruitment and differentiation, including IDO-1. Functionally, IFN-γ release by AML cells drove MSCs to induce Tregs in an IDO1-dependent manner. *In vivo*, mice injected with IFN-γ expressing cells showed a higher percentage of engraftment associated with an increased frequency of BM Tregs. Conversely, mice injected with IFN-γ not expressing cells presented a reduced Treg infiltration with the concomitant decrease of IDO1 expression in MSCs and ultimately with an inhibited leukemia engraftment. In patients, high *IFNG* expression correlated with an increased frequency of suppressive Tregs in the BM and predicted poor overall survival.
Summary/Conclusion: In summary, this study shows that IFN-γ release by AML cells remodels BM transcriptome and immune landscape toward Treg induction contributing to create an immune-tolerant microenvironment. In such process, tolerogenic MSCs behave as professional Treg-inducers. In perspective, our data may help in selecting patients who may benefit from an immunotherapy approach and in designing novel strategies where the activation of effector cells is combined with Treg inhibition.

S126 INHIBITION OF CYSTINE IMPORT BY REPURPOSING OF SULFASALAZINE TO TREAT ACUTE MYELOID LEUKEMIA

B. Pardieu [1], J. Pasanisi [1], F. Ling [1], R. Dal Bello [1], J. Penneroux [1], A. Su [1], R. Joudinaud [1], L. Chat [1], M. Duchmann [1], G. Sodaro [1], C. Chauvel [1], F. Castelli [2], L. [1]U944, INSERM, Paris, [2]Institut des Sciences du Vivant Frédéric Joliot, CEA, Saclay, France, [3]Pediatric Oncology, Dana Farber Cancer Institute, Boston, United States, [4]Saint-Louis Research Institute, Université de Paris, [5]Hopital Saint-Louis, Assistance Publique - Hôpitaux de Paris, Paris, France

Background: Expression of leukemic stemness programs is associated with resistance to anthracycline-cytarabine chemotherapy in Acute Myeloid Leukemias (AML). The metabolic rewiring of leukemic cells may generate targetable vulnerabilities.
Aims: We aimed to identify metabolic pathways associated with leukemic stemness programs targetable by drug repurposing.
Methods: We queried 2 AML patients datasets (TCGA LAML n=179, GSE14468 n=526) by single-sample GSEA and cross-compared hits with a pan-cancer CRISPR screen (AVANA n=517 cell lines) to identify metabolic pathways associated with stemness signatures representing AML-specific vulnerabilities. We next nominated within these pathways druggable genes with poor prognostic value (**Figure top cartoon**). We then validated these candidate therapeutic targets by genetic (shRNA) and chemical inhibition in AML cell lines, primary AML samples and PDX models and sought synergistic combinations with standard-of-care AML therapies.
Results: Analysis of public trancriptomic and CRISPR screen datasets identified the cysteine/methionine pathway as an AML-specific dependency associated with expression of stemness signatures. Among genes with poor prognostic value in patients datasets, SLC7A11, encoding the cystine importer xCT, was the only one validated as an AML dependency by shRNA-mediated inhibition (**Figure A**) and 3 different chemical inhibitors, including the broadly available medicine sulfasalazine (SSZ) in multiple AML cell lines. SSZ inhibited colony formation of AML cell lines in a cysteine-dependent manner (**Figure B**).
In vitro, SSZ impaired the viability of primary AML cells with a >10-fold increased sensitivity compared to healthy CD34+ cells (**Figure C**), and reduced the long-term culture initiating potential of primary AML samples (n=6, p=0.03).
xCT inhibition by SSZ or the chemically unrelated inhibitor CpG resulted in broad metabolic rewiring (**Figure D**) including depletion of intracellular gutathione pools (**Figure E**), leading to a ROS-dependent cell death (**Figure F**, NAC N-Acetyl Cysteine, 2-ME 2-mercaptoethanol) that was only partly reverted by the ferroptosis inhibitor ferrostatin-1.
Anthracyclines were identified among a panel of 8 AML drug classes as the one with top synergism with SSZ in AML cell lines. In a cohort of 48 primary AML samples, addition of low doses SSZ mimicking trough plasma concentrations in humans (4 µM) significantly increased the anti-leukemic activity of a combination of the anthracycline daunorubicin (DNR) with araC in a niche-like ex vivo drug screening assay, regardless of NPM1 status (**Figure G**).
In a PDX model harboring multiple AML mutations (NPM1, DNMT3A, FLT3-ITD and IDH1), SSZ decreased the leukemic burden and significantly prolonged survival as a single-agent, but also improved the anti-leukemic activity of a doxorubicin-cytarabine regimen at maximally tolerated concentrations (**Figure H-I**).
Finally, compassionate treatment with SSZ in a refractory AML patient with high white blood cell counts resulted in transient peripheral blood blast clearance.

Summary/Conclusion: Our results nominate the cystine importer xCT as a therapeutic target in AML and warrant clinical evaluation of SSZ in combination with 7+3 in AML.

S127 FUNCTIONAL IN VIVO CHARACTERISTICS OF PDX AML SINGLE CELL CLONES PREDICT OUTCOME IN LARGE AML PATIENT COHORTS

Medicine III, University Hospital, Ludwig-Maximilians University (LMU), [6]Department of Oncology, Dr von Haunersches Kinderspital, Ludwig-Maximilians University (LMU), Munich, Germany

Background: Acute myeloid leukemia (AML) is characterized by major clonal diversity and the most adverse clone determines patient´s outcome. Single cell sequencing describes inter- and intra-patient diversity and discriminates aggressive subpopulations, while functional insights lag behind.
Aims: We aimed at functionally characterizing AML subclones *in vivo*, in order to identify the most adverse subclone and correlate its features to clinical patient data.
Methods: Primary tumor cells from an AML patient's first and second relapse were transplanted into NSG mice to generate patient derived xenograft (PDX) models. In an innovative approach, limiting dilution transplantation was combined with genetic barcoding to generate PDX single stem cell clones. Clones were subjected to functional assays, using molecular marking and competitive *in vivo* trials. Clones were molecularly characterized on the level of exome, transcriptome and proteome.
Results: Twelve PDX single stem cell clones were generated, eight from relapse one and four from relapse two. Each clone was derived from a single AML stem cell, as proven by presence of a single barcode. AML related mutations and data from exome sequencing revealed a clear evolutionary tree, consisting of four different clusters, two from each relapse. Two clusters showed increased capacity to generate single stem cell clones, indicating increased stemness potential. A different third cluster showed major signs of *in vivo* aggressiveness, with increased growth rates combined with increased *in vivo* resistance towards Cytarabine treatment. These data suggest that stemness and treatment response developed independently from each other in distinct clones in this sample. The resistant cluster revealed yet undescribed characteristics in gene expression and proteomic profile. This gene expression data was compared to genes significantly associated with treatment resistance in three independent cohorts of AML patients to construct a prediction model for Cytarabine resistance using penalized logistic regression. Of clinical relevance, the score obtained from PDX *in vivo* functional data predicted clinical outcome in an additional independent cohort of 281 AML patients.
Summary/Conclusion: We provide proof of concept that clonal variances within a single AML sample mimics the complex heterogeneity between different AML samples. Complementing omics data with *in vivo* functional data allows identifying novel characteristics of general relevance in AML.

S128 STANDARDIZING NGS-MRD IN AML: AN INTERNATIONAL STUDY BY THE ELN-MRD WORKING PARTY

Background: Measurable residual disease (MRD) assessment in acute myeloid leukemia (AML) patients is recommended to refine response assessment in patients being treated with intensive chemotherapy. However, the analysis of MRD results may vary by method and laboratory, and comparability of MRD results across different laboratories is limited. Next-generation sequencing (NGS) has been shown to be a sensitive and prognostic methodology for MRD detection. The reproducibility and repeatability of NGS-MRD across different laboratories has not been systematically studied.
Aims: To evaluate the reproducibility of NGS-MRD analysis among 12 laboratories using a) the established local NGS approach of the participating laboratory or b) a standardized central protocol.
Methods: Two sets of twenty DNA samples with defined mutation frequencies were centrally prepared and shipped to the participating centers. Tru-Q7 DNA was used to assess mutated *IDH1*, *IDH2* and *KIT*, and a patient sample or OCI-AML3 cells were used to assess mutated *TP53* and mutated *NPM1*, respectively (in total 24 variants in 18 MRD positive samples and 2 MRD negative samples). Each mutation was evaluated at 3 different variant frequencies, ranging from 0.039 to 1.55%. Each laboratory quantified MRD with their local NGS-MRD approach, if available, which included error-corrected targeted amplicon sequencing and myeloid panel sequencing using Illumina or Ion Torrent sequencers. The second DNA set was evaluated with a standardized protocol published previously (Thol et al. Blood 2018). Briefly, amplicon libraries were generated by a two-step PCR. After sequencing on an Illumina sequencer error correction was applied following an established analysis pipeline. Local protocols were analyzed with local bioinformatics algorithms. Data generated with the central protocol were analyzed centrally. Descriptive statistics were used to summarize and compare the results.
Results: Twelve laboratories from seven countries contributed MRD data using the central protocol and also, in ten cases, their local protocol. The median number of aligned reads was 21,233 reads (range 59 reads to 1.37 million reads) by local and 124,911 reads (range 11,944 reads to 998,396 reads) by central protocols. The median limit of detection (LOD) was 0.0752% variant alleles (range 0.0031% – 2.0%) by local and 0.0053% variant alleles (range 0.0006% – 0.0507%) by central protocols. The median variant allele frequency (VAF) of the target mutations was 0.169% (range 0.0% – 2.93%) by local and 0.155% (range 0.007% - 1.59%) by central protocols. The median coefficient of variation of the target VAFs was 57.3% (range 11.6% – 213.8%) by local and 12.0% (range 4.0% – 102.4%) by central protocols. The sensitivity for MRD detection was 100% in 6 laboratories and 38-96% in the other four laboratories using the local protocol, while it was 100% in all 12 laboratories when the central protocol was used. The specificity for MRD detection was 100% in 7 and 0-50% in the other laboratories using the local protocol, while it was 100% in all 12 laboratories with the central protocol.
Summary/Conclusion: This is the first international interlaboratory test for NGS-MRD in AML patients. It shows a high sensitivity and specificity for the various local protocols for the majority of participating laboratories. The central analysis shows that a standardized protocol can be quickly and successfully incorporated in the local laboratories, and that NGS-MRD is highly reproducible in a multicenter setting especially when using standardized methods.

S129 ACUTE RESISTANCE TO BET INHIBITORS REMODELS COMPENSATORY TRANSCRIPTIONAL PROGRAMMES VIA P300 CO-ACTIVATION

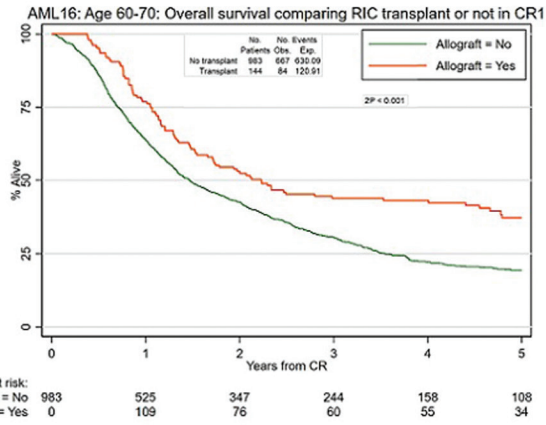
[9]Adaptive Immunity and Immuno-epigenetics Research Unit, GlaxoSmithKline Pharma, Stevenage, United Kingdom

Background: Targeting the epigenetic reader BRD4 with bromodomain and extraterminal protein inhibitors (BETi) serves as a paradigm for novel transcriptional/epigenetic therapies in Acute Myeloid Leukemia (AML). However, clinical trials with single BETis indicate non-genetic resistance, a situation that appears recapitulated with other epigenetic inhibitors. Novel treatment combinations are therefore essential for the rational utilization of BETi in AML.
Aims: To comprehensively explore early routes of epigenetic adaptation to BETi and prevent pending BETi resistance.
Methods: We studied the initial transcriptional and epigenetic response to BET inhibition. Comparing DMSO and BETi-treated KASUMI-1 cells after 24 hours of treatment, we assessed the dynamics of nuclear RNA-Seq, ATAC-Seq and binding (via ChIP-Seq) of *RUNX1-RUNX1T1*-associated transcription factors and chromatin regulators. We then comprehensively explored the functional relevance of the inferred results in a broader range of AML models. Finally, we tested our proposed adaptive resistance mechanism in a novel resistance model to BETi using RNA-Seq and proliferation assays along the longitudinal stages of resistance development.
Results: Dissecting early transcriptional and epigenetic events following BETi, we observed an "acute" compensatory feedback loop that attenuated the consequences of BRD4 release from chromatin. This adaptation loop preserved transcription and led to an aberrant increase of chromatin accessibility at and around promoters and (super)-enhancers of key AML maintenance genes such as *RUNX1, MYC, KIT* and others. Critically, this adaptation was mediated by increased binding of the global transcriptional co-activator protein p300 that normally recruits BRD4. Moreover, as demonstrated by treatment combination assays across a number of AML cell lines of varying genotypes, patient samples and primary murine AML cells, this increased p300-dependency also provided a rational therapeutic opportunity. The sequential treatment with BETi followed by inhibition of p300 HAT activity synergistically suppressed AML proliferation in almost all tested models. This suppression was generally less synergistic using BETi and p300 inhibition concomitantly, while only one cell line demonstrated synergism when p300i was applied ahead of BETi, results in accord with our hypothesis of acute p300-dependence following BETi.
To determine if this acute resistance state persisted, allowing a therapeutic opportunity at relapse, we generated a model of the evolution of acquisition of resistance to BETi in AML using OCI-AML3 cells. Remarkably, p300 addiction was highest only during the earlier stages of adaptation, but declined with full-blown resistance to BETi. Moreover, although p300 inhibition significantly suppressed the AML-maintenance MYC transcriptional programme throughout resistance evolution, this did not correlate with the anti-proliferative response to p300i which attenuated with time. However, we could determine transient transcriptional evolution of a programme of genes, including S100A8/9 and MCM genes, that were only suppressed by p300 inhibition during the earlier stages of resistance and that we speculate are involved with "emergency" AML-maintenance, a hypothesis we are currently testing.
Summary/Conclusion: Taken together, our data identify a novel "acute" resistance state to an epigenetic therapeutic, define a window of therapeutic opportunity before this resistant state becomes fixed and identify a rational up-front sequence combination, BETi followed by p300i, to potentially overcome this in AML patients.



AML classification

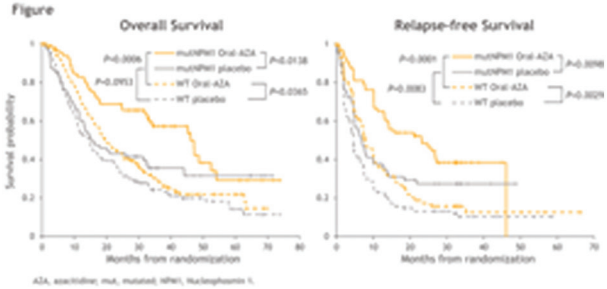
S130 SEQUENTIAL NCRI AML TRIALS SHOW CONSISTENT BENEFIT FOR RIC TRANSPLANT IN CR1 FOR OLDER PATIENTS >60YEARS THAT IS INDEPENDENT OF MRD STATUS AFTER FIRST INDUCTION

N. Russell [1,*], A. Thomas [2], R. Hills [3], R. Wilson [4], I. Thomas [4], A. Khwaja [5], M. Smith [6], D. Weber [7], A. Burnett [8], M. Dennis [9], S. Knapper [10], S. Freeman [11]

[1]Haematology, Guy's Hospital, London, [2]Centre forTrials Research, Cardiff University, Cardiff, [3]Nuffield Department of Population Health, University of Oxford, Oxford, [4]Clinical Trials Research, Cardiff University, Cardiff, [5]Cancer Institute, University College Hospital NHS Foundation Trust, [6]Haematology, Barts Health NHS Trust, London, United Kingdom, [7]Haematology, Odense University Hospital, Odense, Denmark, [8]Blackwatergate, Arran, [9]Haematology, The Christie Hospital NHS Foundation Trust, Manchester, [10]Haematology, Cardiff and Vale University Health Board, Cardiff, [11]Immunology and Immunotherapy, University of Birminhgam, Birmingham, United Kingdom

Background: Reduced Intensity Conditioning (RIC) transplantation is one option for post remission therapy in older patients with acute myeloblastic leukemia (AML).
Aims: Here we report on two consecutive front line NCRI trials for patients >60 years, the AML16 trial (2006-2012) and AML18 (2015-) performed with the aim of identifying which patients benefit from RIC transplantation in CR1.
Methods: Both trials employed a double induction with daunorubicin and clofarabine or AraC +/- Gemtuzumab in AML16 and daunorubicin and AraC (DA) + Gemtuzumab in AML18 which also employed a post course-1 intensification randomization to either FLAG-Ida or DA+Cladribine or DA alone for those patients not in MRD–ve remission after course 1. In AML16, 983 patients in CR1 were studied, with RIC transplant given to 144 (15%) with median follow-up for survival from CR of 60 months. In AML18, 648 out of 847 patients achieved CR of whom 201 (31%) were transplanted with a median follow up of survival from CR of 45 months. Comparisons of RIC transplant in 1st remission versus not were carried out using Mantel-Byar analysis.
Results: In AML16 when comparing allograft versus chemotherapy alone, survival at 5 years for patients 60-70 years was significantly improved (37% vs 19%, HR 0.65 (0.52-0.82) p<0.001) (Figure 1). While the survival for sibling allografts (44%) was better than that for MUDs (34%) this did not reach statistical significance (p=0.19). To avoid selection bias for transplant, analyses when stratified by Wheatley risk group (a prospectively validated risk score for older patients based on age, cytogenetics, WCC, PS and secondary or de novo AML) into good, standard and poor risk showed consistent benefit for RIC across all groups (HR 0.66 (0.53-0.83), p<0.001) with no evidence of interaction (p value for trend =0.75) When stratified by post course-1 flow MRD status (MRD-ve, MRD unknown, MRD+ve, and no CR/CRi post course 1 respectively) there was again consistent benefit for allograft. (HR 0.68 (0.54-0.85) p<0.001) with no heterogeneity (p= 0.20). The benefit for RIC was seen in patients with a *FLT3* ITD or *NPM1* mutation with no evidence of a differential effect by genotype (p-value for heterogeneity by subgroups 0.61). As AML16 had found no group that did not benefit, decision for transplant in the ensuing AML18 trial was based on health status and donor availability. In AML18 interim analysis confirmed the overall benefit of transplant with 3 year survival from remission of 48% versus 37.4% (p 0.027) with chemotherapy; observed benefit was independent of post course 1 MRD status consistent with the AML16 result (HR 0.71 CI. 0.54-0.95, p 0.02). As the transplant rate in AML18 was higher in MRD+ve patients (36% vs 24.8% in MRD-ve) and the survival of post course 1 MRD+ve and MRD-ve patients was not different (51.1% vs 46.6% at 3 years, p0.84) we examined the impact of a second induction course on transplant outcome in those not initially achieving a MRD-ve CR. Although the benefit for transplant appeared greater in patients who converted to an MRD-ve remission post course 2 (HR 0.32 CI 0.11-0.92) lack of heterogeneity (p=0.22) means that benefit for those remaining MRD+ve post course 2 cannot be excluded.

Summary/Conclusion: Two consecutive trials demonstrate benefit for RIC transplant in first remission for older adults that is independent of post course 1 response and MRD status. The overall improvement in outcome for post course1 MRD+ve patients in AML18 compared to AML16 may reflect treatment intensification post course 1 and the impact of the increased uptake of RIC transplant



S131 SURVIVAL OUTCOMES FROM THE QUAZAR AML-001 TRIAL WITH ORAL AZACITIDINE FOR PATIENTS WITH ACUTE MYELOID LEUKEMIA IN REMISSION BY DISEASE SUBTYPE, CYTOGENETIC RISK, AND NPM1 MUTATION STATUS AT DIAGNOSIS

[1]Universitätsklinikum Ulm, Ulm, Germany, [2]Monash University, [3]The Alfred Hospital, Melbourne, Australia, [4]New York Presbyterian Hospital, [5]Weill Cornell Medicine, New York, United States, [6]Hospital Universitari i Politècnic La Fe, Valencia, Spain, [7]Medizinische Hochschule Hannover, Hannover, Germany, [8]Celgene, a Bristol-Myers Squibb Company, Boudry, Switzerland, [9]Bristol Myers Squibb, Princeton, [10]University of Kansas Medical Center, Kansas City, United States, [11]BMS Center for Innovation and Translational Research Europe (CITRE), a Bristol-Myers Squibb Company, Seville, Spain

Background: Oral azacitidine (Oral-AZA; CC-486) is approved in the US for adult patients (pts) with acute myeloid leukemia (AML) who have achieved first complete remission (CR) or CR with incomplete blood count recovery (CRi) after intensive chemotherapy and are ineligible for intensive curative therapy. In the phase 3 QUAZAR trial, Oral-AZA significantly improved overall survival (OS) vs placebo (PBO) (median [med] 24.7 vs 14.8 months [mo], respectively; *P*<0.001). It has not been elucidated which subgroups of pts may derive greater benefit from Oral-AZA maintenance treatment (Tx) based on prognostic features or mutational profile.
Aims: Investigate the relationship between Oral-AZA and survival in *post hoc* analyses based on cytogenetic risk classification, AML subtype (*de novo* or secondary), and *NPM1*/*FLT3* status at diagnosis (Dx).
Methods: Cytogenetic risk classification of intermediate- (int) and poor-risk pts was based on the 2012 NCCN Guidelines; pts with favorable risk were excluded. Pts were randomized 1:1 to Oral-AZA 300 mg or PBO within 4 mo of achieving first CR/CRi. Mutant (mut) or wild-type (WT) *NPM1*/*FLT3*-ITD status was determined at Dx. OS and relapse-free survival (RFS) were estimated using Kaplan-Meier methods. Cox Proportional Hazard Regression was used to obtain hazard ratios (HR; *P* values, Log-rank test). Measurable residual disease (MRD) analysis used a cutoff of ≥0.1% (*P* values, Fisher's exact test).
Results: Of 472 randomized pts, 90.9% had d*e novo* AML, and Oral-AZA provided a significant increase in med OS vs PBO (23.2 vs 14.6 mo; HR 0.73; *P*=0.0068) and RFS (10.2 vs 4.9 mo; HR 0.66; *P*=0.0002). For the underpowered pt group with secondary AML (n=43), there was a trend for increased OS with Oral-AZA vs PBO (28.2 vs 15.7 mo; HR 0.58; *P*=0.11) and significantly increased RFS (4.7 vs 2.4 mo; HR 0.47; *P*=0.0118). 86% of pts had int-risk cytogenetics, and within this population, OS was significantly increased with Oral-AZA vs PBO (25.4 vs 15.9 mo; HR 0.73; *P*=0.0093), as was RFS (11.0 vs 5.8 mo; HR 0.66; *P*=0.0004). The poor-risk cohort (14%; n=66), though underpowered, showed a trend for increased OS with Oral-AZA vs PBO (13.9 vs. 7.4 mo; HR 0.61; *P*=0.06), and RFS was similar (Oral-AZA 4.6 mo, PBO 3.7 mo; HR 0.63; *P*=0.08). Overall, 29.2% of pts had mut*NPM1* at Dx (137/469), 9.8% (n=48) were *FLT3*-ITD positive, and 6% (n=30) had co-mutated *NPM1*/*FLT3*-ITD. In the PBO arm, mut*NPM1* status vs WT was prognostically favorable for RFS (6.9 vs 4.6 mo; HR 0.64; *P*=0.0083) with a trend in increased OS (15.9 vs 14.6 mo; HR 0.75; *P*=0.10). Comparing treatment arms, the med OS for pts with mut*NPM1* was considerably longer in the Oral-AZA arm vs PBO (46.1 vs 15.9 mo; HR 0.57; *P*=0.0138), and med RFS was significantly prolonged (23.2 vs 6.9 mo; HR 0.55; *P*=0.0098) (**Figure**). A larger fraction of pts with mut*NPM1* were MRD– (61.7%) than were MRD+ (38.4%) at screening (*P*=0.0178). For pts with WT *NPM1* (Oral-AZA n=170; PBO n=162), Tx with Oral-AZA significantly increased OS (19.6 vs 14.6 mo; HR 0.77; *P*=0.0365) and RFS (7.7 vs 4.6 mo; HR 0.69; *P*=0.0029). Pts with WT *NPM1* were evenly distributed between MRD– (49.2%) and MRD+ (50.8%) status at screening.

Figure

Summary/Conclusion: Oral-AZA considerably improved survival for pts with *de novo* AML and int-risk cytogenetics. Additionally, pts with mut*NPM1* in the Oral-AZA arm derived an extended OS benefit of more than 2.5 years vs PBO, whereas OS for all pts in QUAZAR AML-001 was lengthened by 9.9 months with Oral-AZA vs PBO. This suggests that mut*NPM1* status is both prognostically favorable in general and independently predictive of increased OS with Oral-AZA.

S132 RUNX1 MUTATIONS IN NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA DO NOT ADVERSELY IMPACT CLINICAL OUTCOMES IN THE MODERN ERA

S. Venugopal [1,*], S. Loghavi [2], C. DiNardo [1], M. Konopleva [1], T. Kadia [1], K. Bhalla [1], G. Issa [1], F. Ravandi [1], N. Daver [1], G. Borthakur [1], E. J. Jabbour [1], G. Montalban-Bravo [1], M. Yilmaz [1], K. Chien [1], A. Maiti [1], H. Kantarjian [1], N. J. Short [1]

[1]Leukemia, [2]Hematopathology, The University of Texas, MD Anderson Cancer Center, Houston, United States

Background: European LeukemiaNet 2017 risk stratification classifies mutated *RUNX1* (m*RUNX1*) as an adverse risk factor in newly diagnosed (ND) acute myeloid leukemia (AML). However, outcomes of m*RUNX1* in ND AML in the current era, including with venetoclax (Ven)-based therapies, are not well defined.
Aims: We characterize the impact of *RUNX1* mutations and variant allelic frequency (VAF) on outcomes of patients with ND AML across contemporary treatment regimens.
Methods: We conducted a retrospective analysis of patients (pts) with ND AML treated at our institution from 11/2009 to 7/2020. Pt were divided into AML with m*RUNX1* and wild type *RUNX1* (wt*RUNX1*); only those with presumed somatic variants based on previous annotation in literature and publicly available databases were included in the m*RUNX1* group. Treatment was classified as intensive chemotherapy (IC) or low intensity chemotherapy including hypomethylating agents (LIC) with and without Ven. Response was defined as achievement of CR or CRi.
Results: Among 907 pts with ND AML, 137 (15%) had AML with m*RUNX1*. The median *RUNX1* VAF was 33% (range, 1-96%); 29 pts (21%) had ≥2 *RUNX1* mutations. Pts with m*RUNX1* AML were older (median age: 71 vs. 66 years; P<0.001), more likely to have secondary AML (20% vs.13%; P=0.03), and less likely to have adverse-risk cytogenetics (20% vs. 34%; P=0.001) compared to pts with wt*RUNX1*. AML with m*RUNX1* was more likely to have a co-mutation of *SRSF2* (40% vs. 12%; P<0.001), *ASXL1* (24% vs. 9%; P<0.0001), and *IDH1/2* (38% vs. 25%; P=0.002), and less likely to have co-mutated *TP53* (5% vs. 25%; P<0.0001).
Frontline therapies received were IC in 35 pts (26%), LIC without Ven in 66 pts (48%) and LIC with Ven in 36 pts (26%). Response rates were similar between pts with m*RUNX1* and wt*RUNX1* AML across therapies (IC, 77% vs. 80%; LIC without Ven, 44% vs. 52%; LIC with Ven, 72% vs. 73%). Among pts with m*RUNX1* AML treated with LIC, response rates were significantly higher in those who received Ven (72% vs. 44%, P=0.007). The benefit of adding Ven to LIC was similar among pts with *RUNX1* VAF <30% (response rate: 82% with Ven vs. 46% without Ven; P<0.05) and VAF ≥30% (68% vs. 43%, respectively; P<0.05). Among pts who received IC, response rates were higher in AML with m*RUNX1* VAF <30% than ≥30% (100% vs. 69%; P=0.06).
Overall survival (OS) was similar in m*RUNX1* and wt*RUNX1* AML in both pts <60 years (P=0.8) and ≥60 years (P=0.8). *RUNX1* mutation status also did not impact OS in those treated with IC (P=0.7) or LIC without Ven (P=0.8); however, among pts who received LIC with Ven, there was a strong trend towards superior OS for pts with m*RUNX1* AML compared to wt*RUNX1* AML (median 25.1 months [m] vs. 11.3 m; P=0.12). Pts with m*RUNX1* AML who received LIC with Ven had superior OS compared to those who received LIC without Ven (median OS 25.1 m vs. 14.9 m; P=0.02).
Among those with m*RUNX1* AML who received IC, OS was higher for those with VAF <30% vs. ≥30% (median OS not reached vs. 18.3 m; P=0.10). Among those with m*RUNX1* VAF <30%, the addition of Ven to LIC significantly improved OS compared to LIC without Ven (median OS 25.4 m vs. 14.9 m; 2-year OS 81% vs. 12%; P=0.02); in contrast, the benefit of adding Ven to LIC in pts with m*RUNX1* VAF ≥30% was less pronounced (median OS 16.4 m vs. 15.3 m; 2-year OS 43% vs. 26%; P=0.2).

Summary/Conclusion: The comparable outcomes between pts with m*RUNX1* and wt*RUNX1* AML question the inclusion of *RUNX1* mutations as an adverse risk group. With Ven-based regimens, a median OS >2 years was observed in pts with m*RUNX1* AML.

S133 A UNIFIED CLASSIFICATION AND RISK STRATIFICATION ALGORITHM TO SUPPORT CLINICAL DECISIONS IN ACUTE MYELOID LEUKEMIA

Background: Despite a detailed understanding of the genomics underlying AML pathogenesis, clinical recommendations for AML classification and risk stratification remain heavily reliant on cytogenetic findings and only consider a few well-characterized gene mutations. In the absence of informative markers, a significant proportion of AML patients are categorized as intermediate risk and display significant heterogeneity in clinical presentation and outcomes.
Aims: To examine the role of acquired gene mutations in clinical decision support algorithms for disease classification, risk stratification and treatment decisions in AML.
Methods: We mapped recurrent gene mutations across 128 genes implicated in myeloid pathogenesis across 2,113 patients. Gene mutations were integrated with cytogenetic findings (fusion genes and chromosomal aneuploidies). Unsupervised clustering using Bayesian Dirichlet Processes was implemented to characterize novel molecular subgroups or biological and clinical relevance. Associations with clinical presentation and outcomes as measured by measurable residual disease (MRD), overall survival, relapse risk and hematopoietic stem cell transplantation (HSCT) response were assessed. Multi-state Hiden Markov Models were implemented to assess class specific risk associations across clinical transitions (complete remission, relapse, death). Findings were validated in 1,540 patients from the AMLSG trials.
Results: 92% of patients were assigned into one of 14 molecular classes. These classes define clinical and prognostic AML subgroups; each associated with a distinct likelihood of response to induction chemotherapy, risk of relapse and death over time. We characterize molecular subgroups that retain independent prognostic relevance irrespective of MRD status post course 1, and define molecular subgroups that derive benefit from HSCT at first remission. Secondary AML-2, a class enriched in secondary like mutations represents the second largest group (24% of patients) in AML. sAML-2 associates with high-risk disease, retains poor prognosis irrespective of flow MRD negativity after course 1, and derives significant benefit from HSCT. Guided by class membership we derive a 3-tier risk stratification score, that re-stratifies 26% of patients with significant improvement in c-index and variance explained. We characterize 32 genes that, with cytogenetics, result in complete patient classification and risk stratification and develop an open-access web calculator that considers molecular, clinical and demographic parameters to deliver individual patient tailored management.
Summary/Conclusion: Using data from 3,653 patients, we identify 14 novel molecular subgroups, and characterize associations with clinical presentation, MRD and treatment response (Induction chemotherapy and transplant). We develop and validate a unified framework for disease classification and risk stratification in AML based on cytogenetics and information from 32 genes that would enable practical adoption in clinical practice.

S134 A NATIONAL DANISH PROOF OF CONCEPT ON FEASIBILITY AND SAFETY OF HOME -BASED INTENSIVE CHEMOTHERAPY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

K. Nørskov [1,*], K. Fridthjof [2], P. Kampmann [1], A. Dünweber [1], T. Renaberg [1], C. Schöllkopf [1], S. Azar Ahmad [1], K. Schou [3], C. F. Jensen [3], P. Mølller [3], B. Wolf Lundholm [4], C. Marcher [4], A. K. Ørntoft [5], H. Beier Ommen [5], L. Andersen [6], C. F. Hasselgren [6], M. Severinsen [6], M. Klinten Grand [7], M. Jarden [1], T. Møller [8], L. Kjeldsen [9]

[1]Hematology, University Hospital of Copenhagen, [2]Amgros, Ambros, Copenhagen Ø, [3]Hematology, Zealand University Hospital, [4]Hematology, Odense University Hospital, [5]Hematology, Aarhus University Hospital, [6]Hematology, Aalborg University Hospital, [7]Department of Biostatistics, University of Copenhagen, [8]Center for Health Research, University Hospital, [9]Hematology, University of Copenhagen, Copenhagen Ø, Denmark

Background: Advances in treatment modalities have made it possible to offer chemotherapy to patients at home without health care professionals being present. Home-based chemotherapy treatment has shown to provide several benefits in patients with cancer however existing evidence does not include patients with hematologic malignancies. In addition, there is no best practice models which can guide coordination and standardization of home-based chemotherapy treatment. Thus, it is relevant to investigate the feasiblity and safety of home-based treatment in this population.
Aims: To investigate the feasiblity and safety of home-based intensive chemotherapy in patients with newly diagnosed acute myeloid leukemia or high-risk myelodysplastic syndrome, and to examine quality of life and psychological wellbeing.
Methods: A national multicenter single-arm feasibility study that included patients from six sites in Denmark with newly diagnosed with acute leukemia or high-risk myelodysplastic syndrome receiving intensive induction and consolidation like chemotherapy (n=104). Participants received intensive chemotherapy on programmed CADD Solis infusion pumps through a central venous catheter. Supportive care was offered in the outpatient unit every second or third day for transfusion or surveillance of infection. Outcome measures included feasibility (primary outcome), safety, anxiety and depression measured by the Hospital Anxiety and Depression Scale, and quality of life by the Functional Assessment of Cancer Therapy – Leukemia and the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire.
Results: In total, 104 patients were included, receiving 264 treatments during the intervention. Total number of days slepping at home during treatment was 1.096 (mean 4.57, SD 3.0) out of 1.644 treatment days (66 %). Patients with no admissions during treatment were in cycle one (n=2), cycle two (n=29), cycle three (n=22), and cycle four (n=11). An overall trend showed a decrease in participants not discharged during treatment and hospital admission days with the greatest decline from treatment cycle one to cycle two. Patients reported high satisfaction with home-based treatment which had positive influence on their ability to be involved in their own treatment as well as socially and physically active. Most participants felt safe while receiving treatment in their home. Reasons for contacting the hospital were either due to fever, nausea or bleeding (n=60), or pump alarm (n=65) which in the majority of cases could be solved by phone (72%). No unexpected adverse events occurred during the intervention. Overall, patients improved in all quality of life
Summary/Conclusion: Providing home-based intensive chemotherapy treatment was feasible and safe in this population and provided a valuable alternative to receiving treatment in an inpatient setting. This may

strengthen the existing supportive care services in Denmark for this population, and the findings are potentially transferable and valuable to a broader context of patients with cancer or other life-threatening diseases. With home-based treatment of acute leukemias, a considerable number of hospital beds can be freed up for other patients in need of in-hospital treatment.

Developments in AML therapy

S135 EFFICACY AND SAFETY OF VENETOCLAX IN COMBINATION WITH GILTERITINIB FOR RELAPSED/REFRACTORY FLT3-MUTATED ACUTE MYELOID LEUKEMIA: UPDATED ANALYSES OF A PHASE 1B STUDY

J. K. Altman [1,*], N. Daver [2], J. Maly [3], M. Levis [4], E. Ritchie [5], M. Litzow [6], J. McCloskey [7], C. C. Smith [8], G. Schiller [9], T. Bradley [10], R. V. Tiu [11], K. Naqvi [12], S. Siddani [13], J. Wang [13], P. Lee [13], A. E. Perl [14]

Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL, [2]Department of Leukemia, University of Texas MD Anderson Cancer Center, Houston, TX, [3]Norton Cancer Institute, Louisville, KY, [4]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD, [5]Division of Hematology and Oncology, Weill Cornell Medical College, New York, NY, [6]Division of Hematology, Mayo Clinic, Rochester, MN, [7]John Theurer Cancer Center at Hackensack Meridian Health, Hackensack, NJ, [8]Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA, [9]David Geffen School of Medicine at UCLA, Los Angeles, CA, [10]Department of Medicine; Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL, [11]Astellas Pharma US, Northbrook, IL, [12]Genentech, South San Francisco, CA, [13]AbbVie Inc., North Chicago, IL, [14]Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA, United States

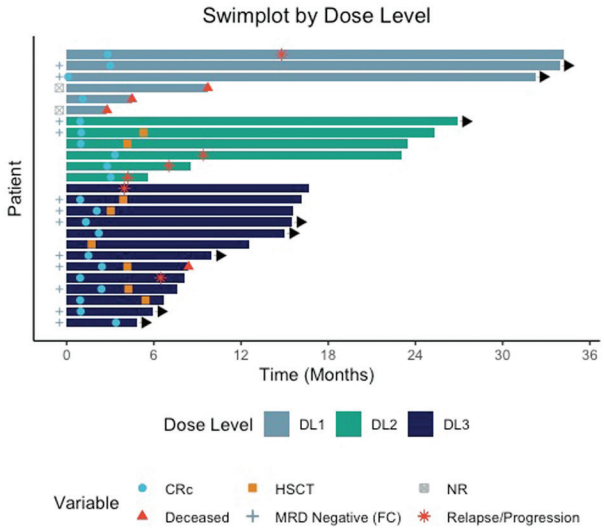
Background: The FMS-like tyrosine kinase 3 (*FLT3*) inhibitor gilteritinib (Gilt) improves survival compared with standard salvage chemotherapy in patients (pts) with *FLT3*-mutated (*FLT3*$^{mut+}$) acute myeloid leukemia (AML) who are relapsed/refractory (R/R) to standard chemotherapy. Interim analysis of an ongoing, multicenter, open-label, Phase 1b trial (NCT03625505) of Gilt + the B-cell lymphoma 2 (BCL-2) inhibitor venetoclax (Ven) in pts with R/R *FLT3*$^{mut+}$ AML reported high rates of marrow blast elimination and a modified composite complete remission (mCRc) rate of 84% (Daver et al. ASH 2020; Abstract 333).
Aims: To provide updated results from a Phase 1b trial of Ven + Gilt in R/R *FLT3*$^{mut+}$ AML.
Methods: The study design has been described previously (Daver et al. ASH 2020; Abstract 333). In brief, pts with R/R AML *FLT3*$^{mut+}$ received dosages up to Ven 400 mg daily with Gilt (80 mg or 120 mg) daily in 28-day cycles, following Ven ramp-up. The primary endpoint was mCRc (complete response [CR] + CR with incomplete platelet recovery + CR with incomplete blood count recovery [CRi] + morphologic leukemia-free state) to align with the Phase 3 ADMIRAL trial CRc responses. Duration of response (DOR) of mCRc was a secondary endpoint; overall survival (OS) and changes in FLT3 allelic burden were exploratory. Safety evaluation included adverse event (AE) monitoring.
Results: At the data cutoff of November 30, 2020, 43 pts with *FLT3*$^{mut+}$ had been enrolled. Median age (range) was 63 years (23–85). *FLT3* internal tandem duplications (ITD) were identified in 37 pts (86%) and 6 pts (14%) had only tyrosine kinase domain (TKD) mutations. Baseline cytogenetic risk was favorable in 2 pts (5%), intermediate in 23 pts (55%), poor in 13 pts (31%), and 5 pts (12%) had no mitoses/missing data. The median (range) prior lines of therapy was 2 (1–5), and 33 pts (77%) had 2 or more prior lines of therapy; 28 pts (65%) had received at least one prior *FLT3* inhibitor and 3 pts (7%) received prior Ven. Fourteen pts (33%) had prior transplant.
Grade 3/4 AEs were reported in 42 pts (98%). Grade ≥3 cytopenias occurred in 34 pts (79%) and were predominantly managed by Ven and/or Gilt dose interruptions and shorter Ven duration on subsequent cycles. The only grade 3/4 nonhematologic AE reported in >20% of pts was pneumonia (n=9; 21%). There was 1 instance of clinical tumor lysis syndrome. Serious AEs were reported in 32 pts (74%). Overall, 30- and 60-day mortality rates were 0% and 12%, respectively. AEs led to either Ven or Gilt interruptions in 24 pts (56%), reductions in 3 pts (7%), and discontinuations in 6 pts (14%).
mCRc was achieved by 86% of the *FLT3*$^{mut+}$ efficacy population (36/42) with a median time to first response of 1.0 month (range: 0.7–4.6), and by 86% of pts with prior *FLT3* tyrosine kinase inhibitor (TKI) exposure (24/28). *FLT3* molecular clearance (<10^{-2}) was observed in 69% of pts with mCRc who had PCR analyzed at baseline and at least one follow-up timepoint (18/26). DoR and OS are summarized in the **Table**.

Table: Summary of median DoR and OS in patients with *FLT3* mutations

	All *FLT3*$^{mut+}$ pts N=42	All ITD pts N=37	Prior TKI use	
			Yes	No
Median OS, months (95% CI)	N=42 10.5 (9.6–NE)	N=36 10.5 (8.0–NE)	N=28 10.5 (7.4–NE)	N=14 10.6 (6.6–NE)
Median DoR, months (95% CI)	N=36 5.6 (4.0–6.6)	N=32 5.6 (3.4–8.3)		

CI, confidence interval; DoR, duration of response; *FLT3*, FMS-like tyrosine kinase 3; *FLT3*$^{mut+}$, *FLT3*-mutated; ITD, internal tandem duplications; N, number of patients with data available for analysis; NE, not estimable; OS, overall survival; TKI, tyrosine kinase inhibitor.

Summary/Conclusion: These updated analyses show that Ven + Gilt achieved high rates of mCRc in pts with heavily pretreated and prior TKI-exposed R/R *FLT3*$^{mut+}$ AML with encouraging molecular clearance rates. Using similar response criteria to previously studied *FLT3*$^{mut+}$ populations, the high mCRc rate with Ven + Gilt reported here suggests strong antileukemic activity. Cytopenias were prominent but manageable. Updated follow-up and molecular data will be presented at the meeting.



S136 A PHASE IB/II STUDY OF IVOSIDENIB WITH VENETOCLAX +/- AZACITIDINE IN IDH1-MUTATED MYELOID MALIGNANCIES

C. Lachowiez [1,*], G. Borthakur [2], S. Loghavi [3], Z. Zeng [2], T. Kadia [2], L. Masarova [2], K. Takahashi [2], G. Tippett [2], S. Smith [4], J. Garcia [4], P. Bose [2], E. Jabbour [2], F. Ravandi [2], N. Daver [2], G. Garcia-Manero [2], B. Stoilova [5], P. Vyas [5,6,7], H. Kantarjian [2], M. Konopleva [2], C. DiNardo [2]

[1]The University of Texas M.D. Anderson Cancer Center, Houston, United States, [2]Department of Leukemia, [3]Department of Hematopathology, The University of Texas M.D. Anderson Cancer Center, Houston, [4]Leukemia Program, Dana-Farber Cancer Institute, Boston, United States, [5]MRC Molecular Haematology Unit, MRC Weatherall Institute of Molecular Medicine, University of Oxford, [6]Department of Hematology, OUH NHS Trust, [7]Oxford Biomedical Research Centre, University of Oxford, Oxford, United Kingdom

Background: Isocitrate dehydrogenase-1 (*IDH1*$^{+}$) mutations are present in 5-15% of myeloid malignancies, promoting leukemogenesis through production of the oncometabolite 2-hydroxyglutarate resulting in arrested myeloid differentiation. *IDH1*$^{+}$ malignancies demonstrate increased reliance on the anti-apoptotic protein BCL-2, enhancing susceptibility to the BCL-2 inhibitor venetoclax (VEN).
Aims: We report an interim safety and efficacy analysis of the IDH1 inhibitor ivosidenib (IVO; 500 mg PO daily D15-continuous) combined with VEN (D1-14) +/- azacitidine (AZA; 75mg/m^2 D1-7 every 28 days).
Methods: Eligible patients age ≥18 with *IDH1*$^{+}$ MDS, newly diagnosed (ND: treatment naïve [TN], secondary/treated secondary AML [sAML]), or relapsed/refractory (R/R) AML were enrolled into three dose levels (DL): DL1 (IVO+VEN 400 mg), DL2 (IVO+VEN 800 mg), DL3 (IVO+VEN 400 mg+AZA). Primary objectives included safety and tolerability, and IWG defined overall response (ORR: CR+CRi+CRh+PR+MLFS). Prior receipt of IVO or VEN was exclusionary.
Results: 25 evaluable patients (DL1: 6, DL2: 6, DL3: 13) enrolled with a median follow-up of 16.1 months (DL1: 34 months, DL2: 24 months, DL3: 13 months). Median age was 67 (range: 44-84). 84% (N=21) of patients had AML (ND: N=13 [TN: 8, sAML: 5], R/R: N=8), while 16% (N=4) had MDS. ELN risk was intermediate and adverse in 16% (n=4) and 56% (N=14). Median *IDH1* VAF at enrollment was 22.7% (range: 5.1%>47.8%). Two patients had received a prior IDH1 inhibitor. The ORR was 92% (DL1: 67%, DL2:100%, DL3: 100%), with both non-responding patients (N=2) treated within the DL1 cohort. Composite CR (CRc:CR+CRi+CRh) was 84% (DL1: 67%, DL2: 100%, DL3: 85%) including 92% (TN: 100%, sAML: 80%), 63%, and 100% of patients with ND-AML, R/R-AML, or MDS. Median time on study was 5 months (DL1: 9 months DL2: 6 months DL3: 5 months), and the median number of cycles received was 4 (DL1: 8.5, DL2: 6, DL3: 4) with ongoing responses in 62% (DL1: 33%, DL2: 50%, DL3: 82%) at 1-year. 8 patients transitioned to SCT (DL1: 0, DL2: 2, DL3: 6), and 8 patients remain on study (DL1: 2, DL2: 1, DL3: 5). 1-year OS was 68% for the entire study population (DL1: 50%, DL2: 67%, DL3: 78%), 75% in ND-AML (TN: 86%, sAML: 60%), 50% in R/R-AML, and 100% in MDS. Measurable residual disease negative CRc by multiparameter flow cytometry was attained in 60% (ND-AML: 75%, R/R-AML: 60%, MDS: 33%) correlating with improved OS (median OS: NR vs. 8.5 months, p-value: 0.038).

Signaling mutations at treatment initiation were enriched in non-responding or relapsing patients with AML (83% vs.27%, p-value: 0.046), and trended with inferior OS (median OS NR vs. 9.7 months, p-value: 0.063). Common grade 3/4 adverse events included febrile neutropenia (28%) and pneumonia (24%). Tumor lysis and differentiation syndrome occurred in two and four patients; all cases resolved with medical management.

Summary/Conclusion: IVO+VEN +/- AZA is an effective treatment regimen in patients with *IDH1*+ myeloid malignancies. The combination therapy is associated with an acceptable and expected toxicity profile with notable efficacy and high rates of MRD-negative CRc in AML. Enrollment into the study continues.

S137 MEASURABLE RESIDUAL DISEASE RESPONSE IN ACUTE MYELOID LEUKEMIA TREATED WITH VENETOCLAX AND AZACITIDINE

Background: In the phase 3 VIALE-A trial, rates of composite complete remission (CRc; complete remission [CR] + CR with incomplete hematologic recovery [CRi]) and measurable residual disease response (MRD<10^{-3}) were higher in patients (pts) treated with venetoclax (Ven) + azacitidine (Aza) compared to Aza alone (23.4%/7.6%, p<0.001). There is limited evidence of the clinical significance of MRD monitoring in pts receiving low-intensity chemotherapy.

Aims: We explored the outcomes of pts treated with Ven+Aza who achieved both CRc and MRD<10^{-3} in the VIALE-A trial (NCT02993523).

Methods: Enrolled pts were ≥18 years and unfit for intensive chemotherapy. Pts received Ven 400 mg orally; days 1–28 and Aza 75 mg/m^2; days 1-7/28-day cycle. Bone marrow aspirate samples for multiparametric flow cytometry assessments by integrated leukemia-associated immunophenotypes and different than normal procedures were collected for central analysis (Covance Central Laboratory Services) at baseline, end of cycle 1, and every 3 cycles thereafter. Assessments were performed independent of disease responses. MRD response was defined as <1 residual blast /1000 leukocytes (<10^{-3}). CRc, DoR, OS, and EFS were assessed. Disease assessments were per modified International Working Group response criteria for AML.

Results: 211/286 (74%) pts treated with Ven+Aza with at least one valid post-baseline MRD assessment were considered MRD evaluable; 78/211 (37%) achieved MRD<10^{-3} and 133/211 (63%) had MRD≥10^{-3}. Median age (MRD<10^{-3}/ MRD≥10^{-3}) was 76 (range: 49-89)/77 (58-91) years.

Pts (MRD<10^{-3}/ MRD≥10^{-3}) received median of 14.5 (range: 1-28) /7.0 (1-30) cycles of Ven+Aza. At a median follow-up of 22.0 (range: 20.1-23.0)/20.8 (19.8-22.3) months (mos), CRc + MRD<10^{-3}/ MRD≥10^{-3} was achieved by 67 (86%)/ 97 (73%); 20/67 (30%) achieved CRc + MRD<10^{-3} by end of cycle 1.

Median DoR, OS, and EFS were not reached in pts with CRc + MRD<10^{-3} response (Table). The 12-mo estimates for DoR, OS, and EFS for pts with CRc + MRD<10^{-3}response were 81.2%, 94.0%, and 83.2%, respectively. Adverse events ≥grade 3 (MRD<10^{-3}/ MRD≥10^{-3}) were febrile neutropenia (50%/43%), neutropenia (50%/35%), and thrombocytopenia (44%/44%), similar to the overall population.

Table: DoR, OS, and EFS in patients with composite complete response treated with venetoclax and azacitidine

	12-mos estimate % (95% CI)		Median months (95% CI)	
	MRD<10^{-3} n=67	MRD≥10^{-3} n=97	MRD<10^{-3} n=67	MRD≥10^{-3} n=97
Duration of response	81.2(69.3, 88.9)	46.6(35.6, 56.8)	NR(19.3, NR)	9.7(8.0. 15.8)
Overall survival	94.0(84.7, 97.7)	67.9(57.6, 76.2)	NR(24.4, NR)	18.7(12.9, NR)
Event-free survival	83.2(71.6, 90.3)	45.4(35.2, 55.0)	NR(19.7, NR)	10.6(9.0, 13.9)

CI: Confidence interval; MRD: measurable residual disease; NR: not reached

Summary/Conclusion: Pts with best response of CRc who achieved MRD<10^{-3}response with Ven+Aza treatment had longer DoR, OS, and EFS than pts who were CRc and MRD positive.

S138 EFFECT OF OLUTASIDENIB (FT-2102) ON COMPLETE REMISSIONS IN PATIENTS WITH RELAPSED/REFRACTORY MUTANT IDH1 ACUTE MYELOID LEUKEMIA. RESULTS FROM A PLANNED INTERIM ANALYSIS OF A PHASE 2 CLINICAL TRIAL

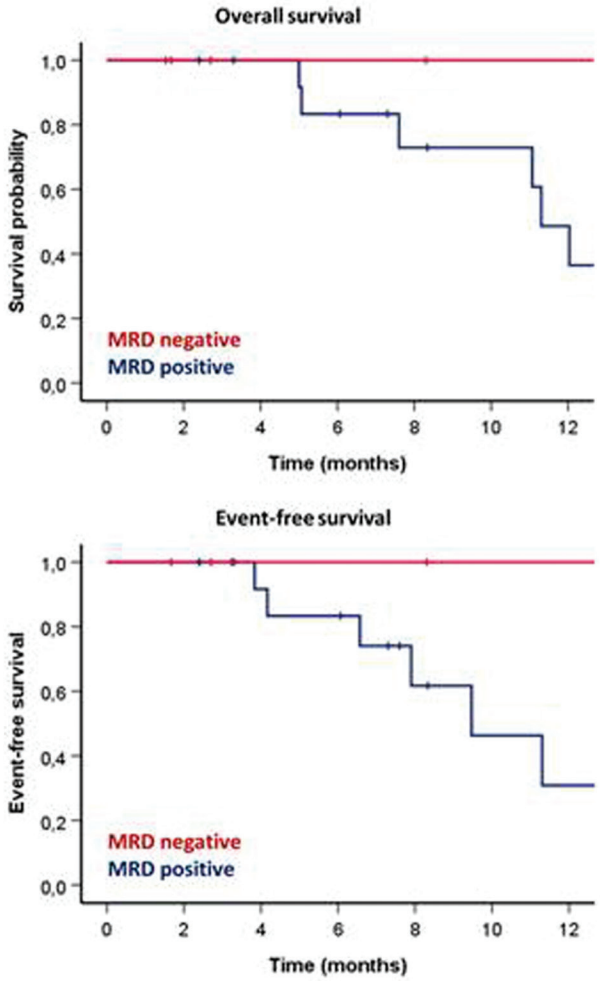
Background: Olutasidenib, a potent, selective, oral, small molecule inhibitor of mutant IDH1 (m*IDH1*), has exhibited favorable tolerability and clinical activity in high-risk acute myeloid leukemia (AML) patients (pts) in a phase 1 trial (Watts, *Blood* 2019).
Aims: Here, we present interim analysis results of a phase 2 trial (NCT02719574) in relapsed/refractory (R/R) m*IDH1* AML pts receiving olutasidenib monotherapy 150 mg twice daily.
Methods: The efficacy evaluable (EE) set comprised m*IDH1*^{R132X} pts whose first dose was ≥180 days before the data cut-off (18-JUN-20). The primary endpoint was CR + CRh (complete remission [CR] or CR with partial hematologic recovery [CRh] according to modified IWG 2003 criteria) rate. CRh was defined as bone marrow blasts <5%, absolute neutrophil count >0.5×10^9/L, *and* platelet count >50×10^9/L. Overall response rate (ORR) comprised CR + CRh + CR with incomplete recovery (CRi) + morphologic leukemia-free state (MLFS) + partial response (PR). Duration of treatment (DOT), duration of response (DOR), and overall survival (OS) were estimated using Kaplan-Meier methodology.
Results: This clinical trial met its pre-specified early enrollment-stopping criteria for efficacy. A total of 153 pts with R/R AML received olutasidenib; median DOT, 5.5 months (95% CI: 4.4–8.7). 43 pts (28%) remain on treatment and 110 pts (72%) discontinued, most commonly due to: disease progression (31%), AEs (14%), death (10%), and transplant (8%). For the EE set (123 pts), the median age was 71 y (range: 32–87) with a median number of prior therapies of 2 (1–7). The ORR was 46% with a median duration of ORR of 11.7 months. Notably, the CR + CRh rate was 33% including 30% of pts in CR. The median duration of CR + CRh was not reached (NR) but found to be 13.8 months based on a sensitivity analysis when HSCT or relapse was deemed end of response. Of responders who were transfusion-dependent at baseline, 56-day platelet transfusion independence (TI) and RBC TI were gained by 100% and 83%, respectively, of pts who achieved CR + CRh, and by 56% and 50% who did not. The median OS was 10.5 months. For patients with CR + CRh, the median OS was NR and the estimated 18-month OS was 87%; the median OS for non-CR/CRh responders was 15.0 months (Figure). TEAEs in ≥25% of pts were: nausea (38%), constipation (25%), and leukocytosis (25%). Grade 3/4 all-causality AEs in >10% of pts were: febrile neutropenia (20%), anemia (19%), thrombocytopenia (16%), and neutropenia (13%). TEAEs of QTc prolongation (all grades) were reported in 13 pts (8.5%) with one grade 3 event in 1 pt (<1%). No events led to dose reduction or discontinuation. Hepatobiliary TEAEs associated with liver enzyme abnormalities (all grades) were reported in 32 pts (21%) with grade 3/4 events in 16 pts (10%)/3 pts (2%). Most pts (n=25) had no dose modification or continued after a rechallenge; 7 pts with grade 3/4 events discontinued treatment (4 pts after positive rechallenge). There were no Hy's law cases. Investigator-assessed IDH1 differentiation syndrome (any grade) was observed in 21 pts (14%); most cases resolved with treatment interruption, dexamethasone, and/or supportive treatment; one case was fatal; 19 pts had concomitant leukocytosis.

Figure: Overall Survival by Response Category



Summary/Conclusion: Olutasidenib induced durable CRs in a subset of high-risk R/R m*IDH1* AML pts. TI was achieved in all response groups, particularly in those achieving CR. Clinical benefit, as evidenced by DOR and OS, extended to pts who responded but didn't achieve CR/CRh. A favorable tolerability profile was observed; additional analyses of safety and efficacy will be presented.

S139 FLAVIDA CHEMOTHERAPY INDUCES MRD-NEGATIVE REMISSION IN PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

R. Shahswar [1,*], G. Beutel [1], R. Gabdoulline [1], C. Könecke [1], M. Stadler [1], G. Göhring [2], B. Schlegelberger [2], Z. Li [1], L. -K. Dallmann [1], C. P. Wienecke [1], P. Klement [1], M. Wichmann [1], B. Neziri [1], Y. Alwie [1], A. Ganser [1], F. Thol [1], M. Heuser [1]

[1]Department of Hematology, Hemostasis, Oncology, and Stem Cell Transplantation, [2]Institute of Human Genetics, Hannover Medical School, Hannover, Germany

Background: Treatment options for relapsed and refractory (R/R) AML patients are limited. Here, we report safety and efficacy data of a novel combination therapy consisting of the BCL-2 inhibitor venetoclax (VEN) with fludarabine, cytarabine, and idarubicin in patients with R/R acute myeloid leukemia (AML).
Aims: To assess MRD response, event-free (EFS) and overall survival (OS) of a seven-day course of venetoclax in combination with standard intensive FLA-IDA chemotherapy (FLAVIDA) in patients with R/R AML reported to the venetoclax registry (NCT03662724; venreg.org).
Methods: In this retrospective controlled study, we included 30 patients aged 18 years or older with R/R AML previously treated with FLAVIDA. VEN dosing was 100 mg/day orally (days 1–7) due to comedication with posaconazole. Safety and efficacy analyses included all patients who received one cycle of FLAVIDA. The overall response rate (ORR) was defined by complete remission (CR) + CR with incomplete blood count recovery (CRi) + morphologic leukemia-free state (MLFS, defined as less than 5% blasts in an aspirate sample without hematologic recovery). MRD was determined by NGS-MRD with a sensitivity of 0.02% (Thol et al. Blood 2018). This study was approved by the local Ethics Review Committee in accordance with the Declaration of Helsinki. The data cut-off for this analysis was February 9th, 2021.
Results: Thirty patients with a median age of 54 years (range 19-70 years) received a maximum of 1 course FLAVIDA. 33% of patients had secondary or therapy-related AML. ELN risk was favorable, intermediate, and adverse in 13%, 57%, and 30% of patients. Patients received a median of 1 (range 1-5) prior lines of therapy and 27% of patients had prior allogeneic hematopoietic cell transplantation (alloHCT). ORR was 73% (22 of 30 patients), with 60% of patients (n=18) achieving a CR/CRi, while the 4 MLFS patients underwent alloHCT before blood count recovery and achieved CR only after alloHCT. Molecular MRD negativity was achieved in 8 of 17 (47%) responding patients with known molecular MRD markers. 75%, 71%, and 78% of patients with ELN favorable, intermediate and adverse risk disease achieved an overall response, respectively. One patient died before response assessment. Nineteen patients (63%) were consolidated with alloHCT, four received chemotherapy, three received donor lymphocyte infusions, and four patients received no additional treatment. After a median follow up of 13.3 months, median OS and EFS of the 30 patients was 12 months and 9.5 months, respectively. Median relapse-free survival in CR/CRi patients was not reached. In the 17 patients with available MRD data, the median OS and EFS were longer in patients who achieved a MRD negative response (OS: MRD- vs. MRD+: NR vs. 11.3 months, P= 0.048; EFS: MRD- vs. MRD+: NR vs. 9.5 months, P= 0.038, Figure 1). In patients who responded to FLAVIDA, the median time from the first day of chemotherapy to recovery of neutrophils (≥0.5x10^9/L) and platelets (≥50x10^9/L) was 33 (95% CI, 30-36) and 35 days (95% CI, 31-39), respectively. The most common grade 3/4 all-causality events were neutropenic fever (71%) and bacteremia (32%), while thrombocytopenia, anemia, and neutropenia were reported in all patients at nadir (100%).

Summary/Conclusion: Short-term VEN can be safely administered in combination with intensive chemotherapy in younger fit adults with AML with tolerable safety-profile, a high ORR rate of 73%, MRD negativity in 47% of responding patients, and promising survival in MRD negative patients.

New biological and translational insights in CLL

S140 CANCER STEMNESS ASSOCIATES WITH HIGH EXPRESSION LEVEL OF ROR1 AND VENETOCLAX RESISTANCE IN CHRONIC LYMPHOCYTIC LEUKEMIA

E. M. Ghia [1,2,*], L. Z. Rassenti [1,2,3], M. Y. Choi [1,2,3,4], M. Quijada-Alamo [5,6], E. Chu [1,2], G. F. Widhopf, II [1,2,3], T. J. Kipps [1,2,3,4]

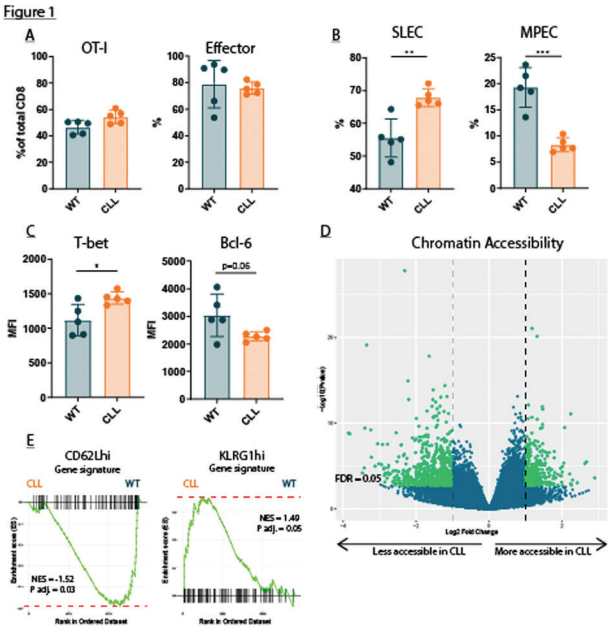
[1]Center for Novel Therapeutics, [2]Moores Cancer Center, [3]Division of Hematology Oncology, Department of Medicine, [4]CIRM Alpha Stem Cell Clinic and Sanford Stem Cell Clinical Center, University of California, San Diego, La Jolla, United States, [5]IBSAL, IBMCC-CSIC, Cancer Research Center, University of Salamanca, [6]Department of Hematology, University Hospital of Salamanca, Salamanca, Spain

Background: Although the BH3-mimetic venetoclax is highly cytotoxic for chronic lymphocytic leukemia (CLL) cells, some patients with CLL fail to clear their leukemia cells and develop progressive disease (PD) on venetoclax therapy. The persistence of measurable disease after at least 1 year of venetoclax therapy associates with the subsequent development of such drug resistance. The acquisition of BCL2 mutations has been noted in CLL cells of some patients who develop venetoclax resistance. However, such mutations apparently do not account for the only mechanism(s) of venetoclax resistance. Indeed recent studies found that CLL cells of refractory patients appeared more resistant to the cytotoxic effects of venetoclax when cultured with accessory cells found in the leukemia microenvironment. Moreover, factors provided by the leukemia microenvironment, such as Wnt5a, may enhance cancer stemness, which itself may mitigate the cytotoxicity of venetoclax.
Aims: We hypothesize that Wnt5a-induced ROR1 signaling may promote cancer stemness by activating genetic programs critical for embryonic stem-cell renewal that enhance resistance to cytotoxic drugs; a corollary of this hypothesis is that inhibition of ROR1-signaling may impair the cancer-cell's capacity for self-renewal and mitigate resistance to therapy. To this end, we examined the leukemia-cell expression of ROR1 and cancer stemness of patients who developed resistance to venetoclax.
Methods: ROR1 expression levels were assessed via flow cytometry. Negative isolation of CLL cells to ≥95% purity was performed prior to RNA extraction and sequencing. Sequencing depth was at least 30 million reads per sample to assure 90-95% sensitivity in detecting variants. GFP-tagged plasmids encoding either wild-type *BCL2* or mutant forms of *BCL2* found in CLL cells of patients resistant to venetoclax were transfected into MEC1 or MEC1-ROR1 cell lines using Neon Transfection System and cells were treated with DMSO or venetoclax (5μM). After 24 hours, for each plasmid, we determined the percentage of specific venetoclax-induced apoptosis of the transfected cells by flow cytometry. Viability of ROR1-high primary CLL cells cultured in serum-free media, with or without cirmtuzumab (20 μg/mL) with or without exogenous Wnt5a (200 ng/mL) and with venetoclax at concentrations ranging from 0.5nM to 4nM, was determined at 16h.
Results: We found that the CLL cells of six patients who developed resistance to venetoclax each used unmutated immunoglobulin heavy-chain-variable region genes (IGHV) and had high-level expression of ROR1 and a high-degree of cancer-stemness that increased after a year or more of venetoclax therapy. We found that high-level expression of ROR1 associates with cancer-stemness independent of IGHV mutation status or therapy. Transfection of the CLL-cell-line MEC1 to express *ROR1* enhanced its cancer-stemness and resistance to venetoclax, even when made to express mutant forms of *BCL2* found in CLL cells of patients resistant to venetoclax. Treatment of ROR1$^+$ CLL cells with Wnt5a enhanced venetoclax resistance, which could be offset by concomitant treatment with an anti-ROR1 mAb (UC-961, cirmtuzumab) that is capable of blocking Wnt5a-induced ROR1-signaling.
Summary/Conclusion: Collectively, these studies indicate that expression of ROR1 can enhance cancer-stemness and venetoclax resistance. Because the resistance of CLL cells to venetoclax can be enhanced by WNT5a-induced ROR1 signaling, strategies targeting ROR1 may enhance the efficacy of venetoclax-based regimens and/or mitigate the risk of developing PD on venetoclax therapy.

S141 SKEWED PRIMARY ANTIGEN-SPECIFIC RESPONSES AND CHROMATIN REMODELING OF T CELLS IN A COMBINED OT-I/TCL-1 ADOPTIVE TRANSFER MODEL

F. S. Peters [1,2,*], A. W. J. Martens [1,2], F. M. Wensveen [3], I. Kavazovic [3], R. Arens [4], A. Jongejan [5], P. D. Moerland [5], E. Eldering [2], G. J. W. van der Windt [1,2], A. P. Kater [1]

[1]Department of Hematology, Cancer Center Amsterdam, Lymphoma and Myeloma Center Amsterdam, [2]Department of Experimental Immunology, Amsterdam Institute of Infection and Immunity, Amsterdam UMC, Amsterdam, Netherlands, [3]Department of Histology and Embryology, Faculty of Medicine, University of Rijeka, Rijeka, Croatia, [4]Department of Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, [5]Department of Epidemiology and Data Science, Amsterdam UMC, Amsterdam, Netherlands



Background: Patients with chronic lymphocytic leukemia (CLL) develop an acquired T cell dysfunction during the disease, hampering efficacy of autologous-based T cell therapeutic strategies such as CAR-T (van Bruggen et al., 2019). Whilst the characteristics and functional capacity of these T cells can be analyzed *in vitro*, it remains to be studied how CLL affects antigen-specific T cell responses. Epigenetic features are increasingly recognized as key regulator, and therefore as therapeutic target, in the differentiation and function of T-cell subsets. By utilizing an adoptive transfer murine model of CLL that displays similar features of T cell dysfunction as in CLL patients (Hofbauer et al., 2011) we developed a model to study the impact of CLL on primary antigen-specific T cell responses.
Aims: To develop a model to study the impact of CLL on primary antigen-specific T cell responses.
Methods: Splenocytes from aged CD45.2$^+$*Eμ-T cell leukemia-1* (*TCL-1*) mice were adoptively transferred into wild-type (WT) mice to initiate CLL (CLL mice). Upon full CLL development, CLL mice and WT mice were injected with 50.000 OT-I splenocytes followed by infection with mCMV-OVA. At day 7 after infection the mice were killed and

spleen, liver and blood samples were analyzed by Flow Cytometry. In addition, 50,000 splenic OT-I cells were FACS-sorted and Assay for Transposase Accessible Chromatin (ATAC)-libraries were generated for sequencing.

Results: Seven days post-infection the percentages of total OT-I cells ($CD45.1^+CD8^+$) and OT-I effector cells ($CD62L^-CD44^+$) were not different between CLL and WT mice, indicating that the magnitude of response was not affected by CLL (Fig 1A). However, within these effector cells, CLL induced skewing towards short-lived effector cells (SLEC; $KLRG1^+CD127^-$) and a lower proportion of effector cells were of a memory precursor (MPEC; $KLRG1^-CD127^+$) phenotype in CLL compared to WT mice (Fig 1B). This was associated with increased expression of the effector-related transcription factor T-bet and reduced expression of the memory-related transcription factor Bcl-6 (Fig 1C).

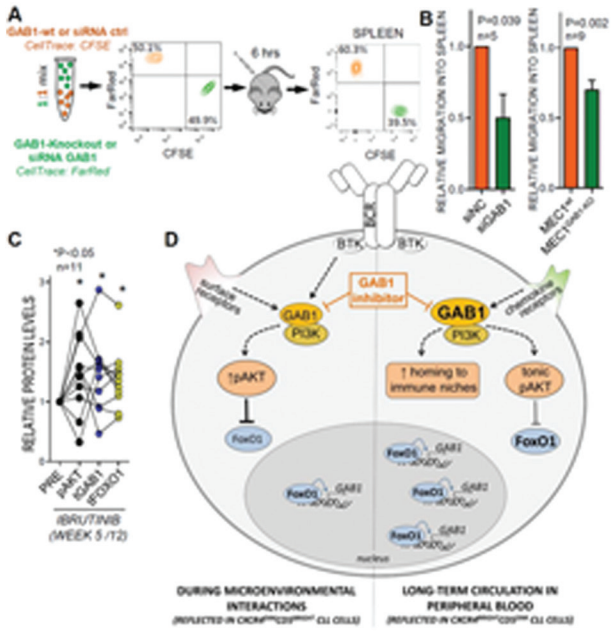
Extensive chromatin remodeling of the OT-I cells was seen in CLL mice with > 3000 differentially accessible regions (Fig 1D). Among the regions with lower chromatin accessibility were memory associated genes such as *Bach2*, *Tcf7* and *Ccr7*, whilst effector-associated genes such as *Klrg1* and *Ifng* showed more accessible chromatin in CLL mice compared to WT. Accordingly, gene set enrichment analysis revealed enrichment of a $KLRG1^{hi}$ core gene signature (Johnnidis et al., 2021) in CLL and enrichment of a $CD62L^{hi}$ core gene signature (Johnnidis et al., 2021) in WT mice (Fig 1E).

Finally, we performed a restimulation of splenic OT-I cells with OVA-peptide *in vitro*. A decrease of effector cytokine production and degranulation was observed in CLL mice derived OT-I cells, indicating reduced functionality and memory capability upon restimulation.

Summary/Conclusion: These results suggest a CLL-antigen independent effect on an acute antigen-specific immune response, driving T cells towards a skewed and functionally impaired effector phenotype, impairing long-lived early memory formation. The altered chromatin accessibility indicates that presence of CLL majorly affects the epigenome of T cells and future studies will unravel the reversibility of these profiles and the potential of the T cells to regain their normal function.

S142 FOXO1-GAB1 AXIS REGULATES HOMING CAPACITY AND TONIC AKT ACTIVITY IN CHRONIC LYMPHOCYTIC LEUKEMIA: NOVEL THERAPEUTIC TARGET

V. Seda [1,2,*], E. Vojackova [1,2], L. Ondrisova [1,2], L. Kostalova [1,2], S. Sharma [1,2], T. Loja [2], D. Zicha [3], J. Verner [1], S. Pospisilova [1], Y. Brychtova [1], A. Panovska [1], Z. Tan [4], S. Zhang [4], M. Doubek [1], J. Mayer [1], M. Mraz [1,2]



[1]Dept of Internal Medicine, Hematology and Oncology, University Hospital Brno, [2]MoI Medicine, CEITEC MU, [3]Experimental Biophotonics, CEITEC BUT, Brno, Czech Republic, [4]Department of Experimental Therapeutics, MD Anderson Cancer Center, Houston, United States

Background: CLL cell recirculation between peripheral blood and immune niches plays an important role in CLL biology. However, it remains largely unknown how precisely CLL cells regulate their homing or how they balance survival in peripheral blood and the decision to return to immune niches.

Aims: We aim to identify and functionally characterize novel regulators of CLL cell migration.

Methods: We performed transcriptome profiling (RNAseq, Illumina) of CXCR4/CD5 intraclonal CLL cell subpopulations (n=20). GAB1 function was investigated by in vitro migration assays and in vivo migration in NSG mice (*GAB1*-knockout MEC1 cells or siRNA transfected CLL cells). The adaptation to BCR inhibitors was analyzed in CLL samples obtained before and during ibrutinib therapy (pre vs. week 5-12, n=22).

Results: CXCR4/CD5 subpopulations have been suggested as a model distinguishing CLL cells ready to re-enter immune niches ($CXCR4^{bright}CD5^{dim}$) versus recent emigrants from lymph nodes ($CXCR4^{dim}CD5^{bright}$) (Calissano et al. 2011). Indeed, intravenous injection of sorted CXCR4/CD5 subpopulations into NSG mice revealed increased migration capacity of $CXCR4^{bright}CD5^{dim}$ cells into the spleen (n=6, P=0,02). Analysis of CXCR4/CD5 subpopulations by RNAseq (n=20) identified 147 migration-related differentially expressed genes, among which we noted upregulation of *GAB1* (2-fold) in $CXCR4^{bright}CD5^{dim}$ cells. GAB1 has been previously suggested as a cell migration regulator in non-immune cells (Vasyutina et al. 2005). GAB1-knockout in MEC1 B cells largely inhibited their migration capacity towards chemokines SDF1, CXCL13, or conditioned media produced by bone marrow stromal cells (CM^{hMSC}). Similar results were obtained with siRNA against *GAB1* in CLL cells (all P<0.01). Importantly, *GAB1* knockout or silencing led to clearly impaired migration of malignant B cells to the spleen of NSG mice (P<0.05, n=14; Fig.A,B). Treating cells with SDF1, CXCL13, or CM^{hMSC} led to rapid (within minutes) GAB1 phosphorylation at activating tyrosines, suggesting that GAB1 is involved in response to multiple soluble factors. We have also identified another GAB1 function in the maintenance of "tonic" AKT phosphorylation via PI3K. Next, we demonstrated that transcription factor FoxO1 induces GAB1 by direct binding to its promotor. Altogether, increased FoxO1/GAB1 levels in $CXCR4^{bright}CD5^{dim}$ CLL cells are contributing to balancing CLL cell survival and their decision to migrate into the immune niches. Notably, administration of ibrutinib therapy in CLL patients induces FoxO1-GAB1, which leads to recovery of phospho-AKT within several days-weeks on ibrutinib (Fig.C, n=11). This "compensatory" AKT activation allows CLL survival but can be therapeutically targeted by novel GAB1 inhibitors tested herein. GAB1 inhibitors can be used to induce apoptosis, inhibit CLL migration, basal AKT activity, and adaptive AKT activation during ibrutinib therapy.

Summary/Conclusion: We described a novel FoxO1/GAB1-dependent regulatory mechanism of CLL homing and maintenance mechanism for "tonic" AKT signaling activity in an intraclonal CXCR4^{bright}CD5^{dim} CLL subpopulation (Fig.D). We showed for the first time that during ibrutinib therapy, CLL cells sustain AKT activity via the FoxO1-GAB1 axis and that this could be targeted by novel GAB1 inhibitors.

Background: The introduction of next-generation sequencing (NGS) rapidly uncovered the genomic landscape of chronic lymphocytic leukemia (CLL). Using whole-genome and/or exome sequencing, a limited number of recurrently mutated genes was observed in more than 10% of patients, while a very long tail comprising hundreds of genes mutated only in a fraction of patients (<5%) has been demonstrated. Several of the more frequent gene mutations have been linked to worse outcomes with shorter time-to-first-treatment (TTFT) and overall survival.

Aims: To assess the prognostic strength of recurrent gene mutations, we collected a large, multi-center cohort including 4,674 well-characterized CLL patients [median age at diagnosis, 64.5 years; male/female, n=2,962 (63%)/n=1,712 (37%); Binet stage A (n=3,369, 74%), B (n=827, 18%), and C (n=387, 8%); IGHV-mutated (n=2,498, 56%) and IGHV-unmutated (n=1,927, 44%); del(13q) only (n=1,868, 41%), trisomy 12 (n=571, 13%), del(11q) (n=503, 11%), and del(17p) (n=249, 5.5%); treated (n=2,745, 59%) and untreated (n=1,929, 41%)].

Methods: We performed NGS and/or Sanger sequencing of 9 genes (*BIRC3, EGR2, NFKBIE, MYD88, NOTCH1, POT1, SF3B1, TP53,* and *XPO1*) on pre-treatment samples in order to study their clinical impact in CLL.

Results: Overall, mutations in any of these genes were detected in 1,720 of 4,674 patients (36.8%, using a variant allele frequency cutoff of 5% for NGS), while the remaining patients were wildtype; two mutations were seen in 361 patients (7.7%) and three or more mutations in 58 patients (1.2%). The mutation frequency for the individual genes was *TP53* (10.4%, including *TP53* mutations and/or del(17p)), *NOTCH1* (10.1%), *SF3B1* (9.3%), *XPO1* (3.9%), *POT1* (3.8%), *NFKBIE* (3.7%), *BIRC3* (3.0%), *EGR2* (2.5%) and *MYD88* (2.5%; Figure 1A). We observed that certain gene mutations appeared almost mutually exclusive, such as *BIRC3* and *SF3B1* mutations (10 *BIRC3*^{mut}/433 (2.3%) *SF3B1*^{mut} cases), and *TP53* aberrations and *XPO1* mutations (18 *XPO1*^{mut}/488 (3.7%) *TP53*^{abn} cases) or *BIRC3* mutations (14 *BIRC3*^{mut}/488 (2.9%) *TP53*^{abn} cases). Except for *MYD88*, mutations in each of the investigated genes were associated with significantly shorter TTFT in univariate analysis. On multivariable analysis (including all genes, unmutated IGHV genes, Binet stage B/C, age > median at diagnosis and male gender), *SF3B1* (Hazard Ratio 1.58; p<0.001), *EGR2* (HR 1.39; p=0.003), *XPO1* (HR 1.26; p=0.006), *BIRC3* mutations (HR 1.25; p=0.031) and *TP53* aberrations (HR 1.20; p=0.004), along with Binet stage B/C (HR 3.73; p-value <0.001) and unmutated IGHV genes (HR 2.95; p<0.001), remained as independent factors for shorter TTFT. As earlier studies have indicated different prognostic importance of genetic aberrations in IGHV-mutated (M-CLL) and IGHV-unmutated CLL (U-CLL), we next studied the impact of gene mutations in relation to IGHV gene mutation status. While *TP53* aberrations, *SF3B1* (Figure 1B) and *BIRC3* mutations were associated with a worse outcome in both U-CLL and M-CLL, *NOTCH1, POT1* and *XPO1* mutations were only linked to a worse outcome in M-CLL, whereas *EGR2* mutations correlated with a poor outcome only in U-CLL.

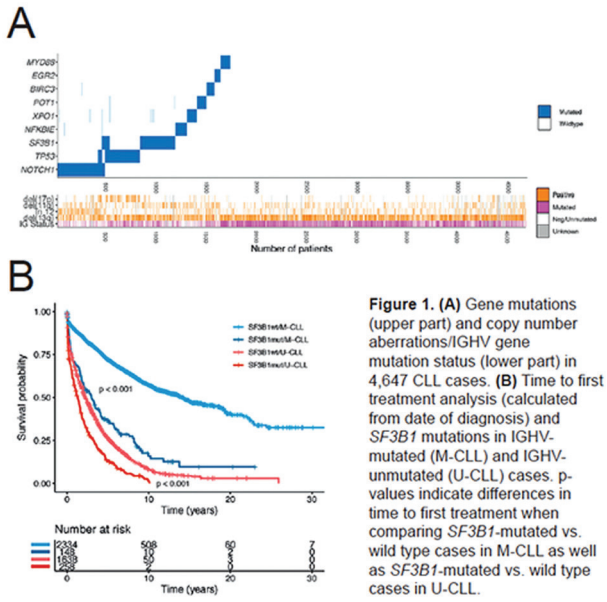

Figure 1. (A) Gene mutations (upper part) and copy number aberrations/IGHV gene mutation status (lower part) in 4,647 CLL cases. **(B)** Time to first treatment analysis (calculated from date of diagnosis) and *SF3B1* mutations in IGHV-mutated (M-CLL) and IGHV-unmutated (U-CLL) cases. p-values indicate differences in time to first treatment when comparing *SF3B1*-mutated vs. wild type cases in M-CLL as well as *SF3B1*-mutated vs. wild type cases in U-CLL.

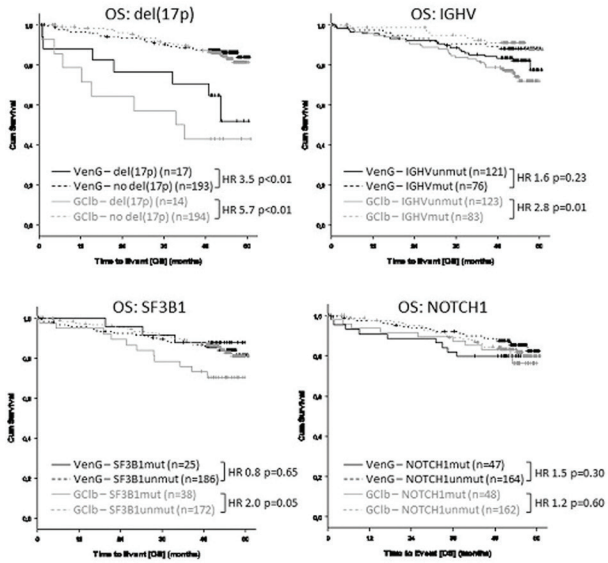
Summary/Conclusion: Based on these results, we conclude that *SF3B1, EGR2, XPO1* and *BIRC3* mutations independently predicted short



TTFT and should be considered for extended molecular testing in CLL. However, considering the different impact of gene mutations in M-CLL and U-CLL, the IGHV mutation status must be taken into account when constructing future prognostic models including recurrent gene mutations.

S144 GENETIC MARKERS AND OUTCOME IN FRONT LINE OBINUTUZUMAB PLUS CHLORAMBUCIL OR VENETOCLAX - UPDATED ANALYSIS OF THE CLL14 TRIAL

E. Tausch [1,*], C. Schneider [1], D. Yosifov [1], S. Robrecht [2], C. Zhang [2], O. Al-Sawaf [2], B. Eichhorst [2], A. -M. Fink [2], J. Bloehdorn [1], K. -A. Kreuzer [2], M. Tandon [3], Y. Jiang [4], S. Y. Kim [5], M. P. Lura [6], H. Döhner [1], K. Fischer [2], M. Hallek [2], S. Stilgenbauer [1]

[1]Department of internal medicine 3, Ulm University, Ulm, [2]Department I of Internal Medicine and Center of Integrated Oncology Aachen Bonn Cologne Duesseldorf, University Hospital Cologne, Cologne, Germany, [3]Roche Products Limited, Welwyn Garden City, United Kingdom, [4]Genentech, South San Francisco, [5]AbbVie, North Chicago, United States, [6]F. Hoffmann-La Roche Ltd, Basel, Switzerland

Background: In 2019 we provided initial analyses of the prognostic and predictive value of genomic aberrations, IGHV mutation status and gene mutations in the CLL14 trial comparing obinutuzumab+chlorambucil (GClb) vs. obinutuzumab+venetoclax (VenG) in 432 patients (1:1) with CIRS>6 and/or creatinine clearance < 70 ml/min.
Aims: This update includes a) an extended follow-up at a median of 52 months, b) assessment of the prognostic value of minor mutations with a variant allele fraction (VAF) of 2-10% c) analysis of 113 samples at relapse for acquired gene mutation in candidate genes and specific resistance mutations such as BCL2 G101V.
Methods: Genomic aberrations were assessed by FISH, IGHV by sequencing with a threshold of 98% homology and mutations via amplicon-based targeted NGS for *TP53*, *NOTCH1*, *SF3B1*, *ATM*, *MYD88*, *FBXW7*, *POT1*, *BIRC3*, *XPO1*, *NFKBIE*, *EGR2*, *RPS15* and *BCL2* in 421 of 432 (94%) patients of the full trial cohort at baseline.
Results: The prevalence of genomic aberrations considering the hierarchical model was del(17p) 7%, del(11q) 18%, +(12q) 18% and del(13q) single 35%. IGHV was unmutated in 60% of patients. The prevalence of gene mutations with a VAF>10% was *NOTCH1* 23% (exon 34, 3'UTR), *SF3B1* 15%, *ATM* 13%, *TP53* 10%, *XPO1* 6%, *RPS15* 5%, *POT1* 5%, *BRAF*, *BIRC3*, *NFKBIE*, *EGR2*, *MYD88* and *FBXW7* (all <5%). Minor mutations (VAF 2-10%) occurred in *BIRC3* with an incidence of 5%, *NOTCH1* 5%, *SF3B1* 5%, *ATM* 4% and *TP53* 3%.
At a median follow-up of 52 months, 199 events for PFS and 75 for OS occurred in the ITT population.
VenG was superior to GClb regarding PFS in most genetic subgroups including del(17p) and mutated and unmutated IGHV (p<0.001).
For GClb del(17p) (HR 3.2, p<0.001), del(11q) (HR 1.84, p<0.01) and mutations in *ATM* (HR 1.8, p=0.01), *BIRC3* (HR 3.0, p<0.01), *NOTCH1* (HR 1.7, p<0.01) and *SF3B1* (HR 1.6, p=0.03) were associated with short PFS, while for VenG del(17p) (HR 3.2, p=0.001) and mutated *TP53* (HR 2.4, p<0.01) remained prognostic factors. Minor *TP53* mutations did not affect outcome, however, minor mutations in *NOTCH1* reduced PFS with GClb significantly (HR 2.1, p=0.02). Unmutated IGHV was prognostic with GClb (HR 3.1, p<0.001) and VenG (HR 2.1, p=0.02) treatment.
Overall survival (OS) was shorter with del(17p) and *TP53* mutation in both treatment arms (GClb: HR 5.7 and HR 3.1, VenG: HR 3.5 and HR 3.0, all p<0.01) and with mutated *SF3B1* (HR 2.0, p=0.05) and unmutated IGHV (HR 2.8, p=0.01) in the GClb arm, while none of the other factors were significantly associated with OS. In multivariate analysis, GClb therapy, high risk for tumor lysis (TLS), IGHV mutation status, del(17p), complex karyotype and *BIRC3* mutations were independent prognostic factors for PFS, while age, b2MG and del(17p) retained independent significance for OS.
Comparative analysis of 88 paired samples at baseline and relapse after GClb revealed acquisition of high risk variants such as *TP53* (n=4), *BIRC3* (5), *SF3B1* (3) and *RPS15* (1). Among 25 paired samples before and after VenG, a single variant was found each in *TP53* and *BIRC3*. Of note, none of the 25 relapse samples from the VenG treatment arm had acquired mutations in BCL2 at a detection limit of 2% VAF.

Summary/Conclusion: At a median follow up of 52 months, IGHV mutation status and del(17p) proved to be prognostic with VenG and GClb, while none of the other prognostic factors besides *TP53* affected outcome with VenG. After time limited VenG no BCL2 resistance mutations were identified at relapse supporting re-treatment concepts.

Clinical trials with targeted therapies in CLL

S145 FIRST RESULTS OF A HEAD-TO-HEAD TRIAL OF ACALABRUTINIB VERSUS IBRUTINIB IN PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA

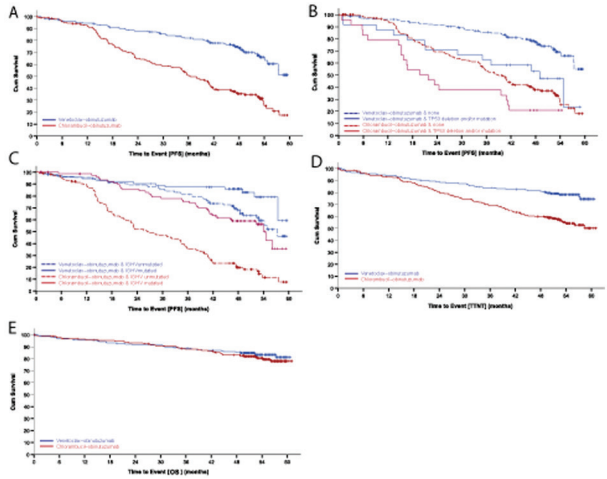
Background: The Bruton tyrosine kinase (BTK) inhibitor acalabrutinib is more selective than ibrutinib, which may improve tolerability.
Aims: We conducted an open-label, randomized, noninferiority, phase 3 trial to compare acalabrutinib and ibrutinib in patients with previously treated chronic lymphocytic leukemia (CLL).
Methods: Patients with previously treated CLL who had del(17p) or del(11q) by central lab were randomized to receive acalabrutinib 100 mg orally twice daily or ibrutinib 420 mg orally once daily until progression or unacceptable toxicity. Randomization was stratified by del(17p) status, Eastern Cooperative Oncology Group performance status (2 vs ≤1), and number of prior therapies (1–3 vs ≥4). The primary endpoint was progression-free survival as assessed by independent review committee; secondary endpoints of all grade atrial fibrillation, grade ≥3 infection, Richter transformation, and overall survival were assessed in hierarchical order. Informed consent was obtained from all patients prior to trial enrollment.

Results: A total of 533 patients (acalabrutinib, n=268; ibrutinib, n=265) were randomized. Patients had a median age of 66 years and had received a median of 2 prior therapies; 45.2% of patients had del(17p), and 64.2% had del(11q). At a median follow-up of 40.9 months (range, 0.0–59.1), acalabrutinib demonstrated noninferiority to ibrutinib, with a median progression-free survival of 38.4 months in both arms (hazard ratio [HR], 1.00; 95% CI, 0.79–1.27). Acalabrutinib was statistically superior to ibrutinib in the incidence of all-grade atrial fibrillation (9.4% vs 16.0%; *P*=0.023). Among the other secondary endpoints, incidences of grade ≥3 infection (acalabrutinib: 30.8%, ibrutinib: 30.0%) and Richter transformation (acalabrutinib: 3.8%, ibrutinib: 4.9%) were comparable between the treatment arms. Median overall survival was not reached in either arm (HR, 0.82; 95% CI, 0.59–1.15), with 63 (23.5%) deaths in the acalabrutinib arm and 73 (27.5%) in the ibrutinib arm. Among any-grade adverse events occurring in ≥20% of patients in either arm, acalabrutinib was associated with a lower incidence of hypertension (9.4%, 23.2%), arthralgia (15.8%, 22.8%), and diarrhea (34.6%, 46.0%) but a higher incidence of headache (34.6%, 20.2%) and cough (28.9%, 21.3%). Adverse events led to treatment discontinuation in 14.7% of acalabrutinib-treated patients compared with 21.3% of ibrutinib-treated patients. Among any-grade events of clinical interest, cardiac events, hypertension, and bleeding events were less frequent with acalabrutinib (Table).

Table. Selected events of clinical interest

	Acalabrutinib (n=266)		Ibrutinib (n=263)	
Events, n (%)	Any grade	Grade ≥3	Any grade	Grade ≥3
Cardiac events	64 (24.1)	23 (8.6)	79 (30.0)	25 (9.5)
Atrial fibrillation[a]	25 (9.4)	13 (4.9)	42 (16.0)	10 (3.8)
Ventricular tachyarrhythmias	0	0	1 (0.4)	1 (0.4)
Hypertension[b]	25 (9.4)	11 (4.1)	61 (23.2)	24 (9.1)
Bleeding events	101 (38.0)	10 (3.8)	135 (51.3)	12 (4.6)
Major bleeding events[c]	12 (4.5)	10 (3.8)	14 (5.3)	12 (4.6)
Infections	208 (78.2)	82 (30.8)	214 (81.4)	79 (30.0)
Second primary malignancies excluding non-melanoma skin cancers	24 (9.0)	16 (6.0)	20 (7.6)	14 (5.3)

[a]Includes preferred terms of atrial fibrillation and atrial flutter
[b]Includes preferred terms of hypertension, blood pressure increased, and blood pressure systolic increased
[c]Any hemorrhagic event that was serious, grade ≥3, or a central nervous system hemorrhage (any grade)



Summary/Conclusion: In this first head-to-head trial of BTK inhibitors in patients with previously treated CLL, acalabrutinib demonstrated non-inferior progression-free survival with less cardiotoxicity and fewer discontinuations due to adverse events compared with ibrutinib.

S146 VENETOCLAX-OBINUTUZUMAB FOR PREVIOUSLY UNTREATED CHRONIC LYMPHOCYTIC LEUKEMIA: 4-YEAR FOLLOW-UP ANALYSIS OF THE RANDOMIZED CLL14 STUDY

O. Al-Sawaf [1,*], C. Zhang [1], S. Robrecht [2], M. Tandon [3], A. Panchal [3], A. Fink [1], E. Tausch [4], M. Ritgen [5], K. Kreuzer [1], S. Kim [6], C. Wendtner [7], B. Eichhorst [1], S. Stilgenbauer [4], Y. Jiang [8], M. Hallek [1], K. Fischer [1]

[1]Department I of Internal Medicine and Center of Integrated Oncology Aachen Cologne Bonn Duesseldorf, [2]University Hospital of Cologne, Cologne, Germany, [3]Roche Products Limited, Welwyn Garden City, United Kingdom, [4]Department III of Internal Medicine, University Hospital Ulm, Ulm, [5]Department II of Internal Medicine, University of Schleswig-Holstein, Kiel, Germany, [6]AbbVie, Inc, Chicago, United States, [7]Department of Hematology, Oncology, Immunology, Palliative Care, Infectious Diseases and Tropical Medicine, Klinikum Schwabing, Munich, Germany, [8]Genentech, San Francisco Bay, United States

Background: The CLL14 study showed significant improvement of progression-free survival (PFS) with venetoclax-obinutuzumab (Ven-Obi) as compared to chlorambucil-obinutuzumab (Clb-Obi) in patients (pts) with previously untreated chronic lymphocytic leukemia (CLL) and coexisting conditions. High rates of undetectable minimal residual disease (uMRD) have been observed after one year fixed-duration treatment with Ven-Obi, suggesting deep remissions and feasibility of the fixed-duration concept with targeted agents for CLL.
Aims: The aim of this report is to provide updated efficacy and safety data from the ongoing follow-up of the CLL14 study with now all pts being off study treatment for at least 3 years.
Methods: Pts with previously untreated CLL and coexisting conditions were randomized 1:1 to receive 12 cycles of venetoclax with 6 cycles of obinutuzumab or 12 cycles of chlorambucil with 6 cycles of obinutuzumab. Primary endpoint was investigator-assessed PFS. Key secondary endpoints were safety, response rates, rates of minimal residual disease (MRD)(measured every 3-6 months up to 5 years after last patient enrolment) and overall survival. Follow-up is ongoing, but all pts are off study treatment. This trial was registered with ClinicalTrials.gov, number NCT02242942.
Results: Of the 432 enrolled pts, 216 were randomly assigned to receive Ven-Obi and 216 to receive Clb-Obi. After a median follow-up of 52.4 months (interquartile range 49.5-56.2), PFS continued to be superior for Ven-Obi as compared to Clb-Obi (median not reached (nr) vs. 36.4 months; hazard ratio [HR] 0.33 [95% CI 0.25-0.45], p<0.0001)(Fig A). At 4 years after randomization, the estimated PFS rate was 74.0% in the Ven-Obi arm and 35.4% in the Clb-Obi arm. This improvement was observed across all clinical and biological risk groups, including pts with TP53 mutation/deletion (4-year PFS 53.0% vs 20.8%) and unmutated IGHV status (4-year PFS 68.0% vs 19.8%)(Fig B,C). Overall, 35 disease progressions in the Ven-Obi arm have been observed, compared to 122 in the Clb-Obi arm. Time to next treatment was significantly longer in the Ven-Obi arm (4-year TTNT 81.1% vs 59.9%; HR 0.46, 95% CI [0.32-0.65], p<0.0001)(Fig D). The majority of pts received and responded to BTK inhibitor monotherapy as a second-line treatment after progressive disease in both arms (57.1% in Ven-Obi arm, 55.6% in Clb-Obi arm).
Assessment of MRD by next-generation sequencing in peripheral blood 30 months after the end of treatment (EoT) showed that 26.9% of pts in the Ven-Obi arm still had uMRD ($<10^{-4}$), 21.8% had low (L)-MRD ($\geq 10^{-4}$ and $< 10^{-2}$) and 13.4% high (H)-MRD ($\geq 10^{-2}$), compared to 3.2% uMRD, 8.8%% L-MRD, 28.2% H-MRD in the Clb-Obi arm.
No difference in overall survival has been observed between the Ven-Obi and Clb-Obi arm; at 4 years 85.4% pts were alive in the Ven-Obi arm and 83.1% in the Clb-Obi arm (HR 0.85 [0.54-1.35], p=0.49)(Fig E). Second primary malignancies were reported in 40 (18.9%) pts in the Ven-Obi arm and 30 (14.0%) in the Clb-Obi arm. No new safety signals were observed.

Summary/Conclusion: The four-year follow-up confirms the superior efficacy with longer PFS and deep remissions after fixed-duration Ven-Obi compared to Clb-Obi. The majority of pts remains without relapse three years after completing Ven-Obi treatment. Although adverse features such as TP53 mutation/deletion were not fully mitigated, fixed-duration Ven-Obi continues to be an effective treatment for all pts with CLL and with coexisting conditions.

S147 PRIMARY ANALYSIS OF THE FIXED-DURATION COHORT FROM THE PHASE 2 CAPTIVATE STUDY OF FIRST-LINE IBRUTINIB + VENETOCLAX FOR CHRONIC LYMPHOCYTIC LEUKEMIA/SMALL LYMPHOCYTIC LYMPHOMA

Background: Ibrutinib (Ibr) + venetoclax (Ven) have synergistic and complementary antitumor activity that mobilizes and clears chronic lymphocytic leukemia (CLL) cells from multiple disease compartments, providing a rationale to evaluate time-limited treatment. We previously reported results from the Minimal Residual Disease (MRD) cohort of the multicenter phase 2 CAPTIVATE study of first-line Ibr + Ven in patients with CLL/small lymphocytic lymphoma (SLL). In that cohort, undetectable MRD (uMRD) was achieved in over two-thirds of patients (pts) with 12 cycles of Ibr + Ven; 30-month progression-free survival (PFS) rates were ≥95% irrespective of subsequent randomized treatment (Wierda, ASH 2020).
Aims: Here we present results from the fixed-duration (FD) cohort, evaluating fixed-duration treatment with Ibr + Ven.
Methods: Eligible patients were aged ≤70 y with previously untreated CLL/SLL. Patients received 3 cycles of Ibr lead-in followed by 12 cycles of Ibr + Ven (Ibr 420 mg/d orally; Ven ramp-up to 400 mg/d orally). The primary endpoint was complete response (CR) rate, including CR with incomplete recovery (CRi); secondary endpoints were overall response rate (ORR), duration of response, uMRD rate ($<10^{-4}$ by 8-color flow cytometry), PFS, overall survival (OS), tumor lysis syndrome (TLS) risk reduction, and adverse events (AEs).
Results: Overall,159 patients were enrolled; median age was 60 y. High-risk features included del(17p)/*TP53* mutation (17%), del(11q) (18%), complex karyotype (19%), and unmutated IGHV (56%). 147/159 (92%) patients completed planned treatment with Ibr, and 149/159 (94%) patients completed planned treatment with Ven. Median time on study was 27.9 months (range 0.8–33.2). With fixed-duration Ibr + Ven, 55% of patients in the overall population achieved a CR; the CR rate was consistent across high-risk subgroups. Of 88 patients who achieved CR, durable CR (duration ≥1 y from initial documentation of response) was confirmed in 78 patients (89%); an additional 9 patients (10%) were not yet evaluable with <1 y of post-CR follow-up and 1 pt died 7 months after achieving a CR. ORR was 96%. Best MRD response of uMRD was achieved in peripheral blood (PB) of 77% of patients and in bone marrow (BM) of 60% of patients. 24-month PFS and OS rates were 95% and 98%, respectively. Similar results were achieved in patients without del(17p) (n=136) (Table). In patients with del(17p)/*TP53* mutation (n=27), the CR rate was 56%, uMRD rates were 81% (PB) and 41% (BM), and the 24-month PFS rate was 84% (95% CI 63%–94%). Of 34 patients with high baseline TLS risk based on tumor burden, 32 (94%) shifted to medium or low risk after Ibr lead-in; no TLS occurred. AEs were primarily grade 1/2. The most common grade 3/4 AEs were neutropenia (33%), hypertension (6%), and decreased neutrophil count (5%). AEs led to discontinuation of Ibr in 4% of patients and to discontinuation of Ven in 2% of patients.

Table. Efficacy outcomes

	Patients without del(17p) n=136	All patients N=159
CR/CRi, n (%)	76 (56)	88 (55)
Durable CR/CRi ≥1 y, n/N (%)*	66/76 (87)	78/88 (89)
ORR, n (%)	130 (96)	153 (96)
uMRD in PB, n (%)	104 (76)	122 (77)
uMRD in BM, n (%)	84 (62)	95 (60)
24-month PFS rate, % (95% CI)	96 (91-98)	95 (90-97)
24-month OS rate, % (95% CI)	98 (93-99)	98 (94-99)

*Denominator is patients with CR/CRi.

Summary/Conclusion: First-line Ibr + Ven is an all-oral, once-daily, chemotherapy-free fixed-duration regimen that provides deep, durable responses in patients with CLL/SLL. Overall, CR, uMRD rates, PFS, and OS appear favorable, and benefit was observed regardless of genomic high-risk features. No new safety signals were identified, and the safety profile of Ibr + Ven was consistent with known safety profiles of each agent.

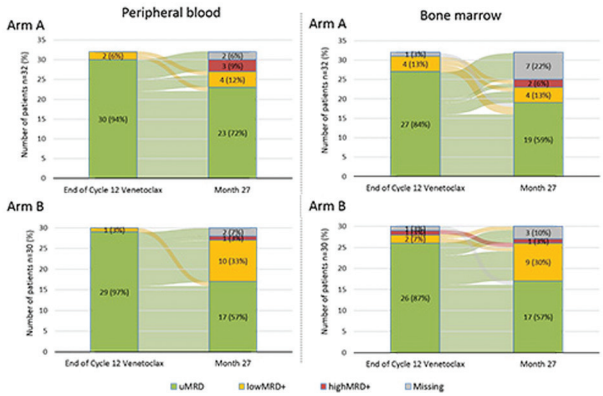
Background: Early results from ELEVATE-TN (NCT02475681) at a median follow-up of 28.3 months demonstrated superior efficacy of acalabrutinib (A) ± obinutuzumab (O) compared with O + chlorambucil (Clb) in patients with treatment-naïve (TN) chronic lymphocytic leukemia (CLL) (Sharman et al. Lancet 2020;395:1278-91).
Aims: To report the updated efficacy and safety results from the ELEVATE-TN study after a median follow-up duration of 4 years.
Methods: Patients received A±O or O+Clb. Crossover to A monotherapy was permitted in patients who progressed on O+Clb. Investigator-assessed (INV) progression-free survival (PFS), INV overall response rate (ORR), overall survival (OS), and safety were evaluated. Informed consent was obtained from all patients prior to trial enrollment.
Results: A total of 535 patients (A+O, n=179; A, n=179; O+Clb, n=177) were randomized. The median patient age was 70 years; 63% of patients had unmutated IGHV and 9% had del(17p). At a median follow-up of 46.9 months (range, 0.0–59.4; data cutoff: Sept 11, 2020), the median PFS was not reached (NR) for A+O and A patients versus 27.8 months for O+Clb patients (both $P<0.0001$). In patients with unmutated IGHV, the median PFS was NR (A+O and A) versus 22.2 months among O+Clb patients (both $P<0.0001$). In patients with del(17p), the median PFS was NR (A+O and A) versus 17.7 months for O+Clb ($P<0.005$). Estimated 48-month PFS rates were 87% for A+O, 78% for A, and 25% for O+Clb. Median OS was NR in any treatment arm with a trend towards significance in the A+O group (A+O vs O+Clb, $P=0.0604$); estimated 48-month OS rates were 93% (A+O), 88% (A), and 88% (O+Clb). ORR was significantly higher with A+O (96.1%; 95% CI 92.1–98.1) versus O+Clb (82.5%; 95% CI 76.2–87.4; $P<0.0001$); ORR with A was 89.9% (95% CI 84.7–93.5; $P=0.035$ vs O+Clb). Complete response/complete response with incomplete hematologic recovery (CR/CRi) rates were higher with A+O (26.8%/3.9%) versus O+Clb (12.4%/0.6%); 10.6%/0.6% had CR/CRi with A. Common adverse events (AEs) and AEs of interest are shown in the Table. Overall treatment discontinuation rates were 25.1% (A+O), 30.7% (A), and 22.6% (O+Clb); the most common reasons were AEs (12.8%, 12.3%, 14.7%, respectively) and progressive disease (4.5%, 7.8%, 1.7%). Most patients (77.4%) completed O+Clb treatment.

	A+O (n=178)		A (n=179)		O+Clb (n=169)	
	Any grade	G≥3	Any grade	G≥3	Any grade	G≥3
Common AEs (in ≥30% of patients [any grade] in any group), n (%)						
Diarrhea	73 (41.0)	9 (5.1)	72 (40.2)	1 (0.6)	36 (21.3)	3 (1.8)
Headache	71 (39.9)	2 (1.1)	68 (38.0)	2 (1.1)	20 (11.8)	0
Neutropenia	60 (33.7)	55 (30.9)	22 (12.3)	20 (11.2)	76 (45.0)	70 (41.4)
Nausea	41 (23.0)	0	41 (22.9)	0	53 (31.4)	0
Infusion-related reaction	25 (14.0)	5 (2.8)	0	0	68 (40.2)	10 (5.9)
Selected AEs of interest, n (%)						
Bleeding	84 (47.2)	5 (2.8)	75 (41.9)	5 (2.8)	20 (11.8)	0
Hypertension	14 (7.9)	6 (3.4)	13 (7.3)	5 (2.8)	7 (4.1)	6 (3.6)
Atrial fibrillation	7 (3.9)	1 (0.6)	11 (6.1)	2 (1.1)	1 (0.6)	0

Summary/Conclusion: With a median follow-up of 46.9 months (~4 years) in the ELEVATE-TN study, the efficacy and safety of A+O and A monotherapy was maintained, with an increase in CR since the interim analysis (from 21% to 27% [A+O] and from 7% to 11% [A]) and low rates of discontinuation.



S149 MRD-GUIDED OR FIXED 12 CYCLES OF VENETOCLAX CONSOLIDATION AFTER VENETOCLAX PLUS OBINUTUZUMAB TREATMENT IN FIRST-LINE FCR UNFIT PATIENTS WITH CLL: PRIMARY ENDPOINT ANALYSIS OF THE HOVON 139/GIVE TRIAL

Background: Fixed duration treatment of chronic lymphocytic leukemia (CLL) patients with venetoclax (V) combined with anti-CD20 antibody both in 1st-line (12 cycles) and relapsed / refractory (RR) (24 cycles) results in high rates of undetectable minimal residual disease (uMRD) and prolonged PFS. The benefit of consolidation treatment in 1st-line patients after Obinutuzumab (O)-V is currently unknown.
Aims: Primary endpoint analysis of a phase 2 randomized trial in 1st-line FCR unfit CLL patients treated with standard O-V, randomized to standard or MRD-based addition of V for 12 cycles.
Methods: FCR-unfit treatment naïve CLL patients with treatment indication according to IWCLL were eligble. Treatment consisted of 4 treatment phases: two cycles of O; 6 cycles of O+V (IND-1); 6 cycles V (IND-2); and a 1:1 randomization phase: maintenance with 12 cycles of V irrespective of MRD (arm A) or MRD guided V maintenance (treatment limited to patients with no uMRD after IND-2 with 12 cycles of V, arm B). MRD was centrally assessed by flow cytometry in bone marrow (BM) after 12 and 24 cycles and in blood (PB) at screening, cycle 6 and 12 and every 3 months thereafter until month 27. Complex genotype (CG), ≥ 3 CNV, was assessed by CGH-array. The primary endpoint was uMRD (<1:10.000 leukocytes by flowcytometry) in BM and no progression after a maximum of 24 cycles of V.

Results: In total, 70 patients were enrolled, of whom 3 were post-hoc excluded because of not fulfilling the diagnosis of CLL. Baseline characteristics were 70% male, median age 71 years (range 57-89 years), 49% unmutated IgVH, 13% del 17p/TP53 and 22% CG. The primary endpoint was reached in 53% and 57% of patients in arm A and arm B, respectively, therefore both arms reached the pre-set requirements. In PB, uMRD and no progression was established in 59% and 57% of patients, respectively. After 2 cycles of O ORR was 43% which improved to 94% (31% CR) after IND-2 (no PD). At the primary endpoint ORR was 88% (16 CR, 3 PD) in arm A versus 97% (19 CR, 1 PD) in arm B. Grade 2, 3, 4 and 5 AE were established 14, 35, 17, 1 times before randomization; 14, 6, 2, 0 times in arm A and 7, 4, 0, 0 in arm B, mainly hematological and infections. Two cycles of O reduced the TLS risk from 28 and 60% to 1 and 15% (high and medium TLS risk, respectively). O was stopped in 4 patients during IND-1 because of mainly hematologic toxicity and 4 patients stopped V, while 22 patients received G-CSF and 17 patients rasburicase. During IND-2 1 patient stopped V, while 14 patients received G-CSF. Five patients were not randomized due to death (1), refusal to continue (1) and excessive toxicity (3). Finally 62 patients underwent randomization, 32 to fixed V and 30 to MRD-guided V treatment (of whom only 2 patients received V due to no uMRD). uMRD in BM was found in 79% after IND-2; and at primary endpoint in arm A 59% and 57% in arm B. uMRD in PB was found in 88% after IND-2, and at primary endpoint 72% and 57% in arm A and arm B, respectively (Figure 1). Estimated overal survival at 48 months was 94%. MRD positive disease was not found more frequently in patients with high-risk baseline characteristics (unmutated IGVH, del17p/TP53mut, CG).

Summary/Conclusion: In this phase 2 study we confirm that treatment with O-V is well tolerated in FCR-unfit patients and both fixed duration V and MRD-guided V consolidation resulted in > 50% of patients with uMRD and without progression after a maximum of 24 cycles of V, which warrants further study of MRD-guided or fixed consolidation treatment after O-V induction.

Response, resistance and treatment-free remission in CML

S150 LOSS OF G0/G1 SWITCH GENE 2 (G0S2) IN CML PROMOTES TKI RESISTANCE BY DEREGULATING THE MITOCHONDRIAL ELECTRON TRANSPORT CHAIN.

M. Gonzalez [1,*], A. Bencomo-Alvarez [1], A. Rubio [1], S. Dang [2], C. Barreto-Vargas [3], I. Olivas [2], S. Glovier [2], J. Lara [4], D. Yan [5], A. Senina [5], J. Ahman [5], K. Varley [5], C. Mason [5], C. Eide [6], B. Druker [6], A. Eiring [1,2,4]

[1]Molecular and Translational Medicine, [2]Graduate School of Biomedical Sciences, Texas Tech University Health Sciences Center, El Paso, United States, [3]Immunology Division, University of Guadalajara, Guadalajara, Mexico, [4]Paul L. Foster School of Medicine, Texas Tech University Health Sciences Center, El Paso, [5]Huntsman Cancer Institute, The University of Utah, Salt Lake City, [6]Knight Cancer Institute, Oregon Health & Science University, Portland, United States

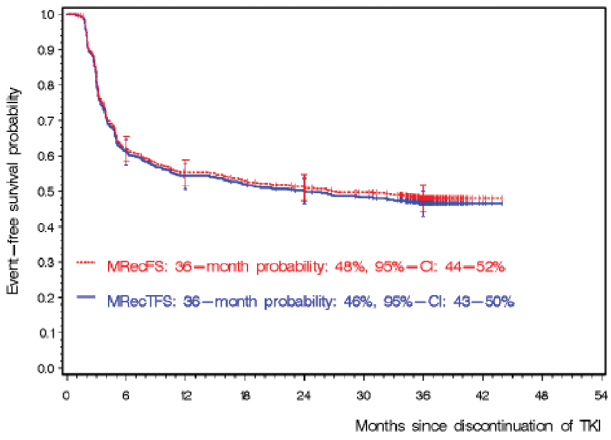
Background: Chronic myeloid leukemia (CML) was turned from a fatal to a chronic disease with the use of tyrosine kinase inhibitors (TKIs) targeting BCR-ABL1. Despite these advances, clinical resistance is a problem, as TKIs do not target the CML leukemic stem cell (LSC), which are independent from BCR-ABL1 kinase activity. Microarray data on TKI-naïve versus TKI-resistant CML patients, after 12 months of therapy,

revealed that mRNA encoding G0/G1 switch gene 2 (G0S2) is downregulated in TKI resistance (>3-fold, p<0.02).
Aims: Identify the mechanism by which G0S2 is downregulated in CML and how it contributes to TKI resistance.
Methods: To assess the functional role of G0S2 in CML and TKI resistance, we used ectopic G0S2 expression and shRNA-mediated G0S2 knockdown in CML cell lines and CD34$^+$ cells from chronic phase (CP-CML) and blast phase (BP-CML) CML patients. The consequence of altered G0S2 expression was measured using colony formation assays, apoptosis assays, and subcutaneous injection into immunocompromised mice. The effect of G0S2 on mitochondrial respiration was identified with RNA sequencing (RNAseq) and metabolomics analyses.
Results: G0S2 mRNA and protein were downregulated in CML CD34$^+$ cells compared with normal cord blood CD34$^+$ cells (p=0.0043), and further downregulated in samples from BP-CML (p=0.0079) and TKI-resistant (p=0.0357) patients. Low levels of *G0S2* correlated with a worse overall survival (n=35, p=0.036) in CP-CML. We observed lower *G0S2* mRNA expression in primitive, TKI-resistant CD34$^+$38$^-$ LSCs compared with more committed CD34$^+$38$^+$ progenitor cells in CML (n=6, p<0.01), and in granulocyte-macrophage progenitors (GMPs) from CML versus normal CD34$^+$ cells (p=0.044). Loss of G0S2 expression in CML was not affected by TKI treatment, and thus occurs in a BCR-ABL1-independent manner. G0S2 ectopic expression significantly reduced colony formation of TKI-sensitive and TKI-resistant K562 cells, and in CD34$^+$ cells from both CP-CML and BP-CML patients. While ectopic G0S2 alone did not alter apoptosis, it restored imatinib-mediated apoptosis in BP-CML CD34$^+$ cells (p<0.05). Consistently, ectopic G0S2 reduced *in vivo* subcutaneous tumor growth of K562 cells injected into nude mice. ShRNA-mediated G0S2 knockdown, conversely, enhanced survival of CML cell lines in the presence and absence of imatinib. DNA bisulfite conversion and patch PCR sequencing on primary CML CD34$^+$ cells revealed that G0S2 downregulation was not due to promoter hypermethylation. Rather, ChIP-PCR revealed the presence of MYC/MAX at the *G0S2* promoter in CML, suggesting MYC-mediated transcriptional repression. Accordingly, ectopic MYC resulted in rapid downregulation of G0S2 mRNA and protein in CML cell lines. G0S2 has been shown to inhibit adipocyte triglyceride lipase (ATGL), the rate-limiting enzyme in intracellular lipolysis. However, ectopic G0S2 impaired survival even in the presence of ATGL knockdown. RNAseq and metabolomics data suggest that reduced G0S2 expression in CML results in deregulation of the mitochondrial ETC. This has implications for TKI response, as CML LSCs were shown to be more dependent on oxidative phosphorylation than their normal counterparts, which could serve as a novel target for therapy.
Summary/Conclusion: Altogether, our data suggest that MYC-mediated G0S2 downregulation contributes to TKI resistance and blastic transformation of CML. Restoring G0S2 expression could have clinical utility by reestablishing TKI sensitivity in TKI-resistant patients and altering mitochondrial metabolism.

S151 MITOCHONDRIAL DNA MUTATIONS ARE ASSOCIATED WITH RESPONSE TO IMATINIB IN CHRONIC MYELOID LEUKAEMIA PATIENTS

I. S. Pagani [1,2,3,*], C. H. Kok [3], P. Dang [3], K. Lim [2], V. A. Saunders [3], M. Hughes [3], M. M. Kutyna [3], D. K. Hiwase [4], D. T. Yeung [4], D. Thomas [2], T. P. Hughes [3], D. M. Ross [4]

[1]Australasian Leukaemia and Lymphoma Group, Melbourne, [2]School of Medicine, Faculty of Health Sciences, The University of Adelaide, [3]Cancer Program, Precision Medicine Theme, South Australian Health and Medical Research Institute, SAHMRI, [4]Department of Haematology and Bone Marrow Transplantation, Royal Adelaide Hospital and SA Pathology, Adelaide, Australia



Background: More than 20% of chronic myeloid leukaemia (CML) patients are resistant to first-line therapy with tyrosine kinase inhibitors (TKIs), with some of them developing fatal blast crisis. Even when treatment is effective most patients require lifelong TKI therapy. New therapies are therefore needed. Metabolic reprogramming is one of the earliest hallmarks of cancer and the identification of deregulated metabolic pathways offers new approaches to target cancer cells. Mitochondrial (mt) metabolism, in particular, may play a key role in controlling survival and proliferation of cancer stem cells and conferring resistance to apoptosis.
Aims: We hypothesize that mtDNA mutations could affect mt function, leading to reduced respiration (oxidative phosphorylation, OXPHOS) and increased sensitivity to TKIs. The role of mutations in mitochondrial-encoded electron transport chain genes has not been elucidated in CML. Therefore, the aim of our work was to investigate the genomic landscape of mtDNA mutations in CML and their association with response to TKIs.
Methods: We sequenced the mt genome of 80 CML patients from the ALLG Tidel I and II trials. Follow-up samples after 12 months of imatinib therapy were used as the inferred germline to identify mtDNA somatic mutations at diagnosis (*Pagani IS, et al 2016*). Patients not achieving major molecular response (*BCR-ABL1* <= 0.1% IS) at 12 months were defined as poor responders (PR). The oxygen consumption rate of primary CML CD34+ cells was measured using the Seahorse XF96 analyser to evaluate OXPHOS function.
Results: We identified 142 mtDNA somatic point mutations in 31/41 (78%) good responders (GR) at diagnosis (median 3 per patient, range 1-21), and 49 mutations in 30/39 (77%) PR (median 1 per patient, range 1-3) (P=0.041). Interestingly, 4 GR patients showed hypermutated sites with a larger number of mtDNA somatic mutations (>11) than expected from the background distribution. The median variant allele frequency (VAF) was 96.6% (range 3.5-100%), with 2 patients carrying 29 homoplasmic mutations (VAF>98%). The remaining GR patients had mutations with a median VAF of 8% (range 2.1-90.8%). All mtDNA somatic point mutations found in PR were heteroplasmic (median 6.6%, range 2-87.2%). Patients with 3 or more mtDNA somatic point mutations more often achieved MMR (90% vs 68%, P=0.0038) and MR$^{4.5}$ (*BCR-ABL1*<0.0032% IS; 63% vs 37%, P=0.011) at 24 months of therapy than did patients with <3 mutations. There was no correlation between Sokal or EUTOS score and the number of mutations.
A limited number of patients had cryovials available for analysis of the mt respiration in CD34+ cells. Four GR had a range of 1-12 mtDNA mutations per patient with median VAF 61.8% (range 5.8-97.1%), and 5 PR had 0-2 mtDNA mutations per patient with median VAF of 5.5% (range 4.2-6.1%). GR had lower maximal respiration (median 115.9 pmol/min, range 76.6-149.7) than PR (median 199.7 pmol/min, range 170.9-222.4; P=0.0055).
Summary/Conclusion: A greater number of mtDNA mutations was associated with a better molecular response in imatinib-treated patients. In a small number of patients we found that mtDNA mutations with a higher VAF were associated with impaired OXPHOS in CD34+ cells at diagnosis. We hypothesize that reduced OXPHOS may sensitize the leukemic cells to imatinib. Functional studies are ongoing.

S152 FINAL ANALYSIS OF A PAN EUROPEAN STOP TYROSINE KINASE INHIBITOR TRIAL IN CHRONIC MYELOID LEUKEMIA: THE EURO-SKI STUDY

S. Saussele [1,*], J. Richter [2], A. Hochhaus [3], P. Panayiotidis [4], A. Almeida [5], J. Mayer [6], H. Hjorth-Hansen [7], J. J. W. M. Janssen [8], S. Mustjoki [9,10], J. Martinez-Lopez [11], H. Background: With the introduction of tyrosine kinase inhibitors (TKIs) for the treatment of chronic myeloid leukaemia (CML), treatment cessation has become a realistic therapy goal for some CML patients. Around 40-60% of patients with stable DMR [deep molecular response, corresponding to <0.01% BCR-ABL (IS)] can stop the TKI successfully, e.g. in accordance with the recommendations given by the European LeukemiaNet. In the interim analysis of the first 200 patients of the EURO-SKI (European stop TKI) trial, 62% were in major molecular response (MMR: <0.1% BCR-ABL1 IS) or better at 6 months. DMR duration prior to TKI stop was most predictive for maintenance of MMR. Here we present the final analysis of the EURO-SKI trial after 3 years of follow-up.
Aims: The EURO-SKI trial was set up to define prognostic markers to increase the rate of patients in durable deep MR after stopping TKI. Further aims are the evaluation of harmonized methods of molecular monitoring, and assessment of prognostic factors.
Methods: Adult CML patients in chronic phase CML on TKI treatment in confirmed DMR for at least one year (>4 log reduction on TKI therapy for >12 months confirmed by three consecutive PCR tests) and under TKI treatment for at least 3 years were eligible. DMR confirmation was performed in standardized laboratories. Primary endpoint was maintenance of MMR after stopping TKI. According to protocol, a 36 months follow-up was planned. The null hypotheses were that MMR maintenance at 6 and 36 months was less or equal 40% and less or equal 35%, respectively.
Results: Between May 30, 2012 and December 03, 2014, 868 CP CML patients were pre-registered by 61 European centres from 11 countries. 140 pts were excluded (consent withdrawal n=1, protocol violation n=38, not eligible n=74 DMR not confirmed n=11, atypical or unknown transcript n=15, missing data n=1) resulting in 728 eligible patents.
Of the eligible 728 patients, 46.8% were female. Median age at diagnosis was 51 years (range, 11 to 85 years). Median duration of TKI treatment was 7.6 years (range, 3.0-14.1 years) and median duration of MR4 before TKI cessation was 4.7 years (range, 1.0-13.3 years).
Nine patients died without MMR loss (none CML related), 15 patients restarted TKI without prior MMR loss.
At 6 months 713 patients were available (without molecular test at 6 months n=6, TKI restart without relapse n=9). Since 434 patients (61%) [95% CI: 57–64] remained without relapse in the first 6 months, the null hypothesis could be rejected (p<0.0001).
At 36 months, 678 patients could be analysed (TKI restart without relapse n=17, no molecular test at 36 months n=33). 309 patients were in MMR or better corresponding to 46% [95% CI: 42–49]. The null hypothesis of 35% or lower was rejected (p<0·0001).
Molecular recurrence-free survival (MRecFS) at 36 months resulted in 48% (CI: 44-52%) and MRecTFS (molecular treatment-free survival) in 46% (CI 43-50%) (s. Fig 1).
No Blast crisis was documented.
Prognostic factors for early (up to 6 months) and late (> 6 months) MMR relapses will be updated and presented.

Summary/Conclusion: With this final analysis we confirm the MRecFS and MRecTFS rate at 6 months from the interim analysis. However, late relapses (15% between 6 and 36 months) occurred. Nevertheless, with 46%, almost half of the patients stayed at least in MRecTFS.

S153 OPTIC PRIMARY ANALYSIS: A DOSE-OPTIMIZATION STUDY OF 3 STARTING DOSES OF PONATINIB (PON)

Background: PON, a third-generation tyrosine kinase inhibitor (TKI), demonstrated deep and long-lasting responses and survival in patients (pts) with chronic-phase chronic myeloid leukemia (CP-CML) resistant/intolerant to second-generation TKI therapy (PACE; NCT01207440); post hoc analysis suggested a relationship between dose and both adverse events and response. Here we present the primary analysis of OPTIC (NCT02467270), an ongoing, randomized, phase 2 trial with a novel response-based dosing regimen of PON in pts with resistant/intolerant CP-CML.
Aims: Evaluate the safety and efficacy of ponatinib response–based dosing regimens in patients with resistant/intolerant CP-CML.
Methods: Informed consent was obtained and pts with CP-CML resistant/intolerant to ≥2 TKIs or with the *BCR-ABL1* T315I mutation were randomized to PON starting doses of 45 mg (cohort A; 45 mg → 15 mg), 30 mg (B; 30 mg → 15 mg), and 15 mg (C) once daily. Doses were reduced to 15 mg with achievement of ≤1% *BCR-ABL1*^{IS} in cohorts A and B. The primary endpoint is ≤1% *BCR-ABL1*^{IS} at 12 mo; secondary endpoints include cytogenetic and molecular responses and safety outcomes. AOEs were adjudicated prospectively by an independent review committee.
Results: 283 pts were randomized (A/B/C: n=94/95/94) and had the following baseline characteristics: median age 48 y (18–81 y); 98% received ≥2 (55% ≥3) TKIs; 99% had resistant disease; 40% had ≥1 baseline mutations (23% T315I). At the primary analysis with 32 mo median follow-up, 134 pts (47%; n=50/41/43) remained on treatment and 204 pts (72%) had PON exposure ≥12 mo. At 12 mo, 44% (41/93) in A, 29% (27/93) in B, and 23% (21/91) in C achieved ≤1% *BCR-ABL1*^{IS} (Table); primary endpoint was met by cohort A. Dose reductions to 15 mg after achieving response (A/B) were 48/30%.
Most common grades ≥3 TEAEs were thrombocytopenia, 27%; neutropenia, 17%; and anemia, 7%. AOEs/serious AOEs were reported in cohorts A (10%/4%), B (5%/4%), and C (3%/3%). Dose reductions or discontinuations for TEAEs (A/B/C) were 46/35/32% and 19/16/14%, respectively.

Response*	Cohort A 45 mg	Cohort B 30 mg	Cohort C 15 mg
BCR-ABL1^{IS} ≤1% at 12 mo, % (n/N)	44 (41/93)	29 (27/93)	23 (21/91)
BCR-ABL1^{IS} ≤1% by 12 mo by mutation status at baseline, % (n/N)	52 (48/93)	35 (33/93)	25 (23/91)
Response in pts with T315I mutation	60 (15/25)	25 (5/20)	11 (2/19)
Response in pts without T315I mutation	48 (32/66)	38 (28/73)	30 (21/71)
Survival probability at 36 mo, % (95% CI)			
PFS	73 (58, 84)	66 (48, 80)	70 (55, 80)
OS	89 (79, 95)	89 (77, 95)	92 (82, 96)

*Includes all pts who are randomized and with measurable *BCR-ABL1*^{IS} at BL.

Summary/Conclusion: The OPTIC primary analysis demonstrates the optimal benefit:risk profile for PON was achieved with a response-based dosing regimen starting with 45 mg/d, followed by dose reduction to 15 mg/d upon achieving ≤*1% BCR-ABL1*^{IS}; 30 mg →15 mg and 15 mg cohorts may provide benefit, especially in pts without T315I mutation (Table). The observed ≤1% *BCR-ABL1*^{IS} responses are supported by robust survival outcomes in pts with CP-CML resistant to second-generation BCR-ABL1 TKI therapy, both with and without *BCR-ABL1* mutations.

S154 COVID-19 INFECTION IN CHRONIC MYELOID LEUKEMIA AFTER 1 YEAR OF THE PANDEMIC IN ITALY. A CAMPUS CML ANALYSIS

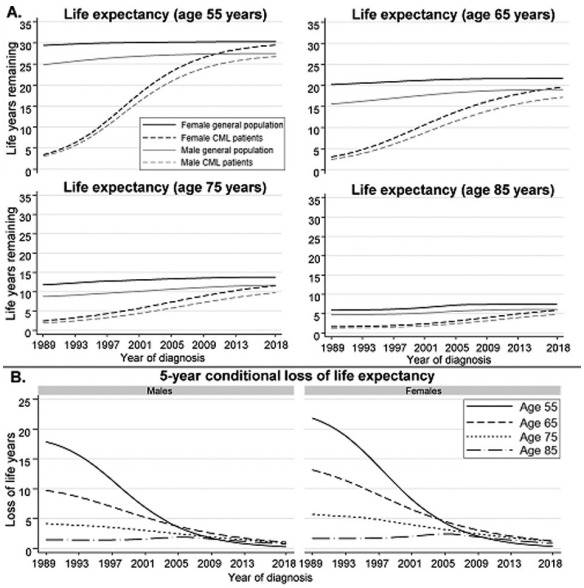
Background: An outbreak of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) started in December 2019 in the province of Hubei in China. Italy was one of the most affected countries with many cases diagnosed already in February 2020 and a lockdown was declared on March 9th. Limited information has been reported with regard to the impact of the pandemic on chronic myeloid leukemia (CML) patients.
Aims: To observe the temporal course of Covid-19 infection and the characteristics of positive patients.
Methods: The Campus CML Italian group carried out a first survey on the management of CML patients during the lockdown. We launched a second survey during the pandemic phases 2 and 3, between May 2020 and January 2021.

Results: We collected retrospective information on 8665 CML patients followed at 46 centers throughout the country. Within this cohort, we recorded 217 Covid-19-positive symptomatic patients (2.5%). Most patients (57%) were diagnosed as having Covid-19 infection between September 2020 and January 2021; 30% were diagnosed in phase 1 (March-April 2020) and only 13% between May and August. Most of the positive patients were between 50 and 65 years (35%), while 26% had less than 50 years, 18.8% were between 65 and 75 years, and 11% had more than 75 years. A male prevalence was observed (73%). The median time from CML diagnosis to Covid-19 infection was 6 years (3 months-18 years). Fifty-six percent of patients presented concomitant comorbidities at the time of infection. When Covid-19 was diagnosed, 27% of patients were receiving imatinib, 26% nilotinib, 18% dasatinib, 8% ponatinib, 8% bosutinib, 2% asciminib, while 11% were not receive treatment. At the time of the infection, 74% of patients were in molecular remission, 6% in complete cytogenetic remission, 3% in partial cytogenetic remission, 6% in complete hematological response and 11% in treatment-free remission. At diagnosis, 28% of patients presented fever and respiratory symptoms, 13% cough, 10% isolated fever, 13% ageusia, 12% anosmia, 4% had more than 1 symptom, while 20% were completely asymptomatic. Twenty-one patients (9.6%) required hospitalization without the need of respiratory assistance, 18 (8.2%) were hospitalized for respiratory assistance, 8 (3.6%) were admitted to an ICU, while 150 patients (69%) were only quarantined. Twenty-three percent of patients discontinued TKI therapy during the infection. The source of contagion was familiar in 49% of patients, 18% due to work, 3% in healthcare professionals, whereas in 30% was not known. Twelve patients died due to Covid-19 infection with a mortality rate of 5.5% in the positive cohort and of 0.13% in the whole cohort. Five patients reported consequences post-infection: 1 patient reported a Guillan-Barrè syndrome, 1 patient a maculopapular rash, 1 patient a pulmonary fibrosis, 1 patient a bacterial endocarditis and 1 patient was diagnosed as having alterations of the microcirculation.
Summary/Conclusion: This study reports the 1-year of data on the Covid-19 infection in a specific hematological malignancy in the European country first hit by the pandemic. A longer follow-up is needed to further define the impact of Covid-19 infection sequelae in CML patients.

Population based studies in myeloid disorders



S155 THE LOSS OF LIFE EXPECTANCY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA: A POPULATION-BASED STUDY IN THE NETHERLANDS, 1989-2018

C. C. Maas [1,2,*], D. van Klaveren [1], G. I. Ector [3], E. F. Posthuma [4,5], O. Visser [6], P. E. Westerweel [7], J. J. Janssen [8], N. M. Blijlevens [9], A. G. Dinmohamed [1,8,10,11]

[1]Public Health, Erasmus University Medical Center, Rotterdam, [2]Department of Research and Development, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [3]Department of Hematology, Radboudmc, Nijmegen, [4]Department of Internal Medicine, Reinier de Graaf Gasthuis, Delft, [5]Department of Hematology, Leiden University Medical Center, Leiden, [6]Department of Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [7]Department of Internal Medicine, Albert Schweitzer Hospital, Dordrecht, [8]Department of Hematology, Amsterdam, UMC, Vrije Universiteit Amsterdam, Cancer Center Amsterdam, Amsterdam, [9]Department of Hematology, Radboudumc, Nijmegen, [10]Department of Hematology, Amsterdam UMC, Universiteit van Amsterdam, Cancer Center Amsterdam, Amsterdam, [11]Department of Public Health, Erasmus University Medical Center, Rotterdam, Netherlands

Background: The treatment of chronic myeloid leukemia (CML) was transformed around the early-2000s with the advent of the first-generation BCR-ABL tyrosine kinase inhibitor (TKI) imatinib. This seminal milestone, along with the introduction of subsequent generations of BCR-ABL TKIs, markedly improved the population-level survival of CML patients. The overall 5-year relative survival rate (RSR) of CML patients in the TKI era is around 80%. While the RSR has an abiding history in population-based cancer research, it does not capture the magnitude of a cancer diagnosis on the life expectancy of cancer patients. At present, only one study assessed trends in CML patients' life expectancy in Sweden during 1973-2013 (Bower et al. *J Clin Oncol* 34, 2016).
Aims: To complement and extend this Swedish study, we assessed how the life expectancy and loss of life expectancy (LOLE) have evolved among CML patients diagnosed in the Netherlands during 1989-2018. In addition to the Swedish study, we estimated the 5-year conditional LOLE to assess time trends in the average number of life-years lost among CML patients who survived five years post-diagnosis.

Methods: We identified 3,353 CML patients aged ≥50 years and diagnosed between 1989-2018—with survival follow-up through December 31, 2019—from the Netherlands Cancer Registry. The age selection was chosen to align with the Swedish study. Flexible parametric relative survival models were used to estimate the LOLE that quantifies the difference between the life expectancy of patients and the general population, of which the latter is matched to the patients by age, sex, and calendar year. The LOLE reflects the average number of life-years lost due to a cancer diagnosis. Also, the 5-year conditional LOLE was estimated, a concept that portrays the patients' LOLE after having survived five years post-diagnosis. The survival measures were presented by year of diagnosis for four ages at diagnosis (i.e. 55, 65, 75, and 85 years), stratified by sex.
Results: The life expectancy of CML patients increased between 1989 and 2018, irrespective of age and sex, especially among patients aged 55 and 65 years (Figure 1A). Consequently, there was a marked decrease in the LOLE, particularly among younger patients since younger individuals have more remaining life-years than older individuals (Figure 1A). For example, a 55-year-old male patient diagnosed in 1990 loses, on average, 21.5 (95% CI: 20.7; 22.3) life-years, whereas a 55-year-old male patient diagnosed in 2018 on average loses 0.7 (95% CI: -0.1; 1.5) life-years. The corresponding estimates for an 85-year-old male patient were 3.4 (95% CI: 3.2; 3.7) and 1.3 (95% CI: 0.8; 1.9) life years, respectively. While the LOLE was low among CML patients diagnosed in 2018, small excess mortality prevailed for patients aged 65, 75, and 85 years. Encouragingly enough, as of 2010, the life expectancy of CML patients who survived five years post-diagnosis came close to the general population's life expectancy, regardless of age (Figure 1B).

Summary/Conclusion: The life expectancy of CML patients improved over time, particularly among younger patients between the 1990s and mid-late-2000s. The most reassuring finding was that the life expectancy of CML patients across all age groups ultimately approached that of the general population. This finding among contemporary diagnosed patients can essentially be attributed to the introduction of several TKIs across various therapy lines. Collectively, CML patients can look forward to a near-normal life expectancy in an era with modern approaches to manage CML.

S156 ELTROMBOPAG FOR MYELODYSPLASTIC SYNDROMES OR CHRONIC MYELOMONOCYTIC LEUKEMIA WITH NO EXCESS BLASTS AND THROMBOCYTOPENIA: A FRENCH MULTICENTER RETROSPECTIVE REAL-LIFE STUDY.

Background: Anemia is generally the predominant cytopenia in Low-Risk Myelodysplastic syndromes (LR-MDS) but thrombocytopenia may predominate in 10 to 15% of these patients. Options to improve thrombocytopenia are limited but recently, two thrombopoietin receptor agonists, romiplostim and eltrombopag (ELT) have been evaluated in clinical trials and yield 30 to 50% platelet responses in relatively selected LR-MDS patients. Only two clinical trials, have been performed in LR-MDS with ELT monotherapy and one in CMML.
Aims: The main objective of this study was to assess the efficacy and safety profile of ELT in thrombocytopenia related to MDS and CMML with no excess blasts (EB), in a "real life" context.
Methods: We collected data from MDS and CMML patients treated by ELT between January 2011 and January 2019 and included in the 'Groupe Francophone des Myélodysplasies' (GFM) registry of MDS patients. Inclusion criteria were (1) MDS or chronic myelo-monocytic leukemia with leucocytes < 13 G/L (according to WHO 2016 classification)(2) less than 5% bone marrow blasts (3) treatment with ELT outside of a clinical trial (4) platelet count ≤ 50.10^9/L at the onset of ELT. The primary endpoint was platelet response (HI-P), according to International Working Group (IWG 2006) response criteria. We also reported other hematological responseswhen available, safety and tolerability, bleeding and thrombotic events. This study has been approved by institutional review board, in accordance with the French data protection authority (MR004, Commission Nationale de l'Informatique et des Libertés, CNIL)
Results: Platelet response occurred in 38 (76%) MDS patients and 9 (82%) CMML. Median (IQR) duration of response was 13 (4-24) months and 6 (4-11) months in MDS or CMML patients respectively. Three MDS and 3 in CMML were still responders 6 to 23 months after ELT discontinuation. Although 34% MDS and 46% CMML were anticoagulated or anti aggregated, only 10% patients experienced ≥ grade 3 bleeding events (6% in responders vs 21% in non-responders). Thrombotic events were observed in 6 (12%) MDS patients, who all but one had a medical history of arterial or venous thrombosis. Progression to AML occurred in 4 (7%) patients.
Summary/Conclusion: We reported for the first-time real-life data about ELT in LR-MDS and CMML patients with thrombocytopenia. We confirmed that ELT is effective with a sustained effect on platelet counts reduction in the platelet transfusion burden and in severe bleeding. The effect of ELT was often prolonged after drug discontinuation. The tolerance profile was favorable in this population with no excess of blast, but previous history of thrombosis remains a major risk factor for thrombotic events on treatment.

S157 EVALUATION OF THE IMPACT OF THE USE OF ELTROMBOPAG IN A REAL-LIFE SETTING IN FRANCE BASED ON DATA IN THE NATIONAL OBSERVATORY FOR MEDULLAR INSUFFICIENCY (RIME): THE REVEPI STUDY

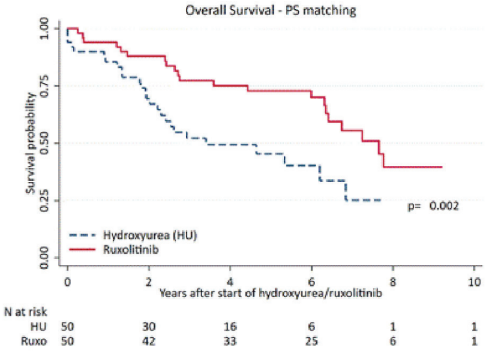
Background: Aplastic anaemia (AA) is characterised by bone marrow failure (BMF), and acquired AAs represent 70% of cases. Eltrombopag (ELT) is indicated in adult patients with acquired severe AA refractory to prior immunosuppressive treatment (IST) not eligible for hematopoietic stem cell transplantation, alone or associated with IST. To date, clinical data about the use of ELT are scarce.
Aims: The aim of this study is to describe patients treated by ELT and to evaluate the impact of ELT use in real-life in terms of survival, clinical benefit, hospitalization, quality of life, tolerance and clonal evolution.
Methods: This study was based on the RIME Observatory whose purpose is to collect prospectively and retrospectively standardised clinical information related to the management of French patients with BMF. The study population was all AA patients included in this observatory, between February 27th 2017 and December 24th 2019, and treated with ELT in second line and above. Adverse events were coded according to MedDRA and detailed by SOC and PT. The quality of life data were collected with QLQ-C30 questionnaires.
Results: A total of 93 AA patients used ELT in second line and above (median age 54 years and 58% women). Most patients were included in the APHP Saint-Louis Center. The median follow-up was 37.2 months from diagnosis and 9.4 months between AA diagnosis and start of ELT. According to the Camitta score, 46% of patients had severe aplastic anemia at diagnosis and 25% at the initiation of ELT. At the initiation of ELT, among patients receiving concomitant treatment (n=65), half used an association cyclosporine/ATGAM®; among patients receiving an adjuvant (n=29), most used an iron chelator.
Regarding ELT discontinuation, 82% (n=76) of patients stopped it at least once and 76% (n=71) permanently. Among these 71 patients, 65% (n=46) stopped for treatment failure and 14% (n=10) for safety concerns. A total of 18% of patients (n=17) died during follow-up, mainly from infection or haemorrhage. The median survival after ELT initiation was 74.4 months and the probability of survival at 20 months was around 90%. Among the 62 patients exposed to ELT in second line and above for at least 6 months, 66% (n=41) were responders of which 42% (n=26) had a complete response. The median response time was 27.5 months. Among the 79 patients having received a transfusion during the study, 59% (n=47) achieved transfusion independence. After the initiation of ELT, 43% of patients (n=40) were hospitalized mainly in conventional hospitalization. The main reasons for hospitalization were scheduled hospitalization and complication (30% and 43% respectively). Quality of life data were collected for 6 patients and cannot be interpreted. Among the 93 patients, 63% (n=59) experienced at least one adverse event during treatment, and the main adverse events reported were infections, hepatobiliary disorders, pain, asthenia and bleeding. Lastly, 11% of patients (n=10) had a clonal evolution (myelodysplastic syndrome (n=9) and acute myeloid leukemia (n=1)).



Summary/Conclusion: This study evaluated the impact of ELT use in real-life in AA. Two-thirds of the patients were responders to ELT. Two years after starting ELT, 42% had a complete response (cumulative incidence). More than half of the patients achieved transfusion independence. Clonal progression was identified in 11% of patients, which is comparable to the data in literature. The safety profile was similar to the one observed in ELT clinical studies. The results of this real-life study confirm the positive benefit-risk ratio of ELT in these patients.

S158 IMPACT OF RUXOLITINIB ON SURVIVAL OF PATIENTS WITH MYELOFIBROSIS IN REAL WORLD – UPDATE OF ERNEST (EUROPEAN REGISTRY FOR MYELOPROLIFERATIVE NEOPLASMS) STUDY

P. Guglielmelli [1,*], A. Ghirardi [2], A. Carobbio [2], A. Masciulli [2], C. Maccari [1], B. Mora [3], E. Rumi [4], A. Triguero [5], M. C. Finazzi [6], H. Pettersson [7], C. Paoli [8], F. Mannelli [8], D. Vanni [4], A. Rambaldi [6], F. Passamonti [9], A. Alvarez-Larràn [5], B. Andreasson [7], A. M. Vannucchi [1], T. Barbui [2]

[1]CRIMM, Azienda Ospedaliera Universitaria Careggi, University of Florence, Florence, [2]FROM Research Foundation, Papa Giovanni XXIII Hospital, Bergamo, [3]Hematology, ASST Sette Laghi, Ospedale di Circolo, Varese, [4]Division of Hematology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [5]Hematology, Hospital Clinic de Barcelona, Barcelona, Spain, [6]Department of Oncology-Hematology, University of Milan and Papa Giovanni XXIII Hospital, Bergamo, Italy, [7]Division of Hematology, NU Hospital Group, Uddevalla, Sweden, [8]CRIMM, Azienda Ospedaliera Universitaria Careggi, Florence, [9]Hematology, ASST Sette Laghi, Ospedale di Circolo, Università degli Studi dell'Insubria, Varese, Italy

Background: Ruxolitinib (RUXO) is a JAK1/2 inhibitor approved for the treatment of patients (pts) with primary (PMF) and secondary myelofibrosis (sMF). In randomized controlled trials, RUXO was effective in controlling symptoms and splenomegaly, while survival improvement, reported in post-hoc analysis, is still debated. In 2013 the ERNEST registry was activated to prospectively enroll MF patients receiving ruxolitinib.
Aims: The aim of the ERNEST project was to collect estimates of clinical outcome of contemporary MF pts in real-life settings.
Methods: Current study describes updates with cut-off deadline at dec 31, 2018 of those ERNEST patients who were reported already as alive and/or in active surveillance at Nov 2014 (Blood 2014; 124:1849). Italy, Spain and Sweden participated in the Registry update. The chi-square test or Fisher's exact test (categorical variables) and t-test or Wilcoxon-Mann-Whitney test (continuous variables) were used. Kaplan-Meier analysis was used for OS. To avoid immortal time bias, only pts exposed to cytoreductive therapy were included and followed from the start of treatment until death or censoring (last contact/study-end fixed at Dec 31, 2018), whichever came first. A multivariable Cox proportional-hazard model was used to investigate predictors of mortality. To assure comparability between patients treated with Hydroxyurea (pts-HU) and RUXO (pts-RUXO), we conducted a propensity score (PS) matching analysis. The PS included age at first administration, gender, type of MF, DIPSS at first administration, year of diagnosis, palpable spleen at first administration and time to first administration. 2-tailed p-values <0.05 were considered significant.
Results: At cut-off, the data of 1,010 pts were analyzed; there were 68% PMF, 20% PET-MF, 22% PPV-MF (median age at diagnosis: 64y). 23%,37% and 40% of diagnosis were performed between 2001-2004, 2005-2008 and 2009-2012. After a median follow-up of 5.2y (2.3–8.2), 625 deaths occurred with a mortality rate (per 100 person-years) of 10.9 (95%CI 10.1-11.8). Median OS: 6.2y (95%CI 2.8-12.6), with no significant difference according to diagnostic categories (P=0.4). Among pts treated with cytoreduction during follow-up (59.2% of total), at first administration pts-RUXO were significantly younger (64.yrs vs 67.0 yrs, p=0.02), with massive splenomegaly (≥20cm from LCM; 37% vs 6.0%, p<0.001) and higher incidence of constitutional symptoms (80% vs 49%;p=0.03) compared to pts-HU. Time to first treatment with HU (median time 0.0y, range 0-1.2y) was significantly shorter than RUXO (median 4.5y range 2.2-6.7y; p<0.001); 64% of pts-RUXO had been previously treated with HU, in 2 cases with interferon. OS was significantly longer in pts-RUXO compared to pts-HU (6.7y vs 5.1y; P=0.001); for those in higher DIPSS category OS was 6.4y for pts-RUXO vs 3.0 for pts-HU (p=0.003). Multivariable analysis identified the following factors that negatively affected OS: age (linear covariate, HR 1.03,p<0.001), male gender (HR 1.58, p<0.001), high DIPSS category (HR 2.96,p<0.001). Conversely, protective variables were more recent diagnosis (2009-2012 vs 2001-2004; HR 0.47,p<0.01) and exposure to ruxolitinib (HR 0.62,p=0.029). After PS matching (n=50 in each group), median OS was 7.7y in pts-RUXO vs 3.4y in pts-HU, respectively (p=0.002;Fig.1), and was not statistically different in those who used RUXO as first line or after HU (6.4y vs 7.8y, p=1.00).

Summary/Conclusion: Within the limitations of an observational study, these real-life data support an overall survival benefit of RUXO over HU alone in pts with PMF and sMF

S159 CLONAL HEMATOPOIESIS, ELEVATED BLOOD CELL COUNTS, AND DECREASED RENAL FUNCTION – A GENERAL POPULATION STUDY

M. K. Larsen [1,2,*], C. Ellervik [1,3,4], T. -P. Stiehl [5,6], V. Skov [2], L. Kjaer [2], N. A. Møller-Palacino [2], S. Koschmieder [7], N. Chatain [7], R. K. Pedersen [6], M. Andersen [6], M. J. Dam [6], J. T. Ottesen [6], H. C. Hasselbalch [1,2]

Background: The Philadelphia chromosome-negative myeloproliferative neoplasms (MPNs) are acquired stem-cell diseases. The molecular basis for MPNs includes the *JAK2*V617F, *CALR* -and *MPL*-mutations. MPNs evolve from clonal hematopoiesis of indeterminate potential (CHIP), which is characterized by an age-dependent acquisition of mutations. In recent years, chronic inflammation has been increasingly recognized as an important pathogenetic mechanism for MPN development – which may even in the CHIP phase be important for clonal evolution and development of comorbidities. Several studies have described a progressive reduction in estimated glomerular filtration rate (eGFR) among MPN patients, hence termed MPN-related nephropathy. However, no studies have focused upon the impact of CHIP mutations on eGFR.
Aims: We investigated the association between CHIP mutations and elevated blood counts on eGFR in a Danish general population study.
Methods: In total, 19,958 participants were included from the General Suburban Population Study, with 645 (3.2%) participants being positive for either the *JAK2V617F* (N=613) or *CALR* (N=32) mutation. All participants with MPN or other hematological malignancy at baseline were excluded from the analysis. eGFR (mL/min pr. 1.73m^2) was calculated by the EPI-CKD formula using plasma-creatinine levels and adjusted for age and gender as recommended for use. Neutrophil/lymphocyte – ratio (NLR) and thrombocyte/lymphocyte– ratio (PLR) were calculated as proxies for chronic inflammation. A composite binary variable for cytosis was calculated, including hemoglobin concentration, hematocrit, erythrocyte, thrombocyte, leukocyte, neutrophil, eosinophil, basophil, and lymphocyte cell counts adjusted for gender. We assessed the impact of CHIP (*JAK2V617F* or *CALR)* on eGFR using inverse-probability weighting (IPW) regression analysis to estimate potential outcome mean (95%CI) differences. The IPW regression was adjusted for age, gender, blood pressure, BMI, smoking status, ischemic heart disease, NLR, and PLR.
Results: Using IPW-regression analysis, CHIP (*JAK2*V617F & *CALR*) had an adjusted mean (95%CI) difference in eGFR of -0.3 (-1.5 - -0.86), *p=0.6* with a -0.39% (-1.8% - 1%) reduction in eGFR compared with non-mutated participants. *JAK2*V617F positive individuals had an adjusted mean(95%CI) difference in eGFR of -0.2 (-1.4 - -0.1), *p=0.7* with a -0.2 % (-1.6% - 1.1%) reduction in eGFR compared with non-mutated participants. *CALR* positive individuals, had an adjusted mean(95%CI) difference in eGFR of -9 (-13.7 - -4.3), *p <0.0001* with a -10.3% (-15.6% - -4.9%) reduction in eGFR compared with non-mutated participants. Cytosis in the general population was associated with an adjusted mean(95%CI) difference in eGFR of -0.5 (-0.9 - -0.04), *p=0.03* with a -0.5% (-1% - -0.04%) reduction in eGFR compared with participants with no cytosis. CHIP participants had a significantly elevated NLR and PLR compared to non-mutated participants with a mean (95%CI) difference of 0.1 (0.03 – 0.17), *p=0.008* and 9.8 (5.6 – 13.7), *p=3.8x10^{-6}*, respectively. NLR was negatively associated with eGFR among CHIP individuals with coefficient (95%CI) -2.2 (-3,6 - -0.78), adjusted R^2=0.04, *p=0.002*).
Summary/Conclusion: This study shows that CHIP *CALR*-mutations in a general population study associate with a significant reduction in eGFR as a proxy for renal function. Furthermore, cytosis is associated with a significant decrease in eGFR. Chronic inflammation and MPN-associated mutations may contribute to a decrease in eGFR even in the very early stage of MPN-development.

Correlating mutations with phenotype in MDS

S160 CONCURRENT MUTATIONS IN ZRSR2 AND TET2 DISRUPT MYELOID AND ERYTHROID DIFFERENTIATION AND CAUSE ABNORMALITIES COMPATIBLE WITH MDS DISEASE IN MICE

C. Garcia-Ruiz [1,*], C. Martínez-Valiente [1], L. Senent [2], A. Liquori [1], A. Gutiérrez-Adán [3], J. Cervera [1,4,5], A. Sanjuan-Pla [1]

[1]Hematology Research Group, Instituto de Investigación Sanitaria La Fe (IISLAFE), [2]Hematology Service, Hospital Universitario y Politécnico La Fe, Valencia, [3]Animal Reproduction Department, INIA, Madrid, [4]Genetics Unit, Hospital Universitario y Politécnico La Fe, Valencia, [5]Centro de Investigación Biomédica en Red de Cáncer (CIBER-ONC), Madrid, Spain

Background: Splicing factor (SF) and epigenetic genes mutations are the most frequent genetic alterations found in patients with myelodysplastic syndromes (MDS). About 25% of patients present concurrent mutations in such pathways, suggesting a cooperative role in the pathogenic mechanism of MDS. Inactivating mutations in the minor spliceosome factor *ZRSR2* and alterations in the epigenetic regulator *TET2* are frequently found together and are associated with higher blast percentage in bone marrow (BM), higher risk of AML transformation, and shorter overall survival. The underlying molecular mechanism of disease remains, however, unclear.
Aims: To investigate the functional role of *ZRSR2* and *ZRSR2-TET2* mutations in hematopoiesis and MDS.
Methods: We generated a *Zrsr2* mutant mouse model (*Zrsr2*^{mut}) by CRISPR/Cas9. A *Zrsr2-Tet2* double mutant model (*Zrsr2*^{mut}*Tet2*^{mut}) was generated by crossing *Zrsr2*^{mut} mice with a *Tet2* knock-out model (*Tet2*^{mut}) previously established in our laboratory. Hematopoietic cell immunophenotype was analyzed by flow cytometry. Peripheral blood (PB) smears were stained for morphologic evaluation. To study hematopoietic stem and progenitor cells (HSPCs) functionality we conducted competitive BM transplantation and colony-forming unit (CFU) assays. Whole transcriptome sequencing of LSK cells was performed to study gene expression and to identify changes in splicing patterns.
Results: *Zrsr2*^{mut}*Tet2*^{mut} mice immunophenotyping indicated a global alteration of hematopoiesis. In BM, Lin$^-$ Sca-1$^+$ c-kit$^+$ (LSK) cell compartment was expanded, being CD48$^+$CD150$^+$ (HPC2) cells significantly increased and CD48$^-$CD150$^-$ (MPP) significantly reduced. Myeloerythroid differentiation was disrupted, showing an increase in the myeloid pre-GM progenitors accompanied by a sharp decrease in GMP. Erythroid progenitors showed a similar behavior, having a significant increase of pre-CFU-E cells and a reduction of CFU-E. CFU assays confirmed a significant increase in myeloid progenitors and an increase of erythroid progenitors in double-mutant mice. Notably, a subset of *Zrsr2*^{mut}*Tet2*^{mut} mice (30%) showed a more striking phenotype, including PB anemia and thrombocytopenia, leukocytosis, splenomegaly, and extramedullary hematopoiesis. Morphologically, peripheral blood cells showed dysplastic features including red blood cell abnormalities and giant platelets.
Transplantation experiments indicated an impairment of *Zrsr2*^{mut} cell capacity to repopulate the receptor BM. Conversely, transplantation of *Zrsr2*^{mut}*Tet2*^{mut} cells revealed an enhanced engraftment capacity when compared to WT BM. Immunophenotypic analysis of *Zrsr2*^{mut}*Tet2*^{mut} recipients recapitulated the erythroid phenotype observed in steady-state animals. One out of the five analyzed mice (20%) showed a more marked phenotype, similarly to what happened in non-transplanted mice.
RNA-seq analysis from *Zrsr2*^{mut}*Tet2*^{mut} cells revealed 2952 differentially expressed genes and 43272 differential alternative splicing events in comparison to controls. Exon skipping (ES) was the most common alternative splicing (AS) event (71%) while intron retention (IR) was less common (7%).
Summary/Conclusion: Here we report that co-occurring mutations in *Zrsr2-Tet2* disturb normal hematopoiesis and cause abnormal myeloid and erythroid differentiation. Thirty percent of these mice displayed some MDS-like abnormalities. Transcriptome analysis revealed an important dysregulation in gene expression accompanied by aberrant mRNA splicing. This study provides new insights into the biology of this MDS subtype and opens the possibility to more in-depth interrogate its molecular disease mechanism.

S161 ACTIVATION OF DISTINCT INFLAMMATORY PATHWAYS IS DRIVEN BY GENETICS IN MDS

M. Schneider [1,*], L. Fischer [2], S. Winter [2], M. Trumpp [1], C. Rolfs [1], A. S. Kubasch [1], K. Metzeler [1], C. Faradyl [3], K. Sockel [2], C. Thiede [2], L. Hofbauer [4], M. Cross [1], U. Platzbecker [1]

[1]Department of Hematology and Cell Therapy, University Clinic Leipzig, Leipzig, Germany, [2]Medical Clinic and Policlinic I, University Hospital Carl Gustav Carus, Dresden, Germany, [3]Translational Clinical Oncology, Novartis Institutes of Biochemical Research, Basel, Switzerland, [4]Department of Medicine III, University Hospital Carl Gustav Carus, Dresden, Germany

Background: Myelodysplastic syndromes (MDS) lie on a continuum of myeloid neoplastic progression between clonal hematopoiesis of indeterminate potential (CHIP) and myeloid leukemia. Innate immune signalling in the marrow has been identified as a determinant of progression, particularly in low-risk (LR)-MDS, suggesting that it may be possible to prevent or delay progression by suitably targeted anti-inflammatory therapy. However, while early data point to a pivotal role for the NLRP3-inflammasome, little is known about the extent or functional relevance of patient-specific variations in inflammatory network activity.
Aims: Our objective was to assess the diversity of pre-treatment bone marrow inflammation in LR-MDS compared to non-CHIP, CHIP, high-risk (HR)-MDS and CMML patients and to investigate associations with phenotype, genotype and outcome in LR-MDS.
Methods: We analyzed a total of 102 bone marrow samples (15 non-CHIP; 12 CHIP; 47 LR-MDS; 14 HR-MDS; 14 CMML) collected under informed consent as part of the MDS registry and the BoHemE Study (NCT02867085) at the University Hospitals in Dresden and Leipzig. BM-MNC RNA was analyzed by qPCR TaqMan® Array for the expression of 12 genes encoding inflammasome-related proteins (*NLRP3*, *PYCARD*, *CASP1*, *IL1B*, *IL18*, *S100A9*, *NLRP1*, *NLRC4*, *AIM2*, *CASP3*, *CASP4*, *CASP5*). In parallel, we measured the levels of 14 circulating inflammatory mediators (e.g. IL1B, IL18, S100A9) in paired plasma samples by Luminex™ and conventional ELISA. Inflammasome data were then correlated with mutation status and clinical parameters.
Results: Inflammasome gene expression was generally higher in LR-MDS than in either CHIP or HR-MDS. In LR-MDS samples selected inflammatory biomarkers such as *NLRP3*, *IL1B*, *IL18*, and *S100A9* were differentially expressed and correlated, indicating the presence of distinct patterns of inflammation within this cohort. A principal component analysis (PCA) performed in order to identify consistent subgroups in the gene expression separated the LR-MDS cohort into three defined clusters based predominantly on the levels of *PYCARD*, *IL18*, *S100A9* and *NLRC4*. Re-examination of these groups for NLRP3-related gene expression confirmed low, medium and high levels (Figure 1).
Low NLRP3-inflammasome state (LR-MDS 1) associated with the presence of SF3B1 mutation/ring sideroblasts, hypercellular bone marrow, transfusion dependence and expanded erythropoiesis, as well as low IL1B mRNA and protein expression. High NLRP3-inflammasome state (LR-MDS 2) associated with del(5q), hypocellular bone marrow and transfusion independence, as well as high IL1B mRNA and protein expression. Medium NLRP3-inflammasome state (LR-MDS 3) associated with fewer mutations, hypocellular bone marrow and expanded erythropoiesis, as well as high IL1B mRNA and protein expression.

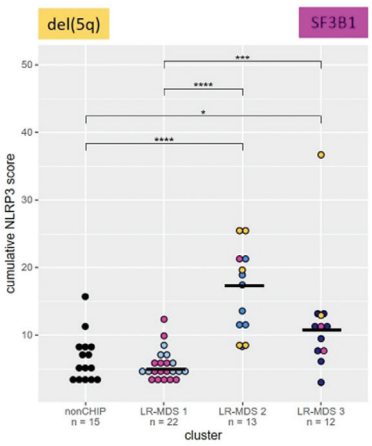

Figure 1. Cumulative NLRP3-score of LR-MDS PCA clusters.
Cumulative NLRP3 score = ∑ *NLRP3, PYCARD, CASP1, IL1B, IL18*; Mann Whitney test: * p ≤ 0.05, ** p ≤ 0.01, *** p ≤ 0.001, **** p ≤ 0.0001; black bold bar depicts median

Summary/Conclusion: We demonstrate the presence of distinct inflammasome activation states in LR-MDS and identify associated biomarkers (IL1B, SF3B1mut, del(5q)) of potential relevance for patient stratification to anti-inflammatory therapies. We are currently analyzing gene expression in sorted cell populations to further increase the resolution of our analysis, which will be validated in the prospective CANFIRE trial investigating the IL1B antibody canakinumab in LR-MDS.

S162 TET2 MUTATIONS IN MYELODYSPLASTIC SYNDROME PATIENTS DISRUPTS NATURAL KILLER CELL'S BIOLOGY

Background: Myelodysplastic syndromes (MDS) are a group of heterogeneous clonal disorders essentially occurring in elderly individuals and associated with a high risk of progression to acute myeloid leukemia (AML). A majority of MDS patients harbors somatic mutations including in genes encoding for epigenetic regulators such as TET2 and IDH1 and 2. Those mutations have been also found in individuals with clonal hematopoiesis of indeterminate potential (CHIP), a preleukemic state. However, mechanisms of disease progression remain largely unknown and may implicate defects in the anti-leukemic immunosurveillance. Among immune cells, Natural Killer (NK) cells are key players in charge of eliminating tumor cells. At diagnosis of AML and MDS, we and others showed impaired NK cell's phenotype and function with a reduction of cytotoxicity and cytokine release (Khaznadar *et al.* 2015 *J Immunol*, Carlsten *et al.* 2010 *Leukemia*). However no data are yet available on the impact on NK-cells of the mutation status in MDS patients at diagnosis.
Aims: We hypothesized that MDS patients with *TET2*/*IDH* mutations could show particular defective NK cell profile leading to the disruption of their anti-leukemic activity, by contrast to other MDS-related mutations.
Methods: Bone marrow (BM) and blood samples from 63 patients with MDS were collected, from the Hematological Departments of Saint Louis Hospital at diagnosis prior any treatment. Next generation sequencing (NGS) using a 80 genes panel was performed on sorted blood NK and T cells. NK cells phenotype was analyzed by flow-cytometry and NK-cell mediated cytotoxicity against the leukemic K562 cell-line was evaluated in calcein-release assays. The NK-cell methylation landscape has been assessed by representation bisulfite sequencing (RRBS). Finally, NK-cells treated *in vitro* with HMA have been analyzed for NK receptor expression before and after HMA exposure.
Results: Phenotyping of NK cells in blood and BM of MDS patients showed a strong reduction of KIR2D receptors expression counterbalanced by the increase of NKG2A at the NK-cell surface in patients harboring *TET2* or *IDH1/2* mutations (Figure 1A). The NGS analysis revealed a shared mutation profile between blasts and NK cells, but not T lymphocytes, in the MDS patients (Figure 1B). Interestingly, KIR expression correlated with the Variation of Allele Frequency (VAF) of *TET2* mutations in NK cells (Figure 1C). Chromatin immuno-precipitation experiments in primary NK cells unveiled the direct binding of TET2 on the KIR promoter region. In parallel, RRBS analysis showed DNA hypermethylation of the KIR locus and other genes involved in NK cell physiology, including *PRF1* and *IFNG*, in the $TET2^{MUT}$ NK-cells by comparison to $TET2^{WT}$ NK-cells. Importantly, *in vitro* HMA treatment of NK-cells restores KIR2D cell-surface expression (figure 1D).

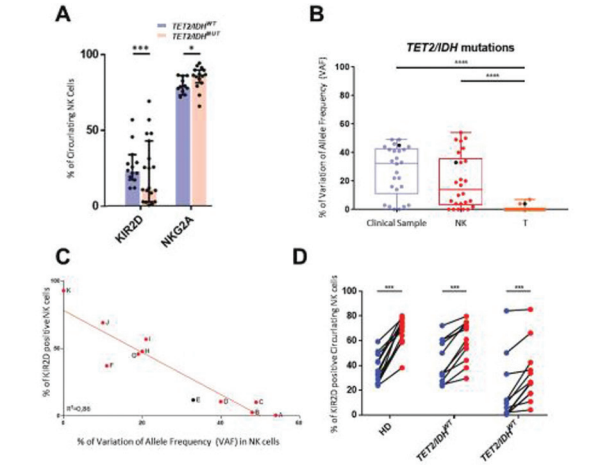

Figure 1 : Impact of *TET2/IDH* mutations in NK cells phenotype
(A) Circulating NK cells phenotyping of KIR2D and NKG2A receptors in *TET2/IDH* WT (n=13) and MUT (n=19) patients
(B) Variation of Allele Frequency (VAF) of *TET2/IDH* mutations at diagnosis and in NK/T sorted cells.
(C) Correlation between VAF of *TET2/IDH* mutations in NK cells and KIR2D expression.
TET2 mutated patients are depicted in red and IDHMUT patient in black.
(D) KIR2D expression at the surface of NK cells after PBMC treatment with 5-Aza-2'deoxycytidine (DEC) at 0,5 µM (in red). DMSO treatment was used as CTRL (in blue).

Summary/Conclusion: Altogether, our findings showed that mutations in *TET2* altered NK-cell biology in MDS patients. This study highlights the potential dual role of mutations in the emergence of MDS and immune defects, which could lead to progression to AML by associating oncogenic mechanisms and tumor escape to immunosurveillance.

S163 E-CADHERIN CONTROLS ERYTHROPOIESIS: A NOVEL AVENUE TO ANEMIA TREATMENT

R. Krimpenfort [1,*], M. Xia [1], C. Duetz [2], L. Janssen [2], H. Verhagen [1], M. Nolte [1], J. Jonkers [3], M. von Lindern [1], E. van den Akker [1], A. van de Loosdrecht [2], M. Nethe [1]

[1]Hematopoiesis, Sanquin, [2]Department of Hematology, Cancer center Amsterdam, Amsterdam UMC, [3]Molecular Pathology, Netherlands Cancer Institute, Amsterdam, Netherlands

Background: In Western world aging-associated bone marrow (BM) dysplasia's, such as Myeloid Dysplastic Syndrome (MDS), increasingly contribute to anaemia incidence. One major goal of MDS-treatment is to treat anaemia with the aim of avoiding or delaying chronic transfusional support, to decrease the risk of transfusion–related complications and improve quality of life. When serum erythropoietin (EPO) is low, MDS-patients are treated with EPO and/or Sotatercept, displaying a ~50% response rate in terms of erythroid hematological improvement. Anaemia-treatment in MDS therefore urgently requires development of novel options to promote erythropoiesis.
Aims: A fundamental requirement to develop novel treatment opportunities that promote erythropoiesis is to obtain improved understanding of the erythroid homeostatic responses in BM to anaemia.
Methods: We analyzed human healthy and MDS BM by flow cytometry to supplement our exploit of existing genomic and proteomic databases. Additionally, we performed functional experiments using genomic knockout of our gene of interest, CDH1, using CRISPR-cas9.
Results: We here identify Epithelial cadherin (E-cadherin) to selectively mark the erythroid lineage in human BM. This is striking, because E-cadherin is well-established to mediate epithelial integrity, as key component in adherens junctions. In the epithelium, E-cadherin functions as mechanosensor and transduction cascades, such as the Wnt pathway. It has been reported that Wnt signaling is aberrantly active in myeloid dysplastic syndrome. We here report our observation that E-cadherin membrane expression is reduced in MDS erythroid progenitors. We hypothesize that consequently, MDS erythroid progenitors lack the gatekeeper function that E-cadherin has on β-catenin signaling.
In our CRISPR-Cas9 KO experiments, we show that E-cadherin in erythroblasts cross talks with the Wnt pathway by stabilizing β-catenin, key Wnt signal transducer, at the cytoplasmic membrane. In addition, we show inhibition of the β-catenin destruction complex results in further accumulation of β-catenin and hampering of erythroid differentiation.
Importantly, we find that E-cadherin expression is not conserved in mouse erythroid progenitors. Erythropoiesis is an evolutionary conserved process and has been extensively studied in vivo using mouse models. Despite many homologies, stress erythropoiesis, the erythroid homeostatic response to anemia, is differently controlled in mice as compared to humans. Stress erythropoiesis in mice is mainly driven extramedullary, in the spleen, and not in BM as seen in humans. The underlying mechanism of stress erythropoiesis in human BM is mostly elusive.
Summary/Conclusion: Due its control on cell adhesion, survival and differentiation we hypothesize that E-cadherin in fact may display an unanticipated BM-specific control on (stress) erythropoiesis in human BM that cannot be uncovered by exploring the anemic response in mouse models. We suggest E-cadherin to function as double edged sword, on the one hand stabilizing, but also sequestering β-catenin at the cytoplasmic membrane. Hereby, E-cadherin links cell adhesion between (pro) erythroblasts in erythroblastic islands with Canonical Wnt signaling. In extension, we suggest deficient E-cadherin to underlie inefficient stress erythropoiesis and anemia as we observe reduced protein expression in the erythroid lineage in MDS patient BM.
Overall, E-cadherin signaling may underlie (stress) erythropoiesis by controlling differentiation of erythroid progenitors in human BM, and is an interesting candidate for targeted treatment of inefficient erythropoiesis.

S164 RVU120/SEL120 CDK8/19 INHIBITOR - A DRUG CANDIDATE FOR THE TREATMENT OF MDS CAN INDUCE ERYTHROID DIFFERENTIATION IN TRANSFORMED CD34+ HEMATOPOIETIC PROGENITOR CELLS

T. Rzymski [1,*], U. Pakulska [1], K. Goller [1], E. Adamczyk [1], K. Dziedzic [1], K. Wiklik [1], M. Combik [1], M. Mikula [2], M. Obacz [1], M. Mazan [1], K. Keska [1], M. Masiejczyk [1], P. Juszczynski [3], J. Flygare [4], K. Brzozka [1]

[1]Ryvu Therapeutics, Cracow, [2]The Maria Sklodowska-Curie National Research Institute of Oncology in Warsaw, [3]Institute of Hematology and Transfusion Medicine, Warsaw, Poland, [4]Lund University, Lund, Sweden

Background: Myelodysplastic syndrome (MDS) is a disorder of hematopoietic cells that as a result of genetic and epigenetic changes do not give rise to mature blood cells. Production and accumulation of dysplastic cells leads to cytopenias and can often evolve to acute myeloid leukemia (AML). Primary clinical goals in MDS are to achieve remissions, alleviate symptoms associated with cytopenias and to minimize the transfusion burden. While supportive red blood cell transfusions and erythropoiesis-stimulating agents may lead to clinical improvement, frequent transfusions may lead to iron overload and decreased quality of life. Several additional therapeutics are now available for the treatment of symptomatic anemia, however there is a need for novel agents as majority of patients eventually develop resistance. RVU120 (formerly known as SEL120) is a specific, selective inhibitor of CDK8 and its paralog CDK19. A first- in- human phase Ib clinical trial with RVU120 in patients with AML or HR-MDS is currently ongoing. Preclinical studies indicated strong antileukemic potential of RVU120 that was often associated with multilineage commitment of CD34+ AML cells. Moreover, RVU120 could improve proliferation and induce erythroid differentiation of CD34+ cells derived from Diamond-Blackfan anemia patients.
Aims: Primary aim was to evaluate erythroid differentiation potential of RVU120 in transformed lineage depleted (Lin-) CD34+ blood cells characterized with the early block in erythroid differentiation.
Methods: Primary cellular model was based on cord blood cells transduced with TLS-ERG - a fusion gene generated from t(16;21)(p11;q22) translocation associated with primary AML and secondary AML associated MDS. Transformed cells displayed increased capacity for self-renewal, proliferation and altered erythroid differentiation. Cells were treated with RVU120 and global transcriptional changes and chromatin status were analyzed by RNAseq, ATACseq and ChIPseq. Cell cycle, proliferation and lineage specific markers were studied by flow cytometry in liquid and semi-solid methylcellulose-based media.
Results: RVU120 treatment leads to transcriptional reprogramming of transformed (Lin-) CD34+ cells. The most profound changes included decreased CDK8 occupancy and increased RNA Pol II loading. RVU120 could repress many genes associated with stem cells and importantly induce the expression of genes involved in erythroid commitment, including regulators of erythroid/megakaryocytic fate, such as RGS18,

KLF1, FLI1, INHBA, GATA1/2 and hemoglobin genes. Detailed analysis by flow cytometry at early and late time points reflected sequential changes in the expression of lineage-specific surface markers, leading to differentiation and the presence of GlyA+/CD71+ erythroblasts. Observed effects on differentiation towards erythroid cells were independent of erythropoietin.
Summary/Conclusion: Presented results indicate strong erythroid differentiation potential of RVU120 in (Lin-) CD34+, that acquired genetic abnormalities resulting in arrested erythroid commitment, characteristics of many MDS and AML subtypes. Observed differentiation phenotype strikingly resembles effects of RVU120 in DBA cells caused by disruption of genes encoding ribosomal proteins. Detailed transcriptomic profiling strongly associated differentiation with enrichment of genes representing regulators of erythroid commitment and hemoglobin metabolism. Further studies are warranted to investigate efficacy of RVU120 in anemias associated with bone marrow failures in AML and MDS patients.

Novel targets in MDS

S165 A PHASE 1, DOSE ESCALATION TRIAL WITH NOVEL ORAL IRAK4 INHIBITOR CA-4948 IN PATIENTS WITH ACUTE MYELOGENOUS LEUKEMIA OR MYELODYSPLASTIC SYNDROME – INTERIM REPORT

G. Garcia-Manero [1,*], S. Tarantolo [2], A. Verma [3], J. Dugan [4], E. S. Winer [5], A. Giagounidis [6], C. Talati [7], C. Lieberman [8], E. Martinez [9], R. von Roemeling [9], U. Platzbecker [10]

[1]Leukemia, Caner Medicine, MD Andrerson, Houston, [2]Nebraska Cancer Specialists, Omaha, [3], Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY, [4]Hematology/Oncology, Novant Health Cancer Institute - Forsyth, Winston-Salem, NC, [5]Medical Oncology, Dana-Faber Cancer Institute, Boston, MA, United States, [6]Oncology, Haematology, Marien Hospital / Univ. of Düsseldorf, Düsseldorf, Germany, [7]Malignant Hematology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, [8]Clinical Operations, Curis, Lexington MA, [9]Clinical Development, Curis, Lexington, MA, United States, [10]Internal Medicine I and head of the Section of Hematology, University Hospital in Leipzig, Leipzig, Germany

Background: Interleukin-1 receptor-associated kinase 4 (IRAK4) plays a critical role in toll-like receptor (TLR) or interleukin-1 receptor (IL-1R) signaling pathway activation. This results in stimulation of NFκB, triggering inflammatory responses, oncogenesis and survival mechanisms of malignant cells. Genetic mutations of myelodysplastic syndromes (MDS) or acute myeloid leukemia (AML) include SF3B1 and U2AF1 affecting spliceosomes in 50% of cases that lead to expression of a longer, highly active isoform of IRAK4 (IRAK4-L) [1,2]. CA-4948 is a novel oral inhibitor of IRAK4 and FLT3 signaling.
Aims: Assessment of safety, tolerability and recommended phase 2 dose (RP2D).
Methods: This is an ongoing, phase 1 dose escalation trial (NCT 042787688). In a 3+3 design, enrolling adult patients with relapsed or refractory high-risk MDS or AML, CA-4948 is orally administered at dose level (DL) cohorts of 200, 300, 400, and 500 mg bid given continuously in 28-day cycles until limiting toxicity or disease progression. Primary objective: Safety and RP2D. Secondary: Early efficacy (ORR; evaluable: patients with baseline- and at least 1 follow-up malignancy assessments); pharmacokinetics (PK). Exploratory: Pharmacodynamic (PD) mechanism-of action (MoA) related biomarkers.
Results: As of February 8, 2021, 15 patients (10 males, 5 females; median age 72, range: 32-84) have been enrolled with higher risk MDS by IPSS-R (N=8), and 7 with AML. Median number of prior therapies was 2 (range 1- 4). Most patients were transfusion dependent at baseline. Three dose levels of 200, 300, and 400 mg bid have been completed for DLT evaluation; DL 4 at 500 mg bid is open for enrollment. Treatment duration ranged from <1 to 7 months with enrollment ongoing.
Safety: Treatment was generally safe and tolerable. No DLT was reported at the first 3 dose levels incl. 400 mg bid. One treatment-related dose reduction (Grade 3 dizziness) resulted in no toxicity-related discontinuation.
Pharmacokinetics/Pharmacodynamics: Drug is rapidly absorbed with a half-life of 6 hours supporting bid dosing. Exposure increased dose proportionally. No major accumulation and no CYP450 inhibition or induction were observed. Pharmacodynamic results are pending, results will be included in presentation.
Efficacy: Bone marrow blast reductions were observed at all tested dose levels in 8 of 9 (89%) evaluable patients with elevated blast counts at baseline. Responses included 1 CR with full hematologic recovery, 1 CRi with negative minimal residual disease, and 2 bone marrow CRs. Three patients had a spliceosome mutation, and all 3 patients achieved a marrow CR or better. Patients with objective responses also saw signs of hematologic recovery.
Summary/Conclusion: CA-4948 monotherapy is so far well tolerated and with signs of clinical activity in this group of patients with advanced disease. Three of 3 patients with spliceosome mutations achieved a marrow CR or better. The study continues to define RP2D and to obtain definitive PK and PD profile.

S166 LOWER RESIDUAL MUTATION LOAD FOLLOWING TREATMENT WITH PEVONEDISTAT+AZACITIDINE VERSUS AZACITIDINE ALONE: COMPARATIVE ANALYSIS OF STUDY ARMS IN P-2001, A RANDOMIZED PHASE 2 TRIAL

S. Friedlander [1], A. Krueger [1], K. Galinsky [1], M. A. Sekeres [2,*], L. Adès [3], R. J. Fram [1], D. V. Faller [1], A. B. Dash [1]

[1]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [2]Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL, United States, [3]University of Paris, and INSERM U944, Paris, France

Background: Pevonedistat (PEVO), a first-in-class small-molecule inhibitor of the neural-precursor-cell-expressed developmentally down-regulated protein 8 activating enzyme, disrupts proteasomal degradation of selected proteins, leading to cancer cell death. In P-2001 (NCT02610777), overall response rate (ORR) among response-evaluable patients (pts) was 70.9% with PEVO + azacitidine (AZA) vs 60.4% with AZA alone.[1] Among pts with higher risk myelodysplastic syndromes (MDS), event-free survival (EFS; defined as time to transformation to acute myeloid leukemia [AML] or death, whichever occurred first) was longer, time to transformation was delayed, CR rate nearly doubled, and median duration of response was almost tripled with PEVO+AZA vs AZA.[1,2] Among pts with low-blast (LB)-AML, OS was numerically longer with PEVO+AZA vs AZA.[1] A highly-sensitive duplex sequencing method was developed to detect low variant allelic fraction (VAF <0.01%) of residual somatic mutation load after treatment and the emergence of new clones as a way to augment clinical observations at a molecular level.
Aims: Based on the clinical findings in P-2001, we hypothesized that PEVO+AZA would induce deeper and more persistent molecular responses than AZA alone. To test this hypothesis, we conducted a pre-specified comparative analysis in which the abundance of mutant allele burden in each study arm was measured over time using ultra-sensitive duplex sequencing.
Methods: In all, 96 bone marrow aspiration samples (55 higher-risk MDS; 15 higher-risk chronic myelomonocytic leukemia [CMML]; 26 LB-AML) were collected at screening and subjected to DNAseq. A custom TruSeq Hybrid Capture panel, incorporating 123 myeloid genes, was utilized to characterize the mutation profile of the baseline samples. Fifty eight longitudinal samples (33 higher-risk MDS; 7 higher-risk CMML; 18 LB-AML) collected at selected timepoints (Day 22 of Cycle [C] 2, C4, and C7, and at relapse) underwent duplex sequencing of a 54-myeloid gene targeted panel to ensure variant bases were identified with support from both DNA strands and to allow for ultra-deep sequencing coverage. Mutations identified at baseline were followed longitudinally to evaluate patterns of clearance over time.
Results: In accordance with the clinical efficacy observed in P-2001, the **Figure** below shows significantly less expansion of treatment-emergent mutations (defined as either newly detected or significantly increased VAF after treatment) in the PEVO+AZA arm compared with the AZA alone arm (29.3% vs 49.6%, respectively; p=0.002), particularly in genes associated with disease progression and leukemic transformation (including Ras-mitogen-activated protein [MAP] kinase signaling and myeloid transcription factors). This is consistent with the significantly larger percentage of mutations with low VAF (<0.01%) in PEVO+AZA vs AZA alone arms (34% vs 21%, respectively; p=0.03).

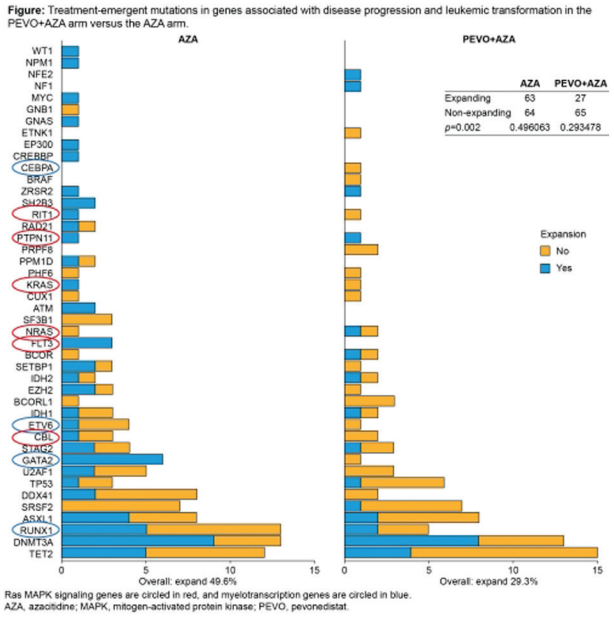

Figure: Treatment-emergent mutations in genes associated with disease progression and leukemic transformation in the PEVO+AZA arm versus the AZA arm.
Ras MAPK signaling genes are circled in red, and myelotranscription genes are circled in blue.
AZA, azacitidine; MAPK, mitogen-activated protein kinase; PEVO, pevonedistat.

Summary/Conclusion: These data suggest that the combination of PEVO+AZA reduces mutation burden and the likelihood of treatment-emergent resistance or progression mutations vs AZA, thereby maintaining response for a longer period. The combination of PEVO+AZA may be beneficial in higher-risk MDS and LB-AML, and potentially as a maintenance treatment in AML. This will be further assessed in the ongoing randomized Phase 3 trial (NCT03268954).

S167 PHASE II STUDY OF THE IDH2-INHIBITOR ENASIDENIB IN PATIENTS WITH HIGH-RISK IDH2-MUTATED MYELODYSPLASTIC SYNDROMES (MDS)

S. Venugopal [1,1,*], C. DiNardo [1], K. Takahashi [1], M. Konopleva [1], S. Loghavi [2], G. Borthakur [1], A. DeZern [3], L. Masarova [1], N. Daver [1], N. J. Short [1], Y. Alvarado [1], F. Ravandi [1], G. Montalban-Bravo [1], K. Sasaki [1], R. Delumpa [1], M. A. Sekeres [4], B. Patel [5], G. J. Roboz [6], H. Kantarjian [1], G. Garcia-Manero [1]

[1]Leukemia, [2]Hematopathology, The University of Texas, MD Anderson Cancer Center, Houston, [3]Hematology, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, [4]Hematology, Sylvester Comprehensive Cancer Center, Miami, [5]Hematology, Cleveland Clinic Taussig Cancer Institute, Cleveland, [6]Division of Hematology & Oncology, Weill Cornell Medical Center, New York, United States

Background: Isocitrate dehydrogenase 2 (*IDH2*) mutations occur in 5% of patients (pts) with MDS. Enasidenib (ENA) is a selective oral inhibitor of the mutant IDH2 enzyme with single-agent activity in relapsed/refractory acute myeloid leukemia (AML).
Aims: An open label phase II study designed to evaluate the efficacy and tolerability of ENA, as monotherapy or in combination with azacitidine (AZA) in pts with higher-risk *IDH2*-mutated MDS. (NCT03383575)
Methods: Pts with higher-risk [Revised International Prognostic Scoring System risk > 3 or high molecular risk (HMR)] MDS/CMML or LB AML naïve to hypomethylating agents (HMA) received ENA100 mg orally daily for 28 d of each 28-d cycle + AZA 75 mg/m2 IV or SC on d 1-7 of each cycle (ENA+AZA), and pts with refractory or progressive MDS to prior HMA therapy received ENA alone (ENA), in 28-d cycles until unacceptable toxicity, relapse, transformation to AML, or progression. The primary endpoint was overall response rate (ORR) [complete remission (CR), marrow CR (mCR), partial remission (PR) and hematologic improvement (HI)]. Other endpoints include safety, and survival outcomes.
Results: 48 pts received ENA+AZA (n = 26) or ENA (n = 22). The median age was 73 yrs (range, 46-83). Most pts (72%) had HMR: *ASXL1* (39%), and *RUNX1* (17%). Median number Tx cycles was 4 (2–32) in the ENA+AZA, and 7 (1–23) in the ENA arm. Common Tx-related grade 3–4 AEs in the ENA+AZA arm were neutropenia (64%), thrombocytopenia (28%), and anemia (8%); these occurred in 10%, 0%, and 5%, in the ENA arm. Grade 3–4 infections occurred in 32% (ENA+AZA) and 14% (ENA). IDH differentiation syndrome occurred in 3 pts (12%) in the ENA+AZA and 5 pts (24%) in the ENA arm. Two deaths occurred during the initial 60 d, both unrelated to study and due to COVID. In response-evaluable pts (n=46), ORR was 84% (n = 21/25; 24% CR + 8% PR+44% mCR+ 8% HI] in the treatment naïve ENA+AZA and 43% (n = 9/21; 24% CR+5%PR+5% mCR+10% HI) in the HMA failure ENA arm (Table). Most common reason for Tx discontinuation was disease progression (ENA+AZA 20%, ENA 33%).5 pts (20%) received HCT in the ENA+AZA and 1 (5%) in the ENA arm. 7 pts in the ENA+AZA and 5 in the ENA arm were ongoing at data cutoff (Dec 31, 2020). After a median follow up of 12.6 mo, median OS was 32.2 mo in the ENA+AZA and 21.3 mo in the ENA arm.

	Response Evaluable (N = 46)	Arm A (Untreated) ENA+AZA (N = 25)	Arm B (HMA-failure) ENA (N = 21)
Overall response rate (ORR), n (%)	**30 (68)**	**21 (84)**	**9 (43)**
Complete remission (CR)	11 (24)	6 (24)	5 (24)
Partial remission (PR)	3 (7)	2 (8)	1 (5)
Marrow CR (mCR)	12 (26)	11 (44)	1 (5)
Hematological improvement (HI) only	4 (9)	2 (8)	2 (10)
No response (NR), n (%)	**16 (35)**	**4 (16)**	**12 (57)**
Stable disease (SD)	14 (30)	4 (16)	10 (48)
Progressive disease (PD)	2 (4)	0 (0)	2 (10)

Summary/Conclusion: ENA is well tolerated and shows promising efficacy in *IDH2*-mutated higher risk MDS. Follow up and accrual is ongoing to better define duration and biomarkers of response.

S168 SABATOLIMAB PLUS HYPOMETHYLATING AGENTS (HMAS) IN PATIENTS (PTS) WITH HIGH-/VERY HIGH-RISK MYELODYSPLASTIC SYNDROME (HR/VHR-MDS) AND ACUTE MYELOID LEUKEMIA (AML): SUBGROUP ANALYSIS OF A PHASE 1 STUDY

Background: Novel therapies providing improved and durable outcomes with a favorable safety profile are needed in higher-risk MDS and AML. Sabatolimab (MBG453) is a novel immuno-myeloid therapy targeting TIM-3, an immune regulator expressed on immune and myeloid leukemic cells but not on normal hematopoietic stem cells. In a Ph 1b study (NCT03066648), sabatolimab+HMA showed promising overall response rates in pts with HR/vHR-MDS (64%) and newly diagnosed (ND)-AML (41%). Response durability was encouraging, with an estimated 84% and 79% still in response after 6 mo. Treatment-emergent AE profile was consistent with that reported for HMA alone (Brunner ASH 2020).
Aims: To further explore safety/tolerability, efficacy in pt subgroups, and biomarkers with sabatolimab+HMA.

Methods: Study design/eligibility criteria have been reported. Pts with HR/vHR-MDS (per IPSS-R) or ND-AML who were HMA-naïve and ineligible for intensive chemotherapy received sabatolimab (1-2 infusions/mo) + decitabine or azacitidine. Primary objectives were safety/tolerability; secondary objectives included PK and preliminary efficacy. Data cutoff 22 Sep 2020; updated data will be presented.
Results: To explore sabatolimab+HMA safety/tolerability, sabatolimab dose interruption (>7 d delay), reduction, and discontinuation due to AE/death were assessed in 89 pts with HR/vHR-MDS (n=41) and ND-AML (n=48). Of 89 pts, 36 (40%) had sabatolimab dose interruption, 1 (1%) had sabatolimab dose reduction, 2 (2%) had dose interruption and reduction, 5 (6%) discontinued, and 3 (3%) had dose interruption and discontinued. Dose interruption rate in first 2 cycles was low (21% [19/89]). Of 8 discontinuations, 4 were due to AE (1/4 related to study treatment) and 4 to death. Of 22 pts with gr 4 neutropenia/thrombocytopenia at baseline (BL), 4 (18%) had dose interruption, 2 (9%) discontinued, 1 (5%) had dose interruption and discontinued, and none had dose reduction.
In analyses of remission rates (CR+mCR/CRi+PR) by BL factors, response was independent of BM blast burden in pts with HR/vHR-MDS or ND-AML. Remission rates were similar in pts ≥75 and 65-74 y: 50% (6/12) and 65% (11/17) with HR/vHR-MDS and 42% (8/19) for both groups with ND-AML. Response durability in pts ≥75 and 65-74 y was encouraging: an estimated 83% and 86% with HR/vHR-MDS and 69% and 88% with ND-AML remained in remission after 6 mo. In pts with *TP53* mutation or pts with ≥1 mutation conferring ELN high risk (*TP53*, *RUNX1*, *ASXL1*), respectively, remission rates were 55% (6/11; 4/6 in remission >200 d) and 59% (13/22; 8/13 in remission >200 d) for HR/vHR-MDS and 25% (1/4; in remission 129 d) and 50% (6/12; 2/6 in remission >200 d) for ND-AML. 6/7 responders with *TP53* mutation had complex karyotype.
Biomarker analyses identified IL-1β, a proinflammatory cytokine reported to promote expansion of AML progenitor cells, as one of the most differentially expressed genes in BM of responders vs nonresponders to sabatolimab+HMA, with expression levels inversely correlated with remission. Single-cell RNA sequencing showed sabatolimab+HMA downregulated IL-1β in blast cells but, consistent with prior observations in TIM-3 deficient pts, it upregulated IL-1β in myeloid cells.
Summary/Conclusion: Sabatolimab+HMA showed favorable tolerability in MDS/AML, including in pts with gr 4 cytopenias at BL. Promising remission rates were seen irrespective of BL blast burden and in older pts and pts with adverse risk mutation. This supports development of sabatolimab+HMA in the STIMULUS trial program in MDS/AML.

S169 CLINICAL CHARACTERISTICS AND SURVIVAL OF GATA2-MUTATED MYELOID NEOPLASMS: SINGLE INSTITUTION EXPERIENCE

A. Nanaa [1,*], D. Viswanatha [2], Z. Xie [1], D. Jevremovic [2], P. Nguyen [2], M. Salama [2], P. Greipp [3], K. Bessonen [2], N. Gangat [1], M. Patnaik [1], A. Pardanani [1], H. B. Alkhateeb [1], M. Shah [1], W. Hogan [1], A. Tefferi [1], M. Litzow [1], R. He [1], A. Al-Kali [1]

[1]Hematology, [2]Hematopathology, [3]Cytogenetics, Mayo Clinic, Rochester, United States

Background: The *GATA2* gene, a DNA binding transcription factor with two zinc finger domains, is crucial for the regulation of hematopoietic stem cell proliferation, differentiation and maintenance (Wlodarski et al. Semin Hematol 2017). *GATA2* mutations are seen in myeloid neoplasms (MN) with different domains being associated with different leukemogenic
Aims: To describe patients (pts) with *GATA2*-mutated MN.
Methods: In this study, we included pts with *GATA2* mutations diagnosed with MN between 2015 and 2020 at Mayo Clinic. Pts characteristics were obtained from medical records. Our institution's next-generation sequencing (NGS) panel (OncoHeme) was analyzed to detect mutations in 42 genes recurrently mutated in MN. JMP® Pro 14.1.0 Software was used for statistical analysis
Results: Out of 3,872 pts who underwent NGS testing, a total of 54 pts were identified harboring 64 *GATA2* mutations in four diagnostic groups; 15 (27.7%) myelodysplastic syndromes (MDS), 16(29.6%) myelodysplastic/myeloproliferative neoplasms overlap (MDS/MPN), 9 (16.6%) myeloproliferative neoplasms (MPN) and 14 (25.9%) acute myeloid leukemia (AML). The median age was 67 years, 67% were males (Table 1).
A) *GATA2 mutations characteristics and co-mutations*: Median *GATA2* mutation VAF was 31% in the total cohort (range 5-74%), with 28%, 37%, 34%, and 39% (p= .6) seen in MDS, MDS/MPN, MPN, and AML, respectively. 31 (57%) mutations clustered in the zinc finger 2 domain (ZF2), 9 (17%) in the ZF1 domain and 14 (26%) were outside the ZF domains (non-ZF). ZF1-mutated pts had lower mean VAF compared to ZF2 pts (22% vs. 38%, p=.03), and the majority occurred in AML cases (6/9, 67%), with the most common mutation type being missense (78%). There was a significant association between mutation type and location (p <.0001). The median number of mutations per pts was 4. We identified 28 co-mutations in 52 (96%) pts. *ASXL1* (60%), *SRSF2* (33%) and *RUNX1* (19%) were the most common co-mutations. *ASXL1* was frequently co-mutated with *GATA2*-ZF2 (74%) and non-ZF (22.6%) (only 1 co-mutated with *GATA2*-ZF1). *ASXL1* was also more commonly co-mutated in chronic MN compared to AML (94% vs. 6%, p=.0001). *KIT*, *CEBPA* and *PTPN11* were co-mutated only in ZF1-mutated pts. *KIT, FLT3*, *PTPN11, CEBPA* were co-mutated only in AML, whereas *CALR* was co-mutated only in MPN.
B) *Survival outcome*: After a median follow-up time of 26.4 months, 34 (63%) pts died with a median OS of 23.9, 22.4, 20.6, and 5.6 months in MDS, MDS/MPN, MPN, and AML pts; respectively. After excluding AML pts for survival analysis, we found that pts with several *GATA2* mutations had poorer median OS (4.9 vs. 24.5 months, p=0.03) compared to those with single *GATA2* mutation. MDS pts with chromatin modification co-mutations (*BCOR, EZH2, ASXL1, KDM6A*) (17 vs. 30 months, p=.04) or frameshift (FS) mutation (10.3 vs. 27.3 months, p=.05) had worse median OS compared to those without chromatin modification co-mutation or non-FS mutation, respectively. MDS/MPN overlap pts with *RUNX1* co-mutation had worse median OS (2.2 vs. 25.7 months, p=.0004) than their un-mutated counterparts. There was no difference in median OS between *GATA2*-ZF1, ZF2, and non-ZF (30 vs. 20.6 vs. 22.4 months, p= .7).

Table1. Characteristics and hematological features of GATA2 patients.

Variable	Value
No. of patients	54
Age years, median(range)	67 (26 – 89)
Sex (male), n (%)	36 (67)
Hemoglobin G/DL, median (range)	8.6 (5.8 – 13)
Leukocytes 109/L, median (range)	12.9 (0.3 – 186)
Thrombocytes 109/L, median (range)	53 (1.5 – 873)
MCV median (range)	93 (77 – 119)
ANC , median (range)	6.64 (0.17 – 96.7)
AMC , median (range)	0.39 (0 – 44.5)
ALC , median (range)	1.44 (0.37 – 38.8)
RDW, median (range)	17.7 (13.1 – 26.8)
Number of mutations, median (range)	4 (1 - 6)

Summary/Conclusion: We describe the spectrum and characteristics of *GATA2* mutations across myeloid neoplasms. There was an impact of different *GATA2*-mutation types, single vs several *GATA2* mutations, and co-mutations pattern on survival. Our work was limited by the small number of patients and inability to completely rule out germline mutation possibility.

New directions in aplastic anemia and PNH

S170 GATA2 HAPLOINSUFFICIENCY REDUCES AGED HEMATOPOIETIC STEM CELL FUNCTIONALITY IN MULTIPLE LINEAGES

C. Koyunlar [1,*], E. Gioacchino [1], H. de Looper [1], M. Ter Borg [1], J. Peulen [1], R. Hoogenboezem [1], D. Bosch [1], P. van Strien [1], K. Gussinklo [1], E. Bindels [1], E. Dzierzak [2], I. Touw [1], E. de Pater [1]

[1]Hematology, Erasmus Medical Center, Rotterdam, Netherlands, [2]Cell Biology, The Queen's Medical Research Institute College of Medicine and Veterinary Medicine, Edinburgh, United Kingdom

Background: Mutations in the *GATA2* transcription factor cause immunodeficiency syndromes, which can present with monocytopenia, B cell, NK cell and dendritic cell deficiencies and an increased lifetime risk for myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML) of 80% at 40 years of age. The role of GATA2 haploinsufficiency in the MDS/AML progression is still poorly understood.
Aims: Because patients with *GATA2* mutations have increased lifetime risk of developing MDS/AML, we hypothesize that aging has a

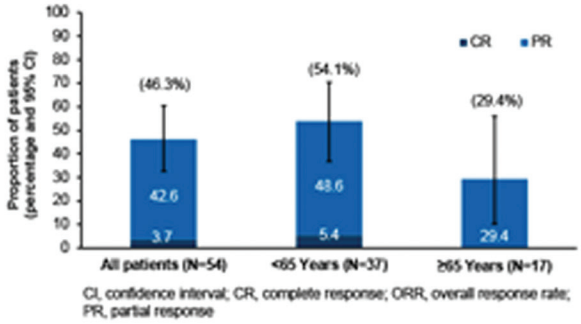
contributing factor in the development of MDS/AML in Gata2 haploinsufficiencies. Therefore, we have analysed *Gata2*$^{+/-}$ mice in aging to reveal the Gata2 dependent mechanisms in leukemic progression.
Methods: We aged *Gata2*$^{+/-}$ and WT mice and performed primary and secondary transplantations of the aged bone marrow to young, lethally irradiated, WT recipients. We have also performed transcriptome analysis on HSCs of the adult, aged and transplanted *Gata2*$^{+/-}$ and WT mice.
Results: We found that HSCs in *Gata2*$^{+/-}$ mice have lost their quiescence. 2 months after transplantation of the aged cells, *Gata2*$^{+/-}$ mice developed B cell cytopenia, which represents the most common feature of GATA2 haploinsufficiency in patients. B cell cytopenia was persistent also after the secondary transplantation. We observed a significantly reduced blood chimerism in *Gata2*$^{+/-}$ mice after secondary transplantation, which suggested HSC exhaustion. 5 months after the secondary transplantation, *Gata2*$^{+/-}$ mice developed neutropenia and monocytopenia in addition to B cell cytopenia.
Summary/Conclusion: These results indicate a reduced functionality of aged and transplanted *Gata2*$^{+/-}$ HSCs in multiple lineages. Currently, we are working on the identification of Gata2 haploinsufficiency phenotype and the analysis of transcriptomic changes in Gata2 haploinsufficient HSCs observed in our aged *Gata2*$^{+/-}$ mouse model. Additionally, we are working on understanding the clonality of HSCs in the aged *Gata2*$^{+/-}$ mice.

S171 GLYCOSYLPHOSPHATIDYLINOSITOL-ANCHORED PROTEIN DEFICIENCY CONFERS RESISTANCE TO ANTIGEN-SPECIFIC T CELLS ON HEMATOPOIETIC STEM PROGENITOR CELLS IN APLASTIC ANEMIA PATIENTS WITH HLA-DR15

N. Tsuji [1,*], K. Hosokawa [1], R. Urushihara [1], M. Tanabe [1], H. Takamatsu [1], K. Ishiyama [1], H. Yamazaki [2], S. Nakao [1]

[1]Department of Hematology, [2]Division of Transfusion Medicine, Kanazawa University, Kanazawa, Japan

Background: Glycosylphosphatidylinositol-anchored protein-deficient (GPI[-]) cells are often detected in patients with acquired aplastic anemia (AA) and are thought to represent immune pathogenesis of bone marrow (BM) failure; however, little is known what kind of immune responses favor the proliferation of *PIGA*-mutated hematopoietic stem progenitor cells (HSPCs) over GPI(+) HSPCs to induce an increase in GPI(-) cells in peripheral blood (PB) of AA patients. We recently identified HLA-DR lacking HSPCs in four AA patients with HLA-DR15 whose hematopoietic function depended on cyclosporine (CsA, ASH2020 abstract #933). Since DR15 has been implicated in the development of PNH and all these patients possessed GPI(-) granulocytes, CD4$^+$ T-cell attack that allows DR15(-) HSPCs to survive may also contribute to the survival advantage of GPI(-) HSPCs.
Aims: To test this hypothesis, we analyzed the HLA-DR expression on GPI(+) and GPI(-) HSPCs in PB of patients with AA or PNH in remission, and determined which HSPC population underwent the HLA-DR loss.
Methods: We determined the HLA-DR expression on HSPCs defined as lineage$^-$CD45^{dim}CD34$^+$CD38$^+$ cells in 52 AA patients (38 with GPI[-] granulocytes and 14 without) and 5 with hemolytic PNH (37 with DR15 and 20 without DR15) as well as 20 healthy individuals using flow cytometry with anti-pan-HLA-DR antibodies. All patients were in remission after immunosuppressive therapy or anabolic steroids, although 20 required low-dose CsA to maintain remission. Nineteen (33%) had HLA-class I allele-lacking (HLA-class I[-]) leukocytes due to 6pLOH and/or allelic mutations.
Results: Eight (14.0%, 6 with AA and 2 with PNH) of the 57 patients had DR(-) cell populations accounting for 11.1% to 56.0% (median 39.8%) of HSPCs, and these cells were not detected among either monocytes or B lymphocytes of the same patients or among HSPCs of any healthy individuals. All 8 of these patients possessed either *HLA-DRB1*15:01* (n=5), *DRB1*15:02* (n=2), or *DRB1*15:01/15:02* (n=1), with the other DRB1 alleles differing among individuals. In addition to HSPCs completely lacking DR, these patients also possessed HSPCs partially lacking DR, findings that were not detected in the other 49 patients or healthy individuals. Of particular interest, DR(-) cells were exclusively detected in GPI(+) HSPCs in four patients (two with AA and two with PNH) whose HSPCs were able to be analyzed separately for GPI(+) and GPI(-) HSPCs. In one patient whose HSPCs were serially evaluable over 6 years, the DR(-) cell proportion increased from 29.2% to 57.1% following temporary discontinuation of CsA, during which period the proportion of GPI(-) granulocytes in PB increased from 0.037% to 3.78%. Only 1 of the 8 patients possessed HLA-class I(-) leukocytes, which were detected in 19 (39%) of 49 patients not possessing DR(-) HSPCs.
Summary/Conclusion: HLA-DR-lacking HSPCs were exclusively detected in AA/PNH patients with DR15, suggesting that CD4$^+$ T cells specific to autoantigens presented by DR15 are involved in the development of BM failure. The presence of HSPCs partially lacking DR in these patients suggests the presence of HSPCs that lack DR15 but retain the other DR allele. Given that DR(-) cells were only detected in GPI(+) HSPCs and the expansion of DR(-) cells occurred concomitantly with the expansion of GPI(-) clones after CsA cessation, the antigen-specific CD4$^+$ T-cell attack against HSPCs is likely responsible for the survival advantage of GPI(-) HSPCs in AA/PNH.



S172 AN INTERVENTIONAL, PHASE 2, SINGLE-ARM STUDY TO ASSESS THE EFFICACY AND SAFETY OF ELTROMBOPAG COMBINED WITH CYCLOSPORINE AS FIRST-LINE THERAPY IN ADULTS WITH SEVERE ACQUIRED APLASTIC ANEMIA (SOAR)

E. Montaño-Figueroa [1,*], C. Vallejo [2], C. Finelli [3], J. Jang [4], R. Peffault de Latour [5], U. Kriemler-Krahn [6], J. Haenig [6], J. Maier [6], P. Scheinberg [7]

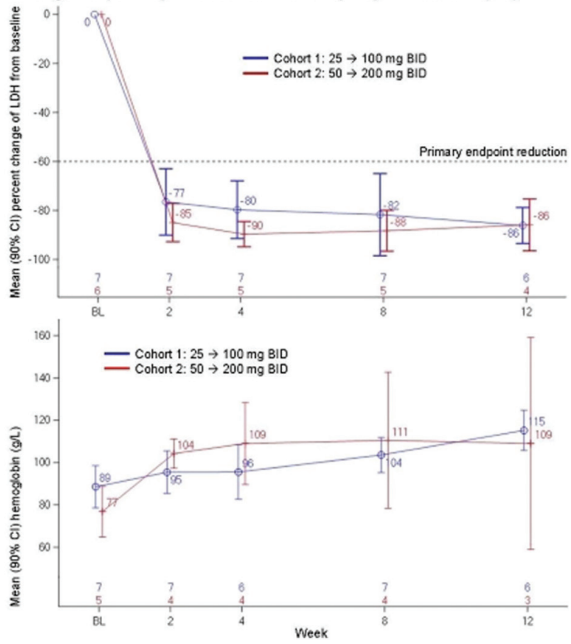
[1]General Hospital of Mexico, Mexico City, Mexico, [2]Donostia University Hospital, San Sebastián, Spain, [3]IRCCS Azienda Ospedaliero-Universitaria di Bologna Institute of Hematology "Seràgnoli", Bologna, Italy, [4]Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of, [5]Saint-Louis Hospital, Paris, France, [6]Novartis Pharma AG, Basel, Switzerland, [7]Hospital A Beneficência Portuguesa, São Paulo, Brazil

Background: Severe aplastic anemia (SAA) is a life-threatening bone marrow failure disorder characterized by pancytopenia and a hypocellular bone marrow. The standard of care for patients that are ineligible for hemopoietic stem cell transplant is immunosuppressive therapy (IST), comprising antithymocyte globulin (ATG) and cyclosporine A (CsA). Horse (h-) ATG is considered more effective than rabbit ATG; however, lack of response, relapse, and clonal evolution remain significant limitations. Expense, individual intolerance, and a lack of global availability of h-ATG also leave many patients (pts) with more limited treatment options and poorer outcomes. Eltrombopag (ETB) is indicated for use in patients with SAA who have had an insufficient response to IST (FDA PI, 2014) or are refractory to IST (EMA SmPC, 2015). More recently in the USA, ETB may also be used in combination with IST as first-line treatment (FDA PI, 2018).
Aims: To assess the efficacy and safety of an ATG-free regimen (ETB + CsA) in treatment-naïve pts with SAA.
Methods: SOAR (NCT02998645) is a Ph2, single-arm, multicenter, open-label study. Adult pts with SAA received ETB + CsA as first-line therapy for 6 months; responders continued CsA therapy for an additional 24 months (subsequently reduced to 18 months). The primary efficacy endpoint was overall response rate (ORR) by 6 months. ORR was defined as the proportion of pts with complete response ([CR] = absolute neutrophil count [ANC] ≥1000/μL AND platelet count ≥100,000/μL AND hemoglobin ≥10 g/dL) plus the proportion of pts with partial response ([PR] = any 2 of the following counts: ANC ≥500/μL; platelet count ≥20,000/μL; automated reticulocyte count ≥60,000/μL, but not sufficient for a CR). CR and PR were confirmed by 2 assessments ≥7 days apart; transfusion restrictions were applied. Based on historical data, an ORR of ≥30% was considered clinically meaningful.
Results: A total of 54 pts were enrolled. The median (interquartile range [IQR]) age was 55.0 (40.0-67.0) years, 63.0% were male, and the majority of pts were White (40.7%) or Asian (40.7%). The median (IQR) duration of exposure to ETB and CsA were 5.7 (2.5-5.8) months and 5.7 (2.4-8.1) months, respectively, and the median (IQR) daily ETB dose was 150.0 (100.0-150.0) mg/day. In the full analysis set, the primary endpoint was met with an ORR by 6 months of 46.3% (25/54); 95% CI, 32.6-60.4% (Fig. 1). Of the 25 responders, 2 (3.7%) achieved CR by 6 months. ORR by 6 months is also shown by age group (<65 and ≥65 years) (Fig. 1). Secondary endpoints included ORR by 3 months (40.7% [22/54]; 95% CI, 27.6-55.0%), and ORR at 6 months (ie, patients with confirmed response at 6-month visit: 37.0% [20/54]; 95% CI, 24.3-51.3%). Adverse events (AEs) occurred in 52/54 pts; 45 (83.3%) pts experienced treatment-related AEs (TAEs), 23 (42.6%) of whom had a grade ≥3 TAE. The most common all-grade AEs were increased blood bilirubin (40.7%), nausea (29.6%), increased alanine aminotransferase (22.2%), and diarrhea (22.2%). Seven (13.0%) pts discontinued study due to AEs. There were 8 on-treatment deaths (aplastic anemia [n=3]; COVID-19, hemorrhage, multi-organ dysfunction syndrome, pyrexia, and thrombosis [all n=1]); no deaths were considered treatment-related.

Figure 1: ORR by 6 months (full analysis set)

CI, confidence interval; CR, complete response; ORR, overall response rate; PR, partial response

Summary/Conclusion: Data from the SOAR study indicate that ETB + CsA therapy may be beneficial as first-line treatment for SAA pts who cannot use ATG. The ORR is particularly notable, given the median age of this pt cohort (55.0 years). No new safety signals were identified.



S173 FIRST-LINE TREATMENT OF PNH PATIENTS WITH IPTACOPAN LEADS TO RAPID AND DURABLE HEMOGLOBIN INCREASE BY CONTROLLING BOTH INTRA- AND EXTRAVASCULAR HEMOLYSIS

J. H. Jang [1,*], L. Wong [2], B. -S. Ko [3], S. -S. Yoon [4], K. Li [5], I. Rozenberg [6], P. K. Nidamarthy [7], R. Chawla [8], G. Junge [8], E. S. Yap [9]

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a severe hematological disease caused by an acquired PIGA mutation in hematopoietic stem cells, leading to loss of regulatory proteins affecting the complement alternative pathway, of which factor B is an essential component. The only regulatory approved treatment for hemolytic PNH is based on antibodies targeting complement component 5 (C5), controlling intravascular hemolysis, reducing thromboembolic events, and eventually improving long-term survival. However, 20-50% of patients remain transfusion-dependent due to persistent extravascular hemolysis, and an additional 20-40% exhibit varying degrees of residual anemia. Iptacopan (LNP023) is a new, oral, selective and potent first-in-class factor B inhibitor, designed to block both intra- and extravascular hemolysis.
Aims: The trial presented here investigates the effect of first-line iptacopan monotherapy on intra- and extravascular hemolysis, the extent of red blood cell (RBC) C3 opsonization, and changes in hemoglobin levels in anti-C5 naive PNH patients with active hemolysis.
Methods: CLNP023X2204 (NCT03896152) is a multi-national, randomized Phase 2 efficacy, safety, pharmacokinetics/-dynamics study assessing four iptacopan doses in two separate cohorts with two treatment periods each in treatment-naive adult PNH patients with active hemolysis. The primary objective is to assess the effect of iptacopan on the reduction of PNH-associated hemolysis. Additional objectives include assessing the effect on hemoglobin levels, the dose-response effect, and the effect on markers associated with a risk of thrombosis.
Results: A total of N=13 patients (ages 20-62; n=7 female) were randomized to either Cohort 1 (iptacopan 25-to-100 mg dose increase at Week 4; N=7) or Cohort 2 (50-to-200 mg; N=6). Median (range) lab values at baseline were: Hb 86.5 (68-107) g/L, reticulocytes 209 (30-352) x10E9/L, LDH 1686 (1008-3761) U/L, bilirubin 27.0 (20.0-51.0) umol/L; haptoglobin was below lower limit of detection for all patients. The primary endpoint of lowering LDH by at least 60% was reached for all patients. Mean LDH levels declined by 79.7 and 86.2% in Cohort 1 and by 89.7 and 85.9% in Cohort 2 at weeks 4 and 12, respectively [Figure 1]. Importantly, all patients remained transfusion-free up until week 12, with the exception of one patient who received a single RBC transfusion on study day 3; Hb levels spontaneously increased by a mean of 23.4 and 37.1 g/L at week 12 in Cohorts 1 and 2, respectively [Figure 1]; and no thromboembolic events were reported. In addition, reticulocyte counts decreased by a mean of 93.0 and 84.9 x10E9/L, and bilirubin decreased by a mean of 21.6 and 23.2 umol/L in Cohorts 1 and 2, respectively. Iptacopan was well tolerated (n=1 discontinued from the trial at Day 2 due to headache); no fatal events and no serious adverse events were reported during the 12-week treatment period.

Figure 1: Mean percent change of LDH from baseline (top) and mean hemoglobin (bottom) over time for cohort 1 (blue) and cohort 2 (red)

Summary/Conclusion: Iptacopan is a new, well-tolerated oral factor B inhibitor that blocks both intra- and extravascular hemolysis in patients with hemolytic PNH. 12-week study results demonstrate that, in anti-C5 naive patients with active hemolysis, iptacopan therapy ≥50 mg BID results in normalization of various hemolytic markers and resolution of anemia. Maximal effects on various efficacy parameters were obtained at 200 mg BID. These results demonstrate that proximal inhibition of the complement cascade parallel and further improve the hematological benefit seen with anti-C5 therapies, with iptacopan eventually offering an alternative first-line therapy for patients with PNH.

S174 FORTY-EIGHT WEEK EFFICACY AND SAFETY OF PEGCETACOPLAN IN ADULT PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA AND SUBOPTIMAL RESPONSE TO PRIOR ECULIZUMAB TREATMENT

Background: Pegcetacoplan (PEG), a PEGylated peptide targeting proximal complement protein C3, can control both intravascular and extravascular hemolysis. In the PEGASUS trial (NCT03500549), a phase 3, randomized, open-label, active-comparator controlled study, PEG was shown to be superior to eculizumab (ECU) after 16 weeks in improving hemoglobin levels (Hb) and clinical outcomes in patients with paroxysmal nocturnal hemoglobinuria (PNH) *(Hillmen P et al, EHA 2020)*.
Aims: We report on the efficacy and safety of PEG through 48 weeks of treatment.
Methods: This study is a continuation of the PEGASUS trial. Eighty patients ≥18 years with PNH, and Hb levels <10.5 g/dL despite stable ECU treatment for ≥3 months, were enrolled. Patients completed a 4-week run-in period with both ECU and PEG before 1:1 randomization to PEG (n=41; 1080 mg subcutaneously twice weekly) or ECU monotherapy (n=39; continued dosing regimen). The primary endpoint was the change from baseline (CFB) in Hb levels to Week 16. After the randomized control period (RCP), patients could continue to an open-label period (OLP), which included a 4-week run-in period for ECU patients (ECU-to-PEG), followed by PEG monotherapy (same dosage as in RCP) for all patients for a 48-week total study period. Key secondary endpoints included blood transfusion avoidance, CFB in absolute reticulocyte count (ARC), CFB in lactate dehydrogenase (LDH), CFB in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score, and adverse events (AEs).
Results: Three patients discontinued PEG during the 16-Week RCP due to hemolysis; the remaining 77 patients entered the OLP. PEG demonstrated superiority to ECU with a mean Hb level improvement of 2.7 g/dL at Week 16, which was sustained throughout the OLP in all patients receiving PEG monotherapy. ECU-to-PEG patients demonstrated Hb improvement with mean Hb levels of 11.6 g/dL at Week 48 (CFB: 2.9 g/dL), while PEG-to-PEG patients maintained high Hb levels through the OLP with a mean Hb level of 11.3 g/dL at Week 48 (CFB: 2.6 g/dL) (Figure A).
Seventy-three percent of PEG-to-PEG patients remained transfusion free for the 48-week study, and 72% of the ECU-to-PEG patients were transfusion free during the OLP through Week 48. Improvements in ARC (PEG-to-PEG: 80.0×10^9 cells/L; ECU-to-PEG: 94.0×10^9 cells/L), LDH (PEG-to-PEG: 222.7U/L; ECU-to-PEG: 224.1 U/L), and FACIT-fatigue score (PEG-to-PEG: 40.6; ECU-to-PEG: 42.5) were also observed at Week 48 (Figure B).
The most common AEs by physician-reported preferred term throughout the study for all patients who received PEG were injection site reactions (36%), hemolysis (24%), and diarrhea (21%). Of all study patients, 30% experienced serious AEs with 6% possibly related to PEG. No cases of meningitis were reported. One death was reported due to COVID-19, unrelated to study treatment. Six patients discontinued due to hemolytic events: 5 classified by the treating physician as "hemolysis" and 1 as "hemolytic anemia." Overall, 12 patients (15%) discontinued PEG: 3 in RCP, 8 in OLP due to TEAEs (6 in ECU-to-PEG, 2 in PEG-to-PEG), and one during follow-up; one patient withdrew due to physician decision.

A.

*PEG run-in in the ECU-to-PEG arm

B.

	PEG			ECU		
	Baseline	Week 16	Week 48 PEG-to-PEG	Baseline	Week 16	Week 48 ECU-to-PEG
Hb level, g/dL; NRR, 12.0-18.0 g/dL Mean (SD)[a]	8.7 (1.1)	11.5 (2.0)	11.3 (1.8)	8.7 (0.9)	8.6 (1.0)	11.6 (2.2)
Transfusion Transfusion avoidance, n (%)	N/A	35 (85)	30 (73)	N/A	6 (15)	28 (78)
ARC, ×10^9 cells/L; NRR, 30-120×10^9 cells/L Mean (SD)	217.5 (75.0)	77.1 (26.6)	80.0 (26.8)	216.2 (69.1)	221.8 (88.7)	94.0 (50.1)
LDH, U/L; NRR, 113-226 U/L Mean (SD)	257.5 (97.7)	189.1 (78.1)	222.7 (141.1)	308.6 (284.8)	353.2 (477.5)	224.1 (133.5)
FACIT-Fatigue Score; population norm (43.6) Mean (SD)	32.2 (11.4)	41.8 (9.6)	40.6 (10.1)	31.6 (12.5)	30.6 (11.8)	42.5 (8.7)

ARC, absolute reticulocyte count; ECU, eculizumab; FACIT, Functional Assessment of Chronic Illness Therapy; Hb, hemoglobin, LDH, lactate dehydrogenase; N/A, not applicable; NRR, normal reference range; PEG, pegcetacoplan; PNH, Paroxysmal Nocturnal Hemoglobinuria; PRBC, packed red blood cell; SD, standard deviation. [a]Observed values by group differ from the combined PEG monotherapy mean CFB described in the text.

Summary/Conclusion: Adult patients with PNH with suboptimal response on prior ECU treatment received PEG in this continuation of the PEGASUS trial and experienced durable treatment effect in all efficacy parameters at Week 48. The safety profile of PEG was consistent with previously reported data. The results suggest that PEG represents a new effective therapeutic option for patients with PNH.

Background: BCMA targeting CAR T-cells or T-cell engaging bispecific antibodies (TCE) show high response rates in relapsed/refractory (RR) multiple myeloma (MM). Beyond BCMA, a number of other plasma cell targets such as SLAMF7, FCRH5, and GPRC5D are currently under investigation with promising preliminary results. Yet, patients continue to relapse and no survival plateau after CAR T-cells or TCEs has been observed so far. Recently, we described the first tumor-intrinsic resistance mechanism to BCMA-directed CAR T-cell therapy, unraveling biallelic loss of the *BCMA* gene as the cause of antigen escape after anti-BCMA CAR T therapy. Whether this mechanism of resistance is also relevant for TCE therapy, is currently unknown.
Aims: (1) To elucidate the mechanism of resistance to BCMA-directed TCE treatment. (2) To analyze genomic alterations in genes encoding for plasma cell targets in MM patients prior to immunotherapy by WGS and RNA sequencing (RNAseq).
Methods: WGS was performed in 100 MM patients (50 newly diagnosed, 50 RR) with WGS libraries prepared from CD138 purified cells and 2x150bp paired-end sequences generated on NovaSeq6000 with 100x coverage. For RNAseq of 72 patients stranded RNA libraries were produced and 2x100bp paired-end reads were sequenced on NovaSeq6000 with a median of 64 million reads per sample. BCMA protein expression was determined by immunohistochemistry (AF193, R&D systems) on paraffin embedded bone marrow sections.
Results: We report on a RRMM patient who experienced homozygous *BCMA* gene deletion after relapse from CD3xBCMA TCE therapy. Initially, the patient responded well to TCE therapy and achieved a CR, but relapsed after 6 months of treatment. Retrospective immunohistochemistry on bio-banked trephine biopsies showed strong and consistent BCMA expression prior to TCE therapy but a complete loss of BCMA expression at relapse. Without knowing about BCMA loss at relapse at that time, belantamab mafodotin was administered, to which the patient was primary refractory. Together, irreversible antigen loss and failure of subsequent BCMA-directed therapy, highlights targeted immunotherapies to present an evolutionary bottleneck in MM progression.
To further explore the relevance of this resistance mechanism, we screened for genomic alterations in *BCMA* and other immunotherapy targets. Indeed, we found heterozygous deletions in *GPRC5D* (15%), *CD38* (10%), *SDC1* (5%), *TNFRSF17* (4%) and *NCAM1* (3%). Overall, heterozygous deletions occurred in 30% of patients, and some patients showed deletions in up to three different immunotarget genes. As expected, we observed a clear trend for more deletions in pretreated patients. Notably, single nucleotide variants (SNV) in genes encoding for immune targets were only found at low frequency. Gains, heterozygous deletions, and SNV in genes encoding for immunotherapy targets did not result in significant changes of gene expression by transcriptome analysis in 72 patients, suggesting that expression of these genes is not solely regulated by their copy number and that antigen loss requires a biallelic event.
Summary/Conclusion: (1) Biallelic *BCMA* gene deletion may be a key immune-evasion mechanism to BCMA targeting T-cell therapies. (2) This mechanism of resistance to immunotherapies may affect alternative antigens as we detected genomic vulnerability in their encoding genes in a significant number of treatment naïve patients. (3) Combination of different immunotargets, e.g. multi-specific CAR T-cells, might be an approach to overcome drug resistance caused by loss of a single antigen.

S176 DISCOVERY OF A SELECTIVE INHIBITOR OF THE SETD2 HISTONE METHYLTRANSFERASE WITH POTENT IN VITRO AND IN VIVO ACTIVITY IN PRECLINICAL MODELS OF MULTIPLE MYELOMA

J. Totman [1,*], J. W. Lampe [1], T. V. Riera [1], C. Tang [1], D. Brach [1], V. Motwani [1], J. S. Alford [1], N. A. Farrow [1], D. T. Dransfield [1], K. W. Duncan [1], E. Deutschman [1], S. T. Eckley [1], S. Howe [1], A. Raimondi [1], M. J. Thomenius [1], J. L. Kutok [1], K. Cosmopoulos [1]

[1]*Research, Epizyme, Inc., Cambridge, United States*

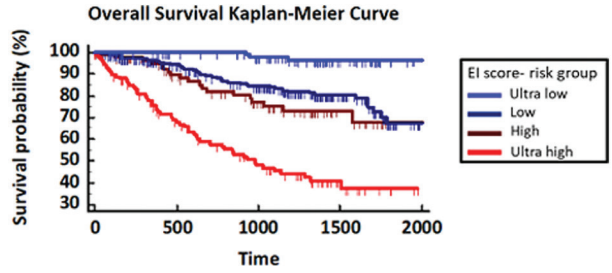
Background: Multiple myeloma (MM) is a heterogeneous disease of monoclonal plasma cells. Nearly 50% of MM patients harbor translocations of the immunoglobulin heavy chain (IgH) gene on chromosome 14q32 leading to overexpression of putative oncogenes (Kuehl, 2002). One of the most common translocations in MM (15-20%) juxtaposes IgH control elements with two genes on chromosome 4, fibroblast growth factor receptor 3 and multiple myeloma SET domain (MMSET). This (4;14) (p16; q32) translocation is associated with poor prognosis and less effective treatment with standard of care (SOC) therapy. MMSET expression has been confirmed as a driver in t(4;14) MM pathogenesis (Keats, 2003), but MMSET remains undruggable. SETD2 is currently the only known histone methyltransferase (HMT) capable of catalyzing H3K36 trimethylation, utilizing MMSET-catalyzed H3K36me2 as its substrate. To date, a gain of function role for SETD2 in oncogenesis and tumor survival has not been demonstrated. Our data suggests that the overexpression of MMSET and subsequent increase in H3K36me2 in t(4;14) MM leads to a dependency on SETD2 for MM cell growth and survival.
Aims: Characterization of a small molecule SETD2 inhibitor exhibiting potent *in vitro* anti-proliferative activity and a pharmacokinetic profile that supports *in vivo* efficacy in preclinical models of MM.
Methods: Biochemical selectivity assays performed in a panel of HMTs and a 14-day cellular proliferation assay determined IC_{50}'s in MM cell lines of diverse genetic subtypes. Combinatorial potential of SETD2 inhibition with anti-MM SOC agents was evaluated in 7-day cotreatment *in vitro* cellular assays. Mouse xenograft studies in MM models assessed tumor growth inhibition. H3K36me3 levels determined by western blot and ELISA to evaluate target engagement by SETD2 inhibitor.
Results: A small molecule inhibitor of SETD2 methyltransferase enzymatic activity was characterized demonstrating an IC_{50} value of 5.3 nM in biochemical assays with greater than 10,000-fold selectivity against a panel of 14 HMTs. Inhibition of SETD2 results in potent inhibition of proliferation in 6 of 7 t(4;14) MM cell lines *in vitro* with an average IC_{50} of 0.14 uM and resulted in marked reduction of H3K36me3. Isogenic t(4;14) cell lines containing allele-specific knock-out of MMSET demonstrated sensitivity to SETD2 inhibition only in the presence of the overexpressed MMSET allele. *In vivo* efficacy studies in the KMS11 t(4;14) cell line-derived xenograft model resulted in robust tumor growth inhibition (TGI) in a dose-dependent manner with maximal TGI of 95% achieved at the top doses administered and corresponding reduction in intratumoral H3K36me3 levels. Interestingly, *in vitro* anti-proliferative activity was also demonstrated in 13 of 15 non-t(4;14) MM cell lines tested with an average IC_{50} of 1.8 uM. SETD2 inhibition in xenografts from the two most sensitive non-t(4;14) MM cell lines resulted in strong TGI with maximal inhibition of 92% at the top dose administered. Lastly, *in vitro* synergy was observed with MM SOCs, supporting a rationale to combine SETD2 inhibition with current MM therapies.
Summary/Conclusion: To our knowledge, these are the first preclinical data to show successful targeting of the underlying oncogenic mechanism driven by MMSET overexpression in t(4;14) MM and the first demonstration of SETD2 as an oncogenic driver. Importantly, this work validates the targeting of SETD2 with a small molecule inhibitor in MM and presents a promising potential therapeutic option for the high-risk t(4;14) MM patient population.

S177 REGULATED MEMBRANE BOUND IL-15 INCREASES BCMA CAR-T EXPANSION, POTENCY, AND DURABILITY OF RESPONSE IN A XENOGRAFT MODEL OF MULTIPLE MYELOMA

B. Dolinski [1,*], M. Langley [1], T. Ross [1], N. Ly [1], R. Prenovitz [1], A. Kulkarni [1], G. Mylvaganam [1], M. Gallo [1], D. Sun [1], D. Thornton [1], K. Tran [1], M. Inniss [1], J. ter Meulen [1], G. Vanasse [1], J. Tchaicha [1], M. Ols [1]

[1]*Obsidian Therapeutics, Cambridge, United States*

Background: B cell maturation antigen (BCMA) is a promising immunotherapy target for patients with multiple myeloma (MM). Although BCMA CAR-T therapies have delivered high overall and complete response rates in heavily pretreated patients, a majority of patients continue to relapse and MM remains incurable, supporting the need for more potent and durable therapies.
Aims: To develop a more potent and persistent BCMA therapy, we engineered BCMA CAR-Ts with membrane bound IL-15 (mbIL15) to determine whether IL15 could improve BCMA CAR-T performance, enabling greater *in vivo* expansion potential and antigen-independent CAR-T persistence following tumor clearance. To engender this potent product with titratable, drug-like properties, we also coupled mbIL15 to Obsidian's regulated cytoDRiVE™ technology, providing superior efficacy and safety for patients with MM.
Methods: Obsidian's cytoDRiVE™ platform consists of small, fully human protein sequences called drug responsive domains (DRD)s that enable regulated expression of a fused target protein under control of FDA-approved, orally bioavailable small molecule ligands. BCMA CAR-T cells were engineered with mbIL15 fused to a carbonic anhydrase 2 (CA2) DRD that facilitates regulation of mbIL15 expression via acetazolamide (ACZ) administration. *In vitro* mbIL15 activity was assessed in an assay of CAR-T expansion and survival in the absence of antigen or exogenous cytokines and by immunophenotyping. CAR-T function was assessed *in vitro* using cytotoxicity and cytokine production assays. We also evaluated IL15-driven antigen-independent BCMA CAR-T cell expansion in non-tumor-bearing NSG mice, as well as anti-tumor efficacy in a $BCMA^+$ MM xenograft tumor model.
Results: mbIL15-BCMA CAR-T cells retained equivalent CAR activity compared with standard BCMA CAR-Ts not expressing mbIL15, as evidenced by cytotoxicity against, and IFNγ and IL2 cytokine production in response to, $BCMA^+$ RPMI8226 MM cells *in vitro*. In the presence of ACZ, functional levels of mbIL15 were expressed on the cell surface of the mbIL15-BCMA CAR-Ts, which supported *in vitro* antigen independent survival, expansion, and development of a $CD45RO^-$, $CCR7^+$, $CD95^+$, $CD27^+$ memory stem cell phenotype. Two weeks after adoptive cell transfer into non-tumor-bearing mice, animals receiving daily ACZ displayed elevated numbers of CAR-Ts in the peripheral blood, and mbIL15 was specifically expressed on CAR-Ts from ACZ- but not vehicle-dosed animals. In RPMI8226 tumor-bearing mice, regulated mbIL15 increased expansion of BCMA CAR-T cells, promoting anti-tumor activity at lower cell doses than BCMA CAR-Ts without mbIL15. Upon tumor rechallenge, regulated mbIL15 prevented tumor growth, demonstrating CAR-T persistence for up to 72 days post initial cell transfer. Regulation of mbIL15 expression on BCMA CAR-Ts also resulted in modulation of inflammatory cytokines detected in the plasma of MM tumor-bearing mice.
Summary/Conclusion: Regulated mbIL15 resulted in BCMA CAR-Ts marked by a memory stem cell phenotype with increased anti-tumor activity and enhanced response duration, even at suboptimal CAR-T cell doses. Regulating mbIL15 levels with our novel DRD control system supports improved antigen-independent T cell expansion and survival, translating to more potent and persistent BCMA CAR-Ts. Thus, Obsidian's cytoDRiVE™ technology confers drug-like properties to CAR-Ts, providing physicians with potentially greater control of CAR-T expansion and survival to optimize durable CAR-T efficacy and safety for patients with MM.



S178 IMPROVING THE RISK STRATIFICATION OF MULTIPLE MYELOMA WITH A BASE EDITORS/INFLAMMATION-BASED SCORING SYSTEM

A. M. Shariatpanahi [1,*], S. Grasedieck [2], M. C. Jarvis [3], F. Borzooee [4], R. S. Harris [3], M. Larijani [4], K. Song [5], A. Rouhi [1], F. Kuchenbauer [1]

Background: Current clinical prognostication of newly diagnosed MM (NDMM) patients relies on clinical parameters and/or recurrent genetic changes, which mainly reflect early events in the development of MM. However, recent insights into the pathogenesis of MM highlighted

genome/transcriptome editing through APOBEC/ADAR genes as well as inflammation as drivers for the onset and progression of MM.
Aims: To build a superior base editors/inflammation-based risk scoring system reflecting biological processes that drive the progression of MM.
Methods: We hypothesized that a prognostic score reflecting biological processes as well as clinical features is superior to the currently used classification systems for MM patients, such as ISS, R-ISS and the Mayo clinic classification. The Multiple Myeloma Research Foundation CoMMpass study genomics dataset, combining mRNA Seq and clinical data from more than 700 patients, allowed us to evaluate the prognostic value of demographic and clinical parameters, cytogenetics, and gene expression levels of ADAR and the APOBEC family as well as inflammation-modulating cytokines of MM patients. We calculated hazard ratios and Kaplan-Meier survival estimates for all extracted features. Combining clinical variables that were significantly associated with PFS and OS, we then applied machine learning approaches to identify the most accurate classification model to define a new risk score that is easy to compute and able to stratify NDMM patients more accurately than cytogenetics-based classifiers.
Results: Based on our machine learning models, we defined a weighted OS/PFS risk score (*E*ditor-*I*nflammation score) based on expression of *APOBEC2, APOBEC3B, APOBEC3C, APOBEC3D, ADAR1, IL10, IL11, IL27, TGFB1, TGFB2,* as well as ß-2-microglobulin, hemoglobin, LDH and creatinine serum levels, that achieved the best classification outcome and showed superior performance compared to ISS and R-ISS. Of note, cytogenetic abnormalities did not proof relevant have therefore not been included in the EI score. Besides superior overall risk stratification, the EI score further allowed to identify subgroups of MM patients with very good prognosis and an "ultra high risk" group of patients who do not benefit from bone marrow transplantation maintenance therapy.

Number at risk				
Group: High				
91	61	43	14	1
Group: Low				
284	200	157	58	5
Group: Ultra high				
108	61	39	11	0
Group: Ultra low				
112	95	80	31	6

Summary/Conclusion: Our findings support the adoption of molecular biomarkers, reflecting dynamic biological processes rather than cytogenetics for a more accurate risk classification of MM. Considering that mRNA-seq is as cost effective as FISH and is being increasingly adopted by diagnostic centres, the EI score is a unique approach to shed light on underlying molecular mechanisms that drive disease progression and the development of true risk-adapted treatment strategies.

S179 MULTIPLE MYELOMA DERIVED MITOCHONDRIAL DAMPS PROMOTE A PRO-INFLAMMATORY SIGNATURE WITHIN THE MYELOMA BONE MARROW MICROENVIRONMENT

A. Jibril [1,*], S. Rushworth [1], K. Bowles [2], C. Hellmich [1], J. Moore [1], J. Mistry [1]

[1]University of East Anglia, [2]Haematology, Norfolk and Norwich University Hospital, Norwich, United Kingdom

Background: Multiple myeloma (MM) is a malignancy of the antibody secreting plasma cells, that is characterized by the accumulation and localisation of tumour cells within the bone marrow microenvironment (BMM). The mitochondrial genome belongs to a group of mitochondrial damage associated molecular patterns (mtDAMPs) and contains islands of unmethylated CpG nucleotide motifs, which have been shown to activate and promote memory B cell antibody secretion and proliferation. Studies have indicated that mitochondrial DNA (mtDNA) is elevated in the circulation of trauma and cancer patients.
Aims: Here we aim to explore the hypothesis that multiple myeloma cells secrete mitochondrial DNA and other mitochondrial DAMPs into the bone marrow microenvironment, leading to the promotion of a state of chronic inflammation that supports multiple myeloma disease progression and expansion.
Methods: Immunocompromised NSG mice were engrafted with human myeloma cell line (MMIS), blood serum samples were taken and analysed using real-time PCR (RT-PCR) to detect the presence of human mtDNA. We established syngeneic mouse models of multiple myeloma using the murine 5TGM1 myeloma cell line, flow cytometry was used to analyse the haematopoietic stem and progenitor cell (HSPC) and macrophage populations within the bone marrow. Bone marrow derived macrophages were sorted from these mice and RT-PCR was used to analyse pro-inflammatory gene expression. To further investigate the role of mtDNA in HSPC expansion, C57BL/6 mice were treated with multiple doses of CpG oligodeoxynucleotides to mimic the mtDNA released by MM. *in vitro*, BMDM were treated with CpG and mtDNA and pro-inflammatory gene expression was analysed via RT-PCR. To further understand the role of mtDAMPs in regulating proinflammatory signals in the MM microenvironment, we used an inhibitor to block TLR9 (toll-like receptor), the key mtDNA sensing receptor.
Results: We detected elevated levels of MM derived mtDNA in the blood serum of immunocompromised NSG mice engrafted with human myeloma cell line (MM1S). Flow cytometry analysis of the HSPC populations showed that 5TGM1 induced an expansion of the stem cell niche, and real-time PCR analysis of the blood serum showed an elevated level of cell free mtDNA in 5TGM1 engrafted mice. Moreover, the frequency of tumour associated macrophages (TAM) was increased in 5TGM1 engrafted mice and RT-PCR analysis of sorted BMDM showed a pro-inflammatory phenotype. Flow cytometry analysis of CpG treated mice revealed an expansion of HSPC populations similarly found in 5TGM1 engrafted mice. Furthermore, *in vitro* analysis of BMDM treated with mtDNA and CpG showed increased expression of pro-inflammatory cytokines including IL-6. Lastly, blocking of the TLR9 receptor resulted in reduced MM tumour burden in 5TGM1 engrafted mice treated with TLR9 inhibitor compared to untreated mice.
Summary/Conclusion: Here we ascertain that MM releases mtDNA into the microenvironment and show the involvement of mtDAMPs in promoting the disease progression of MM via a pro-inflammatory BMM. This data proposes targeting potential receptor signalling pathways as a novel therapeutic intervention for multiple myeloma.

New treatment strategies for newly diagnosed multiple myeloma

S180 DARATUMUMAB MAINTENANCE VS OBSERVATION IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA TREATED WITH BORTEZOMIB, THALIDOMIDE, AND DEXAMETHASONE ± DARATUMUMAB AND ASCT: CASSIOPEIA PART 2 RESULTS

Background: Daratumumab in conjunction with bortezomib, thalidomide, and dexamethasone (D-VTd) and autologous stem cell transplantation (ASCT) is approved for the treatment of transplant-eligible patients with newly diagnosed multiple myeloma (NDMM) based on results from CASSIOPEIA part 1.
Aims: To assess daratumumab maintenance vs observation (OBS) in patients with partial response or better (≥PR) in part 1, regardless of induction/consolidation treatment (CASSIOPEIA part 2 prespecified interim analysis).
Methods: CASSIOPEIA is a 2-part, open-label, randomized, phase 3 study in transplant-eligible patients with NDMM. Written informed consent was obtained from all patients. In part 1, patients received 4 cycles of induction and 2 cycles of consolidation with D-VTd or VTd alone. All responders in part 1 (≥PR; n=886) were rerandomized in part 2 to receive maintenance (intravenous daratumumab 16 mg/kg every 8 weeks for ≤2 years [n=442]) or OBS (n=444) until disease progression (IMWG criteria). Patients were stratified by induction (D-VTd vs VTd) and depth of response (minimum residual disease [MRD] status and ≥PR post consolidation). Progression-free survival (PFS) after rerandomization was the primary endpoint. The efficacy and safety were assessed after 281 PFS events. Key secondary endpoints (preplanned hierarchical order) were time to progression, complete response or better (≥CR), MRD negativity rates by next-generation sequencing, and overall survival (OS).
Results: Median PFS was not reached with daratumumab vs 46.7 months for OBS (median follow up, 35.4 months; hazard ratio [HR] 0.53 [95% CI 0.42–0.68]; $P<0.0001$). Daratumumab showed consistent PFS advantage across most subgroups, except for a significant interaction with induction/consolidation treatment arm ($P<0.0001$; prespecified analysis). The daratumumab vs OBS PFS HR was 0.32 (95% CI 0.23–0.46) in the VTd arm and 1.02 (0.71–1.47) in the D-VTd arm. The median time to progression was not reached for daratumumab vs 46.7 months for OBS (HR 0.49 [0.38–0.62]; $P<0.0001$). Compared with OBS, more patients with daratumumab maintenance achieved ≥CR (60.8% vs 72.9%; odds ratio [OR] 2.17 [1.54–3.07]; $P<0.0001$). In patients with ≥CR at 10^{-5}, the MRD negativity rate was 58.6% with daratumumab maintenance vs 47.1% with OBS (OR 1.80 [1.33–2.43]; $P=0.0001$). Median OS was not reached in either arm. Most common (≥2.5%) grade 3/4 adverse events (AEs) reported with daratumumab maintenance vs OBS were lymphopenia (3.6% vs 1.8%), hypertension (3.0% vs 1.6%), and pneumonia (2.5% vs 1.4%). Serious AEs were reported in 22.7% of patients with daratumumab maintenance vs 18.9% with OBS; the most common (≥2.5%) being pneumonia (2.5% vs 1.6%). Thirteen patients (3.0%) discontinued daratumumab due to an AE. The rate of infusion-related reactions (90% were grade 1/2) was 54.5% in daratumumab-naive patients and 2.2% in daratumumab-pretreated patients. Second primary malignancies occurred in 5.5% of patients with daratumumab maintenance vs 2.7% with OBS.
Summary/Conclusion: CASSIOPEIA part 2 interim analysis showed a significantly longer PFS with daratumumab maintenance vs OBS in transplant-eligible patients with NDMM. The maintenance PFS benefit appeared only in patients treated with VTd as induction/consolidation. Patients who received D-VTd induction/consolidation ± daratumumab maintenance achieved similar PFS; longer follow up is needed for OS and PFS2. Compared with OBS, daratumumab maintenance significantly increased deeper response and MRD negativity rates, and it was well tolerated with no new safety signals.

S181 DEPTH OF RESPONSE AND MRD STATUS IN ULTRA HIGH-RISK MYELOMA AND PLASMA CELL LEUKEMIA TREATED WITH DARA-CVRD AND AUGMENTED AUTOLOGOUS TRANSPLANT: RESULTS OF THE RISK-STRATIFIED UK OPTIMUM/MUKNINE TRIAL

M. Kaiser [1,*], A. Hall [2], K. Walker [2], R. de Tute [3], R. Sadie [2], E. Ingleson [2], K. Bowles [4], M. Garg [5], A. Lokare [6], C. Messiou [7], G. Jackson [8], G. Pratt [9], G. Cook [10], M. Drayson [9], R. Owen [3], S. Brown [2], M. Jenner [11]

[1]The Institute of Cancer Research and Royal Marsden Hospital, London, [2]Clinical Trials Research Unit, Leeds Institute of Clinical Trials Research, University of Leeds, [3]HMDS, St James Hospital, Leeds, [4]Norfolk and Norwich University Hospitals NHS Trust, Norwich, [5]Leicester Royal Infirmary, Leicester, [6]Birmingham Heartlands Hospital, Birmingham, [7]The Royal Marsden Hospital & The Institute of Cancer Research, London, [8]Newcastle University, Newcastle, [9]University of Birmingham, Birmingham, [10]University of Leeds, Leeds, [11]University Hospital Southampton, Southampton, United Kingdom

Background: Patients with ultra high-risk (UHiR) newly diagnosed multiple myeloma (NDMM) as well as patients with plasma cell leukemia (PCL) continue to have dismal outcomes and are underrepresented in clinical trials. Recently, improved and deepened responses with anti-CD38 monoclonal antibody combination therapy have been reported for NDMM patients. We report here outcomes for NDMM UHiR and PCL patients treated in the OPTIMUM/MUKnine (NCT03188172) trial with daratumumab, cyclophosphamide, bortezomib, lenalidomide, dexamethasone (Dara-CVRd) induction, augmented high-dose melphalan (HDMEL) and ASCT. With final analysis follow-up surpassed in Feb 2021, we report here early protocol defined endpoints from induction to day 100 post ASCT.
Aims: To demonstrate response and MRD-negativity rate in UHiR NDMM and PCL prospectively identified by central molecular screening and treated in a risk-stratified trial with Dara-CVRd and augmented ASCT.
Methods: Between Sep 2017 and Jul 2019, 107 patients with UHiR NDMM by central trial genetic (≥2 high-risk lesions (double-hit): t(4;14), t(14;16), t(14;20), gain(1q), del(1p), del(17p)) or gene expression SKY92 (SkylineDx) profiling, or with PCL (circulating plasmablasts >20%) were included in OPTIMUM across 39 UK hospitals. Patients received a maximum of 6 cycles of Dara-CVRd induction, HDMEL and ASCT augmented with bortezomib, followed by Dara-VR(d) consolidation for 18 cycles and Dara-R maintenance. Primary trial endpoints are minimal residual disease (MRD) status post ASCT and progression-free survival. Secondary endpoints include response, safety and quality of life. Data is complete but subject to further data cleaning prior to conference.
Results: Median follow-up for the 107 patients in the safety population was 22.2 months (95% CI: 20.6 – 23.9). Median age was 60 (range 35 to 78) years, 59.8% of patients were male. Ninety eight patients (92%) were included based on UHiR status by central tumour molecular analysis, and 9 because of PCL (8%). At baseline, 22.4% of patients were ISS stage I, 37.4% stage II and 26.2% stage 3 with 14.0% missing data. Two patients died during induction due to infection. Bone marrow aspirates suitable for MRD assessment by flow cytometry (10^{-5} sensitivity) were available for 81% of patients at end of induction and 78% at D100 post ASCT. Responses in the intention-to-treat population at end of induction were 94% ORR with 22% CR, 58% VGPR, 15% PR, 1% PD, 5% timepoint not reached (withdrew, became ineligible or died) and at D100 post ASCT 83% ORR with 47% CR, 32% VGPR, 5% PR, 7% PD, 10% timepoint not reached. MRD status was 41% MRD-negative, 40% MRD-positive and 19% not evaluable post induction and 64% MRD-negative, 14% MRD-positive and 22% not evaluable at D100 post ASCT. Responses at D100 post ASCT were lower in PCL with 22% CR, 22% VGPR, 22% PR, 22% PD, 12% timepoint not reached. Most frequent grade 3/4 AEs during induction were neutropenia (21%), thrombocytopenia (12%) and infection (12%). Grade 3 neuropathy rate was at 3.7%.
Summary/Conclusion: We report, to our knowledge for the first time, on a trial for UHiR NDMM and PCL investigating Dara-CVRd induction and augmented ASCT. Response rates and MRD-negativity were high in this difficult-to-treat patient population, with toxicity comparable to other induction regimens. However, some early progressions highlight the need for innovative approaches to UHiR NDMM and PCL.

S182 EFFICACY OF CARFILZOMIB-BASED INDUCTION/CONSOLIDATION WITH OR WITHOUT AUTOLOGOUS TRANSPLANT AND LENALIDOMIDE OR CARFILZOMIB-LENALIDOMIDE MAINTENANCE IN HIGH-RISK PATIENTS IN THE FORTE TRIAL

R. Mina [1,*], E. Zamagni [1], F. Fazio [1], A. Ledda [1], A. Palmas [1], S. Aquino [1], P. de Fabritiis [1], F. Patriarca [1], D. Oddolo [1], M. Cea [1], N. Giuliani [1], A. Spadano [1], S. Ballanti [1], M. Grasso [1], P. Corradini [1], M. Cavo [1], M. Boccadoro [1], P. Musto [1], F. Gay [1]

[1]European Myeloma Network, GIMEMA, Italy

Background: Cytogenetic abnormalities (CA) are powerful prognostic factors in multiple myeloma (MM). In the FORTE trial, carfilzomib-lenalidomide-dexamethasone induction/consolidation with ASCT (KRd_ASCT) significantly improved progression-free survival (PFS) vs KRd without ASCT (KRd12, HR 0.64) or carfilzomib-cyclophosphamide-dexamethasone plus ASCT (KCd_ASCT, HR 0.53). KR maintenance significantly improved PFS vs R (HR 0.63).
Aims: The primary aim of this analysis was the impact of treatment on PFS and 1-year sustained MRD negativity (1y-MRD neg) rates according to patient (pt) risk.
Methods: Newly diagnosed MM pts were randomized to KRd_ASCT vs KCd_ASCT vs KRd12 and, thereafter, to KR vs R maintenance. Subgroup analyses according to FISH assessed the impact of each single high-risk (HiR) CA [del17p, t(4;14), t(14;16), del1p and 1q gain (3 copies) or amp1q (≥4 copies)] and that of combined HiR CA, defining HiR by the presence of ≥1 HiR CA and double hit (DH) by the presence of ≥2 HiR CA. Standard risk (SR) was defined by the absence of all the CA.
Results: 396 out of 474 enrolled pts were included in the analysis with complete FISH data: 243 HiR, 105 DH and 153 SR. Among HiR pts, 60 had del17p, 65 t(4;14), 20 t(14;16), 44 del1p, 126 1q gain and 49 amp1q. SR pts benefited from intensification with KRd_ASCT vs KRd12 (HR 0.47, p=0.05) and KCd_ASCT (HR 0.38, p=0.01), with a 4-year PFS of 80%, 67% and 57%, respectively. In the overall HiR population, KRd_ASCT improved PFS vs KRd12 (HR 0.6, p=0.04) and KCd_ASCT (HR 0.57, p=0.01), with a 4-year PFS of 62%, 45% and 45%, respectively. The advantage with KRd_ASCT vs KRd12 (HR 0.53, p=0.07) and KCd_ASCT (HR 0.49; p=0.03) was also observed in DH pts (4-year PFS 55%, 31% and 33%, respectively). Analyses by single CA were limited by the small number of pts in each subgroup, but a PFS benefit from KRd_ASCT vs KRd12 was observed in pts with del17p (HR 0.61, p=0.3), t(4;14) (HR 0.59, p=0.2) and 1q gain (HR 0.45, p=0.02), consistently with the overall population. In pts with del1p, KRd_ASCT (HR 0.24, p=0.06) and KRd12 (HR 0.33, p=0.09) showed superiority over KCd_ASCT, while amp1q pts had the worst outcome regardless of treatment (KRd_ASCT vs KCd_ASCT, HR 1.16, p=0.73; KRd12 vs KCd_ASCT, HR 1.34, p=0.45).
KRd_ASCT induced similar 1y-MRD neg rates in SR (50%), HiR (50%) and DH (47%) pts. Lower 1y-MRD neg rates were observed with KRd12 vs KRd_ASCT. With KRd12, 1y-MRD neg rates were similar in SR (36%) and HiR (39%) but lower in DH (25%) pts; with KCd_ASCT, HiR (48% vs 29%, p=0.04) and DH (48% vs 17%, p=0.03) pts had significantly lower 1y-MRD neg rates than SR pts. Importantly, 1y-MRD neg pts showed a similar 4-year PFS regardless of risk status (SR, 87%, HiR 87%, DH 83%) and treatment arm.
KR improved PFS vs R in SR (3-year PFS 90% vs 73%, HR 0.42, p=0.06), HiR (3-year PFS 69% vs 56%, HR 0.6, p=0.04) and DH pts (3-year PFS 67% vs 42%, HR 0.53, p=0.1). Despite the small subgroups, a benefit from KR vs R was observed in pts with del17p (HR 0.59, p=0.37), t(4;14) (HR 0.59, p=0.3), 1q gain (HR 0.54, p=0.07) and del1p (HR 0.23, p=0.08), while amp1q pts showed the worst outcome and no benefit from KR vs R (HR 0.83, p=0.7).
Summary/Conclusion: KRd_ASCT and KR maintenance are highly effective in SR, HiR and DH pts, with impressive 1y-MRD neg rates (KRd_ASCT: HiR 50%, DH 47%), 4-year PFS from diagnosis (KRd_ASCT: HiR 62%, DH 55%) and 3-year PFS from maintenance (KR: HiR 69%, DH 67%), thus supporting their use in HiR pts, who represent an unmet medical need. Achieving 1y-MRD neg mitigated the higher risk of progression/death in HiR and DH pts, as compared to SR pts.

S183 UPDATED INTERIM ANALYSIS OF THE GMMG-CONCEPT TRIAL INVESTIGATING ISATUXIMAB, CARFILZOMIB, LENALIDOMIDE, AND DEXAMETHASONE (ISA-KRD) IN FRONTLINE TREATMENT OF HIGH-RISK MULTIPLE MYELOMA

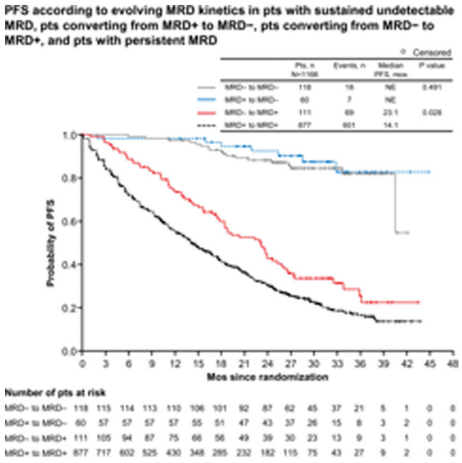
Background: As high-risk (HR) multiple myeloma (MM) patients (pts) still have a significantly impaired prognostic outcome, there is an unmet clinical need for potent therapeutic strategies already in front-line therapy for newly diagnosed (ND) MM, leading to improvement of long-term survival. Ultra-high-risk patients with ≥ 3 HR cytogenetic aberrations (CA) have a median overall survival (OS) of less than 2 years. Recent data indicate that achievement of deep remissions, including negativity for minimal residual disease (MRD) may translate into prolonged progression-free (PFS) and OS.
Aims: The GMMG-CONCEPT trial (NCT03104842) investigates the quadruplet regimen isatuximab plus carfilzomib, lenalidomide, and dexamethasone (Isa-KRd) in HR NDMM pts including primary high-dose melphalan for patients being transplant-eligible. First results showed an overall response rate (ORR) of 100% for induction treatment in the prespecified interim analysis (IA) of the first 50 patients included. Here, we report an update for PFS of the IA population.
Methods: 153 pts with HR NDMM were included into the trial, an extension cohort of another 93 patients is planned to start recruitment in 2021. HR MM is defined by the presence of del17p or t(4;14) or t(14;16) or > 3 copies 1q21 in combination with ISS II or III stage disease. Transplant-eligible (TE) patients undergo high-dose therapy after induction (Arm A) while transplant-ineligible (TI) patients receive 2 additional Isa-KRd cycles (Arm B). Afterwards, both arms receive another 4 Isa-KRd cycles as consolidation, followed by Isa-KR maintenance. Primary endpoint is MRD negativity measured by next-generation flow after consolidation. This IA reports on PFS data of the IA population with PFS defined as combined endpoint of progressive disease (PD) or death, whichever occurs first.
Results: 50 pts (46 arm A, 4 arm B) were included in the IA population. CA defining high-risk were del17p in 52%, t(4;14) in 38%, t(14;16) in 12% and > 3 copies 1q21 in 42%. 20% of pts showed increased LDH, 26% had 2 CA, 4% showed ≥ 3 CA. Overall (ORR) and best response rates were presented previously. ORR defined as best response achieved during induction was 100% with 90% of pts achieving a very good partial response or better. Early data on MRD negativity showed MRD negative remissions in 20/33 evaluated pts during induction. The updated IA analysis was performed with a median follow-up of 24.9 months. For the overall population analysed, 12- and 24-month PFS (95%>confidence level) was 79.6% (68.3%; 90.9%) and 75.5% (63.5%; 87.6%). In Arm A, PFS-rates were 80.0% (68.3%; 91.7%) and 75.6% (63.0%; 88.1%) for 12 and 24 months, respectively. For the 4 TI pts in Arm B, a 12-months-PFS of 75.0% (32.6%; 100%) was reported. With longer follow-up, no new safety signals occurred. End of treatment (EoT) occurred in 20 pts in Arm A and was due to PD in 8 pts, death in 4 pts or other reasons (8 pts). Reason for EoT (1 pt) in Arm B was death.
Summary/Conclusion: With a best ORR of 100% during quadruplet induction treatment, we here report an update of the IA for PFS of the first 50 pts in the CONCEPT trial. In these solely HR NDMM pts an encouraging PFS rate of 79.6% and 75.5% after 12- and 24-months is reported. Our data underline the high potency of quadruplet treatment with Isa-KRd especially in patients with HR disease. The study completed recruitment, further results will be reported.



S184 MEASURABLE RESIDUAL DISEASE (MRD) EVALUATION DURING IXAZOMIB (IXA) MAINTENANCE IN NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM): A LARGE ANALYSIS OF 1280 PATIENTS (PTS) ENROLLED IN TOURMALINE-MM3 AND -MM4

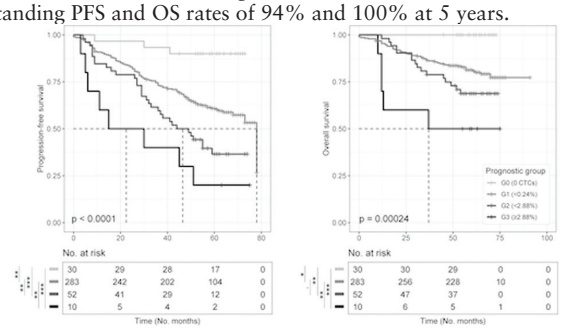
Background: MRD status is the most powerful prognostic factor in NDMM and sustained MRD negativity is a surrogate for prolonged survival. Interest is growing for using MRD to guide treatment intensity and duration, particularly during maintenance. Paradoxically, MRD data in this setting is scarce and knowledge of the volatility of MRD status throughout treatment is limited.
Aims: To present a pooled analysis of the Phase 3 TOURMALINE-MM3 and -MM4 trials, the largest maintenance dataset ever reported, to evaluate the impact of evolving MRD kinetics on progression-free survival (PFS) in NDMM pts receiving ixa or placebo (pbo) maintenance.
Methods: Pts with ≥partial response (PR) following proteasome inhibitor and/or immunomodulatory drug induction plus a single transplant (MM3) or 6–12 months (mos) of standard-of-care induction therapy (MM4) were randomized (3:2) to oral ixa 3 mg (increased to 4 mg if tolerated after 4 cycles) or pbo in 28-day cycles for up to 2 years (or 26 cycles). PFS from randomization was the primary endpoint; correlation of MRD status with outcomes was a prespecified secondary endpoint in both trials. 2077 bone marrow aspirates were collected from all pts in complete response (CR; MM3 & MM4) or very good PR (MM3 only) at screening, cycle 13, and cycle 26/end of treatment, and at time of new suspected CR (MM3 & MM4). MRD status was determined using a validated 8-color flow cytometry approach standardized across three geographic regions (38 countries); median limit of detection was $7.4x10^{-6}$. Pts with
Results: At screening, MRD status was available for 1280 pts: 262 were MRD– (ixa n=161/767 [21%]; pbo n=101/513 [20%]) and 1018 MRD+ (ixa n=606 [79%]; pbo n=412 [80%]). In pts who were MRD+ at study entry, there was significant PFS benefit for ixa vs pbo (median 18.8 vs 11.6 mos, hazard ratio [HR] 0.65, 95% CI 0.55–0.76, p<.001). 10% of pts showed sustained MRD negativity, 5% converted from MRD+ to MRD–, 10% from MRD– to MRD+ and 75% had persistent MRD. Median PFS (mPFS) was not reached in pts with sustained MRD negativity (Figure; ixa vs pbo HR 0.89, p=.815). mPFS was also not reached in pts converting from MRD+ to MRD– during treatment; there was significant benefit with ixa vs pbo (HR 0.14, p=.007). By comparison, mPFS was inferior in pts converting from MRD– to MRD+ (23.1 mos) and dismal in pts with persistent MRD (14.1 mos); mPFS with ixa vs pbo was 23.2 vs 19.3 mos (HR 0.81, p=.411) and 17.5 vs 11.1 mos (HR 0.68, p<.001) in these groups, respectively. Other disease characteristics had no prognostic value once pts were stratified into these four MRD kinetics subgroups. Overall, failure to achieve/sustain MRD– status post-screening resulted in a >8-fold increased risk of progression and/or death (HR 8.20, 95% CI 5.49–12.2, p<.001).

Summary/Conclusion: This large dataset demonstrated that the prognostic value of MRD status at the start of maintenance can be enhanced by measuring MRD kinetics during treatment. Our results support the achievement and sustainability of MRD negativity as a treatment endpoint in the maintenance setting and showed poor outcomes in MRD– pts converting to MRD+, underscoring the value of serial MRD assessments to anticipate relapse and guide treatment decisions. Accordingly, ixa showed significant PFS benefit vs pbo in pts who were MRD+ at study entry and pts with persistent MRD.

New diagnostic and therapeutic approaches in multiple myeloma and AL amyloidosis



S185 CIRCULATING TUMOR CELLS (CTC) ARE THE MOST RELEVANT DIAGNOSTIC BIOMARKER IN TRANSPLANT-ELIGIBLE MULTIPLE MYELOMA (MM)

Background: There is great expectation in liquid biopsies to stratify patients with cancer. These could be particularly valuable in MM where despite patchy infiltration and likelihood of extramedullary disease, quantification of tumor burden continues being performed in bone marrow (BM). However, there are no large studies analyzing if liquid biopsies using next-generation methods yield superior prognostic information than conventional cytology in BM.
Aims: To establish the clinical significance of CTC burden in peripheral blood (PB) and to define cutoffs for risk stratification of newly-diagnosed MM patients.
Methods: This study included 375 transplant-eligible patients enrolled in the GEM2012MENOS65 clinical trial and treated with six induction cycles of VRD followed by autologous transplant and consolidation with two VRD courses. Afterwards, patients received Rd (with or without ixazomib) for two years and either stopped maintenance if MRD negative or continued three more years if MRD positive (GEM2014MAIN). EuroFlow next-generation flow was used to evaluate CTCs in PB at diagnosis and MRD in BM throughout treatment. Cutoffs were defined using maximally selected rank statistics considering PFS. Median follow-up is of 5 years.
Results: CTC were detected in 345/375 (92%) of patients. There was a modest correlation between the percentage of CTCs in PB and tumor burden in BM by morphology (R^2=0.35, p<0.0001) and flow cytometry (R^2=0.41, p<0.0001). These data suggests that CTC egression is not directly related with tumor burden in BM.
Patients stratification into 4 subgroups according to the percentage of CTC (Group 0: 0%, Group 1: >0% to <0.24%, Group 2: ≥0.24% to <2.88%, and Group 3: ≥2.88%) resulted in significant differences in PFS (median not reached [NR] vs 78, 47 and 23 months, and hazard ratios of 4.9, 8.8 and 15.8, respectively; p<0.0001) and overall survival ([OS] 100%, 81%, 69% and 50% at 5 years, p=0.0002). In a multivariable analysis including quantification of tumor burden in PB using NGF and in BM by morphology and flow cytometry, the percentage of CTC was selected as the only independent prognostic factor for PFS (p=0.001). In a subsequent multivariable analysis including the percentage of CTC in PB, ISS, LDH and FISH cytogenetics, quantification of CTC was selected as the most relevant prognostic factor for PFS. Indeed, risk stratification according to the CTC cutoffs previously defined was prognostic in all risk groups including patients with standard-risk FISH (median PFS NR in Groups 0 & 1 vs 44 and 30 months in Groups 2 & 3, respectively: p=0.005).

We further investigated if deep responses to treatment were able to abrogate the poor prognosis of elevated CTC at diagnosis. Patients in Groups 2 & 3 showed significantly inferior PFS (median of 59 and 48 months) than cases in Groups 0 & 1 (median NR; p=0.004) despite achieving CR. By contrast, there were no significant differences in PFS of MRD negative patients stratified according to the percentage of CTC (p=0.017). Patients with 0% CTC and negative MRD before maintenance showed outstanding PFS and OS rates of 94% and 100% at 5 years.

Summary/Conclusion: Evaluation of CTC in PB outperformed quantification of tumor burden in BM and was the most relevant prognostic factor at baseline. Attaining undetectable MRD as opposed to CR should be considered as the treatment endpoint in patients with elevated percentages of CTC in PB. Patients with undetectable CTC at diagnosis and undetectable MRD after treatment intensification showed long-term survival with fixed duration maintenance therapy.

S186 UPDATES FROM ICARIA-MM, A PHASE 3 STUDY OF ISATUXIMAB (ISA) PLUS POMALIDOMIDE AND LOW-DOSE DEXAMETHASONE (PD) VERSUS PD IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA (RRMM)

Background: Isa is an approved monoclonal antibody that binds to a specific epitope on the CD38 receptor. The Phase 3 ICARIA-MM study (NCT02990338) demonstrated significantly improved progression-free survival (PFS) with Isa-Pd vs Pd (*P*=0.001) and a manageable safety profile (Attal M, et al. *Lancet* 2019;394:2096-2107).
Aims: Here we report updated ICARIA results.
Methods: Pts with RRMM (N=307) who have received ≥2 prior therapies, including lenalidomide (Len) and a proteasome inhibitor (PI), were randomized to Isa-Pd (n=154) or Pd (n=153). Isa was administered intravenously at 10 mg/kg weekly for 4 weeks, and every other week thereafter. This preplanned second interim analysis assessed longer term outcomes, including time to next treatment (TTNT), overall survival (OS), time from randomization to disease progression on first subsequent therapy or death (PFS2), and safety.
Results: Pts had a median of 3 prior lines of therapy (IQR 2–4; table). As of Oct 1, 2020 (median follow-up, 35.3 months [mo]), 27 Isa-Pd pts (18%) vs 12 Pd pts (8%) were still on treatment; 60% vs 72% had proceeded to subsequent therapy. Median TTNT was 15.5 mo with Isa-Pd vs 8.9 mo with Pd (hazard ratio [HR] 0.56; 95% confidence interval [CI] 0.42–0.74; *P*<0.0001); 24% vs 58% of pts with subsequent therapy received daratumumab (dara). Overall response rate (ORR) in subsequent treatment with dara monotherapy was higher after Pd (38%) than Isa-Pd (14%), but was similar (32% vs 31%) with dara combination therapy (table). Median PFS2 in the intent-to-treat population was 17.5 mo with Isa-Pd vs 12.9 mo with Pd (HR 0.76; 95% CI 0.58–0.99; *P*=0.0202). Median OS was 24.6 mo with Isa-Pd vs 17.7 mo with Pd (HR 0.76; 95% CI 0.58–1.01; one-sided *P*=0.0280). Median treatment duration was 47.6 weeks (range 1.3–171.6) with Isa-Pd vs 24.0 weeks (range 1.0–168.6) with Pd. Serious treatment-emergent adverse event (TEAEs) were seen in 73% of Isa-Pd pts vs 60% of Pd pts. Most frequent non-hematologic TEAEs (any grade) with Isa-Pd were infusion reaction (38%), upper respiratory tract infection (34%), and diarrhea (30%). Grade 3–4 neutropenia (85% vs 71%) and thrombocytopenia (34% vs 25%) were more frequent with Isa-Pd than with Pd.

Prior treatments, n (%)	Isa-Pd (n=154)	Pd (n=153)
Len	154 (100)	153 (100)
PI	154 (100)	153 (100)
Len-refractory	144 (94)	140 (92)

Summary/Conclusion: Isa-Pd demonstrates a significant improvement in TTNT and PFS2 compared with Pd. A strong trend in OS benefit was also seen in the Isa-Pd arm, with approximately 7 mo improvement in median OS. The overall safety profile remains unchanged from prior analyses.

S187 IBERDOMIDE (IBER) IN COMBINATION WITH DEXAMETHASONE (DEX) AND DARATUMUMAB (DARA), BORTEZOMIB (BORT), OR CARFILZOMIB (CFZ) IN PATIENTS (PTS) WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM)

Background: IBER is an oral, novel cereblon E3 ligase modulator (CELMoD) compound with marked synergistic tumoricidal and immune-stimulatory effects in combination with proteasome inhibitors (PIs) or anti-CD38 monoclonal antibodies, preclinically and clinically. CC-220-MM-001 (NCT02773030) is an ongoing phase 1/2 study evaluating the maximum tolerated dose, recommended phase 2 dose (RP2D), safety, and preliminary efficacy of IBER with different treatment combinations in independent cohorts, in pts with RRMM.
Aims: To report results from the IBER+DARA+DEX (IberDd), IBER+BORT+DEX (IberVd), and IBER+CFZ+DEX (IberKd) cohorts of the CC-220-MM-001 study.
Methods: Eligible pts received ≥2 prior regimens in the IberDd and IberKd cohorts, and ≥1 prior regimen in the IberVd cohort, containing lenalidomide or pomalidomide, and a PI. All pts had progressed ≤60 days of their last MM therapy. Escalating oral doses of IBER were given on Day (D)1–21 of each 28-D cycle in the IberDd cohort and in the IberKd cohort with weekly CFZ, and on D1–14 of each 21-D cycle in the IberVd cohort. DEX was given weekly in all 3 cohorts.
Results: As of Dec 14, 2020, 34 pts had received IberDd, 24 pts IberVd, and 7 pts IberKd. Exposure to prior regimens was heterogeneous (Table), all pts were refractory to their last prior regimen, and median number of

prior therapies was 4.0 (2–12), 5.5 (1–14), and 6.0 (2–8), with IberDd, IberVd, and IberKd, respectively. IBER doses ranged from 1.0mg to 1.6mg. Median follow-up was 3.9 (0.1–20.7), 5.5 (1.2–18.0), and 5.1 (3.5–15.7) months, 15 (44%), 9 (38%), and 3 (43%) pts continue on treatment, and median cycles received was 4.0 (1–21), 7.5 (1–24), and 5.0 (3–16) with IberDd, IberVd, and IberKd, respectively.
Most frequent hematologic grade (G) 3–4 treatment-emergent adverse events (TEAEs) were neutropenia (63%), anemia (28%), leukopenia (28%), and lymphopenia (25%) with IberDd, neutropenia (29%) and thrombocytopenia (25%) with IberVd, and lymphopenia (57%) and neutropenia (43%) with IberKd. In all cohorts, neutropenia was managed with G-CSF. One pt (IberDd; 1.2mg) had G4 neutropenic sepsis. Occurrence of G3–4 non-hematologic TEAEs was low in all 3 cohorts. There were 12 (38%), 8 (33%), and 3 (43%) pts with ≥1 IBER dose reduction, with IberDd, IberVd, and IberKd, respectively.
In the IberDd cohort, the overall response rate (ORR) was 41% (12/29 pts: 1 stringent complete response [sCR], 2 CRs, 2 very good partial responses [VGPRs], 7 partial responses [PRs]), the clinical benefit rate (CBR) was 52%, and disease control rate (DCR) was 86%. In the IberVd cohort, ORR was 58% (14/24 pts: 2 CRs, 5 VGPRs, 7 PRs), CBR was 67%, and DCR was 92%. Responses with IberDd and IberVd were observed in DARA- and BORT-refractory pts, respectively. In the IberKd cohort, ORR was 57% (4/7 pts: 1 sCR, 2 VGPRs, 1 PR), CBR was 57%, and DCR was 86%. Median time to response was 4.1 (4.0–12.0), 3.6 (3.0–13.1), and 4.1 (4.1–8.1) weeks, in the IberDd, IberVd, and IberKd cohorts, respectively. Median duration of response is 63.3 weeks in the IberVd cohort, and not reached in the IberDd and IberKd cohorts.
RP2D was determined at 1.6mg in the IberDd cohort, while dose evaluation continues in the IberVd and IberKd cohorts.
Updated data will be presented at the meeting.

Table. Baseline characteristics and prior therapies

Characteristics	IberDd (n = 34)	IberVd (n = 24)	IberKd (n = 7)
Age, median (range), years	66 (40–77)	64 (47–81)	61 (36–69)
Time since initial diagnosis, median (range), years	8.0 (1.1–19.1)	7.1 (3.0–16.0)	7.7 (2.4–13.5)
ISS at study entry, n (%)			
Stage I	20 (58.8)	13 (54.2)	6 (85.7)
Stage II	9 (26.5)	9 (37.5)	0
Stage III	4 (11.8)	2 (8.3)	1 (14.3)
Presence of EMP, n (%)	7 (20.6)	4 (16.7)	1 (14.3)
Prior therapies, median (range)	4.0 (2–12)	5.5 (1–14)	6.0 (2–8)
ASCT, n (%)	29 (85.3)	21 (87.5)[a]	7 (100)
BORT, n (%)	33 (97.1)	23 (95.8)	7 (100)
CFZ, n (%)	24 (70.6)	11 (45.8)	4 (57.1)
LEN, n (%)	34 (100)	24 (100)	7 (100)
POM, n (%)	24 (70.6)	18 (75.0)	7 (100)
DARA, n (%)	18 (52.9)	19 (79.2)	7 (100)
Anti-BCMA, n (%)	2 (5.9)	2 (8.3)	1 (14.3)
IMiD agent-refractory,[b] n (%)	33 (97.1)	19 (79.2)	6 (85.7)
PI-refractory, n (%)	28 (82.4)	16 (66.7)	5 (71.4)
BORT, n (%)	14 (41.2)	10 (41.7)	4 (57.1)
CFZ, n (%)	21 (61.8)	8 (33.3)	4 (57.1)
Anti-CD38 mAb-refractory, n (%)	16 (47.1)	19 (79.2)	5 (71.4)
DARA, n (%)	16 (47.1)	18 (75.0)	5 (71.4)
Triple-class refractory,[c] n (%)	14 (41.2)	11 (45.8)	4 (57.1)

[a]4 patients received both autologous and allogenic stem cell transplant; [b]Defined as refractory to LEN or POM; [c]Defined as refractory to ≥1 IMiD agent, ≥1 PI, and ≥1 anti-CD38 mAb.

ASCT, autologous stem cell transplant; BCMA, B-cell maturation antigen; BORT, bortezomib; CFZ, carfilzomib; DARA, daratumumab; DEX, dexamethasone; EMP, extramedullary plasmacytoma; IBER, iberdomide; IberDd, IBER+DARA+DEX; IberKd, IBER+CFZ+DEX; IberVd, IBER+BORT+DEX; ISS, International Staging System; IMiD, immunomodulatory drug; LEN, lenalidomide; mAb, monoclonal antibody; PI, proteasome inhibitor; POM, pomalidomide.

Summary/Conclusion: In heavily pretreated pts with RRMM, IberDd, IberVd, and IberKd showed a manageable safety profile and promising efficacy including CRs, even among DARA- and BORT-refractory pts. The study is ongoing. These results support further development of IBER-based regimens in MM, including the initiation of phase 3 combination studies.

S188 ONCE WEEKLY SELINEXOR, CARFILZOMIB, AND DEXAMETHASONE (XKD) IN CARFILZOMIB NONREFRACTORY MULTIPLE MYELOMA (MM) PATIENTS

Background: Exportin 1 (XPO1) mediates the nuclear export and functional inactivation of tumor suppressor proteins (TSPs), is associated with poor prognosis in MM, and contributes to proteasome inhibitor (PI) and immunomodulatory drug (IMiD) resistance. Selinexor (SEL) is a novel, oral, first-in-class selective inhibitor of nuclear export (SINE) compound that blocks XPO1, forcing the nuclear retention and activation of TSPs. SEL in combination with low dose dexamethasone (dex) ± bortezomib (BOR) is FDA approved for previously treated MM. The synergy of SEL with the PI BOR has been confirmed in the phase 3 BOSTON study in MM patients (pts) with 1-3 prior therapies; once weekly (QW) SEL, QW BOR, and dex (XVd) significantly increased progression-free survival (PFS), time to next therapy, and overall response rate (ORR) as compared to standard twice weekly BOR/dex (Vd), despite XVd using 40% less BOR and 25% less dex than standard Vd.
Aims: To determine if the addition of QW SEL to the PI carfilzomib (CAR)-dex (XKd) would be an active and tolerable regimen in pts with heavily pretreated MM.
Methods: In the XKd arm of the multi-arm Phase 1b/2 STOMP study, SEL at 80 or 100 mg QW was evaluated in combination with CAR at 56 or 70 mg/m^2 QW plus dex at 40 mg QW in pts with heavily pretreated MM not refractory to CAR. Study objectives were to determine the maximum tolerated dose and recommended phase 2 dose (RP2D) and assess the safety and activity of the XKd regimen.
Results: As of 4 Jan 2021, 27 pts were enrolled: 18 (67%) were male, median age 71 years (range 50-76), and median of 4 (range 1-8) prior lines of therapy. All 27 pts were previously treated with BOR, 26 (96%) lenalidomide (LEN), 19 (70%) pomalidomide (POM), 18 (67%) daratumumab (dara). The majority of pts (67%) were triple-class treated (PI, IMiD, and anti-CD38 mAb), and 44% had documented triple-class refractory MM. Nine pts (33%) had MM quad-refractory to BOR, LEN, POM, and dara. Common hematologic treatment-related adverse events (TRAEs) (total, grade ≥3) included thrombocytopenia (74%, 56%), anemia (59%, 19%), and neutropenia (30%, 7%), typically without concurrent symptoms. Non-hematologic TRAEs included nausea (67%, 4%), fatigue (52%, 7%), and anorexia (52%, 4%). RP2D was identified as SEL 80 mg QW, CAR 56 mg/m^2 QW, and dex 40 mg QW.
As of 3 Feb 2021, ORR was 78% (21/27) with 5 pts reaching CR (19%), 8 VGPR (30%), and 8 PR (30%). Median PFS was 23.7 months. Among 18 pts previously treated with dara, ORR was 67% and median PFS was 23.7 months. In 9 pts with MM refractory to BOR, LEN, POM, and dara, ORR was 67% and 4 pts had VGPR (44%).
Summary/Conclusion: In pts with heavily pretreated MM, weekly XKd is highly active with an ORR of 78% and deep responses (≥VGPR 48%) with an overall PFS of 23 months. All AEs, including grade 3/4 thrombocytopenia, can be managed with appropriate supportive care and dose modifications. These data support further investigation of XKd in pts with previously treated MM including those with prior dara treatment.

S189 UPDATED RESULTS FROM PHASE 3 ANDROMEDA STUDY OF PATIENTS WITH NEWLY DIAGNOSED LIGHT CHAIN AMYLOIDOSIS TREATED WITH BORTEZOMIB, CYCLOPHOSPHAMIDE, AND DEXAMETHASONE PLUS SUBCUTANEOUS DARATUMUMAB

Davis Myeloma and Amyloid Program, Tufts Medical Center, Boston, United States

Background: Light chain amyloidosis (AL) is a systemic plasma cell disease where organ impairment and death can occur due to insoluble amyloid fibrils deposition. Adding subcutaneous daratumumab to the standard of care (bortezomib, cyclophosphamide, and dexamethasone [VCd]) in ANDROMEDA (NCT03201965) led to superior outcomes versus VCd alone (primary results), including greater hematologic complete response (CR) rates and an acceptable safety profile. In January 2021, Daratumumab+VCd was approved for patients with newly diagnosed AL amyloidosis.
Aims: To report updated primary results with longer follow up from the ANDROMEDA study.
Methods: ANDROMEDA is an ongoing open-label, randomized, active-controlled, phase 3 trial. Adult patients with newly diagnosed AL amyloidosis were randomly assigned 1:1 to receive daratumumab+VCd or VCd for six 28-day cycles. Written informed consent was obtained from all patients. Bortezomib dosed at 1.3 mg/m^2, cyclophosphamide at 300 mg/m^2 (up to 500 mg weekly), and dexamethasone at 40 mg were administered every week. Subcutaneous daratumumab was administered once weekly in cycles 1 and 2 and every 2 weeks in cycles 3 to 6. Patients in the daratumumab+VCd arm received only subcutaneous daratumumab after cycle 6, every 4 weeks (up to a total of 24 cycles from first dose). Disease status was assessed every 4 weeks in cycles 1 to 6 and every 8 weeks thereafter. Overall hematologic CR rate (intent-to-treat population) was the primary endpoint. Time to hematologic response, major organ deterioration progression-free survival, survival, organ response rate, and safety were the secondary endpoints.
Results: Among 388 randomized patients, 195 received daratumumab+VCd and 193 received VCd alone. At the November 2020 cutoff, the median duration of treatment for daratumumab+VCd and VCd arms was 18.5 and 5.3 months, respectively, and 78 patients (40%) in the daratumumab+VCd arm were still receiving treatment. The overall hematologic CR rate in the daratumumab+VCd arm (59%) was significantly higher versus the VCd arm (19%; odds ratio [95% CI], 5.9 [3.7–9.4]; P<0.0001). More patients achieved a very good partial response or better (≥VGPR) with daratumumab+VCd (79%) compared with VCd alone (50%; odds ratio [95% CI], 3.7 [2.4–5.9]; P<0.0001). Among patients who responded, the median time from randomization to ≥VGPR was shorter in the daratumumab+VCd arm (0.56 months) versus the VCd arm (0.82 months). Greater cardiac response rates were achieved at 6 months with daratumumab+VCd (42%) versus VCd alone (22%) and at 12 months (57% versus 28%); similarly, renal response rates were greater with daratumumab+VCd (54%) versus VCd alone (27%) at 6 months and at 12 months (57% versus 27%). Overall, 71 patients died (daratumumab+VCd, 31; VCd, 40). Starting cycle 7, no grade 3/4 treatment-emergent adverse events occurred in ≥5% of patients in the daratumumab+VCd arm. After cycle 6, no systemic administration-related reactions were reported with in the daratumumab+VCd. Major organ deterioration progression-free survival is scheduled to be updated after approximately 200 events.
Summary/Conclusion: Updated results from the ANDROMEDA study further support that in patients with newly diagnosed AL amyloidosis, the daratumumab+VCd combination is clinically superior compared with VCd alone. Following its recent approval, the daratumumab+VCd combination represents a new standard of care for patients with AL amyloidosis.

T cell re-directing therapies in relapsed/refractory multiple myeloma

S190 EFFICACY AND SAFETY OF THE BCMA-DIRECTED CAR-T CELL THERAPY, CILTACABTAGENE AUTOLEUCEL, IN PATIENTS WITH PROGRESSIVE MULTIPLE MYELOMA AFTER 1–3 PRIOR LINES OF THERAPY: INITIAL RESULTS FROM CARTITUDE-2

Background: Ciltacabtagene autoleucel (Cilta-cel) is a chimeric antigen receptor T (CAR-T) cell therapy expressing two B-cell maturation antigen (BCMA)-targeting, single-domain antibodies designed to confer avidity. CARTITUDE-2 (NCT04133636) is a multicohort, phase 2 study evaluating cilta-cel safety and efficacy in various clinical settings for patients with multiple myeloma (MM) and exploring suitability of outpatient administration.
Aims: We report initial results from Cohort A of CARTITUDE-2.
Methods: All patients provided informed consent. Patients from Cohort A had progressive MM after 1–3 prior lines of therapy (LOT), including a proteasome inhibitor (PI) and immunomodulatory drug (IMiD), were lenalidomide refractory, and had no prior exposure to BCMA-targeting agents. A single cilta-cel infusion (target dose: 0.75×10^6 CAR+ viable T cells/kg) was given 5–7 days after initiating lymphodepletion (cyclophosphamide [300 mg/m^2] and fludarabine [30 mg/m^2] daily for 3 days). The primary objective was minimal residual disease (MRD) 10^{-5} negativity. Secondary outcomes were response rates per International Myeloma Working Group criteria and safety (adverse events [AEs] were graded per Common Terminology Criteria for Adverse Events; cytokine release syndrome [CRS] and immune effector cell-associated neurotoxicity syndrome [ICANS] were graded per American Society for Transplantation and Cellular Therapy).
Results: At the data cutoff of Feb 2021 (median follow-up of 5.8 months; range: 2.5–9.8), 20 patients (65% male; median age 60 years [range: 38–75]) had received cilta-cel; one patient was treated in an outpatient setting. Patients received a median of 2 prior LOT (range: 1–3); 12 patients received <3 prior LOT and 8 received 3 prior LOT. All patients were exposed to PI, IMiD, and dexamethasone, 95% to alkylating agents, and 65% to daratumumab. The majority (95%) were refractory to their last LOT, and 40% were triple refractory. The overall response rate was 95% (95% CI: 75–100) with 75% (95% CI: 51–91) achieving ≥complete response, and 85% (95% CI: 62–97) achieving ≥very good partial response. Median time to first response was 1.0 month (range: 0.7–3.3), and median time to best response was 1.9 months (range: 0.9–5.1). The median duration of response was not reached. All patients (n=4) with MRD-evaluable samples at 10^{-5} at the time of data cutoff were MRD-negative. Hematologic AEs (in ≥20% of patients) were neutropenia (95%; grade 3/4: 90%), thrombocytopenia (80%; grade 3/4: 35%), anemia (65%; grade 3/4: 40%), lymphopenia (60%; grade 3/4: 55%), and leukopenia (55%; all grade 3/4). CRS occurred in 85% of patients; 10% were grade 3/4. The median time to CRS onset was 7 days (range: 5–9), with a median duration of 3.5 days (range: 2–11). CAR-T cell neurotoxicity occurred in 20% of patients (all grade 1/2). Three patients had ICANS (1 was grade 1; 2 were grade 2) with median time to onset of 8 days (range: 7–11) and median duration of 2 days (range: 1–2). One patient had grade 2 facial paralysis with time to onset of 29 days and duration of 51 days. One death occurred due to COVID-19, which was assessed as treatment-related by investigator. The safety profile was manageable in the patient treated in an outpatient setting.
Summary/Conclusion: A single cilta-cel infusion at the recommended phase 2 dose led to early and deep responses with manageable safety in patients with MM who had received 1–3 prior LOT. Updated efficacy and safety findings will inform suitability of outpatient treatment in this and other cohorts of CARTITUDE-2 as well as the CARTITUDE-4 study.

S191 TALQUETAMAB, A G PROTEIN-COUPLED RECEPTOR FAMILY C GROUP 5 MEMBER D (GPRC5D) × CD3 BISPECIFIC ANTIBODY, IN RELAPSED/REFRACTORY MULTIPLE MYELOMA: UPDATED RESULTS OF A PHASE 1, FIRST-IN-HUMAN STUDY

Background: As patients with multiple myeloma (MM) continue to relapse on current therapies, new immunotherapy targets are needed. G protein-coupled receptor family C group 5 member D (GPRC5D) is an orphan receptor that is expressed on malignant plasma cells in MM. Talquetamab (JNJ-64407564) is a bispecific immunoglobulin G4 antibody that binds to CD3 and the novel target GPRC5D to redirect T cells to kill MM cells.
Aims: To report updated phase 1 results of patients with relapsed/refractory MM treated with talquetamab at the recommended phase 2 dose (RP2D).
Methods: Eligible pts with MM who had relapsed or refractory disease or were intolerant to standard therapies, were administered talquetamab either intravenously (IV; range 0.5–180 µg/kg) or subcutaneously (SC; range 5.0–800 µg/kg) in a weekly or biweekly dosing schedule. The primary objectives of the study were to identify the RP2D (part 1) and to characterize the safety and tolerability of talquetamab at the RP2D (part 2). Adverse events (AEs) were graded by Common Terminology Criteria for Adverse Events (CTCAE) v4.03, and cytokine release syndrome (CRS) was graded per Lee 2014 criteria. Response was assessed per International Myeloma Working Group criteria. All patients provided informed consent.
Results: As of Feb 8, 2021, 174 patients received talquetamab IV (n=102) or SC (n=72). Across parts 1 and 2 of the study, 28 patients were treated at the RP2D, identified as weekly SC 405 µg/kg, with 10.0 and 60.0 µg/kg step-up doses. Patients treated at the RP2D had a median age of 61.5 years (range 46–80 years) and had received a median of 5.5 prior lines of therapy (range 2–14; 100%/79% triple-class/penta-drug exposed; 71%/18% triple-class/penta-drug refractory; 86% refractory to last line of therapy; 21% with prior B-cell maturation antigen–directed therapy). No dose-limiting toxicities occurred at the RP2D in part 1 of the study. The most common AEs at the RP2D were CRS (79%; 4% were grade 3; median time to onset was day after SC dose), neutropenia (64%; 54% were grade 3/4), anemia (57%; 29% were grade 3/4) and dysgeusia (57%; all were grade 1/2). Infections were reported in 32% of patients (4% were grade 3/4) and neurotoxicity reported in 7% (no grade 3/4 events). In all, 75% of patients who received the RP2D had skin-related AEs, none of which were grade 3/4, including 18% with nail disorders. In response-evaluable patients (n=24), the overall response rate at the RP2D was 63%, with 50% reaching very good partial response or better; 9/17 (53%) evaluable triple-class refractory patients and 3/3 (100%) penta-drug refractory patients had a response. The median time to first confirmed response at the RP2D was 1.0 month (range 0.2–3.8). Responses were durable and deepened over time; the median follow-up was 6.2 month [range 2.7–9.7+] for responders at the RP2D. Talquetamab exposure at the RP2D was maintained over the maximum EC target level from an ex vivo cytotoxicity assay. Consistent T cell activation was also observed at the RP2D.
Summary/Conclusion: Talquetamab, at the RP2D of weekly 405 µg/kg SC, demonstrated a high clinical response rate and was well-tolerated in patients with relapsed/refractory MM. Based on the pharmacokinetic data, other SC dosing strategies are also being explored. The promising efficacy and safety profile, and the convenience of SC dosing support monotherapy development and combination approaches with this novel agent.

S192 MAGNETISMM-1: PHASE 1 STUDY OF ELRANATAMAB (PF-06863135), A B-CELL MATURATION ANTIGEN (BCMA) TARGETED CD3-ENGAGING BISPECIFIC ANTIBODY, FOR PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA (MM)

Background: Elranatamab (PF-06863135) is a humanized bispecific monoclonal antibody (IgG2a) that targets BCMA, a member of the tumor necrosis factor receptor superfamily expressed in MM, and CD3 on T cells. MagnetisMM-1 (ClinicalTrials.gov ID: NCT03269136) is a Phase 1 study of elranatamab designed to evaluate selective therapeutic targeting and activation of T cells re-directed against BCMA-expressing malignant plasma cells.
Aims: The aim of MagnetisMM-1 is to characterize the efficacy, safety, pharmacokinetics, and pharmacodynamics of elranatamab as a single agent and in combination with immunomodulatory agents for patients with relapsed or refractory MM.
Methods: Patients (pts) received single agent elranatamab at 80, 130, 215, 360, 600, and 1000µg/kg/week subcutaneously (SC). A modified toxicity probability interval method was used for escalation, with monitoring for dose-limiting toxicity (DLT) to end of the first cycle. Treatment-emergent adverse events (TEAEs) were graded by Common Terminology Criteria for Adverse Events (v4.03), and cytokine release syndrome (CRS) by American Society for Transplantation and Cellular Therapy criteria (Lee et al. Biol Blood Marrow Transplant. 2019;25:625). Response was assessed by International Myeloma Working Group criteria. Pharmacokinetics, cytokine profiling, and T cell immunophenotyping were performed.
Results: 30 pts had received elranatamab as of 4-Aug-2020 at 80 (n=6), 130 (n=4), 215 (n=4), 360 (n=4), 600 (n=6), or 1000 (n=6) µg/kg SC weekly. Pts had a median of 8 prior treatments; 87% had triple refractory disease, 97% had prior anti-CD38 therapy, and 23% had prior BCMA-directed antibody drug conjugate or chimeric antigen receptor T cell therapy. The most common all causality TEAEs included lymphopenia (n=24, 80%; 20% G3, 60% G4), CRS (n=22, 73%; none >G2), anemia (n=17, 57%; 43% G3, 3% G4), injection site reaction (n=16, 53%; none >G2), thrombocytopenia (n=16, 53%; 23% G3, 17% G4), and neutropenia (n=12, 40%; 17% G3, 17% G4). Both CRS and immune effector cell-associated neurotoxicity syndrome (n=6, 20%) were limited to ≤G2 with median durations of 2 and 1.5 days, respectively. No DLT was observed. Exposure increased with dose, and T_{max} ranged from 3–7 days. Cytokine increases occurred with the first dose, and increased T-cell proliferation was observed in peripheral blood. The overall response rate (ORR) for doses ≥215µg/kg was 75% (n=15/20) including partial response (PR; n=6), very good PR (VGPR; n=3), complete response (CR; n=1), and stringent CR (sCR; n=5). Median time to response was 22 days, and 3 of 4 pts (75%) with prior BCMA-directed therapy achieved response (VGPR, n=2 and sCR, n=1). The recommended Phase 2 dose for single agent elranatamab is 1000 µg/kg SC weekly. Updated data, including duration of response, will be presented.
Summary/Conclusion: Elranatamab demonstrated a manageable safety profile and wide therapeutic index. Doses ≥215µg/kg SC achieved ORR of 75% with CR/sCR rate of 30%. These results demonstrate the safety and efficacy of elranatamab in this relapsed/refractory population, confirm the feasibility and potential of BCMA-directed immunotherapy for malignant plasma cell disorders, and support ongoing development of elranatamab for pts with MM.

S193 TECLISTAMAB, A B-CELL MATURATION ANTIGEN (BCMA) × CD3 BISPECIFIC ANTIBODY, IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA: UPDATED PHASE 1 RESULTS

Background: B-cell maturation antigen (BCMA)-targeted immunotherapies are promising treatment options for patients with relapsed/refractory multiple myeloma (MM). Teclistamab (JNJ-64007957) is a bispecific immunoglobulin G4 antibody that binds to both BCMA and CD3 to redirect CD3+ T cells to BCMA-expressing MM cells.
Aims: To report updated results from the first-in-human phase 1 study of teclistamab in patients with relapsed/refractory MM who were treated at the recommended phase 2 dose (RP2D).
To report updated results from the first-in-human phase 1 study of teclistamab in patients with relapsed/refractory MM who were treated at the recommended phase 2 dose (RP2D).
Methods: Eligible patients had relapsed/refractory MM or were intolerant to established therapies. The primary objectives of the study were to identify the RP2D (part 1) and to characterize the safety and tolerability of teclistamab at the RP2D (part 2). Teclistamab was given either intravenously (IV; range 0.3–19.2 µg/kg biweekly; range 19.2–720 µg/kg weekly) or subcutaneously (SC; range 80.0–3000 µg/kg weekly) in different cohorts, with step-up dosing for doses ≥38.4 µg/kg. Adverse events (AEs) were graded by Common Terminology Criteria for Adverse Events v4.03, and cytokine release syndrome (CRS) was graded by Lee et al 2014 criteria. Response was assessed per International Myeloma Working Group criteria. All patients provided informed consent.
Results: As of Feb 4, 2021, 156 patients had received teclistamab IV (n=84) or SC (n=72). The identified RP2D of weekly SC 1500 µg/kg teclistamab with 60.0 and 300 µg/kg step-up doses, was given to 40 patients; the median follow-up was 4.3 months (range 1.1–10.4+). Of the patients treated at the RP2D, the median age was 62.5 years (range, 39–84), 65% were men and a median of 5 prior lines of therapy was received (range 2–11; 100% triple-class exposed; 65% penta-drug exposed; 83% triple-class refractory; 35% penta-drug refractory; 85% refractory to their last line of therapy). No dose-limiting toxicities occurred at the RP2D in part 1 of the study. The most common AEs at the RP2D were CRS (70%; no grade 3/4 events) and neutropenia (60%; 40% were grade 3/4); grade 1 neurotoxicity was reported in 1 (3%) patient. The median time to CRS onset occurred later with SC dosing compared with IV dosing (day after SC injection vs. day of IV infusion). The overall response rate in response-evaluable patients treated at the RP2D (n = 40) was 65%; 58% of patients achieved a very good partial response or better, and 30% of patients achieved a complete response (CR) or better. The median time to first confirmed response was 1.0 month (range 0.2–3.1). At the RP2D, the median duration of response was not reached with 23/26 responders (88%) alive and continuing treatment at a median follow-up of 5.3 months (range 1.2–10.4+). Responses continued to deepen over time. Of 14 evaluable patients across all cohorts, 9 with CR were minimal residual disease–negative at 10^{-6}. At the RP2D, teclistamab exposure was sustained across the dosing interval and exceeded target levels. Consistent T cell activation was also observed at the RP2D.
Summary/Conclusion: At the RP2D of weekly 1500 µg/kg SC, teclistamab was well-tolerated and demonstrated encouraging efficacy with durable, deepening responses, warranting further investigation as monotherapy and in combination with other agents. With the extended exposure profile at the RP2D and delayed and low-grade CRS observed with SC administration, alternative SC dosing strategies are being explored.

S194 AN UPDATED PHASE 1 STUDY OF A NOVEL FULLY HUMAN BCMA-TARGETING CAR-T CELLS (CT103A) IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

C. Li [1,*], D. Wang [1], J. Wang [1], Z. Li [2,3], H. Huang [4,5,6], J. Liu [7], Y. Song [8], X. Zhang [9,10], D. Zou [11], L. Gao [9,10], Y. Hu [4,5,6], A. -N. Xu [12], W. Wang [12], L. Chen [1], L. Zhu [1], M. Wu [12], J. Zhang [12], J. Zhou [1], L. Qiu [11]

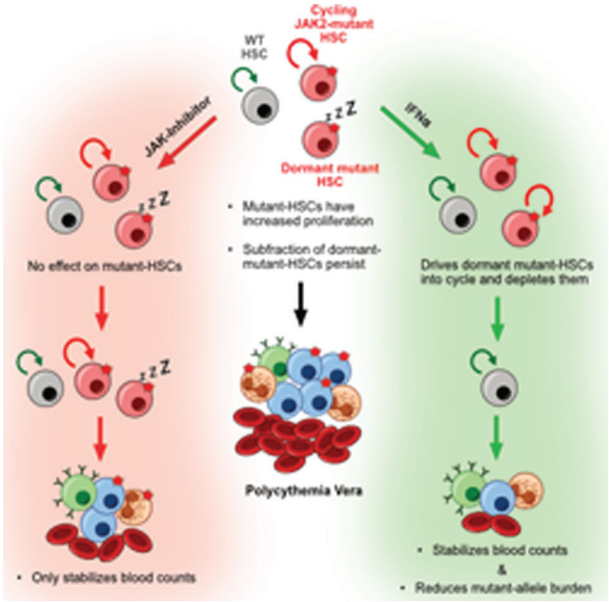
Background: About 33 to 88% of patients with relapsed/refractory multiple myeloma (RRMM) had objective anti-myeloma responses after treatment with anti-B-cell maturation antigen (BCMA) chimeric antigen receptor (CAR)-T cells. However, it remains a great challenge to achieve durable responses, and relapse or disease progression is observed in approximately 28 to 88% of patients. Previous studies suggest that CARs with humanized or fully human single-chain variable fragments (scFvs) may bypass the potential host anti-CAR immunogenicity and retain anti-tumor activity.
Aims: We developed a novel BCMA-targeting CAR construct (CT103A) with a fully human scFv, and conducted an open-label, single-arm phase I clinical trial to evaluate the safety and efficacy, including overall response rate (ORR), minimal residual disease (MRD), and also pharmacokinetics, and pharmacodynamics. The initial results in RRMM have been previously reported. Here, we report updated data of its safety and efficacy in the phase I trial.
Methods: Written informed consent was obtained from each participant, in compliance with the Declaration of Helsinki. Enrolled patients had at least three lines of prior therapies that must include a proteasome inhibitor and an immunomodulatory agent. Clinical response and disease progression were evaluated according to the IMWG consensus criteria at serial time points after CT103A infusion. The definition of extramedullary myeloma (EMM) is the presence of soft tissue masses in extraosseous locations resulting from hematogenous spread, which are not contiguous to the involved bone. MRD was assessed by multiparametric flow cytometry, and CAR transgene copies in the patient peripheral blood mononuclear cell were monitored by digital droplet polymerase chain reaction.
Results: A total of 35 patients were enrolled, among which 29 had high-risk cytogenetics. All patients received 1.0, 3.0, or 6.0 × 10^6/kg CAR-T cells after leukapheresis in the dose-escalation phase and 1.0 dose in the dose-expansion cohort. In escalation, 1.0 dose was determined as RP2D. The cut-off date was December 31, 2020. The median follow-up after CT103A infusion was 520 days (121 to 832 days). Hematologic toxicities were the most common adverse events. 74.3% of the patients experienced grade 1 or 2 cytokine release syndromes (CRS). All CRS could be efficiently controlled. Neurotoxicity (grade 2 ICANS) was observed only in one patient with the symptom of drowsiness, who was later spontaneously relieved without any treatment. For efficacy, 3m ORR rate was 94.2%, ≥VGPR was 74.3%, CR/sCR was 45.7%. 5/8 patients with EMM achieved ≥VGPR, among whom one with both EMM and plasma cell leukemia achieved VGPR. Moreover, 6/9 patients who have received prior CAR-T treatment achieved ≥VGPR. Besides, all 34 patients who performed MRD detection were MRD-negative at one month, and 31 patients kept negative until the last follow-up. The median time to reach the peak of CT103A expansion in 35 patients was 12 (7, 17) days. CAR-T cells were persistent in 100% of the patients, among whom maximum duration had exceeded two years. What's more, only 1 of 35 patients were detected positive for anti-drug antibody, which was reported to be a high-risk factor for disease relapse/progression after CAR-T therapy.
Summary/Conclusion: CT103A is safe, highly productive, and long persistent in RRMM patients and can be developed as a promising therapy for RRMM. Patients who relapsed from prior non-human BCMA CAR T-cell therapy could still benefit from CT103A. This approach is being explored in the phase II study.



New pathways and molecular mechanisms in MPN

S195 INTERFERON-ALPHA TREATMENT RESULTS IN THE DEPLETION OF DORMANT JAK2-MUTANT HSC IN A MURINE MODEL OF POLYCYTHEMIA VERA

J. Jayarajan [1,2,*], J. Knoch [2], M. Ball [2], M. Milsom [2,3]

[1]Heidelberg University, [2]Experimental Hematology, German Cancer Reserach Center (DKFZ), [3]Heidelberg Institute for Stem Cell Technology and Experimental Medicine, Heidelberg, Germany

Background: The majority of patients with *Bcr-Abl* negative myeloproliferative neoplasms (MPN) have a JAK2-V617F mutation. Targeted therapy with JAK-inhibitors have been shown to normalize blood parameters but do not lead to a significant reduction in the mutant allelic burden. Interferon-alpha (IFNα) therapy is the only treatment option available that can achieve molecular remission. However, long-term treatment with IFNα is required and patients frequently exhibit adverse side-effects. Thus it is important to elucidate the mechanism of action of IFNα in achieving molecular remission, which is still not completely understood. Previous studies in JAK2-mutant MPN mouse model have shown that IFNα treatment leads to the depletion of the mutant hematopoietic stem cells (HSCs). Our previous findings have shown that IFNα can drive wildtype dormant HSCs into cell cycle, leading to attrition of functional HSCs. We hypothesize that IFNα treatment eliminates the functional disease-propagating JAK2-mutant HSCs by breaking their dormant status.
Aims: To assess the inherent proliferative index of JAK2-mutant HSCs and the effect of IFNα treatment on mutant-HSC dormancy in comparison to JAK-inhibitor treatment.
Methods: A BrdU pulse-chase experiment was performed on a JAK2-V617F mouse model of MPN, to assess the inherent proliferation of JAK2-mutant HSCs. The dilution of BrdU-label in the mutant HSCs was assessed at different time-points post BrdU-pulse. To further compare the effects of IFN-α and Fedratinib (JAK-inhibitor) on dormant mutant HSCs, mice exhibiting MPN symptoms were pulse-labelled with BrdU as before. The mice were then treated with pegylated-IFNα (600ng or 300ng) or Fedratinib (120mg/kg) for 4 weeks. The proportion of BrdU-label-retaining HSCs in the bone marrow and the changes in blood parameters were assessed 48 hours after final treatment.
Results: The dilution of BrdU-label was observed to be faster in the JAK2-mutant HSCs compared to wildtype-HSCs during disease progression, indicating that JAK2-mutant HSCs have increased cycling and proliferation. However, a sub-fraction of dormant BrdU-label-retaining mutant HSCs were still observed after 20 weeks of chase. While both Fedratinib and peg-IFNα treatment was observed to stabilize blood parameters in the JAK2-mutant mice, only peg-IFNα was observed to significantly reduce the mutant allelic burden in the peripheral blood and eliminate the BrdU-positive dormant mutant HSCs.

Summary/Conclusion: JAK2-mutant HSCs have an inherently higher cycling compared to wildtype-HSCs. However, we identify for the first time a dormant sub-fraction of mutant HSCs within the bone marrow. These dormant HSCs may be responsible for disease propagation and relapse after therapy. In support of this, dormant HSCs were unaffected by Fedratinib treatment in mice where hematologic parameters had been normalized, while peg-IFNα was found to eliminate the dormant mutant HSCs. These data provide a new model to explore novel strategies to eliminate therapy resistant HSCs in the setting of JAK2 mutated MPNs.

S196 CALR FRAMESHIFT MUTATIONS ACCELERATE MATURATION OF MEGAKARYOCYTES IN MPN PATIENT-DERIVED IPS CELLS

K. Olschok [1,2,*], L. Han [1,2,3], M. A. S. de Toledo [1], J. Böhnke [4,5], A. Theocharides [6], A. Maurer [1], H. M. Schüler [7], E. M. Buhl [8], M. Kalmer [1], K. Pannen [1], S. Gupta [1], P. Boor [8], D. Gezer [1], T. H. Brümmendorf [1], M. Zenke [4,5], N. Chatain [1,9], S. Koschmieder [1,9]

[1]Department of Hematology, Oncology, Hemostaseology, and Stem Cell Transplantation, [2]shared first authorship, Faculty of Medicine, RWTH Aachen University, Aachen, Germany, [3]Department of Oncology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China, [4]Department of Cell Biology, Institute for Biomedical Engineering, RWTH Aachen University Medical School, [5]Helmholtz Institute for Biomedical Engineering, RWTH Aachen University, Aachen, Germany, [6]Division of Hematology, University Hospital Zurich and University of Zurich, Zurich, Switzerland, [7]Institute for Human Genetics, [8]Institute for Pathology, Electron Microscopy Facility, [9]shared senior authorship, Faculty of Medicine, RWTH Aachen University, Aachen, Germany

Background: In myeloproliferative neoplasms (MPN), somatic driver mutations of *calreticulin (CALR)*, present in up to 30% of patients with essential thrombocythemia (ET) and primary myelofibrosis (PMF), include 52bp deletions (del52) and 5bp insertions (ins5) in exon 9. Mutant CALR acts by firmly binding to the thrombopoietin receptor (MPL), leading to constitutive activation of Janus kinases (e.g. JAK2) and associated downstream signaling. This results in cellular transformation, including enhanced megakaryopoiesis. The mechanism of increased megakaryopoiesis and the role of mutant *CALR* zygosity has not fully been elucidated to date.
Aims: Establishment of an MPN patient-derived induced pluripotent stem (iPS) cell model focusing on CALR mutations in megakaryocytic development.
Methods: iPS cells were reprogrammed from PBMCs of MPN patients with *CALR*del52 or *CALR*ins5 mutations, or from healthy donors. Since reprogramming of CALR-mutant cells only resulted in homozygous (hom) and heterozygous (het) clones but not *CALR*wt clones, *CALR* mutations were repaired using CRISPR/Cas9n gene editing. iPS cells were differentiated into myeloid cells, with a particular focus on megakaryocytes (MKs). Bulk populations were analyzed by flow cytometry, and CD61+ MKs were purified and further analyzed for RNA expression and ultrastructural morphology.
Results: We established an iPS cell model including *CALR*ins5 and del52 hom and het clones and CRISPR-repaired isogenic (WT_{cr}) clones. Homozygous *CALR*del52 and *CALR*ins5 iPS clones were found to lack myeloperoxidase (MPO) activity, as has been described for patients with hom *CALR* mutations, and MPO activity as an indicator of CALR wt protein function was restored in WT_{cr} clones. We established a protocol allowing efficient generation of iPS cell-derived MKs with characteristics of primary MKs, such as formation of a demarcation membrane system, cytoplasmic pro-platelet protrusions, and MK-typical granules. We demonstrate that hom and het *CALR*ins5- and del52-mutated iPS cells generate a significantly higher number of MKs than related WT_{cr} clones ($p<0.05$ each). Moreover, MK generation of *CALR*ins5 and del52 cells is TPO-independent in contrast to WT_{cr} and healthy donor clones. Enhanced megakaryopoiesis was due to an accelerated maturation process of *CALR*-mutated MKs, since the number of CD42b+ cells among the population of CD61+CD41+ MKs on day 10 was higher in hom (p=0.001[del52], p=0.18[ins5]) and het (p=0.044[ins5]) *CALR*-mutated cells vs. WT_{cr} MKs. In contrast, on day 14, the number of CD42+ MKs in CD61+CD41+ population was similar for all genotypes, suggesting that the WT_{cr} MKs had taken longer to mature. Nonetheless, differences in the expression of megakaryocytic genes were observed between genotypes, with an increased *MPL* expression in *CALR*ins5 MKs compared to WT_{cr} MKs (p=0.0062[het], p=0.052[hom]). Accelerated megakaryopoiesis in *CALR*ins5-mutated clones was corroborated by upregulation of the late MK maturation marker *NFE2* (p=0.0061[het], p=0.052[hom]), and an increased granularity of hom *CALR*ins5 mutated vs. unmutated MKs (p=0.0089).

Summary/Conclusion: We demonstrate that het and hom *CALR*ins5- and del52-mutated iPS cells recapitulate features observed in ET and PMF patients, such as an increased number of MKs, and that this can be reversed by repair of the mutation, suggesting that mutant CALR is responsible for these effects. Mechanistically, our data show that mutant CALR induces an accelerated maturation process of MKs, which is in line with accelerated platelet turnover seen in ET and PMF patients.

S197 TYK2 INHIBITION IS A NOVEL SELECTIVE THERAPEUTIC APPROACH FOR CALR- BUT NOT JAK2V617F-MUTANT MYELOPROLIFERATIVE NEOPLASMS

Background: The classical Philadelphia-chromosome-negative (Ph-) myeloproliferative neoplasms (MPNs) consist of three entities: polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF), carrying three mutually exclusive driver mutations in the genes of janus kinase 2 (*JAK2*), calreticulin (*CALR*) and the thrombopoietin (TPO) receptor (*MPL*). JAK2V617F-mutant cells were shown to be more sensitive to interferon alpha (IFNa) treatment compared to CALR-mutant cells and this IFNa "priming" involved increased phosphorylation of JAK1 and signal transducer and activator of transcription (STAT) 1 in JAK2V617F- vs. CALR-mutant cells. IFNa stimulation leads to phosphorylation of tyrosine kinase (TYK) 2 and JAK1, which are constitutively associated with the IFNa receptor-1 or -2 (IFNAR1/2), respectively, and activate downstream signaling pathways. However, the role of TYK2 in the survival and IFNa response of JAK2- vs. CALR-mutant MPN cells is still incompletely understood.
Aims: Analysis of the role of TYK2 in MPN cells to further investigate the differential response of JAK2V617F- and CALR-mutant cells to IFNa treatment and evaluate TYK2 as a potential target in MPN.
Methods: We used CRISPR/Cas9 technology to generate *TYK2*-deficient $32D^{MPL}$ JAK2V617F or CALRdel52 cells and subsequently analyzed the IFNa response on cell viability (MTT assays), downstream JAK-STAT signaling and gene expression. Furthermore, we evaluated the effects of the TYK2-specific inhibitor deucravacitinib in $32D^{MPL}$ mutant cells and in primary MPN patient material using colony formation unit assays.
Results: Basal phosphorylation of TYK2 (pTYK2) was increased in $32D^{MPL}$ CALRdel52-mutant cells compared to JAK2V617F-mutant as well as empty vector cells ($p<0.001$). Generation of a *TYK2* knockout in $32D^{MPL}$ CALRdel52 cells was not successful, while pTYK2-deficient JAK2V617F-mutant cells were readily produced, underlining an important role of TYK2 in CALR-mutant cells. In pTYK2-deficient $32D^{MPL}$ JAK2V617F cells, IFNa effects were significantly reduced, including loss of viability, activation of pSTAT1 and pSTAT3 and IFNa target genes. However, induction of apoptosis after IFNa treatment was not altered. We analyzed the effect of deucravacitinib and found that cell viability of $32D^{MPL}$ CALRdel52- but not JAK2V617F-mutant cells was significantly decreased even at low concentrations [0.5 µM] of the inhibitor. Western Blotting confirmed complete loss of TYK2 phosphorylation after deucravacitinib treatment in both cell lines as well as reduced phosphorylation of downstream signaling molecules. In primary peripheral blood-derived mononuclear cells of patients with MPN, the TYK2 inhibitor decreased CALR- but not JAK2V617F-mutant allele burden in vitro, and clonogenic growth of ET- and PMF- but not PV-derived cells was inhibited.
Summary/Conclusion: Our data demonstrate an essential role for TYK2 in CALR-mutant but not JAK2V617F-mutant MPN cells and suggest pharmacologic TYK2 inhibition as a novel promising treatment approach in CALR-mutant MPNs.

S198 IDENTIFICATION AND PHENOTYPIC CHARACTERIZATION OF DISEASE-INITIATING CD34+/CD38– STEM CELLS IN BCR-ABL1-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

Background: The classical Philadelphia chromosome-negative myeloproliferative neoplasms (MPN) are characterized by uncontrolled expansion of myeloid progenitor cells, elevated blood counts, phenotype-driver mutations in certain target-genes (*JAK2*, *CALR*, *MPL*) and an increased risk of leukemic transformation. Despite being considered stem-cell disorders, the phenotype of the disease-initiating neoplastic stem cells (NSC) in MPN remains unknown.
Aims: The aim of the study is to identify MPN-initiating NSC and characterize their phenotype in order to facilitate their enrichment and develop novel treatment strategies.
Methods: As assessed by multicolor flow cytometry and a panel of monoclonal antibodies (n=50), we were able to define target expression profiles of putative $CD34^+/CD38^-$ NSC and $CD34^+/CD38^+$ progenitor cells in patients with chronic phase MPN (n=93) and post-MPN secondary acute myeloid leukemia (sAML, n=11). To confirm the disease-initiating ability of primary MPN NSC, xenotransplantation experiments with NSGS mice were performed.
Results: In almost all patients, the MPN NSC expressed several receptors involved in NSC-niche interaction, including CD97, CD99, CD117 and CD184. In contrast, NSC expressed CD26 only in a subset of patients with primary myelofibrosis (PMF). MPN NSC expressed significantly higher levels of CD184 compared to stem cells in healthy controls ($p<0.0001$) or sAML ($p<0.01$). Among the cytokine receptors tested, CD25 was identified on NSC in most patients with PMF and sAML, and in a few with essential thrombocythemia (ET), but not in patients with polycythemia vera (PV). PMF NSC also displayed higher levels of CD25 than the PMF progenitor cells ($p<0.01$). MPN NSC did not exhibit substantial amounts of IL-1RAP and erythropoietin receptor. We next examined the expression of various immunological targets and resistance-mediating immune checkpoints. In all patients tested, NSC were found to express CD33. We also found that $CD34^+/CD38^+$ progenitor cells in ET display higher levels of CD33 than NSC ($p<0.01$). However, neither NSC nor the progenitor cells in MPN expressed higher levels of CD33 compared to normal stem cells or normal progenitor cells. MPN NSC and sAML stem cells consistently expressed the "don't eat me" checkpoint CD47 and the classical checkpoint CD274 (PD-L1). MPN NSC displayed significantly higher levels of CD274 compared to normal stem cells ($p<0.001$) or stem cells in sAML ($p<0.05$). No difference in the expression of surface antigens on MPN NSC were observed between patients harboring mutations in the *JAK2* and *CALR* genes. Engraftment of human $CD45^+CD33^+$ cells in the bone marrow of NSGS mice was found in 15/15 mice injected with bulk mononuclear cells (MNC) containing $CD34^+$ cells and in 0/15 NSGS mice injected with CD34-depleted MNC after 28 weeks. Whereas the $CD38^-$ sub-fraction of MPN MNC produced leukemic engraftment in 10/14 mice (71.4%) only 2/13 mice (15.4%) engrafted when injected with the $CD38^+$ sub-fractions of MPN NSC. Engraftment of clonal MPN cells was confirmed by demonstrating the presence of *JAK2*-V617F mutation in engrafted human cells in mouse BM samples.
Summary/Conclusion: Together, we show that MPN NSC reside in a $CD34^+/CD38^-$ fraction of the malignant clone and display a unique phenotype, including immune checkpoint molecules, cytokine receptors and other target antigens. Our results should support the isolation of MPN NSC and the development of NSC-eradicating therapies in MPN.

S199 BH3-MIMETICS AND AZACITIDINE SHOW SYNERGISTIC EFFECTS ON JUVENILE MYELOMONOCYTIC LEUKEMIA

N. Koleci [1,*], Y. Wu [1], L. Gallego-Villar [1], G. Andrieux [2], J. Rajak [1], K. Aumann [3], C. M. Niemeyer [1], C. Flotho [1], M. Erlacher [1]

[1]Department of Pediatric Hematology and Oncology, [2]Institute of Medical Bioinformatics und Systems Medicine IBSM, Freiburg, Germany., [3]Institute of

Pathology, Freiburg, Germany., University Medical Center Freiburg, Freiburg im Breisgau, Germany

Background: Juvenile myelomonocytic leukemia (JMML) represents an aggressive myeloid neoplasia of early childhood, driven by oncogenic RAS signaling and epigenetic deregulation. Most patients require allogeneic stem cell transplantation (HSCT), but relapse risk remains high. Azacitidine effectively reduces leukemia burden in some JMML patients. Nonetheless, not all patients respond to this treatment, and alternative therapeutic strategies are urgently required. BH3-mimetics inhibit anti-apoptotic BCL-2 proteins (i.e. BCL-2, BCL-XL, MCL-1 and/or BCL-W) thereby inducing apoptosis directly at the mitochondrial level. These compounds hold big promise for anti-cancer therapy, either alone or in combination with other drugs. Recently, venetoclax, a specific BCL-2 inhibitor, was FDA-approved in combination with hypomethylating agents for the treatment of acute myeloid leukemia (AML) in adults.
Aims: Based on these promising results obtained in AML, we investigated different BH3-mimetics in JMML, alone or in combination with azacitidine.
Methods: For this purpose, we generated patient-derived xenograft (PDX) mice and treated them with ABT737, an analogue of navitoclax known to inhibit BCL-2, BCL-XL and BCL-W. Treatment was initiated 8 weeks after transplantating JMML cells. ABT737 was regularly given for the next 28 days (75 mg/kg/d), and on day 29, mice were sacrificed and analyzed by flow cytometry and histopathology. Mock-treated mice were used as controls. In addition, a group of mice was treated with azacitidine as described earlier (i.e. 2 cycles á 5 days followed by 9-day breaks, 3 mg/kg/d).
Results: Both ABT737 and azacitidine led to efficient leukemia depletion. We then analyzed whether both drugs could be used at lower concentration when given in combination, with the aim to minimize any potential side effect. Indeed, a 28 days long treatment with 0.75 mg/kg/d azacitidine (5 days on, 9 days off) and 50 mg/kg/d ABT737 (daily) did not only completely reduce leukemia burden but also depleted all leukemia-initiating cells as confirmed by serial transplantation experiments. The combination of drugs worked significantly better than both drugs alone.
To dissect the roles of BCL-2 and BCL-XL, both inhibited by navitoclax, and to additionally analyze the role of MCL-1 in the survival of JMML cells, we performed *in vitro* experiments using the specific inhibitors ABT199, A1155463 and S63845, respectively. When used alone, only ABT737 and the MCL-1 inhibitor S53845 killed JMML cells efficiently. However, synergistic effects were noted between azacitidine and the BCL-XL inhibitor A1155463. Azacitidine treatment resulted in the upregulation of pro-apoptotic BCL-2 proteins (i.e. BIK, PUMA, BAD and BMF) and a slight downregulation of MCL-1 indicating that azacitidine and the BCL-XL inhibitor synergized at the level of the BCL-2 protein family.
Summary/Conclusion: In sum, our study confirms that the effects of azacitidine are significantly increased by adding BH3-mimetics. Such combination strategies will be especially important for those patients that are resistant to azacitidine monotherapy.

Novel therapies and targets in MPN

S200 RUSFERTIDE (PTG-300) ELIMINATES THE NEED FOR THERAPEUTIC PHLEBOTOMY IN BOTH LOW AND HIGH-RISK POLYCYTHEMIA VERA (PV) PATIENTS

M. Kremyanskaya [1,*], Y. Ginzburg [1], A. Kuykendall [2], N. Pemmaraju [3], A. Yacoub [4], J. Yang [5], F. Valone [6], S. Khanna [6], S. Gupta [6], S. Verstovsek [3], R. Hoffman [1]

[1]Hematology and Medical Oncology, Mount Sinai Hospital, New York, [2]Malignant Hematology, Lee Moffitt Cancer Center, Tampa, FL, [3]Dept of Leukemia, MD Anderson, Houston, [4]Cancer Center, University of Kansas Cancer Center, Faiway, [5]Hematology, Karmanos Cancer Institute, Detroit, [6]Clinical development, Protagonist Therapeutics, Newark, United States

Background: Polycythemia vera (PV) patients are treated with periodic therapeutic phlebotomy (TP) to maintain hematocrit levels <45% in an effort to reduce the incidence of thrombotic events. PV patients likely spend significant time with hematocrit levels >45%, between TP and increase the risk of thrombosis. Hepcidin is the body's main negative regulator of iron metabolism such that elevated hepcidin levels are expected to reduce iron availability and decrease erythropoiesis. Rusfertide (PTG-300) is a hepcidin-mimetic. We hypothesized that rusfertide would decrease erythropoiesis and phlebotomy requirement in PV patients.
Aims: The current study aims to compare the iron status and phlebotomy requirements in high TP-requiring PV patients before and during treatment with rusfertide.
Methods: PTG-300-04 is a Phase 2 trial consisting of 3 parts: (1) a 28-week dose-finding; (2) a 12-week blinded randomized withdrawal (1:1) rusfertide vs placebo; and (3) a 52-week open label extension (**NCT04057040**). Eligibility criteria include PV diagnosis and ≥3 phlebotomies with or without concurrent cytoreductive therapy to maintain hematocrit <45% in the 24 weeks prior to enrollment. Rusfertide doses of 10, 20, 40, 60 and 80 mg administered subcutaneously weekly were added on to each subject's pre-study treatment for PV and the dose of rusfertide was adjusted to maintain hematocrit <45%.
Results: Thirty-five patients were enrolled to date: 16/35 with low-risk PV, age rangd between 31-75yrs. Prior to enrollment all patients received TP range of TP 3-9; median time between TP = 36 days. In addition, out of 35 patients; 8 patients received concurrently hydroxyurea, 3 patients received concurrently interferon, and 1 patient received concurrently ruxolitinib. The rate of TP after starting rusfertide decreased significantly compared to the rate of TP before starting rusfertide (p< 0.0001). Four subjects required one TP early in the dose-finding period (within 12 weeks) and 3 have subsequently been TP-free after increasing the dose of rusfertide. Thirteen patients have completed 28 weeks of dosing in Part 1. Ten patients were TP-free for 28 weeks; 2 patients required 1 TP each and 1 required 2 compared to >3 TP each over 28 weeks pre-study. Hematocrit was <45% at study entry and remained continuously <45% during the study. Prior to treatment, mean ferritin levels were consistent with systemic iron deficiency while serum ferritin increased progressively toward normal range during the study. Furthermore, both MCV and MCH values increased suggesting a redistribution of iron within erythropoiesis. The most frequent adverse events (AE) were injection site reactions (ISR) reported by 9 patients. Most of the ISR were grade 1 and there were no drug related SAE.
Summary/Conclusion: The current results indicate that rusfertide is an effective agent for the treatment of PV, reversing iron deficiency and eliminating the need for TP in PV patients. Elimination of TP requirements for 7 months in TP-dependent PV patients is significant and unexpected. The effect of rusfertide on PV-related symptoms is also being evaluated. Continued patient enrollment will enable more definitive conclusions regarding the efficacy and safety of rusfertide in PV patients. Rusfertide looks very promising in maintaining hematocrit <45% and in eliminating the therapeutic phlebotomies in both low and high-risk PV patients.

S201 EFFICACY AND SAFETY OF AVAPRITINIB IN PATIENTS WITH ADVANCED SYSTEMIC MASTOCYTOSIS: INTERIM RESULTS FROM THE OPEN-LABEL, SINGLE-ARM, PHASE 2 PATHFINDER STUDY

Background: Systemic mastocytosis (SM) is a rare, clonal, hematologic neoplasm which is driven by the *KIT* D816V mutation in ~95% of cases. Treatment outcomes remain poor for patients (pts) with advanced systemic mastocytosis (AdvSM), which includes aggressive SM (ASM),

SM with an associated hematologic neoplasm (SM-AHN), and mast cell leukemia (MCL). In the Phase 1 EXPLORER study (NCT02561988), avapritinib, a potent KIT D816V inhibitor, induced rapid, durable responses which deepened over time in pts with AdvSM regardless of prior therapy or subtype.
Aims: PATHFINDER (NCT03580655) is a pivotal open-label, single-arm Phase 2 study evaluating avapritinib in pts with AdvSM.
Methods: Pts aged ≥18 years with centrally confirmed diagnosis of an AdvSM subtype. Primary endpoint was overall response rate (ORR) by modified International Working Group-Myeloproliferative Neoplasms Research and Treatment and European Competence Network on Mastocytosis (mIWG-MRT-ECNM) criteria. This pre-specified interim analysis (null hypothesis ORR 28% based on midostaurin) included 32 ORR-evaluable pts. Mean baseline change in AdvSM-Symptom Assessment Form Total Symptom Score (TSS) and safety were secondary endpoints. All pts gave informed consent.
Results: As of June 23, 2020, 62 pts with AdvSM received avapritinib primarily at 200 mg orally once daily (QD); 52/62 (84%) pts remained on treatment. Median age was 69 years (range 31–88), 45% were female, 31% had ECOG PS 2–3, and 68% had prior systemic therapy (55% with midostaurin). The primary endpoint was met with an ORR of 75% (95% CI 57–89) in 32 ORR-evaluable pts as per the pre-specified interim analysis (P=1.6x10-9; median follow-up 10.4 months) (**Table**). Complete remission with full or partial hematologic recovery occurred in 6 (19%) pts. Median time to response was 2 (range 0.3–12) months; responses deepened over time. Median overall survival (OS) in the ORR-evaluable population was not reached; estimated 12-month OS was 87%. In the safety population (N=62), there were ≥50% reductions from baseline for serum tryptase (87%; n=54), marrow mast cells (71%; n=44), and *KIT* D816V variant allele fraction (53%; n=33). Mean TSS at baseline (n=56) was 18.3; fatigue, spots, itching, flushing, and abdominal pain were the most severe symptoms; TSS improved rapidly and was sustained through cycle 11 with mean 36% improvement (P<0.001), corresponding to a mean decrease of 9.8 points from baseline (n=22). Common (≥25%) adverse events (AEs; any grade, Grade ≥3) were peripheral (50%, 3%) and periorbital (35%, 3%) edema, thrombocytopenia (32%, 8%), and anemia (29%, 16%). Overall, 3 (5%) pts discontinued due to a treatment-related AE and 3 (5%) pts discontinued due to disease progression, including 1 pt with transformation to acute myeloid leukemia. There were 3 (5%) deaths, all considered unrelated to treatment. Seven (11%) pts had cognitive AEs (all Grade 1–2). Grade 4 subdural hematoma occurred in 1 (2%) pt with severe thrombocytopenia (platelets <50×10^9/L) at baseline and prior to the event. Subsequent pts with pre-treatment severe thrombocytopenia were excluded, platelet monitoring increased, and dose interruption for severe thrombocytopenia recommended.

Table. Confirmed ORR and best response by mIWG-MRT-ECNM criteria in pts with AdvSM[a]

Outcome, n (%)	All (n=32)	ASM (n=2)	SM-AHN (n=26)	MCL (n=4)	All (n=32)			
					Prior therapy (n=23)	No prior therapy (n=9)	Prior Midostaurin (n=17)	No Prior Midostaurin (n=15)
ORR[b]	24 (75)	2 (100)	21 (81)	1 (25)	17 (74)	7 (78)	14 (82)	10 (67)
95%CI	57–89	16–100	61–93	1–81	52–90	40–97	57–96	38–88
CR	0	0	0	0	0	0	0	0
CRh	6 (19)[c]	1 (50)	5 (19)	0	3 (13)	3 (33)	3 (18)	3 (20)
PR	10 (31)	1 (50)	8 (31)	1 (25)	7 (30)	3 (33)	5 (29)	5 (33)
CI	8 (25)	0	8 (31)	0	7 (30)	1 (11)	6 (35)	2 (13)
SD	4 (13)	0	2 (8)	2 (50)	2 (9)	2 (22)	0	4 (27)
PD	1 (3)	0	0	1 (25)	1 (4)	0	0	1 (7)
NE	3 (9)	0	3 (12)	0	3 (13)	0	3 (18)	0

[a]The PATHFINDER pre-specified interim occurred in 32 ORR-evaluable pts with a diagnosis of AdvSM, who received at least 1 dose of avapritinib and were evaluable per mIWG-MRT-ECNM criteria at baseline and had ≥2 complete post-baseline response assessments and ≥6 cycles of therapy (or came off study).
[b]ORR = CRh + PR + CI, all lasting ≥12 weeks.
[c]Median time to CRh: 5.6 months (range 1.8–6.1).
Abbreviations: AdvSM, advanced systemic mastocytosis; ASM, aggressive systemic mastocytosis; 95% CI, 95% confidence interval; CI, clinical improvement; CR, complete remission; CRh, complete remission with partial hematologic recovery; MCL, mast cell leukemia; mIWG-MRT-ECNM, modified International Working Group-Myeloproliferative Neoplasms Research and Treatment and European Competence Network on Mastocytosis; NE, not evaluable for response; ORR, overall response rate; PD, progressive disease; PR, partial remission; pts, patients; SD, stable disease; SM-AHN, systemic mastocytosis with an associated hematologic neoplasm.

Summary/Conclusion: The PATHFINDER registrational study interim analysis showed avapritinib 200 mg QD starting dose induced rapid, durable responses which deepened over treatment regardless of AdvSM subtype or prior therapy and improved symptoms in pts with AdvSM. Avapritinib was generally well tolerated with few pts discontinuing treatment due to AEs.

S202 TRANSFUSION INDEPENDENCE IS ASSOCIATED WITH IMPROVED OVERALL SURVIVAL IN MYELOFIBROSIS PATIENTS RECEIVING MOMELOTINIB

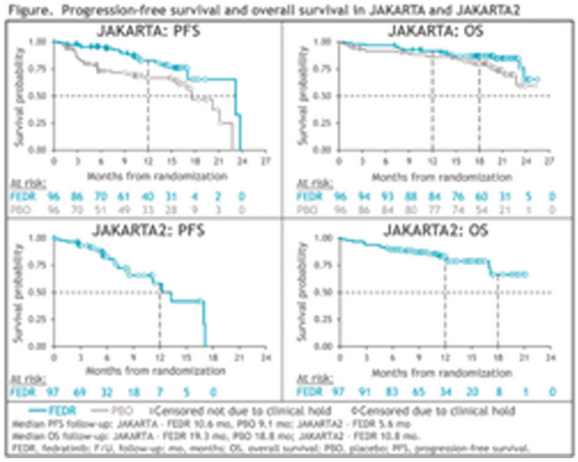
Background: Momelotinib (MMB) is a potent JAK1, JAK2 and ACVR1 inhibitor with clinical activity against the hallmark features of myelofibrosis (MF), namely anemia, constitutional symptoms and splenomegaly, across the continuum of JAKi naïve or previously JAKi treated intermediate/high risk MF patients as demonstrated in the previously conducted Phase 3 SIMPLIFY-1 & -2 clinical trials (S1, S2). S1 enrolled JAKi-naïve patients with MF (n=432) double-blind randomized 1:1 to MMB or ruxolitinib (RUX). S2 enrolled patients with MF with hematological toxicity during prior RUX therapy (n=156) randomized 2:1 to open-label MMB or best available therapy (BAT; consisting of RUX in 88% of patients). In both trials, following the 24-week randomized treatment (RT) period, patients could continue MMB (MMB→MMB) and those randomized to RUX/BAT could cross-over to MMB (RUX/BAT→MMB) for extended treatment (ET).
Previously published data from the SIMPLIFY studies demonstrate robust overall survival (OS) for MMB-treated patients in S1 and S2 (median not reached and 34.3 months, respectively) with a maximum follow up of approximately 5 years and median of 2.9 years in S1 and 2.3 years in S2.
Aims: OS data for patients receiving MMB in S1 and S2 are reported here for subgroups defined by Week 24 (W24) transfusion independence (TI) responders vs non-responders, and also other efficacy endpoints.
Methods: Survival was estimated using KM analysis with descriptive log-rank tests for comparison applied (all p-values are descriptive).
Results: As previously reported, W24 TI rates were higher in the MMB arms of S1 (67% vs 49%) and S2 (43% vs 21%). In S1, W24 TI responders in the MMB group show an OS advantage, with median OS not reached and 3-year survival of 80% (HR=0.30; p<0.0001) compared to MMB TI non-responders. Similarly in S2, W24 TI responders in the MMB group show a trend toward better OS compared to TI non-responders (HR=0.57; p=0.0652). The HRs in S1 for MMB responders vs non-responders for W24 SRR and TSS were 0.59 (p=0.0904) and 0.65 (p=0.1657), respectively. Alternative analyses using OS defined from W24 demonstrated consistent results.
Summary/Conclusion: These new analyses suggest JAKi naïve patients receiving MMB who maintain or achieve TI at W24 have favorable OS compared to MMB TI non-responders, with a similar trend observed in S2. These findings are consistent with anemia and transfusion dependency being key predictors of shortened OS in MF and suggest that TI response at W24 may become a surrogate for clinical benefit, supporting the clinical relevance of MMB's differentiated pro-erythropoietic ACVR1 inhibition.



S203 OVERALL AND PROGRESSION-FREE SURVIVAL IN PATIENTS TREATED WITH FEDRATINIB AS FIRST-LINE MYELOFIBROSIS (MF) THERAPY AND AFTER PRIOR RUXOLITINIB (RUX): RESULTS FROM THE JAKARTA AND JAKARTA2 TRIALS

C. Harrison [1,*], J. -J. Kiladjian [2], S. Verstovsek [3], A. Vannucchi [4], R. Mesa [5], A. Reiter [6], J. Zhang [7], S. Rose [7], J. Mascarenhas [8]

[1]Guy's and St Thomas' Hospital, London, United Kingdom, [2]Hôpital Saint-Louis; Université de Paris; Inserm, Paris, France, [3]The University of Texas MD Anderson Cancer Center, Houston, United States, [4]AOU Careggi, University of Florence, Florence, Italy, [5]Mays Cancer Center at UT Health San Antonio MD Anderson, San Antonio, United States, [6]Universitätsklinikum Mannheim, Mannheim, Germany, [7]Bristol Myers Squibb, Princeton, [8]Icahn School of Medicine at Mount Sinai, New York, United States

Background: FEDR is an oral JAK2 inhibitor (JAKi) that improves splenomegaly and symptoms in patients (pts) with intermediate (INT) or high-risk MF, whether used as first-line (1L) treatment (Tx), or in pts previously treated with RUX. In the phase 3, double-blind JAKARTA trial, 1L Tx with FEDR 400 mg/day (d) significantly improved spleen volume and MF symptoms *vs* placebo (PBO) at 24 weeks. Similarly, in the phase 2, single-arm JAKARTA2 trial, FEDR 400 mg/d improved spleen volume and symptom burden from baseline in pts with MF previously treated with RUX. Survival outcomes from these studies have not been reported previously.
Aims: Determine progression-free survival (PFS) and overall survival (OS) with FEDR 400 mg/d in JAKARTA and JAKARTA2.
Methods: Both trials enrolled pts aged ≥18 years with INT- or high-risk MF, platelet counts ≥50 $\times 10^9$/L, and ECOG PS ≤2. In JAKARTA, pts were randomized 1:1:1 to receive 1L FEDR 400 mg/d, FEDR 500 mg/d, or PBO for ≥6 4-week cycles (randomized Tx period). At the end of 6 Tx cycles (or earlier in cases of disease progression [PD]), pts randomized to PBO could cross-over to FEDR. In JAKARTA2, all pts with MF resistant or intolerant to prior RUX (per investigator assessment) received FEDR 400 mg/d (starting dose). Pts in both trials could continue to receive FEDR until PD or unacceptable toxicity. These analyses include pts who received FEDR 400 mg/d in each study and pts in JAKARTA randomized to PBO.
PFS was the time from randomization to PD (IWG-MRT criteria) or death (in the absence of PD/death, PFS was censored at the date of the last valid assessment), and OS was the time from randomization to death. PFS/OS were estimated using Kaplan-Meier methods. Importantly, PFS/OS results for pts in the JAKARTA PBO arm include time after crossover to FEDR. Due to a clinical hold in Nov 2013 (later lifted), both trials were terminated early and survival follow-up stopped; ongoing pts were censored at the time of the clinical hold.
Results: In JAKARTA, 96 pts were randomized to FEDR 400 mg/d and 96 to PBO; 71 pts (74%) in the PBO arm crossed-over to FEDR on-study. At study termination, survival follow-up was halted for 74 (77%) and 65 (68%) pts randomized to FEDR 400 mg/d and PBO, respectively. PFS was significantly prolonged with FEDR *vs* PBO: median 23.2 *vs* 17.5 mo, respectively (HR 0.42 [95%CI 0.23, 0.76]; *P*=0.004), and 1-year PFS rates were 83% *vs* 67% (**Figure**). Median OS was not reached (NR) in either Tx arm (HR 0.57 [0.30, 1.10]; *P*=0.094); 1-year and 18-mo survival rates in the FEDR arm were 92% and 87%, respectively, and in the PBO arm were 86% and 80%.
JAKARTA2 enrolled 97 pts, and 79 (81%) were censored for survival at study termination. Median PFS was 13.3 mo (95%CI 8.4, 17.1) and 1-year PFS was 59%. Median OS was NR (95%CI 17.1, NR) (**Figure**), and 1-year and 18-mo survival rates were 84% and 67%, respectively.

Figure. Progression-free survival and overall survival in JAKARTA and JAKARTA2

Summary/Conclusion: FEDR significantly improved PFS *vs* PBO as 1L MF Tx. Separation of PFS/OS curves between FEDR and PBO in JAKARTA, despite FEDR Tx in the PBO arm after Tx crossover, suggests pts may derive greater benefit from early FEDR use. For pts in JAKARTA2 treated with FEDR after prior RUX, median PFS, median OS, and 1-year survival rate compare favorably with outcomes after RUX discontinuation from a recent analysis of similar pts with MF included in large healthcare databases (6.0 mo, 11.1 mo, and 47%, respectively) (Mascarenhas, 2020). These survival outcomes were greatly impacted by the FEDR clinical hold. The ongoing FREEDOM and FREEDOM2 trials will further assess survival with FEDR in pts with MF.

S204 JAKTINIB, A NOVAL JAK INHIBITOR IN TREATMENT OF PATIENTS WITH ADVANCED MYELOFIBROSIS: PRELIMINARY RESULTS FROM A PHASE 2 STUDY

Y. Zhang [1], H. Zhou [2], Z. -X. Jiang [3], D. -S. Wu [4], J. -L. Zhuang [5], L. Wei [6], Q. Jiang [7], X. -L. Wang [8], J. -W. Huang [9], H. -L. Zhu [10], R. -J. Zhang [11], X. Du [12], F. Background: Myelofibrosis (MF) is associated with splenomegaly, cytopenias, constitutional symptoms, and bone marrow fibrosis, with limited therapeutic options. Jaktinib, a novel, small-molecule inhibitor of JAK, is currently being studied in MF patients (pts). We present preliminary data from ZGJAK002, a Phase 2 open-label and multi-center study, evaluating two different regimens of Jaktinib in patients with MF.
Aims: To investigate the efficacy and safety of Jaktinib in MF pts.
Methods: Eligibility: MF pts included primary per WHO criteria (2016) or post-essential thrombocythemia / polycythemia vera MF according to IWG-MRT criteria; DIPSS-PLUS ≥int-2 (int-1 with symptomatic splenomegaly or hepatomegaly, require a treatment). By 1:1 ratio, 104 pts from 21 centers were randomized to Jaktinib 100mg BID or 200mg QD, administrated orally. The primary endpoint: the proportion of pts with spleen volume reduction from baseline ≥35% (SVR35) at week 24 (W24), assessed by Independent Review Committee based on MRI/CT images. Secondary endpoints: at W24 compared to baseline, the proportion of pts with ≥50% reduction on MPN-SAF TSS, improvements in RBC transfusion and hemoglobin (Hgb), etc.
Results: As of 30, Nov, 2020, 104 pts completed treatments of 24 weeks and planned visits. Baseline characteristics were generally balanced and shown in Table 1.
At W24, the SVR35 were 51.9% (27/52) in the 100mg BID and 30.8% (16/52) in the 200mg QD (*P*=0.0459), the median duration of response has not reached yet for the 100mg BID and 47.9 weeks for the 200mg QD. The proportion of pts achieved ≥50% improvement in TSS at W24 from baseline for BID and QD arms were 57.7% (30/52) and 53.8% (28/52), respectively. The mean percent of TSS change from baseline was -53.03 and -35.87, respectively. Approximately 1/3 (16/49) of combined pts had Hgb elevated ≥20g/L from baseline's ≤100g/L.
The most common Grade ≥3 hematological TEAEs were anemia (100mg BID 21.2%, 200mg QD 26.9%), thrombocytopenia (13.5%, 11.5%), and neutropenia (3.8%, 11.5%). Most common non-hematological TEAEs were upper respiratory tract infection (26.9%, 28.8%), elevated creatinine (21.3%, 30.8%) and elevated bilirubin (20.5%, 13.5%) predominantly grade 1 or 2. A total of 51 (49.0%) pts had ≥1 dose reduction/interruption, mostly due to thrombocytopenia (30.8%), anemia (22.1%), and neutropenia (8.7%).

Table 1. Demographics and baseline Characteristics.

Variable	100mg Bid (N=52)	200mg Qd (N=52)
Age (year) [median (Min-Max)]	60.0 (25-77)	62.0 (31-75)
Gender [Male/Female n (%)]	29(55.8)/23 (44.2)	31 (59.6)/21 (40.4)
Myelofibrosis subtype [n (%)]		
PMF	38 (73.1)	41 (78.8)
Post-PV MF	10 (19.2)	4 (7.7)
Post-ET MF	4 (7.7)	7 (13.5)
DIPSS-PLUS risk status [n (%)]		
High	1 (1.9)	0
Int-2	31 (59.6)	35 (67.3)
Int-1	20 (38.5)	17 (32.7)
Spleen volume [median (Min-Max)] cm^3	1588.37 (459.08 - 4349.87)	1457.9525 (589.16 - 5207.66)
JAK2 V617F-positive [n (%)]	39 (75.0)	32 (61.5)
Drug exposure duration (Months) [median (Min-Max)]	12.7 (0.5 - 22.8)	11.7 (1.3 - 20.4)

Summary/Conclusion: Jaktinib is generally well-tolerated and safe in MF pts. Reductions in spleen volume and constitutional symptom burden, and improvements in RBC transfusion dependency and Hgb levels were observed. The rate of spleen volume reduction was higher in the 100mg BID arm than the 200mg QD arm.

Hodgkin lymphoma - Clinical

S205 BRENTUXIMAB VEDOTIN WITH CHEMOTHERAPY FOR PATIENTS WITH PREVIOUSLY UNTREATED, STAGE III OR IV CLASSICAL HODGKIN LYMPHOMA: A 5-YEAR UPDATE OF THE PHASE 3 ECHELON-1 STUDY (NCT01712490)

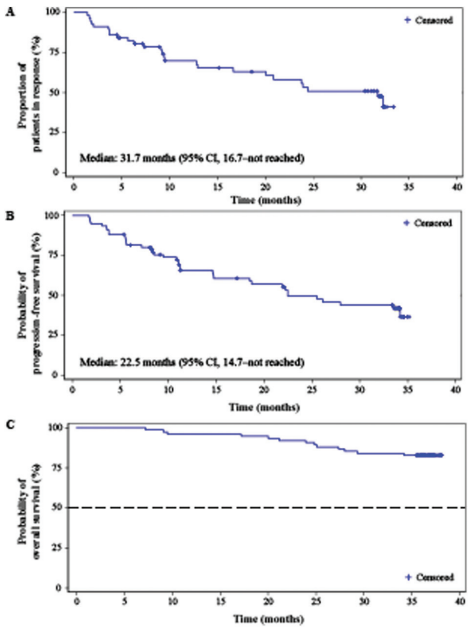
Background: Historically, nearly all relapses in classical Hodgkin lymphoma (cHL) occur within 5 years of treatment (Radford, BMJ 1997). In the phase 3 ECHELON-1 study (NCT01712490) in patients (pts) with newly-diagnosed Stage III/IV cHL, treatment with brentuximab vedotin, doxorubicin, vinblastine, and dacarbazine (A+AVD) significantly improved modified progression-free survival (PFS) per independent review facility vs doxorubicin, bleomycin, vinblastine, and dacarbazine (ABVD) (Connors et al, NEJM 2018). After 3 and 4 years' follow-up, sustained PFS per investigator (INV) benefits were seen with A+AVD vs ABVD in the intent-to-treat (ITT) population as well as across most key pt subgroups (Bartlett, Blood 2019; Straus, Blood 2020). These improvements were irrespective of interim positron emission tomography (PET) scan status, disease stage, and baseline disease risk factor score.
Aims: We report updated efficacy and safety results after 5-years' follow-up of the ECHELON-1 study.
Methods: Pts with previously untreated Stage III/IV cHL were randomized to receive ≤6 cycles of intravenous A+AVD (n=664) or ABVD (n=670) on days 1 and 15 of a 28-day cycle. After cycle 2, pts had an interim PET scan (PET2). Analyses were performed after extended follow-up (cutoff date Sept' 18, 2020) to assess PFS per INV, peripheral neuropathy (PN) resolution and improvement (improvement ≥1 grade from worst grade as of the latest assessment) in pts with ongoing symptoms at end of treatment (EoT), rate of secondary malignancies, and incidence and outcomes of pregnancies among pts and their partners.
Results: At a median follow-up of 60.9 months (95% confidence interval [CI] 55.2–56.7), estimated 5-year PFS per INV rates were 82.2% (95% CI 79.0–85.0) for A+AVD and 75.3% (95% CI 71.7–78.5) for ABVD. A+AVD demonstrated favorable PFS per INV vs ABVD (hazard ratio [HR] 0.681; 95% CI 0.534–0.867; p=0.002) (Table). Estimated 5-year PFS with A+AVD vs ABVD in the ITT population was 84.9% vs 78.9% in PET2-negative pts (HR 0.663; 95% CI 0.502–0.876; p=0.004) and 60.6% vs 45.9% in PET2-positive pts (HR 0.702; 95% CI 0.393–1.255; p=0.229). In the A+AVD and ABVD arms, 85% and 86% of pts with treatment-emergent PN had complete resolution or improvement of symptoms, respectively. Median time to complete resolution of ongoing PN events at EoT was 34 weeks (range 0–262) in the A+AVD arm and 16 weeks (range 0–267) in the ABVD arm; median time to improvement was 49 weeks (range 8–270) and 12 weeks (range 2–70), respectively. Maximum severity of ongoing PN was grade 1 (17%), grade 2 (9%), grade 3 (3%), and grade 4 (<1%) in the A+AVD arm (total=29%), and grade 1 (14%), 2 (6%) or 3 (1%) in the ABVD arm (total=21%). Secondary malignancies occurred in 19 and 29 pts in A+AVD and ABVD arms, respectively. In total, 131 pregnancies were reported; both arms showed similar proportions of ongoing pregnancies or live births in female pts (87% and 75% in the A+AVD and ABVD arms, respectively).

Table: PFS per INV at 60.9 months by PET2 status and age in the ITT population

Group, % (95% CI)	A+AVD	ABVD	HR (95% CI) p-value
All pts	n=664	n=670	0.681 (0.543–0.867)
	82.2 (79.0–85.0)	75.3 (71.7–78.5)	0.002
PET2-negative	n=588	n=578	0.663 (0.502–0.876)
	84.9 (81.7–87.6)	78.9 (75.2–82.1)	0.004
PET2-positive	n=47	n=58	0.702 (0.393–1.255)
	60.6 (45.0–73.1)	45.9 (32.7–58.2)	0.229
Pts aged <60 years	n=580	n=568	0.665 (0.505–0.876)
	84.3 (81.0–87.1)	77.8 (74.0–81.1)	0.003
PET2-negative	n=521	n=493	0.675 (0.492–0.927)
	86.6 (83.3–89.3)	81.5 (77.7–84.7)	0.014
PET2-positive	n=42	n=50	0.702 (0.370–1.331)
	63.1 (46.4–75.9)	49.3 (34.7–62.3)	0.274
Pts aged ≥60 years	n=84	n=102	0.820 (0.494–1.362)
	67.1 (55.1–76.5)	61.6 (50.9–70.7)	0.443
PET2-negative	n=67	n=85	0.720 (0.401–1.292)
	71.9 (59.0–81.3)	64.9 (53.5–74.2)	0.268
PET2-positive	n=5	n=8	0.923 (0.229–3.715)
	40.0 (5.2–75.3)	25.0 (3.7–55.8)	0.910

Summary/Conclusion: After 60.9 months' median follow-up, robust and durable treatment benefits improvements that were independent of disease stage, risk factor score, and PET2 status were seen with A+AVD vs ABVD. Treatment adaptation by interim PET2 status was not required for A+AVD and bleomycin exposure was avoided. Treatment with A+AVD provides sustained PFS benefits and a manageable safety profile with symptoms of PN improving or resolving over time and similar pregnancy rates in both treatment arms, suggesting that A+AVD is an attractive treatment option for all pts with previously untreated Stage III or IV cHL.



S206 CAMRELIZUMAB FOR RELAPSED OR REFRACTORY CLASSICAL HODGKIN LYMPHOMA: THREE-YEAR OUTCOME OF A MULTICENTER, PHASE 2 STUDY

J. Wu [1,*], Y. Song [2], X. Chen [3], T. Lin [4], J. Cao [5], Y. Liu [6], Y. Zhao [7], J. Jin [8], H. Huang [9], J. Hu [10], J. Luo [11], L. Zhang [12], H. Xue [13], Q. Zhang [14], W. Wang [15], C. Chen [15], J. Feng [1], J. Zhu [2]

Ltd, Shanghai, China

Background: Camrelizumab (a humanized high-affinity IgG4 mAb against PD-1) showed potent antitumor activity, well tolerance, and controllable safety in Chinese patients with relapsed or refractory classical Hodgkin lymphoma (r/r cHL), based on the primary analysis results of a multicenter, phase 2 study (ClinicalTrials.gov, NCT03155425). The long-term efficacy and safety of camrelizumab are warranted to be assessed.
Aims: To report the extended follow-up data regarding the durability of response, survival benefit, and long-term medication safety of camrelizumab in r/r cHL patients.
Methods: Between Jun 9, 2017 and Sep 18, 2017, 75 patients who had failed to achieve a remission or experienced progression after autologous stem cell transplantation or had received at least two lines of systemic chemotherapies were enrolled in this study. Camrelizumab at a dose of 200 mg were administrated every two weeks. The primary endpoint was objective response rate per independent review committee (IRC).
Results: As of Aug 31, 2020, the median follow-up duration was 36.2 months (range, 7.2–38.1). Per IRC assessment, objective responses were achieved in 57 patients (76.0%; 95% CI, 64.7–85.1), similar to result of the primary analysis. The Kaplan-Meier estimated median duration of response was 31.7 months (95% CI, 16.7–not reached; Figure A). At data cutoff, 50.7% of patients (38/75) had disease progression or died. The median progression-free survival was 22.5 months (95% CI, 14.7–not reached; Figure B). Thirteen (17.3%) deaths occurred, and the median overall survival was not reached (Figure C). The 36-month OS rate was 82.7% (95% CI, 72.0–89.5). The most common treatment-related adverse events (TRAEs) included reactive capillary endothelial proliferation (RCEP; 73/75, 97.3%), pyrexia (33/75, 44.0%), upper respiratory tract infection (27/75, 36.0%), and hypothyroidism (24/75, 32.0%). Despite a high incidence, all RCEP were grade 1 (59/73, 80.8%) or grade 2 (14/73, 19.2%) in severity. In general, RCEP occurred early during treatment; the median time to onset was 0.9 months (range, 0.1–2.5). Re-occurrence of RCEP was very rare (8 out of 42 patients who were still on camrelizumab therapy after 12 months, 19.0%; 2 out of 32 patients who were still on camrelizumab therapy after 24 months, 6.3%). Complete resolution of all RCEP lesions was observed in 49 of the 73 patients (67.1%), and the median time to regression was 8.2 months (range, 1.7–30.8). Grade 3 or 4 TRAEs were reported in 26 (34.7%) patients. No treatment-related deaths occurred. TRAEs led to treatment discontinuation only in 5 (6.7%) patients. No new safety signals were identified.

Summary/Conclusion: With extended follow-up, camrelizumab monotherapy continues to provide a robust and durable response, long progression-free and overall survival, as well as manageable safety in patients with r/r cHL.

S207 TISLELIZUMAB (BGB-A317) FOR RELAPSED/REFRACTORY CLASSICAL HODGKIN LYMPHOMA: LONG-TERM FOLLOW-UP EFFICACY AND SAFETY RESULTS FROM A PHASE 2 STUDY

Y. Song [1,*], Q. Gao [2], H. Zhang [3], L. Fan [4], J. Zhou [5], D. Zou [6], W. Li [7], H. Yang [8], T. Liu [9], Q. Wang [10], F. Lv [11], H. Guo [12], X. Zhao [12], J. Huang [12], W. Novotny [12], Y. Wang [12], J. Zhu [1]

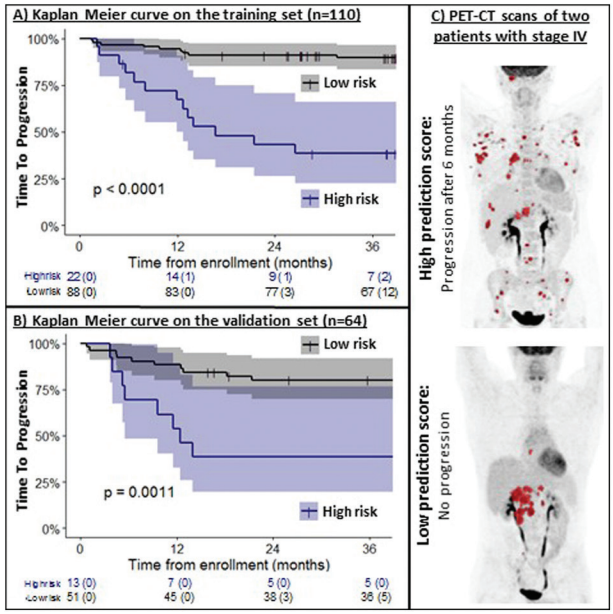
Background: Tislelizumab is a humanized IgG4 monoclonal antibody with high affinity/specificity for programmed cell death protein 1 (PD-1). It was engineered to minimize binding to Fc-γ receptors on macrophages, thereby decreasing antibody-dependent phagocytosis, a potential mechanism of T-cell clearance and resistance to anti–PD-1 therapy. Tislelizumab therapy was highly active in autologous stem cell transplantation (ASCT)-failed or ineligible patients with relapsed/refractory classical Hodgkin lymphoma (R/R cHL; *Leukemia*. 2020;34:533). Here, we report results from up to 3 years of follow-up.
Aims: To evaluate efficacy and safety of tislelizumab monotherapy in patients with R/R cHL in a single-arm, multicenter phase 2 study (ClinicalTrials.gov: NCT03209973).
Methods: Patients were eligible for the study if they failed to achieve a response or progressed after ASCT or received ≥2 lines of prior systemic chemotherapy for cHL and were ineligible for ASCT. Patients with R/R cHL enrolled in this study received 200 mg tislelizumab administered intravenously every 3 weeks until progressive disease or unacceptable toxicity. The primary endpoint was overall response rate (ORR) assessed by an independent review committee per Lugano criteria (*J Clin Oncol*. 2014;32:3059). Secondary endpoints were progression-free survival, duration of response, complete response (CR) rate, and time to response per independent review committee, safety, and tolerability.
Results: A total of 70 patients from 11 centers in China were enrolled and treated; patient characteristics have been previously reported. As of the data cutoff date (Nov 2, 2020), median follow-up was 33.8 months (range, 3.4-38.6). Patients still on treatment at the end of study (n=33; 47.1%) entered a long-term extension study. Efficacy data are presented in the Table. The ORR as assessed by IRC was 87.1%, and 67.1% of patients achieved CR. Among the 13 patients who received prior ASCT, 11 (84.6%) achieved CR. The most common treatment-emergent adverse events (AEs; ≥30%) were pyrexia (57.1%), upper respiratory tract infection (38.6%), hypothyroidism (37.1%), and increased weight (34.3%). Treatment-related grade ≥3 AEs (≥2 patients) were pneumonitis, hypertension, neutropenia, lipase increased, weight increased, and increased creatine phosphokinase (2.9% each). Immune-related AEs were reported in 32 patients (45.7%), with grade ≥3 AEs in 8 patients (11.4%): pneumonitis (n=4) and skin adverse reactions, nephritis, lipase increased, and blood creatine phosphokinase increased (n=1 each). AEs led to treatment discontinuation in 6 patients (8.6%).

Table

	N=70	95% CI
ORR, n (%)	61 (87.1)	77.0-93.9*
CR, n (%)	47 (67.1)	54.9-77.9*
mDOR†, mo	31.3	20.73-NE
mPFS†, mo	31.5	16.53-NE
mOS†, mo	Not reached	NE-NE
24-mo event free rate, %	93.9	84.5-97.7

CR, complete response; DOR, duration of response; m, median; NE, not estimable; ORR, overall response rate; OS, overall survival; PFS, progression-free survival.
*Two-sided Clopper-Pearson 95% CI. †Based on Kaplan-Meier estimation.



Summary/Conclusion: Long-term follow-up data from patients with R/R cHL treated with tislelizumab further demonstrated the substantial therapeutic activity and continued progression-free survival benefit. There were no new safety concerns identified for long-term treatment with tislelizumab.

S208 PREDICTIVE VALUE OF QUANTITATIVE 18F-FDG-PET RADIOMICS ANALYSIS IN 174 PATIENTS WITH RELAPSED/ REFRACTORY HODGKIN LYMPHOMA

J. Driessen [1,*], G. J. Zwezerijnen [2], H. Schöder [3], A. J. Moskowitz [4], M. J. Kersten [1], C. H. Moskowitz [5], J. J. Eertink [6], T. van de Brug [7], H. C. de Vet [7], O. S. Hoekstra [2], J. M. Zijlstra [6], R. Boellaard [2]

[1]Department of Hematology, Amsterdam UMC, University of Amsterdam, LYMMCARE, Cancer Center Amsterdam, [2]Department of Radiology and Nuclear Medicine, Amsterdam UMC, Vrije Universiteit Amsterdam, Cancer Center Amsterdam, Amsterdam, Netherlands, [3]Department of Radiology, [4]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, [5]Department of Medicine, Sylvester Comprehensive Cancer Center, Miami, Florida, United States, [6]Department of Hematology, Amsterdam UMC, Vrije Universiteit Amsterdam, Cancer Center Amsterdam, [7]Department of Epidemiology and Data Science, Amsterdam Public Health research institute, Amsterdam, Netherlands

Background: About 20% of patients with classical Hodgkin lymphoma (cHL) relapse or are primary refractory to first-line treatment and require second-line therapy followed by autologous stem cell transplant. There is no one standard second-line therapy and it is possible that not all patients require such an aggressive approach to achieve cure. An individualized risk-stratified salvage treatment approach could lead to better disease control in high-risk patients and less toxicity in low-risk patients. Quantitative analysis of baseline ^{18}F-FDG-PET-CT scans could provide a comprehensible risk-assessment complementary to clinical risk-factors.
Aims: The aim of this study was to predict the 3-year time to progression (TTP) in relapsed/refractory (r/r) cHL patients using clinical and PET-CT parameters.
Methods: We analysed baseline ^{18}F-FDG-PET-CT scans from r/r cHL patients treated within three clinical trials with ICE, ICE and brentuximab vedotin (BV) or DHAP and BV. For the clinical risk model we used the following parameters: primary refractory *vs* relapse, age, Ann Arbor stage and B-symptoms. Metabolic tumor volume (MTV) was calculated using semi-automatic segmentation method with a fixed threshold of standard uptake value (SUV) ≥4.0. Radiomics features were extracted in compliance with the Image Biomarker Standardization Initiative. We developed a predictive model using logistic regression and backward selection on robust radiomics features, e.g. SUVpeak (highest 1mL region FDG uptake) and several novel dispersity features, representing dissemination and differences in volume and SUV of lesions within a patient. Patients who died without progression were censored at time of death. The model was trained on patients treated with BV + chemotherapy. Model performance was assessed by calculating the area under the curve (AUC) of the receiver operating characteristics curve and cross-validation (CV) of 5 folds with 2000 repeats. Results were validated in an independent cohort of patients treated with chemotherapy only. High-risk groups were defined based on the prevalence of events in the training cohort (22/110; 20%).
Results: We included 174 r/r cHL patients; n=110 in the training set (BV-DHAP and BV-ICE cohort) and n=64 in the validation set (ICE cohort). The clinical model resulted in an AUC of 0.81 on the training set (tAUC), CV-AUC of 0.76 and AUC of 0.74 on the validation set (vAUC). Radiomics analysis resulted in a selection of 6 PET features: MTV and 5 dispersity features. The radiomics model showed a tAUC of 0.73, CV-AUC of 0.63 and vAUC of 0.70. Combining clinical and radiomics parameters yielded a tAUC of 0.90, CV-AUC of 0.79 and vAUC of 0.77. In the training set, patients in the high-risk group (n=22) had a 3-year TTP of 38% *vs* 90% for patients in the low-risk group (n=88)(p<0.0001) (**Figure 1A**). In the validation set, patients in the high-risk group (n=13) had a 3-year TTP of 39% *vs* 80% for patients in the low risk group (n=51)(p=0.0011)(**Figure 1B**). In **Figure 1C** we included an example of PET-CT scans of two patients with stage IV disease and a high and low prediction score.

Summary/Conclusion: This is the first radiomics analysis in a large cohort of r/r cHL patients. Combining radiomics and clinical features results in a strong prediction model for 3-year TTP with a tAUC of 0.90, CV-AUC of 0.79 and a vAUC of 0.77 in an independent validation cohort. The model uses robust PET features that adress inter-lesional heterogeneity in distance, metabolic volume and SUV. Therefore, this model is suitable for application in clinical trials and could guide risk-stratified treatment in r/r cHL.

S209 BRENTUXIMAB VEDOTIN-CONTAINING ESCALATED BEACOPP VARIANTS FOR NEWLY DIAGNOSED ADVANCED CLASSICAL HODGKIN LYMPHOMA: FOLLOW-UP ANALYSIS OF A RANDOMIZED PHASE II STUDY FROM THE GERMAN HODGKIN STUDY GROUP

C. Damaschin [1,*], H. Goergen [1], S. Kreissl [1], A. Pluetschow [1], M. Fuchs [1], A. Engert [1], P. Borchmann [1], D. A. Eichenauer [1]

[1]First Department of Internal Medicine, University Hospital Cologne, Cologne, Germany

Background: Patients with newly diagnosed advanced classical Hodgkin lymphoma (cHL) receiving intensive treatment with escalated BEACOPP (bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, prednisone) (eBEACOPP) have excellent outcomes. However, especially late sequelae represent an ongoing concern in connection with the eBEACOPP protocol. Recent eBEACOPP-based approaches therefore aim at reducing treatment toxicity without compromising efficacy. The BrECADD (brentuximab vedotin, etoposide, doxorubicin, cyclophosphamide, dacarbazine, dexamethasone) and BrECAPP (brentuximab vedotin, etoposide, doxorubicin, cyclophosphamide, procarbazine, prednisone) protocols combining an eBEACOPP backbone with the CD30-directed antibody-drug conjugate brentuximab vedotin (BV) were evaluated in a randomized phase II study conducted by the German Hodgkin Study Group (GHSG). Results at a median observation time of 17 months were published previously. High response rates and reduced acute toxicity in comparison with standard eBEACOPP have been reported.
Aims: To investigate efficacy and safety of the BrECADD and BrECAPP protocols after extended follow-up.
Methods: Between October 2012 and May 2014, a total 104 patients (aged 18 to 60) who had the initial diagnosis of advanced cHL were included in the study. Study participants were randomly assigned to receive either BrECADD or BrECAPP. PFS and OS were estimated using the Kaplan-Meier method.
Results: After a median observation time of 34 months (IQR: 28.7-39.5), the 3-year PFS estimates for patients treated with BrECADD and BrECAPP were 89.7% (95%>CI: 81.0%>98.3%) and 90.2% (95%>CI:

80.9%>99.5%), respectively. Overall, 8 patients had primary disease progression or cHL recurrence (BrECADD: 4 patients; BrECAPP: 4 patients). The median time between the end of first-line treatment and disease progression or relapse was 13 months. Second-line treatment consisted of high-dose chemotherapy and autologous stem cell transplantation in all cases. There were 2 deaths of whom 1 was cHL-related. No second primary malignancies occurred. The 3-year OS estimates were 95.4% (95%>CI: 89.2%>100%) for patients who had received BrECADD and 100% for patients who had been treated with BrECAPP.
Summary/Conclusion: The present follow-up analysis of a randomized phase II study evaluating the BrECADD and BrECAPP protocols in newly diagnosed advanced cHL confirmed the high efficacy of these regimens. There were no new safety signals. The BrECADD protocol currently challenges standard eBEACOPP in the randomized GHSG phase III HD21 study.

Indolent & mantle cell lymphoma - Clinical

S210 EFFICACY AND SAFETY OF TISAGENLECLEUCEL IN ADULT PATIENTS WITH RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA: PRIMARY ANALYSIS OF THE PHASE 2 ELARA TRIAL

S. J. Schuster [1], M. Dickinson [2], M. Dreyling [3,*], J. Martinez-Lopez [4], A. Kolstad [5], J. Butler [6], M. Ghosh [7], L. Popplewell [8], J. C. Chavez [9], E. Bachy [10], K. Kato [11], H. Harigae [12], M. J. Kersten [13], C. Andreadis [14], P. A. Riedell [15], A. Abdelhady [16], A. Zia [17], M. C. Morisse [16], N. H. Fowler [18,19], C. Thieblemont [20]

Background: Most patients with relapsed/refractory follicular lymphoma (r/r FL) experience multiple relapses and progressively worse clinical outcomes with each line of therapy, underlining a need for novel therapies. Tisagenlecleucel has demonstrated durable responses and manageable safety in adult patients with r/r diffuse large B-cell lymphoma.
Aims: To report the primary analysis of ELARA (NCT03568461), an international, single-arm phase 2 trial of tisagenlecleucel in adult patients with r/r FL.
Methods: Eligible patients (≥18 years) had r/r FL (grades 1-3A) after ≥2 lines of therapy or had failed autologous stem cell transplant. Bridging therapy was permitted followed by disease assessment prior to tisagenlecleucel infusion. Patients received tisagenlecleucel (0.6-6×108 CAR+ viable T cells) after lymphodepleting chemotherapy. The primary endpoint was complete response rate (CRR) by central review per Lugano 2014 criteria. Secondary endpoints included overall response rate (ORR), duration of response (DOR), progression-free survival (PFS), overall survival, safety, and cellular kinetics. Predefined primary analysis occurred when ≥90 treated patients had ≥6 months of follow-up.
Results: As of September 28, 2020, 98 patients were enrolled and 97 received tisagenlecleucel (median follow-up, 10.6 months). At study entry, median age among treated patients was 57 years (range, 29-73), 85% had stage III-IV disease, 60% had a FLIPI score ≥3, 65% had bulky disease, and 42% had LDH greater than the upper limit of normal. The median number of prior therapies was 4 (range, 2-13); 78% of patients were refractory to their last treatment (76% to any ≥2 prior regimens) and 60% progressed within 2 years of initial anti-CD20-containing treatment. Of 94 patients evaluable for efficacy, the CRR was 66% (95% CI, 56-75) and the ORR was 86% (95% CI, 78-92). CRRs/ORRs were comparable among key high-risk subgroups. Estimated DOR (CR) and PFS rates at 6 month were 94% (95% CI, 82-98) and 76% (95% CI, 65-84), respectively. Of 97 patients evaluable for safety, 65% experienced grade ≥3 adverse events within 8 weeks post-infusion, most commonly neutropenia (28%) and anemia (13%). Any-grade cytokine release syndrome (per Lee scale) occurred in 49% of patients (grade ≥3, 0%). Any-grade neurological events (per CTCAE v4.03) occurred in 9% of patients (grade 3, 0%; grade 4, 1 patient and recovered). Three patients died from progressive disease.
Cellular kinetic parameters for tisagenlecleucel were estimated using transgene levels (by qPCR) in peripheral blood. Median maximal expansion (C_{max}) and exposure during the first 28 days following infusion ($AUC_{0\text{-}28d}$) were similar between responders (CR or partial response) and non-responders (stable or progressive disease). Maximum transgene levels were reached by a median of 10 days in responders and 12.9 days in non-responders; transgene persistence was detected up to 370 days and 187 days, respectively.
Summary/Conclusion: These data demonstrate the efficacy and acceptable safety of tisagenlecleucel in patients with r/r FL, including high-risk patients after multiple lines of prior therapy, and suggest that tisagenlecleucel may be a promising therapy for patients with r/r FL.

S211 CHRONOS-3: RANDOMIZED PHASE III STUDY OF COPANLISIB PLUS RITUXIMAB VS RITUXIMAB/PLACEBO IN RELAPSED INDOLENT NON-HODGKIN LYMPHOMA

Background: Rituximab (R)-based therapies are standard for patients (pts) with relapsed advanced indolent non-Hodgkin lymphoma (iNHL). Copanlisib (C) is a PI3K inhibitor approved as monotherapy for relapsed follicular lymphoma (FL) in pts who have had ≥2 prior systemic therapies.
Aims: We report primary data from the Phase III CHRONOS-3 study of treatment with C+R *vs* placebo (P)+R in relapsed iNHL (NCT02367040).
Methods: Pts with relapsed iNHL who were progression-free and treatment-free for ≥12 months (mo) after last R-based therapy or unwilling/unfit to receive chemotherapy were randomized 2:1 to receive C+R or P+R. C 60 mg/P was given i.v. on days 1, 8, and 15 (28-day cycle); R 375 mg/m^2 was given i.v. on days 1, 8, 15, and 22 during cycle 1 and on day 1 of cycles 3, 5, 7, and 9. Primary endpoint: centrally assessed progression-free survival (PFS). Secondary endpoints: objective response rate (ORR), duration of response, complete response rate (CRR), overall

survival (OS), and treatment-emergent adverse events (TEAEs). The data cut-off date was August 31, 2020. All pts provided informed consent.
Results: 307 pts were randomized to C+R and 151 to P+R. FL was the most common lymphoma histology subtype (60.0%), followed by marginal zone (MZL, 20.7%), small lymphocytic (SLL, 10.9%), and lymphoplasmacytic/Waldenström macroglobulinemia (LPL/WM, 8.3%). Median age was 63 years (range 28-91). With a median follow-up of 19.2 mo, the primary study endpoint was met: C+R significantly reduced the risk of disease progression/death *vs* P+R (hazard ratio [HR] 0.52 [95% CI 0.39, 0.69]; 1-sided p=0.000002); median PFS was 21.5 mo (95% CI 17.8, 33.0) *vs* 13.8 mo (95% CI 10.2, 17.5), respectively. Reductions in risk of progression/death were seen across all histology subtypes (HR [95% CI]): FL 0.580 [0.404, 0.833]; MZL 0.475 [0.245, 0.923]; SLL 0.243 [0.111, 0.530]; LPL/WM 0.443 [0.160, 1.231]. ORRs were 80.8% (CRR 33.9%) for C+R and 47.7% (CRR 14.6%) for P+R. Higher ORRs and CRRs were seen across all iNHL subtypes with C+R treatment. Median OS was not estimable. Most common TEAEs (all grades [G]/G3+) in pts receiving C+R were hyperglycemia (69.4%/56.4%), hypertension (49.2%/39.7% [all G3]), and diarrhea (33.6%/4.9% [all G3]). For pts receiving P+R, hyperglycemia (23.3%/8.2% [all G3]), hypertension (19.2%/8.9% [all G3]), neutropenia (16.4%/12.3%), and upper respiratory tract infection (16.4%/0%) were the most common TEAEs. Serious adverse events were higher with C+R (47.2%) *vs* P+R (18.5%). G5 TEAEs occurred in 6 pts (2.0%) receiving C+R (1 [0.3%] deemed treatment-related; pneumonitis) and 1 (0.7%) receiving P+R.
Summary/Conclusion: C+R demonstrated broad and superior efficacy *vs* P+R in pts with relapsed iNHL. The safety profile of C+R was manageable and consistent with C and R as monotherapy. Copanlisib is the first PI3K inhibitor to be safely combined with R in relapsed iNHL, representing a potential new therapy option for relapsed iNHL across all subtypes.

S212 ATEZOLIZUMAB + OBINUTUZUMAB + VENETOCLAX IN PATIENTS WITH RELAPSED OR REFRACTORY INDOLENT NON-HODGKIN'S LYMPHOMA (R/R INHL): PRIMARY ANALYSIS OF A PHASE 2 TRIAL FROM LYSA.

C. Herbaux [1,*], E. Bachy [2], J. M. Schiano de Colella [3], S. Guidez [4], E. Gyan [5], R. Gressin [6], N. Morineau [7], L. Ysebaert [8], E. Nicolas Virelizier [9], S. Le Gouill [10], K. Background: Relapsed and refractory (R/R) iNHL treatment remains challenging. Atezolizumab (ATE) and obinutuzumab (OBI) are monoclonal antibodies acting respectively to inhibit T-lymphocyte exhaustion or by inducing lymphoma cells cytotoxicity, whereas venetoclax (VEN) is a small molecule inhibiting BCL-2. Combining tumor-targeted therapies with agents that enhance anti-tumor immunity represents an attractive treatment paradigm. This LYSA sponsored multicenter phase 2 trial (NCT03276468) evaluated ATE, OBI and VEN combination in R/R B-cell lymphomas. Herein, we present primary efficacy and safety data from the iNHL cohort including Follicular Lymphoma (FL) and Marginal Zone Lymphomas (MZL).
Aims: Evaluate the safety and efficacy of atezolizumab, obinutuzumab and venetoclax combination in R/R FL and MZL.
Methods: Patients ≥18 years with biopsy-confirmed R/R FL and MZL who failed at least one line of therapy were eligible. OBI was given IV at 1 g on day (D) 1, 8 and 15 of cycle (C) 1 and on D1 from C2 to C8 every 3 weeks. ATE was given IV, 1.2 g every 3 weeks, started at D2 of C1, then administered at D2 of each cycle for 24 cycles. VEN was given orally at 800 mg/D at full dose, starting on D8C1 for 24 cycles. The primary endpoint was the Overall Response Rate (ORR) evaluated by Lugano criteria at the end of induction (EOI) after 8 cycles of ATE, OBI and VEN (M6) or at premature treatment discontinuation.
Results: At the time of the primary analysis (08 Jan 2021), 78 patients were enrolled. *FL cohort* (n=58): the median follow-up was 14.5 months. Main baseline characteristics were: Ann Arbor Stage III/IV, 85.7%; FLIPI HR, 47.3%; > 2 prior lines of therapy, 32.1%; and exposed to ASCT, 30.4%. The ORR on PET scan at EOI was measured at 53.6% [41.8%>65.1%], including 30.4% of CMR. 37 patients (63%) received the full induction treatment. *MZL cohort* (n=20; 13 nMZL, 5 eMZL, 2 sMZL): the median follow-up was 11.9 months. Main baseline characteristics were: Ann Arbor Stage IV, 100%; bone marrow infiltration, 38.9%; ≥ 2 extra-nodal sites, 50%; and > 2 prior lines of therapy, 22.2%. The ORR on CT scan at EOI was measured at 66.76% [44.6%>84.4%], including 16.7% of CR and 50.0% PR. 11 patients (55%) received the full induction treatment. At time of the present analysis, responses in the 2 cohorts seem durable with only 21,4% of responders who have reported relapse/progression. Out of the 78 pts, a total of 55 (70.5%) pts experienced grade 3–4 adverse event (AE) and 1 patient experienced an AE that led to discontinuation of any drug. Main AE of grade 3 or more were hematologic cytopenias, with only one febrile neutropenia (1.3%). Three pts experienced immune-related AE (1 grade 2 myositis and 2 grade 3 colitis), no tumor lysis syndrome was observed.
Summary/Conclusion: ATE, OBI and VEN triplet appears to be well tolerated, with no unexpected toxicity brought by the combination. The ORR at EOI seems to be comparable to other innovative regiments in this setting, with durable responses to date.

S213 OUTCOMES IN ZUMA-5 WITH AXICABTAGENE CILOLEUCEL IN PATIENTS WITH RELAPSED/REFRACTORY INDOLENT NON-HODGKIN LYMPHOMA WHO HAD THE HIGH-RISK FEATURE OF EARLY PROGRESSION AFTER FIRST CHEMOIMMUNOTHERAPY

Background: Progression within 24 months from initiation of the first anti-CD20–containing chemoimmunotherapy (POD24) is an indicator of poor survival in indolent non-Hodgkin lymphoma (iNHL; Casulo & Barr. *Blood*. 2019). In the ZUMA-5 Phase 2 study of axicabtagene ciloleucel (axi-cel) anti-CD19 chimeric antigen receptor (CAR) T-cell therapy in patients with relapsed/refractory (R/R) iNHL, overall response rates (ORR) after a median of 17.5 months of follow-up were similarly high in those with and without POD24 (93% and 92%; Jacobson et al. ASH 2020. #700).
Aims: To report updated outcomes with longer follow-up of axi-cel in patients in ZUMA-5 with R/R iNHL who had POD24.
Methods: Adults with R/R follicular lymphoma (FL) or marginal zone lymphoma (MZL) after ≥2 lines of therapy underwent leukapheresis followed by conditioning therapy and axi-cel infusion (2×10^6 CAR T cells/kg). Axi-cel–treated patients with available data on progression after an anti-CD20 monoclonal antibody + alkylating agent were included. The updated efficacy analysis occurred when ≥80 treated patients with FL had at least 18 months of follow-up.
Results: Of 129 patients at baseline, 81 patients (63%; 68 FL, 13 MZL) had POD24, and 48 patients (37%; 40 FL, 8 MZL) did not have POD24. Median prior lines of therapy in patients with and without POD24 were 3 and 3.5, respectively. High-risk characteristics of patients with and without POD24 included stage III/IV disease, 83% and 94%; ≥3 FLIPI, 44% and 43%; high tumor bulk (per GELF criteria), 51% and 44%; and refractory disease, 77% and 63%, respectively.
With a 23.3-month median follow-up, the ORR among efficacy-evaluable patients with POD24 (n=61) and without POD24 (n=37) was 92% each

(complete response rates, 75% and 86%). At data cutoff, 52% of patients with POD24 and 70% without POD24 had ongoing responses. Median duration of response, progression-free survival, and overall survival were not reached in patients with and without POD24; 18-month estimated rates were 60% and 78%, 55% and 84%, and 85% and 94%, respectively. Incidences of Grade ≥3 adverse events were similar in patients with and without POD24 (84% and 88%), including cytopenias (69% and 65%) and infections (15% and 21%). Grade ≥3 cytokine release syndrome (CRS) occurred in 9% and 2% of patients with and without POD24, respectively; Grade ≥3 neurologic events occurred in 17% of patients each. Median times to onset were similar in patients with and without POD24 for CRS (4 days each) and neurologic events (8 days and 7 days); median durations of CRS (7 days and 5 days) and neurologic events (11 days and 13 days) were also similar between groups.
In efficacy-evaluable patients with FL, median peak CAR T-cell levels were similar in patients with and without POD24 (35.8 cells/μL and 34.5 cells/μL). Peak levels of key inflammatory biomarkers and axi-cel product attributes were generally similar in patients with and without POD24.
Summary/Conclusion: Axi-cel showed a high rate of durable responses in patients with POD24 iNHL, a population with high-risk disease. Efficacy results, as well as safety and pharmacological profiles, appeared largely comparable between groups, with the exception of progression-free survival rates.

S214 TOLERABILITY AND EFFICACY OF THE COMBINATION OF PI3KΔ INHIBITOR ZANDELISIB (ME-401) AND BTK INHIBITOR ZANUBRUTINIB IN PATIENTS WITH RELAPSED OR REFRACTORY (R/R) B-CELL MALIGNANCIES: INITIAL RESULTS

Background: Despite significant improvement in the management of B cell malignancies with targeted therapies, new therapies are still needed in patients with relapsed disease. Dual inhibition of PI3Kδ and BTK pathways may overcome existing or acquired monotherapy resistance. Dual inhibition of these pathways displays synergistic activity in cell lines that is evident even at suboptimal concentrations [Blood 2015;125(14):2306-09]. Zandelisib is a potent, selective, and structurally differentiated oral PI3Kδ inhibitor (i), and zanubrutinib is an oral BTKi. Based on their efficacy as monotherapy, we hypothesized that the combination of zandelisib and zanubrutinib can be well tolerated and may improve the depth and durability of responses.
Aims: We evaluated this combination therapy in pts with R/R B-cell malignancies to determine the optimal dose and schedule for further evaluation in disease-specific expansion cohorts (NCT02914938).
Methods: This is a multi-cohort Phase 1b study enrolling patients (pts) with FL, CLL, MZL, MCL, DLBCL, or high-grade B-cell lymphoma (HGBCL), ≥1 prior therapy, adequate bone marrow and organ function, ECOG performance status ≤2, and no prior PI3Ki or BTKi therapy. For this combination therapy, two dose levels were evaluated in 28-day cycles: Cohort A: zandelisib 60 mg once daily for 2 cycles followed by an intermittent schedule (IS) on days 1-7 of subsequent 28-day cycles and zanubrutinib 160 mg twice daily (bid). Cohort B: zandelisib 60 mg on days 1-7 starting in Cycle 1 and zanubrutinib at 80 mg bid. Dose limiting toxicity (DLT) observation period was 28 days for cohort A and extended to 56 days for cohort B to include later occurring toxicities in the DLT definition. Response was assessed per iwCLL or Lugano criteria at month 3, 7, 13 and then every 6 months until progression.
Results: 20 pts who provided consent and met eligibility criteria were treated, 7 in cohort A and 13 in cohort B: 8 FL, 5 CLL, 2 DLBCL, 2 HGBCL, 2 MZL, and 1 MCL. Median age 70 years (range, 44-85) and median prior therapies 2 (1-8). Median follow-up of 2.9 months (0.5-17.4+). There were no DLT in cohort 10A, grade (Gr) ≥3 adverse events (AE) occurred after day 28 in 4 pts, including Gr 4 neutropenia (1 pt), Gr 3 neutropenia, fatigue and CMV colitis (1 pt), Gr 3 AST/ALT and rash (1 pt) and Gr 3 AST/ALT (1 pt). The emergence of Grade 3/4 AE's in 4/7 patients after the DLT window prompted exploration of a lower dose in cohort B. In cohort B, 2 pts had DLT with Gr 3 AST/ALT in Cycle 2, with 1 pt successfully resuming both drugs and 1 discontinued treatment due to recurrence of Gr 3 AST/ALT upon rechallenge. Other Gr 3 AE were all laboratory findings: 1 pt (CLL) had laboratory TLS, neutropenia and thrombocytopenia and 2 pts (FL, DLBCL) had neutropenia. 15% DLT(2/13) was observed in cohort B which is deemed safe to proceed with disease expansion cohort. Response rate was 100% (2 CR 14 PR) in the following 16 pts with indolent NHL and MCL evaluable for response: FL (2 CR, 6 PR), CLL (5 PR), MCL (1 PR) and MZL (2 PR). None of the 3 evaluable pts with aggressive B-cell lymphomas has responded.
Summary/Conclusion: The combination of zandelisib 60 mg on IS from Cycle 1 and zanubrutinib 80 mg bid is well tolerated and achieves a high ORR in R/R indolent B-cell malignancies. This schedule is being evaluated in expansion cohorts in R/R FL and MCL

Aggressive lymphoma - CAR-T & transplant

S215 HIGH INCIDENCE OF PROLONGED COVID-19 AMONG PATIENTS WITH LYMPHOMA TREATED WITH B-CELL DEPLETING IMMUNOTHERAPY

R. Duléry [1], S. Lamure [2], M. Delord [3], R. Di Blasi [1], A. Chauchet [4], T. Hueso [5], C. Rossi [6], B. Drenou [7], B. Deau-Fischer [1], S. Malak [8], P. Feugier [9], N. Noël [10], S. Choquet [1], S. Bologna [11], B. Joly [12], L. Philippe [13], C. Thieblemont [1], C. Besson [14,15,*]

[1]APHP, Paris, [2]CHU Montpellier, Montpellier, [3]CH Versailles, Le Chesnay, [4]CH Besançon, Besançon, [5]Gustave Roussy, Villejuif, [6]chu dijon, Dijon, [7]ch-mulhouse, Mulhouse, [8]Curie, Saint Cloud, [9]CHRU Nancy, Nancy, [10]APHP, Le Kremlin Bicetre, [11]Centre d'Oncologie de Gentilly, Nancy, [12]Centre Hospitalier Sud Francilien, Corbeil, [13]Centre Hospitalier d'Annecy, Annecy, [14]CH de Versailles, [15]UVSQ, Le Chesnay, France

Background: Treatment of B-lineage lymphoma with B-cell depleting immunotherapy causes B-cell aplasia and impairs immune response. Case studies have reported patients treated with anti-CD20 therapy who suffered from persistent Covid-19.
Aims: We aimed to assess the incidence, risk factors and long-term outcomes of persistent Covid-19 in patients with lymphoma.
Methods: This retrospective multicentric study was conducted in 16 French hospitals. All adult patients with lymphoma who were admitted for Covid-19 in March and April 2020 were included. Persistent Covid-19 was defined as persisting severe Covid-19 symptoms requiring in-hospital stay for >30 days. Patients who re-experienced severe Covid-19 symptoms after initial improvement, requiring repeated hospitalizations for a total in-hospital length of stay >30 days were added to the persistent Covid-19 cases.
Results: One hundred eleven patients were included. Thirty days after admission for Covid-19, 24 patients had died, 55 had been definitively discharged from hospital, 31 were still hospitalized and 1 was later rehospitalized for Covid-19 recurrence. The incidence of persistent Covid-19 was 32/111 (29%). Patients with persistent Covid-19 had a median age of 64 years (range, 43-87) and 63% were male. Twenty-two patients (69%) had at least one significant comorbidity. None of the patients with T-cell (n=8) lymphoma or classical Hodgkin's disease (n=8) experienced persistent Covid-19. In the 32 patients with persistent Covid-19, the median time between first admission and final discharge was 58 days (range, 31-235) and the median duration of Covid-19 symptoms was 83 days (range, 32-237). Eight patients received corticosteroids and 9 convalescent plasma: all patients recovered from their symptoms, except one. Overall, 9 patients with persistent Covid-19 died (27%).
After a median follow-up of 191 days (range, 3-260), the 6-month overall survival was 69% (95% CI 60-78%) for the whole cohort. In multivariate analysis, administration of anti-CD20 monoclonal antibody within 12 months before admission to hospital for Covid-19 was both associated with decreased overall survival (HR 2.13, 95% CI 1.03-4.44, p = 0.043) and prolonged in-hospital stay (HR 1.97, 95% CI 1.24-3.13, p = 0.004). The two other significant factors associated with decreased overall survival and prolonged in-hospital stay: age ≥ 70 years and refractory or relapsed lymphoma.
Summary/Conclusion: Patients with B-cell non-Hodgkin lymphoma hospitalized for Covid-19 have a high incidence of prolonged evolution of SARS-CoV-2 infection. Administration of anti-CD20 therapy within the last 12 months is one of the main risk factors for longer in-hospital stay and death of Covid-19.

The risk of persistent Covid-19 was also higher in patients older than 70 years or with refractory or relapsed disease. These findings may contribute to guide the management of lymphoma patients during the Covid-19 pandemic.

S216 FIRST RESULTS OF DLBCL PATIENTS TREATED WITH CAR-T CELLS AND ENROLLED IN DESCAR-T REGISTRY, A FRENCH REAL-LIFE DATABASE FOR CAR-T CELLS IN HEMATOLOGIC MALIGNANCIES.

[1]CHU Nantes, Nantes, [2]HCL, lyon, [3]APHP-Hopital Saint-Louis, Paris, [4]CHU Montpellier, Montpellier, [5]CHU Lille, Lille, [6]APHP- Créteil, Créteil, [7]Hematology and cell therapy department, Bordeaux, [8]APHP- La pitié, Paris, [9]IUCT oncopole, Toulouse, [10]CHU Nancy, Nancy, [11]CHU Dijon, Dijon, [12]Service de thérapie cellulaire et d'hématologie clinique adulte, CHU Clermont-Ferrand, site Estaing., Clermont-Ferrand, [13]AP-HP Saint Antoine, Paris, [14]CHU Amiens, Amiens, [15]LYSARC, Lyon, [16]CHU Rennes, Rennes, France

Background: DESCAR-T is the French national registry for patients treated with commercial CAR-T cells (DLBCL and ALL). DESCAR-T has been designed by LYSA/LYSARC and aims to collect real-life data. DESCAR-T was approved by the French authorities in 2019 and is the reference registry for CAR-T cells reimbursement by French health authorities. Data (patients' characteristics, safety, efficacy and long-term outcome…) from time of medical decision to treat with CAR-T cells to up to 15 years after CAR-T cells infusion are registered in DESCAR-T. Several complementary registries are also linked to DESCAR-T database, such as an immune-monitoring database, a blood and tumor biobanking (so-called CeVi-CART) and an imagery platform.
Aims: Herein, we present the first analyses regarding patients' characteristics and outcome of DLBCL patients registered in DESCAR-T.
Methods: All patients with DLBCL registered in DESCAR-T were eligible for the present study. All patients gave informent consent befor DESCAR-T registration.
Results: To date (Jan 2021), 14 out of 24 CAR-T cells accredited French centers have registered patients in DESCAR-T. Seven additional centers will be open for DESCAR-T in the coming months. The first patient was registered in December 2019. At the time of the present analysis, 537 DLBCL patients have been registered. CAR-T cells product has been ordered for 517 patients of whom 463 have been infused with CAR-T cells. At the time of registration in DESCAR-T, median age was 63.0 years (range, 53-70), 40.6% of patients were older than 65 years and 3.5% older than 75 years. Lymphoma subtypes were DLBCL (91%), PMBL (3%), and high-grade B-cell lymphoma (2%). Among patients for whom CAR-T cells have been ordered (n=517), 313 (60.5%) were male, 76 (14.7%) had a PS≥2, 377 (72.9%) had an advanced disease (stage III or IV), and 330 (63.8%) had elevated LDH. Median number of prior lines of treatment was 3 (range, 2 – 3) and 21% of patients have been previously transplanted. Median time from CAR-T cells order to infusion was 50 days [range, 43-60]. Median time from leukapheresis to CAR-T infusion was 41.1 days (range, 36-48). Overall, 65% of patients received Axi-cel and 35% received Tisa-acel. Response was available in 419 infused patients. Best ORR was 70.2% (65.5% - 74.5%). At D30 after CAR-T cell infusion, 157 (38%) patients achieved CR and 112 (27%) achieved PR. Among the 157 patients who achieved a CR at D30, 96 (61%) remained in CR at D90. The median follow-up calculated from CAR-T cells order was 7.4 months (range, 5.8-7.9) and 6m [range, 5.5-6.2] from CAR-T infusion. The median OS calculated from time of CAR-T infusion is 12.7m [range, 10.6-NA].
Summary/Conclusion: This first analysis from DESCAR-T registry seems to confirm CAR-T cells efficacy in real life. And be in line with previously published data. Updated results will be presented at the meeting. Overall, 537 patients with relapsed DLBCL have already been registered in DESCAR-T in 13 months and about 50 new patients are registered each month. This demontrates that CAR-T cells therapy has become a key treatment for R/R DLBCL. In 2021, DESCAR-T will be extended to mantle cell lymphoma and multiple myeloma and treated with CAR-T cells. DESCAR-T is a new CAR-T registry to investigate CAR-T cells products in real life across all hematological malignancies.

S217 GENETIC LANDSCAPES AND CURATIVE EFFECT OF CAR T CELLS IMMUNOTHERAPY IN RELAPSE AND REFRACTORY DLBCLS

H. Shi [1,*], P. Zheng [1], K. Hu [1], X. Ke [1]

[1]Beijing Boren Hospital, Beijing, China

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common non-Hodgkin lymphoma. Although potentially curable with targeted drug, monoclonal antibody, immunochemotherapy, refractory or relapsed lymphoma occurs in 40% of patients.
Aims: We investigated whether molecular subtypes can be robustly identified using methods potentially applicable in routine clinical practice, providing evidence that curative effect of CAR T cells immunotherapy differs in diverse subtype.
Methods: We have studied 105 relapse and refractory DLBCL (R&R DLBCL) patients using target region sequencing. clustering technique was applied to targeted region sequencing data derived from 105 R&R DLBCL patients cohort with full clinical follow-up(n=94).
Results: A total of 745 potential driver mutations were identified in 199 out of the 339 genes with a similar number in GCB and non-GCB. The most frequently mutated genes were TP53, KMT2D, PIM1, MYD88, CREBBP, CD79B and B2M found in more than 15% of cases. The frequency of TP53 in our R&R DLBCL cohort were higher than initial patients as reported. MYD88 CD79B, TNFAIP3, PRDM1 and SPEN were significantly more frequently mutated in more than 10% of non-GCB-DLBCL patients whereas KMT2D, CREBBP, DDX3X, B2M, TNFRSF14, BCL2, EZH2, CARD11, SOCS1, MYC and KRAS mutations were more common in more than 10% of GCB-DLBCL. PIM1, PCLO, TET2, STK11, TBL1XR1, NUDT15, CCND3 and TP53 in the gene were equally distributed in both DLBCL subtypes. Using clustering techniques applied to targeted region sequencing data derived from 105 R&R DLBCL patients cohort with full clinical follow-up (n=94), we investigated whether molecular subtypes can be robustly identified using methods potentially applicable in routine clinical practice. Six molecular subtypes were resolved, termed A53, MCD, BN2, KCB, N1, and JAK/STAT, along with an unclassified group. The subtypes of BN2 and N1 showed good prognosis, whereas MCD, KCB and JAK/STAT had intermediate outcomes. The subtypes characterized by genetic alterations of TP53 acquired the worst survival, as well demonstrated that TP53 mutations were independent predictors of survival in R&R DLBCL patients. The KCB subtype contained the majority of cases of transformed follicular lymphoma and strongly enriched for cases of double-hit GCB-type DLBCL, with inferior outcomes. Most patients (n=80, 76.2%) in our cohort received chimeric antigen receptor (CAR) T cells immunotherapy. These subtypes differed phenotypically, as judged by differences in gene-expression signatures and responses to immunochemotherapy, with favorable frequency of complete reponse (CR) in the BN2 and N1 subtypes, intermediate in MCD, KCB, and JAK/STAT subtypes, inferior outcomes in the A53 subtypes. We suggested that N1 subtype showed good prognosis due to their sensitive curative effect with CAR T cells immunotherapy.
Summary/Conclusion: Our findings confirm the existence of molecular subtypes of R&R DLBCL, providing evidence that curative effect of CAR T cells immunotherapy differs in diverse subtype. CAR T cells immunotherapy can prolong survival times of in some subtyes thought previously associated with worse outcomes. We provide a potential precision-medicine strategies for R&R DLBCL patients with poor prognosis.
Key words: relapse and refractory DLBCL, gene mutation, molecular subtypes, CAR T cells immunotherapy

S218 FIRST-IN-HUMAN STUDY OF THE EZH1 AND EZH2 DUAL INHIBITOR VALEMETOSTAT TOSYLATE (DS-3201B) IN PATIENTS WITH RELAPSED OR REFRACTORY NON-HODGKIN LYMPHOMAS

S. Kusumoto [1,*], K. Izutsu [2], D. Maruyama [2], S. Makita [2], E. D. Jacobsen [3], S. Horwitz [4], K. Ishitsuka [5], P. Allen [6], P. Porcu [7], Y. Imaizumi [8], N. Yamauchi [9], S. Background: Enhancer of zeste homolog 2 (EZH2) and its close homolog, EZH1, catalyze the attachment of 3 methyl groups to histone H3 at lysine 27 (H3K27me3). H3K27me3 is an epigenetic mark involved in downregulating gene expression associated with tumor suppression and cell differentiation. Altered *EZH2* expression has been implicated in the development and progression of non-Hodgkin lymphomas (NHLs), including peripheral T-cell lymphoma (PTCL), adult T-cell leukemia/lymphoma (ATL), and other cancers. Valemetostat tosylate (DS-3201b; also known as valemetostat) is a novel, potent, and selective dual inhibitor of EZH2 and EZH1 that has demonstrated antitumor activity against hematologic malignancies (Maruyama et al, *Blood*. 2017 [abstract 4070]). We report the interim results from the first-in-human trial of valemetostat in patients with relapsed or refractory (R/R) NHLs, focusing on preliminary efficacy results for R/R PTCL and R/R ATL.
Aims: This ongoing multicenter, phase 1, multiple ascending dose study (NCT02732275) evaluates the safety, pharmacokinetics, and pharmacodynamics of single-agent valemetostat for R/R NHLs. Primary objectives include assessing safety and determining the recommended phase 2 dose; secondary objectives include assessing preliminary efficacy.
Methods: Patients ≥18 (United States) or ≥20 years of age (Japan) with R/R NHL have been enrolled. Valemetostat (150-300 mg/day for the dose-escalation cohort; 200 mg/day for the dose-expansion cohort) is orally administered once daily in continuous 28-day cycles until disease progression or intolerance. The enrollment for the dose-expansion cohort is limited to patients with R/R PTCL or R/R ATL.
Results: At the time of data cutoff (November 2, 2020), 78 patients with R/R NHL were treated with 150-300 mg of valemetostat, including 62 patients who were treated with 200 mg. The median age was 68 (range, 37-88) years. With a median follow-up of 28.1 weeks (range, 3.1-190.9), 22 of 78 patients (28.2%) remained on treatment. Safety results from 78 patients with R/R NHL are reported; 76 patients (97.4%) experienced ≥1 treatment-emergent adverse event (TEAE). Grade ≥3 TEAEs occurred in 51 patients (65.4%), and serious TEAEs (SAEs) grade ≥3 occurred in 16 patients (20.5%); no deaths have been associated with valemetostat. Dose interruption or reduction due to TEAEs occurred in 32 (41%) and 7 (9%) patients, respectively. The most common AEs (≥30% of patients) were platelet count decreased (59.0%), dysgeusia (51.3%), anemia (37.2%), neutrophil count decreased (34.6%), alopecia (32.1%), and white blood cell count decreased (30.8%). Grade ≥3 platelet count decreased and thrombocytopenia occurred in 12 (15.4%) and 4 (5.1%) patients, respectively. Safety outcomes in R/R PTCL and R/R ATL subgroups were similar to those in the overall population. Preliminary efficacy data from 45 patients with R/R PTCL and 14 with R/R ATL are summarized in the Table. Valemetostat resulted in a ≥50% overall response rate (ORR), with potentially durable responses in R/R PTCL and R/R ATL. Efficacy was observed across PTCL subtypes.

Median DOR, weeks (95% CI)	56.0 (44.43-NE)	44.43 (5.86-NE)	56.0 (8.14-56.0)	NE	NE (8.14-NE)	NE (6.14-NE)
Median TTR, weeks (range)	8.14 (4.1-24.1)	8.14 (4.1-16.3)	7.93 (7.0-24.1)	16.14 (16.1-16.1)	7.64 (7.4-7.9)	8.14 (7.3-84.1)
Median PFS, weeks (95% CI)	52 (16.14-NE)	NA	NA	NA	NA	NE (8.14-NE)

[a] For PTCL, 43 patients were treated with valemetostat 200 mg, and 2 were treated with 150 mg. For ATL, 12 patients were treated with valemetostat 200 mg, and 2 were treated with 150 mg.
[b] Patients with ALCL include those with ALK-positive and ALK-negative ALCL.
[c] Consists of 7 patients with acute and 7 patients with lymphomatous subtypes.
AITL, angioimmunoblastic T-cell lymphoma; ALCL, anaplastic large cell lymphoma; ALK, anaplastic lymphoma kinase; ATL, adult T-cell leukemia/lymphoma; CR, complete response; DOR, duration of response; NA, not analyzed; NE, not estimable; PD, progressive disease; PFS, progression-free survival; PTCL, peripheral T-cell lymphoma; PTCL-NOS, PTCL not otherwise specified; SD, stable disease; TTR, time to first response.

Summary/Conclusion: These results demonstrate that valemetostat has an acceptable safety profile in patients with R/R NHLs and encouraging efficacy results in patients with R/R PTCL or R/R ATL and warrants further evaluation. Valemetostat is being evaluated in an ongoing phase 2 study in Japan in patients with R/R ATL (NCT04102150) and in a global phase 2 study in patients with R/R PTCL, including R/R ATL (NCT04703192).

S219 MATRIX FOLLOWED BY AUTOLOGOUS TRANSPLANT IS ASSOCIATED WITH EXCELLENT SURVIVAL AND NEUROTOLERABILITY IN PRIMARY CNS LYMPHOMA: RESULTS OF THE IELSG32 TRIAL AT A MEDIAN FOLLOW-UP OF 88 MONTHS

Background: The IELSG32 trial has shown the significantly better activity and acceptable safety profile of MATRIX regimen and a similar efficacy of consolidation with whole-brain irradiation (WBRT) or autologous transplantation (ASCT) in pts ≤70 yo with primary CNS lymphoma (PCNSL). However, events after a more extended follow-up remain to be addressed.
Aims: To establish the associations among different treatment arms of the IELSG32 trial and OS, late toxicity, incidence of secondary tumors, and cognitive impairment at a median follow-up of 88 (IQR 77-99) months.
Methods: HIV-neg pts 18-70 yo with ECOG PS ≤3 (PS ≤2 if 66-70 yo) with untreated PCNSL were randomly assigned to receive 4 courses of methotrexate-cytarabine (arm A), or arm A plus rituximab (arm B), or arm B plus thiotepa (arm C; MATRIX). Pts with responsive/stable disease were further randomized between WBRT (arm D) and BCNU-thiotepa/ASCT (arm E). Primary endpoints were CRR (1st random) and PFS (2nd random). Effects of treatment on cognitive functions and quality of life (QoL) were addressed comparing results of the IPCG tests panel

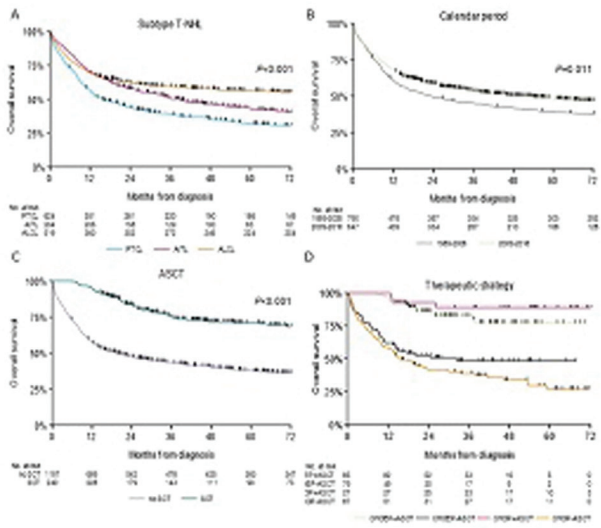
and EORTC-QLQ performed immediately after treatment and at the last follow-up visit.
Results: 219 assessable pts (median age 58; range 18-70) were randomized (arm A 75; B 69; C 75). After induction, 167 (76%) pts had responsive or stable disease; 118 (71%) of them were further randomized (arm D 59; E 59), whereas 49 pts were excluded (poor mobilizers, poor conditions, patients' refusal).
15 (7%) pts died of toxicity during treatment. 87 (40%) pts remain relapse-free (A 17; B 28; C 42); 14 of them died of infections (n=4), sudden death (4), cognitive decline (3), second tumor (2), and car accident (1). 117 (53%) pts experienced relapse: 96 died of lymphoma, 14 achieved tumor remission upon salvage therapy and remained relapse-free at 39-121 months, while 7 died of complications during salvage therapy. Second cancers were diagnosed in 8 (4%) pts after 48-96 months from WBRT (5) or ASCT (3); two of them were lethal, the other six remained relapse-free after surgical resection. Deaths in relapse-free pts, deaths occurred during salvage treatment and secondary tumors were not significantly related to induction or consolidation treatments (Table). Neuropsychological tests showed a statistically significant impairment in some attentive and executive functions in pts treated with WBRT, while a significant improvement was noted in these functions as well as in memory and QoL in transplanted pts.
Pts treated with MATRIX (arm C) showed a significantly better PFS, with a 7-yr PFS of 20±5% for arm A, 29±6% for arm B and 52±6% for arm C (A vs C p=0.00002; B vs C p=0.01). PFS was similar in both consolidation arms (7-yr: 55±7% and 50±7%; p=0.35). 87 pts are alive (arm A 18; B 27; C 42), with a 7-yr OS of 26±5%, 37±6% and 56±6%, respectively (A vs C p=0.00007; B vs C p=0.03). OS was similar in both consolidation arms (7-yr: 63±6% and 57±6%, p=0.17). Pts treated with MATRIX and consolidation had a 7-yr OS of 70±6%, without a difference between WBRT and ASCT. In multivariable analysis, IELSG score, number of lesions and induction arm were associated with OS; gender, CSF cytology and consolidation were not.

Table. Second tumors and late complications in pts who completed the planned treatment

	Arm A (42)	Arm B (50)	Arm C (63)	WBRT (70)*	ASCT (60)*
Second tumors (n=8)#	1 (2%)	2 (4%)	5 (8%)	5 (7%)	3 (5%)
Deaths in relapse-free patients (n= 14)	2 (5%)	6 (12%)	6 (9%)	9 (13%)	3 (5%)
Deaths during salvage treatment (n=7)	4 (9%)	0 (0%)	3 (5%)	2 (3%)	2 (3%)

*Actually delivered consolidation within and outside 2nd randomization.
#Acute erythroid leukemia, high-grade glioma, melanoma (2), Paget's disease of the breast, prostate cancer, colon cancer, basal cell carcinoma.

Summary/Conclusion: MATRIX regimen was associated with excellent long-lasting survival in PCNSL pts ≤70 ys. WBRT and ASCT exhibit similar efficacy. In comparison with the other therapeutic arms, MATRIX and ASCT were not associated with higher non-relapse mortality and incidence of second tumors, whereas impairment of specific cognitive functions after WBRT was confirmed.



Aggressive lymphoma - Combination therapies

S220 IMPACT OF ETOPOSIDE AND AUTOLOGOUS STEM-CELL TRANSPLANTATION ON SURVIVAL AMONG YOUNG PATIENTS WITH PERIPHERAL T-CELL LYMPHOMA IN THE NETHERLANDS; A NATIONWIDE, POPULATION-BASED COHORT STUDY

M. Brink [1,*], F. O. Meeuwes [2,3], M. W. van der Poel [4], M. J. Kersten [5], M. J. Wondergem [5], P. G. Mutsaers [6], L. H. Böhmer [7], F. S. H. Woei-A-Jin [8], O. Visser [9], R. Oostvogels [10], P. M. Jansen [11], J. S. Vermaat [11], M. Nijland [3]

[1]Department of Research and Development, Netherlands Comprehensive Cancer Organisation, Utrecht, [2]Department of Hematology, Martini Hospital, [3]Department of Hematology, University Medical Center Groningen, Groningen, [4]Department of Hematology, Maastricht University Medical Center, Maastricht, [5]Department of Hematology, Amsterdam University Medical Center, Amsterdam, [6]Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, [7]Department of Hematology, Haga Hospital, The Hague, Netherlands, [8]Department of General Medical Oncology, University Hospitals Leuven, Leuven, Belgium, [9]Department of Hematology, Isala Hospital, Zwolle, [10]Department of Hematology, University Medical Center Utrecht, Utrecht, [11]Department of Hematology, Leiden University Medical Center, Leiden, Netherlands

Background: Peripheral T-cell non-Hodgkin lymphoma (T-NHL) is a heterogeneous disease entity with generally a poor survival. Cyclophosphamide-doxorubicin-vincristine-prednisolone (CHOP) has been the standard of care for the majority of T-NHL subtypes for decades. Addition of etoposide to CHOP (CHOEP) and consolidation with autologous stem cell transplantation (ASCT) are offered to young patients with stage II-IV disease, although the efficacy is controversial.
Aims: This nationwide, population-based study aimed to assess the impact of etoposide and ASCT on overall survival (OS) among patients <65 years with stage II-IV disease of the predominant T-NHL subtypes anaplastic large T-cell lymphoma (ALCL), angioimmunoblastic T-cell lymphoma (AITL) and peripheral T-cell lymphoma not otherwise specified (PTCL NOS).
Methods: All patients with stage II-IV ALCL, AITL and PTCL NOS, 18-64 years old and diagnosed between 1989-2018 were identified from the Netherlands Cancer Registry (NCR), with survival follow-up through 2020. Data on primary therapeutic strategy (*i.e.* chemotherapy or no anti-neoplastic therapy) was available. The exact therapeutic strategy was known for patients diagnosed from 2014. Patients were categorized into two periods (1989-2008, 2009-2018) and the calendar periods were chosen based on the implementation of etoposide and ASCT (from 2009 onwards) for T-NHL in the Netherlands. Multivariable analysis of OS was performed using Cox regression.
Results: A total of 1,439 patients (median age 52 years; 62% males) were selected, including 519 ALCL, 294 AITL and 626 PTCL NOS cases. In 2009-2018, the proportion of AITL was higher as compared to 1989-2009 (27% *vs.* 15%, *P*=0.001). The proportion of patients receiving anti-neoplastic therapy was comparable for both calendar periods (88% and 91%, respectively). With similar trends for the three T-NHL subtypes, 31% of the patients received ASCT in 2009-2018 when compared to 5% of patients before 2009 (*P*<0.001). The median OS for the entire cohort was 22 months. As expected, five-year OS was highest for ALCL, followed by AITL and PTCL (57%, 44%, and 32%; Figure, panel A). Five-year OS increased over time with 11% (Figure, panel B) and was higher for patients who received ASCT as compared to patients without ASCT (70% vs 36%; Figure, panel C).
In 352 patients diagnosed in 2014-2018, the use of CHOEP instead of CHOP increased from 16% in 2014 to 67% in 2018. Of the patients who received CHOP or CHOEP, ASCT was applied in 26% and 51%, respectively. Five-year OS rates were 89% and 77% (*P*=0.248) for patients who received CHOP+ASCT and CHOEP+ASCT, respectively. For patients without ASCT, five-year OS rates were 27% and 48% (*P*=0.160) for patients with CHOP and CHOEP, respectively (Figure, panel D). When simultaneously adjusted for sex, age, and subtype of T-NHL in multivariable analysis, OS risk was similar between patients treated with CHOP+ASCT and patients treated with CHOEP+ASCT. However, OS risk for patients treated with CHOP or CHOEP in the absence of ASCT was lower as compared with patients treated with CHOEP+ASCT. T-NHL subtype was an independent predictor of poor prognosis.

Summary/Conclusion: In this large Dutch population of young patients with advanced ALCL, AITL or PTCL NOS, the use of ASCT consolidation, regardless the addition of etoposide to CHOP, significantly improved OS and could explain the survival benefit in the last decade. This nationwide population-based study corroborates other independent studies suggesting CHO(E)P followed by ASCT as first-line therapeutic regimen for young and fit T-NHL patients.

S221 INTER-B NHL RITUX 2010 TRIAL FOR CHILDREN/ ADOLESCENTS WITH HIGH-RISK MATURE B-CELL NON-HODGKIN'S LYMPHOMA/ACUTE LEUKAEMIA: SAFETY AND EFFICACY IN PATIENTS TREATED WITH RITUXIMAB AND LMB CHEMOTHERAPY.

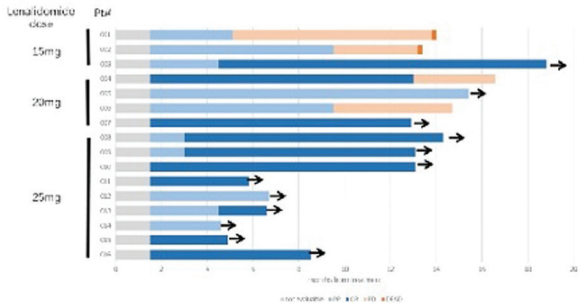
Background: The addition of rituximab to standard Lymphomes Malins B (LMB) chemotherapy improved survival of children and adolescents with high-risk mature B-cell non-Hodgkin's lymphoma and mature acute leukemia (B-NHL/AL) in the international randomized phase III trial Inter-B NHL ritux 2010 (NCT01516580).
Aims: After the first interim analysis, randomization was stopped for efficacy and additional patients were subsequently enrolled and treated with R-LMB for planned secondary aims. Here we report the total cohort of patients treated with R-LMB.
Methods: From December 2011 to June 2017, 298 patients < 18 years with high-risk B-NHL (stage III with LDH level>2N, stage IV) and B-AL were included in the Inter B-NHL Ritux 2010 study and allocated to the R-LMB arm: 164 were reported in the publication (NEJM 2020;382:2207-19) of the randomized part of the study (Main R-cohort) and there are 134 additional patients (Additional R-cohort). Rituximab was given (375 mg/m^2) on days -2 and 1 during the first 2 chemotherapy courses and on day 1 of the 2 following courses (total 6 infusions). Therapeutic groups were as follow: B: Stage III or IV, central nervous system negative; C1: Stage IV/B-AL cerebrospinal fluid (CSF) negative; C3: CSF positive. The endpoint event-free survival (EFS) is defined as the minimum time between inclusion and detection of residual viable tumor cells after the second consolidation course (primary refractory disease), relapse, progressive disease, second cancer, or death from any cause, or the date of the last follow-up for patients who did not have any event.
Results: Median age was 8 years (interquartile range (IQR) 5-12). 88% patients had Burkitt lymphoma (BL). 48% were in group B, 40% in C1 and 12% in C3. 94% patients received at least 6 rituximab administrations. The median follow-up was 45 months (IQR 34-57). There were 20 events (13 treatment failures: primary refractory disease or progression or relapse, 5 toxic deaths, 2 second cancers (histiocytic sarcoma, melanoma)). Seven treatment failures occurred in patients of therapeutic group B, 3 of group C1 and 3 of group C3. All relapses, except one, occurred during the first 10 months. 4-year EFS was 93.0% (95%CI 89.4% to 95.5%) (93.9% in main R-cohort, 91.3% in additional R-cohort). 16 deaths occurred (7 disease-related, 8 toxic deaths at first or further line, 1 from histiocytic sarcoma). 4-year overall survival (OS) was 94.2% (95%CI 90.7% to 96.4%) (95.1% in main R-cohort, 92.0% in additional R-cohort). Among patients with BL, 9 had treatment failures (6 in group B, 2 in group C1, and 1 in group C3) and 7 died. The most frequent grade ≥ 3 acute adverse events after prephase were febrile neutropenia (93%), infection (58%), and stomatitis (78%). One year after inclusion, 102 (59%) of 173 evaluated patients for immunoglobulin level had low IgG level.
Summary/Conclusion: Rituximab in addition to standard LMB therapy achieved outstanding EFS and OS in both randomized and additional parts of the trial in children/adolescents with high-risk B-NHL/AL with significant acute toxicity and hypoglobulinemia. However, some very rare patients still have resistant disease and very poor outcome, notably those with Burkitt lymphoma.

S222 PROMISING TOLERABILITY AND EFFICACY RESULTS FROM DOSE-ESCALATION IN AN ONGOING PHASE IB/II STUDY OF MOSUNETUZUMAB WITH POLATUZUMAB VEDOTIN FOR RELAPSED/REFRACTORY B-CELL NON-HODGKIN'S LYMPHOMA

N. Ghosh [1,*], C. Diefenbach [2], J. Chavez [3], I. S. Lossos [4], A. Mehta [5], K. Dorritie [6], M. Kamdar [7], R. Negricea [8], S. Pham [8], M. Hristopoulos [9], L. -Y. Huw [9], C. O'Hear [9], Y. Oki [9], I. To [9], E. Budde [10]

Hoffmann-La Roche Ltd, Basel, Switzerland, [9]Genentech, Inc., South San Francisco, CA, [10]City of Hope National Medical Center, Duarte, CA, United States

Background: Mosunetuzumab (M), a full-length, humanized, IgG1 bispecific antibody targeting CD20 and CD3, has shown promising efficacy and safety as monotherapy for relapsed/refractory (R/R) B-cell non-Hodgkin's lymphoma (B-NHL) (NCT02500407; Assouline, et al. ASH 2020). The combination of M with the anti-CD79b antibody-drug conjugate, polatuzumab vedotin (Pola), showed synergistic anti-lymphoma activity in a mouse xenograft model. These data supported a Phase Ib/II, open-label, multicenter trial of M-Pola for R/R B-NHL (GO40516, NCT03671018).
Aims: To present early clinical data from the Phase Ib cohort of the GO40516 study.
Methods: Patients (pts) with R/R follicular lymphoma (FL; grade [Gr] 1–3a) or aggressive NHL (aNHL), including *de novo* diffuse large B-cell lymphoma (DLBCL), transformed FL (trFL) and FL Gr 3b (FL3b), received Cycle (C) 1 step-up doses of M on Day (D) 1 (1mg) and D8 (2mg), the target dose on C1D15, then continued at the target dose on C2D1 onwards. M was given every 21 days for eight cycles (or 17 cycles if stable disease or a partial response after C8). Pola (1.8mg/kg) was given with M on D1 of each cycle for six cycles.
Results: As of November 17, 2020, 22 pts had received M-Pola (M target doses: 9mg, n=7; 20mg, n=3; 40mg, n=6; 60mg [with D1 dose of 30mg from C3 onwards], n=6). Pts had DLBCL (n=12), FL (n=3), FL3b (n=3) and trFL (n=4). Pt characteristics include: median age of 70 (38–81) years; median of 3 (1–10) prior lines of therapy; 7 (32%) pts had prior chimeric antigen-receptor T-cell (CAR-T) therapy; 17 (77%) and 19 (86%) pts had disease refractory to last prior therapy and prior anti-CD20 therapy, respectively. Median follow-up duration was 9.6 (0.7–23.7) months. The most frequent treatment-related adverse events (AEs) were neutropenia (45.4%), fatigue, nausea and diarrhea (all 36.4%). Cytokine release syndrome (CRS) was observed in 2 pts (9.1%; both Gr 1 by American Society for Transplantation and Cellular Therapy 2019 criteria). One dose-limiting toxicity (Gr 3 new onset atrial fibrillation) was observed in the 40mg cohort. The maximum tolerated dose was not exceeded. The most common Gr ≥3 and serious AEs were both neutropenia, observed in 8 (36.4%) and 3 (13.6%) pts, respectively. Two (9.3%) Gr 5 AEs occurred: sudden cardiac death (n=1) and respiratory failure (n=1); neither was deemed treatment related. No immune effector cell-associated neurotoxicity was observed. The **Table** shows preliminary efficacy data.



Summary/Conclusion: These data indicate that M-Pola has an acceptable safety profile, with no Gr ≥2 CRS observed, and promising efficacy in pts with R/R NHL with predominantly aggressive disease. The Phase II expansion cohort in R/R DLBCL is ongoing, with no mandatory hospitalization required.

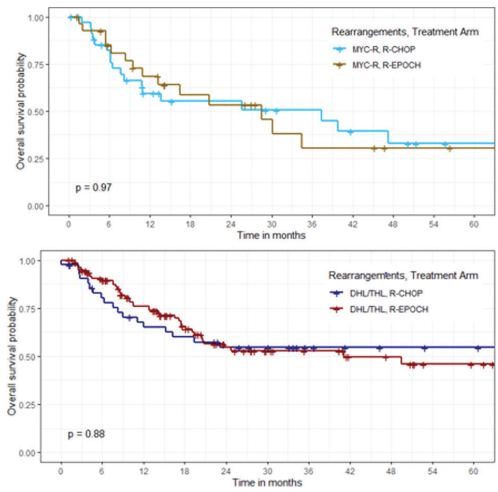
S223 PHASE IB/II STUDY OF LENALIDOMIDE, RITUXIMAB, HIGH-DOSE METHOREXATE (R2-MTX) REGIMEN, FOLLOWED BY LENALIDOMIDE MAINTAINANCE IN NEWLY DIAGNOSED PRIMARY CNS LYMPHOMA

Y. Zhang [1,*], W. Wang [1], W. Zhang [1], D. Zhou [1]

[1]Department of Hematology, Peking Union Medical College Hospital, Beijing, China

Background: Primary central nervous system lymphoma (PCNSL) is a rare subtype of extranodal NHL with an aggressive clinical course and poor outcomes. High-dose methotrexate (HD-MTX) based regimen significantly improves the outcomes, but 10-35% patients are treatment refractory.
Aims: In this study, we evaluated the safety, efficacy, and feasibility of lenalidomide, rituximab and HD-MTX (R2-MTX) regimen for newly diagnosed PCNSL patients.
Methods: This is a multicenter prospective phase Ib/II study(NCT04120350). Eligible patients had newly diagnosed PCNSL, age≥18 and normal end-organ function. The phase Ib study used the 3+3 dose escalation design. Lenalidomide was dosed at 15mg daily (day 1-14) (level 1), 20mg daily (day 1-14) (level 2) and 25mg daily (day 1-14) (level 3); rituximab was dosed at 375mg/m2 (d0), MTX was dosed at 3.5g/m2 (d1) (all dose levels). Every 21 days were as a course of treatment. R2-MTX regimen was given for 6 cycles, then lenalidomide (25mg daily, day 1-21) at 28-day cycles was given for a maximum of 2 years as maintenance. In phase I study, dose-limiting toxicity (DLT) within first 2 cycles was evaluated to determine the recommended phase II dose.
Results: 17 patients were enrolled from August 2019 to December 2020: 10 patients in phase Ib (3, 4, 3 patients received LEN 15mg, 20mg and 25mg, respectively); and 7 patients in phase II study. No DLTs were observed in phase Ib study, and the recommended phase II dose of lenalidimide was 25mg daily. The last follow-up was January 31th 2021. 11(64.7%) pts were male and the median age was 60 (range 32-74). 13 patients were mediate and high risk group according to IELSG score(2-5 points). Common grade ≥3 adverse events (AEs) of induction therapy were neutropenia (41.2%), infection(5.9%), anemia (5.9%), thrombocytopenia (5.9%) and acute kidney injury (5.9%) (all these AE occurred in one patient who suffered from MTX overdose); other AE (grade 1-2, > 10%) were elevated ALT(47.1%), fatigue(29.1%), nausea/vomiting (23.5%), numbness (23.5%), infection(11.8%), renal injury (11.8%) and rush (11.8%). 16 patients were evaluable for response, and the overall response rate (ORR) was 100%: 10 patients achieved complete remission, and 6 patients achieved partial remission. The median follow-up time was 13.2 (1.3-17.3)months, 4 patients relapsed and 2 patients died for disease progression, the median PFS was 13.3 month (Figure 1).



Summary/Conclusion: R2-MTX regimen is a feasible and active combination treatment for newly diagnosed PCNSL patients. It demonstrates excellent response rate, as well as with good tolerability. More clinical data will be updated from this ongoing study (NCT 04120350).

S224 NO DIFFERENCE IN OVERALL SURVIVAL BETWEEN R-CHOP AND R-EPOCH AMONG PATIENTS WITH ADVANCED STAGE MYC-REARRANGED, DOUBLE HIT, OR TRIPLE HIT DIFFUSE LARGE B-CELL LYMPHOMA

T. Magnusson [1,*], M. Narkhede [2], A. Mehta [2], G. Goyal [2]

[1]Internal Medicine, University of Alabama at Birmingham, Birmingham, [2]Hematology and Medical Oncology, University of Alabama at Birmingham, Birmingham, AL, United States

Background: Presence of MYC-rearrangement (MYC-R) in diffuse large B-cell lymphoma (DLBCL) has been associated with poor prognosis, especially if there is presence of concomitant BCL2 and/or BCL6 rearrangements. The latter entities are called double hit lymphoma (DHL) and triple hit lymphoma (THL), respectively. A few retrospective studies and a single arm prospective trial have suggested improved outcomes with the R-EPOCH regimen in DHL and THL patients. Our aim was to evaluate prognostic factors and efficacy of both regimens (R-EPOCH and R-CHOP) in a large cohort of patients with MYC-R DLBCL.
Aims: Our study aimed to compare overall survival of patients with advanced stage MYC-R DLBCL and DHL/THL who were treated with R-CHOP vs. R-EPOCH.
Methods: Data was analyzed from the nationwide Flatiron Health electronic health record–derived de-identified database, for patients diagnosed with DLBCL between 1 January 2011 and 30 June 2020. Only patients with MYC-R/DHL/THL who received R-CHOP or R-EPOCH as a first-line therapy were included in the analysis. Overall survival (OS) from date of diagnosis to date of death or last known alive was calculated using the Kaplan-Meier method and compared between MYC-R and DHL/THL separately using log-rank procedure. Cox proportional hazards regression was used to assess associations between patient characteristics, treatments, and overall mortality. Univariable and multivariable models within MYC-R and DHL/THL cohorts were conducted using these factors to estimate hazard ratios (HRs) and their 95% CIs.
Results: Among 6,809 total DLBCL patients, 443 (6.5%) were found to have MYC-R. Among these, 218 (49%) had advanced stage (III/IV) disease at diagnosis and received R-CHOP or R-EPOCH, and were included in the study. 154 (70%) had high-grade lymphomas (117 DHL, 37 THL). Among those with DHL/THL, 43 received R-CHOP (median age 73y) and 111 received R-EPOCH (median age 67y). Among those with MYC-R DLBCL, 36 received R-CHOP (median age 70y), and 28 received R-EPOCH (median age 61y). There was no difference in 4-year OS rates between R-CHOP and R-EPOCH treatment cohorts among DHL/THL (54.5% [95% CI 40.9-72.6] vs. 49.6% [95%CI 38.8-63.5] Figure). Similarly, there was no difference in 4-year OS rates among MYC-R patients between R-CHOP and R-EPOCH (32.8% [95%CI 17.7-60.9] vs. 30.4% [95% CI 14.4-64.5]). Among DHL/THL patients, 89% deaths occurred within first 2y, and among MYC-R, 78% deaths occurred within 2y of diagnosis. Among entire MYC-R cohort, univariate analysis of treatment type (R-CHOP, R-EPOCH), age ≥60y, sex, race, ECOG ≥2, elevated LDH, and >1 extranodal site, only ECOG ≥2 (p = <0.001) and elevated LDH (p = 0.041) were significant for worse mortality. By multivariate analysis, ECOG ≥2 (HR 2.59 [1.317-5.1]) and elevated LDH (HR 1.61 [1.016-2.6]) were again the only significant variables associated with risk of mortality.

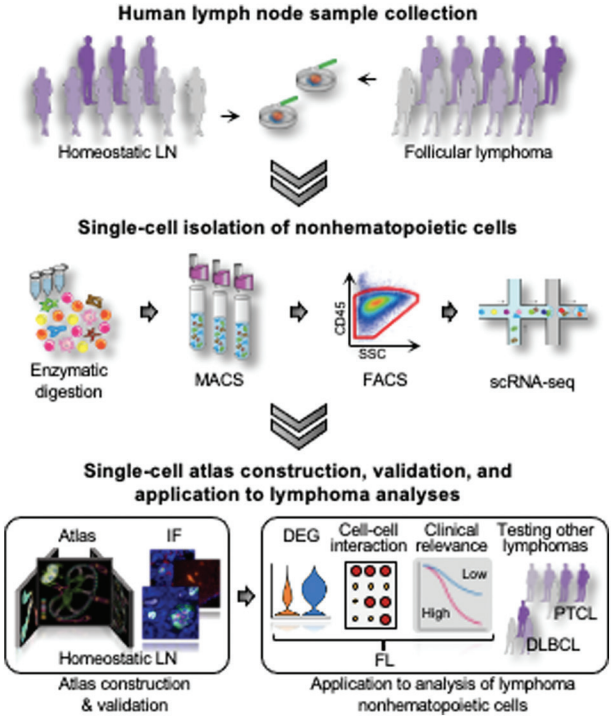
Summary/Conclusion: In our large multi-institutional database study, the 4-year OS was similar between R-CHOP and R-EPOCH among MYC-R DLBCL and DHL/THL. In multivariable analysis, ECOG ≥2 and elevated LDH were the only variables independently associated with poor prognosis in this subgroup. Most deaths occurred within 2y of diagnosis, with similar OS in both arms at 4y. Further studies are needed for better risk stratification of patients with DLBCL for optimizing outcomes.

Lymphoma - Translational research

S225 CIRCULATING TUMOR DNA SEQUENCING REVEALS THE GENOMIC LANDSCAPE OF HODGKIN LYMPHOMA AND FACILITATES HIGHLY SENSITIVE DETECTION OF MINIMAL RESIDUAL DISEASE

S. Borchmann [1,*], S. Sobesky [1], L. Mammadova [1], M. Cirillo [2], E. Drees [3], J. Mattlener [1], H. Dörr [1], J. Altmüller [1], Z. Shi [1], P. Bröckelmann [1], J. Weiss [1], S. Kreissl [1], R. Ullrich [1], S. Reinke [4], W. Klapper [4], M. Roemer [3], P. Nürnberg [1], J. Zijlstra [3], D. M. Pegtel [3], A. Hagenbeek [3], A. Engert [1], P. Borchmann [1], B. von Tresckow [5]

[1]University of Cologne, Köln, Germany, [2]University of Western Australia, Perth, Australia, [3]Vrije Universiteit Amsterdam, Amsterdam, Netherlands, [4]University Hospital Schleswig-Holstein, Kiel, [5]University of Duisburg-Essen, Essen, Germany



Background: In Hodgkin lymphoma, treatment individualization is hindered by a lack of genomic characterization and technology for sensitive, molecular response assessment due to the scarcity of Hodgkin-Reed Sternberg (HRS) cells in the tumor tissue. Sequencing of cell-free (cf) DNA is a powerful strategy for genomic characterization and development of assays for sensitive disease monitoring.
Aims: The aim of this study is to introduce a targeted cfDNA sequencing platform that is then used to decipher the genomic landscape of HL and to facilitate minimal residual disease assessment (MRD).
Methods: We comprehensively genotyped and assessed minimal residual disease in 324 samples from 121 patients targeting approximately 3 Mb of the genome. All samples underwent pre-analytical processing, extraction of ctDNA and matching germline control DNA and sequencing at > 3000x average coverage post deduplication. An in-house, customised bioinformatics pipeline was developed for two-fold error reduction.
Results: First, we performed technical and clinical validation. We show that our approach can identify mutations with an allele frequency of 0.5% in cfDNA at 92.8% sensitivity and 100% specificity. 91.3% of mutations could be confirmed in tissue samples. For MRD detection, we identified a limit of detection of 0.00945%.
We identified 23 tumor suppressor genes (TSG) and 20 oncogenes (OG) in our HL cohort. Recurrent mutations were identified in several known oncogenic pathways in HL such as JAK-STAT signaling (SOCS1, STAT6, CSF2RB, IL4R), Class I MHC mediated antigen processing and presentation (B2M) and NF-kappa B signaling (TNFAIP3, IKBKB, NFKBIE). Novel findings with potential relevance to HL pathogenesis included recurrent mutations in EZH2, IRF4 and IRF8.
Six distinct COSMIC single base substitution (SBS) signatures were identified, the most common being SBS1 (aging), followed by SBS3 (defective homologous recombination (HR)-based DNA damage repair), SBS6 and SBS15 (defective DNA mismatch repair) SBS9 (somatic hypermutation in lymphoid cells) and finally SBS25 (so far only identified in HL cell lines). Interestingly, SBS3 - the defective HR signature - contributed majorly to mutations in genes crucial for HL oncogenesis, highlighting a potential novel role for defective HR in HL pathogenesis.
When linking HL genotypes to phenotypes, mutations in some genes, such as TP53 or NOTCH1, were associated with a high-risk phenotype and inferior treatment response, while other alterations, such as BRCA1 or MGMT loss were associated with a low-risk phenotype possibly mediated by increased sensitivity to commonly used cytotoxic drugs.
Furthermore, we identified a distinct genotype of large mediastinal mass HL, characterized by a higher frequency of B2M and IKBKB mutations, as well as a higher number of mutations in genes involved in Interferon signaling and JAK-STAT signaling. These alterations suggest remarkable biological similarity of large mediastinal mass HL to PMBCL.
Finally, we examined the relationship between MRD measured by following each patient's unique mutational fingerprint at different timepoints, and interim PET-imaging after 2 cycles of treatment. MRD trajectories separated very early on, with clear differences already observable after 1 week. MRD after 1 week differentiated with 100% accuracy between Deauville 1-3 and Deauville 4-5 patients.
Summary/Conclusion: Here, we present the largest genomic landscape of HL to date and introduce our targeted ctDNA sequencing platform allowing for accurate genotyping using pre-treatment samples and highly sensitive minimal residual disease (MRD) detection.

S226 A COMPREHENSIVE SINGLE-CELL ATLAS OF NONHEMATOPOIETIC CELLS IN HUMAN LYMPH NODE AND LYMPHOMA REVEALS LANDSCAPE OF STROMAL REMODELING

Tabata [4], T. Terao [4], Y. Owada [5], T. Enomoto [5], H. Bando [6], M. Nakayama [7], K. Ohshima [2], K. Usuki [8], T. Oda [5], K. Matsue [4], S. Chiba [1]

[1]Department of Hematology, University of Tsukuba, Tsukuba, [2]Department of Pathology, Kurume University, Kurume, [3]Department of Hematology, Mito Medical Center, Mito, [4]Division of Hematology/Oncology, Kameda Medical Center, Kamogawa, [5]Department of Gastrointestinal and Hepato-Biliary-Pancreatic Surgery, [6]Department of Breast and Endocrine Surgery, [7]Department of Otolaryngology, Head and Neck Surgery, University of Tsukuba, Tsukuba, [8]Department of Hematology, NTT Medical Center Tokyo, Tokyo, Japan

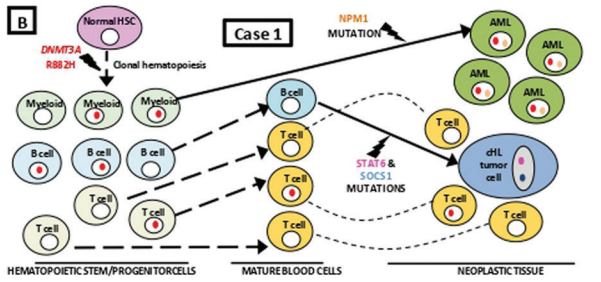
Background: Activities of nonhematopoietic cells (NHCs) in lymphoma, including mesenchymal stromal cells and endothelial cells, reportedly underlie lymphomagenesis. However, understanding of lymphoma NHC activities have been hampered by unexplained NHC heterogeneity even in normal human lymph node (LN). Particularly, human LN blood endothelial cells (BECs) and non-endothelial stromal cells (NESCs) have not been analyzed at single-cell resolution.
Aims: We aimed to complete a transcriptome atlas of human NHCs in homeostatic LN (HLN) and lymphoma to reveal previously unrecognized heterogeneity. We also sought to reveal the single-cell landscape of stromal remodeling in lymphomas, particularly in follicular lymphoma (FL), to advance understanding of stromal contributions in lymphomagenesis.
Methods: We performed single-cell RNA sequencing of NHCs (>100,000 cells) extracted from human HLN (n=9), nodal FL (n=10), peripheral T-cell lymphoma (PTCL; n=5), and diffuse large B-cell lymphoma (DLBCL; n=3) samples. Data from HLN samples was mainly used for the construction of NHC atlas. Immunofluorescence (IF) staining was performed to validate the results of single-cell analysis and to explore the topological localizations of each NHC subcluster in the LN. Using the NHC atlas, we performed comprehensive comparative analysis with FL NHCs by differentially-expressed gene (DEG) and intercellular ligand-receptor analyses. We also investigated the prognostic impact of putative stroma-derived biomarkers using deposited microarray data of FL patients.
Results: Graph-based clustering analysis revealed that the transcriptional features of NHC subpopulations in HLN are highly conserved in FL NHCs. Unsupervised sub-clustering analysis of BECs, lymphatic endothelial cells (LECs), and NESCs revealed 10, 8, and 12 subclusters, respectively, including some lacking mouse counterpart. IF staining successfully identified each NHC subcluster and its localization in the LN. In FL NHCs, the proportion of arterial BEC subclusters markedly increased relative to HLN, while the proportion of LECs decreased. In FL NESCs, the proportion of marginal reticular cells (MRCs) as well as follicular dendritic cells (FDCs) greatly increased. DEG analysis revealed that the greatest changes in gene expression occurs in NESC subclusters, particularly in MRCs, T-zone reticular cells (TRCs), perivascular stromal cells, and FDCs. Notably, in some NESC subclusters, we observed marked upregulation of genes relevant to solid cancers but previously not associated with lymphomagenesis (e.g. *POSTN*, *EGFL6*, and *FAP*). Combined interactome and DEG analysis revealed that interactions mediated through CXCL12 was unexpectedly upregulated only at stromal cells at adventitia. Additionally, the CCR7-CCL19 interaction was extended to non-TRC stromal cell subclusters. Also, the CXCL13-CXCR5 axis was highly activated in MRCs, indicating that MRCs as well as FDCs participate in FL expansion. Based, on these data, we identified putative stroma-derived biomarker LY6H, LOX, TDO2, and REM1 as promising prognostic predictors in FL. We finally confirmed that our NHC atlas is also useful to assess NHCs in more aggressive lymphomas including PTCL and DLBCL.

Summary/Conclusion: We constructed a comprehensive single-cell atlas of NHCs in human LN highly applicable to lymphoma NHC researches. Our study largely updates NHC taxonomy in LNs and provides a rich resource and deeper insights into lymphoma biology, a contribution that should advance lymphoma management and therapy.

S227 TRACKING CLONAL HEMATOPOIESIS IN PATIENTS WITH CLASSICAL HODGKIN LYMPHOMA

A. Venanzi ° [1,*], A. Marra ° [1], G. Schiavoni ° [1], S. G. Milner [1], R. Limongello [1], A. Santi [1], V. Pettirossi [1], S. Ultimo [1], L. Tasselli [1], A. Pucciarini [1], L. Falini [1], S. Sciabolacci [1], M. P. Martelli [1], P. Sportoletti [1], S. Ascani [1], B. Falini § [1], E. Tiacci §; °co-first author; § co-last author [1]

[1]Dept. of Medicine and Surgery, University of Perugia, Perugia, Italy



Background: Clonal hematopoiesis (CH) is frequent in the elderly and predisposes to blood tumors, mostly of myeloid and T-cell origin. CH incidence and trajectories are not well characterized in classical Hodgkin lymphoma (cHL), a B-cell neoplasm frequent in the young and uniquely featuring rare cancer cells embedded in a supportive microenvironment largely of hematopoietic origin.
Aims: To assess whether cHL belongs to the spectrum of hematologic malignancies associated with CH, here we report CH frequency and tissue distribution in 40 cHL patients, including the surprising findings on a young case with massive CH who developed acute myeloid leukemia (AML) following therapy for cHL.
Methods: We subjected 40 cHL cases to whole-exome and/or targeted sequencing (mean unique coverage ~150X and ~1000X, respectively) of tumor cells microdissected from the tissue biopsy in parallel with matched non-neoplastic blood cells (n=26 cases) or microdissected lymphoid cells (n=14 cases).
Results: 5/40 cases (12.5%) had blood and/or tissue CH, including 3/5 with >70 years and 2/35 <70 years (Fig. 1A). In 3/5 cases with CH (aged 30, 45 and 73 years), CH extensively spread through the non-neoplastic tissue microenvironment (92%, 32% and 60% of cells), being respectively driven by mutant *KRAS*^{G60D}, *DNMT3A*^{R882H}, and *DNMT3A*^{R882H}+*TET2*^{Q1274*} (Fig. 1A). Notably, in the latter case (Case 5) CH originated also the tumor cell clone, which was infected by the Epstein-Barr virus and had almost no other somatic mutations exome-wide; this is the first description, in a human B-cell lymphoma clone, of mutant *DNMT3A*^{R882}, a hotspot in myeloid and T-cell neoplasms.
In the other case with *DNMT3A*-mutant CH (Case 1; Fig.1B), the same variant R882H caused a massive CH (94% of blood leukocytes; 96% of blood B cells) that was surprisingly absent from the tumor cell clone (instead carrying *STAT6* and *SOCS1* mutations, typical of cHL) and led, 6 years after therapy for cHL, to a likely therapy-unrelated *NPM1*-mutated acute myeloid leukemia (with normal karyotype, wild-type *TP53* and *PPM1D*). Thus, CH trajectories must be fully disentangled to correctly interpret the histogenesis and pathogenesis of multiple myeloid and lymphoid neoplasms arising in patients with CH, as the latter (even when massive) does not necessarily represent the shared genetic background of all neoplastic clones.
Finally, in the 3 cases with extensive CH propagation in the cHL tissue microenvironment (mostly represented by T cells), we observed a polyclonal status of T-cell receptor gene rearrangements, confirming that the mutations underlying CH had occurred in a bone marrow stem or progenitor cell before T-cell lineage commitment. Interestingly, all these 3 cases progressed after first-line chemotherapy, versus 11/35 (31%; p-value 0.043) evaluable cases with absent or non-extensive tissue CH, who otherwise had similar clinical features and received the same first-line therapy (not shown).

FIGURE 1

A

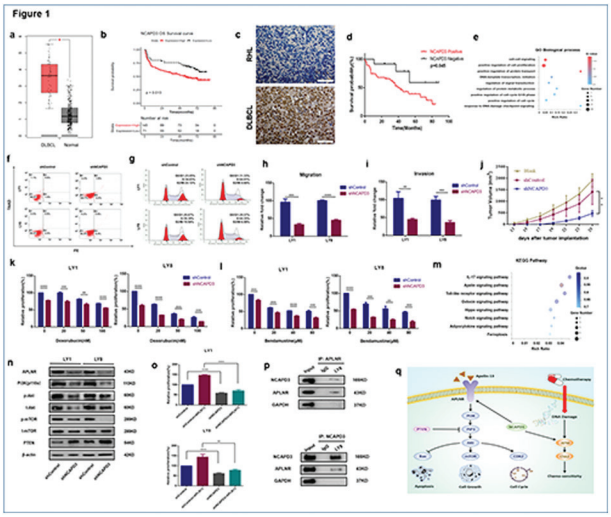
cHL case cohort (n=40)		Pt. #	Time of sampling	Progressed after first-line chemotherapy	CHIP mutation	VAF in whole blood	VAF in microdissected		VAF in whole tissue section
CH PRESENT	AGE (years)						Reactive lymphoid cells	Tumor cells	
YES (n=5)	45	Case 1	Onset	YES	*DNMT3A R882H*	47%	16.4%	ND	NA
	30	Case 2	2nd relapse	YES	*KRAS G60D*	NA	45.9%	ND	22.9%
	83	Case 3	Onset	Not evaluable	*CBL G375S*	NA	2.5%	ND	NA
	81	Case 4	Onset	NO	*TET2 N1487fs84*	3.2%	ND	ND	NA
	73	Case 5	1st relapse	YES	*DNMT3A R882H*	NA	30%	43%	NA
NO (n=35)	Median: 35 Range: 15-75				*TET2 Q1274**		8.4%	31.1%	

VAF, variant allele frequency; NA, Not available; ND, Not detected

Summary/Conclusion: CH can be observed in the cHL tissue, can originate the tumor clone and can propagate to large part of its microenvironment. Considering that both tumor cells and the microenvironment supporting its growth play key roles in cHL pathogenesis, CH might contribute to the development of this lymphoma and influence its prognosis.

S228 BLOCKADE OF NCAPD3 AS A NOVEL THERAPEUTIC APPROACH IN DIFFUSE LARGE B-CELL LYMPHOMA

J. Yang [1,2,*], X. Zhou [1,2], S. Hu [1,2], Y. Cai [1,2], J. Liu [1,2], S. Ren [1,2], X. Chen [1,2], X. Wang 1 2



[1]Department of Hematology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, [2]Department of Hematology, Shandong Provincial Hospital Affiliated to Shandong University, Jinan, China

Background: The Non-SMC Condensin II Complex Subunit D3 (NCAPD3) is a key component of condensin. Existing evidence confirms that somatic mutations in NCAPD3 are linked to deregulated pathways and a large number of diseases, including cancers. However, little is known regarding its biological and clinical significance in diffuse large B-cell lymphoma (DLBCL).
Aims: This series of experiments are aimed to explore the pattern of expression, functional mechanisms and potential clinical relevance of NCAPD3 in DLBCL.
Methods: Archived, paraffin-embedded samples extracted from 70 *de novo* DLBCL patients and 30 reactive hyperplasia cases were collected with informed consents. The GEO and TCGA database were obtained to aid in subsequent survival analysis. Empty lentiviral vectors (shControl) or those coding for shNCAPD3 were stably transfected into DLBCL cell lines which were then assessed using RNA-sequencing (RNA-seq) analysis. DLBCL xenograft models were established by injecting mice subcutaneously with DLBCL cells. ARRIE guidelines were strictly adhered to for all experiments.

Results: TCGA database demonstrated that the expression level of NCAPD3 in DLBCL was raised in comparison to those of normal tissues (Fig. 1a). Kaplan-Meier survival curve revealed that higher NCAPD3 expression levels in DLBCL cases were linked to shorter overall survival times according to GEO database (Fig. 1b). IHC staining showed higher expression levels of NCAPD3 in DLBCL tissues than those in control tissues and significantly related to poorer prognosis (Table 1, Fig 1c, d). High expression levels of NCAPD3 mRNA and protein were confirmed in DLBCL cell lines as well.

Functional enrichment analyses of NCAPD3 according to RNA-seq revealed that NCAPD3 was correlated strongly to cell proliferation, cell cycle and DNA damage signaling (Fig 1e). Knockdown of NCAPD3 significantly suppressed cell proliferation, promoted cell apoptosis, induced cell cycle arrest and impaired cell migration and invasion (Fig 1f-i). Tumors with NCAPD3-repression displayed suppressed tumor growth (Fig 1j) and diminished levels of Ki-67 *in vivo*. Also, NCAPD3 depletion in DLBCL were proved to enhance the chemo-sensitivity of DLBCL through the DNA damage signaling (Fig 1k, l).

With KEGG results derived from the RNA-seq data, NCAPD3 was found to be functionally enriched in the Apelin signaling pathway (Fig. 1m). NCAPD3 and APLNR revealed a significant association in DLBCL according to TCGA database. Western blot demonstrated a decrease in the levels of APLNR and its downstream PI3K/Akt/mTOR components in shNCAPD3 cells in contrast to shControl cells (Fig 1n). The APLNR activator APLN-13 were exposed to DLBCL cells transfected with either shNCAPD3 or shControl, cells containing shNCAPD3 demonstrated decreased proliferation induction (Fig. 1o). The co-IP experiment suggested that NCAPD3 regulates the Apelin/PI3K pathway by directly binding to APLNR (Fig. 1p). In summary, NCAPD3 may modulate DLBCL progression through regulation of the Apelin/PI3K and DNA damage response signaling pathway (Fig. 1q).

Summary/Conclusion: Our clinical and fundamental results highlight the pivotal oncogenic role of NCAPD3 in DLBCL for the first time, suggesting blockade of NCAPD3 as a novel therapeutic approach in DLBCL mediating through the Apelin/PI3K signaling pathway.

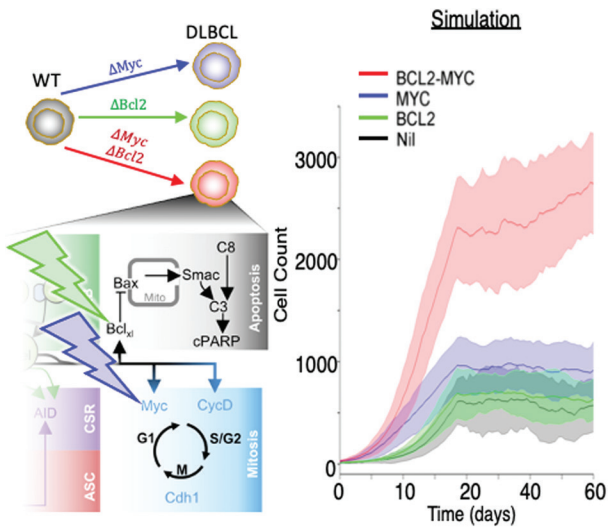
S229 A SYSTEMS BIOLOGY APPROACH TO DLBCL PREDICTS EMERGENT PHENOTYPES FROM MOLECULAR DYSREGULATION AND IDENTIFIES DISTINCT ROLES FOR NF-KB SUBUNITS CREL AND RELA.

S. Mitchell [1,*], K. Roy [2], A. Hoffmann [3]

[1]Brighton and Sussex Medical School, University of Sussex, Brighton, United Kingdom, [2]Institute for Quantitative and Computational Biosciences, University of California Los Angeles, [3]Institute for Quantitative and Computational Biosciences, University of California, Los Angeles, Los Angeles, United States

Background: Heterogeneity in therapeutic response challenges the successful treatment of Diffuse Large B-Cell Lymphoma (DLBCL). Despite the recognition that DLBCL cases have diverse genetic and transcriptional characteristics, standard first-line therapy has remained unchanged for more than a decade. Further, cell-of-origin stratification into Germinal Centre (GC) and Activated B-cell (ABC) DLBCL fails to define much of the heterogeneity.

Canonical Nuclear Factor KappaB (NF-kB) is a dimeric transcription factor usually consisting of either cRel or RelA bound to p50. While aberrant NF-kB activation is frequently observed in DLBCL, subunit composition in individual DLBCL cases is not routinely characterized but has the potential to improve stratification and identify novel molecular targets for treatment. Computational simulations of NF-kB control over B-cell proliferation and apoptosis accurately predict experimental results with accuracy at both single-cell and cell-population scale. However, the key regulatory networks controlling B-cell differentiation were not factored into these predictive models.



Aims: 1. Elucidate, with single-cell resolution, dynamic NF-kB control over B-cell fate decisions.

2. Develop a novel tool to enable rational therapeutic targeting of in B-cell lymphoma despite substantial heterogeneity.

Methods: Mechanistic systems biology approaches were combined with publically available data and targetted experiments designed to test computational predictions.

Results: Simulation of known regulatory interactions between NF-kB and the molecular networks controlling B-cell fate decisions revealed this molecular signalling network was insufficient to explain healthy B-cell differentiation. A computationally-driven prediction, that cRel must be downregulated during differentiation, lead to the discovery that although cRel drives B-cell proliferation it also blocks terminal differentiation to antibody-secreting plasma cells. We find that dynamic downregulation of cRel, through direct inhibition by Blimp1, is a pre-requisite for B-cell differentiation. The refined simulation, incorporating this novel interaction, accurately recapitulates B-cell population dynamics in wild-type (WT) and cRel knockout cells.

To establish whether a computational systems biology approach could enable accurate simulation of DLBCL we incorporated the aberrantly increased NF-kB activity seen in the disease. Interestingly, NF-kB subunit specific phenotypes emerge. Chronic cRel activity resulted in a differentiation block at the germinal centre stage, as seen in GC-DLBCL. RelA hyperactivity resulted in accumulation of a more differentiated cell type as see in ABC-DLBCL. To explore the potential of this approach to understand dysregulation beyond NF-kB, commonly-occurring mutations affecting MYC and BCL2 were simulated. While individual mutations only marginally perturbed cell counts the combination of MYC and BCL2 dysregulation commonly found in "double-hit" lymphoma had a striking synergistic effect in the model as seen in both experimental systems and clinical outcomes.

Summary/Conclusion: The ability of these computational systems biology models to accurately recapitulate clinically-observed emergent phenotypes from mutational changes enables the creation of mutation-specific "*in silico*" DLBCL laboratories. By incorporating the recently characterise vast mutational heterogeneity seen through whole exome sequencing DLBCL, we can use these models as tools to predict efficacious therapeutic approaches and biomarkers to stratify and treat lymphoma beyond current subtype classification.

Stem cell transplantation - Preclinical/experimental

S230 RESTORING M1/M2 MACROPHAGE POLARIZATION VIA UP-REGULATING PI3K-AKT PATHWAY ALLEVIATES PROLONGED ISOLATED THROMBOCYTOPENIA POST-ALLOTRANSPLANT

H. -Y. Zhao [1,*], Y. -Y. Zhang [1], T. Xing [1,2], S. -Q. Tang [1], Q. Wen [1], Z. -S. Lyu [1,2], M. Lv [1], Y. Wang [1], L. -P. Xu [1], X. -H. Zhang [1], Y. Kong [1], X. -J. Huang [1,2]

[1]Peking University People's Hospital, Peking University Institute of Hematology, National Clinical Research Center for Hematologic Disease, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [2]Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Prolonged isolated thrombocytopenia(PT) is a serious complication following allogeneic hematopoietic stem cell transplantation(allo-HSCT). Our previous studies found dysfunctional megakaryopoiesis are responsible for the occurrence of PT. As an important component of the BM microenvironment, macrophages(MΦs) are heterogeneous and polarized into classically activated MΦs(M1) and alternatively activated MΦs(M2) with distinct function. In this regard, our previous study found that the aberrant M1/M2 polarization plays a critical role in regulating hematopoiesis of poor graft function patients, a clinical manifestation of pancytopenia after allo-HSCT. However, the effect of MΦ polarization on regulating megakaryopoiesis and novel approach targeting aberrant MΦ polarization in PT patients remain to be elucidated.
Aims: To address the polarization state and the function of BM MΦs in PT patients. Moreover, to investigate the effect of M1 and M2 on megakaryopoiesis and potential therapeutic target regulating aberrant MΦ polarization for PT patients.
Methods: This prospective case-control study enrolled 12 PT patients, 24 matched good graft function(GGF) patients and 12 healthy donors(HD). BM MΦs subsets were analyzed by flow cytometry and in situ histological analyses. The functions of BM MΦs were evaluated by cytokine secretion assays and coculture experiment with megakaryocytes(MKs). To determine the the effect of MΦ on megakaryopoiesis, both primary human BM MΦs and THP1 were polarized into M1 and M2 and cocultured with MKs. To further investigate the underlying mechanism of MΦ in regulating MKs, RNA-seq analyses were performed in primary MΦs from patients, and polarized M1 and M2 from HD, respectively. To explore potential approach of targeting the aberrant MΦ polarization, the chemical activators or inhibitors and lentivirus for PI3K-AKT pathway were administrated to the primary MΦs from patients and THP1 derived MΦs. BM MΦ specific PI3K-knockdown mice were constructed and megakaryopoiesis were analyzed. Subsequently, subsequent changes in maturation related signaling pathways of MKs were analyzed.
Results: Compared with GGF patients and HD, aberrant BM M1/M2 polarization, characterized by increased M1 and decreased M2 and accompanied by impaired megakaryopoiesis-supporting ability, was found in PT patients. RNA-seq and western blot analysis showed PI3K-AKT pathway was significantly downregulated in BM MΦs of PT patients. Moreover, in vitro treatment with PI3K-AKT activators restored the impaired megakaryopoiesis-supporting ability of MΦs from PT patients. Furthermore, we found M1 suppress, whereas M2 support MK maturation and platelet formation in humans. Chemical inhibition of PI3K-AKT pathway reduced megakaryopoiesis-supporting ability of M2, which could be alleviated by chemical activation of PI3K-AKT pathway. Importantly, genetic knockdown of PI3K-AKT pathway impaired the megakaryopoiesis-supporting ability of MΦs both in vitro and in a MΦ specific PI3K-knockdown murine model. Furthermore, mechanistic study indicated that TGF-β released by M2 may facilitate megakaryopoiesis through upregulation of the JAK2/STAT5 and MAPK/ERK pathways in MKs.
Summary/Conclusion: The current study demonstrated aberrant BM M1/M2 polarization with impaired megakaryopoiesis-supporting ability involved in the pathogenesis of PT. M2, but not M1, support megakaryopoiesis via up-regulating PI3K-AKT pathway. Although further validation is required, restoring M1/M2 MΦ polarization via up-regulating PI3K-AKT pathway might be a potential therapeutic approach for PT patients.

S231 DISULFIRAM ALLEVIATES ACUTE GRAFT-VERSUS-HOST DISEASE BY INHIBITING MACROPHAGE PYROPTOSIS

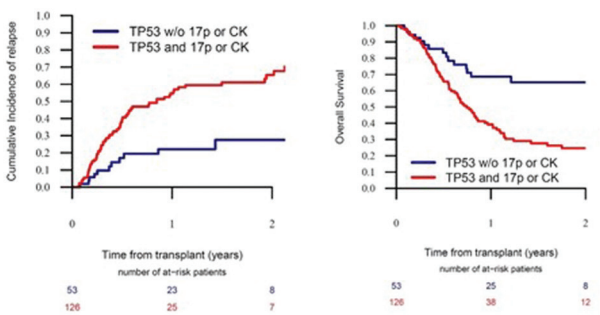
Background: Pyroptosis, a novel form of inflammation-related programmed cell death, often occurs in myeloid cells. Many studies have found that macrophage pyroptosis plays an essential role in multiple inflammatory and autoimmune diseases (Journal of Autoimmunity, 2018). Acute GVHD, an immune disease involving various inflammatory factors, is characterized by macrophage dysfunction, as reported in our previous study (Sci China Life Sci, 2020). However, whether macrophages undergo pyroptosis in aGVHD remains unknown. Disulfiram, an inhibitor of pore formation by GSDMD, could block pyroptosis and cytokine release. Recently, disulfiram treatment was found to be safe to attenuate some immune and inflammatory diseases (Journal of Experimental Medicine, 2019; Nature Immunology, 2020). However, the therapeutic effects of disulfiram on aGVHD remain unknown.
Aims: This study aimed to explore macrophage pyroptosis in aGVHD and investigate the therapeutic effects of pyroptosis inhibitors on aGVHD.
Methods: Macrophages and $CD4^+$ T cells were isolated from the bone marrow and spleens of C57 mice. Morphological analysis was performed by scanning electron microscopy. The expression of GSDMD was assessed by RT-PCR and WB. Cell death was measured by flow cytometry, Hoechst 33342/PI staining and lactate dehydrogenase (LDH) release assays. Inflammatory factors were tested by ELISA and immunohistochemistry. The subgroup of $CD4^+$ T cells was analysed by flow cytometry. The pyroptosis inhibitor disulfiram was administered to the GVHD mouse model to observe its therapeutic effect.
Results: Scanning electron microscopy images showed the formation of membrane pores in the peritoneal macrophages of aGVHD mice. Additionally, more PI positivity and more LDH release were observed in peritoneal macrophages in aGVHD mice. The expression of GSDMD was elevated in the macrophages of aGVHD mice. IL-1β and IL-18 were increased in both serum and target tissues in aGVHD mice. Additionally, elevated levels of IL-1β and IL-18 were observed in the serum of aGVHD patients. These results indicated that macrophages in aGVHD underwent pyroptosis.
Because $CD4^+$ T cells play a critical role in the pathogenesis of aGVHD, we investigated the effect of macrophage pyroptosis on $CD4^+$ T cells. In vitro, macrophage pyroptosis increased the proportion of $CD69^+$, Th1 and Th17 cells in $CD4^+$ T cells, suggesting that macrophage pyroptosis might be involved in the development of aGVHD.
Administration of the pyroptosis inhibitor disulfiram into aGVHD model mice markedly improved the survival of the mice and attenuated the clinical and histopathological scores. Peritoneal macrophages that were PI positive and GSDMD in macrophages of target tissues were decreased in aGVHD mice. IL-1β and IL-18 levels were also decreased in both serum and target tissues in aGVHD mice. Furthermore, disulfiram reduced the proportions of $CD69^+$, Th1 and Th17 cells among $CD4^+$ cells in the spleen of aGVHD mice. These results revealed that macrophage pyroptosis could be a potential therapeutic target in aGVHD and that the pyroptosis inhibitor disulfiram could alleviate aGVHD by inhibiting macrophage pyroptosis.
Summary/Conclusion: Our results firstly demonstrated that macrophage pyroptosis plays a crucial role in the pathogenesis of aGVHD by promoting the activation and differentiation of $CD4^+$ T cells. The pyroptosis inhibitor disulfiram markedly improved the survival and reduced the severity of aGVHD in mice. Macrophage pyroptosis may be a novel supplement to the pathological mechanism in aGVHD and provides a potential therapeutic target for aGVHD.



S232 DISEASE RISK IN TP53 MUTANT ACUTE MYELOID LEUKAEMIA FOLLOWING AN ALLOGENEIC STEM CELL TRANSPLANT IS DEPENDENT ON THE PRESENCE OF CO-EXISTING CYTOGENETIC FEATURES: A REPORT FROM THE ALWP OF THE EBMT

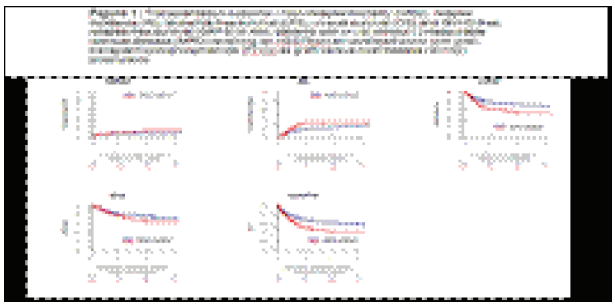
Background: TP53 mutations in patients (pts) with acute myeloid leukaemia (AML) has been associated with an unfavourable outcome including after allogeneic stem cell transplantation (allo-SCT). This has led some to question the benefit of allo-SCT for TP53 mutant AML, although it has not been studied in a large patient cohort.
Aims: To identify factors which influence transplant outcome in pts with mutant TP53 AML.
Methods: We identified pts with AML in first complete remission, and with either intermediate or adverse risk cytogenetics, whose TP53 mutation status was reported to the EBMT registry. All ages, conditioning intensity or donor source were included.
Results: We identified 179 pts with AML with TP53 mutations and compared their characteristics and outcomes to 601 pts with AML without TP53 mutations. Pts were transplanted between 2015-2019. Chromosomal losses in chromosomes 17p (31% vs. 3%), 5q (49% vs. 5%), and 7q (34% vs. 8%) as well as complex (65% vs. 12%) and monosomal karyotypes (41% vs. 8%) were significantly increased in the cohort of pts with mutated TP53, in contrast to those with unmutated TP53.
The overall survival (OS) at 2 years was significantly impaired in pts with mutated TP53 as compared to the cohort without (mutated TP53, 35.1% [95% CI: 26.7-43.7]; without TP53 mutations, 64% [95% CI: 59.1-68.4], p= 0.001). This was a result of an increased cumulative incidence of relapse (CIR) at 2 years in pts with mutated TP53 as compared to the cohort without mutated TP53 (mutated TP53, 55% [95% CI: 45.2-63.8]; without TP53 mutations, 25.2% [95%CI: 21.2-29.3], p= 0.001). The adverse prognostic impact of TP53 mutations on OS (HR=1.5, 95%CI 1.1-2.1) and CIR (HR=1.4, 95%CI: 1.2-1.9) was maintained in a multivariate model that accounted for the adverse prognostic value of other known cytogenetic, and transplant, variables.
In pts with mutated TP53 AML, differences in conditioning intensity, donor source and GVHD prophylaxis strategy did not significantly affect OS or CIR. However, in pts with TP53 mutant AML the presence of either 17p abnormalities (abn17p) or complex karyotype (CK) provided further prognostic value. In pts with mutated TP53 AML without abn17p or CK, the 2-year OS was 65.2% [95%CI: 48.4-77.6]; in comparison, in pts with mutated TP53 AML with either abn17p or CK, the OS was significantly lower (24.6% [95%CI: 16.2-34], p=0.001) (figure). In a multivariate analysis the additive poor prognostic effect of abn17p and CK on the OS of pts with mutated TP53 AML was maintained. In pts with mutant TP53 AML with either abn17p or CK, the leukaemia free survival (LFS) at 2 years was 15.2% ([95% CI: 8-24.6], p=0.001), which was lower than that in pts with mutated TP53 AML, but without abn17p or CK, (LFS: 59.9% [95%CI: 41.7-74.1]). In pts with mutant TP53 AML with either abn17p or CK, the CIR was 65.4% ([95% CI: 53.9-74.8], p=0.001), which was higher than that in pts with mutated TP53 AML, but without abn17p or CK, (CIR: 27.5% [95% CI: 13.4-43.7]) (figure).

Summary/Conclusion: The adverse prognostic effect of TP53 mutations in AML is only evident in pts with co-occurring abn17p or CK. Even in pts with mutated TP53 AML and a co-occurring abn17p or CK, a significant proportion of pts achieved long-term survival. Our data is practice changing and assists in the identification of pts who stand to benefit from an allo-SCT. Finally, the enrichment of abn17p in pts with TP53 mutations, and their additional poor prognostic implication, supports the biological importance of biallelic loss of TP53 activity in AML.



S233 THE ROLE OF PRE -TRANSPLANTATION MEASURABLE RESIDUAL DISEASE (MRD) IN PATIENTS WITH AML IN REMISSION TRANSPLANTED FROM UNRELATED DONORS WITH POST TRANSPLANT CYCLOPHOSPHAMIDE: FROM THE ALWP OF THE EBMT

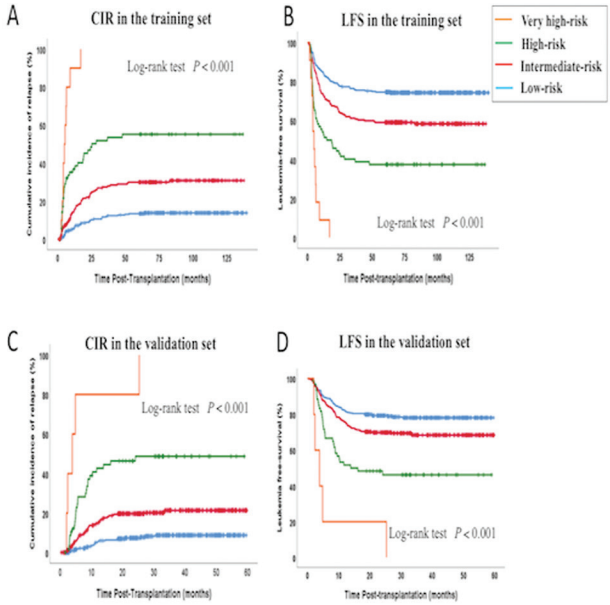
Background: GVHD prophylaxis may affect the transplant (HSCT) mediated graft-versus-leukemia (GVL) effect and post- HSCT relapse (RI). Pre-transplant measurable residual disease (MRD) predicts RI and outcome of HSCT with calcineurin based anti GVHD prophylaxis. Post-transplant cyclophosphamide (PTCy) has changed immune reconstitution post-transplant, upregulating T regulatory (Treg) cells while ablating recipient proliferating NK cells. It is therefore conceivable that MRD prediction of RI post-HSCT with PTCy will be different.
Aims: Study aim was *to assess the prognostic* impact of pre-HSCT MRD in adult patients (pts), aged ≥18 y with AML in CR undergoing HSCT from a 9-10/10 unrelated donor (MUD) with PTCy, in 2010-2019.
Methods: Multivariate analysis (MVA) adjusting for potential confounding factors was performed using a Cox's proportional-hazards regression model for main outcomes.
Results: 290 pts were included: MRD^- -189, MRD^+ -101. Median F/U was 17.7 (13.8-23.8) and 21.6 (16.8-26.5) months (p=0.61). Median age was 46.7 (18-74) and 50 (18-72) y, (p=0.018). 55% and 63.4% were male (p=0.77), 44.4% and 50.5% were classified as intermediate cytogenetic risk, while 15.3% and 18.8%, and 11.6% and 15.8% were classified as adverse and favorable risk cytogenetics, respectively (p=0.069). Pre-MUD disease status was CR1 in 76.2% and 80.2%, and CR2 in 23.8% and 19.8% of the pts, respectively (p=0.44). 45% and 43.1% of the pts harbored the FLT3+ mutation (p=0.83), (missing in ~50%). Conditioning was myeloablative in 64% and 59.4% (p=0.44). In vivo T-cell depletion was used in 28.6% and 18.8% of transplants (p=0.068). Graft was peripheral blood in 92.6% and 91.1% of transplants

(p=0.65). Karnofsky performance score was ≥ 90 in 80.6% and 75.5% of pts (p=0.31).
In MRD⁻ and MRD⁺ pts, engraftment was achieved by 97.4% and 97%, respectively. Day 180 incidence of acute (a) GVHD II-IV and III-IV was 28.1% and 25.6% (p=0.67), and 8.2% and 12.3% (p=0.28), respectively, and 2-y total and extensive chronic (c) GVHD was 27.2% and 31.8 % (p=0.6), and 5.9% and 17.6 % (p=0.03). The 2-y NRM was 8.2% and 13.9% (p=0.32). The 2-y RI was significantly lower in MRD- vs MRD+ pts: 20.4% vs 32%, respectively (HR=1.87; 95% CI: 1.12-3.14; p=0.02)") and it was the main cause of death in 35.9% and 50% of pts who died. The 2-y LFS and GRFS was significantly better in MRD⁻ vs MRD⁺ pts being 71.4% vs 51.4%, and 61.3% vs 40.2% (p=0.021 and p=0.01), respectively, while OS did not differ being 76.1% and 65.8%, respectively (p=0.2). These results were confirmed by MVA: RI was significantly lower while LFS and GRFS were significantly higher in MRD⁻ vs MRD⁺ pts: hazard ratio (HR)=1.87 (95% CI 1.12-3.14, p<0.02), HR=1.59 (95% CI 1.02-2.45, p<0.04) and HR=1.69 (95% CI 1.16-2.47, p< 0.01), respectively. NRM and OS were similar between the groups: H=1.07 (95% CI 0.47-2.43, p=0.88) and HR=1.2 (95% CI 0.73-1.95, p=0.48), respectively. Risk of aGVHD II-IV and total cGVHD was also similar, HR=0.89 (95% CI 0.55-1.45, p=0.63), and HR=1.61 (95% CI 0.94-2.77, p=0.08), respectively.



Summary/Conclusion: In AML pts undergoing HSCT from a 9-10/10 MUD in CR with PTCy as GVHD prophylaxis, pre-transplant MRD negativity predicted transplantation outcome correlating with lower relapse rate and better LFS and GRFS, similar to previous reports using conventional GVHD prophylaxis. These findings may indicate that PTCy does not jeopardize the transplant mediated GVL effect and the importance of the pre-HSCT remission depth, despite the PTCy mediated NK inhibitory and Treg cell potentiating activity leading to a lower incidence of cGVHD

S234 AN INTEGRATIVE SCORING SYSTEM MAINLY BASED ON QUANTITATIVE DYNAMICS OF MINIMAL/MEASURABLE RESIDUAL DISEASE FOR RELAPSE PREDICTION IN PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

R. Ma [1,*], L. -P. Xu [1], X. -H. Zhang [1], Y. Wang [1], H. Chen [1], Y. -H. Chen [1], F. -R. Wang [1], W. Han [1], Y. -Q. Sun [1], C. -H. Yan [1], F. -F. Tang [1], X. -D. Mo [1,2], Y. -R. Liu [1], K. -Y. Liu [1], X. -J. Huang [1,2,3], Y. -J. Chang [1]

[1]Peking University People's Hospital and Peking University Institute of Hematology, National Clinical Research Center for Hematologic Disease, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [2]Research Unit of Key Technique for Diagnosis and Treatments of Hematologic Malignancies, Chinese Academy of Medical Sciences, [3]Peking-Tsinghua Center for Life Sciences, Beijing, China

Background: Leukemia relapse remains one of the main causes of mortality in acute lymphoblastic leukemia (ALL) patients after allogeneic hematopoietic stem cell transplantation (HSCT). The cumulative incidence of relapse (CIR) was strongly influenced by minimal/measurable residual disease (MRD) assessed at timepoints after or during induction therapy, after consolidation therapy, pre-HSCT and post-HSCT. Besides, other variables, such as the T cell lineage of ALL blasts and remission status after induction therapy or pre-HSCT, have been reported to be correlated with high CIR in those who received allo-HSCT. Consequently, it could be hypothesized that an integrative scoring system mainly based on the quantitative dynamics of MRD in combination with other variables could be more effective in distinguishing ALL cases into different CIR groups.
Aims: The aim of the study was to establish an integrative scoring system, which could provide better relapse risk determination for ALL patients.
Methods: In total, 1416 patients with ALL who underwent HLA-matched sibling donor transplantation (n=285) or haploidentical transplantation (n=1131) were enrolled in this study. A training (retrospective) group (n=651) and a validation (prospective) group (n=765) were included. Factors that were related to CIR were identified in the training group with a multivariate Cox model. A weighted risk score to each factor based on the hazard ratio (HR) from the regression analysis were assigned, and the prognostic score was then defined as the sum of single-risk parameters.
Results: In the training group, four risk groups -- low- (score = 0), intermediate- (score =1-2), high- (score =2.5-6) and very high-risk (score≥6.5) -- were stratified using the scoring system based on remission status before transplantation, immunophenotype, and quantitative dynamics of pretransplant- and posttransplant- minimal residual disease. The 3-year CIRs for the low-, intermediate-, high-, and very high-risk groups were 10.9%, 24.5%, 47.2%, and 90.0%, respectively (P<0.001). The c-statistic of this final model was 0.69. The risk score was confirmed for the 3-year leukemia-free survival (LFS, P<0.001; c=0.62) and overall survival (OS, P<0.001; c=0.63). In the validation group, the 3-year CIRs for the low-, intermediate-, high-, and very high-risk groups were 7.6%, 19.6%, 45.4%, and 100%, respectively (P<0.001, c=0.69). The risk score was confirmed for the 3-year LFS (P<0.001; c=0.59) and OS (P<0.001; c=0.57).

Summary/Conclusion: Our data indicate that the integrative scoring system can be used for outcome stratification in ALL patients received allografts.

Stem cell transplantation - GvHD

S235 IBRUTINIB VS PLACEBO IN COMBINATION WITH CORTICOSTEROIDS IN PATIENTS WITH NEW-ONSET CHRONIC GRAFT-VERSUS-HOST DISEASE (CGVHD): RESULTS FROM THE RANDOMIZED, DOUBLE-BLIND PHASE 3 INTEGRATE STUDY

Background: Approximately 34% of patients (pts) who develop cGVHD after hematopoietic cell transplant require systemic treatment. Many pts experience recurrent cGVHD or become refractory to standard of care first-line corticosteroids. Ibrutinib (ibr) has demonstrated sustained efficacy and safety in cGVHD and is currently the only therapy approved in the United States for adults with cGVHD after failure of ≥1 line of systemic therapy.
Aims: We present the efficacy and safety results from the randomized, double-blind, placebo-controlled phase 3 iNTEGRATE study (PCYC-1140; NCT02959944) of ibr plus corticosteroids in previously untreated pts with cGVHD.
Methods: Eligible pts (aged ≥12 y) had newly diagnosed moderate/severe cGVHD, required systemic corticosteroid therapy, and had no prior systemic treatment for cGVHD. Pts were randomized 1:1 to receive ibr 420 mg/d or placebo (pbo) in combination with prednisone (pred) starting at 1 mg/kg/d. The primary endpoint was response rate (complete or partial response) at 48 wks per the 2014 NIH Consensus Development Project Criteria. Other endpoints included event-free survival (EFS; ie, survival without cGVHD progression, malignancy relapse, or start of subsequent cGVHD therapy), duration of response (DOR), time to withdrawal of corticosteroids and immunosuppressants (except ibr/pbo), improvement of Lee cGVHD Symptom Scale score, overall survival (OS), and safety.
Results: In total, 95 pts received ibr-pred and 98 received pbo-pred. Baseline pt characteristics were well balanced between treatment arms. Median time on treatment was 5.4 mo and 6.4 mo for ibr-pred and pbo-pred arms, respectively; median follow-up was 25 mo for both arms. At the time of the primary analysis, 41% (39/95) of pts treated with ibr-pred had a response at 48 wk vs 37% (36/98) of pts receiving pbo-pred (p=0.54). Though the primary endpoint of the study was not statistically significant, ibr-pred resulted in clinically meaningful improvements in several other key endpoints, prompting evaluation of these endpoints with a longer follow up (reported p-values are nominal). With extended follow up, median DOR was 16 mo with ibr-pred vs 10 mo with pbo-pred (p=0.12). Median EFS was 15 mo with ibr-pred and 8 mo with pbo-pred (hazard ratio 0.75 [95% CI: 0.53-1.1]; p=0.1; **Figure**). 48% vs 39% (p=0.15) of pts receiving ibr-pred vs pbo-pred withdrew corticosteroids, and 38% vs 28% (p=0.08) withdrew immunosuppressants. 40% of pts in the ibr-pred arm experienced an improvement in overall Lee cGVHD Symptom Scale score vs 29% in the pbo-pred arm (p=0.09). Median OS was not reached in either arm; 22% (21/95) of pts in the ibr-pred arm and 19% (19/98) in the pbo-pred arm died from any cause. 49% (46/94) of pts in the ibr-pred arm and 46% (44/96) in the pbo-pred arm experienced a grade ≥3 serious adverse event (AE); 22% (21/94) and 25% (24/96), respectively, experienced an AE leading to discontinuation of study drug.

Figure. EFS with ibr-pred vs pbo-pred in pts with moderate/severe cGVHD.

Summary/Conclusion: In this randomized, pbo-controlled trial of ibr in combination with corticosteroids for NIH-defined moderate/severe cGVHD, the primary endpoint did not meet statistical significance. However, numerical trends of improved clinical outcomes in the ibr-pred arm were noted, including longer DOR and EFS and improved patient-reported outcomes. Safety was consistent with the known profiles of ibr and pred and was similar between treatment arms. The positive trends observed in other important clinical endpoints along with no additional safety trends and concerns suggest that ibr may have value in some previously untreated pts with cGVHD.

S236 EFFICACY AND SAFETY OF RUXOLITINIB IN PATIENTS WITH STEROID-REFRACTORY ACUTE GRAFT-VS-HOST DISEASE AFTER CROSSOVER IN THE PHASE 3 REACH2 STUDY

J. Szer [1,*], J. Butler [2], E. Forcade [3], G. Grillo [4], D. Ritchie [1], N. von Bubnoff [5], M. Mohty [6], G. Socié [7], R. Zeiser [8], J. Xu [9], B. Mahuzier [10], J. Morando [9], D. Niederwieser [11]

Background: Historically, the long-term prognosis has been poor in patients (pts) with acute graft-vs-host disease (aGVHD) who fail initial treatment with steroids. REACH2 (NCT02913261; N=309) is a randomized, phase 3 trial investigating the efficacy and safety of the Janus kinase (JAK) 1/JAK2 inhibitor ruxolitinib (RUX) vs best available therapy (BAT) in pts with steroid-refractory (SR) aGVHD. Pts treated with RUX had a significantly higher overall response rate (ORR) at day 28 (primary endpoint) than pts treated with BAT (62.3%; complete response [CR], 34.4%; partial response [PR], 27.9% vs 39.4% [CR, 19.4%; PR, 20.0%]; P<0.001). Durable ORR at day 56 (key secondary endpoint) was also significantly higher with RUX (39.6% vs 21.9%; P<0.001). Pts randomized to BAT could cross over to RUX after day 28. We report safety and efficacy findings from the crossover group in REACH2.
Aims: To evaluate the efficacy and safety of RUX in pts who crossed over from BAT.
Methods: 309 pts aged ≥12 years diagnosed with grade II-IV SR aGVHD were randomized 1:1 to receive RUX 10 mg bid (n=154) or investigator-selected BAT (n=155). All pts provided written informed consent. After day 28, pts in the BAT arm who did not meet the primary endpoint or lost response could cross over to RUX up to week 24.
Results: Overall, 49 pts (31.6%) crossed over to RUX treatment (data cutoff, January 6, 2020). At baseline, the median age in the crossover group was 54 years (range, 13-71 years) and 53.1% of pts were male; 38.8% and 61.2% of pts had grade II and grade III/IV disease, respectively. Overall, ATG (20.4%) and etanercept (20.4%) were the most common BATs; 12 pts (24.5%) were treated with ≥2 BATs. The median time to crossover was 34 days (range, 28-162 days). At data cutoff, 11 pts (22.4%) had completed the crossover treatment period (treatment up to crossover day 56), and 2 were still receiving RUX. 36 crossover pts (73.5%) discontinued RUX treatment, with the most common reasons for discontinuation being adverse events (AEs; 24.5%), death (16.3%), and lack of efficacy (12.2%). A total of 27 crossover pts (55.1%) entered long-term follow-up.
The ORR at day 28 after crossover was 67.3% (CR, 46.9%; PR, 20.4%; 95% CI, 52.5%–80.1%), and the durable ORR at day 56 after crossover was 42.9% (95% CI, 28.8%–57.8%), both consistent with observations in the RUX arm at the primary analysis (Table). The mean EQ-5D-5L health rating improved in pts who crossed over to RUX (crossover baseline, 51.5; crossover week 24, 80.2).
After crossover, the median duration of treatment with RUX was 61.0 days (range, 2.0-383.0 days). Most pts (93.9%) received RUX 20 mg daily. All 49 pts had a dose change, with 63.3% having a dose interruption; 61.2% had a dose change or interruption due to AEs. Dose re-escalation occurred in 38.8% of pts. The safety profile of RUX after crossover from BAT was consistent with that in the RUX arm, with the most common AEs (≥20%) being anemia (30.6%; grade ≥3, 18.4%), thrombocytopenia (30.6%; 26.5%), hypokalemia (22.4%; 8.2%), and neutropenia (20.4%; 20.4%). There were 19 deaths (38.8%), mainly due to aGVHD (n=8).

Table. Overview of Efficacy in the Ruxolitinib Arm, BAT Arm, and Crossover Group in REACH2

Endpoint, n (%)	RUX (n=154)	BAT (n=155)	Crossover group (n=49)
ORR at day 28	96 (**62.3**)	61 (**39.4**)	33 (**67.3**)
Complete response	53 (34.4)	30 (19.4)	23 (46.9%)
Partial response	43 (27.9)	31 (20.0)	10 (20.4%)
Durable ORR at day 56	61 (**39.6**)	34 (**21.9**)	21 (**42.9**)
Complete response	41 (26.6)	25 (16.1)	19 (38.8)
Partial response	20 (13.0)	9 (5.8)	2 (4.1)

Summary/Conclusion: RUX led to high response rates in pts who crossed over from BAT to RUX. ORR and durable ORR were consistent with those seen with RUX during the randomized period. No new safety signals were observed in crossover pts. These findings support the use of RUX in pts with SR aGVHD who failed treatment with other systemic therapies.

S237 A PHASE 1 TRIAL OF THE HEDGEHOG SIGNALLING INHIBITOR GLASDEGIB IN PATIENTS WITH REFRACTORY SCLEROTIC CHRONIC GRAFT-VERSUS-HOST DISEASE

E. Rodríguez-Arbolí [1,*], T. Caballero-Velázquez [1], C. García-Calderón [1], C. Martínez [2], M. A. Bermúdez-Rodríguez [3], L. López-Corral [4], A. Triguero [2], L. Yáñez [3], C. Hidalgo-Calleja [5], J. L. Reguera-Ortega [1], N. Rodríguez-Torres [1], N. Martínez-Cibrián [1], J. A. Pérez-Simón [1]

[1]Department of Hematology, Hospital Universitario Virgen del Rocío, Instituto de Biomedicina de Sevilla (IBIS/CSIC/CIBERONC), University of Seville, Seville, [2]Hematopoietic Stem Cell Transplantation, Hematology Department, Institute of Hematology-Oncology, August Pi i Sunyer Biomedical Research Institute (IDIBAPS), Institute Josep Carreras, Hospital Clínic, Barcelona, [3]Hematology Department, Hospital Universitario Marqués de Valdecilla, Cantabria University, Santander, [4]Hematology Department, Complejo Asistencial Universitario de Salamanca-IBSAL, Centro de Investigación del Cáncer-IBMCC, [5]Rheumatology Department, Complejo Asistencial Universitario de Salamanca-IBSAL, Salamanca, Spain

Background: Sclerotic chronic graft-versus-host disease (scGVHD) represents a distinctive phenotypic variant of GVHD that is characterized by dermal fibrosis, often resulting in severe morbidity. scGVHD is associated with high rates of steroid refractoriness, and therapeutic options in this setting remain limited. Aberrant hedgehog signaling is prominent in scGVHD, leading to the activation of dermal fibroblasts. Targeted inhibition of the pathway ameliorates scGVHD features in experimental models.
Aims: This investigator-led study (NCT03415867) evaluated the safety profile and preliminary efficacy of glasdegib, an oral antagonist of the hedgehog signalling transducer Smoothened (SMO), in adult patients (pts) with active scGVHD after ≥2 lines of prior therapy.
Methods: The trial followed a standard 3 + 3 escalation dose-finding design. Glasdegib was administered once daily (OD) in continuous 28-day cycles. Treatment could be continued beyond Cycle 12 in pts obtaining objective clinical benefit. The primary endpoints of the study were dose-limiting toxicity (DLT) and maximum tolerated dose (MTD). Secondary endpoints included safety, efficacy, PK/PD and immune correlative studies. Responses were assessed per 2014 NIH cGVHD criteria. Additionally, a modified skin/joint partial response category (mPR) was defined as a NIH cGVHD global severity score decrease ≥2 points in the presence of any significant skin/joint scoring improvement (≥1 point for body surface area, skin features or joints/fascia scores; ≥2 points for skin/joint tightening or P-ROM scores). Data cut-off was at the end of Cycle 12.
Results: Twenty pts have been included in the primary analysis. An additional non-DLT-evaluable pt was replaced early after enrolment in Cohort 1 due to a treatment-unrelated cerebrovascular ischemic event. Median age was 47 years (range 27-72). Enrolled pts had failed a median of 4 prior lines of therapy (range 2-10), 50% having received treatment with ruxolitinib. Three pts were included in Cohort 1 (50 mg OD), 3 in Cohort 2 (100 mg OD) and 16 in the expansion cohort (50 mg OD). Two pts in Cohort 2 experienced a DLT (grade [G] 3 muscle cramps), the MTD being thus established at 50 mg OD. Frequent treatment-emergent G≥2 adverse events (AEs) included muscle cramps (85%), alopecia (40%) and dysgeusia (35%). Two pts developed G3 and G4 treatment-related creatine kinase elevations that required interruption of glasdegib but did not result in study discontinuation. Five pts withdrew from the study as a result of treatment-related AEs, and 10 pts required dose adjustments while on treatment. Ten pts remained on the study at the end of Cycle 12. At the data cut-off, 12 (60%) pts had achieved a NIH global severity score PR, 12 (60%) a joints/fascia response (11 PR, 1 CR) and 3 (15%) a skin PR. An improvement ≥2 points in skin/joint tightening and P-ROM scores was observed in 13 (65%) and 11 (55%) pts, respectively. Overall, 12 (60%) pts obtained a skin/joint mPR, with a median time of 3 months to response and a duration ≥6 months in 7 (35%) pts.
In preliminary analyses, treatment with glasdegib was not associated with significant changes in the distribution of T-cell compartments or TCR diversity.

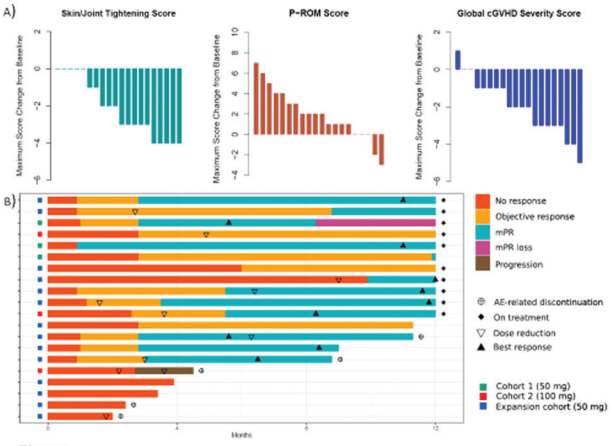

Figure 1.
A) NIH skin/joint tightening, P-ROM and global cGVHD severity scores waterfall plots.
B) Swimmer plot showing treatment courses and clinical outcomes.

Summary/Conclusion: Low doses of glasdegib demonstrate high rates of clinical responses in heavily pretreated pts with scGVHD, resulting in durable responses in one-third of the pts. Treatment schedule adjustments may be required in order to optimise tolerability.

S238 INTERIM RESULTS FROM THE EQUATE STUDY: PRELIMINARY SAFETY AND EFFICACY OF ITOLIZUMAB, A NOVEL TARGETED ANTI-CD6 THERAPY, NEWLY DIAGNOSED ACUTE GRAFT-VERSUS-HOST DISEASE

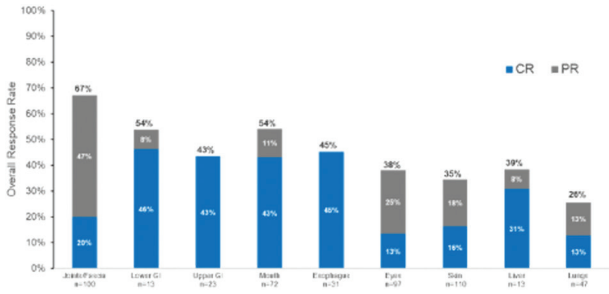
Background: CD6 is a co-stimulatory receptor predominantly expressed on T cells. $CD6^{high}$ CD4+ T cells were recently shown to drive Th1/Th17 immune responses in inflammatory bowel disease and may have a similar role in acute graft-versus-host disease (aGHVD). The CD6 ligand, activated leukocyte cell adhesion molecule (ALCAM), is expressed on antigen presenting cells, as well as epithelial and endothelial cells of aGVHD target organs (e.g. skin, GI tract). Previous studies in patients receiving allogeneic hematopoietic cell transplants showed that ex vivo depletion of donor CD6+ T cells lowered the incidence of aGVHD, providing a rationale for therapeutically targeting CD6 in aGVHD. Itolizumab is a humanized IgG1 monoclonal antibody that binds CD6 and blocks interaction with ALCAM to inhibit T cell activity and trafficking that is being evaluated as treatment for aGVHD.
Aims: Here we present interim study results from the Primary Cohort of EQUATE, an ongoing US-based Phase 1b/2 study of itolizumab in combination with steroids for newly diagnosed aGVHD.
Methods: Phase 1b is an open-label, dose-escalation study evaluating doses from 0.4 to 2.4 mg/kg (IV Q2 weeks through Day 57). The Primary Cohort enrolled patients with Grade III-IV aGVHD that received itolizumab within 72 hours of first steroid dose. The Expansion Cohort also

includes subjects with Grade II aGVHD and an Ann Arbor [AA] Score of 2 or 3 and who received itolizumab within 7 days of first steroid dose.
Results: A total of 10 subjects in the Primary Cohort have completed treatment through Day 85: 0.4 mg/kg (n=4), 0.8 mg/kg (n=3), and 1.6 mg/kg (n=3). Baseline characteristics were mean age of 48, 90% male, 90% white, 80% with peripheral blood graft source, 80% with HLA matched donor, mean time to GVHD onset of 43 days, and 100% with GI involvement. Mean MAGIC algorithm probability (MAP) was 0.468, and 70% had an AA score of 3. One subject in the 0.4 mg/kg cohort received only one itolizumab dose, whereas all other subjects received 2-5 doses.
Across all doses, the overall response rate (ORR) was 80% at Day 29, with 70% of subjects experiencing a complete response (CR) and 10% experiencing a very good partial response (VGPR). ORR was 70% at Day 85 with 100% of responders experiencing CR (Fig 1B). Response was consistent through Day 169. MAP scores also decreased through Day 85 with a median % decrease from baseline of 18%. At Day 85, median % steroid dose reduction was 89%. Itolizumab dose-dependently decreased CD6 levels on T cells within 24 hours of first dose, which was maintained throughout the treatment period, with a more pronounced effect in the 0.8 and 1.6 mg/kg (Fig 1C).
Safety profile is consistent with that of itolizumab observed to date across other trials and with adverse events (AEs) common in this patient population. All subjects experienced at least 1 AE. Most AEs were mild to moderate in severity. One mild infusion reaction AE was noted. Serious AEs were noted in 5 subjects, including recurrent gut GVHD (n=1), sepsis (n=2; 1 was considered a DLT) and fever (n=1), COVID-19 (n=1) and nocardiosis (n=1), physical deconditioning (n=1), and atrial flutter (n=1). There was one death reported due to an SAE of intestinal infarction deemed not related to study drug. Another death occurred >100 days post dose due to progressive aGVHD and was also not related to study drug.

Figure 1. Itolizumab in aGVHD

A. The expression levels of CD6 are increased on T_{eff} cells (such as Th1, Th2 and Th17 cells) and are associated with autoreactivity and pathogenic phenotype. Itolizumab reduces CD6 expression, and low CD6 expression is associated with a low inflammation, non-pathogenic phenotype. B. Response to itolizumab was observed as early as Day 15 and was sustained at the 2 higher doses through Day 85 CR, complete response; VGPR, very good partial response based on Martin Consensus 2009 Criteria; PR, partial response; NR, no response; PD, progressive disease. C. Cell surface CD6 levels on CD4 and CD8 T cells (based on mean fluorescence intensity) of subjects are presented as % of baseline. Itolizumab dose-dependently reduced the surface levels of CD6 on CD4+ and CD8+ cells by 24 hours following the first dose. CD6 trended toward baseline levels by Day 15 (pre 2nd dose) at the lowest dose of itolizumab (0.4 mg/kg) but not at the 2 higher doses (0.8 and 1.6 mg/kg).



Summary/Conclusion: In summary, the safety and efficacy observed to date and benefit-risk profile support continued study and evaluation in future randomized controlled trials.

S239 BELUMOSUDIL FOR CHRONIC GRAFT-VERSUS HOST DISEASE AFTER 2 OR MORE PRIOR LINES OF THERAPY: THE ROCKSTAR STUDY (KD025-213)

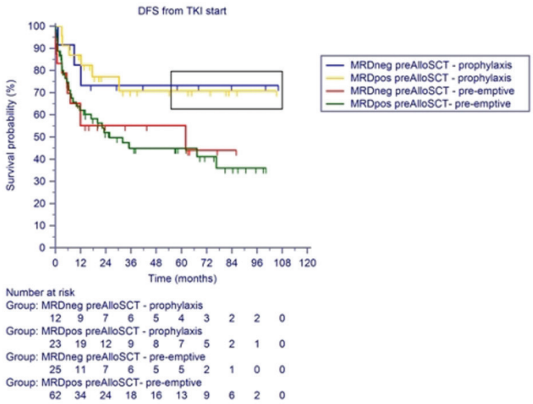
C. Cutler [1,*], S. Lee [2], S. Arai [3], M. Rotta [4], B. Zoghi [5], A. Lazaryan [6], A. Ramakrishnan [7], Z. DeFilipp [8], M. Jagasia [9], B. Blazar [10], S. Pavletic [11], D. Eiznhamer [12], H. Waksal [13], J. Ryan [13]

[1]Hematology Oncology, Dana Farber Cancer Institute, Boston, [2]Fred Hutchison Cancer Center, Seattle, [3]Stanford Medical Center, Stanford, [4]Colorado Blood Cancer Institute, Denver, [5]Texas Transplant Specialists, San Antonio, [6]Moffitt Cancer Center, Tampa, [7]Texas Transplant Institute, San Antonio, [8]Massachusetts General Hospital and Harvard Medical School, Boston, [9]Prior Affiliation: Vanderbilt-Ingram Cancer Center, Nashville, [10]University of Minnesota, Minneapolis, [11]National Cancer Institute, Bethesda, [12]Kadmon Corporation LLC, [13]Kadmon Corporation, LLC, New York, United States

Background: Belumosudil (KD025) is a novel oral selective rho-associated coiled-coil kinase 2 (ROCK2) inhibitor specifically designed for the treatment of cGVHD, an immune-mediated inflammatory and fibrotic disorder.
Aims: In a previous dose-finding study (KD025-208, N=54), two-thirds of patients achieved a partial or complete response with belumosudil. Herein, we report 12 month updated results from the pivotal randomized phase 2 trial (ROCKstar [KD025-213], N=132).
Methods: We randomly assigned cGVHD patients (pts) after 2-5 prior lines of therapy (LOT) to belumosudil 200mg QD (n=66), or belumosudil 200mg BID (n=66), across 28 sites, stratified according to cGVHD severity and prior ibrutinib use. The primary endpoint was the overall response rate (ORR) per 2014 NIH response criteria, assessed by investigators. Additional endpoints include duration of response, Failure-Free Survival (FFS), improvement in symptoms based on change in Lee symptom score (LSS) and corticosteroid (CS) dose reductions or discontinuations. Treatment was until clinically significant progression or unacceptable toxicity.
Results: Pooled baseline characteristics of the two arms revealed a median age of 56 (21-77); median prior LOT 3; median time from cGVHD diagnosis 29 mos (2-162); 67% with NIH defined severe cGVHD; 34% with prior ibrutinib use; 52% with ≥ 4 organ involvement; and 72% refractory to prior line of therapy
The ORR [95% CI] was 73% [60, 83] with belumosudil QD and 77% [65, 87] with belumosudil BID. Responses were consistent across key subgroups and complete responses were observed in all organ systems as shown in Figure 1. Furthermore, in patients with previous ibrutinib or ruxolitinib use, ORRs were 74% [59, 86] and 68% [51, 83], respectively. The median DOR was 50 weeks. FFS was 76% (68%>83%) at 6 months. Sixty percent pts reported a clinically meaningful improvement (≥7 point reduction) in LSS score. Corticosteroids were discontinued in 21% of patients.
Belumosudil was well tolerated, and AEs were consistent with those expected in this population. AEs (QD, BID) in >20% pts were fatigue (38%), diarrhea (33%), nausea (31%), cough (28%), upper respiratory infections (27%), dyspnea (25%), headache (24%), peripheral edema (23%), vomiting (21%) and muscle spasms (20%). At least 1 serious AE occurred in 38% of patients. Fourteen patients died during the study; 8 due to AEs (2 possibly related to belumosudil) and 6 during long term follow-up (>28 days after last dose). There was a report of 1 case of Epstein-Barr viremia, and 1 report of cytomegalovirus reactivation.

Summary/Conclusion: Treatment with belumosudil was well tolerated at both doses and resulted in high ORRs across key subgroups, meeting the primary end point of this pivotal randomized trial in cGVHD. Responses were durable and clinically meaningful, irrespective of patient and cGVHD characteristics and organ involvement.

Stem cell transplantation - Clinical



S240 PROPHYLACTIC OR PRE-EMPTIVE USE OF TYROSINE KINASE INHIBITORS POST-ALLOGENEIC STEM CELL TRANSPLANTATION IN BCR-ABL POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA: A SUBANALYSIS OF GITMO PH-POSITIVE ALL STUDY.

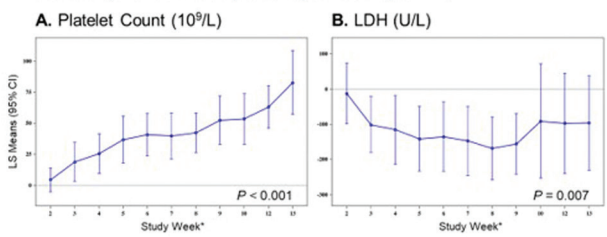
Background: The use of Tyrosine Kinase Inhibitors (TKIs) post-allogeneic hematopoietic stem cell transplant (post-Allo-SCT) is still heterogeneous and their preventive effect on relapse is not clearly established.
Aims: We performed a sub-analysis, focused on this aspect, of the recent published GITMO study (*Candoni et al, BBMT 2019-ClinicalTrials.gov NCT03821727*) that included 441 adult patients with Ph-pos ALL, all treated in the induction phase with TKIs± chemotherapy and undergoing Allo-SCT from 2005 to 2017.
Methods: Only cases in morphological complete remission (CcR) before Allo-SCT and receiving a TKI post-Allo-SCT were included in this analysis, regardless of the pre Allo-SCT Minimal Residual Disease (MRD) status (positive or negative). Patients who started TKIs post-Allo-SCT in a condition of cytological relapse were excluded from this study. MRD (BCR-ABL) was monitored monthly for the first 6 months post Allo-SCT and then every 2 months. TKIs were administered after Allo-SCT prophylactically (starting with MRD neg post-Allo-SCT) or pre-emptively (starting at the first MRD positivity post-SCT and without hematological relapse). The attempt of this analysis was to assess the strategy of use of TKIs post-Allo-SCT (prophylactic or pre-emptive) in patients transplanted while in CcR and to verify the probability of survival and leukemia free survival (OS and DFS) post Allo-SCT, based on TKI strategy adopted (prophylactic or pre-emptive) and according to the MRD status pre-Allo-SCT.
Results: We identified and analyzed 122 cases (85 MRD positive pre-Allo-SCT and 37 MRD negative) that met the inclusion criteria. A pre-emptive TKI strategy was adopted in 87/122-71% cases (25 with MRD neg pre-Allo-SCT) and a prophylactic strategy in 35/122-29% (12 with MRD neg pre-Allo-SCT). The 35 patients treated with TKIs prophylactically started treatment earlier, at a median of 2.97 months (range 0.57-14.17) from Allo-SCT, than the 87 patients treated pre-emptively, which started TKI at a median of 4.37 months (range 0.87-44.27) from Allo-SCT (p=0,01). In the cohort of the MRD pos pre-Allo-SCT, the cases treated pre-emptively had a significant higher percentage of cytological relapse (REL) post-Allo-SCT compared to the cases treated with TKIs prophylactically (cytologic relapse 37% vs 13%, p=0,03). The 5 yrs OS and DFS post Allo-SCT of patients who started TKI in prophylaxis were significantly better (OS 72% and DFS 72%) than those who started TKI in pre-emptive (OS 58% and DFS 47%) regardless of the status of pre-transplant MRD (p=0,008)-**FIGURE 1-DFS.**

Summary/Conclusion: The data obtained from this analysis in a homogeneous population of Ph-pos ALL who underwent Allo-SCT while in CcR, although with the caution of a retrospective study, support the prophylactic use of TKIs post-Allo-SCT as optimal maintenance strategy, resulting in a higher probability of DFS regardless of the MRD status pre-Allo-SCT.



S241 NARSOPLIMAB (OMS721) TREATMENT CONTRIBUTES TO IMPROVEMENTS IN ORGAN FUNCTION IN ADULT PATIENTS WITH HIGH-RISK TRANSPLANT-ASSOCIATED THROMBOTIC MICROANGIOPATHY

M. -A. Perales [1,*], M. Cairo [2], R. Duarte [3], S. Giralt [1], V. Ho [4], J. Laurence [5], N. Leung [6], O. Penack [7], A. Rambaldi [8], M. Scordo [1], N. Nangia [9], S. Whitaker [9]

[1]Memorial Sloan Kettering Cancer Center, New York, [2]New York Medical College, Valhalla, United States, [3]Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain, [4]Dana-Farber Cancer Institute, Boston, [5]Weill Cornell Medicine, New York, [6]Mayo Clinic, Rochester, United States, [7]Charité Universitätsmedizin Berlin, Berlin, Germany, [8]University of Milan and Azienda Socio Sanitaria Territoriale Papa Giovanni XXIII, Bergamo, Italy, [9]Omeros Corporation, Seattle, United States

Background: Transplant-associated thrombotic microangiopathy (TA-TMA) is a serious complication of hematopoietic stem cell transplantation that is associated with significant mortality and morbidity and for which there is currently no approved therapy. TA-TMA results from endothelial injury caused by conditioning regimens, immunosuppressants, infection, and GVHD, which in turn activates the lectin pathway of complement.
Aims: Narsoplimab, an inhibitor of mannan-binding lectin-associated serine protease-2 (MASP-2), the effector enzyme of the lectin pathway and an activator of the coagulation cascade, was studied for treatment of TA-TMA.
Methods: This was a single-arm open-label pivotal trial in adult TA-TMA patients (NCT02222545). All patients provided informed consent. Protocol-specified treatment consisted of IV narsoplimab 4 mg/kg or 370 mg once weekly for 4 or 8 weeks with a 6-week follow-up period. The FDA-agreed primary endpoint required clinical improvements in each of 2 categories: 1) laboratory markers of TMA (platelet count and LDH) *and* 2) organ function (kidney, pulmonary, gastrointestinal, or neurological) or freedom from transfusion (platelets and/or red blood cells). Secondary endpoints included change from baseline in platelet count, LDH, hemoglobin, and haptoglobin. Patients receiving at least 1 dose of narsoplimab (full analysis set [FAS]; N=28) and patients receiving the protocol-specified narsoplimab treatment of at least 4 once-weekly doses (per-protocol [PP]; N=23) were analyzed.
Results: Patients were at high risk for poor outcomes and had multiple comorbidities: kidney and neurological dysfunction were present in 75% (21/28) and 57% (16/28) of patients, respectively, at baseline. Patients received a range of 2–8 scheduled doses of narsoplimab (mean 6.3 doses) and median duration of treatment was 8 weeks. Narsoplimab treatment resulted in clinical response (achievement of the primary endpoint) in 61% (17/28) of the FAS and in 74% (17/23) of the PP population, based on improvements in both laboratory TMA markers and clinical status (organ function and transfusion burden). The time to hematological response (defined as time from first narsoplimab dose to time of achieving both platelet count and LDH primary endpoint criteria) was as early as 7 days (median 36 days) after start of treatment. There was a sustained improvement in platelet count and LDH change from baseline (**Figure 1**). Five patients never achieved platelet engraftment following transplant and were not included in the platelet count analysis. Improvements in kidney function, neurological function, or gastrointestinal function were observed in 67% (18/27), 50% (3/6), and 100% (1/1), respectively, in the FAS and 68% (15/22), 50% (3/6), and 100% (1/1), respectively, in the PP. No patients were evaluable for improvement in pulmonary function. Of patients who received transfusions at baseline, 48% (12/25) in the FAS and 55% (11/20) in the PP achieved freedom from platelet and red blood cell transfusion. Six patients died during the core study period: 1 of septic shock, 2 of progressive AML, 2 of neutropenic sepsis, and 1 of GVHD and TMA. These deaths occurred 3–42 days following the last narsoplimab dose.

Figure 1. Least Squares Means Change from Baseline for Laboratory TMA Markers (Full Analysis Set Population)

* No patient data were censored; all available data were included.
P-values from time-weighted average change from baseline using one-sample *t*-test.

Summary/Conclusion: In this high-risk patient population with TA-TMA, there were no safety concerns observed with narsoplimab, and treatment resulted in clinically meaningful improvements in laboratory markers of TMA and in organ function or freedom from transfusion.

S242 FLUDARABINE AND TBI 8 GY VERSUS FLUDARABINE AND TREOSULFAN CONDITIONING IN PATIENTS WITH AML IN FIRST COMPLETE REMISSION: A STUDY FROM THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

Background: Relapse remains the main cause of treatment failure after allogeneic stem cell transplantation (HSCT) for acute myeloid leukemia (AML) in first complete remission (CR1). The antileukemic activity of myeloablative conditioning is often counterbalanced by an age-dependent increase in non-relapse mortality (NRM). For AML patients >40 years, fludarabine plus a reduced dose of TBI (8Gy) (FluTBI) has yielded favorable long-term outcomes (CIR 30%, NRM 13%; Fasslrinner F et al., Lancet Haematology 2018). Similar data have been obtained with flu plus treosulfan (FT), which is being increasingly used due to its low NRM (Beelen DW et al., Lancet Haematology 2020).
Aims: As no direct comparison of these two conditioning regimens has yet been conducted, we assessed antileukemic activity and safety of FluTBI and FT (30, 36 or 42 mg/m^2) in patients with AML transplanted in CR1.
Methods: This retrospective analysis of data from the EBMT registry included 754 AML (617 FT, 137 FluTBI) patients aged >40 years who underwent a first HSCT in CR1 from 2009-2019. Allografts were from matched siblings (MSD) or 10/10 HLA-matched unrelated donors (MUD). Using propensity score matching, 115 FluTBI patients were pair-matched with 115 FT (exact matching for donor, sAML, adverse cytogenetics and nearest neighbor for age, time diagnosis-HSCT, female to male, Karnofsky performance score (KPS) and in vivo T cell depletion).
Results: Patient characteristics were well balanced in the FluTBI and FT groups with respect to age (median 55.2 [40.1-70.7] vs 54.9 [40.4-74.9] years, KPS <90% (22.6 vs 23.5%), sAML (13% each), adverse cytogenetics (15.7% each), female donor to male recipient (19.1% vs 17.4%) and time from diagnosis to HSCT (median 3.8 (range, 1.8-16.2) vs 4.5 (1.7-16.2) months). An identical proportion of patients in both groups received grafts from MSD (61.7%) and MUD (38.3%). Graft versus host disease (GVHD) prophylaxis was predominantly cyclosporine A (CSA) and methotrexate (85.2 vs 73.9%) or CSA and mycophenolate mofetil (8.7 vs 18.3%), respectively. Additional in vivo T cell depletion with ATG was given in 52.2% and 53.9% of patients, respectively. Median follow-up is 42.4 months (range, 31.5-53.8) in the FluTBI and 23.2 months (20.4-32.7) in the FT group (p=0.14). All but one patient in each group engrafted. FluTBI was associated with a significantly lower relapse incidence (CIR) of 18.3 vs 34.7%, p=0.018, HR 0.51 (95% CI, 0.29-0.89), but higher NRM of 16.8 vs 5.3%, p=0.02, HR 3.0 (1.19-7.59). Infection was the leading cause of death following FluTBI (n=12/38, 31.6%), followed by AML (10/26.3%), GVHD (6/15.7%), interstitial pneumonia (4/10.5%) and secondary malignancy (2/5.3%). In the FT group, 33 patients died, 15 from AML (45.5%), 7 from GVHD (21.2%), and 3 from infection or multiorgan failure (9.1% each), respectively. There was no statistically significant difference between FluTBI and FT in the CI of acute GVHD II-IV (22.8 vs 20.7%; HR 1.05), GVHD III-IV (6.2 vs 9.0%; HR 0.59), chronic GvHD (42.6 vs 47.5%; HR 0.81) or extensive chronic GVHD (16.8 vs 19.6%; HR 0.76). At 2 years, leukemia-free and overall survival were similar in the FluTBI and FT groups (64.9 vs 60.0%, HR 0.84 (0.54-1.31) and 66.9 vs 67.8%, HR 1.08 (0.67-1.75), respectively, with favorable GVHD-free and relapse-free survival in both groups (50.3 vs 45.6%; HR 0.83 [0.58-1.17]).
Summary/Conclusion: Outcomes in LFS, OS and GRFS did not differ between FluTBI and FT. Relapse was lower while NRM higher with FluTBI which may indicate a more intense conditioning.

S243 CMML PATIENTS UNDERGOING ALLOGENEIC HCT HAVE INFERIOR SURVIVAL OUTCOMES IN COMPARISON WITH MDS PATIENTS DUE TO A SIGNIFICANTLY HIGHER RELAPSE RATE. A REGISTRY STUDY OF THE EBMT-CMWP

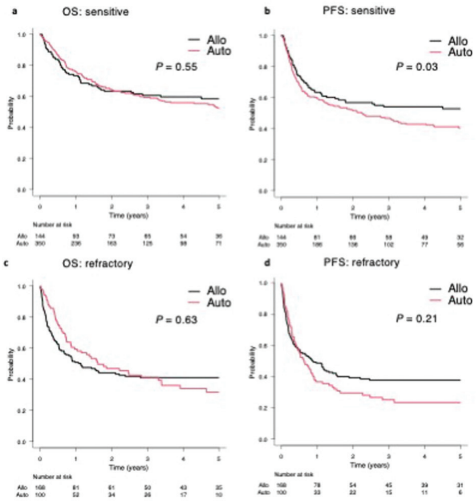
Background: The FAB Group originally classified CMML as a form of MDS. In 2001, the World Health Organization reclassified the disease as part of a newly created MDS/MPN overlap entity. Even though characterized by high mortality and relapse rates, allo-HCT remains the only curative treatment for both CMML and MDS.
Aims: In this retrospective registry study, we aimed to identify factors associated with allo-HCT outcomes in CMML, particularly focusing on age, and to compare them with MDS outcomes.
Methods: Patients ≥18 years old who underwent allo-HCT for CMML or MDS between 2010 and 2018 and who were reported to the EBMT registry were included in the analysis. Transformation to AML was an exclusion criterion. CMML outcomes were compared to those of the MDS population transplanted in the same period. Overall Survival (OS) and Relapse Free Survival (RFS) rates were estimated by Kaplan-Meier methods; relapse incidence (REL) and NRM were analyzed as competing risks. Adjusted (cause specific) hazard ratios (HR) were obtained using Cox proportional hazard models. Age was modeled as a continuous linear variable and using restricted cubic splines.
Results: There were 1,499 CMML patients with a median age of 60.4 (18.9-76.3) years and 69.4% were male. 27% had a Karnofsky status ≤80 and 23% of patients had a Sorror HCT-CI ≥3. 28% had HLA-identical sibling donors, 63% unrelated (MUD or MMUD) donors and 8.3% mismatched related donors. A RIC regimen was used in 62%. There were 12,745 MDS patients with a median age of 59.1 (18-79.7) years and 61.1% were male. Regarding Karnofsky scores, Sorror HCT-CI scores, donor types, conditioning regimens and the rates of primary graft failure, there were no clinically meaningful differences between the CMML and MDS groups. OS, RFS and REL rates, were significantly worse in CMML when compared to MDS (all p<0.0001) whereas NRM was not significantly different, p=0.87 (Figure 1). For CMML, the HR for age as a continuous variable at transplantation (adjusted for other confounders), for each 10-year increase of age, was 1.16 (1.06-1.28) for OS and 1.13 (1.04-1.23) for RFS. The HRs for REL and NRM were 1.06 (0.95-1.19) and 1.21 (1.06-1.37) for each 10-year increase in age, respectively. Age≥65 years in the adjusted model conferred a negative impact on OS, RFS and NRM. The same analysis for MDS shows similar results for each 10-year increase of age as those observed for CMML.

Summary/Conclusion: The comparison of OS, RFS and REL shows significantly worse outcomes in CMML compared to MDS, with no difference in NRM. As expected, age was associated with poorer outcomes in both diseases. Despite observing these significant differences in survival rates between CMML and MDS, we were not able to identify specific factors other than the diseases themselves. The poorer survival outcomes in CMML in comparison to MDS appear to be the consequence of the significantly higher rate of post-transplant relapse. Future research should focus on post-transplant strategies to improve disease control.



S244 AUTOLOGOUS OR ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION FOR PERIPHERAL T-CELL LYMPHOMA-NOT OTHERWISE SPECIFIED AND ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA FAILING FIRST-LINE THERAPY

Background: Management of the patients with peripheral T-cell lymphoma-not otherwise specified (PTCL-NOS) and angioimmunoblastic T-cell lymphoma (AITL) who failed first-line therapy is a difficult challenge. Salvage chemotherapy followed by autologous hematopoietic cell transplantation (auto-HCT) or allogeneic HCT (allo-HCT) represents the treatment of choice for appropriate candidates. However, there is no consensus on which type of HCT should be applied for such patients.
Aims: To evaluate the impact of auto- or allo-HCT on outcome in PTCL-NOS and AITL failing first-line therapy.
Methods: We performed a retrospective analysis using registry data from the Japan Society for Hematopoietic Cell Transplantation. Adult patients who underwent a first HCT after 2, 3, or 4 lines of therapy —which means first-line therapy failed for some reason— between 2006 and 2018 were included.
Results: A total of 762 patients with PTCL-NOS (n = 449) and AITL (n = 313) undergoing auto-HCT (n = 450) or allo-HCT (n = 312) as their first HCT were analyzed. Among them, 494 were chemo-sensitive (172 were first complete-remission, 112 were first partial-remission, and 210 were relapsed-sensitive) and 268 were chemo-refractory (142 were primary-refractory and 126 were relapsed-refractory). The allo-HCT recipients were more likely younger (median ages, 53 vs 58 years; $P < 0.001$), received more than 2 lines of therapy prior to HCT (63% vs 33%; $P < 0.001$), with higher HCT-comorbidity index ($P < 0.001$) and with worse performance status ($P < 0.001$) compared with the auto-HCT recipients. The time from the diagnosis to auto-HCT and allo-HCT were 11 months (range = 2-214) and 11 months (range = 2-154) ($P = 0.64$), respectively. The median follow-up duration for survivors of auto-HCT and allo-HCT were 36 months (range = 1-150) and 54 months (range = 3-160), respectively. For chemo-sensitive patients, the 4-year overall survival (OS) of auto-HCT and allo-HCT recipients were 56% (95% CI: 49.9-61.7) and 59.8% (95% CI: 50.8-67.8), and the 4-year progression-free survival (PFS) of both groups were 43% (95% CI: 37.2-48.6) and 54.2% (45.2-62.2), respectively (Figure). For chemo-refractory patients, the 4-year OS of auto-HCT and allo-HCT were 34.1% (95% CI: 23.5-44.9) and 41.1% (95% CI: 33.4-48.7), and 4-year PFS of both groups were 23.4% (95% CI: 14.9-33) and 37.8% (95% CI: 30.2-45.2), respectively (Figure). The 2-year non-relapse mortality of auto-HCT and allo-HCT recipients with chemo-sensitive disease were 9.7% (95% CI: 6.7-13.3) and 23.3% (95% CI: 16.6-30.7), while those with chemo-refractory disease were 9.7% (95% CI: 4.7-16.8) and 36.3% (95% CI: 29-43.7), respectively. In the multivariable cox analysis, allo-HCT was a significantly better prognostic factor for PFS in chemo-sensitive patients (hazard ratio [HR], 0.68; 95% CI: 0.5-0.92; $P = 0.01$), and marginally better for PFS in.chemo-refractory patients (HR, 0.73; 95% CI: 0.52-1.01; $P = 0.06$). The subgroup analyses suggested that allo-HCT tended to be associated with better OS for relapsed-sensitive disease (HR 0.61; 95% CI: 0.36-1.04; $P = 0.07$) among chemo-sensitive patients, and primary-refractory disease (HR 0.51; 95% CI: 0.29-0.89; $P = 0.02$) among chemo-refractory patients.

Figure Auto- vs Allo-HCT on outcomes stratified with chemo-sensitivity

Summary/Conclusion: These data showed allo-HCT for PTCL-NOS and AITL failing first-line therapy can result in comparable survival outcomes despite being with more unfavorable factors compared with auto-HCT. Patients with relapsed-sensitive and primary-refractory disease may be a good candidate for allo-HCT if suitable donor is available.

Stem cell biology and microenvironment

S245 INFLAMMATORY-RESPONDING MESENCHYMAL STROMAL CELLS MODULATE THE DYNAMIC BONE MARROW MICROENVIRONMENT RESPONSE TO STRESS

S. Sood [1,2,*], Y. Demerdash [1,2], B. J. Bouman [3], R. B. Mascaro [1,2], A. S. Jolly [4], L. S. Klein [1,2], L. Bast [1,2], F. Pilz [1,2], F. Grünschläger [5], L. Haghverdi [3], M. Essers [1,2]

[1]HI-STEM gGmbH, [2]Inflammatory Stress in Stem Cells, DKFZ, Heidelberg, [3]Berlin Institute for Medical Systems Biology (BIMSB-MDC), Berlin, [4]DKFZ, Heidelberg, Germany, [5]HI-STEM, DKFZ, Heidelberg, Germany

Background: Inflammation is a key component in a complex biological response of the body to harmful stimuli. In the context of the bone marrow (BM), inflammation is an overarching process central to most if not all forms of stress challenges and disease setting. Current research in the field is focused on understanding inflammation in the context of the Hematopoietic Stem Cell (HSC) and its microenvironment response. While such research provides a descriptive understanding of the microenvironment and its interplay, it falls short in translating into functional applications confounded by a single marker approach of classifying the microenvironment cell diversity.
Aims: To utilize the power of single-cell sequencing coupled with functional proliferation readout to investigate inflammation response over time of an unbiased BM microenvironment.

Methods: We studied the murine BM response to IFNα driven inflammatory stress over time (early- 3 hours, mid- 24 hours and late- 72 hours), using single-cell transcriptomics coupled to FACS based proliferation analysis at each time point (n=3/4 for each time point). We utilized the GFP tagged interferon-stimulated gene (ISG) report mouse model to substantiate our findings. Moreover, we validated our findings in multiple BM populations using genetic mouse models lacking crucial IFNα pathway elements ($IFNAR^{-/-}$ and $STAT1^{-/-}$). Further, to unravel the BM stromal and HSC crosstalk dynamics we performed mouse matched bulk RNA sequencing of the two populations over time (n=3/4 for each time point).
Results: We identify and describe a unique inflammatory-responding Mesenchymal Stromal Cell subset (iMSC) which unlike its BM stromal counterpart responds directly and dynamically to IFNα stimulation. We show that iMSCs specifically produce key inflammation cytokines and secreted factors at the onset of IFNα response (3h). They markedly downregulate Extra Cellular Matrix (ECM) production and thus facilitate microenvironment remodeling at a late time point (24-72h). Using ligand-receptor mapping, we further identified pivotal inflammation-specific interactions between iMSCs and HSCs within the BM.
Summary/Conclusion: We propose a distinctive iMSC signature with direct application in unraveling inflammation dynamics of the BM microenvironment. The proposed iMSC signature has the potential to significantly contribute to our understanding of BM microenvironment perturbations in disease settings, like leukemia and immunodeficiencies.

S246 DORMANCY PROTECTS FUNCTIONAL POTENTIAL OF HEMATOPOIETIC STEM CELLS UNDER HOMEOSTATIC AND STRESS CONDITIONS

A. -M. Mikecin Drazic [1,*], M. J. Carreno Gonzales [1], J. Vaillant [1], M. Buechler [1], D. M. Egic [1], R. Bogeska [1], T. Holland-Letz [2], M. D. Milsom [1]

[1]Division of Experimental Hematology, [2]Division of Biostatistics, DKFZ, Heidelberg, Germany

Background: Hematopoietic stem cells (HSCs) are responsible for maintaining blood cell production throughout the lifetime of an organism. In the unperturbed state, they mainly remain quiescent, although they do occasionally enter the cell cycle to meet homeostatic demands of the mature blood cell production. Upon stress, such as inflammation, severe blood loss or chemotherapy, HSCs mount a massive proliferative response to enable elevated production of peripheral blood cells. Previously, our group has linked inflammatory-stress induced exit from dormancy with a decrease in the HSC functional potential (Walter et al, 2015, Nature).
Aims: We wanted to investigate if the HSC attrition was specific to the inflammatory challenge used in our previous research or there was a general link between dormancy and functional potential regardless of the stress-stimuli used. Therefore, we used alternative inflammatory and non-inflammatory stimuli that have been shown to promote HSC cycling.
Methods: We used the ScltTA H2B-GFP mouse model to facilitate tracking of the HSC divisional history. Mice were either repeatedly treated with lipopolysaccharide (LPS); fluorouracil (5-FU); or were serially bled. Mice were then allowed to recover for 4 weeks prior to end point analysis, in which we assessed HSC divisional history as well as its relationship to the self-renewal, differentiation and engraftment potency via in vitro proliferation and differentiation assay as well as via transplantation of the FACS sorted HSCs into lethally irradiated recipient mice.
Results: None of the treatment regimens led to sustained suppression of peripheral blood cell counts, indicating a remarkable capability of the hematopoietic system to sustain mature blood production. The bleeding protocol did not lead to an increase in HSC divisional history despite previous reports on upregulation of Ki67 staining in the HSC pool of the serially bled mice. LPS treatment, on the other hand, led to an increase in HSC exit from dormancy and 5-FU challenge resulted in the activation of the entire HSC pool. In the case of all three treatments, HSCs which have divided extensively exerted decreased functional potency in the in vitro assay as well as in vivo in transplantation studies.
Summary/Conclusion: Our data reveals a remarkable capability of HSCs to sustain mature blood cell production under conditions of severe stress imposed by inflammation, repetitive loss of large blood volumes and recurring exposure to cytotoxic chemotherapeutic agents. The HSCs that have engaged into the cell cycle showed loss of functional potency providing further evidence that dormancy indeed protects HSC's potency and that this is irrespective of the type of stimuli used. We would also suggest that this outcome suggests that HSCs do not undergo self-renewal divisions following exposure to such stimuli. In contrast to LPS and 5-FU treatment, and despite the fact that more than 70% of the total blood volume was removed on three separate occasions, the bleeding protocol did not cause dormant label-retaining HSCs into cycle. This could be explained by blood cell production being sustained under these conditions by either non-label retaining "active HSCs, or more differentiated progenitors. We are currently further investigating the effect that serial bleeding has on hematopoietic progenitor cells as well as HSC dormancy and the relationship between dormancy and functional potential after applying doses of 5-FU that do not activate the entire HSC pool.

S247 MICROENVIRONMENTAL SFRP1 REGULATES REPOPULATING ACTIVITY OF HEMATOPOIETIC STEM CELLS VIA PP2A-MEDIATED REGULATION OF CTNNB1/EP300

F. Hettler [1,*], C. Schreck [1], S. Romero Marquez [1], T. Landspersky [1], F. Bassermann [1], R. Naumann [2], R. Istvanffy [1], R. Oostendorp [1]

[1]Klinikum rechts der Isar der TUM, Dept. of Internal medicine III, Technical University of Munich, School of Medicine, München, [2]Transgenic Core Facility, Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany

Background: We have previously found that a *Sfrp1* knock-out environment fails to support the regeneration of hematopoetic stem cells (HSC) with the ability to repopulate secondary recipients (Renström et al., 2009).
Aims: We here aim to dissect cell specific requirements of the *Sfrp1* gene in the hematopoietic microenvironment.
Methods: To study the relevance of *Sfrp1* in niche cells for the maintenance of HSCs, we established the Sfrp1flox/flox mouse strain and deleted *Sfrp1* gene specifically in Osterix+ (Sp7) osteolineage cells (Osx-Cre, Sfrp1Δ/Δ, shortened to OS1Δ/Δ mice).
Results: In these OS1Δ/Δ mice, the number of MSCs is reduced, but these show an increased proportion of colony forming units (CFU-F). Furthermore, stromal cells grown ex-vivo show increased senescence-associated β-galactosidase staining. In the hematopoietic compartment of these mice, we found a decrease in myeloid progenitors in the bone marrow (BM), but, the number of HSC-enriched CD34- CD48- CD150+ HSCs (CD34- SLAM cells) in the BM was unchanged, CD34- SLAM cells from OS1Δ/Δ mice show severely reduced frequency of repopulating HSCs. In single cell cultures, we found that CD34- SLAM cells from OS1Δ/Δ mice show poor proliferation with concomitant increased differentiation into mature myeloid cells. As in embryonic stem cells, differentiation is driven by a β-catenin/p300 complex (Miyabayashi et al., 2007), we hypothesized that this complex also drives HSC differentiation. Indeed, both β-catenin and p300 were expressed at higher levels in CD34- SLAM cells from OS1Δ/Δ mice. To disrupt the β-catenin/p300 complex, we inhibited complex formation by targeting p300 phosphorylation using a specific PP2A inhibitor IQ-1. In *in vitro* experiments, IQ-1 treatment rescued the aberrant behavior of OS1Δ/Δ CD34- SLAM cells. More importantly *in vivo* IQ-1 treatment also restored the serial repopulating activity of CD34- SLAM cells OS1Δ/Δ mice *in vivo*. Renstroem, et al., Cell Stem Cell. 2009; 5: 157-67 Miyabayashi et al., Proc Natl Acad Sci U S A. 2007; 104: 5668-73.
Summary/Conclusion: Our results indicate that deletion of stromal Sfrp1 in niche cells diminishes the repopulating activity of HSCs by increasing their differentiation through PP2A-mediated dephosphorylation of the phospho-Ep300-binding site with β-catenin.

S248 LOW-CYTOKINE ENVIRONMENT DETERMINES THE OUTCOME OF EMBRYONIC HEMATOPOIESIS IN MOUSE FETAL LIVER

F. Soares-Da-Silva [1,*], M. Peixoto [1], L. Freyer [1], R. Santos [2], R. Elsaid [3], E. Gomez-Perdiguero [1], P. Pinto-do-Ó [2], A. Cumano [1]

[1]Institut Pasteur, Paris, France, [2]i3S, Porto, Portugal, [3]Institut Curie, Paris, France

Background: Hematopoietic stem cells (HSCs) are at the top of the hierarchy of the blood system. In the adult, they reside in the bone marrow, where they are mostly quiescent, only dividing to maintain the stem cell pool. During embryonic development, HSCs colonize the fetal liver where they expand. The fetal liver microenvironment is assumed to support HSC proliferation and is the only organ that provides the conditions for physiological HSC expansion. HSC transplantation is a widely used cell therapy in numerous disorders, including immunodeficiencies and leukemias. However, this therapy is still associated with high mortality rates, mainly due to infection, graft-versus-host disease (GvHD), and organ dysfunction, urging the need to improve the therapeutics. Robust and

reproducible conditions to expand HSCs *ex vivo* would allow attaining sufficient numbers to reconstitute hematopoiesis in adult patients.
Aims: Understand the complexity of the HSC microenvironment in the fetal liver that promotes HSC expansion and differentiation into distinct lineages, to devise efficient strategies for HSC expansion *ex vivo*.
Methods: We characterized the stromal compartment of the fetal liver by spectral flow cytometry, and identified cytokine-producing cells by single-cell gene expression analysis. To localize the stromal cells in the tissue we used confocal microscopy in thin and thick sections, allowing a 3D reconstruction of the tissue microanatomy. For lineage tracing of yolk-sac erythromyeloid progenitors or HSCs, we used transgenic mice models.
Results: Characterization of fetal liver from E10-newborn revealed that the non-hematopoietic compartment represents only around 5% of total cells. Analysis of hepatoblasts, endothelial, perivascular, and mesothelial cells showed that all subsets express relevant but distinct patterns of hematopoietic cytokines. The chemoattractant *Cxcl12*, produced by perivascular cells, is the most expressed factor across liver development, while other cytokines such as *Epo* and *Il7* are expressed at low-levels by hepatoblasts. *In situ* analysis showed that from the early stages of liver development, c-Kit^{+} hematopoietic cells are abundant close to the mesothelium and distinct hematopoietic lineages accumulate around blood vessels at E16.5. Lineage tracing experiments showed that, opposite to previous views, HSCs do not contribute to erythrocyte production up until birth, indicating that HSC differentiation in the embryo is skewed. We demonstrate that the low-levels of erythropoietin in the fetal liver confer a selective advantage of yolk sac-derived erythroid progenitors over HSC-derived progeny in the production of red blood cells.
Summary/Conclusion: Altogether, our work supports the premise that embryonic hematopoiesis is influenced by distinct niche cells that cooperate to provide the signals required for expansion and/or differentiation of hematopoietic stem and progenitor cells.

S249 REDUCED LEVELS OF THROMBOPOIETIN CONTRIBUTE TO IMPAIRED HEMATOPOIETIC STEM CELL FUNCTION AND DEFECTIVE MEGAKARYOPOIESIS IN BETA-THALASSEMIA

A. Aprile [1,*], M. Storto [1], A. Malara [2,3], A. Gulino [4], L. Raggi [1], S. Sighinolfi [1], S. Beretta [1], I. Merelli [1,5], S. Marktel [6], M. Ponzoni [7], C. Tripodo [4], A. Balduini [2,3], G. Ferrari [1,8]

Background: In the last decade many studies unraveled the regulation of the bone marrow (BM) niche and hematopoietic stem cells (HSC) in steady state conditions and malignancies, but HSC-niche interactions are still underexplored in inherited disorders. We have recently provided the first demonstration of impaired HSC function caused by an altered BM stromal niche in a non-malignant disease, beta-thalassemia (BT) (*Aprile et al., Blood 2020*). BT is a congenital severe anemia and it is corrected by HSC transplantation from normal donors or by gene therapy with autologous HSC. In addition to the BM stroma, we found altered levels of multiple local and systemic factors, including reduction of systemic thrombopoietin (TPO).
Aims: Further investigation of the BM alterations is pivotal to develop supportive therapies to ameliorate the BM niche and preserve long-term HSC. To this aim, we defined the role of defective TPO on HSC and BM microenvironment.
Methods: Gene expression profiling of HSC and megakaryocytes (Mk) from *Hbb*$^{th3/+}$ (*th3*) BT mice was assessed by RNA-seq analysis. Flow cytometry characterization, *in vitro* Mk maturation, histological analysis on the BM of BT mice and patients, *in vivo* biogenesis, half-life and *in vitro* phagocytosis assays were performed. *In vivo* stimulation of TPO was evaluated.
Results: Since TPO is a key regulator of both HSC and Mk, we investigated the dual role of TPO defect in BT. RNA-seq profiling revealed a downregulation of TPO signaling and target stemness genes in *th3* HSC, including *Cdkn1a*, *Hoxa9* and *Hoxb4*, negatively affecting HSC function. The decreased TPO causes a reduced commitment of HSC towards the Mk lineage, with under-expression of Mk-biased genes and lower frequency of CD41^{+}CD9^{high} HSC. *In vivo* stimulation of TPO axis in *th3* mice restored the pool of quiescent HSC, thus demonstrating the contribution of defective TPO signaling in altering BT HSC.
Consistently, histopathological analyses of *th3* mice showed dysmegakaryopoiesis and this defect was confirmed in BM sections from BT patients. Evaluation of Mk nuclear content revealed a decreased maturation of Mk, with loss of the mature polyploid profile. These findings correlate with a reduced *in vivo* Plt biogenesis and impaired *in vitro* differentiation of *th3* Mk. Sorted BT Mk showed the downregulation of niche factors, as *Pf4*, *Cxcl12*, *TnC*, relevant for HSC maintenance. We highlighted a reduced expression of extracellular matrix molecules by BT Mk, whereas overexpression of IFN response genes. Since Mk play a direct role on HSC activity, we are investigating by *in vivo* and imaging studies their contribution to the impaired HSC-niche crosstalk in BT.
We explored the origin of TPO defect: TPO levels fluctuate in response to platelet (Plt) number and its reduction in *th3* mice is associated to the increased count of Plt. A negative correlation between Plt and TPO was confirmed in BT patients. *In vivo* labeling revealed a higher half-life of BT Plt, which accumulate in the circulation because of a reduced clearance by *th3* spleen phagocytes, as assessed by phagocytosis assays. Iron overload and extramedullary erythropoiesis in BT spleen might cause the impaired phagocytic activity.
Summary/Conclusion: Our results uncovered the underexplored contribution of TPO alteration to HSC and BM niche defects in BT by unraveling the dual role of TPO on HSC and Mk in a condition of chronically reduced stimulation. This research elucidates the multifactorial alterations in the BM microenvironment, with a potential relevance in improving HSC transplantation approaches for BT.

Cellular immunotherapy and gene therapy - Experimental

S250 ADCLEC.SYN1, A COMBINATORIAL CAR PLATFORM FOR AML

S. Haubner [1,*], J. Mansilla-Soto [1], S. Nataraj [1], X. He [2], J. Park [1], X. Wang [1], I. Rivière [1], M. Sadelain [1]

[1]Center for Cell Engineering, Memorial Sloan Kettering Cancer Center, New York, [2]Takeda Pharmaceuticals Company Ltd., Cambridge, United States

Background: Prognosis in relapsed/refractory AML is extremely poor. Despite recent advances with small-molecule therapeutics, the only curative option to date is allogeneic stem cell transplantation, which is often associated with toxicity and therapeutic failure. Therefore, novel therapies with potential for high efficacy yet tolerable safety profile are highly needed. CAR therapy has been clinically validated for CD19-positive B cell malignancies and is currently being evaluated for its application in other malignancies, however suitable CAR targets in AML still need to be identified. Integrating proteomic and transcriptomic target expression data we have previously discovered n=24 CAR candidate targets with a favorable profile in AML and normal tissues and provided a rationale for several combinatorial CAR approaches in AML (Perna et al. Cancer Cell 2017).
Aims: We hypothesized that rational combinatorial CAR design targeting both ADGRE2 and CLEC12A enhances anti-leukemic efficacy without cumulating potential on-target/off-tumor toxicity.
Methods: We validated favorable target pairs among our 24 candidates, based on a multimodal in-depth analysis including multiparameter spectral flow cytometry of primary r/r AML and normal bone marrow samples, along with normal tissue immunohistochemistry studies and mass-spectrometry. To provide a platform for identification of the ideal combinatorial CAR design, we established in-vitro and in-vivo models based on a human AML cell line with up- or down-regulated antigen levels of ADGRE2 and CLEC12A to mimic both AML antigen-low escape and toxicity to normal cells. In addition, we established a humanized mouse model that allowed in-vivo assessment of hematologic toxicities in the context of anti-leukemic CAR efficacy.
Results: We focus here on ADGRE2 and CLEC12A, two cell surface molecules highly co-expressed in AML but with largely non-overlapping expression profiles in normal tissues. Using a bicistronic gamma-retroviral vector, we screened different combinatorial CAR formats targeting ADGRE2 and CLEC12A. Specific to the combined target expression profile in malignant versus normal cells, we fine-tuned both scFv affinities considering total avidity, eventually achieving thresholds for mediating cytolysis in the context of optimized CD3 zeta signaling. In addition, we further optimized the chimeric receptor combination by evaluating different hinge/transmembrane and costimulatory domains. Ultimately, using therapeutically relevant T cell doses we were able to identify a combinatorial CAR format - ADCLEC.syn1 - that allowed complete and durable AML remission across relevant target levels while maintaining a favorable safety profile.
Summary/Conclusion: We developed a novel combinatorial CAR platform – ADCLEC.syn1 – and demonstrated in pre-clinical models its high potential for safe and efficient application in r/r AML.

S251 PRECLINICAL DATA SUPPORTING THE INITIATION OF THE EDIT-301 PHASE I RUBY CLINICAL TRIAL FOR THE POTENTIAL TREATMENT OF SICKLE CELL DISEASE

E. De Dreuzy [1,*], J. Heath [1], P. Sousa [1], T. Janoudi [1], D. Ciulla [1], G. Giannoukos [1], P. Wolf [1], H. An [1], S. Hansen [2], D. K. Wood [2], S. Teixeira [1], T. Monesmith [1], K. Zhang [1], K. -H. Chang [1]

[1]Editas Medicine, Cambridge, [2]Biomedical Engineering, University of Minnesota, Minneapolis, United States

Background: Sickle cell disease (SCD) is an inherited blood disorder affecting ~ 100,000 individuals in the United States. Naturally occurring mutations at the distal CCAAT-box region of the HBG1 and HBG2 promoters are associated with elevated fetal hemoglobin (HbF) expression, which has been shown to be protective against clinical manifestation of SCD.
Aims: EDIT-301 is an investigational autologous cell therapy comprising CD34+ cells genetically modified with CRISPR-Cas at the HBG1 and HBG2 promoters to promote HbF expression for the potential treatment of SCD.
Methods: Editing is achieved using a highly specific CRISPR-Cas12a enzyme, which we have shown to have a superior on-target editing profile at this site compared to *S.pyogenes* Cas9. Preclinical studies were conducted using mobilized peripheral blood (mPB) CD34+ cells from normal and SCD donors transfected at research-scale and/or large-scale. Editing efficiency, HbF induction, functional improvement of SCD red blood cells (RBCs), off-target editing, and engraftment of edited CD34+ cells in NOD scid gamma (NSG) mice were studied.
Results: At research scale, electroporation of mPB CD34+ cells from both normal and SCD donors resulted in on-target editing of ~90%, with more than 50% of HbF expression detected in the erythroid progeny of SCD donor cells in a pancellular fashion (~93% population). This robust HbF induction was associated with significant functional improvement of SCD donor derived RBCs under hypoxia, including reduced sickling and increased deformability. In addition, using a microfluidic assay that mimics blood flow in the microvasculature, we observed a marked improvement in the rheological behavior of SCD RBCs derived from RNP-electroporated CD34+ cells. This rheology improvement was strongly correlated with the high HbF levels achieved in edited RBCs.
We have developed a consistent large-scale process using semi-automated systems. Using this process on normal donor cells, we have achieved CD34+ cell purity >90% and editing levels >80% after RNP electroporation. Evaluation of batches from this representative process demonstrated a highly consistent editing profile and no detectable off-targets. In addition, no HBG transcript or protein variants were detected in the erythroid progeny of the RNP-edited CD34 cells, demonstrating that the editing procedure did not affect the integrity of HbF. Finally, infusion of large scale manufactured edited CD34+ cells into NSG mice led to a polyclonal engraftment, with no difference in hematopoietic reconstitution compared to unedited CD34+ cells. Editing levels of >90% were detected after long term engraftment, demonstrating robust editing of long-term-repopulating hematopoietic stem cells.
Summary/Conclusion: In summary, Cas12a-RNP editing of SCD donor mPB CD34+ cells at the HBG1 and HBG2 promoters resulted in robust HbF induction and reduced sickling as well as markedly improved rheological behavior in erythroid progeny cells. We established a current Good Manufacturing Practices (cGMP) clinical scale process to support EDIT-301 clinical manufacturing. Evaluation of process representative large-scale manufacturing batches demonstrated high and consistent editing of the HBG1 and HBG2 promoters, with no measurable off-targets, and no alteration of the HBG transcript and protein. In vivo, edited CD34+ cells led to polyclonal engraftment and reconstituted all blood cell lineages at levels comparable to unedited cells. These results support the dosing of EDIT301 in the upcoming RUBY trial, a phase 1/2 study of patients with severe SCD.

S252 LAG-3, TIM-3 OR 2B4 DISRUPTION DIFFERENTIALLY REGULATE THE ANTI-TUMOR RESPONSE OF TCR GENE EDITED HUMAN MEMORY STEM T CELLS

B. C. Cianciotti [1,*], Z. I. Magnani [1], B. Camisa [1], A. Potenza [1], V. Vavassori [2], L. Naldini [3], F. Ciceri [4], P. Genovese [2], E. Ruggiero [1], C. Bonini [1]

[1]Division of Immunology, Transplantation and Infectous Diseases - Experimental Hematology Unit, [2]Gene transfer technology and new gene therapy strategies Unit, TIGET, [3]TIGET, San Raffaele Scientific Institute, [4]Hematology and Bone Marrow Transplantation Unit, San Raffaele Scientific Institute, Università Vita-Salute San Raffaele, Milano, Italy

Background: Adoptive immunotherapy with T lymphocytes genetically engineered to overexpress a tumor-specific T cell receptor represents a novel immunotherapeutic option for cancer patients. However, the lack of long-term persistence of infused tumor-reactive T cells and the immunosuppressive tumor microenvironment represent major drawbacks of ACT. Specifically, chronically stimulated tumor-specific lymphocytes become exhausted, a dysfunctional status characterized by loss of effector functions. Exhausted T cells overexpress several inhibitory receptors (IRs), such as PD-1, CTLA-4, Lag-3, Tim-3 and 2B4. The use of monoclonal antibodies targeting IRs (e.g. anti-CTLA-4 and anti-PD-1), can revert T cell exhaustion but proved effective only in a fraction of patients. Also, autoimmune-related adverse events often occur after immune checkpoint blockade, mainly due to the unleashing of autoreactive clones.
Aims: we aim to generate innovative cell therapy products, endowed with long-term persisting capacity and resistance to inhibitory signals and to investigate how the disruption of selected IRs could modulate the resistance to exhaustion in multiple myeloma models.
Methods: CRISPR/Cas9 reagents were used to simultaneously disrupt TIM-3, LAG-3 or 2B4 gene and the TCR alpha chain constant region (TRAC) gene. The frequency of NHEJ was assessed with ddPCR. TRAC-KO-IR-KO T cells were transduced with a lentiviral vector encoding for an HLA-A2-restricted NY-ESO-1-specific TCR. T cells were activated and kept in culture with a protocol to expand long-living early differentiated stem cell memory (T_{SCM}) and central memory (T_{CM}) cells (Cieri et al., Blood 2013). TCR-edited-IR-KO cells and TCR-edited-IR-competent (TCR-edited-IR_{COMP}) cells were challenged in vitro and in vivo with HLA-$A2^{pos}$NY-ESO-1^{pos} multiple myeloma cell lines. HLA-$A2^{neg}$ NYESO-1^{neg} cell lines were used as control.
Results: We efficiently inactivated the endogenous TCR (>98% of NHEJ) and more than 80% of gene disruption was also obtained at LAG-3, Tim-3 or 2B4 locus. TCR disrupted-IR-KO cells were efficiently transduced (> 50%) with the NY-$ESO1_{157-165}$-specific TCR, thus obtaining TCR-edited-IR-KO T cells or TCR-edited-IR_{COMP}T cells. Importantly, TCR-edited-IR-KO T cells retain their expansion capacity and an early differentiated T_{SCM}/T_{CM} phenotype.
Upon chronic stimulation with multiple myeloma cells, TCR-edited-Tim-3-KO and TCR-edited-2B4-KO T cells retained a higher degranulation capacity compared to TCR-edited-LAG-3 KO and TCR-edited-IRCOMP T cells, while TCR-edited-LAG-3-KO T cells showed a limited upregulation of additional inhibitory receptors.
In a preclinical model of aggressive multiple myeloma, TCR-edited-Tim3-KO and TCR-edited-2B4-KO T cells caused higher immunological pressure and were enriched in a higher proportion of highly activated T cells compared to TCR-edited-IR_{COMP}-treated mice. In a similar pre-clinical multiple myeloma model, TCR-edited-LAG-3-KO, but not TCR-edited-IRCOMP, T cells showed a reduced expression of additional IRs and prevented the engraftment of the second infusion of tumor cells, thus indicating an enhanced T cell fitness and resistance to exhaustion of TCR-edited-LAG-3-KO T cells.
Summary/Conclusion: our results show that by combining the versatility of multiplex gene editing by CRISPR/Cas9 with culture conditions designed to engineer T_{SCM} cells, we can generate innovative tumor-specific cellular products redirected against tumor antigens and resistant to different inhibitory signals.

S253 ENGINEERED REGULATORY T CELLS USING ORTHOGONAL IL-2 CYTOKINE-RECEPTOR COMPLEXES PREVENT ACUTE GRAFT-VERSUS-HOST DISEASE.

T. Ramos [1,*], S. B. Wagers [2], T. Hirai [3], P. -Y. Lin [1], L. L. Su [4], L. K. Picton [4], J. Baker [1], J. K. Lohmeyer [1], K. C. Garcia [4], B. R. Blazar [2], R. S Negrin [1]

[1]Division of Blood and Marrow Transplantation, Stanford University, Stanford, [2]Division of Blood & Marrow Transplant & Cellular Therapy, University of Minnesota, Minneapolis, United States, [3]Department of Urology, Tokyo Women's Medical University, Tokyo, Japan, [4]Departments of Molecular and Cellular Physiology and Structural Biology, Stanford University, Stanford, United States

Background: The use of regulatory T cells (Treg) has a positive therapeutic potential to ameliorate acute graft-versus-host disease (GvHD), which represents one of the major complications after allogeneic bone marrow transplantation (allo-BMT). One of the remaining obstacles in the clinical practice of Treg administration is the high dose of Treg cells required to prevent GvHD and the difficulty in expanding these cells ex-vivo.
Aims: In this study, we engineered murine Treg cells to express an altered IL-2 receptor β subunit that selectively interacts with an orthogonal

mutant IL-2 (oIL2) without interacting with the natural cytokine or receptor counterparts, thus selectively expand engineered Treg and prevent acute -GvHD.
Methods: $CD4^{+}CD25^{hi}Foxp3^{GFP}$cells were purified from C57Bl/6 $FoxP3^{DRT\text{-}GFP\text{-}luc+}$ mice and transduced with the construct for murine oIL-2 receptor β chain (oTregs) through a retroviral vector. BALB/c mice were lethally irradiated (8.8 Gy) and transplanted with $5x10^{6}$ T cell-depleted bone marrow cells (TCD-BM) from C57Bl/6 mice alone or together with fresh $1x10^{6}$ C57Bl/6 $FoxP3^{DRT\text{-}GFP\text{-}luc+}$ Treg cells (fTreg) or with oTreg ($0.2x10^{6}$ and $1x10^{6}$) on day 0. On day 2, C57Bl/6 Tcon cells ($1x10^{6}$) were injected to induce GvHD. Recipients were treated with PBS or oIL-2 (25K IU/day) for 14 days and then 3 times a week for another 14 days.
Results: By bioluminescence assays, we observed a significant expansion of oTreg (luc+) cells treated with oIL2 at day 7 post-transplant. The expansion of oTreg with PBS and fTreg was observed on day 14 after allo-BMT. The administration of oTreg-oIL2 and fTreg (1:1 Tcon:Treg ratio) significantly increased the survival of the mice compared to Tcon group (P<0.0001 and P=0.0001, respectively). Further, the group oTreg-oIL2 (1:1) showed a significant increase in the survival curve compared to the fTreg group (P=0.03). When decreasing the number of oTreg administrated (5:1 Tcon:Treg ratio) a significant increase in the survival (Tcon vs Tcon:oTreg (5:1)+oIL2; P<0.0001) in the oIL2 group. Similar survival curves were observed between this group and fTreg group (1:1). oIL-2 injection significantly increased the percentage of $Foxp3^{GFP+}$ in $CD4^{+}$ T cells (PBS;14.96±2.4%, oIL-2; 27.76±23.6%, P=0.02) in the peripheral blood (PB) after 7 days post-transplant. oTreg mice group showed a decrease in the percentage of effector T cells after 7 days compared to Tcon group. However, the oIL2 group showed a significant decrease of $ICOS^{+}CD8^{+}$ cells compared to the PBS group in the PB and spleen (P=0.04 and P=0.006, respectively).
Summary/Conclusion: The administration of a reduced number of oTreg and the selective IL-2 stimulation in vivo early after transplant showed a capacity to ameliorate GvHD, representing a novel approach to the utilization of Treg in allo-BMT.

S254 CORD-BLOOD-DERIVED T AND NATURAL KILLER CELLS ENGINEERED VIA THE PIGGYBAC TRANSPOSON SYSTEM TO EXPRESS A LIGAND-BASED CAR TARGETING THE CD116/CD131 COMPLEX

H. Morokawa [1,*], M. Tanaka [1,2], K. Hirabayashi [1], A. Hasegawa [1], S. Saito [1,2], Y. Nakazawa [1,2,3]

[1]Department of Pediatrics, [2]Center for Advanced Research of Gene and Cell Therapy, Shinshu University School of Medicine, [3]Institute for Biomedical Sciences, Interdisciplinary Cluster for Cutting Edge Research, Shinshu University, Matsumoto, Japan

Background: Chimeric antigen receptor (CAR)-T cell therapy redirected to specific antigens on tumor cells is a promising immunotherapy strategy for various cancers. However, CAR-T cells can induce substantial toxic effects, and it is sometimes difficult to manufacture them because they are produced on an individual-patient basis. Using a non-viral gene delivery, the *piggyBac*-transposon system, we have developed a ligand-based CAR-T cells redirected to the granulocyte-macrophage colony-stimulating factor (GM-CSF) receptor (GMR, CD116/CD131 complex), highly expressed in subtypes of myeloid malignancies. *PiggyBac* transposon-mediated, peripheral blood-derived GMR CAR-T cells are abundant in a native or stem cell-like memory T cells, showing a persistent antitumor effect in a xenograft mouse model. Cord blood (CB) offers an attractive, allogeneic, off-the shelf source for immunotherapy and is widely used as an alternative source of stem cell for allogeneic hematopoietic stem cell transplantation. Additionally, administration of CAR-natural killer (NK) cells has been shown to have antitumor effects without major toxic effects, such as cytokine release syndrome, neurotoxicity, or graft-versus-host disease.
Aims: In this study, we engineered CB-derived GMR CAR-T and CAR-NK cells via the *piggyBac* transposon system for more effective and safer cellular therapeutics.
Methods: Mononuclear cells from frozen CB were electroporated with both GMR CAR-transposon and *piggyBac*-transposase plasmids. The electroporated cells were cultured in a defined T-cell medium supplemented with recombinant interleukin (IL)-7 and IL-15, or in a NK-cell medium supplemented with recombinant IL-2 and IL-15. The cells were collected after 14 days of culture. The GMR CAR-T and CAR-NK cells were counted, and CAR expression and immunophenotype were characterized. To examine the anti-tumor activity, CAR-T and CAR-NK cells were co-cultured with the human acute myeloid leukemia cell line MV4-11 at an E:T ratio of 1:1, 1:2, or 1:4.
Results: We obtained GMR CAR-T and CAR-NK cells from CB via the *piggyBac* transposon system. Most CAR-positive T cells exhibited the CD45RA+ CCR7+ phenotype, suggesting that they exhibited the native or stem-cell memory T-cell phenotype. CAR-T and CAR-NK cells eradicated almost all the MV4-11 cells in culture. The results of additional analyses ongoing at the time of the abstract submission will be disclosed at the annual meeting.
Summary/Conclusion: GMR CAR-T and CAR-NK cells can be successfully generated non-virally from CB via the *piggyBac* transposon system. This approach can greatly improve the limitations of current CAR-T therapies.

Cellular immunotherapy and gene therapy - Clinical

S255 POLATUZUMAB VEDODTIN VS. CAR-T CELL FOR PATIENTS WITH RELAPSED/ REFRACTORY DIFFUSE LARGE B CELL LYMPHOMA - A PROPENSITY SCORE MATCHED ANALYSIS

Background: Introduction –Pola –BR (Polatuzumab –bendamustin-rituximab) and chimeric antigen receptor (CAR)-T cells provide superior outcome compared to conventional chemotherapy in patients with relapsed/refractory diffuse large B cell lymphoma (R/R DLBCL). However, how to sequence these strategies remains controversial.
Aims: compare the outcome of CAR-T CELLS VS pola- based therapy in R/R DLBCL
Methods: Methods: The study included R/R DLBCL patients, treated between 01/2019-08/2020 with commercial CAR-T or Pola/Pola BR after failing ≥2 lines of treatment. Propensity score analysis, matching patients based on age, lymphoma category (*de-novo*/ transformed), cell of origin, number of prior therapy lines, ECOG performance status and LDH level, was performed. Response rate, progression free survival (PFS) and overall survival (OS) were analyzed.
Results: Results: 98 patients, treated with CAR-T (n=49; 35 with Tisagenlecleucel, and 14 with Axicabtagene ciloleucel) or Pola-based regimen (n=49) were included (patient characteristics are presented in Table 1). Median time from progressive disease to CAR-T infusion was 52 days and mostly immediate for Pola/Pola-BR. Non-relapse mortality was 0 in the CAR-T cohort vs 6% (3/49) in the Pola arm. The overall and complete response rates were 73% and 53% for the CAR-T cohort vs 63% and 20% in the Pola arm. Within a median follow-up period of 9.6 (range, 1-19.1) and 7.7 (range, 0.7-26) months for CAR-T and Pola patients, respectively, median PFS were 8.9 month (95% CI n/a) vs. 5.6 months (95% CI 3.7-7.6) (p=0.08) and median OS was not reached vs. 10.8 (2.2-19.4) months, (p=0.12), respectively(Figures 1A, 1B).

Table 1: Patient characteristics

P value	Pola group (n=49)	CAR-T Group (n=49)*	Domain
.38	67 (23-92)	70 (20-85)	Age
.68	21	23	Sex, female
.48	16	14	Transformed vs *De Novo* DLBCL
.53	27	30	Non-GCB
.43	3 (2-7	2 (2-8)	No prior lines
.1	23	31	ECOG PS >1
.8	38	39	Elevated LDH

CAR-T- Chimeric Antigen Receptor- T cell;DLBCL- diffuse large cell B cell lymphoma; ECOG PS- Eastern Cooperative Oncology Group performance status; LDH-; lactic dehydrogenase; No-number Pola-polatuzumab vedotinAxicabtagene ciloleucel, N=14; Tisagenlecleucel, N=35*

Figure 1: Outcome of patients treated with CAR-T cells vs Pola-Based regimen

Summary/Conclusion: Conclusions - In the lack of prospective randomized trials evaluating CAR-T s vs chemo-immunotherapy, a propensity score, comparing CAR-T with Pola-based regimen was performed, demonstrating a tendency for prolonged PFS and OS in R/R DLBCL patients treated with CAR-T.

S256 26 WEEK EFFICACY AND SAFETY OF ETRANACOGENE DEZAPARVOVEC (AAV5-PADUA HFIX VARIANT; AMT-061) IN ADULTS WITH SEVERE OR MODERATE-SEVERE HEMOPHILIA B TREATED IN THE PHASE 3 HOPE-B CLINICAL TRIAL

Background: Etranacogene dezaparvovec is an investigational gene therapy for hemophilia B (HB) comprising an adeno-associated virus serotype 5 (AAV5) vector containing a codon-optimized Padua variant human factor IX (FIX) gene with a liver specific promoter. Early clinical studies and nonhuman primate data suggest that generally prevalent titers of anti-AAV5 NAbs may not preclude successful transduction with etranacogene dezaparvovec.
Aims: A Phase 3, **H**ealth **O**utcomes with **P**adua gene; **E**valuation in Hemophilia **B** (HOPE-B; NCT03569891) trial is ongoing to further assess efficacy and safety of etranacogene dezaparvovec in adults with HB with a wide range of pre-existing NAbs to AAV5. Here we report outcomes at 26 weeks (wks).
Methods: HOPE-B is a Phase 3, open-label, single-dose, single-arm, multi-national trial in adult males with severe or moderate-severe HB (FIX≤2%). All participants (pts) received routine FIX prophylaxis prior to study and were not excluded based on pre-existing NAbs to AAV5. A 6 month prospective lead-in period was followed by a single intravenous dose of etranacogene dezaparvovec ($2x10^{13}$ gc/kg) without prophylactic immunosuppression. Pts will be followed for 5yrs. The co-primary endpoints are change in FIX activity at 26 and 52wks and 52wk annualized bleeding rate compared to lead in. Secondary endpoints include factor replacement use, adverse events (AEs), and reactive use of corticosteroids.
Results: 54 pts were dosed and completed 26wks of follow-up. Mean age (±SD) was 41.5 (15.8) yrs. 38/54 pts (70.4%) had bleeds (n=123) during the lead-in despite prophylaxis, and 23/54 (42.6%) had NAbs to AAV5 at baseline. Following treatment, FIX activity increased rapidly to a mean (SD; min,max) of 37.2% (±19.6; 1.0, 97.1) at wk26, representing a mean (SD; min,max) change from baseline of 36.0% (±19.7; 0, 96.1 $p<0.0001$, confirmed by per-protocol sensitivity analysis). No correlation of pre-existing NAbs with FIX activity was identified up to a titer of 678.2; n=52, $R^2 = 0.078$); one individual had a NAb titer of 3212.3 and did not respond. One additional pt received a partial dose and remained on prophylaxis; all other pts (52/54; 96.3%) successfully discontinued routine prophylaxis. 39/54 (72.2%) pts reported 0 bleeds in the first 26wks post-treatment; 15 pts reported a total of 21 bleeds. Mean (SD) annualized FIX consumption (IU/yr/pt) was 292,304 (±171,079) during lead-in, decreasing to 12,622 (±36,466) at wk26 (96.0% reduction, N=54). Overall, 37/54 (68.5%) pts experienced any treatment-related AE post-treatment, the majority of which (81.5%) were mild. No deaths occurred and no treatment-related SAEs were reported. 7 pts had infusion-related reactions; the infusion was discontinued in 1 pt. Treatment-related elevations in liver enzymes were reported in 9 pts who received steroids per protocol. All discontinued steroid use prior to wk26 and FIX activity was preserved in the mild range. Additionally, the most frequent treatment-related AEs were headache (13.0%) and influenza-like illness (13.0%). No inhibitors to FIX were reported and no relationship between safety and NAbs was observed.
Summary/Conclusion: Following a single dose of etranacogene dezaparvovec, FIX activity increased, without the need for prophylactic immunosuppression, into the mild-to-normal range at 26wks in pts with severe/moderately severe HB. Pts were able to discontinue prophylaxis and bleeding was abolished in the majority. Safety was consistent with early phase AAV5 studies and together these data support a favorable safety and efficacy profile.

S257 BETIBEGLOGENE AUTOTEMCEL GENE THERAPY FOR THE TREATMENT OF TRANSFUSION-DEPENDENT B-THALASSEMIA: UPDATED LONG-TERM EFFICACY AND SAFETY RESULTS

Background: Betibeglogene autotemcel (beti-cel) is a one-time ex vivo gene therapy for transfusion-dependent β-thalassemia (TDT) that adds functional copies of a modified *HBB* gene, $\beta^{A\text{-}T87Q}$, into patients' hematopoietic stem cells. Gene therapy with beti-cel corrects the underlying cause of TDT to enable lifelong, stable production of functional adult hemoglobin (Hb) sufficient for transfusion independence (TI) and reduction of ineffective erythropoiesis. A total of 63 patients were treated with beti-cel in 2 completed phase 1/2 (Ph1/2; HGB-204, HGB-205) and 2 ongoing phase 3 (Ph3; HGB-207, HGB-212) studies. After 2 years of follow-up, patients could be enrolled in a 13-year long-term follow-up study (LTF-303; NCT02633943). We report LTF-303 interim results in 44 patients with up to 6.4 years' follow-up.

Aims: Assess long-term safety and efficacy of beti-cel in patients with TDT.
Methods: Autologous CD34+ cells were transduced with BB305 lentiviral vector and infused into patients after single-agent, pharmacokinetic-adjusted, busulfan-based myeloablation. In Ph3 studies, transduction used a refined manufacturing process compared with Ph1/2 studies. LTF-303 assessments include Hb, erythropoiesis, iron, and safety. Data are reported as median (min–max).
Results: As of 30 November 2020, 44 patients had enrolled in LTF-303 (age at enrollment in parent studies: 19.5 [7–35] y; Ph1/2: n=22, Ph3: n=22); follow-up was 45.6 (22.9–76.4) mo.
Among patients enrolled in LTF-303, TI (weighted average Hb ≥9 g/dL without packed red blood cell transfusions for ≥12 mo) was achieved and maintained over time in 15/22 (68.2%) patients treated in Ph1/2 and 20/22 (90.9%) patients treated in Ph3. Weighted average Hb during TI was 10.3 and 11.8 g/dL in patients in Ph1/2 and Ph3, respectively. In patients who achieved TI, total Hb over time without transfusion support was maintained from 24 mo (Ph1/2: 10.3 [8.6–13.7] g/dL [n=14]; Ph3: 12.5 [9.7–14.0] g/dL [n=19]) to 36 mo (Ph1/2: 10.5 [8.5–13.5] g/dL [n=15]; Ph3: 12.3 [11.7–13.5] g/dL [n=4]). This was driven by beti-cel–derived HbA^{T87Q} levels and remained stable from 24 mo (Ph1/2: 7.3 [2.9–10.1] g/dL [n=15]; Ph3: 9.4 [5.0–12.4] g/dL [n=19]) to 36 mo (Ph1/2: 7.6 [3.7–10.1] g/dL [n=15]; Ph3: 10.6 [8.6–13.0] g/dL [n=7]). In patients achieving TI in Ph3, soluble transferrin receptor decreased from baseline (129.4 [65.9–235.3] nmol/L, n=20; no patient within normal range) to 24 mo (60.0 [17.7–121.2] nmol/L, n=19; 6 patients within normal range).
Iron removal therapy was managed at the discretion of the investigator and did not target an optimal liver iron concentration (LIC). While the LIC increased just after beti-cel infusion, levels decreased over time in patients who achieved TI, particularly in those who had an elevated LIC at baseline (**Figure**).
No drug product–related AEs were reported >2 years post–beti-cel infusion. Serious AEs occurring after 2 years of follow-up included gonadotropic insufficiency, ectopic pregnancy, fetal death, gallbladder wall thickening/polyp, bacteremia with neutropenia, and major depression (all n=1). No deaths, replication competent lentivirus, or insertional oncogenesis were reported in these patients.

Figure. Liver iron concentration (LIC) over time by baseline value in patients who achieved transfusion independence and enrolled in LTF-303

Summary/Conclusion: These results demonstrate durability and stability of response after beti-cel gene therapy in patients with TDT with no AEs considered related to beti-cel by the investigator >2 years post-infusion. Sustained levels of HbA^{T87Q} and effective iron reduction improved hematologic parameters and lowered iron burden.

S258 RETROVIRAL GENE THERAPY FOR THE TREATMENT OF ADA-SCID: LONG-TERM FOLLOW UP AND FIRST CASE OF T-CELL ACUTE LEUKAEMIA DUE TO INSERTIONAL MUTAGENESIS

Background: Haematopoietic stem cell (HSC) gene therapy (GT) using a γ-retroviral vector (γ-RV) (Strimvelis®) has been authorised in the EU for the treatment of Severe Combined Immunodeficiency due to Adenosine Deaminase deficiency (ADA-SCID) in patients with no suitable human leukocyte antigen (HLA)-matched related HSC donor.
Aims: We summarise our experience with ADA-SCID γ-RV GT during clinical development and post-marketing and report the occurrence of the first case of T-cell acute lymphoblastic leukaemia (T-ALL) after GT.
Methods: Since 2000, 40 patients have been infused with autologous CD34+ cells engineered with a γ-RV encoding ADA following low dose busulfan. Patients were monitored long-term with annual visits. Eighteen patients were treated within the Clinical Development Program, 4 in a Named Patient Program (NPP), and 16 with the commercial product. Two patients were treated under Hospital Exemption with mobilised CD34+ peripheral blood cells, instead of bone marrow derived used for Strimvelis. Efficacy was evaluated in the first 36 patients with a sufficient follow-up (FU) up to March 5, 2020; serious adverse events were reported on the entire cohort until November 30, 2020.
Results: All evaluable patients are alive with a median FU of 7.2 years (range 0.3-19.2) with an intervention-free survival of 83.3% (30/36). Of the 6 patients in whom GT failed, 4 underwent allogeneic HSCT and 2 were on long-term enzyme replacement therapy. In all 30 patients with successful outcomes, engraftment of gene corrected cells persisted long-term in multiple haematopoietic lineages, at higher levels in lymphocytes. ADA activity in mononuclear cells was sustained in most patients with adequate systemic detoxification. Immune reconstitution was accompanied in most patients by increased immunoglobulin production, decreased Ig use and antibody response to vaccines. Long-term FU data revealed a decreased rate of severe infections after treatment. Most adverse events were related to disease background, conditioning or immune reconstitution. A drug-related event recently emerged in an NPP patient of 5.75 years of age, who developed T-ALL 4.7 years after GT. Routine FU 3 months earlier did not reveal abnormalities and a polyclonal insertion site profile was present at 1, 1.5 and 3 years post-GT. Clinical onset consisted of haemorrhagic diathesis and weakness. Blood tests showed WBC 291.300/uL and immature lymphocytes (93%) with phenotype CD7+, CD34het, CD2+, CD56-, CD4-, CD8dim, sCD3dim/neg, cyCD3+. There was no CNS or mediastinal involvement. The blast population was transduced (1.18 VCN/genome) and expressed low ADA activity. Integration site analysis identified a single highly dominant clone harboring a vector integration ~40kb upstream the LMO2 gene, which was overexpressed by RT-PCR. Retrospectively, the insertion was found in mature peripheral blood CD4+ T cells at 1 year (7%), stable over time. Whole genome analyses in blasts revealed loss of a large part of chr. 6 and two large LOH regions on chr. 9. The patient showed poor prednisone response, while morphological complete remission was obtained at the end of induction therapy of the AIEOP-BFM ALL 2017 protocol. Further studies are ongoing to better characterize the factors contributing to leukaemogenesis in this patient.
Summary/Conclusion: Efficacy of γ-RV-GT in ADA-SCID is sustained with a FU up to 19.2 years. Due to the identified risk of leukaemogenesis, patients will continue long-term FU to closely monitor the safety of the product. EMA CHMP confirmed that the risk/benefit balance remains favorable for Strimvelis in its approved indication.

S259 A PHASE I-IIA STUDY OF GENETICALLY MODIFIED TIE-2 EXPRESSING MONOCYTES IN PATIENTS WITH GLIOBLASTOMA MULTIFORME (TEM-GBM STUDY)

Background: Genetically modified cell-based therapies are relevant in immunooncology due to their potential for tumor specificity and potential durability. We developed a cell-based treatment, Temferon, relying on ex-vivo transduction of autologous hematopietic stem and progenitors cells (HSPCs) to express therapeutic payloads within the tumor microenvironment. Temferon targets IFNa to Tie-2 expressing macrophages (TEMs).
Aims: The aim of TEM-GBM study is to evaluate the safety and the efficacy of Temferon in up to 21 newly diagnosed patients with glioblastoma and unmethylated MGMT promoter.
Methods: TEM-GBM is an open-label, Phase I/IIa dose-escalation study. Autologous HSPCs are transduced *ex-vivo* with a lentiviral vector encoding for IFN-α. The transgene expression is confined to TEMs due to the Tie2 promoter and the posttranscriptional regulation by miRNA-126.
Results: As of January 17 2021, 15 patients have been enrolled; 9 received Temferon (D+0) with follow-up of 61 – 559 days. There was rapid engraftment and hematological recovery after the conditioning regimen. Median neutrophil and platelet engraftment occurred at D+13 and D+12, respectively. Temferon-derived differentiated cells, as determined by the presence of vector genomes in the DNA of peripheral blood and bone marrow cells, were found within 14 days post treatment and persisted subsequently, albeit at lower levels (up to 18 months). We also detected very low concentrations of IFNa in the plasma (median 5pg/ml at D+30; baseline < LLOQ) and in the cerebrospinal fluid, suggesting tight regulation of transgene expression. Three deaths occurred: two at D+343 and +402 after Temferon administration due to disease progression, and one at D+60 due to complications following the conditioning regimen. Seven patients had progressive disease (PD; range D+27-239) as expected for this tumor type. SAEs include infections, venous thromboembolism, brain abscess, hemiparesis, GGT elevation and poor performance status compatible with autologous stem cell transplantation, concomitant medications and PD. Four patients underwent second surgery. These recurrent tumors had gene-marked cells present and increased expression of IFN-responsive gene signatures compared to diagnosis, indicative of local IFNa release by TEMs. In one patient a stable lesion (as defined by MRI) had a higher proportion of T cells and TEMs within the myeloid infiltrate and an increased IFN-response signature than in a progressing lesion. The T-cell immune repertoire changed with evidence for expansion of tumor-associated clones. Tumor microenvironment characterization by scRNA and TCR sequencing is ongoing.
Summary/Conclusion: Our interim results show that Temferon is well tolerated by patients, with no dose limiting toxicities identified to date. The results provide initial evidence of Temferon potential to modulate the TME of GBM patients, as predicted by preclinical studies.

Changing the scene on sickle cell disease

S260 SAFETY AND EFFICACY OF VOXELOTOR IN PEDIATRIC PATIENTS WITH SICKLE CELL DISEASE AGED 4-11 YEARS

J. Estepp [1], R. Kalpatthi [2], G. Woods [3], S. Trompeter [4], R. Liem [5], K. Sims [6], A. Inati [7], B. Inusa [8], A. Campbell [9], C. Piccone [10], M. Abboud [11], K. Smith-Whitley [12], S. Dixon [13], M. Tonda [13], C. Washington [13], C. Brown [14,*]

[1]St. Jude Children's Research Hospital, Memphis, [2]Children's Hospital of Pittsburgh, University of Pittsburgh Medical Center, Pittsburgh, [3]Children's Mercy Hospital, Kansas City, United States, [4]University College London NHS Foundation Trust, London, United Kingdom, [5]Ann and Robert Lurie Children's Hospital of Chicago, Chicago, [6]St. Jude Affiliate Clinic Baton Rouge, Baton Rouge, United States, [7]Lebanese American University, Beirut and Nini Hospital, Tripoli, Lebanon, [8]Guy's and Saint Thomas' NHS Foundation Trust, London, United Kingdom, [9]Children's National Medical Center, Washington DC, [10]UH Rainbow Babies and Children's Hospital, Cleveland, United States, [11]American University of Beirut Medical Center, Beirut, Lebanon, [12]Children's Hospital of Philadelphia, Philadelphia, [13]Global Blood Therapeutics, South San Francisco, [14]Children's Healthcare of Atlanta, Atlanta, United States

Background: Sickle cell disease (SCD) is an inherited, lifelong disorder characterized by polymerization of deoxygenated sickle hemoglobin (HbS), chronic hemolytic anemia, and vaso-occlusive crises (VOCs). Lifelong ischemic injury and inflammation that begins during childhood in patients with SCD is associated with progressive end-organ damage, substantial morbidity, and early mortality. Voxelotor, an oral, once-daily HbS polymerization inhibitor, is approved in the United States for the treatment of SCD in adults and pediatric patients aged ≥12 years. Here we report the evaluation of safety and efficacy of voxelotor in pediatric patients with SCD aged 4 to 11 years.
Aims: To assess the safety and efficacy of weight-based, 1500-mg-equivalent, once-daily doses of voxelotor in pediatric patients with SCD (HbSS or HbSβ^0-thalassemia) aged 4 to 11 years.
Methods: Patients with SCD aged 4 to 11 years received once-daily voxelotor 1500 mg or 1500-mg weight-based-equivalent dosing for up to 48 weeks. Patients were included if they had a hemoglobin (Hb) concentration of 5.5 to 10.5 g/dL at baseline. Concomitant hydroxyurea was allowed if the dose was stable for ≥3 months at enrollment. Study outcomes included the change from baseline to week 24 in Hb and changes in markers of hemolysis (indirect bilirubin, lactate dehydrogenase, and reticulocyte count). Other outcomes included safety as assessed by adverse events (AEs).
Results: A total of 45 pediatric patients (median [range] age, 7.0 [4-11] years; median [range] weight, 24.0 [12-41] kg; 51.1% female) were enrolled to receive the weight-based dosing of voxelotor equivalent to 1500 mg. Of these patients, 95.6% had HbSS and 4.4% had HbSβ^0 genotypes. At baseline, 84.4% were receiving hydroxyurea, and 53.3% had ≥1 VOC in the year prior to enrollment. At baseline, the mean (SD) Hb level was 8.6 (1.0) g/dL. At week 24, the mean change (SD) in Hb from baseline was +1.0 (1.1) g/dL, and 47.1% (95% CI, 29.8%>64.9%) of patients achieved a Hb response, defined as a >1 g/dL increase in Hb. Reductions in markers of hemolysis, as measured by mean percent change from baseline, were observed for indirect bilirubin (–38.6%), lactate dehydrogenase (–2.6%), and reticulocytes (–3.3%). Improvements in Hb and markers of hemolysis were also observed in those who were managed at the maximally tolerated dose of hydroxyurea. Correlation of Hb response with observed pharmacokinetics and percent Hb occupancy will be presented. Treatment-related AEs not related to SCD were reported in 48.9% of patients; most were grade 1 or 2, and treatment discontinuation rates due to treatment-related AEs were low (9%). The most commonly reported treatment-related AEs were diarrhea (11%), vomiting (11%), and rash (grouped term; 11%).
Summary/Conclusion: Voxelotor increased Hb and decreased markers of hemolysis in pediatric patients with SCD aged 4 to 11 years, the majority of whom were receiving stable hydroxyurea. Additionally, the drug was well tolerated, and no new adverse safety signals were detected. These results were consistent with those in adults and adolescent patients aged ≥12 years treated with voxelotor 1500 mg once daily in the HOPE trial. Overall, these results support the use of voxelotor in pediatric patients with SCD ≥4 years of age as a potential strategy for early mitigation of the morbidity and mortality associated with SCD.

S261 COMPLETE RESOLUTION OF SEVERE VASO-OCCLUSIVE EVENTS AND IMPROVED PATHOPHYSIOLOGY WITH LENTIGLOBIN GENE THERAPY IN SICKLE CELL DISEASE (SCD): ONGOING PHASE 1/2 HGB-206 GROUP C STUDY

Background: SCD is a progressive disease caused by a single point mutation in the β-globin gene. Despite lifelong treatment (tx) options, SCD results in painful vaso-occlusive events (VOEs), progressive vasculopathy, and chronic hemolytic anemia, leading to significant morbidity and early mortality. LentiGlobin for SCD (bb1111) gene therapy (GT) utilizes a modified human β-globin gene that produces GT-derived anti-sickling hemoglobin (Hb)A^{T87Q}.
Aims: The ongoing Phase 1/2 HGB-206 study is the largest clinical trial of GT in SCD to date. Data from Group C are presented here.
Methods: Patients (pts; ≥12–≤50 yrs) with SCD and recurrent severe VOEs, including acute episodes of pain and acute chest syndrome, were enrolled. CD34+ cells were collected by plerixafor mobilization/apheresis and transduced with BB305 lentiviral vector. LentiGlobin was infused after myeloablative busulfan conditioning. Lab evaluations, SCD-related outcomes, pain intensity using Patient Reported Outcomes Measurement Information System (PROMIS)-57, and safety were assessed; data are median (min–max) unless otherwise stated.
Results: As of August 20, 2020, 43 pts (24 [12–38] yrs) had initiated cell collection, 32 of whom were treated with LentiGlobin and followed for 13.0 (1.1–30.9) months. Neutrophil and platelet engraftment were achieved at 19.5 (12–35) and 30 (18–136) days, respectively; all pts stopped RBC transfusions by 90 days post-tx. Near pancellular expression of HbA^{T87Q} was observed ≥6 months post-tx with ~90% of RBCs containing $\beta^{A\text{-}T87Q}$ by 18 months (n=10). At last visit in evaluable pts with ≥6 months follow-up (n=22), total Hb was 12.0 (9.6–15.1) g/dL; HbA^{T87Q} and HbS contribution to total Hb were 5.6 (2.7–8.9) and 6.1 (4.8–7.8) g/dL, respectively. At last visit in adolescents with ≥6 months follow-up (n=6), median total Hb and HbA^{T87Q} were 13.5 and 6.1 g/dL, respectively. At last visit, lactate dehydrogenase, indirect bilirubin, and reticulocytes (n=32) approached normalization along with reductions in nucleated RBCs and serum transferrin receptor levels (n=23).
In 19 pts with a history of ≥4 severe VOEs and 6 months of follow-up, complete resolution of VOEs was observed after 6 months, with no reports of severe VOEs in the 24 months post-tx compared with an annualized severe VOE rate of 3 (2.0–10.5) in the 24 months prior to informed consent (**Fig.**). Overall mean PROMIS-57 pain intensity scores decreased from 4.5 at baseline (n=19) to 1.3 at Month 24 (n=4).
Tx-emergent serious adverse events (TESAEs) reported in 2 pts were abdominal pain, opioid withdrawal syndrome, nausea, and vomiting. All other TESAEs were reported in 1 pt. No SAEs were considered related to LentiGlobin. One pt had a nonserious Grade 2 event of febrile neutropenia considered to be LentiGlobin-related by the investigator. One death, unlikely related to LentiGlobin, occurred >18 months post-tx in a pt with significant baseline SCD-related cardiopulmonary disease. Beyond the August 20, 2020 data cutoff, one pt in Group C with persistent anemia 6 months after transplant was found to have trisomy 8 by fluorescence *in situ* hybridization on a 6-month bone marrow aspirate; the case is currently being investigated for myelodysplastic syndrome.

Figure. Complete resolution of severe VOEs post-LentiGlobin treatment

Protocol severe VOEs are shown; patients with ≥4 severe VOE at baseline before IC and with ≥6 months of follow-up post-DP infusion are included. A severe VOE was defined as an event with no medically determined cause other than a vaso-occlusion, requiring a ≥24-hour hospital or ER observation unit visit, or ≥2 visits to a day unit or ER over ≥2 hours with both visits requiring intravenous treatment for the following: acute episodes of pain, acute chest syndrome, acute hepatic sequestration, and acute splenic sequestration. In the last dataset, one patient had a non-serious VOC at Day 107; this event was recorded as an investigator reported VOE but did not meet the definition of a protocol VOE.
*HbA^{T87Q} expression stabilizes within 6 months; *One death, unlikely related to LentiGlobin, >18 months post treatment in a patient with significant baseline SCD-related cardiopulmonary disease.
DP, drug product; ER, emergency room; IC, informed consent; max, maximum; min, minimum; VOC, vaso-occlusive crisis; VOE, vaso-occlusive event.

Summary/Conclusion: LentiGlobin tx resulted in complete resolution of severe VOEs up to 24 months post-tx and decreased patient-reported pain intensity from baseline. There was near pancellular HbA^{T87Q} expression and improved SCD pathophysiology after tx. The safety profile of LentiGlobin tx regimen remains generally consistent with myeloablative single-agent busulfan conditioning and underlying SCD.

S262 ISCHEMIC WHITE MATTER LESIONS ARE ASSOCIATED WITH COGNITIVE DYSFUNCTION IN ADULTS WITH SICKLE CELL DISEASE

F. Blais [1,2,*], I. Padilha [3], M. Castonguay [1,2], N. Fadiga [4], L. Letourneau-Guillon [3], R. Ward [4,5], F. Guilbert [3], K. Kuo [4,5], D. Soulières [1], S. Forté [1]

[1]Department of Medicine, Centre hospitalier de l'Université de Montréal (CHUM), Montreal, [2]Faculty of Medicine, Laval University, Quebec, [3]Department of Radiology, Centre hospitalier de l'Université de Montréal (CHUM), Montreal, [4]Division of Medical Oncology and Hematology, Department of Medicine, University Health Network (UHN), [5]Division of Hematology, Department of Medicine, University of Toronto, Toronto, Canada

Background: At least 33% of adults with sickle cell disease (SCD) have neurocognitive deficits and up to 50% show radiological signs of ischemia on cerebral imaging. In adults, evidence about the possible association between ischemic white matter lesions (IWML) and cognitive function remains controversial.
Aims: 1) Describe the prevalence of neuroradiological abnormalities on routine screening magnetic resonance imaging and angiography (MRI/A) in a contemporary Canadian cohort of adults with SCD. 2) Test for associations between the presence and severity of brain lesions on MRI/MRA, and performance on cognitive screening using the Rowland Universal Dementia Assessment Scale (RUDAS). We hypothesized that the presence and severity of IWML on screening MRI/A is associated with lower RUDAS performance in SCD adults.
Methods: *Design:* cross-sectional study, two Canadian comprehensive SCD centers (CHUM, Montréal and UHN, Toronto). *Inclusion criteria:* adult out-patients, all SCD phenotypes, tested with RUDAS. *Patient characteristics/outcomes:* Patient information was extracted from electronic patient records. Brain MRI/A reports <1 year from date of cognitive screening were reviewed. Findings were categorized: white matter hyperintensities (WMH), lacunae, cortical infarct (CI), atrophy, Moya-Moya, arterial stenosis or aneurysm. IWML was defined as a WMH and/or lacunae and its burden was graded with an adapted Fazekas score. Previous literature defined a RUDAS score of <23 as suggestive of dementia. *Statistics:* T-test and Fisher exact were used to test for association between RUDAS performance and brain MRI/A findings. The effect of genotype subgroup on the association was assessed using Mantel-Haenszel test. Statistical significance was established at $p<0.05$.
Results: Between July 2018 and September 2019, 252 patients were screened (CHUM 92, UHN 160) with the RUDAS. Contemporary screening MRI/A was available for 166 (65.9%) patients. Mean age was 31.0 [range 18-75] and 83 (50.0%) were female. Phenotype distribution was 108 (65.1%) with SS or Sb^0 and 58 (34.9%) with SC or Sb^+. A history of stroke was recorded in 17 (10.2%). WMH were reported in 71 (42.8%) patients, lacunae in 31 (18.7%), aneurysms in 20 (12.0%), stenosis in 12 (7.2%), atrophy in 8 (4.8%), CI in 4 (2.4%) and Moya Moya in 4 (2.4%). An IWML was described in 92 (55.4%). A RUDAS score <23 was found in 13 (7.8%) patients with recent MRI/MRA, compared to 29 (11.5%) in the overall cohort. Patients with IWML had significantly lower RUDAS scores (t= -2.66, p= 0.009). The odds of having RUDAS <23 was 4.9 times higher in patients with IWML than those without. A significant interaction between genotype subgroup and the association was found. In the presence of IWML, the SC and Sb^+ subgroup had 5.2 times higher odds of low RUDAS score than SS and Sb^0 subgroup (Table).

Table: Distribution of suspected dementia in adults with sickle cell disease, according to the presence or absence of ischemic white matter lesions on routine screening MRI/A. Results are also presented according to phenotype strata.

	N (%)	RUDAS		Odds ratio [95% confidence interval], p-value
		< 23	23 - 30	
All phenotypes	**166**			
Presence of IWML	92 (55.4)	11 (12.0)	81 (88.0)	OR=4.9 [1.0-22.8], p=0.04*
Absence of IWML	74 (44.6)	2 (2.7)	72 (97.3)	
SS and $Sβ^0$	**108**			
Presence of IWML	64 (59.3)	6 (9.4)	58 (90.6)	OR=5.2 [1.1-24.6], p=0.04**
Absence of IWML	44 (40.7)	1 (0.9)	43 (99.1)	
SC and $Sβ^+$	**58**			
Presence of IWML	28 (48.3)	5 (17.9)	23 (82.1)	
Absence of IWML	30 (51.7)	1 (3.3)	29 (96.7)	

*Fisher exact test
** Mantel-Haenszel test
Abbreviations: IWML= ischemic white matter lesion, MRI/A= magnetic resonance imaging and angiography, OR= odds ratio, RUDAS= Rowland Universal Dementia Assessment Scale

Summary/Conclusion: This is the largest study reporting on results from concurrent systematic cognitive screening and MRI/A surveillance in adults with SCD, with all major phenotypes represented. These data confirm the high prevalence of neurologic lesions in a contemporary cohort. The presence of IWML on screening MRI/A is associated with neurocognitive deficits. Independent radiological assessment is under way to grade the severity of the radiological lesions and correlate these findings with dementia. Multivariable analysis will be presented at the meeting. These findings highlight an area of unmet need in the management of neurocognitive morbidity in SCD.

S263 THE SAFETY, PHARMACOKINETICS & PHARMACODYNAMIC EFFECTS OF IMR-687, A HIGHLY-SELECTIVE PDE9 INHIBITOR, IN ADULTS WITH SICKLE CELL DISEASE: PHASE-2A PLACEBO-CONTROLLED & OPEN-LABEL EXTENSION STUDIES

B. Andemariam [1,*], L. Bronte [2], V. Gordeuk [3], J. Howard [4], J. Kanter [5], P. Eleftheriou [6], S. Pancham [7], R. Hagar [8], L. Clarke [9], G. Blyden [2], S. Lugthart [10], T. Mant [4], H. Fok [4], F. Barroso [11], J. Mason [12], J. Yen [13], K. Attie [13], J. Lufkin [13], R. Ballal [13]

[1]University of Connecticut Health Center, Farmington, [2]Foundation for Sickle Cell Disease, Hollywood, [3]University of Illinois, Chicago, United States, [4]Guy's and St Thomas', London, United Kingdom, [5]University of Alabama, Birmingham, United States, [6]University College London Hospital, London, [7]Sandwell & West Birmingham Hospital, Birmingham, United Kingdom, [8]UCSF Benioff Children's Hospital, Oakland, [9]Loretta Hospital, Chicago, United States, [10]University Hospital, Bristol, [11]Royal London Hospital, London, United Kingdom, [12]Baylor Scott & White Medical Center, Temple, [13]Imara, Boston, United States

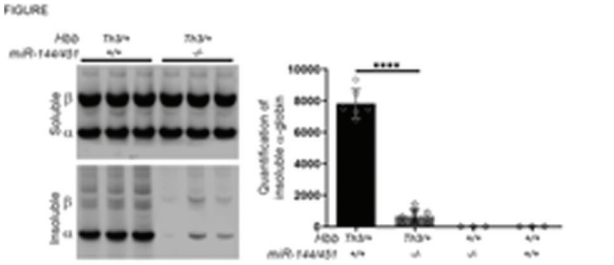
Background: IMR-687 is a highly-selective phosphodiesterase 9 (PDE9) inhibitor being developed as an orally-administered therapy for patients with sickle cell disease (SCD) and beta-thalassemia. IMR-687 increases intracellular cGMP levels by activating the NO-cGMP pathway and has been shown in preclinical studies to increase fetal hemoglobin (HbF) expression and reduce hemolysis and sickling of RBCs, pivotal to the reduction of sickle cell crisis.
Aims: The objective of this Phase 2a study is to evaluate the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of IMR-687 as a monotherapy and in combination with hydroxyurea (HU) when administered to subjects with SCD. An open label extension (OLE) of the Phase 2a study is ongoing to assess the long-term safety and benefit of IMR-687 administered for up to 4 years.
Methods: This Phase 2a, randomized, double-blind, placebo-controlled study (IMR-SCD-102) of IMR-687 was conducted in adult subjects with SCD as a monotherapy or in combination with HU. Subjects received placebo or IMR-687 (50 mg escalated to 100 mg or 100 mg escalated to 200 mg) once daily for 4-6 months. On the OLE, subjects received 200 mg IMR-687 once daily. PK, PD parameters [e.g., HbF, F-cells, hemoglobin (Hb) and markers of hemolysis] and vaso-occlusive crises (VOCs) were measured. In preliminary post-hoc analyses of Phase 2a results, longitudinal data of absolute change from baseline in PD parameters were analyzed using mixed model repeated measures (MMRM) with fixed effect of treatment, visit week, treatment-by-visit-week interaction and covariates of baseline value and baseline-by-visit-week interaction.
Results: A total of 93 subjects were randomized and treated in the 'parent' Phase 2a study. As of data cut-off (31-Dec-2021), 24 subjects from the parent study enrolled in the OLE, with ~12 subjects with evaluable PD data at 4 months. Results to date indicate that IMR-687 was generally safe and well-tolerated as a monotherapy and in combination with HU and had no substantial PK effect on HU. No treatment-related serious adverse events were reported, and the most frequent adverse events (≥10%) were sickle cell anemia with crisis, headache and nausea. In subjects treated with IMR-687 without HU (parent study), the LS mean (SEM) absolute change from baseline to Week 24 in F-cells (%) was +5.66 (2.87) in the 100/200 mg group (N=13), compared with -6.00 (3.77) in the placebo group (N=7), for an LS mean difference of 11.66 (SEM=4.72; p=0.0190). A trend for improvement in HbF (%) was observed in active groups without HU (compared to placebo group). Absolute changes in F-cells (%) and HbF (%) were highly-correlated in the IMR-687 groups without HU after 24 weeks (N=19, r=0.75, p<0.0001). In subjects on the OLE, at month 4, HbF (%) and F-cells (%) showed a mean absolute change of +1.9 and +7.3, respectively, with minimal changes in Hb. Two patients with the longest time on study (18 and 8 months) showed a 64% and 69% reduction, respectively, in rate of VOCs (relative to same time prior to treatment) as well as sustained changes in HbF, F-cells and markers of hemolysis.
Summary/Conclusion: Results from the Phase 2a and OLE studies (as of data cut-off) demonstrate that daily dosing of up to 200 mg IMR-687 was safe and well-tolerated as a monotherapy or in combination with HU. Treatment with 200 mg IMR-687 was shown to increase F-cells (%) with trends for improved HbF, markers of hemolysis and rate of VOCs. Based on these encouraging data, a Phase 2b study testing IMR-687 at higher doses was initiated to further explore IMR-687 as a disease-modifying therapy for SCD.

S264 DIFFERENTIAL ENDOTHELIAL VCAM1 EXPRESSION AND IMPLICATIONS FOR SICKLE CELL ANEMIA VASCULOPATHY

M. Silva [1,*], A. Coelho [1], S. Vargas [1], P. Faustino [1,2]

[1]Departamento de Genética Humana, Instituto Nacional de Saúde Doutor Ricardo Jorge, [2]Instituto de Saúde Ambiental (ISAMB), Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal

Background: Vascular disease is systemic in sickle cell anemia (SCA), with profound effects in organs like the brain, where stroke is the most severe end of the cerebral vasculopathy spectrum. Endothelial dysfunction is an important pathobiological mechanism in SCA systemic vasculopathy, with upregulation of adhesion molecules (e.g., VCAM-1), lower nitric oxide bioavailability, and increased oxidative stress. In previous association studies, we found positive associations between the presence of three specific *VCAM1* gene promoter haplotypes and i) high blood flow velocities in the median cerebral artery, and ii) a chronic hemolysis biochemical marker.
Aims: The aims of our work were: a) to investigate the functional role of those *VCAM1* promoter haplotypes in endothelial cell response following endothelial activation through TNF-α stimulation; b) to assess the modulation role of proinflammatory and/or pro-oxidative stimuli on endothelial *VCAM1* expression; and, finally, to evaluate how hydroxyurea (HU) treatment would affect that expression.
Methods: After molecular cloning of three *VCAM1* promoter haplotype constructs, using pGL4 promoterless vectors, haplotype sequence was confirmed, by Sanger sequencing, prior to transfection. Transfection experiments for each construct were performed, with or without TNF-α stimulation, using EAhy926, and HBEC as macrovascular and microvascular endothelial cell models, respectively. Differences in promoter activity were assessed by luciferase reporter assay. RNA was extracted from non-transfected EAhy926 and HBEC cell cultures stimulated or not with TNF-a and/or hemin, and with or without HU treatment. RT-qPCR was performed to analyze *VCAM1* expression. *HMOX1* and *NOS3* were also analyzed for comparison purposes.
Results: Our results showed that two *VCAM1* promoter haplotypes, previously associated with pediatric cerebral vasculopathy and hemolysis in SCA, increased promoter activity in transfected and TNF-α-stimulated EA.hy926 and HBEC cells, consistent with a higher *VCAM1* expression in macro and microvascular settings. In non-transfected cells, we also observed TNF-a-induced *VCAM1* overexpression as well as heme-induced overexpression of *HMOX1* in both cell models. Heme did not affect *VCAM1* nor *NOS3* expression and the latter was also not affected by TNF-a stimulus. Hydroxyurea treatment lowered TNF-a-induced *VCAM1* and *NOS3* expression but did not affect heme-induced *HMOX1* expression.
Summary/Conclusion: These data further indicate that *VCAM1* haplotypes we previously associated with pediatric cerebral vasculopathy and hemolysis in SCA, induce higher *VCAM1* expression potentially affecting both cerebral and systemic vasculopathy risk. The differential endothelial expression of *VCAM1*, *NOS3*, and *HMOX1* after proinflammatory and/or pro-oxidative stimuli also reinforces their genetic modulation role in SCA systemic vasculopathy.



Changing the scene on thalassemias

S265 MIR-451 FUNCTION ON ULK1-MEDIATED AUTOPHAGY OF FREE ALPHA-GLOBIN IN BETA-THALASSEMIA

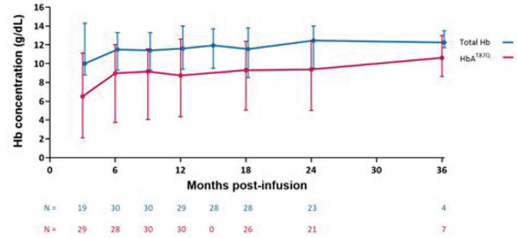
C. Lechauve [1,*], J. Keith [1], K. Mayberry [1], A. Fernandez [1], C. Westbrook [1], J. Zhang [1], Y. Yao [1], H. Tillman [2], M. Weiss [1]

[1]Hematology, [2]Veterinary Pathology, St. Jude Children's Research Hospital, Memphis, United States

Background: β-Thalassemia is a common, frequently debilitating, inherited anemia caused by *HBB* gene mutations that reduce or eliminate the expression of the β-globin subunit of adult hemoglobin (HbA, α2β2). Consequently, excess free α-globin forms toxic precipitates during erythropoiesis, causing destruction of red blood cells (hemolysis) and apoptosis of their precursors (ineffective erythropoiesis [IE]). In many respects, β-thalassemia resembles other protein aggregation disorders in which the accumulation of unstable misfolded proteins leads to tissue destruction. Previously, we showed that free α-globin is eliminated by protein quality-control pathways, including the ubiquitin-proteasome system and autophagy (Khandros *et al.*, Blood 2012). Recently, we identified that free α-globin is eliminated by ULK1-dependent, ATG5-independent autophagy that is suppressed by mTORC1 (Lechauve *et al.* Sci Transl Med 2019). We measured an elevated mTORC1 activity in β-thalassemic erythroid cells and the administration of the mTORC1 inhibitor rapamycin to β-thalassemic mice (strain $Hbb^{Th3/+}$) caused a reduction in α-globin precipitates with lessening of anemia and IE.
Aims: Our overall hypothesis is that inhibition of mTORC1 can alleviate β-thalassemia by stimulating ULK1-mediated autophagy of free α-globin. We will determine how disruption of the *miR-144/451* locus impacts AMPK and mTORC1 activity in erythoird cells and how ablation of miR-144/451 mitigates β-thalassemia.
Methods: Our initial step has been to cross our mouse strains $miR\text{-}144/451^{-/-}$ and $Hbb^{Th3/+}$. miR-451, the most abundant erythroid microRNA, targets the mRNA encoding CAB39/MO25, a cofactor for the LKB1 kinase, which activates AMPK (Fang *et al.* Hematologica 2018). Moreover, activated-AMPK indirectly inhibits mTORC1 by phosphorylating TSC1/2. mTORC1 activity has been analyzed in maturation stage-matched erythroid precursors by immuno-flow cytometry and Western blotting. Afterwards we used mutliple readouts to assess β-thalassemia pathology including complete blood counts, electron microscopy of FACS-purified reticulocytes, RBC fractionation followed by gel electrophoresis to quantify α-globin precipitates, and assessment of extramedullary erythropoiesis in the spleen.
Results: Here we show that genetic elimination of miR-451 alleviates β-thalassemia. Loss of miR-144/451 decreased erythroid mTORC1 activity in β-thalassemic erythroblasts by 33%, as measured by reduction of ribosomal protein S6 phosphorylation ($P<0.01$). In β-thalassemic mice, elimination of miR-144/451 resulted in a 92% reduction of red blood cell α-globin precipitates ($P<0.0001$; figure), with lessening of hemolysis and IE, as evidenced by 27% increased RBC count ($P<0.0001$), 3-fold decreased reticulocyte count ($P<0.0001$), and decreased spleen weight (0.52 ± 0.05 vs 0.22 ± 0.05 g, n=7; $P<0.0001$) compared to β-thalassemic mice with intact *miR-144/451* alleles. Importantly, the beneficial effects of miR-144/451 ablation were significantly reduced by genetic ablation of *Ulk1* or *Cab39*, indicating that loss of miR-451 stimulates ULK1-mediated autophagy of free α-globin through the AMPK/mTORC1 pathway.

Legend: Analysis of soluble and insoluble globin chains by triton–acetic acid–urea gel electrophoresis and insoluble α-globin chain quantification. Results are presented as mean ± SD; ****$p < 0.0001$ by t-test.

Summary/Conclusion: Advances in medical management and hematopoietic stem cell transplantation have improved and extended the lives of β-thalassemia patients significantly, however, new therapies are still required to further optimize care. Our findings suggest two novel therapeutic strategies to treat β-thalassemia by enhancing ULK1-mediated autophagy of free α-globin: pharmacological inhibition of mTORC1 or suppression of miR-451 by antagomirs.



S266 BETIBEGLOGENE AUTOTEMCEL IN PATIENTS WITH TRANSFUSION-DEPENDENT B-THALASSEMIA: UPDATED RESULTS FROM HGB-207 (NORTHSTAR-2) AND HGB-212 (NORTHSTAR-3)

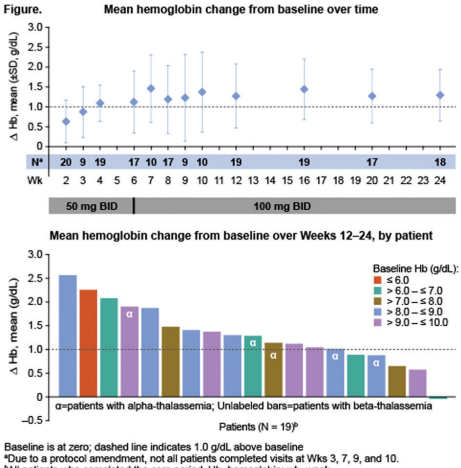
F. Locatelli [1,*], J. L. Kwiatkowski [2,3], M. C. Walters [4], J. B. Porter [5], S. Hongeng [6], E. Yannaki [7], A. E. Kulozik [8], M. G. Sauer [9], A. J. Thrasher [10], I. Thuret [11], A. Lal [4], R. Guo [12], W. Liu [12], R. A. Colvin [12], A. A. Thompson [13,14]

Papanikolaou Hospital, Thessaloniki, Greece, [8]University of Heidelberg, Heidelberg, [9]Medizinische Hochschule Hannover, Hannover, Germany, [10]UCL Great Ormond Street Institute of Child Health, London, United Kingdom, [11]Hôpital de la Timone, Marseille, France, [12]bluebird bio, Inc., Cambridge, [13]Northwestern University Feinberg School of Medicine, [14]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, United States

Background: Transfusion-dependent β-thalassemia (TDT) is a genetic disease requiring lifelong packed red blood cell (pRBC) transfusions and regular iron chelation. Betibeglogene autotemcel (beti-cel) is a one-time ex vivo gene therapy that adds functional copies of a modified *HBB* gene, $\beta^{A\text{-}T87Q}$, into patients' hematopoietic stem cells to correct the underlying genetic cause of TDT and enable lifelong, stable production of functional adult hemoglobin (Hb) sufficient for transfusion independence (TI).
Aims: To evaluate updated efficacy and safety of beti-cel in patients with TDT in ongoing, fully enrolled phase 3 studies, HGB-207 (Northstar-2; non-β^0/β^0 genotypes; NCT02906202) and HGB-212 (Northstar-3; β^0/β^0, $\beta^{+IVS\text{-}I\text{-}110}/\beta^{+IVS\text{-}I\text{-}110}$, and $\beta^0/\beta^{+IVS\text{-}I\text{-}110}$ genotypes; NCT03207009).
Methods: CD34+ cells are mobilized using granulocyte-colony stimulating factor and plerixafor, collected via apheresis, transduced with BB305 lentiviral vector, and infused back into patients after single-agent, pharmacokinetic-adjusted busulfan-based myeloablation. Primary endpoint in both studies is TI (weighted average Hb ≥9 g/dL without pRBC transfusions for ≥12 mo; the primary endpoint for HGB-212 is the result of a protocol amendment dated October 2020). Patients are followed for 2 y and, upon study completion, are eligible for a long-term follow-up study for an additional 13 y. Data are median (min–max).
Results: As of 30 November 2020, 41 patients (29 non-β^0/β^0, 12 β^0/β^0 genotype) had been treated with beti-cel and followed for 24.3 (0.9–42.2) mo. Age at informed consent was 13 (4–34) y. All patients with >1.3 mo follow-up (n=40) achieved neutrophil and platelet engraftment 25.5 (13–39) and 46.0 (13–94) d after infusion, respectively. Lymphocyte nadir within the first mo post-infusion was 0.47 x 10^9/L (0.02–1.81 x 10^9/L; n=41; reference range, 0.9–6.5 x 10^9/L [range varies by laboratory]).
Transfusion independence was achieved by 30/34 (88.2%) evaluable patients, including 6/7 (85.7%) patients with β^0/β^0 genotypes and 24/27 (88.9%) patients with non-β^0/β^0 genotypes (including 10/11 β^+/β^0, 5/6 β^E/β^0, 3/3 β^+/β^+, 2/3 $\beta^{+IVS\text{-}I\text{-}110}/\beta^{+IVS\text{-}I\text{-}110}$, 2/2 $\beta^0/\beta^{+IVS\text{-}I\text{-}110}$, and 2/2 $\beta^+/\beta^{+IVS\text{-}I\text{-}110}$ genotypes). Weighted average Hb during TI was 11.5 (9.5–13.6) g/dL. At last follow-up, all 30 patients had maintained TI for 20.6 (12.3–39.4) mo. All patients who achieved TI had Hb ≥9 g/dL at 6 mo post-infusion. Unsupported total Hb and HbA^{T87Q} over time are shown in the **Figure.**
Adverse events in ≥2 patients considered by the investigator to be related or possibly related to beti-cel included abdominal pain (n=3) and thrombocytopenia (n=3; 1 serious event). Serious adverse events that occurred in ≥2 patients included pyrexia (n=4), thrombocytopenia (n=3), veno-occlusive liver disease (n=3), febrile neutropenia (n=2), neutropenia (n=2), and stomatitis (n=2). There were no deaths and no evidence of clonal dominance or insertional oncogenesis in these studies. Fertility preservation was performed in 30/41 (73.2%) patients. A pregnancy after in vitro fertilization was reported in the partner of a male patient who had banked sperm prior to beti-cel infusion. The pregnancy was ongoing at last follow-up.

Figure. Unsupported Total hemoglobin (Hb) and HbA^{T87Q} Levels Over Time in Patients Who Achieved Transfusion Independence. Unsupported total Hb is defined as the total Hb level without any packed red blood cell transfusions within 60 days prior. Median (min–max) depicted.

Summary/Conclusion: In this analysis, 88% of treated evaluable patients in HGB-207 and HGB-212 achieved TI and demonstrated stable HbA^{T87Q}. The safety profile was consistent with that of busulfan-based myeloablative conditioning. Beti-cel–related events were consistent with side effects of DMSO, a cryoprotectant used in the drug product.



S267 RESULTS FROM A PHASE 2, OPEN-LABEL, MULTICENTER STUDY OF THE ORAL PYRUVATE KINASE ACTIVATOR MITAPIVAT IN ADULTS WITH NON–TRANSFUSION-DEPENDENT ALPHA- OR BETA-THALASSEMIA

K. H. Kuo [1,*], D. M. Layton [2], A. Lal [3], H. Al-Samkari [4], J. Bhatia [5], B. Tong [5], M. Lynch [5], K. Uhlig [5], E. P. Vichinsky [3]

[1]Division of Hematology, University of Toronto, Toronto, Canada, [2]Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom, [3]UCSF Benioff Children's Hospital Oakland, Oakland, CA, [4]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [5]Agios Pharmaceuticals, Inc, Cambridge, MA, United States

Background: Thalassemias are characterized by ineffective erythropoiesis and hemolysis due to imbalanced production and precipitation of globin chains. Adenosine triphosphate (ATP) levels are reduced in thalassemic red blood cells (RBCs), despite increased energy demands to maintain RBC cell integrity. Mitapivat (AG-348) is an oral activator of RBC pyruvate kinase (PKR), an enzyme regulating ATP production via glycolysis. In mice, mitapivat increased ATP synthesis and survival of thalassemic RBCs. Mitapivat has been shown to increase hemoglobin (Hb) in patients (pts) with PK deficiency and sickle cell disease.
Aims: To report the results of the 24-week (wk) core period of a phase 2 open-label trial of mitapivat in adults with α- or β-non–transfusion-dependent thalassemia (NTDT; NCT03692052).
Methods: Key inclusion criteria: β-thalassemia ± α-globin gene mutations, Hb E β-thalassemia, or α-thalassemia (Hb H disease); Hb ≤10.0 g/dL; ≤5 RBC units transfused in prior 24 wks and none in 8 wks prior to study drug. Pts received mitapivat 50 mg orally twice daily (BID), then increased to 100 mg BID at Wk 6 visit, if tolerated. Primary endpoint was % pts who achieved a Hb response (increase ≥1.0 g/dL from baseline [BL] at any time between Wks 4–12, inclusive). Secondary endpoints included sustained Hb response (≥2 Hb increases of ≥1.0 g/dL vs BL during Wks 12–24 after achieving a primary Hb response), time to first ≥1.0 g/dL Hb increase, markers of hemolysis and erythropoiesis, and safety.
Results: Of 20 pts (15 female) who received mitapivat, the mean age (SD) was 45.3 (11.8) yrs (range 29–67); mean (SD) BL Hb was 7.9 (1.4) g/dL (range 5.1–9.8). At Wk 6, all pts were escalated to 100 mg BID. Nineteen pts (95.0%) completed the core period, one discontinued due to adverse event (AE);17 pts continued to the extension period. Sixteen pts (80.0%, 90% CI 59.9, 92.9; p<0.0001) achieved a Hb response, including 5/5 pts with α-thalassemia and 11/15 pts with β-thalassemia. Mean (SD) time to first Hb increase >1.0 g/dL was 4.5 (3.2) wks, and mean Hb (SD) increase from BL during Wks 12–24 was 1.3 (0.6) g/dL. A sustained response was achieved in 65% of pts, including 5/5 pts with α-thalassemia and 8/15 pts with β-thalassemia. Mean Hb change from BL over time and average Hb increase from BL by patient are shown (Figure). Hb increases occurred across the spectrum of BL levels. Directional improvements in markers of erythropoiesis and hemolysis were also observed. The safety profile was consistent with that of previously published mitapivat studies. There was one serious grade 3 unrelated AE of renal impairment which led to treatment discontinuation. There were three non-serious grade 3 AEs leading to dose reduction: 1 resulted in a permanent dose reduction to 50 mg BID, and 2 were successfully rechallenged at 100 mg BID. The most common non-serious AEs occurring in ≥25% of pts were initial insomnia (10/20), dizziness (6/20), and headache (5/20). Dose escalation to 100 mg BID was well tolerated and not associated with any increase in AEs. Twelve pts had DXA scans at BL and 6 months; no notable trends for changes in bone mineral density were observed.

Figure. Mean hemoglobin change from baseline over time

Baseline is at zero; dashed line indicates 1.0 g/dL above baseline
[a]Due to a protocol amendment, not all patients completed visits at Wks 3, 7, 9, and 10.
[b]All patients who completed the core period. Hb=hemoglobin; wk=week.

Summary/Conclusion: These results demonstrate that PKR activation with mitapivat was well tolerated and improved anemia, hemolysis, and ineffective erythropoiesis, and may represent a novel therapeutic approach for pts with α- or β-thalassemia. Pivotal trials will be initiated in 2021.

S268 INHIBITION OF FIBROBLAST GROWTH FACTOR-23 (FGF-23) AS A NOVEL STRATEGY TO TARGET BONE AND HEMATOPOIETIC STEM CELL NICHE DEFECTS IN BETA-THALASSEMIA

A. Aprile [1,*], L. Raggi [1], M. Storto [1], I. Villa [2], S. Bolamperti [2], S. Marktel [3], I. Motta [4,5], M. D. Cappellini [4,5], A. Rubinacci [2], G. Ferrari [1,6]

[1]San Raffaele-Telethon Institute for Gene Therapy (SR-Tiget), [2]Bone Metabolism Unit, Division of Genetics and Cell Biology, [3]Hematology and Bone Marrow Transplantation Unit, IRCCS San Raffaele Scientific Institute, [4]IRCCS Ca' Granda Foundation Maggiore Policlinico Hospital, [5]Department of Clinical Sciences and Community, University of Milan, [6]Vita-Salute San Raffaele University, Milan, Italy

Background: Over decades the research on beta-thalassemia (BT) has been mostly focused on erythropoiesis, leaving the study of the bone marrow (BM) environment and hematopoietic stem cells (HSC) underexplored. We have recently demonstrated that HSC function in BT is negatively affected by an altered BM microenvironment and that targeting of the defective HSC-BM stromal niche crosstalk rescues the impaired quiescence and self-renewal of HSC (*Aprile et al., Blood 2020*). BT can be cured by HSC transplantation from healthy donors or autologous HSC upon gene therapy. Since the quality of HSC and the conditions for engraftment depend on the presence of a healthy BM microenvironment, niche-HSC crosstalk plays a crucial role for post-transplant outcome.
Consistently with the common finding of osteoporosis in BT patients, we found in *Hbb*$^{th3/+}$ (*th3*) BT mice reduced bone deposition and low levels of parathyroid hormone (PTH), negatively affecting stem cell number, quiescence and self-renewal. Fibroblast growth factor-23 (FGF-23) is a hormone mainly secreted by osteocytes, which acts as negative regulator of bone metabolism and PTH production. Since FGF-23 is positively modulated by the anemia-related factor erythropoietin (EPO), we hypothesized that the high EPO levels in BT, subsequent to ineffective erythropoiesis, might contribute to FGF-23 increase, thus affecting bone and BM niche homeostasis.
Aims: We investigated the mechanisms underlying bone and HSC niche defects in BT and we focused on FGF-23. We also explored the role of EPO on enhancing FGF-23 levels.
Methods: We measured levels of FGF-23 in *th3* mice and BT patients by ELISA. We inhibited FGF-23 signaling in *th3* mice by *in vivo* administration of FGF-23 blocking peptide and we analyzed bone density by pQCT, HSC and erythroid populations upon treatment. We neutralized *in vivo* the EPO axis and analyzed FGF-23 levels.
Results: We measured high levels of circulating FGF-23 in BT mice (*n*=10) and patients (*n*=17). To provide proof of concept data of the causative role of FGF-23 on BT bone and stromal niche defects, we inhibited FGF-23 signaling. FGF-23 inhibition rescued the bone defect in *th3* mice, by increasing trabecular bone mineral density. Importantly, the treatment restored the frequency of HSC to levels comparable to wild-type controls by expanding the pool of quiescent cells. FGF-23 inhibition had also a positive anti-apoptotic effect on the expanded BM erythroid compartment, promoting the maturation of erythroid precursors, confirming results obtained in models of secondary anemias. *In vivo* neutralization of EPO axis demonstrated the causative role of EPO on enhancing FGF-23 levels in BT.
Preliminary evidence in BT patients showed negative correlations between FGF-23 and markers of bone homeostasis (e.g. osteocalcin and VitD), whereas positive correlations with ineffective erythropoiesis (e.g. reticulocytes).
Further analysis will unravel the negative impact of high FGF-23 on bone mineralization and BM stromal niche-HSC interactions in BT.
Summary/Conclusion: Our findings uncover an underexplored role of FGF-23 in bone and BM niche defects in BT, as a condition of severe anemia and chronic EPO stimulation, thus proposing FGF-23 as the molecule at the crossroads of erythropoiesis and bone metabolism. The inhibition of FGF-23 signaling might provide a novel strategy to ameliorate bone compartment and restore HSC-BM niche interactions in BT, with a potential translational relevance in improving HSC transplantation and gene therapy/editing approaches.

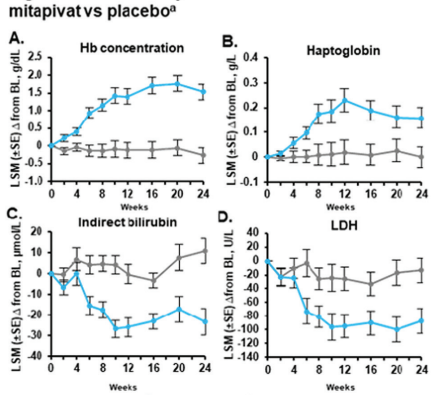
S269 TGF-BETA SIGNALING CONTROLS THE LINEAGE CELL FATE OF HEMATOPOIETIC STEM CELLS TOWARDS ERYTHROID BRANCHING IN BETA-THALASSEMIA

M. R. Lidonnici [1,*], G. Chianella [1], F. Tiboni [1], M. Barcella [1], I. Merelli [2], S. Scaramuzza [1], C. Rossi [1], S. Crippa [1], M. Storto [1], M. E. Bernardo [1,3], F. Ciceri [1,4,5], A. Aiuti [1,3,5], S. Marktel [1,4], G. Ferrari [1,5]

[1]San Raffaele Telethon Institute for Gene Therapy, IRCCS San Raffaele Scientific Institute, Milan, [2]Institute for Biomedical Technologies, National Research Council, Segrate, [3]Pediatric Immunohematology Unit, [4]Haematology and BMT Unit, IRCCS San Raffaele Scientific Institute, [5]University Vita-Salute San Raffaele, Milan, Italy

Background: Beta-thalassemia (Bthal) is a genetic disorder due to mutations in the ß-globin gene, leading to a reduced or absent production of HbA, which interferes with erythroid cell maturation and limits normal red cell production. Patients are affected by severe anemia, hepatosplenomegaly, and skeletal abnormalities due to rapid expansion of the erythroid compartment in bone marrow (BM) caused by ineffective erythropoiesis. In a classical view of hematopoiesis, the blood cell lineages arise via a hierarchical scheme starting with multipotent stem cells that become increasingly restricted in their differentiation potential through oligopotent and then unipotent progenitors. In human, novel purification strategies based on differential expression of CD49f and CD90 enrich for long-term (49f+) and short-term (49f–) repopulating HSCs, with similar myeloid (My) and lymphoid (Ly) potential. In this view, it has been proposed that erythroid (Ery) and megakaryocytic (Mk) fates branch off directly from 49f– cell. Recently, in a new study the use of CLEC9A marker highlighted the separation between multipotent (Ery/My/Ly) long-term repopulating cells (Subset1, defined as CLEC9A^{high}CD34^{low}) and cells with only My/Ly and no Ery potential (Subset2, defined as CLEC9A^{low}CD34^{high}) within the HSC/MPP compartment.
Aims: Recent evidence showed that the BM microenvironment is perturbed in Bthal. Our aim is to understand how the priming and kinetics of HSC undergoing lineage specification and differentiation are changed under this stress environment.
Methods: Immunophenotype and functional analysis of the lineage commitment allowed to characterize of most primitive Bthal HSC/MPP cells. Gene expression profiling of hematopoietic subpopulations sorted from BM samples of Bthal patients and healthy donors (HDs) delineated the transcriptional networks governing hematopoiesis. We evaluated the expression levels of niche factors involved in the regulation of hematopoiesis/erythropoiesis by ddPCR on RNA purified from Bthal mesenchymal stromal cells. Their protein levels in the BM plasma were analyzed by ELISA. Confirmation experiments are ongoing *in vivo* in Bthal murine model (*Hbb*$^{th3/+}$ strain).
Results: An increased proportion of MPPs was observed in Bthal patients compared to HDs. The Subset1 compartment was actually endowed with an enhanced Ery potential. Focusing on progenitors (CD34$^+$ CD38$^+$) and using a new sorting scheme that resolved My, Ery, and Mk lineage fates, we found a reduction of Ery (CD71$^+$ BAH1$^{-/+}$) subsets in Bthal samples. By gene expression profiling of Bthal HSC/MPP, we observed down-regulation of TGFß signaling-induced gene expression and enrichment in erythroid signature. The levels of TGFß molecules were altered in Bthal BM micro-environment and treatment of HD Subset 1 cells demonstrates how TGFß/BMP pathway is instrumental for the erythroid cell lineage specification of HSCs. The analysis of molecular pathways driven by TGFß signaling led to the identification of druggable targets with the potential to improve thalassemic hematopoiesis and to normalize erythropoiesis. Ongoing *in vivo* studies with specific drugs will provide cues to rescue the unbalanced hematopoietic primitive compartment
Summary/Conclusion: Overall, these findings show that Bthal HSCs are exiting from the quiescent state towards a preferential erythroid differentiation. The drivers are likely specific niche signals, linked to the TGFß, and chronic BM stimulation or, alternatively, a specific regulation of the '*erythroid branching*', naturally present in the HSC pool, which is exacerbated by the pathophysiology of the disease.

Changing the scene on congenital anemias



S270 ACTIVATE: A PHASE 3, RANDOMIZED, MULTICENTER, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY OF MITAPIVAT IN ADULTS WITH PYRUVATE KINASE DEFICIENCY WHO ARE NOT REGULARLY TRANSFUSED

H. Al-Samkari [1,*], F. Galactéros [2], A. Glenthøj [3], J. A. Rothman [4], O. Andres [5], R. F. Grace [6], M. Morado Arias [7], D. M. Layton [8], K. Onodera [9], M. Verhovsek [10], W. Barcellini [11], M. P. Judge [12], V. Beynon [12], E. Xu [12], P. Hawkins [12], E. Zagadailov [12], S. Gheuens [12], E. J. van Beers [13]

[1]Division of Hematology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, [2]Unité des Maladies Génétiques du Globule Rouge, CHU Henri Mondor, Créteil, France, [3]Department of Hematology, Rigshospitalet, Copenhagen, Denmark, [4]Duke University Medical Center, Durham, NC, United States, [5]Department of Paediatrics, University of Würzburg, Würzburg, Germany, [6]Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA, United States, [7]Hematology Department, Hospital Universitario La Paz, Madrid, Spain, [8]Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom, [9]Tohoku University Hospital, Sendai, Japan, [10]McMaster University, Hamilton, Canada, [11]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [12]Agios Pharmaceuticals, Inc, Cambridge, MA, United States, [13]Van Creveldkliniek, Department of Internal Medicine, University Medical Center Utrecht, Utrecht, Netherlands

Background: Pyruvate kinase (PK) deficiency is a rare hereditary disease caused by reduced red blood cell PK (PKR) enzyme activity leading to defective glycolysis. The resulting lifelong hemolytic anemia is associated with serious complications, regardless of transfusion status. Management is limited to supportive therapies. Mitapivat (AG-348) is an investigational, first-in-class, oral, allosteric activator of PKR, which was shown to improve hemolysis for up to 42 months in a phase (Ph.) 2 study of patients (pts) with PK deficiency.
Aims: The ACTIVATE study (NCT03548220) evaluated the efficacy and safety of mitapivat in adult pts with PK deficiency who were not regularly transfused.
Methods: ACTIVATE was a Ph. 3, randomized, double-blind, placebo (PBO)-controlled study. A 12-week (wk) dose escalation (5, 20, 50 mg twice daily) period (Part 1) was followed by a 12-wk fixed-dose period (Part 2). Primary endpoint was hemoglobin (Hb) response, defined as ≥1.5 g/dL increase in Hb from baseline (BL), sustained at ≥2 scheduled assessments at Wks 16, 20, or 24 during Part 2. Secondary endpoints were prespecified and tested in a hierarchical order at a 2-sided α=0.05 as follows: change from BL in Hb concentration, indirect bilirubin, reticulocyte percentage (%), and Hochberg testing for change from BL in lactate dehydrogenase (LDH), haptoglobin, and PK deficiency diary (PKDD) and PK deficiency impact assessment (PKDIA). The PKDD and PKDIA are disease-specific patient-reported outcomes (PROs) in which a higher score indicates more severe disease impact.
Results: Eighty pts were randomized (mitapivat n=40; PBO n=40). The population was balanced between the mitapivat and PBO arms: mean age 36.0 vs 37.2 years, 40% vs 40% male, 70% vs 80% white, mean BL Hb 8.6 vs 8.5 g/dL. The primary endpoint was met, with 16 mitapivat pts (40%) achieving a sustained Hb response vs 0 PBO pts (p<0.0001). Secondary endpoints were met, including significant improvements with mitapivat compared with PBO in BL Hb, hemolysis markers, and PROs: average change from BL (difference in least squares mean [95% CI]) in Hb concentration, 1.8 g/dL (1.2, 2.4; p<0.0001), indirect bilirubin, –26.26 µmol/L (–37.82, –14.70; p<0.0001), reticulocyte %, –0.1011 (–0.1391, –0.0632; p<0.0001), LDH, –70.81 U/L (–115.88, –25.74; p=0.0027), haptoglobin 0.158 g/L (0.043, 0.273; p=0.0079), and PKDD –3.11 (–5.80, –0.41; p=0.0247) and PKDIA –3.25 (–6.39, –0.12; p=0.0421). The Hb and hemolysis marker improvements in the mitapivat group were rapid and maintained over time (Figure). Treatment-emergent adverse events (TEAEs) occurred in 35 pts in each arm. TEAEs grade ≥3 occurred in 10 (25.0%) mitapivat vs 5 (12.8%) PBO pts. The most common TEAEs with mitapivat were nausea and headache, which were less frequent for mitapivat vs PBO (n=7; 17.5% vs n=9; 23.1% and n=6; 15.0% vs n=13; 33.3%, respectively). The most common TEAEs grade ≥3 with mitapivat were hypertriglyceridemia and hypertension (both n=2; 5.0%). Transaminase increases any grade/grade ≥3 occurred in 1 (2.5%)/0 (0%) mitapivat pt vs 6 (15.4%)/2 (5.1%) PBO pts. No TEAEs led to discontinuation.

Figure: Hb and hemolysis marker outcomes for mitapivat vs placebo[a]

[a]Difference in LSM for secondary endpoints comparing BL to average change at Weeks 16, 20, and 24; p-values are based on the MMRM method: Hb concentration, p<0.0001; haptoglobin, p=0.0079; indirect bilirubin, p<0.0001; LDH, p=0.0027;. BL=baseline; Hb=hemoglobin; LDH=lactate dehydrogenase; LSM=least squares mean; MMRM=mixed-effect model repeated measure; SE=standard error

Summary/Conclusion: ACTIVATE is the first PBO-controlled study in PK deficiency. Primary and secondary endpoints were met, indicating clinically meaningful benefit for pts treated with mitapivat. No new safety signals were identified. Mitapivat has the potential to be the first disease-modifying drug therapy approved for PK deficiency.

S271 ACTIVATE-T: A PHASE 3, OPEN-LABEL, MULTICENTER STUDY OF MITAPIVAT IN ADULTS WITH PYRUVATE KINASE DEFICIENCY WHO ARE REGULARLY TRANSFUSED

A. Glenthøj [1,*], E. J. van Beers [2], H. Al-Samkari [3], V. Viprakasit [4], K. H. M. Kuo [5], F. Galactéros [6], S. Chonat [7], J. Porter [8], S. Gheuens [9], V. Beynon [9], E. Xu [9], P. Hawkins [9], E. Zagadailov [9], A. Oluyadi [9], W. Barcellini [10]

[1]Department of Hematology, Rigshospitalet, Copenhagen, Denmark, [2]Van Creveldkliniek, Department of Internal Medicine, University Medical Center Utrecht, Utrecht, Netherlands, [3]Division of Hematology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, [4]Siriraj Hospital, Mahidol University, Bangkok, Thailand, [5]Division of Hematology, University of Toronto, Toronto, Canada, [6]Unité des Maladies Génétiques du Globule Rouge, CHU Henri Mondor, Créteil, France, [7]Aflac Cancer and Blood Disorders Center, Children's Healthcare of Atlanta and Department of Pediatrics, Emory University, Atlanta, GA, United States, [8]Department of Haematology, University College London Cancer Institute, London, United Kingdom, [9]Agios Pharmaceuticals, Inc., Cambridge, MA, United States, [10]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Pyruvate kinase (PK) deficiency is a rare hereditary disease caused by reduced red blood cell PK (PKR) enzyme activity leading to defective glycolysis and decreased red blood cell (RBC) lifespan, resulting in lifelong hemolytic anemia and associated comorbidities. In a natural history study, 12% of adult patients (pts) with PK deficiency were found to require regular transfusions, which have been associated with chronic complications, including iron overload and end organ damage. There are currently no approved disease-modifying drug therapies for this condition. Mitapivat (AG-348) is an investigational, first-in-class, oral, allosteric activator of PKR. In a phase (Ph.) 2 study of PK deficiency pts that were not regularly transfused, mitapivat improved hemoglobin (Hb) and hemolysis markers for up to 42 months. This current study was designed to further evaluate mitapivat in the regularly transfused PK deficiency population.
Aims: The ACTIVATE-T study (NCT03559699) evaluated the efficacy and safety of mitapivat in adult pts with PK deficiency who were regularly transfused.
Methods: ACTIVATE-T was a global, multicenter, open-label, Ph. 3 study in regularly transfused adults with PK deficiency. A 16-week (wk) dose escalation (5, 20, 50 mg twice daily) period (Part 1) was followed by a 24-wk fixed-dose period (Part 2). Key inclusion criteria: age ≥18 years (yrs), documented presence of ≥2 mutant alleles in *PKLR* (of which ≥1 was a missense mutation) and ≥6 transfusion episodes in the past 52 wks. Primary endpoint: reduction in transfusion burden, defined as ≥33% reduction in number of RBC units transfused during Part 2 compared with the pt's individual historical transfusion burden standardized to 24 wks. The p-value calculation was based on the binomial exact test of H0: transfusion reduction response rate ≤10% vs H1: transfusion reduction response rate >10% at a 1-sided α=0.025. Pts who discontinued the study before completing 12 wks of treatment in Part 2 were considered non-responders. Secondary endpoints included transfusion-free responders (defined as no transfusions during Part 2) and annualized RBC units transfused.
Results: Twenty-seven pts were enrolled: mean age 36.6 yrs, 26% male, 74% white, mean baseline Hb 9.2 g/dL. Of the 27 pts treated in the study, 20 (74%) completed Part 2, 6 (22%) discontinued treatment, and 1 was lost to follow-up. Ten (37%) pts treated with mitapivat achieved a ≥33% reduction in transfusion burden (1-sided p=0.0002; Table). Mean number of RBC units transfused (annualized) was 11.38 up to the end of the study, compared with 16.63 historically; relative reduction=39%. Six (22%) pts were transfusion-free during Part 2. Treatment-emergent adverse events (TEAEs) occurred in all pts. TEAEs grade ≥3 occurred in 8 (30%) pts. The most common TEAEs (any grade) were increased alanine aminotransferase (n=10; 37%) and headache (n=10; 37%). No TEAEs led to discontinuation of treatment.

Table: Primary and secondary efficacy endpoint outcomes with mitapivat (N=27)

Primary endpoint	Responders, n[d]	Responders, %	95% CI	1-sided p-value[e]
Reduction in transfusion burden[a]	10	37%	19–58%	0.0002
Secondary endpoint	**Responders, n[d]**	**Responders, %**	**95% CI**	
Transfusion-free[b]	6	22%	9–42%	
Secondary endpoint	**Historical mean, n**	**During study mean, n**	**Relative reduction**	
Annualized RBC units transfused[c]	16.63	11.38	39%	

[a]Defined as ≥33% reduction in number of RBC units transfused during Part 2, standardized to 24 wks, compared with historical transfusion burden standardized to 24 wks; [b]Defined as no transfusions during Part 2; [c]Defined as total number of RBC units standardized to 52 wks; [d]Pts who discontinued before completing 12 wks of treatment in Part 2 were considered non-responders; [e]Based on binomial exact test of H0: transfusion reduction response rate ≤10% vs. H1: transfusion reduction response rate >10% at a 1-sided α=0.025.
CI=confidence interval; pts=patients; RBC=red blood cell; wks=weeks

Summary/Conclusion: ACTIVATE-T is the first Ph. 3 clinical study in pts with PK deficiency who are regularly transfused. The study demonstrated a significant decrease in transfusion burden, and 22% of pts were transfusion-free. No new safety signals were identified. These results support that mitapivat, through the novel mechanism of PKR activation, provides meaningful benefit to regularly transfused pts with PK deficiency. Mitapivat has the potential to become the first disease-modifying drug therapy approved for PK deficiency.

S272 IDENTIFICATION OF A NOVEL GENE CAUSING AN AUTOSOMAL RECESSIVE FORM OF CONGENITAL DYSERYTHROPOIETIC ANEMIA TYPE III

G. Hernández [1,*]

[1]Department of Basic Sciences, International University of Catalonia, Sant Cugat, Spain

Background: Congenital Dyserythropoietic Anemia (CDA) Type III was first described in a Swedish family as a disease with a dominant hereditary pattern caused by mutations in the *KIF23* gene, whose protein product is involved in cytokinesis. Despite this, there are several reports of an autosomal recessive inheritance form of CDA III with no identified genetic cause.
Aims: To identify the genetic origin of the recessive forms of Congenital Dyserythropoietic Anemia (CDA) Type III
Methods: Gene variant analysis using WES sequencing coupled with siRNA silencing and microscopy studies. CRISPR/Cas9 technology to generate knock-in models in zebrafish and knock-out cellular models.
Results: Here we report a young Spanish case clinically diagnosed of CDA III with no mutations in any of the known CDA genes, including *KIF23* gene. His bone marrow aspirate showed the typical phenotype of CDA III with giant multinucleated erythroblasts, giant hyperlobulated erythroblast, inter-cytoplasmatic bridges and chromatin bridges. The rest of the family was unaffected pointing to a possible recessive form of CDA III. The family was analyzed by WES and a pathogenic rare missense mutation was identified in homozygosis in the proband; while the rest of the family (father, mother and unaffected sister) were heterozygous. Silencing of the identified gene in HeLa cells mimics the phenotype observed in the bone marrow of our patient. Complete abrogation of this gene in zebrafish shows defects in cytokinesis and erythropoiesis and showing a clear anemic phenotype. The protein product of this gene has a role in cytokinesis and it is highly expressed in erythroid cells.
Summary/Conclusion: All these evidences indicate that we have identified a new gene responsible for an autosomal recessive form of CDA type III. We are currently generating a knock-in zebrafish models with the same mutation as the one presented in our patient, as well as sequencing additional possible CDA type III cases.

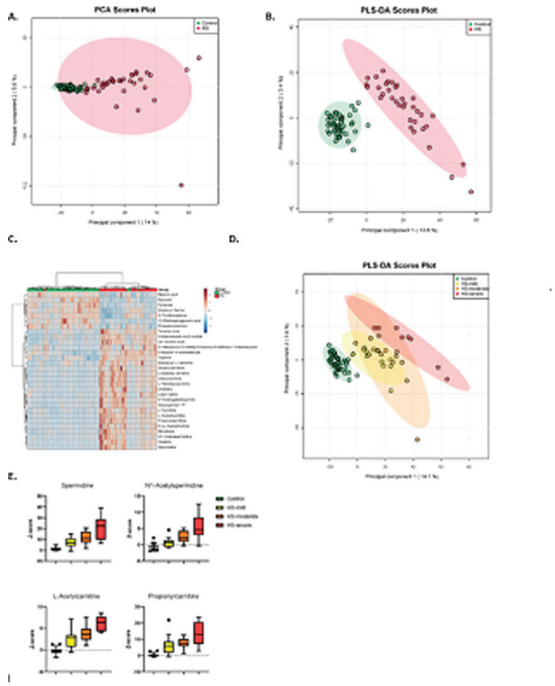
S273 ESTABLISHMENT AND PHENOTYPING OF VIABLE MOUSE MODELS OF X-LINKED SIDEROBLASTIC ANEMIA AND PROTOPORPHYRIA USING CRISPR-CAS9 EDITING

S. Ducamp [1,*], D. Campagna [1], P. Schmidt [1], M. Fleming [1]

[1]Pathology Department, Boston Children's Hospital, Boston, United States

Background: 5-aminolevulinic acid synthase 2 (ALAS2) is the first and rate-limiting enzyme of erythroid heme biosynthesis. It combines glycine

and succinyl-coA to form 5-aminolevulinic acid (ALA), the precursor of porphyrins and heme. ALAS2 is essential in mammals, its expression being precisely regulated during erythropoiesis. Inherited ALAS2 defects cause two rare diseases: X-linked Sideroblastic Anemia (XLSA) and X-linked Protoporphyria (XLPP), due to loss-of-function and gain-of-function mutations, respectively. Male XLSA patients have a microcytic hypochromic anemia of variable severity, characterized by abnormal mitochondrial iron deposits in nucleated and enucleated erythroid cells, termed ring sideroblasts and siderocytes. In two-thirds of patients, the anemia responds to pyridoxine (B6) supplementation. Both male and female XLPP patients develop acute photosensitivity, due to accumulation of free protoporphyrin (PP) in erythrocytes. No curative treatment, other than hematopoietic stem cell transplantation, is available for XLSA or XLPP.
Aims: The lack of ALAS2 mouse models has limited both our understanding of physiopathology, and potential treatment of XLSA and XLPP. We aimed to establish XLSA and XLPP mouse models.
Methods: Employing CRISPR/Cas9 gene targeting technology, we established 3 common XLSA (ALAS2 p.R170H, p.R411H and p.R452H) and 1 XLPP (ALAS2 p.Q548X) mutations in mice. The natural history of the disease was determined for each strain, focusing on blood parameters, free PP levels, and erythropoiesis. We also examined the consequences of vitamin B6 deficient and supplemented diets on each of these parameters.
Results: Four independent injections were performed in E0.5 blastocysts (C57BL/6N) generating a total of founder 45 animals. Animals harboring the expected allele were identified (p.R170H: 3 of 13; p.R411H: 1 of 2; p.R452H: 1 of 14 and Q548X: 4 of 16 animals) and transmitted through the germline. Mutant and control littermate animals have been phenotyped up to one-year of age.
XLSA: Variable numbers of siderocytes are present in peripheral blood smears of animals of all three XLSA lineages as early as 1 week of age and each develops a progressive microcytic, hypochromic anemia.As expected male phenotypes were more severe than female phenotypes, but siderocytes and erythroid defects are also observed in female XLSA carriers. The p.R411H strain has the most severe phenotype. B6 depletion in the p.R411H strain results in a severe ineffective erythropoiesis manifest as extreme splenomegaly and a block in erythroid differentiation.
XLPP: Both XLPP p.Q548X males and females accumulate free PP in erythrocytes. Compared to the Fech^{m1Pas} model (C57BL/6J) of erythroid protoporphyria due to a severe recessive loss-of-function mutation in ferrochelatase, the peak of free PP accumulation occurs earlier in age in XLPP mice. In early stages of the disease (8 weeks), XLPP mice do not develop liver fibrosis.
Summary/Conclusion: For the first time, knock-in ALAS2 mouse strains with viable loss and gain of function mutations have been obtained and each expresses the key features of the corresponding human diseases.



S274 METABOLIC FINGERPRINT IN HEREDITARY SPHEROCYTOSIS CORRELATES WITH RED BLOOD CELL CHARACTERISTICS AND CLINICAL SEVERITY

B. Van Dooijeweert [1,*], M. Broeks [2], N. Verhoeven-Duif [2], W. van Solinge [3], E. van Beers [4], M. Rab [5], E. Nieuwenhuis [6], J. Jans [2], M. Bartels [7], R. van Wijk [3]

[1]Pediatric Hematology/ Central Diagnostic Laboratory Research, [2]Genetics, Section Metabolic Diagnostics, [3]Central Diagnostic Laboratory Research, [4]Van Creveldkliniek, [5]Central Diagnostic Laboratory Research / Van Creveldkliniek, [6]Pediatric Hematology, [7]Pediatric Hematology/Van Creveldkliniek, University Medical Center Utrecht, Utrecht, Netherlands

Background: Hereditary spherocytosis (HS) is one of the most common forms of hereditary hemolytic anemia in people of northern European descent (1:2000-3000). It is characterized by altered red blood cell (RBC) membrane integrity due to disruption of the (vertical) association between the cytoskeleton and the lipid bilayer. The disorder is highly heterogeneous, both clinically and molecularly, and genotype-phenotype correlations are largely unclear. The mechanistic basis of decreased red blood cell (RBC) deformability in HS has been well established but little is known about the metabolic consequences of reduced membrane-cytoskeleton integrity in HS. This question is especially relevant since RBC membrane proteins are implicated in cellular metabolism. In this study we investigated the metabolic impact of membrane defects using untargeted metabolomics in dried blood spots (DBS) and established a metabolic fingerprint for HS.
Aims: Investigating broad metabolic changes in HS by defining a metabolic signature for HS could **1.** contribute to increased understanding of clinical heterogeneity, and **2.** provide new leads for studying pathophysiological mechanisms in HS.
Methods: Untargeted metabolomics was applied on DBS samples obtained from 35 HS patients and 50 healthy controls by direct infusion high resolution mass spectrometry using a previously established protocol. (1,2) Statistical analyses were performed using MetaboAnalyst and Graphpad Prism (Version 8.3.0;538). Red blood cell deformability was evaluated by osmotic ektacytometry on the Laser Optical Rotational Red Cell Analyzer (Lorrca, RR Mechatronics, Zwaag, Netherlands)
Results: In total, 1770 unique metabolite features were identified in the respective DBS samples from patients and controls. Distinct metabolic profiles between groups were identified by principal component analysis and partial least square discriminant analysis (Figure 1A-B). Distinctive increased metabolites in the HS-fingerprint include polyamines and (acyl) carnitines. Vitamin B6 intermediates, 2,3-diphosphoglyceric acid and glyceraldehyde 3-phosphate were significantly decreased in HS ($p<0.0001$) (Figure 1C). Interestingly, when exploring phenotypic heterogeneity, subgroups of mildly, moderately and severely affected patients could be identified, revealing discrete differences in metabolic profiles for especially the mildly and severely affected patients (Figure 1D). Furthermore, the most discriminating metabolites in these metabolic profiles showed a gradient that relates with clinical disease severity (Figure 1E), and they correlated inversely and statistically significant with red cell characteristics. In addition, a trend to significance was observed for these metabolites and red blood cell deformability as measured by osmotic gradient ektacytometry.

Figure 1.

Summary/Conclusion: In this study we identified a metabolic fingerprint for patients with HS using untargeted metabolomics in dried blood spots. The metabolic disturbances include altered levels of 2,3-DPG and polyamines, that correlate with red cell characteristics and clinical severity. Hence, our data show that untargeted metabolomics in DBS is instrumental in investigating phenotypic heterogeneity and it provides promising leads for studying pathophysiological mechanisms in HS.

Focus on iron metabolism

S275 HEPATOCYTES INSTRUCT LIVER SINUSOIDAL ENDOTHELIAL CELLS TO INDUCE BMP6 IN RESPONSE TO IRON

S. Colucci [1,2,*], S. Altamura [1,2], O. Marques [1,2], K. Müdder [2], M. W. Hentze [1,3], M. U. Muckenthaler [1,2]

[1]Molecular Medicine Partnership Unit (MMPU), [2]Department of Pediatric Hematology, Oncology and Immunology, University of Heidelberg, [3]European Molecular Biology Laboratory (EMBL), Heidelberg, Germany

Background: Iron availability is essential for erythropoiesis and needs to be maintained within the physiological range to prevent hematological disorders. The liver hormone hepcidin is the master regulator of systemic

iron homeostasis. It binds and triggers degradation of the sole cellular iron exporter ferroportin (Fpn), blocking dietary iron absorption and iron release from cellular stores. Hepatic iron levels control hepcidin mRNA expression in hepatocytes (HCs) by modulating the BMP signaling pathway. Conditions of iron overload induce the growth factor BMP6 that is released from liver sinusoidal endothelial cells (LSECs), the most relevant cell type of the liver for sensing of iron availability. LSECs account for only a very small percentage of total liver cells and primary cultures are difficult to generate as these cells easily transdifferentiate. Therefore detailed molecular insights into how LSECs sense iron levels and the signaling pathways controlling BMP6 production in response to iron levels are challenging to obtain.
Aims: Our aim is to understand the molecular mechanisms of how the liver senses iron availability, controls BMP6 production and hepcidin synthesis. Results are expected to be translated to new therapeutic strategies for iron-related disorders.
Methods: Murine liver cell suspensions were prepared by *in vivo* liver perfusion and digestion. HCs and LSECs were isolated combining cell gradient isolation and exclusion adherence steps or immunoselection with antibodies conjugated to magnetic beads. The quality of the LSEC preparations was assessed by FACS analysis and Scanning Electron Microscopy. Ferritin protein levels and *Transferrin Receptor 1* mRNA expression served as markers to determine the intracellular iron content of isolated liver cells. RNA-seq of HCs and LSECs isolated from FpnC326S mice was performed with Illumina NextSeq500.
Results: We established highly pure primary murine LSEC cultures with 95% of cells positive for LSEC markers. Analyses of the LSEC ultrastructure indicated the presence of fenestrae - a unique LSEC feature that confirms the absence of transdifferentiation. We show that primary LSECs fail to modulate BMP6 expression in response to iron treatment, but require a co-culture with iron-loaded primary HCs to significantly increase BMP6 expression. These data are supported by findings from a genetic mouse model of systemic iron overload (FpnC326S), hallmarked by iron-loaded HCs and elevated BMP6 levels despite a lack of increased iron content in LSECs. RNA-seq analysis of primary HCs and LSECs isolated from FpnC326S mice identified altered signaling pathways. Experiments are ongoing to combine these results with *in silico* ligand-receptor interaction analysis and experiments in primary cell cultures to unravel the hepatocytic factor essential for the iron-dependent regulation of BMP6.
Summary/Conclusion: We established a high quality preparation of primary LSECs as a fundamental tool to investigate how these cells sense iron to modulate BMP6 expression. Our *ex vivo* data reveal that, contrary to former belief, the LSEC-secreted growth factor BMP6 is not regulated by changes in the LSEC intracellular iron content. Accordingly, we show that LSECs isolated from a mouse model of iron overload are not iron-loaded, despite increased BMP6 expression. Importantly, co-culture of primary LSECs with HCs demonstrates that the latter are essential to induce BMP6 expression when iron levels are increased. These data support a model in which cell-to-cell communication between HCs and LSECs is essential to sense iron availability and activate BMP6 transcription.

S276 NEW INSIGHTS INTO PATHOGENIC MECHANISMS OF HEPATIC IRON METABOLISM DUE TO PIEZO1 GAIN OF FUNCTION VARIANTS.

B. E. Rosato [1], R. Marra [1], V. D'Onofrio [1], V. A. Lasorsa [1], M. Capasso [1], R. Russo [1], A. Iolascon [1], I. Andolfo [1,*]

[1]*Dip. di Medicina Molecolare e Biotecnologie Mediche, University of Naples Federico II, Ceinge biotecnologie avanzate, Napoli, Italy*

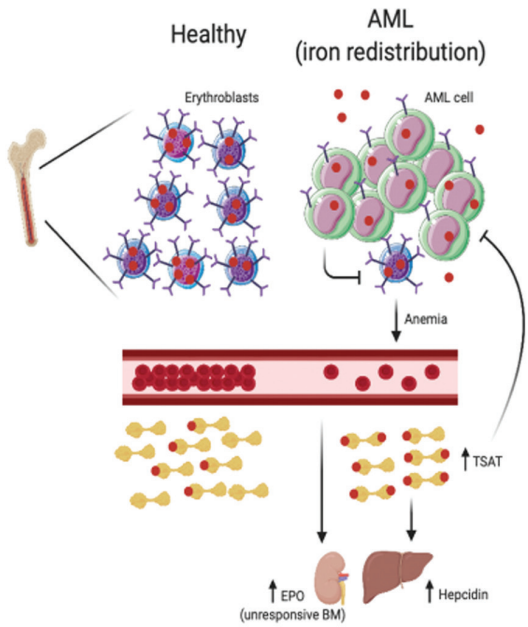
Background: Dehydrated hereditary stomatocytosis (DHS) is an autosomal dominant condition characterized by alterations in red blood cell membrane permeability to the cations. The most frequently mutated gene in DHS is *PIEZO1* that encodes a mechanoreceptor, a cation channel activated by mechanical stimuli. Pathogenic variants in PIEZO1 result in a gain-of-function (GOF) phenotype with delayed inactivation of the cation channel that leads to erythrocyte dehydration. The most harmful complication is the hepatic iron overload (Andolfo et al, AJH 2018; Picard et al Haematologica 2019). We already demonstrated the involvement of PIEZO1 at hepatic level by alterations of ERK1/2 and BMP/SMADs pathways that led to the suppression of hepcidin (Andolfo et al, AJH 2020). This finding was recently confirmed and extended by the study of the mouse model carrying a GOF variant of PIEZO1 that develop age-onset iron overload and specific alterations of the macrophage phagocytic activity (Ma et al, Cell 2021). These recent studies suggest that *PIEZO1* is an important genetic factor involved in iron metabolism but the molecular mechanism by which it regulates iron metabolism in the interplay among RBCs, hepatocytes and macrophage is still unknown.
Aims: This study aims to dissect the mechanism that links *PIEZO1* GOF variants to the suppression of hepcidin by investigation of new players of intracellular signaling pathways.
Methods: Creation of Hep3b engineered R2456H-PIEZO1 knock-in (KI) cells by CRISPR/Cas9; qRT-PCR and western blotting analysis; calcium and potassium ion channel assay; differential proteomics analysis, and RNA sequencing.
Results: To study the involvement of PIEZO1 in the regulation of iron homeostasis we established a KI Hep3b cell model heterozygous for the most frequent variant of PIEZO1, R2456H, by CRISPR/Cas9 technology (Hep3b-GOF-PIEZO1). Hep3b-GOF-PIEZO1 cells showed (i) no alteration of PIEZO1 gene and protein expression; (ii) increased intracellular calcium concentration compared to Hep3b-WT cells; (iii) hyper activation of the potassium channels activity compared to Hep3b-WT; (iv) reduced *HAMP* expression, according to the decreased phosphorylation of the BMP/SMADs pathway. To further dissect the alteration of the transcriptome and proteome of Hep3b-GOF-PIEZO1 model, we performed both differential proteomics and RNA-Seq. Differential proteomics identified 225 total proteins differentially regulated in Hep3b-GOF-PIEZO1 cells compared to Hep3b-WT ones (Protein with Log2 Difference ≥ ± 1 and -Log p-value > 1.3 were considered significantly enriched), 147 upregulated and 78 downregulated. RNA-Seq identified 5689 genes differentially regulated in Hep3b-GOF-PIEZO1 cells compared to Hep3b-WT ones ($p<0.05$, post-hoc correction by FDR), 1695 up-regulated and 1823 down-regulated ($-0.5 \leq$fold change≤ 0.5). Using this *multiomics* integrated approach, Hep3b-GOF-PIEZO1 cells showed alterations in several proteins belonging to MAPK pathways, and revealed new genes and proteins that links the increased calcium concentration to the activation of the intracellular pathways as TGF-b signaling and R-RAS.
Summary/Conclusion: We herein deeply dissected the mechanism by which PIEZO1 GOF mutations cause hepatic iron overload in DHS. The creation of a hepatic engineered cell line for PIEZO1 R2456H variant confirmed the effect on the cation flux and the deregulation of iron status. Proteomic and transcriptomic data give us the opportunity to improve our knowledge identifying new actors in the regulation of the complex landscape of iron metabolism.

S277 ANEMIA OF CHRONIC KIDNEY DISEASE IS PREVENTED THROUGH TRANSFERRIN RECEPTOR 2 INHIBITION

V. Olivari [1,2,*], M. R. Lidonnici [3], M. Aghajan [4], M. Pettinato [1,2], S. M. Di Modica [1], A. Pagani [1], L. Silvestri [1,2], S. Guo [4], G. Ferrari [2,3], A. Nai [1,2]

[1]*Regulation of Iron Metabolism Unit - Division of Genetics and Cell Biology, San Raffaele Scientific Institute,* [2]*Vita-Salute San Raffaele University,* [3]*Gene Transfer into Stem Cell Unit, SR-Tiget, San Raffaele Scientific Institute, Milan, Italy,* [4]*Ionis Pharmaceuticals, Inc., Carlsbad, CA, United States*

Background: Chronic Kidney Disease (CKD) is characterized by progressive kidney failure, low erythropoietin (EPO) levels, inflammation and iron deficiency, factors that contribute to anemia development.
Current EPO-based therapies, often with iron supplementation, are effective but frequently lead to side effects, mainly cardio-vascular. Thus, more specific approaches are needed.
Transferrin Receptor 2 (TFR2) in hepatocytes regulates hepcidin and iron homeostasis, and in erythroid cells interacts with EPO receptor, adjusting EPO sensitivity. In mice, total and hepatic *Tfr2* inactivation causes iron overload, while its ablation in the erythroid compartment boosts erythropoiesis.
Aims: We investigated whether *Tfr2* may be a therapeutic target for renal anemia. Our approach is expected to simultaneously increase iron availability and erythroid EPO responsiveness. Moreover, given the restricted expression of TFR2, off-target effects should be limited.
Methods: Feeding mice an adenine-rich diet for 8 weeks we induced CKD in:
(1) mice with bone marrow (BM)-specific deletion of *Tfr2* ($Tfr2^{BMKO}$) and relative controls, generated through BM transplantation and fed the adenine diet after complete recovery;
(2) mice with reduced *Tfr2* expression in the liver, obtained treating wild type mice twice a week for 6 weeks with antisense oligonucleotides anti-*Tfr2* (*Tfr2*-ASO) after renal damage development;
(3) mice with germline *Tfr2* inactivation in the whole organism ($Tfr2^{KO}$) and relative controls ($Tfr2^{WT}$).
Results: Renal damage and iron restriction were comparable between $Tfr2^{BMKO}$ and control mice, but $Tfr2^{BMKO}$showed enhanced erythropoiesis,



due to the increased EPO responsiveness of erythroid cells lacking *Tfr2*, as suggested by the over-activation of the EPO-EPOR signaling pathway (despite comparable EPO levels). However, anemia was only delayed, since at the end of the 8-week-long protocol iron availability was not adequate to sustain the enhanced erythropoiesis.
Having the proof-of-principle that targeting erythroid *Tfr2* stimulates erythropoiesis in CKD, we moved to *Tfr2*-ASO treatment, which downregulates *Tfr2* in the liver (95-97%), but not in the erythroid compartment. Circulating iron levels were increased in *Tfr2*-ASO mice, that showed also higher red blood cells (RBC) count and hemoglobin (Hb) levels during the first 2 weeks of treatment. However, Hb reverted to control levels before the end of the protocol. Thus, we confirmed that increased iron availability alone, due to hepatic *Tfr2* downregulation, is not sufficient to boost erythropoiesis for a long period.
Finally, despite comparable renal damage, $Tfr2^{KO}$ mice showed higher RBC count and Hb levels compared to $Tfr2^{WT}$ littermates, until the end of the 8-week-long protocol.
Summary/Conclusion: The concomitant targeting of hepatic and erythroid *Tfr2*, here obtained through a total genetic inactivation, is necessary to ameliorate anemia of CKD. Indeed, on one side, selective *Tfr2* inactivation in the BM enhances EPO responsiveness of erythroid cells and stimulates erythropoiesis, without increasing EPO levels per se. On the other side, hepatic *Tfr2* targeting increases iron availability. Therefore, a specific approach able to inhibit both hepatic and erythroid *Tfr2* could adjust iron availability according to the enhanced erythropoiesis, correcting both the drivers of anemia development in CKD. In the future, we will compare this approach to the available therapies and possibly move to a pharmacologic targeting.

S278 LOSS OF ERYTHROBLASTS IN ACUTE MYELOID LEUKEMIA CAUSES IRON REDISTRIBUTION WITH CLINICAL IMPLICATIONS

M. Lopes [1], T. Duarte [1], M. Teles [1,2,3], L. Mosteo [1], S. Chacim [4], E. Aguiar [5], J. Pereira-Reis [1], M. Oliveira [1], A. Silva [6], N. Gonçalves [7], G. Martins [7], I. Kong [8], M. Background: Acute myeloid leukemia (AML) is a heterogeneous disease with poor prognosis and limited treatment strategies. Determining the role of cell-extrinsic regulators of leukemic cells is vital to gain clinical insights into the biology of AML. Iron is a key extrinsic regulator of cancer but its systemic regulation remains poorly explored in AML.
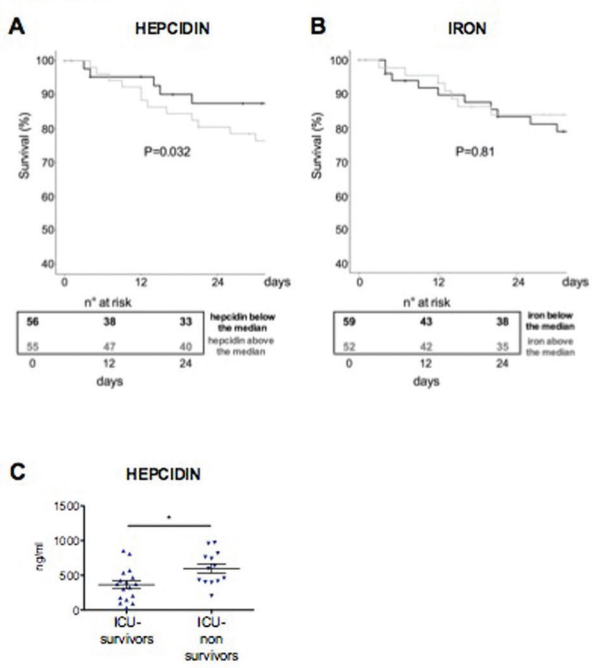
Aims: We aimed at studying iron metabolism in AML and the mechanisms involved in its regulation.
Methods: We analyzed AML patients at diagnosis and explored mechanisms involved in the regulation of iron metabolism using the syngeneic MLL-AF9-induced AML mouse model and mouse mutants.
Results: We analyzed serum iron parameters of 84 AML patients at diagnosis and observed a unique profile not associated with inflammation or red blood cell (RBC) transfusions: high ferritin, low transferrin, normal to high serum iron and elevated TSAT (median 51.5%). We also observed that AML patients had very high circulating hepcidin levels (median 152.0 vs. 14.3 ng/ml; $p < 0.001$), albeit a modest increase in inflammatory C-reactive protein (CRP) and interleukin 6 (IL-6). To explore the mechanism underlying the changes of iron metabolism in AML, we used the syngeneic MLL-AF9 AML mouse model. We observed that only infiltrated mice treated with chemotherapy had increased TSAT. Interestingly, AML-burdened mice had hyperleukocytosis with lymphopenia and thrombocytopenia but normal RBC and reticulocyte counts. A key difference between adult mice and humans is the significant contribution of the spleen to mouse erythropoiesis. We observed that bone marrow (BM) erythroblasts were depleted in human and mouse AML but splenic erythropoiesis was enhanced in leukemic mice. We hypothesized that the loss of erythroblasts in AML could also drive iron redistribution and TSAT increase in mice, if not compensated by an increased splenic erythropoiesis. As predicted, splenectomized mice with AML had anemia, reticulocytopenia, increased TSAT and detectable non-transferrin bound iron (NTBI), demonstrating that loss of BM erythroblasts in AML causes iron redistribution. Through direct quantification, protein and transcriptomic analysis, we demonstrated that iron is partially redistributed into AML cells. This led us to hypothesize that iron redistribution may be clinically relevant in AML. Survival analysis revealed that AML patients with higher TSAT at diagnosis had significantly better overall survival (OS), even after multivariate analysis. Experiments using different mouse models (*Hfe*-KO, iron-dextran) confirmed that increased TSAT is associated with better OS in AML.

Summary/Conclusion: Our study shows that AML patients have a unique iron profile independent of RBC transfusions characterized by increased TSAT due to loss of BM erythroblasts. We propose that TSAT at diagnosis may be a relevant independent prognostic factor in AML.

S279 HEPCIDIN IS A MARKER OF COVID-19 SEVERITY AND MORTALITY IN A COHORT OF HOSPITALIZED ITALIAN PATIENTS

L. Silvestri [1,*], A. Nai [1], N. I. Lorè [2], A. Pagani [1], R. De Lorenzo [3], S. Di Modica [1], F. Saliu [2], D. M. Cirillo [2], P. Rovere-Querini [4], A. Manfredi [5]

[1]Dlv. Genetics and Cell Biology, [2]Emerging Bacterial Pathogens Unit, [3]San Raffaele Vita-Salute University, IRCCS San Raffaele Scientific Institute, [4]Division of Immunology, Transplantation and Infectious Diseases-IRCCS San Raffaele Scientific Institute, [5]San Raffaele Vita-Salute University, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, IRCCS San Raffaele Scientific Institute, Milano, Italy



Background: Several risk factors for Severe Acute Respiratory Coronavirus 2 (SARS-CoV-2) infection are well established, including advanced age, male gender, strong inflammatory response, neutropenia and lymphopenia, and more recently hypoferremia. Hepcidin, the liver peptide hormone whose role is to regulate plasma iron concentration, is at the crossroad between iron metabolism and inflammation, being positively regulated by iron itself and proinflammatory cytokines. However, its role as potential biomarker of COVID-19 severity has not been explored in depth.
Aims: Aim of the study is to investigate whether plasma hepcidin, measured at admission, can be considered a marker of COVID-19 severity and mortality.
Methods: Plasma hepcidin and iron levels were analyzed in a well-characterized cohort of 111 Italian COVID-19 patients hospitalized between March 18th and May 5th, 2020 at San Raffaele University Hospital

(UH), in Milan, Italy, one regional COVID-19 reference hospital. Diagnosis of COVID-19 was based on a positive real-time reverse-transcriptase polymerase chain reaction (RT-PCR) from a nasal and/or throat swab together with signs, symptoms, and/or radiological findings suggestive of COVID-19. The cohort had a median age of 57.6 (48.5-66.3) years, and included prevalently males (64%). Blood samples were obtained at admission, plasma immediately retrieved and frozen until analyzed for the concentration of iron, hepcidin (ELISA kit from Intrinsic LifeSciences), proinflammatory markers as C-reactive protein (CRP) and ferritin, and cytokines with a role in hepcidin modulation, as interleukin IL6, IL1b, TNFa and Interferon gamma (IFNg).

Results: In this cohort of COVID-19 patients, iron concentration was below normal range in 93.7% of patients, whereas hepcidin levels were significantly increased in 61.3% of patients. However, considering that hypoferremia suppresses hepcidin expression, even normal hepcidin is inappropriately high in most cases. Patients with higher hepcidin levels were significantly older and had higher concentrations of markers of inflammation (CRP and ferritin) and cell damage (AST and LDH). Negative correlations were observed with the severity of respiratory failure, as reflected by the PaO2/FiO2 *ratio*. The role of hepcidin is strengthened by the Kaplan-Meier survival curve (**Figure 1A**) and confirmed by the Regression Tree analysis, which identified hepcidin as the most important predictor of death among the others recognized predictors. On the other hand, iron levels do not affect survival, likely because of the uniformly low levels in all patients (**Figure 1B**).

Interestingly, limiting the analysis to critical patients in ICU, high hepcidin predicts mortality (**Figure 1C**), independently of age lung function, inflammation and tissue damage.

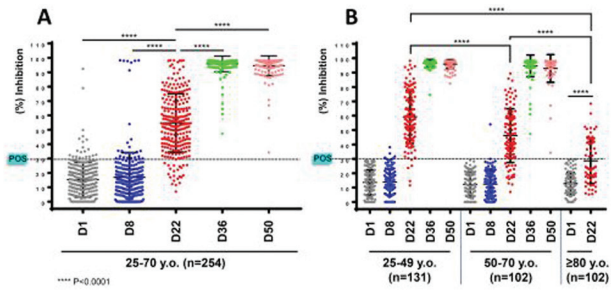
FIGURE 1

Summary/Conclusion: Overall our data suggest that hepcidin can be considered a marker of morbidity and outcome of COVID-19, of special value for severely compromised patients in ICU (Nai et al., AJH 2021). Further studies are needed to verify whether targeting the hepcidin axis may influence the disease outcome.

Fungal, bacterial and viral infections in hematology

S280 DEVELOPMENT OF NEUTRALIZING ANTIBODIES AGAINST SARS-COV-2 IN HEALTHY SANITARY WORKERS AND OCTOGENARIANS POST-BNT162B2 MRNA COVID-19 VACCINE: FIRST RESULTS OF A PROSPECTIVE TRIAL IN 366 INDIVIDUALS

Liacos [1], T. Bagratuni [1], M. Gavriatopoulou [1], T. Psaltopoulou [1], E. Kastritis [1], M. A. Dimopoulos [1]



[1]Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, [2]Department of Cell Biology and Biophysics, National and Kapodistrian University of Athens, Faculty of Biology, [3]Department of Clinical Biochemistry, "Aghia Sophia" Children's Hospital, Athens, Greece

Background: Efficacy of vaccines against SARS-CoV-2 virus is of great importance in order to mitigate COVID-19 pandemic. The BNT162b2 mRNA vaccine is the first approved by both FDA and EMA vaccine with confirmed clinical activity in phase 3 trials. However, the immune responses against SARS-CoV-2 after BNT162b2 vaccination have not been fully elucidated in several population subsets including octogenarians and patients with malignancies or autoimmune disorders.

Aims: The aim of this prospective study (study no: NCT04743388) is to evaluate the development of neutralizing (NAbs) and anti-spike RBD IgG antibodies against SARS-CoV-2, as well as the levels of cytokines and the induced B- and T-cells subpopulations following vaccination with BNT162b2 vaccine. Participating groups include healthy sanitary workers, elderly individuals (above the age of 70) and patients with hematological malignancies or solid tumors under different types of treatment. Herein we present preliminary results of the BNT162b2 vaccine effects in the development of anti-SARS-CoV-2 antibodies in healthy sanitary workers and octogenarians.

Methods: Healthy sanitary (i.e., physicians and nurses) workers of Alexandra hospital, Athens, Greece and volunteered octogenarians were included in this study. The inclusion criteria included (*a*) age higher than 18 years and (*b*) the absence of any known auto-immune or malignant disease. NAbs against SARS-CoV-2 and anti-Spike-RBD IgG antibodies were measured using FDA approved methods, i.e., the cPass™ SARS-CoV-2 Neutralization Antibody Detection Kit (GenScript, Piscataway, NJ, USA) and the Elecsys Anti-SARS-CoV-2 S assay (Roche Diagnostics GmbH, Mannheim, Germany), respectively. Time-points for blood collection were day 1 (D1) (first BNT162b2 dose), D8, D22 (second dose), D36 and D50 for healthy sanitary workers and D1, D22 and D50 for octogenarians. The study includes also a follow-up of the antibodies levels every 3 months till month 18 post the delivery of the second dose (D22) of the vaccine.

Results: The study population included 254 healthy sanitary workers (92 males/162 females; median age: 49 years, range: 25-70 years) (group 1) and 112 octogenarians (51 males/61 females; median age: 85 years, range: 80-95 years) (group 2). Twenty-one donors from group one and ten from group two had NAbs inhibition titers >30% (threshold for positivity) at D1; these titers significantly expanded at D8 indicating the presence of sustained rapid anti-SARS-CoV-2 antibody production in COVID-19 healers (Figure, A). NAbs titers (in negative at D1 donors) from group one, were found to increase significantly already at D22 (day of second vaccination), plateaued two weeks (D36) after the second dose of the vaccine (NAbs inhibition ≥90%) and remained at high levels at D50 (NAbs inhibition ≥90%) (Figure, A). Notably, the NAbs titers (in negative at D1 donors) had lower increases in ages 50-70 *vs*. 25-49 at D22; this age-related effect of the vaccine efficacy was confirmed in octogenarians who at D22 developed significantly lower NAbs titers *vs*. all other age groups (Figure, B). Similar kinetics were found in donors of groups one and two for the anti-spike RBD IgG antibodies.

Summary/Conclusion: We conclude that the BNT162b2 mRNA vaccine is exceedingly effective in producing high anti-SARS-CoV-2 antibody (NAbs and anti-spike RBD IgGs) titers in healthy donors. Given however that this readout is seemingly (up to the delivery of the second dose of the vaccine) age-dependent, we suggest that the second timely vaccination is needed, especially in the elderly population.

S281 EHA GUIDELINE: ANTIFUNGAL PROPHYLAXIS IN ACUTE MYELOID LEUKEMIA TREATED WITH NOVEL AGENTS

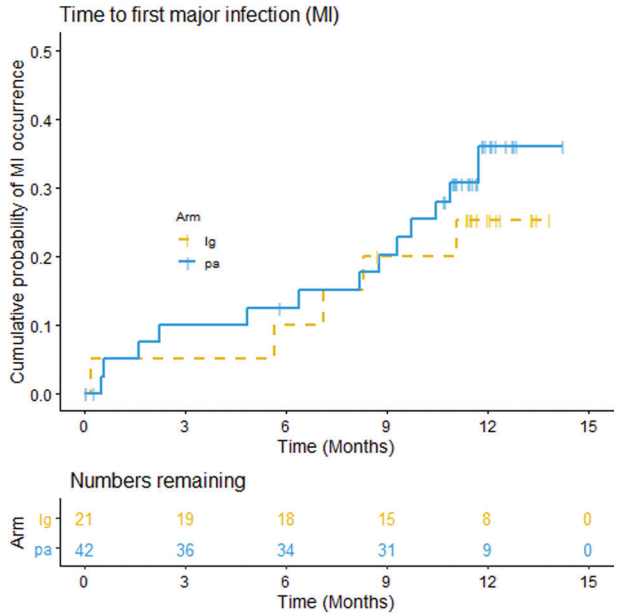
Citta' della Salute e della Scienza di Torino, Torino, Italy, [9]Ustav Hematologie A Krevni Transfuze, Ustav Hematologie A Krevni Transfuze, Prague, Czech Republic, [10]Infectious Diseases division, Infectious Diseases unit, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [11]Cochrane Haematology Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany, [12]Dipartimento di Scienze Mediche e Chirurgichea, Alma Mater Studiorum Università di Bologna, Bologna, Italy, [13]Department I of Internal Medicine, University Hospital of Cologne, [14]German Centre for Infection Research (DZIF), Partner Site Cologne-Bonn, [15]Clinical Trials Centre Cologne (ZKS Köln), University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany



Background: Novel therapeutic agents for acute myeloid leukemia (AML) have become available recently. Antifungal prophylaxis is generally recommended during induction remission chemotherapy, however, treatment settings for AML patients have become diverse and the risk-benefit ratio for antifungal prophylaxis in those settings is not well assessed in clinical trials. Due to cytochrome p450 metabolization and its inhibition by antifungal drugs, there is potential for drug-drug interactions (DDI) between novel AML agents and antifungals.
Aims: To define evidence- or consensus-based recommendations for antifungal prophylaxis for AML patients on treatment with novel agents
Methods: Experts from the European Hematology Association (EHA) Working Group Infections in Hematology and Cochrane Hematology Group develop an evidence and consensus-based guideline according to the GRADE methodology. The following PICO endpoints for each of the novel agents were formulated: occurrence of fungal infection, prolongation of hospitalization, days on intensive-care unit and mortality due to fungal infection, quality-of-life, and potential drug-drug interactions. Systematic literature review was performed. In three consensus-meetings, recommendations for each novel AML drug and specific setting were formulated.
Results: The following novel agents for treatment of AML were identified with not all of them being yet licensed for treatment: Hypomethylating agents (HMA; Azacytidine and decitabine), Midostaurin, Venetoclax (+HMA), Lestaurtinib, Gilteritinib, Sorafenib, Quizartinib, Ivosidenib, Enasidenib, Crenolanib, Glasdegib, Sapacitabine, Custatuzumab, Iomab B, Idanasutlin.
Evidence from the literature was generally scarce since fungal infections and prophylaxis were generally not assessed in randomized controlled trials of the respective AML drug.
Evidence-based recommendations were formulated for HMA, Midostaurin, and Venetoclax/HMA, for all other agents, consensus-based recommendations were given including the patient-specific setting of application of the novel agents (relapsed/refractory AML, single therapy or in combination with chemotherapy, induction treatment or maintenance etc.) into the decision process
Antifungal prophylaxis is not recommended or moderately recommended in most settings, and strongly recommended if the novel AML agent is administered with intensive chemotherapy during induction treatment. Dose adaptations of some of the AML agents (midostaurin, venetoclax, quizartinib, sorafenib, gilteritinib) are moderately recommended with limited evidence if antifungal prophylaxis is administered with a strong CYP3A4 inhibitor due to expected increased exposure
Summary/Conclusion: This guideline document to help supporting the decision if to use antifungal prophylaxis in AML patients under treatment with novel agents will soon become available as the first one assessing this specific setting and will complement existing guidelines for antifungal prophylaxis.

S282 RATIONAL: A RANDOMISED CONTROLLED FEASIBILITY TRIAL COMPARING PROPHYLACTIC IMMUNOGLOBULIN WITH ANTIBIOTICS IN PATIENTS WITH ACQUIRED HYPOGAMMAGLOBULINEMIA SECONDARY TO HAEMATOLOGICAL MALIGNANCIES

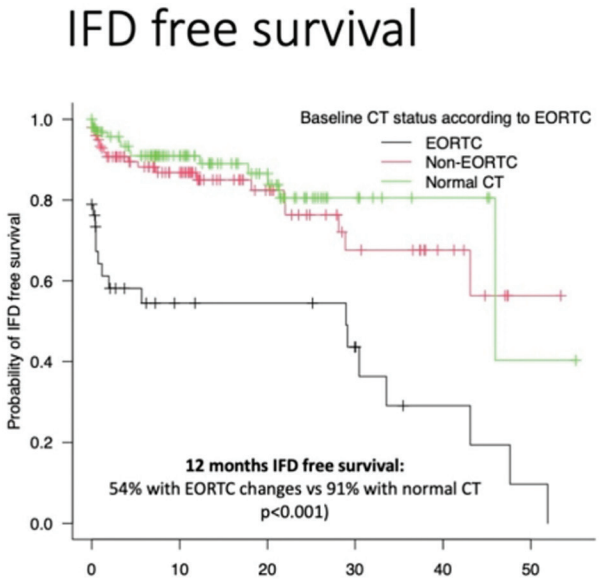
[1]Haematology, Monash Health, [2]School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia, [3]Wellington Blood & Cancer Centre, Capital & Coast District Health Board, [4]Cancer Immunotherapy Programme, Malaghan Institute of Medical Research, Wellington, New Zealand, [5]Canberra Hospital, Canberra, [6]Monash Infectious Diseases, Monash Health, [7]School of Clinical Sciences, Monash University, Melbourne, [8]Royal Hobart Hospital, [9]University of Tasmania, Hobart, [10]Australian Red Cross Lifeblood, [11]Department of Haematology, Fiona Stanley Hospital, Perth, Australia, [12]Department of Haematology, Waikato Hospital, Hamilton, New Zealand, [13]University of Sydney, [14]Concord Repatriation General Hospital, Sydney, [15]Sunshine Coast University Hospital, Sunshine Coast, [16]Alfred Health, [17]ALLG, Melbourne, Australia

Background: Prophylactic immunoglobulin (Ig) replacement and prophylactic oral antibiotics (PA) are used to prevent infections in patients with haematological malignancies and acquired hypogammaglobulinemia. Ig has been shown to reduce infection risk, but is costly and in limited supply. PA have been shown to reduce infection risk in other patient populations and are less expensive, but have side-effects and can increase antimicrobial resistance rates. Guidelines and clinical practice vary internationally, with some recommending a trial of PA prior to commencing Ig replacement, and others omitting PA. The efficacy, safety and cost-effectiveness of Ig and PA have not been directly compared in a randomised controlled trial (RCT) in patients with acquired hypogammaglobulinemia secondary to haematological malignancies.
Aims: To determine the feasibility of delivering PA as an alternative to Ig replacement in patients with haematological malignancies and acquired hypogammaglobulinemia.
Methods: Phase II, multicentre, feasibility RCT (ACTRN12616001723471). Eligible patients had acquired hypogammaglobulinemia due to a haematological malignancy, a history of recurrent or severe bacterial infections or an IgG level <4g/L (excluding paraprotein), and had a life expectancy more than 12 months. Exclusion criteria included prior allogeneic haematopoietic stem cell transplant and prior Ig replacement in the preceding 3 months. Patients were randomised to receive Ig (0.4g/kg IV every 4 weeks, modified to achieve an IgG trough level ≥ lower limit of reference range; or 0.1g/kg/week SC, modified to achieve an IgG trough level of ≥ lower limit of reference rage) or daily oral prophylactic antibiotics (trimethoprim-sulfamethoxazole 160mg/800mg, with 100mg doxycycline as an alternative for hypersensitivity) for 12 months at a 1:2 ratio. Randomisation was stratified by site. Patients allocated to PA were allowed to cross over to Ig if they experienced a CTCAE ≥ Grade 3 infection. Treatment allocation was not blinded but infectious outcomes were adjudicated by an independent, blinded, outcome adjudication committee. The primary outcome was proportion of patients alive and remaining on assigned treatment arm 12 months following randomisation. Secondary outcomes included time to first major infection (defined as CTCAE ≥ Grade 3 infection).
Results: 63 patients were randomised, 60 received treatment and had primary outcome data available. The median age was 69 years (IQR 66-75), 34 (54%) were female, 12 (19%) had myeloma, 29 (46%) chronic lymphocytic leukaemia, 20 (32%) had non-Hodgkin lymphoma and 2 (3%) other haematological malignancy. For the primary outcome, 76% (95% CI 53-92) in the Ig arm and 71% (95% CI 55-84) in the PA arm were alive and on assigned treatment 12 months following randomisation (p=0.77). The time to first major infection was similar between the two groups (see figure 1), with the lower quartile 11.0 months in Ig arm vs 9.7 months in PA arm, (log rank test p=0.54). 74% of patients in the Ig arm and 64% in the antibiotic arm were free of major infection during the 12 months.



Summary/Conclusion: In this phase II trial, a similar proportion of patients allocated to Ig and to PA remained alive and on their assigned treatment arm at 12 months. There was no significant difference in time to first major infection between the two treatment arms. These findings support the feasibility of proceeding with a phase III trial to compare efficacy, safety and cost-effectiveness of Ig replacement to PA in patients with acquired hypogammaglobulinemia.

S283 BASELINE CT THORAX AND RISK OF INVASIVE FUNGAL DISEASE IN ALLOGENEIC STEM CELL TRANSPLANTATION

V. Mehra [1,*], C. Stovin [2], J. Periselineris [2], A. Espehana [3], A. Choy [1], P. Siriwardena [1], V. Mallikarjuna [1], P. Krishnamurthy [1], H. de Lavallade [1], D. Avenoso [1], V. Potter [1], M. Ceesay [1], A. Pagliuca [1]

[1]Haematological Medicine, [2]Respiratory Medicine, Kings College Hospital, London, [3]GKT Medical School, London, United Kingdom

Background: Invasive fungal lung disease (IFD) is a well-recognised complication post haematopoietic stem-cell transplant (HSCT), occurring in approximately 5-21% of patients, despite tri-azole anti-fungal prophylaxis. Baseline CT thorax (BCT) pre-HSCT is increasingly considered as standard practise to evaluate lung disease, however evidence on outcomes from previous studies has been limited by either small or heterogenous cohorts (Ceesay et al 2018, Bitterman et al 2019).
Aims: A number of smaller heterogenous retrospective studies including our centre's previous study by Ceesay et al, BJH 2018, have been published reporting outcomes and risk factors for IFD associated with abnormal baseline CT chest prior to induction chemnotherapy or transplantation,. Based on these findings, we implemented baseline CT chest in all our high-risk group patients due to undergo allogeneic stem cell transplantation and induction chemotherapies from 2015. Routine biomarkr screening and diagnostic clinical algorithm was implemented. This study then set out to prospectively evaluate utility of baseline CT chest in a homogenous cohort of allo HSCTs and its correlation of different morphological imaging changes and baseline patient related factors associated with risk for IFD.
Methods: We conducted a single centre prospective analysis of patients with myeloid malignancies and aplastic anaemia (n=350) who underwent T-cell deplete allogeneic HSCT between Jan 2015 and April 2019. BCT was performed in 235 (67%) patients within 4 weeks of planned HSCT with biomarker driven IFD screening & diagnostic strategy as standard. IFD was defined as probable/proven disease by European Organisation for Research & Treatment of Cancer(EORTC)-2008 criteria.
Results: Baseline CT was abnormal in 58% of patients (136/235). EORTC defined abnormalities were present in 28% of abnormal CT's (38/136). Post HSCT, IFD developed in 9.1% of total patients (n=32/350) and in 12.3% (n=29/235) of those who had BCT. Patients with EORTC defined changes on BCT developed more IFD compared to those with normal BCT findings (34.2% vs 9.4%, p=<0.01). Univariate analysis of baseline characteristics identified that a significantly higher proportion of those with history of previous IFD developed post-HSCT IFD (33.3% vs 8.3%; P=<0.01). Reduced intensity conditioning, poor baseline performance status and co-morbidities, and gas transfer (TLCO <70%) significantly influenced the development of IFD. Risk factors for baseline abnormal CT were Age >60 years, higher HCT-CI, pre-existing lung disease and prior history of IFD.
Although presence of abnormal BCT did not influence overall survival, there was a significant reduction in overall survival at 12 months post HSCT in those who developed IFD(62% vs 76%, p=0.001, log rank). Among patients with EORTC defined changes on BCT, there was a significant reduction in median IFD-free survival (30.5 months vs 47 months, p=0.009) when compared to non-EORTC and normal CT findings (see Figure attached). There was a significant reduction in overall survival at 12 months post HSCT in those who developed IFD(62% vs 76%, p=0.001, log rank).

Summary/Conclusion: Previous IFD history, EORTC changes & multiple non-EORTC changes at baseline CT and abnormal TLCO pre-HSCT influenced IFD related outcomes with a significant reduction survival post IFD event. We suggest early respiratory optimisation including focussed diagnostics in patients with abnormal pre-HSCT chest imaging, to reduce risk of IFD-related mortality. Further evaluation of impact of interventions in patients with abnormal BCT is warranted.

S284 EARLY INFECTIONS FOLLOWING COMMERCIAL ANTI-CD19 CAR-T CELLS INFIRM POPULATION – A SINGLE CENTER RETROSPECTIVE STUDY

O. Beyar-Katz [1,*], N. Kikozashvili [1], Y. Bar On [1], O. Amit [1], C. Perry [2], I. Avivi [2], R. Gold [1], Y. Herishanu [2], N. Benyamini [2], R. Ben-Ami [3], D. Shasha [3], R. Ram [1]

[1]Bone marrow transplant, [2]Hematology, [3]Infectious Diseases Unit, Sourasky Medical Center, Tel Aviv, Israel

Background: Chimeric antigen receptor T cells (CAR-T) cells targeting CD19, demonstrate highly effective anti-tumor response in Diffuse Large B Cell Lymphoma (DLBCL). However, can result in significant side effects such as prolong neutropenia and infections. The incidence of infections in the setting of real world data hasn't been completely identified.
Aims: To perform a comprehensive analysis of infection rate and profile in the first month after CAR-T cells in a cohort of infirm patients treated with commercially available CAR-T cells.
Methods: This is a retrospective, single center study conducted in the Bone marrow transplant unit, Tel Aviv, analyzing the infection rate in consecutive patients with DLBCL who were treated with commercially available axicabtagene ciloleucel or tisagenlecleucel. Following a local protocol, all patients were treated with prophylaxis with ciprofloxacin and fluconazole when neutrophil counts decreased below $0.5*10^3$/µl. Acyclovir was administered at conditioning initiation. Microbiology and clinical documented infections (MDI and CDI, respectively) were defined according to the ECIL guidelines. Following white blood cell recovery, patients carried out weekly full blood count, and

monthly CMV and HHV-6. A logistic regression was performed for the association between baseline characteristics and documented infections.
Results: From June 2019 to December 2020, we included 60 consecutive patients with DLBCL treated with axicabtagene ciloleucel (n=16, 27%) or tisagenlecleucel (n=44, 73%). The median age was 69.3 (range, 19.8-85.2) years and ECOG-Performance status(PS) was 2-3 in most patients (58%). Broad spectrum antibiotics was administered to patients experiencing neutropenic fever (n=53, 88%). Overall infections were noted in 27/60 patients (45%).Bacterial infections were seen in 16 patients (27%) and included CDI in 7 (Pneumonia, n=5; periodontal infection, n=1 and cellulitis, n=1) and MDI in 9 patients (Gram negative rod bacteremia (GNR), n= 5; Gram positive cocci(GPC) bacteremia, n= 3; Both GNR and GPC, n=1). Viral infection was described in 14 patients (23%). The most common viral infection was CMV reactivation (n=10, 17%) leading to initiation of anti-CMV treatment in 6 among these patients. None had CMV disease. HHV-6 was positive in 3 patients (5%) with one of these patients presenting with acute encephalitis. Other viral infections reported were RSV (n=2)COVID-19 (n=1). No fungal infection was documented. Incidence of documented infections was higher in patients with CRS/ICANS compared with patients without [23/44 (52%) vs 4/16 (25%), p=0.005]. While CRP levels predicted documented infections (p= 0.041), ferritin blood levels did not (p=0.130).
In univariate analysis, ICANS (OR= 4.5, p = 0.018) was associated with higher incidence of bacterial infection while there was a trend for lower incidence of bacterial infections in patients with chemo-sensitive disease to bridging therapy (OR= 0.375, p= 0.074)(Table 1). Age or ECOG-PS were not associated with increased risk of bacterial infection. Patients with documented infection had an increase in hospitalization days compared to those without documented infection (26.44 vs 21.7 days, p= 0.085).

Table 1: Risk factor for bacterial infection one months following CAR-T cell infusion using univariate analysis:

Variable	Odds ratio	P value
Age	0.990	0.618
ECOG PS	N/A	0.960
Bridging therapy	1.259	0.738
Chemo-sensitive disease	0.375	0.074
CRS	3.267	0.150
ICANS	4.5	0.018
hypogammaglobulinemia	1.944	0.574
CRP prior to CAR-T cells infusion	1.004	0.331
Ferritin prior to CAR-T cells infusion	1	0.717

CRS; Cytokine release syndrome, ICANS; Immune effector cell-associated neurotoxicity syndrome

Summary/Conclusion: Infections were common in the first month following CAR-T cell administration, however were not increased in elderly patients or those presenting with poorer PS. Patients refractory to bridging therapy and ICANS should be monitored cautiously for the occurrence of infections. CMV monitoring should also be considered.

COVID-19 impact on hematology: How it started - How it's going

S285 SAFETY AND EFFICACY OF THE BNT162B2 MRNA COVID-19 VACCINE IN PATIENTS AFTER ALLOGENEIC HCT AND CD19-BASED CAR-T THERAPY – A SINGLE CENTER PROSPECTIVE COHORT STUDY

R. Ram [1,2,*], D. Hagin [2,3], T. Freund [2,3], N. Kikozashvilli [1,2], O. Amit [2,4], Y. Bar-On [2,4], O. Beyar-Katz [2,4], G. Shefer [5], M. Morales [5], C. Karni [4], R. Gold [4], D. Tshernichovski [4], S. Kay [2,4], C. Glait-Santar [1], R. Eshel [4], C. Perry [2,4], I. Avivi 2 4, A. Apel [2,6], N. Benyamini [2,4], D. Shasha [2,7], R. Ben-Ami [2,7]

[1]Bone Marrow Transplantation, Tel Aviv Sourasky Medical Center, [2]Sackler Faculty of Medicine, Tel Aviv University, [3]Immunology Unit, [4]Bone Marrow Transplantation, [5]Endocrinology Laboratory, Tel Aviv Sourasky Medical Center, [6]Department of Hematology, Shamir Medical Center, [7]Infectious Diseases Unit, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Background: The Pfizer/BioNTech BNT162b2 vaccine, employing mRNA technology, has been recently approved by both the FDA and EMA for the prevention of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection, demonstrating a 94.6% protection rate in a phase 3 study. While this vaccine is recommended by the FDA, EBMT and ASH-ASTCT for immunosuppressed patients, data regarding protection efficacy and safety in patients undergoing immunologic cell therapy are scarce.

Aims: We aimed to evaluate efficacy and toxicity of the BNT162b2 vaccine in patients that underwent hematopoietic cell transplantation and CAR-T therapy.
Methods: All patients under active treatment at the long-term follow-up HCT clinic (n=124) at the Tel Aviv Sourasky Medical Center, were evaluated for immunologic recovery (CD19+, CD4+, and CD8+ cell blood levels) pre-vaccination and were recommended to receive the commercial vaccination based on the EBMT recommendations. Patients were prospectively followed for vaccination-safety profile (laboratory tests, GVHD monitoring, and symptom-based questionnaire). We evaluated the humoral immune response to vaccine, 7-14 days after the second vaccine dose, by *in vitro* quantitative determination of anti-SARS-CoV-2S antibodies using Elecsys® assay and cellular immune response by ELISpot, estimating IL-2 and IFN-gamma secretion in response to a pool of lyophilized SARS-COV-2 S and M peptides (PepTivator; Miltenyi). The trial was approved by the local Ethics Committee and was registered by the clinical trials network (NCT04724642).
Results: From 23-Dec-2020 all sequential patients (allogeneic, n=101 and CAR-T, n=23) were assessed for eligibility based on the EBMT recommendations (Version 5.0, Feb 21, 2021). Of those, 100 patients were eligible and 79 patients (allogeneic, n=65 and CAR-T, n=14) were vaccinated per-protocol. Characteristics of patients are depicted in **Table 1**. Overall, the 2 vaccine doses were well tolerated. Adverse events were reported in 39% of allogeneic HCT recipients (4.6% grade ≥3) and 32% of CART recipients (7% grade ≥3). All events resolved within few days, with the exception of 1 secondary graft rejection which is still under investigation. Among the CAR-T group, 5 patients (36%) had humoral antibody response. Patients with CD19+ lymphocytes >0 had a higher likelihood to develop antibodies compared to those with B cell aplasia (67% vs. 12.5%, p=.036). Among the allogeneic HCT group - 47 patients (81%) had a humoral antibody response. Incidence of positive serology was lower in patients with concomitant high intensity immunosuppressive therapy (IST) compared to those with low intensity IST (69% vs. 94%, p=.016). Linear regressions identified that male sex (beta=-.380, p=.012) and high intensity IST (beta=-.497, p=.014) were associated with lower antibody titer, while age, months from HCT, intensity of conditioning, low CD19 cell count, and active GVHD did not predict response. Analysis of peptide induced cytokine release by ELISpot is ongoing and will be presented at the EHA meeting.

Table 1 – Characteristics of patients

Datum	All cohort (n=79)
Age in years (median, range)	66 (23-82)
Sex, female (n, %)	35 (44%)
Months from infusion (median, range)	
Allogeneic HCT	22 (3-162)
CART	9 (3-17)
Status of disease	
Remission	76 (96%)
Relapse	3 (4%)
Base line disease	
AML	36 (46%)
MDS	7 (9%)
ALL	8 (10%)
DLBCL	12 (15%)
Other lymphoma	8 (10%)
Myeloproliferative neoplasm	7 (9%)
Other	1 (1%)
Preparative regimen (allogeneic pts only)	
Myeloablative	40 (62%)
Reduced intensity/non myeloablative	25 (38%)
Donor (allogeneic pts only, n=65)	
Matched-sibling	17 (26%)
Mismatched-family donor	5 (5%)
Matched unrelated donor	44 (68%)
Mismatched unrelated donor	1 (1%)
Graft-vs-host disease (allogeneic pts only, n=65)	
Active acute GVHD	0 (0%)
Active chronic GVHD	40 (62%)
Previous chronic GVHD	3 (5%)
Concurrent immunosuppressive therapy	(58%) 38
Patients on active chemotherapy	(8%) 8
Total lymphocyte count – cell/microL (median, range)	1100 (100-6500)
Total CD19-positive lymphocyte (median, range)	60 (0-1078)
Total CD4-positive lymphocyte (median, range)	325 (10-1375)
Total CD8-positive lymphocyte (median, range)	766 (48-4258)
CD4/CD8	0.48 (0.14-2.9)

Summary/Conclusion: Humoral response to the BNT162b2 mRNA COVID-19 vaccine in CAR-T patients with B cell aplasia is significantly impaired, while overall response in patients after allogeneic HCT is encouraging. Patients on concomitant high intensity IST had impaired humoral response to BNT162b2. Longer follow-up is mandatory to test persistence of antibodies, and general preventive practices should be continued until more data are available.

S286 OUTCOMES IN PATIENTS WITH ACUTE LEUKAEMIA AND COVID-19: RESULTS OF SUBGROUP ANALYSIS OF CHRONOS19 REGISTRY

O. Gavrilina [1,*], K. Zakurdaeva [2], A. Vasileva [1], L. Butaev [3], A. Sukhareva [3], V. Vorobyev [3], V. Dubov [4], S. Dubov [4], L. Gavrilova [5], I. Toropova [6], M. Popova [7], A. Semashko Republican Clinical Hospital, Ulan-Ude, [9]Regional Clinical Hospital, Ekaterinburg, [10]City Clinical Hospital n.a. V.V. Veresaev Moscow Department of Healthcare, Moscow, [11]N.A. Semashko Regional Clinical Hospital, Nizhniy Novgorod, [12]N.V. Sklifosovsky Emergency Institute, Moscow, Russian Federation

Background: Patients (pts) with acute leukemia (AL) are at high risk of COVID-19 severe and lethal course. Intensive chemotherapy and immunosuppression in these patients are the possible causes of high mortality. Emerging data on risk factors and outcomes in this vulnerable patient population is aimed to support strategies of their medical care.
Aims: To evaluate treatment outcomes and risk factors in pts with AL and COVID-19 in a real-world setting.
Methods: CHRONOS19 [NCT04422470] is an ongoing nationwide observational cohort study of adult (≥18 y) pts with hematologic disease (both malignant and non-malignant) and lab-confirmed or suspected (based on clinical and/or CT findings) COVID-19. We performed a subgroup analysis of pts with AL and COVID-19. Primary objective was to evaluate treatment outcomes and identify risk factors associated with higher mortality in this group of pts. Primary endpoint was 30-day all-cause mortality. Long-term follow-up was performed at 90 and 180 days. Data from 14 centers was collected on a web-based platform and managed in a deidentified manner.
Results: As of data cutoff on January 27, 2021, 575 pts were included in the registry, 132 of them with AL were eligible for primary endpoint assessment n(%): AML – 86(65%), ALL – 37(28%), APL – 9(7%); M/F 55(42%)/77(58%), median age 45 [18-79] years, induction phase/R/R/ treatment in remission 49(37%)/27(21%)/ 54(42%), agranulocytosis in 55(42%) pts, 68(53%) pts were transfusion dependent, comorbidities – in 58(45%) pts. Complications developed in 98(74%) pts: pneumonia (71%), sepsis (9%), CRS (8%), ARDS (6%). One-third of pts had severe COVID-19, 30% were admitted to ICU, 26% required mechanical ventilation. We performed comparative analysis of characteristics between a group of pts with AL and other hematologic diseases (lymphomas, chronic leukemia, multiple myeloma, and other malignant and non-malignant diseases): pts with AL had significantly more frequent agranulocytosis (42% vs 20%, p<0,001), transfusion dependence (53% vs 33%, p<0,001), and a higher rate of admission to ICU (30% vs 20%, p=0,036). All-cause mortality at 30 days was 24% in pts with AL vs. 15% in pts with other hematologic diseases (p=0,03); 70% of deaths were due to COVID-19 complications in pts with AL. At 90 days, one additional death due to COVID-19 occurred. At 180 days, 5 more deaths due to leukemia progression were registered. Risk factors that were significantly associated with overall survival (OS) are listed in Table 1. In multivariate analysis, ICU + mechanical ventilation, HR, 70.258 (19.5-270.0) and age >60 years HR, 3.340 (1.08-10.9) were the most significant risk factors of death. Overall, AL were associated with a higher risk of death, HR, 2.40 (1.28-4.51), compared to less aggressive diseases (CML, CLL, MM, lymphomas, non-malignant), HR, 0.54 (0.37-0.80). COVID-19 affected treatment of AL in 65% of pts, 58% experienced treatment delay for a median of 4 [1-10] weeks. In 11 of 103 (10,7%) pts with AL early relapse/refractory disease was detected, but the association of relapses with affected treatment is unknown. COVID-19 re-infection was described in 2 patients.

Table 1. Univariate analysis of factors associated with lower OS

Risk Factor	HR (95CI)	p
ICU + mechanical ventilation	70.258 (19.5-270.0)	<0.0001
ECOG 4 vs. ≤3	6.83 (3.28-14.21)	<0.00013
Admission to ICU	5.41 (1.46-20.10)	<0.0001
COVID-19 severity	6.83 (3.28-14.21)	<0.0001
COVID-19 complications	2.99 (1.16-7.68)	0.0162
Transfusion dependence	4.31 (1.96-9.50)	0.0004
R/R disease	2.18 (0.97-4.86)	0.151
Age ≥60 vs. <60 y	1.92 (1.00-3.68)	0.0451
MTA	1.62 (0.85-3.09)	0.0389
Male vs. female	1.48 (0.78-2.80)	0.2224
Comorbidities	1.63 (0.85-3.12)	0.1235

Summary/Conclusion: Thirty-day all-cause mortality was significantly higher in SARS-CoV-2-infected pts with AL than in those with other hematologic diseases. Longer-term follow-up (180 days) for AL outcomes and OS will be presented.

S287 KINETICS OF ANTIBODIES AGAINST SARS-COV-2 IN CONVALESCENT PLASMA DONORS AFTER EIGHT MONTHS FROM COVID-19: PERSISTENCE OF SPIKE ANTIBODIES BUT LOSS OF NEUTRALIZING ANTIBODIES IN 24% OF DONORS

E. Terpos [1,*], D. Stellas [2], M. Rosati [2], T. N. Sergentanis [1], X. Hu [3], M. Politou [4], V. Pappa [5], I. Ntanasis-Stathopoulos [1], S. Karaliota [2], J. Bear [3], M. Pagoni [6], E. Background: Elucidating the characteristics of human immune response against SARS-CoV-2 is of high priority for determining vaccine strategies. The duration of the persistence of anti-SARS-CoV-2 antibodies in individuals who suffered from COVID-19 is not clearly defined yet.
Aims: The aim of this study was to assess the kinetics of anti-SARS-CoV-2 antibodies and neutralizing antibodies among convalescent plasma donors during an 8-month period from their first symptoms of COVID-19.
Methods: Participants were enrolled in a phase 2 study of plasma donors (NCT04408209) for the use of convalescent plasma for the treatment of COVID-19 in Greece. For the detection of anti-SARS-CoV-2 antibodies, we used four in-house ELISA assays measuring antibodies to (i) trimeric Spike (S), (ii) Spike Receptor Binding Domain (Spike-RBD), (iii) Nucleocapsid, and (ii) Nucleocapsid RNA Binding Domain (N-RBD). For the Neutralizing Antibody (NAb) assay using SARS-CoV-2 pseudotyped virus, serial dilutions of heat-inactivated sera were incubated with an equal volume of the pseudotyped virions (pHIVNLEnv-Nanoluc) and the virion-Ab mixture was used to transduce HEK293T/ACE2wt cells. Two days later, the luciferase levels were measured in the cell extracts and the ID50 (50% Inhibitory Dose) was calculated using GraphPad Prism version 8.0 for MacOS X (GraphPad Software, Inc, La Jolla, CA) with nonlinear regression curve fit using inhibitor vs responses variable slope (four parameters).
Results: In total, 148 convalescent plasma donors (median age: 50 years, range: 18-65) with a median follow-up of 8.3 (range 6.8-10.5) months post their first disease symptoms were included in this analysis. Ninety-one patients did not need hospitalization and 57 were hospitalized due to COVID-19. At the initial screen, all patients showed positive antibody responses recognizing trimeric Spike, Spike-RBD, Nucleocapsid and N-RBD. At the 6-month follow-up, we continue to detect positive responses to Spike, Spike-RBD, Nucleocapsid and N-RBD in all plasma donors but at lower levels compared to screening (p<0.001). At the 8-month follow-up, no significant reduction was observed compared to 6-month values. A piecewise, random-effects, generalized least squares multivariate regression analysis showed a two-phase pattern of antibody responses, with more pronounced decrease during the first 6 months and a plateau phase after the 6th month post-symptoms onset. Spike antibodies showed better persistence than Nucleocapsid antibodies, whereas antibodies recognizing only the Spike-RBD or N-RBD persisted less than the mixture of antibodies recognizing the respective complete proteins. Neutralization ability contracted faster, since neutralizing antibodies persisted in 76% of patients at the last time point. In the multivariate analysis, older age and hospitalization were independently associated with higher antibody Spike, Spike-RBD, Nucleocapsid, N-RBD and NAb levels.
Summary/Conclusion: We found persistence of anti-SARS-CoV-2 antibodies, especially against Spike and Spike-RBD, up to 8 months post-symptoms onset. However, a loss of neutralizing antibodies became

evident in 24% of convalescent donors at 8 months from initial symptoms of COVID-19. A prolonged follow-up of the donors is necessary to further characterize the kinetics of anti-SARS-CoV-2 B-cell mediated immunity over time and to establish a link between the presence of antibodies and the level of protection against re-infection. Such data should help to optimize vaccination strategies and public health decisions.

S288 COVID-19 AMONG PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: A NATIONAL ISRAELI RETROSPECTIVE ANALYSIS

Background: The first COVID-19 patient was diagnosed in Israel in February 2020. It is of importance to evaluate outcomes across patients with hematological malignancies which are generally immunosuppressed and more susceptible to infectious complications.
Aims: We aimed to characterize the clinical course of COVID-19 infection among patients with various lymphoid or myeloid malignancies and determine which of these patients were most at risk of severe infection or mortality.
Methods: This was a national Israeli multicenter retrospective study. Patients with hematological malignancies who were diagnosed with COVID-19 from February 20, 2020 until January 31, 2021 were centrally reported and included in the retrospective analysis with no need for informed consent signing. Clinical and laboratory data regarding baseline characteristics, hematological management, and course and treatment of the COVID-19 disease were collected. Multivariate regression analyses were used to determine the variables associated with severe disease, hospitalization and mortality.
Results: In total, 272 patients from 14 medical centers were included in the analysis. Among them, 140 (51.5%) were men, and the median age was 70yrs. The most frequent malignancies included lymphoma (44.5%), multiple myeloma (22.8%), and chronic lymphocytic leukemia (12.1%). 90 (33.1%) patients developed a severe or critical respiratory infection, and 58 (21.3%) died. According to multivariate regression analyses, both age > 70yrs (OR=2.26; 95% CI: 1.04; 4.95; p=0.041) and current steroid treatment (OR=3.23; 95% CI: 1.06, 9.90; p=0.040) at time of COVID-19 diagnosis were associated with severe to critical disease, while current treatment with monoclonal antibodies was associated with mild to moderate disease (OR=2.86; 95% CI: 1.17, 6.99; p=0.022). Among the 159 hospitalized patients, the hospitalization was longer in patients with severe to critical respiratory infection (IRR=1.53; 95% CI: 1.36, 1.72; p<0.001), or treated with dexamethasone (IRR=1.22; 95% CI: 1.08, 1.38; p=0.002), with enoxaparin (IRR=1.18; 95% CI: 1.06, 1.33; p=0.004) or convalescent plasma (IRR=1.17; 95% CI: 1.04, 1.32, p=0.012); while the hospitalization was shorter in patients treated with remdesivir (IRR=0.78; 95% CI: 0.69, 0.89; p<0.001). The mortality rate was higher in patients > 70yrs (OR=3.41; 95% CI: 1.13, 10.34; p=0.030), with severe to critical infection (OR=27.27; 95% CI: 7.40, 100.48, p<0.001), or in those treated with dexamethasone (OR=5.89; 95% CI: 1.47, 23.63; p=0.012) for COVID-19 respiratory condition, and lower in patients treated with remdesivir (OR=0.19, 95% CI: 0.04, 0.82, p=0.026).
Summary/Conclusion: Respiratory infection with COVID-19 seems to be particularly severe in patients with hematological malignancies. While steroids seem to increase both baseline severity of the infection and mortality, it seems that treatment with remdesivir was associated with reduced mortality and duration of hospitalization. These particularities of haemato-oncological patients may be explained by a remarkably severe COVID-19 viremia that might cause the high mortality rate, while the cytokine release syndrome which generally responds to steroid treatment may be milder in these patients. The management of hematological malignancies during acute COVID-19 infection should be individualized and further investigated.

S289 SEROCONVERSION AND LONGEVITY OF ANTI SARS-COV-2 ANTIBODIES IN ONCO-HEMATOLOGIC PATIENTS WHO EXPERIENCED SARS-COV-2 INFECTION.

A. Candoni [1,*], U. Pizzano [1], M. Fabris [2], C. Marcon [1], R. Stella [1], S. Volpetti [1], R. Stocchi [1], M. E. Zannier [1], J. Olivieri [1], A. Sperotto [1], F. Curcio [2], R. Fanin [1]

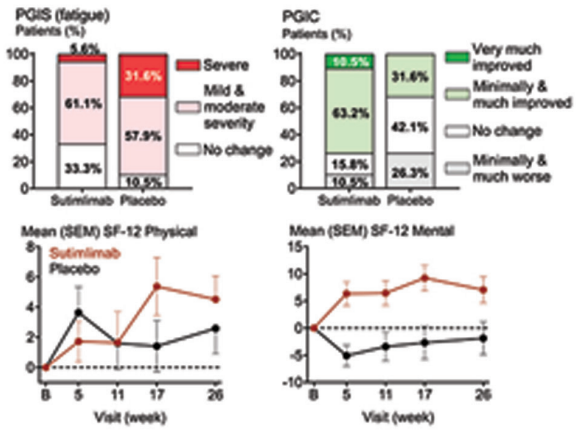
[1]University Hospital of Udine- ASUFC, Division of Hematology and SCT, [2]Department of Medicine and Clinical Pathology Institute, University of Udine and Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy

Background: Data on the dynamics and duration of immune response to SARS-CoV-2 infection in hematologic patients are still lacking. Preliminary studies, in non immunocompromised subjects with COVID-19, reported that seroconversion was observed 7 to 14 days following symptom onset with an increase of the IgM and IgG titers during the first month. IgM levels, after peaking by day 30, gradually decreased and can be undetectable by day 180 post-onset. The long-lasting persistence of IgG is not clearly confirmed.
Aims: We evaluate the seroconversion and the kinetics of IgM and IgG against SARS-CoV-2 in hematologic patients who were followed after reverse-transcription quantitative polymerase chain reaction (RT-qPCR) confirmation of SARS-CoV-2 infection.
Methods: Here we report the preliminary data regarding the first 25 COVID-19 positive hematologic patients that were tested for humoral response. The median age was 59 years (range 21-85). The underling hematologic diseases were: lymphoma (10/25), myeloma (7/25), chronic lymphoproliferative diseases (5/25) and acute leukemia (3/25). SARS-CoV-2 infection was mild symptomatic in 5/25 cases and symptomatic in 20/25. Four of these 20 patients had pneumonia that required hospitalization. The median value of IgG, IgM and IgA, at onset of the SARS-CoV-2 infection, was 832 mg/dl (167-2210), 54,5 mg/dl (6-2510) and 54 mg/dl (8-605), respectively. The median value of lymphocytes was 1100/mmc (250-3300). The IgM and IgG antibodies against SARS-CoV-2 spike protein (subunity S1 and S2) were tested by chemiluminescence immunoassay (CLIA) with a positive cut-off value of 15 UA/ml for both IgG and IgM. To assess the kinetics of antibody titers, in our convalescent COVID-19 patients, serum IgM and IgG levels were longitudinally measured at established time points: one month (T1) two months (T2), three months (T3) and four months (T4) after their first positive nasopharyngeal swab test.
Results: Among these first 25 COVID-19 cases, 21/25 (84%) developed specific anti SARS-CoV-2 antibodies with a titer > 15 UA/ml in almost one of the specific time points. However, as reported in Figure *A and B*, after a peak of the IgG and an overall mild increase of IgM, the antibody titer declined from 4 months after the disease onset under the positive cut-off value, although variation between patients was detected. In detail the mean and median titers were: 1) at T1: 56 UA/ml and 75,5 UA/ml for IgG, 15 UA/ml and 6 UI/ml for IgM; 2) at T2: 68 UA/ml and 73 UA/ml for IgG, 7 UA/ml and 2,6 UA/ml for IgM; 3) at T3: 54 UA/ml and 55 UA/ml for IgG and 5 UA/ml and 1,35 UA/ml for IgM; 4) at T4: 7 UA/ml and 5,3 UA/ml for IgG and 0,2 UA/ml and 0,2 UA/ml for IgM.

Summary/Conclusion: Although the number of patients is still limited, our preliminary results show a short lifespan of antibody response in hematologic patients, suggesting a short duration of antibody-mediated

protection against re-infection with SARS-CoV-2. If confirmed in a larger number of cases, these results would suggest to maintain infection prevention and control measures even for hematologic patients who have recovered from COVID-19. In addition, this population should get vaccinated periodically. Additional studies, exploring both humoral and cellular immunity (T cells and memory B cells), will be require to better understand the overall immunologic response against SARS-CoV-2 (and its duration) in hematologic patients.

Transfusion medicine



S290 SUTIMLIMAB, A TARGETED COMPLEMENT C1S INHIBITOR, IMPROVES QUALITY OF LIFE (QOL) IN PATIENTS WITH COLD AGGLUTININ DISEASE (CAD): RESULTS FROM THE RANDOMIZED, PLACEBO-CONTROLLED PHASE 3 CADENZA STUDY

A. Röth [1,*], C. M. Broome [2], W. Barcellini [3], B. Jilma [4], Q. A. Hill [5], D. Cella [6], T. H. A. Tvedt [7], M. Yamaguchi [8], M. Lee [9], F. Shafer [9], M. Wardecki [10], B. Schaible [9], X. Jiang [9], P. Patel [9], F. Joly [11], I. C. Weitz [12]

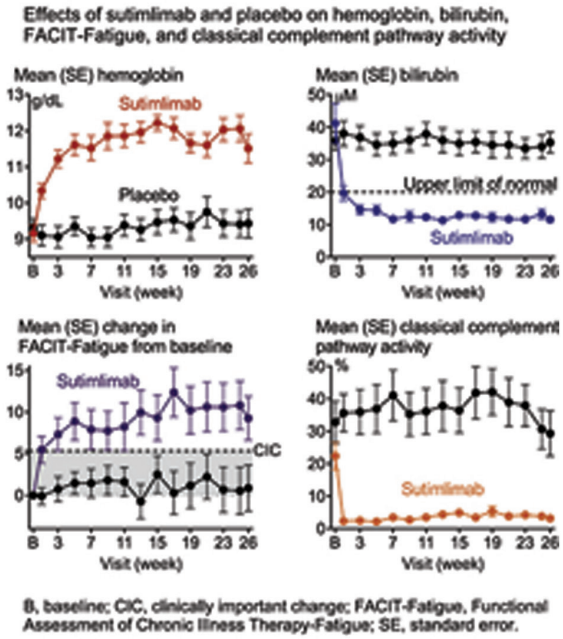
Background: CAD is chronic autoimmune hemolytic anemia mediated by classical complement pathway activation. CAD patients also may experience profound fatigue (secondary to the anemia and chronic inflammation) (Weitz et al. *Blood*. 2020), anxiety, and depression (Patel et al. *Blood*. 2020). Sutimlimab (formerly BIVV009), a first-in-class humanized monoclonal G_4 antibody, selectively inhibits C1s of the C1 complex, preventing classical pathway activation. In the single-arm CARDINAL study (NCT03347396), sutimlimab rapidly improved all patient-reported outcomes (PROs) in CAD patients and recent transfusion history. CADENZA (NCT03347422) is a randomized, double-blind, placebo (PBO)-controlled Phase 3 study to assess sutimlimab in CAD patients without history of recent transfusion.
Aims: To report the effects of sutimlimab versus PBO on QOL PROs from CADENZA Part A (initial 26-week treatment period).
Methods: Adult patients with confirmed CAD diagnosis, baseline hemoglobin ≤10 g/dL, total bilirubin above normal, ≥1 recent CAD-related symptom, and no recent transfusion were enrolled. Patients were randomized 1:1 to receive sutimlimab (<75 kg, 6.5g; ≥75 kg, 7.5 g; N=22) or PBO (N=20) on Days 0 and 7, then biweekly infusions. A secondary objective is to evaluate QOL using the PROs, Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue, Patient Global Impression of (fatigue) Severity (PGIS), Patient Global Impression of Change (PGIC), EuroQol 5-dimension 5-level (EQ-5D-5L; index and visual analog scale [VAS] scores) questionnaire, and 12-Item Short Form Health Survey (SF-12; physical and mental components). Treatment assessment time point (TAT) was the mean value for Weeks (W) 23, 25, and 26 for FACIT-Fatigue. FACIT-Fatigue was analyzed by a mixed model for repeated measures; W26 change from baseline for other PROs was analyzed by analysis of covariance with baseline as the covariate.
Results: Baseline QOL (mean FACIT-Fatigue, 32.3) was comparable to other hemolytic anemias, such as paroxysmal nocturnal hemoglobinuria (Schrezenmeier et al. *Haematologica*. 2014), and cancer (Escalente et al. *Cancer Med*. 2019). As early as W1, sutimlimab, but not PBO, elicited a clinically meaningful increase (≥5 points) in mean FACIT-Fatigue. At TAT, the least squares (LS) mean (standard error of the mean [SEM]) difference in FACIT-Fatigue between sutimlimab and PBO groups was 8.9 (2.5) (P<0.001). At W26, severe fatigue was present in 5.6% of patients in the sutimlimab group compared with 31.6% in PBO (PGIS; **Figure**). W26 overall health (PGIC) was assessed as "improved" by 73.7% of patients receiving sutimlimab compared with 31.6% on PBO (**Figure**). Strong trends were present for improved (higher) W26 SF-12 physical and mental scores in the sutimlimab group compared with PBO (LS mean [SEM] difference physical: 4.0 [2.1], P=0.064; mental: 6.1 [3.2], P=0.065) (**Figure**). A strong trend also existed for improved (higher) W26 EQ-5D-5L VAS in the sutimlimab versus PBO groups (LS mean [SEM] difference: 10.8 [5.3], P=0.052). W26 change in EQ-5D-5L index score was not different between groups.

Effects of sutimlimab and placebo on fatigue severity (PGIS), overall health (PGIC), and SF-12 physical and mental components

B, baseline; PGIC, Patient Global Impression of Change; PGIS, Patient Global Impression of Severity; SF-12, 12-item Short Form Health Survey; SEM, standard error of the mean.

Summary/Conclusion: Classical complement pathway inhibition by sutimlimab elicited a rapid, clinically meaningful and significant improvement in fatigue. Nearly three-quarters of patients on sutimlimab considered their overall health improved compared with approximately one-third on PBO. Improvements in some other PROs were also observed. In addition to the single-arm CARDINAL study, these PBO-controlled results support targeting the classical pathway via C1s inhibition in CAD.

S291 C1S-TARGETED INHIBITION OF CLASSICAL COMPLEMENT PATHWAY BY SUTIMLIMAB IN COLD AGGLUTININ DISEASE (CAD): EFFICACY AND SAFETY RESULTS FROM THE RANDOMIZED, PLACEBO (PBO)-CONTROLLED PHASE 3 CADENZA STUDY



A. Röth [1,*], S. Berentsen [2], W. Barcellini [3], S. D'Sa [4], B. Jilma [5], M. Michel [6], I. C. Weitz [7], M. Yamaguchi [8], J. -I. Nishimura [9], J. Vos [10], P. Patel [11], B. Schaible [11], X. Jiang [11], D. Vagge [12], M. Wardecki [13], F. Shafer [11], M. Lee [11], C. M. Broome [14]

Background: CAD is a rare autoimmune hemolytic anemia mediated by classical complement pathway activation. Sutimlimab, a first-in-class humanized monoclonal anti-C1s G_4 antibody, selectively inhibits this pathway, halts hemolysis, and improves hemoglobin (Hb) and quality of life (QOL) in CAD patients with recent transfusion history (pivotal single-arm CARDINAL study [NCT03347396]). CADENZA (NCT03347422) is a 26-week (Part A) randomized, double-blind, PBO-controlled Phase 3 study with open-label extension (Part B) to assess sutimlimab in CAD patients without recent transfusion history.
Aims: To report efficacy and safety results from CADENZA Part A.
Methods: Confirmed CAD-diagnosed patients with baseline Hb ≤10 g/dL, abnormally high bilirubin, transfusion independence, and ≥1 CAD symptom were enrolled after informed consent. Patients were

randomized 1:1 to receive sutimlimab (<75 kg, 6.5 g; ≥75 kg, 7.5 g; N=22) or PBO (N=20) on Days 0 and 7, then biweekly infusions. The composite primary endpoint (sutimlimab vs PBO compared using the Cochran-Mantel-Haenszel method) was the proportion of patients with Hb increase ≥1.5 g/dL at the treatment assessment time point (TAT; mean of Weeks 23, 25, and 26), and avoidance of transfusion and study-prohibited CAD therapy (Weeks 5–26). Secondary endpoints (analyzed with mixed model for repeated measures and summary statistics) included TAT change from baseline in Hb, bilirubin, and Functional Assessment of Chronic Illness Therapy [FACIT]-Fatigue. Safety was evaluated.

Results: Baseline mean (standard deviation) g/dL Hb was 9.2 (1.1) for sutimlimab and 9.3 (1.0) for PBO. Composite primary endpoint criteria were met by 16 (73%) patients in sutimlimab and 3 (15%) in PBO (odds ratio, 15.9 [95% confidence interval, 2.9–88.0; *P*<0.001]). Sutimlimab, but not PBO, increased mean Hb and QOL (FACIT-Fatigue) and normalized mean bilirubin by Week 1, which were sustained to TAT (**Figure**). At TAT, the least squares mean (standard error) difference in Hb and FACIT-Fatigue between sutimlimab and PBO was 2.6 (0.4) g/dL (*P*<0.001) and 8.9 (2.5) points (*P*<0.001). Improvements coincided with near-complete classical pathway inhibition and C4 normalization. One (5%) patient in sutimlimab and 4 (20%) in PBO received transfusions from Weeks 5 to 26. There were 146 (62% of events) treatment-emergent adverse events (TEAE) in sutimlimab and 90 (38%) in PBO. Three (14%) sutimlimab and 1 (5%) PBO patients had ≥1 serious TEAE (TESAE). One TESAE of cerebral venous thrombosis was related to sutimlimab as assessed by the investigator. Serious infections were reported but none were meningococcal. No TESAE of hypersensitivity or anaphylaxis were reported. No TEAE was suggestive of the development/worsening of autoimmune disease or systemic lupus erythematosus. All PBO and 86% of sutimlimab patients completed Part A and entered Part B; 3 sutimlimab patients discontinued study due to TEAE (acrocyanosis and Raynaud's phenomenon [n=1], infusion-related reactions [n=1], increased blood immunoglobulin M [n=1]). Acrocyanosis and infusion-related reactions were assessed as related to sutimlimab by the investigator. Hypertension (23% vs 0%), Raynaud's phenomenon (18% vs 0%), and acrocyanosis (14% vs 0%) were reported more often in the sutimlimab vs PBO group. No deaths were reported in either group.

Summary/Conclusion: Sutimlimab, but not PBO, rapidly halted hemolysis, markedly increased Hb, and improved QOL (fatigue). In addition to the single-arm CARDINAL study, the CADENZA PBO-controlled results support targeting C1s in CAD.

S292 HEMOSTATIC CHARACTERIZATION OF POST-COVID-19 CONVALESCENT PLASMA DONORS: THE BERGAMO EXPERIENCE

C. J. Tartari [1,*], G. Milani [1], F. Salvetti [1], M. Marchetti [1], L. Russo [1], A. Vignoli [1], M. Vitali [1], L. Barcella [1], M. Cefis [1], P. Gomez-Rosas [1], F. Schieppati [1], G. Ravasio [1], L. Castellani [1], G. Marchesi [1], E. Sanga [1], D. Romeo [1], A. Falanga [1,2]

[1]Immunohematology and Transfusion Medicine, Papa Giovanni XXIII Hospital, Bergamo, [2]School of Medicine and Surgery, University of Milano Bicocca, Milan, Italy

Background: Severe COVID-19 is associated with a profound derangement of the hemostatic system characterized by hypercoagulability, complement activation and endothelial cell perturbation. After disease resolution, some convalescent subjects still experience post-COVID-19 symptoms. No information is available on persistence of hemostatic alterations in this setting. Bergamo city, represents one of the first and most affected area by SARS-CoV-2 infection in the world. For this reason, since the beginning we were actively involved in hyperimmune plasma collection from COVID-19 convalescent subjects.

Aims: In this study, in a large cohort of convalescent donors of hyperimmune plasma, we aimed to characterize select hemostatic parameters of hypercoagulability and endothelial cell perturbation and their association with disease severity, demographic characteristics, and antibody levels.

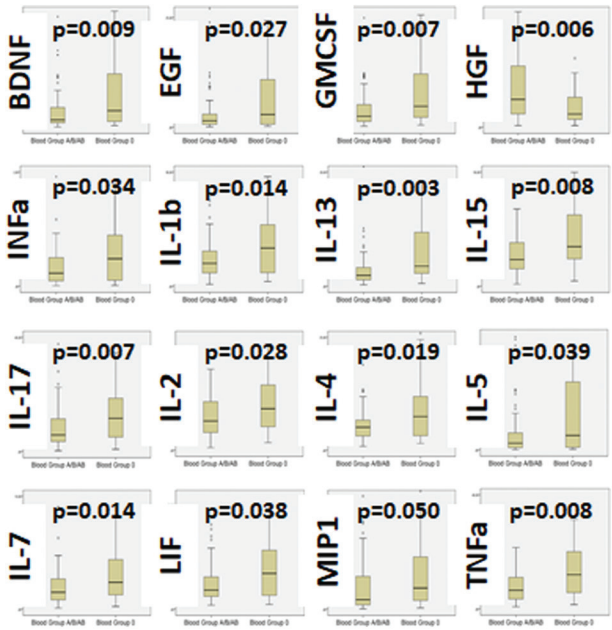
Methods: Recovered COVID-19 patients eligible to plasma donation were tested for the SARS-CoV-2 antibodies by the anti-N IgG SARS-CoV-2 antibodies (Abbott Laboratories, IL, USA, Anti-N Abs), and/or the anti-S IgG SARS-CoV-2 antibodies (Liaison-Diasorin, Sallugia-VC, Italy, Anti-S Abs), according to the manufacturer's instructions. Fibrinogen, protein C, protein S, factor V, factor VIII, factor XIII, D-dimer, and von Willebrand factor (vWF) were assessed.

Results: 425 subjects have been included (275M/150F) with a median age of 48 years (range: 19-67 years). Among convalescent subjects admitted to the donation, male gender, age > 40 years, and previous hospitalization for COVID-19, were identified as independent predictive factors for significantly ($p<0.001$) higher levels of SARS-CoV-2 IgG (both anti-S and anti-N). Hemostatic parameters including fibrinogen, protein S, factor V, factor VIII, factor XIII, and D-dimer were not different between severe and non-severe COVID-19. Differently, convalescent subjects with previous severe COVID-19 showed significantly higher levels of vWF (124±40 vs 121±41 %, $p<0.001$) and PC (119±19 vs 109±19 %, $p<0.001$) compared with non-severe COVID-19 subjects. In addition, significant positive correlations were found between vWF levels and anti-S Abs (vWF antigen $r=0.216$; vWF activity $r=0.257$ and vWF RiCof $r=0.226$, $p<0.01$).

Summary/Conclusion: Our data show that gender, age and severe disease can be potential predictors of an increased immunological response. Furthermore, convalescent subjects show a persistently high vWF levels, suggesting a persistence of the endothelial activation, despite of clinical disease remission.

S293 DESCRIPTION OF THE INFLAMMATORY PROFILE WITH 45 CYTOKINES ACCORDING TO ABO BLOOD GROUP IN COVID-19 AND ITS IMPLICATIONS ON SEVERITY AND MORTALITY.

A. Tamayo-Velasco [1,*], I. De la Fuente Graciani [1], S. Pérez González [1], C. Bombín Canal [1], J. C. Caballero Berrocal [1], C. Pérez Martínez [1], R. Acevedo García [1], A. García Bacelar [1], K. Herrera Robles [1], M. Bourgeois [1], E. Golvano [1], M. J. Cebeira [1], A. García de Coca [1], R. Cuello [1], L. Gómez García [1], L. Rico [1], T. Jiménez [1], A. Sánchez [1], M. Hijas [1], H. Gonzalo Benito [2], P. Martínez-Paz [3], M. Martín-Fernández [3], M. J. Peñarrubia [1]



[1]Haematology and Hemotherapy Service, [2]Hospital Clinico Universitario (Valladolid, Spain), [3]University of Valladolid, Valladolid, Spain

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is currently one of the worst pandemics ever. ABO blood groups are associated with different risk of viral infections and they could also play a role in COVID-19 disease. In vitro, studies demonstrated how anti-A and B antibodies neutralized the infectious capacity of SARS-CoV-2. Both SARS-CoV-2 and antibodies let a strong competitive inhibition of angiotensin converting enzyme 2 (ACE2). Those biological mechanisms could be associated with the lower risk of severity and mortality in blood group O patients.

Aims: Prospectively perform a cytokine array in plasma samples from COVID-19 patients who were stratified based on their bloody type, in order to describe the inflammatory response and provide a further insight about the possible protective mechanisms elicited by the blood type O.

Methods: Prospective and consecutive study including blood samples from 108 adult patients diagnosed with COVID-19 and admitted to the "Hospital Clínico Universitario" (Valladolid, Spain) between March 24 to April 11,

2020. Percentage distribution of ABO blood type correspond to 54.6%, 9.3%, 3.7% and 32.4% for A, B, AB and O group respectively. Patients were divided into 2 groups: i. Blood type O (n=35); ii. Blood types A/B/AB (n=73). Forty-five Cytokines, Chemokines and Growth Factors were measured in duplicate for each patient using a MAGPIX system (Luminex). Statistical analysis was performed using the R statistical package version 4.0.2.
Results: In both groups, most frequent comorbidities were hypertension, diabetes and chronic obstructive pulmonary disease. According to analytical profile, blood type O displayed higher lymphocytes (p=0.057) and lower total bilirubin (p=0.009) plasma levels than the A/B/AB group. We found a lower risk (2.16 times) of mechanical ventilation or death in patients with blood type O [Log Rank: p=0.042, Hazard Ratio: 0.463, CI 95% (0.213-1.004), p=0.050]. Moreover, 15 cytokines were over-express (and 1 under-expressed) in blood type O (**Image upload. Left box-plots: Group A/B/AB. Right Box-plots: Group O**). Last, a multivariate model found BDNF, IL-13 and IL-27 as the best cytokines able to differentiate the immune profile based on the blood type.
Discussion: In first place, blood type of the general population covered by our hospital are 42%, 9%, 4% and 47% for blood types A, B, AB and O respectively. Nevertheless, our cohort found increase blood type A (54.6%) and decrease in blood type O (32.4%). Therefore, and according our results, blood type O was not only associated to a lower risk of mortality or mechanical ventilation, but also to the need of hospital admission. In second place, a strong ACE2 downregulation – competitive inhibition of ACE2 by SARS-CoV-2 and anti-A and B antibodies – associates high Ang-II plasma levels which allows the production of inflammatory cytokines and, at the same time, a possible lower infectious capacity by SARS-CoV-2 in O blood type patients. Moreover, the existence of a higher activation status of the immune system could also let a rapid activation of the immune response in patients with the O blood type and associate a quicker viral clearance.

Summary/Conclusion: Our cohort showed how blood type O associated with both lower rates of hospital admission and lower risk of intubation or death. Indeed, these patients produced higher amounts of cytokines in response to SARS-CoV-2, hence mounting an effective immune response which allowed them to control the viral infection and therefore decrease the risk of further complications.

S294 LARGE-SCALE PRODUCTION OF CULTURED ERYTHROCYTES USING BIOREACTORS

M. -J. Claessen [1,2,*], J. Gallego Murillo [2], A. Hoogendijk [3], G. Iacono [2], E. Varga [2,4], M. Hansen [2,4], T. Klei [5], N. Yagci [2], M. Thiel [4], E. Sellink [4], M. J. Kersten [1], M. van den Biggelaar [3], E. van den Akker [2], M. von Lindern [2]

[1]Hematology, Amsterdam UMC, [2]Hematopoiesis, Sanquin Research, [3]Proteomics, [4]Laboratory Cell Therapy, [5]Product and Process Development Blood transfusion technology, Sanquin, Amsterdam, Netherlands

Background: Transfusion of donor-derived red blood cells to alleviate anaemia is the oldest and most common form of cellular therapy. In addition, red blood cells hold great promise as delivery agents of e.g. specific drugs of enzymes. However, the source depends on donor availability, and carries a potential risk of alloimmunization and blood borne diseases. In vitro cultured, customizable red blood cells (cRBC) negate these concerns and introduce precision medicine both in transfusion medicine as well as in drug delivery applications.
Aims: Here we investigated the requirements to produce red blood cells from erythroid cultures in stirred bioreactors in order to upscale the process.
Methods: Using inhouse generated serum-free GMP-grade media we optimize a protocol to expand erythroblast and differentiate cultures using 0.5 and 3.0 L stirred bioreactors. Culture parameters, e.g. oxygen availability, shear stress, impellor speed, culture density and perfusion speeds were measured. Sheer stress-induced effects on cells was evaluated by assessing specific signal transduction pathways and globally by RNA-sequencing. Cultured red blood cells were subjected to quality assessment including deformability by Automated Rheoscope and Cell Analyser (ARCA) and oxygen equilibrium curves as measured with a Hemox analyser. Flow cytometry was used to asses enucleation rates and differentiation progression.
Results: In stationary cultures, more than 90% of the cells enucleated and expressed adult haemoglobin as well as the correct blood group antigens. Passaging cRBC through a leukodepletion filter yielded 100% enucleated, stable cRBC. Deformability and oxygen association/dissociation were similar in cRBC and peripheral blood erythrocytes. RNA sequencing and proteomics was performed daily during differentiation and revealed expression dynamics of important erythroid processes, e.g. increased expression of genes involved in blood group expression, globin regulation, erythroid specific metabolic enzymes, and autophage/mitophage degradation of intracellular organels as well as / downregulation of processes involved in cell proliferation. Next, we optimized a protocol to expand erythroblast cultures using 0.5 and 3.0 L stirred bioreactors. Erythroblasts produced in this system showed similar proliferation potential compared to static conditions. Oxygen availability is a critical process parameter and erythroblasts could be cultured at oxygen concentrations as low as 0.7 mg/L, controlled by intermittent sparging. Maximum shear stress at the impeller tip, predicted to be ~1.8 Pa, was mimicked in an orbital shaker setup to evaluate the effect of mixing on the culture. This level of shear stress induced Ca2+-dependent signaling pathways, including the calcineurin/NFAT pathway, and PKC-enhanced STAT5 signaling. As a result, erythroid maturation under differentiation conditions is accelerated by this level of shear stress. Cell erythroblast densities of up to 10 x 106 cells/mL were reached upon continuous media perfusion, 5X higher compared to the current expansion culture systems. Erythroblasts cultured at high density with perfusion maintained high viability and low spontaneous differentiation. This perfusion strategy leads to smaller culture volumes.
Summary/Conclusion: Our culture protocols enable us to culture RBC from adult peripheral blood mononuclear cells both in static and bioreactor settings. The use of bioreactor is projected to be significantly more cost-effective compared to static cultures. Currently we prepare for a clinical trial with cRBC.

ITP: from bench to bedside

S295 A RESERVOIR OF RITUXIMAB-RESISTANT SPLENIC MEMORY B CELLS CONTRIBUTES TO RELAPSES AFTER B-CELL DEPLETION THERAPY

E. Crickx [1,*], P. Chappert [1], A. Sokal [1], S. Weller [1], I. Azzaoui [2], A. Vandenberghe [2], G. Bonnard [2], G. Rossi [1], T. Fadeev [1], S. Storck [1], J. Fadlallah [3], V. Meignin [4], E. Riviere [5], S. Audia [6], B. Godeau [7], M. Michel [7], J. -C. Weill [1], C. -A. Reynaud [1], M. Mahevas [1]

[1]Institut Necker Enfants Malades, INSERM U1151/CNRS UMS 8253, INSERM, Paris, [2]INSERM U955, équipe 2, Université Paris Est Créteil, INSERM, Creteil, [3]Service d'immunologie clinique, Hôpital Saint-Louis, Assistance Publique-Hôpitaux de Paris, Université Paris Diderot, Sorbonne Paris Cité, [4]Service d'anatomopathologie, Hôpital Saint-Louis (AP-HP), APHP, Paris, [5]Service de médecine interne, Hôpital Haut-Lévêque, Bordeaux, [6]Service de médecine interne, CHU de Dijon, Dijon, [7]Service de Médecine Interne, Centre national de référence des cytopénies auto-immunes de l'adulte, Hôpital Henri Mondor, APHP, Creteil, France

Background: We previously showed that RTX-resistant, autoreactive plasma cells contribute to primary failures of RTX in patients with immune thrombocytopenia (ITP). Such cells are presumably absent in patients achieving a complete response to RTX. However, many of these patients eventually relapse during B cell reconstitution, suggesting a new generation of autoreactive plasma cells.
Aims: To decipher the contribution of different B-cell subsets in relapses occurring after B cell depletion in ITP.
Methods: We performed flow cytometry, high-throughput sequencing of V(D)J genes, and single-cell RNA-sequencing of B cells and plasma cells from spleen samples of ITP patients with distinct clinical history: 1) Patients that achieved a complete response after a course of RTX and relapsed during B-cell reconstitution (n=8), 2) patients with primary failure of RTX, i.e. who did not respond to treatment at the time of B-cell depletion (n=16), and 3) patients with active ITP that were not treated with RTX (n=7) as controls.
Results: Analysis of B and plasma cells VH gene repertoire at bulk and single-cell antigen-specific level revealed the coexistence of two simultaneous responses in germinal centers, originating from both previously mutated memory B cells that survived RTX treatment and newly generated B cells. We identified memory B cells recognizing GPIIbIIIa, one of the most common auto-antigen in ITP, that harbored a very high number of VH mutations, suggesting they resisted RTX. These memory B cells belonged to clones shared with plasma cells and germinal centers populations, confirming that autoreactive RTX-resistant memory B cells can return in germinal centers and/or differentiate into plasma cells, thus contributing to disease relapse.
In RTX-refractory ITP patients, we further identified by single cell RNA-sequencing a population of quiescent splenic memory B cells, which presents a unique, yet reversible, RTX-shaped phenotype characterized by down-modulation of B cell specific factors including $CD20^-$ and expression of pro-survival genes. These RTX-resistant memory B cells included anti-GPIIbIIIa clones. Importantly, their continued surface expression of CD19 make them efficient targets for current anti-CD19 therapies.
Summary/Conclusion: Overall, our results clearly demonstrate that RTX-resistant autoreactive memory B cells reactivate as RTX is cleared from the organism. This study thus uncovers a new pathogenic entity in ITP that can be targeted by available therapeutic agents.

S296 LONG-TERM SURVIVAL IN PATIENTS WITH PRIMARY AND SECONDARY IMMUNE THROMBOCYTOPENIA - A NATIONWIDE POPULATION-BASED COHORT STUDY

N. Mannering [1,2,*], D. L. Hansen [1,2], A. Pottegård [3], H. Frederiksen [1,2]

[1]Department of Hematology, Odense University Hospital, [2]Clinical Institute, [3]Department of Public Health, University of Southern Denmark, Odense, Denmark

Background: Immune thrombocytopenia (ITP) exists in a primary form with no underlying cause (pITP), and a secondary form (sITP). Survival in pITP has been found to be reduced compared to background populations. However, only few studies on long-term outcomes and prognosis have been conducted, and prognosis of sITP is to our knowledge unknown.
Aims: In this study, we leverage the unique Danish patient registries to present long-term survival for patients with chronic primary and secondary immune thrombocytopenia.
Methods: Incident chronic ITP patients aged ≥ 18 years were identified as patients with two defined WHO ICD-8 or ICD-10 ITP-diagnosis codes registrations ≥ 12 months apart in any Danish hospital during 1980-2016. Patients with prevalent ITP at the beginning of the study period were excluded (using data from 1977-1979).
Among patients with chronic ITP, sITP cases were identified using the designated ICD10-code (D695) or through registration of an associated diagnosis before or up to 12 months after the first ITP diagnosis.
For each ITP patient, we identified and matched up to 50 individuals from the background population and not previously registered with ITP, matching on age and sex. Patients' index date were the date of the second diagnosis registration after ≥ 12 months, assigning comparison individuals an index date corresponding to the matched ITP patient. Individuals were followed from index date until death, emigration, or end of study, whichever came first.
Results: We identified 3,402 patients fulfilling primary criteria for chronic ITP. Of these, 836 were excluded (210 were prevalent, 506 were <18years of age, 80 had congenital platelet disorders and 40 had Evans syndrome) yielding a total of 2,566 patients with chronic ITP in the period 1980-2016. Comparisons comprised 123,244 individuals.
Among patients with chronic ITP 90.3% (n=2,318) were classified as pITP and 9.7% (n=248) as sITP (associated diagnoses were immunodeficiency (<5), autoimmunity (n=119), infection (n=46), hematological cancer (n=48) or D695 ICD-code only (n=48), with some overlap between groups).
The entire cohort included 60.3% women and mean age at index date was 55.5 [95% CI: 55.4; 55.6], 19.9% (n=511) of all patients with chronic ITP and 0.2% (n=251) of all comparisons were splenectomized. Survival analysis showed that median survival [95%CI] was 17.3 years [15.3; 20.0] for patients with pITP and 25.5 years [25.2; 26.0] for their corresponding comparisons. For patients with sITP, median survival was reduced to 12.3 years [8.9; 15.2], and 25.8 years [24.6; 27.1] for their comparisons (Figure 1).
When performing Cox-regression, hazard ratio (HR) for death between groups was 1.85 [1.74; 1.97] when comparing all patients with chronic ITP to all comparisons (total number of comparisons in the cohort). Risk of death for patients with sITP vs. pITP (adjusted for age) was also elevated with a HR of 1.50 [1.24; 1.81].
Subgroup analyses for both pITP and sITP vs. respective comparisons were also performed. For patients with pITP vs. comparisons HR was 1.77 [1.66; 1.89], and among patients with sITP vs. comparisons HR was 2.79 [2.33; 3.33].

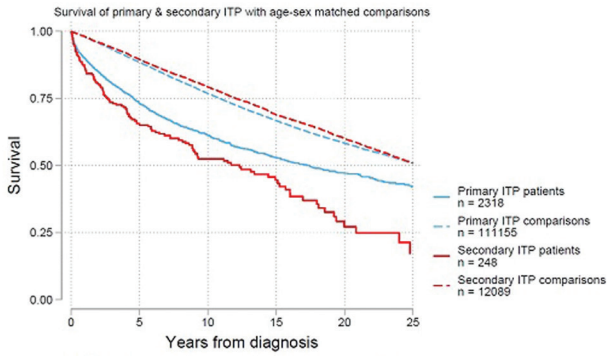


Figure 1 - Kaplan-Meier *survival curves for patients with chronic ITP* Solid lines illustrate patients with primary and secondary ITP while dashed lines show their respective comparisons

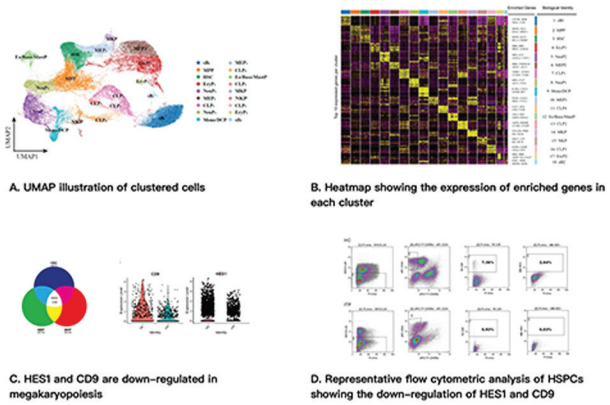
Summary/Conclusion: Survival for both pITP and sITP are reduced compared to the general population.
This cohort provides a unique possibility of future outcome studies of patients with pITP and sITP.
Analyses of temporal trends and comorbidity are ongoing and will be presented with the abstract.

S297 FEATURES OF HEMATOPOIETIC STEM AND PROGENITOR CELLS IDENTIFIED THROUGH SINGLE-CELL RNA SEQUENCING IN IMMUNE THROMBOCYTOPENIA



Y. Liu [1,2,*], A. Liu [1,2], J. Peng [1,2]

[1]Shandong University, [2]Department Of Hematology, Qilu Hospital Of Shandong University, Jinan, China

Background: Primary immune thrombocytopenia (ITP) is an acquired autoimmune disease characterized by isolated thrombocytopenia. A growing body of emerging evidence indicates that abnormalities during any stage of thrombopoiesis and megakaryocytopoiesis can influence platelet production.
Aims: Our study concentrated on the hematopoietic stem and progenitor cells (HSPCs) in ITP patients from the perspective of single cell transcriptome.
Methods: $CD34^+$ HSPCs were isolated from BM of four newly diagnosed ITP patients and four healthy adults as controls by fluorescence-activated cell sorter (FACS), and Single-cell RNA sequencing (scRNA-seq) data was collected using the recommended protocol for the 3' scRNA-seq 10X genomics platform.
Results: We perform scRNA-seq for 69,178 single $CD34^+$ HSPCs, and detected over 3000 expressed genes per cell on average. Uniform manifold approximation and projection (UMAP), a method for nonlinear dimensionality reduction, showed a visualized image of the cells (Fig 1. A). Heatmap showed the scaled expression of top 10 differentially expressed genes in each cluster (Fig 1. B). Cell clusters expressed established markers of hematopoietic populations, revealed diverse hematopoietic cell

types and implied differentiation trajectories consistent with current views of hematopoiesis. We identified an unambiguous feature of HSPCs in ITP patients with the down-regulation of HES1 and CD9 (Fig 1. C). And the results were verified by flow cytometry (Fig 1. D). Furthermore, through cell culture, we found that lin$^-$CD45ra$^-$CD34$^+$CD9$^+$ cells produced fewer mature megakaryocytes in ITP patients than healthy controls. Our study suggested that HES1 and CD9 were involved in the pathogenesis of ITP.

Fig1. ScRNA-seq analysis of the BM HSPCs from ITP patients and controls

A. UMAP illustration of clustered cells

B. Heatmap showing the expression of enriched genes in each cluster

C. HES1 and CD9 are down-regulated in megakaryopoiesis

D. Representative flow cytometric analysis of HSPCs showing the down-regulation of HES1 and CD9

Summary/Conclusion: Using scRNA-seq, we revealed a hierarchically-structured transcriptional landscape of hematopoietic differentiation of BM CD34+ HSPCs. We observed a significantly descreased expression of HES1 and CD9 in newly diagnosed ITP patients, which might relate with the generation of abnormal MKs and be a biomarker potentially using in diagnosis.

S298 HIGH LEVEL OF ESTRADIOL INDUCES MEGAKARYOCYTE APOPTOSIS AND IMPAIRS PROPLATELET FORMATION VIA MST1-FOXO1 AXIS DURING PREGNANCY IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

Q. Chen [1,*], F. -Q. Liu [1], X. -Y. Sun [1], C. -C. Wang [1], X. -L. Zhu [1], Y. He [1], M. -Y. Liang [2], J. -L. Wang [2], X. -H. Zhang [1]

[1]Peking University Institute of Hematology, [2]Peking University People's Hospital, Beijing, China

Background: Immune thrombocytopenia (ITP) affects 1-10 in 10000 pregnancies. Although most patients were remaining relatively stable throughout pregnancy, the platelet counts may decrease following the prolongation of gestation, especially in the third trimester. The pathogenesis is usually considered to be secondary to physiologic changes during gestation, such as an increase in blood volume, platelet activation, or increased platelet clearance. However, the precise pathogenesis of ITP during pregnancy has not been fully understood.
Aims: It is to explore the relationship between the high level of estradiol (E2) and defective thrombopoiesis in ITP during pregnancy.
Methods: Twenty consecutive successful pregnancies in 20 ITP patients were studied. Blood samples were analyzed to determine the concentration of E2 at different gestational ages using ELISA. BM-derived CD34$^+$ cells from healthy controls (HCs), ITP patients and pregnant ITP (P-ITP) patients were cultured. BM-derived CD34$^+$ cells from ITP patients were treated with different concentrations of E2. he differentiation of megakaryocytes (MKs) and polyploidization were assessed by flow cytometry. Proplatelet formation (PPF) were observed with a phase-contrast microscope and a confocal microscope. MK apoptosis and markers of apoptosis pathways were detected via flow cytometry, and western blotting was used to evaluated the expression of FoxO1 and Mst1.
Results: P-ITP patients experienced significant reduction in platelet counts during gestation, particularly in the late stages. BM-derived CD34$^+$ cells from HCs, ITP patients and P-ITP patients were sorted and cultured. It was observed that the percentage of CD41$^+$CD42b$^+$ MKs and high ploidy MKs were significantly lower in ITP patients than in HCs. In addition, few MKs with proplatelets were observed in ITP patients. A higher percentage of CD41$^+$CD42b$^+$ MKs and high ploidy MKs were found in P-ITP samples than in ITP samples. However, in P-ITP samples, fewer MKs with proplatelets were observed. The results indicated that the thrombopoiesis ability differed between ITP and P-ITP patients.
The concentration of E2 was founded to be sharply increased during pregnancy in ITP. To explore whether there is a link between the levels of E2 during gestation and thrombopoiesis in ITP patients during pregnancy, BM-derived CD34$^+$ cells from ITP patients were treated with different concentrations of E2, which were determined by the serum levels of P-ITP patients. E2 was observed to dose-dependently promote the MKs differentiation and polyploidization. However, at high E2 levels of 10 nM and 100 nM, few proplatelet-generating MKs were observed. In the 10 nM and 100 nM groups, a high percentage of apoptotic MKs was detected. The physiologic concentration of 0.1 nM had no obvious influence on MKs apoptosis. The expression of Bak, Bax, and cleaved caspase-3, which were components of the intrinsic apoptosis pathway, were significantly increased in the 10 nM and 100 nM groups. Increased apoptotic MKs were also observed in BM biopsy samples from P-ITP patients. These findings indicated that a high concentration of E2 could induced activation of the intrinsic apoptosis pathway in ITP MKs and impaired PPF. The activation of the Mst1-FoxO1 axis, which induced activation of the intrinsic apoptosis pathway, was found in ITP MKs treated with a high level of E2.
Summary/Conclusion: For the first time, our study demonstrated that a high level of E2 during pregnancy impaired proplatelet formation by activating the intrinsic apoptosis pathway via the Mst1-FoxO1 axis in ITP.

S299 PHASE I/II UPDATED SAFETY AND EFFICACY RESULTS OF ORAL BRUTON TYROSINE KINASE (BTK) INHIBITOR RILZABRUTINIB IN RELAPSED/REFRACTORY IMMUNE THROMBOCYTOPENIA (ITP)

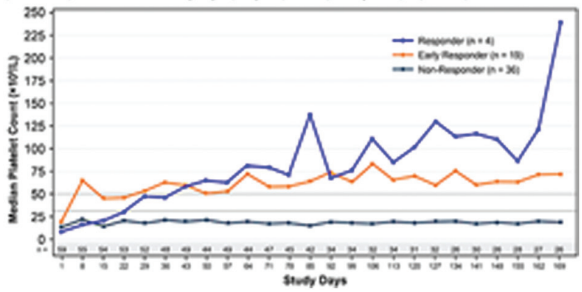
Background: Immune thrombocytopenia (ITP) is characterized by immune-mediated platelet destruction and impaired production, triggering thrombocytopenia, and a predisposition to bleeding. Despite recent therapeutic advances, durable remission remains an unmet need for relapsed/refractory ITP patients. Rilzabrutinib is an oral, reversible, covalent inhibitor of BTK that targets immune-mediated ITP activities and has simultaneous rapid anti-inflammatory effects and neutralization and prevention of autoantibody signaling preclinically. The ongoing phase I/II study (NCT03395210) assesses the safety and efficacy of rilzabrutinib in patients with relapsed or refractory ITP who previously responded to ≥1 prior ITP therapy and have no available treatment options. Initial results have shown rapid and durable clinical activity and a well-tolerated safety profile in patients responding to rilzabrutinib.
Aims: Phase II evaluation of rilzabrutinib in the overall study population and patients initiating 400 mg BID rilzabrutinib.
Methods: Eligible patients with 2 baseline platelet counts <30×10^9/L received oral rilzabrutinib at starting doses of 200 mg QD, 400 mg QD, 300 mg BID, or 400 mg BID; intrapatient dose escalation was allowed to improve efficacy. Rilzabrutinib was given for 24 weeks; additional long-term therapy was administered at the 400 mg BID dose in responders only. Stable doses of concomitant ITP medication (corticosteroids and thrombopoietin-receptor agonists) were permitted for patients without adequate platelet response. The primary endpoints are safety and ≥2 consecutive platelet counts ≥50×10^9/L and increased ≥20×10^9/L from baseline without requiring rescue medication. All patients provided informed consent.



Results: The overall study population comprises 59 patients, of whom 44 had a starting dose of 400 mg BID; data cutoff was 09Nov2020. Overall, patients had a median age 50 years (range, 21-74), median duration of ITP 6.4 years (range, 0.4-52.5), and a median of 6.0 prior therapies (range, 1-53; 25% prior splenectomy). Baseline median platelet counts were 15-16×10^9/L (range, 2-33). Baseline demographics were similar for patients initiating 400 mg BID. A total of 23 patients (39%) overall and 17 (39%) initiating 400 mg BID achieved the primary efficacy endpoint (Table). Primary responses were observed irrespective of prior treatments or responses. Responders maintained platelet counts ≥50×10^9/L for a median of 75% of weeks, as well as increased platelet counts of ≥20×10^9/L above baseline levels for a median of 87% of weeks (Figure). Approximately half of all patients attained platelet counts of ≥30×10^9/L by day 8. Day 8 platelet count was associated with a high negative predictive value for achieving the primary endpoint (>80%) and may assist with identifying patients unlikely to reach the targeted primary platelet response. Related treatment-emergent adverse events (all grade 1/2) were observed in 29 of 59 (49%) patients overall; most common were 31% diarrhea and 25% nausea (all others were <10%). There were no related bleeding/thrombotic events, ECG abnormalities, hypertension, or liver enzyme elevations.

Table. Summary of Platelet Response with Rilzabrutinib in ITP

	All Patients (N = 59)		400 mg BID Starting Dose (n = 44)	
Primary endpoint response*, n (%)	23 (39)		17 (39)	
Prior splenectomy	5/15 (33)		3/11 (27)	
No prior splenectomy	18/44 (41)		14/33 (42)	
TPO-RA naive patients	10/17 (59)		8/14 (57)	
Based on response to prior therapy	Responded	No Response	Responded	No Response
TPO-RA	6/20 (30)	7/22 (32)	3/14 (21)	6/16 (38)
Rituximab	3/9 (33)	3/14 (21)	2/7 (29)	3/14 (21)
Fostamatinib	2/6 (33)	1/2 (50)	2/5 (40)	1/2 (50)
Percent of weeks with target platelet counts, median (range)				
≥50×10^9/L	75% (25%-100%)		75% (37%-100%)	
≥20×10^9/L above baseline	87% (29%-100%)		87% (33%-100%)	
Achieved ≥30×10^9/L by day 8†				
Yes, n (%)	30 (51)		22 (50)	
Positive predictive value	63%		59%	
No, n (%)	29 (47)		22 (50)	
Negative predictive value	86%		82%	

BID, twice daily; ITP, immune thrombocytopenia; TPO-RA, thrombopoietin receptor agonists.
*At least 2 consecutive platelet counts ≥50×10^9/L and increased ≥20×10^9/L from baseline without requiring rescue medication.
†In patient-was-enrolled-and-did-not-have-day-8-platelet-counts.

Figure. Median platelet counts during main rilzabrutinib treatment period based on no response or platelet responses of ≥50×10^9/L by day 8 (early responders) or any time (responders)

Summary/Conclusion: Rilzabrutinib was well-tolerated and showed rapid and durable responses, with half of the patients achieving platelet counts ≥30×10^9/L by day 8, potentially providing a tool for predicting early response to treatment, and a durable primary endpoint response. Taken together, these findings support further investigation of the magnitude and durability of rilzabrutinib clinical benefit.

Dilemmas in coagulation and thrombosis

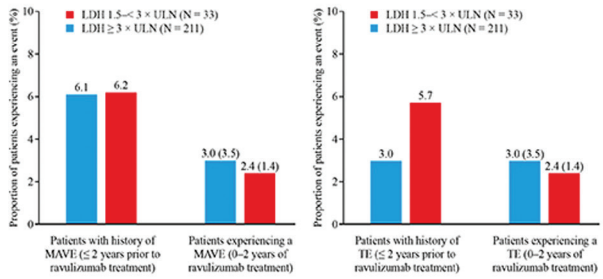
S300 CHIP-ASSOCIATED MUTANT ASXL1 ACTIVATES INNATE IMMUNE PATHWAY IN MYELOID CELLS AND PROMOTES ATHEROSCLEROSIS IN MICE

N. Sato [1,*], S. Goyama [2], Y. -H. Chang [1], T. Fujino [1], S. Asada [3], S. Shikata [1], X. Liu [2], T. Yonezawa [2], R. Takeda [1], K. Yamamoto [1], T. Shibata [4], M. Sekiya [5], S. Koide [6], A. Iwama [6], K. Miyake [4], H. Shimano [5], T. Kitamura [1]

[1]Division of Cellular Therapy, The Institute of Medical Science, The University of Tokyo, [2]Division of Molecular Oncology, Department of Computational Biology and Medical Sciences, Graduate School of Frontier Sciences, The University of Tokyo, [3]The Institute of Laboratory Animals, Tokyo Women's Medical University, [4]Division of Infectious Genetics, Department of Microbiology and Immunology, University of Tokyo, Tokyo, [5]Department of Internal Medicine (Endocrinology and Metabolism), Faculty of Medicine, University of Tsukuba, Ibaraki, [6]Division of Stem Cell and Molecular Medicine, Center for Stem Cell Biology and Regenerative Medicine, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan

Background: Recent epidemiological studies showed the significant association between cardiovascular diseases (CVD) and clonal hematopoiesis of indeterminate potential (CHIP). CHIP is defined as the clonal expansion of blood cells driven by somatic mutations in hematopoietic genes, such as *DNMT3A*, *ASXL1*, *TET2*, or *JAK2*. Previous studies have shown that *TET2*-, *DNMT3A*- and *JAK2*-driven CHIP in fact promote atherosclerosis or worsen heart failure using mice models. In contrast, whether and how ASXL1 mutations contribute to atherosclerosis remains unknown despite the robust clinical association between mutant *ASXL1*-driven CHIP and CVD.
Aims: We aim to investigate the crosstalk between hematopoiesis with mutant ASXL1 and CVDs.
Methods: We previously established knockin (KI) mice expressing a C-terminally truncated form of ASXL1-mutant (ASXL1-MT). Using these mice, we assessed if the high-fat diet (HFD) affects the reconstitution and differentiation of hematopoietic cells with ASXL1-MT. We also assessed the role of hematopoietic cells derived from ASXL1-MT KI mice in the development of atherosclerotic CVDs using the atherosclerosis-prone Ldlr-/- mice. To study the mechanisms underlying the promotive effect of ASXL1 mutation on atherosclerosis, we used mouse and human cell lines (RAW264.7 cells, 293T cells), BaF/3 cells expressing Toll-like receptor (TLR), and bone marrow-derived macrophages derived from the ASXL1-MT KI mice.
Results: The Ldlr$^{-/-}$ mice transplanted with bone marrow from ASXL1-MT KI mice showed significantly larger atherosclerotic lesions in the aorta and aortic valves than the control mice. We also found that HFD conferred growth advantage to ASXL1-MT cells over wild-type cells, particularly in the population of the inflammatory monocytes. Consistent with these findings, RNA-seq of the plaque-macrophages derived from ASXL1-MT KI mice showed more inflammatory signatures than those from control mice. Thus, these data suggest that mutant ASXL1 promotes HFD-induced expansion of inflammatory monocytes and macrophages, thereby accelerates atherosclerosis.
Mechanistically, we found that wild-type and mutant ASXL1 have different effects on the innate immune pathway. NF-κB reporter assay revealed that wild-type ASXL1 suppressed, while mutant ASXL1 promoted, the reporter activation induced by the TLR stimulation. Furthermore, we found that wild-type ASXL1, but not mutant ASXL1, suppresses the activation of TAK1 in TLR-NF-κB signaling pathway through direct interaction with IRAK1 and TRAF6. These results suggest that ASXL1 inhibits the innate immune pathway through interactions with IRAK1/TRAF6/TAK1 in myeloid cells, while mutant ASXL1 loses this regulatory function. Finally, we assessed the effect of IRAK1/4 inhibitor on atherosclerosis in HFD-fed ASXL1-MT mice. As expected, IRAK1/4 inhibition decreased the number of inflammatory monocytes and attenuated the development of atherosclerosis driven by ASXL1-MT.
Summary/Conclusion: Our study demonstrated the causative role of the CHIP-associated *ASXL1* mutation to promote atherosclerosis. Inhibition of the innate immune pathway may prevent the development of CVD associated with CHIP harboring *ASXL1* mutations.

S301 RAVULIZUMAB REDUCES THE RISK OF THROMBOSIS IN ADULT PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA AND HIGH DISEASE ACTIVITY: 2-YEAR DATA FROM A PHASE 3, OPEN-LABEL STUDY



R. Peffault de Latour [1,*], A. Hill [2], W. Füreder [3], C. Piatek [4], M. Griffin [5], M. Ogawa [6], J. Wang [6], K. Usuki [7], A. Röth [8], J. W. Lee [9]

[1]Hôpital Saint-Louis AP-HP, Paris, France, [2]Alexion Pharmaceuticals, Inc., Leeds, United Kingdom, [3]Department of Internal Medicine I, Division of Hematology and Hemostaseology, Medical University of Vienna, Vienna, Austria, [4]Jane Anne Nohl Division of Hematology, Keck School of Medicine of USC, Los Angeles, United States, [5]Haematology Department, St James University Hospital, Leeds, United Kingdom, [6]Alexion Pharmaceuticals, Inc., Boston, MA, United States, [7]Department of Hematology, NTT Medical Center Tokyo, Tokyo, Japan, [8]Department of Hematology and Stem Cell Transplantation, University Hospital Essen, Essen, Germany, [9]Department of Hematology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Democratic People's Republic Of

Background: Patients with paroxysmal nocturnal hemoglobinuria (PNH) are at an increased risk of thromboembolism (TE) which may be fatal. Results of a univariate retrospective analysis from the International PNH Registry showed that patients with intravascular hemolysis, defined as lactate dehydrogenase (LDH) ≥ 1.5 × upper limit of normal (ULN; 246 U/L), and ≥ 2 × ULN, high disease activity (HDA) symptoms, and history of TEs and major adverse vascular events (MAVEs) are at significantly greater risk of experiencing TE. Where available, ravulizumab is the current standard of care for PNH, however, its long-term effectiveness in preventing TEs and MAVEs in patients with HDA is unknown.

Aims: To evaluate the long-term effectiveness of ravulizumab at preventing TEs and MAVES in patients with PNH and HDA in a phase 3 study stratified by baseline LDH levels.
Methods: This ongoing phase 3, multicenter, randomized, open-label study (NCT02946463) enrolled adult patients (aged ≥ 18 years) with PNH and HDA (LDH levels ≥ 1.5 × ULN and presence of 1 or more PNH-related symptoms within 3 months of screening) who were complement-inhibitor-naïve. Patients received weight-based dosing of ravulizumab every 8 weeks or eculizumab (900mg every 2 weeks) during the randomized treatment period and continued or switched to ravulizumab during the extension period (5 years). In this post-hoc analysis, patients who received ravulizumab were stratified by baseline LDH levels into two groups: 1.5 – < 3 × ULN (Group A) or ≥ 3 × ULN (Group B). Proportion of patients experiencing MAVE or TE in 2 years prior to enrollment and after receiving ravulizumab during 2 years of the study were compared for each group. TEs included thrombophlebitis/deep vein thrombosis (DVT), renal vein thrombosis, renal arterial thrombosis, mesenteric/visceral vein thrombosis, mesenteric/visceral arterial thrombosis, hepatic/portal vein thrombosis, dermal thrombosis, acute peripheral vascular disease occlusion, cerebral arterial occlusion/cerebrovascular accident, cerebral venous occlusion, and pulmonary embolus. MAVEs include both TEs and non-TEs (amputation [nontraumatic, nondiabetic], myocardial infarction, transient ischemic attack, unstable angina, gangrene [nontraumatic, nondiabetic], and specified if other).
Results: Patients were stratified to Group A (n = 33) or Group B (n = 211), respectively. Patient demographics were comparable between the two groups, with mean (SD) age at first infusion of 48.2 (15.5) years for Group A and 44.9 (15.6) years for Group B. However, more patients in Group A were white compared with Group B (51.5% and 36.5%, respectively). Over the 2 years of study, patients in Group A and Group B underwent 56.7 and 361.2 patient-years of exposure to ravulizumab, respectively. Treatment with ravulizumab resulted in fewer reported MAVEs and TEs compared with the 2 years prior to enrollment in both groups (**Figure 1**). MAVEs reported during the 2 years of treatment with ravulizumab were all TEs. Only 1 patient (3.0%) in Group A experienced TE, which was classified as a pulmonary embolism event. In Group B, 5 patients (2.4%) experienced TE, including 2 DVT events, and 1 event each of thrombosis, jugular vein thrombosis and peripheral artery thrombosis. Ravulizumab was well-tolerated in all patients for up to 2 years with no new safety signals.

Figure 1 Summary of MAVEs and TE events in patients with PNH and high disease activity

Data label values in parentheses represent the MAVE or TE event rate per 100 patient-years during the 2 years of ravulizumab treatment.
LDH, lactate dehydrogenase; MAVE, major adverse vascular events; PNH, paroxysmal nocturnal hemoglobinuria; TE, thromboembolism; ULN, upper limit of normal.

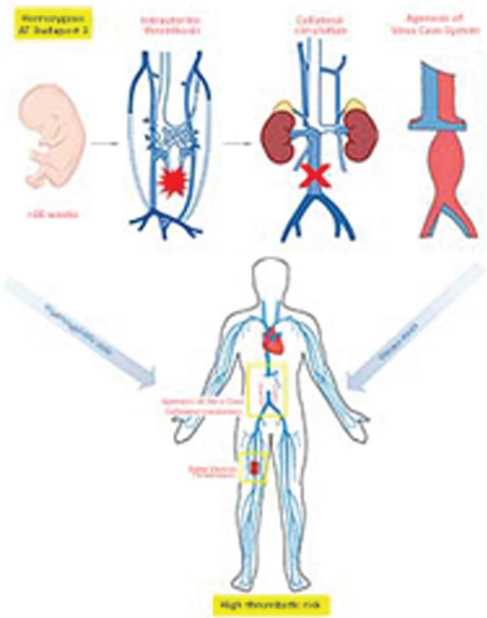
Summary/Conclusion: Ravulizumab reduces the risk of thrombosis in patients with PNH and HDA, who are at an increased risk of TE.

S302 HALF-LIFE PROLONGATION OF VON WILLEBRAND FACTOR: A NEW THERAPEUTIC STRATEGY FOR HAEMOPHILIA A AND VON WILLEBRAND DISEASE

K. Kovacevic [1,*], B. Jilma [1], P. Quehenberger [1], S. Zhu [2], J. C. Gilbert [2], M. Beliveau [3], C. Schoergenhofer [1], U. Derhaschnig [1]

[1]Medical University of Vienna, Vienna, Austria, [2]Band Therapeutics, Lexington, United States, [3]Certara, Montreal, Canada

Background: Von Willebrand Factor (VWF) and coagulation Factor VIII (FVIII) circulate in a noncovalent complex in blood and promote primary haemostasis and clotting respectively. As well as mediating platelet adhesion, VWF reduces the clearance of FVIII. VWF deficiency causes mucocutaneous bleeding, and FVIII deficiency mainly causes spontaneous joint bleedings. Both of them can result in life-threatening bleeding during surgery or after trauma, and may necessitate VWF or factor VIII replacement therapy in severe cases. Only recently, VWF has become a target for therapeutic interventions in prothrombotic diseases. However, intravenous infusion of the A1 domain blocking aptamer ARC1779 was also effective in patients with hyperactive VWF (VWD type IIb), and increased their plasma levels of VWF, FVIII and platelet counts pointing towards a potential hemostatic function, which may also be exploited. A new generation of aptamer, BT200, was recently designed, which showed good subcutaneous bioavailability and a long half-life in non human primates.
Aims: This first-in human, randomised, placebo-controlled trial set out to test the hypothesis, that BT200 is well tolerated, safe and has favourable pharmacokinetic and pharmacodynamic effects.
Methods: Normal healthy volunteers received single ascending doses of the anti VWF aptamer BT200 ranging over 2.5 orders of magnitude from 0.18 mg to 48mg by subcutaneous injection or sc or iv. infusions. Blood samples were collected over 4 weeks after the last dose. This was followed repeated dosing in a multiple ascending dose part of the trial. Pharmacokinetics were characterised and the effects were measured by VWF parameters, FVIII, platelet function tests, viscoelastometry and thrombin generation.
Results: BT200 plasma concentrations increased dose-proportionally. Mean plasma peak of BT200 concentration ranged from 0.01 to 5.53 µg/mL. Mean plasma BT200 terminal elimination half-life (t½) ranged between 118 to 284 hours following subcutaneous injection. Bioavailability increased dose-dependently and reached 90% at the highest dose level. BT200 inhibited the A1 domains of VWF in a dose dependent fashion particularly at doses >=12mg. BT200 decreased VWF activity, ristocetin induced aggregation, and prolonged collagen adenosine diphosphate closure times. At maximal doses complete inhibition of VWF was achieved ($p<0.001$), with clinical signs of mild mucosal bleedings. However, BT200 also dose-dependently increased VWF:Antigen levels and Factor VIII clotting activity >4-fold ($p<0.001$). This resulted in increased thrombogenicity as measured by thrombin generation and enhanced clotting. In the absence of an increase in VWF propetide levels, this effect is considered due to decreased clearance of VWF. Interestingly a clinically meaning full increase in VWF/FVIII (2-fold increase) was already visible at doses <=6mg. Simulations indicate that BT200 will be able to achieve a 2-3 fold increase in endogenous VWF/FVIII levels in mild/moderate bleeding disorders, as well as a substantial half-life prolongation of all kind of substituted VWF/VIII products in severe hemophilia or type III VWD.
Summary/Conclusion: This trial identified a novel mechanism of action for BT200: it decreases the clearance of VWF/FVIII, which can be exploited for congenital bleeding disorders. This built a solid foundation for an ongoing basket trial in patients with von Willebrand disease or haemophilia A, which already confirms the expected effect sizes.



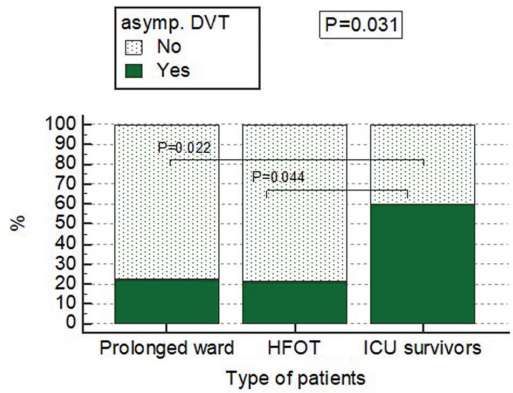
S303 SEVERE ANTITHROMBIN DEFICIENCY, HOMOZYGOUS ANTITHROMBIN BUDAPEST 3, CAUSES AGENESIS OF THE INFERIOR VENA CAVA SYSTEM.

M. E. De La Morena-Barrio [1,*], C. Bravo-Pérez [1], R. Gindele [2], P. Ilonczai [3], I. Zuazu [1], M. Speker [2], Z. Oláh [4], J. J. Rodríguez-Sevilla [5], L. Entrena [6], M. S. Infante [7], J. M. García [7], B. de la Morena-Barrio [8], A. Schlammadinger [9], A. Miñano [8], V. Vicente [8], J. Corral [10], Z. Bereczky [2]

Hospital del Mar, Barcelona, [6]Servicio de Hematología. Hospital Virgen de las Nieves, Granada, [7]Servicio de Hematología y Unidad Central de Radiodiagnóstico. Hospital Infanta Leonor, Madrid, [8]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CIBERER, Murcia, Spain, [9]Department of Internal Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary, [10]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CIBERER, Murcia, Spain

Background: Agenesis of inferior vena cava (IVC) is a rare congenital malformation with unknown etiology that might be associated with intrauterine IVC thrombosis. The identification of IVC agenesis in a case with early idiopathic venous thrombosis and antithrombin deficiency caused by the homozygous SERPINC1 c.391C>T variant (p.Leu131Phe; antithrombin Budapest 3), encouraged to evaluate the role of severe thrombophilia in this vascular abnormality.
Aims: To study the mechanisms and molecular base of inferior venca cava system.

Methods: Retrospective study of the worldwide largest series of patients homozygous for the Budapest 3 variant (N=60) selected from two cohorts of patients with congenital antithrombin deficiency (Spain, N=638 and Hungary, N=426). Image analysis included computed tomography and phlebography.
Results: IVC system agenesis was observed in 16 out 23 cases homozygous for antithrombin Budapest 3 with available computed tomography (69.6%), fifteen had agenesis of IVC and one atresia of the left iliac vein. All cases with vascular defects had compensatory mechanisms, azygos-hemiazygos continuation or double IVC, and five had other anatomic defects. Short Tandem Repeat analysis supported the specific association of the IVC system agenesis with SERPINC1.



Summary/Conclusion: We show the first evidence of the role of a severe thrombophilia in IVC system agenesis. The impaired control of thrombin in carriers might facilitate intrauterine or perinatal thrombosis at this localization. Moreover, the underlying thrombophilia also explains the high risk of thrombosis described in patients with agenesis of IVC. Our results encourage the search for severe thrombophilic states in patients with agenesis of IVC and to consider the use of antithrombotic prophylaxis at risk situations with these vascular defects.

S304 ASYMPTOMATIC DEEP VENOUS THROMBOSES ARE HIGHLY PREVALENT AMONG PROLONGED HOSPITALIZED SEVERE COVID-19 PATIENTS DESPITE THROMBOPROPHYLAXIS

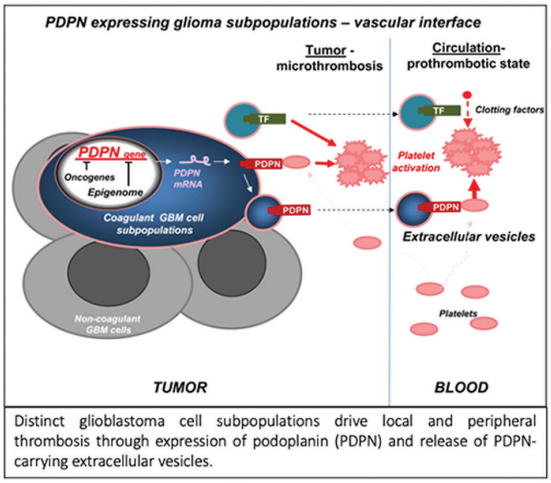
M. Lucijanic [1,*], N. Piskac Zivkovic [2], M. Ivic [1], M. Sedinic [1], B. Brkljacic [3], A. Mutvar [4], D. Rudan [5], B. Barsic [6], I. Luksic [6], R. Kusec [1], G. Ivanac [3]

[1]Hematology, [2]Pulmology, [3]Radiology, [4]Nuclear Medicine, [5]Cardiology, [6]University hospital Dubrava, Zagreb, Croatia

Background: Patients with severe symptoms of COVID-19 often require prolonged hospitalization with reduced mobility due to both imposed restrictions and objective decline in functional status.
Aims: Prompted by literature reports of high asymptomatic VTE prevalence in COVID-19 patients and our own clinical experience, we aimed to assess a prevalence of DVT among prolonged hospitalized COVID-19 patients without deep venous thrombosis (DVT) clinical suspicion and to investigate its potential predictors.
Methods: During January 2021 we have prospectively undertaken bilateral lower extremity deep veins duplex ultrasound evaluation in 102 consecutive COVID-19 patients without clinical suspicion of DVT that were prolonged hospitalized in our institution. Eligible patients were adult (≥18 years) ward patients that required hospitalization for ≥7 days. Patients who developed clinical suspicion of DVT, unable to cooperate with the ultrasound procedure or were not sufficiently stable to undergo the ultrasound procedure were considered ineligible for the study. All patients received at least prophylactic doses of low molecular weight heparin.
Results: Median age was 71.5 years. A total of 54/102 (52.9%) patients were males, 96/102 (94.1%) required oxygen-supplementation therapy. Median length of hospitalization at the time of evaluation was 18 days and median time from the start of COVID-19 symptoms was 27 days. DVT was detected in 26/102 (25.5%) patients without clinical suspicion. Distal DVT was the most common [22 patients (84.6% of the DVT cohort; 21.6% of the overall cohort)]. Proximal DVT was present in four patients (16% of the DVT cohort; 3.9% of the overall cohort), among them three had popliteal thrombosis and one had femoral thrombosis. Pulmonary embolism (PE) was detected in 17/70 (24.3%) patients who were similarly distributed among patients with and without asymptomatic DVT [5/17 (29.4%) and 12/53 (22.6%); P=0.571]. Patients that were mechanically-ventilated ICU survivors presented with highest frequency of DVT [6/10 (60%)], whereas patients treated with high-flow oxygen therapy and prolonged-hospitalized patients had similar DVT frequency [7/33 (21.2%) and 13/59 (22%), respectively]; P=0.031, Figure. D-dimers at the time of hospital admission showed no significant association with the presence of DVT (P=0.280) but there was a statistically significant trend of higher frequency of asymptomatic DVT among patients with higher level of control D-dimers (P=0.034). Patients with and without DVT significantly differed in modified IMPROVE (median 3 and 2 points, respectively; P=0.021) and IMPROVEDD VTE risk-scores (median 4 and 3 points, respectively; P=0.029). Only 17/26 (65.4%) of patients with DVT would fulfill post-discharge thromboprophylaxis criteria (modified-IMPROVE score ≥2 and D-dimers 2x above normal or modified IMPROVE score ≥4 (COVID-19 Treatment Guidelines Panel 2021)). Other variables that were significantly associated with the presence of DVT were known thrombophilia (P=0.015) and higher body temperature on admission (P=0.001). Intensity of thromboprophylaxis, previous anticoagulation, CRP, age, sex, COVID-19 clinical prognostic-scores (MEWS, 4C-mortality score) and Padua VTE risk-score were not significantly associated with the occurrence of DVT (P>0.05 for all analyses).

Summary/Conclusion: Systematic ultrasound assessment of prolonged hospitalized severe COVID-19 patients prior to hospital discharge is probably needed, especially of ICU survivors, to timely recognize and appropriately treat patients with asymptomatic DVT.

Malignancies and thrombosis



S305 GLIOBLASTOMA CELL POPULATIONS WITH DISTINCT ONCOGENIC PROGRAMS RELEASE PODOPLANIN AS PROCOAGULANT EXTRACELLULAR VESICLES

N. Tawil [1,*], R. Bassawon [2], B. Meehan [3], L. Montermini [3], A. Nehme [2], D. Choi [3], C. Spinelli [3], L. Adnani [3], S. Chennacrishnaiah [3], J. Rak [3]

[1]Experimental Medicine, McGill - RI-MUHC, [2]McGill, [3]McGill - RI-MUHC, Montreal, Canada

Background: Vascular anomalies, including thrombosis, are a hallmark of glioblastoma (GBM) and an aftermath of dysregulated cancer cell genome and epigenome. The upregulation of podoplanin (PDPN) by cancer cells has recently been linked to an increased risk of venous thrombo-embolism (VTE) in GBM patients. Thus, regulation of this platelet activating protein by transforming events and release from cancer cells is of considerable interest.
Aims: I. (a) Investigate the pattern of PDPN expression and characterize PDPN expressing populations. (b) Evaluate the contribution of oncogenic driver pathways to PDPN expression modulation in GBM models. (c) Explore the modes of PDPN expression modulation by implicated oncogenic drivers.

II. (a) Investigate the potential involvement of extracellular vesicles as route for systemic dissemination of GBM-associated PDPN. (b) Examine the role of GBM-associated and systemically disseminated PDPN in peripheral activation of platelets. (c) Assess the contribution of PDPN to intratumoral thrombosis and explore the possible cooperation with TF.
Methods: We used single cell and bulk transcriptome data mining, as well as cellular and xenograft models in mice to analyze the nature of cells expressing PDPN, their impact on activation of coagulation system, and platelets. We also took advantage of various analytical techniques including immunoblotting, immunofluorescence, electron microscopy, density gradient fractionation, Cytoflex, and ELISA.
Results: We report that PDPN is expressed by distinct (mesenchymal) GBM cell subpopulation and downregulated by oncogenic mutations of EGFR and IDH1 genes, via changes in chromatin modifications (EZH2) and DNA methylation, respectively. GBM cells exteriorize their PDPN and/or tissue factor (TF) as cargo of exosome-like extracellular vesicles (EVs) shed from cells in vitro and in vivo. Injection of glioma PDPN-EVs activates platelets, while TF-EVs weakly activate the clotting cascade. Similarly, increase of platelet activation (PF4) or coagulation markers (D-dimer) occurs in mice harboring the corresponding glioma xenografts expressing PDPN or TF, respectively. Co-expression of PDPN and TF by GBM cells cooperatively affects tumor microthrombosis.

Distinct glioblastoma cell subpopulations drive local and peripheral thrombosis through expression of podoplanin (PDPN) and release of PDPN-carrying extracellular vesicles.

Summary/Conclusion: In GBM distinct cellular subsets drive multiple facets of cancer-associated thrombosis and may represent targets for phenotype and cell type-based diagnosis and antithrombotic intervention. Accordingly, we suggest that the preponderance of PDPN expression as a risk factor in GBM and involvement of platelets in our GBM model may merit investigating antiplatelets for potential inclusion in VTE management strategies in GBM setting.

S306 THROMBOPHILIA AS RISK FACTOR FOR ASPARAGINASE RELATED VENOUS THROMBOEMBOLISM IN PEDIATRIC AND YOUNG ADULT PATIENTS AFFECTED BY ACUTE LYMPHOBLASTIC LEUKEMIA

A. Serrao [1,*], G. M. Assanto [1], C. Santoro [1], S. Bianchi [1], S. Olivieri [1], F. Barone [1], M. Canichella [1], A. M. Testi [1], A. Chistolini [1]

[1]*Sapienza, Roma, Rome, Italy*

Background: Venous thromboembolism (VTE) is one serious complication in patients with acute lymphoblastic leukemia (ALL) with an incidence of 1-14% in thromboembolic symptomatic patients and up to 37% in the asymptomatic. In these patients, VTE is a multifactorial event: leukemia, central venous catheter (CVC), chemotherapy, in particular, asparaginase (ASP), and steroids. ASP is an effective chemotherapeutic agent that catalyzes the hydrolysis of asparagine. Treatment with ASP increases the risk for VTE. Among the causes that can determine an increased thromboembolic risk, the presence of congenital or acquired thrombophilia can play a crucial role.
Aims: The aim of our study was to evaluate the role of thrombophilia on VTE events in pediatric patients (age < 18 years) and in adolescents and young adults (AYA) < 40 years old with ALL during ASP chemotherapy regimens.
Methods: We defined ASP-associated thrombosis when the event occurred within 1 month from the drug administration. The types of drugs used were: the native form derived from E. Coli (Medac® and Kidrolase®); the form derived from Erwinia Chrysanthemi (Erwinase®); and the pegylated E. coli ASP (PEG-ASP -Oncaspar®). Patients were treated according to the following chemotherapy protocols: GIMEMA LAL 1913; GIMEMA LAL 1308; GIMEMA LAL 2000; NILG-LAL 10/07; GIMEMA LAL 0904; GIMEMA LAL 0496; ESPHALL; AIEOP-EURO-LB02; AIEOP-BFM LAL2009; AIEOP-BFM LAL2000. All patients performed the inherited and acquired thrombophilia assays at disease diagnosis before chemotherapy start. In patients with clinical signs of thrombotic occlusion, the diagnosis of VTE was made with Doppler ultrasonography examination of vessels; chest computerized tomography (CT) for pulmonary embolism; magnetic resonance imaging (MRI) in case of thrombosis of the cerebral circulation.
Results: We studied 96 ALL patients and their characteristics are summarized in table 1. Thrombotic complications occurred in 15/96 (15.6%) patients, including 12 deep vein thromboses (DVT) of upper limbs, 1 thrombosis of the central vein of retina, 1 thrombosis of the superior sagittal sinus, 1 DVT extended to both lower and upper limbs associated with pulmonary embolism. Overall, 6/15 (40%) patients with the thrombotic complication presented thrombophilia (p = 0.265). Of the 15 thrombotic events, 7/15 (47%) were associated with the use of ASP. Three/seven (43%) patients presented B-ALL and 4/7 (57%) T-ALL (p = 0.027). Five/7 were treated with PEG-ASP (Oncaspar®) and 2/7 with the native E.coli ASP (p = 0.511); notably, 5 were thrombophilic (p=0.008). In the multivariate analysis, among the predictive factors for ASP-related thrombosis considered (sex, age, thrombophilia, and T-ALL), the only significant factor for thrombotic events development was thrombophilia (p = 0.0029, IC 0.025-0.823; HR 0.143).

TABLE I. Patients' characteristics.

	Number Of patients	Percentage Of Population	Median value
Sex			
Male	53	56,3%	
Female	43	44,8%	
Type of ALL			
B-ALL	79	67,5%	
T-ALL	38	32,5%	
Age (Years)			13 (range 1.7 -47.5)
Plts (10^3/mmc)			103 (range 19-630)
WBC (10^3/mmc)			9.4(range 0,140-400)
Screening for thrombophilia			
Normal	60	55,2%	
Mutated	36	37,5%	
Thrombosis			
None	81	84,4%	
At least 1 event	15	15,2%	
ASP related thrombosis			
No	89	92,7%	
Yes	7	7,3%	

ALL= acute lymphoblastic leukemia; Plts= platelets; WBC= white blood count; ASP= asparaginase

Summary/Conclusion: Although thrombophilia is a well-known risk factor for VTE in ALL, our study focused on its link with ASP-related VTE. We suggests that screening for thrombophilia should be performed in ALL patients before ASP administration, since thrombophilic ALL patients may benefit from VTE prophylaxis.

S307 THROLY SCORE SUCCESSFULLY CLASSIFIES HODGKIN LYMPHOMA PATIENTS AT RISK OF THROMBOEMBOLIC COMPLICATION

D. Antic [1,2,*], V. Otasevic [2], S. Borchmann [3], H. Müller [3], V. Vukovic [2], V. Djurasinovic [2], K. Tomic [2], B. Mihaljevic [2], A. Engert [3], G. Gerotziafas [4], J. Fareed [5]

[1]*Faculty of Medicine, University of Belgrade,* [2]*Lymphoma Center, Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia,* [3]*Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf and German Hodgkin Study Group (GHSG), University of Cologne, Cologne, Germany,* [4]*Cancer, Haemostasis and Angiogenesis Research Group, INSERM U938, Institut Universitaire de Cancérologie, Faculty of Medicine, Sorbonne Universities, Paris, France,* [5]*Pathology, Loyola University Medical Center, Maywood, IL, United States*

Background: Thromboembolism (TE) in lymphoma patients is gathering substantial attention due to its impact on morbidity and mortality of those patients. The association between lymphoma and increased risk for TE development, especially venous thromboembolism (VTE), has lately been well established through numerous publications. Thrombosis Lymphoma (ThroLy) score has been initially developed as a simple risk assessment model for the risk of TE development in lymphoma patients. It has been both internally and externally validated in several studies, which dominantly included patients with non-Hodgkin lymphoma (NHL).

Aims: Therefore, the aim of our study is to analyse and validate ThroLy score in an extensive cohort of Hodgkin lymphoma (HL) patients.
Methods: A total of 5509 newly diagnosed HL patients, from the German Hodgkin Study Group (GHSG) HD13-15 trials, were included in this study. Data has been obtained for all venous and arterial TE events in HL patients from time of diagnosis to 3 months after the last cycle of therapy. TE was diagnosed objectively based on radiographic studies (duplex venous ultrasound, contrast-enhanced thoracic computed tomography scan, magnetic resonance imaging (MRI) - for central nervous system (CNS) thrombosis, or angiograms (for arterial thrombosis), clinical examination and laboratory evaluation. Based on ThroLy score, patients were divided in three risk categories: low (score 0-1), intermediate (score 2-3) and high risk (score >3). Patients with intermediate and high-risk score were classified at risk. The validation was conducted through Chi-square test, ROC analysis and logistic regression.
Results: The mean patients' age was 35.9 years (range, 18-75 years); 55.7% were males. The majority of patients had limited or intermediate stage of disease: Ann Arbor stage I 10.6%, and stage II 57.5%. 190 (3.4%) patients developed thromboembolic events, 173 patients with VTE (3.14%), and 17 with arterial TE (0.31%), respectively. Chi-square test showed statistically significant association between TE and ThroLy score, both in three risk groups (chi-square = 18.236, p≤0.001) and two risk groups: low and at risk (chi-square = 18.029, p≤0.001). The sensitivity, specificity, negative and positive predictive value were 49%, 65%, 95%, and 97%, respectively. Binary logistic regression of ThroLy score showed statistically significant performance in prediction of TE events in HL patients, with satisfactory validity indicators (Ombinus Test chi-square = 11.668, p=0.001; AIC=44.956, BIC = 97.869). Diagnostic accuracy of ThroLy score was calculated via ROC curve (area under curve (AUC)=0.57).
Summary/Conclusion: ThroLy score demonstrated its capability of risk prediction for TE events in HL patients. The limited statistical performance of the ThroLy score requires further research towards possible score enhancement.

S308 FREQUENCY AND RISK FACTORS FOR THROMBOSIS IN ACUTE MYELOID LEUKEMIA TREATED WITH INTENSIVE CHEMOTHERAPY: A TWO CENTERS OBSERVATIONAL STUDY

F. Martella [1], M. Cerrano [2,*], D. Di Cuonzo [3], C. Secreto [1,2], M. Olivi [1,2], S. D'Ardia [2], C. Frairia [2], V. Giai [2], G. Lanzarone [1], V. Apolito [1,2], I. Urbino [1,2], R. Freilone [2], L. Giaccone [4], A. Busca [4], C. Dellacasa [4], E. Audisio [2], D. Ferrero [1], E. Beggiato [1]

[1]Department of Molecular Biotechnology and Health Sciences, Division of Hematology, Università degli studi di Torino, [2]Department of Oncology, Division of Hematology, [3]Unit of Clinical Epidemiology, CPO, [4]Department of Oncology, SSD Trapianto Allogenico, "Città della Salute e della Scienza" Hospital of Turin, Torino, Italy

Background: Thrombosis is one of the most frequent complication in cancer. Although recent studies suggest that patients with blood cancers may be at a similar or even higher thrombotic risk than those with solid tumors, the frequency of thrombosis in acute myeloid leukemia (AML) has been evaluated in a few reports only and no validated predictive model is currently available.
Aims: In this study we aimed to evaluate the frequency of thrombosis in AML patients treated with intensive chemotherapy and to assess the ability of genetic and clinical factors to predict the risk of thrombosis, including the Khorana risk score (KRS) or disseminated intravascular coagulation (DIC) score.
Methods: We performed a retrospective observational study including 222 newly diagnosed adult AML patients treated with intensive chemotherapy between January 2013 and February 2020, stratified by European Leukemia Net (ELN) 2010 genetic/cytogenetic risk assessment. The diagnosis of thrombosis was confirmed by imaging modalities including venous ultrasonography, computer tomography or magnetic resonance imaging and clinical, enzymatic and electrocardiographic criteria for myocardial infarction.
Results: 222 patients (52% males) were included, with a median age of 59.5 years (range 20-78), 20.5% in the ELN2010 adverse risk category. With a median follow-up of 43.5 months, we observed 50 thrombotic events and 90% were venous (VTE): twenty-eight patients (62.2% of VTE) had catheter-related thrombosis (CRT), 93% of which were peripherally inserted central catheter (PICC)-related; in 6 and 5 case VTE occurred in lower and upper extremity, respectively, while 3 patients experienced pulmonary embolism. Among arterial thrombosis, 2 myocardial infarctions and 3 cerebral vascular accidents occurred. The prevalence of thrombosis was 22.5% and 6-months, 1-year and 2-year cumulative incidence was 10%, 22% and 25%, respectively. The median time to thrombosis was 84 days and 52% of the events occurred within 100 days from AML diagnosis, during induction/consolidation chemotherapy or just before starting treatment. History of a thrombotic event (p=0.043), especially VTE (p=0.0053), and baseline platelet count higher than 100x10^9/L (p=0.036) significantly increased the risk of thrombosis while AML genetic profile did not affect its occurrence with statistical significance. A sub-analysis considering only early thromboses (i.e. occurring within day 100) confirmed these results. Conversely, if only no-CRT VTE were considered, ELN Intermediate-1 risk group was significantly associated with thromboses (p=0.039), especially FLT3-ITD/NPM1 mutated patients. KRS and DIC score failed to stratify patients according to their thrombotic risk, but DIC score at diagnosis was independently associated with reduced survival (p=0.004) by multivariate analysis. No impact of thrombosis on survival was observed.
Summary/Conclusion: Thromboses are a frequent complication in AML, especially during chemotherapy, and most of them are VTE. However, no impact on survival was observed. Previous VTE and baseline platelet count could predict thrombotic risk, while AML genetic profile did not significantly affect thrombosis occurrence. We confirmed that KRS is not a robust tool in this setting, and we could not validate the association of DIC score with thromboses, warranting further studies on the subject to better predict thrombosis occurrence, hopefully allowing to design therapeutic measures to prevent it.

S309 OUTCOME OF ELDERLY PATIENTS WITH VENOUS THROMBOEMBOLISM TREATED WITH DIRECT ORAL ANTICOAGULANTS - A RETROSPECTIVE COHORT STUDY

I. Ayalon Dangur [1,*], Y. Vega [2], M. R. Israel [1], A. Grossman [2,3], G. Spectre [2,4], T. Shochat [5], L. Leibovici [1,2], A. Gafter-Gvili [2,4,6]

[1]Internal medicine E, Beilinson, Petah Tikva, [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, [3]Internal medicine B, [4]Institute of Hematology, Davidoff Cancer Center, [5]Bio-Statistical Unit, [6]Internal medicine A, Beilinson, Petah Tikva, Israel

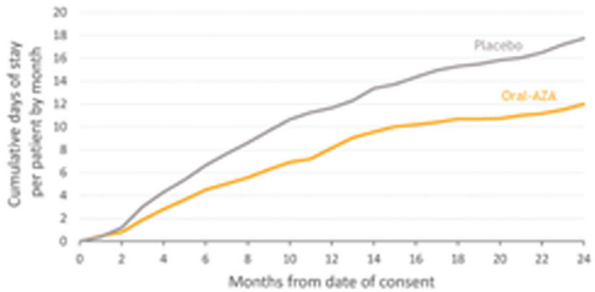
Background: Large randomized controlled trials that compared direct oral anticoagulants (DOACs) to vitamin K antagonists (VKA), for the treatment of venous thromboembolism (VTE), demonstrated both efficacy and safety of DOACs.
Aims: The aim of the current study was to compare DOACs to low molecular weight heparin (LMWH)/VKA in terms of efficacy and safety, for the treatment of VTE in the elderly, in a real-life setting
Methods: Retrospective cohort study performed in Rabin Medical Center encompassing a 7 –year period. We included all hospitalized patients > 65 years old, with a diagnosis of lower extremity deep vein thrombosis (DVT) and/or pulmonary emboli (PE) discharged with DOACs or LMWH/VKA. The primary outcome was a composite of all-cause mortality, major bleeding events, recurrent VTEs and hospitalizations throughout the follow up period of one year. Secondary outcomes included recurrent VTEs, major bleeding events and all-cause mortality in one year. Overall survival was assessed by the Kaplan Meier model, with the log-rank test. The Cox Proportional Hazards model was used to calculate hazard ratios (HR). Medication was included in the Cox model as a time dependent covariate. Propensity score matching was used to create a matched cohort
Results: Overall, 603 patients were identified and included in the final analysis. A total of 476 patients were treated with VKA/LMWH and 127 patients were treated with DOACs. The mean age was 79.9 ± 8.5 years) VKA/LMWH group(and 78.6 ± 8.1 years)DOAC group(, P=0.24. The primary unadjusted composite outcome of all-cause mortality, major bleeding events, recurrent VTEs and hospitalizations occurred in 355/476 patients (74.6%) in the VKA/LMWH group and in 72/ 127 (56.7%) patients in the DOACs group, hazard ratio (HR) of 0.59, 95% confidence interval (CI) 0.46 to 0.76, in favor of the DOAC group. HR for recurrent VTEs and major bleedings events was 0.58 (95% CI 0.26 to 1.29) and 1.15 (95% CI 0.50 to 2.65), respectively for the DOAC group. There was a significant reduction in mortality in the DOAC group - HR 0.30, 95% CI 0.20 to 0.44. In a multivariable analysis, treatment with DOACs, as well as age, elevated creatinine levels and malignancy were all significantly associated with the composite outcome of all-cause mortality, major bleeding, recurrent VTE and hospitalizations, HR of 0.64 (CI of 0.49-0.83) for the treatment with DOAC. In a matched cohort analysis, the results were the same as the original analysis, with a HR of 0.66 for the DOAC group for the composite outcome, 95% CI 0.51 to 0.87
Summary/Conclusion: In the elderly population, treatment of VTE with DOACs was associated with a lower rate of the composite outcome of all-cause mortality, major bleeding, recurrent VTE and hospitalizations in a follow up of one year. DOACs are safe and effective for elderly patients with VTE

Patient's voice and health outcomes in hematology

S310 INTEGRATION OF A MACHINE LEARNING-BASED MODEL INTO ROUTINE CYTOMORPHOLOGICAL DIAGNOSTICS: FIRST EXPERIENCES FROM THE BELUGA TRIAL

C. Pohlkamp [1,*], N. Nadarajah [1], A. Wahida [2], I. Heo [3], W. Wetton [3], R. Drescher [4], S. Hänselmann [4], T. Lörch [4], C. Haferlach [1], W. Kern [1], T. Haferlach [1]

[1]MLL Munich Leukemia Laboratory, [2]Torsten Haferlach Leukämiediagnostik-Stiftung, Munich, Germany, [3]Amazon Web Services, Envision Engineering, Herndon, United States, [4]MetaSystems, Altlussheim, Germany



Background: Cytomorphology is essential to quickly assess hematological neoplasms. Experienced personnel and short TAT of <24 hours are mandatory. Machine learning (ML) has proven its power in image classification. Following our pilot study (ASH 2020, Blood 136, # 195) we report on our first experiences with an ML-based blood cell differentiation tool in daily routine.
Aims: To evaluate feasibility in a prospective blinded trial in parallel to daily routine workflow, we registered the BELUGA study (ClinicalTrials.gov Identifier: NCT04466059) which includes a head-to-head-comparison between human investigators and the ML-based classifier regarding accuracy over all malignant/non-malignant cell types in peripheral blood.
Methods: We established an automated routine workflow including the capture of 500 digital cell images per blood smear in 40x oil magnification after focusing on regions of interest (Metafer Scanning System, MetaSystems, Altlussheim; Zeiss Axio Imager.Z2 microscope). Cells are classified by the ML-based deep neural network (DNN). Resulting data are compared to the independent microscopic cell differentiation done by hem specialists. With regard to future use in routine, misclassifications can be corrected by humans. Corrected images can be manually flagged to join a dataset for continuous retraining of the DNN.
Results: Since Jan 1, 2021 the BELUGA trial included 1,586 blood samples. The most common malignant diagnoses were: CLL, MPN, mature B-cell neoplasm, MDS, MBL, CML, AML and CMML. In all cases human investigators reach out to count 100-200 cells according to WHO guidelines. The addressed cell classes were PMN, lymphocytes, monocytes, eosinophils, basophils, bands, metamyelocytes, myelocytes, promyelocytes, myeloblasts, atypical/bilobulated promyelocytes in APL/APLv, hairy cells, atypical lymphocytes (potentially neoplastic), plasma cells, normoblasts, smudge cells, plus one garbage class for damaged cells. 155,159 cells were differentiated by humans (12 individuals, median experience in the field: 8 years), 769,347 cells (median 500 per sample) by the DNN model as described (ASH 2020, Blood 136, # 195). While human analysis took 5-10 minutes per sample, the DNN processes ~500 cells/images within 15 seconds after automated scanning time of 7min. Probability of prediction was ≥0.95 for 46% of images, ≥0.90 was achieved for 55%. During the pilot study, we noticed misclassifications in cells representing neighbouring stages of maturation or in reactive vs. neoplastic lymphocytes. For refining the DNN, we reduced the number of images used for training, keeping only 10% (8,425 cells) of the original dataset. Our new version (V.2) tested now in the BELUGA study achieves an overall accuracy of 96.6% (vs. 89.6% in V.1) on this separate prospective test set. First evidence of clinical relevance could be seen in two cases with low count APL. The DNN (V.1) was able to detect atypical promyelocytes at a probability of ≥0.98.
Summary/Conclusion: We successfully integrated a fully automated process (cell scanning and classification by DNN) parallel to our diagnostic routine workflow without critical delay in TAT. The DNN outperformed human experts (investigation time, number of cells investigated) in a real-life setting and seems to also provide a higher sensitivity and specificity for critical cell types, thus being a helpful support for cytomorphologists. Such infrastructure being cloud-based and allowing access for uploading/classifying digital cell images could serve experts worldwide 24/7.

S311 ESTIMATED HOSPITALIZATION-RELATED COSTS WITH ORAL AZACITIDINE (ORAL-AZA) VS PLACEBO (PBO) FOR REMISSION MAINTENANCE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) IN SPAIN AND THE UNITED KINGDOM (UK)

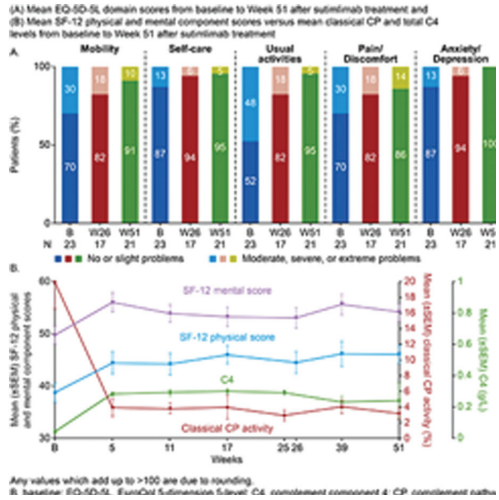
C. Pocock [1], P. Montesinos [2], T. Braun [3], S. Kambhampati [4,5], A. Oriol [6], I. La Torre [7], B. Skikne [8,9], C. Beach [8], J. Zhong [8], C. Chen [8], S. Ranjan [10], R. Potluri [11], E. Natalie Oliva [12,*]

[1]Kent & Canterbury Hospital, Canterbury, United Kingdom, [2]Hospital Universitari i Politecnic La Fe, Valencia, Spain, [3]Hopital Avicenne, AP-HP, Paris XIII University, Bobigny, France, [4]Sarah Cannon at Research Medical Center, [5]VA Medical Center, Kansas City, United States, [6]Institut Català d'Oncologia and Josep Carreras Research Institute, Hospital Germans Trias i Pujol, Badalona, Spain, [7]Celgene, a Bristol-Myers Squibb Company, Boudry, Switzerland, [8]Bristol Myers Squibb, Princeton, [9]Kansas University Medical Center, Kansas City, United States, [10]SmartAnalyst India Pvt. Ltd, Gurgaon, India, [11]SmartAnalyst, Inc., New York, United States, [12]Grande Ospedale Metropolitano Bianchi Melacrino Morelli, Reggio Calabria, Italy

Background: While ~50% of patients (pts) with AML aged >60 years attain complete remission (CR) with intensive chemotherapy (IC), up to 90% who do will eventually relapse. In the continuum of AML care, the highest costs are related to relapsed/refractory disease, and hospitalization is the largest component (~70%) of direct healthcare costs. In the randomized, phase 3 QUAZAR AML-001 trial, maintenance treatment (Tx) with Oral-AZA significantly prolonged overall and relapse-free survival vs. PBO for pts with AML in first remission after IC.
Aims: Determine rates of hospitalization and days (d) in hospital with Oral-AZA and PBO for all pts in QUAZAR AML-001, and estimate associated hospitalization costs in Spain from the Spanish National Health System (NHS) perspective, and in the UK from the UK NHS perspective.
Methods: Eligible pts were age ≥55 yrs, had intermediate- or poor-risk cytogenetics and ECOG PS ≤3, and were not candidates for transplant. Within 4 months (mo) of achieving CR or CR with incomplete blood count recovery (CRi) after induction ± consolidation, pts were randomized 1:1 to Oral-AZA 300-mg or PBO QD for 14d/28d cycle. Pts who received ≥1 study drug dose were followed for hospitalization from informed consent through 28d after last dose. The mean number of hospital days/mo (30d) was the total number of days in hospital divided by the number of ongoing pts each mo. Hospitalization rates and durations were adjusted for total drug exposure. Confidence intervals (CI) for relative risk (RR) estimates and related *P* values are based on asymptotic methods.
Unit cost of hospitalization in Spain was derived from literature (Arenaza et al. *Clinicoecon Outcomes Res*, 2019), and in the UK from NHS reference costs (https://improvement.nhs.uk/resources/reference-costs/#rc1718), as the average total AML-related hospitalization costs per day, adjusted for inflation to 2019 prices, using the medical component of the consumer price index for each country.
Results: 469 pts received Oral-AZA (n=236) or PBO (n=233); median time on Tx was 11.6 vs 5.7 mo, respectively, and total exposures were 363.8 pt-years (PY) and 234.9 PY. Similar proportions of patients were hospitalized during the study: Oral-AZA 46% (n=108), PBO 51% (n=118). Total number of hospitalization events was numerically higher in the Oral-AZA arm (173 vs 151 in the PBO arm), but the exposure-adjusted hospitalization rate was significantly lower with Oral-AZA: 0.48/PY vs. 0.64/PY (RR 0.740 [95%CI 0.595, 0.920]; *P*=0.0068). Total days hospitalized were 2,872 in the Oral-AZA arm and 3,139 in the PBO arm; the exposure-adjusted rate was also significantly lower with Oral-AZA (7.89 vs. 13.36 d/PY, respectively; RR 0.591 [95%CI 0.562, 0.621]; *P*<0.0001).
Mean hospitalization cost in Spain was €1,398/d. Using exposure-adjusted days-in-hospital, estimated mean costs of hospitalization in Spain were €11,030/PY with Oral-AZA and €18,676/PY with PBO. Cumulative cost savings with Oral-AZA vs. PBO ranged from €557 at mo 2 to €8,025 by mo 24 (**Figure**).
In the UK, mean hospitalization cost was £696/d, resulting in estimated exposure-adjusted mean costs of £5,490/PY with Oral-AZA and £9,296/PY with PBO. Cumulative cost savings with Oral-AZA in the UK ranged from £277 at mo 2 to £3,995 by mo 24 (**Figure**).

Month	2	4	6	8	10	12	14	16	18	20	22	24
Estimated cumulative hospitalization cost savings per patient with Oral-AZA vs placebo												
Cumulative cost savings in Spain*	€557	€2,101	€3,976	€4,250	€5,233	€4,900	€5,322	€5,795	€6,429	€7,104	€7,455	€8,025
Cumulative cost savings in the UK†	£277	£1,046	£1,481	£2,115	£2,605	£2,439	£2,649	£2,885	£3,200	£3,536	£3,711	£3,995

*Based on average cost per day in hospital in Spain (€1,398) (Arenaza et al. 2019).
†Based on average cost per day in hospital in the United Kingdom (£696) (from NHS Reference costs).



Summary/Conclusion: Compared with PBO, Oral-AZA was associated with significantly reduced exposure-adjusted rates of hospitalization and days in hospital, and considerable estimated cost savings in Spain and the UK. Delaying relapse with Oral-AZA may lead to substantial economic benefits due to lower hospitalization costs.

S312 SUSTAINED IMPROVEMENTS IN PATIENT-REPORTED OUTCOMES WITH SUTIMLIMAB IN PATIENTS WITH COLD AGGLUTININ DISEASE: 1-YEAR FOLLOW-UP INTERIM RESULTS FROM THE CARDINAL STUDY

A. Röth [1,*], C. M. Broome [2], W. Barcellini [3], T. H. A. Tvedt [4], Y. Miyakawa [5], D. J. Kuter [6], Q. A. Hill [7], J. Su [8], F. Joly [9], X. Jiang [10], P. Patel [10], F. Shafer [10], I. C. Weitz [11]

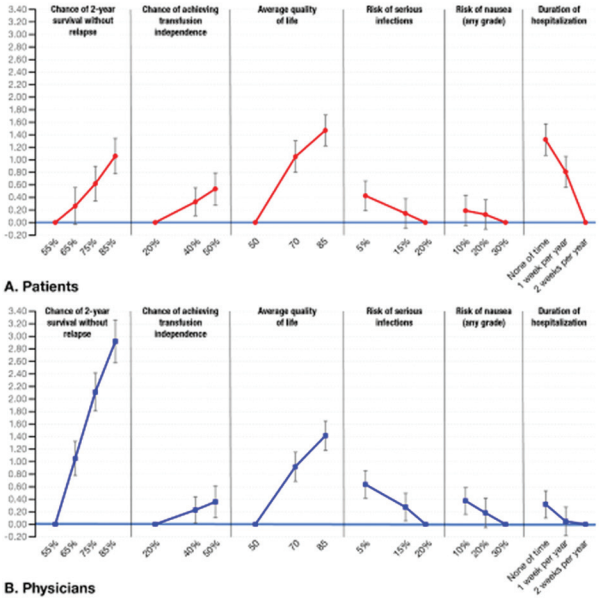
Background: Cold agglutinin disease (CAD) is a rare autoimmune hemolytic anemia characterized by classical complement pathway (CP)–mediated hemolysis. Apart from anemia, patients with CAD experience fatigue and poor quality of life (QOL). Before the CARDINAL study, QOL and patient-reported outcomes (PRO) such as Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue were not examined in CAD patients. Sutimlimab (formerly BIVV009), a humanized monoclonal antibody that selectively inhibits C1s of the C1 complex, prevents classical CP activation, while leaving alternative and lectin pathways intact. In CARDINAL Part A, sutimlimab treatment resulted in rapid, clinically meaningful improvement in all PRO measures (Röth et al. ASH 2020), in addition to halting hemolysis, improving hemoglobin (Hb) levels, and normalizing bilirubin levels, in patients with CAD (Röth et al. ASH 2019).
Aims: To report sutimlimab effect on PROs at 1-year, from the ongoing CARDINAL Part B extension (data cut: January 16, 2020).
Methods: CARDINAL is a Phase 3, open-label, single-arm, multicenter, two-part study. After informed consent and study enrollment, sutimlimab was administered on Days 0 and 7, followed by biweekly infusions, in both Parts A and B. Interim Part B efficacy endpoints included evaluation of Hb levels and other hemolytic markers over 1-year and QOL assessed by the FACIT-Fatigue Scale, to Week 51 (last scheduled visit within 1-year of treatment), in patients with CAD. Mean change from baseline for exploratory QOL endpoints such as EuroQol 5-dimension 5-level (EQ-5D-5L) scores, 12-Item Short Form Health Survey (SF-12), Patient Global Impression of Change (PGIC), and Patient Global Impression of (fatigue) Severity (PGIS) were also assessed at Week 51. Outcomes were reported using descriptive statistics.
Results: Of 24 enrolled patients, 22 patients completed Part A, and all entered Part B. At baseline, mean (standard deviation [SD]) FACIT-Fatigue score was 32.5 (10.6) points and mean (SD) EQ-5D-5L index and visual analog scale (VAS) scores were 0.70 (0.23) and 62.0 (14.7), respectively. Mean (SD) SF-12 physical and mental component scores were 38.7 (8.7) and 49.8 (8.2). One-third of patients (33%) had severe PGIS fatigue status at baseline. Upon sutimlimab treatment, mean (SD) FACIT-Fatigue scores improved within 1-week (n=22/24), with scores >40 from Week 3 (Part A) to Week 51. Overall, from baseline to Week 51, mean (SD) FACIT-Fatigue score (n=18/22) was improved by 11.4 (11.9) points. The mean (SD) change from baseline in EQ-5D-5L index and VAS scores (n=20/23) at Week 51 was 0.08 (0.19) and 14.50 (19.05). At Week 51, among 21 evaluable patients, none reported anxiety/depression; considerable improvements were seen in mobility, self-care, and usual activities domains of the EQ-5D-5L (**Figure A**). The mean (SD) increase in SF-12 physical and mental component scores (n=19/22) from baseline to Week 51 were 6.6 (9.7) and 3.6 (9.4). SF-12 score increases appear to coincide with reduction in classical CP activity and normalized total C4 levels (**Figure B**). At Week 51, among 21 evaluable patients, a majority (90.5%) indicated "improved" disease state on the PGIC scale; no patients reported severe fatigue on completing PGIS, compared with one-third at baseline (n=2/6).

Summary/Conclusion: One-year interim follow-up CARDINAL study results demonstrate that continuous classical CP inhibition with sutimlimab resulted in rapid, sustained improvements in all PRO measures evaluated, further demonstrating the meaningful impact of sutimlimab on patient QOL.

S313 PATIENT AND PHYSICIAN PREFERENCES FOR POST–HEMATOPOIETIC STEM CELL TRANSPLANTATION MAINTENANCE TREATMENT OF ACUTE MYELOID LEUKEMIA



M. Zhou [1,*], H. Yang [1], Y. Song [1], D. A. Marshall [2], J. D. Griffin [3], L. Saini [4], M. V. Shah [5]

[1]Analysis Group, Boston, MA, United States, [2]Cumming School of Medicine, University of Calgary, Calgary, Alberta, Canada, [3]Dana-Farber Cancer Institute, Boston, MA, United States, [4]London Health Sciences Centre, London, Ontario, Canada, [5]Astellas Pharma, Inc., Northbrook, IL, United States

Background: Patients with acute myeloid leukemia (AML) who have received a hematopoietic stem cell transplant (HSCT) may consider post-HSCT maintenance therapy to prolong remission. Since there are no universally accepted standard maintenance therapies, patients and physicians need to weigh the risks and benefits of each potential regimen when making treatment decisions. A better understanding of the differences in how patients and physicians each weigh the value of various treatment attributes, and whether either group's preferences affect the other's, would be of value in understanding why various treatments are selected.
Aims: To quantify patients' and physicians' preferences for post-HSCT AML maintenance treatment.
Methods: A targeted literature review and one-on-one patient (n=6) and physician (n=4) phone interviews informed the post-HSCT AML maintenance treatment attributes used in this discrete choice experiment (DCE). Attribute levels were selected to reflect the range of maintenance treatments available for post-HSCT patients. Patients with AML who had received HSCT and physicians who treat patients with AML in the US, UK, Canada, and Australia were recruited from physician panels to complete a web-based DCE. The DCE participants were presented choice cards each showing a pair of hypothetical treatment profiles with six attributes (chance of 2-year relapse-free survival [RFS], average quality of life [QoL], risk of serious infections, risk of nausea, chance of achieving transfusion independence, and duration of hospitalization per year) of varying levels and asked to choose a preferred treatment per card. This preliminary analysis used conditional logit regression models to estimate preference weights and analyze the impact of treatment attributes on participants' post-HSCT maintenance therapy treatment choices.
Results: A total of 78 patients with AML post-HSCT (US, n=46; UK, n=30; Canada, n=2) and 145 physicians who treat this population (US, n=48; UK, n=52; Canada, n=29; Australia, n=16) completed the DCE. For patients, average QoL was the most important treatment attribute for post-HSCT maintenance therapy based on preference weights, followed by duration of hospitalization and chance of 2-year RFS (**Figure A**). Post-HSCT patients were willing to accept a less effective treatment if it reduced hospital stay or improved QoL: the benefit of a 2-week reduction in hospitalization per year or an improvement of QoL by 35 on a 0-100 scale each compensated

for a 30% reduction in 2-year RFS. For physicians, chance of 2-year RFS was the most important treatment attribute, followed by average QoL and risk of serious infections (**Figure B**). Physicians valued duration of hospitalization and chance of achieving transfusion independence less when selecting treatments. Responses from physicians suggested that a 2-week reduction in hospitalization per year could compensate for having to bear an additional 5% risk of serious infection or 10% risk of nausea.

Figure. Preference Weights From DCE in the Post-HSCT Maintenance Therapy Setting

Abbreviations: DCE, discrete choice experiment; HSCT, hematopoietic stem cell transplantation.

Summary/Conclusion: Differences in treatment attribute importance for post-HSCT maintenance therapy were observed between patients and physicians. The DCE results highlight the value patients place on treatments that improve their QoL and reduce the duration of hospitalization. Physicians also valued patients' QoL when making treatment decisions, so informing physicians of patients' preferences may influence their choices regarding treatments that better meet patients' needs and improve patients' treatment satisfaction.

S314 THE BURDEN OF SICKLE CELL DISEASE (SCD) ON PATIENTS IN GHANA AND NIGERIA COMPARED WITH OTHER LOW-/MIDDLE-INCOME AND HIGH-INCOME COUNTRIES: RESULTS FROM THE SICKLE CELL WORLD ASSESSMENT SURVEY (SWAY)

I. Osunkwo [1,*], J. James [2], B. Andemariam [3], F. El Rassi [4], B. Francis-Gibson [5], C. Minniti [6], C. Trimnell [7], M. R. Abboud [8], J. -B. Arlet [9], R. Background: SCD is a group of inherited blood disorders associated with a range of clinical complications mainly mediated by vaso-occlusion and hemolytic anemia. Vaso-occlusive crises (VOCs) are the hallmark of SCD, and the most common cause of hospitalization. SCD is a global public health problem, with African countries having the highest disease prevalence.
Aims: To use SWAY data to compare the negative impact of SCD (examining symptoms, complications and quality of life) on patients (pts) in Ghana/Nigeria vs pts in other low-/middle income (LMIC) and high-income countries (HIC). SCD impact stratified by primary care provider (specialist vs non-specialist HCP) was also assessed.
Methods: SWAY was a multicountry survey (Apr–Oct 2019) developed by international SCD experts, pt advocacy groups and Novartis. Pts with SCD ≥6 years old completed the survey (completion by proxy [parent/guardian/caregiver] was required for pts aged 6–11 years, optional for pts ≥12 years). The World Bank definition of an HI economy (gross national income/capita ≥US$12,536) was used to stratify countries into LMIC and HIC. VOCs (defined as 'severe pain crises'), symptoms (experienced in the month preceding survey completion [excluding VOCs]), complications (ever experienced) and genotype were all self-reported. Responses to questions on the impact of SCD were classified on a 1–7 Likert scale (1=not severe/strongly disagree, 7=worst imaginable/strongly agree; with 5–7 indicating high impact/agreement). Pt participants (N=2145) were grouped into Ghana/Nigeria (n=519), other LMIC (Brazil, India, Lebanon [n=422]) and HIC (Bahrain, Canada, France, Germany, Italy, Netherlands, Oman, Panama, Saudi Arabia, USA, UK [n=1204]).
Results: Pts in Ghana/Nigeria were younger than those in other LMIC/HIC, and the mean number of VOCs experienced in the year before survey completion was lower in Ghana/Nigeria (4.5) and other LMIC (4.2) vs HIC (6.0) (Table). The top 3 most commonly reported symptoms in the month preceding survey were headache (Ghana/Nigeria 58%; LMIC 39%; HIC 44%), fatigue (Ghana/Nigeria 34%; LMIC 69%; HIC 77%) and bone aches (Ghana/Nigeria 32%; LMIC 56%; HIC 58%). Of the top 10 most frequently reported complications, all (except blood clots and fever) were reported by a lower proportion of pts in Ghana/Nigeria vs pts in other LMIC/HIC (Table). In Ghana/Nigeria, pts treated by a non-specialist HCP generally reported greater symptom prevalence than those treated by a specialist HCP. In contrast, the proportion of pts in other LMIC reporting symptoms was higher in the specialist HCP-treated group for most symptoms assessed. Pts in Ghana/Nigeria reported a lower or similar use of analgesics compared with other LMIC/HIC, with 26% ever prescribed opioids (other LMIC 28%; HIC 73%) and 30% ever receiving OTC analgesics (LMIC 63%; HIC 64%). In Ghana/Nigeria, 52% of pts reported that SCD had a high negative impact on their emotional wellbeing vs 56% of pts in other LMIC and 64% in HIC.

Table. Baseline characteristics, VOC burden and SCD-related complications grouped by Ghana/Nigeria, other LMIC and HIC

	Ghana/Nigeria			Other LMIC			HIC		
	Overall (n=519)	Specialist HCP (n=217)	Non-specialist HCP (n=302)	Overall (n=422)	Specialist HCP (n=230)	Non-specialist HCP (n=192)	Overall (n=1204)	Specialist HCP (n=849)	Non-specialist HCP (n=355)

*In the 12 months prior to survey completion; †Complications listed are the top 10 ever experienced across the entire patient population in SWAY.
HCP, healthcare professional; IQR, interquartile range; SD, standard deviation.

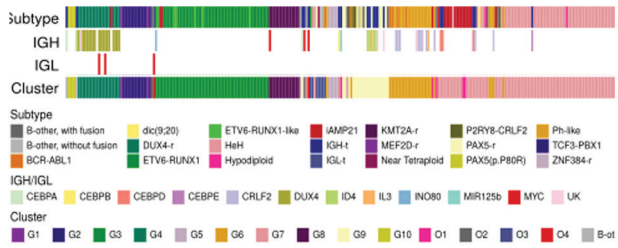
Summary/Conclusion: The reported overall burden of SCD appeared to be lower on pts in Ghana/Nigeria than for those in other LMIC/HIC. A possible explanation for this is the younger age of pts from Ghana/Nigeria, where a high infant mortality rate means many pts do not live long enough to develop chronic complications. Other explanations may include limited availability of resources to detect symptoms/complications, warmer climate, low usage of analgesics and poor education for both pts (and, potentially, non-specialist HCPs) in Ghana/Nigeria vs other countries participating in SWAY.

Acute lymphoblastic leukemia - Biology & Translational Research

EP316 BRANCHED CHAIN AMINO ACID TRANSAMINASE 1 IS OVER-EXPRESSED IN NOTCH1 ACTIVATED T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA CELLS AND MODULATES RESPONSE TO DNA DAMAGING AGENTS.

L. Di Martino [1,*], V. Tosello [2], S. Dalla Santa [1], P. Van Vlierberghe [3], E. Piovan [1,2]

[1]Department of Surgery, Oncology, Gastroenterology Sciences of Padua University, University of Padua, [2]Immunology and Molecular Oncology Unit, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy, [3]Department of Biomolecular Medicine, Ghent University, Ghent, Belgium



Background: T-cell acute lymphoblastic leukemia (T-ALL) is a biologically and clinically heterogeneous disease mostly associated with NOTCH1 mutations that characterize over 60% of cases. Therapy-resistant or refractory T-ALL remains a major clinical challenge. Recently, the metabolism of Branched Chain Amino Acids (BCAAs) has been associated with tumor growth and survival. In-fact, aberrant expression of BCAA Transaminase 1 (BCAT1), a cytosolic aminotransferase, involved in the first step of BCAAs metabolism, has been demonstrated in different tumor models, including leukemia. However, its biological role in T-ALL remains to be elucidated.
Aims: The purpose of this study was to evaluate the role of BCAT1 in T-ALL leukemogenesis, with particular emphasis on a putative link between BCAT1 and NOTCH1 in promoting T-ALL initiation and progression.
Methods: We evaluated BCAT1 expression using RNAseq data from 264 T-ALL samples (TARGET cohort enrolled on Children's Oncology Group ALL0434 protocol). BCAT1 transcript (qRT-PCR) and protein levels (western blot) were determined in T-ALL cell lines (n=13) and patient derived xenografts (n=12). Five T-ALL samples were treated with a g secretase inhibitor (DBZ) to dampen NOTCH signaling. BCAT1 promoter occupancy by NOTCH1 was determined in two T-ALL cell lines using Chromatin Immunoprecipitation (ChIP) coupled with qPCR. Tandem affinity purification (TAP) and mass spectrometry (MS) analysis were used to identify BCAT1 interacting proteins from CUTLL1 T-ALL cells. Further, BCAT1 knock-down experiments were performed to address its role on T-ALL cell growth, proliferation and drug sensitivity.
Results: We found variable BCAT1 expression levels amongst the different T-ALL molecular subgroups, with higher expression levels in TLX1 ($p<0.001$), HOXA-TLX3 ($p<0.05$) and NKX2-1 ($p<0.01$) subtypes. Considering recurrent genetic alterations, we found BCAT1 expression to be significantly higher ($p<0.01$) in NOTCH1 mutated cases compared to un-mutated samples. Further, BCAT1 was more highly expressed in the phenotypically mature cortical T-ALL subgroup. Analysis of T-ALL cell lines and PDX samples also evidenced heterogeneous BCAT1 expression levels, with a trend toward higher expression in these cells compared to their normal cellular counterparts (thymocytes). In agreement with our previous analysis, NOTCH1 mutated PDX samples showed higher BCAT1 expression compared to un-mutated cases. Inhibition of NOTCH1 signaling with DBZ decreased BCAT1 expression in numerous T-ALL models. In addition, ChIP analysis demonstrated binding of NOTCH1 on BCAT1 promoter in T-ALL cells, suggesting that NOTCH1 may directly regulate its expression. Functionally, we found BCAT1 knock-down T-ALL cells to have a compromised capacity to form tumors in vivo. Further, TAP followed by MS analysis of BCAT1 interacting proteins disclosed that BCAT1 may be implicated in non-metabolic processes such as DNA replication and repair. Indeed, we found BCAT1 KD cells to be particularly sensitive to topoisomerase inhibitors such as etoposide.
Summary/Conclusion: BCAT1 is highly expressed in a subgroup of T-ALL cases, particularly in NOTCH1 mutated T-ALL. NOTCH1 may directly regulate BCAT1 expression. Genetic depletion of BCAT1 slows tumor growth in vivo and renders cells particularly sensitive to topoisomerase inhibitors. Our results identify BCAT1 as a novel therapeutic target and suggest that a combination of BCAT1 inhibitor and topoisomerase inhibitor could be particularly useful in BCAT1 overexpressing T-ALL cases.

EP317 TRANSCRIPTOMIC CHARACTERISATION OF IGH-TRANSLOCATED B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKAEMIA: THE IMPACT OF IGH PARTNER GENES

K. Fung [1,*], M. Bashton [2], A. Enshaei [1], J. Murray [1], S. Ryan [1], E. Barretta [1], C. Schwab [1], M. Singh [1], H. Blair [1], E. Law [1], A. Carroll [3], N. Heerema [4], E. Raetz [5], M. Loh [6,7], K. Rabin [8], C. Harrison [9], A. Moorman [1], O. Heidenreich [1,10], L. Russell [1]

[1]Wolfson Childhood Cancer Centre, Translational and Clinical Research Institute, Newcastle University, [2]The Hub for Biotechnology in the Built Environment, Faculty of Health and Life Sciences,, Northumbria University, Newcastle upon Tyne, United Kingdom, [3]Department of Genetics, University of Alabama at Birmingham, Birmingham, AL, [4]Department of Pathology, The Ohio State University, Columbus, OH, [5]Division of Pediatric Hematology-Oncology, New York University, New York, NY, [6]Department of Pediatrics, UCSF Benioff Children's Hospital, [7]UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, [8]Baylor College of Medicine, Houston, TX, [9]Wolfson Childhood Cancer Centre, Translational and Clinical Research Institute, Newcastle University, Newcastle upon Tyne, United States, [10]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands

Background: Acquired genetic changes are essential diagnostic and prognostic markers in acute lymphoblastic leukaemia (ALL) used in the risk stratification of patients for treatment.
Chromosomal translocations result in either the formation of a fusion protein, or, in the case of translocations involving the *Immunoglobulin heavy chain* locus (*IGH*-t), they result in the activation of proto-oncogenes driven by strong regulatory elements.
IGH-t are observed in 5-10% of B-cell precursor ALL (BCP-ALL) and are associated with a poor prognosis in adults[1]. The *IGH* locus is highly promiscuous, rearranging with many different chromosomal partners. These observations led us to question the consequences of such rearrangements and their impact on gene expression signatures. Do all *IGH*-t lead to deregulation of the same signalling pathways or can we subdivide patients according to the function of the partner gene involved?
Aims: We hypothesise that the transcriptomic and clinical characteristics of *IGH*-t ALL are determined by the translocation partner gene. The aims of this study are (1) to characterise the transcriptome of *IGH*-t ALL; (2) to identify any potential druggable pathways to improve treatment options.
Methods: RNA sequencing data from 270 BCP-ALL cases (195 cases from Lund University (EGAS00001001795)[3] and 75 in-house cases), including 52 *IGH*-t cases, were processed for cluster analysis, with LASSO feature selection using label in Li et al.[4], followed by hierarchical cluster analysis. Gene set enrichment analysis (GSEA) was performed to identify enrichment in drug-related gene sets. The results were validated *in vitro* using patient derived xenograft cells (PDX). Drug experiments were conducted using an in-house high-throughput drug screening system.
Results: Cluster analysis revealed that *IGH-DUX4* plus *IGH-CRLF2* and *IGH-IL3* clustered together with *DUX4*-rearranged (G4) and *BCR-ABL1*(-like) (G6) cases, respectively (Fig. 1). One novel observation was that *IGH-ID4* cases, which were reported to associate with *PAX5* deletions[5], clustered with *PAX5*-rearranged (*PAX5*-r) and *P2RY8-CRLF2* (G9) cases (Fig. 1). GSEA indicated that *IGH-DUX4* ALL may have reduced sensitivity to asparaginase, characterised by higher expression of ribosome-related genes and GATA3. Asparaginase treatment of PDX samples revealed a higher IC50 for IGH-DUX4 (n=1) compared to non-IGH-DUX4 PDX (n=2) (logIC50: 0.4791 vs -2.896). Addition of dexamethasone (1nM), a GATA3 phorsphorylation inhibitor, enhanced the inhibition of *IGH-DUX4* PDX by asparaginase (logIC50: -2.761), suggesting potential synergism (Average ZIP score: 5.377).

Summary/Conclusion: *IGH*-t ALL comprises a heterogeneous subtype in which further subtyping may provide insight into novel therapeutic avenues. Patients with *IGH-DUX4* and *IGH-CRLF2* clustered with *DUX4*-r and *BCR-ABL1*-like cases, as expected.We report a novel observation that *IGH-ID4* patients cluster with *PAX5*-r ALL. Although *IGH-DUX4* ALL has been shown to confer a good prognosis, our study suggests these patients may have reduced sensitivity to asparaginase, a drug used in induction phase chemotherapy. Further investigation of their response to induction phase chemotherapy is required to understand its clinical implication.

Background: B cell precursor acute lymphoblastic leukemia (BCP-ALL) is a molecularly heterogenous disease, characterized by uncontrolled proliferation of early lymphoid progenitor cells. As fusion-driven disease, it is further characterized by limited therapeutic options at relapse in adults. In recent years, it has been shown that non-coding RNAs (ncRNAs) exhibit oncogenic properties. Especially, circular RNAs (circRNAs) are of increasing interest, as these are remarkably stable, covalently closed structures with tissue-specific expression and oncogenic potential.
Aims: Since their role in ALL remains largely uncharacterized, we investigated the expression pattern of circRNAs in BCP-ALL to identify and characterize new molecular markers for a deeper biological understanding.
Methods: We isolated ribosomal depleted RNA from a well-characterized cohort of 84 BCP-ALL samples from 63 patients (46 adults and 17 pediatric patients), consisting of 61 samples from initial diagnoses (ID) and 23 (21 paired) relapses (REL). RNA paired-end sequencing was performed on an Illumina HiSeq2500 with ~50 million reads per sample. Subgroup classification was based on mRNA expression and underlying driver fusion genes (FusionCatcher) in an established reference cohort of ~600 ALL samples. We used CIRCexplorer for circRNA detection and examined both individual circRNAs and circRNA variants condensed to their gene of origin. Differential expression analysis using DESeq2 was applied, and circRNA existence was confirmed by RT-PCR. All differentially expressed circRNAs were used for subsequent pathway analyses with ShinyGO.
Results: We identified a total of 79280 different circRNAs from 9400 genes in 84 analyzed samples. According to their mRNA expression, we defined molecular subgroups for all samples: DUX4 (ID n=15, REL n=10), Ph-pos (ID n=13), Ph-like (ID n=22, REL n=7) and others (ID n=11, REL n=6). To elucidate relapse specific circRNA expression, we compared paired samples from ID and REL in the subgroups of DUX4 and Ph-like, however found no significant change in circRNA expression. Due to minor difference in circRNA expression and the biological similarity of Ph-pos and Ph-like these samples were pooled and compared to DUX4 samples. Molecular BCP-ALL subgroups were classified by a unique circRNA expression pattern (Figure) with 259 differentially expressed circRNAs (FDR ≤ 0.05, log2 fold change ≥2) in DUX4 vs. Ph-pos/-like samples. We carried out pathway analyses and obtained over-represented pathways related to EGFR tyrosine kinase inhibitor resistance and cancer associated pathways involving known oncogenes like IGF1R, PIK3R1 and MDM2 (FDR ≤ 0.05). Of interest is the association to miRNAs in cancer, reflecting a potential sponge function of our identified circRNAs. Ph-pos/-like ALLs are characterized by deregulated JAK-STAT. In supervised analyses of circRNA expression of JAK-STAT members (DUX4 vs. Ph-pos/-like), we identified circAKT3 as potential target candidate (FDR ≤ 0.05, fold change 4.3).

Expression pattern of differentially expressed circRNAs in DUX4 vs Ph-pos/-like. Heatmap demonstrates supervised hierarchical clustering of 31 differentially expressed circRNAs (FDR ≤ 0.1). CircRNA variants were summed to their gene of origin. Upper bars demonstrate clustering of the samples (n=61). ID: initial diagnosis, REL: relapse.

Summary/Conclusion: We present a comprehensive analysis of circRNA expression in BCP-ALL in a well characterized cohort. Detected circRNA expression profiles discriminated BCP-ALL samples in molecular subgroups and remained stable between initial diagnosis and relapse. Moreover, we found differentially expressed circRNAs, corresponding to their gene of origin, enriched in different cancer pathways. Within JAK-STAT signaling, circAKT3 emerged as target candidate in BCP-ALL. These findings introduce circRNAs as new deregulated layer in BCP-ALL, warranting further exploration of potential therapeutic options.

EP319 COMBINING GENOMIC AND EXPRESSION PROFILES OF INTRACHROMOSOMAL AMPLIFICATION OF CHROMOSOME 21 B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA TO IDENTIFY POTENTIAL LEUKEMIC TARGETS

F. M. Hormann [1,2,*], A. Q. Hoogkamer [1,2], A. Boeree [1,2], E. Sonneveld [3,4], V. de Haas [3,4], M. L. den Boer [1,2,5], J. M. Boer [1,2]

[1]Research, Princess Máxima Center for Pediatric Oncology, [2]Pediatric Oncology, Oncode Institute, [3]Diagnostics, Princess Máxima Center for Pediatric Oncology, [4]Laboratory, Dutch Childhood Oncology Group, Utrecht, [5]Department of Pediatric Oncology and Hematology, Erasmus MC - Sophia Children's Hospital, Rotterdam, Netherlands

Background: Intrachromosomal amplification of chromosome 21 (iAMP21) is a rare, but high-risk subtype of pediatric B-cell acute lymphoblastic leukemia (B-ALL). iAMP21 was discovered by routine screening for the *ETV6-RUNX1* fusion, resulting in the current definition of iAMP21 as three or more extra copies of *RUNX1* on a single abnormal chromosome 21. Using copy number profiling, iAMP21 can also be detected as regions of amplifications, deletions and inversions. It is currently unknown how the abnormal chromosome 21 contributes to development of leukemia.
Aims: We aimed to determine the common region of amplification in iAMP21 patients. In addition, by correlating the chromosome 21 copy number gain, and resulting gene expression change, to genome wide gene expression, we aimed to shed light on the potential leukemic target of the abnormal chromosome 21.
Methods: Copy number aberrations were determined in a population based pediatric B-ALL cohort using array Comparative Genomic Hybridization (aCGH). As an independent cohort, the supplementary SNP array data from Gu et al (Nature genetics, 2020) was used. Gene expression was evaluated using Affymetrix U133 Plus2 expression arrays. Differential gene expression was evaluated using Limma and Globaltest was used to evaluate genome wide gene expression correlations. As an independent cohort, publicly available RNA expression data from B-other and *BCR-ABL1*-like B-ALL patients from the PeCan database was used.
Results: Within our population based aCGH cohort, 12 out of 398 patients showed an aCGH profile suggestive of iAMP21 (median age = 8.5 years, range = 5-14; median white blood cell count = 7.6 x 10^9/L, range = 2-129). By scoring their chromosome 21 copy number gain per probe, we identified three regions of a total of 3.9 Mb that were commonly amplified (at least 2 copies gained). A similar strategy was applied to the supplementary SNP array data of 34 pediatric and young adult iAMP21 patients from Gu et al (Nature Genetics, 2019). Combined with the common region of amplification (CRA) determined by Rand et al (n = 18, Blood, 2011), it resulted in a narrowed down CRA of 1.5 Mb, containing 12 protein-coding genes. Interestingly, the CRA was located telomeric from *RUNX1*, but did not include this gene. Although gained in all patients, in 4 of our 12 iAMP21 patients the highest amplified region was located telomeric from *RUNX1*. In accordance, *RUNX1* expression did not correlate with copy number (p = 0.371, spearman correlation) and was only moderately overexpressed in iAMP21 cases, both in our samples (n = 155 of which 12 iAMP21, fold change (FC) = 1.6, adjusted p-value = 0.030), as well as in the independent PeCan dataset (n = 246 of which 17 iAMP21, FC = 1.4, p-value < 0.001). Only 7 of these 12 protein-coding genes were significantly upregulated (adjusted p-value < 0.01). *RIPPLY3* was the highest overexpressed gene (FC = 4.2) within the CRA, confirmed in the independent PeCan dataset (FC = 9.8). The expression of *RIPPLY3* was most correlated to the expression of the 1128 differentially expressed probesets in iAMP21 (R = 0.59).
Summary/Conclusion: We narrowed down the common region of amplification in iAMP21 B-ALL to 1.5 Mb which surprisingly did not include the *RUNX1* gene. Our data suggest that *RIPPLY3*, a negative regulator of the transcriptional activity of TBX1 and suggested to regulate STAT3 transcriptional activity, is the potential target of the iAMP21 transformation, making it an interesting gene for further functional studies.

EP320 METABOLIC ALTERATIONS TRIGGERED BY NPAT/JAK2, A NOVEL FUSION GENE ACTIVATING KINASE SIGNALING IN CHILDHOOD BCR/ABL1-LIKE ALL

J. Lukes [1,2], E. Potuckova [1,2], K. Hlozkova [1,2], N. Alquezar-Artieda [1,2], J. Stary [1,3], J. Trka [1,2,3], M. Zaliova [1,2,3], J. Starkova [1,2,3,*]

[1]Department of Paediatric Haematology and Oncology, Second Faculty of Medicine, Charles University, [2]CLIP - Childhood Leukaemia Investigation Prague, [3]University Hospital Motol, Prague, Czech Republic

Background: The JAK2 kinase plays an essential role in mediating growth-promoting activities of various cytokines. Constitutive activation of this kinase, via chromosomal translocations, has been previously described in acute lymphoblastic leukemia (ALL), with PAX5, BCR and ETV6 being the most common partner genes. ALLs with JAK2 fusions usually have the BCR-ABL1-like phenotype associated with unfavorable outcome. The metabolic consequences potentially contributing to leukemogenesis in cells harboring JAK2 fusion genes have not been investigated so far.
Aims: We identified and studied in detail a novel JAK2 involving fusion gene, NPAT-JAK2, in a patient with high-risk B-cell precursor ALL.
Methods: Seahorse Metabolic Analysis
Results: The NPAT gene is located on chromosome 11 and encodes a nuclear protein acting as a co-activator of histone gene transcription. No functional domains in the N-terminal part of the NPAT protein involved in the NPAT/JAK2 chimera, have been described, but, importantly, the chimera involved the complete JAK2 kinase domain. We cloned the full-length coding sequence of NPAT/JAK2 and studied its biological properties in model cell lines. We found that the NPAT/JAK2 protein is localized both in the cytoplasm and in the nucleus of transfected cells and that it is autophosphorylated on Y1007/Y1008 in the activation loop of JAK2 whose phosphorylation is essential for JAK2 kinase function. Next, we tested the oncogenic potential of NPAT/JAK2 in the Ba/F3 cells dependent on interleukin 3 (IL3), in which the fusion induced cytokine independent growth. This effect was abolished by a mutation of the NPAT/JAK2 ATP-binding site, demonstrating its dependence on the JAK2 kinase activity. Western blot analysis of the transformed BAF3 cells showed increased phosphorylation of STAT1 and STAT5. Importantly, the phosphorylation and pro-proliferative effect was blocked by the JAK1/2 inhibitor Ruxolitinib.
The cell energy phenotype test revealed an overall enhanced metabolic state of the NPAT/JAK2 transformed BA/F3 cells grown without IL3, with elevations of both the mitochondrial and the glycolytic function. Differences were visible already under steady-state cultivation conditions, however the major divergence between the NPAT/JAK2 transformed cells and controls occurred after stress induction. Concomitantly, the ATP production was increased in NPAT/JAK2 transformed cells, together with the NAD+/NADH ratio when compared to the empty vector and NPAT/JAK2-positive BAF3 cells dependent on IL3 (in pre-transformation phase), as assessed by a luciferase assay. To validate our result, we used 2-deoxy-D-glucose (2DG), a competitor of glucose which is a main substrate utilized in bioenergetics pathways of cancer cells. The proliferation of NPAT/JAK2 transformed cells treated with 2DG was dramatically inhibited, compared to controls. Interestingly, metabolic differences were not observed in the case of the recurrent JAK2 kinase fusion PAX5-JAK2. Therefore we presume that the here described metabolic alterations most likely do not represent a general mechanism for all of the fusion genes involving the JAK2 kinase domain.
Summary/Conclusion: To conclude, we identified and characterized in detail a novel druggable JAK2 fusion gene, NPAT/JAK2, with a constitutively active chimeric tyrosine kinase. The oncogenic potential of cells harboring this fusion is likely driven by signaling pathway alterations and intensive metabolic changes with dependencies on sufficient energy substrate supply, a mechanism that could potentially be exploited in future therapeutical strategies.

EP321 GENOMIC ANALYSES IN T-ALL PATIENTS IDENTIFY RECURRENT AND NOVEL ABNORMALITIES

L. Eadie [1,2,*], J. Rehn [1,2], S. Heatley [1,2], B. McClure [1,2], C. Schutz [1], J. Breen [1,3], T. Hughes [1,2,4,5], D. Yeung [1,2,4,5], R. Sutton [6], D. White [1,2,5,7]

[1]Precision Medicine, South Australian Health & Medical Research Institute (SAHMRI), [2]Faculty of Health & Medical Sciences, University of Adelaide, [3]South Australian Genomics Centre (SAGC), [4]Royal Adelaide Hospital, Adelaide, [5]Australasian Leukaemia & Lymphoma Group, Melbourne, [6]Children's Cancer Institute Australia, Sydney, [7]Australian Genomics Health Alliance, Melbourne, Australia

Background: 15% of pediatric and 40% of adult T-cell Acute Lymphoblastic Leukemia (T-ALL) patients fail conventional therapy highlighting the need for novel therapeutic strategies based on the genomic alterations of individuals.
Aims: We interrogated genomic alterations in Australian T-ALL patients for patterns of mutation and druggable targets. A subset of samples were used to establish patient-derived xenograft (PDX) models to evaluate novel therapies.
Methods: T-ALL patients' samples underwent transcriptomic analyses (148 total samples including diagnosis, refractory and relapse timepoints from 137 patients of all age groups). mRNA sequencing (mRNAseq) identified gene fusions and structural variants and assessed differential gene expression (n=120). Fusion calling relied on FusionCatcher, SOAPfuse, JAFFA; variant calling utilized GATK HaplotypeCaller. Possible germline alterations and common SNPs were filtered prior to manual curation. DNA copy number variations (CNVs) were detected via MLPA (MRC Holland, P202/P335/P383; n=80). Establishment of PDX models from patient material (bone marrow, peripheral blood) is ongoing.
Results: Genomic fusion genes were identified in 58/120 samples (48%) by mRNAseq; the most common was *STIL-TAL1* (n=9). Increased expression of *LCK* and/or *LAT* (encoded proteins are involved in T-cell receptor (TCR) signal transduction) was observed in patients harbouring *STIL-TAL1* indicating TCR signaling may be perturbed in this sub-group. Other common gene fusions were *MLLT10-DDX3X* (n=5) and *KMT2A-MLLT4/AFDN* (n=4). We also observed *SET-NUP214, KMT2A-MLLT1, PICALM-MLLT10, NUP214-ABL1*, several fusions involving TCR subunits as well as novel fusions involving *KMT2A*, *NOTCH1*, *SUZ12, CTCF*, *ZEB2*.
Nonsynonymous mutations were identified in 106/120 patients (88%) with mRNAseq data. Broadly, mutated genes encode proteins in the following categories: oncoproteins (*NRAS, KRAS*); tumour suppressors (*TP53, PTEN*); epigenetic regulators (*DNMT3A*, *EZH2*, *IDH1/2*, *PHF6*); regulators of NOTCH signalling (*NOTCH1/2*, *FBXW7*); transcription factors and regulators (*ETV6*, *IKZF1*, *LEF1*, *RUNX1*, *WT1*); kinase and cytokine signal regulators (*JAK1*, *JAK2, JAK3, TYK2*). Clinically relevant INDELS were identified in 67/120 patients (56%) including alterations to: *CDKN2A, FBXW7*, *IL7R*, *JAK3, LEF1*, *NOTCH1*, *PHF6*, *PTEN*, *WT1*.
The most common copy number alterations identified were *CDKN2A/B* deletions (37/80 patients, 46%), *PHF6* duplication (30/80 patients, 38%) and *MLLT3* deletion (14/80 patients, 18%). In patients with homozygous *CDKN2A/B* deletions and additional CNVs, *PHF6* duplication (n=9) and *MYB* duplication (n=4) were mutually exclusive. *MLLT3* deletion always co-occurred with *CDKN2A/B* deletions (19/19 patients with *MLLT3* deletion), but was rarely observed with *PTEN* deletion (1/11 patients with *PTEN* deletion). Patients with either *CDKN2A/B* deletions or *PHF6* duplications frequently harbored *NOTCH1* abnormalities: 24/36 patients (67%) and 15/26 patients (58%), respectively.
PDX primagrafts investigated the engraftment latency and peripheral organ infiltration. Primagrafts established from patients harboring gene fusions typically engrafted at a slower rate (n=4, 70-93 days) than primagrafts from patients harboring *CDKN2A/B* deletions (n=2, 32-53 days).

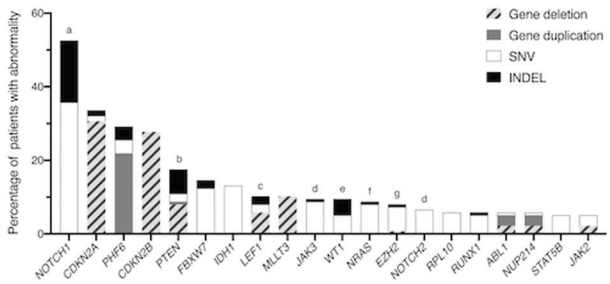

Figure 1: Top 20 genes with copy number variations and mutations in T-ALL patient cohort (n=137 patients). SNV=single nucleotide variant; INDEL=insertion or deletion

[a] 15 cases had either multiple SNVs/INDELs or an SNV+INDEL; [b] 4 cases had either multiple SNVs/INDELs or an SNV+INDEL; [c] 1 case had multiple SNVs and 1 case had multiple INDELs; [d] 4 cases had multiple SNVs; [e] 4 cases had SNV+INDEL; [f] 1 case had multiple INDELs; [g] 1 case had SNV+INDEL. In all instances, multiple mutations were counted as SNVs only

Summary/Conclusion: In our cohort the majority of cases harbor rearrangements, structural variations and duplication/deletion of genes associated with malignant transformation. We identified several co-occurring

lesions as well as mutually exclusive genomic abnormalities. Secondary PDX models investigating targeted treatment strategies are ongoing.

EP322 WHOLE GENOME SEQUENCING PROVIDES NOVEL INSIGHTS INTO GENOMIC LANDSCAPE OF PEDIATRIC T CELL ACUTE LYMPHOBLASTIC LEUKEMIA

M. Dawidowska [1,*], R. Jaksik [2], M. Drobna-Śledzińska [1], N. Maćkowska [1], M. Kosmalska [1], B. Szarzyńska [3], L. Sędek [4], T. Szczepański [5], M. Witt [1]

[1]Institute of Human Genetics Polish Academy of Sciences, Poznań, [2]Deptartment of Systems Biology and Engineering, Silesian University of Technology, Gliwice, [3]Polish Stem Cells Bank, Warsaw, [4]Deptartment of Microbiology and Immunology, [5]Deptartment of Pediatric Hematology and Oncology, Medical University of Silesia in Katowice, Zabrze, Poland

Background: T-cell acute lymphoblastic leukemia (T-ALL) is a highly heterogeneous and aggressive hematological malignancy. Genomic landscape of T-ALL has been largely characterized by whole exome sequencing (WES) and RNA-seq. Whole genome sequencing (WGS) enables to extend beyond the coding sequence but also offers more uniform sequencing coverage as compared to WES. Here we focus on protein coding genes affected by mutations detected by WGS in pediatric T-ALL.
Aims: To provide novel insights into genomic landscape of pediatric T-ALL by WGS
Methods: We performed WGS in 64 T-ALL samples from diagnosis (Dg) and 24 matched remission samples (Rem). TruSeq Nano DNA library kit and Illumina HiSeq X-Ten were used to generate 150bp paired-end reads. WGS coverage was 60x for Dg and 30x for Rem samples. FastQC and FastQ Screen were used for sequencing data quality control. Reads were aligned to GRCh38 using BWA mem, achieving an average alignment rate of 99.6%. Mapped reads were de-duplicated using MarkDuplicates (Picard tools) and processed with BaseRecalibrator (GATK v4.1.0.0). Average read duplication rate was 10.3%, thus true mean coverage across the entire genome was 72x for Dg samples (54x-82x) and 36x for Rem (31x-45x). Somatic variants were identified with Mutect2 (v4.1.4.0) and annotated using VariantEffectPredictor (v97). Potential germline variants were removed based on AF>0.05 in the NFE population (non-Finnish Europeans) as reported in gnomAD database and POLGENOM database (126 whole genomes of healthy long living Polish individuals). We then focused on single nucleotide variants (SNVs) and indels affecting coding sequence with moderate and high impact. Variants and affected genes were analyzed for potential involvement in processes classified by cancer-related terms selected from KEGG, Gene Ontology and Reactome databases. Affected genes were checked for previous reports as genes mutated in T-ALL patients in WES, WGS and RNA-seq studies [1-5].
Results: We identified 5535 somatic SNVs and indels affecting 4117 protein coding genes. In total, we identified 3817 genes not previously reported as affected in T-ALL studies [1-5]. Out of these genes, 764 (20%) were mutated in ≥2 Dg samples (2/64; frequency >3%), 54 genes (1.4%) were mutated in ≥5 Dg samples (5/64; frequency >7%). Among 'novel' T-ALL-mutated genes with >10% frequency, we identified 5 members of *Neuroblastoma Breakpoint Family* (*NBPF*) of putative roles in several cancer types. By functional classification of all mutated genes, according to KEGG terms, we revealed several processes to be affected in T-ALL patients, including: signal transduction (in 100% of T-ALL samples), transport and catabolism (97%), cell growth and death (86%), signaling molecules and interaction (81%), immune system (80%), translation (70%), folding, sorting and degradation (61%), transcription (48%), replication and repair (47%), membrane transport (38%).
Summary/Conclusion: WGS with high coverage (>60x) performed in a relatively high number of T-ALL Dg samples, identified numerous genes recurrently mutated in T-ALL patients, not previously reported to be affected in T-ALL. These findings provide further insights into genomic landscape of this heterogeneous malignancy. Results of this study form the basis for investigation of the biological and clinical relevance of novel genes in T-ALL.

EP323 ANTI-CD47 MONOCLONAL ANTIBODY THERAPY EFFECTIVELY ELIMINATES ADRIAMYCIN RESISTANCE IN ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

S. Kalayu Yirga [1], J. Hu [1,*]

[1]Department of Hematology, Fujian Institute of Hematology, Fujian Provincial Key Laboratory of Hematology, Fujian Medical University Union Hospital, 29 Xinquan Road, Fuzhou 350001, Fujian, China, Fuzhou, China

Background: Acute lymphoblastic leukemia (ALL) is a common hematological malignancy with poor survival, especially in adults. Adriamycin (ADM)-based chemotherapy is a standard regimen of human lymphoid malignancies, including ALL. However, chemo-resistance & relapse hindered the outcome of the chemotherapy in high risk ALL patients. Human CD47 is an integrin-associated protein and highly expressed in hematological malignancy cells. CD47 served as a ligand for signal regulatory protein-α (SIRP-α) which expressed on phagocytic cells and CD47 interaction with SIRP-α promotes to inhibit phagocytosis activity. Blocking anti-CD47 monoclonal antibody (mAb) can stimulate phagocytosis activity of macrophages. So far, anti-CD47 mAb and antibody combination with ADM therapy against drug resistance human ALL is not clearly investigated.
Aims: This study targeted to detect cell surface expression level of CD47 in ADM resistant ALL cells and investigate the efficacy treating potential of anti-CD47 mAb against ADM resistant ALL cells in preclinical mouse models.
Methods: Stably luciferase expressing parental Nalm-6-Luc-cells were subjected with ADM to establish ADM resistant cells. CD47 expression in ALL cells was analyzed using FACS. Anti-CD47 mediated phagocytosis in vitro assay was performed. NOD/SCID mouse in vivo preclinical model using anti-CD47 mAb, mAb combination with ADM, and ADM alone therapy against human ALL were established. Tumor volume and burden were monitored. Survival of the leukemic mice were observed in using different treatments.
Results: We successfully established potently ADM drug resistant human ALL cells Nalm-6-Luc-ADMR. We found that CD47 was highly expressed (over 98%) in the resistant Nalm-6-Luc-ADMR, Nalm-6-Luc (parental), Molt-4 and Jurkat ALL cells. High expression level of drug resistance genes and proteins in ADM resistant ALL cells were detected. Anti-CD47 mAb with the presence of macrophage enabled phagocytosis of drug resistant ALL cells in vitro assay. The anti-CD47 antibody enabled significant levels of phagocytosis with blast ALL cells using macrophage effector cells as compared to blank control and anti-CD45 antibody ($P = 0.0001$). In our preclinical mouse model, drug resistant ALL cells were significantly eliminated in ALL engrafted mice when treated with anti-CD47 mAb and mAb combination with ADM, whereas ADM alone and control mice remained at risk of leukemia burden. Moreover, with anti-CD47 antibody alone treatment, the highest (leukemia free) survival rate (over 5 months) without any relapse case was achieved.
Summary/Conclusion: Our current results indicated that targeting CD47 with anti-CD47 antibody therapy could effectively eliminate drug resistant ALL cells and provided a promising preclinical evidence for novel treatment in relapsed/refractory ALL.

EP324 B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA INDUCES AN INTERFERON-SIGNATURE IN MESENCHYMAL STROMAL CELLS

M. W. Smeets [1,2,3,*], F. Stalpers [1,3], M. M. Vermeeren [1,2,3], J. Orsel [1,3], A. Q. Hoogkamer [1,3], S. Nierkens [1,4], C. van de Ven [1,3], M. L. den Boer [1,2,3]

[1]Research, Princess Máxima Center, Utrecht, [2]Dept. Of Pediatric Oncology, Erasmus MC, Rotterdam, [3]Oncode Institute, [4]Center for Translational Immunology, University Medical Center, Utrecht, Netherlands

Background: B-cell precursor acute lymphoblastic leukemia (BCP-ALL) cells that are present in the bone marrow microenvironment are able to hijack the normal hematopoietic stem cell niches to create a leukemic niche. The importance of this microenvironment for leukemic cells is demonstrated by the protection that the niche provides against chemotherapeutic agents. Patient derived mesenchymal stromal cells (MSCs) mimic this protective effect *in vitro*. Unraveling the mechanism of protection is important to provide potential novel therapeutics. Therefore, our research is focused on the interaction between ALL cells and MSCs.
Aims: We aimed to determine gene expression changes in ALL cells and MSCs after co-culture compared to mono-culture, and to investigate

which cyto/chemokines are differentially secreted upon contact between ALL cells and MSCs.
Methods: We performed mono- and co-cultures of primary MSCs and ALL cells for 40 hours to determine gene expression changes. Viable cells were sorted by FACS and RNA was isolated. Total-RNA sequencing data (Illumina) were analyzed using R. Supernatant was saved to determine cyto/chemokine profiles by Luminex technology, and to investigate the effect of these cyto/chemokines on the survival and migration of the leukemic cells. Migration experiments using transwells (3.0µm pores) were performed to determine the level of ALL migration towards chemokines of interest. Moreover, using lentivirus, knockdowns (KD) of genes of interest were performed in MSCs. KD efficiency was tested using Taqman qPCR. Subsequently, co-cultures of ALL cells and KD- or control-MSCs were performed to study the role these genes in ALL survival.
Results: RNA sequencing data from 15 independent co-culture experiments revealed that interferon (IFN)-related genes, such as *IFI6, MX1, IFI27, and OAS1,* were 2.5 to 3.1-fold upregulated in the MSCs after co-culture with ALL compared to MSC mono-culture. The type of upregulated pro-inflammatory genes and amount of upregulation varied between ALL patients. However, the observed changes were always similar when an ALL case was co-cultured with different MSC samples, suggesting that the changes are induced by the leukemic cells. Survival benefit (0.3 - 37.9%) was observed in ALL cells after co-culture with MSCs compared to ALL mono-culture. Co-cultures of KD-MSCs and ALL cells showed that ALL cell viability was affected upon KD of some IFN-related genes. The effect of the number of viable MSCs in these cultures is currently being addressed. Moreover, pro-inflammatory cytokines, and migration-related chemokines such as CCL2, CXCL8, and IP10 were upregulated after co-culture compared to the sum of the separate ALL and MSC mono-cultures. A gradient of IP10 in transwell experiments showed that this chemokine did not enhance primary ALL cell migration, suggesting that the ALL-induced secretion of IP10 serves a different role in BCP-ALL. The role of IP10 and other cyto/chemokines in immune regulation at the time of overt leukemia is part of ongoing studies.
Summary/Conclusion: Our data show that IFN-related genes, pro-inflammatory cytokines and migration-related chemokines become upregulated in bone marrow MSCs upon exposure to ALL. These induced changes may be important for ALL cell survival, affecting the mobility of other immune cells, and/or ensure that leukemic cells remain in close contact with MSCs. We postulate that interference with these affected genes and cyto/chemokines may disrupt the direct contact between leukemic cells and their niche and may provide an alternative way to eliminate leukemic cells more efficaciously.

EP325 OPTICAL GENOME MAPPING FOR THE ASSESSMENT OF STRATIFICATION-RELEVANT GENOMIC ABERRATIONS IN ACUTE LYMPHOBLASTIC LEUKEMIA

J. Lühmann [1,*], M. Stelter [1], M. Wolter [1], J. Kater [1], J. Lentes [1], A. K. Bergmann [1], M. Schieck [1], G. Göhring [1], A. Möricke [2], G. Cario [2], M. Schrappe [2], B. Schlegelberger [1], M. Stanulla [3], D. Steinemann [1]

[1]Human Genetics, Hannover Medical School, Hannover, [2]Pediatrics I, ALL-BFM Study, Christian-Albrechts University Kiel and University Medical Center Schleswig-Holstein, Kiel, [3]Pediatric Hematology and Oncology, Hannover Medical School, Hannover, Germany

Background: Acute lymphoblastic leukemia (ALL) is the most prevalent type of pediatric cancer. Even though, 85-90% of patients with ALL can reach a long-term cure, ALL does reoccur in about 15-20% of all patients and can be cured in just 30-50% of the relapsed cases. ALL is molecularly characterized by an increasing number of structural genomic aberrations that strongly correlates with prognostic and clinical outcomes. Usually, a combination of cyto- and molecular genetic methods (karyotyping, array-CGH, FISH, RT-PCR, RNA-seq) is needed to identify all the underlying genomic aberrations present in ALL.
Aims: This research aims to investigate the feasibility of next-generation cytogenomics to detect structural variants in an all-in-one approach.
Methods: As proof of principle, twelve pediatric B-cell precursor ALL samples from ALL-BFM-2000 and AIEOP-BFM-ALL-2017 were analyzed by means of optical genome mapping (OGM), a DNA-based approach for structural variant detection, using the Saphyr system (Bionano Genomics). Intensive validation of the results was performed by comparing OGM data to existing data from routine diagnostic workflows.
Results: All structural alterations among translocations (e.g., t(1;19), dic(9;12)), aneuploidies (e.g., -7, -11, high hyperdiploidy), and copy number variations (e.g., *IKZF1*^{plus} profile) detected by established techniques were identified by OGM as well. Additionally, OGM revealed a more complex structure of a known translocation t(12;21) and detected further alterations, among those a small deletion in *SETD2* as well as a stratification relevant gene fusion of *JAK2/NPAT* in an archived sample.
Summary/Conclusion: In this pilot study of very well characterized pediatric ALL cases we show that all previously known genomic aberrations were detected by means of OGM as well and that OGM has the potential to detect stratification-relevant markers in an all-in-one approach.

EP326 CD16XCD33 BI-SPECIFIC KILLER CELL ENGAGER (BIKE) AS POTENTIAL IMMUNOTHERAPY IN PEDIATRIC PATIENTS WITH AML AND BIPHENOTYPIC ALL

S. Reusing [1], D. Vallera [2], A. Manser [3], M. Felices [4], J. Miller [4], M. Uhrberg [3], F. Babor [1,*]

[1]Department of Paediatric Oncology, Haematology and Immunology, CENTER FOR CHILD AND ADOLESCENT HEALTH, HEINRICH HEINE UNIVERSITY, Düsseldorf, Germany, [2]Department of Therapeutic Radiology-Radiation Oncology, University of Minnesota, Masonic Cancer Center, Minneapolis, United States, [3]Institute for Transplantation Diagnostics and Cell Therapeutics, Heinrich Heine University, Düsseldorf, Germany, [4]Department of Medicine, Division of Hematology, Oncology, and Transplantation, Minneapolis, United States

Background: Similar to pediatric acute myeloid leukemia (AML) the subgroup of biphenotypic acute lymphoblastic leukemia (ALL) is a rare complex entity with adverse outcome, characterized by the surface expression of CD33. Despite novel and promising anti-CD19 targeted immunotherapies such as chimeric antigen receptor T cells and bispecific anti-CD19/CD3 antibodies, relapse and resistance remain a major challenge in about 30% to 60% of patients.
Aims: Aim of this study was to investigate the potential role of the fully-humanized bi-specific antibody CD16×CD33 (BiKE) in children with CD33$^+$ acute leukemia.
Methods: For this purpose, we tested whether the reagent was able to boost NK cell effector functions against CD33$^+$ pediatric AML and biphenotypic CD33$^+$ pediatric ALL blasts.
Results: Stimulation of primary NK cells from healthy volunteers with 16x33 BiKE led to increased cytotoxicity, degranulation, and cytokine production against CD33$^+$ cell lines. Moroever, BiKE treatment significantly increased degranulation, IFN-γ, and TNF-α production against primary ALL and AML targets. Importantly, also NK cells from leukemic patients profited from restoration of effector functions by BiKE treatment, albeit to a lesser extent than NK cells from healthy donors. In particular those patients with low perforin and granzyme expression showed compromised cytotoxic function even in the presence of BiKE. In patients with intrinsic NK cell deficiency, combination therapy of CD16xCD33 BiKE and allogeneic NK cells might thus be a promising therapeutic approach.
Summary/Conclusion: Taken together, CD16xCD33 BiKE successfully increased NK cell effector functions against pediatric AML and biphenotypic ALL blasts and constitutes a promising new option for supporting maintenance therapy or "bridging" consolidation chemotherapy before hematopoietic stem cell transplantation.

EP327 DASATINIB AND NAVITOCLAX REVERSE GLUCOCORTICOID RESISTANCE IN PRE-T-CELL RECEPTOR ACTIVATED T-CELL ACUTE LYMPHOBLASTIC LEUKAEMIA

A. Poll [1,*], Y. Shi [2], E. Law [1], H. Bell [1], J. Irving [1], F. van Delft [1]

[1]Centre for Cancer, Newcastle University, Newcastle upon Tyne, United Kingdom, [2]Memorial Sloan Kettering Cancer Centre, New York, United States

Background: Outcomes in patients with T-cell Acute Lymphoblastic Leukaemia (T-ALL) have improved markedly over the recent decades, with intensive glucocorticoid-based chemotherapy accounting for 5-year event free survival (EFS) rates of over 80% in paediatric cases. [Patrick, et al, British Journal Haematology, 2014] Outcomes for patients refractory to or relapsing after treatment remain extremely poor. Overcoming glucocorticoid resistance is central to improving outcomes in these patients. Physiological T-lymphocyte development is directed by pre T Cell Receptor (pTCR) signalling and expression of pro-survival factors, such as BCL2 and BCL2L1. We have shown that pTCR signalling activity is

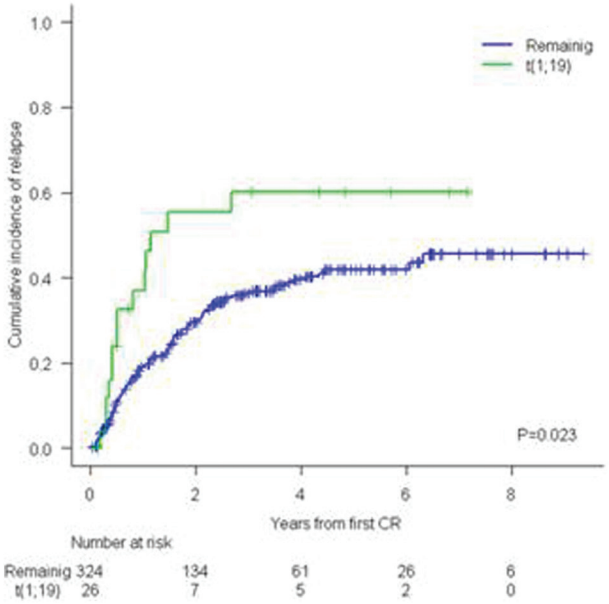
relevant in T-ALL. Dasatinib (DAS) effectively blocks the kinase LCK, which is an instrumental signalling molecule in the pTCR pathway. Combination of DAS with dexamethasone (DEX) impairs in vivo T-ALL expansion and results in cell death. [Shi, et al, Haematologica, 2020] Potent inhibitors of the BCL2 family have entered the clinical arena, and demonstrated single drug activity against T-ALL.
Aims: Establish efficacy of DEX+DAS and a BCL2 family inhibitor in T-ALL cell lines and patient-derived samples.
Methods: Cell viability assays combining DEX+DAS at a fixed ratio and BCL2 family inhibitors Venetoclax (ABT-199) or Navitoclax (ABT-263) were performed. Cell viability was determined by resazurin assay.
T-ALL PDX, in OP9-DL1 co-culture, were exposed to DEX+DAS and BCL2 inhibitors. Cell viability was assessed by resazurin assay, CytoQuant analysis and quantitative imaging.
Results: Both Venetoclax and Navitoclax act in an additive manner when combined with DEX+DAS in T-ALL cell lines and primary samples. In PDX samples sensitive to DAS, we observed superior cell kill with the addition of Navitoclax when compared to Venetoclax. Conversely, we observed that PDX samples resistant to dasatinib are more likely to respond to Venetoclax. The latter group is particularly enriched for Early T-cell Precursor ALLs, which rely on BCL2 for cell survival.
Summary/Conclusion: Based on these preliminary data, we suggest that T-ALL patients with activation of pTCR signalling, as exemplified by LCK status, benefit from DEX+DAS + Navitoclax treatment to overcome GC resistance. Other subgroups, including ETP ALL, may benefit from Venetoclax-based treatment. We will test this treatment recommendation in preclinical models to inform future patient management.

EP328 CHARACTERIZATION OF RNA-PROTEIN INTERACTION NETWORKS IN ACUTE LEUKEMIAS

K. Schuschel [1,*], S. Werner [1], E. Regényi [2], M.-L. Yaspo [2], D. Heckl [1], J.-H. Klusmann [1], J. I. Hoell [1]

[1]Department of Pediatric Hematology and Oncology, Martin-Luther-University Halle-Wittenberg, Germany, Halle (Saale), [2]Max Planck Institute for Molecular Genetics, Berlin, Germany

Background: Treatment of pediatric acute lymphoblastic leukemia (ALL) and acute myeloid leukemia (AML) remains challenging, in particular after relapse. In both pediatric ALL and especially AML, death from intensity-maximized conventional chemotherapies is still unacceptably high, and outcome re-mains poor in both AML and high-risk ALL. Thus, there is still an urgent need to identify new targetable structures and/or pathways. Transcriptional regulation in leukemias has been extensively studied and targeted therapies are under evaluation, however, the post-transcriptional layer of gene-regulation remains underexplored. Mutations and aberrant expression patterns of RNA-binding proteins (RBPs) has been detected in leukemia and implicated in leukemic transformation, with notable examples like IGF2BP3 (IGF2 mRNA binding protein 3) and MSI2 (Musashi 2). However, the oncogenic potential of most of the more than 1500 RBPs has not been studied in pediatric acute leukemias.
Aims: We aim to identify oncogenic RBPs that play a significant and targetable role in hard-to-cure subtypes of leukemias.
Methods: We performed pooled CRISPR-Cas9 dropout screenings followed by next generation sequencing using a pool of sgRNAs directed against 1500 RBPs. The screens were performed in four AML and five ALL cell lines (CMK, NOMO1, M-07e, SKNO1, NALM6, HAL-01, SEM, REH, KOPN8), representing either common leukemic subtypes or those associated with poor prognosis. SgRNA frequencies were quantified at the outset of the experiment and after 16 doublings using deep sequencing (Illumina HiSeq 4000). MAGeCK analysis was conducted for each cell line, with negative scores indicating depleting sgRNAs.
Results: We identified 191 putative oncogenes whose knockout led to a significant loss of cell fitness in at least one of the 9 screens. We further observed overlaps of depleting RBPs between the ALL cell lines and the AML cell lines. To differentiate between a general essential role of a given RBP in any cell (e.g. essential in RNA/cellular metabolism) and a putative necessary function in initiating or promoting leukemic growth, we integrated our data with cell line data collected in the framework of the project Achilles. We compared essentiality scores in leukemic cell lines to those cell lines of all origins to derive those RBPs, which display oncogenic properties (as opposed to just representing core essential factors).
One of 191 identified putative oncogenes is CAD, which pro-proliferative potential was verified experimentally in both, AML and ALL. In terms of clinical relevance, we found a tendency towards reduced overall survival (OS) in AML patients with high CAD protein expression. Since CAD protein is a multi-domain enzyme and plays a pivotal role in pyrimidine synthesis, we will dissect its independent function as an RBP.
Summary/Conclusion: Our CRISPR-Cas9 screening in combination with functional validation states the pro-proliferative potential of many RBPs including CAD in AML and ALL cell lines and highlights its utility for identifying novel targetable mechanisms in leukemia.



EP329 T(1;19)(Q23;P13) TCF3-PBX1 MAY NOT BE AN INTERMEDIATE-RISK SUBTYPE IN ADULT B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED WITH MRD-ORIENTED PROTOCOLS FROM THE PETHEMA GROUP

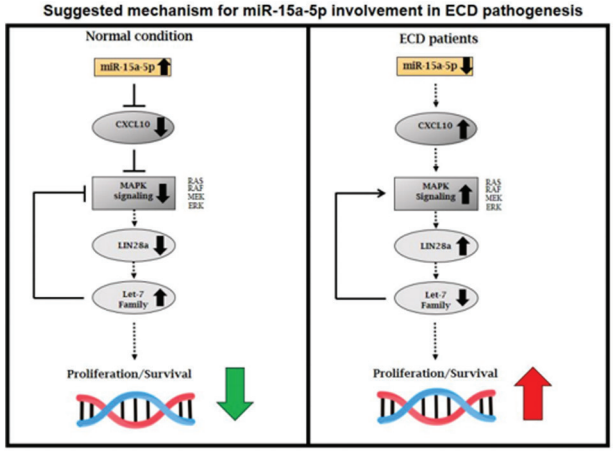
Background: Translocation t(1;19)(q23;p13) encoding the TCF3-PBX1 fusion gene is considered an intermediate-risk B-cell precursor acute lymphoblastic leukemia (BCP ALL) subtype. In adult BCP ALL there is a debate regarding the impact of this alteration. While German, English and American study groups have shown no prognostic significance, French and Italian groups have reported poor outcomes.
Aims: To analyze the frequency and clinical impact of t(1;19) in a series of adult BCP ALL patients (pts) treated with protocols from the PETHEMA Group.
Methods: A review of 513 adult BCP ALL pts (15 to 60 years) diagnosed between 2003 and 2017 and treated with MRD-oriented protocols of the PETHEMA Group was done. G-banding and FISH were performed on BM samples. Measurable residual disease (MRD) was centrally assessed by multi-parametric flow cytometry. Main outcome measures were complete response (CR), overall survival (OS) and cumulative incidence of relapse (CIR), assessed by competing risk analysis.
Results: A total of 26 pts with t(1;19)/TCF3-PBX1 were identified, representing 5% of all BCP ALL. 9/23 (39%) cases showed isolated t(1;19) while 14/23 (61%) had additional chromosomal aberrations (ACA) (in 3 cases the TCF3-PBX1 fusion was detected by FISH in the context of a normal karyotype). Pts with t(1;19) were more likely to be female (73% vs. 45%, p=0.006) and to have a pre-B phenotype (63% vs. 17%, p<0.001). Although TCF3-PBX1 pts showed higher WBC count than the remaining patients, the difference was not statistically significant (median 16.2 [0-199.5] vs. 12 [0.23-638] x10^9/L, p=0.144).
CR was achieved in 100% of t(1;19) vs. 90%, in the remaining BCP ALL pts (p=0.151). The proportion of pts with end induction MRD level <0.01% was similar (70% vs. 61%, p=0.417). No differences in OS were observed (5y-OS t(1:19) 41% [19%>63%] vs. 44% [38%>50%], p=0.562). Pts with t(1;19) experienced more deaths due to disease progression (77% vs. 59%) and less deaths due to treatment-related toxicity (15% vs. 38%). No differences were observed in OS among pts with isolated t(1;19) and those with t(1;19) with ACA (5y-OS 59% [23%>95%]

vs. 33% [1%>65%], p=0.645). A significantly higher CIR was observed for patients with t(1;19) compared with the remaining BCP ALL pts (5y-CIR 60% [36%>77%] vs. 42% [35%>48%], p=0.023)(Figure). The 5y-CIR of patients with isolated t(1;19) showed a trend to be lower to that of t(1;19) with ACA (28% [3%>63%] vs. 71% [36%>89%], p=0.119). All outcome parameters were also calculated for patients with balanced t(1;19) or unbalanced der(19)t(1;19) without statistical differences between them.



Summary/Conclusion: Although showing favorable initial treatment response, pts with t(1;19) experience a higher rate of relapse (especially those with ACA to t(1;19)) than the remaining BCP ALL pts, without differences in OS. A deeper genetic analysis may identify markers of poor outcome enabling a more precise risk stratification of t(1;19) pts.

EP330 MICRORNA-15A-5P ACTS AS A TUMOR SUPPRESSOR IN ERDHEIM-CHESTER DISEASE BY MEDIATING THE CXCL10-ERK-LIN28A-LET7 AXIS

O. Hershkovitz-Rokah [1,2,*], R. Weissman [1,2], E. L. Diamond [3], J. Haroche [4], B. H. Durham [5,6], J. Buthorn [3], F. Cohen [4], Z. Amoura [4], J.-F. Emile [7,8], R. D. Mazor [9], N. Shomron [10], O. I. Abdel-Wahab [5], O. Shpilberg [9,11,12]

Safra Center for Bioinformatics, Tel Aviv University, Tel Aviv, [11]Department of Medicine, Adelson School of Medicine, Ariel University, Ariel, [12]Translational Research Lab, Assuta Medical Center, Tel Aviv, Israel

Background: Erdheim-Chester disease (ECD) belongs to a group of rare hematological diseases and is characterized histologically by proliferation of mature histiocytes on a background of inflammatory stroma. The disease is systemic, with clinical manifestations ranging from focal indolent bone lesions to a multi-systemic, life-threatening disease. We have recently reported an aberrant expression of microRNAs (miRNAs) in ECD patients (Weissman et al, *Cancers*, 2020). NanoString analysis revealed downregulation of 95% of differentially expressed miRNAs in ECD patients compared to healthy controls. Subsequent bioinformatics analysis suggested that lower expression of certain miRNAs in ECD results in upregulation of target genes that participate in cell survival signaling and inflammation. The most prominent and significant change detected between ECD and healthy controls was downregulation of miR-15a-5p. The miR-15/16 cluster represents the most frequently deregulated miRNAs reported in hematological malignancies, and has been associated with disease progression, prognosis, and drug resistance.
Aims: To study the biological role of miR-15a-5p in ECD pathogenesis.
Methods: Global miRNA expression was analyzed in plasma samples of untreated ECD patients (n=34) and healthy controls (n=15) using the NanoString nCounter miRNA assay. As several lines of evidence have suggested that ECD may originate from a myeloid progenitor, we used the human myeloid cell lines KG-1a and OCI-AML3 as a model to study the biological effects of miR-15a-5p. Cytokine-dependent murine pro-B Ba/F3 lymphoid cells that stably expressed the MIGII-BRAF^{V600E} vector were also used. The effects of aberrantly expressed miRNAs on potential molecular targets was analyzed using quantitative real-time polymerase chain reaction (qRT-PCR), luciferase assay, enzyme-linked immunosorbent assay (ELISA), Western analysis, proliferation assay, cell-cycle analysis and Annexin-propium iodide staining.
Results: Bioinformatics target predictor (TargetScan) identified a conserved target site for miRNA-15a-5p in the 3' UTR of the chemokine ligand 10 (CXCL10). A luciferase assay confirmed that CXCL10 is a target gene regulated by miRNA-15a-5p. Low levels of miR-15a-5p in ECD patients were associated with upregulation of CXCL10 in patients plasma samples. Increased expression of miR-15a-5p, by transfection of miR-15a-5p mimic, resulted in CXCL10 downregulation, followed by downregulation of the oncogene *LIN28a* and p-ERK signaling, leading to upregulation of the tumor suppressor let-7 family miRNAs. Furthermore, overexpression of miR-15a-5p in cell lines and in a primary culture, derived from an ECD patient, inhibited cell growth and induced apoptosis by decreased levels of Bcl-2 and Bcl-xl. Finally, analysis of sequential samples from 7 ECD patients treated with MAPK inhibitors (vemurafenib/cobimetinib) for 4 months resulted in upregulation of miR-15a-5p and downregulation of CXCL10.

Summary/Conclusion: Our findings strongly suggest that miR-15a-5p acts as a tumor suppressor in ECD patients through the CXCL10-ERK-LIN28a-let7 axis, highlighting an additional layer of post-transcriptional regulation in this disease. Upregulation of miR-15a-5p in ECD patients may have a potential therapeutic role.

EP331 IDENTIFICATION AND MOLECULAR CHARACTERIZATION OF BCR-ABL1-LIKE ACUTE LYMPHOBLASTIC LEUKEMIA IN INDIAN PATIENTS

D. G. Gupta [1,*], N. Varma [1], S. Naseem [1], M. U. S. Sachdeva [1], J. Binota [1], P. Bose [1], M. Gupta [1], P. Sonam [1], P. Rana [1], A. Kumar [2], P. Malhotra [3], S. Varma [3]

[1]Hematology, Post Graduate Institute of Medical Education & Research (PGIMER), Chandigarh, India, Chandigarh, [2]ICGEB, International Centre for Genetic Engineering and Biotechnology, New Delhi, [3]Internal Medicine, Post Graduate Institute of Medical Education & Research (PGIMER), Chandigarh, India, Chandigarh, India

Background: A new provisional entity 'B-lymphoblastic leukaemia/lymphoma, *BCR-ABL1*-like' has been incorporated in the revised edition of WHO classification (2017). Authors across globe employ two approaches namely Microarray Gene Expression Profiling (GEP) or targeted Next-Generation Sequencing (NGS) and LDA (low-density array) card for its detection. In India, both these techniques are either not available or are prohibitively expensive. Therefore, we planned to perform identification and molecular characterisation of Indian *BCR-ABL1*-like ALL patients, using a different approach.

Aims: To identify *BCR-ABL1*-like ALL cases using two different platforms, followed by its molecular characterization.
Methods: Flowcytometric Immunophenotying (FCM-IP) and multiplex RT-PCR were performed on 611 B-lineage ALL cases to detect *BCR-ABL1* fusion transcripts. Further, microarray profiling of 12 *BCR-ABL1*-positive cases was performed using Affymetrix U133 Plus 2.0 array. A total of 96 B-ALL cases were subjected to a targeted panel of 50 genes using nCounter GEP. Furthermore, we performed a deep molecular analysis in various genetic subgroups of identified *BCR-ABL1*-like ALL cases using nCounter GEP, quantitative Real time (RQ)-PCR & digital droplet PCR (DD-PCR). Lastly, we performed quantification of chosen 8 best differentially expressed (DE) genes on 551 B-ALL cases, to make a logistic regression model for its rapid detection.
Results: Multiplex RT-PCR assay revealed *BCR-ABL1* transcripts in 17.67% (108/611) cases. Global transcriptome profiling of 12 *BCR-ABL1* RNA transcripts revealed a total of 1574 as DE genes. DE genes were further filtered through hierarchical clustering analysis and a total of 45 DE genes were identified. Based on previous literature and regression coefficient values, 15 best classifier genes were selected using penalized logistic regression. Out of 78 examined *BCR-ABL1*-negative cases, 33 (42.30%) cases were clustered together with 15 *BCR-ABL1*-positive cases and were categorised as *BCR-ABL1*-like ALL cases in principal component analysis. Further, we categorised *CRLF2* into two categories; high *CRLF2* cases 5/33 (15.15%) & low 28/33 (84.84%) among *BCR-ABL1*-like ALL cases. *JAK2* exon 16 was sequenced in 5 *CRLF2* high cases and we found 2 missense variants, R683S and P694L, by Sanger sequencing. The average log fold change of -1.105 & -4.574 was seen in *P2YR8* & *CSF2RA* respectively by RQ-PCR. In *CRLF2* low expressing cases, the average log fold change of 12 kinase genes showed -1.11 in *CENPC*, -0.77 *FOXP1*, -0.20 *NUP153*, 1.12 *RCSD1*, 0.76 *PAX5*, -0.19 *FLT3*, -4.41 *EPOR*, -4.01 *ILR2B*, -1.58 *CSFIR* -3.43 *PDGRFB*, -5.98 *NTRK3* and -1.99 *ZNF274*. The average log fold change of *IKZF1* in 78 *BCR-ABL1*-negative cases was found to be 10.93 in nCounter GEP and 1.07 in RQ-PCR. We found the CNV incidence of 8.33% (9/108) in *IKZF1* (4-7 deletion) gene and the ratio of *IKZF1* deletion ranged from 6.14 to 69.8% using DD-PCR. Further, 8 genes were selected and quantified in 511 *BCR-ABL1*-negative cases and we found 104/551 (18.87%) *BCR-ABL1*-like ALL cases using RQ-PCR. Further, we created a dynamic nomogram using logistic regression based classifier for its rapid detection.

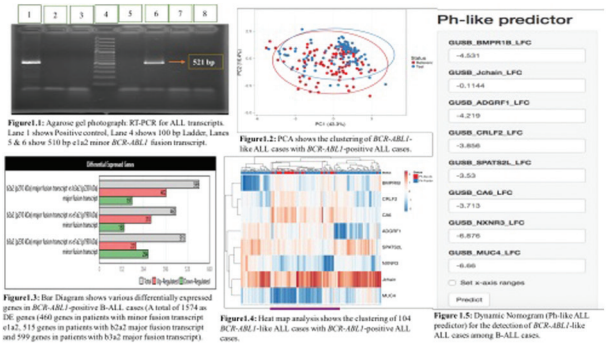


Figure1.1: Agarose gel photograph: RT-PCR for ALL transcripts. Lane 1 shows Positive control, Lane 4 shows 100 bp Ladder. Lanes 5 & 6 show 510 bp e1a2 minor *BCR-ABL1* fusion transcript.
Figure1.2: PCA shows the clustering of *BCR-ABL1*-like ALL cases with *BCR-ABL1*-positive ALL cases.
Figure1.3: Bar Diagram shows various differentially expressed genes in *BCR-ABL1*-positive B-ALL cases (A total of 1574 as DE genes (466 genes in patients with minor fusion transcript e1a2, 515 genes in patients with b2a2 major fusion transcript and 599 genes in patients with b3a2 major fusion transcript).
Figure1.4: Heat map analysis shows the clustering of 104 *BCR-ABL1*-like ALL cases with *BCR-ABL1*-positive ALL cases.
Figure 1.5: Dynamic Nomogram (Ph-like ALL predictor) for the detection of *BCR-ABL1*-like ALL cases among B-ALL cases.

Summary/Conclusion: We have reported the incidence and devised a logistic regression based simple, efficient, cost-effective classifier for the rapid detection of *BCR-ABL1* like ALL cases for the first time; which is likely to be suitable for developing countries. It is very important to detect *BCR-ABL1*-like ALL cases, so as to provide these patients the benefits of treatment stratification (including desirable TKI therapy) and prognostication.

EP332 PH+ ALL CELL LINE WITH PTPN11 MUTATIONS IS RESISTANT TO ALL TKIS AS WELL AS VENETOCLAX BUT SENSITIVE TO THE COMBINATION

G. Poudel [1,2,*], K. Asari [1,2], D. T. Yeung [1,2,3,4], D. L. White [1,2,3,5,6], T. P. Hughes [1,2,3,4], I. S. Pagani [1,2,3]

[1]Cancer Program, Precision Medicine Theme, South Australian Health and Medical Research Institute, [2]School of Medicine, Faculty of Health and Medical Sciences, The University of Adelaide, Adelaide, [3]Australian Leukaemia and Lymphoma Group, Melbourne, [4]Department of Haematology and Bone Marrow Transplantation, Royal Adelaide Hospital and SA Pathology, [5]School of Biological Sciences, Faculty of Sciences, [6]Department of Paediatrics, School of Medicine, The University of Adelaide, Adelaide, Australia

Background: Philadelphia positive acute lymphoblastic leukaemia (Ph+ ALL) is a high risk ALL subtype with an aggressive clinical course. While the incorporation of tyrosine kinase inhibitors (TKIs) into the chemotherapy regimen has improved upfront treatment, the development of resistance/relapse to TKIs is still a major problem. RAS pathway mutations (*PTPN11*, *NRAS* and *KRAS*) are prevalent in relapsed B-ALL and confer poor prognosis. Therefore, new targeted therapies to overcome the resistance induced by these mutations are needed.
Aims: To investigate targeted therapies to overcome the resistance induced by activating lesions in the RAS pathway in cell line models of Ph+ ALL.
Methods: Three Ph+ ALL SUP-B15 (p190 *BCR-ABL1*) resistant cell lines were generated by long term dose escalation of imatinib (to 5 µM, SUP-B15 IR), dasatinib (to 200 nM, DR) and ponatinib (to 200 nM, PR). Drug sensitivity was measured by Annexin V and viability stain 780. RNAseq and western blot analysis were performed to identify mechanisms of resistance. The combination index (CI) was calculated by Calcusyn software.
Results: In comparison to parental, the SUP-B15 IR, DR and PR cell lines were resistant to all TKIs (imatinib, nilotinib, dasatinib and ponatinib) and to asciminib. Interestingly, SUP-B15 IR showed primary resistance to venetoclax (VEN) (LD50 = 74.94 nM vs 2.1 nM in the parental, p=0.0054), while DR and PR cell lines were sensitive (LD50 = 8.36 nM and 5.98 nM respectively) (Figure 1A). RNAseq analysis identified *KRAS* p.G12S (VAF 37%) and *NRAS* p.G12S (VAF 100%) mutations in the DR and PR cell lines respectively. Two *PTPN11* (p.A461T, VAF 63.7% and p.P491H, VAF 40.2%) mutations were identified in the catalytic domain of tyrosine-protein phosphatase in SUP-B15 IR cells. Activating lesions in PTPN11 cause an oncogenic ERK signalling, which stabilises the anti-apoptotic protein Mcl-1 and is the likely cause of venetoclax resistance in acute myeloid leukaemia. We therefore investigated the activation of the MAPK/ERK pathway and Mcl-1 by western blot. SUPB15 IR^{PTPN11mut} had increased expression of pBCR-ABL (P=0.002), pERK1/2 (P<0.0001), Mcl-1 (P<0.0001) and similar levels of Bcl-2 in comparison to the sensitive cell lines. Because treatment with imatinib alone (0, 2, 5 and 10µM) led to a dose-dependent reduction of pBCR-ABL1 (Y177), pERK1/2 and Mcl-1 without affecting Bcl-2, we investigated whether co-targeting Mcl-1 and Bcl-2 could be an effective strategy for inducing cell death in SUPB15 IR$^{PTPN11\,mut}$ cell lines. Whilst these cell lines were resistant to the Mcl-1-selective inhibitor S63845 (LD50=290 nM vs 78.5 nM for parental), combination therapy with venetoclax was synergistic in overcoming resistance (CI=0.051 for 50 nM S63845 and 5 nM venetoclax). Interestingly, combination treatment with imatinib and venetoclax (CI = 0.075 for 2 µM IM and 5 nM VEN) (Figure 1B and 1C) or asciminib and venetoclax (CI=0.032 for 2 µM asciminib and 5 nM venetoclax) was also effective in inducing cell death. This combination therapy significantly reduced pERK1/2 (P<0.0001) and Mcl-1 expression (P<0.0001) and increased cleaved-PARP level (P=0.024).
The DR^{KRASmut} and PR^{NRASmut} lines instead showed overexpression of Bcl-2 (P=0.0079 and P=0.01 respectively), but not pBCR-ABL or Mcl-1, which could explain why venetoclax alone overcame resistance in these cell lines

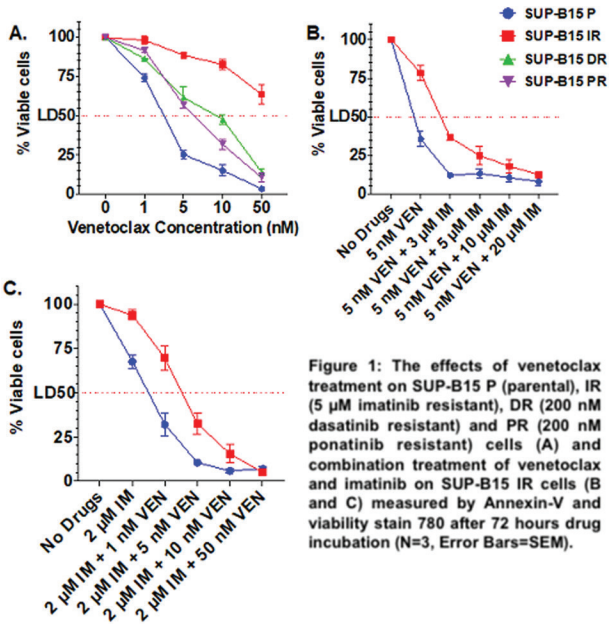

Figure 1: The effects of venetoclax treatment on SUP-B15 P (parental), IR (5 µM imatinib resistant), DR (200 nM dasatinib resistant) and PR (200 nM ponatinib resistant) cells (A) and combination treatment of venetoclax and imatinib on SUP-B15 IR cells (B and C) measured by Annexin-V and viability stain 780 after 72 hours drug incubation (N=3, Error Bars=SEM).

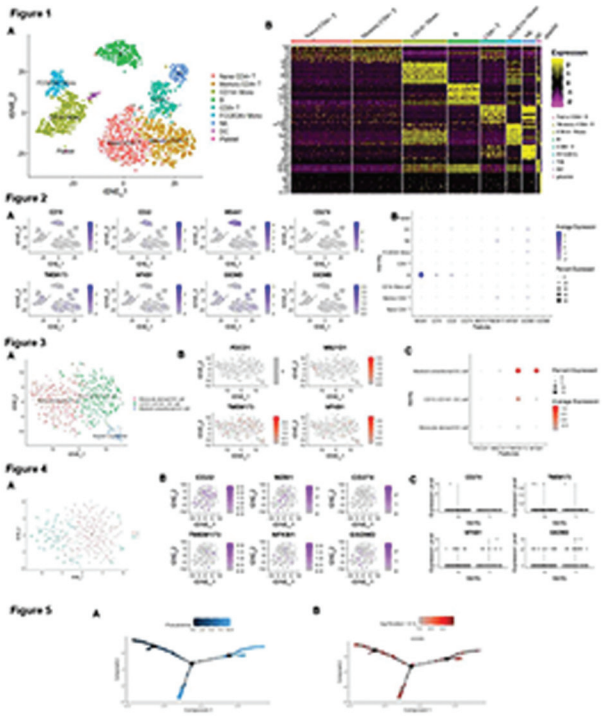
Summary/Conclusion: Combination therapy of TKIs and venetoclax could be promising for Ph+ ALL patients carrying *PTPN11* mutations and Mcl-1 overexpression. Studies are ongoing to determine the role of the mutations in *PTPN11* in the development of the resistance.

EP333 PARALLEL HIGH-THROUGHPUT PROFILING OF TRA, TRB, TRG, TRD, IGH, IGK, IGL REPERTOIRES USING ADVANCED UNBIASED MULTIPLEX PCR FOR CLONALITY ASSESSMENT IN ALL

A. Komkov [1,2,*], A. Miroshnichenkova [1,2], A. Smirnova [1], E. Volchkov [2], A. Popov [1,2], Y. Olshanskaya [1,2], Y. Lebedev [1], M. Maschan [2], D. Chudakov [1], I. Mamedov [1,2]

[1]Department of Genomics of Adaptive Immunity, Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, [2]National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation



Background: Immune receptors (T-Cell Receptor, TCR and B-Cell Receptor, BCR) repertoire profiling is one of the key sources of basic and applied immunology insights. In clinical hematology, it is used for monitoring of immune system recovery after treatment, clonality assessment and minimal residual disease monitoring in lymphoid malignancies.
Aims: The most sensitive approach for TCR and BCR repertoire profiling in clinics is DNA-based multiplex PCR with subsequent high-throughput sequencing. The key drawbacks of existing protocols are quantitative bias, inability to receive the full repertoires in low input samples and absence of one of TCR genes – TRA. Here we resolve these issues, presenting the first method for simultaneous and unbiased profiling of all existing TCR and BCR genes named «7G».
Methods: 7G system includes primers for all V and J segments of all existing immune receptor genes, including TRA, TRB, TRG, TRD, IGH, IGK, IGL. The target multiplex PCR is performed in single tube using primer mix quantitatively calibrated with original iROAR software. The sequencing is performed on any Illumina platform. TCR and BCR rearrangements extraction from sequencing data is performed with modified MiXCR software allowing for the identification of incomplete D-J, D-D and Kde rearrangements in addition to complete ones. The remaining amplification bias is detected and removed with the use of iROAR (Immune Repertoire Over Amplification Removal) software. 20 genomic DNA samples from PBMC of healthy volunteers and 20 DNA samples from bone marrow of pediatric T-ALL or B-ALL patients were used for the method testing.
Results: The developed method was successfully tested on DNA samples from both healthy individuals and leukemia patients. We were able to reconstruct repertoires of all 7 immune receptor genes in all healthy individuals. The proportions of TCR and BCR repertoire size correlates with the phisiological B and T cell ratio in the blood. The repertoires containe 95% of all possible V-J segment combinations. V and J segment usages are in a range established for the European population in previous studies. The major clonal rearrangements (comprising 20-98% of total repertoire) were detected in all leukemia samples. In B-ALL patient BM samples we detected both BCR and TCR rearrangements. T-ALL patient samples are characterized by TCR rearrangements only. TRA gene rearrangement were detected in both T-ALL (50%) and B-ALL (5%) samples. Analysis of replicates showed high reproducibility of the method (R-square=0.98). Analysis of serial dilutions of DNA from both healthy donors and ALL patients showed that sensitivity of the method is sufficient for TCR and BCR profiling in small amount of DNA up to 10 genome equivalents.
Summary/Conclusion: The possibility to simultaneously analyze all TCR and BCR gene rearrangements makes the proposed method the most cost and labor effective among all analogous methods. The sensitivity of the method allow to analyze any small lymphoid cell populations, that makes it suitable for a wide spectrum of diagnostical tasks. This work was supported by RSF grant № 20-75-10091.

EP334 SINGLE-CELL TRANSCRIPTOME PROFILING REVEALS THE EXPRESSION PATTERN OF STING IN BONE MARROW CELLS OF B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

Y. Cai [1,*], X. Zhou [1,2], X. Chen [1], T. Lu [1], M. Ding [1], J. Liu [1], Y. Zhao [1], S. Ren [1], X. Wang [1,2]

[1]Department of Hematology, Shandong Provincial Hospital Affiliated to Shandong University, [2]Department of Hematology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: B-cell acute lymphoblastic leukemia (B-ALL) is an aggressive type of acute leukemia. Despite the high complete remission (CR) rate following first-line therapy, treatment refractoriness and frequent recurrence are remained to be solved. Immunotherapy and targeted therapy have been confirmed as the effective approach for refractory and relapse (r/r) B-ALL. Although immunotherapy has achieved higher complete remission rate, remission stage can be destroyed by genomic heterogeneity and instability. Mechanistically, the occurrence of r/r B-ALL not only relied on intrinsic properties of malignant leukemic cells, but also on extrinsic protective environment provided by the tumor microenvironment (TME), especially bone marrow (BM) TME.
Aims: To clarify the transcriptome patterns in BM cells of B-ALL, single cell RNA sequencing (scRNA-seq) data was performed to be analyzed.
Methods: ScRNA-seq data of BM cells from 3 B-ALL patients were obtained from the Gene Expression Omnibus (GEO, GSE130116). Raw data was firstly processed by Seurat package. After quality control and data normalization, variable genes were extracted for dimensionality reduction. Principal component analysis (PCA) and t-distributed stochastic neighbor embedding (t-SNE) were then executed to cluster cells, following with cell types' classification. To determine the features of cell subgroups, B cell and dendritic cell (DC) were isolated respectively and followed with gene expression analysis. Finally, pseudo-time analysis functioned by Monocle package was performed to display cell development trajectory and gene expression features over time.
Results: Based on cell clustering, 9 cell types were profiled in B-ALL BM, including naïve and memory $CD4^+$ T cell, $CD14^+$ monocyte, B cell, $CD8^+$ T cell, $FCGRA3^+$monocyte, nature killer (NK) cell, DC, and platelet (Fig.1A). Top 10 marker genes in each cell cluster were exhibited in heat map, demonstrating an effective cell classification (Fig.1B). Differential gene analysis further revealed that PD-L1 (CD274) was hardly expressed on BM cells while TMEM173 (STING), NFKB1 (NF-κB) were widespread, especially on immune cells (Fig.2A). In particular, elevation of STING and NF-κB indicated that BM cells were sensitive to the type I innate immune response rather than PD-1 mediated response (Fig.2B). Previous studies had revealed that immune cells activation and tumor cell pyroptosis could be induced by STING. To analyze the features of STING and its downstream molecules in B-ALL BM cells, DCs and B cells were isolated from total cells respectively. DCs were separated into 3 subtypes, including monocyte derived DC, CD1C-CD14-DC and myeloid conventional DC (Fig.3A). Gene expression analysis confirmed that the expression of cyclic GMP-AMP synthase (cGAS), STING and NF-κB were higher than PDCD1 (PD-1) in DCs (Fig.3B, 3C). Compared with DC, although STING and PD-L1 were hardly expressed in B cells, NF-κB and pyroptotic effector (GSDMD) were partially elevated (Fig.4). In other words, GSDMD might rescue the inefficiency of PD-L1 inhibitors by inducing cell pyroptosis. Furthermore, pseudo-time analysis of B cells profiled that the expression of GSDMD gradually decreased over time (Fig.5).

Summary/Conclusion: Our study firstly profiles the features of STING and its downstream molecules in BM cells of B-ALL at a single cell resolution. Activation of STING is expected to be an effective approach in the treatment of B-ALL in the future.

EP335 MULTICOLOR FLOW CYTOMETRY REVEALS IMMUNOPHENOTYPIC SUB-POPULATIONS IN T-ALL

V. Poort [1,*], R. Hagelaar [1], E. Kroeze [1], J. Buijs-Gladdines [1], B. van Wijk [2], J. Meijerink [1]

[1]Princess Máxima Center for Pediatric Oncology, [2]Pediatric Heart Surgery, Wilhelmina Children's Hospital, University Medical Centre Utrecht, Utrecht, Netherlands

Background: Despite intensified treatment regimens, the outcome for T-ALL patients remains inferior to pre-B-ALL patients, especially for patients that are refractory to treatment or that relapse within 4 years after the start of therapy. An important prognostic factor for cancer relapse, in general, is tumor heterogeneity at the time of diagnosis. Yet, it remains unclear to what extend intra-tumor heterogeneity appears in pediatric T-ALL patients, and especially whether this reflects the heterogeneity in T-cell developmental arrest or heterogeneity in acquired mutations. T-ALL is initiated by the activation of specific oncogenic transcription factors due to chromosomal rearrangements. Activation of specific oncogenes has been linked to four different subtypes, namely: ETP-ALL/Immature, TLX, NKX2-1/TLX1, or TALLMO. The gene expression signatures and immunophenotypes of these four T-ALL entities reflect differences in developmental arrests comparable to the various developmental stages of healthy thymocytes. In the current study, we aim to decipher the immunophenotypic make-up and intra-tumor heterogeneity in T-ALL patients at diagnosis. Accessing T-ALL intra-tumor heterogeneity will further increase our insights on T-ALL disease onset and development that may drive therapy resistance and relapse.
Aims: To investigate the level of immunophenotypic heterogeneity in T-ALL patients.
Methods: We have designed and optimized a 20-parameter multi-color flow cytometry panel to identify all known thymocyte developmental stages using thymus samples of healthy donors. Thereafter this optimized panel was used to screen 28 bio-banked diagnostic T-ALL patient samples from all four T-ALL subtypes. Bioinformatic analysis using t-stochastic neighbor embedding (t-SNE) was used to visualize immunophenotypic heterogeneity in each T-ALL sample. Samples were also matched with normal thymocyte subpopulations to assess the stage of developmental arrest. Lastly, we use the FlowSOM package to differentially compare levels of heterogeneity in matched diagnostic and relapse patient samples and diagnostic PDX models.
Results: We show immunophenotypic heterogeneity in 26 of 28 diagnostic T-ALL patient samples. Within each patient, immunophenotypic subclones reflect differential sites of normal developmental arrest. Next, we observed that immunophenotypic heterogeneity is preserved in diagnostic and relapsed PDX samples, where relapse PDX samples grow out from minor subpopulations that are present already at diagnosis.
Summary/Conclusion: T-ALL patients show a high degree of immunophenotypic heterogeneity at diagnosis suggesting differential sites of developmental arrest at disease initiation. Moreover, the persistence of immunophenotypic subclones after PDX generation shows the competition of subclones under selective pressure while still maintaining heterogeneity. Our future efforts will focus on correlating the immunophenotypic heterogeneity with underlying mutations to improve our understanding of T-ALL intra-tumor heterogeneity at different multi-omic levels. Deciphering the different layers of T-ALL heterogeneity will greatly impact the current targeted treatment strategies that focus on specific mutations but may not acknowledge underlying heterogeneity.

EP336 RETROSPECTIVE ANALYSIS OF COPY NUMBER VARIATION OF IKZF1, CDKN2A/B, PAX5, EBF1, ETV6, BTG1, RB1 AND PAR1 GENES IN PEDIATRIC PATIENTS WITH B-ALL

G. Hidalgo Gómez [1,2,*], P. Velasco [3], L. Murillo [3], T. Murciano [3], N. Martínez Morgado [1], A. Blanco [1,2], B. Tazón Vega [1,2], C. Palacio Garcia [1,2], L. Gallur [1,2], S. Saumell [1,2], M. Navarrete [1,2], C. Díaz de Heredia [3], F. Bosch [1,2], M. Ortega [1,2]

[1]Hematology, Hospital Universitari Vall d'Hebron, [2]Experimental Hematology, Vall d'Hebron Institute of Oncology, [3]Pediatrics Oncology and Hematology, Hospital Universitari Vall d'Hebron, Barcelona, Spain

Background: Copy number variation (CNV) of *IKZF1*, *RB1*, *EBF1* genes and/or PAR1 region in childhood acute lymphoblastic leukemia B (B-ALL) confers a worse prognosis, with event-free survival (EFS) at 10 years of 68%. Recently, a new classification has been proposed to stratify pediatric patients with B-ALL according to cytogenetic alterations and CNV, defining four risk groups with prognostic impact.
Aims: The aim of this study has been to determine if CNV can change the prognosis determined by cytogenetic alterations in a series of pediatric patients with B-ALL.
Methods: We perform a retrospective analysis of CNV in 106 patients diagnosed with B-ALL in our hospital between January-2014 and January-2021, included in the ALL/SEHOP-PETHEMA 2013 therapeutic recommendation guidelines. We use SALSA MLPA P335 kit (MRC Holland), which includes probes for *IKZF1*, *CDKN2A/B, PAX5, EBF1, ETV6, BTG1, RB1* and PAR1 (*CRLF2* and *P2RY8*).
Results: Of the 106 cases, 55 were included in the study as they fulfilled the criteria to perform the MLPA (≥30% blasts in bone marrow and high-quality DNA). The clinical-biological characteristics are detailed in Table 1. The genes that were deleted with the highest prevalence were: *ETV6* (43%), *PAX5* (27%), *CDKN2A/B* (27%) and *IKZF1* (18%). CNV was not observed in 24% of the cases, while 26%, 16% and 34% showed 1, 2 or ≥3 CNV, respectively.
Good risk CNV profile (CNV-GR) was presented in 53% of the cases, 25 had good risk cytogenetics (CYT-GR) (45%), four intermediate risk cytogenetics (CYT-IR) (7%) and any patient showed poor risk cytogenetics (CYT-PR). Poor risk CNV (CNV-PR) was observed in 31% of the cases, of them, six patients had CYT-GR (11%), ten had CYT-IR (18%) and one had CYT-PR (2%). Age ≥10 years, phenotype, intermediate and poor cytogenetic risk, not achieving complete remission, relapse and lower EFS occurred more frequently in the CNV-PR group, with significant differences (Table 1). The 4-years EFS was 100% for CNV-GR, 80% for CNV-IR and 38% for CNV-PR.
Of the 55 patients, six relapsed, all of them within the good or intermediate cytogenetic group; five with CNV-PR and one with CNV-IR. Three cases had *CRLF2* rearrangements and a CNV profile with *IKZF1*, *CDKN2A* and *CDKN2B* deletions, among others. One case had a complex karyotype with *PAX5* rearrangement and a CNV-IR profile with *CDKN2A/B* biallelic deletion and *PAX5* deletion. Another patient had high hyperdiplod karyotype and an isolated *IKZF1* deletion. Finally, the last case had a complex karyotype with t(1;19) and a CNV-PR profile with deletion of *PAX5* and *RB1*. All of them were treated according to the ALL/SEHOP-PETHEMA 2013 protocol, five within the high-risk group and one in the good risk group.

Table 1. Clinical-biological characteristics according to the CNV risk group.

	CNV risk group*			
	CNV-GR	CNV-IR	CNV-PR	p
Patients	29	9	17

*CNV risk group: CNV of good risk (CNV-GR: no deletion of the genes studied; isolated deletions of *ETV6*, *PAX5* or *BTG1* and cases with deletions of *ETV6* accompanied by an additional isolated deletion of *BTG1*, *PAX5* or *CDKN2A/B*), poor risk CNV (CNV-PR: deletion in *IKZF1*, *PAR1*, *EBF1* or *RB1*) and CNV of intermediate risk (CNV-IR: any other pattern not mentioned above) (Hamadeh et al. 2019).
Δ Cytogenetic risk group: good (CYT-GR; *ETV6-RUNX1*, high hyperdiploidy), poor (CYT-PR; *BCR-ABL1*, *KMT2A* rearrangements, near haploidy, low hypodiploidy, iAMP21 or t(17; 19)) and intermediate (CYT-IR; all other cases with altered or normal cytogenetics).
It has been considered significant when p <0.05

Summary/Conclusion: Despite it is a small cohort, the results confirm that the combination of conventional cytogenetic risk and CNV analysis

allows a better classification of the biological risk of the disease. We can identify a group with a very good prognosis (CYT-GR and CNV-GR) with 4-years EFS of 100% and a group with higher probability of relapse (CYT-GR/IR and CNV-PR) with 4-years EFS of 38%.

EP337 GENOME-SCALE SCREENING WITH CRISPR/CAS9 FOR PROLIFERATION RELATED GENES IN ACUTE LYMPHOBLASTIC LEUKEMIA

J. Li [1], P. Jiang [1], Y. Huang [1], L. Wang [1], J. Hu [1,*]

[1]*Fujian Institute of Hematology, Fujian Provincial Key Laboratory of Hematology, Fujian Medical University Union Hospital, Fuzhou, China*

Background: Abnormal proliferation of leukemia cells is one of the characteristics of acute lymphoblastic leukemia (ALL). But at present, we don't fully understand the molecular mechanism of ALL cell proliferation, and there is no research about ALL proliferation-related genes from the whole genome level.
Aims: Here, CRISPR/Cas9-mediated genome-wide knockout negative screening method was used to screen ALL proliferation-related genes on genome-wide level.
Methods: After Genome-scale CRISPR-Cas9 knockout (GeCKO) v2 library plasmid amplification, lentivirus packaging, virus infection, Jurkat and Nalm6 cells at day 0 and day 14 were collected for high-throughput sequencing, and two biological replicates were performed. Then gene ontology (GO) and pathway enrichment analysis were conducted by DAVID database to analyze the proliferation-related genes obtained from the screening. And one of the genes was selected as a candidate gene. After knockout of candidate gene using CRISPR/Cas9 technology, MTS method was performed to detect cell proliferation, and flow cytometry was used to detect cell cycle. Using the database to explore the expression of candidate gene and the relationship with the prognosis of ALL.
Results: After successful establishment of the screening model, Jurkat and Nalm6 cells of two screening time point were collected for high-throughput sequencing, and the data met the quality control standards. A total of 155 proliferation-related genes were screened. The GO analysis showed that proliferation-related genes were mainly related to translation and post-transcriptional modification, while pathway enrichment analysis was closely related to metabolic pathways. PTPTM1, which was closely related to metabolism, was selected for further verification. The cell proliferation ability of Jurkat and Nalm6 cells were significantly reduced, and the cell cycle G1 phase was blocked after PTPMT1 being knocked out. Through database analysis, it is found that PTPMT1 was generally highly expressed in tumor cell lines. Comparing with normal people, PTPMT1 had higher expression levels in ALL. In children with B-ALL, those with high PTPMT1 expression have a worse prognosis.
Summary/Conclusion: In this study, CRISPR/Cas9-mediated genome-wide screening system was used to screen out 155 proliferation-related genes of Jurkat and Nalm6 cells. PTPMT1, one of the candidate genes, can inhibit the cell proliferation and block G1 phase of Jurkat and Nalm6 cells, and its expression level associated with the prognosis in children ALL.

EP338 DOXORUBICIN/NUCLEOPHOSMIN BINDING PROTEIN-CONJUGATED

NANOPARTICLE (DOX-PMS-NPMBP) ENHANCES ANTI-LEUKEMIA ACTIVITY IN ACUTE LYMPHOBLASTIC LEUKEMIA CELLS IN VITRO AND IN VIVO
Background: Acute lymphoblastic leukemia (ALL) is an aggressive malignancy. Adults with ALL have more than 50% relapse rates. We have previously validated that overexpression of nucleophosmin (NPM) is involved in the multidrug resistance (MDR) development during ALL; and a synthetically engineered recombinant NPM binding protein (NPMBP) has been developed in our group; NPMBP and doxorubicin (DOX) can be conjugated in a nanoparticle-based drug delivery system named DOX-PMs-NPMBP to counteract MDR during ALL.
Aims: Here, we evaluated the antileukemia potential of DOX-PMs-NPMBP in resistant ALL cells. This study demonstrates that DOX-PMs-NPMBP significantly enhances chemosensitivity to DOX in ALL cells. Despite at variable concentrations, both resistant and primary ALL cells from relapsed patients were sensitive to DOX-PMs-NPMBP.
Methods: In detail, the half maximal inhibitory concentration (IC50) values of DOX-PMs-NPMBP were between 1.6- and 7.0-fold lower than those of DOX in cell lines and primary ALL cells, respectively; and apoptotic cells ratio was over 2-fold higher in DOX-PMs-NPMBP than DOX. Mechanistically, p53-driven apoptosis induction and cell cycle arrest seem central in DOX-PMs-NPMBP-induced anti-leukemia effects. Moreover, DOX-PMs-NPMBP significantly inhibited tumor growth and prolonged mouse survival of ALL xenograft models; and no systemic toxicity occurrence was observed after treatment during follow-up.
Results: In conclusion, these data indicate that DOX-PMs-NPMBP may significantly exert growth inhibition and apoptosis induction, and markedly improve DOX antileukemia activity in resistant ALL cells. This novel drug delivery system may be valuable to develop as a new therapeutic strategy against multidrug resistant ALL.
Summary/Conclusion: Acute lymphoblastic leukemia (ALL) is an aggressive malignancy. Adults with ALL have more than 50% relapse rates. We have previously validated that overexpression of nucleophosmin (NPM) is involved in the multidrug resistance (MDR) development during ALL; and a synthetically engineered recombinant NPM binding protein (NPMBP) has been developed in our group; NPMBP and doxorubicin (DOX) can be conjugated in a nanoparticle-based drug delivery system named DOX-PMs-NPMBP to counteract MDR during ALL. Here, we evaluated the antileukemia potential of DOX-PMs-NPMBP in resistant ALL cells. This study demonstrates that DOX-PMs-NPMBP significantly enhances chemosensitivity to DOX in ALL cells. Despite at variable concentrations, both resistant and primary ALL cells from relapsed patients were sensitive to DOX-PMs-NPMBP. In detail, the half maximal inhibitory concentration (IC50) values of DOX-PMs-NPMBP were between 1.6- and 7.0-fold lower than those of DOX in cell lines and primary ALL cells, respectively; and apoptotic cells ratio was over 2-fold higher in DOX-PMs-NPMBP than DOX. Mechanistically, p53-driven apoptosis induction and cell cycle arrest seem central in DOX-PMs-NPMBP-induced anti-leukemia effects. Moreover, DOX-PMs-NPMBP significantly inhibited tumor growth and prolonged mouse survival of ALL xenograft models; and no systemic toxicity occurrence was observed after treatment during follow-up. In conclusion, these data indicate that DOX-PMs-NPMBP may significantly exert growth inhibition and apoptosis induction, and markedly improve DOX antileukemia activity in resistant ALL cells. This novel drug delivery system may be valuable to develop as a new therapeutic strategy against multidrug resistant ALL.

EP339 THE LABORATORY EXAMINATION CHARACTERISTICS AND CLINICAL OUTCOMES OF T(12;17)(P13;Q21)/TAF15-ZNF384 POSITIVE ACUTE LEUKEMIA

T. Wang [1,2,*], X. Chen [1,3], X. Ma [1], J. Ni [1], Y. Zhang [1], X. Wang [1], H. Zhang [1], S. Xu [1], L. Yuan [1], P. Cao [1], H. Liu [1,2,3]

[1]*Division of Laboratory Medicine, Hebei Yanda Lu Daopei Hospital, Langfang,* [2]*Division of Pathology & Laboratory Medicine, Beijing Lu Daopei Hospital,* [3]*Beijing Lu Daopei Institute of Hematology, Beijing, China*

Background: TAF15-ZNF384 is a recurrent but rare fusion gene in leukemia and lacks relevant reports.
Aims: To investigate the laboratory characteristics and clinical outcomes of acute leukemia (AL) with t(12;17)(p13;q21)/TAF15-ZNF384.
Methods: Laboratory examination results and clinical records of t(12;17)(p13;q21)/TAF15-ZNF384 positive cases admitted to Hebei Yanda Ludaopei Hospital from Feb.1, 2009 to Nov. 30, 2020 were retrieved and analyzed, including G-banding karyotyping, flow cytometry, fluorescence in situ hybridization (FISH, ZNF384 separation probe), RNA sequencing (RNA-seq), PCR, gene panel mutation screening, as well as routine inspections.
Results: A total of 12 positive cases were enrolled in this cohort, including 8 males and 4 females, with a median age of 25.5 (3-49) years. Eight cases had complete blood count records at the time of disease onset, and the white blood cell count ranged 1.58-38×10^9/L. Immunophenotyping showed that 11 cases were acute B lymphocytic leukemia (B-ALL) with myeloid antigen expression, and 1 was mixed-phenotype AL with B/myeloid lineage markers. All cases expressed CD19, CD34, CD13 and/or CD33, 10 cases expressed CD22, 7 cases expressed or partially expressed CD10, and only 1 case weakly expressed CD20. Nine cases

were positive for t(12;17)(p13;q21) at the disease onset or relapse, and 7 of them with additional chromosomal abnormalities (CAs). Among the 3 cases with t(12;17)(p13;q21) negative, 1 was normal karyotype, 1 was complex karyotype (CK) with t(11;17)(q21;q21) and ectopic 12p12, and 1 was t(5;17))(p12;p11.2) with additional CAs. All of them were tested positive for TAF15-ZNF384 transcript by RNA-seq and PCR. FISH detection showed 9 cases with typical ZNF384 separation signals, 1 case lost 1 ZNF384 signal, 1 CK case lost partial of one ZNF384 signal, and 1 normal karyotype case also showed a normal FISH signal. RNA-seq and PCR analysis identified TAF15 exon6-ZNF384 exon3 transcript in these 3 cases who manifested atypical FISH signal. TAF15-ZNF384 transcripts were analyzed by RNA-seq and PCR in 7 cases, there were 4 TAF15 exon6-ZNF384 exon3, 2 TAF15 exon9-ZNF384 exon3, and 1 TAF15 exon11-ZNF384 exon3 (Fig.1 A). Ten cases underwent 86 gene panel mutation analyses, 8 of them carried FLT3-PTPN11-CBL-NRAS/KRAS-NF1 pathway mutations, and other mutation genes included ETV6, TET2, and KMT2D. Induction and consolidation chemotherapy mainly include VDCLP/CVDP/CAM/VDLP/asparaginase and methotrexate (Fig.1 B). The overall response to induction chemotherapy was favorable, except for one case, which failed to achieve complete remission (CR). However, 9 cases relapsed during consolidation chemotherapy, and 5 of them relapsed within 8 months after diagnosis. Four cases underwent allogeneic hematopoietic stem cell transplantation (allo-HSCT). Two cases who underwent salvage HSCT relapsed 3 months and 6 months after transplantation, respectively; the other 2 cases had been followed up after HSCT and survived without relapse for 63 months and 13 months, respectively.

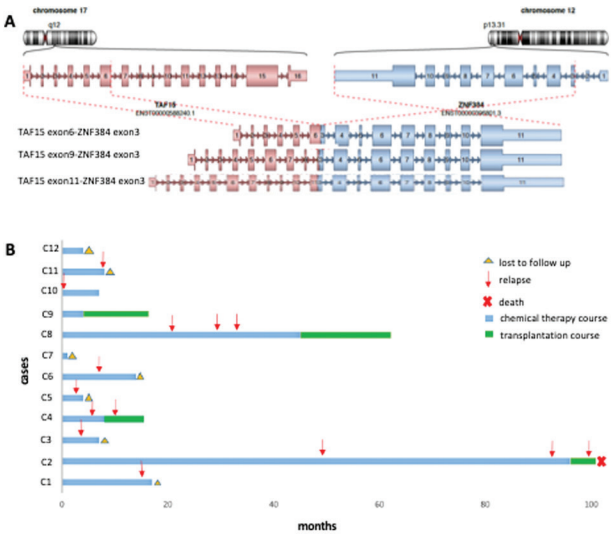

Fig. 1 Transcript isoforms (A) and clinical course (B) of acute leukemia cases with t(12;17)(p13;q21)/TAF15-ZNF384 positive.

Summary/Conclusion: AL cases with (12;17)(p13;q21)/TAF15-ZNF384 have unique genetic and immunophenotypic characteristics. They are often accompanied by FLT3-PTPN11-CBL-NRAS/KRAS-NF1 pathway mutations. There is a significant t(12;17)(p13;q21) negative rate, which may be attributed to CK and cryptic ectopic; RNA-seq and PCR analysis can help to ensure the detection rate. The immunophenotype is mostly B-ALL with myeloid antigen expression. The general response to conventional chemotherapy is favorable, but prone to relapse. Cases of this sub-entity may benefit from allo-HSCT at the first CR.

EP340 GENOMIC HETEROGENEITY CONTRIBUTED TO THE DIFFERENT PROGNOSIS OF ADULT AND PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

Y. Chen [1,*], Y. Huang [1], J. Wen [1], J. Hu [1]

[1]*Department of Hematology, Fujian Institute of Hematology, Fuzhou, China*

Background: Prognosis of acute lymphoblastic leukemia (ALL) in adults is inferior than children. Hence, ALL is still a challenging disease to be cured in adult population. Aberrant genetic alterations has been observed previously in ALL, while the patterns of differential gene alteration have not much been comprehensively determined in the adult and pediatric ALL on a genome-wide scale.

Aims: This study attempted to investigate the biological differences in genomic profiling between the adults and children with ALL, and the relationship between the genomic heterogeneity and prognosis.

Methods: 39 adults and 54 children patients with ALL in our institution were studied. All patients were de novo and treated with standard chemotherapy regimens. Clinical data were collected on all patients. Exome sequencing and anaiysis was performed. The genomic mutation was calculated. The driver genes of the mutated genes were selected from the COSMIC platform. The overlapped gene was subjected to Gene ontology and pathway enrichment analyses and mapped the PPI network.

Results: The results showed the similar common mutation types but the increased prevalence of genetic alterations in adult ALL. The median number of detected gene mutations was 19 (range: 1–53) per sample in adult ALL and 4.5 (range: 1–19) in pediatric ALL(P<0.001). A significant correlation between the increased number of gene mutations and age was found (R^2 = 0.3096, P<0.001). 67 and 53 driver genes were identified in adult and pediatric ALL samples, respectively. The SETD2 and TTN mutations were significantly enriched in adult ALL. While the KRAS, ARID1A and CREBBP mutations were significantly enriched in pediatric ALL. (P<0.05). 67 and 53 driver genes were identified in adult and pediatric ALL samples, respectively. Using integrated genomic analysis, we identified 4 functional pathways recurrently mutated in adult ALL: transcriptional regulation, VEGF signaling pathway, T cell receptor signaling pathway, and Fc epsilon RI signaling pathway(P<0.05), 5 in pediatric ALL: Transcriptional regulation, PI3K-AKT-mTOR signaling, JAK-STAT signaling, NOTCH1 signaling, FoxO signaling pathway(P<0.05). Using cytoHubba analysis, among the 53 nodes, NRAS, IDH1, WT1, FLT3, NF1, DNMT3A, CEBPA, PTPN11, TP53, ASXL1, the ten central node genes with degree >10, were considered as hub driver genes in the PPI network of adult ALL. While as to the pediatric ALL, MYC, EZH2, CDKN2A, CREBBP, SMARCA4, ATRX, NF1, EP300, NOTCH1, BRCA1, the ten central node genes with degree >10, were considered as hub driver genes in the PPI network.The incidence of relapse was 33.3% and 7.7% in the adult and pediatric ALL, respectively(P=0.003). The overall survival(OS) and relapse free survival (RFS) of adult ALL were poorer than pediatric ALL(P=0.003, P<0.001, respectively).

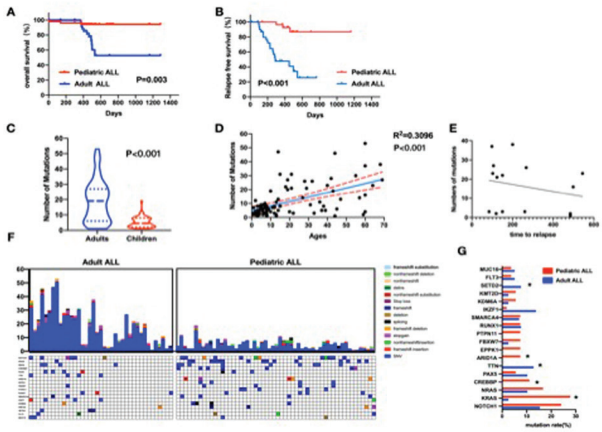

Figure. The genomic heterogeneity and survival of adult and pediatric ALL. (A, B) Survival of adult and pediatric ALL. The OS and RFS of adult ALL were poorer than pediatric ALL (P=0.003, P<001). (C) Violin plot of mutation counts in adult and children (P=0.001). The median number of detected gene mutations was 19 (range: 1–53) per sample in adult ALL and 4.5(range: 1–19) in pediatric ALL. (D)Correlation between mutation counts and age of ALL patients. A significant correlation between the number of gene mutations and age was found (R2 = 0.3096, P<0.001). (E)Correlation between mutation counts and times to relapse of ALL patients.(F)The genomic landscape of adult and pediatric ALL. The mutational heatmap indicated the most recurrently altered genes in the 93 ALL samples. Color coded by the genetic alteration types. (G) The percent of mutated genes in adult and pediatric ALL. The mutation rate was different in the adult and pediatric ALL.

Summary/Conclusion: This genomic landscape enhanced the understanding of the biological differences of ALL between the two populations and provided a clue for novel therapeutic approaches.

Acute lymphoblastic leukemia - Clinical

EP341 ZUMA-4 PHASE 1 LONG-TERM RESULTS: KTE-X19 CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY IN PEDIATRIC/ADOLESCENT PATIENTS WITH RELAPSED/ REFRACTORY B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

A. S. Wayne [1,*], V. Huynh [2], N. Hijiya [3], R. Rouce [4], P. A. Brown [5], J. Krueger [6], C. L. Kitko [7], E. D. Ziga [8], M. L. Hermiston [9], M. K. Richards [10], A. Baruchel [11], J. Benoun [12], L. Zhou [12], L. Goyal [12], R. Vezan [12], R. Jain [12], B. K. Masouleh [12], D. W. Lee [13]

[1]Children's Hospital Los Angeles, USC Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA, [2]CHOC Children's Hospital, Orange, CA, [3]Lurie Children's Hospital of Chicago, Chicago, IL, [4]Texas Children's Hospital, Houston, TX, [5]Johns Hopkins University School of Medicine, Baltimore, MD, United States, [6]The Hospital for Sick Children, University of Toronto, Toronto, Ontario, Canada, [7]Vanderbilt University Medical Center, Nashville, TN, [8]University of Miami Miller School of Medicine, Miami, FL, [9]University of California San Francisco, San Francisco, CA, [10]Children's Minnesota, Minneapolis, MN, United States, [11]Hôpital Universitaire Robert Debré (APHP) and Université de Paris, Paris, France, [12]Kite, a Gilead Company, Santa Monica, CA, [13]University of Virginia, Charlottesville, VA, United States

Background: We present long-term Phase 1 results of ZUMA-4, a study of KTE-X19 autologous anti-CD19 chimeric antigen receptor (CAR) T-cell therapy in pediatric/adolescent patients with relapsed/refractory B-cell acute lymphoblastic leukemia (R/R B-ALL).
Aims: To evaluate the long-term safety and efficacy of KTE-X19 in pediatric/adolescent patients with R/R B-ALL.
Methods: Patients (aged 2–21 years) with R/R B-ALL (Philadelphia chromosome-positive allowed) and >5% bone marrow blasts received 2×10^6 or 1×10^6 CAR T cells/kg after conditioning chemotherapy. The primary endpoint was incidence of dose-limiting toxicities. KTE-X19 formulation was optimized in a second 1×10^6-dose group using a lower infusion volume (40-mL vs 68-mL).
Results: As of 9/9/2020, the median follow-up was 36.1 months (range, 24.0–53.9), with 24 patients (median age, 14 years [range, 3–20]) of 31 enrolled receiving KTE-X19. The median time from leukapheresis to KTE-X19 product release was 14 days. Four patients received 2×10^6 cells/kg, with no dose-limiting toxicities in evaluable patients (n=3). Additionally, the 1×10^6 cells/kg dose level was explored (68-mL, n=11; 40-mL, n=9). Overall, Grade ≥3 adverse events occurred in 100% of patients, most commonly hypotension (50%) and anemia (42%). Rates of Grade ≥3 neurologic events/cytokine release syndrome were 25%/75% (2×10^6), 27%/27% (1×10^6 [68-mL]), and 11%/22% (1×10^6 [40-mL]). All 4 Grade 5 events (B-ALL, n=2; disseminated mucormycosis, n=1; *Escherichia* sepsis, n=1) were considered unrelated to KTE-X19. Overall complete remission rates (complete remission plus complete remission with incomplete hematologic recovery) were 75%, 64%, and 67% in the 2×10^6, 1×10^6 (68-mL), and 1×10^6 (40-mL) groups, respectively. Of responding patients, 100% had undetectable minimal residual disease. Sixteen patients (2×10^6, n=2; 1×10^6 [68-mL], n=8; 1×10^6 [40-mL], n=6) underwent subsequent allogeneic stem cell transplantation (median, 2.3 months post–KTE-X19). In the 2×10^6, 1×10^6 (68-mL), and 1×10^6 (40-mL) groups, the medians for duration of response (months) were 4.14, 10.68, and not reached, respectively. The median overall survival was not reached for the 1×10^6 groups (24-month rate: 68-mL, 73%; 40-mL, 88%) and was 8 months for the 2×10^6 group. In the 1×10^6 40-mL group (selected as Phase 2 dose), the median peak (range) of CAR gene copies per microgram of DNA in blood was 2.5×10^4 (0–2.5×10^5); among responders in this group, CAR T cells were undetectable by 3 months post-infusion.
Summary/Conclusion: Treatment with KTE-X19 at the recommended Phase 2 dose led to high complete remission rates, with the median overall survival not yet reached and a manageable safety profile. Phase 2 of ZUMA-4 is enrolling pediatric patients with R/R B-ALL or non-Hodgkin lymphoma, including patients with minimal residual disease-positive disease and early relapse (<18 months) after first-line therapy.

EP342 ANTIBODIES TO PEGYLATED E. COLI ASPARAGINASE PREDICT THE OCCURRENCE OF HYPERSENSITIVITY REACTIONS IN HIGH-RISK PATIENTS UNDERGOING THE CONSOLIDATION PHASE OF THE AIEOP-BFM ALL 2009 PROTOCOL.

C. Lanvers-Kaminsky [1,*], C. Rizzari [2], G. Würthwein [1], J. Gerss [3], A. Möricke [4], M. Zimmermann [5], P. Smisek [6], M. Zucchetti [7], C. Nath [8], A. Attarbaschi [9], B. Schild [10], T. König [10], M. Schrappe [4], J. Boos [1]

[1]Department of Pediatric Hematology and Oncology, University Hospital of Münster, Münster, Germany, [2]Pediatric Hematology-Oncology Unit, Department of Pediatrics, University of Milano-Bicocca, MBBM Foundation, Monza, Italy, [3]Institute of Biostatistics and Clinical Research, University of Muenster, Münster, [4]Department of Pediatrics, University Medical Center Schleswig-Holstein, Kiel, [5]Department of Pediatric Hematology and Oncology, Medical School Hannover, Hannover, Germany, [6]Department of Pediatric Hematology and Oncology, University Hospital Motol, Praha, Czech Republic, [7]Laboratory of Cancer Pharmacology, Department of Oncology, Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy, [8]Departments of Biochemistry and Oncology, The Children's Hospital at Westmead, Sydney Pharmacy School, University of Sydney, Sydney, Australia, [9]Department of Pediatric Hematology and Oncology, St. Anna Children's Hospital, Department of Pediatrics and Adolescent Medicine, Medical University of Vienna, Vienna, Austria, [10]medac GmbH, Wedel, Germany

Background: In the AIEOP-BFM ALL 2009 study, hypersensitivity reactions (HSR) to pegylated E.coli asparaginase (PEG-ASNase) were most commonly reported in high-risk (HR) patients.[1] After induction with 2 doses of PEG-ASNase 2 weeks apart, HR patients - in contrast to standard and intermediate-risk patients - received 3 doses of PEG-ASNase, one in each of the three HR blocks (HR1-3), followed by three additional doses, one in each of the three subsequent PIII blocks (PIII 1-3).
Aims: We analyzed antibodies to native E.coli ASNase (anti-E.coli ASNase IgG/IgM), PEG-ASNase (anti-PEG-ASNase IgG/IgM) and polyethylenglycol (PEG) (anti-PEG IgG and anti-PEG IgM) in serum prior to administration of PEG-ASNase in the HR and PIII blocks and assessed the predictive value for HSR of the antibodies to PEG-ASNase.
Methods: A total of 563 samples from 202 patients were analyzed. 46 patients developed HSR (CTCAE grade ≥1) to PEG-ASNase (14 patients in HR1, 27 patients in HR2, 5 patients in HR3 and none in PIII).
Results: In each HR block pre-existing anti-PEG-IgG, anti-PEG-IgM, anti-PEG-ASNase-IgG/IgM or anti-E.coli-ASNase-IgG/IgM significantly increased the risk of HSR to PEG-ASNase ($p<0.05$, Fisher test). No HSRs were observed in the PIII blocks, which coincided with an overall low prevalence of pre-existing antibodies (1-4.5%) compared to the HR blocks where the prevalence was 13-26%.
The areas under the receiver operating characteristic (ROC) curve regarding the predictive accuracy of pre-existing antibodies for subsequent HSR to PEG-ASNase (Table 1) showed high predictivity of pre-existing antibodies for HSR in HR2. Among the four antibodies, pre-existing anti-PEG IgG predicted HRS with the highest sensitivity (true positive rate: 80 % for HR1 and HR3 and 100 % for HR2) and specificity (true negative rate: of 94 %, 96 % and 98 % for HR1, HR2 and HR3, respectively).
Table 1: Areas under the receiver operating characteristic (ROC) curves for pre-existing antibodies and HSR in HR blocks. The closer the AUC is to 1, the higher the predictive accuracy of a test.

	HSR to PEG-ASNase in		
pre-existing antibody	**HR1**	**HR2**	**HR3**
anti-E.coli ASNase IgG/IgM	0.63	0.78	0.89
anti-PEG-ASNase IgG/IgM	0.63	0.92	0.80
anti-PEG IgG	0.87	0.98	0.89
anti-PEG IgM	0.82	0.97	0.78

Summary/Conclusion: In the AIEOP-BFM ALL 2009 study, we observed a highly accurate predictivity of anti-PEG IgG antibodies for HSR in HR patients. This finding might be useful for future clinical decisions.

Background: EORTC-CLG 58081 was designed as a translational-observational study for the identification of prognostic factors in children ≥1 year with Ph-negative ALL. Treatment recommendations were built on the best arms of the randomized phase 3 trial EORTC-CLG 58951: prednisolone (PRED) 60 mg/m^2 in induction for all risk groups but for average risk (AR) T-ALL (dexamethasone (DEX) 10 mg/m^2) and AR2 B cell precursor (BCP)-ALL (DEX 6mg/m^2). The AR2 group comprised patients (pts) with BCP-ALL (≥100x10^9/L WBC or CNS or extramedullary involvement at diagnosis) and pts with T-ALL (no CNS involvement or VHR features). Very low risk (VLR) pts had high-hyperdiploïdy, WBC<10x10^9/l, age <10 years, and no very high risk (VHR) features (D8 blood blasts≥1x10^9/l, adverse genetic features, no CR or MRD≥10^{-2} at end of induction (EOI)). The risk stratification was left unchanged, except that MRD≥10^{-3} at the end of consolidation was added to VHR criterion in the 58081 study.
Aims: To evaluate event-free survival (EFS), (1) overall and according to each risk group in the 58081 as compared with the 58951 study (reference arm with PRED), and (2) from CR according to the EOI MRD level.
Methods: Between 2011 and 2017, 833 pts were enrolled in the 58081 study. The median follow-up was 5.5 yrs. Primary endpoint was EFS from date of first CR until relapse or death in CR; lack of CR achievement was an EFS event at T0.
Results: Results are presented in the Table. The 5-yr EFS rate were similar in the 2 studies, overall and in the BCP ALL subgroup, but in the T-ALL pts it was significantly higher in the 58081 study than in the 58951 study. Comparable EFS were obtained in both studies for AR1 and VHR pts (76.5% of the total). The EFS of VLR group was shorter in the 58081 study. In contrast, the EFS of AR2 pts significantly increased in the 58081 study, overall, and similarly in both subgroups, as same as the overall survival of AR2 patients which was 95.4% for the 58081 *vs* 88.3% for the 58951 (HR: 0.35; 95%CI 0.09-1.27, *P*=0.02). The 5-yr EFS for pts who reached CR was shorter for those with MRD≥10^{-2} at EOI (68.4%, HR=3.23) and those with 10^{-3}≤MRD<10^{-2} (55.2%, HR=5.63) as compared to pts with MRD<10^{-3} (89.8%).
Table
*: 95% CI

	58081		58951		
	n	5-yr EFS, % (95% CI)	n	5-yr EFS, % (95% CI)	HR (58081 vs 58951) (99% CI)
Overall	833	84.8 (82.0-87.2)	951	83.6 (81.1-85.9)	0.96 (0.76-1.21)*
Immuno-phenotyping					
BCP-ALL	693	84.3 (81.2-86.9)	803	84.9 (82.2-87.3)	1.07 (0.76-1.50)
T-ALL	140	87.3 (80.3-92.0)	148	76.6 (68.9-82.7)	0.58 (0.28-1.22)
EORTC Risk Group					
VLR	75	86.0 (74.7-92.5)	120	94.0 (87.7-97.1)	2.47 (0.75-8.19)
AR1	510	85.6 (82.0-88.5)	583	85.1 (81.8-87.8)	0.99 (0.65-1.48)
AR2	120	93.0 (86.5-96.5)	150	78.2 (70.6-84.1)	0.33 (0.13-0.88)
BCP-ALL	47	91.3 (78.5-96.7)	56	72.2 (57.9-82.3)	0.30 (0.07-1.26)
T-ALL	73	94.1 (85.0-97.8)	94	81.7 (72.2-88.2)	0.37 (0.10-1.38)
Initial VHR	128	73.5 (64.8-80.4)	97	71.7 (61.4-79.6)	0.96 (0.50-1.87)

Summary/Conclusion: The poor EFS of patients with intermediate MRD at EOI confirm the value of this early timepoint to distinguish patients with high relapse risk. The disappointing results obtained for patients in the VLR group despite unchanged therapy and a more stringent definition of risk (age 1-9 yrs) are difficult to interpret but should prompt caution about therapeutic de-escalation. The improved EFS in the AR2 group is most likely due to the use of DXM, in induction for all pts and in VCR-DEX pulses in pts with BCP-ALL, together with improved MRD-based stratification. This allowed a dramatic EFS improvement in T-ALL subgroup, which for the first time and although using a risk stratification based solely on response to treatment outperforms that of BCP-ALL.

EP344 CD22-TAGETED CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY FOR ADULTS WITH REFRACTORY OR RELAPSED B ACUTE LYMPHOBLASTIC LEUKEMIA

Z. Feng [1,*], L. Hui [1]

[1]Heamatology, Beijing Boren Hospital, Beijing, China

Background: Although CD19-specific chimeric antigen receptor (CAR) T-cell therapy has achieved high complete remission rates in relapsed/refractory B-cell lymphoblastic leukemia (r/r B-ALL), some patients relapse after CAR-T. This has become an urgent problem to be solved. CD22 isalso expressed in most cases of B-ALL. We conducted a CD22 CAR T-cell therapy in 19 relapsed orrefractory (r/r) B-ALL adult patients, including 18 patients who failed from previous CD19 CAR T-cell therapy and 1 patient without CD19 CAR T-cell therapy because of lossing CD19 antigen.
Aims: To evaluate the treatment efficacy of CD22 CAR T-cell for adults with refractory or relapsed B acute lymphoblastic leukemia.
Methods: From July 2017 to October 2020, a total of 19 treated adult r/r B-ALL patients were enrolled. The patients were hematological relapse. Eighteen patients had accepted prior CD19 CAR-T therapy, and relapsed with CD22 antigen expression identified by flow cytometer (FCM), 1 case had not a history of CD19 CAR-T therapy because of lossing CD19 antigen. CAR-T cells were produced by lentiviral vectors encoding second generation CARs composed of CD3ζ and 4-1BB. All patients accepted fludarabine and/or cyclophosphamide before infusion. The treatment effect was evaluated on day 30 after cell infusion, MRD was quantified by FCM and PCR for fusion gene. The last follow-up was as of October 24, 2020.
Results: The median age of 19 patients was 30 (range, 18-63) years, including 7 underwent allogeneic transplantation. All patients received ≥1×105 /kg CD22-CAR T cells.Complete remission (CR) or CR with incomplete count recovery (CRi) was achieved in 15 of 19 patients (78.9%) that could be evaluated on day 30 after infusion.Cytokine release syndrome (CRS) occurred in all patients,But most patients only experienced mild cytokine-release syndrome and neurotoxicity.In 15 CR and CRi patients, 8 patients followed by allogeneic hematopoietic cell transplantation after CD22 CAR-T, These patients remained in remission at 4 to 39.7 months after transplantation, another 7 patients did not undergo HCT, 1 relapsed at 1 months,6 of them remained in remission at 4 to 26.5 months after infusion. Among 4 NR patients, 3 died of disease progression, and 1 accepted salvage transplantation who had survived for 4.6 months.
Summary/Conclusion: CD22 CAR T-cells was highly effective in inducing remission in adult r/r B-ALL patients,transplantation followed-by CD22-CART allowed CR patients to obtain a remission of 4-39.7months.

EP345 EXTRAMEDULLARY RELAPSE AND DISEASE PROGRESSION AFTER BLINATUMOMAB THERAPY FOR TREATMENT OF ACUTE LYMPHOBLASTIC LEUKEMIA

I. Aldoss [1,*], S. Otoukesh [1], J. Zhang [2], S. Mokhtari [3], M. Al Malki [1], A. Salhotra [1], H. Ali [1], A. Aribi [1], K. Sandhu [1], S. Arslan [1], F. Stewart [1], P. Curtin [1], A. Artz [1], R. Nakamura [1], G. Marcucci [1], S. Forman [1], A. Stein [1], V. Pullarkat [1]

[1]Hematology/HCT, [2]Computational and Quantitative Medicine-BRI, [3]Clinical Translational Project Development, City of Hope, Duarte, United States

Background: Blinatumomab (BLINA) administration induces high response rates for treatment of relapsed/refractory (R/R) and persistent minimal residual disease (MRD+) acute lymphoblastic leukemia (ALL). A few reports have addressed the unique pattern of BLINA-failure during ALL therapy, manifesting either as extramedullary (EM) progression/relapse (P/R) or loss of CD19 antigen expression. However, EM P/R ALL phenomena during BLINA therapy remains largely underrecognized and is not fully understood.

Aims: We perform this study to identify the prevalence and factors influencing EM R/P in ALL following BLINA therapy.
Methods: We retrospectively reviewed outcomes of adults with B-cell ALL who were treated with BLINA at City of Hope between 2013 and 2021, and analyzed potential factors impacting response and EM P/R following BLINA therapy.
Results: We identified 132 patients treated with BLINA for either R/R (n= 103; 78%) or MRD+ (n= 29; 22%) B cell ALL. Median age at the time of BLINA treatment was 39 years (range:18-88). Higher response rate to BLINA was associated with treatment in the MRD+ ALL setting (p=0.008), lower bone marrow (BM) blast burden in R/R setting (p=0.029), no history of prior EM disease (p=0.001), and fewer lines of pre-BLINA therapies (p=0.048). In multivariable analysis, only lower pre-BLINA BM blast burden (p=0.049) and the lack of EM disease history (p=0.019) remained significantly associated with higher response to BLINA. BLINA failure (defined as initial progression in non-responders or post BLINA relapse in responders) was noted in 89 patients. At the time of BLINA failure, 38 (43%) patients P/R EM, including 24 patients as isolated EM disease without BM involvement. 17 (36%) patients of those were refractory to BLINA and 21 (50%) responders to BLINA who relapsed subsequently progressed EM. History of EM involvement (53% vs. 24%, p= 0.005) and P/R with CD19+ ALL (97% vs. 74%, p= 0.012) were associated with higher risk for EM P/R at the time of BLINA failure. Factors did not impact EM P/R include; response to BLINA, pre-BLINA stem cell transplant, disease setting (MRD vs. R/R), or pre-BLINA BM blast burden. EM P/R involving the central nervous system (CNS) occurred in 15 (39%) patients, and more frequently encountered in responders at the time of relapse (n= 12; 57%) compared to refractory patients at the time of progression (n= 3; 18%).

Table 1. Factors impacted ALL EMD relapse/progression post BLINA

	EMD R/P	No EMD R/P	P-value
Number	38	51	
Median age (range)	40 (18-74)	39 (19-88)	0.478
Sex			0.517
Male	22 (58)	26 (51)	
Female	16 (42)	25 (49)	
Response to blina			0.188
YES	21 (55)	21 (41)	
NO	17 (45)	30 (59)	
Prior alloHCT			0.432
YES	6 (16)	12 (24)	
NO	32 (84)	39 (76)	
History of EMD			0.005
YES	20 (53)	12 (24)	
NO	18 (47)	39 (76)	
Disease setting			0.547
MRD	7 (18)	7 (14)	
R/R	31 (82)	44 (86)	
Median blast% pre BLINA	70 (0.01-100)	70 (0.01-95)	0.803
N of prior lines of therapies	2 (1-5)	2 (1-5)	0.935
CD19 expression at P/R			
N of evaluable			
Positive	29	46	
Negative	28 (97)	34 (74)	0.012
	1 (3)	12 (26)	

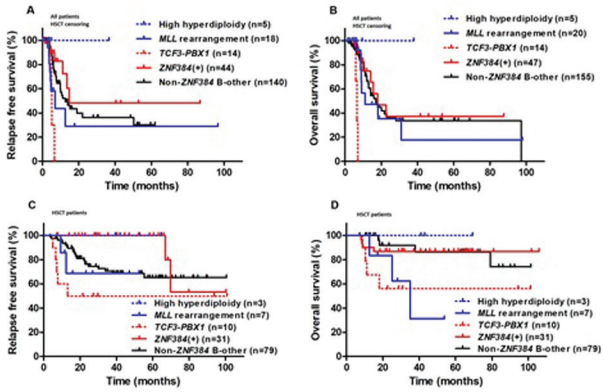
Summary/Conclusion: In conclusion, EM P/R is common during BLINA therapy in ALL, especially in responders; since half of them relapsed EM (+/-BM). History of EM disease during ALL course predicted inferior response to BLINA and higher risk for P/R EM. CNS P/R is frequently observed at the time of BLINA failure, and the majority of extramedullary P/R cases retained CD19 expression. Therefore, BLINA therapy should be cautiously used in patients with history of EM disease and patients should be closely monitored for EM progression during treatment.

EP346 THE SALVAGE TREATMENT OF HUMANIZED-CD19 CAR-T CELLS FOR RELAPSED B-ALL AFTER PRIOR MURINIZED-CD19 CAR-T CELL THERAPY

L. An [1], S. Liu [1,*], Y. Lin [1], D. Zhao [1], D. Liu [1], H. Yan [1], Z. Lin [1], H. Guan [1], C. Tong [1]

[1]*Beijing Boren Hospital, Beijing, China*

Background: Although CD19-specific chimeric antigen receptor (CAR) T-cell therapy has achieved high complete remission rates in relapsed/refractory B-cell lymphoblastic leukemia (r/r B-ALL), some patients relapse after CAR-T. For CD19-positive relapsed B-ALL, reinfusion of CD19-CART cells is a salvage treatment option. At present, most of CD19 CART cell products are murinized (mCD19-CART), reinfusion of mCD19-CART may not be effective owing to anti-mouse scFv antibody caused by mCD19-CAR. In this study, we used humanized CD19-CART (hCD19-CART) cells to treat relapsed B-ALL patients who had previously accepted mCD19-CART cells.
Aims: To evaluate the treatment efficacy of hCD19-CART cells for B-ALL patients relapsing after mCD19-CART therapy.
Methods: From January 2019 to October 2020, a total of 18 heavily treated adult and pediatric r/r B-ALL patients were enrolled. Seventeen patients were hematological relapse or with extramedullary diseases (EMD, n=6), 1 was minimal residual disease (MRD) relapse. All patients had accepted prior murinized-CD19 CAR-T therapy (once, n=15; twice, n=3), and relapsed with CD19 antigen expression identified by flow cytometer (FCM), 11 cases had a history of CD22 CAR-T therapy. CAR-T cells were produced by lentiviral vectors encoding second generation CARs composed of CD3ζ and 4-1BB. All patients accepted fludarabine and/or cyclophosphamide before cell infusion. The treatment effect was evaluated on day 30 after cell infusion, MRD was quantified by FCM and PCR for fusion gene, EMDs were evaluated by PET-CT/CT/ultrasound. The last follow-up was as of December 31, 2020. The informed consents were obtained in accordance with the Declaration of Helsinki.
Results: The median age of 18 patients was 19 (range, 4-49) years, including 10 adults and 8 children younger than 18 years old, 2 with BCR-ABL fusion gene and 2 with TP53 gene mutation, 10 underwent allogeneic transplantation. The median dose of infused CAR-T cells was 5.0 x 10^5/kg (range, 1.0-18.0 x 10^5/kg). Cytokine release syndrome (CRS) occurred in all patients, including 14 with grade 1, 3 with grade 2 and 1 with grade 4 CRS. Except for supportive care, 9 patients were administered steroids, 3 were given additional plasmapheresis. There were no neurotoxicity and treatment-related death.
On day 30 after T-cell infusion, 12 (67%) cases achieved complete remission (CR, 11 MRD-negative CR) and 6 had no response (NR). In 12 CR patients, 10 followed by allogeneic hematopoietic cell transplantation (allo-HCT, 3 were second HCT) in 1.3-2.3 months after CAR-T, 9 (9/10, 90%) patients remained in CR with a median remission period of 6.7 months (2.4-22 months), only 1 relapsed at 3 months after HCT. Another 2 CR patients did not undergo HCT, 1 relapsed at 9.9 months and 1 remained in CR for 8.9 months. Among 6 NR patients, 3 died of disease progression, and 3 accepted salvage transplantation (all were second HCT), of them, 2 relapsed at 4 and 8.5 months after HCT, and 1 had survived for 9.2 months.
Summary/Conclusion: The salvage treatment of humanized CD19-CART cells resulted in a 67% CR in CD19-positive relapsed B-ALL patients who had a prior murinized CD19-CART therapy, and transplantation followed-by hCD19-CART allowed 90% CR patients to obtain a remission of 2.4-22 months. The prognosis of NR patients was still poor.



EP347 THE PROGNOSTIC SIGNIFICANCE OF ZNF384 FUSIONS IN ADULT PH-NEGATIVE B CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

Y.-Z. Qin [1,*], Q. Jiang [1], L.-P. Xu [1], Y. Wang [1], H. Jiang [1], F.-T. Dao [1], W.-M. Chen [1], X.-S. Zhao [1], Y.-R. Liu [1], X.-H. Zhang [1], K.-Y. Liu [1], X.-J. Huang [1]

[1]*Peking University Institute of Hematology, Peking University People's Hospital, BEIJING, China*

Background: Novel recurrent fusion gene types such as zinc finger protein 384 (*ZNF384*) fusions have been identified in B-cell precursor acute lymphoblastic leukemia (BCP-ALL) with the application of next-generation sequencing technologies. However, the comprehensive large-scale clinical cohort study for clarifying their prognostic significance remains scarce to date.
Aims: To comprehensively evaluate the prognostic role of *ZNF384* fusions in adult BCP-ALL.
Methods: A total of 242 consecutive adult Ph-negative BCP-ALL patients treated in our institute were retrospectively screened *ZNF384* fusions at diagnosis by multiplex real time quantitative PCR.
Results: *ZNF384* fusions were identified in 47 patients (19.4%), 38 had *EP300-ZNF384*, 5 had *CREBBP-ZNF384*, 2 had *TCF3-ZNF384*, 1 had *TAF15-ZNF384* and 1 had *EWSR1-ZNF384*. All patients with *ZNF384* fusions belonged to B-other ALL (having no high hyperdiploid karyotype, *BCR-ABL1*, *TCF3-PBX1*, *ETV6-RUNX1* or *MLL* rearrangement).

In the whole cohort, patients with *ZNF384* fusions had significantly higher 3-year relapse-free-survival (RFS) and tended to have a higher 3-year overall survival (OS) than those with no *ZNF384* fusions (80.1% vs 52.5%, *P* = 0.011; 67.6% vs 54.0%, *P* = 0.10). For both patients receiving chemotherapy alone and when patients who received allo-HSCT were censored at the time of transplantation (Figure A, B), patients with *ZNF384* fusions had both similar RFS rate and similar OS rate to B-other ALL patients with no *ZNF384* fusions (RFS: P =0.94 and 0.30; OS: P =0.94 and 0.51). Furthermore, for patients receiving chemotherapy alone, patients with *ZNF384* fusions had both similar RFS and similar OS to those with *MLL* rearrangement and *TCF3-PBX1* fusion transcript, respectively (RFS: *P* = 0.45 and 0.13; OS: *P* = 0.80 and 0.45). When patients who received allo-HSCT were censored at the time of transplantation, patients with *ZNF384* fusions had significantly higher 3-year RFS and OS than those with *TCF3-PBX1* fusion transcript (P=0.0093 and 0.0009), and significantly higher 3-year RFS than and similar 3-year OS to those with *MLL* rearrangement (P=0.036 and 0.80). For patients receiving transplantation (Figure C, D), those with *ZNF384* fusions had significantly higher 3-year RFS than B-other ALL patients with no *ZNF384* fusions and their OS were similar (P = 0.022 and 0.24). Furthermore, patients with *ZNF384* fusions had significantly higher 3-year RFS and tended to have significant high OS than those with *MLL* rearrangement and *TCF3-PBX1* fusion transcript, respectively (RFS: *P* = 0.0026 and 0.0038; OS: *P* = 0.062 and 0.065). In addition, *ZNF384* fusion was not an independent prognostic factor for both RFS and OS in both adult Ph-negative BCP-ALL and B-other patients.

Summary/Conclusion: *ZNF384* fusion is common in adult BCP-ALL, which may define a new group from BCP-ALL containing no classical fusion transcript with better prognosis through receiving allo-HSCT.

EP348 ACUTE NEUROLOGICAL ADVERSE EVENTS DURING THE TREATMENT FOR CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

S. Spadini [1,*], A. Di Paola [2], V. Conter [3], C. Rizzari [3], A. Colombini [3], F. Canonico [4], D. Silvestri [5], D. Onofrillo [6], R. Parasole [7], P. Stellato [7], R. Mura [8], E. Barisone [9], S. Cesaro [10], O. Ziino [11], A. Biffi [1], R. Manara [12], M. C. Putti [1]

Santobono-Pausilipon, Napoli, [8]Paediatric Haematology and Oncology, Ospedale Pediatrico Microcitemico, Cagliari, [9]Division of Pediatric Onco-Hematology, Regina Margherita Children's Hospital, Torino, [10]Pediatric Hematology-Oncology, Woman and Child Hospital, University Hospital, Verona, [11]Department of Pediatric Hemato-Oncology, ARNAS Ospedali Civico, G Di Cristina, Palermo, [12]Neuroradiology, University Hospital, Padova, Italy

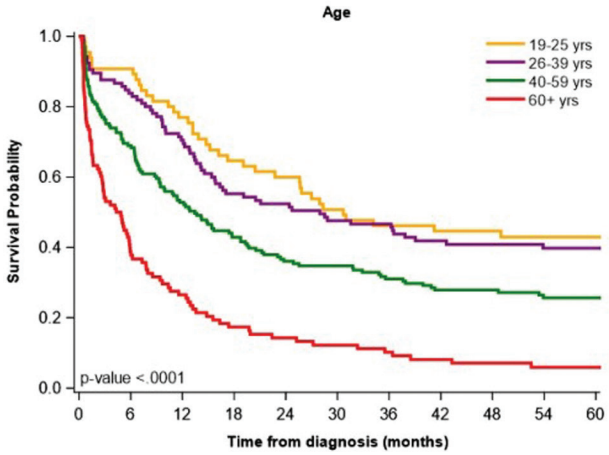
Background: In pediatric acute leukemias, balance of treatment results and toxic events has been addressed by the Ponte di Legno Toxicity Working Group (PdLTWG), stressing the need of correct reporting. Acute neurological adverse events (ANAE) on the central nervous system during chemotherapy for Acute Lymphoblastic Leukemia (ALL) are frequent (5,4%), but definitions of clinical and radiological criteria are challenging.
Aims: We collected the ANAE recorded during chemotherapy treatment in children enrolled in ALL AIEOP (Associazione Italiana di Emato-Oncologia Pediatrica) protocols to evaluate their incidence, clinical and radiological characteristics and severity.
Methods: Among patients enrolled in ALL AIEOP protocols, 115 ANAE were reported by 27 Centres from 2009 to 2018. Demographic, hematological and treatment data were obtained from the AIEOP Web database. These CNS ANAE were analyzed: seizures, Posterior Reversible leukoEncephalopathy Syndrome (PRES), Methotrexate Stroke-Like-Syndrome (MTX SLS), depressed level of consciousness (DLC). Vascular, infectious and peripheral ANAE were excluded. When available, MRI performed within 7 days from the NAE and follow-up images were evaluated centrally by two pediatric neuroradiologists blinded to clinical data.
Results: One hundred fifteen ANAE were reported in 113 children. The clinical diagnosis was decided by the reporting center and confirmed centrally, based on reporting details.
The most frequently reported event was PRES (42 patients), which occurred mostly (one third) in high risk leukemia patients and mostly during induction and delayed intensification. Seizures were reported in 25 patients, mostly during induction phase. MTX-SLS occurred in 14 patients, predominantly older ones (median 11 y); almost all these events occurred during consolidation or delayed intensification. ANAE were severe (CTCAE ≥3) in 64% of patients but long-term outcomes were rarely reported (9%). One patient died (0.8%). Stopping or reducing chemotherapy occurred in 36% of patients.
MRI images from 67 events were available for centralized analysis. MRI was unremarkable in 22 cases, mostly patients presenting with seizures (n=17). Abnormal MRI (n=37) outlined three main radiological patterns: PRES (32%); MTX-SLS (22%); non-specific leukopathy (9%). Central evaluation confirmed PRES in 18/19 cases, 1 case was considered MTX-SLS; diagnosis changed from DLC to PRES in 1 case. MTX-SLS were confirmed in 9/13 cases; 4 more cases of MTX-SLS were found, changing the diagnosis from PRES (1 case) and seizure (3 cases). Leukopathy was identified in patients with seizures (n=2), DLC (n=2) and MTX-SLS (n=1). On follow-up scans, 43% of the patients displayed radiological sequelae: cortico-subcortical atrophic changes, leukopathy and in one case hippocampal sclerosis. Sequelae were statistically related (p<0,05) with holo-hemispheric watershed pattern in PRES and with FLAIR hyperintensity in MTX-SLS; their clinical meaning requires further observation.
Summary/Conclusion: This study confirms the need for accurate reporting and centralized clinical and radiological review of ANAE, to allow modulations of chemotherapy on evidence criteria.

EP349 THE EPIDEMIOLOGY, TREATMENT PATTERNS AND SURVIVAL OF ADULT ACUTE LYMPHOBLASTIC LEUKAEMIA (ALL) IN TAIWAN, 2002-2017

H.-H. Huang [1,*], M.-Y. Lu [2], C.-M. Chen [3], M.-T. Chen [3], H.-M. Chen [4], B.-S. Ko [1,5], F.-Y. Hsiao [3,6,7]

[1]Division of Hematology, Department of Internal Medicine, [2]Division of Hematology, Department of Pediatrics, National Taiwan University Hospital, [3]Graduate Institute of Clinical Pharmacy, College of Medicine, [4]Health Data Research Center, National Taiwan University, [5]Department of Hematological Oncology, National Taiwan University Cancer Center, [6]School of Pharmacy, College of Medicine, National Taiwan University, [7]Department of Pharmacy, National Taiwan University Hospital, Taipei City, Taiwan, Republic of China

Background: The clinical features, treatments, and survivals of adult ALL patients are very different from the paediatric ALL patients. In the past decades, tyrosine kinase inhibitors (TKI) demonstrate clinical benefits in *Philadelphia* chromosome-positive ALL patients. Nevertheless, data on the epidemiology, treatment patterns, and survivals of adult ALL patients in the era of TKI are very limited, particularly in the Asia Pacific region.
Aims: The aim of this study was to investigate the incidence, treatment patterns, and survivals of adult ALL patients in Taiwan.
Methods: We conducted a population-based retrospective cohort study and used data from the Taiwan Cancer Registry Database (TCRD), the National Health Insurance Research Database, and the National Death Registry. From the TCRD, we identified patients older than 18 years with newly diagnosed ALL from January 2002 to December 2017. The crude



and adjusted annual incident rates of adult ALL were reported. Among all identified adult ALL patients, we further included the patients with newly diagnosed B-ALL from 2009 to 2015 for further analysis of treatment patterns and survivals. We stratified the newly diagnosed B-ALL patients by the use of TKI (TKI-containing treatments or TKI-free treatments). The clinical features, treatment patterns, and clinical outcomes including complete remission rate, refractory rate, and survival of the two groups were reported.

Results: We identified 1800 adult ALL patients between 2002 and 2016. The incidence of adult ALL was 0.69 cases per 100,000 person-years with male predominance. The median age at diagnosis was 44 years old. The incidence rates of adult ALL was highest in the age group of 19-25 and 60+ with 0.8 and 0.88 cases per 100,000 person-years, respectively.

Among 765 adult patients with newly diagnosed B-cell ALL during 2009 and 2015, 429(56.1%) patients received TKI-free treatments, 223(29.2%) patients received TKI-containing treatments, and others did not receive standard chemotherapies. The median age of patients receiving TKI-free treatments and TKI-containing treatments was 46 and 48 years old, respectively. Age is an important prognostic factor in adult B-ALL patients. The median overall survival (mOS) was 37.51, 32.36, 17.59, and 3.56 months in the age groups of 19-25 years, 26-39 years, 40-59 years and 60+ years respectively.

In the TKI-free treatment group, the median time to induction treatment was 7 days. 217 (50.6%) patients achieved complete remission, 40(9.3%) encountered refractory disease, and 172 (40.1%) died within 9 months after the initiation of induction chemotherapy. The median followed up duration was 30.2 months with a cumulative mortality of 74.8%, and 128(29.8%) patients underwent allogeneic hematopoietic stem cell transplantation (allo-HSCT). The mOS was 13.67(95% CI: 11.87-16.33) months in the TKI-free treatment group.

In the TKI-containing treatment group, the median time to induction treatment was 16 days. 210(94.2%) patients received imatinib and 13(5.8%) patients received dasatinib as the first line TKI. The median followed up duration was 36.2 months with a cumulative mortality of 64.6%. 90(40.4%) patients underwent allo-HSCT. The mOS was 26.89 (95% CI: 19.51-33.97) months in the TKI treatment group.

Summary/Conclusion: This study is the first population-based study conducted in Asia providing comprehensive evidence of epidemiology, treatment patterns and survival of adult ALL. Compared with patients receiving TKI-free treatments, patients receiving TKI-containing treatments had better survival and higher proportion of them underwent allo-HSCT.

EP350 CHARACTERISTICS AND OUTCOME OF ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA AND COVID 19 INFECTION IN THE FIRST VS. SECOND EPIDEMIC WAVE IN SPAIN: A STUDY FROM THE PETHEMA AND GETH GROUPS

Background: SARS-CoV-2 infection has bimodal distribution in Europe with a 1st wave in March-June 2020 and a 2nd in September 2020-February 2021. In cancer patients (pts) the lethality of COVID-19 infection was 25%>35% in the 1st wave. Comparison on impact of COVID-19 infection in the 1st vs. 2nd waves have not been performed in ALL.

Aims: We compared the frequency, clinical characteristics and outcome of adults with ALL and COVID-19 infection in the 1st vs. 2nd waves in Spain.

Methods: Between March 1, 2020-May 31, 2020, and between September 12, 2020- January 12, 2021 (date of vaccination onset in Spain), a registry from the PETHEMA (Programa Español de Tratamientos en Hematologia) and GETH (Grupo Español de Trasplante Hematopoyético y Terapia Celular) groups prospectively recruited adult ALL pts with COVID-19 infection confirmed by PCR. Demographic and clinical characteristics of ALL and COVID-19 infection, comorbidities, treatment and outcome were collected and compared in the two periods. In addition, prognostic factors for survival were analyzed.

Results: Fifty-six patients were collected in 82 centers contacted, 4 of them being excluded (COVID infection >3 yr. after end of ALL therapy [n=3] and Burkitt lymphoma [n=1]). Twenty-eight pts were collected in the 1st wave and 24 in the 2nd. Median age was 46 (range 20-83), (34 pts [65%] >40 yr). Comorbidities were present in 18 pts (35%). ALL was of B-cell precursors in 38 pts (74%) (Ph+ in 8, 15%). Thirty-one pts (60%) were under frontline treatment, 16 (31%) in rescue, 1 (2%) palliative and 4 (7%) had recently finished the therapy. Eight pts had received allogeneic HSCT (5 of them at COVID-19 infection diagnosis), CAR T (n=1, 2 yr prior to COVID-19 infection) or received immunotherapy (inotuzumab, n=6, 2 at COVID-19 infection, and blinatumomab, n=1, prior to COVID-19 infection). Eleven pts were receiving immunosuppressive drugs at COVID infection (fludarabine in 6, among others).

No significant differences were observed in ALL characteristics in the two COVID-19 waves, except for a significantly higher number of patients on first line therapy in the second wave, and a higher frequency of severe neutropenia and lymphocytopenia in the first wave. COVID19 therapy was different in the two periods, with significantly higher use of hydroxychloroquine, remdesivir and lopinavir-ritonavir in the first wave and corticosteroids in the second wave. No significant differences were observed in need of oxygen support (12 vs. 8 pts), ICU requirement (7 vs. 4 pts), days in ICU (medians 16 vs. 21) and time to COVID infection recovery (medians 17 vs. 13 days). Seventeen patients (33%) died (11 vs. 6), being death attributed to COVID infection in 15 (29%), without significant differences in the 100-day survival probabilities (Figure 1). By multivariable analysis only comorbidities at COVID-19 infection had a negative impact on survival (HR: 5.358 [95% CI: 1.875; 15.313]).

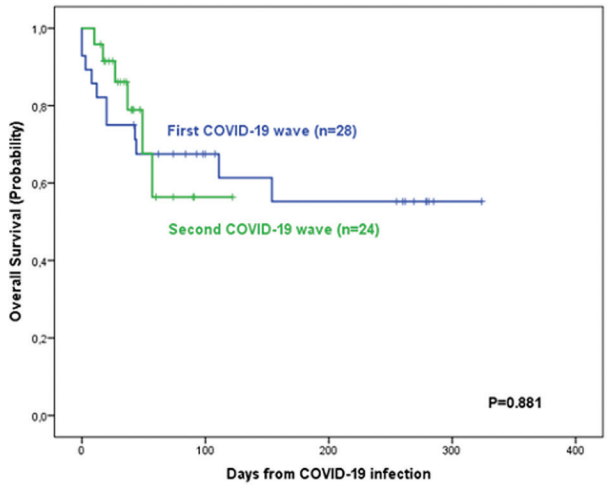

Figure 1. Survival probability of COVID-19 infection according to the period studied.

Summary/Conclusion: COVID-19 infection was frequent in ALL pts, especially in those with advanced age and under ALL frontline or rescue therapy. The frequency of severe COVID-19 infection and mortality were high, with negative impact of comorbidities on survival. No significant differences were observed in ALL characteristics, response to therapy and outcome in the two waves of COVID infection. The poor outcome of COVID infection makes vaccination a priority for ALL patients in this pandemic period.

Supported in part by 2017 SGR288 (GRC) Generalitat de Catalunya and "la Caixa" Foundation.

EP351 FAVORABLE OUTCOMES AFTER NOVEL THERAPIES FOR RELAPSE/REFRACTORY PHILADELPHIA-LIKE ACUTE LYMPHOBLASTIC LEUKEMIA

I. Aldoss [1,*], M. Afkhami [2], D. Yang [3], S. Mokhtari [4], V. Tomasian [2], Z. Gu [1], M. Al Malki [1], A. Salhotra [1], H. Ali [1], A. Aribi [1], S. Khaled [1], K. Sandhu [1], S. Arslan [1], P. Koller [1], B. Ball [1], I. Amnam [1], S. Otoukesh [1], F. Stewart [1], P. Curtin [1], A. Artz [1], A. Stein [1], R. Pillai [2], G. Marcucci [1], S. Forman [1], V. Pullarkat [1], R. Nakamura [1]

[1]Hematology/HCT, [2]Departement of Pathology, [3]Computational and Quantitative Medicine-BRI, [4]Clinical Translational Project Development, City of Hope, Duarte, United States

Background: Philadelphia-like (Ph-like) acute lymphoblastic leukemia (ALL) is a high-risk disease associated with high rates of persistent minimal residual disease (MRD+) and relapse rate when treated with conventional chemotherapy. Several novel therapies such as blinatumomab (BLINA), inotuzumab (INO), CAR T cell therapy (CAR), and venetoclax-based regimens have shown promising activity in treatment of relapsed/refractory (r/b) B-cell ALL regardless of prior chemo-refractoriness or high-risk genetics; but the impact of Ph-like genotype on response to novel therapies in r/r ALL remains largely unknown.

Aims: Here, we retrospectively analyzed CR/CRi rates in adults with Ph-like ALL who were treated at City of Hope with novel agents from 2013 to 2021.

Methods: To identify the Ph-like status, we utilized our Anchored Multiplex PCR™-based multi-gene NGS assay designed to detect known and novel fusions, and elevated gene expression levels using a proprietary algorithm in ALL.

Results: We identified 67 adult patients with Ph-like ALL treated with 84 novel therapies. The median age was 33 years (range: 18-71) and the majority were males (n=45; 67%) and Hispanics (n=57; 85%). CRLF2r was detected in 49 (73%) patients. BLINA was administered to 43 (64%) and 6 (9%) patients for overt relapsed/refractory (r/r) or persistent MRD+ ALL, respectively. Eighteen patients (27%) received INO, 13 (19%) received CD19CAR and 4 (6%) were treated with venetoclax-navitoclax. Median number of prior lines of therapies were 2, 3, and 4 for patients treated with BLINA, INO, and CAR, respectively. Only one patient who was treated with BLINA received prior INO, while 72% and 6% of patients treated with INO had BLINA and CAR before, and 85% and 38% of patients treated with CAR had BLINA and INO before, respectively.

Complete remission/complete remission with incomplete hematologic recovery (CR/Cri) rates were 64%, 89% and 85% in patients treated with BLINA, INO and CAR, respectively. MRD- rate was 93%, 70%, and 100% in responders who received BLINA, INO, and Car, respectively. Once in CR, 57%, 56% and 55% of responders to BLINA, INO and CAR underwent allogeneic hematopoietic cell transplantation (HCT) consolidation. 12-month relapse-free survival for responders from the time of BLINA, INO and CAR response were 67%, 41% and 75% (p=0.54), respectively. All 6 patients with Ph-like ALL treated with BLINA in MRD setting achieved MRD, of whom 5 received consolidation with HCT; and 3 out of 4 patients treated with venetoclax-navitoclax achieved CR/CRi and only one received HCT afterward.

	Blinatumomab (r/r)	Blinatumomab (MRD)	Inotuzumab	CAR T cell	Venetoclax-Navitoclax
Number	43	6	18	13	4
Median age (range)	36 (18-71)	35 (23-49)	32 (22-71)	25 (19-52)	36 (24-48)
Ph-like subtype					
CRLF2r	29 (67)	4 (67)	14 (78)	10 (77)	4 (100)
Non-CRLF2r	14 (33)	2 (33)	4 (22)	3 (23)	0
Prior alloHCT					
Yes	9 (21)	0	5 (28)	7 (54)	2 (50)
No	34 (79)	6 (100)	13 (72)	6 (46)	2 (50)
Median lines of therapies (range)	2 (0-5)	1 (1-2)	3 (1-6)	4 (2-7)	5 (4-5)
Median BM blast% (range)	69 (5-95)	0.2 (0.01-0.5)	82.5 (15-95)	60 (0.5-85)	50 (0.2-99)
Prior Novel therapy					
Blinatumomab	NA	NA	13 (72)	11 (85)	4 (100)
Inotuzumab	1 (2)	0	NA	5 (38)	4 (100)
CAR T cell	0	0	1 (6)	NA	1 (25)
Venetoclax	0	0	0	2 (15)	NA
CR/CRi; N (%)	28 (65)	6 (100)	16 (89)	11 (85)	3 (75)
MRD-negative response	13/14 (93)	6/6 (100)	7/10 (70)	9/9 (100)	2/3 (67)
Post response alloHCT	16/28 (57)	5/6 (83)	9/16 (56)	6/11 (55)	1/3 (33)

Summary/Conclusion: In conclusion, treatment of r/r Ph-like ALL with novel therapies resulted in excellent CR/CRi and MRD- response rates and successfully transitioned over half of patients to HCT. Response rates to INO and CAR were high despite most patients in these treatment groups had prior treatment with BLINA. Integrating these novel therapies in the frontline setting could improve outcomes of Ph-like ALL and overcome their refractoriness to conventional chemotherapy.

EP352 OUTCOME OF ADULTS WITH REFRACTORY OR RELAPSED (R/R) T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (T-ALL) INCLUDED IN MINIMAL RESIDUAL DISEASE (MRD)-ORIENTED TRIALS

Background: Despite a high complete remission (CR) rate is obtained with frontline therapy, relapses are a frequent event in T-ALL, with limited salvage options to date. Studies on outcome of patients (pts) with R/R T-ALL treated with MRD-oriented therapies are scarce.
Aims: We analyzed the outcome of pts with R/R T-ALL included in two successive MRD-oriented trials (ALL-AR-03 and ALL-HR-11) from the Spanish PETHEMA Group.
Methods: Retrospective study of R/R T-ALL adults diagnosed between 2003 and 2019 and included in the ALL-AR-03 (NCT00853008) and ALL-HR-11 (NCT01540812) protocols. The clinical characteristics at baseline and at relapse, the salvage therapies and outcomes (CR and OS) were analyzed, and a study of prognostic factors for response to rescue regimens and OS was performed.
Results: Seventy-four pts were identified (ALL-HR03 [n=36], ALL HR-11 [n=38], refractory [n=5], and relapsed [n=69]). Median age (range) at diagnosis was 31 (16-58) yrs., 57 were males (77%), with CNS involvement in 9 (12%), mediastinal mass 32 (43%), PB blast count 30.6 x10^9/L (0-284), early T-cell precursor (ETP) 17 (25%), pre-T 11 (16%), cortical 27 (40%), mature 13 (19%), T-unspecified 5. Post-induction-1 MRD level ≥0.1% was found in 13/56 pts (23%), and ≥0.01%: in 20/53 (38%). Fourteen pts (19%) received 2nd induction therapy (resistant disease after induction-1 [n=9], MRD≥0.1% after induction-1 [n=5]). Allogeneic-HSCT was performed in CR1 to 11/69 pts (16%). Interval CR1-relapse: 9.4 (0.1-36.7) months.
Relapse was located in BM (n=29, 42%), BM+extramedullary (n=20, 29%) and extramedullary (n=20, 29%). CNS involvement at relapse was found in 23 pts (33%, isolated in 11 cases). Median number of salvage lineages was 2 (range: 1-5). The most frequent salvage-1 schedules were FLAG-Ida (n=41, 56%), HyperCVAD (n=9, 12%) and nelarabine (n=6, 8%) (other schedules: 18 pts). Second CR was attained in 33/74 pts (44%), being higher for patients treated with FLAG-Ida vs. the remaining regimens (23/41 (56%) vs 10/33 (30%), p=0.026). The CR rate and outcome were not significantly different on comparison of ETP vs. the remaining T-ALL subtypes. Good morphologic and/or MRD response after Induction-1 in first line therapy and salvage treatment with FLAG-IDA were independently associated with CR after salvage therapy (OR: 5.077 [95%CI 1.275-20.218] and 2.879 [95%CI 1.052-7.876], respectively). Allogeneic-HSCT was performed to 35 pts (29 in CR2). Sixty pts died (progression: 34, toxicity of rescue regimens: 15, TRM: 11). Median OS (95%CI) was 6.2 (3.9-8.6) months, with a 5yr OS probability of 18% (9%>27%). By multivariable analysis, only the interval between CR1 and relapse >12 months and CR after salvage-1 therapy emerged as favorable prognostic factors for OS (HR 2.071, 95%CI: 1.185-3.622 and HR 3.227, 95% CI: 1.859-5.780, respectively) (Figure 1 A-B).

Figure 1. Overall survival according to first CR duration (A) and to response to salvage-1 therapy (B).

Summary/Conclusion: This study shows poor outcome of adults with R/R T-ALL, with CR to first salvage therapy of 44% and median OS of 6 months. Good cytological or MRD response to first line therapy and FLAG-Ida rescue therapy were associated with better response to salvage-1 treatment, whereas late relapse and response to salvage-1 regimen were associated with better OS. This study highlights the unmet need for novel effective therapies for T-ALL.

EP353 A REGISTRY-BASED, OBSERVATIONAL SAFETY STUDY OF INOTUZUMAB OZOGAMICIN (INO) IN PATIENTS WITH B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) PROCEEDING TO HEMATOPOIETIC STEM CELL TRANSPLANT (HSCT)

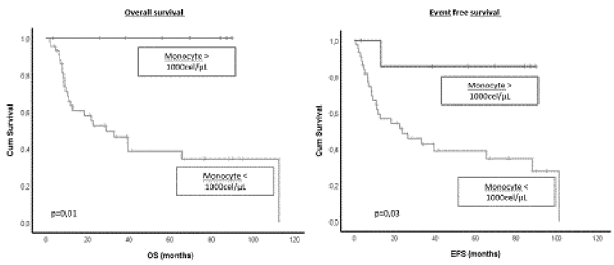
D. Marks [1,*], M. de Lima [2], P. Kebriaei [3], F. Lanza [4], C. Cho [5], S. Giralt [5], G. Popradi [6], M. T. Hemmer [7], X. Zhang [8], R. Shah [9], V. Welch [9], E. Vandendries [10], M. Stelljes [11], W. Saber [7]

[1]University Hospitals Bristol, Bristol, United Kingdom, [2]UH Cleveland Medical Center, Cleveland OH, [3]The University of Texas MD Anderson Cancer Center, Houston, TX, United States, [4]Ospedale di Ravenna, Ravenna, Italy, [5]Memorial Sloan Kettering Cancer Center, New York, NY, United States, [6]McGill University Health Centre, Montreal, QC, Canada, [7]CIBMTR, Medical College of Wisconsin, Milwaukee, WI, United States, [8]Pfizer Inc, Shanghai, China, [9]Pfizer Inc, New York, NY, [10]Pfizer Inc, Cambridge, MA, United States, [11]Universitätsklinikum Münster, Münster, Germany

Background: InO is a CD22-directed antibody-drug conjugate indicated for treatment of relapsed/refractory (R/R) ALL. InO has been associated with hepatotoxicity and hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS), particularly post-HSCT.
Aims: To assess toxicity in patients (pts) with ALL who received InO prior to HSCT, utilizing registry data from the Center for International Blood and Marrow Transplant Research (CIBMTR).
Methods: CIBMTR patient data are being collected for a 5-year period after US approval of InO (Aug 2017 – Aug 2022). Data from US pts age ≥18 y treated with InO who proceeded to allogeneic HSCT were included. Using interim data at 3 y, we evaluated post-HSCT outcomes, including clinical status, overall survival, transplant-related (non-relapse) mortality (NRM), relapse, death after relapse (time from HSCT to death after the first 28 d from any cause with prior relapse/progression post-HSCT), and investigator-defined adverse events, including hepatic VOD/SOS. All statistical analyses are descriptive.
Results: Data accrued from 18 Aug 2017 to 17 Aug 2020 for 131 adult pts (median age 40 y) who proceeded to first allogeneic HSCT: 31% in first complete remission (CR1), 46% in CR2, 13% in ≥CR3, 5% in 1st relapse, 2% in ≥3rd relapse, and 3% in primary induction failure. A majority (70%) had transplants from peripheral blood stem cells, and 47% involved an HLA-identical sibling or other related donor. Nearly half received myeloablative conditioning regimens. Before HSCT, 36% of pts received 1 cycle of InO, 46% had 2 cycles, and 17% had ≥3 cycles. Half (48%) received InO as a single agent. Median time from last dose of InO to HSCT was 2.0 mos (range: 0.4–26.2). At the time of data lock (11 Nov 2020), post-transplant data were available for 131 pts. Outcomes for these pts are shown in the Table. Among a subgroup of adults with active R/R ALL (n=91) at the time of HSCT (median of 4 lines of prior therapy), VOD/SOS incidence within 100 d of HSCT was 18%.

	Adults (n=131)
VOD/SOS within 100 d post-HSCT, n (%)	17 (13)
Post-HSCT continued complete remission (CR)*, n (%)	117 (89)
Post-HSCT overall survival, 12 mo, % (95% CI)	55 (45–65)
HSCT-related mortality (NRM), 12 mo, % (95% CI)	21 (14–29)
Post relapse mortality, 12 mo, % (95% CI)	25 (17–33)
Post-HSCT relapse, 12 mo, % (95% CI)	36 (27–45)

*Continued CR is defined as a patient who underwent HSCT during CR, and the CR is sustained post-HSCT



Summary/Conclusion: Incidence of VOD/SOS after first HSCT in InO-treated pts with R/R ALL in this study was similar to the 18-19% reported in pooled analyses of 2 clinical trials among InO-treated pts with R/R ALL (Marks et al, *Biol Blood Marrow Transplant* 2019) and in the INOVATE study (Kantarjian et al, *Lancet Haematol* 2017). The NRM at 1 y of 21% (23% R/R ALL) is lower than the NRM at 1 y of 38% reported in the pooled analyses of R/R ALL InO recipients.

EP354 POST INDUCTION MONOCYTOSIS IS ASSOCIATED WITH HIGHER PROGRESSION FREE SURVIVAL AND OVERALL SURVIVAL IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA/ LYMPHOBLASTIC LYMPHOMA PATIENTS

A. Vagos Mata [1,*], J. Medeiros [1], E. Espada [1,2], H. Martins [1], C. Lopes [1], M. J. Costa [1], G. Esteves [1], J. Forjaz Lacerda [1,2,3], J. Raposo [1]

[1]Hematology and Bone Marrow Transplant Department, Centro Hospitalar Universitário Lisboa Norte, EPE, [2]Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Universidade de Lisboa, [3]Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

Background: Unlike paediatric patients, adult ALL/LL patients face lower cure rates of about 40-50%.[1] Certain cytogenetic abnormalities and advanced age are well accepted prognostic factors, as well as the presence of minimal residual disease.[2] However, little is known about ALL/LL microenvironment and its impact on response to treatment and incidence of relapse. Monocytes are cells of the innate immune system that play an important role in cancer development. Different subsets of monocytes have been linked both to pro and anti-tumoral immunity.[3] Recent work showed that a high monocyte count at diagnosis was associated with higher mortality and relapse rate on B ALL patients, suggesting a protective role on tumour cell survival.[4] On the other hand, a normal monocyte count at first relapse have showed a benefit on overall survival (OS).[5]There is still uncertainty about the significance of monocytes on other time points of the disease course and what role they play on tumour cell survival at each moment.
Aims: To evaluate the prognostic significance of post induction monocyte count in ALL/LL adult patients.
Methods: Single centre, retrospective study of ALL/LL patients diagnosed between 2011-2020. Blood monocyte count at the time of response to induction assessment was correlated with OS and event free survival (EFS). Kaplan-Meier curves and log-rank test were used for comparison of OS and EFS. Univariate and multivariate Cox proportional hazard models were used for investigating factors associated with OS.
Results: Sixty-eight patients were included, 61.8% were male, median age of 46 years (IQR 24-64). Most patients (58) were diagnosed with ALL, 79.3% of B lineage and CD20+ in 26.9%. LL was diagnosed in 10 patients, 8 of T lineage. 21 patients had t(9;22), hyperdiploid karyotype was present in 6 patients, 2 patients had t(1;19) and 1 had complex karyotype. 7% of patients had CNS disease at diagnosis.
Most patients (70.6%) were treated with high intensity protocols, either HyperCVAD or DFCI-11001. The remaining patients were unfit for this approach and were treated with age-adjusted protocols. Response to induction was assessed in 52 patients, 85.5% of which were in complete response after induction.
OS and EFS were analysed according to monocyte count >1000cel/µL after induction. No significant differences on patient and disease characteristics were found between the two groups. At median follow up (FU) (10.5 months), OS and EFS were significantly higher in patients with >1000 monocytes/µL after induction: OS of 100% vs 68.5%, p=0.01; EFS of 85.7% vs 67%, p=0.03. In univariate analysis, blood monocyte count as a continuous variable had impact on OS (HR 0.99, 95% CI 0.997-1.00, p=0.018). This impact persisted in multivariate analysis against covariates hyperleukocytosis at diagnosis and age (HR 0.998, 95% CI 0.997-0.999, p=0.014). Of note, none of the patients with >1000 monocytes/µL after induction died so far and only one relapsed, with a median FU of 63 months in this subgroup.

Summary/Conclusion: Higher monocyte counts after induction were associated with higher OS and EFS. Interestingly, of all patients who had monocytosis after induction, only one relapsed, and all remain alive. These findings may represent a shift to an anti-tumoral monocyte phenotype and may be surrogate markers for bone marrow recovery and better disease control. To address these specific questions, prospective and translational studies are needed. Nevertheless, to the best of our knowledge, this is the first study on the impact of monocyte recovery after induction therapy concerning patients with B an T phenotype ALL/LL.

EP355 VORICONAZOLE PROPHYLAXIS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

N. Karadaş [1,1,*], Z. Sahbudak Bal [2], G. Ortan [3], S. Onen Goktepe [1], D. Ece [1], H. Hekimci Ozdemir [1], S. Yildirim Aslan [2], C. Balkan [1], Y. Aydinok [1], D. Yilmaz Karapinar [1]

[1]Pediatric Hematology, [2]Pediatric Infectious Disease, [3]Pediatrics, Ege University School of Medicine, Izmir, Turkey

Background: Despite improvements in diagnosis and management, invasive fungal infections (IFIs) remain a major cause of morbidity and mortality in children receiving chemotherapy. Therefore, primary antifungal prophylaxis (PAP) has been recommended for patients treated in centers with a high incidence of IFI.
Aims: The aims of this study were to determine the effects of PAP on incidence, morbidity and mortality in children with acute lymphoblastic leukemia (ALL) and to compare those results with the historical study.
Methods: Children with ALL who were diagnosed before 31th January 2013, did not receive any primary antifungal prophylaxis (NoP Group), the patients who were diagnosed ALL between 1st February 2013 and 31st Jan 2020 received voriconazole (VCZ) as PAP(AFP Group).
PAP was started following the first occurrence of neutropenia after the diagnosis of ALL. VCZ was given 2x 9 mg/kg/ day per orally. If the patients had febrile neutropenia VCZ was switched to intravenous route. Because of the interaction of the drugs, during induction and reinduction phases of chemotherapy protocol patients did not receive VCZ on the days when they were given vincristine (7th, 15th, 22nd and 29th days of induction and reinduction phases). Additionally, patients who were stratified in the high risk group didn't receive VCZ during HR Blocks for the same reason. They were given liposomal amphotericin B at the dose of 3 mg/ kg/ day during HR block therapies.
The medical records of the children with ALL who were diagnosed after February 2013, were retrospectively reviewed. The chart review of the patients who underwent PAP and developed a proven or probable IFI according to EORTC (as in historical study) was completed.
Results: During the study period 166 children were diagnosed ALL and received PAP together with chemotherapy. Twenty-three patients (13.9%) with a mean age of 98.6 months (6.8- 206.0) were determined and male to female ratio was 9/14. The proven and probable IFI incidence was (13.9%) which was less than previous study (24%). Seventeen (73.9%) of 23 episodes were defined as proven IFI and 6 (26.1%) episodes were defined as probable IFI. The proven IFI incidence was similar to previous study (10.2% *vs.* 14.6%). However, there was a decline in probable IFI incidence (3.6% *vs*.10.4%). The majority of proven IFIs were candidemia (15/17;88.2%), one episode was caused by *Rhizopus* spp. (1/17;5.8%) as previous report and one episode was caused by *Fusarium* spp. (1/17;5.8%). Seventeen patients (73.9%) were neutropenic (<500/ mm^3) at the time of IFI diagnosis. None of the children developed major adverse events due to voriconazole that could lead discontinuation of voriconazole. Attributable mortality and crude mortality was 4.3%.
Summary/Conclusion: Primary prophylaxis has been recommended for centers with a high incidence of IFI. This study showed dramatically decline in probable IFI episodes those were commonly caused by a mold. In our study, the majority of proven IFI episode were due to Candida spp. one of the proven IFI episode was casued by *Rhizopus* and the other one was caused by *Fusarium* spp. Breakthrough Mucor infections under voriconazole prophylaxis had been well described. However, there was no increase in the incidence of *Mucorales* spp. caused infections. In conclusion, voriconazole was well tolerated and had effects on the incidence of mold infections. However, significant effect was not observed in the incidence of yeast infections.

EP356 HAPLOIDENTICAL TRANSPLANT HAS SUPERIOR GRAFT-VERSUS-LEUKEMIA EFFECT THAN HLA-MATCHED SIBLING TRANSPLANT FOR PH- HIGH-RISK B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

M. Fan [1,*], Y. Wang [2], R. Lin [1], T. Lin [1], F. Huang [1], Z. Fan [1], Y. Xu [3], T. Yang [4], N. Xu [1], P. Shi [1], D. Nie [5], D. Lin [6], Z. Jiang [7], S. Wang [8], J. Sun [1], X. Huang [2], Q. Liu [1], L. Xuan [1]

[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, [2]Department of Hematology, Peking University People's Hospital, Peking University Institute of Hematology, Beijing, [3]Department of Hematology, Xiangya Hospital, Central South University, Changsha, [4]Department of Hematology, Fujian Institute of Hematology, Fujian Medical University Union Hospital, Fuzhou, [5]Department of Hematology, un Yat-Sen Memorial Hospital, Sun Yat-Sen University,

[6]Department of Hematology, the Third Affiliated Hospital, Sun Yat-Sen University, [7]Department of Hematology, Guangzhou General Hospital of Guangzhou Military Command, [8]Department of Hematology, Guangzhou First People's Hospital, Guangzhou, China

Background: Compared with HLA-matched sibling donor (MSD) transplantation, whether haploidentical donor (HID) transplantation has superior graft-versus-leukemia (GVL) effect for Philadelphia-negative (Ph-) high-risk B-cell acute lymphoblastic leukemia (B-ALL) remains unclear.
Aims: This study aimed to compare the GVL effect between HID and MSD for Ph- high-risk B-ALL.
Methods: This study population came from two prospective multicenter trials (NCT01883180, NCT02673008). Immunosuppressant withdrawal, prophylactic or preemptive donor lymphocyte infusion (DLI) was administered in patients without active graft-versus-host disease (GVHD) for preventing relapse. All patients with measurable residual disease positive post-transplantation (post-MRD+) or non-remission pre-transplantation received prophylactic/ preemptive interventions. The primary endpoint was the incidence of post-MRD+.
Results: A total of 335 patients with Ph- high-risk B-ALL were enrolled, including 145 in HID and 190 in MSD group. The 3-year cumulative incidence of post-MRD+ was 27.2% (95% CI: 20.2-34.7%) and 42.6% (35.5-49.6%) in the HID and MSD groups (P=0.003). A total of 156 patients received DLI, including 60 (41.4%) in HID and 96 (50.5%) in MSD group (P=0.096). The 3-year relapse rate was 18.6% (95% CI: 12.7-25.4%) and 25.9% (19.9-32.3%; P=0.116) in the two groups. The 3-year overall survival was 67.4% (95% CI: 59.1-74.4%) and 61.6% (54.2-68.1%; P=0.382), leukemia-free survival was 63.4% (95% CI: 55.0-70.7%) and 58.2% (50.8-64.9%; P=0.429), and GVHD-free/ relapse-free survival was 51.7% (95% CI: 43.3-59.5%) and 37.8% (30.9-44.6%; P=0.041), respectively, in the HID and MSD groups.
Summary/Conclusion: HID transplantation has lower incidence of post-MRD+ than MSD transplantation, suggesting HID might have superior GVL effect than MSD for Ph- high-risk B-ALL patients.

EP357 VENETOCLAX PLUS DECITABINE IN THE TREATMENT OF MRD-PERSISTENT AND RELAPSED/REFRACTORY T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

G. Isinova [1,*], E. Parovichnikova [1], O. Gavrilina [1], K. Zarubina [1], E. Kotova [1], V. Troitskaya [1], A. Sokolov [1], I. Galtseva [1], Y. Davidova [1], T. Obukhova [1]

[1]Scientific Research Department for Intensive High-Dose Chemotherapy of Hemoblastoses and Hematopoesis Depressions, Federal State Budgetary Institution "National Medical Research Center of Hematology " of Ministry of Healthcare of Russian Federation, Moscow, Russian Federation

Background: The outcome of relapsed/refractory T-cell acute lymphoblastic leukemia (ALL) is dismal. The only evaluable effective, though quite toxic, therapeutic option is Nelarabine combinations followed by allogeneic HSCT (allo-HSCT). Recent preclinical studies and few case reports suggested that inhibition of antiapoptotic protein BCL-2 could be effective in T-cell ALL and this effect could be potentiated by hypomethylating agents.
Aims: We have conducted a small pilot study aiming to evaluate the efficacy of venetoclax with decitabine in the treatment of MRD persistent and relapsed/refractory T-cell ALL patients (pts) included in the RALL-2016 study (NCT01193933).
Methods: Since February 2019 till January 2021 seven T-ALL pts were included: 5 m, 2 f, median age 32 (range 19-39) yy. Two pts (ETP-TI-ALL and T-III ALL) had persisting MRD at day +133/+190 of the study, 3 had overt relapses (1 ETP-ALL, 1 T-I/II ALL, 1 T-II ALL), two – refractory (1 TII-ALL, 1 T/B ALL). Three pts (42%) had a complex karyotype, one (14%) – deletion in chromosome 17p [del(17p)]. All pts were monitored for MRD by MFC. Decitabine 20 mg/m2 was infused i.v. for 5 days, Venetoclax was used 400 mg by mouth daily in 28 day cycles. Two pts (29%) had second relapse after previous Nelarabine exposure followed by allo-HSCT.
Results: All of the 5 pts with relapse/primary refractory T-cell ALL achieved complete remission, 4 (80%) of them reached MRD-negativity. Both pts with MRD persistence achieved MRD negativity. The median time to remission was 0.9 month (range 0.7 – 2.1 months). Six pts (86%) underwent subsequent allo-HSCT, for one of them it was the second allo-HSCT. One patient is awaiting for allo-HSCT. The median follow-up since the start of venetoclax was 9,5 months (range 1,6 – 18,8). Three pts are alive (43%), 4 died (57%), and the 1-year OS in the whole cohort was 20% (Figure 1a). In total, 3 of the 7 pts had relapsed, and the median DFS was 7.3 months (0,6 – 15,14). The 1-year DFS was 27,8% (Figure 2b).

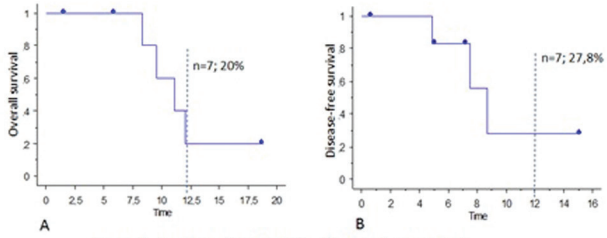


Figure 1. A – Overall survival, B – Disease-free survival

Summary/Conclusion: Though very small our study has demonstrated high efficacy (six out of seven deep responses) with low toxicity in the extremely poor prognostic group of pts. Though the responses are short and relapses occurred even after allo-HSCT. It could be supposed that the pts need after allo-transplant treatment with the same Ven+Dac combination.

EP358 PROGNOSTIC FACTORS IN INFANTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA AND 11Q23/KMT2A REARRANGEMENTS ENROLLED IN MLL-BABY TRIAL

G. Tsaur [1,*], A. Popov [2], T. Riger [1], A. Kustanovich [3], Y. Olshanskaya [2], A. Solodovnikov [4], A. Demina [1], E. Nokhrina [1], O. Plekhanova [1], T. Verzhbitskaya [1], E. Shorikov [5], O. Arakaev [1], O. Streneva [1], O. Makarova [1], L. Saveliev [1], O. Aleinikova [6], E. Lapotentova [6], N. Miakova [2], V. Fominykh [2], K. Kondratchik [7], E. Boichenko [8], N. Ponomareva [9], A. Karachunskiy [2], A. Roumiantsev [2], L. Fechina [1]

[1]Regional Children's Hospital, Research Institute of Medical Cell Technologies, Ekaterinburg, [2]National Research and Clinical Center for Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation, [3]The Sharett Institute of Oncology, Hadassah Medical Center, Jerusalem, Israel, [4]Ural State Medical University, [5]PET-Technology Center of Nuclear Medicine, Ekaterinburg, Russian Federation, [6]Belarussian Research Center for Pediatric Oncology, Hematology and Immunology, Minsk, Belarus, [7]Morozov Children's City Hospital, Moscow, [8]City Children's Hospital #1, Saint-Petersburg, [9]Republican Children's Hospital, Moscow, Russian Federation

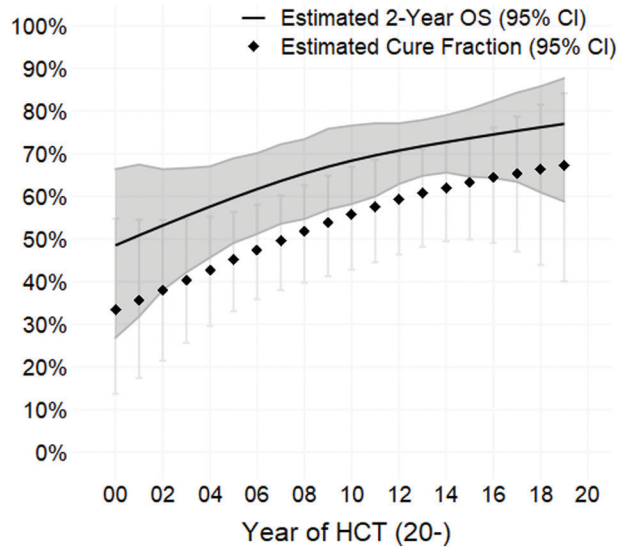
Background: Many attempts have been made worldwide to improve a prognosis of infants, with 11q23/*KMT2A*-rearranged acute lymphoblastic leukemia (*KMT2A*-r ALL). However, currently treatment outcome in infants with ALL is worse in comparison to older children.
Aims: To evaluate various prognostic factors (excluding MRD) in infant *KMT2A*-r B-cell precursor ALL enrolled in Russian-Belarus multicenter trial MLL-Baby
Methods: The study cohort comprised 100 consecutive infants aged 0–365 days with newly diagnosed *KMT2A*-r ALL enrolled between September 2003 and April 2016 (follow-up updated in January 2021). Among them there were 36 (36%) boys and 64 (64%) girls. Infants with translocation t(4;11)(q21;q23) were allocated to the high-risk (HR) arm, while all other *KMTA2*-r ALL patients who achieved complete remission (CR) by the end of induction (EOI) were treated by Intermediate-risk (ImR) arm. Only 2 of 100 patients were transplanted. EFS was estimated according to the Kaplan–Meier method [with Greenwood standard error (SE)], and differences between groups were compared using the log-rank test. The cumulative incidence of relapse (CIR) was estimated after adjusting for competing risks of other events and compared with the Gray test. Analysis of the prognostic relevance of various clinical and laboratory parameters was performed using the Cox model on the cause-specific hazard of event and the Wald test. Informed consent was obtained in all cases.
Results: EFS in the ImR group (n=50) of MLL-Baby trial was 35.1±6.9%, in the HR group (n=50) 38.3±7.1% (p=0.941). Patients older than 6 months (n=38) had better, but not statistically significant outcome (EFS 45.5±8,4%, CIR 43.3±8,7%) compared to younger than 6 mo infants (n=62) (EFS 31.2±6,0%, CIR 54.9±6,8%) (p=0.132 and p=0.245, correspondingly). Among various *KMT2A* rearrangements the most unfavorable prognosis had infants with translocation t(9;11)/ *KMT2A-MLLT3*: EFS 18.8±9.8%, CIR 75.0±9.7%. Intermediate results were obtained in patients

with translocations t(4;11)/*KMT2A–AFF1* and t(11;19)/*KMT2A-MLLT1:* EFS 36.9±7,2% and 32,7±10.4%, respectively; CIR 46.3±7.8% and 50.9±12.3%. The most favorable treatment outcome was achieved in infants carrying translocation t(10;11)(p12;q23)/*KMT2A-MLLT10:* EFS 83.3±15.2%, CIR 0,0%. CD10-negative immunophenotype (n=72) neither influenced on outcome (p=0.897) nor on relapse risk (p=0.350). Initial CNS involvement led to lower EFS (p=0.007) and higher CIR (p=0.001) in comparison to patients without CNS leukemia. Dexamethasone good response on day 8 (n=82) was not associated with better treatment outcome (p=0.060 for EFS and p=0.332 for CIR). Alternatively, M1 status of BM on day 15 (n=72) improved both EFS (p=0.016) and CIR (p=0.002). So CR achievement on day 36 (n=97) did (p=0.001 for EFS). Multivariate analysis of hazard on unfavorable event showed that unfavorable outcome of *KMT2A*-rearranged infant ALL was associated with initial CNS involvement (n=44) (p=0.020), initial white blood cell count higher than 300×10^9/L (n=26) (p=0.028), M2/M3 bone marrow status on day 15 (p=0.012) and presence of translocation t(11;19)/*KMT2A-MLLT1* (p=0.012). EOI CR achievement (n=97) had borderline significance (p=0.051).

Summary/Conclusion: Our data revealed several prognostic factors that led to unfavorable outcome in infants with *KMT2A*-r ALL enrolled in MLL-Baby trial. We did not include MRD in this analysis as we previously showed its prognostic value (G. Tsaur et al doi.org/10.1111/bjh.17304).

EP359 IMPROVED LONG-TERM SURVIVAL AFTER ALLOGENEIC TRANSPLANTATION FOR ACUTE LYMPHOBLASTIC LEUKEMIA IN ADULTS: A DANISH POPULATION-BASED STUDY

L. K. Gjærde [1,2,*], C. U. Rank [1], J. L. Marott [3], M. K. Andersen [4], O. J. Nielsen [1], H. Sengeløv [1], G. Olesen [5], B. Kornblit [1], H. Marquart [6], L. S. Friis [1], S. L. Petersen [1], N. S. Andersen [1], N. Toft [1], I. Schjødt [1]



[1]Department of Hematology, Rigshospitalet, [2]Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, [3]Frederiksberg Hospital, Frederiksberg, [4]Department of Clinical Genetics, Rigshospitalet, Copenhagen, [5]Department of Hematology, Aarhus University Hospital, Aarhus, [6]Department of Clinical Immunology, Rigshospitalet, Copenhagen, Denmark

Background: Survival after allogeneic hematopoietic cell transplantation (HCT) of high-risk acute lymphoblastic leukemia (ALL) is challenged by high risk of relapse and non-relapse mortality (NRM) due to conditioning toxicity or graft-versus-host disease (GvHD).

Aims: We aimed to investigate temporal trends of survival in a nationwide population-based cohort study of adults (≥18 years) who received HCT for ALL in Denmark between 2000–2019.

Methods: Indications for HCT comprised high-risk ALL (including Philadelphia chromosome positive [Ph+] ALL) or ALL in >1st complete remission (CR). From 2011, non-myeloablative HCT was perfomed for patients >50 years or with comorbidities, and from 2012, Ph+ patients received a tyrosine kinase inhibitor one year post-HCT. Temporal trends in overall survival (OS) were examined in a Royston–Parmar survival model. A non-mixture cure model was used to estimate temporal trends in short- and long-term survival, respectively (long-term survival estimated as the cure fraction, i.e. the fraction of patients who experienced no excess mortality compared to the Danish general population matched on calendar year, age and sex). Hazard ratios (HR) of relapse and NRM were estimated in cause-specific Cox models. Cumulative incidences of HCT outcomes were calculated by the Aalen-Johansen method and compared between patients transplanted in the earliest vs. latest quartile (years 2000–2005 vs. 2016–2019).

Results: From 2000 to 2019, 181 adults were transplanted for ALL in Denmark; 83% with B-cell, 17% with T-cell and 31% with Ph+ ALL. Median (min–max) age at transplant was 36 (18–74) years. Most patients (72%) were transplanted in CR1, and the median time from diagnosis to transplant was 7 months. The most common regimen was myeloablative (84%) transplant (Eto- or CyTBI) with a matched unrelated donor (56%). In later time periods, more patients were transplanted in CR1 and with non-myeloablative conditioning, while the proportion of patients with Ph+ ALL was constant. At a median follow-up of 8.1 years, 77 (43%) patients had died. The 2- and 5-year Kaplan–Meier OS (95% CI) were 69% (63%, 76%) and 62% (55%, 70%) in the entire cohort. OS increased with year of HCT (p = 0.03) with an estimated 2-year OS (95% CI) of 49% (27%, 66%) in patients transplanted in year 2000 vs. 77% (59%, 88%) in 2019 (Figure). The estimated cure fraction increased over time (odds ratio for cure per calendar year increase: 1.08; 95% CI: 1.01, 1.15; p = 0.03), whereas the short-term excess hazard of dying did not change significantly (HR per calendar year: 1.00; 95% CI: 0.93, 1.07; p = 0.97). This was reflected in the decreased risk of relapse over time (HR 0.92 per calendar year; 95% CI: 0.87, 0.98, p = 0.01; 2-year cumulative incidence in years 2000–2005: 26% [95% CI: 12%, 39%] vs. 12% [95% CI: 3%, 21%] in years 2016–2019), and the stable risk of NRM (HR 0.98 per calendar year; 95% CI: 0.93, 1.04, p = 0.49; 2-year cumulative incidence in years 2000–2005: 21% [95% CI: 9%, 33%] vs. 16% [95% CI: 6%, 26%] in years 2016–2019). The incidence of GvHD did not change markedly over time (grade II–IV acute GvHD: 35% [95% CI: 20%, 49%] in years 2000–2005 vs. 37% [95% CI: 24%, 51%] in years 2016–2019; chronic GvHD at 2 years: 40% [95% CI: 25%, 54%] in years 2000–2005 vs. 51% [95% CI: 37%, 65%] in years 2016–2019).

Summary/Conclusion: In a nationwide cohort study of HCT-treated ALL-patients, we found an improved long-term survival from 2000 to 2019, likely because of decreased relapse rates over time as NRM and short-term survival remained stable.

EP360 TWO CONSECUTIVE MULTICENTER RUSSIAN ACUTE LYMPHOBLASTIC LEUKEMIA (RALL) STUDIES IN PH-NEGATIVE ADULT ALL: SUCCESSES AND PITFALLS

Semashko, Nizhny Novgorod, [12]Hematology department, City Clinical Hospital named after S.P. Botkin, Moscow, [13]Hematology department, Surgut Regional Clinical Hospital, Surgut, [14]Hematology department, Sverdlovsk Regional Clinical Hospital No. 1, Ekaterinburg, [15]Hematology department, Kaluga regional hospital, Kaluga, [16]Hematology department, Yaroslavl Regional Clinical Oncological Hospital, Yaroslavl, [17]Laboratory of karyology, [18]Head of National Research Center for Hematology, National Research Center for Hematology, Moscow, Russian Federation

Background: Since 2009 RALL-study group has conducted two clinical multicenter trials on the treatment of adult patients with Ph-negative ALL. The majority of adult ALL studies are highly intensive with substantial numbers of allogeneic HSCT in 1CR and tailor their treatment according to MRD levels after the induction phase. RALL studies were based on the non-intensive, but non-interruptive approach without high dose consolidations and without many allo-HSCTs but with autologous HSCT for T-cell ALL as late consolidation. Pregnant women were included in both trials. MRD measurement was carried out only in the second RALL-2016 study.
Aims: to present the comparison of long-term results of both studies and evaluate the impact of MRD measurement in RALL-2016.
Methods: From Jan, 2009, till Dec, 2016, 30 centers had enrolled 330 and since Dec 2016 till Jan 2021, 10 centers included 207 acute Ph-negative lymphoblastic leukemia patients. The main trials characteristics are presented in Table 1. There were no difference between two trials in numbers of autologous HSCTs for T-ALL (42/125 (33%) pts in RALL-2009 and 23/85 (27%) in RALL-2016); no difference in numbers of allo-HSCTs in 1CR (19/281 (6,8%) in RALL-2009 and 19/170 (11,2%) in RALL-2016). But the total number of allo-HSCTs was somewhat higher in RALL-2016: 21/305 (6,9%) in RALL-2009 and 25/186 (13,5%), p=0,02).
Results: Two trials look quite similar in main characteristics, though pts in RALL-2016 were older. Both trials have demonstrated identical stable results with optimistic long-term outcome (Pic.1. A,B). High early death rate (~10%) remains an obstacle that decreases CR rate and overall survival especially in Regional centers. MRD-positivity discriminated BCP-ALL patients at day+70 (Pic.1C) and T-ALL patients at day +133 (Pic.1D) to a poor prognostic group.

Table 1

	RALL-2009, n=330	RALL-2016, n=207	p, χ^2

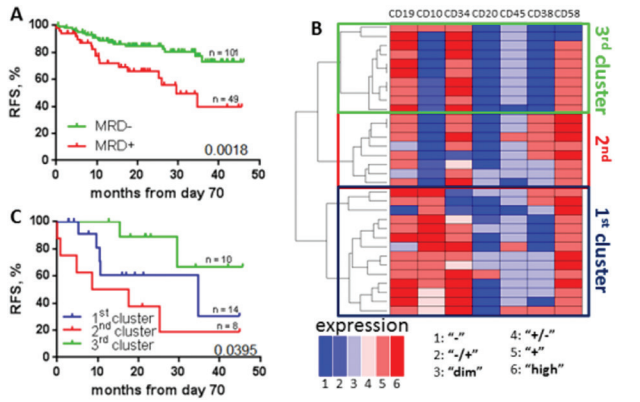
Picture 1. Overall survival according to the study (A). Disease free survival according to the study (B). Disease-free survival according MRD on day +70 for BCP-ALL (C). Disease-free survival according MRD on day +133 for T-ALL (D).



Summary/Conclusion: It was shown that disregard the absence of high-dose consolidations with high-dose methotrexate/ARA-C and low numbers of allo-HSCT in 1CR, both trials had demonstrated stable, high and reproducible results regarding overall and disease-free survival. In our setting MRD-positivity at day+70 for BCP-ALL and at day 133+ for T-ALL identifies patients that need different approach aimed to early MRD treatment with targeting drugs followed by allo-HSCT.

EP361 IMMUNOPHENOTYPE OF RESIDUAL BLASTS, NOT ONLY MRD-POSITIVITY, DOES MATTER IN LONG-TERM PROGNOSIS OF B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

Y. Davydova [1,*], I. Galtseva [1], O. Aleshina [1], N. Kapranov [1], K. Nikiforova [1], G. Isinova [1], K. Zarubina [1], E. Kotova [1], A. Sokolov [1], V. Troitskaya [1], E. Parovichnikova [1]

[1]*National Research Center for Hematology, Moscow, Russian Federation*

Background: Measurable residual disease (MRD) is an independent prognostic factor in numerous acute lymphoblastic leukemia (ALL) studies. An unfavorable outcome may be dependent not only on the persistence of MRD, but on immunophenotype of residual blasts too. Immunophenotype could reflect the biology of tumor cells, especially their genetics (Gupta N. et al., 2019).
Aims: The aim was to investigate a significance of MRD and immunophenotype of residual blasts at the end of induction in Russian treatment protocol RALL-2016.
Methods: The multicenter study RALL-2016 (NCT03462095) included 207 adult patients from 2016 to 2020 years. The MRD was assessed at the end of induction (day 70) in 150 patients (80 patients with B-ALL and 70 patients with T-ALL) who achieved a complete remission. Analysis of MRD was performed in the bone marrow samples by flow cytometer instruments FACSCanto II (Becton Dickinson) or CytoFLEX (Beckman Coulter). The sensitivity was at least 0.01%. Seven basic antigens (CD19, CD34, CD10, CD20, CD38, CD45 and CD58) were analyzed to detect MRD and were used to describe the immunophenotype of residual blasts in B-ALL at day 70. The relative expression of these antigens was determined compared to normal cells of bone marrow (Dworzak M.N. et al., 2017) and translated into numerical equivalent as it was described earlier (Davydova Y. et al, HemaSpere – materials of EHA 2020). A dendrogram was constructed using the "ward.D2" method in R 3.4.4. The probability of relapse-free survival (RFS) was estimated with the Kaplan–Meier method, and comparisons were assessed using the log-rank test. A $p < 0.05$ was considered significant.
Results: At the end of induction 101 (67.3%) patients (48 B-ALL, and 53 T-ALL) were MRD-negative, and 49 (32.7%) patients (32 B-ALL, and 17 T-ALL) remained residual blasts. RFS was higher in MRD-negative than in MRD-positive patients (median undefined vs 29.5 months, p=0.002) in whole ALL cohort (fig. A). Analyzing B-ALL cohort, the RFS was depended on MRD (median undefined vs 29.5 months, p=0.004), but in T-ALL MRD was not significant (medians undefined, p=0.25).
Cluster analysis revealed 3 clusters in B-ALL MRD based on immunophenotype of residual blasts (fig. B). The 1st cluster (n=14) included cases with presence of CD10 while 2nd (n=8), and 3rd (n=10) clusters included CD10-negative cases. The expression of CD38, and CD58 was higher in 2nd than in 3rd cluster.
RFS probability differed in these 3 clusters: medians were 34.7 months, 13.1 months, and undefined in 1st, 2nd, and 3rd clusters, respectively (p=0.04) (Fig.C).

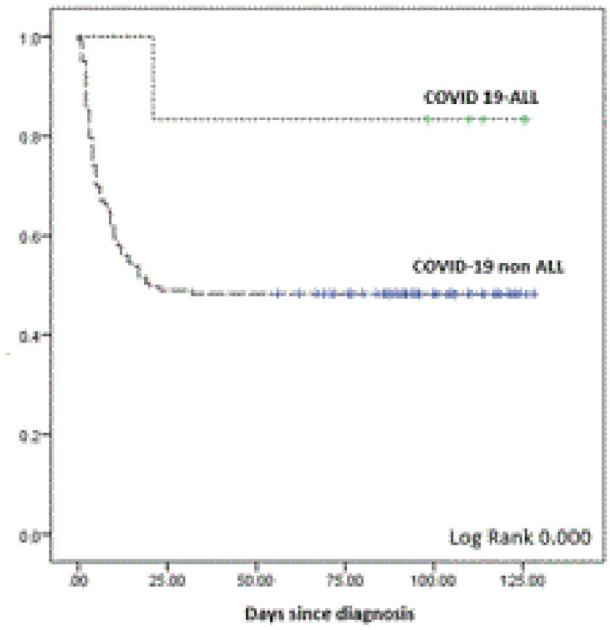
Summary/Conclusion: MRD measured by flow cytometry at the end of induction was confirmed as an important prognostic factor in RALL-2016 protocol among B-ALL patients. Immunophenotype of residual blasts was in association with the RFS. The most unfavorable prognosis was in cases that lack CD10 expression but have relatively high expression of CD58, and CD38.

EP362 PEG ASPARAGINASE INDUCED SEVERE HYPERTRIGLYCERIDEMIA IN ADULTS ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH PEDIATRIC-INSPIRED REGIMEN: IS IT SAFE TO RECHALLENGE THESE PATIENTS?

I. Al Nabhani [1,*], D. Maze [1], V. Gupta [1], A. Schimmer [1], K. Yee [1], A. Schuh [1], S. Chan [1], T. Murphy [1], H. Sibai [1]

[1]*Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, Canada*

Background: PEG-asparaginase, a long-acting formulation of L-asparaginase, is used as part of treatment protocols for Philadelphia negative acute lymphoblastic leukemia (ALL). In pediatric studies,



triglycerides were more affected by PEG asparaginase compared to native L-asparaginase (10.0% vs 5.5%). Using PEG asparaginase for ALL was associated with a higher incidence of hypertriglyceridemia up to 50% in adult patients. The clinical significance of this and if re-challenging these patients is safe or not is not clear.
Aims: We sought to determine the safety of re-challenging adult patients with PEG asparaginase after experiencing an episode of severe hypertriglyceridemia (> 1000mg/dl or 11.4mmol/L).
Methods: At Princess Margaret Cancer Center, we recently switched from native E. coli asparaginase to PEG asparaginase using modified pediatric Dana Farber Cancer Institute (DFCI) protocols. 46 consecutive adult patients received PEG-asparaginase as part of DFCI protocol for first-line treatment of Philadelphia negative ALL between February 2020 and December 2020. We analyzed the incidence of hypertriglyceridemia and their subsequent outcomes.
Results: The median age of the patients was 38 years, and 17 (36.9%) were female. 11 patients out of 46 (23.9%) have elevated triglycerides with levels above 2.2mmol/L. Elevated triglycerides occurred a median of 2 weeks after initial treatment; 4 out of 46 patients had severe hypertriglyceridemia with levels above 11.4 mmol/L (8.7%). The management of these patients was supportive in the form of a low-fat diet, hydration and fenofibrate or gemfibrozil. Their next treatment cycle with PEG-asparaginase was delayed by two weeks on average (range 1-3) until normalizing their triglycerides level. None of these patients required plasmapheresis or insulin infusion as a treatment for hypertriglyceridemia. Only one of 11 patients (9%) developed acute pancreatitis after the second cycle of intensification; he had severe hypertriglyceridemia with the first intensification cycle and proceeded to the next cycle before normalizing the triglyceride. This patient did not re-challenge subsequently with PEG-asparaginase. The remaining ten patients were re-challenged after dropping triglyceride levels without developing pancreatitis. Among the 4 patients with severe hypertriglyceridemia, two completed their intensification phase therapy with PEG asparaginase. One patient continues to receive PEG asparaginase as part of the intensification treatment and one patient was not re-challenged as he developed acute pancreatitis as mentioned above.
Three patients with severe hypertriglyceridemia were noted to have high anion gap metabolic acidosis with hypobicarbonatemia and or hyperammonemia. This was normal on repeat testing using venous blood gas and testing with an alternative device for ammonia. The evaluation revealed that the low bicarbonate level was fictitious and was related to lipemic serum.
Summary/Conclusion: With moving from native asparaginase to PEG asparaginase in adult patients with ALL, hypertriglyceridemia incidence was high. Checking triglycerides at baseline and monitoring levels while receiving PEG asparaginase is needed to safely receive their treatment on subsequent cycles after the initial PEG asparaginase exposure. In patients with hypertriglyceridemia not complicated by acute pancreatitis, re-challenging these patients who did not have pancreatitis is safe once the triglycerides level normalizes.

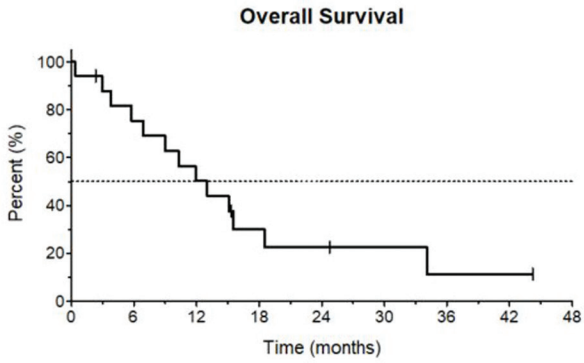
EP363 ACUTE LYMPHOBLASTIC LEUKEMIA AND SARS-COV-2, RESPONSE TO TREATMENT AND SPONTANEOUS REMISSIONS. EXPERIENCE OF TWO COVID-19 HOSPITALS IN MEXICO CITY.

C. Ramos [1,*], C. Martinez Murillo [1], E. Madera [2], C. Balderas [2], I. Olarte [3], A. Martinez [3], G. Barranco [4], M. Bejarano [5]

[1]Hematology, Hospital General de México, [2]Hematology, Hospital Regional Ixtapaluca, [3]Molecular Biology Lab, [4]Hematology, [5]Nutrition, Hospital General de Mexico, Mexico City, Mexico

Background: From the end of December 2019, the new beta coronavirus named COVID-19 has significantly affected the greater number of countries in the world. The major part of the recommendations for the treatment of ALL in the era of COVID-19 includes delaying as long as possible chemotherapy, except in cases of high risk of complications or disease progression. In Mexico, the number of cases of leukemia has diminished due to hospital conversion such as limited access to treatments. The object of this study was to describe the cases with *de novo* acute lymphoblastic leukemia in two institutions assigned as COVID-19 hospitals in Mexico City
Aims: Describe patients' clinical and prognostic behavior with ALL and COVID-19 infection at diagnosis as at any stage of treatment.
Methods: A prospective, observational study in patients *de novo* diagnosed with ALL according to the WHO criteria, cared for in the Hematology Department of the Hospital Regional de Alta Especialidad de Ixtapaluca and the Hospital General de México. The clinical records of the patients diagnosed with ALL from April to December 2020 were included; they received treatment based on intermediate intensity program (CALGB-10403) or high-intensity program (Hyper-CVAD), maintaining the majority of patients as outpatients. ALL the confirmed COVID-19 cases with ALL were compared with non-cancer COVID-19 cases to describe the difference. Support treatment for COVID-19 was based on local considerations. This research was registered on the ClinicalTrials platform (NCT04745416).
Results: Thirty patients were studied (April to December 2020); one case was excluded from the analysis (spontaneous remission). Of the 29 cases, 6 (20.7%) were COVID-19 confirmed cases, four at diagnosis and two during the induction period.There were no differences in gender, age (24 vs. 30 years, p=0.261), or mean leukocyte count at diagnosis (156.3 vs. 116.5 x109/L, p=0.564, 95%CI). BCR-ABL was detected in one case with COVID-19; two cases with COVID-19 showed AF4-MLL and ELN-MLL. According to risk, 66.7% (n=4) of the cases with COVID-19 were considered high risk.
The treatment for COVID-19 was high-flow oxygen, azithromycin, anticoagulation. Upon analyzing the response to induction, the group negative to COVID-19 showed a higher proportion of response than the cases with a background of COVID-19 (78.3% vs. 66.7%), but without statistical significance (p=0.628). The group with COVID-19 showed a higher proportion of leukemia refractory to induction (33% vs. 17.4%), requiring a second treatment program. There were no deaths in the COVID-19 arm.
Comparing the survival with non-cancer COVID-19 patients, the mortality was 51.7% for individuals without leukemia and 16.7% (n=1) for leukemia COVID-19 cases.
Two female patients showed ALL patients' morphological remission: (19 years and 38 years of age). Both debuted with fever as the main manifestation, cytopenias (patient 1: WBC 0.5 x 109/L, platelets 13 x109/L; patient 2: 0.7 x109/L, platelets 123 x109/L) without cytogenetic abnormalities. From day 10 of hospital stay, they showed improvement in leukocyte and platelet counts, reaching the normal range by day 21, requiring evaluation of extended bone marrow, which showed an absence of blasts. Patient 1 had a negative finding after beginning an induction program, and patient two is still without treatment.

Summary/Conclusion: The prognosis of individuals with COVID-19-ALL is better due to the null development of cytokine storm; similar to



other tumors, spontaneous remission can be seen, especially in young individuals, and decreased tumor burden.

EP364 OUTCOME OF RELAPSED OR REFRACTORY ACUTE B-LYMPHOBLASTIC LEUKEMIA PATIENTS WITH EXTRAMEDULLARY DISEASE RECEIVING INOTUZUMAB OZOGAMICIN

S. Kayser [1,2,3,*], C. Sartor [4,5], N. Panitz [2], M. Fante [6], C. Lutz [7], D. Wolff [6], A. Ho [3], C. Papayannidis [4]

[1]NCT Trial Center, National Center of Tumor Diseases, DKFZ, Heidelberg, [2]Hematology and Cellular Therapy, University Hospital of Leipzig, Leipzig, [3]Department of Internal Medicine V, Heidelberg University Hospital, Heidelberg, Germany, [4]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Istituto di Ematologia "Seràgnoli" Bologna, [5]Dipartimento di Medicina Specialistica, Diagnostica e Sperimentale Università di Bologna, Bologna, Italy, [6]Department of Hematology and Oncology, Internal Medicine III, University Hospital Regensburg, Regensburg, [7]Praxis for Hematology and Oncology Koblenz, Koblenz, Germany

Background: Extramedullary involvement of B-cell acute lymphoblastic leukemia (EM-ALL) is a rare occurrence, characterized by dismal outcome and the lack of a defined and shared therapeutic approach. Inotuzumab ozogamicin (InO) is a humanized anti-CD22 monoclonal antibody conjugated to calicheamicin. It was developed as a targeted therapy for B-cell malignancies.
Aims: To characterize a series of relapsed/refractory (r/r) adult EM-ALL patients (pts) and evaluate outcome after InO treatment.
Methods: We studied 17 r/r pts (median age, 31 years; range, 19-68 years), who were treated with InO between 2015 and 2020 within a compassionate use program (n=7) or in-label after EMA approval (n=10). Three of the 17 pts were previously treated with tyrosine kinase inhibitors for chronic myeloid leukemia and progressed to blast crisis of B-lymphoid lineage. Bone marrow evaluation and immunophenotyping by flow cytometry revealed acute B-lymphoblastic leukemia in all three pts. All 17 pts were CD22 positive at relapse/progressive disease. Up to six InO cycles (≤2 cycles, n=11; 3-4 cycles, n=4; 5-6 cycles, n=2) were administered according to the previously approved regimen. EM response assessment was performed by CT or PET-CT.
Results: Localization of EM disease included lymph nodes (in total, n=9; including gastric and skin; bone and skin; lung, bone and skin; hepatic and bone; hepatic, n=1 in each of these combinations), bones (n=4), kidney (n=1), peripheral nerves (n=1), pancreas and bone (n=1), and ovary (n=1). At the time of r/r EM-ALL median white blood cell and platelet counts were 4.9/nl (range, 0.7-10.3/nl) and 94.5/nl (range, 11-515/nl), respectively. Eleven pts (49%) were female; ECOG was ≤ 2 in all pts. Cytogenetic analysis at the time of r/r EM-ALL was available in five pts. One patient had a normal karyotype, two were complex and two pts displayed a t(9;22). Complete remission assessed by PET-CT (CR; including EM and hematological/bone marrow CR) after the first InO cycle was achieved in 7 pts (41%), 7 pts had a partial remission (PR) (41%), one (6%) had stable disease (SD) and one patient (6%) died at day 11 of the first InO cycle due to cerebral hemorrhage. One patient had no response assessment after the first induction cycle (6%). After two InO cycles, overall response rate was 94% (n=16), including CR in 9 pts (56%) and PR in six (38%); the patient with SD did not receive further InO treatment (6%). Median follow-up was 12.1 months (range, 0.4-44.9 months) and median overall survival (OS) 11.9 months (95%>CI, 8-20 months; Figure 1). One-year and two-years OS rates were 50% (95%>CI, 25-71%) and 23% (95%>CI, 6-46%), respectively. Age above 60 years had no impact on OS (p=0.48). Seven pts proceeded to allogeneic hematopoietic stem cell transplantation (allo-SCT; CR, PR, n=3, each; progressive disease, n=1). Prior to allo-SCT four pts received ≤2 cycles InO and three pts ≤4 cycles. No occurrence of veno-occlusive disease was reported. Relapse/progressive disease occurred in nine pts and all pts succumbed of their disease. Cumulative incidence of relapse after 12 months was 38%. One patient experienced a molecular relapse, which could be successfully treated with InO again. Four pts died in remission and four pts are in ongoing CR including the patient with prior molecular relapse and InO re-exposure.

Summary/Conclusion: This outcome analysis demonstrates that treatment with InO is an effective and promising approach including a successful bridge-to-transplant strategy in this rare subgroup of patients with r/r EM-ALL and abysmal prognosis.

EP365 ACUTE LEUKEMIA OF AMBIGUOUS LINEAGE: A SINGLE CENTRE RETROSPECTIVE REVIEW OF DISEASE CHARACTERISTICS, TREATMENT STRATEGIES, OUTCOMES AND NOVEL THERAPEUTIC TARGETS

K. Brown [1,*], S. Narayanan [1], M. Power [1], Y. Abou Mourad [1], D. Forrest [1], K. Hay [1], F. Kuchenbauer [1], S. Nantel [1], T. Nevill [1], J. Rodrigo [1], M. Seftel [1], K. Song [1], H. Sutherland [1], C. Toze [1], J. White [1], S. Chung [1], D. Sanford [1]

[1]Leukemia and Bone Marrow Transplant Program of British Columbia, Vancouver, Canada

Background: Acute leukemia of ambiguous lineage (ALAL) is a rare form of acute leukemia, with a reported incidence of 1-6%, associated with a poor prognosis with median survival of 14.8 to 18 months. The World Health Organization (WHO) Classification of Tumors of Hematopoietic and Lymphoid Tissues 2016 Revised Edition classifies ALAL as a separate category from acute myeloid leukemia and acute lymphoblastic leukemia.
Treatment generally consists of acute myeloid leukemia (AML) induction, acute lymphoblastic leukemia (ALL) induction or hybrids of AML and ALL induction. Patients with t(9;22) are generally treated with a tyrosine kinase inhibitor. Eligible patients who achieve complete remission after induction are often treated with a consolidative allogeneic hematopoietic stem cell transplant (HSCT). Little evidence is available for the use of novel therapeutics such as antibody-drug conjugates, bispecific T-cell engagers or chimeric antigen receptor T-cells (CAR-T) in ALAL.
Aims: 1. To determine the incidence of ALAL in a single center
2. To determine the characteristics of ALAL patients and their disease
3. To review the treatment employed in ALAL patients
4. To report outcomes of ALAL patients
5. To report incidence of specific immunophenotypic markers which may be therapeutic targets in ALAL
Methods: Using the British Columbia Cancer Agency Leukemia Database, patients with diagnosed the an ALAL between 2000 and 2020 were identified. Information including demographics, date of diagnosis, pathology results, treatment employed and survival data from the database was reviewed by two clinical hematologists. If the diagnosis was felt to meet another diagnosis other than ALAL, the patient was excluded from the analysis. Patient sex, age at diagnosis, immunophenotypic markers, first treatment regimen and bone marrow transplant status were quantified. A survival analysis was performed using a Kaplan-Meier analysis.
Results: 63 patients were identified as having ALAL. 16 patients were removed from analysis because of the diagnosis meeting another WHO leukemia classification.
The characteristics of patients, disease and treatment strategies employed for these patients is demonstrated in **Table 1.** CD33 and CD19 were the most common immunophenotypic targets, with more than 40% of patients being positive, respectively.

The median overall survival was 30.2 months (12.4-48.0 months, CI 95%) with a median follow-up time of 22.1 months. Three-year overall survival was 42.6%. Three-year overall survival was 59.9% and 24.8% in the transplant group and non-transplant group, respectively.

Table 1: Characteristics of ALAL Patients

Median Age at Diagnosis (N=47)	Range

Bone Marrow/Stem Cell Transplant (N=47)	
Yes	24
No	23

Summary/Conclusion: This single-centre, retrospective cohort study offers the first data of ALAL using the updated WHO 2016 criteria for ALALs. That 16 patients were deemed to have alternative diagnoses demonstrates the advances in understanding of acute leukemias and may indicate that the incidence of ALALs is decreasing as more refined diagnostics are used.
MPAL with t(9;22) was the most common subtype of ALAL that was demonstrated. Further review of data is required to determine what percentage of these patients received tyrosine kinase inhibitors. The majority of the patients in our cohort received either an AML or ALL type induction regimens with 51% of the patients going on to receive an allogeneic transplant. This is consistent with previously reported treatment strategies. Most patients had an immunotherapeutic target. This supports the future study of novel immunotherapeutics such as gemtuzumab ozogomicin, blinatumomab, CD19-directed CAR-T products and inotuzumab ozogamicin in ALAL.

EP366 HETEROGENEITY OF TREATMENT RESPONSE DEFINITIONS IN REFRACTORY/RELAPSED ADULT ACUTE LYMPHOBLASTIC LEUKEMIA (R/R ALL): FINDINGS FROM A SYSTEMATIC LITERATURE REVIEW (SLR) OF CLINICAL TRIALS

S. Keeping [1,*], C. Feng [2], N. Ballew [1], J.-G. Castaigne [2], I. Faghmous [2], R. Vezan [2], B. Kharabi Masouleh [2]

[1]PRECISIONheor, Inc, Vancouver, Canada, [2]Kite, A Gilead Company, Santa Monica, United States

Background: Treatment response measures for R/R aALL have evolved with improved understanding of ALL characteristics, which has led to different definitions in clinical trials.
Aims: This study aimed to examine the comparability of response measurements used in trials of current standard of care (SoC) treatments for R/R aALL, with a focus on complete remission (CR) and CR with incomplete hematologic recovery (CRi).
Methods: An SLR was conducted to identify clinical trials reporting treatment response with SoC for R/R aALL. Searches of the MEDLINE, EMBASE, and Cochrane Central Register of Controlled Trials databases as well as conference proceedings/trial registries were conducted in November 2020. Inclusion criteria were applied to restrict to trials of licensed and recommended treatments for R/R aALL, i.e. blinatumomab, inotuzumab ozogamicin, tyrosine kinase inhibitors (imatinib, dasatinib, ponatinib), and chemotherapies (fludarabine-, cytarabine-, alkylator-containing regimens). Additionally, criteria were further applied to exclude clinical trials with no full-text publications that reported CR alone or both CR and CRi by search completion date.
Results: The SLR identified 15 treatment arms in 12 studies which reported CR, and 14 treatment arms in 11 studies which reported both CR and CRi. Across the 15 treatment arms reporting CR, the definitions were comparable, i.e., an absolute neutrophil count (ANC) response ≥1 x 10^9/l and platelet count ≥100 x 10^9/l along with ≤5% bone marrow blasts. For the 14 treatment arms in 11 studies with both CR and CRi, the CRi definitions varied in hematologic criteria. Many of the 11 studies were heterogenous in terms of specific ANC and platelet thresholds employed for CRi. Moreover, some studies did not require hematologic recovery. Specifically, six studies included a hematological recovery requirement in ANC and/or platelets for CRi with variant thresholds. Three studies did not have a minimum requirement for ANC or platelets, and two studies did not explicitly describe the hematological criteria. Among all studies with CRi hematological recovery thresholds, the most stringent criteria were used in the TOWER trial, defined as ANC ≥1 x 10^9/l or platelet count ≥100 x 10^9/l. The differences in CRi definitions were clinically meaningful and led to significantly different response rates.
Summary/Conclusion: Whereas CR definitions were comparable across trials, CRi definitions were very heterogenous in terms of hematologic recovery criteria, with older definitions being less stringent or requiring no hematological recovery. The lack of standardized CRi definitions make it challenging for cross-trial efficacy comparisons with composite response endpoints such as CR+CRi due to the different levels of stringency in criteria for CRi. This suggests that treatment response outcome measures for historical control studies should be based on CR alone. Outcomes with comparable definitions across trials such as CR and standard efficacy measures such as overall survival are likely to provide more robust and clinically relevant cross-trial efficacy comparisons.

EP367 A PHASE II STUDY OF BLINATUMOMAB FOR THE TREATMENT OF MEASURABLE RESIDUAL DISEASE-POSITIVE B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

N. Short [1,*], H. Kantarjian [1], M. Konopleva [1], N. Jain [1], F. Ravandi [1], N. Daver [1], Y. Alvarado [1], K. Takahashi [1], G. Garcia-Manero [1], M. Velasquez [1], R. Garris [1], E. Jabbour [1]

[1]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Persistent or recurrent measurable residual disease (MRD) is associated with high rates of relapse in B-cell acute lymphoblastic leukemia (ALL). We evaluated the CD3-CD19 bispecific T-cell engaging antibody, blinatumomab, in patient (pts) with B-cell ALL in complete remission (CR) who did not achieve MRD negativity with standard therapy or who experienced MRD relapse.
Aims: We evaluated the efficacy and safety of blinatumomab in pts with B-cell ALL and MRD-positive disease.
Methods: This is a single-arm, phase II trial of pts with B-cell ALL in CR who did not achieve MRD negativity or had MRD relapse after at least 3 months of frontline therapy (i.e. CR1) or after at least 1 month of salvage therapy (i.e. CR2 and beyond). Positive MRD was defined as ≥0.01% by flow cytometry in pts with Philadelphia chromosome (Ph)-negative ALL and a *BCR-ABL1/ABL1* transcript ratio by PCR of ≥0.01% for pts with Ph-positive ALL. MRD negativity was defined as undetectable MRD by flow and PCR at a sensitivity of 10^{-4}. Blinatumomab was given at standard doses (up to 28 µg/day, if tolerated) in 42-day cycles for up to 5 total consolidation cycles. Pts

who did not proceed with ASCT could receive blinatumomab maintenance with one cycle every 3 months for up to 4 maintenance cycles (9 cycles total). A TKI of the treating physician's choice was added to the regimen for pts with Ph-positive ALL.

Results: Between 12/2015 and 2/2021, 31 pts with MRD-positive B-cell ALL in CR were enrolled. The median age was 42 years (range, 22-84 years). Thirteen pts (42%) had Ph-positive ALL; 10 pts received concomitant ponatinib, 2 received dasatinib, and 1 received imatinib. Twenty-three pts (74%) were in CR1, and 8 (26%) were in CR2 and beyond (5 in CR2 and 3 in CR3). Nineteen pts (61%) had persistent MRD and 12 (39%) had MRD relapse. Two pts had undergone prior ASCT.

Pts received a median of 3 cycles of blinatumomab consolidation (range, 1-5 cycles). Overall, 23 pts (74%) achieved MRD negativity at any time. Fifteen of 18 pts (83%) with Ph-negative ALL achieved MRD negativity, and 8 of 13 pts (62%) with Ph-positive ALL achieved MRD negativity. Three additional pts with Ph-positive ALL achieved a major molecular response as best response. Among the 23 MRD responders, 21 (91%) responded after 1 cycle; 1 after 2 cycles, and 1 after 4 cycles. MRD response occurred in 65% of pts in CR1 and 100% in CR2+. Eight pts (35% of MRD responders) proceeded to ASCT (5 in CR1 and 3 in CR2+) with median time to ASCT of 3 months (range, 2-6 months).

Blinatumomab-related adverse events were as expected, with adverse events of any grade observed in 12 pts (39%). All resolved with supportive management. One pt discontinued blinatumomab due to adverse event (grade 3 altered mental status). There were no grade 4 or 5 adverse events.

With a median follow-up of 25 months (range, 5-60 months), 7 pts have relapsed (30% of MRD responders). One relapse was in a pt who underwent ASCT and 6 were in pts who did not undergo ASCT (3 in CR1, 2 in CR2, and 1 in CR3). Four relapses were hematologic only, 1 was hematologic plus CNS, 1 was extramedullary only, and 1 was MRD only. The 3-year overall survival (OS) and relapse-free survival (RFS) rates were both 63%. The 3-year OS rates were similar for pts who underwent ASCT and those who did not (75% vs. 63%; P=0.95). The 3-year OS rates for pts with an MRD level of 0.01%>0.1% (n=10) and those >0.1% (n=21) were 72% and 60%, respectively.

Summary/Conclusion: Blinatumomab is well-tolerated and highly effective in eradicating MRD in pts with B-cell ALL who have persistent MRD or who experience MRD relapse.

EP368 EPIDEMIOLOGY, TREATMENT PATTERNS AND CLINICAL OUTCOMES OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS IN TAIWAN: A POPULATION-BASED COHORT STUDY

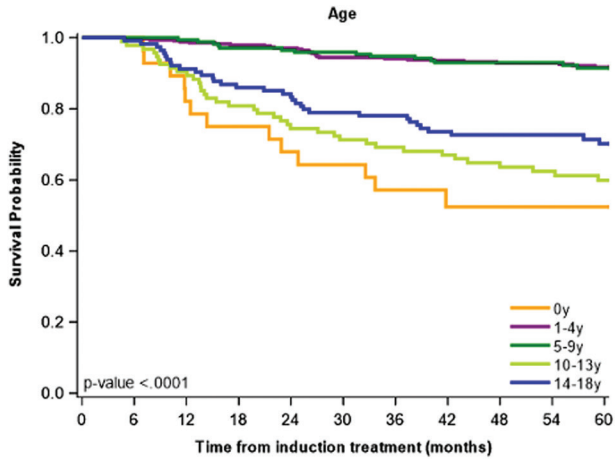
M.-Y. Lu [1,*], C.-M. Chen [2], M.-T. Chen [2], H.-H. Huang [3], H.-M. Chen [4], B.-S. Ko [3], F.-Y. Hsiao [2]

[1]Department of Pediatrics, National Taiwan University Hospital, [2]Graduate Institute of Clinical Pharmacy, National Taiwan University, [3]Division of Hematology, Department of Internal Medicine, National Taiwan University Hospital, [4]National Taiwan University, Taipei, Taiwan, Republic of China

Background: Acute lymphoblastic leukemia (ALL) is the most common type of leukemia in children. However, the epidemiology, treatment patterns, and clinical outcomes of pediatric ALL in Asian population are still limited.

Aims: To investigate the incidence of ALL in pediatric population and their baseline characteristics, treatment patterns as well as clinical outcomes in Taiwan.

Methods: We conducted a nationwide population-based retrospective cohort study using the Taiwan Cancer Registry (TCR) and National Health Insurance Research Database (NHIRD). In the first part of our analysis, pediatric patients newly diagnosed with ALL from 2002 to 2017 were identified from the TCR and the annual incidence of ALL were reported. In the second part of our analysis, we further focused on the pediatric patients diagnosed with B-cell ALL during 2009 to 2015 and investigated their baseline characteristics, treatment patterns and clinical outcomes. Outcomes of interest included refractory disease, disease relapse and all cause mortality. Kaplan-Meier survival analysis were performed with stratification by induction therapy or not, age at diagnosis and response of induction therapy.



Results: The annual incidence of ALL in pediatric population ranged from 2.36 to 3.19 cases per 100,000 persons, with the highest incidence in the age group of 1 to 4 years. Mean age at diagnosis was 7.1 years.

Among 787 pediatric patients with B-cell ALL identified in TCRD, 761 (96.7%) patients received their induction therapy within 4 months after diagnosis of ALL and were identified for further analysis. Their median age ranged from 3 to 5 years old in the different fiscal year. Most of the patients (97.4 %) were treated in a medical center and initiated induction therapy within the first week after diagnosis, with median time internval ranging from 0 to 7 days.

The proportion of the patients who achieved remission state increased steadily over the years and achieved 97.0% in 2015. In patients who achieved remission state, approximately 20% of them encountered relapse. The cumulative mortality were 26.4% in 2009 and 8.0% in 2015. The proportion of patients received stem cell transplantation (SCT) were 11.2% in 2009 and 7.0% in 2015.

As for the survival analysis, the 3-year survival rate is 87% in patients with induction therapy, with best 3-year survival rate of 94% and 95% in age groups of 1 to 4 and 5 to 9.

The survival of patients who received induction therapy were significantly better than those who did not. The survival were also significantly different in different age at diagnosis, with age groups ranging from 1 to 4 and 5 to 9 having the best survival. Patients who did not encountered refractory disease also showed better survival. Similar trend were observed in relapse-free survival, with better survival in age group 1 to 4 and 5 to 9.

Summary/Conclusion: Our study, with the advantage of 16 years of longitudinal data, has provided epidemiology, treatment patterns and survivals of pediatric ALL in the past decades in Taiwan. The annual incidence of ALL were approximately 2.8 per 100,000 person in Taiwanese pediatric population, with the highest incidence in the age group of 1 to 4 years. Most of the patients achieved remission state after induction therapy, of whom approximately 20% encountered relapse. The 3-year survival rate is 87% in patients with induction therapy. Best survival were observed in the age groups of 1 to 4 and 5 to 9, with 3-year survival rate of 94% and 95%.

EP369 CORRELATION OF BLINATUMOMAB THERAPY IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA OUTCOME WITH MINIMAL RESIDUAL DISEASE, CYTOGENETICS AND ABSOLUTE LYMPHOCYTE COUNT:RETROSPECTIVE MULTICENTER STUDY.

M. Essa [1,2,3,*], R. Abdellatif [4], W. Ballourah [5], R. AL Sudairy [4], M. Alkaiyat [6], W. Jastaniah [7,8]

[1]King Abdullah Specialist Children's Hospital, [2]King Saud bin Abdulaziz University for Health Sciences, [3]King Abdullah International Medical Research Center, [4]King Abdullah Specialist Children's, [5]King Fahd medical city, [6]King Abdulaziz medical city, Riyadh, [7]Princess Noorah Oncology Center, Ministry of National Guard Health, Jeddah, [8]Umm AlQura University, makkah, Saudi Arabia

Background: The management of Refractory/Relapsed B cell Acute Lymphoblastic Leukemia (R/R ALL) is still challenging. The use of Blinatumomab in such patients is an option with encouraging results.
Aims: To study the outcome of pediatric patients with R/R ALL or persistent Minimal Residual Disease (MRD) in three centers and correlate their outcome with MRD level, Cytogenetics and Absolute Lymphocyte Count(ALC) prior to Blinatumomab therapy.
Methods: A total of 33 patients with R/R ALL or persistent Minimal Residual Disease (MRD) in three different centers who received Blinatumomab therapy.Their outcome was studied based on MRD level, Cytogenetics and Absolute Lymphocyte Count(ALC) prior to Blinatumomab therapy.MRD measurement was done using flowcytometry method. Results were described and associaction analysis was done using chi-square and Fisher's tests.
Results: Clinical characteristics and outcome are demonstrated in Table attached. Complete remission (CR) with MRD <0.01 after one or two cycles was achieved in 25 patients then proceeded with other assigned treatment. 20 patients (60%) remained alive without disease recurrence. MRD levels, cytogenetics abnormalities and Absolute Lymphocyte Count (ALC) prior to Blinatumomab therapy in relation to disease response are shown in Table. In addition, patients with t(1,19) had worse outcome compared to other cytogenetic abnormalities.Follow-up duration was (0.4–5) years.

Characteristics	N	Disease response (%)	
NCI risk at diagnosis			
Standard risk	19	13 (68)	
High risk	14	12 (85)	p=0.4
Gender			
Male	20	14 (70)	
Female	13	11(85)	p=0.43
Age at relapse(years)			
1-9.9	24	17(70)	
>10	9	8 (88)	p=0.73
Molecular/Cytogenetics:			
ETV6/RUNX1	6	4 (66)	
Hyperdiploidy	5	5 (100)	
t (1;19)	5	1(20)	
iAMP21	5	5(100)	
KMT2A-rerrangement	2	2(100)	
BCR ABL	2	1(50)	
Negative	3	3(100)	
others	5	4 (80)	p=0.24
ALL relapse :			
1st Relapse/Very early	4	3 (75)	
1st relapse/Early	7	3 (42)	
1st Relapse/Late	4	4(100)	
2nd Relapse including after HSCT	7	6(85)	
Relapse Site:

Chemotherapy/awaiting HSCT	17	13(76)	p=0.55
Overall outcome	20	60%	
Disease free	5	15%	
Alive with disease	8	24%	
Deceased			p=0.002

Summary/Conclusion: Blinatumomab therapy was associated with excellent response especially in ALL patients with positive MRD. MRD level <0.1% and Absolute Lymphocyte Count (ALC) > 1000/ul prior to Blinatumomab therapy were associated with better outcome. Large prospective studies are ongoing to study Blinatumomab upfront therapy in pediatric ALL patients with persistent MRD.

EP370 THE PATIENT EXPERIENCE OF ACUTE LYMPHOBLASTIC LEUKEMIA AND ITS TREATMENT: A SOCIAL MEDIA REVIEW

R. Morrison [1,*], S. Sikirica [2], R. Crawford [1], J. Cappelleri [3], A. Russell-Smith [2], R. Shah [2], H. Chadwick [1], L. Doward [1]

[1]RTI-Health Solutions, Manchester, United Kingdom, [2]Pfizer Inc., New York, [3]Pfizer Inc., Groton, United States

Background: Adult patients with acute lymphoblastic leukemia (ALL) report substantial disease- and treatment-related impacts on their health-related quality of life (HRQOL) despite improvements in treatment strategies over the past 10 years. As novel therapies are developed, greater insight into patients' experiences of current ALL treatments is needed. Patient-reported information (PRI) shared on social media provides a distinct opportunity to understand patients' perspectives outside of the formal research context.
Aims: This study—to our knowledge the first of its kind in ALL—thematically analyzed PRI shared on patient advocacy websites and YouTube to better understand patients' experiences of ALL and its treatment.
Methods: Searches were conducted of 3 patient advocacy websites (Patient Power, The Patient Story, and Leukemia Care) and YouTube to identify individual social media posts describing self-reported PRI on experiences of ALL and/or ALL treatments. English-language posts were included for review if posts were shared by adults (aged ≥ 18 years) with a self-reported ALL diagnosis and if content was relevant to patient ALL and treatment experience. Patients' demographic and disease characteristics were extracted from posts (where available), and the posts were analyzed thematically. A network analysis was conducted to delineate relationships among ALL symptoms, HRQOL impacts, and treatment-related symptoms and impacts.
Results: Of the 935 social media posts identified, 63 met the review criteria: 40 videos, 5 comments posted in response to videos, and 18 blog posts. The 63 posts were contributed by 41 individual patients. Twenty-one (51%) of the patients were male. Fatigue (n=20, 49%), shortness of breath (n=13, 32%), and bruising (n=12, 29%) were the symptoms prior to treatment that were most frequently discussed by patients. Substantial HRQOL impacts were also recorded, with 26 (63%) patients discussing impacts on personal relationships, 25 (61%) discussing psychological and emotional impacts, and 16 (39%) discussing impacts on work. Key themes relating to patients' treatment experiences included perspectives on inpatient treatment, treatment expectations and preferences, and treatment decision-making. Although inpatient treatment restricted patients' independence and social functioning, it also provided a few patients with a sense of safety. Patients also preferred treatments that minimized impact on their HRQOL; treatment intensity and time commitment were key drivers of HRQOL impact. Patients frequently relied on their doctors to drive their treatment decisions but were also influenced by family members. The network analysis indicated that ALL symptoms primarily affected patients' physical functioning, activities of daily living, and ability to work, while treatment-related symptoms and impacts primarily affected patients' emotional well-being.
Summary/Conclusion: This study provides novel and valuable insight into the patient experience of ALL and its treatments through an analysis of PRI shared on social media. ALL and treatment-related symptoms have distinct and often detrimental impacts on patients' HRQOL. Results were largely intuitive, with treatment side effects being particularly burdensome for patients and impacting their HRQOL. Patients report that in-patient care is associated with certain challenges (e.g., restricted independence and social functioning) but is also appreciated by a few patients for providing them with a sense of security. Overall, patients hope for treatments with less severe impacts on their HRQOL.

EP371 INOTUZUMAB OZOGAMICIN IN RELAPSED OR REFRACTORY ACUTE LYMPHOBLASTIC LEUKAEMIA: A REAL-WORLD RETROSPECTIVE STUDY IN THE UK

D. Marks [1,*], M. Alexander [2], J. Eva [2], S. Purcell [3], S. Wood [4]

[1]Bristol Haematology and Oncology Centre, University Hospitals Bristol NHS Foundation Trust, Bristol, [2]Real-World Evidence, Open Health Communications LLP, Marlow, [3]Global Pfizer Oncology, [4]Pfizer Oncology, Pfizer Ltd., Surrey, United Kingdom

Background: Inotuzumab ozogamicin (InO) is a CD-22 directed antibody-drug conjugate indicated for the treatment of relapsed or refractory B-cell acute lymphoblastic leukaemia (R/R ALL). In the randomised phase 3 INO-VATE study (Kantarjian 2016), InO demonstrated increased efficacy compared to conventional chemotherapy. We sought to evaluate the safety and efficacy of InO in the Real-World setting.
Aims: We aimed to characterise patients with R/R ALL initiated on InO in the UK, and evaluate disease response, survival, and occurrence of adverse events, including the risk of veno-occlusive disease / sinusoidal obstruction syndrome (VOD/SOS).
Methods: We conducted a retrospective chart review of 19 adult patients diagnosed with R/R ALL and initiated on InO at 3 centres across the UK between 1st June 2016 and 31st December 2020 (interim analysis, data from 9 patients from an additional site to be added to the poster). The study received ethics approval prior to study set up and data collection. All data was extracted by the patients' medical team in pseudonymised format prior to data analysis, therefore informed consent was not required.
Results: In total, 10/19 (53%) patients were Females, median age at initiation of InO was 50.8 (range 22.7–85.1) years, and median time since ALL diagnosis was 8.5 (1.3–30.5) months.
At initiation of InO, 17/19 (89%,) patients were experiencing their first relapse. 2/19 (11%) patients were BCR-ABL positive.
At the time of InO treatment initiation, 3/19 (16%) patients had previously received blinatumomab, and 6/19 (32%) patients had undergone a prior haematopoietic stem-cell transplant (HSCT).
After InO discontinuation, 4/19 (21%) patients underwent HSCT, and all received 2 cycles of InO; whilst in the remaining 15 patients, the number of cycles ranged from 1 to 6 (median 3). Among the 4 patients who underwent HSCT, 1 experienced VOD/SOS. Of the 15 patients not proceeding to HSCT, 1 patient experienced VOD/SOS, and subsequently died of this complication. This gave an overall incidence of VOD/SOS of 11%. Additionally, 2/19 (11%) patients experienced a grade 3/4 treatment related adverse event, and 1/19 (5%) patient had abnormal liver function tests not due to VOD/SOS.
After InO discontinuation, in the 16 patients who had available response data, 12 (75%) patients achieved CR/CRi. Of 10 evaluable complete responders, 9 (90%), achieved minimal residual disease (MRD) negativity (8 by flow cytometry and 1 by molecular assessment at a level of 10^{-4}).
At last contact, patients had a median overall survival of 9.4 months (range: 0.1 -37.2). In total, 13/19 (68%) patients were known to be alive at 6 months after InO initiation, and 7/19 (37%) patients at 12 months. All 6/19 (32%) patients who were still alive at the time of data collection had achieved CR with a median follow-up of 14.6 months.
Summary/Conclusion: In this sample of UK patients, InO was an effective treatment for patients with R/R B-cell ALL. Response rates, MRD negativity and safety profile were broadly consistent with the established profile of InO in the published phase 3 INO-VATE study.

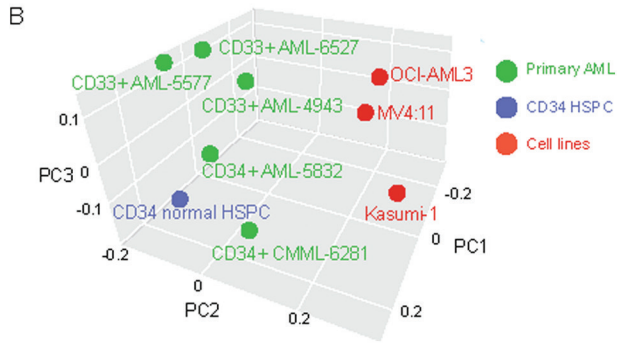
Acute myeloid leukemia - Biology & Translational Research



EP372 3D GENOMICS OF ACUTE MEYLOID LEUKEMIA REVEALS THE IMBALANCE BETWEEN DNA METHYLATION CANYON INTERACTIONS AND LEUKEMIC SPECIFIC ENHANCER NETWORK INTERACTIONS

X. Zhang [1,2,*], D. Wang [2], F. Feng [3], J. Liu [4], Y. Dou [5]

[1]Pathology, The University of Michigan, Ann Arbor, [2]Center for Epigenetics, Van Andel Institute, Grand Rapids, [3]The department of computational medicine, University of Michigan, [4]The department of computational medicine, The University of Michigan, Ann Arbor, [5]The University of Southern California, Los Angeles, United States

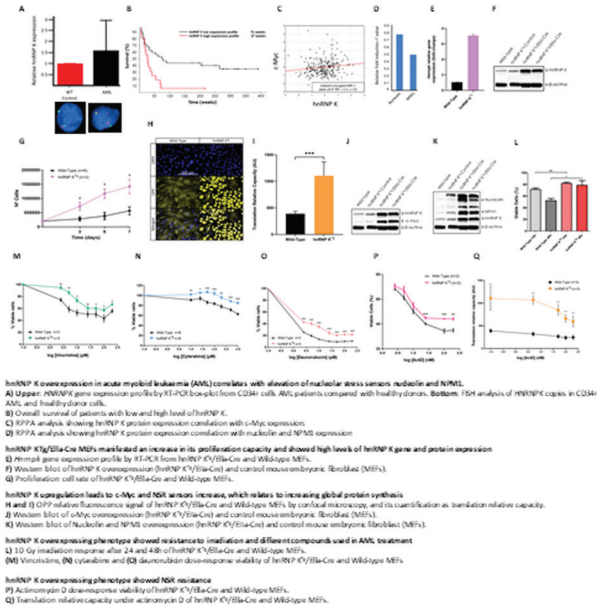
Background: Changes in 3D chromatin organization like enhancer hijacking are believed to the driver for disease development like leukemia. Here we performed high-resolution HiC assays on primary acute myeloid leukemia (AML) samples and cell lines to dissect the abnormal 3D chromatin organization in AML. We have recently generated a high-resolution map for normal human hematopoietic stem cells (HSC) (Zhang et al. Mole Cell. 2020).
Aims: To dissect the pathogenic alteration in 3D genomics of acute meyloid leukemia
Methods: We use *in situ* HiC to generate the high resolution HiC contact map. Our data set covers 5 AML samples and 3 AML cell lines. This dataset includes the common genetic abnormalities in AML: *MLL*-rearrangement, *NPM1* mutation, *RUNX1* mutation, and *IDH1/TET2* mutations (Figure 1A,B).
Results: In comparison with the HSC 3D chromatin organization, we found TADs and loops are very stable in both primary leukemia samples and cell lines. Less than 5% of all TADs in HSC without disruption of gene expression for genes located in the fused TAD. Interestingly, in *TET2* or *IDH1* mutated AML, two-fold more TAD fusion events occurred in comparison with *RUNX1* and *MLL-r* leukemia, with a hypermethylation on the TAD fusion break point regions.
Compared with normal HSC, we found in AML, the AML-specific H3K27ac marked regions form leukemia specific loops and transcription stripes in both cell lines and primary samples. Particularly in MLL-r primary leukemias, we found broad H3K27ac covered, hyperacetylated domains (10kb to 200kb). 22 such hyperacetylated domains were identified and associated with leukemogenic genes such as *SATB1*, *ZEB2* and *HOXA*. All these domains formed distinct 3D micro-TAD in the MLL-r primary leukemia in comparison with the HSPC, and CTCFs are not located at the border of these domains. Taken together, suggest active leukemia specific transcription created new 3D genomic interactions which is independent of cohesion-CTCF mediated loop extrusion. Particularly, we found the driving oncogenic transcriptional factor HOXA9 and MEIS1 is driving the leukemia specific 3D genomic interactions in *MLL-AF9* and *NPM1* mutant leukemias.
We previously found in HSC, the Polycomb marked DNA methylation Canyons (DMC) form multi-Mb size long-range interactions. DMC interactions in general decrease in primary AMLs. AMLs with *IDH1* or *TET2* mutations shows the biggest reduction in DMC interactions. Hypermethylation in the DMCs is observed in the all AML samples, but *IDH1* and *TET2* mutated AML shows the biggest reduction in the H3K27me3 enrichment in DMC regions, suggesting the level of H3K27me3 enrichment is directly correlated with the strength of DMCs. Remarkably, we found some DMCs switched to active state with gain of active chromatin market H3K27ac. Particularly, two Iroquois homeobox genes, which lies in proximity on chromosome 16 - *IRX3* and *IRX5* are activated in *NPM1c* leukemia. We found that *IRX3* and *IRX5* form the long-range stripe interactions with *FTO* intron enhancer as in the muscle and brain. Further test shows IRX3 and IRX5 is essential for the leukemia growth and the expression is directly maintained by NPM1c in a NPM1c targeted degradation system.

Summary/Conclusion: In summary, we have found in AML, specific 3D genomics interactions associated with leukemia specific transcription is established *de novo*. Particularly, we discovered the DNA methylation Canyon in AML switch from polycomb repressed state to activation state by direct activation of NPM1c.

EP373 FUNCTIONAL COOPERATION OF CEBPA AND TET2 MUTATIONS IN ACUTE MYELOID LEUKEMIA

E. Heyes [1,*], A. S. Wilhelmson [2,3,4], A. Wenzel [2,3,4], M. B. Schuster [2,3,4], M. Ali [3,4], T. D'Altri [2,3,4], T. Eder [1], G. Manhart [1], E. Rzepa [1], L. Schmidt [1,5], M. Meggendorfer [6], T. Haferlach [6], G. Volpe [7,8], C. Nerlov [9], J. Frampton [8], K. J. Won [3,4], F. Grebien [1], B. T. Porse [2,3,4]

[1]Institute of Medical Biochemistry, University of Veterinary Medicine Vienna, Vienna, Austria, [2]The Finsen Laboratory, Rigshospitalet, Faculty of Health Sciences, [3]Biotech Research and Innovation Center (BRIC), [4]Novo Nordisk Foundation Center for Stem Cell Biology, DanStem, Faculty of Health Sciences, University of Copenhagen, Copenhagen, Denmark, [5]Roche Austria GmbH, Vienna, Austria, [6]MLL Munich Leukemia Laboratory, Munich, Germany, [7]Laboratory of Integrative Biology, Guangzhou Institutes of Biomedicine and Health, Chinese Academy of Sciences, Guangzhou, China, [8]Institute of Cancer and Genomic Sciences, College of Medical and Dental Sciences, University of Birmingham, Birmingham, [9]MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom



Background: The transcription factor CCAAT-enhancer-binding protein alpha (C/EBPα) is a master regulator of granulopoiesis. Usage of two alternative translation initiation sites in the *CEBPA* mRNA results in expression of a full-length C/EBPα protein, termed p42 (42 kDa) and a shorter p30 isoform (30 kDa). *CEBPA* is mutated in 10-15 % of Acute Myeloid Leukemia (AML) patients. While N-terminal frameshifts that ablate the expression of p42 represent the predominant type of lesions, mutations in the C-terminal basic-region leucine zipper (bZip) that disrupt the DNA-binding ability of C/EBPα are also found. AML patients harbor either mono- or biallelic *CEBPA* mutations (CEBPAmo or CEBPAbi) and both genotypes are frequently associated with concurrent mutations in other genes. The most commonly co-occurring mutations in both groups are loss-of-function mutations in the methylcytosine dioxygenase TET2 (44.4 % in CEBPAmo / 34.8 % in CEBPAbi), resulting in adverse overall survival. We hypothesized that combinatorial effects of *CEBPA* mutations together with *TET2* loss specifically rewire transcriptional and epigenetic circuitries in AML cells, thereby strongly influencing disease outcome.
Aims: We aimed to elucidate the molecular mechanisms behind cooperative effects of *CEBPA* and *TET2* mutations through state-of-the-art transcriptomic and epigenomic analyses of relevant *in vitro* and *in vivo* models as well as data from AML patients.
Methods: We used the CRISPR-Cas9 technology to introduce *Tet2* mutations into murine cell lines expressing only the p30 isoform (*Cebpa*$^{p30/p30}$) or mimicking biallelic *CEBPA* mutations (*Cebpa*$^{p30/C\text{-}mut.}$) to study functional cooperation of these mutations *in vitro*. A *Cebpa*$^{-/p30}$ *Tet2*$^{-/-}$ mouse model was used to study effects of *Tet2* loss in *CEBPA* mutated AML. We performed RNA-, C/EBPα-ChIP-, ATAC- and Bisulfite-seq to generate a comprehensive dataset for in-depth comparative analysis and correlation with relevant patient data from the beatAML collection.
Results: CRISPR/Cas9-mediated introduction of *Tet2* mutations into *Cebpa*$^{p30/p30}$ and *Cebpa*$^{p30/C\text{-}mut.}$ cell lines conferred a strong proliferative advantage to *Tet2*-targeted cells *in vitro*. In line, loss of *Tet2* in a mouse model of *CEBPA* mutant AML shortened leukemia latency. TET2 loss caused decreased global chromatin accessibility and increased DNA methylation, which was accompanied by downregulated expression of numerous genes. Integration of transcriptomic and epigenomic data from *in vitro* and *in vivo* models with gene expression analyses in AML patients harboring *CEBPA* and *TET2* mutations identified the transcription factor GATA2 as a conserved target of the CEBPA-TET2 axis. ChIP-seq showed that p30 binds to multiple regions in the *Gata2* locus, and Tet2 loss caused reduced accessibility and increased DNA methylation of the *Gata2* promoter. RNAi-mediated silencing revealed a dose-dependent effect of *Gata2* expression on leukemia cell fitness *in vivo*. Furthermore, treatment with the demethylating agent 5-azacytidine restored *Gata2* expression in an AML model with *Cebpa* and *Tet2* mutations and caused a significant survival benefit.
Summary/Conclusion: The datasets generated from these novel models enable deeper insights into the global epigenetic and transcriptomic changes that depend on *CEBPA* and *TET2* mutations in a physiologically relevant mutational context. Our results reveal deregulated *GATA2* expression as a result of mutational disruption of *CEBPA* and *TET2* in AML and show that restoration of *GATA2* expression can be beneficial for AML patients with *CEBPA* and *TET2* mutations.

EP374 HNRNP K OVEREXPRESSION CONTRIBUTES TO POOR PROGNOSIS AND CHEMORESISTANCE IN AML BY DEVELOPING SUPER-NUCLEOLUS

P. Aguilar-Garrido [1,*], M. Velasco-Estévez [1], M. Hernández-Sánchez [1], P. Malaney [2], M. JL Aitken [2], K. H Young [2], R. Duan [2], P. C. Hu [2], X. Xhang [2], S. Kornblau [2], M. Á. Navarro Aguadero [1], D. Megías Vázquez [3], J. Gómez Alonso [3], M. Pérez Martínez [3], G. Mata Martínez [3], J. Martínez López [1], M. Gallardo Delgado [1]

[1]Haematological Malignancies Clinical Research Unit, Spanish National Cancer Research Center, Madrid, Spain, [2]Leukemia Department, MD Anderson, Texas, United States, [3]Confocal Microscopy Unit, Spanish National Cancer Research Center, Madrid, Spain

Background: hnRNP K is a ribonucleoprotein involved in processing hnRNAs into mature mRNAs, transcription, and translation control. hnRNP K participates in the nuclear-cytoplasmic shuttling and transmission of information from the nucleus to the cytoplasm. In previous studies, we noticed that *HNRNPK* overexpression is linked with acute myeloid leukaemia's (AML) poor prognosis, which is also related to an oncogenic event, i.e. Nucleolar Stress Response (NSR) resistance. Thus, our objective is to decipher the underlying molecular mechanism by which hnRNP K is related to AML's poor outcomes.
Aims: Our aim is to test the impact on proliferation and tumour development of hnRNP K overexpression due to the generation of NSR resistance
Methods: Clinical bone marrow samples from AML patients with high and low levels of hnRNP K (n=415) were used to study HNRNPK protein expression. Additionally, we analyzed *HNRNPK* copy number by FISH (n=205). Moreover, reverse-phase protein array (RPPA) of AML patients was performed and showed HNRNPK and C-MYC overexpression correlation. hnRNP K overexpression mice models, hnRNP K^{Tg}/EIIa-Cre and hnRNP K^{Tg}/UBC-Cre were used as validation of human samples. Molecular analysis (RT-qPCR, WB and Confocal Microscopy) of hnRNP K, c-Myc, B23 and NPM1 were performed using Mouse Embryonic Fibroblast (MEFs) from our mice models. Also, we analyzed protein synthesis capacity (OPP assay) and NSR sensors by confocal microscopy. Finally, viability and dose-response assays with genotoxic compounds were performed using trypan blue and WST-1
Results: AML patient samples revealed an amplification in the copy number of *HNRNPK* and the consequent gene overexpression and poor outcomes. Moreover, HNRNPK overexpression correlates with c-MYC and NSR sensors (B23 and C23) overexpression (Fig. A, B, C, D). MEFs showed gene and protein high levels of hnRNP K, which correlates with an increase in its proliferation capacity (Fig. E, F, G). Molecularly, this increase leads to c-Myc and NSR sensors upregulation, contributing to increasing global protein synthesis (Fig. H, I, J, K). In addition, these cells showed resistance to irradiation and genotoxic compounds such as vincristine, cytarabine and daunorubicin (Fig. L, M, N, O). Furthermore, this hnRNP K upregulated phenotype manifests NSR resistance when we exposed these MEFs to Actinomycin D. This event could correlate with an increase in NSR sensors such as B23 and C23 (Fig. P, Q).

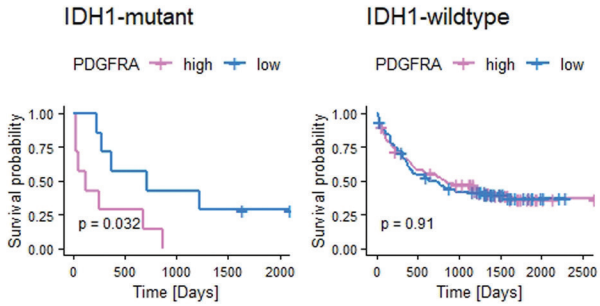
hnRNP K overexpression in acute myeloid leukaemia (AML) correlates with elevation of nucleolar stress sensors nucleolin and NPM1.
A) Upper: *HNRNPK* gene expression profile by RT-PCR box-plot from CD34+ cells. AML patients compared with healthy donors. **Bottom:** FISH analysis of HNRNPK copies in CD34+ AML and healthy donor cells.
B) Overall survival of patients with low and high level of hnRNP K.
C) RPPA analysis showing hnRNP K protein expression correlation with c-Myc expression.
D) RPPA analysis showing hnRNP K protein expression correlation with nucleolin and NPM1 expression

hnRNP K Tg/EIIa-Cre MEFs manifestated an increase in its proliferation capacity and showed high levels of hnRNP K gene and protein expression
E) *Hnrnpk* gene expression profile by RT-PCR from hnRNP K^{Tg}/EIIa-Cre and Wild-type MEFs.
F) Western blot of hnRNP K overexpression (hnRNP K^{Tg}/EIIa-Cre) and control mouse embryonic fibroblast (MEFs).
G) Proliferation cell rate of hnRNP K^{Tg}/EIIa-Cre and Wild-type MEFs.

hnRNP K upregulation leads to c-Myc and NSR sensors increase, which relates to increasing global protein synthesis
H and I) OPP relative fluorescence signal of hnRNP K^{Tg}/EIIa-Cre and Wild-type MEFs by confocal microscopy, and its cuantification as translation relative capacity.
J) Western blot of c-Myc overexpression (hnRNP K^{Tg}/EIIa-Cre) and control mouse embryonic fibroblast (MEFs).
K) Western blot of Nucleolin and NPM1 overexpression (hnRNP K^{Tg}/EIIa-Cre) and control mouse embryonic fibroblast (MEFs).

hnRNP K overexpressing phenotype showed resistance to irradiation and different compounds used in AML treatment
L) 10 Gy irradiation response after 24 and 48h of hnRNP K^{Tg}/EIIa-Cre and Wild-type MEFs.
(M) Vincristine, **(N)** cytarabine and **(O)** daunorubicin dose-response viability of hnRNP K^{Tg}/EIIa-Cre and Wild-type MEFs

hnRNP K overexpressing phenotype showed NSR resistance
P) Actinomycin D dose-response viability of hnRNP K^{Tg}/EIIa-Cre and Wild-type MEFs.
Q) Translation relative capacity under actinomycin D of hnRNP K^{Tg}/EIIa-Cre and Wild-type MEFs.



Summary/Conclusion: HNRNPK is amplified and overexpressed in AML patients, which manifest less survival than patients without this upregulation. Moreover, hnRNP K regulates c-Myc that triggers the global translation process. Therefore, the c-Myc upregulation leads to an increase in ribosome biogenesis and function, enhancing global translation. In addition, overexpression of hnRNP K drives B23 and C23 increase, which could establish a hyperactivated nucleolus. These events evoke an oncogenic event known as "Nucleolar Stress". Moreover, hnRNP K overexpression showed NSR resistance. Super-nucleolus drives the NSR resistance that promotes the chemo-resistance to different AML treatments, explaining these poor outcomes. Thus, the development of a specific hnRNP K inhibitor would potentially open the door to new treatments of AML patients that do not respond to treatment due to hnRNP K overexpression.

EP375 IDH MUTATIONS DRIVE LEUKEMOGENESIS BY ONCOGENIC ACTIVATION DUE TO INSULATOR DYSFUNCTION

S. Steinhäuser [1,*], P. Silva [2], S. Hänzelmann [1], M. Neumann [1], L. Bastian [1], K. Richter [1], S. Xia [3,4], L. Lenk [5], F. Vogiatzi [5], D. M. Schewe [5], M. Spielmann [6], C. Röllig [7], C. D. Baldus [1]

Background: Acute myeloid leukemia (AML) is a heterogenous disease, characterized by complex patterns of molecular alterations and somatic driver mutations in genes of numerous functional categories, such as *NPM1*, *DNMT3A* or *IDH1/2*. In younger adults, *IDH1* mutations occur in 6-10% of AML cases, whereas elderly AML patients show a significantly higher *IDH1* mutation frequency of 17.2% accompanied by DNA hypermethylation. Despite advances in targeted therapy due to the recent approval of *IDH* inhibitors (Enasidenib, Ivosidenib), elderly AML patients with *IDH* mutations still have an inferior outcome irrespective of cytogenetic group with high rates of chemotherapy resistance and relapses. Recently, the *IDH1* p.R132H mutation was linked to altered DNA loop formation by disrupted CTCF binding, leading to oncogene activation in glioma cells, which correlated with inferior outcome.
Aims: Here, we investigate the role of the *IDH1* p.R132H mutation in altering 3D DNA architecture and subsequent activation of oncogene expression in AML.
Methods: To identify upregulated oncogenes in *IDH1*-mutant (-mut) AML, differential gene expression was analyzed in two independent AML datasets, the BeatAML RNA-Seq dataset with n = 264 patients with annotated *IDH1*-status (Tyner et al. 2018) and a microarray dataset with n = 247 patients (Verhaak et al. 2009). To validate enhanced oncogene expression by RT-qPCR and investigate DNA loop formation, we generated a KG1a-based cellular model containing the *IDH1* p.R132H point mutation using CRISPR base editing. Confirmed oncogenes were correlated with differential occupancy and methylation of corresponding CTCF binding sites using chromatin immunoprecipitation (ChIP) and methylation-sensitive restriction followed by RT-qPCR. Clinical relevance of identified oncogenes was investigated by comparing survival of patients with high or low oncogene expression with or without *IDH1* mutation in two independent clinical datasets (BeatAML and Bamopoulos et al. 2020, n = 246).
Results: Differential expression analysis of AML datasets identified 179 genes upregulated by >1.5 fold (ANOVA, $p < 0.05$) in *IDH1*-mut AML patients compared to *IDH1*-wildtype (-wt) patients, including 13 oncogenes. Upregulated oncogene expression was confirmed in the KG1a *IDH1* p.R132H model revealing highest upregulation (2.5 fold) of the receptor tyrosine kinase gene *PDGFRA*. Quantification of CTCF occupancy identified decreased CTCF binding by 30% at the CTCF anchor region 1.7 Mb upstream of the *PDGFRA* locus. In addition, DNA methylation of the identified CTCF binding site was increased by 2-fold in cells harboring the *IDH1* p.R132H mutation. Analysis of AML clinical data revealed significantly decreased survival of AML patients with high *PDGFRA* expression among *IDH1*-mut but not *IDH1*-wt patients (Fig. 1, OS of *IDH1*-mut/-wt patients with high/low *PDGFRA*, data: Bamopoulos). Interestingly, *IDH1*-mut KG1a cells showed higher sensitivity towards the tyrosine kinase inhibitor Dasatinib in a WST-based drug screen, supporting Dasatinib as novel candidate for treatment of AML patients with *IDH1* mutation.

Summary/Conclusion: Our data suggest that *IDH1* p.R132H mutation leads to 3D conformational changes in AML, disrupting DNA loop formation and insulation of the tyrosine kinase *PDGFRA*, which subsequently results in upregulated *PDGFRA* oncogene expression. As high *PDGFRA* expression correlated with poor prognosis, treatment with tyrosine kinase inhibitor Dasatinib may be an option for *IDH1* p.R132H mutant AML patients. Our findings offer a base for novel treatment strategies and tackling resistance in AML patients with *IDH1* mutations.

EP376 NEXT-GENERATION SEQUENCING (NGS)-BASED MEASURABLE RESIDUAL DISEASE (MRD) MONITORING IN ACUTE MYELOID LEUKEMIA WITH FLT3 INTERNAL TANDEM DUPLICATION (FLT3-ITD+ AML) TREATED WITH ADDITIONAL MIDOSTAURIN

Background: *FLT3*-ITD occurring in ~25% of adult AML patients (pts) is associated with poor prognosis. *FLT3*-ITD represents an attractive target for MRD monitoring particularly in pts treated with a tyrosine kinase inhibitor. We have recently demonstrated that NGS can overcome the limitations of the broad heterogeneity of ITD length and insertion site (IS) offering the opportunity for MRD monitoring in *FLT3*-ITD$^+$ AML.
Aims: To validate our NGS-based *FLT3*-ITD MRD assay and to evaluate the prognostic impact of *FLT3*-ITD MRD monitoring in *FLT3*-ITD$^+$ AML treated within the AMLSG16-10 trial (NCT01477606) combining intensive chemotherapy with midostaurin followed by midostaurin maintenance.
Methods: Using *FLT3*-ITD paired-end NGS (Illumina MiSeq) and getITD with a variant allele frequency (VAF) sensitivity of 10^{-4}-10^{-5}, 336 bone marrow (BM) and 36 peripheral blood samples from 96 *FLT3*-ITD$^+$ AML pts were analyzed at diagnosis (Dx), after two cycles of chemotherapy (Cy2), at end of treatment (EOT), and during 3-12 months follow-up (FU). All pts achieved complete remission (CR) after Cy2. Allogeneic hematopoietic cell transplantation in first CR (HCT in CR1) was performed in 72 (75%) pts. *NPM1* and *DNMT3A* mutation status were available for all pts (*NPM1*^{mut}, n=74; *DNMT3A*^{mut}, n=48; *NPM1*^{mut}/*DNMT3A*^{mut}, n=46); *NPM1*^{mut} MRD data in 67 pts.

Results: At Dx we identified 296 ITDs; with 71% of the pts exhibiting >1 ITD at Dx (median 2; range, 1-15). Median length was 48 nucleotides (range, 9-240) and median VAF 0.280% (0.006-90.21). Of the 296 ITDs, 69% located in the juxtamembrane domain and 31% in the tyrosine kinase domain-1. VAF did not correlate with length or IS, whereas ITD length correlated with IS: the more 3´ the IS, the longer the ITD (Rho=0.51; p<.001). Median total ITD VAF per pt was 32.6% (0.57-90.21) and correlated positively with white blood cell count (WBC, Rho=0.233; p=.024), and inversely with ITD number (Rho=-0.221; p=.03). There were no correlations with other clinical or genetic features. Pts' total ITD VAF significantly decreased after Cy2 and at EOT (median $\log_{10}$ reduction: 4.4 and 4.7; p<.001, each), and MRD negativity (MRD^-) was achieved in 64% and 87%, respectively. Concurrent *NPM1*^{mut} favorably impacted on $\log_{10}$ VAF reduction (median, 4.7 for *NPM1*^{mut} vs 4.7 for *DNMT3A*^{mut}/*NPM1*^{mut} vs 2.9 others; p<.001) and MRD^- (78 vs 72 vs 30%; p=.001) after Cy2, but exerted no impact at EOT. *NPM1*^{mut} and *FLT3*-ITD MRD course correlated positively after Cy2 (Rho=0.423; p=.001), but not at EOT, likely due to the higher sensitivity of the *NPM1*^{mut} MRD assay (qRT-PCR).
Median follow-up was 3.8 years (95% CI, 3.0-4.7). Survival analyses for cumulative incidence of relapse (CIR) and overall survival (OS) revealed in strong trend lower CIR for total VAF per pt at Dx >32.6% (p=.055), significantly lower CIR for VAF reduction >4.4 $\log_{10}$ ($MR^{4.4}$) after Cy2 (p=.028), $MR^{4.7}$ at EOT (p=.007), and for MRD^- at EOT (p<.001). There was no impact on OS. In exploratory Cox regression (n=72), including BM blasts, WBC, lactate dehydrogenase, age, *NPM1*^{mut}, and HCT in CR1 as time dependent variable, MRD^- at EOT was the only consistent favorable variable for CIR (HR, 0.1; p=.001) and OS (HR, 0.33; p=.046). *NPM1*^{mut} (HR, 0.04; p<.001) and HCT in CR1 (HR, 0.1; p=.002) were favorable for CIR.
Summary/Conclusion: In this cohort of *FLT3*-ITD$^+$ AML treated with intensive chemotherapy and midostaurin we could demonstrate that a large proportion of pts became MRD^- at EOT by *FLT3*-ITD NGS-based MRD monitoring which reveals as a promising tool to monitor therapy response and to identify pts at a higher risk of relapse.

EP377 AGEING MIMICS LEUKEMIC ADAPTATION OF BONE MARROW STROMAL CELLS AND PROMOTES ACUTE MYELOID LEUKEMIA INITIATION

X. Ren [1,*], A. Thomas [1], S. Valletta [1], C. Nerlov [1]

[1]*Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom*

Background: The incidence of acute myeloid leukemia (AML) increases with age and elderly patients display increased frequency of unfavorable cytogenetics. However, when compared to similarly-treated younger patients from the same cytogenetic risk group, elderly patients still experience lower overall survival, indicating that age-related differences extrinsic to hematopoietic cells contribute to AML therapy resistance and disease relapse. Interactions between leukemic cells and the bone marrow (BM) microenvironment are crucial for myeloid leukemia progression. Indeed, leukemic cells have the ability to shape their microenvironment in order to support their expansion and BM stromal cells can support malignant hematopoiesis at the expense of normal hematopoiesis. The BM microenvironment also changes during ageing, contributing to the age-associated decline in adaptive immunity, and platelet-myeloid bias of cellular output. These changes can potentially contribute to the increased prevalence of myeloid malignancies seen in the elderly population.
Aims: Address the potential role of the aged microenvironment in myeloid leukemogenesis by investigating the correlation between AML- and ageing-related changes in the BM microenvironment.
Methods: We developed a murine model of *Cebpa* mutant AML, where *Cebpa* mutant leukemic initiating cells (LICs) were injected into sub-lethally irradiated young mice, reproducibly leading to AML in 4 weeks. Flow cytometry was used to study the changes that occur to the abundance of BM niche during AML development. Molecular profiling of leukemic cells and BM stromal cells during leukemogenesis was performed, and the identified changes were overlaid with those occurring during physiological ageing.
Results: In our *Cebpa* mutant AML model, the 2-, 3- and 4-week time points represented 3 key stages of leukemia progression: i) an early expansion phase with no overt leukemia; ii) a late expansion phase with leukemia cells highly abundant in hematopoietic organs, and iii) a terminal phase where normal BM hematopoiesis is displaced (Figure 1A). As most AML cells occupy the central BM (CBM), we focused on CBM vascular endothelial cells (VECs) and perivascular cells (PVCs). We observed a decrease in the number of CBM VECs in leukemic, compared to mock transplanted mice, which was similar to that observed during normal ageing. CBM VECs and PVCs were profiled by RNA sequencing at the 3 key time points after LIC transplantation, with cells from mock transplanted mice profiled as controls. In CBM VECs, we observed a significant overlap between the genes and process networks altered during ageing and those altered at week 3 of AML (Figure 1B). In addition, several cytokines produced by leukemic cells were capable of expanding myeloid progenitors (the closest normal counterpart of LIC) *in vivo*. These cytokines were also upregulated in aged BM stromal cells, consistent with the aged BM microenvironment sharing characteristics with that adapted to AML (Figure 1C-D). This hypothesis was confirmed when we observed leukemia engraftment only in non-irradiated aged mice injected with *Cebpa* mutant LICs but not in young mice (Figure 1E).

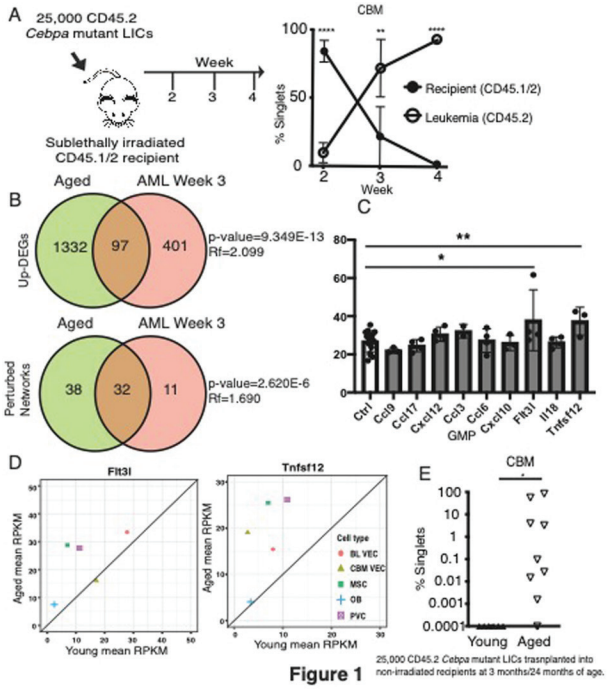

Figure 1

Summary/Conclusion: Molecular and functional similarities exist between the BM microenvironment generated during leukemia progression and physiological ageing. These similarities may contribute to increased AML incidence and progression by providing support for the expansion of myeloid progenitors, including LICs.

EP378 SELECTIVE REQUIREMENT OF MYB FOR ONCOGENIC HYPERACTIVATION OF A TRANSLOCATED ENHANCER IN ACUTE MYELOID LEUKEMIA

L. Smeenk [1,2,*], S. Ottema [1,2], R. Mulet-Lazaro [1,2], A. Ebert [3], M. Havermans [1,2], A. Arricibita Varea [1,2], M. Fellner [3], D. Pastoors [1,2], S. van Herk [1,2], C. Erpelinck [1,2], T. Grob [1], R. Hoogenboezem [1], F. G. Kavelaars [1], D. R. Matson [4], E. H. Bresnick [4], E. Bindels [1], A. Kentsis [5], J. Zuber [3,6], R. Delwel [1,2]

[1]*Department of Hematology,* [2]*Oncode Institute, Erasmus University Medical Center, Rotterdam, Netherlands,* [3]*Research Institute of Molecular Pathology (IMP), Vienna BioCenter (VBC), Vienna, Austria,* [4]*Department of Cell and Regenerative Biology, Madison, WI,* [5]*Tow Center for Developmental Oncology, Sloan Kettering Institute, Department of Pediatrics, Weill Medical College of Cornell University, Memorial Sloan Kettering Cancer Center, New York, United States,* [6]*Medical University of Vienna, Vienna BioCenter (VBC), Vienna, Austria*

Background: Chromosomal inversion or translocation between 3q21 and 3q26 (inv(3)/t(3;3)) results in the aberrant expression of the proto-oncogenic transcription factor *EVI1* located at 3q26, causing the development of Acute Myeloid Leukemia (AML). It has been shown that in those AMLs a single *GATA2* enhancer at chromosome 3q21

translocates to 3q26 and turns into a hyperactive super-enhancer, driving overexpression of *EVI1*. AMLs with inv(3)/t(3;3) are dependent on *EVI1* and are characterized by an aggressive course and are refractory to therapy.
Aims: In this study we aimed to investigate how the hijacked *GATA2* enhancer leads to *EVI1* activation. To this purpose, we identified sequence motifs in this enhancer essential for *EVI1* transcription in inv(3)/t(3;3) AML.
Methods: We generated a model to study *EVI1* regulation in inv(3)/t(3;3) AML cells by inserting a *GFP* reporter 3' of endogenous *EVI1* into the inv(3) MUTZ3 cell line. To uncover important transcription factor binding elements essential for driving *EVI1* transcription in the *GATA2* hijacked enhancer, we applied an unbiased CRISPR/Cas9 enhancer scan. To this end, we constructed a lentiviral library containing all sgRNAs covering the translocated region and transduced it into MUTZ3-EVI1-GFP cells at a low multiplicity of infection to analyze the effect of single mutations in the enhancer on *EVI1* expression.
Results: The unbiased CRISPR/Cas9 scan of the translocated *GATA2* enhancer in 3q26-rearranged AMLs pinpointed a single regulatory element of approximately 1 kb of open chromatin that is critically required for aberrant *EVI1* expression. This element contained a DNA binding motif for the transcription factor MYB, which specifically occupied this site at the translocated allele. This motif was required for *EVI1* expression but dispensable for *GATA2*. *MYB* knockout as well as peptidomimetic blockade of CBP/p300-dependent MYB functions resulted in downregulation of *EVI1* but not of *GATA2*. Targeting *MYB* or mutating its DNA-binding motif within the translocated *GATA2* enhancer resulted in myeloid differentiation and cell death.
Summary/Conclusion: Our data show an essential role for MYB in the regulation of *EVI1* expression via the translocated *GATA2* enhancer. This is a novel paradigm in which chromosomal aberrations reveal critical regulatory elements that are non-functional at their endogenous locus. This knowledge provides a rationale to develop new compounds to selectively interfere with oncogenic enhancer activity.

EP379 MENIN INHIBITION DECREASES BCL-2 AND SYNERGIZES WITH VENETOCLAX IN NPM1/FLT3-MUTATED AML

B. Z. Carter [1,*], W. Tao [1], P. Y. Mak [1], D. Mak [1], G. McGeehan [2], P. Ordentlich [2], M. Andreeff [1]

[1]MD Anderson Cancer Center, Houston, [2]Syndax, Waltham, United States

Background: Nucleophosmin (NPM1) is the most commonly mutated gene in adult AML (approximately 30%), which results in its aberrant cytoplasmic localization (NPM1c). The interaction of mixed-lineage leukemia (MLL1) with menin in NPM1 mutated AML shares a common HOX gene signature and dependencies as that of MLL-rearrangements (MLL1-r) with menin. Indeed, inhibition of menin has demonstrated anti-leukemia activity in both NPM1c and MLL-r AML. NPM1 mutations in AML frequently occur in patients with other mutations, such as FLT3-ITD and FLT3 tyrosine kinase domain (TKD) mutations. Co-inhibition of menin and FLT3 has demonstrated enhanced anti-leukemia activity in MLL-r/FLT3- and NPM1c/FLT3-mutated AML.
Targeting Bcl-2, a critical factor for AML cell and AML stem/progenitor cell survival, has emerged as a promising therapeutic option for patients with AML. However, despite the major improvement of combining the Bcl-2 inhibitor venetoclax with hypomethylating agents, most patients develop resistance and ultimately relapse.
Aims: To investigate the anti-leukemic activity and potential synergism and mechanisms of the combination of the menin-MLL1 inhibitor SDNX-50469, an equipotent surrogate of the clinical compound SNDX-5613 and venetoclax *in vivo* in an NPM1c/FLT3-ITD/TKD patient-derived xenograft (PDX) model.
Methods: The PDX cell engrafted NSG mice were treated with 0.05 or 0.1% SNDX-50469-spiked chow, venetoclax (50 mg/kg), or 0.1% SNDX-50469 plus venetoclax for one month. Engraftment and disease progression were assessed by flow cytometric measurement of human $CD45^+$ cells in mouse peripheral blood. Survival was monitored. The treatment effects on various leukemia cell populations and their protein expression levels were determined by CyTOF mass cytometry.
Results: Menin inhibition exhibited strong anti-leukemia activity and significantly prolonged mouse survival, which was further enhanced when combined with venetoclax, while venetoclax alone had minimal effect. The combination was most effective in extending mouse survival (143 d for 0.1% SNDX-50469 plus venetoclax, $P = 0.0003$; 131 d and 125 d for 0.1% or 0.05% SNDX-50469, respectively, $P = 0.0001$ for both; 69 d for venetoclax, $P = 0.025$; vs. 61 d for controls). At the end of treatments, bone marrow cells were collected and CyTOF analysis demonstrated that menin inhibition preferentially targeted $CD34^+CD38^+$ cells, while venetoclax targeted $CD34^+CD38^-$ cells. Only the combined inhibition of menin and Bcl-2 effectively eliminated bulk and $CD34^+CD38^+$/$CD34^+CD38^-$ stem/progenitor cells. Menin inhibition also increased the $CD11b^+$ myeloid cell population. Mechanistically, menin inhibition decreased multiple anti-apoptotic Bcl-2 proteins including Bcl-2 and Bcl-xL, and concomitantly increased pro-apoptotic Bcl-2 proteins such as Bax that seemingly enhanced the activity of Bcl-2 inhibition by venetoclax. However, we observed increases of p-FLT3 in the surviving leukemia cells at the end of the treatments, particularly in the combination treated group, which may contribute to the regrowth of leukemia cells.
Summary/Conclusion: Our study further validated menin as a therapeutic target and demonstrated that its inhibition synergizes with venetoclax in NPM1/FLT3-mutated AML, which warrants further clinical evaluation. Inhibition of FLT3 may further enhance the therapeutic efficacy of menin and Bcl-2 co-targeting in NPM1 and FLT3 mutated AML.

EP380 IDENTIFICATION OF FUNCTIONAL GENETIC DEPENDENCIES AND DIRECT TRANSCRIPTIONAL TARGET GENES OF NUP98-JARID1A IN ACUTE MYELOID LEUKEMIA

S. Troester [1,*], J. Schmoellerl [2], T. Eder [1], G. Winter [3], J. Zuber [2], F. Grebien [1]

[1]Institute for Medical Biochemistry, University for Veterinary Medicine Vienna, [2]Research Institute of Molecular Pathology (IMP), [3]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria

Background: The Nucleoporin 98 (*NUP98*) gene is recurrently involved in the formation of oncogenic fusion proteins in acute myeloid leukemia (AML). While more than 30 partner genes have been identified to participate in *NUP98* gene fusions, NUP98-JARID1A is the most frequent NUP98-rearrangement in infant leukemia and is associated with particularly poor prognosis. As no targeted therapy exists, there is an urgent need for a better understanding of the molecular mechanisms of NUP98-fusion-protein-dependent leukemogenesis to enable the development of tailored treatments. We and others have shown that oncogenic NUP98-fusion proteins act as transcriptional regulators, but it is incompletely understood how NUP98-fusion proteins directly regulate gene expression to drive leukemia.
Aims: To unravel critical effectors of NUP98-fusion-driven leukemogenesis we aimed to identify direct transcriptional targets of NUP98-JARID1A and characterize their requirements for the development and maintenance of NUP98-JARID1A-expressing AML.
Methods: To investigate functional genetic dependencies we conducted a genome-scale CRISPR/Cas9 loss-of-function screen in a cellular model of NUP98-JARID1A-dependent AML. Next we reasoned that a detailed understanding of the underlying transcriptional circuitries is critical to understand NUP98-fusion-dependent gene regulation. Using a newly developed model for ligand-induced degradation of the NUP98-JARID1A protein via the degradation tag (dTAG) system and performing nascent RNA-seq (SLAM-seq), we measured immediate transcriptional changes upon acute NUP98-JARID1A degradation.
Results: Analysis of the CRISPR/Cas9 screen identified 2550 genes that are required for the proliferation and survival of a NUP98-JARID1A AML cells. With the newly established model for ligand-induced NUP98-JARID1A loss we achieved complete degradation of the fusion protein within one hour after ligand addition, leading to terminal differentiation and apoptosis of leukemia cells. Global analysis of nascent mRNA expression by SLAM-seq revealed that 45 genes were significantly downregulated upon NUP98-JARID1A degradation. By intersecting these candidates with the 2550 genes that were required for NUP98-JARID1A-AML cell growth, we identified 12 high-confidence essential direct targets of NUP98-JARID1A.
Summary/Conclusion: This approach allows the identification of functional genetic dependencies and direct transcriptional target genes of NUP98-JARID1A in AML. Multi-layered validations of high-confidence candidates in a variety of models, including primary patient samples, will provide new insights into the molecular mechanisms and transcriptional circuitries of NUP98-JARID1A-driven leukemia and might identify novel actionable gene targets.

EP381 FUNCTIONAL ANALYSIS OF ABERRANT GENE REGULATORY PROGRAMS AND SELECTIVE DEPENDENCIES IN EVI1/MECOM-DRIVEN ACUTE MYELOID LEUKEMIA

J. Schmoellerl [1,*], I. Barbosa [1], J. Jude [1], T. Eder [2], T. Neumann [1], F. Andersch [1], M. Fellner [1], A. Ebert [1], M. Steininger [1], F. Grebien [2], J. Zuber [1,3]

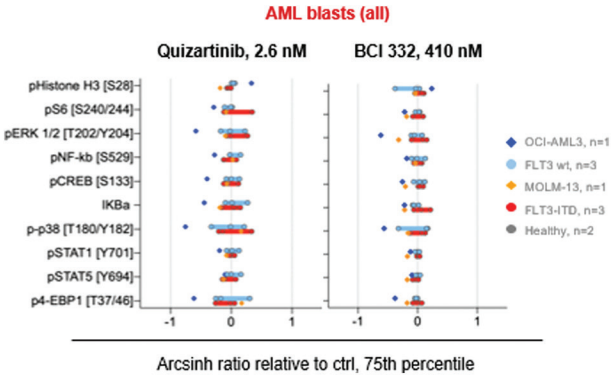
[1]Research Institute of Molecular Pathology (IMP), [2]Institute for Medical Biochemistry, University of Veterinary Medicine Vienna, [3]Medical University of Vienna, Vienna, Austria

Background: With a two-year survival of <10% chromosomal rearrangements involving EVI1/MECOM represent the most adverse genetic event in acute myeloid leukemia (AML). As established treatment options commonly fail in these patients, there is an urgent need for rational therapeutic concepts that will require a better understanding of molecular and cellular functions of the EVI1 oncogene in AML.
Aims: This study aimed to identify transcriptional programs and genetic dependencies evoked by aberrant EVI1/MECOM expression in AML.
Methods: We have developed a panel of murine and human models of EVI1-driven AML that recapitulate common phenotypic and transcriptional features of human EVI1-rearranged AML, enable conditional expression of EVI1 itself, as well as the RNAi- and CRISPR/Cas9-based genetic exploration of EVI1-associated candidate targets.
Results: We have characterized transcriptional programs evoked by EVI1 in cell culture models and in vivo, and systematically identified genetic dependencies through comparative CRISPR/Cas9-based screens. By integrating orthogonal data from transcriptome profiling, we identify factors that are both, aberrantly expressed and specifically required in EVI1-driven AML. Among these, we identify aberrant activation of ERG, an ETS-related transcription factor that is overexpressed in subgroups of patients suffering from AML and T-ALL, as highly selective dependency in EVI1-driven AML. Suppression of ERG triggers potent and selective anti-leukemic effects and terminal differentiation in human and murine models of EVI1-driven AML, while ectopic expression of ERG functionally rescues loss of the EVI1 oncogene.
Summary/Conclusion: We find that a major oncogenic function of EVI1 is to drive aberrant expression of ERG and thereby maintain leukemia cells in an immature state. Interfering with this regulatory axis may provide new entry points for rational therapies that are urgently needed for this group of AML patients.

EP382 NUP98/NSD1-POSITIVE AML IS ADDICTED TO A FUNCTIONAL MENIN-MLL INTERACTION

M. Rasouli [1,*], K. Szoltysek [1], R. Cameron [1], A. Krippner-Heidenreich [1], M. Zwaan [1], G. McGeehan [2], O. Heidenreich [1]

[1]Prinses Maxima Centrum, Utrecht, Netherlands, [2]Syndax Pharmaceuticals, Waltham, United States



Background: The chromosomal translocation t(5;11)(q35;q15.5) encoding the *NUP98/NSD1* fusion gene is a frequent rearrangement in pediatric high-risk AML. In more than 80% of all cases, *NUP98/NSD1* co-occurs with *FLT3-ITD* or *WT1* mutations. This AML subtype is characterized by a *HOXA/B* programme, where MLL binds to the N-terminus of the NUP98/NSD1 fusion protein and recruits it to the *HOXA* and *MEIS1* loci. In general, transcriptional activation by MLL depends on its interaction with its cofactor Menin. SNDX-5613 is a novel selective Menin-MLL inhibitor that resides with high affinity in the binding pocket of Menin and disrupts the Menin-MLL interaction. This inhibitor has recently been shown to have substantial single agent activity against MLL-rearranged and NPM1 mutant leukemia. Based on these combined findings, we hypothesized that the NUP98/NSD1 leukaemic programme depends on a functional Menin-MLL interaction that can be targeted by SNDX-5613.
Aims: The aim of this study was to examine the significance of the MLL – MEN1 interaction for *NUP98/NSD1*-driven gene expression and to explore the potency of SNDX-5613 to interfere with t(5;11)-AML propagation.
Methods: Patient AML samples positive for *NUP98/NSD1* were provided by the Princess Maxima Center for Pediatric Oncology. All samples were also positive for FLT3-ITD with VAFs > 0.35. AML samples were co-cultured with bone marrow-derived mesenchymal stromal cells (MSCs) and treated with different concentrations of SNDX-5613 (Syndax Pharmaceuticals) followed by evaluation of proliferation, gene and protein expression, clonogenicity and differentiation. Changes in cell surface marker expression were investigated after 2 weeks using flow cytometry.
Results: Co-culture of *NUP98/NSD1*-positive patient samples resulted in a 3 – 6-fold expansion of total cells and a 15 – 200-fold expansion of immature CD34+ CD38- CD117+ CD45RA+ leukaemic cells over a period of 14 days. Treatment of four different *NUP98/NSD1*-positive AML samples in this setting resulted in a profound dose-dependent inhibition of proliferation with latency of 10 days and IC50 values between 2 and 50 nM. On the contrary, primary AML cells lacking *NUP98/NSD1* translocation were not affected even by 250 nM of SNDX-5613, demonstrating on-target mechanism of action of this compound. This growth inhibitory effect was associated with a 70% reduction in clonogenicity both by colony number and size when compared with DMSO-treated cells. Furthermore, SNDX-5613 treatment induced myeloid differentiation in AML blasts as demonstrated by diminished expression of CD34 and CD45RA and concomitant elevated expression of CD11b, CD14 and MNDA. Transcriptional profiling upon SNDX-5613 treatment revealed specific changes in leukemogenic gene expression with downregulation of *HOXA7 – 10* and *MEIS1*. SNDX-5613 also reduced *CDK6* levels, a key regulator of cell cycle progression and an established direct transcriptional target of MLL and NUP98/NSD1. Notably, we found that and its potential target gene *FLT3* are uniformly downregulated in a dose dependent manner suggesting an impact of this drug on a secondary leukaemic driver.
Summary/Conclusion: This study demonstrates the relevance of the Menin-MLL interaction for NUP98/NSD1-driven leukemogenesis in primary patient cells and highlights the pharmacologic inhibition of this interaction as a promising therapeutic option for this poor prognosis AML.

EP383 MECHANISTIC STUDIES OF TENOFOVIR-DERIVED TYROSINE KINASE INHIBITORS TARGETING FLT3 IN ACUTE MYELOID LEUKEMIA

I. K. F. Motzfeldt [1,*], M. Hellesøy [1], M. Sabir [2], C. Amiable [3], M. L. Popa [2], K. Sletta [2], E. McCormack [2], V. Andresen [2], D. Surleraux [3], B. T. Gjertsen [1,2]

[1]Department of Medicine, Helse Bergen HF, [2]Department of Clinical Science, University of Bergen, Bergen, Norway, [3]BCI Pharma, Grabels, France

Background: About 25% of patients with acute myeloid leukemia (AML) have internal tandem duplications (ITDs) in the Fms-Like Tyrosine kinase-3 (FLT3) receptor, leading to constitutive activation of the receptor and downstream signaling pathways, and uncontrolled cell division. Several approved and investigational small molecule kinase inhibitors are available, although all kinase inhibitors show off target effects.
Aims: We investigated a novel library of highly selective FLT3-targeting inhibitors built on the chemical backbone of the anti-HIV drug tenofovir, aiming to identify new clinically safe inhibitors with superior FLT3-specificity and reduced off-target effects.
Methods: A panel of 40 analogs with kinase inhibitory properties were synthetized and screened in multiple cell lines expressing wild type (wt) and ITD-mutated FLT3 receptor using the WST-1 assay to define anti-leukemic effect IC_{50}, validated by Hoechst. The novel inhibitor BCI 332 was selected for further evaluation, using quizartinib as a reference compound. BCI 332 was investigated for in vivo toxicity and efficacy in an NSG (NOD/SCID IL2rγ^{null}) subcutaneous mouse model using MV4-11 (ITD/null) cells. Functional assessments of anti-leukemic effects (Annexin V/PI and cell cycle analysis) were performed by flow cytometry in MOLM-13 (FLT3 ITD/wt) and OCI-AML3 (FLT3 wt/wt) cells. Downstream effects of FLT3-inhibition were assessed by mass cytometry (CyTOF) in ex vivo treated mononuclear cells (bone marrow) from healthy donors and FLT3 wt (n=3) and FLT3-ITD mutated (n=3) AML patients, in addition to the cell lines MOLM-13 and OCI-AML3. Samples were stained with a panel of 19 extracellular and 13 intracellular antibodies, and cell subsets were identified by unsupervised clustering based on surface marker expression using the phenograph algorithm.
Results: We identified several potent inhibitors with differential effect on cells expressing FLT3 wt and FLT3-ITD. The inhibitor BCI 332 showed selectivity towards FLT3-ITD, and was therefore further assessed. *In vivo* toxicity and efficacy studies demonstrated low toxicity and potent anti-leukemic effect. Functional assays of MOLM-13 and OCI-AML3 cells showed that BCI-332 induced apoptosis in FLT3-ITD cells, although less potent than quizartinib. CyTOF analyses of healthy (monocytes and CD4 T cells) and leukemic cell subsets revealed heterogeneous response profiles in patient samples, although we did not identify significant differences between FLT3 wt and -ITD mutated samples (Figure).

Summary/Conclusion: The novel inhibitor BCI 332 induced apoptosis in FLT3-ITD mutated cells, and our results indicate higher specificity towards FLT3-ITD than the reference compound quizartinib. Our analyses did not reveal an ITD-specific intracellular response profile to BC I332, likely due to a small sample size and high inter-patient heterogeneity. Thus, work continues to expand the patient cohort, and to provide assessment of inhibition in immunophenotypically distinct leukemic cell subsets.

EP384 CIRCULATING EXTRACELLULAR VESICLES FROM ACUTE MYELOID LEUKEMIA PATIENTS REVEAL SPHINGOLIPID DEPLETION AND REDOX METABOLIC FUNCTION

D. Forte [1,*], R. M. Pellegrino [2], F. Fabbri [3], I. Vannini [3], S. Bruno [1], G. Corradi [1], G. Cristiano [1], S. Buratta [2], L. Urbanelli [2], C. Emiliani [2,4], M. Cavo [1,5], A. Curti [5]

(IRST) IRCCS, Meldola, [4]Centro di Eccellenza sui Materiali Innovativi Nanostrutturati (CEMIN), University of Perugia, Perugia, [5]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Institute of Hematology "L. e A. Seràgnoli", Bologna, Italy

Background: Extracellular vesicles (EVs) have emerged as a powerful reservoir of biomarkers for liquid biopsy in hematological malignancies. Indeed, EVs are small vesicles released by various blood cells and contain tumor-derived materials such as nucleic acids, proteins, and lipids. Interestingly, cell metabolism could be influenced by EVs through the regulation of redox processes. Of interest, redox metabolism plays a critical role in normal and leukemic hematopoiesis. Thus, although the role of EVs and their lipid cargo as disease biomarkers have been recently acknowledged in various diseases, the lipidomic profile of circulating EVs and their function on redox metabolism are still elusive in acute myeloid leukemia (AML).
Aims: We aimed to explore the lipidomic profile of EVs as a metabolic biomarker for AML and the effects of EVs on redox metabolism of hematopoietic stem/progenitor cells (HSPCs).
Methods: Peripheral blood was collected from AML patients at diagnosis (n=20) and healthy donors (HD, n=20). Immunomagnetically isolated $CD34^+$ cells from umbilical cord blood or AML patients were characterized by analyzing the HSPC-specific cluster of differentiation marker expression, redox profiling (using CellROX, glutathione detection, and MitoTracker) after co-culture with circulating EVs from HD/AML. EVs were purified from platelet-poor plasma by size exclusion chromatography (SEC) and quantified using the NanoSight technology. Quantitative lipidomic profiling was performed by Liquid Chromatography coupled with High-Resolution Mass Spectrometry (LC/HRMS).
Results: In this study, we observed a significant increase in the size of AML EVs compared to HD counterparts ($p= 0,008$). Interestingly, more than 200 molecular lipid species were quantitatively identified in circulating EVs with a total of 25 (out of 200) independent lipid species significantly different between AML-derived EVs and HD. Notably, we reported the abundance of both glycerolipid and fatty acids (FA) species in AML EVs. Within bioactive lipid markedly increased in AML-derived EVs, fatty acid esters of hydroxy fatty acids (FAHFA-18:0_30) were inversely correlated to the percentage of leukemic blasts in the bone marrow ($r= -0,72$, $p=0,009$) suggesting the role as a putative biomarker of disease severity. Through a multivariate statistical analysis of EV lipid profile, we also revealed that AML EVs are depleted in sphingomyelin classes (SMs), a class of lipids that are interconnected to the modulation of oxidative stress. Moreover, after co-cultures of EVs with umbilical cord blood HSPCs, we observed that only EVs isolated from HD increased the granulocyte-macrophage progenitors ($p=0.02$). Conversely, both HD- ($p=0.03$) and AML-derived EVs ($p=0.003$) reduced the megakaryocyte erythroid progenitors. Next, we explored redox metabolism function driven by EVs and we demonstrated a reduction in AML HSPC fraction with high ROS levels in the presence of AML EVs ($p=0.03$). In parallel, AML EVs increased the proportion of AML HSPCs with both high glutathione and mitochondrial potential (p=0.03). Finally, according to the 2017 ELN risk stratification system, we found that EVs from patients with adverse risk were depleted in specific ether-linked phosphatidylethanolamine (EtherPE) and phosphatidylethanolamine (PE) species that are important modulators of EV release and formation.
Summary/Conclusion: This work provides a unique lipid signature of circulating EVs from AML patients and identifies prognostic biomarkers for patients' risk stratification that might reveal novel metabolic vulnerabilities driven by microenvironmental signals.

EP385 FILT3R: AN NGS-BASED ALGORITHM FOR ROBUST DETECTION AND QUANTIFICATION OF FLT3-ITD IN CLINICAL PRACTICE

A. Boudry [1,*], N. Duployez [1,2], M. Figeac [3], S. Geffroy [1], M. Bucci [1], K. Celli-Lebras [4], M. Duchmann [5], R. Jourdinaud [1], L. Fenwarth [1,2], O. Nibourel [1], S. Darmon [6], L. Goursaud [7], R. Itzykson [4,5], H. Dombret [4], M. Hunault [8], C. Preudhomme [1,2], M. Salson [6]

[1]Laboratory of Hematology, CHU LILLE, [2]UMR-S 1277, INSERM, [3]Functional and Structural Genomic Platform, Lille University, Lille, [4]Department of Hematology, Saint Louis Hospital, Assistance Publique-Hôpitaux de Paris (AP-HP), [5]INSERM/CNRS UMR 944/7212, Saint-Louis Research Institute, Paris Diderot University, Paris, [6]CNRS, CRIStAL, Université Lille, Inria Lille, [7]Department of Hematology, CHU LILLE, Lille, [8]Department of Hematology, CHU Angers, Angers, France

Background: *Fms-like tyrosine kinase 3* internal tandem duplications (*FLT3*-ITD) occur in 20-30% of acute myeloid leukemia (AML) cases. These mutations represent both strong prognostic biomarkers and therapeutic targets. Hence, *FLT3*-ITD are systematically sought and quantified using quantitative fragment analysis, as per European LeukemiaNet guidelines. This method estimates the mutant allele fraction as the ratio of the area under the mutant allele (M) peak divided by the area under the wild type (WT) allele peak. Although robust, this technique has several limitations (high limit of quantification 1%, determination of the size of the ITD, limited application). Next generation sequencing (NGS) may represent an alternative method to detect these mutations with high detection sensitivity and the possibility of sequencing several other genes simultaneously.
However, the use of NGS technologies to detect *FLT3*-ITD mutations remains challenging because these mutations are heterogeneous in terms of size and/or insertion site, and the perfect or near perfect duplication of the wild-type sequence. These specificities raise new concerns about bio-informatic processes, and several algorithms have been created to detect this duplication (GetITD, km, ScanITD...). However, most of them fail to detect and annotate the broad variety of ITDs. Others are more efficient but must be used in conjunction with manual analysis which is subjective and thus incompatible with routine activity.
Aims: This work aims to develop a kmer-based algorithm named FiLT3r to detect and quantify ITDs and to compare it with existing algorithms to the reference method.
Methods: The different algorithms were tested and compared to the reference method using patients from a multicenter prospective randomized study BIG1 (NCT02416388). This clinical trial included 500 patients aged 18 to 60 years with de novo AML at diagnosis (Acute promyelocytic leukemia and core binding factor AML were excluded from these protocols). Peripheral blood or bone marrow samples from AML patients were screened with our standard NGS routine with a capture method targeting 81 genes (SSQXT Agilent®) and sequenced with Illumina® technology.
Results: A total of 147 ITDs from 114 *FLT3*-ITD positive patients (23%) and 71 randomized *FLT3*-ITD negative patients (14%), determined according to the fragment method, were sequenced (with an average coverage of 2000 paired-end reads on exon 14-15 *FLT3*). FiLT3r provided results mostly comparable to those obtained by the validated technique, with a sensitivity of 1 and no false positive above a threshold

of 1% (limit of quantification of the reference method). All the ITDs detected with fragment analysis of the 114 patients were confirmed using our NGS-based algorithm even in patients with multiple ITDs. The ratios (M/WT) calculated with our algorithm showed a correlation with the reference method estimated at 0.92 (Figure 1) which appears as the highest correlation coefficient of all the algorithms tested (range: 0.42 – 0.92). Among the patients considered negative using fragment analysis, FiLT3r detected five positive cases but these were found at ratios below the quantification threshold of the reference method. Indeed, this algorithm could detect ITD ratios of about 10^{-4}.

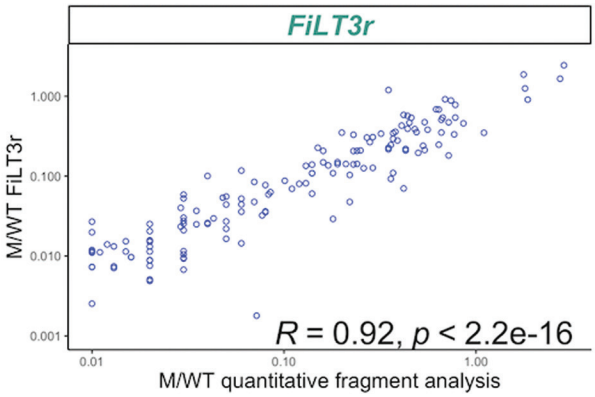


Figure 1: Comparison of FLT3-ITD ratio (M/WT) estimates by fragment analysis versus FiLT3r algorithm

Summary/Conclusion: FiLT3r can accurately and quickly identify *FLT3*-ITDs with a robust estimation. These results need further confirmation on a larger cohort but this algorithm represents a promising NGS-based approach to detect *FLT3*-ITD mutations.

EP386 FREQUENCY AND STIMULATION OF NPM1-SPECIFIC IMMUNE RESPONSES BY ANTI-PD1 ANTI-BODIES IN NPM1-MUTATED AML

J. Greiner [1,2,*], V. Schneider [2], H. Schrezenmeier [3], M. Wiesneth [3], L. Bullinger [4], S. Hofmann [5], M. Götz [2]

[1]Department of Internal Medicine, Diakonie Hospital Stuttgart, Stuttgart, [2]Department of Internal Medicine III, University of Ulm, [3]Institute of Clinical Transfusion Medicine and Immunogenetics, German Red Cross Blood Transfusion Service Baden-Württemberg-Hessen and University Hospital Ulm, Ulm, [4]Department of Hematology, Oncology and Tumorimmunology, Charité University Medicine Berlin, Berlin, [5]Department of Internal Medicine V, University of Heidelberg, Heidelberg, Germany

Background: In AML Nucelophosmin1 (NPM1) is one of the most frequently mutated genes and, according to the WHO classification, represents a separate entity that is often associated with a favorable prognosis. Other groups and ours described specific immune responses against immunogenic epitopes derived from the mutational region of NPM1 in AML patients (pts), as well as specific immune responses against leukemic progenitor and stem cells (LPC/LSC).
In a further step, we added the immune checkpoint inhibitor anti programmed death 1 (anti-PD-1), an inhibitory receptor expressed on T cells, to colony forming immunoassays (CFI), to discover whether the immune responses intensify against LSC/LPC comparing $NPM1^{mut}$ and $NPM1^{wt}$ pts.
Aims: In a larger cohort of 15 $NPM1^{mut}$ and 15 $NPM1^{wt}$ AML pts, we investigated immune responses against the mutational epitope NPM1 but also other LAA like PRAME (P300), Wilms' Tumor 1 (WT1) and RHAMM (R3), and compared $NPM1^{mut}$ to $NPM1^{wt}$ pts in CFI to detect CTL mediated immune responses against LSC/LPC.
Methods: We analysed the influence of anti-PD-1 on antigen-specific immune responses by allogeneic cytotoxic T lymphocytes (CTL) against LPC/LSC in functional T cell assays using ELISpot, FACS analysis and colony forming immunoassays (CFI) in $NPM1^{mut}$ vs. $NPM1^{wt}$ pts.
Results: We set out by detecting the reduction of colonies in CFI with the epitope NPM1 and several LAA. In $NPM1^{mut}$ AML pts 9/15 (60%) showed immune responses against all four epitopes. Mean colony reduction for LAA were 32% for P300, 45% for WT-1 and 43% for R3. In $NPM1^{WT}$ AML patient's inhibitory potential of all LAA was seen in 8/15 (53%) samples. Mean colony reduction for LAA was 33% for P300, 34% for WT-1 and 46% for R3. Against the NPM1 epitope $NPM1^{mut}$ patients showed 35% reduction and, as expected, in $NPM1^{WT}$ patients no responses were found, the responses against the other antigens were comparable to the NPM1 mutated patients.
With the addition of anti-PD-1 to CTL before starting CFI, for AML $NPM1^{mut}$ pts the inhibition in CFI using the LAA P300 as target ranged from 0-81% (mean: 32%), for WT1 from 0-74% (mean: 22%), and for R3 from 0-75% (mean: 21%). For AML $NPM1^{WT}$ pts the reduction with P300 with anti-PD-1 as target ranged from 0-59% (mean: 25%), for WT1 from 0-81% (mean: 34%), and for R3 from 0-60% (mean: 23%). Results for LAA were again comparable in both cohorts.
Remarkably, the immune effect in $NPM1^{mut}$ patients increased markedly with the epitope NPM1 and even more when anti-PD-1 was added to CFI, with a mean reduction of 47%. All 15 showed a reduction with anti-PD1, even those that did not show any reduction with the epitope NPM1 alone. A particularly strong additional reduction with the anti-PD1 antibody in CFI of 50% or more was observed in 7/15 $NPM1^{mut}$ pts. 4 of 15 pts showed a slightly lower additional reduction with anti-PD1 in the range of 44-28%.
Summary/Conclusion: We investigated the immune responses of AML pts to LPC/LSC with NPM1/LAA-specific T cells in a larger cohort. With the addition of anti-PD-1 to CFI, the immune resistance could be overcome. In conclusion, the immune checkpoint inhibitor anti-PD-1 increases the cytotoxic effect of T cells against LPC/LSC. The effect was strongest in $NPM1^{mut}$ pts with the epitope NPM1 and even stronger when adding anti-PD-1 to CFI. These data suggest that immunotherapy with a PD-1 antibody, for instance in combination with a NPM1-specific vaccine, possibly in the context of minimal residual disease or maintenance therapy, could be an interesting option for NPM1-mutated patients.

EP387 TARGETING THE IRE1A-XBP1 PATHWAY INDUCES APOPTOSIS IN FLT3-ITD+ AML AND ENHANCES THE EFFECT OF TKI INDUCED FLT3-ITD INHIBITION

T. Jaquet [1,*], C. Preisinger [2], M. Bütow [1], S. Tillmann [1], N. Chatain [1], M. Huber [3], S. Koschmieder [1], E. Jost [1], T. H. Brümmendorf [1], B. Kharabi Masouleh [1], I. Appelmann [1], M. Schemionek [1]

[1]Department of Hematology, Oncology, Hemostaseology, and Stem Cell Transplantation, University Hospital RWTH Aachen, [2]Proteomics Facility, Interdisciplinary Centre for Clinical Research, RWTH Aachen University Medical School, [3]Institute of Biochemistry and Molecular Immunology, RWTH Aachen University, Aachen, Germany

Background: The unfolded protein response (UPR) is a stress sensing signaling network that allows cells to deal with endoplasmic reticulum (ER) stress, a condition characterized by an accumulation of mis- and unfolded proteins in the ER. Acute myeloid leukemia (AML) stem cells reside in the bone marrow niche, where they face stressful conditions, such as hypoxia, low pH and nutrient fluctuations. Together with their oncogene-driven metabolism, they are prone to develop ER stress. Elevated UPR gene expression levels, particularly of IRE1α and XBP1, were found in FLT3-ITD$^+$ AML patient cells. Patients with high XBP1 mRNA expression showed an inferior overall survival compared to those with low XBP1 mRNA expression.
Aims: In this study, we aimed to uncover the potential of pharmacological IRE1α-XBP1 inhibition as a new therapeutic strategy in FLT3-ITD$^+$ AML in combination with a 2nd generation FLT3 tyrosine kinase inhibitor (TKI; quizartinib, AC220). We further wanted to elucidate whether this approach is efficient under hypoxia, the physiological condition in the bone marrow niche that potentially counteracts the TKI response.
Methods: Human FLT3-ITD$^+$ MV4-11, FLT3 wildtype (WT) RS4-11 and murine 32D cells transduced with FLT3-ITD or FLT3 WT were analyzed via Western blot and qRT-PCR. Cell viability was assessed by MTT assay, cell death and apoptosis were measured with propidium iodide (PI) or AnnexinV staining using FACS analysis. The clonogenic potential was determined in CFU assays, using primary patient-derived cells. Hypoxic cell culture conditions were applied (2-3% O_2). Analysis of phosphoproteomics was performed by mass spectrometry.
Results: Pharmacological inhibition of the IRE1α RNase activity using STF-083010 blocked XBP1 splicing and reduced the cell viability of human AML cell lines in a dose dependent way. Interestingly, FLT3 inhibition strongly enhanced the IRE1α mRNA level in 32D FLT3-ITD cells (9.3-fold $p<0.05$) but only weak in 32D FLT3 WT cells (1.5-fold $p<0.01$). 32D FLT3-ITD also showed a 3-fold higher number of PI$^+$ cells after IRE1α inhibition compared to 32D FLT3 WT cells ($p<0.01$). While single treatment of human FLT3-ITD$^+$ MV4-11 cells with either the IRE1α inhibitor or AC220 significantly induced apoptosis, the combinatorial treatment strongly enhanced

this effect (by 3-fold p<0.001). This potent induction of cell death was only observed in FLT3-ITD$^+$ MV4-11 cells, but not in FLT3 WT expressing RS4-11 cells. Likewise, the combination significantly decreased the clonogenic potential of FLT3-ITD$^+$ AML cell lines and AML mononuclear patient cells, but not of healthy donor cells. Cultivation of MV4-11 cells under hypoxia further induced IRE1α signaling and revealed that the effect of AC220 was largely abolished under hypoxia (normoxia: 58.4-fold induction of dead cells p<0.01 hypoxia: 2.2-fold induction p>0.05). Western blot and phosphoproteomic analysis revealed that FLT3 signaling was reduced under hypoxia. Intriguingly, combined targeting of IRE1α and FLT3 overcame this hypoxia-induced AC220 resistance and strongly induced cell death.
Summary/Conclusion: IRE1α-XBP1 signaling is activated in FLT3-ITD$^+$ AML and further enhanced by hypoxic conditions in the bone marrow niche. Targeting IRE1α in FLT3-ITD$^+$ cells is effective to decrease proliferation, clonogenic potential and induces apoptosis. Our data demonstrate that hypoxia-conferred resistance against AC220 can be overcome by simultaneous IRE1α inhibition, making this pathway an interesting novel therapeutic target.

EP388 SWATH-MS PROTEOMIC ANALYSIS IDENTIFIES C/EBPB SUPPRESSION BY RUNX1-ETO AS A POTENTIAL MEDIATOR OF BLOCK IN DIFFERENTIATION

A. Azevedo [1,*], A. Pierce [2], B. Geary [2,3], A. Whetton [3], R. L. Darley [1], A. Tonks [1]

[1]Department of Haematology, Division of Cancer & Genetics, School of Medicine, Cardiff University, Cardiff, [2]Stem Cell and Leukaemia Proteomics Laboratory, School of Medical Sciences, Faculty of Biology, Medicine and Health, [3]Stoller Biomarker Discovery Centre, The University of Manchester, Manchester, United Kingdom

Background: Acute myeloid leukemia (AML) is a heterogenous disease with multiple morphological, immunophenotypic and genetic features. The t(8;21), which results in the expression of RUNX1-ETO (aka AML1-ETO), is accountable for 12% of AML cases. Even though several studies have determined the transcriptomic changes observed in cells expressing RUNX1-ETO, there is a paucity of studies quantitating proteomic changes.
Aims: To analyze the proteomic profile of RUNX1-ETO expressing cord blood-derived human hematopoietic stem progenitor cells (HSPC) using mass spectrometry techniques.
Methods: We performed quantitative proteomics by SWATH-MS to determine the impact of RUNX1-ETO expression on the proteome using HSPC. Further, to determine changes in subcellular localization induced by RUNX1-ETO, cytosolic or nuclear fractions from these cells were separately analyzed.
Results: We quantified 4,635 proteins of which 2,787 were detected in the cytoplasm, and 1,848 in the nucleus. Statistical analysis identified 257 significantly differentially expressed proteins in RUNX1-ETO HSPC compared to controls, of which 71% were detected in cytoplasm and 29% in the nucleus. We also identified 29 proteins that were seen only in the cytosol and 24 that were seen only in nuclear preparations of RUNX1-ETO cells. Pathway analysis demonstrated significant changes to 'myeloid differentiation' ($p=2.5x10^{-6}$) pathway. Thus, we focused our analysis on identifying the transcription factors potentially responsible for differential expression in RUNX1-ETO cells. Using Metacore™'s transcription factor overconnectivity algorithm we identified C/EBPβ as a novel significant regulator ($p=1.4x10^{-4}$) of the observed 257 proteomic changes. C/EBPβ is a transcription factor belonging to the C/EBP family and related to C/EBPBα, which is mutated in approximately 5-10% of AML patients. In our data, RUNX1-ETO significantly downregulated the expression of C/EBPβ protein *vs* control (2-fold; p=0.01). Analysis of parallel transcriptomic data from the same model showed a 1.4-fold reduction in *C/EBPβ* mRNA level compared to controls suggesting transcriptional suppression by RUNX1-ETO. Further, *C/EBPβ* mRNA is significantly downregulated in t(8;21) patients compared to non-t(8;21) AML FAB M2 patients (2.7-fold; p<0.05). Since *C/EBPβ* is normally upregulated during myeloid development, these data suggest that RUNX1-ETO may inhibit myeloid differentiation by suppressing *C/EBPβ* expression. In support of this, *C/EBPβ* knockdown (KD) in the RUNX1-ETO-expressing cell line, SKNO-1, completely suppressed myeloid cell surface marker expression (CD13, CD33 and CD38) and gave a concomitant 4-fold increase in cell proliferation (p<0.001; n=3). Interestingly, in non-t(8;21) cells lines (HEL and U937) KD of C/EBPβ ablated cell growth (p<0.001) and increased the frequency of apoptotic cells (Annexin V$^+$ 7-AAD$^-$ cells increased by 6-fold in HEL, p<0.01; n=3 and 2-fold in U937 cells, p<0.01; n=3), suggesting that the effects of *C/EBPβ* KD are context dependent.
Summary/Conclusion: In conclusion, proteomics identified hundreds of significantly differentially expressed proteins arising from RUNX1-ETO expression in the cytoplasmic and nuclear compartments. Importantly, we identified C/EBPβ as significantly downregulated mimicking the reduced expression of this transcription factor seen in t(8;21) patients compared AML FAB M2 patients without t(8;21). Functional studies suggest that reduced C/EBPβ expression inhibits myeloid differentiation in a RUNX1-ETO-dependant manner. Currently, we are determining the effect of C/EBPβ KD on normal HSPC growth and differentiation.

EP389 GLUTATHIONE HOMEOSTASIS AND ABCC1 (MRP1) MODULATE THE RESPONSE OF ACUTE MYELOID LEUKEMIA (AML) CELLS TO BCL2 INHIBITION

J. Ebner [1,*], M. Piontek [1], J. Schmöllerl [2], G. Manhart [1], G. Szakacs [3], F. Grebien [1]

[1]Institute for Medical Biochemistry, University of Veterinary Medicine Vienna, [2]IMP, Research Institute of Molecular Pathology, [3]Institute for Cancer Research, Medical University of Vienna, Vienna, Austria

Background: The BCL2 inhibitor Venetoclax is a promising targeted anti-cancer agent for the treatment of AML. Despite its overall success, the understanding of molecular mechanisms that modulate Venetoclax efficacy is of utmost importance for successful personalized therapy. It is well established that ATP-binding cassette (ABC-) transporters are important mediators of cancer chemotherapy resistance, but it was unknown if ABC-transporters can modulate the efficiency of BCL2-inhibitors in AML.
Aims: We aim to understand the complex interplay of ABC-transporters and BCL2-inhibitors by systematically evaluating their essentiality in untreated versus BCL2-inhibitor treated AML cell lines.
Methods: We used CRISPR/Cas9-enabled functional genomics, pharmacological and cell biological approaches in human AML cell lines to systematically evaluate the genetic requirements for ABC-transporters in drug-naïve AML. Furthermore, we analyzed how particular ABC-transporters affect the sensitivity of AML cells towards BCL2-inhibitors.
Results: Using CRISPR/Cas9-mediated knockout of all 48 genes encoding ABC-transporters in human AML cells, we show that only *ABCE1, TAP2, ABCA3 and ABCF1* were essential for cell growth of drug-naïve cells. However, we found that knockout of *ABCC1* (*MRP1*) strongly increased the sensitivity of AML cells to the BCL-2 inhibitor Venetoclax. Genetic and pharmacological inhibition of ABCC1 also sensitized AML cells to the BCL2-inhibitors ABT-737, navitoclax and AZD-4320, but not to other drugs that are used to treat AML, such as cytarabine, midostaurine or IDH inhibitors. ABCC1 overexpression induced Venetoclax resistance in leukemia cells. Importantly, MCL1-overexpressing Venetoclax-resistant AML cells could be re-sensitized to BCL2 inhibition by knockout or inhibition of ABCC1. It has been shown that ABCC1-mediated export of molecules requires their conjugation to oxidized glutathione (GSSG). To test whether the ABCC1-mediated effect on BCL2-inhibition requires this pathway, we used buthionine sulfoximine (BSO). As an inhibitor of the glutamate cysteine ligase (GCL), BSO reduces intracellular glutathione (GSH) levels. While BSO treatment alone did not affect the viability of AML cells, it strongly synergized with BCL2 inhibition, improving the efficacy of Venetoclax and AZD-4320.
Summary/Conclusion: Currently, we are investigating the molecular mechanisms underlying the synergy between glutathione homeostasis, ABCC1 and BCL2-inhibition *in vitro* and *in vivo*. In addition to novel molecular insights, our findings could help to establish ABCC1 as a biomarker that helps to predict the efficiency of Venetoclax in the treatment of AML.

EP390 IRAK4 INHIBITOR CA-4948 POTENTIATES ANTITUMOR EFFECTS OF AZACITIDINE AND VENETOCLAX IN HUMAN ACUTE MYELOID LEUKEMIA

A. Ugolkov [1,*], R. Hok [1], R. von Roemeling [1], R. Martell [1]

[1]Curis Inc., Lexington, United States

Background: Acute myeloid leukemia (AML) is known to be associated with high lethality despite intensive treatment. Recently published study demonstrated that expression of IRAK4-L is mediated by mutant splicing factor U2AF1 and is associated with oncogenic signaling in human AML and myelodysplastic syndromes (MDS). Preliminary data from our ongoing Phase 1 dose escalation study demonstrated that treatment with IRAK4 inhibitor CA-4948 has shown early signs of clinical activity in patients with relapsed/refractory AML and high-risk MDS.

Aims: Our goal was to identify an effective combination of CA-4948 with standard-of-care (SOC) drugs for the treatment of FLT3-WT AML.
Methods: We used CellTiter Glo cell viability assay to evaluate the anti-tumor effects of CA-4948 in combination with AML SOC drugs daunorubicin, Ara-C, decitabine, azacitidine and venetoclax in FLT3-WT AML cell lines THP-1, F-36P, OCl-AML2 and GDM-1. GI50 (the concentration for 50% of maximal inhibition of cell proliferation) was determined for each drug in AML cell lines. Either GI50 (below peak plasma concentration) or peak plasma concentration (if GI50 was higher than peak plasma concentration) of each drug was used as clinically relevant concentration for combination experiments.
Results: We identified THP-1 and F-36P cell lines as resistant to clinically relevant concentrations of venetoclax, whereas OCl-AML2 cell line was resistant to the treatment with azacitidine. Synergistic effect of combining CA-4948 with Ara-C was observed in THP-1 cell line. We found that CA-4948 potentiated antitumor effects of azacitidine in 3 of 4 FLT3-WT AML cell lines whereas we did not observe any additive or synergistic effect of combining CA-4948 with decitabine. The combination of venetoclax and CA-4948 inhibited the cell growth in 2 of 4 AML FLT3-WT cell lines more effectively than either of the two agents alone. Moreover, we found that CA-4948 significantly potentiated antitumor effects of azacitidine+venetoclax in all AML FLT3-WT cell lines.
Summary/Conclusion: Our results demonstrate that combination of CA-4948, azacitidine and venetoclax exhibits synergistic activity in FLT3-WT leukemia cells providing a rationale for clinical testing of this combination in FLT3-WT AML patients.

EP391 RECURRENT DELETIONS IN CLONAL HEMATOPOIESIS ARE DRIVEN BY MICROHOMOLOGY-MEDIATED END JOINING

T. Feldman [1,*]

[1]*Immunology, Weizmann Institute of Science, Rehovot, Israel*

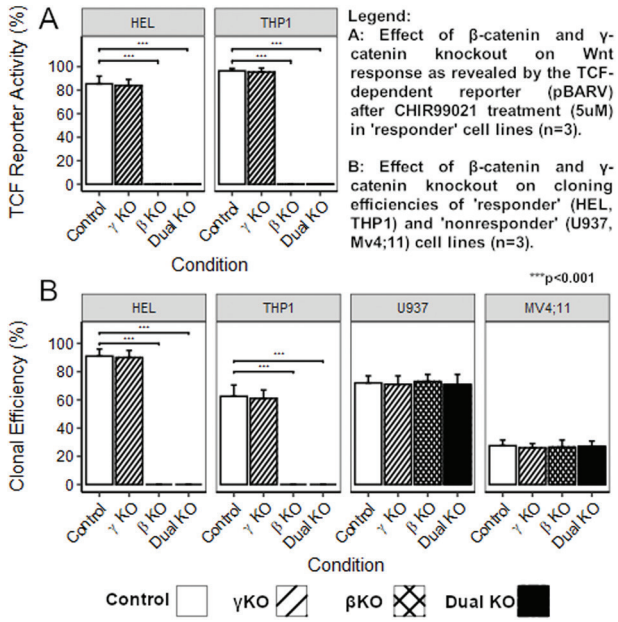
Background: Human aged hematopoietic stem and progenitor cells (HSPCs) are prone to clonal expansion due to the acquisition of recurrent somatic mutations. This phenomenon is known as age-related clonal hematopoiesis (ARCH). While somatic pre-leukemic mutations (pLMs) which define ARCH are mostly nonsynonymous single nucleotide variants (SNVs), insertions and deletions (indels) are less common and the mutational mechanisms underlying indels are less understood.
Aims: In the current study we aim to characterize mutational processes leading to recurrent deletions in clonal hematopoiesis.
Methods: We used CRISPR/Cas9 system to introduce targeted DSBs into the hotspot region of *ASXL1* and *SRSF2* genes to recapitulate recurrent deletions in these genes. We further studied the mutational mechanisms leading to these deletions by in vitro knock out models and PARP1 inhibitor treatments.
Results: In the current study we inspected the genomic regions around recurrent deletions in myeloid malignancies, and identified microhomology (MH)-based signatures in *CALR*, *ASXL1* and *SRSF2 loci*. We demonstrate that these deletions are the result of double stand break (DSB) repair by a PARP1 mediated Microhomology-mediated end joining (MMEJ) pathway. Importantly, we provide evidence that recurrent MH-based deletions originate in pre-leukemic HSCs, suggesting an MMEJ predominance in clonal hematopoiesis. While polymerase theta (POLQ) is considered a key component in MMEJ repair, we provide evidence that pre-leukemic MMEJ (preL-MMEJ) deletions can be generated in *POLQ* knock out cells. In contrast, inhibition of the replicative polymerases (which are co-expressed with *PARP1* in human HSCs) resulted in a significant reduction in preL-MMEJ.
Summary/Conclusion: Our data indicate an association between polymerase theta independent MMEJ and clonal hematopoiesis and elucidate mutational mechanisms involved in the very first steps of leukemia evolution.

EP392 TARGETING THE RUNX1-RUNX1T1 FUSION GENE USING CRISPR-CAS9 TECHNOLOGY EFFECTIVELY INHIBITS PROLIFERATION AND DECREASES TUMOR VOLUME IN VITRO AND IN VIVO

S. Neldeborg [1,2,*], J. F. Sørensen [3], C. T. Møller [4], M. Nyegaard [4], Y. Luo [4], P. Hokland [2,3], M. Bill [3], M. Ludvigsen [2,3], M. Stougaard [1,2], C. K. Holm [4]

[1]*Department of Pathology, Aarhus University Hospital,* [2]*Department of Clinical Medicine, Aarhus University,* [3]*Department of Hematology, Aarhus University Hospital,* [4]*Department of Biomedicine, Aarhus University, Aarhus, Denmark*

Background: Acute myeloid leukemia (AML) with translocation 8;21 (AML8;21) is a core-binding factor AML characterized by the oncogenic fusion protein RUNX1-RUNXT1. AML8;21 is one of the most common types of AML and is associated with a favourable prognosis with an estimated 5-year overall survival of 60-70%. However, 30% of patients relapse following first line treatment, leaving these patients with very limited treatment options. Patients older than 65 years represent a particular challenge as many are not candidates for treatment with cytarabine and daunorubicin. The RUNX1-RUNX1T1 fusion protein impairs differentiation and maturation of hematopoietic cells and is unique to the malignant clone, thus constituting a potential target for treatment. In recent years, CRISPR-Cas9 technology has shown great promise in various gene therapy applications. In cancers with known oncogenic drivers, such as AML8;21, there is further potential for novel treatment strategy development utilizing CRISPR-Cas9.
Aims: In this study, we aimed to utilize a novel CRISPR-based treatment strategy to target the *RUNX1-RUNX1T1* fusion gene.
Methods: The oncogenic fusion gene *RUNX1-RUNX1T1*, was targeted with CRISPR-Cas9 in the human AML cell line, Kasumi-1, and in archival cells obtained from *RUNX1-RUNX1T1*-positive AML patients treated at the Department of Hematology at Aarhus University Hospital, Denmark. CRISPR-Cas9-based disruption of the *RUNX1-RUNX1T1* fusion gene was validated using targeted polymerase chain reaction (PCR) and Sanger sequencing. Kasumi-1 cell population growth and cell population proliferation was investigated following CRISPR-CAS9-based disruption of *RUNX1-RUNX1T1*. Six nude mice were injected with CRISPR-Cas9 *RUNX1-RUNX1T1* disrupted Kasumi-1 cells or non-treated Kasumi-1 cells in the right and left flank, respectively. Animals were sacrificed after four weeks and tumor volume was evaluated.
Results: We show CRISPR-Cas9-based disruption of *RUNX1-RUNX1T1* in Kasumi-1 cell line and AML-patient-derived cells. *In vitro* cell growth rate and proliferation were decreased by 58 % and 74 %, respectively, in CRISPR-Cas9 *RUNX1-RUNX1T1* disrupted Kasumi-1 cells compared to controls. Four out of 6 mice had tumor growth following injection with *RUNX1-RUNX1T1* disrupted or control Kasumi-1 cells an thus allowed for analysis of *RUNX1-RUNX1T1* disruption effect on tumor volume. Two mice developed a tumor in only the control flank while the two other mice developed tumors in both flanks. In the two mice with tumor development in both flanks, tumor volumes were decreased by 69 % and 91 % in the CRISPR-Cas9 *RUNX1-RUNX1T1* disrupted flank, as compared to the control flank.
Summary/Conclusion: In this proof of principle study, we demonstrate a novel CRISPR-based technology that effectively inhibits proliferation and decreases tumor volume *in vitro* and *in vivo*. Our results suggest that targeting the *RUNX1-RUNX1T1* fusion gene can potentially be a future treatment strategy for patients with AML8;21.



EP393 CANONICAL WNT SIGNALING-RESPONSIVE ACUTE MYELOID LEUKEMIA CELLS ARE DEPENDENT ON BETA-CATENIN BUT NOT GAMMA-CATENIN FOR CLONAL GROWTH

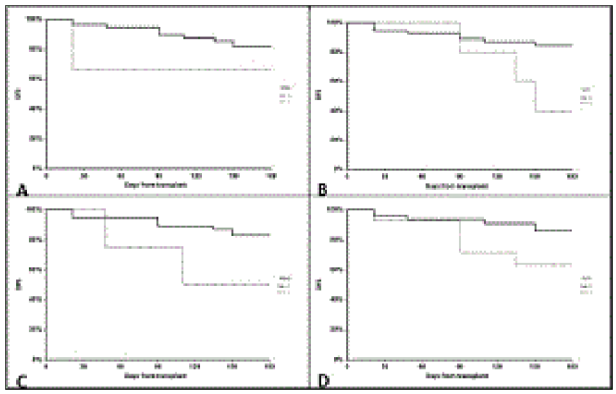
A. Leckenby [1,*], A. Tonks [1], R. Darley [1]

[1]*Haematology Department, Cardiff University, Cardiff, United Kingdom*

Background: Canonical WNT signaling is a critical pathway for normal development. β-catenin, the central mediator, is constitutively degraded in the absence of an agonist. Following activation, stabilized β-catenin localizes to the nucleus and associates with TCF/LEF factors to create a transcription complex that targets genes involved in survival, proliferation, cell fate determination and stemness. WNT signaling has been identified as one of the most frequently dysregulated pathways in acute myeloid leukemia (AML), with β-catenin prominently overexpressed at mRNA and protein levels in patients where it is associated with poor clinical outcomes. In addition, overexpression of β-catenin in human hematopoietic stem cells (HSC) blocks multilineage differentiation, mimicking the AML phenotype. However, whether canonical WNT signaling has an essential role in AML remains contentious due to leakiness in gene targeting and RNAi approaches and failure to exclude possible redundancy in respect of its close homologue, γ-catenin. Furthermore, only a subset of patients and cell lines demonstrate nuclear translocation of β-catenin, suggesting dependency is unlikely to be universal in AML.
Aims: To establish whether AML cells are dependent on β-catenin and/or γ-catenin expression for their growth and survival using CRISPR-Cas9 to genetically edit cells.
Methods: We employed CRISPR-Cas9 lentivirus to generate single and dual knockout of β-catenin (βKO) and γ-catenin (γKO) to study the

functional impact of complete knockout of canonical WNT signalling in AML cell lines. All KO cultures were validated by sequencing alongside ablation of protein expression and TCF reporter response. Equivalent non-targeted CRISPR-Cas9 lines were used as controls.
Results: As previously shown, we found that AML cell lines are heterogeneous in their response to β-catenin agonists with "responders" (such as HEL and THP1) showing strong nuclear localization of β-catenin and TCF-dependent transcriptional responses to agonist, whilst "non-responders" (such as U937 and Mv4;11) failed to localize β-catenin to the nucleus and generated no transcriptional response. We generated complete knockouts of β-catenin and γ-catenin (singly and in combination) in all these lines starting with clonal populations co-expressing a TCF-dependent YFP reporter. βKO resulted in ablation of TCF reporter signal in responder lines, whilst γKO had no effect (Fig.1A), showing that β-catenin is essential for canonical WNT signaling and its role was not redundant in respect of γ-catenin. We found βKO was incompatible with clonal growth in responder lines whereas γKO had no effect. Predictably, colony forming efficiency of non-responder lines was unaffected by any KO condition (Fig.1B). Clonal growth of βKO lines could be rescued by co-cultivation with WT cells (but not with WT conditioned medium, supplementary cytokines, or stromal support) suggesting rescue by a short-range/labile autocrine factor or engagement with a cell surface molecule. Rescued clonal βKO cultures grew autonomously in bulk culture when purified by FACS, but could not be re-cloned, demonstrating stable and continuing dependence on β-catenin for clonal growth.

Summary/Conclusion: Together these data show that β-catenin has functional relevance for clonal growth in WNT-responsive AML lines but not in lines that are unresponsive to WNT agonist. We saw no dependency on γ-catenin in any context. We are currently performing RNAseq to identify candidate genes mediating β-catenin-dependent survival under clonal conditions.



EP394 BASELINE SOMATIC MUTATIONS PREDICT DISEASE FREE SURVIVAL AFTER ALLOGENEIC STEM CELL TRANSPLANTATION IN ACUTE MYELOID LEUKEMIA: A RETROSPECTIVE MONOCENTRIC REPORT

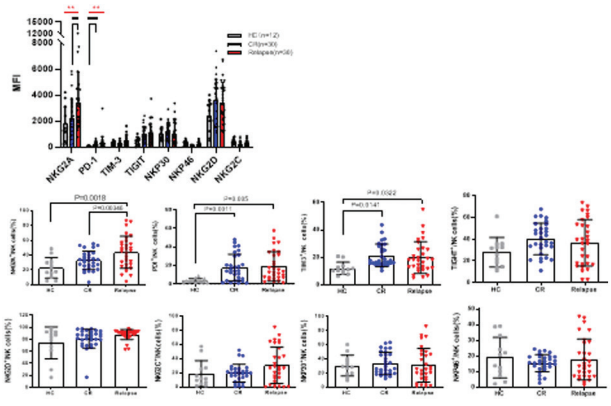
E. Metafuni [1], V. Amato [2], S. Giammarco [1], S. Bellesi [1], M. Rossi [1], G. Minnella [2], L. Pagano [1], F. Sorà [1], L. Laurenti [1], A. Bacigalupo [1], S. Sica [1], P. Chiusolo [1,*]

[1]Hematology Department, Fondazione policlinico Universitario Agostino gemelli-IRCCS, [2]Hematology Department, Università Cattolica Del sacro Cuore, Rome, Italy

Background: In the last years the advent of Next Generation Sequencing (NGS) contributed to the identification of new somatic mutations involved in the leukemogenesis process, allowing a revised stratification of the biological risk for acute myeloid leukemia (AML) and providing a new tool for minimal residual disease evaluation.
Aims: We evaluated the impact between NGS profile and post transplant outcome, with particular interent on relapse occurrence.
Methods: We enrolled 64 patients with AML submitted to allogeneic stem cell transplantation (HSCT) in our department between November 2015 and September 2020. NGS panel performed at diagnosis included 18 genes: CBL, SF3B1, U2AF1, ZRSR2, KRAS, ASXL1, CEBPA, KIT, DNMT3A, EZH2, IDH1, IDH2, RUNX1, SRSF2, TET2, TP53, WT1, NRAS.
Results: Mutation distribution was as follows: CBL (n=1), SF3B1 (n=1), U2AF1 (n=1), ZRSR2 (n=1), KRAS (n=1), ASXL1 (n=9), CEBPA (n=9), KIT (n=15), DNMT3A (n=22), EZH2 (n=17), IDH1 (n=10), IDH2 (n=10), RUNX1 (n=6), SRSF2 (n=2), TET2 (n=30), TP53 (n=3), WT1 (n=6), NRAS (n=4). Median age was 55.5 years (17-73). Risk group according to European Leukemia Net was as follows: favourable (n=8), intermediate (n=42), adverse (n=14). Thirty-nine patients achieved a first complete remission before transplant, 8 were in second remission, 14 had relapsed disease and 3 received HSCT upfront. A significant difference in terms of DFS was found accordingly to some mutations. Patients mutated for TP53 (n=3) showed a 6 months DFS of 66.7% as compared to 81.4% in non mutated (n=61) (p=0.02, Fig.1A). Mutated WT1 patients (n=6) had a 6 months DFS of 40% as compared to 84.8% in non mutated (n=58) (p=0.047, Fig.1B). Six-months DFS was of 63.5% and 83% in patients with (n=4) and without (n=60) NRAS mutation, respectively (p=0.005, Fig1C). Accordingly to FLT3 mutation, 6 months DFS was of 63.5% in mutated patients (n=14) as compared to 83% for non mutated (n=49) (p=0.048, Fig1D). Multivariate analysis for DFS confirmed TP53 (HR 12.96, 95% CI 4.16-39.61, p=0.0009), WT1 (HR 5.03, 95% CI 1.08-23.37, p=0.04), FLT3 (HR 4.63, 95% CI 1.22-17.50, p=0.02) and NRAS (HR 8.17, 95% CI 4.42-39.62, p=0.0004) together with absence of complete remission at the time of transplant (HR 7.89, 95% CI 2.23-27.92, p=0.001) as independent factors for relapse after transplant. Moreover, we found a detrimental impact of triple mutation FLT3+NPM1+DNMT3A on DFS. Patients with any of these mutations (n=30) had 6 months DFS of 85.2% as compared to 89.8% for patients with one or two mutations (n=23) and 50% in patients triple mutated (n=8) (p=0.04). We then evaluated if a difference might be in young (<60 years) and old patients in terms of mutations influence. TP53, WT1, FLT3 and triple mutation DNMT3A, FLT3 and NPM1 were confirmed in young whereas only NRAS was confirmed in old patients.

Figure 1:6-months DFS according to TP53 (A), WT1 (B) NRAS (C) and FLT3 (D) mutations.

Summary/Conclusion: The presence of some mutations like as WT1, TP53, NRAS, FLT3 or concomitant mutated status for FLT3, NPM1 and DNMT3A worsened post transplant outcome in terms of disease free survival, independently from transplant features. Certainly, these finding need to be confirmed in a larger study population.



EP395 NK-CELLS EXHAUSTION WHICH DUE TO NKG2A OVER-EXPRESSION IS ASSOCIATE WITH RELAPSED IN ACUTE MYELOID LEUKEMIA PATIENTS

X.-F. Liu [1,*], L. liu [1], Y.-J. Chang [1], X.-S. Zhao [1,2], Y. Wang [1], L.-P. Xu [1], X.-H. Zhang [1], K.-Y. Liu [1], X.-Y. Zhao [1,3], X.-J. Huang [1,2]

Peking-Tsinghua Center for Life Sciences, Beijing, [3]Peking-Tsinghua Center for Life Sciences, beijing, China

Background: Leukemia relapse is the main cause of treatment failure in leukemia.Natural killer (NK) cell is effective lymphocytes and play irreplaceable role in anti-leukemia procession. However,whether the status of NK cells affects recurrence is rarely discussed.
Aims: To evaluate the prognostic impact of NK-cells exhaustion in relapsed patients, and explore its impact due to NKG2A over expression
Methods: We perform analyses on 72 bone marrow samples, enrolled from 12 health donors (HC) and 30 AML patients who had experienced first hematological relapse after HSCT (Relapse) as well as 30 matched AML patients in remission (CR), to detect NK-cells phenotype,cytotoxicity, proliferation as well as RNA-sequences in the above group. The cytotoxicity and cytokine secretion of NK cells was determined using CD107a expression and IFN-γ production against K562 or THP-1 cell line as targets. In each of the above groups, NK cells were sorted for killing AML blasts to detect NK lysis function.
NK cells or blocking the NKG2A receptor NK cells were xenografted into NPG mice with or without leukemia to detect NK cells survival in vivo. NK cells sorted from spleen were used for cytotoxicity assessment of anti-leukemia in vitro. And tumor burden in NPG mice was monitored by using in vivo imaging system.
Results: The results declared that exhausted NK-cells expansion showed with naïve phenotype which $CD56^{bright}$ (P=0.0002) and NKG2A receptor (P=0.00346) overexpression in AML relapsed patients. Although there existed NK-cells expansion in AML relapsed patients with the frequency of $KI67^{+}$NK cells significantly higher(P=0.002),the cell cycle of NK cells was stagnated in G1 stage in AML relapse patients(P<0.0001) compared to those patients in CR group. After 48 hours of co-incubation, NK-cells sorted from relapsed patients resulted in significantly less leukemia blasts apoptosis(P=0.0245) in vitro. Further-more, NK cells display compromised cytotoxicity of CD107a degranulation (P=0.0008) and IFN-γproduction (P=0.0167) in the presence of K562 target cells ex vivo. The RNA-seq data show NK-cells exhaustion is followed up down-regulation of the transcription factors T-bet(P=0.0122)and up-regulation of the cyclin D2(P=0.0035).
Among the 30 AML relapsed patients, only 21 patients received chemotherapy and/or DLI treatment, of which 13 patients were treated effectively and the rest were ineffective.Surprisingly, in these patients with curative effects after treatment, the proportion of $NKG2A^{+}$NK cells sharp dipped(P=0.0075), and the IFN-γproduction (P=0.0263) also improved, comparing with their data on relapsed time one by one. Whatever, in patients who have failed treatment, the expression of NKG2A is further up-regulated(P=0.0075), and the function of NK cells remains unchanged, corresponding to their data on first relapsed time one by one.
In immunodeficiency mice model with adoptive NK cells infusion, we found that NK-cells exhausted with elevated NKG2A expression(P<0.005)and limited anti-leukemia function(P<0.05)and shorter persistent time in leukemia-infiltration mice compared with those mice without leukemia(P<0.05).Meanwhile, in immunodeficient mice with leukemia-burden, infusion of NK cells blocking NKG2A receptor can significantly reduce tumor burden(P<0.001)and improve the long-term survival rate of mice compared to those xenografted with untreated NK cells(P<0.001).

Summary/Conclusion: NK-cells exhaustion is associated with relapse in AML patients. NKG2A receptor blocking could rescue NK cells exhaustion and may be considered as a penitential effective therapy to improve the therapy efficacy for relapsed AML patients.

EP396 LONGITUDINAL PATIENT-DERIVED XENOGRAFT MODELS REVEAL CONVERGENT MOLECULAR EVOLUTION IN ACUTE MYELOID LEUKAEMIA

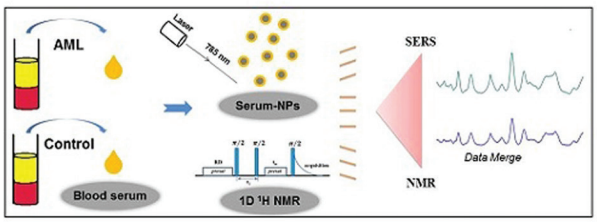
Background: Acute myeloid leukaemia (AML) is considered a highly heterogeneous disease. Novel therapeutic approaches in AML aim to target the molecular mechanisms thought to drive leukemogenesis, but emergent evidence suggests that intra-leukemic composition may be more diverse than previously appreciated. To improve AML outcome, the representation of leukaemic composition in patient derived xenografts and their potential in precision oncology has to be elucidated.
Aims: Interpreting the intra-leukaemic heterogeneity and hierarchy may be challenging in large patient cohorts. Here, we decipher the temporal disease composition of an AML patient through longitudinal sampling and explore the inherent leukaemogenic potential of the primary samples through establishment of serial patient-derived xenograft (PDX) models.
Methods: Primary and PDX-derived samples were analysed in parallell by high-resolution genetic and phenotypic approaches, including sequencing, immunophenotyping and *ex vivo* drug sensitivity testing.
Results: Comparison of the genetic composition revealed that all PDX samples bore a closer resemblance to other PDX samples than to the distinct primary samples from which they originated, indicating a pattern of convergent molecular evolution likely resulting from the selective force of the murine environment.
Across the primary and PDX samples, we identified at least six discrete leukaemia-initiating cell populations, of which five were characterised by known recurrent mutations in AML, including mutations in *ASXL1*, *FLT3* and two independent NRAS mutations. These populations correlated with immunophenotypically defined cell subsets displaying distinct drug sensitivity profiles, suggestive of distinct functional properties.
Summary/Conclusion: Our results indicate that the genetic and phenotypic development are closely intertwined, and that diversity in the leukaemic gene-environment likely influences disease trajectories.



EP397 DIFFERENTIATION OF ACUTE MYELOID LEUKEMIA SUBTYPES BY SERUM-BASED SPECTROSCOPY COUPLING WITH NON-TARGETED METABOLIC FINGERPRINTS

Y. Chen [1,2,*], M. Ye [1], Y. Wang [1], Y. Cao [3], H. Lin [2], J. Zhang [3], T. Yang [2], J. Feng [4], J. Hu [2]

[1]Department of Laboratory Medicine, Fujian Medical University, [2]Department of Hematology, Fujian Institute of Hematology, Fujian Provincial Key Laboratory

on Hematology, [3]Department of Clinical Laboratory, Fujian Medical University Union Hospital, Fuzhou, [4]Department of Electronic Science, Fujian Provincial Key Laboratory of Plasma and Magnetic Resonance, Xiamen University, Xiamen, China

Background: The proportion of adult non-M3 AML patients with poor prognosis is relatively large, which is mainly restricted by the current clinical detection limits and sensitivity. To explore new markers that can realize rapid screening and sensitive diagnosis of de novo non-M3 diagnosis of AML subtypes has important clinical significance.
Aims: The aim of this study is to explore serum-based markers in non-M3 AML patients after developing a synthetic approach on Ag nanoparticles-based surface-enhanced Raman spectroscopy (SERS) and non-targeted proton NMR metabolomics.
Methods: According to FAB classification, the serum samples were prepared from five types of non-M3 AML patients (including M0~M2, M4, and M5, n=50 for each type) and healthy controls (n=50, age and gender matched). The Ag substrate nanoparticle-serum complex was first prepared for SERS measurement. The serum metabolites were identified by 1D ^{1}H NMR method. Statistical methods were utilized in unsupervised and supervised analyses. Both SERS band-intensity data and the metabolite-concentration data were set to merge in classification model for determination of relative diagnostic markers. The receiver operating characteristic (ROC) curves were used to assess the performance of these markers.
Results: We found significant changes in non-M3 AML patients with different subtypes. These appeared in tryptophan, serine, phenylalanine, proline and valine, as well as a variety of nucleic acid bases, phospholipids, D-mannose and collagen. These components were specifically characterized according to vibration mode due to their secondary structure. Several amino acids including tryptophan, serine, phenylalanine, proline and valine, as well as D-mannose were shared in serum metabolites analysis. These metabolites/components were shown to be the key to identify different AML subtypes. Further metabolic pathway analysis suggested disorders in multiple pathways, among which all five types can be separated when SERS and NMR data were set to merge for classification. Typically, the M5 AML was found to be abnormally active in glutathione metabolism, which may show some specificity for diagnosis, but its underlying mechanism still need to be addressed.

Summary/Conclusion: We have proposed the combined analysis of serum-based optics and metabolomics to provide rapid screening markers for AML patients with non-M3 diagnosis. It was also demonstrated that this method was of great value in clinical application with acceptable accuracy and good reproducibility.

EP398 MEGAKARYOCYTIC TRANSCRIPTION FACTOR ARID3A SUPPRESSES GATA1S-INDUCED MALIGNANT TRANSFORMATION

O. Alejo-Valle [1,*], K. Weigert [1], R. Bhayadia [1], M. Ng [1], S. Emmrich [2], C. Beyer [1], H. Issa [1], M. Flasinski [3], E. Regenyi [1,4], M. Labuhn [5], D. Reinhardt [6], M.-L. Yaspo [4], D. Heckl [1], J.-H. Klusmann [1]

[1]Pediatric Hematology and Oncology, Martin-Luther-University Halle-Wittenberg, Halle (Saale), Germany, [2]University of Rochester, Rochester, United States, [3]University of Würzburg, Würzburg, [4]Max Planck Institute for Molecular Genetics, Berlin, [5]Hannover Medical School, Hannover, [6]Pediatric Hematology and Oncology, University Hospital Essen, Essen, Germany

Background: Down syndrome-associated myeloid leukemia (ML-DS) is characterized by the triad of trisomy 21, fetal origin and mutations in *GATA1* (*GATA1s* mutations). We previously described that miR-125b synergized with mutated GATA1s via downregulation of the transcription factor ARID3A. However, the mechanisms of this synergy remained to be understood.
Aims: We aimed to understand the function of ARID3A in normal hematopoiesis and unravel its role in the pathogenesis of Down syndrome (trisomy21)-associated leukemia in cooperation with oncogenic GATA1s.
Methods: We combined CRISPR-Cas9 genome editing with lentiviral gain- and loss-of-function studies in hematopoietic stem/progenitor cells (HSPCs) and primary patient blasts. We integrated gene expression profiling after *Arid3a* modulation in *GATA1s* fetal cells with CUT&RUN and mass spectrometry analyses to identify key ARID3A-regulated pathways involved in leukemic transformation.
Results: RNA-Seq data of sorted blood cells indicated increased *ARID3A* expression in megakaryocytes compared to erythroid cells. Accordingly, *Arid3a* overexpression in fetal and adult HSPCs promoted megakaryocytic differentiation (1.73x and 2.89x fold increased CD41a^{+}CD42d^{+} megakaryocytes, p=0.0.17 and p=0.018, respectively), while shRNA-mediated *Arid3a* knockdown in fetal HSPCs caused a 40% reduction (p=0.04). Interestingly, while *Gata1s* perturbs erythroid differentiation and induces hyperproliferation of fetal HSPCs, *Arid3a* knockdown blocks their otherwise unperturbed megakaryocytic differentiation, leading to the expansion (3.6x fold) of CD117^{+}CD41^{+} megakaryocytic progenitors *in vitro* and development of ML-DS-like leukemia (CD41^{+}CD117^{+}) upon transplantation into syngeneic C57BL/6J recipients *in vivo* (71 days median disease-free survival and 100% penetrance).
To understand the ARID3A molecular network and its role in leukemia progression, we leveraged gene expression data (RNA-Seq), chromatin occupancy (CUT&RUN) and mass spectrometry (LC-MS/MS). Integrated analysis uncovered that ARID3A promotes terminal differentiation by occupying and inducing megakaryocytic genes in concert with GATA1. In parallel, ARID3A binds SMAD2/3, forming a complex that mediates TGFβ-induced cell cycle arrest and apoptosis. In line with a role as tumor suppressor, low expression in pediatric AML patients (NCI-TARGET) associates with poorer overall survival (53.9% vs. 67.7%; P-log-rank = 0.025). Importantly, restoring expression of *ARID3A* in ML-DS patient-derived xenografts suppressed leukemic growth and promoted megakaryocytic differentiation *in vitro* and *in vivo*.
Summary/Conclusion: We uncovered a novel function of ARID3A in promoting megakaryocytic differentiation in concert with GATA1 and mediating TGFβ-induced cell cycle arrest and apoptosis in complex with SMAD2/3. Inversely, ARID3A repression is a key event in the pathogenesis of ML-DS as *Arid3a* knockdown blocks the otherwise unperturbed megakaryocytic differentiation of hyperproliferative *Gata1s* megakaryocytic progenitors arresting them in an undetermined differentiation status and causing leukemia. Our work provides a basis to develop refined treatment approaches by restoring the ARID3A-induced differentiation program.

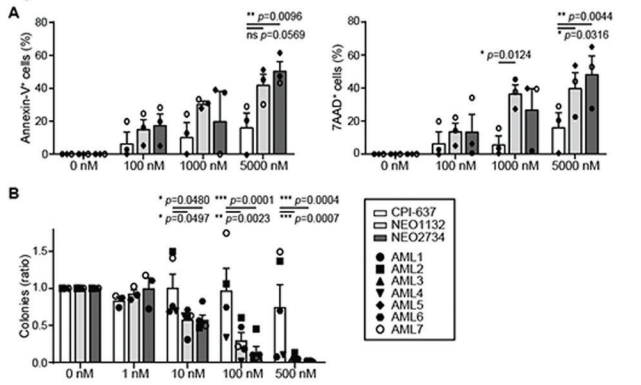
EP399 SIGNALLING INTERACTIONS OF MEGAKARYOCYTE-ERYTHROID PROGENITOR CELLS AT TIME OF DIAGNOSIS PREDICT SURVIVAL IN ACUTE MYELOID LEUKAEMIA

D. Kleftogiannis [1,*], B. Tislevoll [2], M. Hellesøy [3], E. Griessinger [4], I. K. Motzfeldt [3], O. Fagerholt [2], S.-E. Gullaksen [3], J. J. Schuringa [4], B. T. Gjertsen [2,3], I. Jonassen [1]

[1]Department of Informatics, Computational Biology Unit, University of Bergen, [2]Department of Clinical Science, University of Bergen,Bergen,Norway, [3]Department of Medicine, Hematology Section, Haukeland University Hospital, Helse Bergen HF, Bergen, Norway, [4]Department of Experimental Hematology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands

Background: Although high rates of initial responders to cancer therapies are observed, relapse and metastasis are the most frequent causes of cancer-related death. Providing insights into cancer cell populations, and elucidating biological mechanisms of relapse is necessary for tailoring more effective treatment options. This is also apparent in Acute Myeloid Leukaemia (AML), a highly heterogeneous aggressive blood cancer with poor overall survival. Hence, there is a major challenge that could be addressed using high-throughput single-cell technologies combined with effective bioinformatics tools.

Aims: We hypothesised that characterizing hematopoietic cells in AML, and investigating the strength of signalling interactions between proteins at time of diagnosis, could identify predictors of survival.
Methods: To investigate our hypothesis, we performed CyTOF analysis on peripheral blood samples collected from 45 AML patients. The samples were stained with an antibody panel consisting of 21 surface and 15 intracellular markers, allowing for deep phenotypic profiling as well as monitoring of signalling pathways. To improve phenotypic characterisation of hematopoietic cells, a gating strategy was implemented using data from seven healthy donors. Next, Linear Discriminant Analysis allowed us to align cancer cells to their closest healthy cell phenotypes, resulting in a single-cell hematopoietic classifier. To alleviate the challenge of modelling complex single-cell data, Conditional Density Resampled Estimate of Mutual Information (DREMI) was utilised. DREMI quantifies the information transfer between pairs of proteins measured with single-cell resolution. Application of Machine Learning (ML) on DREMI-derived features combined with Feature Selection, allowed us to develop cell type specific models for survival, and to rank the most informative signalling interactions.
Results: By applying ML to DREMI-derived features extracted from different hematopoietic cell populations, we constructed cell type specific models for survival that were validated twice, with repeated cross-validation (n=38) and an independent validation cohort (n=7). Our analysis suggested that signalling interactions of cancer cells aligned to Megakaryocyte-Erythroid Progenitor (MEP) cells defined on the basis of CD45-low/CD34+/CD38+/CD123-low markers at time of diagnosis, predicted clinical outcome with an average performance of 0.83 Area Under the Curve, 0.78 Balanced Accuracy, 0.86 Positive Predictive Value and 0.82 F1 score. Our analysis also suggested that three signalling interactions of MEP cells between, pCREB-pSTAT5, pSTAT1-pSTAT5 and pHistone3-pSTAT5 were the most informative predictors. Retrospective analysis of both training/testing and validations cohorts (n=45), using Cox proportional-hazards modelling and Kaplan-Meier survival analysis, re-confirmed the potentials of the identified interactions to predict clinical outcome. Finally, our framework allowed us to investigate the dynamics of the identified interactions, using paired CyTOF samples collected 4 and 24 hours after chemotherapy initiation.
Summary/Conclusion: We presented a novel data-drive approach that leverages hematopoietic single-cell classification with ML modelling of signalling interactions to predict survival. In this way, our work provides direct associations between cell phenotypes, signalling states and clinical outcome. Although, the developed computational framework, has been specifically designed and applied for the analysis of signalling dynamics in AML, it can be applied to other cancer types as well.



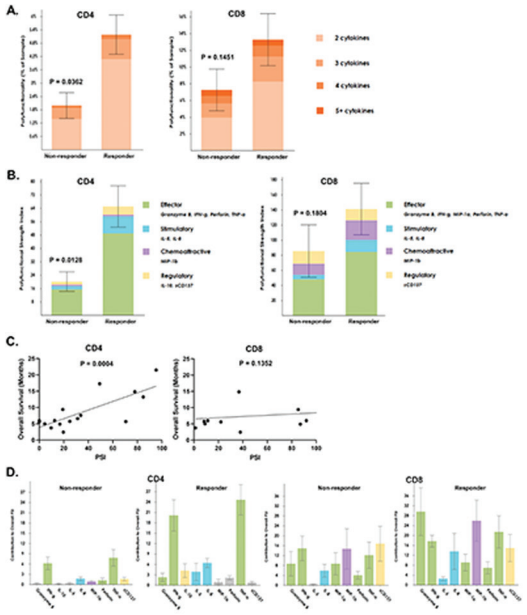
EP400 THE NOVEL ORAL BET-CBP/P300 DUAL INHIBITOR NEO2734 IS HIGHLY EFFECTIVE IN ERADICATING ACUTE MYELOID LEUKEMIA BLASTS AND STEM/PROGENITOR CELLS

N. van Gils [1,*], T. Martianez Canales [1], E. Vermue [1], A. Rutten [1], F. Denkers [1], T. van der Deure [1], G. Ossenkoppele [1], F. Giles [2], L. Smit [1]

[1]Hematology, UMC Amsterdam, location VUmc, Cancer Center Amsterdam, Amsterdam, Netherlands, [2]Developmental Therapeutics Consortium, Chicago, United States

Background: Acute myeloid leukemia (AML) is a disease characterized by transcriptional dysregulation, that results in a block in differentiation and aberrant self-renewal. Inhibitors directed to epigenetic modifiers, aiming at transcriptional reprogramming of AML cells, are currently in clinical trials for AML patients. Several of these inhibitors target bromodomain and extra-terminal domain (BET) proteins, cyclic AMP response binding protein-binding protein (CBP), and the E1A-interacting protein of 300 kDa (p300), affecting histone acetylation. Unfortunately, single epigenetic inhibitors showed limited efficacy due to appearance of resistance and lack of effective eradication of leukemic stem cells.
Aims: To evaluate the efficacy of the novel dual BET and CBP/p300 inhibitors NEO2734 and NEO1132 in the elimination of AML (stem/progenitor) cells.
Methods: We investigated the efficacy of NEO2734, NEO1132 and the CBP/p300 inhibitor CPI637 to induce cell death in AML cell lines and primary AML (stem/progenitor) cells. Moreover, we studied the effect of treatment with the NEO drugs on myeloid blast proliferation, apoptosis, clonogenic capacity of long- and short-term surviving AML cells *ex vivo*, on engraftment potential in a patient-derived xenograft AML mouse model (NSG mice injected with primary AML), and we determined the toxicity of the NEO drugs on normal hematopoietic cells.
Results: The two novel, orally available inhibitors NEO1132 and NEO2734 targeting both the BET and CBP/p300 proteins inhibited proliferation of a panel of AML cell lines, NEO2734 being the most potent, with IC50 values ranging from 27 nM to 125 nM. Both NEO1132 and NEO2734 induced apoptosis by downregulating c-Myc and Bcl2. Moreover, incubation of primary AML samples with the NEO drugs eliminated leukemic CD45dim blasts, myeloid CD45dimCD33+ leukemia cells, and CD45dimCD34+ immature blasts, while the lymphocytes were unaffected. Both NEO2734 and NEO1132 induced apoptosis in primary CD45dim leukemic blasts (Figure 1A). Importantly, treatment with NEO1132 and NEO2734 resulted in a significant reduction in clonogenic capacity of leukemic stem/progenitor cells from AML patient samples. Already after treatment with 10 nM a significant reduction in the number of colonies was observed in all tested primary AML cases (Figure 1B). To evaluate the potential of the NEO drugs to reduce human AML burden *in vivo*, primary AML cells were injected into NSG mice and the mice were orally treated with NEO2734 or NEO1132 (10 mg/kg for 11 times). A significant reduction in leukemic burden in the bone marrows of the mice was observed after treatment with NEO2734. Finally, we demonstrated that NEO2734 increased effectiveness of combination chemotherapy treatment *in vivo*.
To restore normal hematopoiesis after therapy, therapeutic approaches targeting leukemia cells should spare normal hematopoietic cells. Both NEO2734 and NEO1132 reduced the survival of normal human bone marrow cells only at high concentrations (1 μM), and with a 3.4-fold and 2.0-fold lower efficiency than the drugs affected primary AML cells. Oral treatment with NEO2734 or NEO1132 did not significantly reduce the weight of the mice, and did not affect the survival of normal mouse hematopoietic cells.

Figure 1



Summary/Conclusion: The dual BET-CBP/P300 inhibitor NEO2734 eliminates AML blasts and LSCs/progenitors in a nanomolar concentration, implicating that dual inhibition of BET and CBP/p300 using NEO2734 is a promising therapeutic strategy for AML patients, making it a focus for clinical translation.

EP401 POLYFUNCTIONALITY DETERMINED BY SINGLE-CELL PROTEOMICS OF BONE MARROW-DERIVED CD4 T-CELLS FROM PATIENTS WITH ACUTE MYELOID LEUKEMIA PREDICTS PATIENTS RESPONDING TO ANTI-PD-1-BASED THERAPY

H. Abbas [1,*], S. Mackay [2], M. Cyr [2], J. Zhou [2], G. Issa [3], M. Alfayez [3], S. Kornblau [1], E. Jabbour [3], G. Garcia-Manero [3], M. Konopleva [3], M. Andreef [3], N. Daver [3]

Background: In a phase 2 clinical trial in patients with relapsed/refractory AML, combining azacitidine with nivolumab demonstrated encouraging response rates (33%), median event-free and overall survival, compared with a historical cohort of contemporary patients treated with azacitidine-based therapies. Biomarkers of response are yet to be determined.
Aims: In this sudy, we aimed to identify biomarkers of response to nivolumab-based therapy using single cell polyfunctional proteomic assays.
Methods: Eleven non-responders and 5 responders to treatment based on ELN2017 response criteria had available samples and were analyzed. Bone marrow samples were collected prior to and at end of second treatment cycle. A total Polyfunctional T cells co-secreting 2+ cytokines were assessed with the 32-plex proteomics. The polyfunctional strength Index (PSI) of single T cells was computed as the percentage of polyfunctional cells, multiplied by mean fluorescence intensity of the proteins secreted by those cells.
Results: A total of 16 patients (5 CR/CRi and 11 non-responders) with R/R AML who received a median of 3 (range 2-17) cycles and a median of 11 (range 3-33) doses of nivolumab were analyzed (Table 1). The pretreatment bone marrow CD4+ but not CD8+ T cells had significantly higher frequency of polyfunctional cells (p=0.04 and 0.15, respectively) and significantly higher PSI (p=0.01 and 0.18, respectively) in responders compared with non-responders (**Figure 1A-B**). Also, pretreatment bone marrow PSI of CD4+ (P<0.001) but not CD8+ (P=0.14) subsets demonstrated a significant positive association with overall survival (OS) across all patients, likely partly driven by response enrichment, suggesting that the degree of polyfunctional state of CD4+ cells may potentially also predict outcomes in AML patients treated with azacitidine/nivolumab (**Figure 1C**). Further evaluation of the PSI composition across cell types revealed that IFN-g and TNF-a were the major drivers of enhanced PSI of pretherapy CD4+ subset, whereas Granzyme B, IFN-g, MIP-1b and TNF-a drove the non-significantly enhanced pretreatment PSI of CD8+ subset in the responders (**Figure 1D**). Using t-SNE dimension reduction, CD4+ and CD8+ cells from responders and non-responders had distinct clustering patterns. Highly polyfunctional groups clustered together in both CD4+ and CD8+ T cells. The most dominant functional group across CD4+ and CD8+ cells was the effector protein pattern, which was more notable in the pretreatment bone marrows of responders compared to non-responders and also corresponded to the highly polyfunctional group. Compared to non-responders, the pretherapy CD4+ T cells of responders had more distinct and unique polyfunctional groups (green rectangles) such as co-expression of TNF-a/IFN-g/IL-8, TNF-a/IFN-g/Granzyme B or TNF-a/IFN-g/Perforin/IL-8 proteins.

Summary/Conclusion: The single-cell multiplexed functional proteomics precision profiling demonstrated that the pretreatment PSI of CD4+ cells was significantly associated with response and OS in relapsed patients treated with azacitidine/nivolumab and should be evaluated prospectively to ascertain whether this could be an effective biomarker to select AML patients for PD-1 based therapies. Pretreatment PSI may have a potential role as a biomarker in the wider sphere of immunotherapy in AML. Such analyses are warranted and encouraged.

EP402 RAPID GENOMIC PROFILING IN ACUTE MYELOID LEUKEMIA WITH MYELODYSPLASIA-RELATED CYTOGENETIC ABERRATIONS

A. Dolnik [1,*], C. K. Lai [2], R. Gabdoulline [2], J. E. Sträng [1], E. Panina [3], N. Damrah [2], M. Wichmann [2], J. F. Schrezenmeier [1], J. Westermann [1], F. Damm [1], G. Göhring [4], B. Schlegelberger [4], F. G. Rücker [3], H. Döhner [3], A. Ganser [2], F. Thol [2], O. Blau [1], K. Döhner [3], L. Bullinger [1], M. Heuser [2]

[1]Department of Hematology, Oncology and Tumor Immunology, Charité-University Medicine, Berlin, [2]Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, [3]Department of Internal Medicine III, University Hospital of Ulm, Ulm, [4]Department of Human Genetics, Hannover Medical School, Hannover, Germany

Background: Despite recent advances in the understanding of the molecular biology of acute myeloid leukemia (AML), the outcome of patients in the high risk subgroup, especially of AML with myelodysplasia-related changes (AML-MRC), remains poor. Newly developed therapeutic options such as CPX-351 offer the possibility to more refined treatment approaches. However, this requires fast detection of cytogenetic abnormalities that define AML-MRC. Conventional karyotyping is still the golden standard in routine AML diagnostics, but this analysis is labor and time consuming. To select the best available therapeutic option, it is crucial to determine copy number and structural variations in the shortest time possible.
Aims: To establish and validate karyotyping based on low coverage whole genome sequencing (WGS) of AML patients using long read Oxford Nanopore technology (ONTseq) that offers the possibility for diagnostic testing within a short timeframe of 48-72 hours.
Methods: Cytogenetically characterized diagnostic samples from peripheral blood or bone marrow of AML patients with MRC, such as complex karyotype or monosomal karyotype, were sequenced on a GridION sequencer within a ~20 hours sequencing run. Sequencing was performed using SQK-LSK109 kits according to the manufacturer's instructions. Analysis of sequencing reads and generation of profiles was performed using an 'in house' bioinformatics pipeline based on publicly available tools, such as nglmr aligner, samtools, IGVTools, R package ACE, and a custom script for transforming graphical genome profiles to karyotype formula. For the current analysis copy number variations by ONTseq were only considered if ≥30% of a chromosome arm was aberrant.
Results: Sequencing of the first 47 cases achieved a 3.1-fold genome coverage (range: 1.9-5.0) and established copy number profiles of all samples at a high resolution of ≤0.1 Mbp. To check reproducibility, n=10 AML cases were sequenced and profiled at two medical centers. All 83 aberrations of these cases with gain or loss >10 Mbs were identified by both laboratories, and the fraction gained/lost was highly concordant (R^2=0.998). Considering all 47 cases, the median number of unbalanced aberrations found by cytogenetics were 4 (range 1-11) and by ONT-profiling were 3 (0-14) per patient. Additional 59 and 49 aberrations were identified by ONTseq that affected 10-30% and 5-10% of the chromosome arm, respectively, that were not considered here. Comparing the copy number status of all chromosome arms for all patients we found a 91% concordance, while 5% of chromosome arms were aberrant by ONT and 4% by cytogenetics only. Those discrepancies were expected and could be explained on the one hand by a higher resolution of ONT profiling, and on the other hand by the fact that 'marker chromosomes' often contain the genomic material that is classified as lost in conventional cytogenetics. Of note, ONT profiles captured also very complex rearrangements, such as chromothripsis and focal amplifications, at high resolution.
Summary/Conclusion: Our retrospective analysis of a well characterized cohort of cytogenetically aberrant AML patients demonstrates the feasibility of ONTseq-based low-coverage WGS with excellent reproducibility and resolution. Thus, ONTseq provides an opportunity to rapidly

and reliably delineate AML-MRC within 48-72 hours and thereby advance genotype-based treatment strategies.
AD and CL, LB and MH contributed equally to this work.

EP403 ENHANCED EFFICACY OF THE DCP-001 RELAPSE VACCINE WHEN COMBINED WITH VENETOCLAX AND 5-AZACITIDINE IN A HUMANISED IMMUNOCOMPETENT MOUSE MODEL OF AML

C. Leitch [1,2], M. Popa [1,2], S. Kaur Singh [3,*], E. Manting [3], B. T. Gjertsen [1], E. McCormack [1,4,5]

[1]Centre for Cancer Biomarkers CCBIO, Department of clinical science, University of Bergen, [2]KinN Therapeutics AS, Bergen, Norway, [3]DCPrime BV part of Immunicum AB, Leiden, Netherlands, [4]Centre for Pharmacy, Department of clinical science, [5]Vivarium, Department of clinical science, University of Bergen, Bergen, Norway

Background: The allogeneic, leukemia-derived dendritic cell vaccine, DCP-001, is a relapse vaccine capable of generating cellular and humoral immune responses in acute myeloid leukemia patients (AML). In an ongoing phase II study (Clintrials.gov: NCT03697707), DCP-001 is observed to induce immune response specifically against tumour associated antigens relevant for AML. Preclinical efficacy studies have previously shown DCP-001 vaccination to significantly repress subcutaneous tumour growth in a humanised immunocompetent mouse model of AML. The reproducibility of the preclinical model provides a platform for optimizing vaccination strategies and evaluating DCP-001 efficacy in combination with established AML treatment agents.
Aims: To determine, in a preclinical setting, whether DCP-001 vaccination was compatible with the approved AML drug therapy comprised of 5-Azacitidine (5-AZA) and Venetoclax (VEN).
Methods: 25 female NSGS mice were inoculated with 1 x 10^5 human CD34$^+$ cells. A 12-week maturation period was permitted for engraftment and human immune cell development during which blood was sampled to track chimerism by FACS (hCD45, mCD45, hCD3 and hCD19) and complete blood count (CBC) analysis. Subsequently, the leukemia cell line DCOne^{LUC} was engrafted subcutaneously (5 x 10^6 cells/mouse) and animals were randomized by weight and chimerism and assigned to the following groups: untreated control (n = 6), vaccination (DCP-001, QWx2., n = 7), treatment (AZA 1mg/kg and VEN 50 mg/kg, QDx5, n = 6) and combination (DCP-001, QWx2 + AZA 1mg/kg and VEN 50 mg/kg, QDx5, n = 6). Disease progression and therapy response were monitored by calliper-based measurement of tumour volumes and optical imaging of the bioluminescent cell line, DCOne^{LUC}.
Results: Tumour volumes indicated that all therapy groups were capable of slowing DCOne^{LUC} tumour growth as compared with control group. Importantly, mean tumour volume (± SEM) 6 weeks after therapy initiation was significantly reduced in the combination group (181.8 ± 29 mm^3) as compared to control (522 ± 97.5 mm^3), but also vaccination (326.9 ± 54.6 mm^3) or drug treatment alone (293.8.8 ± 29 mm^3). Bioluminescence imaging and quantification corroborated tumour volume data indicating combination therapy to be the most efficient. AZA-VEN treatment was associated with transient but reversible weight loss and also a reduction in chimerism as determined by the fraction of peripheral blood cells expressing hCD45 at endpoint.
Summary/Conclusion: Preclinical modelling of AML in a humanized mouse model reproduced evidence that DCP-001 vaccination is capable of slowing AML cell line derived tumour growth. Furthermore, vaccination efficacy was significantly enhanced when combined with AZA-VEN drug treatment. Off target effects of drug treatment reduced circulating human immune cells, suggesting optimization of treatment and vaccination scheduling may further enhance the anti-leukemic effect of the combination therapy. These preclinical results support use of DCP-001 as add-on to treatment with AZA-VEN in clinical trials in AML patients.

EP404 TARGETING DOWN SYNDROME-ASSOCIATED LEUKEMIA AT ITS CORE: LSD1 INHIBITION IN COMBINATION WITH DISRUPTION OF JAK-STAT SIGNALING

J. Grimm [1,*], R. Bhayadia [1], D. Heckl [1], J.-H. Klusmann [1]

[1]Martin-Luther-University Halle-Wittenberg, Halle, Germany

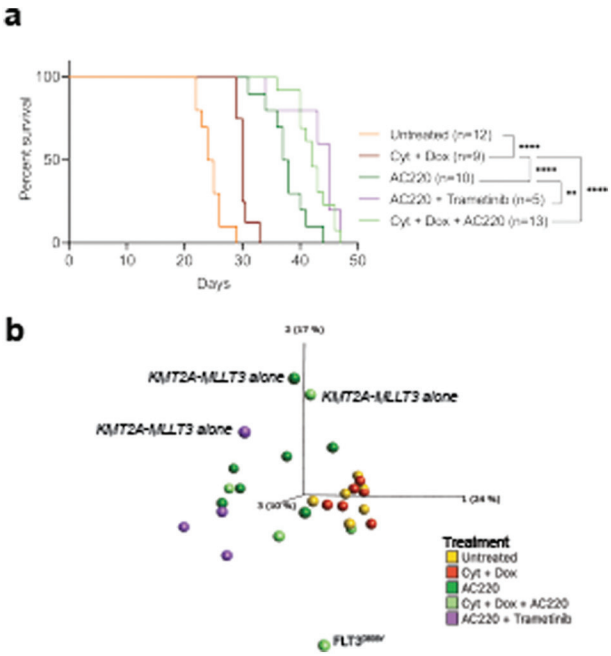
Background: Children with Down syndrome are predisposed to develop acute megakaryoblastic leukemia (ML-DS). Thereby, ML-DS leukemogenesis is a stepwise process evolving from pre-leukemic transient abnormal myelopoiesis (TAM). Previously, we showed that the transition from TAM to ML-DS is characterized by the activation of target genes of the histone demethylase LSD1 and acquisition of mutations in signaling pathway genes, *e.g.* JAK-STAT signaling. As children with Down syndrome often suffer from severe toxicities upon intensive chemotherapy, targeted approaches for the treatment of ML-DS are desirable.
Aims: Here we set out to investigate pharmacological LSD1 inhibition (LSD1i) – also in combination with the JAK1/2 inhibitor Ruxolitinib – as therapeutic strategy in ML-DS.
Methods: *In vitro* drug efficacy screens for LSD1 inhibitors as monotherapy or in combination with Ruxolitinib were performed in pediatric AML cell lines as well as different patient-derived xenografts (PDX) calculating EC50 and Bliss synergy score. This drug combination of LSD1i and Ruxolitinib was further investigated *in vivo* in a PDX-based ML-DS mouse model. To identify molecular mechanisms of drug synergy between LSD1i and inhibition of JAK-STAT signaling we performed RNAseq in two different PDX.
Results: In line with the activation of genes positively regulated by LSD1, we observed particularly high LSD1 protein expression in ML-DS primary samples. LSD1i in the ML-DS cell line CMK as well as in five different PDX induced myeloid differentiation displayed by increased expression of CD86 and CD11b. However, LSD1i only led to proliferation arrest without increasing the rate of apoptotic cells. Thus, we tried various drugs in combination with LSD1i (*e.g.* Azacytidine, Venetoclax) to enhance the antileukemic effect, and identified the JAK1/2 inhibitor Ruxolitinib as the most effective. The combination of LSD1i and Ruxolitinib caused a synergistic as opposed to a merely additive antileukemic effect in ML-DS samples measured by the Bliss synergy score. Consequently, we tested LSD1i and Ruxolitinib in a PDX-based murine ML-DS model, where the combination led to a significant reduction in blast count compared to monotherapies and control group. Concerning molecular mechanisms of drug synergy, RNAseq data revealed that LSD1i and Ruxolitinib synergistically inhibited pathways involved in cell division, such as DNA replication or transition from G1 to S phase during cell cycle. On the contrary, LSD1i induced interleukin signaling in mono- and combination therapy, which was repressed by Ruxolitinib. Western blot analysis confirmed increased STAT phosphorylation upon LSD1i that was abrogated in combination with Ruxolitinib. Hence, our data point towards increased interleukin signaling after LSD1i as potential mechanism to sensitize cells to additional Ruxolitinib treatment.
Summary/Conclusion: We identified LSD1i in combination with disruption of JAK-STAT signaling by Ruxolitinib as potential new treatment strategy in ML-DS with efficacy *in vitro* and *in vivo*. Thereby, both drugs synergized in inducing proliferation arrest and differentiation. The regulation of interleukin signaling by LSD1i might be a potential mechanism of sensitizing ML-DS blasts to Ruxolitinib.

EP405 MESENCHYMAL STROMAL CELLS PROTECT ACUTE MYELOID LEUKEMIA CELLS FROM VENETOCLAX-INDUCED APOPTOSIS THROUGH CONTACT-DEPENDENT MECHANISMS

G. Corradi [1,*], J. Nanni [1], A. Polimeno [1], D. Forte [1], M. Ciciarello [2], M. Cavo [1,3], A. Curti [3]

[1]Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, [2]Institute of Hematology "Seràgnoli", Bologna, Italy, [3]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Institute of Hematology "Seràgnoli", Bologna, Italy

Background: Acute myeloid leukemia (AML) is a heterogeneous clonal disorder characterized by immature myeloid cell proliferation. Leukemic cells reside in highly specialized bone marrow (BM) niches composed of distinct cell populations, including mesenchymal stromal cells (MSCs). AML cells depend for survival on B-cell lymphoma 2 (BCL-2) family members, which regulate the intrinsic pathway of programmed cell death. Venetoclax (VEN) was the first BCL-2-selective agent to enter the clinic and it showed breaking through effect in combination with demethylating agents in older patients with treatment-naïve AML. Despite the encouraging clinical results of VEN, mechanisms of resistance were also described. Of note, the high rate of relapse may in part be explained by the inability of treatments to efficiently overcome the protection of the BM niche. Indeed, recent evidence demonstrated that BM-derived MSCs provide a protective microenvironment, which modulates drug sensitivity in several hematological disorders, including AML. However, the role of MSCs in modulating the response to VEN treatment has been poorly elucidated.



Aims: The aim of this study is to investigate the mechanisms of MSC-mediated VEN resistance in AML, to unravel new MSC–dependent mechanisms promoting leukaemia progression.
Methods: We isolated BM-derived mononuclear cells from healthy donors (HDs, undergoing stem cell transplant) and AML patients to generate HD/AML-MSCs. Next, we set up co-cultures with HD/AML-MSCs and the AML cell line (MV4-11) or primary AML cells. Before and after co-culture, we investigated the viability of AML cells treated with different doses of VEN.
Results: First, we studied the effects of single-agent therapy with VEN on the AML cell line, MV4-11. We evaluated cell apoptosis and we confirmed that VEN reduced significantly the viability of MV4-11 in a dose-dependent manner, with an enhanced effect at higher concentration. Next, we performed co-culture experiments between MV4-11 and HD-/AML-MSCs. We set up the co-cultures with and without trans-wells to unearth if the MSC-mediated protection is contact-dependent or is based on the release of soluble factors. We found that both HD- and AML-MSCs, significantly reduced the apoptosis of MV4-11 after VEN exposure, regardless VEN dose, supporting the fundamental role of MSCs in drug resistance. Interestingly, we clarified that the mechanisms involved in MSC-mediated protection were contact-dependent. Indeed, the addiction of trans-wells to the co-culture system almost abrogated the MSC-protective effect on VEN-induced apoptosis, suggesting a complex interplay between AML cells and adhesion molecules in our setting (a set of experiments to identify the signaling pathway involved is ongoing). Finally, we performed the co-culture experiments with primary AML cells, isolated at diagnosis. We found that AML cells, treated with VEN, showed different apoptotic rates, suggesting that AML cells have intrinsic factors making them more resistant or sensitive to the treatment. Furthermore, we found that both HD- and AML-MSCs protected AML cells from apoptosis induced by VEN, confirming the key role of MSCs in drug resistance.
Summary/Conclusion: For the first time, our data clarify that both primary HD- and AML-MSCs protect AML cells, including primary samples, from VEN-induced apoptosis, through contact-dependent mechanisms. Overall, our results indicate that the BM microenvironment, in particular MSCs, can promote leukemia progression, favoring drug resistance to VEN treatment.

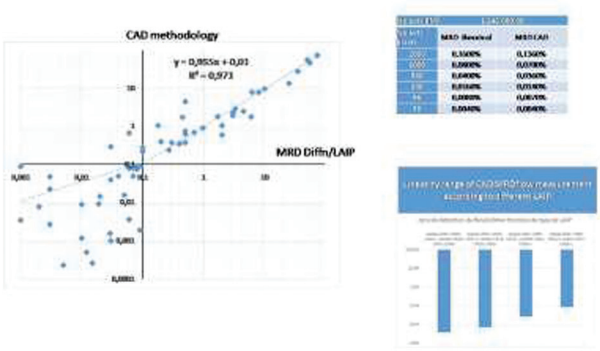
EP406 TREATMENT IS SHAPING CLONAL EVOLUTION AND RESISTANCE PATTERNS IN MURINE KMT2A-REARRANGED LEUKEMIA WITH SUBCLONAL FLT3N676K

T. Falqués-Costa [1,*], M. Pilheden [1], Q. Zhang [1], L. Ahlgren [1], H. Sturesson [1], L. Rönnstrand [2,3,4], A. Hyrenius-Wittsten [1], J. U. Kazi [2,3], A. K. Hagström-Andersson [1]

[1]Department of Laboratory Medicine - Division of Clinical Genetics, [2]Department of Laboratory Medicine - Division of Translational Cancer Research, [3]Department of Laboratory Medicine - Stem Cell Center, Lund University, [4]Division of Oncology, Skane University Hospital, Lund, Sweden

Background: Our understanding of how individual mutations, whether present in all or just a fraction of the leukemia cells, affect cellular responses to therapy is limited. Leukemia mouse models provide a unique possibility to explore how therapy affects the evolution of genetically distinct clones and identify mechanisms of resistance allowing transfer to human disease.
Aims: Herein, we studied how different therapies influenced survival, clonal evolution, and resistance patterns in mouse *KMT2A-MLLT3* leukemia with subclonal $FLT3^{N676K}$.
Methods: Bone marrow (BM) from a leukemia expressing *KMT2A-MLLT3*-mCherry in all cells and a $FLT3^{N676K}$-GFP in 40% of cells, were re-transplanted to sublethally irradiated recipients. Upon engraftment, treatment was started with either chemotherapy (cytarabine for 5 days (d)+doxorubicin for 3 d), the FLT3 inhibitor AC220, chemotherapy followed by AC220, or AC220+Trametinib, a MEK inhibitor. Targeted treatment was given for 28d; controls received vehicle. The leukemias were analyzed by flow-cytometry, RNA-sequencing and targeted gene re-sequencing.
Results: Each treatment prolonged survival with a median latency of 30d for chemotherapy, 37.5d for AC220, 42d for chemotheraphy+AC220, and 45d for AC220+Trametenib, versus 25.5d for the control (**Fig 1a**). Most cells expressed our marker genes and mice displayed splenomegaly and leukocytosis.
We next determined how treatment impacted evolution of the *KMT2A-MLLT3+*$FLT3^{N676K}$ cells and while they constituted all cells in control and chemotherapy-treated mice, the other treatments impacted their evolution. Three distinct patterns were discerned with either >80% of *KMT2A-MLLT3+*$FLT3^{N676K}$ cells, >80% of cells expressing *KMT2A-MLLT3* alone, or dual similar sized clones of cells expressing *KMT2A-MLLT3* alone or *KMT2A-MLLT3+*$FLT3^{N676K}$. Eradication of the FLT3-leukemia cells was rare, but most common in mice receiving AC220+Trametinib and the frequency of dual clones increased when mice received chemotherapy followed by AC220, in line with treatment selectively affecting evolution.
To find clues to treatment resistance, RNA-sequencing (N=44) revealed segregation into three major clusters: 1) leukemias expressing *KMT2A-MLLT3* alone, 2) control and chemotherapy-treated leukemias and 3) AC220 treated leukemias. Notably, a set of AC220-treated mice clustered close to the control and chemotherapy-treated mice (**Fig 1b**). Flow-cytometry data showed that the clustering correlated with the fraction of a myeloid cell population aberrantly expressing B220, which constituted most cells in the control and chemotherapy treated leukemias. Gene set enrichment analysis revealed enrichment of gene sets correlating with stem cells and oxidative phosphorylation, suggesting a switch in cellular phenotype and metabolic state upon resistance in those AC220 treated leukemias. By contrast, the AC220 leukemias in cluster 3, instead showed enrichment of gene sets correlating with granulocyte/macrophage progenitors and immune regulatory pathways, indicating selective dependence of distinct cellular pathways upon resistance. Finally, acquisition of AC220 resistance mutations was rare with a $FLT3^{D835Y}$ and a $Ptpn11^{G503V}$ in two leukemias.

Summary/Conclusion: The specific treatment given affected survival and impacted the evolution of genetically distinct cells. The general lack of acquired mutations upon targeted treatment suggests that target-independent mechanisms that result in alternate activation of survival/proliferation explains acquired resistance in a majority of mice.



EP407 COMPUTER AIDED DESIGN (CAD) FLOW IN ASSESSMENT OF AML MRD FLOW -ALFA FRENCH FLOW AML MRD INTERGROUP

F. Dumezy [1,*], C. Roumier [2], J. Gutrin [3], I. Helali [2], O. Cadassou [3], D. Manzoni [3], C. Berthon [4], X. Thomas [3], C. Preudhomme [2], A. Plesa [5]

[1]Hematology Laboratory, University Hospital, [2]CHRU, Lille, [3]CHU, Lyon, [4]Department of Hematology, Lille, [5]Lyon, CHU-HCL, France

Background: MRD monitoring is now mandatory for treatment response evaluation in AML clinical trials (ELN-2017 guidelines). In this setting, beside to molecular biology methods, multiparameter flow cytometry assay represents the most reliable approach.
Aims: The aim of this study was to compare conventional MRD flow analysis (LAIP/diff normal) versus computer aided design (CAD) flow in assessment of AML MRD flow using panel and settings of -ALFA French Flow AML MRD.

Methods: 120 Bone marrow AML samples issued from 60 patients (between 2018-2020) who received conventional chemotherapy regimen (3+7) or Vyxeos, 30 diagnosis and 30 follow-up MRD1 after induction.
Results: The CAD method is based on the use of an R script that compares the MRD sample to a panel of 20 reference BM and the diagnostic sample using the unsupervised clusterisantion method flowsom. It is applied following a basic cytometry analytical strategy of cleaning up confounding events (debris, aggregates...). It can be used with any software that can extract data from cytometry files (FCS, LMD) in the form of text files of type csv (comma separated values). The script then combines the files extracted from the follow-up diagnosis and the reference samples.
The extracted data are limited to blast populations (SSlow CD45+ CD117+ and or CD34+) that have been perfectly cleaned of cell debris or doublets or contamination by mature cells.
Carries out an unsupervised clustering on all the data with the FlowSOM algorithm, then produces an FCS file that integrates the results of this unsupervised clustering into additional parameters (FlowSOM mapping, metacluster among others). It is then easy to reuse this new FCS file in a cytometry software and to condition the populations on the results of this clustering in order to quantify the residual population and compare it to the reference bone marrows.Finally, our script performs a pre-analysis: it identifies and quantifies the SOM flow metaclusters in the CD34+ CD117+ space for all samples (diagnosis, followup and references). It then extracts the metacluster whose proportion of events at the monitoring point is significantly different from that observed for the reference pith (> mean+6sd) and displays the combination(s). It calculates the mrd in % of WBC CD45+ of the owup sample. The limits of sensitivity of the CAD method shows that a MRD remains evaluable by CAD up to 0.004% (50 events in 1 000 000). We compared the results between the conventional method and the CAD method on 60 MRD sample half from BDplatform and half from navios platform, the slope of the correlation line was 0.95 with an R2 of 0.97 and the coeficient as shown in Figure 1.Using the definition threshold of a positive MRD at 0.1%, the agreement of the results between the two methods was evaluated by the cohen kappa coeficient of 0.87, which reflects an almost perfect agreement between the two methods.

Summary/Conclusion: The advantage of this way of proceeding lies on the one hand in the rapidity of the detection of abnormal populations: the calculations performed by the PC being relatively fast <1min, but also in the absence of subjectivity of the observer: the metaclusters are determined by the algorithm and clearly identified in the file resulting from the script and finally a major advance: the comparison of the follow-up sample to the reference samples is independent of the diagnostic sample allowing detection of phenotypic shift. Finally, this method shows a very strong correlation with the conventional method.

EP408 THE IMPACT OF MUTATIONAL LOAD (VAF) DETECTED IN THE TP53, EZH2, U2AF1, WT1, FLT3 AND SF3B1 GENES WAS IDENTIFIED AS AN INDEPENDENT PROGNOSTIC MARKER FOR OS OR RFS IN A COHORT OF 497 CASES WITH AML

N. Álvarez Sánchez-Redondo [1,*], M. L. Morales [1], A. Rodríguez-García [1], R. García-Vicente [1], X. Gutierrez [2], M. Pozas [2], R. Colmenares [2], L. Moreno [1], L. Rufián [1], A. Gimenez [1], P. Martinez [2], I. Rapado [1,2], M. Linares [1,3], S. Barrio [1], J. Martínez-López [1,2,4,5], R. Ayala [1,2,4,5]

[1]Translational Hematology, Fundación de investigación biomédica Hospital 12 de Octubre de Madrid, [2]Translational Hematology, Hospital 12 de Octubre, [3]Department of Biochemistry and Molecular Biology, Faculty of Pharmacy, Complutense University, Madrid, Spain., [4]Department of Medicine, Faculty of Medicine, Complutense University, Madrid, Spain, [5]CIBERONC, CIBERONC, Madrid, Spain

Background: The prognostic classification of acute myeloid leukemia (AML) proposed by the European Leukemia Net (2017) is based on the presence of mutations in FLT3 (ITD), NPM1, CEBPA, RUNX1, ASXL1 and TP53. However, there is little information about the role of mutational load in the genes involved in AML. The impact of mutant ASXL1, DNMT3A, JAK2, TET2, TP53, and NPM1 variant allelic frequency (VAF) in newly diagnosed acute myeloid leukemia has been previously described (Short NJ, Blood advances 2020; Sasaki K, Cancer 2020), but not in other genes involved in AML.
Aims: The objective of the current study was to evaluate the prognostic impact of the VAF, detected by NGS in a custom panel of genes associated to myeloid pathology in a cohort of AML patients, who have been treated in the healthcare practice at the Hospital 12 de Octubre in Madrid, according to the type of treatment received (intensive treatment, hypomethylating agents or low-dose cytarabine).
Methods: The study was conducted in a series of 535 patients diagnosed with AML, whose median age is 67 years. Patients evaluated for Overall Survival (OS) and Relapse-Free Survival (RFS) were 497 cases: 238 cases had received intensive treatment (3+7 schemes or similar), 113 had received hypomethylating agents (azacitidine or decitabine) and 146 with low-dose cytarabine schemes. 38 patients received supportive care and were excluded from the analyses. The mutational profile at diagnosis was identified by NGS (Ion Torrent System), using a panel of 41 genes involved in myeloid pathologies: ASXL1, BCOR, BCORL1, CALR, CBL, CEBPA, DNMT3A, EPAS1, EPOR, ETV6, EZH2, FLT3, IDH1, IDH2, JAK2, KDM6A, KIT, KMT2A, KRAS, MPL, NF1, NPM1, NRAS, PHF6, PRPF40B, RAD21, RUNX1, SETBP1, SF3A1, SF3B1, SH2B3, SMC1A, SRSF2, STAG2, TET2, THPO, TP53, U2AF1, VHL, WT1 and ZRSR2.
Pathogenic or likely pathogenic variants with >1% VAF were considered. Mutational load (VAF) was assessed as a continuous variable.
Results: The percentage of mutations in older and younger patients was 97.7% and 89.8% respectively.
Younger AML patients have more frequently mutated NPM1 (34.4% vs 18.6%; P=0.004) and patients over 60 years old have more frequently mutated RUNX1 (18.4% vs 8.6%; p=0.005) and ASXL1 ((16.6% vs 3.9%; p<0.001) genes.
In the Cox multivariate analysis, the variables associated with worse OS in patients with intensive treatment were older age or higher TP53_VAF, U2AF1_VAF and EZH2_VAF; and higher TP53_VAF or the presence of EZH2-mutated were found as adverse factors for RFS. In patients who received hypomethylating agents, the variables associated with lower OS were higher TP53_VAF and WT1_VAF; and the presence of mutations in the BCOR, KIT or ETV6 genes was associated to worse RFS. Finally, in patients treated with low-dose cytarabine, TP53 is associated with worse OS and a higher mutational load of TP53 or mutations in the BCOR gene are associated with a worse RFS.

A. Group 1: Intensive treatment (3+7 scheme or similar) (n=238)				
	OS		RFS	
	HR (95% IC)	p-value	HR (95% IC)	p-value
Age	1,026 (1,010 - 1,04)	0,001	-	-
EZH2_VAF	4,97 (1,48 - 16,71)	0,009	-	-
TP53_VAF	13,79 (4,86 - 39,13)	p < 0,001	12,45 (2,9 - 52,97)	p < 0,001
U2AF1_VAF	598 (57 - 8.6273)	p < 0,001	-	-
EZH2	-	-	3,54 (1,76 - 7,12)	0,002
SF3B1_VAF	-	-	54,46 (4,6 - 647,6)	0,001

B. Group 2: Treatment with hypomethylating agents (azacitidine, decitabine...) (n=113)				
	OS		RFS	
	HR (95% IC)	p-value	HR (95% IC)	p-value
TP53_VAF	3,48 (1,89 - 6,38)	p < 0,001	-	-
WT1_VAF	17,9 (1,5 - 203,4)	0,02	-	-
BCOR	-	-	4,58 (1,56 - 13,41)	0,005
BCORL1	-	-	6,15 (1,7 - 21,9)	0,005
ETV6	-	-	3,19 (1,3 - 7,6)	0,009
KIT	-	-	3,94 (1,49 - 10,45)	0,006
FLT3_VAF	-	-	5,97 (1,3 - 26,9)	0,02
NF1_VAF	-	-	16,49 (4,1 - 65,9)	p < 0,001

C. Group 3: Treatments with schemes that include low-dose cytarabine (n=146)				
	OS		RFS	
	HR (95% IC)	p-value	HR (95% IC)	p-value
TP53	3,024 (1,89 - 4,8)	p < 0,001	-	-
TP53_VAF	-	-	2,63 (1,36 - 5,10)	0,004
BCOR	-	-	3,4 (1,6 - 7,2)	0,001

Table 1. Cox multivariate analysis for OS and RFS in the three treatment groups. The variables included are: age (continuous variable), high-risk score, mutational load (VAF) and mutated panel genes (No/Yes).

Summary/Conclusion: The impact of TP53 mutational load has prognostic influence on the 3 treatment groups. There are other genes where the impact of their mutational load depends on the treatment received: Variants-VAF of splicing genes such as U2AF1 and SF3B1 and chromatin modifying genes such as EZH2 only has an influence on the intensive treatment group.

EP409 LONG NON-CODING RNA FAM30A AS A NOVEL REGULATOR OF LEUKEMIC STEM CELL FATE IN ACUTE MYELOID LEUKEMIA

J. Calvo Sánchez [1,*], M. Köhn [1], L. Müller [2]

[1]Charles Tanford Protein Center, Institute of Molecular Medicine, Martin Luther-University of Halle-Wittenberg, [2]Department of Internal Medicine IV, University Hospital Halle - Martin-Luther University of Halle-Wittenberg, Halle, Germany

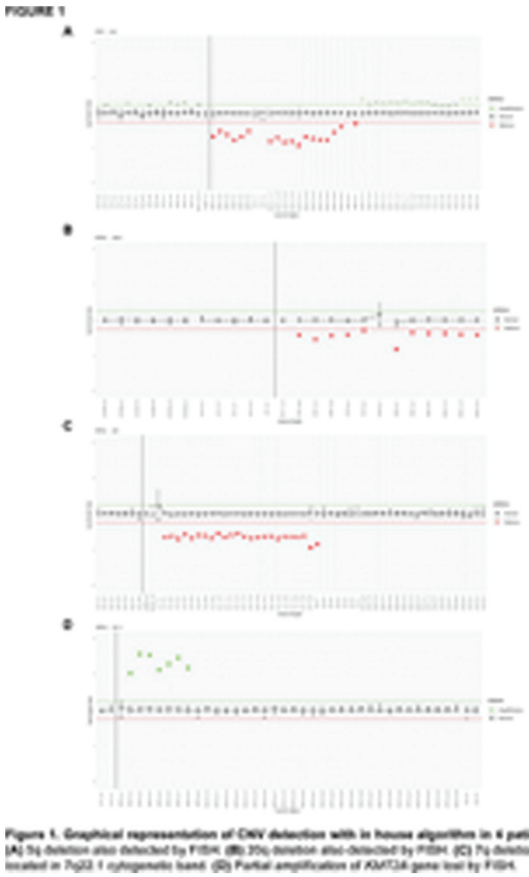
Background: High long-term relapse after induction chemotherapy is frequently observed among acute myeloid leukemia (AML) patients largely due to the presence of a heterogenous population of leukemic stem cells (LSC) with uncontrolled self-renewal ability and capable of maintaining an undifferentiated state. Based on a 17-gene stemness signature for high-risk AML (Ng SW, *Nature*. 2016), we identified FAM30 as a novel long non-coding RNA (lncRNA) highly expressed in the most primitive hematopoietic lineage. Nonetheless, the role of FAM30A in hematopoiesis as well as its clinical significance in AML remain unknown.
Aims: We aimed to characterize FAM30A at a molecular level and unravel the functional roles of this lncRNA in differentiation and chemoresistance processes in AML.
Methods: Colony-forming unit (CFU) methylcellulose assays were performed to assess the role of FAM30A in differentiation. FAM30A gain- or loss-of function studies were used to monitor RNA expression levels of LSC- and myeloid markers. Protein and RNA immunoprecipitation and RNA pulldown (biotinylated-tagged RNA) assays were performed in order to demonstrate RNA-protein specific interactions. To determine whether FAM30A has any protein-coding potential, we used sucrose gradient-based fractionation and performed targeted polysome profiling. Localization of FAM30A was revealed by cell fractionation.
Results: FAM30A expression levels were compared between AML patients and healthy donors based on a RNAseq dataset of a TCGA cohort (PanCancerAtlas) and revealed a significantly higher expression of FAM30A in AML samples compared to healthy donors ($p<0.001$, n=186). Importantly, high levels of FAM30 significantly correlated with unfavourable karyotypes and refractory disease. AML cell lines expressing high levels of FAM30A were used as a mechanistic model to study the molecular mechanisms in AML LSC residing in the CD34+ CD38- fraction as these cells have been shown to be most therapy-resistant and least immunogenic. Polysome profiling showed that FAM30A is indeed a long multi-exonic non-coding protein transcript, predominantly not found in polysomal fractions. However, we observed that FAM30A is mainly cytoplasmic at steady state. *In silico* prediction of potential binding sites of RNA-binding proteins (RBP) binding sites showed several putative conserved binding motifs for Musashi-2 (MSI2), a well-characterised oncoRBP known to play a critical role in regulating chemoresistance and LSC fate. Accordingly, detailed analysis of FAM30A sequence revealed MSI2-binding sites organized in tandem repeats. CFU-assays showed that exogenous expression of the MSI2-interacting region of FAM30A massively enhanced the potential of colony-formation ($p<0.001$) and promoted a monocyte-like differentiation status in AML LSC-like cell lines. Reversely, FAM30A knockdown in FAM30A^{high} cell lines was able to impair differentiation. Nonetheless, rescue experiments of the MSI2-binding region of FAM30A could not restore the original stem cell-like phenotype, suggesting a MSI2-dependent regulation of LSC stemness by FAM30A.
Summary/Conclusion: We identified the novel lncRNA FAM30A and its binding partner MSI2 as a potential novel regulatory axis of leukemic stem cell phenotypes which mediates differentiation and chemoresistance in AML. Moreover, we suggest that modulation of FAM30A expression could be exploited as a new therapeutic avenue in refractory and relapse AML.

EP410 COMBINATORIAL INHIBITION OF TIGIT AND CD39 INCREASE T-CELL MEDIATED KILLING IN AML

F. Brauneck [1,*], S. Menzel [2], J. Wellbrock [1], J. Schulze zur Wiesch [3], C. Ackermann [3], W. Fiedler [1]

[1]II. Department of Medicine, Center for Oncology, University Medical Center Hamburg-Eppendorf, [2]Institute of Immunology, University Medical CenHamburg-Eppendorf (UKE),, [3]I. Department of Medicine, Section Infectious Diseases, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: The inhibitory receptor TIGIT, as well as the ectonucleotidases CD39 and CD73 constitute potential exhaustion markers for T cells. Detailed analysis of these markers may shed light into dysregulation of the T-cell response in acute myeloid leukemia (AML) and help to identify potential therapeutic targets.
Aims: In the current study we analyzed multiple inhibitory receptors and members of the purinergic system which have also been involved into downregulation of T-cell effector function aiming to identify relevant new pathways of T-cell mediated immune failure in AML.
Methods: The differentiation state, phenotype and expression of transcription factors was assessed on T cells derived from peripheral blood (PB n=38) and bone marrow (BM n=43). PB and BM collected from patients with newly diagnosed primary AML, at relapse after intensive chemotherapy and in remission were compared to healthy volunteers (HD n=12). The surface expression of PD-1, TIGIT, CD73, and CD39, as well as of the differentiation markers CD45RO, CCR7, CD25 and CD127 were determined on CD8$^+$and conventional and regulatory CD4$^+$T (CD4$^+$CD127$^-$CD25^{hi})cells using multiparameter flow cytometry.
Results: An increased frequency of terminally differentiated (CD45R$^-$CCR7$^-$) CD8$^+$ T cells was confirmed in the PB and BM regardless of the AML disease status ($p<0,05$). Moreover, CD39 was aberrantly expressed on this population: we observed an increased frequency of CD39$^+$TIGIT$^+$CD73$^-$CD8$^+$ T cells in PB from patients with newly diagnosed AML and relapsed AML compared to PB from HDs (13,47 ± 4,03 vs. 15,8 ± 3,04 vs. 3,03 ± 1,21; $p<0.05$; $p<0.01$). For analysis of the functional relevance of the CD39$^+$TIGIT$^+$CD73$^-$CD8$^+$ T cells mononuclear cells of the PB (PBMC) from HDs were pre-incubated with inhibitors against TIGIT (50µg/ml) and CD39 (50µg/ml) and co-cultured with either AML OCI-3 or OCI-5 cells (E:T Ratio 6:1, n=3). After 24 hours of co-culture lysis of AML cells was assessed by flow cytometry. Treatment of anti-TIGIT, anti-CD39 or the combinatorial inhibition significantly increased T-cell mediated lysis of AML cells (lysis of AML OCI-3 cells measured by fold change: anti-CD39 1,53; anti-TIGIT 2,22; anti-CD39 + anti-TIGIT 2,67 and lysis of AML OCI-5 cells: anti-CD39 2,21; anti-TIGIT 1,63; anti-CD39 + anti-TIGIT 2,81).
Summary/Conclusion: CD8$^+$ T cells in the PB and BM from patients with AML exhibit a key signature of CD39$^+$TIGIT$^+$CD73$^-$CD8$^+$ T cells that were specifically increased at different stages of the disease. Through inhibition of CD39 in combination with TIGIT T-cell mediated lysis could be increased in AML. These results provide a rationale to further evaluate the TIGIT checkpoint blockade in combination with inhibition of the purinergic signaling to improve T-cell mediated cytotoxicity in AML.



EP411 NEW CUSTOM ALGORITHM FOR COPY NUMBER DETECTION IN MYELOID MALIGNANCIES USING A TARGETED NGS PANEL

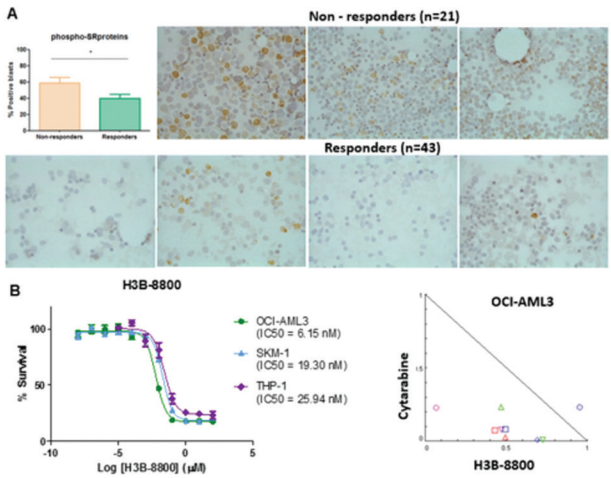
B. Ariceta [1,2,*], P. Aguirre Ruiz [1], M. J. Larráyoz [1,2], A. Mañú [1,2], O. Churruca [1], N. Gordillo Valencia [1], I. Vázquez [1,2], F. Prósper [2,3,4], A. Pardo-Saganta [5], B. Saez [6], M. J. Calasanz [1,2,7]

[1]Hematological Diseases Laboratory, CIMA LAB Diagnostics, [2]Navarra Institute for Health Research (IdiSNA), [3]Hematology Department, Clínica Universidad de Navarra (CUN), [4]Advanced Genomics Laboratory, Hematology-Oncology Program, [5]Regenerative Medicine, [6]Hematology-Oncology, Center for Applied Medical Research (CIMA), [7]Scientific co-Director of CIMA LAB Diagnostics, CIMA LAB Diagnostics, Pamplona, Spain

Background: Diagnosis of myeloid malignancies requires multiple testing strategies to characterize the genetic makeup of these pathologies. Single nucleotide variants (SNVs), short insertions and deletions (INDELs), copy number variants (CNVs) and other structural variants (inversions and translocations) are the critical genetic abnormalities that dictate therapeutic decisions. While, Next Generation Sequencing (NGS) allows for the detection of all those alterations, only SNV and INDELs detection has been implemented in clinical diagnostic laboratories, limiting the potential of NGS. In fact, CNV detection still relies on karyotype and fluorescence in situ hybridization (FISH) for their detection.
Aims: To develop an algorithm that confidently identifies copy number alterations using a capture-based NGS custom panel currently used only for SNV and INDELs detection.
Methods: We designed a capture-based NGS panel with SOPHiA GENETICS that includes 72 genes with clinical relevance in myeloid neoplasms. The panel includes genes in chromosomes 5, 7, 8, 11, 17 and 20.

The algorithm is based in depth of coverage of the samples, taking into account a unique sample, and comparing it to the whole batch of samples. To generate a batch of normal samples we use 114 samples that have not any previous myeloid neoplasm diagnosis. For the analysis group, we selected a cohort of 19 patients with myeloid malignancies with available NGS data and FISH data for any of the 6 following markers: del(5q), del(7q), +8, amp(11q), del(17p) and del(20q).
Libraries were built according to the SOPHiA GENETICS protocol and sequenced on 600 cycles V3 flow cells in a MiSeq sequencer (Illumina) in batches of 8 samples. The runs were demultiplexed using MiSeq Reporter, and alignment was done by SOPHiA DDM software. Finally, SAMTools was used for depth of coverage calculation and R for custom CNV analysis.
Results: A median of 6.03M reads per sample was obtained, in which 70.13% were on target aligned. We calculated the depth of coverage of those samples and a median of 2835X was obtained. We called every exon on the panel for the copy number.
For the 47 FISH results, the concordance was 95.74% (45/47). We detected 8 alterations in 7 patients using NGS approach. We confirmed by NGS the two positive results detected by FISH, a 5q deletion and a 20q deletion (Figure 1A, Figure 1B). In two patients, we detected two alterations in the relevant markers that were not tested by FISH. Additionally, we detected two more alterations in other regions no analyzed by FISH (del(20p) and amp(21q)) in two patients. The two discordant results could be explained taking into account the two different approaches for the analysis.
In UPN12 we detected a 7q deletion by NGS approach (Figure 1C), while it was negative by FISH. This 7q deletion is located in *CUX1* gene (7q22.1 cytogenetic band) while our FISH probe is located in 7q31 cytogenetic band.
In UPN14 we detected a partial amplification of *KMT2A* gene (11q23.3 cytogenetic band) by NGS (Figure 1D), whereas FISH probe was negative. The amplification detected affects exon 2 to exon 8 of the gene, potentially making it undetectable by routine FISH approaches.

Summary/Conclusion: Our new designed algorithm allows for the accurate and diagnostic detection of CNV using NGS data. The high concordance between data obtained with our new algorithm and the current gold standard (FISH) demonstrate the feasibility of using NGS data for the detection of CNV in myeloid malignancies. Most importantly, data obtained from NGS offers additional genetic information often overlooked by FISH due to its limitations.



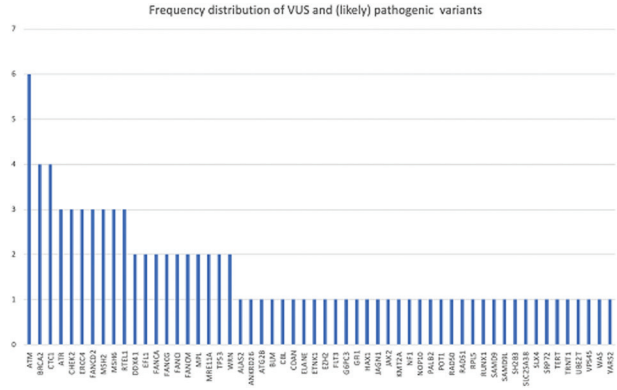
EP412 STUDY OF THE ROLE OF SR PROTEINS IN CYTARABINE TREATMENT RESISTANCE IN ACUTE MYELOID LEUKEMIA

M. L. Morales* [1,*], R. García-Vicente* [1], A. Rodríguez-García [1], N. Álvarez [1], A. Ortiz-Ruiz [1], A. Reyes-Palomares [2], R. Sánchez [1], V. Garrido-García [1], G. Carreño-Tarragona [1], R. Ayala# [1,3], J. Martínez-López# [1,3], M. Linares# [1,4]

[1]Department of Translational Hematology, Research Institute Hospital 12 de Octubre (i+12), Hematological Malignancies Clinical Research Unit H120-CNIO, CIBERONC, [2]Department of Biochemistry and Molecular Biology, Veterinary School, Universidad Complutense de Madrid, [3]Department of Medicine, Medicine School, Universidad Complutense de Madrid, [4]Department of Biochemistry and Molecular Biology, Pharmacy School, Universidad Complutense de Madrid, Madrid, Spain

Background: In recent years, several targeted therapies have received the approval for treating AML. Nevertheless, for many patients 7 + 3 chemotherapy regimens remain as the treatment of choice, and so, their lack of efficacy are the main cause of death in the disease. Therefore, there is still a necessity of more appropriate and personalized treatments, which try to avoid resistance development.
Aims: In this study, we elucidate the implication of splicing factor SR proteins in cytarabine resistance and propose new combinational therapies.
Methods: The public database GEPIA was used to compare the expression levels of genes codifying SR proteins from the LAML (TGCA) repository versus the GTEx repository (controls). Expression levels of *SRRM2* and *SRSF12* in controls, AML patients, and other myeloid disorders (MPNs and MDS) were studied by qPCR (n=54). The analysis of the proteomic profile associated to cytarabine treatment resistance was performed by LC-MSMS after IMAC enrichment (n=3). Expression levels of SR proteins and phospho-SR proteins were assayed by immunohistochemistry of paired bone marrow smears from 7 AML patients, and at the diagnosis moment of different cytarabine-response groups (n=64). The efficacy of different spliceosome inhibitors (H3B-8800, Madrasin, SPHINX31, and SRPKIN-1) and their combination with cytarabine were studied in AML cell lines.
Results: Public data showed differences in the expression levels of 4 SR proteins (*SRRM2*, *SRSF12*, *SRSF9*, and *U2AF1L5*). *SRRM2* and *SRSF12* genes exhibited overexpression in bone marrow of AML patients compared to controls, MPNs and MDS. Likewise, proteomic analysis identified an increase in the phosphorylation of SRRM2, among other SR proteins comparing paired samples before and after cytarabine resistance development. These data were validated by immunohistochemistry in which the levels of phospho-SR proteins were significantly lower in cytarabine-responders AML patients compared to non-responders (figure 1A). Finally, different spliceosome inhibitors demonstrated *in vitro* efficacy in the nanomolar (H3B-8800) or micromolar range (Madrasin, SPHINX31, and SRPKIN-1). The combination of cytarabine plus H3B-8800 showed synergism activity in OCI-AML3 cells (figure 1B).

Figure 1. (A) Immunohistochemistry of bone marrow smears of AML patients at diagnosis with anti-phospho - SR proteins antibody. (B) IC50 of H3B-8800 and its combination with cytarabine in AML cells.



Summary/Conclusion: The spliceosome pathway seems to be involved in cytarabine resistance in AML patients. The levels of *SRRM2* and *SRSF12* are higher in AML compared to controls and other myeloid disorders. The levels of phospho-SR proteins increase after cytarabine treatment in AML patients that relapse, and are especially higher at diagnosis in refractory patients. Certainly, the study of phospho-SR proteins at diagnosis could serve as a possible predictive biomarker of cytarabine response. The combination of cytarabine plus spliceosome inhibitors as H3B-8800, a small molecule that binds to the SF3b spliceosome complex, could improve the response in AML patients.

EP413 ANALYSIS OF GERMLINE PREDISPOSITION IN PATIENTS WITH MYELOID NEOPLASMS: ASSOCIATION BETWEEN MOLECULAR ALTERATIONS AND CLINICAL HISTORY

M. Santiago Balsera [1,2,*], A. Liquori [3], J. V. Gil [3], G. Avetisyan [3], L. Cordón [3], B. Martín [3], E. Mora [1], M. Ibáñez [3], C. Sargas [3], E. González [3], M. Boluda [3], M. Morote [3], C. García [3], C. Martínez [3], A. SanJuan [3], M. Llop [1], P. Montesinos [1], E. Barragán [1], M. Á. Sanz [1], G. Sanz [1], Á. Zúñiga [2], E. Such [1], J. Cervera [1,2]

[1]Hematology, [2]Genetic Unit, Hospital Universitario y Politécnico La Fe, [3]Hematology, Instituto Investigación Sanitaria La Fe, Valencia, Spain

Background: Hereditary myeloid malignancies syndromes (HMMSs) are rare but increasingly important clinical entities. These affect ~5-10% of patients with myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML). In the 2016 revision, the WHO distinguished them from sporadic myeloid neoplasms, by proposing a specific category: myeloid neoplasms with germline predisposition.
Aims: We prospectively studied the prevalence of HMMSs in a cohort of consecutive patients diagnosed at our institution and explored if there was any association with patients´ medical history.
Methods: So far, we have examined 56 paired somatic/germline samples from 21 MDS and 35 AML consecutive patients (16-80 years). Fifteen (27%) of them were considered secondary neoplasms. The germinal samples included 31 fibroblasts culture from skin biopsy, 22 $CD3^+$ lymphocytes isolated from peripheral blood (PB) and 3 PB in remission. We analyzed them, through targeted Next-Generation sequencing (NGS) using a custom gene panel of >170 genes including all those previously associated to HMMSs. Besides, we conducted a thorough interview with patients to learn about their personal and family history of cancer and signs related to HMMSs.
Results: In 10 patients, we did not identify any clinically relevant germinal variant. We found 91 germline variants in 82% (46/56) of patients categorized as variants of uncertain significance (VUS) or (likely) pathogenic according to American College of Medical Genetics and Genomics (ACMG) criteria. Their frequency is shown in figure 1. Mean number of variants per patient was 1.62. In total, 13 (14%) variants were considered as (likely) pathogenic and were present in 12 (21%) patients. Six of them (11% patients) have been associated to HMMSs with an autosomal dominant (AD) inheritance pattern (*ANKRD26, CHEK2, ELANE, SAMD9, and TP53* in 2 patients), indicating a potential molecular cause of the disease. Two variants (*EZH2, SH2B3*) have been related to sporadic myeloid neoplasms but not to a germline origin. Although other heterozygous variants (in genes *CTC1, FANCM, SLC25A38, SLX4*) have been related to HMMSs, their inheritance pattern is autosomal recessive. Considering those 6 patients with AD (likely) pathogenic variants, mean age was 54 (47-67years). Four of them (67%) presented a personal history of cancer and their myeloid neoplasms were considered secondary to it. In contrast, we noted that only 33% of them exhibited at least one 1st grade relative with cancer and that none of them showed >1 family history of cancer. Patient with *CHEK2* and one of those with *TP53* mutations presented with typical described phenotype (gynecological cancer history and Li Fraumeni related neoplasms, respectively). However, in the other patients with AD (likely) pathogenic variants, we did not find any sign related to hereditary predisposition syndromes.

Summary/Conclusion: In agreement with previous studies, 11% of patients in our series had a potential hereditary myeloid malignancy syndrome, although only 33% of them presented typical phenotypes. Some patients with HMMSs may not initially have suspicious personal or family history due to lack of knowledge about their own or relatives past blood test results, unexplained causes of death in the family, incomplete penetrance, variable expressiveness, or *de novo* mutations. On the other hand, it is necessary to expand this series to obtain more information on these entities in order to be able to select appropriately those patients who require a germline study and a different clinical management.

EP414 THE MOLECULAR BASIS AND CLINICAL OUTCOMES OF CALM-MLLT10 FUSION POSITIVE ACUTE LEUKEMIA

T. Wang [1,2,*], X. Ma [1], H. Zhang [1], J. Fang [1], Q. Zhang [1], Z. Li [1], Y. Zhang [1,3], L. Yuan [1], P. Cao [1], H. Liu [1,2,3]

[1]Division of Laboratory Medicine, Hebei Yanda Lu Daopei Hospital, Langfang, [2]Division of Pathology & Laboratory Medicine, Beijing Lu Daopei Hospital, [3]Beijing Lu Daopei Institute of Hematology, Beijing, China

Background: CALM-MLLT10 is a recurrent but rare fusion gene in leukemia and lacks relevant reports.
Aims: To investigate the cytogenetic and molecular characteristics of t(10;11)(p13;q21)/CALM-MLLT10 positive acute leukemia (AL), and to observe the clinical outcome with chemotherapy and allogeneic hematopoietic stem cell transplantation (allo-HSCT) of this molecular entity leukemia.
Methods: The G-biding karyotype and reverse transcriptase PCR results of 9627 AL cases admitted to Hebei Yanda Ludaopei Hospital from Jan. 1, 2015 to Dec. 31, 2020 were retrieved and analyzed to determine the cases positive for t(10;11)(p13;q21)/CALM-MLLT10. Eighty-six gene panel mutation screening results, RNA sequencing (RNA-seq), and clinical records of the positive cases were further analyzed.
Results: A total of 21 CALM-MLLT10 positive cases were enrolled in this cohort, including 16 males and five females, with the male-to-female ratio=3.2:1. There were 12 adults and nine children, with a median age of 24 (4-37) years. According to the lineage of leukemia, there were 12 cases of acute myeloid leukemia (AML), five T-cell acute lymphoblastic leukemia (T-ALL), one B-ALL, one mixed-phenotype AL (MPAL) with T/B antigen expressed, one MPAL with T/M antigen expressed, and one B lymphoblastic lymphoma. 91.6% (11/12) of CALM-MLLT10 positive AML cases had complex abnormal karyotypes or had additional abnormalities. PHF6 gene mutations frequently accompanied in CALM-MLLT10 positive AML cases, with an incidence of 87.5% (7/8), which is significantly higher than 3% in the CALM-MLLT10 negative AML cases, and the other frequently mutated genes include TET2, EZH2, and TP53. In CALM-MLLT10 positive T-ALL cases, JAK1/3 mutation incidence is 80%, and PHF6 mutation incidence is 40%. RNA-seq analysis showed that HOXA family genes were extensively overexpressed in CALM-MLLT10-positive AL cases. MYCN, MEIS1, SOX4, BAALC, and FLT3, which relate to poor prognosis in hematological malignancies, were also significantly overexpressed. The overall response to induction chemotherapy of these cases was poor, and 13 of them underwent allo- HSCT. Two of them underwent the second HSCT and the third HSCT, respectively, due to relapse. There were 8 cases that underwent allo-HSCT died

from relapse (5 cases), infection (2 cases), and severe graft verse host disease (1 case), respectively.
Summary/Conclusion: The total incidence of CALM-MLLT10 in AL is about 0.2%, with the majority were male cases, and it can clinically manifest with AML, T-ALL, B-ALL, and MPAL. This suggests that the founder CALM-MLLT10-positive leukemia cells are at an early stage of the hematopoietic stem and progenitor cells. The accompanying PHF6, JAK1/3, and other gene mutations may synthetically determine the lineage of the leukemias. Early hematopoietic differentiation stage, complex or additional aberrant karyotypes, extensive HOXA family genes and other poor prognostic gene overexpression, high-frequency PHF6 and JAK1/3 mutations, together contributed to the poor response to chemotherapy and even poor prognosis of allo-HSCT. There is an urgent demand to find molecular targets and targeted therapy to improve this molecular entity leukemia's clinical outcome.

EP415 PRL-PRLR AXIS IMPLICATION IN CHEMORESISTANCE AND PROLIFERATION IN ACUTE MYELOID LEUKEMIA

L. Cuesta-Casanovas [1,2,*], J. M. Cornet-Masana [1], J. M. Carbó [1], A. Banús-Mulet [1], J. Delgado-Martínez [1,3], F. Guijarro [4,5], J. Esteve [1,4,5,6], R. M. Risueño [1]

[1]Josep Carreras Leukemia Research Institute, Badalona, [2]Faculty of Bioscience, Universitat Autònoma de Barcelona, [3]Faculty of Pharmacy, Universitat de Barcelona, [4]Hematology, Hospital Clínic, [5]Faculty of Medicine, Universitat de Barcelona, [6]Institut d'Investigacions Biomèdiques August Pi I Sunyer, Barcelona, Spain

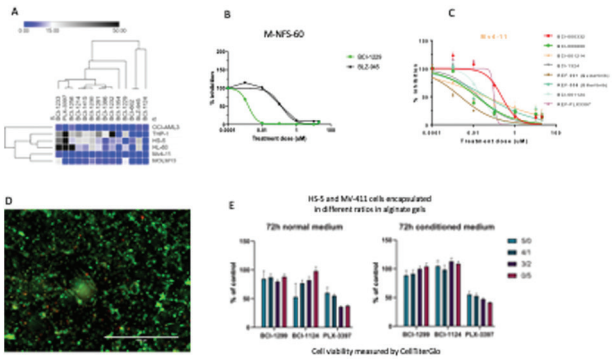
Background: Current cytotoxic treatments for acute myeloid leukemia (AML) eliminate the bulk of proliferating cells, but leave the majority of quiescent leukemic stem cells (LSC) and chemoresistant cells unaffected. The latter, might be able to generate a subpopulation of cells with the same characteristics, promoting chemotherapy resistance. A previous *in silico* study performed in our laboratory identified the prolactin receptor (PRLR) as one of the main pathways implicated in AML progression and the study of its signalling pathways lead us to investigate its role in chemoresistance and AML progression.
Aims: The main objective was the identification of the role of the prolactin (PRL):PRLR axis in the transformation events associated with the initiation and maintenance of AML and its druggable potential.
Methods: The surface expression of PRLR was assessed by flow cytometry. The effect in cell viability of the natural ligand prolactin (hPRL) and its antagonist (hPRL-G129R) was studied by flow cytometry. Experiments using wildtype (PRLRwt) and a dominant negative (PRLRsh) receptor ectopically expressed and an active (PRLwt) and a dominant negative (PRLmut) ligand expressed on AML cells were performed to assess their effect on chemotherapy resistance. Gene expression analyses were done by real time quantitative PCR. To determine the role of PRLR-PRL axis *in vivo,* conditioned NSG mice were transplanted with RLuc-AML cells and mice were treated with hPRL or hPRL-G129R and monitored during the experiment. Next, conditioned NSG mice were transplanted with PRLwt- and PRLmut-transduced AML cells and the engraftment was analysed by flow cytometry.
Results: PRLR surface expression correlated positively with a higher resistance to Cytarabine, but not Azacytidine or Daunorubicine. The same results were observed when PRLRwt isoform was overexpressed. Nevertheless, changes in genes related to Cytarabine resistance were not observed and no differences were observed on PRLR surface expression in refractory vs non-refractory AML primary samples. On the other hand, cells transduced to secrete active PRL did not possess such resistance.
PRLRwt overexpression promoted a higher proliferative rate in comparison to parental and PRLRsh transduced cells. In addition, hPRL treatment, but not hPRL-G129R, induced proliferation only due to ectopic PRLRwt expression. hPRL treatment increased the proliferation of AML cells in comparison to hPRL-G129R treatment *in vivo*. What is more, mice injected with PRLmut transduced cells had a lower engraftment capacity in comparison to PRLwt injected ones *in vivo* and a lower clonogenicity capacity *in vitro*.
Summary/Conclusion: PRLR expression, but not increased levels of its ligand PRL, confers resistance to Cytarabine *in vitro*, but genes implicated in this process were not affected, suggesting that other mechanism should be involved.
PRL-PRLR signalling promotes proliferation signals in AML, both *in vivo* and *in vitro*. An overexpression of PRLR generates a worse AML prognosis due to its effect in proliferation, while antagonizing the receptor decreases proliferation. Interestingly, the inactive form of hPRL confers a lower clonogenicity *in* vitro and engraftment capacity *in vivo*.
In summary, PRLR and PRL have an important role in AML proliferation and prognosis, so targeting PRLR and using inactive forms of its ligand may be a useful treatment against AML.

EP416 MAIT CELLS NUMBERS AND FREQUENCIES IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AT DIAGNOSIS: ASSOCIATION WITH CYTOGENETIC PROFILE AND GENE MUTATIONS.

T. Comont [1,*], M.-L. Nicolau-Travers [2], S. Bertoli [3], C. Recher [3], F. Vergez [2], E. Treiner [4]

[1]Internal Medicine, IUCT Oncopole, [2]Laboratory of Hematology, [3]Hematology, [4]Laboratory of Immunology, Toulouse University Hospital, Toulouse, France

Background: Intensive chemotherapy (iCT) remains the main therapeutic option for a majority of patients with acute myeloid leukemia (AML). However, relapses are frequent and cause a high fatality rate, prompting the need for new therapeutic strategies, as well as a better stratification of patients to guide treatment choice. Multiple ongoing pre-clinical and clinical studies aim at harnessing the immune system against AML. Mucosal-Associated Invariant T cells (MAIT) constitute one of the largest subset of innate-like, cytotoxic T cell subsets in humans. A small but increasing number of papers suggest a role for MAIT cells in cancer but their functionality show different trends according to different studies.
Aims: In this study, we quantified circulating MAIT cells at diagnosis in a prospective cohort of newly diagnosed AML patients. We also monitored MAIT cells during intensive chemotherapy in a subset of these patients.
Methods: This study included patients with a newly diagnosed AML admitted at the Hematology department of Toulouse University Hospital-IUCT-O from 1st January 2015 to 31st October 2019. A written informed consent was obtained from all patients in accordance with the Declaration of Helsinki. All cytometry analyses were performed on fresh whole-blood lymphocytes and data were acquired on the Navios cytometer, and analyzed with the Kaluza software. Statistical analyses were performed with the Graphpad Prism software.
Results: We included 216 patients in this study. We observed a dramatic decrease of MAIT cell, compared to Healthy donors ($p<0.0001$). Whereas the relative proportions of CD4+ and CD8+ T cells were conserved in disease, the frequency of MAIT cells decreased importantly in AML patients ($p<0.0001$). In stark contrast, the percentage of activated MAIT was significantly higher in patients than controls ($p=0.0065$). We evaluated whether MAIT cells dynamics during this induction phase would differ, as compared with conventional CD4+ and CD8+ T cells. In our cohort, 25 patients were monitored at D15 post-induction, at the nadir of circulating lymphocyte numbers. The drop in MAIT cell numbers was more pronounced than for CD4+ ($p<0.0001$) and CD8+ T cells ($p<0.001$). We also obtained samples from 78 patients at D35 post-induction, which is the time point at which remission is evaluated, and leucopoiesis usually resumes. Indeed, at D35, CD4+ and CD8+ concentrations raised back to baseline levels, although CD4+ concentrations remained slightly lower than their D0 levels. MAIT cells showed the same trend, with no significant difference between pre- and post-treatment levels. We could obtain cytogenetic parameters in 207 (90.4%)patients and MAIT cells numbers dropped significantly according to the cytogenetic profile. Finally, we obtained at least partial mutation data for a total of 119/123 patients (96,7%) FLT3-ITD mutation were associated with higher numbers of CD4+, CD8+ and MAIT cells. IDH1/2 mutations were found in 29/118 patients (24.6%), and were associated with higher MAIT cell numbers only.
Summary/Conclusion: In this study we observed a significant MAIT cell deficiency in AML patients, which is differently associated with the cytogenetic and molecular profile of the patients, and the occurrence of complete remission after iCT.



EP417 PRECLINICAL DEVELOPMENT OF NOVEL COMBINED CSF1R/FLT3 INHIBITORS IN ACUTE MYELOID LEUKEMIA

K. Sletta [1,*], B. T. Gjertsen [1], M. Hellesøy [1], D. Surleaux [2], H. Haslene-Hox [3], I. Motzfeldt [1], O. Castells [1], L. Rane [1], M. Sabir [1]

[1]University of Bergen, Bergen, Norway, [2]BCI Pharma, Montpellier, France, [3]SINTEF, Trondheim, Norway

Background: Despite emerging insight into the molecular pathogenesis of acute myeloid leukaemia (AML), few new therapeutic drugs have been approved and overall survival in elderly patients remains poor. Tumor-stromal interactions in AML are important for disease development and therapy resistance, and bone marrow stroma seem like an attractive therapeutic target. Inhibition of colony stimulating factor 1 receptor (CSF1R) is proposed to be an effective target to block

infiltrating monocytes and tumor-associated macrophages that support tumor growth. Our laboratory is currently developing a novel class of small molecule kinase inhibitors towards FLT3 and CSF1R through a collaboration with BCI Pharma to target high-risk mutations. We propose an increased beneficial effect of conventional and novel therapeutics by targeting the supportive microenvironment in addition to direct leukemic cell death. Experimental evidence positioning inhibitors of CSF1R as treatment should, together with data from preclinical and early phase clinical trials, facilitate translation and clinical development of CSF1R-targeted therapy in AML.
Aims: We propose the potential of CSF1R/FLT3-targeted therapy as well as to elucidate the supportive mechanisms of the tumor microenvironment in AML.
Methods: We have established IC-50 values of various CSF1R and FLT3 inhibitors on multiple leukemic and stromal cell lines by high-throughput dose-response WST-1 assay. To further investigate the interactions of leukemic cells with the stromal compartment of the bone marrow in AML, a 3D co-culture model using alginate gel was established. The leukemic cell line MV-4-11, and the stromal cell line HS-5 were incapsulated in different ratios in 5% alginate gel and exposed to a few selected CSF1R and FLT3 inhibitors, as well as stromal-conditioned media. An *in vivo* maximum tolerable dose (MTD) experiment was performed for the selected FLT3 and CSF1R inhibitors. We are currently running an orthotopic MV-4-11 experiment were FLT3 and CSF1R inhibitors are given in sequence and as monotherapies. Malignancy and effect of treatment are assessed through bioluminescent imaging.
Results: Dose-response assays of several CSF1R and FLT3 inhibitors on leukemic and stromal cell lines showed significant inhibition and reduced viability by several compounds (Figure 1A),where the most potent inhibitors were selected for further *in vitro* and *in vivo* experiments. CSF1R inhibitor BCI-1229 is more potent than the commercially available inhibitor BLZ-945 in the CSF1R-dependent cell line M-NFS-60 (Figure 1B). Several FLT3 inhibitors show inhibitory effect on the cell line MV-4-11 that is comparable to commercially available reference compounds (Figure 1C). Further, the co-culture alginate gel is compatible withthe leukemic and stromal cells illustrated by live/dead imaging (Figure 1D). Interestingly, FLT3-inhibitors has significantly reduced effect on leukemic and stromal cells cultured in stromal-conditioned media after 72 hours (Figure 1E).

Summary/Conclusion: In summary, we employ a novel approach to develop combined CSF1R/FLT3 targeted therapy for AML to assess the protective tumor microenvironment and by direct leukemic cell death. Ultimately, our goal is to facilitate translational medicine by performing rigorous preclinical experiments and to select compounds to be tested in a clinical trial setting combined with conventional and other novel therapeutics.

EP418 CHECKPOINT KINASE 1 IS OVEREXPRESSED, BY POST-TRANSCRIPTIONAL REGULATION, IN IMMATURE AND MONOBLASTIC / MONOCYTIC ACUTE MYELOID LEUKEMIA

L. M. Sarmento [1,2,*], S. Gonçalves Pereira [2], F. Costa [2], A. Monteiro [2], J. Caldas [2], P. Ribeiro [2], J. T. Barata [1]

[1]João Barata Laboratory, Instituto de Medicina Molecular João Lobo Antunes, [2]Hematologia Clínica, Hospital Santo. António dos Capuchos, Centro Hospitalar Universitário Lisboa Central, Lisbon, Portugal

Background: Checkpoint kinase 1 (CHK1), encoded by *CHEK1*, supports tumor cell survival by restraining replication stress (RS), either induced, endogenously, by oncogenic transformation or, exogenously, by chemotherapy. CHK1 upregulation in cancer cells has been associated with decreased proteasomal degradation, challenging a direct correlation between CHK1 transcript and protein levels. CHK1 inhibition appears to be an attractive strategy for acute myeloid leukemia (AML) treatment (NCT02649764; NCT03735446). However, CHK1 protein expression in AML patients (pts) remains uncharacterized, precluding the identification of AML subgroups that may benefit the most from CHK1 targeted therapy.
Aims: We sought to measure CHK1 expression and activity in AML and assess whether it associates with specific clinical or biological AML features.
Methods: Bone marrow aspirate and peripheral blood cells from *de novo* diagnosed AML pts (n=29) were processed for RNA and protein extraction. Normal bone marrow (NBM) aspirates (n=8) were used as controls. *CHEK1* transcript was quantified by qRT-PCR. CHK1 protein was quantified by total CHK1 immunoblot and its kinase activity was detected by immunoblotting Serine 296-phosphorylated CHK1. AML pts were then divided according to low or high *CHEK1* mRNA levels, low or high protein expression, or detectable *versus* undetectable CHK1 activity and the various subgroups were tested for differences in the frequency of clinically relevant characteristics.
Results: We found no correlation between *CHEK1* mRNA and CHK1 protein levels or activity in our AML cohort. Furthermore, AML pts expressed similar *CHEK1* transcript levels to those observed in healthy controls. In contrast, CHK1 protein was significantly upregulated in AML when compared to NBM. This led us to hypothesize that CHK1 protein may be biologically and clinically more relevant than the transcript levels in AML. Indeed, there were no significant differences between *CHEK1* mRNA-low and -high pts in any of the features analysed (age, sex, WBC, morphologic classification and ELN genetic risk). In contrast, AML pts with high CHK1 protein were significantly enriched in monocytic/monoblastic morphology (90% of all monocytic AML, n=10), and also included all immature AML cases (n=5). Notably, CHK1-high pts were significantly enriched in ELN intermediate-risk cases. Finally, we observed that constitutive CHK1 activation was associated with hyperleukocytosis, with a 10-fold higher median of WBC at presentation.
Summary/Conclusion: Our data show that CHK1 upregulation takes place during AML development in a post-transcriptional manner. We propose that highly proliferative AML activate CHK1, affording protection against proliferation-associated RS. CHK1 upregulation occurs preferentially in immature and monocytic lineage committed AML, suggesting these subgroups may be optimal candidates for therapeutic intervention with CHK1 inhibitors.

EP419 DEEP HYPOXIA REDUCES SENSITIVITY OF ACUTE MYELOID LEUKEMIA CELL LINES TO THE PAN-AURORA INHIBITOR TOZASERTIB

S. Bruno [1,*], M. Mancini [2], C. Monaldi [1], S. De Santis [1], M. Cavo [1,2], S. Soverini [1]

[1]Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Istituto di Ematologia "Seràgnoli", Bologna, Italy

Background: The pivotal role of hypoxic bone marrow microenvironment (BMM) has been demonstrated in acute myeloid leukemia (AML) development and maintenance, however whether it influences the fitness of leukemic stem cells (LSCs) and their susceptibility to drug treatment still remains to be clarified. Increasing evidences suggest that hypoxic BMM represents a key regulator of transcriptomic and metabolomic profiles of LSCs, influencing their proliferation capacity and leading resistance to chemotherapeutic treatments. Aurora kinases A and B are crucial actors during mitosis and their over-expression has been described in AML, making them a promising therapeutic target. Phase II studies of Aurora kinase inhibitors combined with induction chemotherapy have demonstrated good tolerability and efficacy in patients with high-risk AML (Brunner, Lancet Haematol 2020).
Aims: The present study aim to explore the effects of Aurora kinases inhibitor Tozasertib in AML cell lines cultured either under normoxic or hypoxic conditions.
Methods: AML cell lines (NOMO-1: t(9;11); MOLM-13: FLT3-ITD; MV-4-11: t(4;11), +8, +19; KASUMI-1 t(8;21), c-KIT and p53 mutated)

were treated under either normoxia or hypoxia (1%O_2) with the pan Aurora inhibitor Tozasertib (100 and 2500nM). After 24 and 48h of treatment, Annexin V and PI staining were performed to evaluate the induction of apoptosis and proliferation capacity. Protein level alterations were analyzed by Western blotting (WB).
Results: Tozasertib strongly inhibited growth and proliferation in AML models, but it was less effective in a low oxygen environment. In particular, all tested AML cell lines showed increased cell death in a dose-dependent manner, however under hypoxic conditions the apoptotic cell death was significantly reduced compared to the normoxic counterpart (AnnexinV$^+$ cells were 32-60% under hypoxia *vs* 47-70% under normoxia after 48h treatment; $p<0.05$). Of note, inhibition of Aurora kinases induced mitotic arrest; therefore, we evaluated the effect of tozasertib on cellular proliferation demonstrating a reduced ability of the drug to induce the accumulation of cells in G2/M phase under hypoxic culture conditions. The reduced anti-leukemic activity of tozasertib in hypoxic AML cell lines was confirmed also at the protein level. WB analysis demonstrated that inhibition of Aurora kinases was associated with activation of the *TP53* pathway, inducing the expression of p-p53(ser15), p21 and γH2AX as well as the cleavage of CASPASE 3 and PARP in all tested cell lines. However, the upregulation of the above proteins was less pronounced under hypoxic conditions. Interestingly, the drug treatment correlated, in an O_2 independent manner, with a strong increase of trimethylation levels at lysine 36 of histone H3 (H3K36me3), that is involved in regulation of the DNA damage response (DDR) network.
Summary/Conclusion: Cytostatic and cytotoxic effects after treatment with Tozasertib were observed in MLL-AF9 translocated, FLT3-ITD, and both *wt* and mutant TP53 AML models, which represent an important goal in AML therapy. Nevertheless, the hypoxic microenvironment strongly influenced the efficacy of Aurora kinase inhibition in AML cell lines, highlighting the crucial role of environment in AML treatment. In conclusion, our study confirmed the pivotal role of low oxygen environment in regulating cellular response to Aurora kinase inhibition and sets the *rationale* for further investigations aimed to identify new combination therapies against AML LSCs.
This study was supported in part by AILBologna.

EP420 METABOLIC PECULIARITY OF PML/RARA EXPRESSING CELLS AND ARSENIC TRIOXIDE RESISTANCE

N. Noguera [1,*], C. Banella [2], G. Catalano [3], E. Ammatuna [4], E. Pelosi [5], I. Faraoni [6], M. Divona [7], T. Ottone [6], S. Lavorgna [6], U. Testa [8], W. Arcese [6], M. T. Voso [6]

[1]Biomedicine and Prevenzione, [2]Santa Lucia Foundation, Tor Vergata University, Roma, [3]Biomedicine and Prevenzione, Tor Vergata University, Italy, Italy, [4]Hematology, University Medical Centre Groningen, Goningen, Netherlands, [5]Oncologia e Medicina Molecolare, Instituo Superiore di Sanità, [6]tor vergata University, [7]Policlinico Tor Vergata, Rome, [8]Instituto Superiore di Sanità, Roma, Italy

Background: Central in the pathogenesis of APL, the PML/RARa fusion protein rewires metabolic pathways to feed anabolic cell growth. ATRA and ATO-based therapies render APL the most curable subtype of AML, yet approximately 5% of cases are resistant and 5 to 10% relapse.
Aims: To characterize the metabolic peculiarity and the energy requirements of PML-RARa expressing cells, to identify new therapeutic targets and strategies.
Methods: we analyzed primary samples from 5 APL with PMLRARa, normal CD34+ cells differentiated to promyelocytes and granulocyte, the U937-PR9 (PML-RARa inducible system), the NB4 APL cell line, and two NB4-ATO-resistant clones. We measured cell's metabolism using a Seahorse Bioscience XFe96 analyzer, the rate of oxidation of each fuel was measured by means of mitochondrial respiration using the XF Mito Fuel Flex Test. We assessed expression of carnitine transporter CT2 (SLC22A16), PRDX, p-AMPK, MCL-1 and Glut 1 by western blot; *SLC22A16* by q-RTPCR; cellular viability by ATP Glow Assay and ROS by mytosox assay.
Results: APL samples showed reduced respiratory and glycolytic capacity compared with normal promyelocytes (Fig. 1a). Expression of PML-RARa in U937-PR9 cell lines increases mitochondrial respiration rate (OXPHOS) and inhibits glycolysis. We evaluated dependency (cells' reliance on a particular fuel source), flexibility (difference between fuel capacity and dependency, the oxidation of an alternative fuel) and capacity (the ability of a cell's mitochondria to oxidize a fuel when other fuel pathways are inhibited). Primary APL blast cells depends mainly on fatty acids (FA), (FA: 63±20 % vs glucose: 5 ± 7 % and glutamine: 5 ± 7 %) ($p<0.0005$); they display a great flexibility, switching to glucose, glutamine or FAO to meet their energetic need (FA: 35±21 % vs glucose: 51± 30 % and glutamine: 36 ± 17 %) (Fig. 1b), consistent with the high adaptability of APL cells. Normal promyelocytes depend on FA and glucose for mitochondrial respiration, conversely APL blasts show enhanced FAO, increase in the carnitine transporter CT2, and lose pyruvate dependence, featuring flexibility for glucose utilization, and high lactate production when mitochondrial respiration is inhibited (Fig. 1c). The enhanced FAO and CT2 over-expression observed in APL blast was confirmed in the PR9 system after PML/RARa induction. ATO resistance involves a switch towards glycolysis, reduced viability at low glucose cc (p= 0.0008) and 1.5 times increase of the glucose transporter Glut1, increase in glycolytic and in mitochondrial ATP production; an increase in FAO confirmed by a higher sensitivity to Perexilin, inhibitor of CPTA1 (p=0.003), and a 1.7 fold increase in the expression of CT2. One clone shows also high level of ROS (p=0.0001), the cellular integrity is protected by increased levels of Periredoxin in both, and a 1.5 fold increase in pAMPK that induces FAO and glycolysis. The apoptosis escape in ATO resistant cells has been related to a concomitant increase (1.7 folds) in the expression of Mcl1.

Figure 1

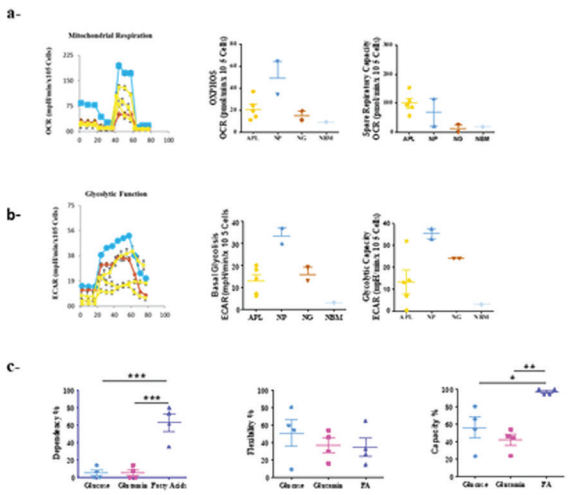


Figure 1 a) Mitochondrial respiration measured by Seahorse assay in normal promyelocyte (NP), Normal granulocyte (NG) and APL primary blasts b) Glycolytic respiration measured by Seahorse assay in NP, NG and APL primary blasts c) Evaluation of the mitochondrial fuel used by primary blast obtained from APL patients using the XF Myto Fuel Flex Test. The graphs shown dependency, capacity, and flexibility of the cells to oxidize three mitochondrial fuels: glucose (pyruvate), glutamine (glutamate) and long-chain fatty acids.

Summary/Conclusion: FA is the principal fuel used by APL blasts and PML/RARa induces FAO. Metabolic shift from respiration to glycolysis and FAO in NB4-ATO resistant cells is mediated by pAMPK, the increase of glycolytic flux contributes to NADPH production and cell survival under oxidative stress. The increase in Mcl1 contributes to apoptotic resistance. ATO resistant patients could benefit from treatment with ATO in combination with glycolysis' and FAO inhibitors.

EP421 ZINC IN THE MODULATION OF THE DNA DAMAGE RESPONSE – PREVENTIVE, GENOTOXIC AND CYTOTOXIC ROLES IN ACUTE MYELOID LEUKEMIA

I. Costa [1], N. Magalhães [1,2], D. Roque [1,2], E. Gomes [1], R. Alves [1,3,4,5], J. Jorge [1,3,4,5], B. Lapa [1,3], J. M. Nascimento Costa [1,3,4,5,6], A. B. Sarmento-Ribeiro [1,3,4,5,7,*], A. C. Gonçalves [1,3,4,5]

University of Coimbra, [7]Clinical Haematology Department, Centro Hospitalar e Universitário de Coimbra (CHUC), Coimbra, Portugal

Background: Genome integrity is maintained by the DNA damage response (DDR). DDR defects are described to contribute to leukemogenesis, namely to Acute myeloid leukemia (AML) development and progression. Micronutrients are DDR cofactors, critical for optimal DDR functioning. Zinc (Zn) is particularly relevant in apoptosis, cell cycle and DNA repair. AML patients commonly present decreased serum Zn levels, but its biological significance and impact in the DDR is not understood.
Aims: We explored the role of Zn in DDR modulation in AML cells and its therapeutic potential in combination with conventional chemotherapy and with a DDR inhibitor.
Methods: The AML cell line HEL was incubated for 15 days in three culture conditions: standard Zn concentration (Std), Zn depletion (ZnD) and supplementation with 40µM of $ZnSO_4$ (ZnS). After 2, 7 and 15 days, cells were exposed to genotoxic stimuli: 10µM of H_2O_2 for 30 minutes or 1 minute of UV radiation (E_e=2.9841 $W.cm^{-2}$). Chromosomal damage, cell death and division rates were studied by cytokinesis-block micronucleus assay. To monitor repair kinetics, levels of γH2AX were evaluated 0h, 1h and 24h after exposure. Expression of 14 DDR genes (*PARP1*, *XRCC1*, *MSH2*, *MSH6*, *MLH1*, *XPA*, *ERCC1, RAD23B*, *RAD51, PRKDC*, *XRCC6*, *PALB2*, *FANCD2*, and *MGMT*) was analysed by qRT-PCR. An immortalized cell line of normal lymphocytes (IMC) was submitted to the same experiments. Lastly, HEL cells were incubated with the DDR inhibitor olaparib and the chemotherapeutic compound cytarabine in monotherapy and combination with 40µM of $ZnSO_4$. Cell viability was analysed by trypan blue assay and cell death by annexin V/7-AAD staining by flow cytometry. Data was analysed considering a confidence level of 95% ($p<0.05$).
Results: ZnS lymphocytes displayed lower basal damage than those in Std conditions. Lymphocytes in ZnD shown increased damage biomarkers through time (1.3-fold, p=0.0234). Cell death was lower in ZnS lymphocytes and division rates slightly increased, whereas in ZnD an increase in cell death and lowered division rates were observed. Oppositely, in AML cells, basal damage through time of Zn supplementation increased (1.2-fold, p=0.0470), cell death slightly increased and division rates decreased (1.1-fold, p=0.0117). After genotoxic stimuli, ZnS lymphocytes shown less damage levels, particularly after 7 and 15 days of supplementation. ZnD lymphocytes presented more damage biomarkers. AML cells cultured in ZnS had considerably higher damage levels after exposure than in Std conditions and the lowest damage scores were found in ZnD. γH2AX monitorization shown a repair response in ZnS lymphocytes that was not achieved in Zn absence. In AML cells, γH2AX activation persisted 24h after exposure, but ZnD cells shown a more evident repair kinetics. No significant differences were observed in DDR genes expression among all conditions. Olaparib and cytarabine reduced cell proliferation and viability in a dose and time-dependent manner, inducing cell death by apoptosis. Further, $ZnSO_4$ improved cytotoxic effects as a marked decrease of the IC_{50} of each compound comparatively to monotherapy was observed (2.8-fold and 5.4-fold, respectively).
Summary/Conclusion: ZnS improved the DDR in normal cells while ZnD favoured genomic instability, confirming the importance of Zn in genome integrity. In AML cells, Zn increased the genotoxicity of H_2O_2 and UV radiation and the therapeutic effects of olaparib and cytarabine. These results suggest that Zn supplementation is a potential co-adjuvant strategy improving genotoxic or DDR-targeting therapies in AML.

EP422 LINKING CDK6 TO THE EPIGENOME

B. Schmalzbauer [1], S. Nebenführ [1], G. Heller [2], V. Sexl [1], K. Kollmann [1,*]

[1]University of Veterinary Medicine, Vienna, [2]Medical University of Vienna, Vienna, Austria

Background: Cyclin-dependent kinase (CDK) 4 and CDK6 are key players mediating G1 progression. In addition, CDK6 - but not CDK4 - has been implicated in gene transcription. High CDK6 levels are frequently observed in human malignancies and CDK4/6 inhibitors show promising efficacy against different types of tumors, including hematopoietic malignancies. One hallmark of leukemia is aberrant DNA methylation patterns. The molecular mechanisms underlying these aberrant genomic methylation patterns are poorly understood. We here provide evidence for a role of CDK6 in epigenetic alterations in leukemia.
Aims: We aim at understanding how CDK6 interferes with the epigenetic landscape and which leukemic subtypes will have an advantage from combinatorial drug treatment with CDK6 inhibitors and drugs interfering with epigenetic players.
Methods: To study the interplay between CDK6 and the epigenome, we use a murine Bcr/Abl p185 ALL model and murine hematopoietic progenitor cells (HPC^{LSK}) transformed with different AML oncogenes generated from wildtype and Cdk6 knockout mice and/or treated with CDK4/6 inhibitors. We performed RNA-Seq, Chip-Seq, Phosphoproteomics and RRBS as well as in vitro assays to investigate proliferation, apoptosis and differentiation.
Results: CDK6 activity is associated with specific changes in CpG methylation. ChIP-seq revealed that CDK6 binds to genomic regions of DNMTs. Phosphoproteomic studies and RNA-Seq analysis uncover the regulation of several epigenetic factors by CDK6 at different levels. RNA-seq data from human ALL and AML samples assessed the correlation between CDK6 and DNMT expression. Reduced representation bisulfite sequencing analysis uncovers reversible and cell line-specific changes in DNA methylation patterns upon CDK6 loss. As a consequence, CDK6 interferes with the response to epigenetic agents.
Summary/Conclusion: We show that CDK6 affects the methylation pattern by altered expression and phosphorylation of several epigenetic modifiers, such as DNMTs and EZH2, in leukemia and therefore enhances the sensitivity towards specific epigenetic agents.

EP423 GENOMIC LANDSCAPE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA OLDER THAN 70 YEARS

F. G. Rücker [1,*], M. Hoyos [2], A. Dolnik [3], T. J. Luck [1], S. Skambraks [1], Z. Xia [1], V. I. Gaidzik [1], E. Panina [1], J. K. Herzig [1], D. Weber [1], M.-A. Wattad [4], G. Held [5], H. A. Horst [6], F. Thol [7], M. Heuser [7], A. Ganser [7], J. Sierra [2], H. Döhner [1], K. Döhner [1], L. Bullinger [3,8]

Background: Acute myeloid leukemia (AML) is mainly a disease of older patients (pts) with median age of 70 years (yrs) at diagnosis. Age and age-related unfavorable prognostic factors, like adverse genetic changes, impact management and outcome. While large cohorts of younger AML have been extensively studied at the molecular level, genomic aberrations underlying elderly AML have by far been less well characterized.
Aims: To evaluate the mutational landscape of 294 elderly AML (median age 76 yrs; range, 70-90 yrs) entered into the AMLSG BiO Registry (NCT01252485). Primary treatment was intensive chemotherapy (IC, n=33), hypomethylating agents (HMA, n=164) or best supportive care (BSC, n=97).
Methods: Custom Haloplex HS target enrichment system (Agilent) for resequencing of the entire coding regions of 94 myeloid disease related genes (Illumina MiSeq).
Results: Based on an average gene coverage of 300x(fold) for consensus reads and a defined variant allele frequency (VAF) ≥5%, we identified 1095 mutations (mut) in 83 genes in 286 of the 294 pts with a median of 4 mut/pt (range 0-9). The vast majority were missense mut (n=743, 67.9%) followed by indels (n=214, 19.5%), nonsense (n=112, 10.2%) and splice site mut (n=26, 2.4%). Within our cohort of older pts most frequently mutated genes were *TET2* (23.2%), *TP53* (22.8%), *FLT3* (ITD and TKD, 24.5%), *SRSF2* (22.8%), *DNMT3A* (21.8%), *RUNX1* (18.0%), *NRAS* (13.3%), *NPM1* (12.6%), *IDH2* (10.5%), *ASXL1* (9.5%), *SF3B1* (8.5%) and *U2AF1* (7.8%). Observing a broad variance for VAF most pts displayed a dominant clone with a VAF in ~50% range. For mut affecting the functional gene classes methylation, chromatin-spliceosome, signaling, transcription, tumor suppressors, and others, VAF differed significantly ($P<.001$).
According to ELN 2017 risk classification 34 (12.2%) had favorable, 76 (27.3%) intermediate and 168 (60.4%) adverse risk. Risk groups did not correlate with age, categorized as 70-74 yrs, 75-80 yrs, and

≥80 yrs, but with functional classes. Within the favorable, intermediate and adverse risk groups 68%, 67% and 49% of pts (*P*=.002) had methylation mut and 74%, 57%, and 68% (*P*=.002) signaling mut, respectively. Methylation mut were correlated with higher white blood cell counts (*P*<.001), lactate dehydrogenase, and bone marrow blasts (*P*=.002 each).
Genomic classification based on cytogenetics and patterns of comutations (Papaemmanuil et al, NEJM 2016) revealed chromatin-spliceosome (n=101), *TP53*-aneuploidy (n=86), not classifiable (n=36), *NPM1* (n=33), other classes (n=17), and no class (n=21).
Median follow-up was 3.1 years (95% CI: 2.1-4.1). Due to the different treatment regimens, outcome analyses were restricted to overall survival (OS). Median OS was 0.5 years (0.3-0.7 yrs) with no difference for ELN risk groups (*P*=.302). According to treatment median OS was 0.97 yrs for IC, 0.76 yrs for HMA and 0.15 yrs for BSC (*P*<.001) with no significant difference between IC and HMA (*P*=.475). The general beneficial effect for HMA compared to BSC, decreased with age (70-74 yrs, *P*<.001; 75-80 yrs, *P*=.029; ≥80 yrs, *P*=.889). The *TP53*-aneuploidy group had the worst and the spliceosome group the best OS (*P*=.046). A significant benefit for HMA compared to BSC was seen for the *TP53*-aneuploidy group (*P*<.001), but not the spliceosome group (*P*=.394).
Summary/Conclusion: The mutational landscapes of elderly AML differs significantly from that of younger AML. Adapting genomic classification of younger AML, distinct subgroups of prognostic relevance were also observed in elderly AML.
FGR and MH, KD and LB contributed equally.

EP424 MELFLUFEN DEMONSTRATES HIGH EFFICACY IN CYTARABINE AND VENETOCLAX RESISTANT AML MODELS

J. Miettinen [1], P. Sergeev [1], N. N. Nupponen [2], V. Rrakli [2], K. Byrgazov [2], M.-E. Huppunen [1], F. Lehmann [2], A. Slipicevic [2,*], C. A. Heckman [1]

[1]Institute for Molecular Medicine Finland - FIMM, HiLIFE – Helsinki Institute of Life Science, iCAN Digital Precision Cancer Medicine Flagship, University of Helsinki, Helsinki, Finland, [2]Oncopeptides AB, Stockholm, Sweden

Background: Acute myeloid leukemia (AML) is an aggressive hematologic malignancy characterized by the accumulation of immature myeloid cells resulting in hematopoietic insufficiency such as cytopenia or anemia. SOC consists of cytarabine (ara-C) and anthracyclines or combinations of hypomethylating agents or low dose ara-C with BCL-2 protein inhibitor venetoclax. These strategies provide high initial response rates, yet only a fraction of patients achieve cure. Up-front resistance as well as relapse following initial therapy underlines the need for novel therapeutic approaches. Melphalan flufenamide (melflufen) is a first-in-class peptide-drug conjugate that leverages aminopeptidases and thereby rapidly delivers and releases alkylating agents in tumor cells. Increased expression of aminopeptidase N (ANPEP) has been associated with the malignant AML phenotype and is detected on stem cells and leukemic blasts. APN has been shown to hydrolyze melflufen providing a rational to evaluate melflufen efficacy in the relapsed/refractory (RR) AML setting.
Aims: To investigate the therapeutic potential of melflufen in cytarabine and venetoclax resistant AML cell lines *in vitro* and *in vivo* as well as in cells from relapsed AML patients ex vivo. A secondary aim was to investigate the expression profile of aminopeptidases and their relation to clinical parameters in AML patients.
Methods: The parental AML cell line MV4-11 and its venetoclax (MV4-11_VXR) and ara-C (MV4-11_aCR) resistant sublines were obtained from the RCCI collection of the University of Kent. *In vitro* drug toxicity was assessed using the CellTiter-Glo (CTG) viability assay. The expression of aminopeptidase was analyzed on previously sequenced/published AML samples. *In vivo* assessment of melflufen efficacy using chicken embryo chorioallantoic membrane (CAM) assay and *ex vivo* drug sensitivity assessment of melflufen in AML patient samples using high throughput multi-color flow cytometry are ongoing.
Results: Expression analysis of aminopeptidase in AML patient samples showed that multiple aminopeptidases, previously shown to hydrolyze melflufen including DPP7, LTA4H, RNPEP, ANPEP, are abundantly expressed in AML. *In vitro* drug efficacy evaluation showed that in parental MV4-11 cells 72h melflufen treatment results in high cell viability reduction similar to venetoclax (IC50 range 2-10 nM), while somewhat lower efficacy is seen for ara-C (IC50 400nM). Interestingly, MV4-11_VXR also displayed increased resistance to ara-C (IC50 2.5µM) indicating overlapping resistance mechanisms for the two drugs. Importantly, in both MV4-11_VXR and MV4-11_aCR sublines melflufen efficacy was retained, suggesting that melflufen could target both resistant cell populations.
Summary/Conclusion: In summary, melflufen demonstrates high efficacy in venetoclax and ara-C resistant AML models *in vitro*. In addition, abundant expression of aminopeptidases in the AML patient samples provides rational for further clinical evaluation of melflufen in the RR AML setting.

EP425 ASSOCIATION OF ATG10 FUNCTIONAL GENETIC VARIANTS IN ACUTE MYELOID LEUKEMIA

A. Areias [1,*], I. Castro [1], B. Sampaio-Marques [1], H. Sousa [2], Â. Fernandes [3], J. M. Sanchez-Maldonado [4], C. Cunha [1], A. Carvalho [5], J. Sainz [4], P. Ludovico [1]

[1]Life and Health Sciences Research Institute (ICVS), University of Minho, Braga, [2]Virology Service and Molecular Oncology and Viral Pathology Group (CI-IPOP), Portuguese Oncology Institute of Porto, [3]Institute for Research and Innovation in Health (i3S), University of Porto, Porto, Portugal, [4]Genomic Oncology Area, GENYO. Centre for Genomics and Oncological Research: Pfizer, University of Granada, Granada, Spain, [5]Institute for Research and Innovation in Health (i3S), University of Minho, Braga, Portugal

Background: Acute myeloid leukemia (AML) is the most common type of acute leukemia with higher incidence among the elderly population. Furthermore, individuals with genetic predisposition, previous cancer and with an age-related genetic condition, named Clonal Hematopoiesis of Indeterminate Potential (CHIP) are also at a higher risk of developing AML. Thus, finding new tools for monitoring these risk groups would be of great interest for the field. AML is characterized by altered autophagy, a vital mechanism to remove and recycle unnecessary or dysfunctional cellular components. *ATG10* is one of the autophagy core genes, involved in the autophagosome formation, a crucial step in the autophagy process.
Aims: We hypothesize that single nucleotide polymorphisms (SNPs) located in regulatory regions of the *ATG10* gene might contribute to the development of this hematological neoplasm. In this study, we examined the association of three potentially functional genetic polymorphisms in the *ATG10* gene: rs1864182T>G, rs1864183C>T and rs3734114T>C, with AML.
Methods: A multicenter cohort involving 309 AML patients and 356 healthy subjects for three *ATG10* SNPs were screened. The allele frequencies and their association to AML were obtained for the dominant and recessive models adjusted for age and gender. For the three SNPs the Hardy-Weinberg equilibrium was verified. The functional consequences of the *ATG10* SNPs in its canonical function were investigated in vitro using peripheral blood mononuclear cells (PBMCs) from a cohort of 46 healthy individuals. Autophagy flux for the most interesting SNPs was performed using gold standard protocols. Informed consent was obtained from all subjects involved in the study.
Results: Logistic regression analysis adjusted for age and gender revealed that patients carrying the $ATG10_{rs1864182G}$ allele showed a significantly decreased risk of developing AML under the dominant model (OR[odds ratio]=0.58, p=0.006), whereas patients carrying the homozygous $ATG10_{rs3734114C}$ allele had a significantly increased risk of AML in the recessive model (OR=of 2.70, p=0.024). We did not find any association between $ATG10_{rs18641823}$ with AML. Functional analysis showed that individuals carrying the $ATG10_{rs1864182G}$ allele had both decreased levels of ATG10 protein, as well as autophagy flux when compared to homozygous major allele carriers. In particularly, we found a reduced degradation step in the autophagy process when compared with the homozygous major allele group. The correlation between the $ATG10_{rs3734114}$ SNP and autophagy flux could not be determined due to the low proportion of subjects carrying the homozygous $ATG10_{rs3734114C/C}$ in the healthy cohort, which in agreement with the observed frequency in the European population.
Summary/Conclusion: Our results indicate that *ATG10* genetic variants show potential clinical implications in AML. Elderly and patients at higher risk could be screened for $ATG10_{rs3734114}$ to define further monitoring, while our results regarding $ATG10_{rs1864182}$ suggest a new target that is worth to be further explored in the context of AML.

Sanitarias (Madrid, Spain), grant number ISCIII-FEDER PI20/01845, ISCIII-FEDER PI12/02688, and ISCIII-FEDER PI17/02276.

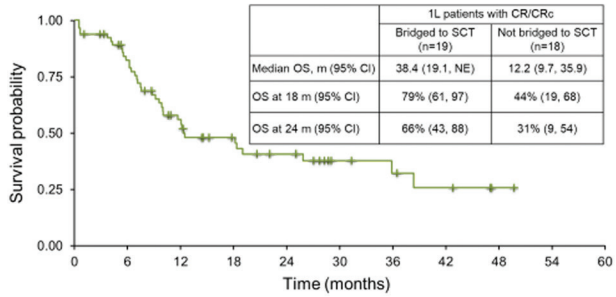
EP426 IL-3 RESCUES MUTANT FLT3 AND KIT-POSITIVE AML CELLS FROM TARGETED THERAPY

E. Vagapova [1,*], T. Lebedev [1], P. Spirin [1], V. Prassolov [1]

[1]*Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, Moscow, Russian Federation*

Background: Receptor tyrosine kinases *FLT3* and *KIT* are mutated in up to 40% of AML patients. Mutant receptor tyrosine kinases (RTK) are promising targets for cancer treatment. Especially, selective FLT3 inhibitors (quizartinib, sorafenib, midostaurin, etc) show significant clinical activity in AML patients. However, relapses associated with the acquired drug resistance by leukemia cells remain major limitation of the monotherapy with RTK inhibitors.
Aims: We aimed at identifying cytokines and growth factors mediating response of leukemia cells to RTK inhibitors to better understand the mechanisms of therapy escape by leukemia cells.
Methods: We used a panel of human leukemia cells lines - Kasumi-1, MV4;11, HL-60, Kg1a, THP-1 and stroma-derived cell line - HS-5. qPCR was used to measure cytokine and growth-factor receptors expression at the mRNA level in cells treated with inhibitors. Confocal microscopy and flow cytometry were applied to detect KIT, FLT3, TrkA and IL3-R proteins at the protein level. By the lentiviral transduction we obtained cells with the overexpression of mutant KIT (N822K) and FLT3-iTD based on the murine cytokine-dependent cell line FDC-P1. We also established ERK-KTR reporter cell lines based on the HS-5 and THP-1 cells to study MAPK activity in living stroma and macrophages at the single-cell level when co-cultivated with leukemia cells. THP-1 cells were differentiated into macrophages with phorbol 12-myristate 13-acetate.
Results: Up-regulation of IL-3R and NTRK1 (encoding TrkA) in response to RTK targeted therapy was a unique feature of AML cells with mutant RTK - FLT3 and KIT. Recombinant IL-3 rescued Kasumi-1 and MV4;11 cells from KIT and FLT3 inhibition, respectively, and this effect was enhanced by NGF (ligand of TrkA). Overexpression of mutant *KIT* in IL-3-dependent FDC-P1 resulted in the up-regulation of *IL-3R*, that points to the direct link between mutant RTKs and IL-3R at the transcription level. Combination of RTK inhibitors with SRC (bosutnib and bafetinib) and JAK2 (ruxolitinib), but not MAPK targeting drugs, abrogated IL-3 rescue-effect on AML cells. Moreover, SRC and JAK2 inhibition sensitized Kasumi-1 and MV4;11 cells to several RTK inhibitors. Notably, the toxic effect of RTK inhibition with respect to leukemia cells was attenuated in the presence of HS-5 or THP-1 cells. RTK and downstream kinase inhibitors differently changed ERK activity in stroma cells and model macrophages in the presence or abscence of leukemia cells. Thus, dual targeting of RTK and SRC or JAK2 is promising for the effective suppression of leukemia cells proliferation via abrogation of cytokine-mediated death-escape by leukemia cells.
Summary/Conclusion: IL-3 and NGF play a vital role in the development of therapy-resistant AML cells with mutant RTKs. Studies with patient-derived xenotransplantation models are needed to clarify the findings. All in all, our study provides a rational for the use of RTK inhibitors in combination with agents blocking compensatory cytokine and growth factor signaling.

Acute myeloid leukemia - Clinical



EP427 TAGRAXOFUSP IN PATIENTS WITH BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM: LONG-TERM RESULTS FROM A PIVOTAL TRIAL

N. Pemmaraju [1,*], A. Lane [2], K. Sweet [3], A. Stein [4], S. Vasu [5], D. Rizzieri [6], E. Wang [7], N. Habboubi [8], C. Brooks [8], H. Kantarjian [1], T. Mughal [8,9], M. Konopleva [1]

Lee Moffitt Cancer Center, Tampa, FL,* [4]*City of Hope National Medical Center, Duarte, CA,* [5]*The Ohio State University, Columbus, OH,* [6]*Duke University Medical Center, Durham, NC,* [7]*Roswell Park Comprehensive Cancer Center, Buffalo, NY,* [8]*Stemline Therapeutics, New York, NY,* [9]*Tufts University Medical School, Boston, MA, United States*

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare and aggressive hematologic malignancy. CD123, the interleukin-3 (IL3) receptor alpha subunit, is overexpressed in BPDCN cells, making it an attractive therapeutic target. Tagraxofusp (TAG, SL-401) is a CD123-directed immunotherapy consisting of recombinant human IL3 and a truncated diphtheria toxin. TAG was FDA approved in 2018 for BPDCN treatment in adult and pediatric (≥2 y) patients (pts) and was recently approved in the EU as monotherapy for first line (1L) treatment in adults. Herein, we show long-term follow-up results from the largest prospective trial (NCT02113982) in pts with BPDCN.
Aims: To study the long-term safety and efficacy of TAG in pts with BPDCN.
Methods: This multicenter, open-label, phase 1/2 study consisted of Stages 1–4 (dose escalation, expansion, confirmatory, and continued access, respectively). Pts received TAG by IV infusion once daily on d 1–5 of a 21-d cycle; the dose was 7 or 12 mcg/kg in Stage 1 and 12 mcg/kg in Stages 2–4. The primary outcome was complete response (CR, defined as CR + clinical CR [CRc, CR with residual skin abnormality not indicative of active disease]). Pts with CR/CRc undergoing allogeneic (allo)/autologous (auto) stem cell transplantation (SCT) discontinued TAG treatment; pts with CR/CRc not undergoing SCT and the remaining pts received TAG until disease progression/unacceptable toxicity. Long-term data were analyzed in all pts for safety and in 1L pts for efficacy.
Results: Of the 89 pts with BPDCN enrolled and treated (3 with TAG 7 mcg/kg and 86 with TAG 12 mcg/kg) over a 4-y period, 65 1L pts who received TAG monotherapy at a 12-mcg/kg dose were assessed for efficacy. The median age of 1L pts was 68 y (range: 22–84) and 80% were male. At study completion in March 2020 (cutoff date), the median follow-up was 34 m. Most common treatment-emergent adverse events (TEAEs; in >40% of pts [N=89]) were increased alanine (64%) or aspartate (60%) aminotransferase, hypoalbuminemia (51%), fatigue (44%), pyrexia (44%), thrombocytopenia (43%), nausea (42%), and peripheral edema (42%). Most TEAEs occurred during cycle 1; 19 (21%) pts had capillary leak syndrome (CLS; grade 2 in 12 [14%], grade 3 in 2 [2%], grade 4 in 2 [2%], grade 5 in 3 [3%]). All but 1 CLS events occurred in cycle 1; the median time (range) to CLS onset from therapy start was 6 d (3–51) and to CLS resolution was 5 d (2–69). CLS was managed by albumin supplementation, diuretics, and steroids, per recommended guidelines. For 1L pts, overall response rate was 75% (49/65) and 37/65 (57%) achieved CR/CRc, with a median time to CR/CRc of 39.0 d. Pts with CR/CRc received a median 4 TAG cycles (range: 1–76) and the median duration of CR/CRc was 24.9 m (95% CI: 3.8, not estimable; range: 1.0–57.4). Nineteen (51%) pts with CR/CRc bridged to SCT (13 allo, 6 auto) after a median time on study of 81 d (range: 27–182). The 18-m survival probability for 1L pts was 50% (95% CI: 36.7, 61.4) and median overall survival was 15.8 m (Figure).

Figure

1L, first-line; CR, complete response; CRc, clinical CR; NE, non-estimable; OS, overall survival; SCT, stem cell transplantation.

Summary/Conclusion: In 1L pts with BPDCN, TAG monotherapy led to high response rates with durable responses. Overall, TAG therapy had a well-characterized and manageable safety profile. CLS management guidelines were developed and implemented during the trial. The high CR rate allowed pts to receive a median 4 cycles of TAG and 51% of responders were bridged to SCT. TAG is the first CD123-targeted therapy and first approved treatment for BPDCN in the US and EU. It is under investigation in other CD123-expressing hematologic malignancies.

EP428 PROGNOSTIC FACTORS OF OVERALL AND RELAPSE-FREE SURVIVAL FOR PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) IN REMISSION: MULTIVARIATE ANALYSES FROM THE QUAZAR AML-001 TRIAL OF ORAL AZACITIDINE (ORAL-AZA)

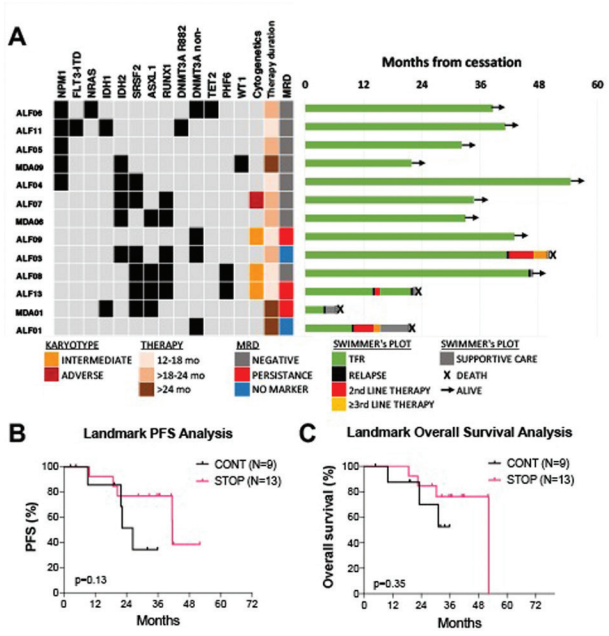
G. Roboz [1,2,*], A. Wei [3,4], F. Ravandi [5], C. Pocock [6], P. Montesinos [7], H. Dombret [8,9], K. Porkka [10], I. La Torre [11], B. Skikne [12,13], J. Zhong [13], C. Beach [13], H. Döhner [14]

[1]Weill Cornell Medicine, [2]New York Presbyterian Hospital, New York, United States, [3]The Alfred Hospital, [4]Monash University, Melbourne, Australia, [5]The University of Texas MD Anderson Cancer Center, Houston, United States, [6]Kent & Canterbury Hospital, Canterbury, United Kingdom, [7]Hospital Universitari i Politècnic La Fe, Valencia, Spain, [8]Hôpital Saint-Louis, Assistance Publique – Hôpitaux de Paris (AP-HP), [9]Institut de Recherche Saint-Louis, Université de Paris, Paris, France, [10]HUS Comprehensive Cancer Center, Hematology Research Unit Helsinki and iCAN Digital Precision Cancer Center Medicine Flagship, University of Helsinki, Helsinki, Finland, [11]Celgene, a Bristol-Myers Squibb Company, Boudry, Switzerland, [12]University of Kansas Medical Center, Kansas City, [13]Bristol Myers Squibb, Princeton, United States, [14]Universitätsklinikum Ulm, Ulm, Germany

Background: Demographic and disease factors influence survival outcomes for patients (pts) with AML. In the phase 3 QUAZAR AML-001 trial, Oral-AZA significantly prolonged overall (OS) and relapse-free (RFS) *vs*. placebo (PBO) for pts with AML in first remission after intensive chemotherapy (IC) (Wei, *NEJM*, 2020). Univariate analyses showed OS and RFS benefits with Oral-AZA *vs*. PBO across pt subgroups defined by baseline characteristics.
Aims: Multivariate analyses were performed to identify baseline characteristics independently predictive of OS and RFS in the QUAZAR AML-001 trial, and to assess Tx effects of Oral-AZA *vs*. PBO on OS and RFS when adjusted for baseline factors.
Methods: Pts were aged ≥ 55 yrs with AML in complete remission (CR) or CR with incomplete blood count recovery (CRi) after induction ± consolidation. Within 4 months of attaining CR/CRi, pts were randomized 1:1 to receive Oral-AZA 300 mg or PBO for 14d of repeated 28d cycles. Cox proportional hazards models were used to estimate the Tx effects of Oral-AZA *vs*. PBO on OS and RFS, adjusting for baseline age, sex, ECOG PS score, cytogenetic risk at diagnosis, prior myelodysplastic syndrome (MDS), geographic region, response after induction (CR or CRi per investigator) and at baseline (per sponsor), measurable residual disease (MRD) status, receipt of consolidation therapy, number of consolidation cycles, baseline platelet count, and baseline ANC. In a stepwise procedure, randomized Tx and baseline variables were selected incrementally into a Cox model if $P \leq 0.25$. After each addition, the contribution of the covariate, adjusted for other covariates in the model, was evaluated and retained in the model if $P \leq 0.15$.
Results: Oral-AZA Tx remained a significant independent predictor of improved OS (hazard ratio [HR] 0.70; $P = 0.0017$) and RFS (HR 0.57; $P < 0.0001$) *vs*. PBO after controlling for baseline characteristics (**Table**). MRD status at baseline, cytogenetic risk at diagnosis, and pt age were each also independently predictive of OS and RFS (**Table**). Response after induction (CR *vs*. CRi) and baseline ANC were predictive of OS but not RFS, whereas prior MDS, non-CR/CRi vs. CRi at baseline, and number of consolidation cycles were predictive only of RFS.

Variable	Overall Survival HR [95%CI]; *P* value	Relapse-free Survival HR [95%CI]; *P* value
Oral-AZA vs PBO	**0.70 [0.56, 0.88]; 0.0017**	**0.57 [0.45, 0.70]; <0.0001**
MRD– *vs*. MRD+ at baseline	0.54 [0.43, 0.67]; <0.0001	0.49 [0.39, 0.61]; <0.0001
Intermediate *vs*. Poor cytogenetic risk at diagnosis	0.57 [0.42, 0.76]; 0.0002	0.49 [0.36, 0.66]; <0.0001
Age (continuous variable)	1.03 [1.01, 1.05]; 0.0046	1.02 [1.00, 1.04]; 0.0468
ANC (continuous variable)	1.25 [1.03, 1.50]; 0.0202	NIFM
Prior MDS (Yes *vs*. No)	NIFM	1.60 [1.11, 2.30]; 0.0116
CR *vs*. CRi response after induction	0.80 [0.60, 1.06]; 0.1138	NIFM
non-CR/CRi *vs*. CRi at baseline	NIFM	0.39 [0.18, 0.87]; 0.0216
0 *vs*. 2 consolidation cycles	NIFM	1.28 [0.92, 1.78]; 0.1355
1 *vs*. 2 consolidation cycles	NIFM	1.35 [1.04, 1.89]; 0.0224

NIFM, not in final multivariate model.



Summary/Conclusion: Tx with Oral-AZA reduced the risk of death by 30% and the risk of relapse by 43% *vs*. PBO, independent of baseline characteristics. Cytogenetic risk at diagnosis, MRD status at baseline, and pt age also independently predicted OS and RFS outcomes. CR vs. CRi response after induction, and no consolidation vs 2 consolidation cycles, did not significantly influence OS or RFS outcomes.

EP429 TREATMENT FREE REMISSION (TFR) AFTER CEASING VENETOCLAX-BASED THERAPY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

C. C. Chua [1,2,*], D. Hammond [3], A. Kent [4], I. S. Tiong [1,2], D. M. Ong [1,2], M. Konopleva [3], D. A. Pollyea [4], C. D. DiNardo [3], A. H. Wei [2,5]

[1]Department of Haematology, The Alfred Hospital, [2]Australian Centre for Blood Diseases, Monash University, Melbourne, Australia, [3]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, Texas, [4]Division of Hematology, University of Colorado School of Medicine, Aurora, United States, [5]Department of Leukemia, The Alfred Hospital, Melbourne, Australia

Background: Phase 3 studies have confirmed the benefit of adding venetoclax (VEN) to azacitidine (AZA) or low dose cytarabine (LDAC) in older/unfit patients (pts) with newly diagnosed AML. For pts responding to VEN-AZA or VEN-LDAC, the median duration of response was 18 and 12 months, respectively. Therefore, remission duration will exceed 12 months in majority of responders. It is currently unknown whether pts should continue therapy until progression and whether elective cessation of therapy could detrimentally impact long-term outcome.
Aims: To compare the natural history of pts receiving ≥12 months of VEN-based therapy in first remission after electively ceasing therapy or continuing treatment until progression.
Methods: Pts with AML receiving VEN combined with either hypomethylating agents (HMA) or LDAC for ≥12 months and in first remission were included in this retrospective analysis. Two treatment approaches were compared: elective cessation of therapy in remission followed by monitoring (STOP cohort) or continued therapy until relapse (CONT cohort). Data cut-off was 31Jan2021.
Results: 25 pts from 2 centres were included: 13 in STOP cohort and 12 in CONT cohort. The median follow-up was 55 months. Median age at AML diagnosis was 74 years (range 65-80). Treatments included VEN-HMA (68%) or VEN-LDAC (32%). Both STOP and CONT cohorts had comparable rates of ELN 2017 adverse risk (50% vs 46%). The median number of cycles received was shorter in the STOP (17; range 12-29) vs CONT (30; range 12-57) cohort. Median time on therapy (TOT) was also shorter in the STOP cohort (19.1 vs 33.2 months). In the STOP group, the reason for treatment cessation was patient request in 46% and medical in 54%. After ceasing therapy in the STOP cohort, the median treatment-free remission (TFR) was 45.8 months (range 3.8-54.5)(Figure 1A). Five pts (38%) subsequently relapsed, of which 3 had concurrent *SRSF2* and *ASXL1*mutations. 2/5 relapses occurred >36 months of TFR. In the CONT cohort, 5 pts were receiving ongoing therapy at data cut-off. Eight (67%) have relapsed, with 5 relapsing >24 months of therapy. More pts had acquisition of cytogenetic abnormalities at relapse in the CONT cohort (6/8; 75%), compared to the STOP group (2/5; 40%).
Overall, 14 pts had *NPM1* and/or *IDH2* mutations (mut): 8 in the STOP and 6 in CONT cohort. 10 achieved undetectable MRD (by flow cytometry and/or qPCR), of which 1 patient (10%) relapsed. In the STOP cohort, 7/8 with *NPM1* and/or *IDH2* mut are still in TFR. We next performed a landmark analysis to compare OS among pts in the STOP and CONT cohorts. The landmark was taken from the median TOT in the STOP group (19 months), in order to exclude lead-time bias in pts relapsing early in the CONT group. This revealed no significant difference in progression free (p=0.13, Figure 1B) or overall survival (p=0.35, Figure 1C) between the two groups. Among relapsed pts, 3/5 in the STOP and 4/8 in CONT cohorts were salvaged. In the STOP group, 2/3 relapsing pts re-challenged with the same VEN-based regimen achieved second CR/CRi. The median time from relapse to death was similar in both groups: median 9.8 vs 6 months in the STOP vs CONT cohorts, respectively (p=0.15).

Summary/Conclusion: In elderly/unfit pts with AML receiving front line VEN-based treatment and in CR/CRi after 12 months therapy, the likelihood of a durable TFR is highest among pts with *NPM1/IDH2* mutation and MRD negativity at the time of therapy cessation. A prospective, randomised, discontinuation study in pts in CR_{MRDneg} after 12 months should be considered.

EP430 QUIZARTINIB WITH DECITABINE AND VENETOCLAX (TRIPLET) IS HIGHLY ACTIVE IN PATIENTS WITH FLT3-ITD MUTATED ACUTE MYELOID LEUKEMIA

M. Yilmaz [1,*], H. Kantarjian [1], M. Muftuoglu [1], C. Dinardo [1], T. Kadia [1], M. Konopleva [1], G. Borthakur [1], N. Pemmaraju [1], N. Short [1], Y. Alvarado [1], A. Maiti [1], G. Montalban-Bravo [1], C. Jurisprudencia [1], A. Pike [1], E. Jabbour [1], G. Garcia-Manero [1], V. Ruvolo [1], F. Ravandi [1], M. Andreeff [1], N. Daver [1]

[1]*MD Anderson Cancer Center, Houston, United States*

Background: The outcomes in patients (pts) with newly diagnosed FLT3 mutated (m) acute myeloid leukemia (AML) who are ineligible for intensive induction chemotherapy (IC) are poor. Added to a low-intensity chemotherapy backbone, first-generation FLT3 inhibitors (FLT3i), such as midostaurin and sorafenib, result in a median OS of 8 months in the frontline (Gallogly ASH 2017, Ohanian AJH 2018), and 4-8 months in relapsed/refractory (R/R) settings (Yilmaz JHO 2020, Ravandi Blood 2013). Quizartinib, a potent second-generation FLT3i, demonstrated synergy with venetoclax (VEN) in AML cell lines and PDX models (Mali Haematologica 2020). We designed this study to evaluate the safety and efficacy of quizartinib, VEN, and decitabine (DAC) combination in pts with R/R or newly diagnosed *FLT3*m AML.
Aims: To establish recommended phase 2 dose (RP2D) and optimal schedule of DAC + quizartinib + VEN in R/R or newly diagnosed *FLT3*m AML.
Methods: Frontline cohort included pts who are ineligible for IC, and R/R cohort included pts who received ≤ 5 prior treatments. All pts had a performance status of ECOG ≤2, QTcF <450 msec prior to therapy. All pts underwent day 14 bone marrow, and VEN (400 mg/day) was put on hold in patients with bone marrow (BM) blasts ≤ 5% (or marrow aplasia). Pts with day14 BM blast >5% continued venetoclax for 21 days during cycle 1. All pts induced with 10 days of DAC (20 mg/m2). In subsequent cycles, DAC was administered for 5 days. Quizartinib (30 or 40 mg/day) was administered daily continuously.
Results: Overall 21 pts were enrolled and 17 evaluable at the time of this report (4 are still in cycle 1) (Table). Of 13 pts with R/R AML (median 3 [range 1-5] prior therapies, 85% with ≥1 prior FLT3i's), 9 (69%) achieved CRc (2 CR, 7 CRi) with 4/9 and 5/9 evaluable responders FLT3-PCR (sensitivity 10^{-2}) and multicolor flow cytometry (MFC) negativity (sensitivity 10^{-4}), respectively. The median number of cycles to response was 1 [range 1-2]. 30- and 60-day mortality rates were 0% and 8%. Of 4 patients with newly diagnosed AML, all achieved CRc (2 CR, 2 CRi) with 4/4 and 2/3 evaluable responders negative MRD by FLT3-PCR and MFC, respectively. No pts developed a dose-limiting toxicity (DLT) with 30 mg/day quizartinib, however with the 40mg/day quizartinib, the first 2 patients treated developed hematologic DLT (grade ≥3 neutropenia with a <5% cellular bone marrow with no residual AML lasting ≥42 days). Hence, quizartinib 30 mg/day dose was declared RP2D for the triplet. Grade ≥3 non-hematologic toxicities in >2 pts included lung infections (N=9) and neutropenic fever (N=6). No unexpected toxicities were noted. No QTcF prolongations >480 msec were noted. With a median follow-up of 7.2 months, the median OS was not reached in the frontline cohort and was 7.1 months in R/R cohort. 2/4 and 5/9 CRc pts underwent ASCT in frontline and R/R cohorts, respectively. All frontline patients were alive at the last follow-up; 3 in CR and 1 relapsed disease on salvage therapy. Of 9 CRc pts in the R/R cohort, 4 are alive (3 CR, 1 relapse), and 5 died (4 from relapse, 1 death in CR from sepsis). Baseline and longitudinal 36-marker mass cytometry (CYTOF), including FLT3, STAT, RAS-MAPK, and apoptosis pathway markers, is ongoing.

Patient Characteristics	DAC + Quizartinib + Venetoclax (n=21) N (%), Median [Range]

40 mg/day	1 (7)	1 (25)

*Mutation analysis missing in 1 patient, ≥2 mutations included, RAS/MAPK - RAS, PTPN11, CBL, NF1

Summary/Conclusion: DAC + VEN + quizartinib is active in heavily pretreated and prior FLT3i exposed R/R *FLT3*-ITDm pts, with CRc rates of 69% (55% of responders were negative MRD by MFC) and the med OS of 7.1 months. The regimen was well tolerated with no 30-day mortality. Accrual to the triplet continues and updated clinical and correlative data will be presented.

EP431 SECOND ALLOGENEIC STEM CELL TRANSPLANTATION FOR SECONDARY AML RELAPSING AFTER FIRST TRANSPLANTATION-A COMPARISON BETWEEN MYELOABLATIVE AND REDUCED INTENSITY CONDITIONING: FROM THE ALWP OF THE EBMT

Background: Secondary acute myeloid leukemia (sAML) has been associated with inferior outcomes compared to *de novo* AML. Relapse (rel) is the most frequent cause of transplant failure reaching up to 50% in high-risk AML. Median OS in sAML is 8 months. The available data for patients (pts) with sAML undergoing a second hematopoietic stem cell transplantation (HSCT2) for rel post first transplantation (HSCT1) is limited. Furthermore, no study has compared myeloablative (MAC) versus reduced intensity conditioning (RIC) for HSCT2 in sAML.
Aims: The study aimed to assess HSCT2 outcome for sAML comparing MAC to RIC.
Methods: This was a retrospective analysis based on data from the EBMT registry, including adult pts aged ≥18 years with sAML undergoing HSCT2 during the years 2005-2019 for rel post-HSCT1. Allografts were from a matched sibling donor (MSD), unrelated donor (UD), or haploidentical donor (Haplo) for both HSCT1 and HSCT2. Multivariate analysis (MVA) adjusting for potential confounding factors was performed using a Cox's proportional-hazards regression model for main outcomes.
Results: 215 pts were included: RIC (n=134), MAC (n=81). Median F/U was 41.0 (27.7-69.3) and 28.5 (23.9-75.4) months. Median age was 55.1 (23.9-70.1) and 52.5 (18.2-67.8) years (p=0.10), and 56.0% and 54.3% were male (p=0.81), respectively. Median time from HSCT1 to rel for MAC and RIC was 19 and 24 months (p=0.55). Disease status was CR in 40.3% and 40.8%, and active disease in 59.7% and 59.2% (p=0.95), respectively. KPS was ≥90 in 55.8% and 56.7% of pts, respectively (p=0.90). Donors were MSD in 24.6% and 25.9%, UD in 61.2% and 56.8%, and Haplo in 14.2 and 17.3%, respectively (p=0.77). Graft was peripheral blood in 94.8% and 88.9% of transplants (p=0.11) and TBI was administered to 20.1% and 27.2%, (p=0.24), respectively. The most frequent RIC was Fludarabine/ Busulfan (Flu/Bu)-13.2%, Flu/TBI-10.1%, and Flu/Melphalan (Mel)-9.3%, while the most frequent MAC was Flu/Bu-9%, Flu/Thiotepa (Thio)/Treosulfan (Treo)-9%, and Flu/TBI-6.4%. In vivo T-cell depletion with antithymocyte globulin (ATG) was used in 51.3% and 55.6 % of transplants (p=0.56). Graft-versus-host disease (GVHD) prophylaxis was cyclosporine A (CSA)/mycophenolate mofetil ± ATG in 31.9 % and 34.7%, and CSA/methotrexate + ATG in 15.9% and 19.4% of the pts. At 2-years the rel incidence was 58.3% vs 51.1% in MAC and RIC, respectively (p=0.24). The 2-y LFS was 26.6% vs 26%, (p=0.55), and the GRFS was 16.4% vs 12.1% (p=0.88), while OS was 31.4% and 39.7%, (p=0.41), respectively. 68% and 61.7% of pts receiving MAC and RIC died.Main cause of death was original disease 58.4% and 40.8% followed by infections and GVHD 10.1% and 10.2%; and 6.7% and 4.1%, respectively. MVA showed a significantly lower rel and improved LFS with MAC vs RIC, HR=0.46 (95% CI, 0.26-0.8, p=0.006) vs HR=0.62 (95% CI, 0.39-0.98, p=0.042), respectively, while OS, HR=0.72 (95% CI, 0.44-1. 17, p=0.18) and GRFS, HR=0.89 (95% CI, 0.59-1.36, p=0.6), respectively, did not differ significantly. Other significant prognostic factors for HSCT2 outcome were disease status, time from HSCT1 to relapse, and KPS.

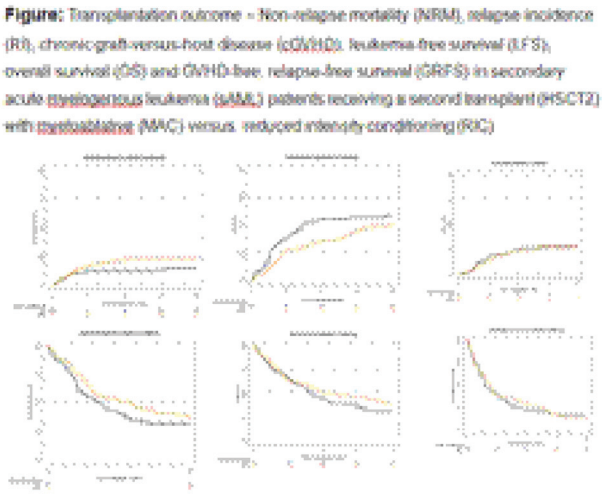

Figure: Transplantation outcome - Non-relapse mortality (NRM), relapse incidence (RI), chronic graft-versus-host disease (cGVHD), leukemia-free survival (LFS), overall survival (OS) and GVHD-free, relapse-free survival (GRFS) in secondary acute myelogenous leukemia (sAML) patients receiving a second transplant (HSCT2) with myeloablative (MAC) versus reduced intensity conditioning (RIC)

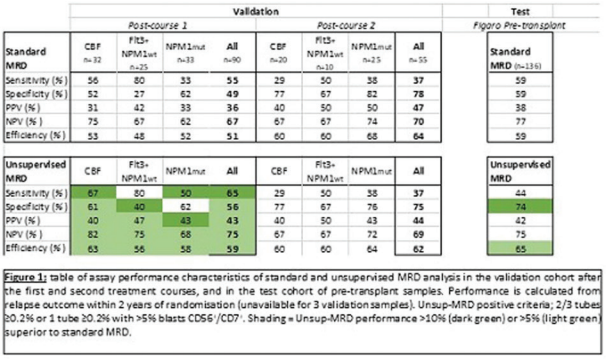
Summary/Conclusion: In this EBMT registry study of HSCT2 for sAML, MAC was associated with a lower relapse risk and superior LFS. Disease status, time from HSCT1 to relapse, and KPS are additional prognostic factors for transplantation outcome. These results are consistent with our previously reported findings in pts with sAML undergoing HSCT1 (Blood Advances 2:2127-2135, 2018), in favor of MAC for pts with sAML who received an HSCT2 after relapse.



EP432 VALIDATION AND CLINICAL APPLICATION OF AN UNSUPERVISED ANALYSIS APPROACH TO MEASURABLE RESIDUAL DISEASE TESTING IN ACUTE MYELOID LEUKEMIA

N. McCarthy [1,*], J. Loke [2], G. Andrew [3], A. Jackson [4], A. Hodgkinson [4], J. Mason [4], C. Roumier [5], A. Plesa [6], F. Dumezy [5], N. Khan [1], C. Craddock [2], S. Freeman [1]

[1]Institute of Immunology and Immunotherapy, University of Birmingham, [2]Centre for Clinical Haematology, Queen Elizabeth Hospital, Birmingham, Birmingham, United Kingdom, [3]National Heart Lung and Blood Institute, Bethesda, United States, [4]Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, United Kingdom, [5]Laboratory of Hematology, Biology and Pathology Center, CHU Lille, Lille, [6]Laboratory of Hematology and Flow Cytometry, CHU Lyon-Sud Hospital, Hospices Civils de Lyon, Lyon, France

Background: Multiparameter flow cytometric assessment of measurable residual disease (MFC-MRD) in acute myeloid leukaemia (AML) has important prognostic value in predicting future relapse in patients who achieve a complete response to front-line chemotherapy. Efforts to harmonise MFC-MRD are ongoing but considerable expertise is still required for its analysis stage, with potential for variable interpretation and therefore prognostic value.
Aims: Prognostic evaluation of an unsupervised (Unsup) analysis method, developed to generate MFC-MRD results that are reproducible without reliance on significant expertise or diagnostic samples.
Methods: Comparison of the prognostic performance of our Unsup pipeline to conventional MFC-MRD analysis was performed, first for validation on post induction MFC-MRD samples and then on pre-transplantation samples from the FIGARO trial (*Craddock et al, JCO 2020*). Bone marrow samples (BM) were assessed in these trials for MFC-MRD as previously described (*Freeman et al, JCO 2018*). Phenograph clustering was performed on downsampled blast flow files in runs of up to 50 AML samples plus ~40 control BMs. Fluorescence intensity of markers on control blasts in each algorithm-defined cluster was used to statistically define the limits of normal marker expression per cluster. Blasts with aberrant expression defined by these cluster-specific reference range limits were quantified to produce Unsup-MRD results as a % of leukocytes.

Results: Results for assay validation were generated from 148 BMs after 1st and 2nd induction from 111 patients (39 CBF, 44 *NPM-1*^{mut} and 28 *Flt3-ITD*$^{+}$*NPM1*^{wt} AMLs).
Unsup-MRD values were higher than standard MFC-MRD (which estimates %MRD from a single leukemic aberrant immunophenotype) but correlated positively. Polynomial regression showed 0.32% Unsup-MRD to have equivalence to the ELN recommended cut-off of 0.1% for standard MFC-MRD positivity. Duplicate testing demonstrated result repeatability (r2=0.876; p<0.001). Minimum analytical sensitivity determined from clustering runs of control BMs tested against reference control BMs was 0.13% for the limit of blank / 0.20% for the limit of detection. From *in silico* spiking of AML blasts into control blasts, mean recovery was 84-108% with Unsup-MRD detected at >5% of blasts at the lowest dilution.
To optimise test specificity, Unsup-MRD positivity criteria were set at ≥0.2% in ≥2 tubes unless CD56+/ CD7+ at ≥0.2%. Importantly, assay statistics for relapse within 2yrs were highly similar between Unsup-MRD and standard MRD in the test cohort (Figure 1). Of note, the negative predictive value of Unsup-MRD post-C1 was 82% and 75% for CBF and *Flt3-ITD*$^{+}$*NPM1*^{wt} patients respectively.
We then applied the validated Unsup-MRD criteria to the pre-transplant BMs from 136 FIGARO patients. Assay performance was again comparable to standard MRD (Figure 1). 2yr cumulative incidence of relapse (CIR) was 22.2% for MRD^{neg} vs 42.1% for MRD^{pos} by Unsup criteria (p=0.03).
We next tested the higher cut-off (≥0.3%) equivalent to 0.1% standard MFC-MRD. This had little impact on test efficiency for the post-induction validation cohort but increased pre-transplant Unsup-MRD specificity (82% from 71%) with a 2yr CIR of 21.2% MRD^{neg} vs 51.9% MRD^{pos} (p<0.001). These results support previous observations that relapse risk after reduced intensity allogeneic transplant. may not be significantly increased when MFC-MRD is detected at low levels pre-transplant.

	Validation								Test
	Post-course 1				Post-course 2				Figaro Pre-transplant

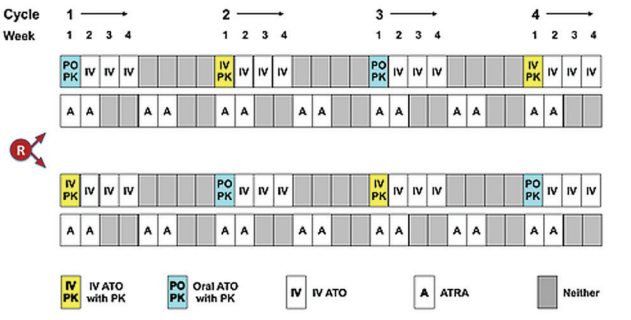
Sensitivity (%)	67	80	50	65	29	50	38	37	44
Specificity (%)	61	40	62	56	77	67	76	75	74
PPV (%)	40	47	43	43	40	50	43	44	42
NPV (%)	82	75	68	75	67	67	72	69	75
Efficiency (%)	63	56	58	59	60	60	64	62	65

Figure 1: table of assay performance characteristics of standard and unsupervised MRD analysis in the validation cohort after the first and second treatment courses, and in the test cohort of pre-transplant samples. Performance is calculated from relapse outcome within 2 years of randomisation (unavailable for 3 validation samples). Unsup-MRD positive criteria; 2/3 tubes ≥0.2% or 1 tube ≥0.2% with >5% blasts CD56^{+}/CD7^{+}. Shading = Unsup-MRD performance >10% (dark green) or >5% (light green) superior to standard MRD.

Summary/Conclusion: The prognostic performance of a novel unsupervised approach for assessing AML MFC-MRD is at least equivalent to standard MFC-MRD analysis.



EP433 COMPARATIVE BIOAVAILABILITY OF A NOVEL ORAL FORMULATION OF ARSENIC TRIOXIDE IN PATIENTS UNDERGOING CONSOLIDATION THERAPY FOR ACUTE PROMYELOCYTIC LEUKEMIA: FINAL ANALYSIS OF THE ALLG APML5 TRIAL

H. J. Iland [1,2,*], J. Reynolds [3], A. Boddy [4], H. Schultz [4], A. Wei [5], L. Khoo [1,2], T. Armytage [6], R. Harrup [7], S. Lane [8], P. Tan [9], R. Filshie [10], A.-M. Watson [11], J. Kwan [12], R. Gasiorowski [13], W. Stevenson [14], A. P. Ng [15], A. Dunne [16]

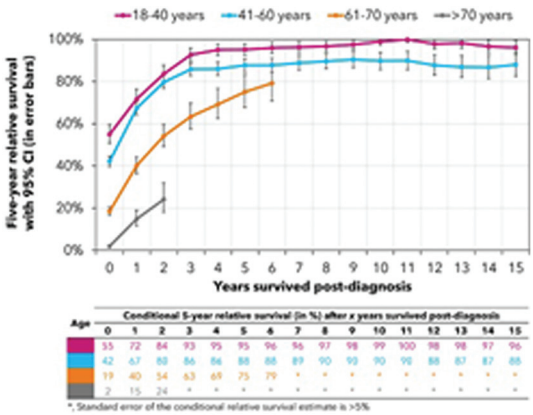
Background: All-*trans* retinoic acid (ATRA) and intravenous arsenic trioxide (IV ATO) cure most patients with acute promyelocytic leukemia (APL), but the requirement for 2-hourly ATO infusions over several months is problematic. Orally administered ATO has the potential to significantly reduce resource utilization and improve the therapeutic experience without compromising efficacy.
Aims: To characterize the bioavailability of encapsulated oral ATO (Phebra, Australia) in patients with APL by comparing the total arsenic $AUC_{0\text{-}24}$ and C_{max} in whole blood (WB) and plasma (PL) after oral and IV ATO administration.
Methods: The APML5 trial (ACTRN12616001022459) was a phase I, 2-part, 2-sequence, 4-period, bioavailability study in 31 consenting patients with previously untreated APL, embedded within a standard-of-care consolidation regimen (ATRA + IV ATO; Lo-Coco *et al*, NEJM 369:111,2013). Eligibility required documented hematological complete remission after induction with ATRA + IV ATO (+ idarubicin for high-risk APL). Initial pharmacokinetic (PK) data from the APML5 part 1 pilot (n=9) indicated oral and IV ATO provide comparable arsenic exposure over repeated cycles of consolidation (Iland *et al*, EHA 2019, HemaSphere doi:10.1097/01.HS9.0000562408.61553.8e).
To conclusively establish bioequivalence, 22 patients at 12 sites were randomised in APML5 part 2 (Jan 2019-June 2020) to IV or oral ATO 0.15mg/kg/d with PK sampling in week 1 of cycles 1 & 3, and the alternate route in week 1 of cycles 2 & 4 (Figure). Total arsenic was quantitated by inductively coupled plasma mass spectrometry. Point estimates of mean oral/IV arsenic ratios ± 90% confidence intervals (CI) for $AUC_{0\text{-}24}$ (μmol/l.h) and C_{max} (μmol/l) in WB and PL were calculated by linear mixed model analysis incorporating fixed and random effects.
Results: The target accrual of 20 evaluable patients was reached after 2 replacements (insufficient PK data as per protocol). Median age was 45.9 years (range 23.4-75.2), 10 male, 10 female, 14 Sanz standard-risk, and 6 high-risk. Both ATO formulations were associated with significant increases in $AUC_{0\text{-}24}$ and C_{max} in WB and PL from day 1 to day 4 of each cycle (p<0.001), indicative of short-term arsenic accumulation, but no accumulation occurred between sequential cycles. Estimates of the geometric mean of the oral/IV ratio for each PK parameter closely approximate unity (Table), and the 90% CI fall within the conventional bioequivalence limits (0.80, 1.25). Distinguishing adverse events (AEs) specifically related to oral ATO from those related to IV ATO is problematic, since IV ATO was also administered for 3 weeks in cycles that commenced with 1 week of oral ATO (Figure). Nevertheless, no excess of grade 3-4 AEs (including gastrointestinal toxicity) was noted in cycles that contained oral ATO, and no instances of oral or IV ATO-associated QTc prolongation were observed during part 2 of APML5, despite monitoring with twice weekly electrocardiograms in each cycle. One patient with high-risk disease relapsed after consolidation.

PK parameter	Estimated geometric mean of oral/IV ratio	Lower limit (90% CI)	Upper limit (90% CI)
WB $AUC_{0\text{-}24}$	0.9931	0.9542	1.034
PL $AUC_{0\text{-}24}$	1.030	0.9773	1.087
WB C_{max}	0.9174	0.8709	0.9663
PL C_{max}	0.9692	0.8923	1.053



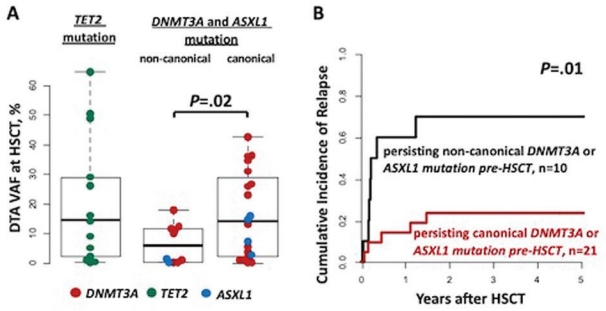
Summary/Conclusion: This randomized crossover bioavailability study confirmed bioequivalence of the oral and IV formulations of ATO when administered in the context of standard-of-care consolidation, and unexpected toxicity signals were not evident. Overall, the results of the APML5 trial provide a sound rationale for incorporating oral ATO in the management of patients with APL.

EP434 AGE-SPECIFIC CONDITIONAL RELATIVE SURVIVAL AMONG LONG-TERM ACUTE MYELOID LEUKEMIA (AML) SURVIVORS IN THE NETHERLANDS

A. Dinmohamed [1,2,3,*], O. Visser [4], W. Posthuma [5,6], G. Huls [7], A. van de Loosdrecht [3]

[1]Research and Development, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [2]Public Health, Erasmus University Medical Center, Rotterdam, [3]Hematology, Amsterdam UMC, Amsterdam, [4]Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [5]Internal Medicine, Reinier de Graaf Gasthuis, Delft, [6]Hematology, Leiden University Medical Center, Leiden, [7]Hematology, University Medical Center Groningen, Groningen, Netherlands

Background: The connotation surrounding AML is often grim because of the heightened risk of mortality within the first few years post-diagnosis. Therefore, survival estimates measured from diagnosis, which is usually presented in population-based cancer research, might be somewhat pessimistic for long-term AML survivors and their caregivers who desire to obtain information on the prognosis after having survived some years post-diagnosis.
Aims: Against this background, this population-based study aimed to estimate the conditional 5-year relative survival among AML patients up to 15 years post-diagnosis.
Methods: All adult (≥18 years) AML patients diagnosed between 1989-2018—with follow-up for survival through December 31, 2019—were selected from the Netherlands Cancer Registry. We excluded patients with acute promyelocytic leukemia. Relative survival (RS) was calculated to estimate disease-specific survival as the ratio of the observed to the expected survival, based on national life tables stratified by age, sex, and calendar year. We computed 5-year RS at diagnosis and for each additional year survived up to 15 years post-diagnosis. RS was estimated using a hybrid approach to predict up-to-date survival probabilities. This approach was applied for patients diagnosed between 1989-2018 who were alive during the follow-up interval 2008-2019. The produced estimates can be interpreted as the predicted survival probability of patients diagnosed during 2008-2019. Survival estimates were computed—with associated 95% confidence intervals (CIs)—according to age at diagnosis (18-40, 41-60, 61-70, and >70 years). Only survival estimates with a standard error of ≤5% were presented. This choice relates to the precision of the survival estimates. Excess mortality is minimal when RS is ≥95%.
Results: A total of 16,177 adult AML patients (median age, 68 years) were diagnosed in the Netherlands between 1989-2018, of whom 8,182 (51%) were alive at some point during the follow-up interval and contributed to the survival estimates. There was a prognostic effect of age on 5-year RS at diagnosis, with corresponding estimates (95% CI) of 55% (51% - 60%), 42% (40% - 45%), 19% (17% - 21%), and 2% (2% - 3%) across the four age groups (Figure). This effect essentially persisted up to 15 years post-diagnosis (Figure). Notwithstanding, excess mortality decreased with each additional year survived across all age groups (Figure). Encouragingly enough, patients aged 18-40 years at diagnosis hardly experienced excess mortality after four years post-diagnosis (Figure). In contrast, excess mortality remained substantial for patients aged >40 years, especially among those aged >60 years (Figure).



Summary/Conclusion: The prognosis of adult AML patients improved with each additional year survived. Reassuring is that patients aged 18-40 years at diagnosis can look forward to a near-normal life expectancy after four year post-diagnosis. This finding, unfortunately, does not hold for patients aged >40 years at diagnosis. Late treatment-related sequelae and late relapses might cause the ongoing excess mortality among patients aged 41-70 years, a group mostly considered for intensive, potentially curative treatment. The poor outcome among patients aged >70 years is inherently tied to the virtually incurable nature of AML in this age group. Statistics on CRS in AML may offer patients and physicians a better apprehension of the changing survival expectations with each additional year survived post-diagnosis. This information can also be used to tailor age-specific surveillance and follow-up activities.

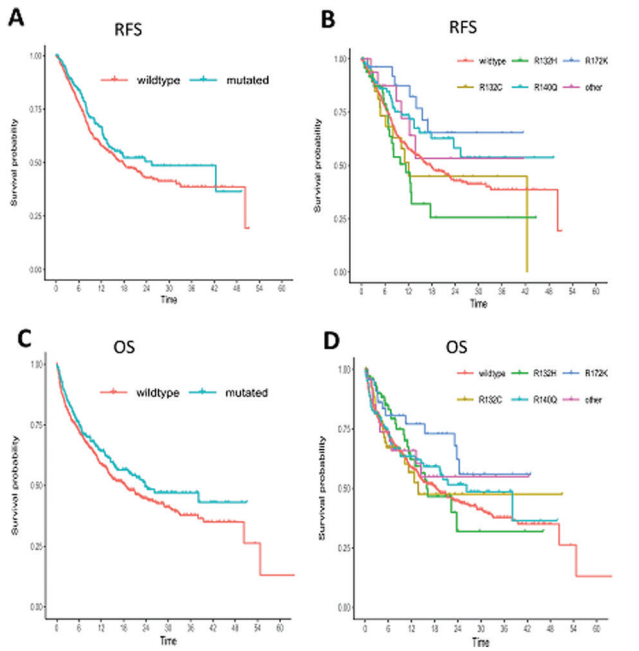
EP435 CLINICAL IMPACT OF SENSITIVE DNMT3A, TET2, OR ASXL1 MUTATION DETECTION IN ACUTE MYELOID LEUKEMIA PATIENTS PRIOR TO ALLOGENEIC STEM CELL TRANSPLANTATION

M. Jentzsch [1,*], D. Brauer [1], J. Grimm [1], M. Bill [1], J. Küpper [1], D. Backhaus [1], J. Schulz [1], D. Niederwieser [1], U. Platzbecker [1], S. Schwind [1]

[1]Medizinische Klinik I - Hämatologie und Zelltherapie, UNIVERSITÄTSKLINIKUM LEIPZIG, Leipzig, Germany

Background: In acute myeloid leukemia (AML), mutations in the genes *DNMT3A*, *TET2*, and *ASXL1* (DTA) are frequent and appear early in leukemogenesis. In older, otherwise healthy individuals DTA mutations may be present as clonal hematopoiesis of indeterminate potential (CHIP). While *TET2* mutations do not have a common hotspot, mutations in *DNMT3A* and *ASXL1* frequently occur at specific positions (*DNMT3A* in R882 and *ASXL1* as G646fs*12, referred to as "canonical"). The persistence of gene mutations prior to allogeneic hematopoietic stem cell transplantation (HSCT) as consolidation therapy may identify AML patients (pts) at high-risk of relapse. Until today, no study genuinely evaluated the applicability of DTA mutations - including canonical *vs.* non-canonical mutations - as residual disease markers in AML pts receiving HSCT consolidation.
Aims: To evaluate DTA mutations as residual AML disease markers in pts prior to allogeneic HSCT.
Methods: We analyzed 68 AML pts harboring at least one DTA mutation (*DNMT3A*, n=41; *TET2*, n=18; *ASXL1*, n=15) at diagnosis, who received HSCT (median age 64, range 35-75 years) in complete remission (CR; n=50) or CR with incomplete recovery (CRi, n=18). Conditioning regimens were non-myeloablative (n=57), reduced intensity (n=7) or myeloablative (n=4). At diagnosis, the mutational status of 54 genes was evaluated using next generation sequencing at diagnosis. Applying highly sensitive mutation-specific digital droplet PCR (ddPCR) assays at the timepoint of HSCT, we tested for the persistence of DTA mutations. Median follow up was 5.0 years.
Results: At diagnosis, 41 pts had a *DNMT3A* mutation (62%; canonical: 61%; non-canonical: 39%) 18 had a *TET2* mutation (33%) and 15 had an *ASXL1* mutation (22%; canonical: 80%; non-canonical: 20%). Most frequently co-mutated genes were *NPM1* (43%), *RUNX1* (19%), *IDH2* (16%), and *BCOR*, *IDH1*, and *FLT3*-ITD (each with 15%). At HSCT, DTA mutations persisted in the majority of pts (overall 84%; *DNMT3A* 86%, *TET2* 93%, and *ASXL1* 60%). The rate of sustained detection did not differ significantly between canonical and non-canonical mutations (*DNMT3A*: 89% *vs* 80%, *P*=1 and *ASXL1*: 57% *vs* 67%, *P*=1). Of the analyzed non-canonical mutations in *DNMT3A* 10% were frameshift, 60% were missense, and 30% were nonsense, while in *ASXL1* all non-canonical mutations were nonsense. In pts with persisting *DNMT3A* and *ASXL1* aberrations, non-canonical mutations persisted at significantly lower variant allele frequencies (VAFs) compared to canonical mutations (*P*=.02, Figure 1A). Overall, the retained detection of DTA mutations did not associate with a higher cumulative incidence of relapse (CIR, *P*=.37) or overall survival (OS, *P*=.34) after HSCT. However, in *DNMT3A* or *ASXL1* mutated pts, the persistence of a non-canonical mutation associated with significantly higher CIR (*P*=.01, Figure 1B) and shorter OS (*P*=.04) compared to the persistence of canonical mutations.

Summary/Conclusion: In general, the continuing detection of DTA mutations prior to HSCT did not associate with outcomes in AML pts transplanted in CR/CRi. In pts with *DNMT3A* or *ASXL1* mutations, non-canonical mutations persisted at lower VAF levels than canonical mutations. The persistence of non-canonical *ASXL1* or *DNMT3A* mutations associated with worse outcomes compared to the persistence of canonical mutations, challenging the paradigm that all DTA mutations are unsuitable as residual disease markers in AML.



EP436 PREVALENCE AND PROGNOSTIC IMPACT OF IDH MUTATIONS IN THE REAL-WORLD SETTING: RESULTS FROM THE PROSPECTIVE IDH SCREENING COHORT OF THE SAL AML REGISTRY

C. Röllig [1,*], M. Hanoun [2], B. Steffen [3], S. W. Krause [4], S. Scholl [5], S. Kraus [6], K. Schäfer-Eckart [7], M. Kaufmann [8], E. Jost [9], C. Schliemann [10], M. Hänel [11], M. Medizinische Klinik, Carl-Thiem-Klinikum, Cottbus, [19]Medizinische Klinik II, DIAKO Bremen, Bremen, [20]Medizinische Klinik V, Universität Heidelberg, Heidelberg, [21]Klinik für Innere Medizin II, Universitätsklinikum Schleswig-Holstein, Kiel, [22]Medizinische Klinik und Poliklinik I, Hämatologie und Zelltherapie, Universitätsklinikum Leipzig, Leipzig, Germany

Background: Mutations in the *IDH1* and *IDH2* genes belong to the most frequent recurrent genetic alterations in AML. Whereas IDH mutations in total do not have a favorable nor adverse prognostic impact, certain subtypes may be associated with a more favorable or adverse clinical course. The majority of available data on prevalence and prognostic impact was obtained in selected patient groups, who were most commonly treated intensively as part of clinical trial protocols.
Aims: We set up a study to prospectively screen for *IDH* mutations and collect prognostic information on *IDH* in a large real-world cohort of patients (pts) enrolled in the AML registry of the SAL study group.
Methods: Between April 2016 and March 2020, all pts from centers participating in the SAL registry were screened for *IDH* mutations by a sensitive amplicon-based NGS approach. Both newly diagnosed and relapsed/refractory (r/r) pts receiving either intensive or non-intensive treatments were screened. Pts did not receive IDH inhibitors. The study was approved by the responsible Ethics Committee as part of the SAL AML registry (NCT03188874).
Results: 2690 pts were screened, of which 2457 were obtained at initial diagnosis and 233 in r/r AML. The prevalence of *IDH1* and *IDH2* mutations was 9.7% and 13.3%, respectively, which was identical at initial diagnosis and in r/r disease. Mutations R132C and R132H were the most common mutations in *IDH1*, whereas in *IDH2*, R140Q and R172K were most frequently found.
In newly diagnosed AML, the CR rate in *IDH*-mut versus (vs) *IDH*-wt was 68% vs 67% (p=0.919). The median relapse-free survival (RFS) in mut vs wt pts was 25.4 vs 17.8 months (m) (p=0.106). Subgroup analyses revealed a superior survival of *IDH2*-R172K mut pts with a 1-year RFS of 88% vs 58% in *IDH*-wt pts (p=0.037). A trend for superior overall survival (OS) was observed in *IDH*-mut pts with a median OS of 24 vs 18 m (p=0.066). *IDH2*-R172K pts had a significantly better prognosis than *IDH*-wt pts with a 1-year OS of 77% vs 59% (p=0.037). The described patterns were similar if pts eligible for intensive treatment were analysed separately.
In 137 pts with *de novo* AML ineligible for intensive treatment, median RFS in pts achieving a CR was longer in *IDH*-mut vs *IDH*-wt (8.5 vs 6.3 m; p=0.041); however, median OS in all unfit pts did not differ significantly between *IDH*-mut and *IDH*-wt (4.9 vs 4.3 m; p=0.326).
In 105 evaluable r/r AML, the CR rate in *IDH*-mut vs *IDH*-wt was 42% vs 59% (p=0.132), 1-year RFS 67% vs 40% (p=0.309) and 1-year OS identical with 67%.

Figure: RFS and OS depending on *IDH* mutational status in newly diagnosed AML (*IDH1*-R132C, *IDH1*-R132H, *IDH2*-R149Q, *IDH2*-R172K). A, RFS in *IDH*-mut vs *IDH*-wt; B, RFS in *IDH*-mut subgroups vs *IDH*-wt; C, OS in *IDH*-mut vs *IDH*-wt; D, OS in *IDH*-mut subgroups vs *IDH*-wt.

Summary/Conclusion: In this prospectively analyzed cohort of AML pts from a real-world setting, we detected *IDH* mutations in 23% of cases, irrespective of the disease status. Whereas *IDH* mutations were not associated with differences in RFS and OS in the total cohort, significantly prolonged survival outcomes could be identified for the subgroup of newly diagnosed pts with *IDH2*-R172K. Our results confirm the favorable prognosis of the *IDH2*-R172K subgroup. Furthermore, the results from this real-world cohort including r/r AMLs and pts ineligible for intensive treatment match the results of previously published newly diagnosed and fit patient groups from clinical trials.[1]

EP437 A PHASE 1 STUDY OF GILTERITINIB IN COMBINATION WITH INDUCTION AND CONSOLIDATION CHEMOTHERAPY IN PATIENTS WITH NEWLY DIAGNOSED AML: FINAL RESULTS UPDATE

K. W. Pratz [1,*], M. Cherry [2], J. K. Altman [3], B. W. Cooper [4], J. C. Cruz [5], J. G. Jurcic [6], M. J. Levis [1], T. L. Lin [7], A. E. Perl [8], N. A. Podoltsev [9], G. J. Schiller [10], J. E. Hill [11], A. James [11], Q. Lu [11], R. V. Tiu [11]

[1]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, [2]Stephenson Cancer Center, University of Oklahoma, Oklahoma City, [3]Robert H. Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, [4]University Hospitals, Cleveland Medical Center, Cleveland, [5]Methodist Physician Practices, San Antonio, [6]Columbia University Medical Center, New York, [7]University of Kansas Medical Center, Kansas City, [8]Abramson Comprehensive Cancer Center, Philadelphia, [9]Yale School of Medicine, New Haven, [10]David Geffen School of Medicine at UCLA, Los Angeles, [11]Astellas Pharma Global Development, Northbrook, United States

Background: Gilteritinib, an oral *FMS*-like tyrosine kinase 3 (FLT3) inhibitor, demonstrated antileukemic responses in patients (pts) with *FLT3*-mutated (*FLT3*^{mut}) relapsed/refractory acute myeloid leukemia (AML).
Aims: We report updated final data from a phase 1 study of once-daily oral gilteritinib + intravenous chemotherapy in pts with newly diagnosed (ND) AML.
Methods: As detailed previously in Pratz et al. *Blood* 2020;136(supp1):16-17, this 4-part, open-label, phase 1 study (NCT02236013) assessed the safety/tolerability and antileukemic effects of gilteritinib plus 7 + 3 induction and ≤3 cycles of high-dose cytarabine consolidation, and as single-agent maintenance treatment (tx) in adults with ND AML. During induction, cohorts varied in their gilteritinib dose (40–200 mg during dose escalation and 120 mg in cohort expansion), gilteritinib administration schedule (days 4–17 or 8–21), and anthracycline choice (idarubicin or daunorubicin). Eligible patients could receive a second 7 + 3+gilteritinib induction cycle. During consolidation, gilteritinib was administered at induction dose on days 1–14 or 1–56 of each cycle (cohort dependent). During maintenance, gilteritinib was given daily (28-day cycles) for up to 26 cycles. Pts with a composite complete remission (CRc) or partial remission could undergo hematopoietic stem cell transplant (HSCT) and resume maintenance gilteritinib tx post HSCT. Safety and tolerability were the primary endpoints.
Results: As of 23 June 2020, 80 pts were allocated to tx (safety analysis set, n=79); median age was 59.0 y (range, 23–77) and 44 were *FLT3*^{mut}. Median follow-up was 35.8 mo. HSCT was performed in 30.4% (24/79) of pts. Dose-limiting toxicities (DLTs) occurred in 15/79 (19.0%) pts. DLTs in the 200 mg/d cohort were prolonged neutropenia (n=1) and neutropenic enterocolitis (n=1). The maximum tolerated dose was 120 mg/d. Serious tx-related adverse events (AEs) and AEs leading to discontinuation of gilteritinib occurred in 29.1% (n=23) and 22.8% (n=18) of pts, respectively. Grade ≥3 nonhematologic AEs (≥10% of pts) were increased alanine aminotransferase (13.9%), pneumonia (13.9%), sepsis (11.4%), and bacteremia (11.4%). A 120 mg/d dose of gilteritinib was received by 38 (86.4%) *FLT3*^{mut} pts. In Pratz et al. *Blood* 2020, we reported clinical responses at end-of-induction but now report response at end-of-treatment, consistent with previous disclosures. Among *FLT3*^{mut} pts who received gilteritinib 120 mg/d, the CRc rate was 89.5% (complete remission [CR], 71.1%; CR with incomplete hematological recovery, 18.4%) and median overall survival has not been reached (**Figure**). Anthracycline choice had no significant impact on CRc rate or toxicity. Estimated 1- and 2-year survival probabilities were 85.9% and 72.3% respectively. The 60-day mortality rate was 0%. Median (95% CI) disease-free survival was 13.3 (4.9–18.7) mo. In pts who received gilteritinib 120 mg/d and achieved CRc, mutational clearance of *FLT3* internal tandem duplication (ITD) (summed *FLT3* ITD:WT signal ratio of ≤10^{-4}) after induction or consolidation was 84.6% (11/13).

Summary/Conclusion: Gilteritinib + induction and consolidation chemotherapy is well-tolerated in pts with ND *FLT3*^{mut} AML and often leads to CR, clearance of *FLT3* ITD, and long-term survival. Based on these data, randomized trials of gilteritinib vs midostaurin as part of intensive frontline therapy of *FLT3*^{mut} AML have been initiated.

EP438 FOLLOW-UP OF PATIENTS WITH FLT3-MUTATED RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA IN THE PHASE 3 ADMIRAL TRIAL

Background: The phase 3 ADMIRAL trial demonstrated the superiority of gilteritinib to salvage chemotherapy (SC) in patients with *FLT3*-mutated (*FLT3*$^{mut+}$) relapsed or refractory (R/R) acute myeloid leukemia (AML).
Aims: A follow-up of ADMIRAL assessed long-term survivors, hematopoietic stem cell transplantation (HSCT) outcomes, and gilteritinib safety beyond 1 year.
Methods: A data cut was performed on September 20, 2020—2 years after the primary analysis. Patients who were alive without relapse, patients who underwent HSCT, and adverse events (AEs) of interest in Years 1 (≤12 months) and 2 (>12 months) of gilteritinib therapy were evaluated.
Results: As of September 20, 2020, 17% (n=63/371) of patients in the intention-to-treat (ITT) population were alive (gilteritinib, n=49; SC, n=14); 16 patients assigned to gilteritinib remained on treatment. After a median follow-up of 37.1 months, 26 of the 49 patients in the gilteritinib arm who were alive were also without relapse; 18 of these 26 patients underwent HSCT, with 16 receiving post-HSCT gilteritinib maintenance therapy. Nineteen of the 26 patients in the gilteritinib arm without relapse continued gilteritinib beyond 1 year and remained in complete remission (CR).
Of the 371 patients in the ITT population, 83 (22%) underwent HSCT during the study (gilteritinib, n=64; SC, n=19). Pre-HSCT composite CR (CRc) rates were similar across arms (gilteritinib: n=40/64; 63%; SC: n=11/19; 58%); 10 of 11 patients preselected for low-intensity SC achieved pre-HSCT CRc (i.e., the sum of patients who achieved CR with or without complete hematologic or platelet recovery) (gilteritinib, n=9; SC, n=1). Forty of 64 (63%) transplanted patients in the gilteritinib arm received post-HSCT gilteritinib maintenance after achieving pre-HSCT CRc; the 24-month relapse rate in patients who resumed gilteritinib after pre-HSCT CRc was 19%. Post-HSCT treatment with chemotherapy or other tyrosine kinase inhibitors was administered in 26 patients who received gilteritinib before transplantation.
Cumulative 24-month relapse rates in gilteritinib-treated patients who achieved pre-HSCT CR and CRc were 20% and 45%, respectively. Median post-HSCT overall survival (landmarked to the date of HSCT) was similar across arms (gilteritinib, 16.1 months; SC, 15.3 months; HR=1.076; 95% CI: 0.536, 2.160).
Overall, 10.2% of patients (n=25/246) had ≥24 months of gilteritinib exposure. The most common AEs of interest during Years 1 and 2 of gilteritinib therapy were elevated alanine or aspartate aminotransferase levels. Incidences of all AEs of interest declined in Year 2. Cardiac AEs of interest in Year 2 were nonfatal cardiorespiratory arrest (n=1) and ventricular tachycardia (n=1). One case of differentiation syndrome and cutaneous squamous cell carcinoma occurred in Years 1 and 2, respectively.
Summary/Conclusion: A high proportion of gilteritinib-treated R/R *FLT3*$^{mut+}$ AML patients who were alive without relapse had received HSCT followed by gilteritinib maintenance. Among all transplanted patients in ADMIRAL, pre-HSCT remission rates and post-HSCT survival were similar across arms. Post-HSCT gilteritinib maintenance may relate to the low post-HSCT relapse rate in the gilteritinib arm. The safety profile of gilteritinib is stable at 2 years with no new or significant safety signals.

EP439 CYTOPENIA MANAGEMENT IN THE PHASE 3 VIALE-C STUDY OF VENETOCLAX PLUS LOW-DOSE CYTARABINE FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA INELIGIBLE FOR INTENSIVE CHEMOTHERAPY

A. H. Wei [1,*], P. Panayiotidis [2], P. Montesinos [3], V. Ivanov [4], J. Novak [5], K. Laribi [6], I. Kim [7], D. ?. Stevens [8], W. M. Fiedler [9], J. Bergeron [10], J.-Z. Hou [11], V. Murthy [12], A. McDonald [13], T. Yamauchi [14], K. Ishizawa [15], J. Wang [16], Y. Duan [17], M. T. Ghanim [17], W. Mendes [17], C. D. DiNardo [18]

Background: Patients (pts) with acute myeloid leukemia (AML) who are older or ineligible for intensive chemotherapy have low remission rates and poor survival. In the phase 3, randomized, placebo (Pbo)-controlled VIALE-C study (NCT03069352), median overall survival was 8.4 mo with venetoclax (Ven) + low-dose cytarabine (LDAC) vs 4.1 mo with Pbo+LDAC in older or unfit pts with newly diagnosed AML (*Blood*. 2020;135:2137-45).
Aims: To analyze the frequency and management of cytopenia in pts who achieved a best response of complete remission (CR) or CR with incomplete count recovery (CRi) in VIALE-C.
Methods: Enrolled pts had newly diagnosed AML and were ineligible for intensive chemotherapy due to age (≥75 y) or comorbidities. Pts were randomized 2:1 to once-daily 600 mg oral Ven or Pbo in 28-day cycles plus 20 mg/m^2 subcutaneous LDAC on Days 1–10. After pts achieved blast clearance (bone marrow blasts <5%), dose modifications were used to manage cytopenia (**Table 1**). Cytopenia was defined as Grade 4 neutropenia (absolute neutrophil count <500/μL) or Grade 4 thrombocytopenia (platelet count <25×10^3/μL) lasting ≥7 days and was assessed using laboratory data.
Results: Of randomized pts who received Ven+LDAC (n=142) and Pbo+LDAC (n=68), 69 (49%) and 9 (13%), respectively, achieved a best response of CR/CRi. Of 69 pts in CR/CRi in the Ven+LDAC arm, cumulatively, 74%, 84%, 88%, 97%, and 99% achieved blast clearance by the end of Cycles 1, 2, 3, 4, and ≥7, respectively (1 pt achieved clearance after treatment discontinuation). Of 9 pts in CR/CRi in the Pbo+LDAC arm, cumulatively, 33%, 56%, 56%, 89%, and 100% achieved blast clearance by the end of Cycles 1, 2, 3, 4, and ≥7, respectively. After achieving blast clearance, delayed start of the next cycle to allow for count recovery occurred in 71% and 44% of pts in the Ven+LDAC and Pbo+LDAC arms, respectively, with a median delay (min-max) to the next cycle of 8 (2–31) and 3 (2–7) days, respectively. More pts in CR/CRi who received Ven+LDAC vs Pbo+LDAC had postremission cytopenia (75% vs 33%). The proportion of pts in CR/CRi with in-cycle dose interruptions (ie, days without Ven/Pbo exposure between a cycle's first and last Ven/Pbo dose) was similar between arms (Ven+LDAC, 22%; Pbo+LDAC, 22%), with a median duration (min-max) of 3 days (1–12) for Ven+LDAC and 5 days (1–10) for Pbo+LDAC. A greater proportion of pts in CR/CRi who received Ven+LDAC vs Pbo+LDAC experienced postremission cycle delays due to cytopenia (62% vs 33%). More pts in CR/CRi had postremission reductions in Ven/Pbo dosing days and/or within cycle dose interruptions totaling ≥7 days due to cytopenia in the Ven+LDAC arm (61%) vs the Pbo+LDAC arm (22%). Of these pts, the median percentage of days (min-max) without Ven or Pbo administration while in remission (out of the total no. of remission days) was 14% (1–73) in the Ven+LDAC arm and 7% (4–9) in the Pbo+LDAC arm. Ultimately, 29 pts in CR/CRi (42%) in the Ven+LDAC arm and 1 (11%) pt in the Pbo+LDAC arm received ≤21-day Ven/Pbo dosing postremission, with a median (min-max) time from remission to first ≤21-day cycle of 71 days (1–339) for Ven+LDAC and 1 day (1–1) for Pbo+LDAC.

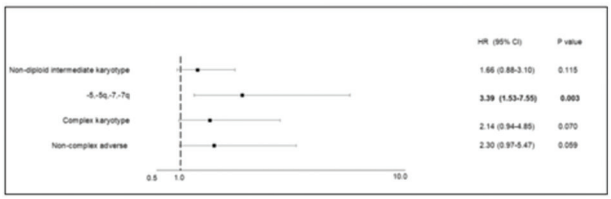
Table 1. Dose Modifications to Manage Cytopenia

Timing	Efficacy Assessment	Event	Action
After Cycle 1	CRi or MLFS at end of Cycle 1	Incomplete count recovery	**Delay upcoming cycle** • Ven/Pbo and LDAC interruption from Day 29 until ANC ≥500/μL and platelet count ≥25×10^3/μL up to 21 days[a] • Ven/Pbo and LDAC resumed on the same day after the interruption
After Cycle 2 and subsequent cycles	CR/CRi/MLFS at end of Cycle 1 or subsequent cycle	New Grade 4 neutropenia or thrombocytopenia lasting >1 week[b]	**Delay upcoming cycle** • Ven/Pbo and LDAC interruption once cycle completed and until ANC ≥500/μL and platelet count ≥25×10^3/μL (unless medically necessary to interrupt drug within cycle) • Ven/Pbo and LDAC resumed on the same day after the interruption
	CR/CRi/MLFS at end of Cycle 2 or subsequent cycle	Persistent cytopenia[c]	**Reduce Ven/Pbo duration or dose** • Ven/Pbo and LDAC interruption once cycle completed • The next treatment cycle is delayed until ANC ≥500/μL and platelet count ≥25×10^3/μL up to 21 days[a] • Dose reduction guidelines were followed in the next treatment cycle: ○ 1st reduction: Ven/Pbo 600 mg administered for 21/28 days for subsequent cycles ○ 2nd reduction: Ven/Pbo 600 mg administered for 14/28 days for subsequent cycles ○ 3rd reduction: Ven/Pbo 400 mg administered for 14/28 days for subsequent cycles • Ven/Pbo and LDAC resumed on the same day after the interruption

[a]If no recovery by Day 21, a discussion between the investigator and the AbbVie medical director was required.
[b]Unless due to underlying disease (eg, relapse).
[c]Cytopenias that occur after Day 28 of a cycle (ie, during Cycle 2 and beyond).
ANC, absolute neutrophil count; CR, complete remission; CRi, complete remission with incomplete count recovery; LDAC, low-dose cytarabine; MLFS, morphologic leukemia-free state; Pbo, placebo; Ven, venetoclax.

Summary/Conclusion: In this study, bone marrow blast clearance for responding pts at the end of Cycle 1 was higher among pts who received Ven+LDAC (74%) vs Pbo+LDAC (33%). Although postremission cytopenia and dose modifications were more frequent with Ven+LDAC, cytopenia was successfully managed with dose modifications, representing an important practice consideration in helping pts to prolong disease control.

EP440 PROGNOSTIC IMPACT OF CONVENTIONAL CYTOGENETICS IN ACUTE MYELOID LEUKEMIA (AML) TREATED WITH DECITABINE AND VENETOCLAX (DEC10-VEN)



S. Venugopal [1,*], A. maiti [1], C. DiNardo [1], W. Qiao [2], J. Ning [2], S. Loghavi [3], N. Daver [1], T. Kadia [1], C. Rausch [4], Y. Alvarado [1], M. Ohanian [1], K. Sasaki [1], N. J. Short [1], K. Takahashi [1], M. Yilmaz [1], F. Ravandi [1], H. Kantarjian [1], M. Konopleva [1]

[1]Leukemia, [2]Biostatistics, [3]Hematopathology, [4]Pharmacy, The University of Texas, MD Anderson Cancer Center, Houston, United States

Background: Cytogenetic risk (CGR) is an important prognostic factor in AML, but its role is less established for VEN based lower intensity therapy.
Aims: To determine the prognostic impact of CGR in pts treated with DEC10-VEN (NCT03404193)
Methods: Older pts with newly diagnosed (ND) (>60 years) and adult pts >18 years with secondary AML (sAML) with or without prior therapy, and relapsed/refractory (R/R) AML, with ECOG performance status <3 without prior BCL-2 inhibitor exposure were enrolled. Patients received 10-day decitabine at 20 mg/m2/day for induction followed by 5-days for consolidation. VEN dose was 400 mg PO daily or equivalent. Cytogenetic subgroups, response and outcomes were per ELN2017 criteria. Written informed consent was obtained from all pts.
Results: We included 179 pts including ND (N=74), untreated sAML (N=16), treated sAML (N=27), and R/R AML (N=62). The median age was 71 yrs (range 59-74 yrs). Overall response rate was 74% in the entire cohort, and negative MRD by flow cytometry was attained in 69 (64%) of 108 responding pts. In the treatment naïve cohort: the CR/CRi was 88% in diploid, 92% in non-diploid intermediate, 67% with abnormalities of chr 5,7,17, 66% in complex, and 66% in non-complex karyotype abnormalities and 63%,73%,11%,22%,26% CR in the pretreated cohort. On multivariable analysis: compared to diploid CG, pts with complex (OR 0.17; 95% CI 0.06,0.48; P <.001) and non-complex adverse (OR 0.07; 95% CI 0.01, 0.76; P=.028) groups are significantly less likely to achieve CR, and patients harboring Chr 5,7,17 abnormalities were significantly less likely to achieve CR/CRi (OR 0.17; 95% CI 0.05,0.65; P=.009), and at increased chance of death (HR 3.39; 95% CI 1.53, 7.55; P=.003). In the treatment naïve cohort, the median OS was 29.6 months (95% CI 0.6 to 3.7 mo) in diploid, 19.4 mo (95% CI 0.3 to 1.6 mo) in non-diploid intermediate;9.3 mo in in Chr 5,7,17 subgroup,6.9 mo in complex and 17.1 mo in the non-complex adverse subgroup. In the previously treated cohort, the median OS was 13.7 mo (95% CI 0.6 to 2.7 mo) with diploid,11.1 mo (95% CI 0.4 to 1.8 mo) in

non-diploid intermediate (95% CI 0.4 to 1.8 mo),7.1 mo in Chr 5,7,17 subgroup, 4.9 mo in complex, and 6.8 mo in non-complex adverse group. Achievement of complete cytogenetic response (CCyR) was an independent predictor of improved OS compared to those who did not achieve CCyR (mOS 16.2 vs. 8.0 mo, HR 0.4, 95% CI 0.2, 0.9, p=.01).

Patient characteristics	Treatment-naïve patients		Previously treated patients	
	Newly Diagnosed AML (N=74)	Untreated Secondary AML (N=16)	Treated Secondary AML (N=27)	Relapsed or Refractory AML (N=62)
Age, years	74 (63-86)	72 (64-89)	70 (49-84)	59 (18-85)
ELN 2017 cytogenetic risk				
Diploid	24 (32)	3 (19)	8 (30)	14 (23)
Others	18 (24)	5 (31)	6 (22)	23 (37)
(-5, -5q, -7, -17)	7 (10)	2 (13)	5 (19)	7 (15)
Complex	21 (28)	6 (38)	5 (19)	13 (21)
Other adverse	3 (4)	0	1 (4)	4 (6)
ORR	65 (88)	13 (81)	18 (67)	36 (79)
CR/CRi	45 (61)/15(20)	7 (44)/ 4 (25)	7 (26)/ 5 (19)	14 (23)/ 11 (18)
MRD neg by FCM	37/60 (62)	5/11 (45)	9/12 (75)	18/25 (72)
CCyR (in other than diploid)	25/36 (51)	5/10 (50)	4/8 (50)	13/23 (57)

Summary/Conclusion: CGR remain highly prognostic for response and survival, with CCyR conferring significant survival benefit in pts with AML receiving DEC10-VEN.

EP441 OUTCOMES IN GILTERITINIB-TREATED FLT3-MUTATED R/R AML PATIENTS WHO UNDERWENT TRANSPLANTATION

Y. Maeda [1], N. Hosono [2], H. Yokoyama [3], M. Onozawa [4], S. Chiba [5], Y. Kanda [6], A. E. Perl [7,*], N. Hasabou [8], Q. Lu [8], R. Tiu [8], M. Kusano [9]

[1]Okayama University Hospital, Okoyama, [2]University of Fukui, Fukui, [3]Tohoku University Graduate School, Sendai, [4]Hokkaido University, Hokkaido, [5]University of Tsukuba, Tsukuba, [6]Jichi Medical University Saitama Medical Center, Saitama, Japan, [7]Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA, [8]Astellas Pharma, Inc., Northbrook, IL, United States, [9]Astellas Pharma, Inc., Tokyo, Japan

Background: Gilteritinib is an oral FLT3 inhibitor approved for patients with *FLT3*-mutated (*FLT3*$^{mut+}$) relapsed or refractory (R/R) acute myeloid leukemia (AML) based on findings from the phase 3 ADMIRAL trial, which demonstrated the superiority of gilteritinib to salvage chemotherapy in this patient population.
Aims: To evaluate response and safety outcomes in patients with *FLT3*$^{mut+}$ R/R AML treated with gilteritinib who underwent hematopoietic stem cell transplantation (HSCT) during the ADMIRAL trial.
Methods: Outcomes were evaluated for patients with *FLT3*$^{mut+}$ R/R AML treated with gilteritinib who underwent HSCT during the phase 3 ADMIRAL trial and were without relapse for 60 days after HSCT.
Results: Of the 63 *FLT3*$^{mut+}$ R/R AML patients treated with gilteritinib who underwent HSCT during the trial, 51 were without relapse for 60 days after transplantation. Of these 51 patients, 35 (69%) resumed gilteritinib therapy post-HSCT after a median of 1.9 months. Median gilteritinib exposures in patients who resumed gilteritinib were 3.0 months pre-HSCT and 6.4 months post-HSCT, respectively. With a median follow-up of 12.4 months, patients who resumed gilteritinib had longer median overall survival than patients who did not (16.2 vs 8.4 months; hazard ratio for death: 0.387; 95% CI: 0.164, 0.915). In patients who resumed gilteritinib, pre-HSCT rates of complete remission (CR), composite CR, and CR with full or partial hematologic recovery were 11%, 71%, and 31%, respectively. Common adverse events during the post-HSCT period in patients who resumed gilteritinib were increased alanine aminotransferase (46%) and pyrexia (37%); common grade ≥3 adverse events were thrombocytopenia and lung infection (both 14%). Fatal adverse events included cardiac arrest, acute graft-versus-host disease in the intestine, pneumothorax, and pulmonary embolism (all n=1).
Summary/Conclusion: Overall, patients with *FLT3*$^{mut+}$ R/R AML who resumed gilteritinib post-HSCT had high response rates prior to HSCT and longer overall survival than patients who did not resume gilteritinib therapy. No new safety signals during the post-HSCT period were identified in patients who resumed gilteritinib therapy.

EP442 PRELIMINARY RESULTS OF V-FAST, A PHASE 1B MASTER TRIAL TO INVESTIGATE CPX-351 COMBINED WITH TARGETED AGENTS IN NEWLY DIAGNOSED AML

V. Pullarkat [1,*], M. Levis [2], G. Mannis [3], S. A. Strickland [4], T. L. Lin [5], S. Faderl [6], D. Chakravarthy [6], V. Chandrasekaran [7], R. S. Cheung [6], H. P. Erba [8]

[1]City of Hope Medical Center, Duarte, CA, [2]Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD, [3]Stanford University Medical Center, Palo Alto, CA, [4]Vanderbilt-Ingram Cancer Center, Nashville, TN, [5]University of Kansas Medical Center, Kansas City, KS, [6]Jazz Pharmaceuticals, Palo Alto, CA, [7]Jazz Pharmaceuticals, Philadelphia, PA, [8]Duke University School of Medicine, Durham, NC, United States

Background: CPX-351 (EU: Vyxeos® Liposomal; US: Vyxeos®), a dual-drug liposomal encapsulation of daunorubicin and cytarabine in a synergistic 1:5 molar drug ratio, is approved by the EMA and US FDA for the treatment of adults with newly diagnosed therapy-related AML (t-AML) or AML with myelodysplasia-related changes. Preclinical data suggest CPX-351 may exert synergistic activity when combined with agents such as the BCL-2 inhibitor venetoclax or FLT3 inhibitor midostaurin.
Aims: The objective of the V-FAST study is to evaluate the safety and establish the recommended phase 2 dose (RP2D) of CPX-351 combined with other agents for the treatment of adults with previously untreated AML.
Methods: V-FAST (*V*yxeos – *F*irst Phase *A*ssessment With *T*argeted Agents) is an open-label, multicenter, phase 1b master trial (NCT04075747) to evaluate CPX-351 in combination with targeted agents in patients aged 18 to 75 years with untreated AML who are fit for intensive chemotherapy. The study includes a dose-exploration phase (3 + 3 design) and subsequent expansion phase. Patients received CPX-351 (dose level 1 for first induction [DL1]: 100 units/m^2 on Days 1, 3, and 5) plus venetoclax (Arm A; DL1: 400 mg on Days 1 to 14), midostaurin (Arm B; DL1: 50 mg BID on Days 8 to 21), or the IDH2 inhibitor enasidenib (Arm C; DL1: 100 mg on Days 8 to 28) based on mutation testing.
Results: Among 21 patients with available data enrolled by 06 November 2020 (24 pts enrolled total; data cut-off: 19 January 2021), the median age was 54 years (range: 35, 69). In Arm A (n=17), 11 (65%) patients had *de novo* AML, 5 (29%) had an antecedent hematologic disorder (2 [12%] had myelofibrosis), and 2 (12%) had t-AML; 12 (71%) had adverse-risk AML; and 6 (35%) had mutated *TP53*. In Arms B (n=3) and C (n=1), all patients had intermediate-risk *de novo* AML. DL1 was the RP2D in Arms A and B; the RP2D in Arm C is still under investigation. In Arm A, 1 of 6 patients in the dose-exploration phase had 2 dose-limiting toxicities (DLTs) of grade 4 neutropenia and thrombocytopenia that extended beyond 49 days; no DLTs have occurred for Arms B and C. The combinations exhibited manageable safety profiles (**Table**). Of patients with available response data, complete remission (CR) or CR with incomplete platelet or neutrophil recovery was achieved by 6 of 14 (43%) patients in Arm A, including 4 (29%) with CR. All patientts in Arms B and C achieved CR.

n (%)	Arm A CPX-351 + venetoclax (n=17)	Arm B CPX-351 + midostaurin (n=3)	Arm C CPX-351 + enasidenib (n=1)
Any TEAE	17 (100)	3 (100)	1 (100)
Thrombocytopenia	11 (65)	2 (67)	0
Febrile neutropenia	10 (59)	2 (67)	1 (100)
Nausea	9 (53)	2 (67)	1 (100)
Neutropenia	9 (53)	2 (67)	0
Constipation	9 (53)	1 (33)	0
Headache	7 (41)	3 (100)	0
Any grade ≥3 TEAE	15 (88)	3 (100)	1 (100)
Thrombocytopenia	11 (65)	2 (67)	0
Febrile neutropenia	10 (59)	2 (67)	1 (100)
Neutropenia	9 (53)	2 (67)	0
Early mortality			
Day 30	0	0	0
Day 60	2 (12)	0	0

TEAE, treatment-emergent adverse event.
TEAEs reported in ≥40% of patients overall.

Summary/Conclusion: These preliminary results suggest CPX-351 can be combined with venetoclax or midostaurin with manageable toxicities in newly diagnosed AML patients, with DL1 determined to be the RP2D. The study is ongoing and actively enrolling patients; updated results will be presented at the meeting.

EP443 PHASE 1 FIRST-IN-HUMAN STUDY OF IRREVERSIBLE FLT3 INHIBITOR FF-10101-01 IN RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA

M. J. Levis [1,*], C. C. Smith [2], A. E. Perl [3], G. J. Schiller [4], A. T. Fathi [5], G. J. Roboz [6], E. S. Wang [7], J. K. Altman [8], M. Ando [9], T. Suzuki [10], R. A. Subach [10], G. Maier [10], T. Madden [10], M. Johansen [10], K. Cheung [10], M. R. Kurman [10]

[1]The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, [2]University of California, San Francisco, San Francisco, [3]University of Pennsylvania, Philadelphia, [4]University of California, Los Angeles, [5]Massachusetts General Hospital, Harvard Medical School, Boston, [6]Weill Cornell Medicine and The New York Presbyterian Hospital, New York, [7]Roswell Park Comprehensive Cancer Institute, Buffalo, [8]Northwestern University, Chicago, United States, [9]FUJIFILM Corporation, Tokyo, Japan, [10]FUJIFILM Pharmaceuticals U.S.A., Inc., Cambridge, United States

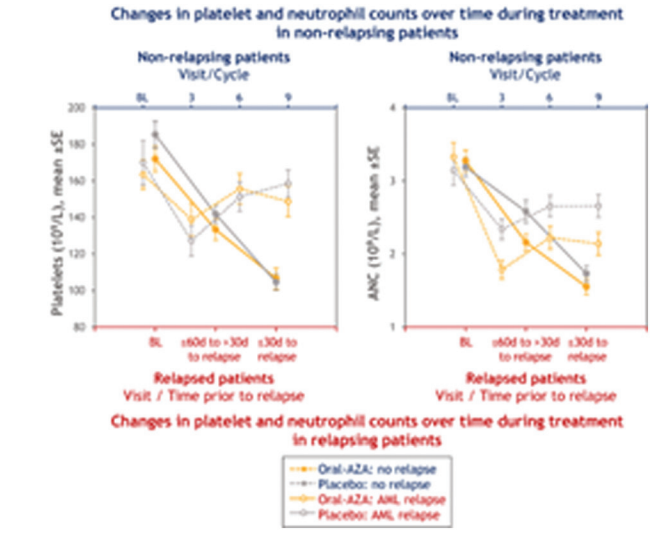
Background: FF-10101-01 is a selective and irreversible FMS-like tyrosine kinase 3 (FLT3) inhibitor with potent *in vitro* activity against *FLT3*-mutated AML. FF-10101-01 is highly active against *FLT3* internal tandem duplication (ITD) mutations associated with high relapse and low survival/remission rates, as well as resistance-conferring D835 and F691 tyrosine kinase domain (TKD) and non-canonical FLT3 activating mutations.
Aims: Here we report on a Phase 1 dose escalation trial examining the safety, efficacy, pharmacokinetics, and pharmacodynamics of FF-10101-01 in patients (pts) with relapsed/refractory primary or secondary AML.
Methods: To determine the recommended Phase 2 dose, pts with or without a FLT3 mutation received FF-10101-01 orally once (QD) or twice (BID) daily until unacceptable toxicity was observed or pts had no further clinical benefit (1 cycle = 28 days). Composite complete remission (CRc) and partial remission (PR) rates were assessed. Inhibition of FLT3 phosphorylation was evaluated using a plasma inhibitory activity assay and was correlated with associated FF-10101-01 exposure.
Results: Fifty-two pts [median age 61 (range, 21-84); 52% female; FLT3: ITD [22 (42%)], TKD [5 (10%)], ITD+TKD [1 (2%)], Wt [24 (46%)] received continuous dosing of FF-10101-01 at 10 - 225 mg QD or 50 - 100 mg BID. Median number of prior therapies was 3 (range, 0-6) and the majority [23/28 (82%)] of pts with known FLT3 mutations had received prior FLT3 inhibitors. The median duration on study was 5.7 (range, 0.1-36) weeks. FF-10101-01 was generally well-tolerated up to total daily doses of 150 mg. The most common treatment related adverse events included nausea [n=18 (35%)], diarrhea [14 (27%), 2 Grade (Gr) 3/4], elevations in creatine kinase [CK; 14 (27%), 4 Gr 3/4], vomiting [10 (19%)] and increased AST [10 (19%), 2 Gr 3]. Grade 3/4 differentiation syndrome (n=4, 8%) was observed at 75 - 150 mg/day. Dose-limiting cardiac toxicity (heart failure with reduced ejection fraction; Gr 3 increased troponin/CK) was observed at total daily doses ≥200 mg. The CRc rate was 13% (4/30 pts evaluable for response): 1 CR at 75 mg BID (FLT3-ITD); 1 CRp at 100 mg BID (Wt-FLT3); and 2 CRi's at 50 mg BID, one that previously progressed on gilteritinib. The median time to overall response was ~13.3 weeks. Four pts achieved a PR (≥50% decrease in BM blasts to 5 - 25% abnormal cells) at total daily doses of 50 - 150 mg; 2 had ITD mutations, and all had received prior FLT3 kinase inhibitors. At ≥75 mg BID, trough plasma concentrations were >90 ng/ml and associated with >90% p-FLT3 inhibition maintained over the dosing interval.
Summary/Conclusion: The FF-10101-01 FLT3 inhibitor has shown activity in pts with refractory/relapsed AML, including those with activating FLT3-ITD mutations resistant to gilteritinib and other FLT3 kinase inhibitors. Doses of 50-75 mg BID were well tolerated and resulted in sustained FLT3 inhibition.

EP444 RELATIONSHIP BETWEEN VENETOCLAX EXPOSURE AND POST-REMISSION CYTOPENIAS IN SUBJECTS WITH TREATMENT-NAÏVE ACUTE MYELOID LEUKEMIA TREATED WITH VENETOCLAX PLUS AZACITIDINE IN THE VIALE-A STUDY

D. Brackman [1,*], R. Menon [1], D. Miles [2], A. H. Salem [1], Y. Duan [1], J. Potluri [1], B. Jonas [3], K. Pratz [4], M. Montez [2], M. Werner [1], J. Zha [1]

[1]AbbVie Inc., North Chicago, IL, [2]Genentech Inc., South San Francisco, CA, [3]Department of Internal Medicine, Division of Hematology and Oncology, University of California Davis, Sacramento, CA, [4]Division of Hematology and Oncology, Hospital of the University of Pennsylvania, Philadelphia, PA, United States

Background: Venetoclax (VEN) is an orally bioavailable selective BCL-2 inhibitor that promotes apoptosis in cancer cells. VIALE-A, a placebo-controlled randomized Phase 3 trial comparing VEN in combination with azacitidine (VEN+AZA) to placebo in combination with azacitidine (PBO+AZA), showed superior efficacy with VEN combination on key endpoints such as overall survival and overall response rates in subjects with treatment-naïve acute myeloid leukemia (AML) who were ineligible for intensive chemotherapy. Hematologic adverse events including anemia, neutropenia, febrile neutropenia, and thrombocytopenia are common in AML patients due to their underlying disease. In VIALE-A, subjects taking VEN+AZA had higher rates of neutropenia and febrile neutropenia than subjects taking PBO+AZA (DiNardo et al. *N Engl J Med*. 2020).
Aims: Here, we aimed to describe the relationship between VEN exposure, overall survival, and post-remission cytopenias, as defined by Grade 4 neutropenia or thrombocytopenia lasting ≥7 days, in subjects who achieved complete remission (CR) or complete remission with partial hematological recovery (CRh) in the VIALE-A study.
Methods: Data from 185 subjects treated with VEN+AZA and 33 subjects treated with PBO + AZA who achieved CR or CRh (blast clearance with neutrophil count > 0.5×10^3/μL and platelet count > 0.5×10^5/μL) in the VIALE-A study were included in the analysis. The VIALE-A protocol recommended dose interruptions and reduced VEN dosing duration per cycle for management of cytopenias following blast clearance. Therefore, VEN exposure was calculated as the average plasma concentration (C_{avg}) from blast clearance to the event of interest to account for these dosing modifications. Logistic regression and Cox proportional-hazards models were used to characterize the relationships between venetoclax exposure (C_{avg}) and frequency or timing of cytopenias. Cox proportional-hazards models were also used to characterize the relationships between venetoclax exposure (C_{avg}) and overall survival in subgroups based on dosing duration.
Results: Subjects taking VEN+AZA had a range of 0 to 15 post-remission cytopenias lasting ≥7 days in VIALE-A. Within subjects experiencing post-remission cytopenias on VEN+AZA, there was no apparent relationship between VEN exposure and frequency of post-remission cytopenias. However, subjects with no post-remission cytopenias on VEN+AZA had significantly ($p < 0.01$) lower VEN exposure than those with one or more post-remission cytopenias. Consistently, higher VEN exposure was associated ($p < 0.01$) with a shorter time to first episode of post-remission cytopenia. There were no apparent relationships between VEN exposure and overall survival in VEN+AZA subjects who achieved CR/CRh and experienced post-remission cytopenias, including in a subset of subjects who switched to 21-day dosing in 28-day cycles following the first episode of post-remission cytopenia. These results indicate that lower exposures associated with VEN dose reductions to manage cytopenias in patients who achieved a CR/CRh did not affect OS.
Summary/Conclusion: For treatment-naïve AML patients who achieve CR/CRh on VEN+AZA, VEN exposure may be a contributing factor to post-remission cytopenias.



EP445 HEMATOLOGIC ADVERSE EVENTS AND MANAGEMENT STRATEGIES FOR PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) IN FIRST REMISSION RECEIVING ORAL AZACITIDINE (ORAL-AZA) IN THE PHASE 3 QUAZAR AML-001 TRIAL

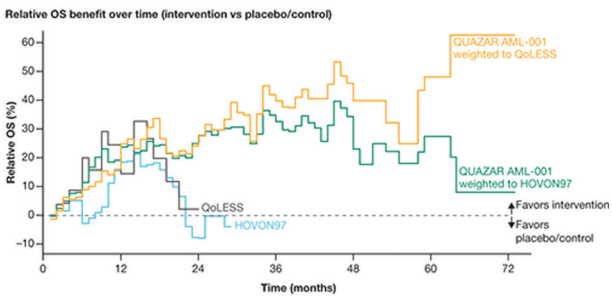
Background: Most older patients (pts) who attain AML remission with intensive chemotherapy (IC) eventually relapse. Oral-AZA is a hypomethylating agent (HMA) that allows for extended dosing schedules to sustain drug activity. In the phase 3 QUAZAR AML-001 trial, Oral-AZA significantly prolonged overall and relapse-free survival (OS/RFS) *vs* placebo (PBO) in older pts with AML in first remission after IC. Neutropenia (N), thrombocytopenia (T), and anemia (A) were the most common hematologic adverse events (AEs) in both treatment (Tx) arms, occurring more often with Oral-AZA *vs* PBO. Cytopenias are a known side effect of HMAs, especially during early Tx, but may also portend AML relapse. Thus, it can be challenging to discern whether cytopenias during Oral-AZA Tx are related to Tx or to disease progression.
Aims: Assess the rate of cytopenias over time, via AE reporting and laboratory parameters, for pts receiving Oral-AZA in the QUAZAR AML-001 study, and determine whether cytopenias presaged impending AML relapse.
Methods: Pts were aged ≥55 yrs, had intermediate- or poor-risk cytogenetics and ECOG PS score ≤3, and were not candidates for transplant. Within 4 months (mo) of achieving first complete remission (CR) or CR with incomplete blood count recovery (CRi) after induction ± consolidation, pts were randomized 1:1 to Oral-AZA 300 mg or PBO QD for 14d/28d Tx cycles. Pts who received ≥1 study drug dose were monitored for AEs from first dose until 28d after last dose.
In these *post hoc* analyses, we report hematology parameters (ANC, platelets, hemoglobin [Hgb]) for pts who relapsed on-study at baseline (BL), at 1–2 mo (≤60 to >30d) before relapse, and during the 1 mo (≤30d) before relapse, inclusive of relapse date. For context, we also assessed these parameters at BL and at cycles 3, 6, and 9 for pts who did not relapse on-study.
Results: 469 pts (Oral-AZA 236, PBO 233) were followed for safety. Median age was 68 yrs (range 55–86). Pts received a median of 12 (range 1-80) Oral-AZA Tx cycles and 6 (1-73) PBO cycles.
Rates of any grade N, T, and A in the Oral-AZA arm were 44%, 33%, and 20%, respectively. At cycles 1–2, 3–4, and 5–6, rates of N in the Oral-AZA arm were 22%, 20%, and 18%, respectively; of T were 16%, 9%, and 6%; and of A were 6%, 4%, and 4%. Oral-AZA Tx was interrupted or dose reduced, respectively, in 45% and 12% of 105 pts who experienced N; in 25% and 5% of 79 pts with T; and in 6% and 2% of 48 pts with A. Only 1 pt (1%) discontinued Oral-AZA due to N, T, or A (T). 23% of pts in the Oral-AZA arm (PBO 22%) received RBC transfusions on-study and 19% (PBO 22%) received platelet transfusions. G-CSF use was infrequent: 8 pts (3.4%) in the Oral-AZA arm and 7 pts (3%) in the PBO arm. 154 Oral-AZA pts (65%) and 179 PBO pts (77%) relapsed on-study; median RFS was 10.2 *vs* 4.8 mo, respectively ($P<0.001$). Pts who relapsed showed steep decreases in ANC and platelets (**Figure**) but not Hgb, in the 2 mo before AML relapse. Pts who did not relapse showed initial decreases in platelet counts and ANC, but signs of recovery were evident after cycle 3 (**Figure**).



Summary/Conclusion: Hematologic AEs with Oral-AZA, particularly N, occurred most often during early Tx. N, T, and A were mainly managed with temporary Tx interruptions. Infrequent G-CSF use and rare Tx discontinuation indicate cytopenias were manageable with dosing modifications. Non-relapsing pts showed early decreases in platelets and ANC, with recovery after cycle 3. Relapsing pts showed steep declines in platelets and ANC with clear differences from non-relapsing pts within 30d of relapse.

EP446 COMPARATIVE EFFICACY OF ORAL VERSUS INJECTABLE AZACITIDINE IN PATIENTS WITH AML IN FIRST REMISSION AFTER INTENSIVE CHEMOTHERAPY: AN INDIRECT TREATMENT COMPARISON (SUB-ANALYSIS UPDATE)

C. Chen [1,*], M. Siddiqui [2], R. Gavanji [2], I. La Torre [1], B. Skikne [1,3], H. Cameron [2], T. Disher [2], C. Cameron [2]

[1]Bristol Myers Squibb, Princeton, United States, [2]Eversana, Burlington, Canada, [3]Kansas University Medical Center, Kansas City, United States

Background: Maintenance therapy with oral azacitidine (AZA) significantly improved overall survival (OS) versus placebo in patients (pts) with acute myeloid leukemia (AML) who achieved remission after intensive induction chemotherapy in the phase 3 QUAZAR AML-001 study. Although there are no head-to-head trials comparing oral and injectable AZA, results from a recent indirect treatment comparison (ITC) favored oral AZA (Chen C, et al. ASH 2020); however, ITCs do not fully account for potentially effect-modifying variables between trials.
Aims: To compare the relative efficacy of maintenance therapy with oral versus injectable AZA in pts with AML in first remission after chemotherapy.
Methods: Anchored matching-adjusted indirect comparisons (MAICs) for OS were performed by matching individual pt data (IPD) from QUAZAR AML-001 (oral AZA vs placebo) to summary-level data from the comparator trials, HOVON97 (SC AZA vs control) and QoLESS (SC/IV AZA vs control). The QUAZAR AML-001 population was adjusted to comparators based on age, sex, AML disease stage, and cytogenetic risk; additionally, adjustment to HOVON97 included platelet count, response status at baseline, and ECOG performance status, and adjustment to QoLESS included minimal residual disease. After matching and adjustment, relative OS benefit was calculated within each trial as the difference in the Kaplan–Meier (KM) estimates of OS between the intervention and placebo/control arms, divided by the KM estimate of OS for placebo/control. The difference in restricted mean survival time (RMST) between intervention and placebo/control was estimated with a parametric survival model at 1, 2, 3, 4, and 5 years.
Results: Of 472 pts in QUAZAR-AML-001, 402 and 328 were included in the analysis populations after matching to HOVON97 (N=116) and QoLESS (N=54), respectively; after adjustment, the effective sample size for the primary analysis population was reduced to 310 and 222 pts, respectively. Matching and adjustment led to small changes in estimates of oral AZA versus placebo/control compared with unweighted analyses. The weighted oral AZA population showed a sustained and numerically higher relative OS benefit through 60 months versus SC AZA and SC/IV AZA (Figure). The relative benefit of injectable AZA versus control observed in the initial 12 months appeared to fade, reaching close to zero around month 20. Difference in the area under the curve (ΔAUC) between the weighted oral AZA populations and placebo/control showed improvement over time in point estimates of mean survival time. RMST from QUAZAR-AML-001 IPD weighted to HOVON97 showed a statistically meaningful improvement compared with placebo/control in mean survival time at 1, 2, 3, 4, and 5 years (ΔAUC: 0.94, 2.43, 3.68, 4.68, and 5.48); a similar effect was observed with QUAZAR-AML-001 IPD weighted to QoLESS (ΔAUC: 0.75, 2.41, 4.18, 5.83, and 7.32), whereas injectable AZA was not associated with significant benefits at any time-point in HOVON97 (ΔAUC: 0.46, 0.95, 1.17, 1.18, and 1.08) or QoLESS (ΔAUC: 1.12, 2.01, 2.11, 1.70, and 0.96). All scenario analyses conducted supported the results of the primary analyses.

Summary/Conclusion: Adjustment via MAIC resulted in consistent conclusions to the previously reported unadjusted analyses of oral versus injectable AZA. Weighted analysis of oral versus injectable AZA continued to show early and sustained relative OS benefits with oral AZA. Additionally, weighted estimates of oral AZA showed statistically meaningful improvement in mean survival time versus placebo/control, and numerical superiority to injectable AZA.

EP447 MIDOSTAURIN PLUS INTENSIVE CHEMOTHERAPY VERSUS INTENSIVE CHEMOTHERAPY IN FLT3 MUTATED ACUTE MYELOID LEUKEMIA. A RWE STUDY

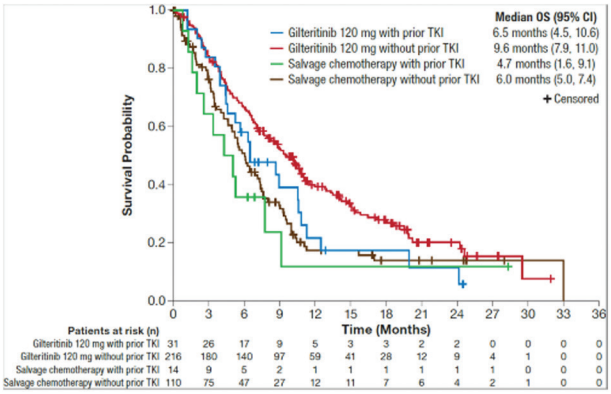
Background: Introduction. Midostaurin has been approved by EMA and FDA in combination with IC for FLT3-mutated AML based on improved overall survival noted in the RATIFY phase 3 trial (Stone et al, N Engl J Med 2017) The experience with midostaurin in day to day practice is limited.
Aims: Aim: The aim of this study is to analyze effectiveness and tolerability of midostaurin plus intensive chemotherapy (midos+IC) vs intensive chemotherapy alone (IC) as first lines in AML FLT3 positive patients and to identify risk factors.
Methods: Methods: We carried out the analysis on previously untreated AML FLT3 mutated patients included in PETHEMA AML epidemiological registry (NCT02607059). Selection criteria for the study were as follows: Age >18, diagnosis of AML FLT3 positive (ITD and TKD) under WHO criteria, treated with midos+IC or IC (IC defined as 7+3 induction and HiDAC or intermediate dose AraC consolidations) during the period 01/01/2010 to 01/03/2020, patients who died before day 7 of treatment were excluded. Response were assessed using the ELN-2010 criteria, toxicity by the CTCAE v4.0 scale, OS by Kaplan-Meier and early mortality as mortality within the first 8 weeks (M8wks).
Results: Results: A total of 385 of previously untreated AML FLT3 positive patients were analyzed (54 treated with Midos+IC and 331 with IC), median age 52yrs (20-70) and 53yrs (18-70), ECOG ≥2: 18.5% and 12.7% respectively. Baseline characteristics are summarized in table 1. Antifungal triazole prophylaxis was the standard in both cohorts. Early mortality M8wks was 3.7% and 6.6% and complete response rate (CR after 1 or 2 Inductions) 86% vs 66% (p 0.005) for midos+IC and IC respectively.
Overall survival is significantly longer in the mido+IC group than in the IC group (not reached vs 19 months, p=0.022), 24mOS 79.2% vs 54.2% (p0.026).
We observed a trend of benefit in all the following subgroups, a: FLT3 ITD low with NPM1 mut, b: FLT3 ITD low with NPM1 wt plus FLT3 ITD high with NPM1 mut; and c: FLT3 high with NPM1 wt. In our study we observe in midos+IC cohort a higher rate of patients consolidated in CR1 with alloSCT and a significantly longer OS for these patients (42.5% vs 28.7%) and (not reached vs 44.7 months).

Total 385 p	Midos+IC (54)	IC (331)
Age median	52 (20-70)	53 (18-70)
M/F	24/30	139/192
ECOG ?2	18.5%	12.7%
FLT3 ratio available	28p	251p
FLT3 ITD low with NPM1 mut	9 (32%)	68 (27%)
FLT3 ITD low with NPM1 wt	11 (39.2%)	134 (53.3%)
FLT3 ITD high with NPM1 mut		
FLT3 high with NPM1 wt	7 (25%)	40 (16%)
alloSCT consolidation in CR1	42.5%	28.7%

Summary/Conclusion: Conclusions: The results of this study confirm in a real-world setting that midostaurin associated with IC improve the outcome of AML FLT3 positive patient compared versus IC alone.

EP448 CLINICAL OUTCOMES IN PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA TREATED WITH GILTERITINIB WHO RECEIVED PRIOR MIDOSTAURIN OR SORAFENIB



A. E. Perl [1,*], J. K. Altman [2], N. Hosono [3], P. Montesinos [4], N. Podoltsev [5], G. Martinelli [6], C. C. Smith [7], M. J. Levis [8], C. Röllig [9], M. Groß-Langenhoff [10], N. Hasabou [11], Q. Lu [11], R. V. Tiu [11]

[1]Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA, [2]Robert H. Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, IL, United States, [3]University of Fukui, Fukui, Japan, [4]Hospital Universitario y Politécnico La Fe, Valencia, Spain, [5]Yale School of Medicine, New Haven, CT, United States, [6]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRST IRCCS, Meldola, Italy, [7]University of California-San Francisco, San Francisco, CA, [8]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD, United States, [9]Universitätsklinikum Carl Gustav Carus, Dresden, [10]Astellas Pharma GmbH, Munich, Germany, [11]Astellas Pharma US, Northbrook, IL, United States

Background: Gilteritinib is a FLT3 inhibitor with demonstrated efficacy and safety in patients with *FLT3*-mutated relapsed or refractory (R/R) AML. The phase 1/2 CHRYSALIS trial demonstrated the safety and antileukemic activity of gilteritinib in a *FLT3*-mutation–enriched R/R AML population (Perl AE, et al. *Lancet Oncol.* 2017). The phase 3 ADMIRAL trial demonstrated the superiority of gilteritinib to salvage chemotherapy (SC) in *FLT3*-mutated patients based on longer median overall survival (OS) with gilteritinib (9.3 vs 5.6 months; hazard ratio [HR]=0.64 [95% CI: 0.49, 0.83]; *P*<0.001) (Perl AE, et al. *N Engl J Med*. 2019).
Aims: To determine whether prior TKI therapy affected response and survival in these two trials.
Methods: We retrospectively analyzed clinical outcomes in patients with R/R AML previously treated with TKIs midostaurin or sorafenib, before receiving 120- or 200-mg gilteritinib in the CHRYSALIS trial, or before receiving 120-mg gilteritinib in the ADMIRAL trial. Patients randomized to SC in the ADMIRAL trial were also assessed. Patients in the CHRYSALIS trial had received at least one line of prior AML therapy; patients in the ADMIRAL trial received only one line of prior AML therapy.
Results: Of the 145 *FLT3*-mutation–enriched patients who received 120- or 200-mg gilteritinib in the CHRYSALIS trial, 33 (23%; 120 mg, n=15; 200 mg, n=18) had received a prior TKI (all received sorafenib). Baseline characteristics among patients who received (n=33) or did not receive prior TKIs (n=112) were similar. Rates of composite complete

remission (CRc) were similar in patients who received prior TKIs (42%; n=14/33) and in those who did not (43%; n=48/112). Among patients who received prior TKIs, rates of CRc were 53% (n=8/15) in the 120-mg dose group and 33% (n=6/18) in the 200-mg dose group; rates of CRc in patients who did not receive prior TKIs were similar across both the 120- and 200-mg dose groups (44% [n=18/41] and 42% [n=30/71], respectively). Among patients treated with prior TKIs across the 120- or 200-mg dose groups (n=33), most (73%; n=24) had received ≥3 lines of any prior AML therapy.

In the phase 3 ADMIRAL trial, 31 of 247 (13%) R/R *FLT3*-mutated AML patients in the gilteritinib arm and 14 of 124 (11%) patients in the SC arm had received prior TKIs. Demographic and baseline characteristics were well balanced between treatment arms and were also similar between prior TKI–treated (n=45) and non-treated patients (n=326). In the gilteritinib arm, CRc rates were comparable in patients who received (48%; n=15/31) and did not receive prior TKIs (55%; n=119/216); lower CRc rates were observed in the SC arm in both TKI–treated and non-treated groups (21% [n=3/14] and 22% [n=24/110], respectively). Median OS in patients treated with prior TKIs, albeit not statistically significant, remained high in patients treated with gilteritinib compared with those treated with SC (6.5 vs 4.7 months, respectively; HR=0.671 [95% CI: 0.328, 1.376]) (**Figure**). In patients who did not receive prior TKIs, median OS was 9.6 months in the gilteritinib arm and 6.0 months in the SC arm (HR=0.625 [95% CI: 0.474, 0.824]) (**Figure**).

Summary/Conclusion: Patients with R/R AML who received prior TKIs (midostaurin or sorafenib) were able to achieve remission with gilteritinib. High response rates with gilteritinib were observed in heavily pretreated *FLT3*-mutation–enriched patients in the CHRYSALIS trial who received prior TKIs. Higher response rates with gilteritinib than with SC were observed in prior TKI–treated patients with *FLT3* mutations in the ADMIRAL trial.

EP449 CLONAL HEMATOPOIESIS IN PERIPHERAL STEM CELLS AT LEUKAPHERESIS AS PREDICTIVE FACTOR FOR THERAPY-RELATED MYELOID NEOPLASMS AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION

D. Gramegna [1,*], D. Bertoli [2], C. Cattaneo [1], C. Almici [3], R. Daffini [1], A. Re [1], A. Belotti [1], S. Archetti [2], E. Borlenghi [1], M. Sciumè [1], A. Roccaro [4], A. Tucci [1], G. Rossi [1]

[1]Hematology, [2]Clinical Chemistry Laboratory, Diagnostic Department, [3]Laboratory for Stem Cells Manipulation and Cryopreservation, Department of Transfusion Medicine, [4]Clinical Research Development and Phase I Unit, ASST-Spedali Civili, Brescia, Italy

Background: The detection of mutations in genes known to be associated with hematologic malignancies has been termed clonal hematopoiesis (CH). CH detected in cryopreserved cells of patients (pts) undergoing autologous stem-cell transplantation (ASCT) for hematologic neoplasia has been associated with an increased risk of therapy-related myeloid neoplasm (t-MN), but its role in the development of t-MN and the variations of the mutational profile occurring in the single pt between ASCT and t-MN are still partially known.

Aims: The primary objective of this study was the comparison of the mutational profile and of variant allele frequency (VAF) of mutated genes at leukapheresis and at t-MN in ASCT pts who actually developed t-MN. The mutational profile at leukapheresis was also compared with that of matched control ASCT pts, who did not develop t-MN.

Methods: Among the entire cohort of lymphoma and myeloma pts treated with high-dose chemotherapy and ASCT at the Hematology Dpt of Spedali Civili in Brescia between 2001 and 2019, we selected pts who developed t-MN after ASCT and had available backup cryopreserved CD34+ stem cells. Pts who did not experience t-MN, matched for demographic and clinical characteristics, acted as controls. Pre- and post-ASCT samples were sequenced on the Genestudio S5 Prime, using an On-Demand NGS panel designed with Ion Ampliseq Designer software, that included 45 genes known to be associated with either CHIP, myelodysplastic syndrome (MDS) or acute myeloid leukemia (AML).

Results: Out of 1075 lymphoma or myeloma pts undergoing ASCT, 35 developed t-MN (3.3%). Frequency was significantly higher in lymphoma (27/592, 4.6%) than in myeloma (8/483, 1.7%) (p=0.0088). In 19 of them (lymphoma: n. 16; myeloma: n. 3), the mutational profile was assessed both at ASCT and at t-MN (AML: n.8; MDS: n.11). Their median follow up was 6 years (range 2-14). A higher number of mutations of 20 genes was detected at t-MN diagnosis (n. 46 in 16/19 patients; 84%), as compared to ASCT (n. 16 in 11/19 patients; 58%;). Control pts had a significantly lower number of mutations at ASCT (n. 7 in 6/26; 23%) compared to pts developing t-MN (n. 16, in 11/19; 58%; p=0.029); median follow-up of controls was 7 years (range 3-13). Epigenetic regulation, including DNMT3A, and DNA repair gene mutations, specifically PPM1D, were most frequently mutated at ASCT. At t-MN mutations in these genes showed a modest increase and their VAF did not change except in one patient. Conversely, TP53 mutations were the most represented at t-MN (28% of total); they appeared de novo in 8 pts and VAF increased from 14% to 49% in the single pt with mutated TP53 also at ASCT. In addition, mutations in genes of intracellular signaling or encoding transcription factors (e.g. RAS, RUNX1) were also commonly detected at t-MN. They were absent in controls, whose mutations at ASCT also occurred mainly in epigenetic genes.

Summary/Conclusion: These data confirm that CH at ASCT is associated with a higher risk of developing t-MN. They also show that the mutational profile varies markedly between ASCT and t-MN. Epigenetic and DNA repair gene mutations are characteristic at ASCT and do not increase significantly at t-MN; they may represent a marker of genetic instability favoring the development of t-MN. Conversely, mutations of TP53 and transcription factor encoding or intracellular signaling genes appear more strictly associated with the pathogenesis of t-MN and their emergence may be promoted by the high-dose cytotoxic treatments delivered as conditioning regimens before ASCT.

EP450 ALICE MAINTAINS HIGH CLINICAL RESPONSE RATES SUPPORTING THE EFFICACY OF IADADEMSTAT COMBINATION WITH AZACITIDINE IN AML MANAGEMENT

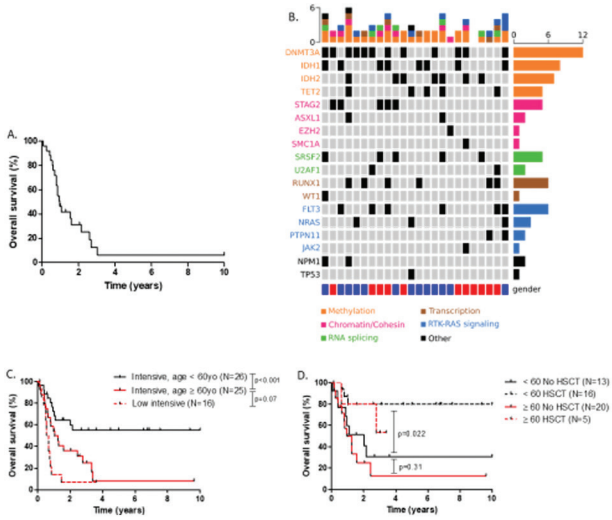
O. Salamero [1,*], T. Somervaille [2], A. Molero [1], E. Acuña [3], J. A. Perez-Simon [4], A. Perez [1], I. Cano [3], R. Rodriguez-Veira [3], S. Gutierrez [5], C. Buesa [5], F. Bosch [1], P. Montesinos [3]

[1]Vall d' Hebron University Hospital, Barcelona, Spain, [2]Cancer Research UK Manchester Institute, The University of Manchester, Manchester, Manchester, United Kingdom, [3]Hospital Universitario La Fe, Valencia, [4]Hospital Virgen del Rocío, Sevilla, [5]Oryzon Genomics, S.A., Cornellà de Llobregat, Spain

Background: Acute Myeloid Leukemia (AML) in elderly unfit patients remains a challenge. Recently approved combinations have improved the treatment of unfit patients. Yet, a significant percentage of patients is refractory or relapse during the first year. Iadademstat (iada) is a first, and best in class LSD1 inhibitor that produces differentiation in leukemic stem cells. In different clinical trials, iada has been administered so far to ~100 oncology patients showing a good safety profile. Based on iada's ADME profile and low dosing regimen, a low DDI risk is anticipated. This makes iada suitable for drug combinations with hypomethylating agents or targeted therapies and may offer additional therapeutic options for this patient population.

Aims: This is an update of the ongoing ALICE study (EudraCT 2018-000482-36).

Methods: ALICE is a Phase IIa study to assess the safety, tolerability and dose finding of iada in combination with azacitidine for the treatment of elderly AML patients. Secondary endpoints investigate anti-leukemic activity including overall response rate (ORR), time to response (TTR) and duration of responses (DOR). Additional assessments include hematological improvement, overall survival and PK/PD measures. ALICE includes adult patients diagnosed with AML (as per WHO classification),



who have not received prior treatment for AML other than hydroxyurea and are ineligible for intensive chemotherapy (or refuse this treatment option).
Results: At EHA 2020, ALICE data from 18 patients (median age 78 y) were reported. Main safety events included 96 grade 3-4 AEs related to the study drugs in 12 patients, most of them neutropenia and thrombocytopenia. Only 3 non-hematological AEs were observed, asthenia and dysgeusia in one patient and weight reduction in another patient. Among the 38 SAEs reported, only one was considered related to iadademstat, a differentiation syndrome (Grade 3) and another, a fatal intracranial hemorrhage on C1D15 was considered as possibly related to the combination therapy. Besides the hematological impact, the combination was safe and well tolerated by older AML patients. From the 18 patients recruited in 2020, 13 had at least 1 bone marrow evaluation (evaluable as per protocol). Ten (77%) achieved an objective response (4 CR, 2 CRi and 4 PRs) with a mean TTR of 37 days. The longest response in CR at that time was 488 days. Those patients with longer treated periods had also improved or overcome their dependency on blood transfusions.
By the time this abstract is written, 24 patients have been included (median age 77) and 18 are evaluable; ORR has increased to 87%, TTR is now 35 days and median DOR is 335 days, with 5 patients having a response longer than one year and one longer than 2 years. 4 out of the current 8 durable responses (longer than 6 months) also show transfusion independence. The safety findings continue to support an acceptable tolerability profile of the combination, with most of the adverse effects being transient or amenable. At EHA 2021, an update on the trial results will be provided, with all patients recruited by the cut-off of May 2021.
Summary/Conclusion: ALICE data sets confirm that the combination of iadademstat with azacitidine in unfit AML patients has a manageable safety and tolerability profile. ALICE maintains encouraging response ratios as the trial progresses. Current efficacy data support iadademstat as a suitable candidate for combination therapies in AML.

EP451 ALLOGENIC STEM CELL TRANSPLANTATION ABROGATES NEGATIVE IMPACT ON OUTCOME OF AML PATIENTS WITH KMT2A PARTIAL TANDEM DUPLICATION

G. Antherieu [1,*], A. Bidet [2], S. Huet [3], S. Hayette [3], M. Migeon [2], L. Boureau [2], P. Sujobert [3], X. Thomas [1], H. Ghesquières [1], A. Pigneux [4], M. Heiblig [1]

[1]Department of Hematology, Hospices Civils de Lyon, Pierre-Bénite, [2]Laboratoire d'Hématologie Biologique, Centre Hospitalo-Universitaire CHU Bordeaux, Bordeaux, [3]Department of Molecular Hematology, Hospices Civils de Lyon, Pierre-Bénite, [4]Department of Hematology, Centre Hospitalier Universitaire de Bordeaux, Bordeaux, France

Background: KMT2A partial tandem duplication (PTD) has been reported in 3–10% of adult AML cases and is mutually exclusive of 11q23 rearrangements. Clinical implications of KMT2A-PTD on outcome remain unclear with conflicting results in the literature. As a consequence, if KMT2A-rearranged AML are considered of unfavorable prognosis within ELN 2017 classification, KMT2A-PTD is not included in current AML prognostic classifications, and so, not considered as an independent factor for hematopoietic stem cell transplantation (HSCT) allocation.
Aims: In this study, we aimed to evaluate KMT2A-PTD impact on outcome in newly diagnosed AML patients according to treatment intensity and HSCT.
Methods: Seventy-nine patients treated in Lyon and Bordeaux, France, with newly diagnosed KMT2A-PTD mutated AML were included in this retrospective study, between November 2005 and August 2019.
Results: Median age of the entire cohort was 66 years old (range 19-87). Overall, most of the patients had a normal karyotype (65.3%). Regarding 2013 ELN classification, 11.4, 77.2 and 11.2% were favorable, intermediate I/II and unfavorable respectively. The median overall survival (OS) was 12.1 months with an OS rate of 50.1 % at 1 year and 30.9% at 3 years (Figure A). NGS was available for 24 intensively treated patients. The most frequently observed mutations were those affecting DNA methylation (DNMT3A, TET2, IDH1/2), found in 91% (21/23) of cases. Receptor tyrosine kinase (RTK) and RAS pathways were mutated in about 44% of patients. Other pathways commonly found altered was the chromatin/cohesin complex (ASXL1, STAG2, SMC1A, EZH2), spliceosome (U2AF1, SRFS2) and transcription factors (RUNX1, WT1) in 39%, 30% and 30% of cases respectively (figure B). Regarding the impact of co-mutations on survival, the presence of FLT3-ITD was associated with an inferior outcome (median OS: 9.36 vs 33.4 months, p=0.033). Median OS was not reached, 33.4 and 29.4 months for NPM1, IDH1/2 and DNMT3A mutated patients respectively. In contrast, median OS was shorter for patients harboring RTK (FLT3-ITD, NRAS, PTPN11) and TP53/ASXL1/RUNX1 mutations (9.6 and 11.9 months respectively).
In patients younger than 60 years old treated with intensive chemotherapy, median overall survival was not reached compared to 12.6 months in older ones (p<0.001). In contrast, there was no statistical difference in OS in elderly patients treated with intensive or low intensive regimens (Figure, C). Twenty-one patients underwent HSCT in first CR (CR1). For patients receiving HSCT at any time in CR, median OS was not reached, whatever was the age group. For those who did not underwent HSCT, median OS was 24.2 and 13.2 months in patients younger and older than 60 years old respectively, with no statistical significance between age group in these settings (Figure D). In the multivariate analysis only HSCT at any time in CR (HR=2.35; p0.034) and FLT3-ITD status (HR=0.29; p=0.014) were independent variables associated with OS.

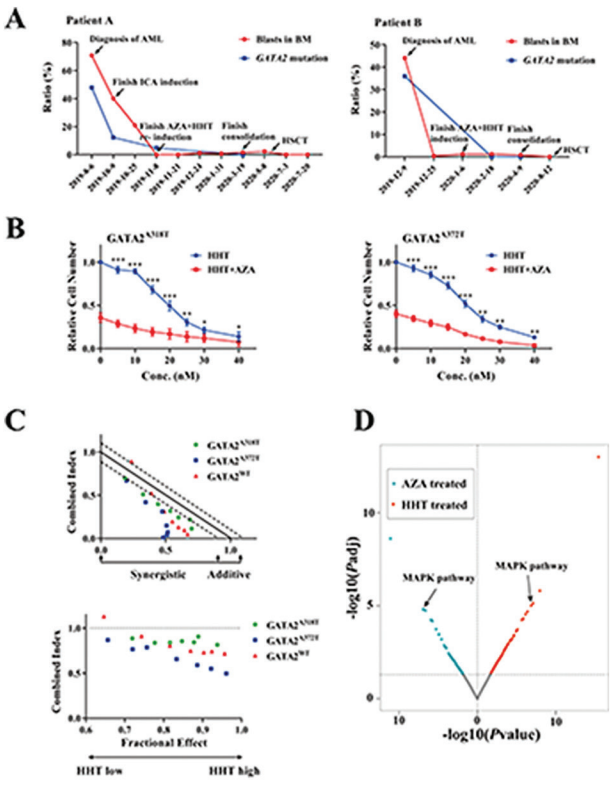
Summary/Conclusion: This study is one of the largest KMT2A-PTD cohort emphasizing mutation impact according to treatment intensity and HSCT. In real life settings, patients harboring such mutation are characterized by a poor outcome especially in elderly. We showed that the negative impact of this mutation might be overcome by HSCT in younger patients. In elderly unfit patient, targeted therapies such as IDH inhibitors and venetoclax-based regimens might be of interest.

EP452 A PHASE 1A/B DOSE ESCALATION STUDY OF THE MYC REPRESSOR APTO-253 IN PATIENTS WITH RELAPSED OR REFRACTORY AML OR HIGH-RISK MDS

M. Ohanian [1], M. Arellano [2], M. Levy [3], K. O'Dwyer [4], H. Babiker [5], H. Zhang [6], N. Rastgoo [6], K. Benbatoul [6], Y. Jin [6], M. Thayer [6], J. Marango [6], S. Howell [7], W. Rice [6], R. Bejar [6,7,*]

[1]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, [2]Winship Cancer Institute, Emory University School of Medicine, Atlanta, [3]Baylor University Medical Center, Dallas, [4]University of Rochester Medical Center, Rochester, [5]Department of Medicine, The University of Arizona Cancer Center, Tucson, [6]Aptose Biosciences, Inc, [7]Moores Cancer Center, University of California San Diego Health, San Diego, United States

Background: APTO-253 represses expression of the MYC oncogene by targeting a conserved G-quadruplex structure in its promoter, down-regulates MYC mRNA and protein levels and induces apoptosis in AML cell lines and marrow samples from patients with AML, MDS, and MPN. After injection, a large fraction of APTO-253 binds iron and transforms to the $Fe(253)_3$ adduct which retains full activity. APTO-253 has been granted orphan drug designation for AML by the US FDA and is being studied in a Phase 1a/b clinical trial in patients with relapsed or refractory AML (R/R AML) or high-risk myelodysplasias (high-risk MDS) (NCT02267863).



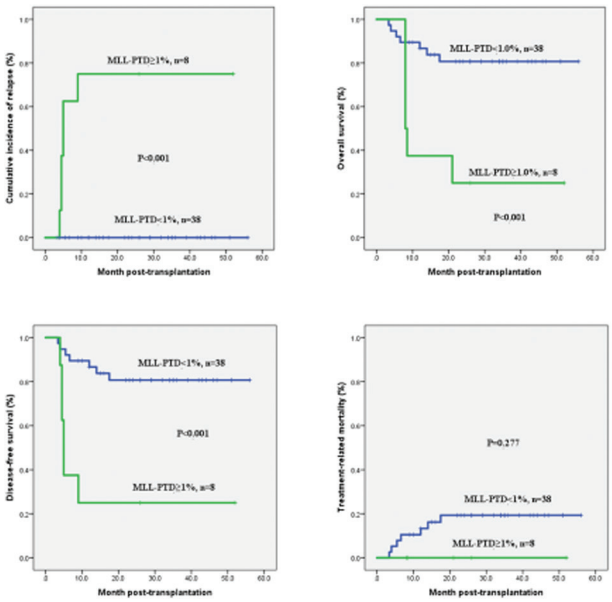
Aims: Primary objectives are to determine the safety and tolerability of APTO-253, MTD, dose limiting toxicities (DLT), and the RP2D. Key secondary objectives are to assess the pharmacokinetic (PK) profile, pharmacodynamic (PD) activity, and preliminary evidence of antitumor activity.
Methods: Eligible patients have R/R AML or high-risk MDS for which either standard treatment has failed, is no longer effective, or can no longer be administered safely. Treatment- emergent adverse events (TEAEs) and tumor responses are evaluated using International Working Group criteria. APTO-253 is administered by IV infusion once weekly on days 1, 8, 15, and 22 of each 28-day cycle; ascending dose cohorts were enrolled at a starting dose of 20 mg/m^2 with planned escalation to 403 mg/m^2.
Results: As of January 4, 2021, a total of 14 patients (age 64.4 ± 15.5, 12 AML and 2 high-risk MDS) with a median of 2.5 prior treatments (range of 1 – 9) have been treated with APTO-253 at doses of 20 (n=1), 40 (n=1), 66, 100 and 150 mg/m^2 (n=4 each). All but 1 AML patient were RBC and/or platelet transfusion-dependent. No DLTs or drug-related serious adverse events have been reported. Possible drug-related grade 2 TEAEs included fatigue, increased alkaline phosphatase, decreased appetite, hematoma, hypokalemia, thrombophlebitis, upper respiratory tract infection in 1 (7.1%) patient each. Only 1 drug-related TEAE of grade 3 or greater (fatigue, possibly related) has occurred to date. Preliminary PK analysis showed that serum levels of APTO-253 were dose proportional. C_{max} and $AUC_{0\text{-}24h}$ on C1D1 were 0.06, 0.02, 0.11 ± 0.04 and 0.44 ± 0.41 µM and 0.11, 0.15, 1.14 ± 0.57, 2.38 ± 0.90 µM*h for dose levels of 20, 40, 66, and 100 mg/m^2, respectively. Plasma levels for $Fe(253)_3$ were significantly higher than those for the APTO-253 monomer. For example, C_{max} and $AUC_{0\text{-}24h}$ of $Fe(253)_3$ on C1D1 of patients in Cohort 100 mg/m^2 were 2- and 8-fold higher than the native ATPO-253 at 0.91 ± 0.33 µM and 16.14 ± 6.26 µM*h, respectively. Following dosing at 100 mg/m^2, serum concentrations of $Fe(253)_3$ were above 0.1 µM for >72 h (0.66 ± 0.12, 0.39 ± 0.11 and 0.24 ± 0.08 µM at 24, 48 and 72 hours post dosing, respectively) which approaches the therapeutic range based on *in vitro* studies. The levels of MYC mRNA in the whole blood, a PD biomarker of APTO-253 and $Fe(253)_3$ measured by RT-qPCR, were reduced 20-48% at 24 h post-dose as compared to pre-dose in the first 3 cohorts, suggesting target engagement by the drug.
Summary/Conclusion: APTO-253 has been well-tolerated at doses of 20, 40, 66, 100 and 150 mg/m^2 over multiple cycles. PK analysis revealed that APTO-253 is rapidly transformed to and co-exists with the $Fe(253)_3$ in serum and their exposures resulted in suppression of MYC expression in whole blood samples from R/R AML and high-risk MDS patients. Enrollment of patients at the 150 mg/m^2 dose level is ongoing and updated clinical data will be presented at the meeting.

EP453 SYNERGISTIC EFFECT OF AZACITIDINE AND HOMOHARRINGTONINE IN ACUTE MYELOID LEUKEMIA WITH GATA2 MUTATION

Q. Han [1], J. Zi [1], Y. Huang [1], Z. Ge [1,2,*]

[1]Department of Hematology, Zhongda Hospital, Medical School of Southeast University, Institute of Hematology Southeast University, Nanjing 210009, China, [2]Hershey Medical Center, Pennsylvania State University Medical College, Hershey,PA17033, United States

Background: Homoharringtonine (HHT) is a natural alkaloid derivate from Cephalotaxus which has potent anti-leukemia effect in acute myeloid leukemia (AML). Azacitidine (AZA), a DNA hypomethylation agent, has been approved to treat AML. GATA2 is an essential transcription factor in hematopoietic differentiation. Mutations in *GATA2* have been detected in AML and are widely recognized as to be associated with inferior clinical outcome. However, no specific treatment regimen has been tested or recommended for AML with GATA2 mutations.
Aims: This study is to investigate the synergistic anti-leukemia effect of combination of AZA and HHT in *GATA2*-mutated AML in a registered clinical study (ClinicalTrials.gov ID: NCT04248595) and explore the potential underlying mechanisms of AZA+HHT in *GATA2*-mutated AML.
Methods: U937 AML cell line was used to construct *GATA2* mutated cells ($GATA2^{A318T}$ and $GATA2^{A372T}$) and *GATA2* wild type cells ($GATA2^{WT}$) by lentiviral transfection. CCK-8 cell proliferation assay and CalcuSyn software were used to analyze the synergistic effect of AZA+HHT in *GATA2* mutated and wild type cells in vitro. RNA sequencing (RNA-seq) was performed before and after U937 cells treated with AZA, HHT and vehicle control for 48 hours.
Results: Two *GATA2* mutations were identified in two AML patients. Patient A is a transformed AML (M2) with a history of granulocytic sarcomas. Flow cytometry revealed 86.38% blasts in the bone marrow at the diagnosis of AML. Whole exome sequencing (WES) showed that there was a 47.8% missense mutation in *GATA2* (c.1114G>A, p.A372T). No remission was achieved after one cycle of induction therapy with ICA regimen. Then, the patient was recruited to the Clinical study and AZA+HHT based regimen was given as the re-induction therapy. A complete remission (CR) was achieved after 14 days and the *GATA2* mutation ratio significantly declined to 4.82%. Allogeneic hematopoietic stem cell transplantation (allo-SCT) was performed after two cycles of high-dose cytarabine consolidation (Figure 1A). Patient B is a de novo AML (M2) with 44% blasts and 35.95% *GATA2* missense mutation (c.952G>A, p.A318T) at diagnosis. The patient was recruited to the Clinical study and achieved CR with negative *GATA2* mutation after AZA+HHT based regimen as the induction therapy. Two cycles of high-dose cytarabine consolidation were received followed by allo-SCT (Figure 1A). In vitro assay revealed a synergistic effect of AZA+HHT on cell proliferation arrest in $GATA2^{A318T}$ and $GATA2^{A372T}$ cells compared with single drug (P<0.05 in all concentration groups) (Figure 1B). The synergistic effect was stronger (lower combined index) in both $GATA2^{A318T}$ and $GATA2^{A372T}$ cells than $GATA2^{WT}$ cells in low HHT concentration groups (Figure 1B). AZA+HHT presented more potent synergistic effect in $GATA2^{A372T}$ cells compared with $GATA2^{WT}$ and $GATA2^{A318T}$ cells in all HHT concentration groups, suggesting that $GATA2^{A372T}$ was more sensitive to AZA+HHT (Figure 1C). Furthermore, RNA-seq revealed that MAPK pathway was significantly altered in both AZA and HHT treated groups (Padj<0.001), indicating that AZA+HHT exhibited strong synergistic anti-leukemia effect in *GATA2*-mutated AML and may rely on their common effect of targeting MAPK pathway (Figure 1D).



Summary/Conclusion: Our data for the first time showed that the synergistic efficacy of novel combination-based regimen AZA+HHT in *GATA2*-mutated AML. Targeting MAPK pathway may be one of the potential downstream mechanisms of AZA+HHT in treating *GATA2*-mutated AML.

EP454 MONITORING OF POST-TRANSPLANT MLL-PTD AS MINIMAL RESIDUAL DISEASE CAN PREDICT RELAPSE AFTER ALLOGENEIC HSCT IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROME

K. Jun [1], G. Mengge [1,*], Q. Yazhen [1], W. Yu [2], Y. Chenhua [1], S. Yuqian [2], C. Yingjun [1], X. Lanping [2], Z. Xiaohui [1], L. Kaiyan [1], H. Xiaojun [1], Z. Xiaosu [1]

[1]Peking University People's Hospital, [2] Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China

Background: MLL-PTD is a special MLL rearrangement gene that occurs in about 5-10% of acute myeloid leukemia (AML) with a normal karyotype and in 5-6% of myelodysplastic syndrome (MDS) patients. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is currently one of the curative therapies available for AML and MDS with excess blasts (MDS-EB). However, how the prognosis of patients with high levels of MLL-PTD after allo-HSCT, including AML and MDS, and whether MLL-PTD could be used as a reliable indicator for minimal residual disease (MRD) monitoring in transplant patients remains unknown.
Aims: Our study purposed to analyze the dynamic changes of MLL-PTD peri-transplantation and the best threshold for predicting relapse after transplantation.
Methods: We retrospectively collected the clinical data of 48 patients with MLL-PTD AML or MDS-EB who underwent allo-HSCT in Peking University People's Hospital. The MLL-PTD was examined by real-time quantitative polymerase chain reaction (RQ-PCR) at the diagnosis, before transplantation and the fixed time points after transplantation. Detectable MLL-PTD/ABL>0.08% was defined as MLL-PTD positive in this study.
Results: The 48 patients included 33 AML patients and 15 MDS-EB patients. The median follow-up time was 26(0.7-56) months after HSCT. In AML patients, 7 patients (21.2%) died of TRM, 6 patients (18.2%) underwent hematological relapse and died ultimately. Of the 15 patients with MDS-EB, 2 patients (13.3%) died of infection. The 3-year cumulative incidence of relapse (CIR), overall survival (OS), disease-free survival (DFS) and treatment-related mortality (TRM) were 13.7%±5.2%, 67.8%±6.9%, 68.1%±6.8% and 20.3%±6.1%, respectively. ROC curve showed that post-transplant MLL-PTD≥1.0% was the optimal cut-off value for predicting hematological relapse after allo-HSCT. There was statistical difference between post-transplant MLL-PTD≥1.0% and MLL-PTD<1.0% groups (3-year CIR: 75%±15.3% vs. 0%, P<0.001; 3-year OS: 25.0±15.3% vs. 80.7%±6.6%, P<0.001; 3-year DFS: 25.0±15.3% vs. 80.7%±6.6%, P<0.001; 3-year TRM: 0 vs. 19.3±6.6%, P=0.277). However, whether MLL-PTD≥1% or MLL-PTD<1% before transplantation has no significant difference on the prognosis.

Summary/Conclusion: Our study indicated that MLL-PTD had a certain stability and could effectively reflect the change of tumor burden. The expression level of MLL-PTD after transplantation can serve as an effective indicator for predicting relapse.

EP455 RESULTS FROM DIAMOND-01 (CLI24-001) TRIAL: FIRST IN HUMAN STUDY OF SEL24/MEN1703, A DUAL PIM/FLT3 KINASE INHIBITOR, IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

S. Solomon [1,*], P. Montesinos [2], A. Nazha [3], S. Strickland [4], G. Martinelli [5], A. Santoro [6], R. Walter [7], R. Cook [8], M. Calbacho [9], S. Vives [10], S. Fazal [11], K. Brzózka [12], S. Shamsili [12], S. Baldini [13], D. Laurent [13], A. Pellacani [13], F. Ravandi [14]

[1]Northside Hospital Cancer Institute, Atlanta, United States, [2]Hospital Universitari i Politècnic La Fe, Valencia, Spain, [3]Cleveland Clinic, Cleveland, [4]Vanderbilt University Medical Center, Nashville, United States, [5]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, [6]Humanitas University, Humanitas Clinical and Research Center IRCCS, Milan, Italy, [7]Fred Hutchinson Cancer Research Center, Seattle, [8]Oregon Health and Science University, Portland, United States, [9]Hospital 12 de Octubre, Madrid, [10]ICO-Hospital Germans Trias i Pujol, Badalona, Spain, [11]Allegheny Health Network, Pittsburgh, United States, [12]Ryvu Therapeutics, Krakow, Poland, [13]Menarini Group, Florence, Italy, [14]MD Anderson Cancer Center, Houston, United States

Background: SEL24/MEN1703, a dual PIM/FLT3 kinase inhibitor shows activity in both primary Acute Myeloid Leukemia (AML) cells and AML cell lines, regardless of FLT3 status. In the dose escalation (DE) part of the First in Human, Phase I/II DIAMOND-01 trial (CLI24-001, NCT03008187, EudraCT No. 2019-000941-10), SEL24/MEN1703 demonstrated an acceptable safety profile up to the recommended dose (RD) of 125 mg along with initial evidence of single agent activity and meaningful target engagement in heavily pre-treated AML patients (pts) (Solomon et al, EHA 2020; Tomirotti et al, ASH 2020). Here we present updated data including pts enrolled in the Phase II, cohort expansion (CE) of the study.
Aims: The key objectives of the CE part of the study were the confirmation of the safety profile determined in the DE part along with further investigation of the single agent activity.
Methods: DIAMOND-01 trial enrolled pts unsuitable for chemotherapy having relapsed or refractory (R/R) (DE and CE) or previously untreated (DE) AML. Previous target therapies were allowed with the only exception of previous PIM inhibitors treatments. SEL24/MEN1703 was given orally, QD, 14 days ON / 7 days OFF until disease progression/unacceptable toxicity. In the DE of the study MEN1703 escalating doses ranging from 25 to 150 mg were tested, whereas in the CE the RD (125 mg) was administered. Adverse events (AEs) were graded according to NCI-CTCAE v.4.03; responses assessed as per ELN 2017 criteria.
Results: As of January 21, 2021 (cut-off date), n=48 pts were treated across DE (n=25) and CE (n=23). All pts signed the informed consent form prior to undergoing any study procedure. Median age was 69 (25-84) years. Overall, 20 (43%) and 15 (32%) pts had non de novo AML and primary refractory AML, respectively. Adverse karyotype was reported in 7 (15%) pts. Most frequently reported mutations were FLT3/ITD (23%, n=11), DNMT3A (15% n=7), NPM1 (15%, n=7), IDH1 (13%, n=6) and IDH2 (4%, n=2), CEBPA (4%, n=2), FLT3/TKD (2%, n=1). Median number of cycles was 2 (1-8). At the RD (n=30), most frequent serious treatment-emergent AEs (serious TEAEs) were pneumonia (23%), sepsis and febrile neutropenia (13%) and pulmonary mycosis (10%), whereas most frequent G≥3 TEAEs were febrile neutropenia and pneumonia (23%), leukocytosis (20%) and neutrophil count decrease, platelet count decrease, lymphocyte count decrease and sepsis (13%). Responses occurred in 2 pts in the CE, both with IDH1 mutant disease (naïve to IDH inhibitors) who achieved complete remission with incomplete hematologic recovery (CRi). Both responses occurred by Cycle 3, with a duration of 79 (ongoing at cut-off date) and 43 days, respectively. Across DE and CE, 4 CR/CRi occurred, three of which in pts with IDH mutations. A total of 3 out of 6 pts with IDH mutations treated at doses ≥75 mg achieved CR/CRi, including a CR in a patient with IDH2 mutant AML relapsed on Enasidenib.
Summary/Conclusion: SEL24/MEN1703 confirmed a manageable safety profile at RD and showed preliminary single agent efficacy in R/R AML, particularly clustering in pts with IDH mutant disease either naïve or previously exposed to IDH inhibitors. These results warrant further

investigation of SEL24/MEN1703 in AML, with potential focus in the IDH mutated subset.

EP456 AZACITIDINE IN COMPARISON TO INTENSIVE CHEMOTHERAPY AND BEST SUPPORTIVE CARE IN RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA, A DATAML REGISTRY STUDY

N. Gadaud [1,*], H. Leroy [2], E. Bérard [3], S. Tavitian [1], T. Leguay [4], J.-B. Rieu [5], I. Luquet [5], L. Largeaud [6], A. Bidet [7], E. Delabesse [6], E. Klein [8], A. Sarry [1], A.-C. de Grande [2], P. Bories [9], A. Pigneux [2], C. Récher [1], P.-Y. Dumas [4], S. Bertoli [1]

[1]Service d'Hématologie, Centre Hospitalier Universitaire de Toulouse, Institut Universitaire du Cancer de Toulouse-Oncopole, TOULOUSE, [2]Centre Hospitalier Universitaire de Bordeaux, Service d'Hématologie Clinique et de Thérapie Cellulaire,, BORDEAUX, [3]Service d'Epidémiologie, Centre Hospitalier Universitaire de Toulouse, TOULOUSE, [4]Centre Hospitalier Universitaire de Bordeaux, Service d'Hématologie Clinique et de Thérapie Cellulaire, BORDEAUX, [5]Laboratoire d'Hématologie, Centre Hospitalier Universitaire de Toulouse, Institut Universitaire du Cancer de Toulouse-Oncopole,, [6]Laboratoire d'Hématologie, Centre Hospitalier Universitaire de Toulouse, Institut Universitaire du Cancer de Toulouse-Oncopole, TOULOUSE, [7]Laboratoire d'Hématologie Biologique, [8]Laboratoire d'Hématologie Biologique,, CHU Bordeaux, BORDEAUX, [9]Service d'Hématologie, Centre Hospitalier Universitaire de Toulouse, Institut Universitaire du Cancer de Toulouse-Oncopole, TOULOUSE, France

Background: Azacitidine is a hypomethylating agent was until recently offered as monotherapy for older and frail patients as first line treatment. In relapsed or refractory (R/R) acute myeloid leukemia (AML), no randomized trial was conducted to position azacitidine (AZA) respective to other standards of care.
Aims: To compare the outcome of R/R AML treated with AZA, intensive chemotherapy (IC) or best supportive care (BSC).
Methods: Our work studied 526 AML refractory (Ref, N=171, 32.5%) to one course of intensive chemotherapy or relapsed after first complete remission (Rel, N=355, 67.5%) in Toulouse or Bordeaux university hospitals (DATAML registry) between 2007 and 2016. At R/R, they received either intensive chemotherapy (IC, N=270; Ref=112, Rel=158), azacitidine (AZA, N=97; Ref=13, Rel=84) or best supportive care (BSC, N=159; Ref=46; Rel=113).
Results: Median age was 64.3 years (IC: 60.1; AZA: 66.3; BSC: 69.4); ECOG performance status (PS) was 0-1 in 77.7% (IC: 82.7%; AZA: 86.6%; BSC: 64.4%). CCI comorbidities score was ≥1 in 34.7%, without difference between groups. Median WBC was $3.0.10^9$/L (IQR, 1.54-7.2). Bone marrow blasts (BMB) at R/R were ≥20% in 63.9% (IC: 72%; AZA: 51.6%; BSC: 61.5%). Karyotypes were intermediate or adverse in 71.7% and 28.3% respectively. Myelodysplasia-related changes (MRC) were observed in 34.8%. At relapse, *FLT3*-ITD mutations were identified in 19/87 (22.4%; IC: 36.2%, AZA: 4.2%; BSC: 7.1%) and *NPM1* mutations in 27/67 (40.3%; IC: 53.3%, AZA: 6.2%; BSC: 33.3%). IC regimens were mainly high-dose cytarabine associated to an anthracycline (N=105, 48.2%). In total, 148 patients received an anthracycline (54.8%) and median total cytarabine dose was 10 grams/m² (IQR, 5-24). 39.3% underwent alloSCT. Median number of AZA cycles was 4 (IQR: 2-8, range: 1-27). 10.3% underwent alloSCT. Complete response (CR or CRi) was 32.2% (IC: 37.0%, AZA: 18.6%; P=0.0008), and early death at day 30 rate was 11.6% (IC: 4.8%, AZA: 3.1%; BSC: 28.3%; P<0.0001). With AZA, CR (7.2%) or CRi (11.3%) occurred in median after 4.6 months (IQR, 2.8-7.3). Partial response (PR) was obtained in 2.1%, stable disease (SD) in 20.6%, hematological improvement (HI) in 15.5%. AZA was independently associated to a significantly lower rate of CR/CRi (OR, 0.23; P<0.0001).With a median follow-up of 56.1 months, the overall survival (OS) was 6.2 months (IC: 8.2 months [5-year: 15.6%]; AZA: 9.6 months [5-year: 6.0%]; BSC: 2.2 months [5-year: 1.7%]). With AZA, OS varied depending on response (CR/CRi: 27.2 months; PR/HI/SD: 12.5 months; failure: 5.3 months (P<0.0001). Independent predictive factors for OS were: for IC, age (HR, 1.53; P=0.002), ECOG PS (HR, 1.53; P=0.02), WBC (HR, 1.78; P=0.02), MRC-AML (HR, 1.57; P=0.002); for AZA, AML status (post-MDS/CMML: HR, 2.70; P=0.023; t-AML: HR, 0.26; P=0.001), BMB ≥20% (HR, 1.85; P=0.011), adverse cytogenetics (HR, 2.22; P=0.006), alloSCT at R/R (HR, 0.30; P=0.012). We then analyzed the effect of treatment using a Royston and Parmar model: after adjustment on confounding factors, death risk is significantly inferior in the AZA group during the first month, is not statistically different between 1 and 7 months, and becomes significantly superior from 8 months.
Summary/Conclusion: At R/R, AZA gives response and overall survival rate similar to those obtained at first line and could represent a fair therapeutical option for the most frail and older patients, but with few late survivors. Nevertheless, these results will need to be updated in a few years, when the treatment of 2nd line will involve associations between azacitidine and targeted therapies or immunotherapies.

EP457 A PHASE 3 STUDY OF ENASIDENIB (ENA) VERSUS CONVENTIONAL CARE REGIMENS (CCR) IN OLDER PATIENTS WITH LATE-STAGE MUTANT-IDH2 (MIDH2) RELAPSED/ REFRACTORY ACUTE MYELOID LEUKEMIA (R/R AML)

Background: Prognosis is bleak for older patients (pts) with R/R AML, especially if multiple lines of treatment (Tx) have failed. Attaining response is more difficult after each Tx failure. *IDH2* mutations occur in ~8-19% of pts with AML. ENA is an oral mIDH2 inhibitor shown to induce responses in pts with R/R AML.
Aims: Report clinical outcomes with ENA *vs* CCR from a phase 3 trial in older pts with late-stage m*IDH2* R/R AML.
Methods: This open-label trial enrolled pts aged ≥60 yrs with ECOG PS ≤2 and who received 2-3 prior AML Tx. Pts were first preselected to 1 of 4 CCR—azacitidine (AZA; 75 mg/m² ×7d), intermediate-dose Ara-C (IDAC; 0.5–1.5 g/m² ×3–6d), low-dose Ara-C (LDAC; 20 mg BID ×10d), or best supportive care (BSC) only—and then randomized 1:1 to ENA (100 mg QD) or preselected CCR in 28d cycles. Endpoints in the ITT cohort included overall survival (OS; primary), event-free survival (EFS), time to Tx failure (TTF), overall response rate (ORR), hematologic improvement (HI), and transfusion independence (TI). OS was also estimated in pts with m*IDH2*-R172 AML; in pts preselected for lower intensity Tx (AZA, LDAC, BSC) before randomization; and in efficacy-evaluable (E-E) pts (received ≥1 study drug dose and had ≥1 response evaluation on-Tx).
Results: 319 pts were randomized to ENA (n=158) or to CCR (n=161; AZA 69, IDAC 33, LDAC 37, BSC 22). Baseline (BL) characteristics were similar between Tx arms. Median age was 71 yrs, 21% of pts received ≥3 prior AML Tx, 40% had primary refractory AML, and 63% had ELN adverse-risk AML. In the ENA and CCR arms, respectively, median numbers of Tx cycles were 6 (range 1–44) and 2 (1–37), and Tx durations were 142d (3–1270) and 36d (1–1166). 20 CCR pts (12%) and 1 ENA pt did not receive any study Tx. 47 ENA pts (30%) and 69 CCR pts (43%) received subsequent AML Tx, including 19 CCR pts (12%) who received subsequent ENA.
Median OS (ITT) was not significantly different between ENA and CCR: 6.5 mo *vs* 6.2 mo (HR 0.86; *P*=0.23); 1-yr survival rates were 37.5% *vs* 26.1%. ENA also prolonged EFS and TTF *vs* CCR: median EFS

was 4.9 *vs* 2.6 mo (*P*=0.008) and TTF was 4.9 *vs* 1.9 mo (*P*<0.0001). ORR was higher with ENA (40.5% *vs* 9.9%; *P*<0.0001), as were rates of CR (23.4% *vs* 3.7%; *P*<0.0001), HI (42% *vs* 11%; *P*<0.0001), and TI (**Table**). For pts preselected to lower-intensity Tx (ENA n=139; CCR n=128), median OS was 6.8 *vs* 6.2 mo with ENA *vs* CCR (HR 0.74; *P*=0.029). At BL, 88 pts had m*IDH2*-R172 AML; pts with the R172 variant had fewer BL co-mutations than m*IDH2*-R140 pts. In m*IDH2*-R172 pts, median OS was ~2-fold longer with ENA (n=43) *vs* CCR (n=45): 14.6 *vs* 7.8 mo (HR 0.59; *P*=0.039). In E-E pts (ENA 147; CCR 129), median OS was 6.8 *vs* 5.7 mo with ENA *vs* CCR (HR 0.77; *P*=0.047).

ENA safety was consistent with prior studies. IDH differentiation syndrome occurred in 14% of ENA pts, with median time to onset of 22d, and 17d to resolution. Tx-related G ≥3 hyperbilirubinemia occurred in 9% of pts.

	ENA N=158	CCR N=165

*Time from randomization to relapse, PD, or death.
†Treatment discontinuation for any reason.
‡ORR includes CR, CRi/CRp, PR, and MLFS, per International Working Group (IWG) 2003 response criteria for AML.
§No postbaseline marrow collected (considered nonresponders; included in denominator for response assessments)
¶Date of first morphologic response to relapse, PD, or death.
#Per IWG 2006 response criteria for MDS.
BL, baseline; CCR, conventional care regimens; CR, complete remission; CRi/CRp, CR with incomplete blood count/platelet recovery; ENA, enasidenib; HR, hazard ratio; MLFS, morphologic leukemia-free state; PR, partial remission; PD, progressive disease; RBC, red blood cell; TD, transfusion-dependent.

Summary/Conclusion: Median OS was not significantly different between Tx arms in ITT analysis but results may be confounded by number of pts randomized but not treated, early Tx discontinuation, and subsequent Tx (including ENA)—which were all higher in the CCR arm. When the influence of no Tx or early Tx discontinuation was reduced (E-E analysis), OS was superior with ENA. ENA provided meaningful improvements in 1-yr survival, EFS, and morphologic response *vs* CCR, and ENA prolonged OS for pts preselected to lower-intensity Tx and pts with m*IDH2*-R172 AML. HI and TI benefits also support ENA as appropriate oral outpatient Tx for pts with m*IDH2* R/R AML.

EP458 INDUCED SYSTEMIC T-CELL SPECIFIC RESPONSES TO MULTIPLE TUMOR-ASSOCIATED ANTIGENS AFTER ALLOGENIC LEUKEMIA-DERIVED DENDRITIC CELL VACCINE DCP-001 IN AML PATIENTS WITH PERSISTENT MRD

H. J. Van Zeeburg [1,*], E. Wagner [2], U. Platzbecker [3], T. Holderried [4], J. van Elssen [5], J. Rovers [1], J. Cloos [6], B. T. Gjertsen [7], A. A. van de Loosdrecht [6]

[1]DCPrime BV part of Immunicum AB, Leiden, Netherlands, [2]Universitatsmedizin der Johannes Gutenberg-Universitat, Mainz, [3]Universitatsklinikum, Leipzig, [4]Universitatsklinikum (UKB), Bonn, Germany, [5]Maastricht University Medical Centre, Maastricht, [6]Department of Hematology, Amsterdam UMC, Location VU University Medical Center, Cancer Center Amsterdam, Amsterdam, Netherlands, [7]Haukeland Universitetssykehus, Bergen, Norway

Background: Patients with acute myeloid leukemia (AML) and persistent measurable residual disease (MRD) have a poor prognosis and new treatment modalities for prevention of relapse i.e. by conversion of MRD status are being investigated. In a phase I study it was shown that the allogeneic leukemia-derived dendritic cell vaccine, DCP-001, induces both humoral and cellular immune responses (van de Loosdrecht et al., Cancer Immunol. Immunother. 2018).

Aims: A phase II trial is currently conducted to investigate the ability of DCP-001 to generate an anti-leukemia response in patients with AML in CR but MRD positive and to convert patients to from MRD positive to a MRD negative status (Clinicaltrials.gov: NCT03697707). Immunological analyses are planned to elucidate the height and breadth of the vaccination on the local and systemic immune responses before, during and after the vaccination regimen.

Methods: An intended total of 20 patients (10 at 25e6 and 10 at 50e6 dose) ineligible for HSCT will receive a primary regimen consisting of 4 doses given biweekly (week 0, 2, 4 and 6) followed by the booster regimen with 2 doses (10e6) at week 14 and 18. MRD status (flow cytometry and/or qPCR based according to ELN guidelines) is assessed at baseline, before booster vaccination (week 14) as well as 2 weeks and 3 months after the booster to monitor clinical efficacy of the vaccinations. At present (March 1, 2021), the 25e6 dose cohort has been fully enrolled and most patients have completed the 32 week end of treatment visit, while the 50e6 cohort has been nearly completed with 7 patients having received at least one vaccination.

Results: First analyses of skin biopsies taken 2 days after the 1st, 4th and 6th dose of patients whom have completed the full vaccination schedule showed acute inflammation in the skin reflected by induration and redness of the skin. Infiltrating immune cells consisted mainly of CD4 and CD8 T-cells as well as CD68+ cells.

Flow cytometric analysis on PBMC showed an increase in antigen experienced CD8+ CD137+ T-cells already 2 days after vaccination. After the primary schedule, immune responses to known AML tumor-associated antigens such as PRAME and WT-1 were induced post- DCP-001 vaccination as measured by IFNγ ELISPOT. Patients showed multiple detectable responses, either boosted from preexisting or as an induced primary response upon DCP-001 vaccination. Up to a 4-fold median increase to baseline levels after initial vaccinations was detected, in patients with positive ELISPOT responses. After primary vaccinations, retraction of the cellular responses was observed, but could be boosted, with a 1.5 fold median increase compared to pre-boosting levels.

Consecutive samples of 3 patients were analyzed by TCRbeta sequencing and showed increased breadth and height of T-cell clones after DCP-001 vaccination. As DCP-001 is known to induce responses to tumor associated antigens, not only expressed by DCP-001, such a NY-ESO-1, a broad range of different TCRs to several published TAA was detected.

At time of reporting, 2 of 5 patients with immune response data available, MRD negativity was achieved. In both patients multiple antigenic responses after DCP-001 vaccination and high levels of immune cells infiltrates at the injection site were observed.

Table 1. Overview of immune responses after DCP-001 vaccination in 5 patients with full data set available. Skin biopsy: ++ or +++ (level 4 or 5 on scale of 5 of pathologist evaluated immunohistochemistry of the skin biopsy). Flow and ELISPOT +: increase.

	skin biopsy		Flow	IFNγ ELISPOT		
	T-cells	CD68	CD8+CD137+ increase	WT1	PRAME	RHAMM
M, 41y	+++	+++	+	+	-	+
M, 63y	+++	+++	-	+	+	-
F, 73y	++	++	+	-	+	+
M, 64y	++	++	+	-	-	-
M, 67y	+++	+++	-	-	+	-

Summary/Conclusion: DCP-001 used as a relapse vaccine in AML patients, showed recruitment of immune cells to the skin, increased cellular responses to a broad range of tumor associated antigens, and resulted in reversion of the MRD status in some patients.

EP459 PROGNOSTIC IMPACT OF MINIMAL REDISUAL DISEASE ASSESSMENT IN ELDERLY PATIENTS WITH SECONDARY ACUTE MYELOID LEUKEMIA. A COMPARISON BETWEEN CPX-351 AND INTENSIFIED FLUDARABINE-BASED REGIMENS

F. Guolo [1,*], P. Minetto [1], M. Clavio [1], M. Miglino [1], R. Marcolin [1], M. Passannante [1], M. Frello [1], E. Tedone [2], N. Colombo [1],

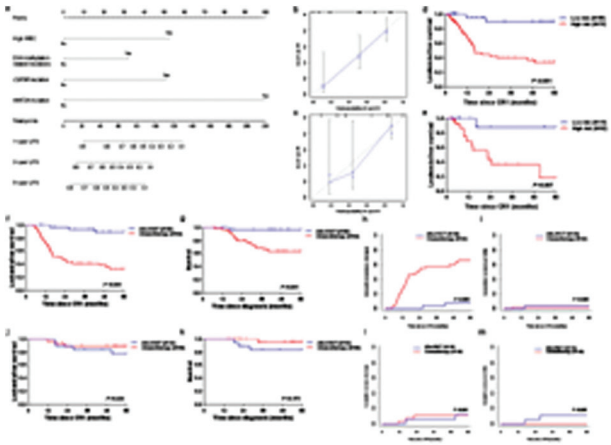
[1]Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, [2]Service of Flow Cytometry, IRCCS Ospedale Policlinico San Martino, GENOVA, Italy



Background: Minimal residual disease (MRD) assessment retains high prognostic value in Acute Myeloid Leukemia patients (AML) undergoing intensive induction therapy. Widely available MRD techniques include multicolour flow cytometry (MFC), RT-PCR for recurrent genetic lesion and, for patients lacking specific markers, RT-PCR for the pan-leukemic marker WT1. However, most of the data on the prognostic value of MRD come from trials including younger patients treated with conventional 3+7 regimen. AML arising from a previous myelodisplastic syndrome (s-AML) and therapy-related AML (t-AML) are usually under-represented in trial involving younger patients and are unlikely to respond to conventional induction. Few data are therefore available on the kinetics and the prognostic value of MRD in elderly s-AML and t-AML patients, particularly in the context of alternative induction regimens.
Aims: We evaluated MRD in a cohort of elderly s-AML or t-AML patients receiving induction therapy either with a fludarabine-containing regimen or CPX-351, in order to compare the probability of achieving MRD negativity, to disclose the prognostic value of MRD in this setting and to define the best time-points for MRD assessments.
Methods: A total of 136 elderly (>60 year, median age 67, range 60-75) patients were analyzed in this study. Patients were treated between January 2005 and January 2020 in our Center, either with CPX-351 (n=35) or fludarabine- high dose cytarabine-idarubicin (FLAI), with (n=72) or without (n =29) gemtuzumab-ozogamicin (GO). MRD was retrospectively analyzed in all patients achieving hematological complete remission (CR) with both MFC and WT1 expression levels.All patients were affected by s-AML or t-AML, defined according to the WHO 2016 criteria.
Results: After induction, CR was achieved in 83 patients (61%). CR rate was 28/35 in patients treated with CPX-351 (80%), significantly higher when compared to patients receiving FLAI (55/101, 54.5%, p<0.05). The addition of GO to FLAI did not increase CR rate. Among CR patients, a total of 41 (49.4%) and 44 patients (53%) achieved MRD negativity, with MFC or WT1-based methods, respectively. MFC MRD negativity probability was higher among patients receiving CPX-351 as induction therapy (MFC MRD negativity rate of 16/28, 57% and 25/55, 45% in CR patients who received CPX-351 or FLAI, respectively, p<0.05). Adding GO to FLAI did not improve MRD negativity probability. Moreover, MRD showed significant prognostic value in terms of Overall Survival in all treatment group (2-year OS of 74 and 36% in patients with or without residual MFC MRD after induction, respectively, p<0.05). WT1-based MRD lead to similar results.
Summary/Conclusion: In conclusion MRD assessment retains a strong prognostic value and may help to identify patients with suboptimal response to treatment. The higher rate of MRD negativity observed with CPX-351 may be related with a more efficient anti-leukemic activity of the drug in this particular setting. The evaluation of MRD with both MFC and WT1-based assessment lead to superimposable conclusions and allowed us to obtain MRD data from virtually all AML patients treated in the selected time period.

EP460 ALLOGENIC HEMATOPOIETIC CELL TRANSPLANTATION WAS SUPERIOR TO CONSOLIDATION CHEMOTHERAPY IN HIGH-RISK CN-AML WITH BIALLELIC CEBPA MUTATIONS BASED ON A MUTI-GENE PANEL AND NOMOGRAM MODEL

L.-X. Wu [1,*], H. Jiang [1], Y.-L. Zhou [1], J. Wang [1], Z.-L. Wang [1], L.-M. Cao [1], J.-L. Li [1], Q.-Y. Sun [1], S.-B. Cao [2], F. Lou [2], T. Zhou [2], M.-M. Zhang [2], C.-C. Wang [2], Y. Wang [1], Q. Jiang [1], L.-P. Xu [1], X.-H. Zhang [1], K.-Y. Liu [1], X.-J. Huang [1,3,4], G.-R. Ruan [1]

[1]Peking University Institute of Hematology, National Clinical Research Center for Hematologic Disease, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Peking University People's Hospital, [2]AcornMed Biotechnology Co., Ltd., [3]Peking-Tsinghua Center for Life Sciences, [4]Research Unit of Key Technique for Diagnosis and Treatments of Hematologic Malignancies, Chinese Academy of Medical Sciences, 2019RU029, Beijing, China

Background: Cytogenetically normal acute myeloid leukemia (CN-AML) patients with biallelic *CEBPA* (bi*CEBPA*) mutations have a favorable prognosis compared with patients with wild-type or monoallelically mutated *CEBPA*. However, this subgroup is still not homogeneous with relapse rate reaching approximately 40% and the best post-remission therapy remains unclear.
Aims: Elucidate the cooperating events in CN-AML with bi*CEBPA* mutations, identify the risk factors and explore the optimal post-remission therapy in different risk subgroups.
Methods: A total of 158 CN-AML patients with bi*CEBPA* mutations were enrolled for targeted region sequencing by a panel with 236 genes. Patients were assigned to a training cohort (*N* =111) and a validation cohort (*N* =47) at a ratio of 7:3 randomly to construct a nomogram model. Risk factors identified in nomogram were incorporated to stratify the cohort. Post-remission therapies were compared in different risk subgroups. Receiving an allo-HSCT was recorded as a censored event to identify the prognostic factors before an allo-HSCT. Landmark analysis was performed to revise bias from early relapse or death when comparing the outcomes of post-remission therapies.
Results: We identified 1,306 mutations in 203 genes other than *CEBPA*. The median mutation number was 8 (1–20). Patients with low mutational context (mutation number <8) showed significantly higher 5-year leukemia-free survival (LFS) (61.6% *vs.* 39.0%, *P* =0.033) and 5-year survival (85.6% *vs.* 62.9%, *P* =0.030), lower 5-year cumulative incidence of relapse (CIR) (38.4% *vs.* 59.5%, *P* =0.0496) and comparable 5-year non-relapse mortality (NRM) (0 *vs.* 1.5%, *P* =0.407). Four variables were in the nomogram model: WBC (high *vs.* low, represents >18.30×10^9/L *vs.* ≤18.30×10^9/L), *CSF3R* mutation (+ *vs.* -), *KMT2A* mutation (+ *vs.* -) and DNA methylation related mutation (mutations in *TET2*, *DNMT3A*, *IDH2*, *BAZ2A* and *IDH1*) (Figure 1a). The C-index was 0.750 (95% CI, 0.670–0.830) in training cohort and 0.771 (95% CI, 0.661–0.881) in the validation with good calibration in the two cohorts (Figure 1b-c). According to the nomogram model, patients with none of the risk factors were classified as the low-risk subgroup (*N* =50) and the remain were high-risk (*N* =108). Low-risk patients had significantly lower positive MRD after induction (25.5% *vs.* 57.7%, *P* <0.001) and better prognosis both in training and validation cohorts (5-year LFS, 89.3% *vs.* 33.8%, *P* <0.001; 87.5% *vs.* 18.2%, *P* =0.009) (Figure 1d-e). Post-remission therapies analyses indicated that allo-HSCT had better 5-year LFS (89.6% *vs.* 32.6%, *P* <0.001), 5-year survival (96.9% *vs.* 63.6%, *P* =0.001) and lower 5-year CIR (7.2% *vs.* 65.8%, *P* <0.001) compared with consolidation chemotherapy in high-risk subgroup (Figure 1f-h). However, in low-risk subgroup, these two post-remission therapies did not show significant difference (allo-HSCT *vs.* consolidation chemotherapy, 5-year LFS, 77.4% *vs.* 88.9%, *P* =0.424; 5-year survival, 83.9% *vs.* 95.5%, *P* =0.173; 5-year CIR, 11.7% *vs.* 11.1%, *P* =0.901) (Figure 1j-l). The 5-year NRM was comparable in high- (3.1% *vs.* 1.6%, *P* =0.685) (Figure 1i) and low-risk (10.9% *vs.* 0, *P* =0.099) (Figure 1m) subgroups.

Summary/Conclusion: CN-AML patients with bi*CEBPA* mutations were prognostically heterogeneous with different mutational context. Only approximately one third of these patients represented the low-risk subgroup, and consolidation chemotherapy should be given as the first line post-remission therapy. While in the high-risk subgroup, allo-HSCT is recommended.

EP461 N-TERMINAL FRAGMENT OF BRAIN NATRIURETIC PEPTIDE (PBNP) IS A NOVEL INDEPENDENT PROGNOSTIC MARKER FOR SURVIVAL AND RESPONSE TO INTENSIVE CHEMOTHERAPY IN AML

I. Graf [1,*], G. Greiner [2,3,4], R. Marculescu [2], K. Gleixner [1], S. Herndlhofer [1], G. Stefanzl [1], P. Knoebl [1], U. Jaeger [1], A. Hauswirth [1], M. Kundi [5], G. Hoermann [3,6], G. Mitterbauer-Hohendanner [2], P. Valent [1,3], W. R. Sperr [1,3]

[1]Department of Internal Medicine I, Division of Hematology and Hemostaseology, [2]Department of Laboratory Medicine, [3]Ludwig Boltzmann Institute for Hematology and Oncology, Medical University of Vienna, [4]Ihr Labor, Medical Diagnostic Laboratories, [5]Institute of Environmental Health, Medical University of Vienna, Vienna, Austria, [6]MLL, Munich Leukemia Laboratory, Munich, Germany

Background: Acute myeloid leukemia (AML) is a heterogeneous hematologic neoplasm resulting from abnormal proliferation and differentiation of clonal myeloid precursor cells. Karyotype, genomic abnormalities and patient-related factors are known to play an important role in the prognostication of AML. However, little is known about the effects of serologic markers like N-terminal fragment of brain natriuretic peptide (pBNP) on the outcome of AML patients.
Aims: The aim of the present study was to evaluate the role of pBNP as prognostic marker in patients with AML.
Methods: We analyzed 312 AML patients (median age: 61 years; range 17-89 years; f:m-ratio: 1:1.15) treated between February 1998 and September 2020 with 3+7-based induction chemotherapy and consolidation with up to 4 cycles of intermediate-dose or high-dose ARA-C.
Results: In 199 patients (63.8%), elevated pBNP levels were detected, and in 113 patients (36.2%), pBNP levels were within normal range (0-125 pg/ml). In 20 patients (6.4%), pBNP exceeded 2000 pg/mL. We found a weak correlation between age and pBNP (R=0.18) and a significant difference in pBNP levels when comparing high-risk (226.5 pg/mL), intermediate-risk (156.0 pg/mL) and low-risk patients (139.3 pg/mL) by Charlson comorbidity index (CCI) (p=0.002). No significant difference in pBNP levels was observed between male (median pBNP 193.5 pg/mL; range: 1-19833) and female (median pBNP 192 pg/mL; range: 1-15930) patients (p=0.33) or when comparing the body mass index (BMI) with pBNP levels (p=0.94). Following induction therapy, 219 patients (70.2%) achieved a complete remission (CR), 63 (20.2%) had no remission (NR), and 30 (9.6%) died from early death (ED). Median pBNP levels differed significantly among CR, NR and ED patients, with 153.3, 225.9, and 735.5 pg/mL, respectively (p=0.001). In multivariate analyses including age, sex, the ELN-2009 classification, BMI, CCI and pBPN, only pBNP and the ELN-2009 classification were independent predictors for response to induction therapy (p=0.007 and p<0.0001, respectively). Overall survival (OS) differed significantly between patients with normal, moderately elevated (125-2000 pg/mL) and highly elevated pBNP (>2000 pg/mL) (p<0.001). This difference was also observed when analyzing OS in patients <60 years (p=0.012), but was not seen in patients aged ≥60 years. Inmultivariate analysis (including age, the ELN-2009 classification, white blood counts, sex, CCI and pBNP) age, the ELN-2009 classification and pBNP remained independent predictive variables for OS (p=0.002, p<0.0001, and p=0.035, respectively). There was no significant difference in pBNP levels at diagnosis between patients who died from progressive disease, bleedings, infections, multi organ failure, pulmonary deterioration, cardiac problems or other reasons during the observation period (p=0.26). With regard to continuous complete remission pBNP was of prognostic significance in the cohort aged <60 years (p=0.011) but not in patients aged ≥60 years.
Summary/Conclusion: Together, pBNP is an independent prognostic factor and new biomarker indicating the risk of induction failure, early death and reduced OS in AML. Our data also show that the predictive power of pBNP as independent risk factor is most evident and most useful in patients <60 years.

EP462 EFFICACY AND SAFETY OF ASPACYTARABINE (BST-236) AS A FIRST-LINE MONOTHERAPY FOR PATIENTS WITH ACUTE MYELOID LEUKEMIA UNFIT FOR STANDARD CHEMOTHERAPY

[1]Robert H. Lurie Comprehensive Cancer Center Northwestern University, Chicago, [2]John Theurer Cancer Center Hackensack University Medical Center, Hackensack, [3]Georgia Cancer Center Augusta University, Augusta, [4]University of Maryland School of Medicine, University of Maryland, Baltimore, [5]University of Michigan Comprehensive Cancer Center, Ann Arbor, [6]Baylor Scott & White Research Institute, Dallas, [7]Abramson Cancer Center, University of Pennsylvania, Philadelphia, United States, [8]Rambam Health Care Campus, Haifa, Israel, [9]Arthur G James Cancer Hospital Comprehensive Cancer Center, Ohio State University, Ohio, United States, [10]Rabin Medical Center, Petach Tikva, [11]Shaare Zedek Medical Center, Jerusalem, [12]Soroka University Medical Center, Beer Sheva, [13]BioSight Ltd., Lod, Israel

Background: Cytarabine, the backbone of acute myeloid leukemia (AML) standard of care chemotherapy, is associated with a toxicity which precludes its administration to older patients and those with comorbidities. Aspacytarabine (BST-236) is a prodrug of cytarabine. Its pharmacokinetics and metabolism lead to gradual release of cytarabine with shorter duration at peak toxic levels compared to direct cytarabine administration, resulting in relative sparing of normal tissues and enabling delivery of high cytarabine doses to patients otherwise unfit to receive it.
Aims: To evaluate the efficacy and safety of aspacytarabine as a first-line, single-agent therapy in newly-diagnosed AML patients unfit for standard induction therapy.
Methods: Aspacytarabine is administrated at a dose of 4.5 g/m^2/d (equimolar of 3 g/m^2/d cytarabine). Therapy is time-limited, with only 1-2 induction courses and 1-3 consolidation courses, each consists of 6 daily 1-hour intravenous infusions. Newly-diagnosed AML patients unfit for standard chemotherapy, including those with secondary AML, previously treated with HMA, and patients with therapy-related AML, are eligible.
Results: To date, 71 AML patients were treated with aspacytarabine; 47 newly-diagnosed AML patients unfit for standard chemotherapy (median age 75 years) completed 1-4 courses of 4.5 g/m^2/d aspacytarabine in an ongoing phase 2b study, including 30 patients (64%) with *de novo* AML and 17 (36%) with secondary AML. Six patients (13%) were previously treated with HMA (median 12 courses), and 21 (45%) patients had ECOG Performance Status 2. The median baseline bone marrow blast percentage was 45 (range 13-94), and 54% and 29% of patients had adverse or intermediate ELN score, respectively.
Aspacytarabine is safe and well-tolerated in repeated-course administration. Grade >2 drug-related adverse events include mainly hematological events and infections. The 30-day mortality rate is 11%.
Of the 43 phase 2b patients evaluable for efficacy analysis to date, 15 patients (35%) reached a complete remission (CR) following 1 (13 patients) or 2 (2 patients) aspacytarabine induction courses. All responders reached a complete hematological recovery (median 27.5 days, range 22-39 days). The CR rate excluding patients with prior HMA therapy is 41%, and 46% in *de novo* AML patients. The CR rate in patients at the age of ≥75 years and patients with adverse ELN score is 33%.
Of note, of the 11 patients evaluable to date for minimal residual disease (MRD) analysis, 8 (73%) are MRD negative.
While aspacytarabine treatment consists of a limited number of courses, median duration of response (DOR) and median overall survival (OS) for responders are not reached (NR) at end of follow up, 12 (95% CI 5-NR) and 24 (95% CI 6-NR) months, respectively. The median OS for all patients is 6.8 (95% CI 6-NR) months (Figure 1A). Median OS for *de novo* AML patients is NR (95% CI 6-NR) and 6.8 (95% CI 2.7-NR) for secondary AML patients (Figure 1B).
Follow-up is ongoing with additional patients enrolling on study; updated analysis will be presented at the meeting.

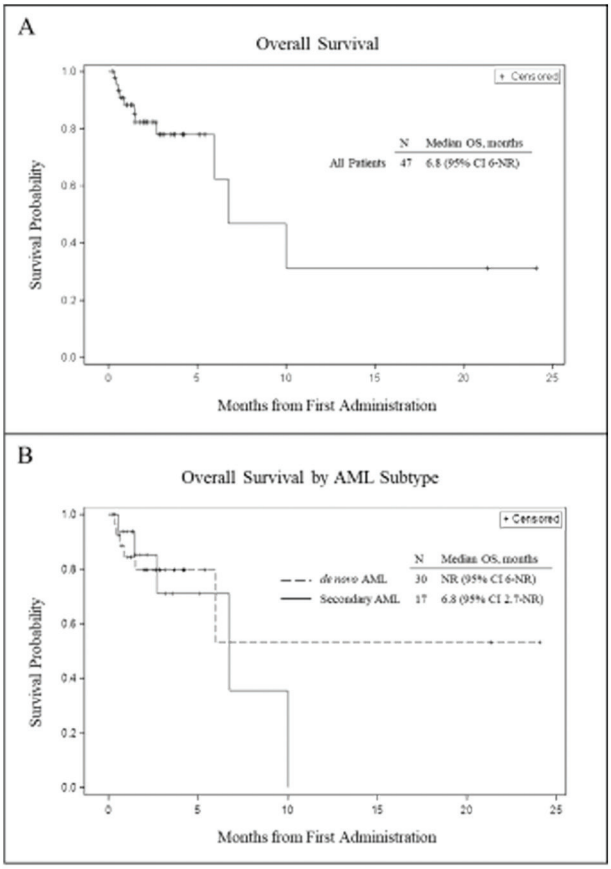

Figure 1. Overall Survival

Summary/Conclusion: The cumulative clinical data suggest that aspacytarabine monotherapy is safe and efficacious as a first-line therapy for patients who are unfit for intensive chemotherapy, including patients with adverse cytogenetics and patients ≥75 year of age. The data may establish aspacytarabine, already granted Fast Track designation from the FDA, as a new intensive therapy backbone of AML and may, for the first time, allow older adults benefit from standard intensive therapy.

EP463 THE COMBINATION OF AXL INHIBITOR BEMCENTINIB AND LOW-DOSE CYTARABINE IS WELL TOLERATED AND EFFICACIOUS IN ELDERLY RELAPSED AML PATIENTS: UPDATE FROM THE ONGOING BGBC003 PHASE II TRIAL (NCT02488408)

Croce e Carle, Cuneo, Italy, [11]Department of Personalised Oncology, University Medical Center Mannheim, Mannheim, Germany, [12]Haukeland University Hospital, [13]BergenBio ASA, Bergen, Norway, [14]Translational Biomarkers, BergenBio ASA, [15]Data Analysis, BerGenBio, [16]Centre for Cancer Biomarkers, University of Bergen, Bergen, Norway, [17]University Medical Center Hamburg, Hamburg, Germany, [18]The University of Texas M.D. Anderson Cancer Center, Houston, United States, [19]Haukelands University Hospital, Bergen, Norway

Background: Low-dose cytarabine (LDAC) in elderly relapsed (REL) & refractory (REF) (r/r) AML patients (pts) unfit for intensive therapy shows limited response (CR rate up to 17%) and survival benefit (mOS 4-6mos). This population has significant unmet need for new treatments. Bemcentinib (BEM) is an oral selective small molecule inhibitor of AXL, a RTK mediating poor prognosis, resistance to chemotherapeutics and decreased antitumor immune response. AXL is overexpressed on leukemic cells, especially in the stem cell compartment, and represents an important novel target in pts with AML.

Aims: The ongoing BGBC003 PhII trial cohorts receiving BEM+LDAC (B+L) include newly diagnosed (ND) and r/r AML pts unfit for intensive therapy. Based on observed activity, r/r AML pts were selected in an expansion cohort, to explore safety and efficacy and to undertake translational biomarker analysis. Here, we report on preliminary efficacy in r/r pts, with a safety overview for all pts treated with the combination.

Methods: Pts received BEM at the RP2D (200mg PO/d)+LDAC SoC schedule. Efficacy endpoints included objective response (OR) and clinical benefit (OR+SD [unchanged disease for at least 3 BEM cycles]). Secondary objectives include overall survival (OS) and exploratory biomarker analyses. Single cell RNA sequencing and T-cell repertoire analysis are being conducted to unravel the immunotherapeutic MOA of B+L.

Results: As of 06 Jan 21, the B+L cohorts (n=31) comprised 7 ND and 24 r/r (17 REL, 7 REF) AML pts; here, we focus on r/r pts. Median prior lines of therapy: 1 [1-8] in REL, 3 [1-4] in REF. Median age: 75yrs [66-86] for REL, 75 [71-81] for REF. Adverse cytogenetic risk profile: 5/17 (29%) in REL, 2/7 (29%) in REF. Median bone marrow (BM) myeloblast count at screening: 32% [6-94] for REL, 40% [3-54] for REF.

12 REL pts were evaluable for efficacy (BM assessment at C2D1). 5/12 (42%) achieved remission (4 CR/CRi, 1PR). Notably, first CR/CRi's were reported between wk13(C5)–wk19(C7). These later onset responses may reflect the importance of AXL-related immunological mechanisms for relatively chemo-resistant relapsed pts and contribute to a longer time-on-treatment (ToT).

An additional 3 had SD; with clinical benefit rate 67%.

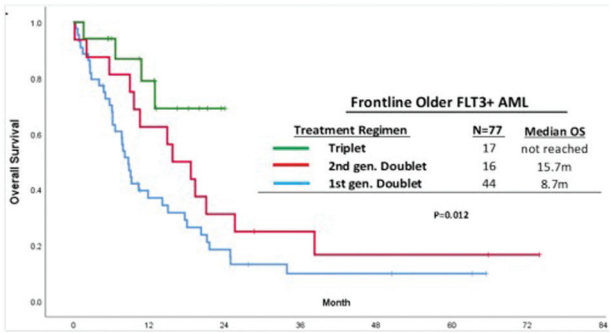
Median ToT was 28.0wks for CR/CRi pts. mDOR was 13.1wks [2.1-43.1+] in all responders and 14.0wks [10.0-43.1+] in CR/CRi pts. 7 pts remain on treatment. Survival outcomes continue to mature.

In contrast, no REF pts showed response (0/7), with 2/7 (28%) reporting clinical benefit; median ToT was 8.0wks. No pts remain on treatment.

Previously-reported results of preliminary scRNAseq analysis of these pts indicated differences in the T- and NK cell compartment associated with treatment response, pointing to BEM-mediated immune MOA in context of synergy of B+L. Further analyses of scRNAseq and CITE-seq data are ongoing.

Overall, the safety of B+L (compared with previously published BEM monotherapy) was in keeping with the known safety profile of LDAC. TRAEs of ≥G3 observed in ≥10% of pts were anemia (29% B+L; 0% BEM), platelet count decr. (29% B+L; 0% BEM), thrombocytopenia (19% B+L; 8% BEM), neutrophil count decr. (13% B+L; 0% BEM), white blood cell count decr. (13%B+L; 0% BEM) and ECG QT prolonged (10% B+L; 6% BEM). No G5 TRAEs reported.

Summary/Conclusion: These data show that B+L is efficacious and well tolerated in the elderly/unfit REL AML population. An in-depth translational research program aiming to identify predictive molecular and biological factors associated with response is ongoing. B+L should be considered for evaluation in a randomized pivotal trial in this population.



EP464 TRIPLE COMBINATION OF HMA, VENETOCLAX, AND FLT3 INHIBITOR PRODUCES HIGHER FLT3 PCR CLEARANCE, FLOW MRD NEGATIVITY, AND IMPROVED MEDIAN OS COMPARED WITH DOUBLETS OF HMA WITH FLT3 INHIBITOR

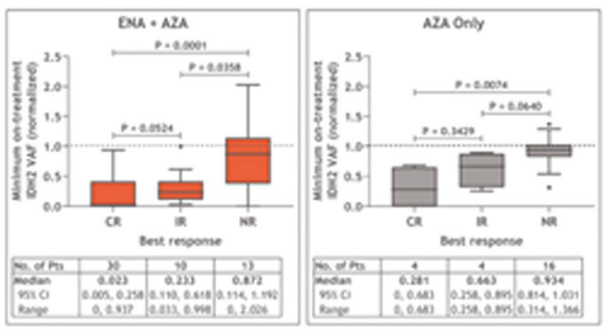
M. Yilmaz [1,*], F. Ravandi [1], S. Loghavi [1], S. Wang [1], G. Borthakur [1], C. Dinardo [1], T. Kadia [1], R. Kanagal-Shammanna [1], N. Pemmaraju [1], B. Oran [1], U. Popat [1], S. Pierce [1], E. Jabbour [1], N. Short [1], G. Issa [1], M. Ohanian [1], G. Garcia-Manero [1], M. Andreeff [1], K. Patel [1], M. Konopleva [1], H. Kantarjian [1], N. Daver [1]

[1]MD Anderson Cancer Center, Houston, United States

Background: First-generation FLT3i's (sorafenib, midostaurin) combined with low-intensity chemotherapy (LIC) failed to improve outcomes (median overall survival (OS) ~8 months in frontline) in intensive chemotherapy (IC) non-eligible older patients (pts) with acute myeloid leukemia (AML) [Ohanian AJH 2018, Gallogly Blood 2017]. The expected median OS in *FLT3-ITD* mutated (m) pts with a frontline hypomethylating agent (HMA) with venetoclax (VEN) was 11.5 months [Konopleva Blood 2020]. Clinical trials exploring triplet combinations (HMA+VEN+ FLT3i) are ongoing.

Aims: We retrospectively analyzed IC non-eligible older pts with newly diagnosed *FLT3*m AML treated with HMA + VEN + FLT3i (triplet regimen) at MDACC between 2012-2020 and compared CR/CRi rates, measurable residual disease (MRD) dynamics, and OS with pts who received LIC + FLT3i (doublet regimen).
Methods: We identified 77 adult pts with newly diagnosed *FLT3*m (ITD and/or TKD) AML who were treated with LIC including first-generation (sorafenib, midostaurin) LIC doublet (n=44), second-generation (quizartinib) LIC doublet (n=16), and HMA-VEN-FLT3i (sorafenib, gilteritinib, midostaurin) triplet (n=17). Measurable residual disease (MRD) assessments were done at initial CR/CRi and longitudinally on therapy by multiplex PCR for ITD and D835, sensitivity 10^{-3} (Luthra, 2014, Haematologica), and by multicolor flow-cytometry (MFC), sensitivity 10^{-4} (Jaso, 2014, BMT).
Results: The median age was 71 [51-83], 71 [64-83], and 69 [40-80] year-old among first-generation LIC doublet, second-generation LIC doublet, and HMA-VEN-FLT3i triplet groups.
Among 77 pts treated with LIC (60 doublets, 17 triplets), 74% (57/77) achieved CR/CRi with the best PCR and MFC MRD-negativity rates of 67% (36/54) and 56% (31/55). Comparing pts treated with second-generation (n=16) versus first-generation (n=44) FLT3i based LIC doublets we noted increased CR/CRi (88% vs 64%, P=0.07) but no statistically significant difference in best FLT3 PCR (62% vs 50%, p=0.5) and best MFC MRD (50% vs 42%, p=0.6) clearance. Pts who received triplet regimens (n=17) achieved a 88% CR/CRi (similar to second-generation doublet), but with a significantly higher best FLT3 PCR (100% vs 54%, p=0.001) and higher best MFC MRD (87% vs 45%, p=0.006) clearance, compared with all patients treated with LIC doublets (n=60).
With a median follow-up of 28 months, pts treated with triplets achieved the best median OS compared with pts treated with first- or second-generation FLT3i based LIC doublets (not reached vs 15.7 vs 8.7 months (m), respectively, p=0.01) [Figure].
Across the 55 evaluable LIC patients, the achievement of MRD negativity by MFC at any time on therapy was associated with improved med OS (21m vs 12m, p=0.04. Achieving FLT3 PCR clearance at any time on therapy was associated with a non-statistically significant improved med OS (21m vs 9m, p=0.18). Pts who achieved both PCR and MFC vs MFC or PCR only clearance vs clearance of neither at any time on therapy had med OS of 21m, 20m, and 9m, resp (p=0.06).

Summary/Conclusion: The outcomes in older patients who received LIC+FLT3i (doublets) are poor, although combining LIC with second-generation inhibitors such as quizartinib appeared to improve OS. Triplet combination of HMA-VEN-FLT3i appeared to be most effective in improving OS, FLT3 PCR, and MFC clearance. Achievement of MRD negativity (especially MFC negativity) significantly improved OS, irrespective of LIC or IC backbones, and may be a surrogate endpoint to consider for future FLT3 frontline trials.



EP465 UPDATED PHARMACODYNAMIC AND SURVIVAL OUTCOMES FROM THE AG221-AML-005 TRIAL OF ENASIDENIB (ENA) PLUS AZACITIDINE (AZA) IN PATIENTS WITH MUTANT IDH2 NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (ND-AML)

C. DiNardo [1,*], A. Schuh [2], E. Stein [3], P. Montesinos [4], A. Wei [5,6], S. de Botton [7], A. Zeidan [8], A. Fathi [9], H. Kantarjian [1], P. Martin-Regueira [10], F. Lersch [10], H. Maniar [10], J. Gong [10], P. Vyas [11], H. Döhner [12]

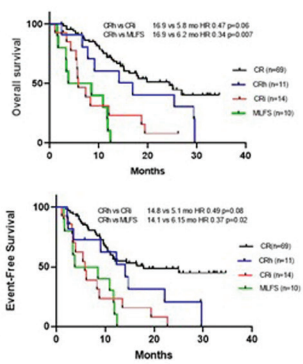
[1]The University of Texas MD Anderson Cancer Center, Houston, United States, [2]Princess Margaret Cancer Centre, Toronto, Canada, [3]Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, United States, [4]Hospital Universitari i Politecnic La Fe, Valencia, Spain, [5]The Alfred Hospital, [6]Monash University, Melbourne, Australia, [7]Gustave Roussy, Villejuif, France, [8]Yale School of Medicine, New Haven, [9]Harvard Medical School and Massachusetts General Hospital Cancer Center, Boston, [10]Bristol Myers Squibb, Princeton, United States, [11]Oxford Biomedical Research Centre and Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom, [12]Universitätsklinikum Ulm, Ulm, Germany

Background: Adding ENA to AZA *in vitro* enhances leukemic apoptosis *vs* AZA alone. ENA suppresses the oncometabolite, 2-hydroxyglutarate (2-HG), restoring function to α-ketoglutarate-dependent enzymes. In the AG221-AML-005 trial, combination ENA+AZA significantly improved overall response and complete remission (CR) rates *vs* AZA alone in patients (pts) with mutant-*IDH2* (m*IDH2*) ND-AML not eligible for intensive chemotherapy. At an August 2019 data cutoff, median overall survival (OS) was impressive at 22 mo in both arms; OS in the AZA only arm was far longer than previously reported for AZA in ND-AML (~10-14 mo).
Aims: Assess longitudinal changes in 2-HG and *IDH2* variant allele frequency (VAF) and their correlations with response, and update survival outcomes for pts in AG221-AML-005.
Methods: Pts were randomized 2:1 to ENA+AZA or AZA only. Pts received SC AZA 75mg/m^2/day (d) ×7d ± ENA 100mg PO QD (continuous) in repeated 28d cycles (C). Blood 2-HG was assessed by HPLC, and BMMC m*IDH2* VAF by digital PCR (LLQ 0.02–0.04%). Changes from baseline (BL) in 2-HG and *IDH2* VAF were assessed in pt subgroups defined by response: CR, incomplete response (IR; CRi/CRp, PR, MLFS), or no response (NR). Updated event-free survival (EFS) and OS were assessed in August 2020. EFS was the time from randomization to relapse, PD, or death, and OS was the time from randomization to death.
Results: 101 pts were randomized to ENA+AZA (n=68) or AZA only (n=33). Median age was 75 yrs (57-85). At BL, median 2-HG concentration was similar between treatment (Tx) arms (*P*=0.97). Median maximum 2-HG reduction from BL was –98% with ENA+AZA *vs* –54% with AZA (*P*<0.01). Median 2-HG reductions from BL with ENA+AZA were not significantly different among pts who achieved CR (–100%; n=37), IR (–98%; n=12), or NR (–93%; n=14), but in the AZA arm, median 2-HG reductions were significantly greater for pts who achieved CR (–79%; n=4) or IR (–85%; n=8) *vs* NR (–28%; n=17).
Median BL *IDH2* VAF was 28% in the ENA+AZA arm and 34% in the AZA arm (*P*=0.06). *IDH2* VAF was significantly reduced from BL in the ENA+AZA arm by C3 (–23%; *P*≤0.01) and continued to decrease through C11 (–98%; *P*≤0.001); maximal median change from BL was significantly greater with ENA+AZA *vs* AZA (–83.4% *vs* –17.7%; *P*<0.01). In the ENA+AZA arm, median *IDH2* VAF reductions were significantly greater for pts who achieved CR (–98%; n=30) or IR (–77%; n=10) *vs* NR (–13%; n=13), and in the AZA arm, for pts who achieved CR (–72%; n=4) *vs* NR (–7%; n=16) (**Figure**). 10 pts achieved *IDH2* molecular clearance, 9 of whom achieved CR (ENA+AZA n=8).
In August 2020, median ENA+AZA exposure was 12.1 mo and AZA exposure was 6.2 mo; 12 ENA+AZA pts remained on Tx. During follow-up, 24% of pts (16/68) in the ENA+AZA arm and 58% (19/33) in the AZA arm received subsequent AML Tx, including 11 pts in the AZA only arm (33%) who received commercially available ENA. Median EFS was nominally longer with ENA+AZA *vs* AZA (15.7 *vs* 11.9 mo; HR 0.59 [95%CI 0.31, 1.12]; *P*=0.10). Median OS was 22.0 mo with ENA+AZA *vs* 18.6 mo with AZA (HR 0.78 [0.46, 1.33]; *P*=0.36); 2-yr survival rates were 48.3% *vs* 39.9%.

Figure. Reductions from baseline in IDH2 variant allele frequency by clinical response category and randomized treatment arm

Clinical responses were classified per International Working Group (IWG) 2003 response criteria for AML. The IR category includes CR with incomplete blood count or platelet recovery (CRi/CRp), partial remission (PR), and morphologic leukemia-free state (MLFS). The NR category includes stable disease (SD) and disease progression (PD).
AZA, azacitidine; CI, confidence interval; CR, complete response; ENA, enasidenib; IDH2, isocitrate dehydrogenase 2; IR, incomplete response; No, number; NR, no response; Pts, patients; VAF, variant allele frequency.

Summary/Conclusion: Reductions in 2-HG and *IDH2* VAF were significantly greater with ENA+AZA *vs* AZA only. 2-HG changes with ENA+AZA were not correlated with response but changes in *IDH2* VAF were greater in responding pts. Survival was promising in both arms, and may be confounded by the high rate of subsequent AML Tx, including commercial use of ENA, in the AZA only arm during survival follow-up. Approximately one-half of pts treated with ENA+AZA were alive at 2 yrs.



EP466 PROGNOSTIC VALUE OF CRH IN ACUTE MYELOID LEUKEMIA TREATED WITH VENETOCLAX AND DECITABINE

M. Siddiqui [1,*], A. Maiti [1], N. Daver [1], T. Kadia [1], C. Rausch [2], Y. Alvarado [1], M. Ohanian [1], N. Short [1], K. Takahashi [1], M. Yilmaz [1], F. Ravandi [1], H. Kantarjian [1], C. DiNardo [1], M. Konopleva [1]

[1]Leukemia, [2]Clinical Pharmacy, MD Anderson Cancer Center, Houston, United States

Background: Recent FDA approvals of novel therapies and hypomethylating agents / venetoclax has transformed therapy of newly diagnosed older patients with AML. While achievement of complete remission (CR) has been the gold standard for AML response, novel therapies with different response dynamics warrant re-evaluation of response criteria. CR with partial hematological recovery (CRh, bone marrow blasts ≤ 5%, ANC > 0.5 x 10^9 /L *and* platelet count >50 x 10^9 /L) has been employed as a surrogate marker for efficacy and clinical benefit.
Aims: We evaluated the impact of CRh on long-term outcomes of older pts with newly diagnosed AML treated with 10-day decitabine and venetoclax (DEC10-VEN, NCT03404193).
Methods: Patients with newly diagnosed AML ages >60 years, or secondary AML were included. Patients received decitabine 20 mg/m^2 IV for 10 days with oral venetoclax 400 mg daily for induction and decitabine for 5 days with daily venetoclax for consolidation. Definitions of best response were as following: CR (Bone marrow blasts ≤ 5% blasts, absence of circulating blasts and blasts with Auer rods, absence of extramedullary disease and ANC > 1 x 10^9 /L with platelet count >100 x 10^9 /L), CR with incomplete hematologic recovery, CRi (All CR criteria but with residual cytopenia such as ANC < 1 x 10^9 /L or platelet count <100 x 10^9 /L) and morphological leukemia free state, MLFS (CR criteria without hematologic recovery). Outcomes of interest included overall survival (OS) and event-free survival (EFS). Full study protocol and interim results have been published previously (DiNardo et al. Lancet Haematol. 2020;7:e724-36.)
Results: From January 2018 - February 2021 125 patients with a median age of 71 yrs (range 48-89) were included. 79 (63%) pts were newly diagnosed AML and 46 (37 %) had secondary AML with antecedent hematological disorder (**Figure 1**). 69 patients achieved CR (55%), 11 (8%) pts achieved CRh, 14 (11%) pts achieved CRi, 10 (8%) pts achieved MLFS and 21 (17%) pts were refractory. Of the 11 pts who met the criteria for CRh, 8 (73%) patients were previously classified as CRi and 3 (27%) as MLFS. Among 69 pts achieving CR, the median OS was 24.5 months (mo) and median EFS was 18.0 mo. CRh was achieved with a median of 1 (range 1-3) cycles. Median OS of CRh as compared to CRi was 16.9 vs 5.8 mo (HR 0.47, 95% CI 0.19-1.13, p=.06) and CRh vs MLFS was 16.9 vs 6.2 mo (HR 0.34, 95% CI 0.13-0.93, p=.007). Median EFS of pts with CRh vs CRi was 14.1 vs 5.8 mo (HR 0.49, 95%CI 0.21-1.14, p=.08) and CRh vs MLFS was 14.1 vs 6.2 mo (HR 0.37, 95% CI 0.14-1.01, p=.016). Pts achieving CRh defined a group with durable remission with duration of response of 6.0 vs 2.5 mo with CRi and 1 mo with MLFS. Additional analyses are ongoing and will be presented.

Summary/Conclusion: In pts with newly diagnosed AML and secondary AML treated with DEC10-VEN, pts achieving CRh had a trend towards improved OS and EFS compared to pts with CRi or MLFS. These findings support the use of CRh as an endpoint demonstrating clinical benefit for patients receiving venetoclax-based therapy. Larger analyses are warranted.

EP467 ACTIVITY OF DECITABINE COMBINED WITH ALL-TRANS RETINOIC ACID IN OLIGOBLASTIC AML: RESULTS FROM A RANDOMIZED 2X2 PHASE II TRIAL

Background: DNA-hypomethylating agents are the backbone for non-intensive combination treatments of AML/MDS patients (pts). In elderly AML pts, the decitabine (DAC) + all-trans retinoic acid (ATRA) combination resulted in an improved response rate and survival compared to DAC without ATRA (DECIDER, Lübbert et al., *J. Clin. Oncol.* 2020), also in pts with prior hematologic disorder (mostly MDS).
Aims: We hypothesized that the outcome of pts with oligoblastic AML may also be improved by the addition of ATRA to DAC. Therefore, pts from the DECIDER cohort with 20-30% bone marrow blasts were analyzed for clinical outcome in this exploratory subgroup analysis.
Methods: Key inclusion criteria: newly diagnosed pts >60 years (yr), unfit for induction with non-M3 AML, ECOG performance status (PS) 0-2. Treatment: DAC 20 mg/m^2 day 1-5 (treatment arms A/B/C/D), ATRA p.o. day 6-28 (arms C/D), VPA p.o. continuously from day 6 (arms B/D) of each 28-day course (repeated until relapse/progression, prohibitive toxicity, withdrawal or death). Key endpoints: objective response rate (ORR): CR/CRi/PR, overall (OS) and event-free survival (EFS). For a power of 80% (test in this phase II study at 1-sided alpha=0.1) for an

increase of ORR to 40% with ATRA or VPA, 176 pts were necessary, planned sample size 200. Between 12/2011 and 2/2015, 200 pts were randomized and treated. Efficacy analyses were performed in the intention-to-treat (ITT) population. ATRA was investigated by comparing arms C+D vs arms A+B, VPA by comparing arms B+D vs arms A+C, ORR was analyzed with logistic regression estimating odds ratios (OR), OS/EFS with Cox regression estimating hazard ratios (HR), each with 95% confidence intervals (CI), and presented with descriptive two-sided p values of the tests of no treatment effect.

Results: Bone marrow blasts were 20-30% (median, 25%) defining oligoblastic AML in 56/200 pts of the DECIDER cohort. The number of pts in the randomized arms were: 13 in arm A, 21 in arm B, 9 in arm C, 13 in arm D. Baseline pt characteristics: male 77%, median age: 75 yr (range 61-88), median WBC: 3400/µl (range 500-52,600), adverse genetics (ELN 2010) present in 25%, ECOG 2 in 13%, comorbidities (HCT-CI) ≥ 3 in 48%, AHD in 68%, tAML in 11%. A median of 5 DAC courses were administered (per arm: 2/5/11/4). Six pts attained a CR, 7 pts a CRi, and 1 pt a PR, resulting in an ORR of 25% (arm A: 7.7%, arm B: 28.6%, arm C: 33.3%, arm D: 30.8%, respectively). Effect on ORR of ATRA vs no ATRA (31.8 vs 20.6%): OR 1.85, CI [0.54,6.37], p=0.33; and of VPA vs no VPA (29.4 vs 18.2%): OR 1.93, CI [0.51,7.24], p=0.33. With 40 deaths out of 56 pts, median OS was 9.5 mths (arm A: 7.6 mths, arm B: 8.9 mths, arm C: 37.2 mths, arm D: 11.2 mths, respectively). Effect on OS of ATRA vs. no ATRA (12.5 vs 7.6 mths median OS, Fig. 1): HR 0.47, CI [0.24,0.94], p=0.032 (after adjustment for PS, HCT-CI, WBC, LDH, genetic risk: HR 0.42, CI [0.19,0.90], p=0.025); and of VPA vs. no VPA (10.0 vs 8.4 mths median OS): HR 0.99, CI [0.51,1.92], p=0.98. A comparable benefit on EFS of ATRA vs. no ATRA (but not VPA vs. no VPA) was observed.

Fig. 1: Overall survival of patients with oligoblastic AML is improved when decitabine is combined with ATRA (red curves) compared to decitabine without ATRA (blue curves, Kaplan-Meier method). Solid curves: unadjusted; broken curves: adjustment for performance status (ECOG), comorbidities (HCT-CI), WBC, LDH, genetic risk (ELN 2010)

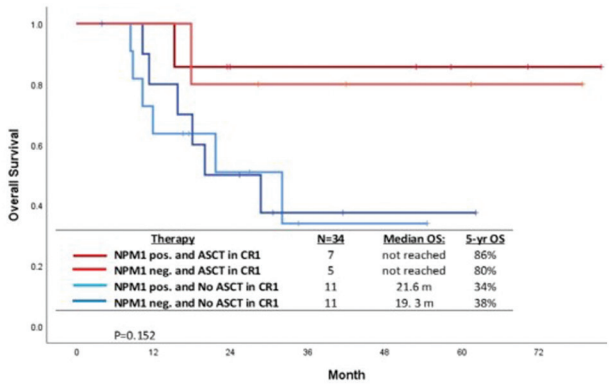
Summary/Conclusion: In elderly pts with oligoblastic AML ineligible for induction chemotherapy, the addition of ATRA, but not VPA, to DAC resulted in a clinically meaningful survival benefit. It is tempting to speculate that the combination of an HMA with a retinoid may also be active in MDS pts with excess of blasts. In this regard, a novel and potent RARα receptor agonist (SY-1425) is under clinical development combined with an HMA in AML/MDS (De Botton S. et al., *ASH Abs. 112*, 2020).

EP468 FLT3 INHIBITOR BASED INDUCTION AND ALLOGENEIC STEM CELL TRANSPLANT IN CR1 IMPROVE OUTCOMES IN PATIENTS WITH NEWLY DIAGNOSED AML VERY LOW FLT3 ALLELIC BURDEN

M. Yilmaz [1,*], F. Ravandi [1], G. Borthakur [1], T. Kadia [1], C. Dinardo [1], R. Kanagal-Shamanna [1], S. Loghavi [1], B. Oran [1], U. Popat [1], S. Pierce [1], E. Jabbour [1], N. Short [1], G. Issa [1], N. Pemmaraju [1], M. Konopleva [1], K. Patel [1], H. Kantarjian [1], N. Daver [1]

[1]*MD Anderson Cancer Center, Houston, United States*

Background: The use of FLT3 inhibitors (FLT3i) has improved overall survival (OS) in patients with newly diagnosed *FLT3*-mutated acute myeloid leukemia (AML). However, the role of FLT3i in patients with very low *FLT3*-ITD allelic burden is unclear.



Aims: To analyze the role and impact of FLT3i's, NPM1 co-mutation, and allogeneic stem cell transplantation (ASCT) in patients with a very low FLT3 allelic burden.

Methods: A multiplex PCR-based DNA analysis followed by capillary electrophoresis was utilized to detect *FLT3*-ITD mutations at diagnosis and relapse. Allelic frequency (AF) is defined as the ratio of mutated *FLT3*-ITD divided by wild type plus mutated FLT3-ITD. We identified 50 patients with newly diagnosed AML (excluding core-binding factor AML and acute promyelocytic leukemia) from 2012 – 2020 at our institusion who had a *FLT3*-ITD AF ≤0.10 (i.e. ≤10%) at baseline.

Results: Of the 50 patients, 30 (60%) received frontline therapy not including a FLT3i (no FLT3i cohort), and 20 with a FLT3i (FLT3i cohort) containing regimen. Patients in the FLT3i cohort were younger than the no FLT3i cohort (median age 58 [28-83] vs. 67 [23-84] years old, p=0.03), and more often received intensive (cytarabine and antracycline based) induction (80% vs 43%, p=0.01). Otherwise, there were no other significant baseline clinical difference between the two cohorts. Baseline median ITD AFs were not significantly different between FLT3i (0.05) and no FLT3i (0.03) cohorts. Of the 20 patients in FLT3i group, 19 (95%) received sorafenib, and 1 (5%) received quizartinib based therapies.

Overall, 37 of 50 (74%) patients achieved a complete remission (CR). With a median follow-up of 42 months, 12 (32%) patients relapsed. The incidence of *FLT3*-ITD positivity at relapse was 42% (5 of 12). All *FLT3* positive relapses were identified in the no FLT3i cohort (5 of 8), with no FLT3 positive relapses observed in the FLT3i cohort (0 of 4): 63% vs. 0%, respectively (p=0.04). There was a trend for better OS in the FLT3i cohort compared with no FLT3i cohort, not reached vs. 17 months (p=0.31). The 5-year OS rate was improved in patients who received a FLT3i with induction and ASCT compared with patients who did not receive a FLT3i with induction and did not receive ASCT (100% vs 27%, p=0.08).

Overall, 14 patients underwent ASCT (6 FLT3i and 8 no FLT3i cohort) in first remission with a median time to ASCT from induction of 114 days (range 79-230 days). A landmark analysis (at 3-month post ASCT) showed that 5-year OS rate was superior in patients who underwent ASCT in CR1 (N=14) compared with those who did not (N=22), 85% vs. 34%, respectively (p=0.01). Interestingly in this low FLT3-ITD VAF (≤0.1) population the 5-year OS in patients with NPM1 co-mutation who received ASCT (N=7), NPM1 without ASCT (N=11), no NPM1 with ASCT (N=5), and no NPM1 without ASCT (N=11) were 86%, 34%, 80%, and 38%, respectively (p=0.15) [Figure].

Summary/Conclusion: The use of FLT3i reduced the incidence of FLT3 positive relapses. The use of FLT3i with induction and ASCT showed improved OS in AML patients with very low FLT3-ITD AFs. Even among patients with very low FLT3-ITD VAF and NPM1 comutations, ASCT appeared to improve 5-year OS (86% vs 34%). We recommend that all FLT3-ITDm patients receive a FLT3i with induction and be considered for ASCT in CR1 irrespective of baseline FLT3 AF and/or NPM1 co-mutation status. To better understand the impact of very low FLT3 burden, future clinical trials investigating FLT3i should include low VAF FLT3-mutated AML patients.

EP469 RE-STRATIFYING THE PROGNOSES OF ACUTE MYELOID LEUKEMIA PATIENTS WITH CEBPA DOUBLE MUTATIONS BY CSF3R MUTATIONS AND MINIMAL RESIDUAL DISEASE

L. Su [1], Y. Tan [1], J. Sun [1], H. Lin [1], Q. Liu [1], C. Liu [1], Y. Yang [1], S. Gao [1,*]

[1]*Department of Hematology, The First Hospital of Jilin University, Changchun, China*

Background: Although AML with *CEBPA*^{dm} indicates a favorable outcome, both our study and data from other studies showed that approximate half of the patients finally relapsed consolidated with chemotherapy alone. Therefore, the heterogeneity of acute myeloid leukemia (AML) with *CEBPA*^{dm} attracts much attention in recent years.
Aims: The aim of this study was to evaluate the influence of *CSF3R* mutations and chemosensitivity indexes on prognoses of AML patients with *CEBPA*^{dm}.
Methods: Sixty-six AML patients with complete genetic mutations and sequential minimal residual disease (MRD) information were retrospectively analyzed in this study.
Results: In AML patients with *CSF3R* mutations, 56.25% (9/16) of the patients achieving negative MRD after two courses of chemotherapy, which was significantly lower than those without mutation (82.00%, 41/50, P = 0.049). Both *CSF3R* mutations and MRD status after the second course of chemotherapy associated with long-term outcomes of patients. *CSF3R* mutated patients showed inferior relapse-free survival (RFS) (5-year RFS: 15.19% *vs.* 38.7%, *P* = 0.006) and overall survival (OS) (5-year OS: 8.2% *vs.* 60.6%, *P* = 0.038) compared with those with wide-type *CSF3R*. Negative MRD after the second course of chemotherapy was also an unfavorable indictor for both RFS (5-year RFS: 0.00% *vs.* 45.5%, *P* = 0.004) and OS (5-year OS: 0.00% *vs.* 65.4%, *P* = 0.050). Finally, a new prognostic model was proposed for AML with *CEBPA*^{dm} in this study.
Summary/Conclusion: Both *CSF3R* mutations and positive MRD after the second course of chemotherapy were associated with poor outcomes for AML patients with *CEBPA*^{dm}. An integrity model based on *CSF3R* mutations and MRD status may be beneficial for evaluating the prognoses of these patients.

EP470 SUPERIOR OUTCOMES FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION IN FIRST REMISSION FOR NPM1/FLT3-ITD MUTATED AML

C. Wright [1,*], B. Newman [1], E. Gudgin [1], A. Godfrey [1], C. Crawley [1], F. Basheer [1], A. King [1], B. Huntly [1], K. Tawana [1]

[1]Department of Haematology, Addenbrooke's Hospital, Cambridge, United Kingdom

Background: Multiple studies have revealed the prognostic utility of combining *FLT3*-ITD and *NPM1* mutation status to identify patients benefiting from allogeneic stem cell transplantation (alloSCT) in first remission (CR1). In recent years, analysis of peripheral blood measurable residual disease (MRD) has superseded genetic risk stratification for *NPM1* mutated (*NPM1*+) AML within the UK. This strategy aims to reduce SCT-related toxicity, but requires demonstration of chemo-sensitivity at relapse for higher-risk genotypes, in particular patients with *FLT3*-ITD mutations.
Aims: We aimed to assess clinical outcomes in *NPM1*+ AML, comparing the impact of *FLT3*-ITD mutations in patients receiving consolidation with chemotherapy versus alloSCT in CR1 and reviewing responses to second-line therapies at relapse.
Methods: Retrospective analysis identified 115 patients with *NPM1*+ AML eligible for intensive therapy between 2014-2020. The median age was 59y, 53% were male and median follow-up was 3.2y. *FLT3*-ITD mutations were detected in 38% of cases (*NPM1*+/*FLT3*-ITD+, n=44), for the purposes of this study, *FLT3* tyrosine kinase domain mutations (n=16) were classified as *FLT3*-ITD negative (*FLT3*-ITD-ve) AML.
Results: CR rates were comparable for both *FLT3*-ITD+ and *FLT3*-ITD-ve cases following induction therapy (91% vs 94%, p=0.48). Within *FLT3*-ITD+ cases, 32% (n=14) underwent alloSCT in CR1, compared with only 11% (n=8) of *FLT3*-ITD-ve cases. Notably, *FLT3*-ITD+ AML demonstrated lower survival (hazard ratio, 2.18, p=0.02) and a higher risk of relapse (HR 1.88, p=0.03) compared to *FLT3*-ITD-ve cases, regardless of therapy.
Further analysis revealed a significantly higher risk of relapse (HR 3.84, p=0.02), inferior median disease-free survival (0.80y vs not reached, p=0.002) and median overall survival (1.21y vs not reached, p=0.02) for *FLT3*-ITD+ cases receiving chemotherapy consolidation, compared with alloSCT in CR1. Interestingly, the small number of *FLT3*-ITD-ve cases undergoing alloSCT in CR1 (n=8) also demonstrated superior outcomes, with no deaths or relapses, compared with those receiving chemotherapy alone (median DFS not reached vs 2.0y, p=0.03 and median OS not reached vs 5.7y, p=0.34), Fig 1 a) and b).
Relapse was observed in 47% of patients receiving chemotherapy alone (n=44); of these cases 39% (n=17) were *FLT3*-ITD+ and exhibited a significantly shorter median time to relapse vs *FLT3*-ITD-ve cases (247 days vs 413 days, p=0.01). In contrast, only 18% (n=4) of all patients undergoing alloSCT in CR1 relapsed and each harboured *FLT3*-ITD mutations. Importantly, 52% (n=14) of *FLT3*-ITD-ve cases achieved a second remission (CR2) with chemotherapy, while only 24% (n=5) of *FLT3*-ITD+ cases were able to reach CR2 (p=0.049 [data precede availability of Gilteritinib at relapse]). These findings highlight the chemo-refractory nature of relapsed *FLT3*-ITD mutated AML, with a significantly reduced median survival post-relapse, compared with *FLT3*-ITD-ve cases (0.5y vs 1.1y, p=0.03).

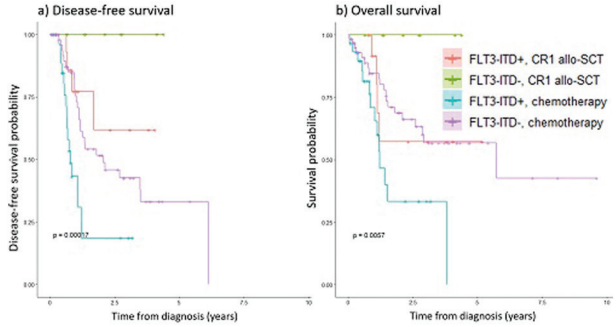


Figure 1. (a) Disease free survival (DFS) (b) Overall survival (OS) for NPM1+ AML cases comparing FLT3-ITD positivity and consolidation with chemotherapy vs alloSCT in CR1. Both median DFS and OS were significantly improved in FLT3-ITD+ patients undergoing alloSCT vs consolidation with chemotherapy alone.

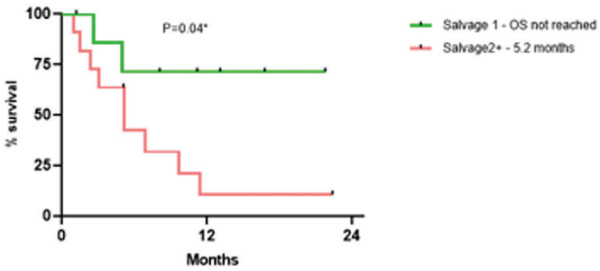
Summary/Conclusion: This study demonstrates favourable survival for patients with *NPM1*+/*FLT3*-ITD+ AML undergoing alloSCT in CR1. Significantly higher relapse rates were observed in *FLT3*-ITD+ cases treated with chemotherapy alone, followed by poor responses to salvage chemotherapy and fewer patients achieving CR2. Collectively, our data suggest that alloSCT consolidation should be prioritised in *NPM1*+/*FLT3*-ITD+ AML to achieve improved long-term outcomes within this higher risk cohort.

EP471 EFFICACY AND SAFETY OF ENASIDENIB AND AZACITIDINE COMBINATION IN PATIENTS WITH IDH2 MUTATED ACUTE MYELOID LEUKEMIA AND NOT ELIGIBLE FOR INTENSIVE CHEMOTHERAPY



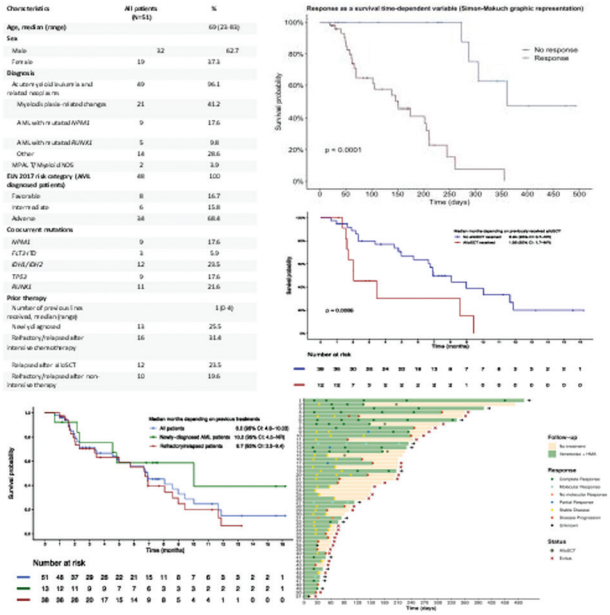
S. Venugopal [1,1,*], K. Takahashi [1], N. Daver [1], G. Borthakur [1], S. Loghavi [2], N. J. Short [1], M. Ohanian [1], L. Masarova [1], G. C. Issa [1], C. Bueso-Ramos [2], M. Yilmaz [1], T. Kadia [1], M. Andreef [1], F. Ravandi [1], M. Konopleva [1], H. Kantarjian [1], C. DiNardo [1]

[1]Leukemia, [2]Hematopathology, The University of Texas, MD Anderson Cancer Center, Houston, United States

Background: ENA is approved in the US for adult pts with relapsed/refractory (R/R) m*IDH2* AML. Azacitidine (AZA) is a hypomethylating agent that prolongs survival *vs*. conventional care regimens in older unfit pts with newly diagnosed (ND) AML. *In vitro*, combination ENA + AZA enhances cell differentiation. Venetoclax (VEN), a small molecule BCL2 inhibitor (i) is also effective in m*IDH2* AML related to 2-hydroxyglutarate mediated inhibition of cytochrome C oxidase. In preclinical models, the combination of ENA+VEN demonstrates synergistic anti-leukemic activity.
Aims: Evaluate the efficacy and safety of combination ENA + AZA +/- VEN in ND and R/R m*IDH2* AML
Methods: Patients (pts) with documented m*IDH2* AML: ≥ 60 yrs with ND AML and ineligible for intensive chemotherapy; >18 yrs with secondary AML (sAML) and/or R/R AML were enrolled. All pts received AZA 75 mg/m2/d x 7 d/cycle and ENA 100 mg QD continuously on NCT03683433. Cytoreduction prior to start, and concomitant BCL2 i and FLT3 i were allowed as indicated. Primary objective was overall response rate (ORR) and secondary objectives included safety and overall survival (OS).
Results: This high-risk cohort included 26 patients with a median age of 68 years (46% of pts ≥70 yrs), 28% pts had ECOG PS ≥2, 42% had received ≥2 salvage therapy, and 41% pts had ELN2017 adverse-risk AML (Table 1). 30 and 60-day mortality were both 0 for ND pts,5% and 5%, respectively, in R/R pts. Treatment-emergent adverse events (TEAE) of grade 3-4 were reported in 22/26 pts (85%), with the most frequent TEAEs including febrile neutropenia (23%), indirect hyperbilirubinemia (35%), and vomiting and diarrhea (12% each). Most AEs were manageable without dose interruption. Differentiation syndrome was reported in 2 pts (8%), occurring on days 18 and 31 of treatment.

The CR/CRi rate in ND AML was 100% (n=7/7), and in R/R AML was 58% (n=11/19) (Table). CR/CRi rate was 75% in pts in first relapse (n=6/8); and 45% in ≥2 relapse (n=5/11). CR/CRi rate in pts with prior HMA was 67% (n=6/9), in pts with prior ENA was 75% (n=3/4), and in pts with prior stem cell transplantation (SCT) was 60% (n=3/5). 39% of all responders (n=7/18) achieved MRD negativity by flow cytometry (MRD ^{neg} FCM) and MRD ^{neg} status was associated with longer OS (NR vs 6.9 mo, HR 0.16, 95% CI 0.05-0.5, p=0.04). At median follow-up of 13.1 months (mo), the 1-year OS in ND AML was 85%, in first relapse was 75%, in ≥2 relapse was 10%. Median OS was not reached in ND AML; Pts treated in first relapse had a significantly superior OS than those in ≥2 relapse. (median OS not reached vs 5.2 mo; HR 0.24, 95% CI 0.07-0.79, p=0.04, Fig.)
In the m*IDH2* R/R AML cohort, 7 pts received the ENA+AZA+VEN triplet, among which 4 had received prior HMA and one had received prior HMA and ENA separately. None had received prior VEN. The CR/CRi rate was 86% (n=6/7) with 33% MRD^{neg} FCM (n=2/6) with one patient proceeding to SCT. At a median follow up of 11.2 mo, median OS was not reached, and 6-mo OS was 70% in those who received ENA+AZA+VEN. With a median follow-up of 13.1 mo, 38% (n=9) remain on treatment and 54% alive (n=14) at last follow up. Reasons for treatment discontinuation(n=17): relapse (n=1, 4%), SCT (n=4, 15%), death (n=8, 31%), refractory disease (n=3, 12%), and personal choice (n=1,4%).

	ND N= 7	R/R N=19
ORR, n (%)	7 (100)	11 (58)
Complete remission (CR)	5 (72)	5 (26)
MRD neg CR	5 (100)	2/5 (40)
Complete remission with incomplete hematological recovery	2 (28)	6 (32)
Not evaluable	0	1 (5)
No response	0	7 (37)
Median number of cycles given (range)	3 (1-8)	4 (1-17)
Median time to best response, months (range)	1.6 (1.0-4.2)	1.8 (0.8-5.4)



Summary/Conclusion: AZA+ENA is an effective therapy for IDH2-mutated AML.ENA+AZA+VEN may be an effective combination therapy for mIDH2 R/R AML, even in patients having received prior enasidenib.

EP472 REAL-LIFE PRELIMINARY EXPERIENCE OF TREATMENT OF NEWLY-DIAGNOSED AND REFRACTORY/RELAPSED (R/R) ACUTE MYELOID LEUKEMIA PATIENTS WITH COMBINATION OF VENETOCLAX WITH HYPOMETHYLATING AGENTS

C. Jimenez-Vicente [1,*], A. Martinez-Roca [1], A. Bataller [1], S. Castaño-Diez [1], F. Guijarro [2], D. Esteban [1], M. Gomez-Hernando [1], C. Castillo-Giron [1], A. Alvarez-Larran [1], N. Socoro [3], G. Riu [3], I. Monge [3], E. Carcelero [3], F. Fernandez-Aviles [1], M. Diaz-Beya [1], J. Esteve [1]

[1]Haematology Department, [2]Haematopathology Unit, [3]Pharmacy Department, Hospital Clinic of Barcelona, Barcelona, Spain

Background: Combination of venetoclax (Ven), a specific BCL-2 inhibitor, with hypomethylating agents (HMA) provides a clinical benefit to newly-diagnosed acute myeloid leukaemia (AML) patients ineligible for standard chemotherapy, with a reported overall response rate over 60% and a low early death rate, improving previous results obtained with HMA monotherapy (DiNardo CD, et al., NEJM 2020). Moreover, role of VenHMA is being explored in other clinical settings. In 2019 we introduced in our institution this regimen for both patients with newly-diagnosed AML (ND-AML) ineligible patients for standard chemotherapy and R/R AML without alternative salvage options.
Aims: Herein, we present the outcome of the patients treated with VenHMA, focusing on the analysis of possible predictors of clinically meaningful benefit.
Methods: We analyzed the overall response and follow-up of 51 patients diagnosed with AML and mixed-phenotype acute leukaemia (MPAL, n=2) who received a combination of off-label venetoclax (400mg/24h; initial ramp-up 100-200-400mg in 3 consecutive days, with dose adjustment in patients who also received CYP3A4 inhibitors), with standard-dose azacytidine (75mg/m^2) or decitabine (20mg/m^2) from March 2019. Response to treatment was evaluated following the European LeukaemiaNet 2017 criteria. Effect of response in overall survival was evaluated as a time-dependent variable (Mantel-Byar method, Simon-Makuch survival plot). Event was defined as death, progressive disease or refractoriness to treatment.
Results: Characteristics of our cohort are described in table 1. Notably, our cohort was enriched with high-risk ELN subtypes, in two thirds of patients. Median number of VenHMA cycles received was two (range 1-11), with on-going treatment in 14 patients. Early mortality in the first 30 days was only 2% (1 patient). Response rate (Complete response (CR) + complete response without haematological recovery (CRi) + partial response (PR)) was 54% in ND-AML (CR= 23%) and 29% in R/R AML (CR= 12%) with a median of one cycle to achieve the best response (range: 1-5). Four patients were treated in a molecular-MRD positive status, 3 of them achieving a molecular response (3/3 *NPM1*mut AML). Four patients proceeded to an allogeneic haematopoietic cell transplantation (alloHSCT). Median overall survival in the cohort was 6.9 months (1.52). Median overall survival was respectively 10 months (2.78) in ND-AML patients and 6.7 months (1.8) in R/R AML patients. 6-month overall survival was 56.2% (14.9) and event-free survival was 6.6 months. Response to treatment after two cycles, estimated with Mantel-Byar method, segregated two groups of patients, with an overall survival of 12 months in patients who achieved a CR/CRi versus 5 months in non-responders (p<0.0001). Furthermore, patients treated after alloHSCT relapse presented a dismal outcome (6.94 vs. 1.88 months, p<0.001). There were no other significant clinical or biological variables able to predict outcome.

Summary/Conclusion: VenHMA is a highly active low-intensity regimen associated to a relatively low toxicity profile, providing a meaningful antileukaemic effect in a subset of patients not considered appropriate for higher intensity regimens, including the possibility to bridge some patients to alloHSCT. Despite the precise subset of patients who can

benefit from this combination is still uncertain, especially in the R/R AML setting, its role in post-alloHSCT failure seems very limited. Early scope of response allows a rapid identification of those patients who benefit from continued treatment with VenHMA.

EP473 PROGNOSTIC SIGNIFICANCE OF ACHIEVING A COMPLETE REMISSION AFTER ONE OR TWO CYCLES OF INDUCTION CHEMOTHERAPY IN NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA: ANALYSIS OF DATA FROM THE DATOOL-AML DATABASE

L. Semerad [1,*], P. Cetkovsky [2], P. Jindra [3], Z. Koristek [4], J. Novak [5], Z. Novakova [1], Z. Racil [2], T. Szotkowski [6], B. Weinbergerova [1], P. Zak [7], Z. Pospisil [8], J. Mayer [1]

[1]University Hospital Brno, Brno, [2]Institute of Hematology and Blood Transfusion, Prague, [3]University Hospital Pilsen, Pilsen, [4]University Hospital Ostrava, Ostrava, [5]University Hospital Kralovske Vinohrady, Prague, [6]University Hospital Olomouc, Olomouc, [7]University Hospital Hradec Kralove, Hradec Kralove, [8]Masaryk University, Brno, Czech Republic

Background: The achievement of a complete remission (CR) of acute myeloid leukemia (AML) after induction chemotherapy is an important factor for long-time survival. A good effect of the 1st induction cycle is a reduction of blast count to <5% in bone marrow on the day 15 or at the time of the blood count restitution. Otherwise, the patients receive the 2nd induction cycle, which can be based on the repeated 7+3 regimen as in the 1st induction cycle, or on a regimen with high-dose cytarabine. Resistant disease after the 2nd induction cycle has a poor prognosis. However, the prognosis of patients who achieved CR only after the 2nd induction cycle, compared to patients who achieved CR after the 1st induction cycle, is less clear.
Aims: First, to assess whether the relapse free survival (RFS) and the overall survival (OS) of patients who achieved CR only after the 2nd induction cycle differ from those who achieved CR after the 1st induction cycle. Second, to assess whether the type of regimen of the 2nd induction cycle (high-dose cytarabine regimens versus 7+3 regimen) correlates with CR rate, early death rate, RFS and OS of patients.
Methods: A retrospective analysis of real-world nationwide data from the database DATOOL-AML. Intensively treated adult patients with newly diagnosed AML (except AML M3) were included. The study period was 2007-2019.
Results: During the study period, 1010 patients (pts.) have initiated intensive induction chemotherapy; 631 (62.5%) pts. achieved CR after the 1st induction cycle (*CR I group*) and 191 (18.9%) pts. achieved CR only after the 2nd induction cycle (*CR II group*). The median age was 53 (18-74), the median follow-up was 24.7 months. There was a significantly higher proportion of intermediate I, intermediate II and adverse risk patients (ELN 2010 risk category) in the *CRII group*. On the contrary, the frequency of favorable risk patients in the *CR II group* was significantly lower, see Table 1. Allogeneic hematopoietic stem cell transplantation (HSCT) in the first CR was performed more frequently in *CR II group* and the difference was most evident in low and intermediate I risk categories, see Table 1. At 4 years, RFS of pts. in *CR I group* and in *CR II group* was 39.0% and 38.0%, respectively (p=0.179). At 4 years, OS of pts. in *CR I group* and *CR II group* was 52.6% and 46.2%, respectively (p=0.069). The high-dose cytarabine regimens administered during the 2nd induction cycle did not differ regarding the CR rate or early death rate in comparison to 7+3 regimen. CR rate after high-dose regimens versus 7+3 regimen was 62.4% and 69.8%, respectively (p=0.656), and early mortality rate was 6.6% and 4.7%, respectively (p=1.000). At 4 years, RFS of pts. treated by high-dose cytarabine regimens versus 7+3 regimen was 38.0% and 40.7% (p=0.449), and OS at 4 years was 43.3% and 68.8%, respectively (p=0.267).

	CR after the 1st induction cycle N (%)	CR after the 2nd induction cycle N (%)	P-value
Overall	631	191	x
ELN 2010 Category			
Favorable	216 (36.4)	19 (10.6)	<0.001
Intermediate I	221 (37.3)	82 (45.8)	0.049
Intermediate II	73 (12.3)	34 (19.0)	0.023
Adverse	83 (14.0)	44 (24.6)	0.001
Missing	38	12	x
Allo HSCT in 1st CR	245 (38.8)	128 (67.0)	0.001
Favorable	31 (14.4)	11 (57.9)	<0.001
Intermediate I	107 (48.4)	55 (67.1)	0.004
Intermediate II	38 (52.1)	23 (67.6)	0.147
Adverse	45 (54.2)	33 (75.0)	0.023

Summary/Conclusion: We did not demonstrate any difference in RFS in patients who achieved CR after the 2nd induction cycle compared to patients who achieved CR after the 1st induction cycle. There was a trend in inferior OS of patients who achieved CR after the 2nd induction cycle, but it was not statistically relevant. The results might be explained by the significantly higher number of allogeneic HSCT performed in the first remission in patients who achieved CR after the 2nd induction cycle. High-dose cytarabine reinduction regimens did not result in a substantial prolongation of RFS or OS compared to standard 7+3 regimen.

EP474 SORAFENIB IN COMBINATION WITH INTENSIVE CHEMOTHERAPY FOR RELAPSED OR REFRACTORY FLT3-ITD POSITIVE ACUTE MYELOID LEUKEMIA: A SINGLE-INSTITUTION EXPERIENCE

I. Urbino [1,2,*], C. Secreto [1,2], V. Apolito [1,2], M. Olivi [1,2], S. D'Ardia [1], C. Frairia [1], V. Giai [1], C. Dellacasa [3], G. Iovino [1], L. Giaccone [2,3], A. Busca [3], D. Ferrero [2], E. Audisio [1], M. Cerrano [1]

[1]Department of Oncology, Division of Hematology, A.O.U. Città della Salute e della Scienza di Torino, [2]Department of Molecular Biotechnology and Health Sciences, Division of Hematology, University of Torino, [3]Department of Oncology, SSCVD Trapianto di Cellule Staminali, A.O.U. Città della Salute e della Scienza di Torino, Torino, Italy

Background: patients (pts) with relapsed/refractory (R/R) FMS-like tyrosine kinase 3 (*FLT3*)-mutated acute myeloid leukemia (AML) have a poor prognosis. In this setting, response to salvage chemotherapy (CHT) alone has been unsatisfactory and first generation FLT3-inhibitors have shown limited activity in monotherapy. New selective and strong inhibitors, including the recently approved gilteritinib, are rapidly changing the treatment paradigm, being able to induce remission in a significant proportion of pts with limited toxicities. However, little is known about the efficacy and safety of intensive CHT combined with FLT3-inhibitors in R/R AML population.
Aims: we assessed the safety and efficacy of salvage chemotherapy in combination with the FLT3-inhibitor sorafenib in R/R AML pts.
Methods: we retrospectively analyzed R/R *FLT3*-ITD AML patients aged ≥ 18 years treated with intensive chemotherapy and sorafenib at our institution from July 2015 to December 2020. All patients had received a 3+7-like induction regimen with or without a FLT3 inhibitor. In case of refractoriness to induction or relapse, patients were treated with fludarabine and high-dose cytarabine-based chemotherapy plus sorafenib, at the dose of 400 mg BID for 14 days continuously after the end of CHT. The dose of sorafenib could be reduced in frailer patients.
Results: twenty-two pts were included, (male 59%), with a median age of 50 years (21-73). Eight pts (36%) harbored a *NPM1* mutation, 6 pts other molecular anomalies (*MLL*-PTD in 5, *IDH1* and *IDH2* in 1 each) and in 4 cases cytogenetic alterations were identified (+6, +8; -7; del7q). Sixty-four per cent of the pts (n=14) were refractory to induction, while 36% (n=8) relapsed after having achieved a remission. Complete remissions (CR) plus CR with incomplete hematologic recovery (CRi) after salvage CHT combined with sorafenib was of 63% (64% in refractory cases vs. 62.5% in relapsed ones). Patients with *NPM1* mutation had a CR/CRi rate of 88% vs. 50% in the remaining ones. After a median follow up of 45 months, median overall survival (OS) after salvage therapy was of 13 months, with 4-year OS of 35.9%. For the 14 patients achieving CR/CRi, median relapse-free survival (RFS) was of 5 months, with 4-year RFS of 35.7%. Consolidation with allogeneic stem cell transplantation (HSCT) was performed in 13 pts (59%), 4 of them with active disease. Median OS of transplanted pts was not reached, with 4-year OS of 50.4%. The most common toxicities of CHT plus sorafenib were neutropenic fevers (95%), gastrointestinal (54%) and hepatic (54%) and cutaneous (27%) toxicities, pneumonia (27%) and cardiac complications (18%). Grade 4 toxicities were observed in 3 pts (1 pneumonia, 1 neutropenic enterocolitis, 1 QTc prolongation).
Summary/Conclusion: sorafenib in association with high-dose CHT represented a feasible second line option for the treatment of *FLT3*-ITD positive R/R AML, with encouraging rates of CR/CRi, especially in *NPM1*-mutated cases, and roughly 50% of transplanted patients experiencing long-term survival. Toxicities were not negligible, but in line with those expected after intensive CHT in this population. The potential benefit of combining FLT3 inhibitors with intensive chemotherapy should be further explored in this setting for fit patients, and this strategy is currently under investigation in clinical trials testing new FLT3 inhibitors.

EP475 RISK FACTORS AND MANAGEMENT OF CATHETER-RELATED THROMBOSIS IN ADULT PATIENTS WITH NEWLY-DIAGNOSED ACUTE MYELOID LEUKEMIA

S. Perek [1,2], A. Khatib [1], N. Izhaki [1], A. S. Khalaila [3], N. A. Horowitz [2,4,*]

[1]Internal Medicine A, Rambam Health Care Campus, [2]Bruce Rappaport Faculty of Medicine, Technion, Haifa, [3]Internal Medicine, Nazareth Hospital EMMS, Nazareth, [4]Department of Hematology and Bone Marrow Transplantation, Rambam Health Care Campus, Haifa, Israel

Background: Newly-diagnosed acute myeloid leukemia (NDAML) patients (pts) frequently develop catheter-related thrombosis (CRT) despite concurrent thrombocytopenia. The risk of symptomatic CRT in these pts varies between 5%>10%. While risk factors for CRT occurrence in pts with solid tumors are well-established, such data in NDAML are scarce. CRT treatment in NDAML is challenging due to concomitant severe thrombocytopenia and high bleeding risk. Current treatment strategies include catheter removal and full/low dose anticoagulation supported by platelet transfusion. Modification of anticoagulant therapy is based on platelet counts, with predetermined cutoffs for dose adjustment (25-50x10^9) and treatment cessation (<25x10^9).
Aims: We aimed to identify risk factors for CRT development in NDAML and to assess the efficacy of anticoagulation [low molecular weight heparin (LMWH)] along with its complications.
Methods: This retrospective analysis included all consecutive pts treated at the Rambam Health Care Campus between 2006-2019 for NDAML using a central venous catheter (CVC). Data on patient demographics, clinical characteristics, lab results and vital signs at diagnosis were automatically collected using a designated big-data platform (MDClone, Beer-Sheba, Israel). Intensity of CRT treatment and related bleeding complications were recorded along with the rate of venous thromboembolism (VTE) recurrence. Rates or proportions were compared using t-test or Wilcoxon test for continuous variables, and Chi-square test or Fisher's exact test for categorical variables. A multivariable logistic regression analysis was performed.
Results: Out of 632 evaluable NDAML pts 64 (10.1%) developed CRT. In a univariate analysis, the following CRT risk factors were identified: AML subtype [non-acute promyelocytic leukemia (non-APL) vs. APL, OR 0.39; 95%CI 0.17-0.86; p=0.02)], BMI (OR 1.05; 95%CI 1.01-1.10; p=0.01), heart rate at diagnosis (OR 0.76; 95%CI 0.63-0.91; p=0.003), and history of prior VTE (OR 16.87; 95%CI 5.33-53.41; p<0.001). In multivariate analysis, BMI, heart rate and history of prior VTE provided a good prediction model (C-Statistic 71.6%) (Table 1). While pts with CRT had lower platelet levels at diagnosis (107000; SD 148000 vs. 146000; SD 139; p=0.003), this parameter was found to be a poor CRT predictor (ROC curve area-under-curve 61.4%; 95%CI 54.1%>68.7%). The CVC was removed in 51 (80%) of 64 pts, which was in most cases associated with catheter-related bloodstream infection (p=0.050). Pts treated with full-dose LMWH were more likely to suffer from gastrointestinal bleed than those receiving reduced dose or no anticoagulant at all (p=0.003). There was no significant difference in blood products use before or after CRT-related anticoagulant treatment initiation (blood product per week per each patient). The lack of correlation between CRT or anticoagulation and blood product use could be explained by other medical conditions requiring blood transfusion (e.g., symptomatic anemia, severe thrombocytopenia).
At a mean follow-up of 2.9 years, CRT recurrence was recorded in 8 pts (12.5%). There was no difference in CRT recurrence between pts treated with different anticoagulant doses (p=0.40).

Table 1: Multivariate logistic regression analysis of CRT risk factors

	Adj. OR	95%CI		P-value
		Low	High	
BMI	1.086	1.034	1.140	0.0009
Heart rate ¥	0.756	0.622	0.919	0.0050
Prior VTE	16.034	5.852	43.932	<.0001

¥ For 10 unit increase; Adj. OR = adjusted odds ratio
Hosmer and Lemeshow Goodness of fit p=0.5717; C-statistics = 71.6%

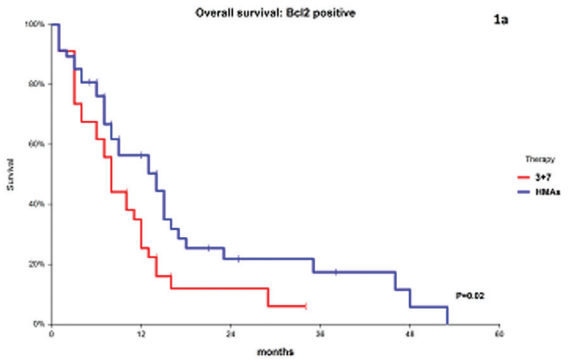
Summary/Conclusion: In this large cohort of NDAML patients treated at a tertiary care center, BMI, heart rate and history of prior VTE emerged as significant CRT risk factors. Neither complete blood count nor platelet levels were found to be reliable CRT predictors. Importantly, platelet count-based modification of anticoagulation dose appeared to be efficacious and relatively safe.

EP476 INVESTIGATING THE INCIDENCE OF SECONDARY PRIMARY CANCER IN ACUTE PROMYELOCYTIC LEUKEMIA PATIENTS

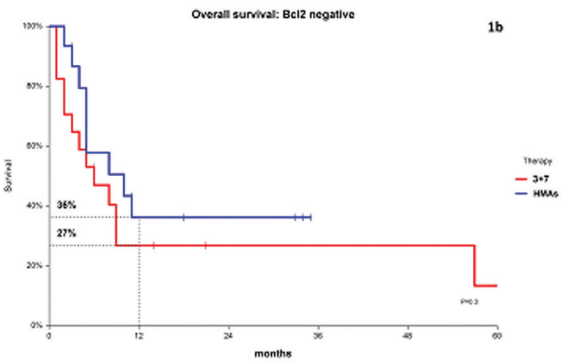
Y.-G. Chen [1,2,*], Y.-Y. Wu [2], C.-L. Ho [2], Y.-C. Chen [2], M.-S. Dai [2], C.-H. Chung [3], W.-C. Chien [3], T.-C. Huang [2], R.-H. Ye [2], P.-Y. Chang [2], S.-W. Liang [2], J.-H. Chen [2]

[1]Cancer Institute, University College London, London, United Kingdom, [2]Internal Medicine, [3]Tri-service General hospital, National defense Medical Center, Taipei, Taiwan, Republic of China

Background: With the advance of diagnostic tools, standard of cares and therapeutic strategies, there is an obvious improvement in terms of overall survival and clinical responses in patients with acute promyelocytic leukemia (APL). In comparison with other hematological malignancy, APL has been now considered a highly curable disease, with 2-year event-free survival rates of 75–84%. Most cases achieved complete remission status after induction and consolidative therapies, which only required regular follow-up in outpatient department. In line with this, the incidence of second primary malignancies (SPMs) among APL survivors would be expected and investigated further.
Aims: Despite the fact two studies have reported the incidence and cancer types of SPM in APL patients, the data still remain unclear in Asia APL patients. We aim to investigate the incidence, types and possible risk factor of SPM comprehensively through a national wide database.
Methods: Through a longitudinal and nationwide database- the National Health Insurance database (NHIRD), totally 492 APL cases were enrolled into this retrospective analysis. SPM was investigated in different APL populations undergoing ATRA (vesanoid) alone or ATRA and ATO (arsenic trioxide) with/without chemotherapy. Additionally, in order to deciphering molecular association behind this notion, a public genomic database (GSE 155779) was utilized for further analysis the effect of these therapeutic agents in APL cases.
Results: Two different study groups were identified, which included the patients with APL undergoing ATO/ATRA or ATRA alone. In APL patients under ATO/ATRA or ATRA alone, SPM was identified in 30 out of 246 cases and 40 cases out of 246 cases in these study cohorts, respectively. Looking into detailed distribution of cancer types, SPM included malignant melanoma, breast, pancreatic, liver, lung, bladder and hematopoietic malignancy in both APL group. Intriguingly, the majority of SPM is acute lymphocytic leukemia in both study cohorts. GSEA analysis demonstrated gene signatures in terms of cytokine response, NF-kB inflammatory signaling and angiogenesis pathways are enriched positively in NB4 cells undergoing ATRA treatment compared to NB4 control groups. Surprisingly, MLL-AF4 fusion target gene signatures are also enriched in NB4 cells with ATRA treatment group, which indirectly unveiled a possible explanation regarding an increased incidence of ALL among APL patients treated with ATRA or ATRA/ATO in our study.
Summary/Conclusion: In the current study, our results raised a consideration regarding the incidence and detailed cancer types of SPM in APL cases. Otherwise, this study demonstrated a distinctive distribution of SPM compared to previous studies.



EP477 BCL-2 EXPRESSION IN ELDERLY ACUTE MYELOID LEUKEMIA PATIENTS AND IMPACT ON OUTCOMES ACCORDING TO DIFFERENT THERAPEUTIC STRATEGIES



M. Tiribelli [1,2,*], A. Michelutti [2], M. Cavallin [2], S. Di Giusto [2], E. Simeone [2], R. Fanin [1,2], D. Damiani [1,2]

[1]Department of Medical Area, University of Udine, [2]Division of Hematology and BMT, Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy

Background: Bcl-2 overexpression has been associated with resistance to chemotherapy and reduced survival in acute myeloid leukemia (AML), but few data are available in elderly patients, a subset accounting for majority of AML cases and with dismal prognosis. Promising results have been reported with the use of bcl-2 inhibitor venetoclax.
Aims: We aimed to elucidate the prognostic role of bcl2 expression in elderly AML and its impact on outcomes across different therapeutic strategies, i.e. conventional 3+7 chemotherapy or hypomethylating agents (HMAs).

Methods: We retrospectively analyzed 114 AML patients aged >65 years treated with induction 3+7 chemotherapy (n=51) or HMAs decitabine or azacytidine (n=62) at the Division of Hematology of the University of Udine from 2010 to 2019. Bcl-2 expression on leukemic blasts was tested by flow cytometry, results were expressed as the mean fluorescence index (MFI) and bcl-2 was considered overexpressed for an MFI ≥17). Complete remission (CR) was defined according to conventional ELN 2017 criteria after one 3+7 course or 3-4 HMAs cycles; overall survival (OS) probability was estimated by the KM method.
Results: The characteristics of the 114 patients at diagnosis were: median age 68 years (range: 65-85); de novo AML n=49 (43%) and secondary AML n=65 (57%); leukocytes >30x10^9/L n=27 (24%); CD34-positive n=91 (80%); CD56-positive n=36 (32%); ELN 2017 genetic risk: favorable n=17 (15%), intermediate n=48 (42%), adverse n=49 (43%). Fifty-one patients (45%) received 3+7 induction chemotherapy while 62 patients (55%) were treated with HMAs.
Bcl-2 was expressed in 81 patients (71%), without differences according to clinical and biological variables in bcl-2 positive and negative AML. CR was achieved in 36%, being equal in bcl-2+ and bcl-2- patients; in bcl-2 positive cases, CR rate was higher with HMAs (20/44, 45.5%) than with 3+7 (8/34, 23.5%; p=0.04). One-year OS in the entire population was 39%, without differences among bcl-2+ (42%) and bcl-2- (32%) cases and with a trend toward a superior 1-year OS in patients treated with HMAs compared to 3+7 (51% vs 26%, p=0.07). The only factors affecting survival in multivariable analysis were WBC count (OR=3.2) and ELN risk (OR=3.0 for intermediate risk and OR=15.8 for adverse risk). While bcl-2 expression and induction therapy per se had no impact on OS in the whole cohort, when analyzing patients according to bcl-2 expression we found a significant better survival with HMAs than chemotherapy in bcl-2 positive cases (1-year OS 56% vs 25%, p=0.02, OR=1.8 – figure 1a) while no differences were found in bcl-2 negative ones (1-year OS 36% with HMAs and 27% with 3+7, p=0.3 – figure 1b).

Summary/Conclusion: Bcl-2 overexpression was not associated with inferior CR rate or survival in elderly AML, but bcl-2 positivity, that is preeminent among patients over 65 years, seems to be associated with a more favorable response to HMAs compared to conventional chemotherapy. Thus, the combination of HMAs with venetoclax appears to be particularly appealing in bcl-2 overexpressing patients.

EP478 ABERRANT CD7 EXPRESSION IN PEDIATRIC ACUTE MYELOID LEUKEMIA: SIGNIFICANCE AND CLINICAL IMPLICATIONS

F. Cacace [1,*], D. De Novellis [1], V. Caprioli [1], M. Iannalfo [2], M. R. D'amico [1], G. De Simone [1], R. Cuccurullo [1], G. Maisto [1], R. Penta De Vera D'Aragona [1], F. P. Tambaro [1]

[1]Pediatric Onco-Hematology Department, AORN Santobono-Pausilipon, [2]Hematology Department, AOU Federico II, Naples, Italy

Background: CD7 is a lymphoid marker that can be aberrantly expressed in Acute Myeloid Leukemia (AML). Several studies have investigated the significance of this marker in adult AML, but the significance is still unclear.
Aims: We investigated CD7 expression in newly diagnosed pediatric AML and correlated with clinical and genetic features and outcomes.
Methods: We retrospectively reviewed data from 55 pediatric patients diagnosed with *de novo* AML from January 2010 to December 2020. AML diagnosis was assessed according to World Health Organization (WHO) criteria. All patients were enrolled in the Italian Association of Pediatric Hematology Oncology (AIEOP) AML 2002/01 and AML 2013/01 protocol. They were risk stratified and treated according to their respectively assigned protocol.
Induction chemotherapy was similar for the two clinical trials, while consolidation was based on risk stratification (standard vs high) for the first protocol and on risk stratification (standard, intermediate and high) and donor availability in the second. Patients with Down Syndrome AML underwent specific treatment. One CD7+ patient initially with ALL features was treated on the AIEOP LLA 2000R protocol, then was treated with AML-directed protocol (IDA FLA) since they were refractory to first line.
Results: Patients, disease and transplant characteristics are summarized in the Table. Thirty-five (64%) and 20 (36%) patients presented with CD7- and CD7+AML, respectively, four CD7+AML patients were with Down Syndrome (p=0.006).
Eleven/20 (55%) and 17/35 (49%) were male and median age was 7 and 8 years, among the CD7- and CD7+ subgroups, respectively.
Twenty-three (66%) and 8 (40%) patients underwent Allogenic Hematopoietic Stem Cell Transplantation (allo-HSCT) in the CD7+ and CD7- subgroups.
Measurable Residual Disease (MRD) on day +33, +78 (first and second time-points) and before transplant was negative in 22 (63%), 23 (66%), 17 (74%) and 12 (60%), 13 (65%), 5 (62%) in CD7- and CD7+ subgroups, respectively. Cytogenetic abnormalities, usually associated to a favorable outcome such as t (8;21), inv (16) or t (16;16) were less frequent in CD7+ compared to CD7- subgroup (5% vs 29%; p=0.042). No difference in median OS was noted between the 2 subgroups as described in Table.

	Total Cohort	CD7$^+$AML	CD7$^-$AML
N (%)	55 (100)	20 (36)	35 (64)
Median Age, years (range)	8 (0-17)	7 (1-17)	8 (0-17)
Sex, Male (%)	28 (51)	11 (55)	17 (49)
Down syndrome, n (%)	4 (7)	4 (20)	0
1st line chemotherapy, n (%)			
AIEOP 2002/01	31 (56)	6 (30)	25 (71)
AIEOP 2002/01 Down	4 (7)	4 (20)	0
AIEOP 2013/01	19 (35)	9 (45)	10 (29)
AIEOP LLA 2006R	1 (2)	1 (5)	0
HSCT	31 (56)	8 (40)	23 (66)
MRD-negative, n (%)			
+ 33	34 (62)	12 (60)	22 (63)
+ 78	36 (65)	13 (65)	23 (66)
Pre-HSCT	22 (71)	5 (62)	17 (74)
Median OS, months (range)	NR (2-141)	NR (4-141)	NR (2-139)
2-year OS %	81	85	79
5-year OS %	74	79	72
Cytogenetic risk, except Down S., n (%)			
Standard	11 (20)	2 (10)	9 (26)
Intermediate	25 (55)	11(55)	14 (40)
High	14 (25)	2 (10)	12 (34)
No metaphases	1 (2)	1 (2)	0
Cytogenetic features, n (%)			
Diploid	12 (22)	6 (30)	6 (18)
t (6;9)	1 (2)	1 (5)	0
t (1;22)	2 (4)	1 (5)	1 (3)
t (8;21)	6 (11)	0	6 (18)
Inv (16) or t (16;16)	5 (9)	1 (5)	4 (12)
Complex karyotype	9 (16)	3 (15)	6 (17)
No Metaphases	1 (2)	1 (5)	0

Summary/Conclusion: Aberrant expression of the lymphoid CD7 antigen is associated with pediatric Down Syndrome AML. In contrast to early T-cell precursor lymphoblastic leukemias, where the expression of a myeloid marker is predictive of a worse outcome, the expression of this lymphoid marker in myeloid leukemias was not correlated with prognosis in terms of response to treatment, MRD or transplant outcomes.

EP479 ENASIDENIB IN PATIENTS WITH IDH2-MUTATED ACUTE MYELOID LEUKEMIA (AML). A "REAL LIFE" MULTI-CENTER EXPERIENCE FROM SPANISH HOSPITALS

M. Diaz-Beya [1,*], P. Beneit [2], I. Cano [3], B. Merchan [4], M. Arnan [5], M. García [6], C. Martínez [7], A. Alfonso [8], M. Martínez [9], J. Alonso [10], O. López-Godino [11], S. Castaño-Díez [12], J. Esteve [1], A. De la Fuente [13]

Background: Enasidenib (ENA), an oral inhibitor of mutated IDH2 (IDH2mut), has recently been approved by the FDA in monotherapy based on a phase 2 clinical trial in patients with relapsed/refractory (R/R) acute myeloid leukemia (AML) (Stein et al Blood 2019). To date, as far as we know there are no studies reporting enasidenib efficacy and safety outside of Clinical trial.
Aims: To analyze the characteristics of the population that has received this treatment and the effectiveness and tolerance of ENA used outside of clinical trial.
Methods: Multicenter retrospective study including patients with IDH2-mut AML and MDS treated in Spain (2017-2020) with ENA outside of Clinical trial (compassionate use).
Results: ENA was requested for 25 patients in 11 Spanish centers. Three patients died before starting ENA due to disease progression. Of the remaining 22, 3 did not complete the first course of ENA due to disease progression. We analyzed 19 patients for effectiveness and toxicity, 17 were AMLs, 1 AREB II and 1 CMML. Median age was 71 years (44-89) other baseline characteristics detailed in Table 1. The disease stage and treatment received prior to ENA were: 4 patients were refractory to intensive treatment (IT), 3 refractory after non-intensive treatment (NIT), 9 relapsed [5 after NIT and 4 after IT (3 of them post-allotransplant)] and 3 patients received ENA in the first line (1L). Most (11 patients) had received a previous line of treatment, 5 patients ≥ 2 lines.
The overall response rate (ORR) was 47% (N=9), 6 patients (31%) achieved complete response (CR). One patient performed a subsequent allogeneic transplant. The median number of cycles to best response was 3 (extremes 1-8). There were no differences in ORR according to disease or patient characteristics. Four (30%) of the 13 transfusion-dependent patients achieved transfusion independence.
With a median follow-up of 10.3 months (m) (3.4-19.8), median overall survival (OS) was 8.7m, with an OS at 1 year (1y-OS) of 47%±24%. Excluding the 3 patients treated in 1L there was no difference in OS depending on disease status/previous treatment. 1y-OS was significantly better in patients who achieved ORR (83%±30% vs 12%±22%; p<0.001). The median event-free survival (EFS) was 6.9 m (95%CI 2.01-11.78), being significantly better in the group that achieved ORR compared to the rest (1y-OS:74%±32% vs 10%±18%; p<0.001) and better in those who achieved CR (1y-OS: 100% vs 11%±20%; p=0.001). Remarkable the three patients treated after alloSCT are alive and disease free at time of reporting.
There were no treatment related deaths. Regarding specific toxicities of ENA 4(21%) cases presented leukocytosis, 3 (15%) differentiation syndrome, 6 (31%) hyperbilirubinemia. There were 3 admissions due to toxicity and in 2 patients ENA was definitively discontinued due to toxicity.

Demographic and disease characteristics at baseline	
Median age (range) years	71(44-89)

Background: SEL120/RVU120, a novel CDK8/CDK19 kinase inhibitor has shown significant efficacy in preclinical AML models. The First in Human phase Ib clinical trial with SEL120 in patients with relapsed/refractory (R/R) AML or HRMDS is currently open for enrollment at 6 sites in the US (NCT04021368). Here we present the preliminary safety, efficacy and pharmacokinetic (PK) data of the first 4 dose escalation single patient cohorts.
Aims: The primary objective of the study is to determine preliminary safety profile, dose limiting toxicities (DLTs), maximum tolerated dose (MTD) and the recommended phase 2 dose of SEL120 as a single agent. Secondary objectives include the characterization of PK, antitumor activity and exploratory pharmacodynamic effects.
Methods: All pts signed the informed consent. The study comprises at least 8 dose escalating cohorts. The first four cohorts followed an accelerated scheme, 1 patient enrolled/cohort, with the following cohorts switching to a modified Fibonacci 3+3 design. Data from each cohort was evaluated by a study data review committee (DRC). SEL120 was administered orally every other day, for a total of 7 doses, in a 3-week treatment cycle until disease progression/unacceptable toxicity. Adverse events were graded according to NCI-CTCAE v.5.0. DLTs were assessed at completion of C1. Disease evaluation was performed according to Dohner 2017 and Cheson 2006 response criteria for AML and MDS respectively. Plasma PK parameters were calculated by non-compartmental analysis
Results: Cohorts 1 to 4, each enrolled 1 DLT evaluable patient who received SEL120 at dose levels from 10 to 75mg. 3 patients had a diagnosis of R/R AML, 1 patient had persistent HR-MDS. The median age of patients was 74 years and the number of median prior lines of treatment was 3. No DLTs were observed, 4 Serious Adverse Events were reported and assessed by the investigator, as unlikely related to study drug (G3: pseudomonas sepsis; urinary tract infection; febrile neutropenia; lung infection). Cohort 1 patient, at 10mg dose level, and cohort 2 patient, at 25mg showed stable disease (SD) and progressive disease, respectively at C1. Cohort 3 patient, who started at 50mg dose level, is an 81-year-old male with HRMDS who showed evidence of an Erythroid Response at C5D8. He is now in C8, at 75mg, following to a dose escalation during C7. Cohort 4 patient, at 75mg dose level, is a 62-year-old male with persistent AML and extramedullary skin leukemia, who failed prior venetoclax/decitabine. This patient achieved a complete hematological recovery at C2 and absence of bone marrow blasts and continuous improvement of skin leukemia, now ongoing in C5, however, the profound post ven/dec pancytopenia complicates assessments of magnitude of the contribution of SEL120 to this response. PK parameters of these 4 patients, were similar across all dose levels. SEL120 absorption was relatively rapid with Tmax 4 -8hr after drug administration. Exposure, based on Cmax and AUC, was linear with doses between 10 and 75mg, both after single and repeat dosing. SEL120 elimination half-life in plasma was 22 to 40hr with low accumulation (1.3 to 1.8-fold). Within patient variability of plasma concentrations of SEL120, over at least 6 cycles, was low.
Summary/Conclusion: Preliminary results of the first four single patient dose escalation cohorts have shown a favorable safety and a linear PK profile of SEL120. The first signal of activity is observed at doses 50 to 75mg. Enrollment is currently ongoing, with switching to 3+3 design.

EP481 A HOME CARE PROGRAMME FOR THE RAMP-UP AND FIRST COURSES OF TREATMENT WITH VENETOCLAX AND HYPOMETHYLATING AGENTS IN THE TREATMENT OF ACUTE MYELOID LEUKEMIA

A. Martínez-Roca [1,*], C. Jiménez-Vicente [1], A. Bataller [1], C. Gallego [1], N. Ballestar [1], M. Carreras [1], F. Guijarro [1], D. Esteban [1], M. Gómez-Hernando [1], C. M. Castillo-Girón [1], A. Alvarez-Larrán [1], S. Castaño-Diez [1], M. Díaz-Beyá [1], J. Esteve [1], F. Fernández-Avilés [1]

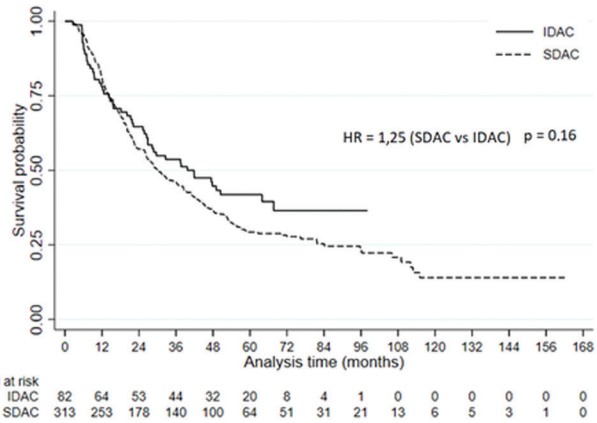
[1]Hematology, Hospital Clinic Barcelona, Barcelona, Spain

Background: The combination of venetoclax (Ven) with hypomethylating agents (VenHMA) has shown promising results both in newly diagnosed and relapsed or refractory acute myeloid leukaemia (AML) patients, ineligible for intensive chemotherapy. Due to our expertise acquired in at-home management of diverse complex haematological procedures, we initiated in February 2020 an at-home (AH) programme for the VenHMA regimen. This AH-VenHMA programme included the initial dose ramp-up to prevent tumour lysis syndrome (TLS), a phase usually recommended to be performed as an inpatient hospital admission.
Aims: Herein we present preliminary results of our AH experience during the first two cycles of VenHMA treatment for AML patients.
Methods: Before implementation of AH-VenH programme, ramp-up was performed during a hospital admission (n=29, reference cohort). In Feb 2020, we initiated the VenH programme; outcome of in this patient cohort are compared with the reference cohort.
In AH programme, prior to VenHMA initiation, medical evaluation is performed by a haematologist and a liaison nurse. Medical history, potential drug interactions and TLS risk are thoroughly evaluated. Laboratory tests (LT) including blood count and biochemistry are completed. Extensive health education is provided to patient and caregiver before the first cycle. A peripheral insertion intravenous catheter (PICC) is placed to all patients before starting ramp-up. Intravenous (IV) fluids by a portable pump (PP) are started 24hrs before the beginning of VenHMA, as well as uricosurics agents; patients are advised to maintain oral hydration. Daily morning visits during ramp-up are performed by trained nurses who complete vital sign, obtain LT, review therapeutic compliance, replaced PP and administer hypomethylating agent. Patients are started on Ven in an escalation schedule of 100mg on day 1, 200mg on day 2, and 400mg on day 3 of the cycle, they are advised to take Ven after dinner, following an explicit indication of our team given after daily LT review. An appropriate dose reduction is performed in patients receiving concomitantly CYP3A4 inhibitors. After achieving planned Ven full dose, IV fluids are ceased (Image 1). Patients are followed throughout the whole cycle by the AH team. Platelet transfusions are administered at-home while red cell concentrates are administered at the hospital, due to our transfusion policy.
Results: Between February 2020 and January 2021, 22 AML patients (40 cycles) received VenHMA at-home. Fourteen patients were men (63.6%), with a median age of 73 years (23-83). Main characteristics were well balance in both patient cohorts.
Neutropenia (86.3%), thrombocytopenia (90.9%) and anaemia (86.4%) were the most frequent adverse events (AEs). A trend to a lower proportion of febrile episodes was observed in the AH program (19/29 *vs.* 8/22, p=0.074). Hospital readmission rate after ramp-up was markedly low in the AH cohort, significantly lower than in the reference cohort (4/22 vs. 19/29, p = 0.001). TLS was not observed in any group. Main AEs are shown in table 1. Median days of at-home treatment were 49 (19-187). Discontinuation was due to refractoriness in 5 (22.7%) patients. Two patients presented SARS-CoV-2 infection in early March 2020, resulting in death in both cases.

Table 1. Adverse Events during the first two cycles of VenHMA treatment

Adverse Events during the first two cycles of treatment	All patients (N = 51)	Hospitalized (n=29)	At-home (n=22)	P
Any Adverse Event, no. (%)	50 (98)	29 (100)	21 (95.5)	NS
Neutropenia, no. (%)	48 (94.1)	29 (100)	19 (86.3)	NS
Grade 3	5 (9.8)	5 (17.2)	0 (0)	
Grade 4	43 (84.3)	24 (82.8)	19 (86.3)	
Thrombocytopenia, no. (%)	45 (88.2)	25 (86.2)	20 (90.9)	NS
Grade 2	4 (7.8)	1 (3.4)	3 (13.6)	
Grade 3	3 (5.9)	0 (0)	3 (13.6)	
Grade 4	38 (74.5)	24 (82.8)	14 (63.6)	
Anaemia, no. (%)	45 (88.2)	27 (93.1)	19 (86.4)	NS
Grade 2	22 (43.1)	14 (48.3)	9 (40.9)	
Grade 3	21 (41.1)	12 (41.4)	9 (40.9)	
Grade 4	2 (3.9)	1 (3.4)	1 (4.5)	
Fever, no. (%)	27 (52.9)	19 (65.5)	8 (36.4)	0.074
Fever in neutropenia	13 (25.5)	9 (31)	4 (18.2)	NS
Bacterial infection	12 (23.5)	9 (31)	3 (13.6)	NS
Viral infection	5 (9.8)	3 (10.3)	2 (9.1)	
Fungal infection	4 (7.8)	3 (10.3)	1 (4.5)	NS
SARS-Cov-2 infection	2 (3.9)	0 (0)	2 (9.1)	
Sepsis, no. (%)	3 (5.9)	2 (6.9)	1 (4.5)	NS
Acute bleeding, no. (%)	3 (5.9)	2 (6.9)	1 (4.5)	NS
Deep vein thrombosis, no. (%)	2 (3.9)	2 (6.9)	0 (0)	NS
Hospital admissions, median (range)	0 (0-4)	1 (0-4)	0 (0-1)	NS
Hospital admission after ramp-up, no. (%)	25 (49)	19 (71.4)	4 (21.7)	0.001
Hospitalization days after ramp-up, median (range)	0 (0-63)	8 (0-63)	0 (0-14)	0.23

Summary/Conclusion: Home care during the ramp-up and early phase of VenHEM regimen is a feasible and safe option. An AH programme was followed by a low readmission rate and offers diverse benefits such as optimization of health resources and increase of the comfort and well-being of patients and their caregivers.



EP482 INTERMEDIATE OR STANDARD DOSE CYTARABINE AS POST REMISSION THERAPY IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA: IMPACTS ON OUTCOMES AND HEALTH CARE RESOURCE CONSUMPTION

J. GALTIER [1,*], C. ALRIC [2], E. BERARD [3], T. LEGUAY [1], S. TAVITIAN [2], A. BIDET [4], E. DELABESSE [5], A.-C. DE GRANDE [1], A. SARRY [2], A. PIGNEUX [1], C. RECHER [2], S. BERTOLI [2], P.-Y. DUMAS [1]

[1]Hematology, CHU de Bordeaux, PESSAC, [2]Hematology, [3]Epidemiology, ICUT Oncopole de Toulouse, TOULOUSE, [4]Hematology biology, CHU de Bordeaux, PESSAC, [5]Hematology biology, ICUT Oncopole de Toulouse, TOULOUSE, France

Background: High-dose cytarabine is currently a well accepted post remission therapy for younger patients with acute myeloid leukemia (AML) in first complete remission (CR1). No standard exists for older (≥ 60 years) patients. Although intermediate-dose cytarabine (IDAC) delivered every 12 hours for three days is regularly used in older fit patients, several academic groups also apply an outpatient schedule by standard dose cytarabine associated with single-dose anthracycline in monthly courses (SDAC).
Aims: To compare outcome of elderly patients with AML in CR1 receiving post-remission therapy, either with SDAC and anthracycline or with IDAC as single agent
Methods: Patients ≥ 60 years-old with non-M3 AML in CR1 after intensive chemotherapy included in French DATAML registry (Bordeaux and Toulouse) between 2007 and 2017 were retrospectively reviewed for study specific data collection. Patients had to receive at least one course of post-remission chemotherapy, either with SDAC or with IDAC. SDAC regimen consisted of six to seven 28-days courses of idarubicine (8mg/m^2) D1 plus cytarabine (50mg/m^2 BID in sub-cutaneous injection) D1-D5. IDAC regimen consisted of three 35-days course of cytarabine (1,5g/m^2 in 2 hours infusion) every 12h for a total of 6 injections. Allogeneic stem cell transplantation (alloSCT) was performed at the physician's discretion.
Results: Population: 395 patients were included. Median age was 68 years. 82 patients received IDAC regimen and 313 received SDAC regimen. IDAC patients were younger (median age 65 versus 69, p <0.001), but have more adverse cytogenetics risk (31% *vs* 11%, p < 0.001) and were more likely secondary (35% *vs* 18%) or therapy related (18% *vs* 3%) (p < 0.001). Median course of post-remission therapy was 3 for IDAC and 5 for SDAC regimen. AlloSCT has been performed in 62 patients. **Outcome:** After a median follow up of 72 months, median OS was 40 months for IDAC *vs* 30 months for SDAC patients (p = 0.16), and median LFS was 21 months vs 17.5 months, respectively (p = 0.187). In multivariate analysis, factors associated with better OS were only Charlsons comobirdity index < 2, favorable ELN2010 category and alloSCT in CR1 (with an HR = 0.5). Post remission schedule was not independently associated to outcome. **Tolerance:** 1 year non relapse mortality was 10% for the whole cohort, without statistical difference between IDAC and SDAC patients. Deaths in remission during treatment were unfrequent (< 5%) in both groups. The rate of infectious events needing parenteral antibiotic was significantly lower with SDAC compared to IDAC (36.1% *vs* 74.4%) (*p* < 0.01) as well as the rate of documented bacteremia (15.7% *vs* 41.5%, p < 0.001). Median red blood cell transfusion requirement per cure was 1 (IQR 0,3 – 2) for SDAC *vs* 3 (IQR 2 – 4) for IDAC, and median platelet transfusion requirement per cure was 0,8 (IQR 0,2 – 1,4) *vs* 2,5 (IQR 1,6 – 3,3), respectively (p < 0.001 for both). Duration of hospitalization for the whole post-remission program was shorter with SDAC (12 days, IQR 7 – 19) compared to IDAC (32.5 days, IQR 22.5 – 38.5) (p < 0.001).

Figure 1: overall survival of study population

Summary/Conclusion: Although IDAC is feasible in fit AML patients over 60, the outpatient SDAC regimen induced low myelosuppression, decreased rate of infections and transfusions, and therefore significantly reduced the length of hospital stay without affecting outcomes.

EP483 APPLICATION OF MACHINE LEARNING IN STRATIFYING MINIMAL RESIDUAL DISEASE LEVEL WITH FLOW CYTOMETRY IN ACUTE MYELOID LEUKEMIA

B.-S. Ko [1,2,*], Y.-F. Wang [3,4], C.-C. Lee [5], H.-A. Hou [1], J.-L. Li [5], T.-Y. Chang [3], W.-T. Hsieh [3], J.-L. Tang [2,6]

[1]Department of Internal Medicine, National Taiwan University Hospital, [2]Department of Hematological Oncology, National Taiwan University Cancer Center, Taipei, Taiwan, Republic of China, [3]AHEAD Medicine Corporation, Berkeley, CA, United States, [4]National Taiwan University, Taipei, [5]Department of Electrical Engineering, National Tsing Hua University, HsinChu, [6]Tai-Cheng Stem Cell Therapy Center, National Taiwan University, Taipei, Taiwan, Republic of China

Background: Residual disease detection and monitoring by flow cytometry guides clinical physicians to modify treatment strategies according to patient's risk profile. Current flow cytometry analysis approach is based on manual interpretation, which is relatively labor-intensive and time-consuming.
Aims: We propose to use machine learning algorithm for residual disease percentage (RDP) classification by using clinical flow cytometry (FC) data.
Methods: Retrospective clinical FC data of AML patients, as well as demographic data (age & gender) were collected from National Taiwan University Hospital. From 2013 to 2016, a total of 487 FC data positive for residual disease from 249 AML patients were enrolled in this study. There are 81 FC data with RDP within 0.01 to less than 1%, and 406 FC data with RDP greater than or equal to 1%. The median age at flow cytometry test performed was 51.8 years old.
Our proposed machine learning framework includes a phenotype representation learning paradigm and a classification model. To derive the phenotype representation, we trained a multivariate Gaussian Mixture Model (GMM) on the 38-dimension FC data to capture the training data distribution and characteristics in a probabilistic unsupervised manner. Then, a Fisher-scoring method derived from the differential of the learned GMM parameters was used to vectorize each sample as a high dimensional representation. This Fisher vectorization method transformed samples to a high dimensional feature space as phenotype vectors, which were finally fed into the random forest (RF) classifier. To alleviate the negative effects of imbalance classes in RDP identification tasks, we applied synthetic minority oversampling technique (SMOTE) algorithm which augmented the minority class by linearly interpolating synthetic samples from existing samples in the minority class. We train RF models for original fisher vectorization feature set and oversampled set separately to discriminate the RDP classes. The algorithm is evaluated by randomly divided 5-fold cross validation which separates 80% data for training and 20% for testing.
Results: The accuracy (ACC) and area under the ROC curve (AUC) of RDP prediction models achieved 0.897 and 0.934, respectively (Table 1a). Around 91.9% of those FC data with RDP greater than or equal to 1%, and 79.0% of those FC data with RDP within 0.01 to less than 1% are correctly classified when using oversampled set (Table 1b).

Table 1a. RDP Classification with and without Oversampling Performance Using RF Model

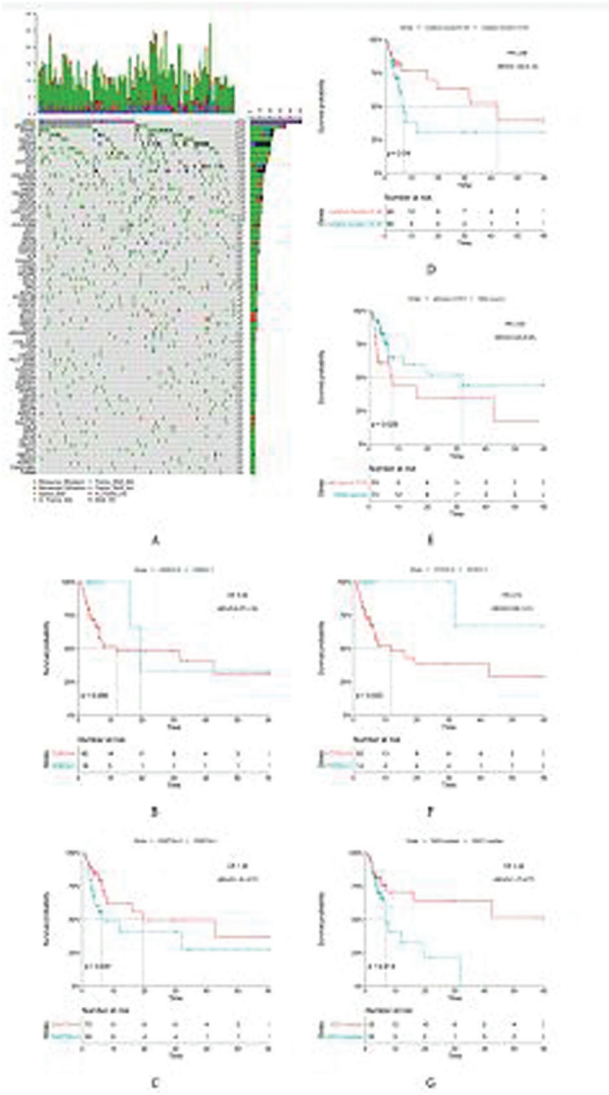
	ACC (%)	AUC
Original fisher vectorization set	86.9	0.909
Oversampled fisher vectorization set	98.7	0.934

Abbreviations: ACC: accuracy; AUC: area under the ROC curve; RF: random forest.

Table 1b. Confusion Matrix of RDP Classification Model Using Oversampled Set

Predicted class / True class		0.01% ≤ RDP ≤ 1%	RDP ≥ 1%	Total
		n (%)	n (%)	
0.01% ≤ RDP ≤ 1%	n (%)	64 (79.0)	17 (21.0)	81 (100)
RDP ≥ 1%	n (%)	33 (8.1)	373 (91.9)	406 (100)

Abbreviations: RDP: residual disease percentage.



Summary/Conclusion: This study demonstrated the potential of machine learning algorithm used in RDP prediction in patient with AML. Further study with larger cohorts or different data sources are needed to validate this machine learning based prediction model as a clinical support tool to assist physicians in clinical decision making.

EP484 THE PROGNOSTIC SIGNIFICANCE OF FLT3 INTERNAL TANDEM DUPLICATIONS' CHARACTERISTICS AND CO-MUTATIONS IN ACUTE MYELOID LEUKEMIA

L.-M. Cao [1,*], L.-X. Wu [1], Y.-L. Zhou [1], Z.-L. Wang [1], J.-L. Li [1], Q.-Y. Sun [1], L.-X. Liu [2], C.-C. Wang [2], H. Jiang [1], Q. Jiang [1], L.-P. Xu [1], X.-H. Zhang [1], K.-Y. Liu [1], X.-J. Huang [1,3,4], G.-R. Ruan [1]

[1]Peking University People's Hospital, Peking University Institute of Hematology, National Clinical Research Center for Hematologic Disease, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China, [2]AcornMed Biotechnology Co., Ltd., Beijing, China, [3]Peking-Tsinghua Center for Life Sciences, Beijing, China, [4]Research Unit of Key Technique for Diagnosis and Treatments of Hematologic Malignancies, Chinese Academy of Medical Sciences, 2019RU029, Beijing, China

Background: About 25% of newly diagnosed adult AML patients(pts) with normal cytogenetics have Fms-like tyrosine kinase 3 internal tandem duplication (FLT3-ITD). And it confers unfavorable prognosis, however, factors associated with clinical outcomes of FLT3-ITD$^+$ mutations are still controversial.
Aims: To find out the variables associated with the different outcomes of ITD+ patients(pts).
Methods: We evaluated 106 adult AML pts with this genotype who were diagnosed at Peking University People's Hospital and achieved histological complete remission within two cycles of induction therapy. And we analysis the status of mutations for all pts based on next-generation sequencing.
Results: In our cohort, we totally found 171 ITDs(1 ITD: 60 pts, 2 ITDs: 31 pts, 3 ITDs: 11 pts and 4 ITDs: 4 pts). Of the 171 ITDs, 102(59.6%) located in the juxtamembrane domain(JMD); 24(14.0%) located in the tyrosine kinase domain-1(TKD1); 25(14.6%) located in the hinge region(HR) and 20 (18.7%) located in the other region of FLT3 receptor. Median of insert lengths was 65 bp[range,18-259 bp], median of variant allele frequency (VAF) was 0.45[range,0.04-0.78]. We founded that a better prognosis could be noticed if the inserted sequence is derived from wild type FLT3 gene fragment sequence[p=0.026 for leukemia-free survival (LFS) with transplant censored, p=0.039 for overall survival (OS) with transplant censored].We also focused on the co-mutated genes of FLT3-ITD and noticed pts with CEBPA$^{bi\text{-}mut}$[n=16, p=0.066 for LFS, p=0.092 for OS],and POTEH[n=14, p=0.023 for LFS, p=0.2 for OS] showed an advantage in survival. However, high mutation burden[VAF> 0.45(established by using the ROC curve for maximum LFS), p=0.04 for LFS, p=0.077 for (OS)]; the mutation of DNMT3A [n=36, p=0.041 for LFS, p=0.13 for OS]; high WBC[> 29.83*10^9cells/L(median), p=0.014 for LFS, p=0.015 for OS] predicted worse survival. In addition, there were no obvious correlation of the insert site, the lengths of ITDs and the insert ITD number with the unfavorable prognosis of FLT3-ITD$^+$ pts.

Summary/Conclusion: In this study, we revealed that POTEH^{mut}, CEBPA$^{bi\text{-}mut}$ and ITDs which were derived from wild type FLT3 gene fragment always had a better survival, however, DNMT3A^{mut}, high mutation burden and high WBC had a worse survival. Our study was beneficial to in-depth understanding of the FLT3-ITD's characteristics and the genes combined with it. It also had guiding significance for clinical risk stratification of FLT3-ITD$^+$ AML patients with normal cytogenetics.

EP485 SURVIVAL OUCOMES IN PATIENTS WITH ACUTE MYELOID LEUKEMIA PRESENTING WITH HYPERLEUCOCYTOSIS

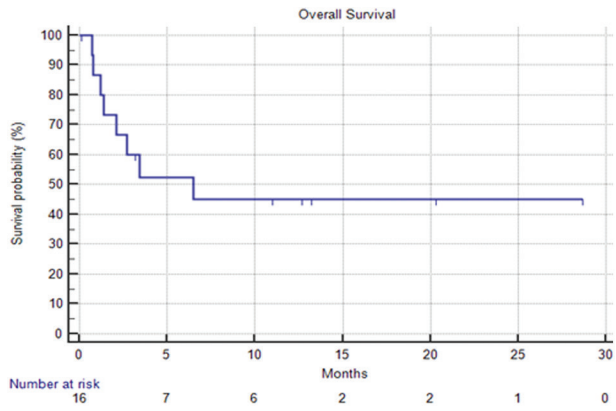
J. Sillar [1,2,*], M. V. Nievas [3], L. Munshi [3], M. Tracy [1]

[1]Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre/University Health Network, Toronto, Canada, [2]Department of Haematology, Calvary Mater Newcastle, Newcastle, Australia, [3]Interdepartmental Division of Critical Care Medicine, Department of Medicine, Sinai Health System, Toronto, Canada

Background: Approximately 10% to 20% of patients with acute myeloid leukemia (AML) present with hyperleukocytosis. Hyperleukocytosis can result in leukostasis leading to end organ dysfunction and critical illness requiring admission to intensive care unit (ICU) admission. Institutional practices vary on the management of patients with hyperleukocytosis and leukostasis including location of chemotherapy administration and thresholds for ICU admission. There is paucity of data on the short- and long- term outcomes of

these patients, particularly across those managed on in-patient wards compared to ICU.
Aims: To describe the characteristics of patients with hyperleukocytosis and factors associate with ICU admission and 60 day mortality.
Methods: We conducted a retrospective cohort study of consecutive admissions to Princess Margaret (PM) Cancer Center or Mount Sinai Hospital ICU between 2014-2019. All adult patients with a white blood cell count (WBC) >50x10^9/L and a new diagnosis of AML were included. Their clinical and laboratory data were evaluated across the first 5 days after presentation with hyperleukocytosis. Our primary outcome was ICU admission and our secondary outcome was 60 day mortality.
Results: One-hundred and sixty-nine patients were admitted with a diagnosis of AML and hyperleukocytosis. Mean age was 58 (SD 15) and 59% were male with 43% having greater than 2 comorbidities. Median WBC on the first day of hyperleukocytosis was 103 x 10^9/L (IQR 67-152), with 55% having a WBC >100x10^9/L and 15% having a WBC >200x10^9/L. On the first day of hyperleukocytosis, 63% had hypoxemic respiratory failure, 25% had biochemical tumor lysis syndrome, and 49% were diagnosed with acute kidney injury (8% requiring dialysis) (*Table 1*). ICU admission was required in 44% of the cohort and the median time to ICU was 1 (IQR 0-3) day. Across entire cohort, median change in WBC from day 1 to 2 was – 17x10^9/L (IQR -31 - -1), the median greatest decrease in WBC over a 24 hour period was 58x10^9/L (31-88). Drop in WBC in first 5 days was higher in those not admitted to ICU and across survivors (Table 1). Across the ICU cohort, 59% required invasive mechanical ventilation, 76% had acute kidney injury and 48% require vasopressors. Across those admitted to the ICU, 81% were admitted within 4 days of hyperleukocytosis. Sixty-day mortality across the whole cohort was 30% (57% across the ICU cohort and 8% across the non-ICU exposed). ICU mortality was 82% across those who required invasive mechanical ventilation during the first 5 days post diagnosis of hyperleukocytosis. Hospital admission factors associated with ICU admission included hypoxia on day 1 of hyperleukocytosis (PaO2/FiO2 OR 0.97 (95% CI 0.96-0.98, p<0.001) and acute kidney injury (OR 12.2 95% CI 1.8-83, p 0.011). Factors associated with 60 day mortality included male sex, WBC >100x10^9/L, lower PaO2/FiO2, any invasive mechanical ventilation and a lower drop over a 24 hour period in the WBC across the first 5 days.

TABLE 1	Entire Cohort (N=169)	ICU Cohort (N=75)	No ICU (N=94)	60-day Mortality (N=50)
DEMOGRAPHIC VARIABLES				
Age	58 SD 15	59 (15)	58 (14)	59 (16)
Comorbidities	1 (IQR 0-2)	2 (IQR 1-3)	1 (IQR 0-2)	2 (IQR 1-3)
Sex-Male	100 (59%)	48 (64%)	52 (55%)	38 (76%)
WBC DETAILS				
WBC >100 on presentation	92 (55%)	44 (59%)	48 (52%)	31 (65%)
WBC >200	25 (15%)	16 (21%)	9 (10%)	12 (24%)
WBC day 1	103 (67-152)	106 (61-187)	102 (69-143)	114 (71-195)
Greatest decrease in 24 hours over first 5 days*	58 (31-88)	48 (18-91)	62 (37-87)	48 (21-80)
CLINICAL VARIABLES				
ICU admission	75 (44%)	N/A	N/A	43 (86%)
PaO2/FiO2 Day 1	280 (IQR 140-450)	168 (112-251)	452 (442-461)	145 (108-206)
Any hypoxia day 1	80 (63%)	71 (96%)	9 (11%)	
AKI day 1	82 (49%)	54 (72%)	28 (31%)	39 (79%)
Dialysis day 1	14 (8%)	14 (19%)	0	10 (20%)
OUTCOMES				
60-day mortality	50 (30%)	43 (57%)	7 (8%)	N/A
Death within 24 hours	11 (7%)	11 (15%)	0	11 (22%)



Summary/Conclusion: Patients with hyperleukocytosis managed on the inpatient wards had a mortality rate of 8%. Patients admitted to ICU and particularly those requiring invasive mechanical ventilation on admission had inferior survival.

EP486 GLASDEGIB IN COMBINATION WITH LOW DOSE CYTARABINE FOR ELDERLY ACUTE MYELOID LEUKEMIA PATIENTS FAILING HYPOMETHYLATING AGENTS

A. Zucenka [1,2,*], K. Maneikis [1], U. Ringeleviciute [1], B. Pugaciute [1], L. Davainis [1], P. Burzdikaite [2], G. Daukelaite [1], L. Griskevicius [1,2]

[1]Hematology, Oncology, Transfusion Medicine Center, Vilnius University Hospital Santaros Klinikos, [2]Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Vilnius, Lithuania

Background: The prognosis of relapsed or refractory acute myeloid leukemia (R/R AML) in elderly and unfit patients who fail hypomethylating agents remains very poor. Glasdegib is a novel small-molecule inhibitor of the Smoothened (SMO) receptor and its efficacy is based on down-regulation of the Hedgehog signaling pathway which is involved in the resistance of AML cells. Glasdegib combined with low dose Cytarabine (LDAraC) is currently approved for newly diagnosed unfit AML patients, however data in the R/R AML setting are lacking. Here, we present data on 16 elderly and unfit R/R AML patients who had previously failed Decitabine or Azacitidine based therapies and were treated with outpatient Glasdegib + LDAraC.
Aims: The aim of our study was to evaluate the efficacy and toxicity of Glasdegib + LDAraC therapy in R/R AML patients with prior exposure to hypomethylating agents.
Methods: We retrospectively collected clinical data on AML patients who had R/R AML and failed Decitabine or Azacitidine based therapies at Vilnius University Hospital Santaros Klinikos in 2018-2020. Glasdegib was kindly provided by Pfizer via the compassionate use program and the treatment was approved by the institutional Ethics Committee. The data collection was approved by Vilnius Regional Biomedical Research Ethics Committee. The treatment cycles consisted of self-administered Cytarabine 20mg/m^2 s/c Day 1-10 and Glasdegib 100mg p/o daily on outpatient basis. The cycles were repeated every 28-35 days, longer interruptions were allowed in case of toxicity or social reasons. Glasdegib was continued after Day 28 even if the start of the next cycle was postponed. Indications for stopping the treatment were progressive disease with no further clinical benefit observed, excessive toxicity or availability of alternative treatment strategies.
Results: 16 patients (11 female) were enrolled. The median age was 77 (71-86) years. The median ECOG performance status was 2 (1-3). Extramedullary involvement was confirmed in 12% (2/16) of cases. 14 (88%) patients had previously received 1 treatment line, whereas 2 (12%) patients failed two therapies. All patients had previously received low intensity frontline therapies with Decitabine or Azacitidine, 4 (25%) patients had Venetoclax exposure. Adverse cytogenetics were identified in 38% (6/16) of patients. Based on the ELN2017 risk group stratification criteria, 12% (2/16), 50% (8/16) and 38% (6/16) of patients were stratified to favorable, intermediate and adverse risk groups, respectively. A median of 2 (1-17) treatment cycles were administered, 5 patients (31%) received at least 4 cycles. Responses were evaluated in 13 cases. Four patients achieved CR, one patient achieved CRp and one PR was confirmed. The composite CR+CRp rate was 39% (5/13) and the overall response rate (CR+CRp+PR) was 46% (6/13). The median response duration was 2 months (0.3-6) Stable disease was confirmed in 23% (3/13), whereas 31% (4/13) were diagnosed with progressive disease. After the median observation time of 13.2 months, the median overall survival was 6.5 months (95% CI 2.1-6.5). The most common grade III-V adverse events of Glasdegib + LDAraC were infections (57%, 9/16). Grade 3 QT prolongation was confirmed in 1 case (6%), no episodes of life-threatening arrhythmias were observed. Day 30 and day 60 mortality rates were 12% (2/16) and 19% (3/16), respectively.

Summary/Conclusion: Glasdegib + LDAraC is a fairly safe, non-intensive outpatient regimen that may achieve disease stabilization and induce responses in elderly and unfit R/R AML patients after unsuccesful therapy with hypomethylating agents.

EP487 GEMTUZUMAB OZOGAMICIN ADDED TO HIDAC CONSOLIDATION THERAPY FOR STANDARD-RISK ACUTE MYELOID LEUKEMIA IS SAFE AND EFFICACIOUS

N. Horesh [1,*], R. Leiba [2], B. Krayem [2], A. Frisch [2], S. Shimony [3], O. Wolach [3], Y. Moshe [4], J. Canaani [5], Y. Ofran [2]

[1]Department of Hematology and Bone Marrow Transplantation, [2]Rambam Health Care Campus, Haifa, [3]Rabin Medical Center, Petah Tikva, [4]Tel Aviv Sourasky Medical Center, Tel Aviv, [5]Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: Patients (pts) with standard-risk acute myeloid leukemia (AML) are not regularly planned for up-front allogeneic stem cell transplantation (allo-SCT). Yet, some of these pts fail reaching minimal residual disease (MRD) negativity with standard chemotherapy and are allocated to allo-SCT during 1st complete remission. Gemtuzumab ozogamicin (GO), an antibody-toxin conjugate targeting $CD33^+$ cells, is associated with overall survival (OS) benefit and reduced relapse rate in standard-risk AML. The FDA approval of GO use as an addition to intensive chemotherapy relies on results of the French ALFA-0701 trial where pts were assigned to receive GO (3mg/m^2 on days 1,4,7) combined with the 7+3 regimen as induction and combined with daunorubicin/cytarabine (GO: 3mg/m^2 on day 1) for 2 courses as consolidation. However, in many countries, reimbursement issues preclude the use of GO as part of induction.
Aims: The Israeli Leukemia Group recommended including GO (capped at 4.5mg total on day 1) in any consolidation therapy comprising high-dose cytarabine (HIDAC) for standard-risk AML pts, even if GO was not applied as part of induction. The present study aimed to evaluate outcomes of pts who received GO+HIDAC as consolidation, in terms of MRD clearance and toxicities.
Methods: Electronic medical records of 4 Israeli tertiary care centers were retrospectively reviewed to identify standard-risk AML pts treated with 7+3 induction and HIDAC consolidation. Pts were then grouped into two cohorts based on GO use in combination with HIDAC (GO vs No-GO). The cohorts were compared in terms of OS, progression-free survival (PFS) and MRD clearance after 2 intensive chemotherapy cycles. For toxicity evaluation, the number of infectious events, blood products used, hemorrhage events, mucositis (≥grade 3) events, veno-occlusive disease (VOD) events and occurrence of prolonged thrombocytopenia (platelet count <100 at 30 days post-treatment) were analyzed. The dose intensity per unit time was also assessed. Of note, hospitalization duration was not included in the final analysis due to inter-hospital admission policy differences.
Results: The GO and No-GO cohorts included 22 and 21 pts, respectively. They were comparable in terms of age, sex and specific driver mutations other than the combination of *NPM1*+ low allelic ratio-*FLT3-ITD* that was less prevalent in the GO cohort (5% vs 27%; p=0.046). The majority of pts (77% vs 57%; p=0.2) received intensified induction (daunorubicin 90mg/m^2 or its equal). Among the pts whose MRD data were available, MRD clearance was reached in all those who received GO and only in two thirds of the No-GO cohort (12/12 vs 7/11; p=0.037). No VOD or treatment-related death occurred. A total of 113 consolidation cycles were given: 55 HIDAC+GO and 58 HIDAC cycles (Table 1). The GO+HIDAC regimen was associated with higher rates of platelet transfusion (median 3.5 vs 1 of pooled or apheresis platelets) and prolonged thrombocytopenia (42.3% vs 5.2%; p<0.001). Only 7 bleeding events occurred (5 after GO injection). No life threatening bleeds were recorded. GO administration did not entail higher neutropenic fever rates (74.5% vs 60%; p=0.12), excessive use of packed cell units (p=0.44), treatment delays or therapy-related death.

Table 1. Consolidation treatment-associated toxicity

	HIDAC + GO (n=55)	HIDAC only (n=58)	P-value
Neutropenic fever events	41 (74.5%)	35 (60%)	0.12
Packed red blood cell administration (mean)	2.44±2.08	2.14±1.59	0.44
Platelet (pooled or apheresis) administration (median)	3.5 (1.75-6.0)	1 (1-3)	0.004
Prolonged thrombocytopenia (platelet count <100K on day 30)	22 (42.3%)	3 (5.2%)	<0.001
Hemorrhage	47/52(90%)	55/57 (96%)	0.25
Mucositis (≥grade 3)	5 (9%)	6 (10%)	1.00
Days between each cycle (mean)	42.6±16.6; N=37	40.2±14.9; N=33	0.54

Summary/Conclusion: While associated with high bleeding risk attributed to severe and prolonged thrombocytopenia, consolidation with HIDAC+GO is safe and provides high rates of MRD eradication. Standard-risk AML patients who do not receive GO in induction may benefit from its addition to consolidation regimens.

EP488 INDUCTION CHEMOTHERAPY WITH CYTARABINE, DAUNORRUBICIN AND ETOPOSIDE VERSUS STANDARD-DOSE CYTARABINE AND DAUNORRUBICIN IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

C. Sol Reis [1,*], P. Monteiro [1], I. Marques [1], E. Aguiar [1], A. Carneiro [1], A. L. Pinto [1], F. Ferreira [1], I. Carvalhais [1], J. Cancela Pires [1], J. Bastos [1], L. Marques [1], P. Rocha Silva [1], R. Pinto [1], R. Damas [1], R. Duarte [1], R. Bergatim [1], M. Sobrinho Simões [1,2,3], F. Trigo [1]

[1]Clinical Hematology, Centro Hospitalar e Universitário São João, [2]Faculdade de Medicina da Universidade do Porto, [3]i3S - Instituto de Investigação e Inovação em Saúde, Porto, Portugal

Background: Intensive induction chemotherapy is the standard approach in patients (pts) with acute myeloid leukaemia (AML) for achieving complete remission (CR), enabling the delivery of consolidation treatment. Since achievement of CR is a strong predictor of survival, it is important to optimize the induction chemotherapy protocol.
Aims: Comparison induction regimen for AML with standard-dose 7+3 versus 10+3+etoposide.
Methods: Unicentric retrospective review of pts diagnosed with AML (excluding M3) from January 2012 to June 2020 treated with standard-dose 7+3 (cytarabine 200mg/m^2 day 1-7 + daunorubicin 60mg/m^2 day 1-3) and 10+3+E (cytarabine 100mg/m^2 day 1-10 + daunorubicin 50mg/m^2 day 1, 3, 5 + etoposide 50mg/m^2 day 1-5).
Results: Identified 173 pts - median age 50 years (19-70y), 53% women. Secondary AML was diagnosed in 18.5% and according to the European Leukemia Net (ELN) risk stratification 38% had favourable risk, 43% intermediate and 19% unfavourable. Median leukocyte at diagnosis was 10.56x10^9/L and bone marrow blast 52%. Age (median 53y in 7+3 vs 48y in 10+3+E; p<0.001) was the only characteristic that differed between treatment (tt) arms. From the pts identified, 61 received 7+3 and 112 received 10+3+E. A total of 78% achieved CR after one cycle of induction tt – 77% in 7+3 vs 78.6% in 10+3+E, without statistically significant difference (p=0.817). Only ELN risk had statistical impact on CR - 94% in favourable vs 77% in intermediate vs 48% in unfavourable (p<0.001). Partial remission and refractory disease were both obtained in 8%, without statistically significant difference. 10 pts died before evaluation of response, all of them as a consequence of bone marrow aplasia, with no difference between tt arms. Median neutrophil-recovery time was different between tt [27days (10-74d) in 7+3 vs 31days (10-65d) in 10+3+E; p=0.02]. Median myelosuppression-recovery time (Hb>8g/dL; Leuk>1.5x10^9/L; Plaq>20x10^9/L) wasn't statistically significant between tt (median 28days in 7+3 vs 30days in 10+3+E; p=0.216). Also the number of febrile neutropenia wasn't different, with a median 2 episodes/patient. 16 pts required ICU admission, with no difference between tt.
Early relapse rate (≤6 months after induction tt) was 6.4%, lower in 10+3+E arm (3.6% vs 11.5%; p=0.047), regardless ELN risk. Overall relapse rate was 47% with statistically difference according to ELN risk (61% vs 50% vs 38% in unfavourable, intermediate and favourable risk; p<0.001) but no difference by tt arm (p=0.296). Median overall survival (OS) was 20months (95%CI 16-24months), without difference by tt (p=0.651).
At univariate analysis, several factors were associated with poor OS: ELN risk (p<0.001; HR 2.166), myelosuppression ≥50days (p=0.005; HR 18.717), neutropenia ≥60days (p<0.001; HR 17.711), ICU admission (p<0.001; HR 3.152) and disease relapse (p<0.001; HR 1.029). CR after induction was a protective factor (p<0.001; HR 0.389). At multivariate analysis factors that remained significant were: ELN risk (p<0.033; HR 2.148), myelosuppression ≥50days (p=0.003; HR 5.302), ICU admission (p=0.015; HR 2.706) and disease relapse (p<0.001; HR 13.937).
Summary/Conclusion: Outcomes were similar, with both induction regimens increased CR rates without increasing mortality in patients with AML fit for intensive treatment.
The only identified difference was that addiction of etoposide to 7+3 regimen had a lower early relapse rate but with slightly increased haematological toxicity. No difference was observed in overall relapse rate. Thus, both induction regimens are effective and tolerated in fit adult patients with AML.

EP489 NEXT STEP AFTER COMPLETE REMISSION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

C. Núñez-Torrón Stock [1,*], C. Jiménez Chillon [1], A. Luna de Abia [1], A. J. Saez Marín [1], J. Marquet Palomanes [1], F. Martín Moro [1], L. Rubio Lopes-García [1], A. Lario Arribas [1], A. Chinea Rodríguez [1],

V. García Gutiérrez [1], G. Moreno Jiménez [1], J. López Jiménez [1], P. Herrera Puente [1]

[1]*Hematology, Hospital Ramon y Cajal, Madrid, Spain*

Background: patients with Acute Myeloid Leukemia (AML) who achieve Complete Remission (CR) after 1 or 2 courses of chemotherapy need consolidation treatment to avoid relapse. We do not know what is the most effective chemotherapy scheme just after CR.
Aims: to analyse the impact of the first consolidation treatment (HDAC based, more intensive regimens including anthracyclines or directly transplant (HSCT) in terms of Relapse-Free Survival (RFS) and OS (OS) in patients with AML in CR after induction.
Methods: we reviewed retrospectively 190 patients with AML who were diagnosed between 2011 and 2020. We analysed 114 who achieve CR after 1 or 2 courses of intensive chemotherapy and received at least 1 cycle of consolidation or were directly transplanted after induction. We consider CR <5% blast by cytology and MRD+ ≥0.1% by Multiparameter Flow Cytometry (MFC). We divided the cohort according to the first consolidation treatment: Group 1 HDAC based consolidation, Group 2 intensive regimen including anthracyclines, and Group 3 HSCT directly HSCT. The decision on the first consolidation chemotherapy treatment (HDAC vs anthracyclines-based) was at the discretion of the prescribing physician. In table 1 are reflected the baselines characteristics of our cohort.
Results: we didn't find differences among the groups, except Group 3 had more percentage of secondary AML and adverse risk profile and they needed more frequently 2 cycles to achieve CR. With a median follow up of 19 months (12-47.5), the 3year (3y) EFS was 35%, the 3y-OS 45% and the 3y Cumulative Incidence of Relapse (3y-CIR) 43%. The 3y-EFS according to the first consolidation was 49% in Group 1 vs 30% Group 2 vs 39% in Group 3 (HR 1.2, p=0.2) and the 3y-OS was 54% Group1 vs 43% Group 2 vs 45% in Group 3 (HR 1.3, p=0.3). The CIR was 27% vs 49% vs 34% respectively (Grey test 3.2,p=0.2). Differences remained not significant after patients who received HSCT in CR were censored at the time of infusion for the EFS (HR 1.4, p=0.4). The response by both cytology and MFC before and after first consolidation were available in 21 HDAC-based first consolidation patients (9 MRD- after induction and 12 MRD+) and in 50 anthracycline-based first consolidation patients (25 MRD- and 25 MRD+). In patients with MRD- after induction, 1/9 patients had MRD+ and 1/9 patients had Active Disease (AD) after consolidation with HDAC and 1/25 patients had MRD+ and 1/25 AD after the consolidation with anthracyclines-based regimen (p=0.5). In patients with MRD+ after induction we found than in HDAC group, 3/12 patients achieve MRD- after the consolidation, 7/12 maintained MRD+ and 2/12 had AD while in anthracyclines-based first consolidation group, 13/25 patients achieved MRD-, 7/25 maintained MRD+ and 5/25 had AD (p=0.2). We analysed the impact of the first consolidation stratifying patients according to the MRD after induction (MRD+ and MRD-), the number of cycles (1 or 2) to achieve complete remission, the ELN at diagnosis (Favorable Intermediate and Adverse). We did not find statistical differences for EFS and OS according to the first consolidation in any of these subgroups.

	HDAC n=25	Intensive regimen including anthracyclines n=74	TPH n=15
Sex M (%)	17 (68%)	44 (59.5%)	7 (46.7%)
Age, median	57 (43.5-62)	56.5 (44-62)	59 (40-62)
Hb median	9.6 (8.1-11.3)	9.6 (7.9-11.3)	9.7 (8.3-11.3)
Platelets	75550 (33750-151000)	75550 (35250-152000)	73600 (19000-122250)
WBC	3910 (2035-24340)	6390 (2070-24780)	2415 (1347-18225)
Median blasts	54% (43.5%-62%)	53% (33.3%-81.2%)	54% (29%-70%)
Secondary AML	13 (52%)	28 (38.4%)	11 (73.3%)
ELN classification			
Favorable Risk	5 (20%)	15 (20.3%)	0 (0%)
Intermediate Risk	16 (64%)	42 (56.8%)	6 (42.9%)
Adverse Risk	4 (16%)	17 (23%)	8 (57.1%)
Nº induction cycles to achieve CR			
1	22 (88%)	69 (93.2%)	8 (53.3%)
2	3 (12%)	5 (6.8%)	7 (46.7%)
Best response after induction			
MRD- by flow cytometry	9 (36%)	34 (45.9%)	7 (46.7%)
MRD+ by flow cytometry	15 (60%)	36 (48.6%)	8 (53.3%)
Unknown	1 (4%)	4 (5.4%)	0 (0%)
Received HSCT, yes n(%)	19 (76%)	59 (79.7%)	15 (100%)
Patients transplanted in 1RC	15 (78.9%)	38 (64.4%)	13 (86.7%)
Type of HSCT, n (%)			
AloTPH	19 (100%)	54 (91.5%)	15 (100%)
AutoTPH	0 (0%)	5 (8.5%)	0 (0%)
Conditioning intensity			
Myeloablative	12 (63.2%)	33 (55.9%)	9 (60%)
Reduce Intensity	6 (31.6%)	23 (39%)	6 (40%)
Sequential conditioning	1 (5.3%)	3 (5.1%)	0 (0%)
PreHSCT disease state, n(%)			
MRD- by flow cytometry	13 (68.4%)	41 (69.5%)	10 (66.7%)
MRD+ by flow cytometry	6 (31.6%)	10 (16.9%)	4 (26.7%)
Active disease	0 (0%)	5 (8.5%)	1 (6.6%)
Unknown	0 (0%)	3 (5%)	0 (0%)
Number chemotherapy cycles, median (range)	3 (3-5)	3 (2-3)	1 (1-2)
Days since diagnosis to HSCT, median (range)	190 (146-245)	182 (141-236)	113

Summary/Conclusion: the EFS and OS was not better using a first consolidation anthracycline-based compare to HDAC or patients that consolidate directly with HSCT regardless the MRD by flow cytometry after induction, the number of cycles to achieve CR or the cytogenetic risk. In patients with MRD+ after induction the first consolidation with another cycle of intensive chemotherapy based in anthracyclines did not significantly improve the depth of the response compare to standard HDAC regimen.

EP490 ROLE OF EXTRACELLULAR VESICLE-INDUCED MYELOID-DERIVED SUPPRESSOR CELLS IN ACUTE MYELOID LEUKEMIA

H. Xing [1,*], C. Liang [1], Q. Li [1], X. Xu [1], Z. Jiang [1]

[1]*Department of Hematology, The First Affiliated Hospital of Zhengzhou University, zhengzhou, China*

Background: Acute myeloid leukemia (AML) is the most common malignant of the hematopoietic system. Allogeneic hematopoietic stem cell transplantation not only improves the prognosis of patients, but also emphasizes the role of immunity in the development of AML. Myeloid-derived suppressor cells (MDSCs) are immunosuppressive cell populations derived from myeloid cells, However, their role in AML has not been extensively elucidated in bone marrow (BM) or peripheral blood (PB). Furthermore, it remains unclear whether the percentage of MDSCs derived from BM and PB of patients with AML are consistent. Extracellular vesicles (EVs) as mediator in intercellular communication and play an important role in tumor immunity. However, the role of EVs derived from AML (AML-EVs) in MDSCs expansion is not well understood.
Aims: This study aimed to investigate the role of MDSCs in patients with newly diagnosed AMLand evaluate the role of extracellular vesicle-induced MDSCs in AML.
Methods: Collected BM or PB from newly diagnosed AML patients and healthy donors (HD) to extract mononuclear cells (MNCs), and the percentage of MDSCs and its subpopulation was determined by flow cytometry. Analyzed the relationship between MDSCs and clinicopathological characters, MICM classification, survival. In addition, extracted and identified the EVs in the serums from HDs and AML patients. AML-EVs and HD-EVs were incubated with peripheral blood mononuclear cells (PBMCs) or MNCs from hematopoietic stem cell (HSCs) suspension. And the percentage of MDSCs were detected by flow cytometry.
Results: The MDSCs and its subpopulation percentage was significantly higher in patients with AML than in HDs, with no significant difference between PB and BM. The MDSCs percentage in AML patients was positively correlated with WBC, β-MG, LDH, ferritin, and negatively correlated with PLT. However, MDSCs percentage was not correlated with RBC, HGB, PB blasts cells and BM blasts cells. The MDSCs percentage was positively correlated with AML risk stratification which the higher risk displayed the elevated MDSCs. The MDSCs percentage varied among those with different fusion genes and gene mutations, with higher frequency observed in those with *FLT3- ITD* mutation and *NUP98- HOXA9* fusion genes. The MDSCs percentage at the time of diagnosis was not significant different among the CR, PR, and NR groups, and was also no significantly differ between the MRD positive and negative group. Further categorized into low- and high-MDSC groups based on the median MDSCs percentage of 3.07% at the time of diagnosis, and the OS was significantly longer in the low-MDSC group than in the high-MDSC group. EVs entered into MNCs was observed by fluorescence microscopy. The MDSCs frequency was significantly higher in myeloid cells incubated with AML-EVs, but the MDSCs frequency was no significant change in PBMCs incubated with AML-EVs.
Summary/Conclusion: The MDSCs percentage was significantly elevated in both the BM and PB of AML patients, and there was no statistical difference in PB and BM. The percentage of MDSCs was positively correlated with AML risk stratification which the higher risk displayed the elevated MDSCs. The OS was significantly longer in the low-MDSCs group than in the high-MDSCs group. Taken together, MDSCs level at the time of diagnosis could predict AML prognosis. AML-EVs could promote the transformation of myeloid cells into MDSCs, and the role of AML-EVs in inducing MDSCs was stronger in myeloid cells than in PBMCs.

EP491 MULTICENTER OBSERVATIONAL RETROSPECTIVE STUDY ON BACTERIAL/FUNGAL/VIRAL INFECTIONS IN PATIENTS WITH SECONDARY ACUTE MYELOID LEUKEMIA TREATED WITH CPX-351 IN "REAL-LIFE"

Citta' della Salute e della Scienza di Torino P.O. Molinette, Torino, Italy

Background: CPX-351, a dual-drug liposomal encapsulation of cytarabine and daunorubicin has been approved for the treatment of adults with newly diagnosed therapy-related AML (t-AML) or AML with myelodysplasia-related changes (AML-MRC).
Aims: The primary endpoint of this study was to evaluate the absolute infectious risk in the real-life setting of AML patients (pts) treated with CPX-351. Secondary endpoints were the evaluation of the type, incidence and outcome of infections and to assess the infection-related mortality rate.
Methods: This retrospective, multicentre, observational study includes all consecutive AML pts receiving at least 1 CPX-351 course in 26 Italian hematological centers belonging to the SEIFEM (Sorveglianza Epidemiologica Infezioni nelle Emopatie) group from July 2018 to June 2020.
Results: Overall 152 pts [M/F 77/75; median age 64.5 y.o. (range 49-73)] have been included in this study: 110 with AML-MRC and 42 with t-AML. Overall, 253 courses of CPX-351 had been administered: all 152 pts received first induction course, 12 pts (8%) received second CPX induction, whereas 62 pts (41%) proceeded with the first CPX-351 consolidation course with 27 (43.5%) of them receiving also the second consolidation course.
A total of 179 (71%) febrile events were recorded: 141 (79%) during first or second induction, 25 (14%) and 12 (7%) after first and second consolidation respectively.
After a diagnostic workup in 55 cases (31%) the event has been defined as febrile neutropenia of unknown origin (FUO); the remaining 124 events were classified as microbiologically documented in 99 cases (55%) and clinically documented in 25 cases (14%).
The type of clinically documented infections was 11 pneumonia, 7 cellulitis/ abscesses, 3 arthritis, 2 colitis, 1 sinusitis, 1 cystitis.
Most microbiologically documented infections were of bacterial origin (91/99, 92%) with Gram-positive bacteria detected in 49 cases (54%) and Gram-negative in 42 (46%). Among bacterial infections, sepsis occurred in most cases (80/91) associated with pneumonia in 8 cases; other types of infections were pneumonia (3), abscesses (2), cystitis (4), discitis (1), sinusitis 1.
Overall, a fungal infection due to *Aspergillus spp* was diagnosed in 9 cases (in 1 case associated with bacterial sepsis) classified as proven 1 case, probable 7 cases, possible 1 case. Sites of aspergillosis were lung in 8 cases and orbital in 1 case.
Only 1 case of CMV reactivation associated with bacterial sepsis occurred.
Stratifying infections according to the treatment phase 141 events (79%) occurred during induction and 38 (21%) during consolidation. Interestingly all *Aspergillus* infections were diagnosed during the induction phase.
All pts were deeply neutropenic during infections [median duration of neutrophils count< 100 /mL and <500/mL was 12 days (range 1-42) and 16 days (range 2-60) respectively].
The overall 30-days mortality rate was 14% (22/152); most of the deaths (18/22) occurred during the induction phase. Causes of death were infection in 8 pts, AML progression in 8 pts, cerebral hemorrhage 3 pts, cardiac complication 3 pts.
Attributable mortality-infection rate resulted therefore 5.2% (8/152, 7 bacterial and 1 fungal). Notably, all infection-related deaths occurred in pts refractory to CPX-351 treatment.
Summary/Conclusion: Our data compared to those of previous registered studies show similar results in terms of infection incidence during CPX-351 induction treatment. Despite prolonged neutropenia infection-related mortality rate resulted relatively low.

EP492 DELAY IN THE DIAGNOSIS OF ACUTE MYELOID LEUKEMIA, COMPARISON BEFORE AND AFTER SARS-COV-2: A SINGLE CENTRE STUDY

C. Alburquerque-Prieto [1,2,*], M. C. Mateos [1,2], A. Torres-López [1,2], I. Peris [2,3], M. D. Odero [2,3,4], C. Ceballos-Bolaños [1,2], J. M. Sánchez-Iglesias [1,2], I. Múgica-Muñagorri [1,2], tttA. M. Redondo-Izal [1,2]

[1]Hematology Service, Complejo Hospitalario de Navarra, [2]IdiSNA, Instituto de Investigación Sanitaria de Navarra, [3]Centro de Investigación Médica Aplicada (CIMA), [4]Biochemistry and Genetics Department, University of Navarra, Pamplona, Spain

Background: Since the first case of severe acute respiratory infection by coronavirus 2 (SARS-CoV-2), Coronavirus Disease 2019 (COVID-19) has been the priority in any centre. This situation has produced collateral damage in patients with other acute diseases, with a delay in diagnosis and associated poorer outcomes. Acute myeloid leukemia (AML) is considered a hematologic emergency and delayed induction chemotherapy can harm these patients.
Aims: To analyse the impact of the COVID-19 epidemic outbreak on patients diagnosed with AML. We examined the impact on the times from symptom onset to hospital admission, performance status, possibility of administrating treatment and short-term outcome.
Methods: Patients diagnosed with AML between January 1, 2019 and December 31, 2020 were included. Cases were grouped into two periods, depending on the year. Demographic and clinical data were recorded including age, sex, detection of symptoms to diagnosis, Eastern Cooperative Oncology Group (ECOG) performance status, diagnoses using World Health Organization (WHO) classification, treatment administered, overall survival, and mortality. Comparisons between groups were made using chi-square tests to compare categorical variables and the Student test for continuous variables; with Kaplan-Meier estimates and Log-Rank test for survival analysis.
Results: In total 17 patients with AML were studied (male 9; 52.94%; median age 66; interquartile range (IQR) 59-74). Table 1 shows the comparison of baseline characteristics of the patients between the two years. In 2020 there was an increase in the time until the admission to the hospital (30.55 days vs 11.55 days, p=0.0419), with a worsening in ECOG punctuation on arrival statistically significant (Xi2=7.8254, p=0.020). In 2019, all the patients received treatment; and in 2020, 3 patients due to their status; did not received treatment, just best supportive care. Overall survival time was inferior in the cohort of 2020 (3.064 vs 14.028 months; p=0.045).

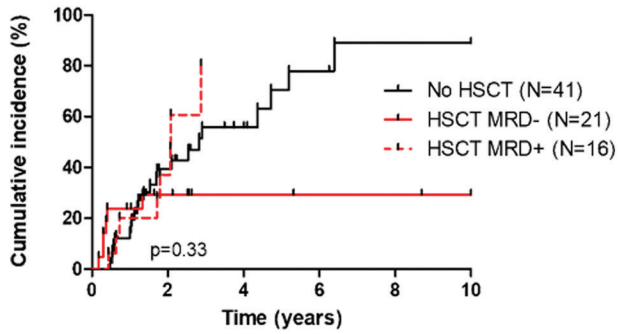
	2019 N=8	2020 N=9
Sex (n, %)		
Male	5, 62.50%	3, 33.33%
Female	3, 37.50%	6, 66.67%
Age (median, IQR)	62, (58.5-75)	66 (64-82)
ECOG (n, %)		
0-1	6, 75%	1, 11.11%
1-2	2, 25%	5, 55.56%
>3	0, 0%	3, 33.33%
Days before medical attention (median, IQR)	6.5, (4-22.5)	16 (8-55)
Classification according to WHO criteria (n, %)		
AML with recurrent genetic abnormalities	1, 12.50%	1, 11.11%
AML with myelodysplasia-related-changes	3, 37.50%	4, 44.44-%
Therapy-related myeloid neoplasms	3, 37.50%	2, 22.22%
Acute leukaemia of ambiguous lineage	0, 0%	1, 11.11%
AML, not otherwise specified	1, 12.50%	1, 11.11%
Treatment		
Cytarabine plus idarubicin (3+7)	2, 25%	2, 22.22%
Fludarabine plus cytarabine (FLUGA)	3, 37.50%	0, 0%
Fludarabine plus cytarabine plus idarubicin and granulocyte-colony stimulating factor (FLAG-Ida)	1, 12.50%	1, 11.11%
3+7 plus midostarin	1, 12.50%	0, 0%
3+7 plus quizartinib or placebo	0, 0%	1, 1.11%
Azacitidine	1, 12.50%	1, 1.11%
Azacitidine plus Venetoclax	0, 0%	1, 1.11%
No treatment	0, 0%	3, 33.33%
Overall survival (Median, IQR, months)	15.5 (6.5-21.66)	1 (0.56-4.43)

Summary/Conclusion: This retrospective study realized in our centre illustrates the collateral damage caused by the COVID-19 pandemic. Delay in seeking medical attention in a time-course-dependent pathology such as AML; it is followed by an increase in morbidity and mortality.

EP493 AN UPDATE ANALYSIS OF PROGNOSTIC SIGNIFICANCE OF PERIPHERAL BLOOD BLASTS ON DAY 7 OF INDUCTION CHEMOTHERAPY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

L. Su [1], W. Zhao [1], Q. Liu [1], J. Sun [1], H. Lin [1], Y. Tan [1], S. Gao [1,*]

[1]Department of Hematology, The First Hospital of Jilin University, Changchun, China



Background: In previous study, we found that peripheral blood blast percentages on day 7 (D7PBBP) of induction chemotherapy significantly associated with remission and long-term outcomes of patients with acute myeloid leukemia (AML). Moreover, D7PBB7 was proven to be an independent indicator for unfavorable prognosis.
Aims: The aim of this study was to assess the prognostic significance of D7PBBP for AML patients with a larger patient sample.
Methods: A retrospective analysis was performed with 137 AML (excluding those with acute promyelocytic leukemia) patients enrolled in this study between October 1, 2015 to October 31, 2018. D7PBBP was determined by flow cytometry. The previous patient cohort in our published study was used as training set, and patients of the present study were regarded as validation set.
Results: Of the 137 patients received one course of standard induction chemotherapy, 100 cases (73.0%) achieved complete remission (CR). With the cut-off value of 0.945% used in training set, the significant association between D7PBBP and achieving CR after one course of chemotherapy also could be observed in validation set (CR rates of patients with D7PBBP ≥0.945% *vs*. <0.945% were 38.2% *vs*. 84.5%; $P < 0.001$). Furthermore, D7PBBP was significantly related with levels of minimal residual disease (MRD) in the bone marrow (negative MRD rates were 17.7% and 40.8% in patients with D7PBBP ≥0.945% and <0.945%, respectively; $P = 0.014$). Similar to our training set, the cutoff value of 0.43% could be used to re-stratify prognosis of patients with AML. Patients with low D7PBBP (<0.43%) had significantly superior relapse-free survival (RFS) and overall survival (OS) compared with those with high levels of D7PBBP (≥0.43%). Additionally, we found that D7PBBP was potential marker for prognostic re-stratification in AML patients with low and intermediate cytogenetic karyotypes.
Summary/Conclusion: In summary, these results indicated that D7PBBP could predict treatment responses and long-term outcomes for patients with AML. Furthermore, D7PBBP was potential index to be integrated into cytogenetics-based risk adapted prognostic system for AML patients in low and intermediate risk group.

EP494 IMPACT OF TREATMENT INTENSITY, MRD AND HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ELDERLY R/R AML PATIENTS: A MONOCENTRIC RETROSPECTIVE STUDY

Z. Gross [1,*], H. labussiere-wallet [1], F. barraco [1], M.-V. larcher [1], M. balsat [1], G. fossard [1], S. ducastelle-lepretre [1], L. gilis [1], X. thomas [1], H. ghesquieres [1], M. heiblig [1]

[1]rhone, centre hospitalier lyon sud, Lyon, France

Background: The management of acute myeloid leukemia (AML) in patients older than 60 years remains a major challenge as it is still rather unclear which patients will benefit or not from intensive chemotherapy compared to low intensity regimens according to clinical, molecular or cytogenetic markers. In relapse/refractory (R/r) settings, outcome in the elderly is usually very poor and there is currently no standard of care regarding second line or salvage therapy.
Aims: In this study, we aimed to investigate retrospectively the impact on the outcome of salvage/second line of treatment in R/r AML patients aged over 60 years old.
Methods: In this monocentric study, we analyzed 236 patients who were refractory to intensive (N=182) or semi-intensive (LIC) (low dose cytarabine/hypomethylating agents) (N=54) first line of treatment for newly diagnosed AML. Flow cytometry minimal residual disease (MRD) after intensive salvage chemotherapy was available in 42 patients and based on leukemia-associated immunophenotype (LAIP) using ELN recommendations (bulk lyses, and at least 500 000 live cells to achieve a sensitivity of 0.1%). MRD flow was performed in bone marrow samples using 8-color panel.
Results: Overall, 50%, 24.6% and 25.4% of patients received either intensive (3+7 based), LIC or best supportive care (BSC) respectively. With a median follow-up of 15.2 months (range: 1.1-190), median overall survival (OS) of the entire cohort was 15.3 months. Median OS was 19.2, 21.6 and 14 months in patients receiving intensive salvage (N=118), LIC (N=58) and BSC (N=59) respectively (p=0.02). Regarding baseline characteristics at R/r, duration of 1st complete remission (CR) ELN 2013 classification and NPM1/FLT3-ITD status were predictive for long term survival. Median OS for NPM1+FLT3-, NPM1+FLT3-ITD and NPM1-FLT3-ITD was 25.4, 14.3 and 7 months respectively (p<0.001). Next generation sequencing at diagnosis was available in 83/237 patients. Median OS was higher in IDH1/2 mutated cases (46.8 months) compared to TP53, ASXL1/RUNX1 and MAPK/RTK mutated cases (p<0.001). Late relapse (LR) (defined as relapse occurring after 12 months after 1st CR) was associated with a better outcome independently of the treatment intensity compared to early relapse (ER)/refractory status. For intensively salvaged patients, CR and CRi/MLFS (according to ELN definition) was 21.2% and 23.7% respectively. Median OS was 34.9 and 21.2 months for CR and CRi/MLFS compared to 12.8 months in refractory patients (p<0.001). Post-induction MRD1 negativity (defined positive when ≥ 0.1%) for patients in CR2 was reached in 60.9% of cases. Among intensively salvaged patients, 20 received GO-based regimen. Sixty percent (12/20) of them reached CR2 (compared to 44.9% in non-GO based salvage, p=0.06). Cumulative incidence of relapse at 3 years was 49.1% and 77.5% in MRD1- and MRD1+ patients respectively. For those who underwent HSCT in CR2 (N=38), pre-HSCT MRD positivity was associated with a high rate of relapse which was similar to non-transplanted patients (figure). HSCT treatment related mortality was 31.5%.

Summary/Conclusion: These results suggest that intensive salvage chemotherapy might be preferred for patients eligible for HSCT in CR2. Post-intensive salvage MRD1 by flow cytometry might also identify patients with a more favorable outcome, even if HSCT seems to be detrimental for long term survival. Low intensive regimens might also be a suitable option in unfit and/or HSCT non-eligible patients, especially in the era of venetoclax and anti-IDH based regimens.

Aggressive Non-Hodgkin lymphoma - Clinical

EP495 PROPHYLACTIC CORTICOSTEROID USE WITH AXICABTAGENE CILOLEUCEL IN PATIENTS WITH RELAPSED/REFRACTORY LARGE B-CELL LYMPHOMA

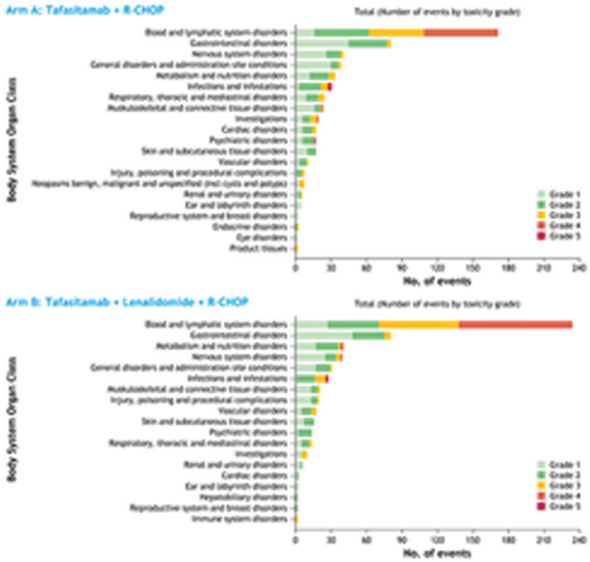
Background: In Cohorts 1 + 2 (C1 + 2; N=101) of ZUMA-1, the pivotal Phase 1/2 study of axicabtagene ciloleucel (axi-cel) in patients with refractory large B-cell lymphoma, rates of Grade ≥3 cytokine release syndrome (CRS) and neurologic events (NEs) were 13% and 28% at the 6-month primary analysis (*N Engl J Med*. 2017;377:2531), and the objective response rate (ORR) was 82% (54% complete response [CR] rate). With a median follow-up of 51.1 months, median overall survival (OS) was 25.8 months and the 4-year OS rate was 44% (*Blood*. 2020;136[suppl, abstr]:40-42). In safety management Cohort 4 (C4; N=41), with its earlier corticosteroid use than C1 + 2, rates of Grade ≥3 CRS and NEs were 2% and 17%, and the ORR was 73% (51% CR; *Blood*. 2019;134[suppl, abstr]:243). In Cohort 6 (C6), the effect of prophylactic corticosteroid use on CRS and NEs was evaluated.
Aims: To present the primary analysis of C6, alongside those of C4 and C1 + 2 for context.
Methods: Eligible patients were leukapheresed, could receive optional bridging chemotherapy (in C4 and C6 but not C1 + 2), and received conditioning chemotherapy before axi-cel (target dose, 2×10^6 chimeric antigen receptor [CAR] T cells/kg). Patients in C6 received dexamethasone 10 mg orally on Days 0 (before axi-cel), 1, and 2 and earlier intervention with corticosteroids and tocilizumab. Primary endpoints were incidence and severity of CRS and NEs.
Results: As of 6/16/20, 40 C6 patients had received axi-cel, with median follow-up of 8.9 months. The median age was 64 years (50%, ≥65 years); 58% of patients were male; 55% had Eastern Cooperative Oncology Group performance status of 1; 65% had disease stage III/IV, and 53% received bridging. C6 patients had median tumor burden (by sum of product diameters post-bridging, if given, but before conditioning) lower than C1 + 2 and C4 (C6, 1184 mm^2; C1 + 2, 3723 mm^2; C4, 2100 mm^2). Median baseline lactate dehydrogenase level was similar in C6 and C4 but lower than C1 + 2 (C6, 236 U/L; C4, 262 U/L; C1 + 2, 356 U/L).
Among patients who received corticosteroids, median cumulative corticosteroid use (cortisone-equivalent dose) in C6 (1252 mg [n=40]) was greater than that in C4 (939 mg [n=30]) but less than that in C1 + 2 (6388 mg [n=24]). In C6, there was no Grade ≥3 CRS; 13% of patients had Grade ≥3 NEs, and there were no Grade 5 CRS or NEs. Onset of CRS appeared to be delayed in C6 (median, 5 versus 2 days in C4 and C1 + 2), and 68% of patients had no NEs or CRS within 72 hours of axi-cel. ORR was 95% (80% CR), and 63% of patients had ongoing responses at the data cutoff.
Median peak CAR T-cell levels trended higher in C6 versus C1 + 2 and C4 (C6, 64 cells/μL; C1 + 2, 42 cells/μL; C4, 53 cells/μL), which was corroborated by median CAR area under the curve in blood (C6, 526 cells/μL × day; C1 + 2, 462 cells/μL × day; C4, 511 cells/μL × day). Median peak serum levels of biomarkers associated with CAR T-cell treatment-related adverse events (eg, C-reactive protein, interferon-γ, granulocyte-macrophage colony-stimulating factor, interleukin-2) were lower in C6 versus C4 and C1 + 2.
Summary/Conclusion: Prophylactic corticosteroid use appears to reduce the rate of severe CRS and NEs and delay onset of CRS, without affecting median peak CAR T-cell levels or responses. Differences in cohort sizes and baseline characteristics should be considered when comparing cohorts. Longer follow-up is required to determine the impact on duration of response and survival.



EP496 FIRST-MIND: A PHASE IB, OPEN-LABEL, RANDOMIZED STUDY TO ASSESS SAFETY OF TAFASITAMAB OR TAFASITAMAB + LENALIDOMIDE IN ADDITION TO R-CHOP IN PATIENTS WITH NEWLY DIAGNOSED DLBCL

D. Belada [1,*], K. Kopeckova [2], J. M. Bergua Burgues [3], M. André [4], E. Pérez Persona [5], P. Pichler [6], P. Klöpfer [7], B. Brackertz [7], E. Lohrmann [7], A. Lahiry [7], N. Shah [7], W. Brugger [7], J. M. Burke [8], G. S. Nowakowski [9]

Background: Tafasitamab is a humanized, Fc-modified anti-CD19 monoclonal antibody that enhances antibody-dependent cellular cytotoxicity and phagocytosis. It is FDA-approved in combination with lenalidomide for adult patients with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) not otherwise specified (NOS), including arising from low-grade lymphoma, who are ineligible for autologous stem cell transplant (ASCT).
Aims: First-MIND (NCT04134936) is a Phase Ib, open-label, randomized study to assess the safety and preliminary efficacy of tafasitamab + R-CHOP or tafasitamab + lenalidomide + R-CHOP in patients with newly diagnosed DLBCL.
Methods: Eligible patients were aged ≥18 years, treatment-naïve, with DLBCL, international prognostic index (IPI) 2–5 and Eastern Cooperative Oncology Group (ECOG) performance status (PS) 0–2. Patients with known double- or triple-hit and transformed lymphoma were excluded. Treatment comprised six 21-day cycles of R-CHOP + tafasitamab (12 mg/kg IV, Day [D] 1, 8 and 15) (arm A) or R-CHOP + tafasitamab (12 mg/kg IV, D1, 8 and 15) + lenalidomide (25 mg orally, D1–10) (arm B). G-CSF and VTE prophylaxis was mandatory. Primary objective is safety; secondary objectives include overall response rate (ORR) and PET-CR rate at end of treatment, progression-free survival, long-term safety, pharmacokinetics and immunogenicity.
Results: From Dec 2019 to Aug 2020, 83 patients were screened in nine countries across Europe and the US; 66 were randomized (arm A: n=33; arm B, n=33). Data cut-off: 9 Dec 2020; the study is ongoing. Median age was 64.5 years (range 20–86 years). Overall, 30% of patients (20/66) were ≥70 years and many had high-risk disease: IPI 2 28.8%, IPI 3 45.5%, IPI 4 25.8%. ECOG PS: 47.0% of patients were ECOG PS 0, 43.9% PS 1, 9.1% PS 2. Most patients had stage III/IV disease (92%); 45.5% had bulky disease.
All patients experienced a treatment-emergent adverse event (TEAE); 555 events occurred in arm A and 570 in arm B. Grade ≥3 neutropenia was observed in 54.5% (arm A) and 66.7% (arm B) of patients. Grade ≥3 thrombocytopenia was observed in 12.1% (arm A) and 30.3% (arm B) of patients. Six patients in each arm experienced febrile neutropenia. Diarrhea, fatigue and vomiting were comparable between the two arms. Grade ≥3 nervous system disorders were experienced by 6.1% of patients in arm A and 12.1% in arm B (the majority of events were polyneuropathies related to vincristine). Infusion-related reactions to both rituximab and tafasitamab occurred in 12.1% (arm A) and 18.2% (arm B) of patients, and 21.2% (arm A) and 27.3% (arm B) of patients had a grade ≥3 infection and/or infestation (TEAEs by system organ class [SOC] shown in Figure 1). Serious TEAEs occurred in 42.4% (arm A) and 51.5% (arm B) of patients. There were three deaths unrelated to tafasitamab and/or lenalidomide (sepsis, urosepsis and COVID-19 pneumonia). Dose intensity of R-CHOP was maintained in both treatment arms.
Among 60 patients who completed tumor assessments after cycle 3, ORR was 89.7% (arm A) and 93.5% (arm B).

Figure 1: TEAEs by system organ class and toxicity grade

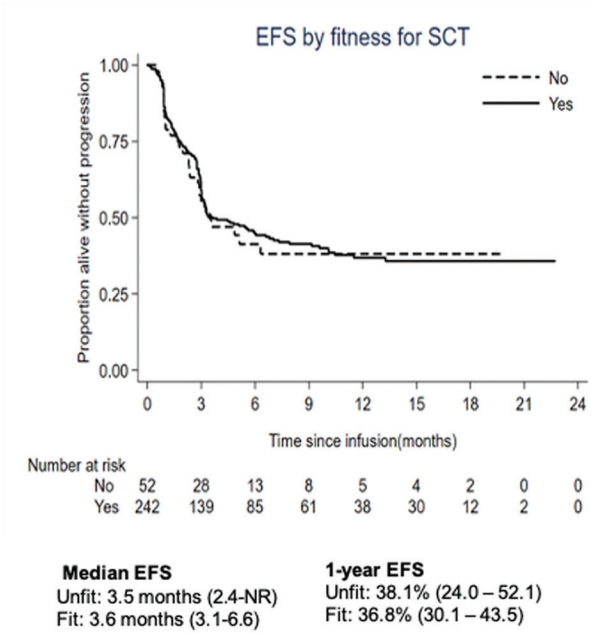
Summary/Conclusion: These data suggest that R-CHOP + tafasitamab or tafasitamab + lenalidomide is tolerable in patients with treatment-naïve DLBCL. Dosing and scheduling of R-CHOP is not affected by the addition of tafasitamab. Toxicities are similar to those expected with R-CHOP alone or R-CHOP + lenalidomide. Updated safety and early efficacy data will be presented at the conference.

EP497 EARLY RESPONSE AT ONE MONTH IS PREDICTIVE OF THE OUTCOME OF THE PATIENTS WITH RELAPSE/ REFRACTORY LARGE B-CELL LYMPHOMA AFTER CAR T-CELL

J. GALTIER [1,*], L. VERCELLINO [2], P. OLIVIER [3], C. TABOURET-VIAUD [4], C. MESGUICH [5], R. DIBLASI [1], M.-T. RUBIO [6], A. DURAND [7], L. RAFFY [5], F.-X. GROS [8], P. FEUGIER [6], I. MADELAINE [9], J. LARGHERO [10], O. CASASNOVAS [7], S. CHEVRET [11], C. THIEBLEMONT [1]

[1]Hematology, [2]Nuclear Medecine, Saint-Louis Hospital, PARIS, [3]Nuclear medecine, Nancy hospital, NANCY, [4]Nuclear Medecine, CHU Dijon, DIJON, [5]Nuclear Medecine, CHU de Bordeaux, PESSAC, [6]Hematology, Nancy hospital, NANCY, [7]Hematology, CHU Dijon, DIJON, [8]Hematology, CHU de Bordeaux, PESSAC, [9]Pharmacy, [10]Cell therapy, [11]Biostatistics, Saint-Louis Hospital, PARIS, France

Background: Anti-CD19 CAR T-cells, Tisagenleuclecel (Tisa-cel) and Axicabtagene ciloleucel (Axi-cel), have been approved for pts with relapsed or refractory aggressive large B-cell lymphomas (R/R LBCL) after 2 lines of therapy, with durable remissions observed in 30% to 40% of the pts, and median progression-free survival (PFS) at 2.9 and 5.9 months (M), respectively. Predictive value of early response assessments at M1 and M3 on patient outcome has not been described.
Aims: To evaluate the predictive value of early response at M1 and M3 after CAR T-cells infusion in R/R LBCL, using clinical evaluation and visual and semi-quantitative PET approach analysis.
Methods: Clinical, biological and metabolic characteristics, including, SUVmax, SUVpeak and total metabolic tumor volume (TMTV) before CART infusion (baseline), at M1 and at M3 were retrospectively collected. Complete metabolic response (CMR) was defined by a Deauville Score (DS) 1,2,3. Conversion rate from partial response (PR)/stable disease (SD) at M1 to complete response (CR) at M3 were assessed. Optimal ΔSUVmax at M1 or M3 able to predict PFS events were identified using time-ROC. Survivals were estimated by the Kaplan-Meier method. Cox models were used to select prognostic covariates based on landmark at M1 or M3.
Results: 151 patients with R/R DLBCL (n= 122), transformed follicular lymphoma (tFL) (n= 19) or PMBL (n=10) were treated with Tisa-cel (n= 61) or Axi-cel (n=90). Median age was 63 (21-77). At time of decision, 131 (87%) patients were PS 0-1, 86 (57%) were IPI low or intermediate risks, 84 (56%) had abnormal LDH levels. Median number of prior lines was 3 (2-7). PFS at 6 and 12 months for the whole cohort were 48% and 42% respectively, and overall survival (OS) were 80% and 64%, respectively. Median time from infusion to progression was estimated at 3.7 months (95%CI, 3.0 to 16.7). At baseline: median SUVmax was 21.5 and median TMTV was 54ml. 66 (44%) patients presented a high TMTV (>80ml). At M1: 61/151 (40%) patients are in CR, 37/151 (24.5%) in PR and 10/151 (7%) in SD. Among 128 patients evaluable with DS, 52 (41%) are in CMR with DS 1-3, 32 (25%) have DS-4 and 44 (34%) have DS-5, with 6-month PFS and OS rates (from M1) at 78% and 95% for DS1-3, 76% and 97% for DS-4, 10% and 63% for DS-5, respectively. At M3: 64/108 (59%) were in CR and 14/108 (13%) were in PR or SD. 13 PR patients at M1 converted to CR at M3, while 13 stayed in PR/SD, and 11 progressed. 9/10 SD progressed. Among 103 patients evaluable with DS, 53 (51%) are in CMR with DS 1-3, 17 (17%) have DS-4 and 33 (32%) have DS-5, with 6-month PFS and OS rates (from M3) at 87% and 92% for DS1-3, 97% and 100% for DS-4, 9% and 71% for DS-5, respectively. ΔSUVmax cutoffs identifying good responder patients were a decrease of at least 73% at M1 and 85% at M3 with 51.6% and 51.6% of the patients who reached these cutoffs, respectively. Patients below the 73% threshold at M1 had decreased PFS (HR 3.96, p<0.001) and OS (HR=4.45, p<0.001). By contrast, patients below the 85% threshold at M3 had a decreased PFS (HR=4.18, p<0.001) but no different OS (HR=1.34, p=0.55), probably because early progressor with the poorest outcome have been excluded from this analysis.
Summary/Conclusion: Early metabolic response at M1 is strongly associated with better outcome. These data argue for an early monitoring of patients using functional imaging, and innovative strategies for very high-risk patients.



EP498 CD19 CAR-T IN LESS FIT PATIENTS WITH R/R HIGH-GRADE LYMPHOMA

A. Kuhnl [1,*], A. Kirkwood [2], C. Roddie [3], T. Menne [4], E. Tholouli [5], A. Patel [6], C. Besley [7], S. Chaganti [8], W. Osborne [4], J. Norman [5], K. Sharplin [7], M. Cuadrado [1], L. Neill [3], A.-L. Latif [9], C. Arias [10], C. Jones [11], B. Uttenthal [12], A. McMillan [13], R. Johnson [14], R. Sanderson [1], W. Townsend [3]

[1]King's College Hospital, [2]University College London CTC, [3]University College London Hospital, London, [4]Freeman Hospital, Newcastle, [5]Manchester Royal Infirmary, [6]The Christie Manchester, Manchester, [7]Bristol University Hospital, Bristol, [8]Queen Elizabeth Hospital, Birmingham, [9]Queen Elizabeth University Hospital, Glasgow, [10]Royal Marsden Hospital, London, [11]Cardiff University Hospital, Cardiff, [12]Addenbrooke's Hospital, Cambridge, [13]Nottingham University Hospital, Nottingham, [14]St James's Hospital, Leeds, United Kingdom

Background: Relapsed/refractory (r/r) lymphoma patients with comorbidities and/or advanced age are increasingly considered for treatment with CD19 CAR-T. However, there are no clear criteria to define fitness and limited data on the clinical benefit of CAR-T in the less fit patient population.
Aims: To analyse the outcomes of lymphoma patients approved for licenced CD19 CAR-T in the UK who were deemed unfit for autologous stem cell transplant (ASCT).
Methods: We analysed 400 consecutive r/r high-grade lymphoma patients approved for treatment with axicabtagene ciloleucel (axi-cel) or tisagenlecleucel (tisa-cel) between Dec 2018 and Nov 2020 across 10 UK centres. Data on patients' fitness and comorbidities were retrospectively collected. Fitness for ASCT was defined by the treating team based on physical suitability irrespective of disease status.
Results: 80/400 (20%) of patients approved for CAR-T were deemed unfit for ASCT (40 for age alone, 10 frailty, 11 cardiac function, 6 kidney function, 13 other/multiple comorbidities).
52/80 (65%) of patients in the ASCT-unfit cohort underwent CAR-T infusion; Reasons for not proceeding with treatment were as follows: 20 progressive disease (PD), 2 manufacturing failures, 1 cardiac failure, 1 diagnosis of dementia, 3 deaths. The drop-out rate from approval to infusion in the ASCT-unfit vs. ASCT-fit group was 34% vs. 24% (p=0.062). 27/52 (52%) patients received tisa-cel, 25 (48%) axi-cel (vs. 20% tisa-cel in fit patients; p‹0.0001). Patients' median age was 71 years (range 47-78) vs. 56 years (range 18-72) in the ASCT-fit cohort (p‹0.0001). ASCT-unfit patients were more likely to have ECOG PS 1 at baseline (65% vs. 46%; p=0.02), high-risk IPI (24% vs. 9%; p=0.005), HCT-CI comorbidity score of 3+ (17% vs. 5%; p=0.005), lower GFR (‹50ml/min: 25% vs. 5%; p‹0.0001), and lower LVEF (‹50%: 18% vs. 6%; p=0.01). No other significant difference in baseline characteristics was observed.

The ongoing 6-months ORR was 31% (all CR). With a median follow-up of 10.5 months, the median EFS/OS were 3.5/10.6 months and the 12-months EFS/OS 38/42%. There was no significant difference in efficacy outcomes between the ASCT-unfit and -fit cohorts. Moreover, no evidence of a difference between groups who were unfit due to age or comorbidities, nor evidence of worse prognosis for patients with impaired kidney- or cardiac function or high HCT-CI.
Among 52 ASCT-unfit patients, there was one case with G3 CRS (2%), and 6 patients (11%) with G3+ ICANS. No significant difference was observed in the incidence of any grade/G3+ CRS or ICANS, the use of tocilizumab or steroids, ICU admission rate, and the incidence of G3+ cytopenias post CAR-T compared to the ASCT-fit cohort.

Summary/Conclusion: Results from our large, prospective real-world cohort demonstrate that CD19 CAR-T can be safely delivered in carefully selected older patients and patients with comorbidities who are not deemed suitable for transplant. There was a trend towards a higher drop-out rate in less fit patients, but patients who successfully undergo infusion appear to have the same long-term benefit from CD19 CAR-T as ASCT-fit patients and should be considered for this potentially curative treatment.

EP499 SUBCUTANEOUS EPCORITAMAB IN PATIENTS WITH RELAPSED/REFRACTORY B-CELL NON-HODGKIN LYMPHOMA: SAFETY PROFILE AND ANTI-TUMOR ACTIVITY

R. Mous [1,*], P. Lugtenburg [2], M. Hutchings [3], P. Johnson [4], K. Linton [5], D. J. Lewis [6], M. Chamuleau [7], A. Sureda Balari [8], D. Cunningham [9], B. Elliott [10], D. DeMarco [10], K.-M. Chen [10], M. Roost Clausen [11]

Background: Epcoritamab is a CD20xCD3 bispecific antibody that induces T-cell–mediated killing of CD20–positive malignant B-cells.

Aims: To present updated data, including progression-free survival (PFS) from the dose escalation part of the first-in-human phase 1/2 study of epcoritamab in patients with relapsed or refractory (R/R) B-cell non-Hodgkin lymphoma (B-NHL; NCT03625037).

Methods: Adults with R/R CD20+ B-NHL received flat-dose 1 mL SC epcoritamab (step-up dosing approach) in 28-day cycles (q1w: cycles 1–2; q2w: cycles 3–6; q4w thereafter) until disease progression or unacceptable toxicity. Step-up dosing and standard prophylaxis were used to mitigate severity of cytokine release syndrome (CRS). Informed consent was obtained from all patients prior to trial enrollment.

Results: At data cut off (31 January 2021), 68 patients with B-NHL were enrolled across histologies including diffuse large B-cell lymphoma (DLBCL; n=46 [67.6%]; de novo and transformed), follicular lymphoma (FL; 12 [17.6%]), mantle cell lymphoma (MCL; 4 [5.9%]), and others (6 [8.8%]). The majority of patients were heavily pretreated (median [range] prior lines: DLBCL, 3 [1–6]; FL, 4.5 [1–18]); including prior CAR-T (n=6) and prior ASCT (n=10). At median follow-up of 14.1 months (DLBCL, 10.2 months; FL, 15.2 months), treatment was ongoing in 15 (22%) patients. The most common treatment-emergent adverse events (AEs) were pyrexia (69%), CRS (59%), and injection site reaction (47%). CRS events were all grade 1 or 2 and most occurred in cycle 1; neurotoxicity was limited (6%; grade 1: 3%; grade 3: 3%; all transient). One case of tumor lysis syndrome was observed (1.5%; grade 3); there were no cases of febrile neutropenia or treatment-related death. Overall response rates (ORRs) for patients with DLBCL at doses ≥12 mg (n=22) and ≥48 mg (n=11) were 68% (CR=46%; PR=23%) and 91% (CR=55%; PR=36%), respectively. The ORR for patients with FL at doses ≥12 mg (n=5) was 80% (CR=60%; PR=20%); the ORR for patients with MCL at doses ≥0.76 mg (n=4) was 50% (CR=25%; PR=25%). Responses deepened over time (PR converted to CR: DLBCL, 6 patients; FL, 3 patients). For patients with DLBCL, median (range) time to response was 1.4 (1.0–4.0) months; median (range) time to CR was 2.7 (1.1–3.9) months. For patients with FL, median (range) time to response was 1.9 (1.0–4.0) months. Among DLBCL patients achieving CR with doses ≥6 mg (n=11), none relapsed while on treatment. The median PFS for patients with DLBCL ≥12 mg (n=22) was 9.1 months (95% CI: 1.6, NE; median follow-up 9.3 months) and for patients with DLBCL ≥48 mg (n=11) median PFS was not reached (median follow-up 8.8 months) (Figure). Updated analyses will be presented.

Summary/Conclusion: With longer follow-up, SC epcoritamab demonstrated substantial single-agent activity, inducing deep and durable clinically meaningful responses, with a consistent safety profile. Notably no severe (grade ≥3) CRS events, no febrile neutropenia, and limited neurotoxicity was observed.

EP500 PIRTOBRUTINIB (LOXO-305), A NEXT GENERATION, HIGHLY SELECTIVE, NON-COVALENT BTK INHIBITOR IN PREVIOUSLY TREATED MCL, WM AND OTHER NHLS: RESULTS FROM THE PHASE 1/2 BRUIN STUDY

Background: Despite the marked efficacy of covalent BTK inhibitors (BTKi) in MCL, WM, and MZL, the development of resistance and discontinuation for adverse events can lead to treatment failure. Moreover, pharmacological liabilities of these agents such as low oral bioavailability or short half-life, can lead to suboptimal BTK target coverage and ultimately result in acquired resistance in some patients (pts). To address these limitations, pirtobrutinib (LOXO-305), a highly selective, non-covalent BTKi that inhibits both WT and C481-mutated BTK with equal low nM potency was developed.
Aims: To evaluate safety and efficacy of pirtobrutinib in previously treated MCL and other NHLs.
Methods: BRUIN is a multicenter phase 1/2 trial (NCT03740529) enrolling pts with advanced B-cell malignancies who have received ≥2 prior therapies. Oral pirtobrutinib was dose escalated in a standard 3+3 design in 28-day cycles. The primary endpoint was MTD/RP2D identification. Efficacy evaluable pts included all dosed pts who underwent their first response evaluation or discontinued therapy. Safety was assessed in all pts (n=323). Response was assessed according to Lugano Classification or iWWM.
Results: As of 27 September 2020, 323 pts with B-cell malignancies (170 CLL/SLL, 61 MCL, 26 WM, and 66 other B-cell lymphomas) were treated on 7 dose levels (25-300mg QD). Median age was 69 (range 50-87) years for MCL pts, 68 (42-84) for WM pts, and 68 (27-86) for other NHLs pts. Median number of prior lines of therapy was 3 (range, 1-8) for MCL, 3 (2-11) for WM, and 4 (2-10) for other NHLs. 93% of MCL, 70% of WM and 36% other NHL pts had received a prior BTKi. Pirtobrutinib demonstrated high oral exposures, with doses ≥100mg QD exceeding the BTK IC90 for the entirety of the dosing interval. No DLTs occurred. Consistent with pirtobrutinib's selectivity, the only treatment emergent adverse events regardless of attribution or grade in ≥10% of pts (n=323) were fatigue (20%), diarrhea (17%) and contusion (13%). Grade 3 atrial fibrillation/flutter was not observed; 1 pt had grade 3 hemorrhage in the setting of mechanical trauma. Responses were observed at the first dose level of 25mg QD. A RP2D of 200mg QD was selected. At the efficacy cutoff date, 35 (57%) MCL pts, 18 (69%) WM pts and 34 (52%) other NHL pts remained on therapy. Among the 52 efficacy evaluable prior BTKi treated MCL pts, the ORR was 52% with 13 CR, 14 PR and 9 SD. Median follow up was 6 months (range 0.7-18.3+) for MCL. Responses in MCL were observed in 9/14 pts (64%) with prior autologous or allogeneic transplant, and 2 of 2 with prior CAR-T cell therapy. Among the 19 efficacy-evaluable pts with WM, the ORR was 68% (9 PR, 4 MR, 3 SD), and 69% in prior BTKi treated pts. 10 of 13 WM responders were ongoing (follow-up time from initial response: 0.8-9.2 months). For the 55 efficacy-evaluable other NHL pts, best response was as follows: DLBCL - 24% ORR (4 CR, 2 PR, 2 SD, 12 PD, 5 NE), FL - 50% ORR (2 CR, 2 PR, 1 SD, 3 PD), MZL - 22% ORR (2 PR, 7 SD), Richter's transformation - 75% ORR (6 PR, 1 SD, 1 NE) and Other (2 B-PLL, 3 Low grade transformation) 1 SD, 2 PD, 2 NE.
Summary/Conclusion: Pirtobrutinib demonstrated promising efficacy in MCL pts following multiple prior lines of therapy, including a covalent BTKi. Pirtobrutinib also showed efficacy in previously treated other NHLs. Pirtobrutinib was well tolerated and exhibited a wide therapeutic index.

EP501 GLOFITAMAB STEP-UP DOSING (SUD): UPDATED EFFICACY DATA SHOW HIGH COMPLETE RESPONSE RATES IN HEAVILY PRETREATED RELAPSED/REFRACTORY (R/R) NON-HODGKIN LYMPHOMA (NHL) PATIENTS (PTS)

Background: Glofitamab (RG6026), a T-cell-engaging, bispecific, full-length antibody, allows bivalent binding to CD20 (B-cells), and monovalent binding to CD3 (T-cells). In NP30179 (NCT03075696), an ongoing multicenter, Phase I dose-escalation and expansion study, 0.6–25mg glofitamab fixed-dosing with obinutuzumab pretreatment (Gpt), showed high, durable complete responses and manageable safety in heavily pretreated R/R NHL (Dickinson, et al. EHA 2020). Glofitamab SUD, in addition to Gpt, allowed dose escalation up to 30mg to maximize efficacy, while mitigating cytokine release syndrome (CRS) (Hutchings, et al. J Clin Oncol 2021).
Aims: To present updated efficacy data from glofitamab monotherapy SUD cohorts.
Methods: Gpt (1000mg) was given to pts 7 days pre-glofitamab initial dose. Intravenous SUD of glofitamab was given on Day (D) 1 and 8 of Cycle (C) 1 and then at the target dose from C2D1 (2.5/10/16mg or 2.5/10/30mg); treatment continued for up to 12 cycles, every 21 days. Response rates were based on the Lugano criteria (Cheson, et al. J Clin Oncol 2014).
Results: Fifty-two pts received glofitamab SUD; 17 and 35 pts received 2.5/10/16mg and 2.5/10/30mg, respectively. Twenty-eight pts (53.8%) had aggressive NHL (aNHL) and 24 pts had indolent NHL (iNHL). Pts had a median age of 68 (44–85) years and received a median of 3 (1–12) prior lines of therapy. Forty (76.9%) and 38 (73.1%) pts were refractory to their most recent and any prior CD20 therapy, respectively.
After a median follow-up of 6.3 months, an updated efficacy analysis was conducted on December 1, 2020. For pts with aNHL (N=28), the best overall response (OR) and complete metabolic response (CMR) rates were 64.3% and 57.1%, respectively; a trend of improved response was observed with increased target dose, with a CMR rate of 71.4% at 2.5/10/30mg (N=14). Notably, 4/5 pts (80%) with mantle cell lymphoma (2.5/10/16mg, n=2; 2.5/10/30mg, n=2) had CMR. For aNHL, 13/16 CMRs are ongoing, with 8 CMRs lasting >3 months. For pts with iNHL (N=24), OR and CMR rates were 79.2% and 70.8%, respectively; 14/17 CMRs are ongoing, with 10 CMRs lasting >3 months.
As of August 3, 2020, common adverse events (52 pts) were CRS (63.5%), neutropenia (38.5%), and pyrexia (32.7%). CRS was mostly confined to C1: 24/50 pts had CRS after 2.5mg; 20/49 pts after 10mg; 2/16 and 8/32 pts had CRS after 16 and 30mg (C2D1), respectively. Grade [Gr] 1 and 2 CRS was reported in 18 (34.6%) and 12 (23%) pts, respectively; 3 pts had Gr 3 CRS; none had Gr 4/5 events (ASTCT 2019). Updated data, including biomarker data on baseline CD20 expression and CD8 levels in the tumor, will be presented.
Summary/Conclusion: Updated data for glofitamab monotherapy SUD show higher preliminary response rates than previously reported in pts with R/R NHL who have failed multiple lines of therapy. CRS was mostly manageable, of low grade, and confined to the first cycle of treatment.

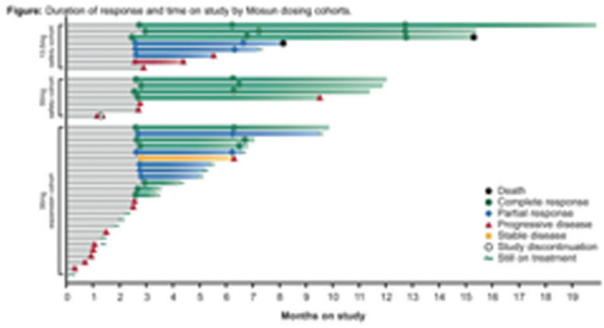
Background: Ibrutinib is a first-in-class, potent, orally-administered covalently-binding small molecule, an inhibitor of Bruton's tyrosine kinase (BTK). It was found to be effective in Diffuse large B cell lymphoma Lymphoma (DLBCL) specifically of the Activated (ABC) type. Ibrutinib, bendamustine, and rituximab (IBR) combination was found to be effective for the treatment of B cell lymphomas, including DLBCL in phase I clinical trial.
Aims: To explore the efficacy of the IBR regimen in relapse & refractory (RR) DLBCL.
Methods: We performed a phase II single-center trial. Patients (pts) with RR DLBCL and transformed low-grade lymphoma were eligible. Patients with CNS lymphoma, inadequate bone marrow function or previous exposure to bendamustine or ibrutinib were excluded. FDG/PET-CT's were interpreted according to the Lugano criteria. Rituximab and bendamustine were given in a 28 days cycle in their standard dose. Ibrutinib 560mg, was administered continuously from day 1. FDG/PET-CT was repeated afters cycles 3 and 6, and then every 16 weeks. Patients who achieved response after 3 cycles and were eligible were reffered to stem cell transplantation (SCT). For the time of this analysis, 62 pts were screened, and 56 were treated.
Results: Thiry pts (54%) were male. Median age was 69.7 years (28-94). Lymphoma subtype which was defined by the Hans criteria was as follows: GCB in 7 (12.5%), non GCB in 21 (37.5%), double/triple hit in 9 (16.1%), follicular grade 3B in 2 (3.6%), mediastinal in 3 (5.4%) transformed low grade in 4 (7.1%) and NA in 10 (17.9%). Thirty eight pts had refractory disease (67.9%). Thirty patiens (53%) had stage IV disease at screening. Sixteen pts received the therapy as second line and 40 as third line. Nine pts (16.1%) had previous autologous stem cell transplantation. ORR was 27.2% for the entire cohort and 36.1% for the pts that completed 3 cycles of therapy (n=36). Only 19% of the non-GCB pts responded to treatment. Thiry nine pts died during follow-up, 36 of them due to disease progression, the others due to stroke, myocardial infarction and allogeneic stem cell transplantation complications. Median follow-up was 7.9 months. Median OS of the entire cohort was 9.7 months (figure 1A). Refractoy pts had median OS of 7.3 months, while relapsed pts had 16.2 (figure 1B p=NS).Patients who achieved CR had median OS of 38.5 months while those who did not had 7.7 (p=0.057 figure 1C).Median PFS of the enitre chorot was 5 months and for the pts that completed at least 3 cycles of therapy 7 months. Patients that achieved response had significantly longer PFS than others (p<0.0001). Five pts underwent either autologous or allogeneic SCT after 3 cycles of treatment, all of them are alive and 4 in remission. Altogether 37 serious adverse event (SAE) were recorded in 20 pts (35.7%). Fifteen of them were related to ibrutinib, and the most common were infections.



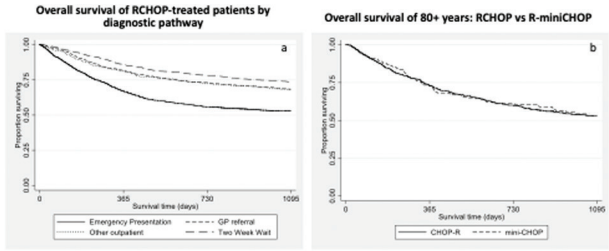
Summary/Conclusion: The IBR protocol is a conveniently administered ambulatory regimen. The regimen was found to be safe and effective in this cohort of elderly pts whose disease was mostly refractory to previous lines of treatment. Patients that achieved response had significantly better PFS and OS than those who did not. Response rate in the non-GCB group was not better than all other subtypes. Although the median OS of the entire cohort is short, pts who achieved remission and underwent SCT survived so far. We conclude that the IBR regimen should be considered for the treatment of R/R DLBCL pts and can also serve as a bridge to transplant.

EP503 MOSUNETUZUMAB (MOSUN) MONOTHERAPY FOR ELDERLY/UNFIT PATIENTS (PTS) WITH FIRST-LINE DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) CONTINUES TO SHOW PROMISING SAFETY AND EFFICACY WITH DURABLE COMPLETE RESPONSES

A. Olszewski [1,*], A. Avigdor [2,3], S. Babu [4], I. Levi [5], H. Eradat [6], U. Abadi [3,7], H. Holmes [8], M. McKinney [9], D. Woszczyk [10], K. Giannopoulos [11], W. Jurczak [12], R. McCord [13], Y. Xie [14], K. Sarouei [13], N. Qayum [15], C. O'Hear [13], G. Sellam [16], N. Horowitz [17]

Hoffmann-La Roche Ltd, Mississauga, Canada, [15]Roche Products Ltd, Welwyn Garden City, United Kingdom, [16]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [17]Ramban Healthcare Campus, Hifa, Israel

Background: Elderly/unfit pts with DLBCL who are ineligible for standard first-line (1L) chemoimmunotherapy (CIT) due to frailty and comorbidities often receive either no treatment, reduced-dose R-CHOP, or therapies such as R-CVP and R-bendamustine: outcomes are often poor (Shewade, et al. ASH 2020). Mosun, a full-length, humanized, IgG1 CD20xCD3 bispecific antibody, has promising efficacy and tolerable safety in relapsed/refractory DLBCL (ongoing Phase I study NCT02500407; Schuster, et al. ASH 2019). Preliminary data from the Phase I/II, multicenter GO40554 study (NCT03677154) show notable efficacy and tolerability with Mosun monotherapy for elderly/unfit pts with 1L DLBCL who cannot tolerate full-dose CIT (Olszewski, et al. ASH 2020).
Aims: To describe updated clinical data from the GO40554 study.
Methods: Two safety-evaluation cohorts were assessed (Mosun 13.5mg and 30mg), followed by an expansion phase (Mosun 30mg). Pts were aged ≥80 years, or 60–79 years with impairment in ≥1 activity of daily living (ADL) or instrumental ADL, or impaired cardiac, renal or liver function precluding full-dose CIT. Pts received optional pre-treatment with prednisone (+/- vincristine), followed by intravenous Mosun in step-up doses on Days (D) 1 (1mg), 8 (2mg) and 15 (full dose: 13.5/30mg) of Cycle (C) 1 and full (C1D15) dose Mosun on D1 of each subsequent 21-day cycle. Pts with a complete response (CR) stop Mosun after 8 cycles; pts with a partial response (PR) or stable disease can continue Mosun for a total of 17 cycles.
Results: As of January 15, 2021, 40 pts had received Mosun (13.5mg safety cohort, n=8; 30mg safety cohort, n=7; 30mg expansion, n=25). Median age was 84 (67–100) years, 27 (67.5%) pts were female, 27 (67.5%) had ECOG performance status 0–1, 20 (50%) had Ann Arbor Stage III–IV and 32 (80%) had an IPI score ≥2. Pts received a median of 6 (range: 1–13) Mosun cycles; 2 pts in PR continued Mosun after 8 cycles. Of 40 pts, 35 (87.5%) had ≥1 adverse event (AE), 27 (67.5%) had ≥1 Mosun-related AE; 15 (37.5%) pts had a grade (Gr) 3–4 AE, 8 of which were Mosun-related. The most common (>10%) treatment-emergent AEs were cytokine release syndrome (CRS; n=9, 22.5%), abdominal pain (n=7, 17.5%), rash (n=5, 12.5%) and neutropenia (n=5, 12.5%); one pt had febrile neutropenia. Six (15%) pts had Gr 1 CRS per ASTCT (Lee, et al. 2019). Three (7.5%) pts had Gr 2 CRS events, all were managed with supportive care and fluids for hypotension, steroids and low-flow oxygen, as required (no tocilizumab, vasopressors, high-flow oxygen or intensive care required). One pt with Gr 1 CRS had Mosun-related Gr 2 neurotoxicity on C1D2 (inability to answer questions, drowsiness and weakness), which resolved after 2 days. One pt had a Gr 2 non-serious headache. No fatal AEs or Gr ≥3 neurologic AEs were observed. Between C1–C8, 14 (35%) pts discontinued Mosun due to progressive disease (PD); no pts discontinued due to AEs. For efficacy-evaluable pts (n=31), the overall response rate was 67.7% and CR rate was 41.9%. Responses after C8 (n [%]) with Mosun 13.5mg (N=8) were: CR: 3 (37.5); PR: 3 (37.5); PD: 2 (25); and after C4 or C8 with Mosun 30mg (N=23) were: CR: 10 (43.5); PR: 5 (21.7); PD: 3 (13). Of 13 pts with CR (11 ongoing), 4 durable responses have been observed ≥12 months from the start of therapy (**Figure**). Biomarker analyses are ongoing and will be provided.



Summary/Conclusion: Mosun continues to show promising efficacy, including durable responses, and tolerable safety for elderly/unfit pts with 1L DLBCL and should be further evaluated as a chemotherapy-free backbone for pts unable to tolerate standard CIT.

EP504 DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) IN PATIENTS OLDER THAN 65 YEARS: ANALYSIS OF 3 YEAR REAL WORLD DATA OF PRACTICE PATTERNS AND OUTCOMES IN ENGLAND

L. Hounsome [1], T. Eyre [2,*], R. Ireland [3], A. Hodson [4], R. Walewska [5], K. Ardeshna [6], S. Chaganti [7], P. McKay [8], A. Davies [9], C. Fox [10], N. Kalakonda [11], P. Fields [12]

[1]Public Health England, London, [2]Haematology, Oxford University Hospitals NHS Foundation Trust, Oxford, [3]Haematology, Kings College London Hospitals, London, [4]Haematology, Ipswich Hospitals, Ipswich, [5]Haematology, University Hospitals Dorset, Bournemouth, [6]Haematology, UCLH, London, [7]Haematology, University Hospitals Birmingham, Birmingham, [8]Haematology, Beatson Cancer Centre, Glasgow, [9]Medical Oncology, Southampton General Hospital, Southampton, [10]Haematology, Nottingham University Hospitals NHS Trust, Nottingham, [11]Dept of Molecular and Clinical Cancer Medicine, University of Liverpool, Liverpool, [12]Haematology, Guys and St Thomas' Hospital, London, United Kingdom

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common non-Hodgkin lymphoma. In the UK, the NHS Cancer Plan in the year 2000 announced the NHS urgent cancer referral pathway - the 'Two Week Wait' diagnosis pathway is an initiative for the implementation of all suspected cancer patients (pts). This national pathway is designed to expedite urgent specialist referral (within 2 weeks) for pts whose signs or symptoms were suggestive of cancer, with the aspiration to enable early diagnosis and improve patient outcomes.
Aims: We wished to examine real-world practice, treatment and outcome patterns in older pts, with a focus on the effect of route to initial diagnosis to outcome. No prior published analyses have examined the effect of the diagnostic pathway on pt survival with aggressive lymphoma.
Methods: Data were extracted from Public Health England's National Cancer Registration and Analysis Service between 2013-2015 which included route to initial diagnosis, disease characteristics, socio-economic deprivation quintiles, and survival. The Systemic Anti-Cancer Therapy dataset identified front-line regimens, cycle number and doses. Overall survival (OS) was defined from DLBCL diagnosis until time of death from any cause and differences in OS were determined by log-rank tests. Lymphoma-specific survival (LSS) was defined from DLBCL diagnosis until the time of death from DLBCL, with censoring occurring at the cause of death for causes other than DLBCL. To account for the impact of multiple variables on survival, a cox-regression model was implemented using the 'stcox' command. Differences in proportions for descriptive statistics were tested with a 2-sided Z-test. Data were interrogated to explore potential associations between route to diagnosis and baseline characteristics with OS and LSS.
Results: A total of 9186 DLBCL pts ≥65 years across a 3-year period (2013-2015) were identified. Median follow-up of the whole cohort was 2.1 years. 68% were aged 65-79 years. Gender distribution was equal. 4536 presented with stage III-IV (61%). Routes to initial diagnosis were emergency (34%), NHS urgent cancer referral pathway (29%) and standard GP referral (25%). The most common regimen was R-CHOP (n=4392), administered to 80.5% of those with a known regimen. 313 pts received R-miniCHOP (7% of all R-CHOP). For all pts, 3-year OS for those 65-79 years was 57% (95% confidence interval (CI) 56%>58%) and for ≥80 years was 32% (95% CI 30%>33%). 3-year OS for R-CHOP-treated pts diagnosed via emergency presentation (n=1160) was 54% (reference 1.00, GP referrals (Fig A): fully-adjusted hazard ratio (HR) 1.63 (95% CI:1.43-1.86, p<0.01) and 75% (fully-adjusted HR 0.81 (95% CI:0.71-0.93, p<0.01) on the NHS urgent cancer referral pathway (n=1635). NHS urgent cancer referral pathway retained its association with an improved LSS (HR 0.71, 95% CI 0.53-0.95, p=0.02), whilst pts with an emergency presentation had a significantly worse LSS by MVA (HR 1.95, 95% CI 1.49-2.54, p<0.01). 3-year OS was equivalent (54%) for both R-miniCHOP and R-CHOP in those ≥80 years (Fig B).

Summary/Conclusion: Our large, comprehensive real world practice analysis are the first to show that the NHS urgent cancer referral pathway leads to superior lymphoma-specific and overall survival in R-CHOP treated DLBCL pts even after adjusting for multiple confounders. Equivalent survival for R-CHOP and R-mini-CHOP in those ≥80 years supports the use of the latter in this setting.

EP505 HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH CONDITIONING INCLUDING ALLOGENEIC BISPECIFIC CAR-T CELLS TARGETING BOTH CD19 AND CD22 FOR REFRACTORY/RELAPSED B-CELL NON-HODGKIN LYMPHOMA

F. Yang [1,*], R. Hou [1], Y. Feng [1], S. Feng [2], Y. Geng [1], H. Shi [1], H. Liu [2], R. Li [1], T. Wu [1], K. Hu [2]

[1]Department of Bone Marrow Transplantation, [2]Department of Adult Lymphoma, Beijing Boren Hospital, Beijing, China

Background: The prognosis of refractory/relapsed aggressive B-cell non-Hodgkin lymphoma (r/r B-NHL) is extremely poor, especially for the patients who failed to autologous chimeric antigen receptor-T (CAR-T) cells.
Aims: For r/r B-NHL, a clinical trial using haploidentical hematopoietic stem cell transplantation (Haplo-HSCT) with conditioning including allogeneic bispecific CAR-T cells targeting both CD19 and CD22 from the same donor (allo-CD19/CD22 CAR-T) has been registered, and the safety and efficacy will be evaluated.
Methods: From September 2020 to January 2021, 7 patients with r/r B-NHL were enrolled. The median age was 43 (26-54) years old. The diagnosis included diffuse large B-cell lymphoma (DLBCL, n=6) and Burkitt lymphoma (n=1). Four cases were with TP53 mutations. All patients failed to multi-line therapies, including chemotherapy (n=7), autologous HSCT (n=1), autologous CAR-T (n=6), local irradiation (n=4) and anti-PD1 antibodies (n=2). The disease status before transplant was stable disease (SD) in 1 case, partial remission (PR) in 3 and progressive disease (PD) in 3. Before the trial, the expression of CD19 and/or CD22 antigen in tumor tissue of all patients was positive confirmed by pathology. Conditioning with busulfan, fludarabine-based regimen combined with allo-CD19/CD22 CAR-T was applied. Tacrolimus, mycophenolate mofetil, a short-term methotrexate and antithymocyte globulin were used for graft-versus-host disease (GVHD) prophylaxis. The kinetics and function of CAR-T cells was monitored by quantitative PCR and flow cytometry. The efficacy was evaluated by PET-CT at 60 days after CAR-T infusion.
Results: The median CAR-T cells infused were 3.6 (1.87-4.0)×10^6/kg. Cytokine release syndrome (CRS) occurred in all cases with 2 cases in grade I, 2 cases in grade II and 3 cases in grade III. No immune effector cell-associated neurotoxicity syndrome (ICANS) was noted. Three cases with grade III CRS were relieved with methylprednisolone. Granulocyte colony-stimulating factor–mobilized peripheral blood stem cells were infused 7 days after CAR-T with the median $CD34^+$ cells 6 (3-8.19)×10^6/kg. The neutrophil engraftment was achieved in all cases on median days 16 (11-24) post-transplant. Platelets were engrafted in 4 cases on median days 19 (16-65). No acute GVHD (aGVHD) was seen. CMV viremia occurred in 3 cases. Three patients developed grade I BKV hemorrhagic

cystitis. The highest proportion of CAR-T cells in vivo was 90.2 (0.096-502) % on median 7 (6-71) days after CAR-T cell infusion. CAR-T cells were detected persistently in vivo in 6/7 (85.7%) patients and the longest lasting time was 140 days post-transplant so far. B-cell aplasia was documented in all cases during the follow-up. With the median follow-up 62 (30-153) days, all patients survived. Four cases have been evaluated by PET-CT, one case with DLBCL achieved PR first and then progression, one case obtained PR, and two cases achieved complete remission. For the other 3 cases short than 60 days after CAR-T therapy, the tumor sizes have shrinked significantly measured by B ultrasound.

Summary/Conclusion: CRS is manageable and has no influence on hematopoiesis reconstitution. CAR-T cells still exist persistently post-transplant in majority of patients, which may contribute a long-term anti-lymphoma effect. With current protocol, no aGVHD was observed, viral reactivation was mild and encouraging disease control was found. Haplo-HSCT with conditioning including allo-CD19/CD22 CAR-T cells is a safe and effective strategy for r/r B-NHL. Long-term follow-up is needed.

EP506 ECHELON-2, (NCT01777152), 5-YEAR RESULTS OF A RANDOMISED, DOUBLE-BLIND, PHASE 3 STUDY OF FRONTLINE BRENTUXIMAB VEDOTIN + CHP VS CHOP IN PATIENTS WITH CD30-POSITIVE PERIPHERAL T-CELL LYMPHOMA

Background: ECHELON-2 (NCT01777152), a phase 3, randomised, double-blind, double-dummy, placebo-controlled, active-comparator, multicentre study, established the superiority of frontline brentuximab vedotin + cyclophosphamide, doxorubicin, and prednisone (A+CHP) vs cyclophosphamide, doxorubicin, vincristine, and prednisone (CHOP) for the treatment of patients (pts) with systemic anaplastic large cell lymphoma (sALCL) or other CD30-expressing peripheral T-cell lymphomas (PTCLs) (Horwitz, Lancet 2019). Both risk of progression-free survival (PFS) per blinded independent central review (primary endpoint) and overall survival (OS) events favoured A+CHP over CHOP at the primary analysis. A+CHP was the first treatment regimen to increase OS compared with CHOP in this population.

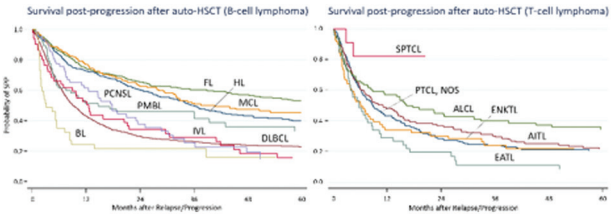
Aims: We report the 5-year data from ECHELON-2, including PFS per investigator (INV) data and the following key secondary endpoints: OS, PFS in sALCL, complete remission (CR) rate, and objective response rate (ORR) in re-treated pts.

Methods: Adults with untreated CD30-positive PTCL (targeting 75% ± 5% with sALCL) were randomized 1:1 to receive 6–8 cycles of A+CHP or CHOP. Pts were stratified by histological subtype and international prognostic index (IPI) score. Brentuximab vedotin-based subsequent therapies were allowed.

Results: Of 452 pts enrolled, the majority had sALCL (n=316 [70%]; 218 [48%] anaplastic lymphoma kinase [ALK]-negative, and 98 pts [22%] ALK-positive) and had advanced disease (27% Stage III, 53% Stage IV; 78% IPI ≥2). At data cutoff, median follow-up was 47.6 months for PFS and 66.8 months for OS. A+CHP was favoured over CHOP with a hazard ratio (HR) for PFS per INV of 0.70 (95% confidence interval [CI]: 0.53, 0.91; p=0.0077) and OS HR of 0.72 (95% CI: 0.53, 0.99; p=0.0424). Median PFS was 62.3 months (95% CI: 42.0, not evaluable) for A+CHP, and 23.8 months (95% CI: 13.6, 60.8) for CHOP. Estimated 5-year PFS was 51.4% (95% CI: 42.8, 59.4) and 43.0% (95% CI: 35.8, 50.0) with A+CHP and CHOP, respectively. Median OS was not reached in either arm. Estimated 5-year OS was 70.1% (95% CI: 63.3, 75.9) for A+CHP vs 61.0% (95% CI: 54.0, 67.3) for CHOP. PFS in prespecified subgroups and overall PFS were generally consistent (Figure). The HR for PFS (0.55 [95% CI: 0.39, 0.79]) also favoured A+CHP over CHOP in pts with sALCL, with an estimated 5-year PFS of 60.6% (95% CI: 49.5, 69.9) for the A+CHP arm vs 48.4% (95% CI: 39.6, 56.7) for the CHOP arm. Subsequent systemic therapy with brentuximab vedotin was administered to a total of 29 pts (13%) in the A+CHP arm (sALCL [n=19]; PTCL not otherwise specified [n=5], angioimmunoblastic T-cell lymphoma [n=5]) and 54 pts (24%) in the CHOP arm. Median time to retreatment for pts in the A+CHP arm was 15.0 months (range, 3–64); 17 pts (ORR: 59%) had CR (n=11) or partial remission (n=6) after retreatment with brentuximab vedotin monotherapy (n=25) or a brentuximab vedotin-containing regimen (n=4). Of the treatment-emergent peripheral neuropathy (PN) in the A+CHP (n=117) and CHOP arms (n=124), 72% in the A+CHP arm and 78% in the CHOP arm had resolved or improved. In pts with ongoing events at last follow-up (A+CHP [n=47] vs CHOP [n=42]) PN was grade 1, 2 and 3 in 70% vs 71%, 28% vs 26% and 2% vs 2%, respectively.

Prespecified subset analyses: PFS

Summary/Conclusion: After 5 years' follow-up, frontline A+CHP continued to provide clinically meaningful improvements in PFS and OS vs CHOP, including sustained remission in 59% of re-treated pts with sALCL, as well as a manageable safety profile, including continued resolution or improvement of PN.



EP507 RELAPSE AND SURVIVAL POST-PROGRESSION IN LYMPHOMA PATIENTS AFTER STEM CELL TRANSPLANTATION

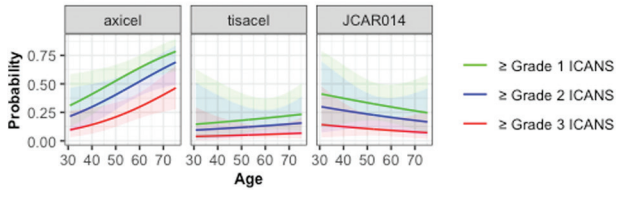
Cell Transplantation, National Cancer Center Hospital, [4]Hematology, Federation of National Public Service Personnel Mutual Aid Associations Toranomon Hospital, Tokyo, [5]Hematology, Kitakyushu City Hospital Organization, Kitakyushu Municipal Medical Center, Kitakyushu, [6]Hematology, Department of Medicine, Keio University School of Medicine, Tokyo, [7]Hematology and Oncology, Anjo Kosei Hospital, Anjo, [8]Hematology, Kobe City Medical Center General Hospital, Kobe, [9]Medicine and Biosystemic Science, Kyushu University Graduate School of Medicine, Fukuoka, [10]Hematology, Japanese Red Cross Kyoto Daiichi Hospital, Kyoto, [11]Hematology/Oncology, Tokai University School of Medicine, Isehara, [12]Hematology and Oncology, Research Institute for Radiation Biology and Medicine, Hiroshima University, Hiroshima, [13]Japanese Data Center for Hematopoietic Cell Transplantation, Nagoya, [14]Hematology, Kawasaki Medical School, Okayama, Japan

Background: The prognosis of patients who relapsed after hematopoietic stem cell transplantation (HSCT) is generally poor. However, the survival post-progression (SPP) after HSCT in lymphoma patients has not been well evaluated.
Aims: The aim of this study is to evaluate and identify the prognostic factors for SPP.
Methods: Using the Japanese transplant registry, adult patients (> 15 years old) who underwent their first autologous (auto-HSCT) or allogeneic HSCT (allo-HSCT) for lymphoma in 1980–2018 were analyzed. SPP was defined as the time from progression or relapse after HSCT to death. To identify the prognostic factors for SPP, univariate and multivariate analyses were conducted. This study was approved by the Japan Society for Hematopoietic Cell Transplantation Ethical Committee.
Results: A total of 15,097 transplant cases, including 10,973 and 4,124 after auto-HSCT and allo-HSCT, respectively, were analyzed. In patients who underwent auto-HSCT, the major primary disease included diffuse large B-cell lymphoma (DLBCL) in 5,803 patients, Hodgkin lymphoma (HL) in 1,261, follicular lymphoma (FL) in 1,139, mantle cell lymphoma (MCL) in 659. In patients who underwent allo-HSCT, the primary disease included DLBCL in 1,201 patients, FL in 894, peripheral T-cell lymphoma, not otherwise specified (PTCL-NOS) in 448, extranodal NK/T-cell lymphoma (ENKTL) in 334. Enteropathy associated T-cell lymphoma (EATL) patients had the highest relapse rate among patients after auto- and allo-HSCT (62% and 75%, respectively). Among patients after auto-HSCT, the median SPP was poor in patients with BL (3.1 months) and EATL (5.8 months). In contrast, the 2-year SPP was more than 60% in patients with HL, FL, MCL, and subcutaneous panniculitis like-T-cell lymphoma (SPTCL). In the univariate and multivariate analyses, patients' age, disease status at HSCT, HSCT year, time from HSCT to relapse or progression, subsequent HSCT, and lymphoma subtype were identified as risk factors. Chemo-resistant or relapsed disease was a risk factor for worse SPP [hazard ratio (HR) 1.5 (95% confidence interval (CI) 1.3-1.6), vs complete response (CR)]. Early relapse or progression [within 3 months (HR 3.0, 95% CI 2.7-3.3) and 6 months (HR 1.7, 95% CI 1.5-1.9) vs more than 1 year] was also significant prognostic factor. All lymphoma subtypes, except for MCL and SPTCL, were significantly associated with worse SPP compared with FL. Subsequent HSCT was associated with better SPP (HR 0.8, 95% CI 0.7-0.9). In the subgroup analyses by lymphoma subtypes, subsequent HSCT improved SPP in patients with HL, DLBCL, and most T-cell lymphomas. Among patients after allo-HSCT, the median SPP was shortest in patients with Burkitt lymphoma (BL) and aggressive NK-cell leukemia (ANKL) (both, 1.9 months), whereas it was longest in HL patients (13.6 months). In the univariate and multivariate analyses, age, disease status, time from HSCT to relapse or progression, and lymphoma subtype were identified as risk factors. Chemo-resistant disease was a prognostic factor for SPP (HR 2.0, 95%CI, 1.6-2.4). Majority of lymphoma subtypes, except for several subtypes including FL, MCL and ENTKL, were significantly associated with worse SPP compared with HL. The strongest association with poor SPP was observed in BL (HR 2.4, 95%CI 1.7-3.5) and ANKL (HR 3.3, 95%CI 2.1-5.1).

Summary/Conclusion: The lymphoma subtype, as well as age and disease status, were identified as risk factors. Subsequent HSCT after auto-HSCT play an important role in improving SPP in several lymphoma subtypes. For patients with poor SPP, an improvement of subsequent treatment strategy is warranted.



EP508 CRS AND ICANS RISK ACROSS THREE CD19 CAR-T CELL PRODUCTS IN PATIENTS WITH AGGRESSIVE NHL

J. Gauthier [1,2,3,*], N. Gazeau [1], A. Cearley [1,3], P. Perkins [1,3], A. Kirk [1], M. Shadman [1,2,3], S. Williamson [4], J. Myers [4], A. Chen [4], S. Nagle [4], B. Hayes-Lattin [4], L. Schachter [4], D. Maloney [1,2,3], C. Turtle [1,2,3], M. Sorror [1,2,3], R. Maziarz [4]

[1]Fred Hutchinson Cancer Research Center, [2]University of Washington, [3]Seattle Cancer Care Alliance, Seattle, [4]Oregon Health and Science University, Portland, United States

Background: CD19-targeted chimeric antigen receptor-engineered (CD19 CAR) T cells can achieve high response rates in patients (pts) with relapsed or refractory (R/R) aggressive B-cell non-Hodgkin lymphoma (NHL). Despite its promising efficacy, CD19 CAR T-cell therapy remains limited by two significant toxicities: cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Varying incidence and severity of CRS and ICANS have been reported across distinct CD19 CAR T-cell products, but these observations could have been confounded by differences in pt and disease characteristics.
Aims: To estimate the independent effect of 3 CD19 CAR T-cell products (axicabtagene ciloleucel[axicel], tisagenlecleucel [tisacel], and JCAR014) on CRS and ICANS severity in pts with R/R aggressive NHL.
Methods: We retrospectively analyzed 136 aggressive NHL pts treated with cyclophosphamide and fludarabine lymphodepletion (LD) followed by CD19 CAR T-cell therapy. Axicel and tisacel pts were treated off trial using commercial products. JCAR014 (defined-composition 4-1BB-costimulated CD19 CAR T cells) was administered in all pts at the dose of $2x10^6$/kg on a phase I/II clinical trial (NCT01865617). CRS and ICANS were graded according to the ASTCT criteria and CTCAE 4.03, respectively. We used multivariable proportional odds logistic regression to model CRS and ICANS grade. We used propensity score estimation to reduce confounding based on age, hematopoietic cell transplantation comorbidity (HCT-CI), preLD LDH, preLD albumin, lymphoma type.
Results: Lymphoma type was diffuse large B cell lymphoma non-otherwise specified in 74%, large B cell lymphoma transformed from indolent histologies in 15%, and other aggressive lymphoma types in 11% of pts. Pts received axicel, tisacel, or JCAR014 in 50%, 28%, and 22% of cases, respectively. Compared to axicel pts, we observed higher preLD LDH levels in tisacel and JCAR014 pts, and lower preLD albumin with tisacel ($p < 0.001$) with comparable age and HCT-CI across CAR T-cell products. Higher day-28 overall response rates by Lugano criteria were observed after axicel (71%) compared to tisacel (56%) and JCAR014 (53%).
Adjusting for age, HCT-CI, preLD LDH, preLD albumin, CAR T-cell product type remained associated with CRS severity (tisacel versus [vs] axicel, OR = 0.45, p = 0.05; JCAR014 vs axicel, OR = 0.29, p = 0.005;). Age had limited or no impact on CRS severity (OR 95%CI, 0.97-1.02), while the effect of HCT-CI was undetermined (OR 95%CI, 0.85-1.27).
In a multivariable model including the same covariates as above, CAR T-cell product type (tisacel vs axicel, OR = .14, p < .001; JCAR014 vs axicel, OR = 0.31, p = 0.009), preLD LDH (OR = 3.96 per log10 increase; p = 0.04) and age (OR =1.32 per 10-year increase; p = .06) were associated with ICANS severity. Interaction effect testing suggested effect modification of age by the CAR T-cell product type (tisacel/JCAR014 versus axicel, p = 0.06). Predictions of ICANS severity according to age and the CAR T-cell product type are shown in the Figure.
The independent impact of CAR T-cell product type on CRS and ICANS severity was confirmed after propensity score adjustment.

Figure

Summary/Conclusion: CAR T-cell product type was independently associated with CRS and ICANS severity in NHL pts. We observed higher ICANS severity in older patients treated with axicel; in contrast, age had limited impact on ICANS severity in those receiving tisacel or JCAR014. While further analyses comparing efficacy are warranted, our findings provide insights to guide CAR T-cell product selection in older patients.

EP509 EFFICACY AND SAFETY OF MOGAMULIZUMAB BY PATIENT BLOOD CLASSIFICATION

J. Scarisbrick [1,*], P. L. Zinzani [2], R. Cowan [3], J. P. Nicolay [4], D. Caballero [5], L. Sokol [6], L. Pinter-Brown [7], J.-P. Rosen [8]

[1]University Hospital Birmingham, Birmingham, United Kingdom, [2]Institute of Hematology "Seràgnoli", University of Bologna, Bologna, Italy, [3]Christie Hospital and University of Manchester, Manchester, United Kingdom, [4]University Medical Centre Mannheim, Mannheim, Germany, [5]Hospital Universitario de Salamanca, Salamanca, Spain, [6]Division of Medical Oncology, Moffitt Cancer Center, Tampa, [7]University of California-Irvine Chao Family Comprehensive Cancer Center, Orange, United States, [8]Kyowa Kirin International, Buckinghamshire, United Kingdom

Background: Cutaneous T-cell lymphomas (CTCL) are rare, serious and potentially life-threatening forms of non-Hodgkin lymphoma that primarily present in skin. Mycosis fungoides (MF) and Sézary syndrome (SS) are the classic subtypes and together account for around two-thirds of all CTCLs. Initial methods of disease staging in MF and SS built upon the tumour-node-metastasis (TNM) classification using disease-specific findings. Blood classification (B0–2) was added to staging in 2007 based upon the recognition of blood involvement as a prognostic factor; increasing blood tumour burden has previously been linked with worsening of overall survival (OS) and disease-specific survival (DSS), and an increased risk of disease progression (RDP) (Agar 2010, Am Soc J Clin Oncol), although this is a subject of debate and further study. Patients with B1 disease have previously been shown to have a median survival of just 3.2 years, similar to B2 for which it was 3.1 years (Agar 2010, Am Soc J Clin Oncol). The addition of blood classification allows for more specific disease staging which may inform clinical management strategy, whilst also contributing to a better understanding of prognostic factors and treatment response in MF and SS.
Aims: This post hoc analysis examined the efficacy and safety of mogamulizumab (MOGA) compared with vorinostat (VORI), stratified by patient blood classification.
Methods: MAVORIC (NCT01728805) was an open-label, phase 3 study where patients were randomized 1:1 to receive either intravenous MOGA 1.0 mg/kg weekly for the first 28 day cycle, then on days 1 and 15 of subsequent cycles, or oral VORI 400 mg once daily. VORI patients who experienced disease progression or intolerable toxicity could cross over to MOGA. The primary endpoint was investigator-assessed progression-free survival (PFS).
Results: In MAVORIC, investigator-assessed PFS was significantly greater for MOGA than VORI overall at 7.7 months and 3.1 months, respectively ($P<0.0001$). When data were stratified by blood classification, PFS was found to be significantly superior for MOGA as compared to VORI in patients with both B1 and B2 disease (**Table 1**). Overall response rate (ORR) was also significantly greater for MOGA than VORI in MAVORIC at 28.0% and 4.8% respectively ($P<0.0001$), and was found in this analysis to be significantly greater for MOGA than VORI in those patients with B2 disease (**Table 1**). ORR for B1 was not significant, but showed a trend (25.8% vs 6.5% for MOGA and VORI, respectively). Time-to-next-treatment (TTNT) was not significant for patients without blood involvement (B0), but was significantly greater for MOGA in patients with blood involvement (B1 or B2) with 13.70 and 3.30 months for MOGA and VORI respectively ($P<0.0001$) (**Table 1**). Drug-related treatment-emergent adverse events (TEAEs) were similar in patients regardless of blood involvement and were lower for MOGA than VORI at each blood classification level (**Table 1**).

Table 1. Investigator-assessed PFS, ORR and TTNT in the intent-to-treat set, and TEAEs by blood classification in safety analysis set

	VORI (N=186)	MOGA (N=186)	
PFS, median months (n)			***P*-value**
B0	4.37 (62)	4.7 (64)	0.9480
95% CI	2.87–6.80	2.90–5.97	
HR (95% CI)	1.05 (0.67–1.65)		
B1	2.53 (31)	8.63 (31)	**0.0142**
95% CI	1.40–3.07	3.97–15.03	
HR (95% CI)	0.32 (0.16–0.64)		
B2	3.30 (93)	11.17 (91)	**<0.0001**
95% CI	2.83–4.70	7.63–17.07	
HR (95% CI)	0.36 (0.24–0.53)		
ORR, % (n)			
B0	6.5 (62)	15.6 (64)	0.0549

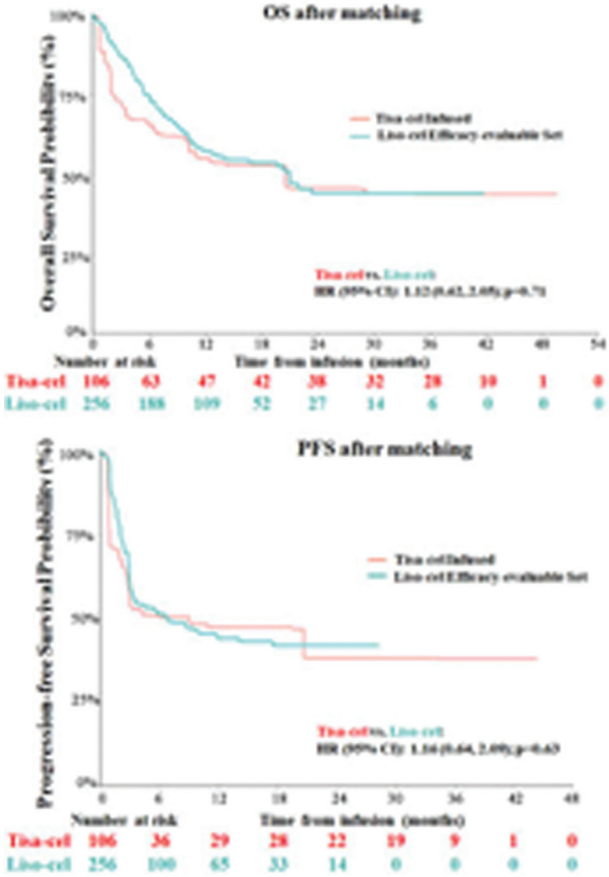
Risk diff (95% CI)	19.4 (0.6–38.6)		
B2	3.2 (93)	37.4 (91)	**<0.0001**
95% CI	0.7–9.1	27.4–48.1	
Risk diff (95% CI)	34.1 (22.9–45.2)		
TTNT, median months (n)			
B0	4.13 (50)	6.77 (46)	0.0928
95% CI	3.00–5.60	4.87–8.80	
HR (95% CI)	0.68 (0.46–1.02)		
B1 and B2	3.30 (105)	13.07 (70)	**<0.0001**
95% CI	2.83–4.00	11.00–16.73	
HR (95% CI)	0.32 (0.23–0.44)		
Drug-related TEAEs (any grade), n (%)			
B0	58 (93.5)	51 (79.7)	
B1	30 (96.8)	25 (80.6)	
B2	90 (96.8)	80 (87.9)	
Drug-related TEAEs (≥Grade 3), n (%)			
B0	18 (29.0)	11 (17.2)	
B1	14 (45.2)	8 (25.8)	
B2	33 (35.5)	28 (30.8)	

MOGA, mogamulizumab; TEAE, treatment-emergent adverse event; VORI, vorinostat.
B0 = <15% CD4+CD26- or CD4+CD7- cells by flow cytometry.
B1 = ≥15% CD4+CD26- or CD4+CD7- cells by flow cytometry (not B2).
B2 = ≥1000/μL Sézary cells with positive clone, CD4:CD8 ≥ 10, CD4+CD7- cells ≥40%, or CD4+CD26- cells ≥ 30%.

Summary/Conclusion: MOGA is effective in patients with blood involvement (B1 and B2), including patients with MF. Drug safety is similar between patients irrespective of level of blood involvement.

EP510 COMPARATIVE EFFICACY OF TISAGENLECLEUCEL (TISA-CEL) AND LISOCABTAGENE MARALEUCEL (LISO-CEL) IN PATIENTS WITH RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA (R/R DLBCL)



M. J. Kersten [1,*], J. Zhang [2], H. Yang [3], A. Agarwal [2], W. Tang [3], M. Martinez-Prieto [2], V. Bollu [2], D. Kuzan [2], S. Schuster [4], R. Maziarz [5]

[1]Academic Medical Center, Amsterdam, Netherlands, [2]Novartis Pharmaceuticals Corporation, East Hanover, [3]Analysis Group, Inc., Boston, [4]Abramson Cancer Center of the University of Pennsylvania, Pennsylvania, [5]Knight Cancer Institute, Oregon Health and Science University, Portland, United States

Background: The efficacy of chimeric antigen receptor T-cell therapies tisacel and liso-cel as effective treatments for r/r DLBCL was demonstrated in JULIET and TRANSCEND (Schuster 2019, Abramson 2020), respectively.
Aims: To compare efficacy outcomes of tisa-cel and liso-cel in r/r DLBCL using matching-adjusted indirect comparison (MAIC).
Methods: Individual patient-level data (IPD) from JULIET (tisa-cel; NCT02445248; 02/2020 datacut) were weighted to match the patient population in TRANSCEND (liso-cel; NCT02631044; 08/2019 datacut). Baseline prognostic factors available in both trials were adjusted for age, sex, histology, ECOG performance status (ECOG PS), left ventricular ejection fraction, radiologic sum of product diameters, lactate dehydrogenase, prior stem cell transplantation (SCT), use of bridging therapy, and number of and refractoriness to prior therapies in the MAIC. Overall survival (OS), progression-free survival (PFS), complete response (CR) rate, and overall response (OR) rate were compared. Primary analyses

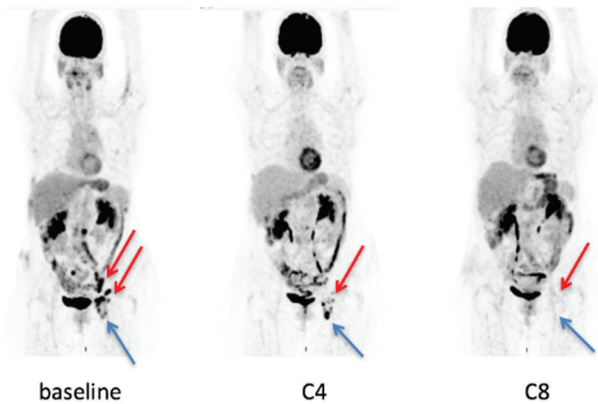
compared infused patients in JULIET (N=106, excluding 8 without lymphodepleting chemotherapy [LDC] and 1 large cell neuroendocrine carcinoma) with the efficacy-evaluable set in TRANSCEND (N=256, infused patients). A scenario analysis compared JULIET infused to the TRANSCEND primary analysis set (PAS) (N=133, dose level 2, excluding those with ECOG PS 2, prior allogeneic SCT, primary mediastinal B-cell lymphoma, follicular lymphoma [FL] 3B, or transformation from indolent lymphoma besides FL). Sensitivity analyses included JULIET patients with only fludarabine-based LDC or only adjusted significantly different baseline prognostic factors. Safety outcomes were not compared because adverse event management has evolved and differed between the two trials; MAIC is unable to adjust for such differences.

Results: After adjusting for differences in baseline characteristics, no significant differences were observed in OS (hazard ratio [95% confidence interval (CI)]: 1.12 [0.62, 2.05], p=0.71) or PFS (1.16 [0.64, 2.09], p=0.63) between tisa-cel infused patients and the liso-cel efficacy-evaluable set (Figure). CR was also comparable (rate difference [95% CI]: -5.4% [-15.5%, 4.7%], p=0.29). The results comparing OS, PFS, and CR were consistent across all scenario and sensitivity analyses. The OR rate trended higher in the TRANSCEND efficacy-evaluable set (-9.7% [-20.0%, 0.6%], p=0.07) and was higher in the TRANSCEND PAS than in the respectively matched JULIET infused set (-13.5% [-25.6%, -1.5%], p<0.05).

Summary/Conclusion: The MAIC results indicate there is no evidence suggesting differences in OS, PFS, and CR between tisa-cel and liso-cel in r/r DLBCL. Analyses using IPD from both trials and/or real-world evidence are warranted to confirm these findings.

EP511 PROSPECTIVE EVALUATION OF LYMPHOMA RESPONSE TO IMMUNOMODULATORY THERAPY CRITERIA (LYRIC) IN GATA TRIAL FROM THE LYSA GROUP

Y. Al Tabaa [1,*], O. Casasnovas [2], C. Baillet [3], E. Bachy [4], E. Nicolas Virelizier [4], J. M. Schiano de Colella [5], C. Bailly [6], S. Kanoun [7], S. Guidez [8], E. Gyan [9], R. Gressin [10], N. Morineau [11], L. Ysebaert [12], S. Le Gouill [13], H. Tilly [14], R. Houot [15], F. Morschhauser [16], G. Cartron [17], C. Herbaux [18]



[1]Nuclear Medicine, Montpellier, [2]Hematology, Dijon, [3]Nuclear Medecine, Lille, [4]Hematology, Lyon, [5]IPC Hematology, Marseille, [6]NUcleaar Medecine, Nantes, [7]Nuclear Medecine, Toulouse, [8]Hematology, Poitiers, [9]Hematology, Tours, [10]Hematology, Grenoble, [11]Hematology, Vendée, [12]Hematology, Toulouse, [13]Hematology, Nantes, [14]Hematology, Rouen, [15]Hematology, Rennes, [16]Hematology, Lille, [17]Hematology, [18]CHU de Montpellier Hématologie clinique, Montpellier, France

Background: Checkpoint blockade may complicate response assessment by the development of a flare reaction or pseudoprogression (PP). To avoid the mistake of considering a new agent ineffective, it was proposed to add the category called "indeterminate response" (IR) to Lugano classification, in the LYmphoma Response to Immunomodulatory Therapy Criteria (LYRIC): 1/ increase in overall tumor burden in the first 12 weeks of therapy, without clinical deterioration (IR1), 2/ development of new lesions without overall progression (IR2), or 3/ increased F-fluorodeoxyglucose avidity despite no change in lesion size (IR3). These 3 patterns are defined as progressive metabolic disease (PMD) in the Lugano criteria. A PP was defined as an IR that became a partial or complete metabolic response (PMR or CMR) in comparison to baseline, at next evaluation.

Aims: The aim of this study is to assess in a practical and prospective manner the LYRIC criteria in relapsed/refractory diffuse large B cell lymphomas (DLBCL) and follicular lymphomas (FL) treated with atezolizumab, venetoclax and obinutuzumab (GATA trial), as well as measuring the incidence of PP.

Methods: The GATA study is a LYSA sponsored multicenter phase 2 trial (NCT03276468) evaluating the combination of atezolizumab, obinutuzumab and venetoclax in biopsy-confirmed R/R DLBCL and FL patients who failed at least one line of therapy (rituximab and anthracycline containing regimen). Local imaging practitioners were invited to use the LYRIC classification. Clinical investigators were warned of the possibility of PP, and a coordinating investigator's approval was required before stopping treatment. A centralized imaging review on Positron Emission Tomography (PET) and Computed Tomography (CT) scan was performed at three time points: baseline, cycle 4 (C4, 12 weeks) and cycle 8 (C8, 24 weeks), on Lugano and LYRIC criteria.

Results: Our study has included 116 patients (58 DLBCL and 58 FL) from GATA trial. With a median follow-up of 9 months the overall metabolic response rate (OMRR) at C8 was measured at 23.6% for DLBCL patients. With a median follow-up of 14.5 months the OMRR at C8 was measured at 53.6% for FL patients. Ninety-five patients had a centralized review at C4 and 57 at C8. Missing patients are those who progressed prior to the restaging by PET and CT scan. *Lugano criteria*: At C4, 84 reviewed responses (88.4%) were concordant with local response. At C8, 47 reviewed responses (82.5%) were concordant with local response. The differences were mainly between NMR (no MR) and PMR. *LYRIC criteria:* At C4, 9 PMD were classified as IR by both local reading and centralized review, 4 DLBCL and 5 FL. A discordance in the type of IR (1, 2 or 3) was seen in 6 out of 9 cases. During the follow-up, 4 cases turned out to be PP (1 DLBCL and 3 FL) and 5 cases real PD. One of the PP is illustrated on Figure 1, with IR3 at C4 (both locally and centrally), and CMR at C8. At C8, 7 PMD were classified as IR by centralized review (IR2 and IR3), only 2 of them were IR by local reading. During the follow-up, all of those cases turned-out to be real progressive diseases within 1 to 3 cycles of therapy.

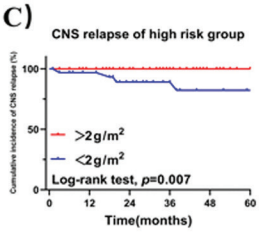
Summary/Conclusion: We did observe 3.4% of PP, all classified as IR at C4. A high frequency of discrepancy between local and centralized

reading was observed with LYRIC criteria, probably due to the novelty of this classification. Interestingly, all IRs at C8 were found to be real progressions. Overall, these data are in favor of using the LYRIC classification, but only for early evaluation.

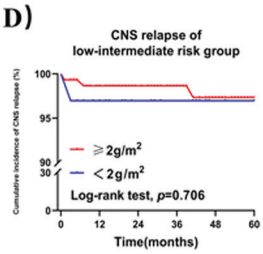
EP512 INTRAVENOUS HIGH DOSE METHOTREXATE FOR PREVENTION OF CNS RELAPSE IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): REAL-WORLD OUTCOMES AND PRACTICE PATTERNS FROM CHINESE INSTITUTION

Q. Cai [1,2,*], Y. Fang [1,2], N. Su [1,2], J. Wang [1,2], X. Tian [1,2], S. Ma [1,2], J. Cai [1,2], Y. Zhang [1,2], H. Huang [1,2], Z. Li [1,2], H. Huang [1,2], Y. Xia [1,2], P. Liu [1,2]

[1]Department of Medical Oncology, [2]State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China



Background: Central nervous system (CNS) relapse occurs in 2-10% of DLBCL patients but carries a poor prognosis. Prophylactic intravenous high-dose methotrexate (HD-MTX) is recommended for patients with risk factors of CNS relapse, which requires hospital admission and increases the risk of treatment-related toxicity. However, there is limited evidence to guide whether it should be intercalated between cycles or given at the end of induction chemotherapy (EOI), and whether the optimal dosage of MTX is different between different risk groups.
Aims: To compare the toxicity and preventive efficacy on CNS relapse of intercalated HD-MTX with EOI delivery, and explore the optimal dosage of MTX for patients of different risk groups.
Methods: We conducted a retrospective analysis of 275 DLBCL patients from Sun Yat-sen University Cancer Center who received prophylactic HD-MTX with either intercalated (n=218) or EOI HD-MTX (n=57). We stratified the patients into two risk groups: patients with CNS-IPI 4-6, and/or testis involvement, and/or double hit lymphoma in the high risk group, and others in the low-intermediate risk group. Multivariable analyses (MVA) of risk factors for toxicity and delays were performed. The log-rank test and χ^2 test was applied to determine factors associated with CNS relapse, progression-free survival (PFS), and overall survival (OS).
Results: Figure 1A describes selected baseline characteristics. A total of 939 doses of intercalated HD-MTX and 127 doses of EOI HD-MTX was given. The treatment related adverse events were mainly hematological toxicity, including leucopenia (27%), neutropenia (20%) and thrombocytopenia (6%). Non-hematological toxicity mainly included gastrointestinal reactions (6%) and mucositis (3%). Nephrotoxicity was uncommon in this set (n=2, 1%). 197 (21%) intercalated HD-MTX cycles were associated with grade 3/4 toxicity, compared with 3 (2%) of EOI HD-MTX cycles (p<0.001). Intercalated HD-MTX was the only factor associated with grade 3/4 toxicity (HR 5.28(95% CI 2.11-13.23), p<0.001) and subsequent chemotherapy delays (HR 4.27(95% CI 2.45-7.45), p<0.001) on MVA. MVA also identified that intercalated HD-MTX delivery (HR 0.41 (95%CI 0.17-0.98), p=0.04) and induction therapy without rituximab (HR 0.37 (95%CI 0.16-0.88), p=0.03) were the significant factors negatively associated with complete remission (CR) rate of induction therapy. Overall, ten CNS relapses occurred (median time to relapse 17 months). The 3 year cumulative incidence of CNS relapse showed no significant difference between two kinds of MTX delivery either in all patients or in two risk groups (Figure 1B). There was no difference in PFS or OS either in all patients or in two risk groups (median follow-up 36.0 months). In addition, the optimal dosage of MTX was discussed. Relatively high MTX dose (≥2g/m^2) decreased CNS relapse(Figure 1C) and improved the PFS (p=0.001) and OS (p=0.009) in high risk patients significantly. However, there was no significant difference in CNS relapse(Figure 1D) and survival outcomes between different dosage groups in low-intermediate risk patients.



A)

Characteristic	All (n=275)	Intercalated (n=218)	End of treatment (n=57)	P
Age (median, range)	48 (13-75)	48 (13-75)	48 (21-73)	0.95
Male Sex	179(65%)	140(64%)	39(68%)	0.55
ECOG PS≥2	28(10%)	19(9%)	9(16%)	0.07
Stage III or IV	212(77%)	163(75%)	49(86%)	0.27
Testis involvement	52(19%)	46(21%)	6(11%)	0.07
Double/tripple hit	4(%)	3(%)	1(2%)	1.00
CNS-IPI	49(18%)	37(17%)	12(21%)	0.11
IT prophylaxis	200(73%)	163(75%)	37(65%)	0.14

B)

Group	CNS relapses	3-year cumulative incidence	95% CI	P
All (n=275)	10 (3.6%)	4.9%	1.4-5.9	
Intercalated (n=218)	7 (3.2%)	3.7%	0.9-5.6	0.29
EOI (n=57)	3 (5.7%)	8.8%	0.0-11.2	
High risk (n=90)	4 (4.4%)	5.7%	0.1-8.8	
Intercalated (n=72)	3 (4.2%)	4.9%	0.0-8.9	0.73
EOI (n=18)	1 (5.6%)	8.3%	-6.2-17.3	
Low-intermediate risk (n=185)	6 (3.2)	3.4%	0.7-5.8	
Intercalated (n=146)	4 (2.7%)	1.5%	0.1-5.4	0.15
EOI (n=39)	2 (5.1%)	9.1%	-2.1-12.4	

Summary/Conclusion: Intercalated HD-MTX was associated with increased toxicity and subsequent chemotherapy delays compared to EOI delivery, which may decrease the efficacy of induction therapy. However, there was no significant difference of CNS relapse and survival outcomes between two kinds of MTX delivery, even in high risk group. For low-intermediate risk patients, high dosage of MTX may not improve efficacy of CNS prophylaxis or bring additional survival benefit compared with low dosage.

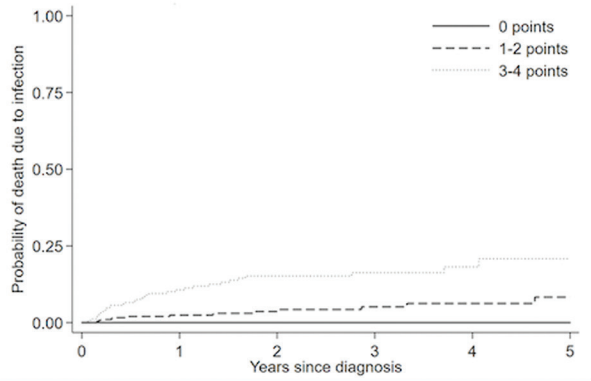
EP513 COMPREHENSIVE GERIATRIC ASSESSMENT-DRIVEN TREATMENT DECISION VERSUS CLINICAL JUDGMENT IN ELDERLY PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA IN CHINA

J.-F. Bai [1], Y. Li [1], J. T. Li [1], R. Feng [1], H. Liu [1,*]

[1]Beijing Hospital, National Center of Gerontology, P.R. China., Beijing, China

Background: Diffuse Large B-cell lymphoma (DLBCL) is the most common subtype of non-Hodgkin lymphoma in the elderly.some elderly patients can not tolerate the standard dose of R-CHOP due to age, poor physical condition, and severe complications. At present, the decision to treat a patient is made by clinical experience of clinicians, which is subjective. It is a major challenge to identify which patients can tolerate the standard dose of R-CHOP regimen in our clinical work. Comprehensive Geriatric Assessment (CGA) has been proposed as an objective tool for supporting treatment decision by age, evaluating activity of daily living, Instrumental activities of daily Living, and comorbidity score according to the Cumulative Illness Rating Score for Geriatrics (CIRS-G).However, It is still unknown whether comprehensive geriatric assessment or clinical judgment was more effective at guide the treatment in elderly patients with diffuse large B-cell lymphoma (DLBCL).
Aims: This prospective, observational, controlled cohort trial aims to investigate whether comprehensive geriatric assessment (CGA) is more effective than clinical judgment to guide the treatment in elderly patients with diffuse large B-cell lymphoma (DLBCL) in China.
Methods: 152 patients in Beijing Hospital were enrolled if they fulfilled the following inclusion criteria: 1)age ≥60 years; 2) newly diagnosed of DLBCL according to WHO classification by two independent pathologists; 3) no previous history of hematologic malignancies; 76 patients will received CGA-driven therapy at CGA-guided therapy group, and 76 patients will received therapy based on clinical judgement at clinical judgement-guided therapy group. the 2-year Overall Survival (OS), Progression Free Survival (PFS), Overall Response Rate (ORR) and toxicities were analyzed between the two group.
Results: according to CGA, 76 patients in the CGA-guided therapy group were classified into three groups: fit (41 patients, 53.9%), unfit(4 patients, 5.3%) and frail group (31 patients, 40.8%). patients assessed as unfit or frail group received a reduced dose of anthracycline of R-CHOP or R-miniCHOP or R-COP. the ORR was 94.7% (72/76), including CR rate was 73.7% (56/76). 2-year OS rates was 80.9%, 2-year PFS rates

was 72.7%. however, in the clinical judgement-guided therapy group, based on the CGA assessment, 41(53.9%) patients were assessed as fit group,including 36 patients received a standard dose of R-CHOP regimen.4(5.3%) as unfit group, 31(40.8%) as frail group including 4 patients in the frail group received a standard dose of R-CHOP regimen.the ORR was 81.6% (62/76), including CR rate was 57.9% (44/76). 2-year OS rates was 63.0%, 2-year PFS was 52.7%. there were significant difference between the two groups(ORR: x^2=5.104, p=0.024; CR:x^2=4.209, p=0.04; 2-year OS rates: x^2=7.348, p = 0.007; 2-year PFS: x^2=10.768, p = 0.001). Subgroup analysis showed that the complete remission rate in the fit group of patients in the CGA-guided therapy group was 82.9%(34/41), which was significantly higher than that in the clinical judgement-guided therapy group(58.5%, 24/41)(P = 0.015). The 2- year OS rate and 2-year PFS rate of patients in the CGA-guided therapy group were 86.9% and 76.5%, respectively, which were significantly higher than those in the clinical judgement-guided therapy group(62.1%, P = 0.000) and 62.9% (P = 0.000), respectively. the toxicity between two group was similar.
Summary/Conclusion: Using CGA to guide therapy for elderly patients with DLBCL can significantly improves the clinical efficacy and survival rate.



EP514 INFECTION-RELATED MORBIDITY AND MORTALITY FOR ELDERLY DLBCL PATIENTS TREATED WITH FULL OR ATTENUATED DOSE R-CHOP

T. Eyre [1,*], W. Wilson [2], A. Kirkwood [2], J. Wolf [3], C. Hildyard [4], H. Plaschkes [1], J. Griffith [3], P. Fields [5], A. Gunawan [5], R. Oliver [6], S. Booth [1], J. Kothari [1], C. Fox [7], N. Martinez-Calle [7], A. McMillan [7], M. Bishton [7], G. Collins [1], C. Hatton [1]

[1]Haematology, Oxford University Hospitals NHS Trust, Oxford, [2]Cancer Research UK & UCL Cancer Trials Centre, UCL Cancer Institute, London, [3]Haematology, Great Western Hosptail, Swindon, [4]Haematology, Milton Keynes Hopsital, Milton Keynes, [5]Haematology, Guys and St Thomas' Hospitals NHS Foundation Trust, London, [6]Haematology, University Hospitals Bristol NHS Foundation Trust, Bristol, [7]Haematology, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Background: Infection-related morbidity and mortality are increased in elderly patients (pts) treated for DLBCL compared to population-matched controls. Key predictive factors for infection-related hospitalisation during R-CHOP and infective deaths in elderly pts during and following R-CHOP remain incompletely understood.
Aims: We aimed to examine the influence of baseline characteristics, presentation, comorbidities, and intended dose intensity (IDI; combined % dose: cyclophosphamide & doxorubicin at cycle 1) in a 690 consecutive elderly (≥70 years (ys)) DLBCL pts on the risk of both infection-related morbidity (i.e. single &/or multiple infective admissions), & infection-related mortality occurring on or following therapy
Methods: Pts receiving full or mini R-CHOP were analysed for risk of infection-related admission & infection-related death. Factors potentially related to such endpoints were analysed by standard & ordinal logistic regression.
Results: Median age was 77 ys. 34.4% were ≥80 ys. Median follow-up was 2.8 ys. Pt and baseline disease characteristics were assessed in addition to IDI. 17% received primary quinolone prophylaxis. 72% of pts were not hospitalised with infection. Across all ages, the mean rate per R-CHOP cycle of an admission due to neutropenic infection was 7.9% in those with an IDI ≥80% compared to 3.3% in those with an IDI <80% (rank-sum p<0.0001). Increased risk of infection-related admission was independently associated with IDI >80% across all pts. In 331 pts receiving an IDI ≥80%, 33% were hospitalised with ≥1 infection compared to 23.3% of 355 pts receiving IDI <80% (univariable OR:1.61 (95% CI 1.14-2.26), p=0.006; multivariable OR: 2.12 (1.38-3.25), p=0.001. Antibiotic prophylaxis was associated with lower risk of infection (univariable OR: 0.37 (0.22-0.64), p<0.001, multivariable OR: 0.29 (0.16-0.51), p<0.001). In those ≥80 ys, risk of ≥1 infection-related admission was 32.4% (11/34) in those with an IDI >80% versus 21.3% (43/202) in those with an IDI <80% (OR:1.77, 95% CI 0.80-3.91, p=0.16). In this same group ≥80 ys, mean rate of admission per cycle specifically with neutropenic fever was numerically higher at 7.4% for those with an IDI ≥80% versus 2.9% with an IDI <80% (rank-sum p=0.06). 51 pts (7.4%) died due to infection. 6-month, 12-month, 2-yr and 5-yr cumulative incidence of infection-related death was 3.3%, 5.0%, 7.2% and 11.1% respectively. Key independent factors associated with infection-related death were: IPI 3-5, CIRS-G ≥6 and low albumin; enabling production of a predictive risk score. CIRS-G ≥6 were assigned 2 points, IPI 3-5 were assigned 1 point and baseline albumin ≤36 were assigned 1 point. 3 distinct cohorts were defined. Risk groups included 106 pts (15.5%, score 0), 316 pts (46.4%, score 1-2) and 259 pts (38.0%, score 3-4) respectively. 2-yr cumulative incidence of infective mortality with a score of 0 was 0%, score 1-2 was 3.6% (95% CI 1.8%>6.9%) & score of 3-4 15.2% (95% CI 10.8%>21.1%). 5-yr cumulative incidence of infective mortality: score of 0 was 0%, score 1-2 was 8.3% (95% CI 4.3%>15.8%) & score 3-4 was 20.8% (95% CI 14.0%>30.3%) respectively.

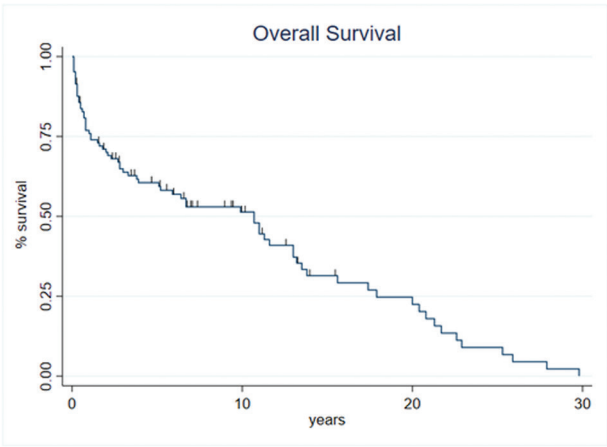
Figure: Risk model for predicting infection-related mortality: cumulative incidence of death due to infection

Risk score	Events/N*	HR (95% CI)	P-value	Death due to infection rate	
				2-year	5-year
0	0/106	N/A		0%	0%
1-2	13/316	1.00	<0.001	3.6% (1.8%-6.9%)	8.3% (4.3%-15.8%)
3-4	34/259	3.52 (1.87-6.63)		15.2% (10.8%-21.1%)	20.8% (14.0%-30.3%)
All patients with risk score				7.2% (5.3%-9.8%)	11.1% (7.9%-15.5%)

*Only patients with data for all three variables included in risk score analysis. Log-rank test for trend – p<0.001, Log-rank 1-2 vs 0 – p=0.02, Log-rank 3-4 vs 0 – p<0.001, Log-rank 3-4 vs 1-2 – p<0.001

Summary/Conclusion: Increased risk of infection-related admission is independently associated with R-CHOP IDI>80% and no antibiotic prophylaxis in elderly DLBCL pts. Independent factors associated with infection-related death were IPI 3-5, CIRS-G ≥6 & low albumin, enabling a predictive risk score. Whether high risk pts could be targeted with enhanced anti-microbial prophylaxis remains unknown and requires a randomised trial.

EP515 POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDER IN KIDNEY TRANSPLANT PATIENTS: A MULTICENTER REPORT IDENTIFYING THE IMPORTANCE OF ALLOGRAFT PRESENTATION



E. Chong [1,*], D. Tsai [2], M. Hughes [1], M. A. Lim [1], B. Besharatian [1], Y. El Kassiss [1], R. Bloom [1], D. Jagadeesh [3]

[1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, [2]Duke University, Durham, [3]Cleveland Clinic, Cleveland, United States

Background: Post-Transplant Lymphoproliferative Disorder (PTLD) is a complication of transplantation that often arises due to reactivation of the Epstein-Barr Virus (EBV). Given the rarity of this disease, a full understanding of its presentation and optimal therapies has yet to be determined.
Aims: To describe the presentation, prognostic features, therapies, and outcomes of PTLD.
Methods: A multicenter retrospective analysis was performed utilizing data from kidney transplant patients (pts) who developed PTLD at the Hospital of the University of Pennsylvania and the Cleveland Clinic. The association between categorical variables and clinical response were assessed via Fisher's exact testing.
Results: 117 pts had diagnoses of PTLD after kidney transplantation. The median age at PTLD diagnosis was 52 yrs (range 17-89 yrs), and the median time from transplantation to diagnosis was 3.6 yrs (range: 7 days-36 yrs). Pt characteristics included: 84% Caucasian, 57% male, and 11% combined kidney and pancreas transplant patients. 68% pts had received unrelated donor transplants; 41% had prior rejection episodes. PTLD histology was 72% monomorphic and 28% polymorphic. Polymorphic PTLD was more likely to be EBV+ than monomorphic PTLD (81% vs. 54%, p=0.05). At diagnosis, immunosuppression included: steroids (95%), mycophenolate (44%), azathioprine (40%), sirolimus (30%), cyclosporine (46%), and/or tacrolimus (45%). Common PTLD symptoms included fever (34%), pain (38%), weight loss (30%), fatigue (30%), and/or mass (26%). The

most common sites of involvement were lymph nodes (64%), kidney allograft (22%), and/or GI tract (17%). At diagnosis, 61% of patients' tumors were EBV+ and 59% of patients had elevated serum LDH. Overall, the majority of pts responded to first-line PTLD therapy, with 61% CR and 14% PR. Reduction of immunosuppression (RI) alone (36% of pts) led to 48% CR and 12% PR; RI with rituximab (16%) led to 47% CR and 7% PR; and RI with chemotherapy (14%) resulted in 58% CR and 42% PR. Patients treated with RI as well as resection (n=18) of their limited stage disease had better outcomes (p=0.05). Overall survival for all patients was 10.7 years (95% CI: 5.1-13 years) (Figure), suggesting that a majority of patients achieve long term survival. PTLD patients <40 yrs were more likely to achieve CR after first line therapy (91% vs. 50%, p<0.001), have allograft involvement (43% vs. 14%, p=0.003), and have a polymorphic histology (52% vs. 17%, p=0.002).

Allograft involvement tended to occur sooner after transplant, occurring a median of 70 days (IQR: 29 days-2.6 yrs), whereas PTLD with no allograft involvement occurred a median of 5.4 yrs (IQR: 2.0-13.0 yrs, p=0.001). Allograft involvement was more likely to present with allograft failure (48% vs. 17%, p=0.003). PTLD with allograft involvement were more likely to achieve CR after first therapy than regular PTLD (88% vs. 54%, p=0.007) and often responded well to complete resection and RI.

Summary/Conclusion: Pts with PTLD may achieve a CR through different initial therapies. Younger patients and those able to undergo complete resection of disease and RI had better prognoses. Allograft involvement by PTLD carries a good prognosis and should be identified and treated differently from other presentations.

EP516 SAFETY AND EFFICACY OF TISAGENLECLEUCEL PLUS PEMBROLIZUMAB IN PATIENTS WITH RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA: UPDATED ANALYSIS OF THE PHASE 1B PORTIA STUDY

U. Jaeger [1,*], N. Worel [1], J. McGuirk [2], P. Riedell [3], I. Fleury [4], P. Borchmann [5], Y. Du [6], A. Abdelhady [7], X. Han [7], M. Martinez-Prieto [7], E. Waller [8]

[1]Medical University of Vienna, Vienna, Austria, [2]University of Kansas Medical Center, Kansas City, [3]University of Chicago, Chicago, United States, [4]Maisonneuve-Rosemont Hospital, University of Montreal, Montreal, Canada, [5]University Hospital Cologne, Cologne, Germany, [6]Novartis Pharma AG, Shanghai, China, [7]Novartis Pharmaceuticals Corporation, East Hanover, [8]Emory University Winship Cancer Institute, Atlanta, United States

Background: Tisagenlecleucel showed durable responses and manageable safety in patients with relapsed/refractory diffuse large B-cell lymphoma (r/r DLBCL) in the phase 2 JULIET trial. High baseline programmed cell death 1 (PD-1) expression associated with higher probability of no response (Schuster et al. *NEJM* 2019).

Aims: To report an updated analysis of PORTIA, a phase 1b, multicenter, open-label study of tisagenlecleucel plus pembrolizumab in patients with r/r DLBCL.

Methods: Eligible patients (≥18 year) had r/r DLBCL after ≥2 lines of therapy and relapsed after or were not candidates for autologous stem cell transplant (autoSCT). Patients received a single tisagenlecleucel infusion on Day 1 and were enrolled in 1 of 3 cohorts that initiated pembrolizumab (200 mg q 21 days, for up to 6 doses) on either Days +15, +8, or –1. Primary endpoints were incidence of dose-limiting toxicities (DLTs) and overall response rate (ORR; complete response [CR] and partial response [PR]). Secondary endpoints included duration of response, progression-free survival, overall survival, safety, and cellular kinetics.

Results: As of November 9, 2020, 15 patients were enrolled and 12 received tisagenlecleucel (n=4 patients for each Days +15, +8, and –1 cohorts; median follow-up, 4 mo). At study entry, the median age among treated patients was 62 year (range, 35-79), 100% had an International Prognostic Index score ≥2, 67% had ≥3 prior lines of therapy, 58% had stage IV disease, 58% had lactate dehydrogenase greater than upper limit of normal, and 42% had prior autoSCT. All 12 patients had ≥1 adverse events (AE). Grade ≥3 AEs suspected to be related to tisagenlecleucel and/or pembrolizumab were neutropenia (n=4); neutrophil count decreased (n=3); febrile neutropenia, lymphocyte count decreased, malnutrition (each n=2); anemia, leukopenia, diarrhea, white blood count decreased, liver function tests increased, thrombocytopenia, hepatitis, and cytokine release syndrome (CRS; each n=1). No neurotoxicity or DLTs were observed. Among the Day +15, +8, and –1 cohorts (each n=4), the ORR was 50% (2/4; CR n=0, PR n=2), 25% (1/4; CR n=1, PR n=0), and 25% (1/4; CR n=1, PR n=0; longer follow-up is needed for n=2 patients), respectively. Tisagenlecleucel exposure and peak expansion were consistent with JULIET, with a trend toward delayed expansion in the Day –1 cohort (n=4). There was no sign of secondary expansion following pembrolizumab administration regardless of the number of doses. Compared with JULIET, lower CRS severity and frequency and lower cytokine profiles were observed for all 3 cohorts.

Summary/Conclusion: The combination of tisagenlecleucel plus pembrolizumab was feasible and showed manageable safety. The lack of improved efficacy in PORTIA with the addition of pembrolizumab compared with tisagenlecleucel alone may be related to more patients with ≥3 prior lines of therapy (67% vs 51%, respectively), and/or patients with more advanced disease in PORTIA. Additional studies with larger patient cohorts are needed to determine the value of adding PD-1 inhibitors to CAR-T cell therapy in patients with r/r DLBCL.

Clinical trial information: NCT03630159

EP517 INTERIM-PET IS NOT PREDICTIVE OF OUTCOME IN DLBCL PATIENTS WITH MYC REARRANGEMENTS DUE TO ABERRANT RESPONSE PATTERNS

J. J. Eertink [1,*], A. I. Arens [2], J. E. Huijbregts [3], F. Celik [4], B. de Keizer [5], S. Stroobants [6], D. de Jong [7], S. E. Wiegers [1], G. J. Zwezerijnen [8], C. N. Burggraaff [1], R. Boellaard [8], H. C. de Vet [9], O. S. Hoekstra [8], P. J. Lugtenburg [10], M. E. Chamuleau [1], J. M. Zijlstra [1]

[1]Amsterdam UMC, Vrije Universiteit Amsterdam, department of Hematology, Cancer Center Amsterdam, Amsterdam, [2]Radboud University Medical Center, Department of Radiology, Nuclear Medicine and Anatomy, Nijmegen, [3]Department of Radiology and Nuclear Medicine, Gelre Ziekenhuizen, Apeldoorn, [4]Department of Radiology and Nuclear Medicine, Deventer Ziekenhuis, Deventer, [5]University Medical Center Utrecht, Department of Radiology and Nuclear Medicine, Utrecht, Netherlands, [6]Antwerp University Hospital (UZA), Department of Nuclear Medicine, Antwerp, Belgium, [7]Amsterdam UMC, Vrije Universiteit Amsterdam, department of Pathology, Cancer Center Amsterdam, [8]Amsterdam UMC, Vrije Universiteit Amsterdam, department of Radiology and Nuclear Medicine, Cancer Center Amsterdam, [9]Amsterdam UMC, Vrije Universiteit Amsterdam, department of Epidemiology and Data Science, Amsterdam Public Health research institute, Amsterdam, [10]Erasmus MC Cancer Institute, University Medical Center Rotterdam, department of Hematology, Rotterdam, Netherlands

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common subtype of non-Hodgkin lymphoma with a large spread in outcome. Part of the heterogeneity can be explained by genetic abnormalities, such as *MYC* oncogene rearrangements. *MYC* rearrangements are often accompanied by *BCL2* and/or *BCL6* rearrangements and occur in approximately 10-15% of patients and has been associated with poor prognosis.

Aims: The aim of this study was to analyse the patterns of ^{18}F-fluorodeoxyglucose positron emission tomography computed tomography (^{18}F-FDG PET/CT) response in DLBCL patients with *MYC* rearrangements (*MYC*+) compared to the response patterns of DLBCL patients without *MYC* rearrangements (*MYC*-).

Methods: 80 *MYC*+ DLBCL patients included in the HOVON-130 study, and 126 *MYC*- DLBCL patients in the HOVON-84 study were analysed. *MYC*, *BCL2* and *BCL6* positivity was assessed by Fluorescence In Situ Hybridization. For the *MYC*+ patients, 25% of patients had a single hit, and 75% a double or triple hit lymphoma. *MYC*+ patients were treated with 6 cycles of rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP21) combined with lenalidomide, followed by 2 gifts of rituximab. *MYC*- patients were randomized between 6-8 cycles of R-CHOP14 with or without rituximab intensification. ^{18}F-FDG PET/CT scans were performed at baseline, after 3-4 cycles of treatment (I-PET) and at end of treatment (EoT-PET). All scans were centrally reviewed and evaluated according to the Deauville 5-point scale (DS). DS 1-3 was regarded as PET-negative and DS 4-5 as PET-positive. I-PET and EoT-PET positivity rates were compared between *MYC*+ and *MYC*- groups using the chi-square test for independence. Positive predictive value (PPV) and negative predictive value (NPV) of I-PET and EoT-PET were calculated for 2-year overall survival, defined as date of registration to death, as outcome. Metabolic tumour volume was calculated at baseline, I-PET and EoT-PET using the ACCURATE tool.

Results: As expected, *MYC*+ DLBCL patients had significantly more positive EoT-PET scans compared to MYC- patients (33% (26/79) vs 15% (18/118), p=0.004, Table 1). I-PET response rates were comparable between *MYC*+ and *MYC*- DLBCL patients. Of the I-PET negative patients 23% (13/56) of the *MYC*+ patients turned out positive at EoT-PET, compared to 2% (2/91) for the MYC- patients. In total, 81% (21/26) of EoT-PET positive *MYC*+ patients presented with new nodal and/or extranodal lesions compared to I-PET, and 35% of EoT-PET positive *MYC*+ patients showed new lesions at EoT-PET in regions that were not initially involved at baseline. For the *MYC*- patients, 22% (4/18) of the EoT-positive patients presented with new nodal and/or extranodal lesions compared to I-PET, and 5.6% of the EoT-PET positive patients had new lesions in regions that were not initially involved at baseline. Out of the *MYC*+ patients that were positive at I-PET and EoT-PET, 60% showed enhancement of tumor volume at EoT-PET, this was the case of 38% of the *MYC*- DLBCL patients. 50% (13/26) of the EoT-PET positive *MYC*+ patients had negative I-PET assessment, compared to 11% (2/18) of the EoT-PET positive *MYC*- patients. Positive predictive values of I-PET and EoT-PET were higher for the *MYC*+ DLBCL patients compared to *MYC*- DLBCL patients (range: 31.6%>61.5%), whereas negative predictive values were higher for *MYC*- DLBCL patients (range: 81.8%>94.1%).

Table 1. Response rates of *MYC*+ and *MYC*- DLBCL Patients on interim PET and end of Treatment PET

		EoT-	EoT+	No EoT
MYC+	**I-PET-**	43	13	1
(n=80)	**I-PET+**	10	13	
MYC-	**I-PET-**	89	2	5
(n=126)	**I-PET+**	11	16	3

Abbreviations: I-PET: interim PET, EoT: End of Treatment PET
PET-: Deauville score 1-3, PET+: Deauville score 4-5

Summary/Conclusion: *MYC*+ DLBCL patients demonstrate specific response patterns, therefore I-PET is less predictive in *MYC*+ DLBCL patients.

EP518 DURATION OF RESPONSE TO LONCASTUXIMAB TESIRINE IN RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA BY DEMOGRAPHIC AND CLINICAL CHARACTERISTICS: SUBGROUP ANALYSES FROM LOTIS-2

P. F. Caimi [1,*], W. Ai [2], J. P. Alderuccio [3], K. M. Ardeshna [4], M. Hamadani [5], B. Hess [6], B. S. Kahl [7], J. Radford [8], M. Solh [9], A. Stathis [10], P. L. Zinzani [11], J. Feingold [12], D. Ungar [12], Y. Qin [12], S. He [12], C. Carlo-Stella [13]

Background: Outcomes for patients with refractory/relapsed diffuse large B-cell lymphoma (R/R DLBCL) are poor, particularly for those with high-risk clinical characteristics. There remains an unmet need for new treatment options for these patients. Loncastuximab tesirine (Lonca) is an antibody-drug conjugate comprising a humanized anti-CD19 antibody conjugated to a potent pyrrolobenzodiazepine dimer toxin. LOTIS-2 was a pivotal Phase 2 study that demonstrated substantial single-agent anti-cancer activity of Lonca in patients with R/R DLBCL. Efficacy and safety data were presented at ASH 2020 (Caimi *et al*, ASH 2020; abstract 1183).

Aims: Here we present subgroup analyses of duration of response (DoR) to Lonca by demographic and clinical characteristics.

Methods: Adult patients with R/R DLBCL who had received ≥2 prior therapies were enrolled in this Phase 2, multicenter, single-arm, open-label study of single-agent Lonca (150 µg/kg every 3 weeks for 2 doses, followed by 75 µg/kg thereafter for up to 1 year). Informed consent was obtained. The primary analysis has previously been reported, with a primary endpoint of overall response rate (ORR). Patients are being followed-up every 12 weeks for up to 3 years. DoR was a key secondary efficacy endpoint, defined as time from the first documentation of response (central review) to disease progression or death. We analyzed pre-specified demographic and clinical characteristic subgroups for DoR.

Results: As of data cut-off (August 6, 2020), ORR in the total population (N=145) was 48.3% (24.8% had complete response [CR] and 23.4% had partial response [PR]). Median DoR (mDoR) for the 70 responders was 12.58 months. mDoR for patients with CR and PR was 13.37 months and 5.68 months, respectively.

Overall, subgroups with high-risk characteristics for poor prognosis had a DoR comparable to the whole study population. mDoR for patients with double-/triple-hit DLBCL was 13.37 months, with advanced stage disease was 12.58 months, and with transformed disease was 12.58 months. The mDoR for older patients was longer than for younger patients (≥75 years, 13.37 months; 65 to <75 years, 12.58 months; <65 years, 9.26 months). Patients with DLBCL refractory (defined as no response to therapy) to first-line, most recent line, and all prior lines of therapy had mDoRs of 9.63 months, 9.26 months, and 9.63 months, respectively.

Summary/Conclusion: Durable responses were observed with the recommended Phase 2 dose regimen of Lonca in heavily pre-treated patients and those at high risk of poor prognosis, including older patients and those with double-/triple-hit, advanced stage, transformed, and primary refractory DLBCL. Updated DoR data will be presented at the meeting.

Research funding: ADC Therapeutics SA (NCT03589469).

EP519 PROGNOSTIC SIGNIFICANCE OF TIME FROM LAST THERAPY IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: A RETROSPECTIVE ANALYSIS OF ELECTRONIC HEALTH RECORDS AND CLAIMS DATA IN THE US

M. Dickinson [1,*], F. Castro [2], Y. Liu [3], A. Abraham [3], Y. Oki [4], M. Matasar [5]

[1]The Peter MacCallum Cancer Centre, Royal Melbourne Hospital and The University of Melbourne, Melbourne, Australia, [2]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [3]Genesis Research, Hoboken, NJ, [4]Genentech, Inc., South San Francisco, CA, [5]Memorial Sloan Kettering Cancer Center, New York, NY, United States

Background: Primary refractory disease is a major challenge in patients (pts) with diffuse large B-cell lymphoma (DLBCL), and is commonly defined as disease progression during first-line (1L) therapy or within 6 months (mo) of completing 1L therapy. Poor outcomes in pts with primary refractory DLBCL were reported in SCHOLAR-1, a study based on data primarily from academic centers (Crump, et al. Blood 2017). A limited number of studies have evaluated real-world outcomes of pts with primary refractory DLBCL in the broader healthcare setting. Here, we report the results of real-world data (RWD) analyses from two US sources.
Aims: To describe outcomes of pts with DLBCL receiving second-line (2L) therapy from RWD according to the time from last treatment (TLT), defined by the time from end of 1L to the start of 2L therapy.
Methods: This study used the nationwide Flatiron Health (FH) electronic health record-derived de-identified database and the Surveillance, Epidemiology, and End Results (SEER)-Medicare (SEER-M)-linked database, which combines the SEER Cancer Registry and Medicare claims database. The majority of pts in the FH database originate from community oncology settings; relative community/academic proportions may vary depending on study cohort. The data of pts with DLBCL who received 2L therapy between Jan 2011–Jan 2020 in FH and Jan 2011–Dec 2015 in SEER-M were reviewed. Pts aged ≥18 years (pts in SEER-M were aged >65 years) with DLBCL, who were treated with cyclophosphamide- and doxorubicin-containing regimens in the 1L setting, were included for analysis. For SEER-M, all pts enrolled in fee-for-service Medicare were required to have complete claims. Data of pts who developed a secondary malignancy were censored at the time of the malignancy, and medical review of treatment regimens was performed for the final cohorts. Pts were grouped into three categories of TLT (<6 mo, 6–12 mo and >12 mo), and the impact of TLT was analyzed for association with overall survival (OS), defined by the time from the start of salvage therapy to death.
Results: Overall, 866 pts were included (FH: n=442; SEER-M: n=424) for analysis. Pt characteristics were similar between the cohorts, except median age at diagnosis (FH: 65 years; SEER-M: 74 years). Pts were mostly white (FH: 72.9%; SEER-M: 91.5%), male (FH: 63.1%; SEER-M: 52.1%), with Stage III–IV disease (FH: 64.9%; SEER-M: 69.5%). The most common 2L regimens were: rituximab (R) + carboplatin + etoposide + ifosfamide (39.8% in FH and 7.5% in SEER-M), R + bendamustine (14.0% in FH and 29.2% in SEER-M), and R + gemcitabine + oxaliplatin (8.4% in FH and 12.5% in SEER-M). Using a TLT cut-off of <6 mo, 236 (53.4%) pts in the FH cohort and 197 (45.3%) pts in the SEER-M cohort were classified as primary refractory. In the FH cohort, median OS for TLT <6 mo, 6–12 mo, and >12 mo were 9.1 mo (95% confidence interval [CI]: 8.1–13.1 mo), 20.9 mo (95% CI: 13.7–47.5), and 42.9 mo (95% CI: 22.8–57.3), respectively (**Figure**). In the SEER-M cohort, median OS for TLT <6 mo, 6–12 mo, and >12 mo were 8.6 mo (95% CI: 6.7–11.4), 11.7 mo (95% CI: 8.8–16 .1), and 18.9 mo (95% CI: 15.7–32.9), respectively.

Figure: OS from start of 2L treatment according to TLT category (<6 mo, 6–12 mo, and >12 mo) in FH

1L, first-line; 2L, second-line; FH, Flatiron Health; mo, months; OS, overall survival; TLT, time from last treatment (defined by the time from end of 1L to start of 2L therapy)

Summary/Conclusion: Our RWD analysis highlights the poor outcomes of pts with shorter TLT, particularly those with primary refractory DLBCL (TLT <6 mo). Novel therapeutic approaches are needed for this high-risk patient population, and future studies of 2L therapy should stratify enrollment by TLT to control for this source of confounding.

EP520 PROGNOSIS AND HEPATIC TOXICITY IN HEPATITIS C VIRUS-POSITIVE PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Zhang [1,*], H. Huang [1], B. Ni [1]

[1]*Division of Hematology, Renji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China*

Background: Increasing evidence suggested that viral infection contributes to lymphomagenesis. Plenty of studies indicated that hepatitis C virus (HCV) infection is associated with diffuse large B-cell lymphoma (DLBCL). However, no clear consensus has been reached about the impact of HCV infection on DLBCL patients' clinical features and outcomes.
Aims: We therefore performed a systematic review and meta-analysis to explore the clinical characteristics and prognosis in DLBCL patients with HCV infection.
Methods: PubMed, Embase and Cochrane Library database were searched for retrospective study up to Dec 31, 2020. The primary outcome was survival outcomes, including overall survival (OS) and progression-free survival (PFS). The secondary outcomes measured rate of complete remission (CR) and partial remission (PR), the incidence of hepatic dysfunction during chemotherapy and clinical characteristics. Newcastle-Ottawa Quality Assessment Scale (NOS) was adopted to assess the methodological quality of included studies. Hazard ratio (HR) or odds ratio (OR) corresponding to 95% confidence interval (CI) were calculated to estimate outcomes. Publication biases were assessed by funnel plots. Statistical analyses were performed by the software RevMan 5.4.
Results: There were in total 11 studies included in the current meta-analysis, comprising of 532 HCV infected DLBCL patients and 7907 HCV non-infected DLBCL patients. All the included studies had reliable quality as indicated by NOS scores ≥ 6 points. Our data demonstrated that DLBCL patients with HCV infection showed significantly shorter OS (HR 2.29; 95% CI 1.85~2.84, P<0.00001) and PFS (HR 1.52; 95% CI 1.27~1.82, P<0.00001), lower rate of CR+PR (OR 0.55; 95% CI 0.42~0.72, P<0.00001) and higher incidence of hepatic dysfunction during chemotherapy (OR 5.89; 95% CI 2.31~15.01, P=0.0002) compared with DLBCL patients without HCV infection. Furthermore, HCV infected DLBCL patients were characterized by higher International Prognostic Index scores (OR 1.36; 95% CI 1.10~1.68, P=0.005), higher level of LDH (OR 1.45; 95% CI 1.16~1.80, P=0.0009) and more frequent involvement of spleen (OR 2.75; 95% CI 1.92~3.95, P<0.00001) and liver (OR 1.87; 95% CI 1.22~2.85, P=0.004) at diagnosis in comparison to HCV non-infected DLBCL patients. However, there was no significant difference in age of disease onset, disease stage, present of B symptoms and incidence of involvement of bone marrow between two groups of patients. Funnel plots indicated no evidence for publication bias.
Summary/Conclusion: The current study provided the compelling evidence about an inferior prognosis and distinct clinical characteristics in HCV infected DLBCL patients. DLBCL patients with HCV infection were prone to undergoing hepatic dysfunction during chemotherapy.

EP521 BASELINE TOTAL METABOLIC TUMOR VOLUME >220CM³ AND DEAUVILLE 5-POINT SCALE OF ≥4 AFTER FOUR CYCLES OF R-CHOP ARE STRONGLY ASSOCIATED WITH INFERIOR PROGRESSION FREE SURVIVAL IN PATIENTS WITH DLBCL

S. Hatzl [1,*], P. Kalmar [2], F. Posch [3], J. M. Riedl [3], C. Beham-Schmid [4], K. Prochazka [1], H. Greinix [1], T. Schwarz [5], C. Gstettner [5], P. Neumeister [1], E. Schulz [1]

[1]Department of Internal Medicine, Division of Hematology, [2]Department of Radiology, Division of Vascular and Interventional Radiology, [3]Department of Internal Medicine, Division of Oncology, [4]Institute of Pathology, [5]Department of Radiology and Division of Nuclear Medicine, Medical University of Graz, Graz, Austria

Background: ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography (PET-CT) is the standard imaging modality for disease staging and end of treatment assessment of diffuse large B-cell lymphoma (DLBCL). However, its use for response prediction has not been standardized, yet. Baseline total metabolic tumor volume (TMTV) ≥220 cm^3 and change of maximum standardized uptake value (ΔSUV_{max}) after two cycles of R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone) have been reported to be superior to the visual Deauville 5-point scale (DS).

Aims: Our aim was to assess the prognostic value of TMTV, ΔSUV_{max} and DS in contemporary "real-world" DLBCL patients uniformly treated with R-CHOP given every 21 days (R-CHOP21).

Methods: We conducted a retrospective analysis of 144 patients with DLBCL who were diagnosed and treated with R-CHOP21 at our institution during January 1st 2015 and December 31st 2019. This study was approved by the ethics committee of the Medical University of Graz. All patients underwent PET-CT at diagnosis and after four cycles of R-CHOP21 (i-PET4). SUV_{max} and TMTV were computed using the semiautomatic software Hermes Hybrid 3D Tumorfinder (Hermes Medical Solutions, Stockholm, Sweden). Statistical analyses were performed with Stata (Windows version 15.0, Stata Corp.). Median follow-up was estimated with a reverse Kaplan-Meier estimator. Primary endpoint for all time-to-event analyses was 5-year progression free survival (PFS). PFS was estimated with Kaplan-Meier estimators, and compared between groups using log-rank tests. Uni- and multivariable modeling of PFS functions was performed with Cox proportional hazards models. Harrell's concordance index was calculated to evaluate model fit of different PET parameters.

Results: Results:

Thirty-seven patients were excluded (HIV, n=2; transformed low-grade lymphoma, n=23; primary testicular lymphoma, n=3; primary central nervous system lymphoma, n=4; no interim imaging, n=5). Patients had a median age of 67 years (interquartile range [IQR], 53-74) and a median R-IPI score of 3 points (IQR, 2-4). During a median follow up of 2.4 years (IQR, 1.4-3.6), we observed 19 (18%) primary disease progressions during first line therapy, ten (9%) relapses after initial CR or PR, 16 (15%) deaths related to DLBCL and four deaths from other causes. The estimated 5-year PFS and OS of the whole cohort were 63% (95% CI, 51-73) and 75% (95% CI, 63-84), respectively.

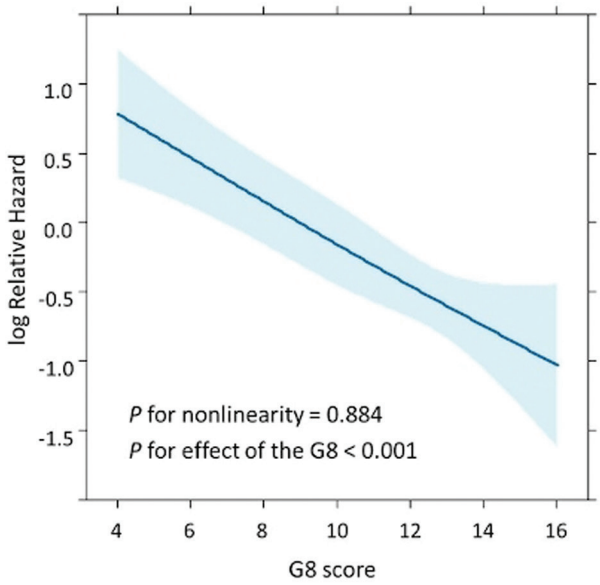
Higher baseline TMTV predicted for higher risk of progression and death. The baseline TMTV threshold of >220cm^3 could be confirmed (Table 1). At i-PET4, TMTV, SUV_{max}, and DS comparably predicted PFS with a good discriminatory performance (c-indices between 0.76 and 0.80). Five-year cumulative incidences of primary disease progression or relapse were 32% and 76% in patients with DS of 1-3 points (n=67) and 4-5 points (n=34), respectively (Gray's test p <0.0001). Complete metabolic response (CMR), a composite of interim TMTV of 0 and SUVmax of 0 (n=60 patients), showed 5-year PFS of 83% and 31% in patients with and without a CMR (log-rank p<0.0001). In a multivariable model of PFS including CMR at i-PET4, double expressor lymphoma biology, cell of origin, and NCCN-IPI, only CMR prevailed as an independent predictor of PFS (HR 9.88, 95% CI 3.94-24.79, Wald test p<0.0001). ΔSUV_{max} was predictive of PFS but not superior to DS.

Variable	N missing (%)	Measured value [IQR], or absolute count (%)	Univariable		Harrell's c-index for PFS
			HR for PFS	95%CI (P)	
Markers at baseline					
TMTV (per doubling)	0	86 [26-188]	1.34	1.11-1.61 (0.002)	0.67
TMTV >220cm³	0	20 (19%)	3.54	1.73-7.22 (0.001)	0.63
NCCN-IPI (points)	0	3 [2-5]	1.34	1.08-1.67 (0.008)	0.60
Interim markers					
SUVmax (per doubling)	6 (5,6%)	0 [0-7]	1.71	1.44-2.03 (<0.001)	0.80
TMTV (per doubling)	6 (5,6%)	0 [0-11]	1.42	1.25-1.60 (0.001)	0.78
DS (per point increase)	6 (5,6%)	1 [1-4]	2.18	1.66-2.87 (<0.001)	0.80
DS	6 (5,6%)	/	/	/	0.76
---1-2 points	/	60 (59%)	ref.	ref.	/
---3 points	/	7 (7%)	1.22	0.15-9.79 (0.849)	/
---4-5 points	/	34 (34%)	8.86	3.86-20.36 (<0.001)	/
Change between baseline and interim					
$\Delta SUVmax_{rel}$ (per doubling)	7	-100 [(-100) – (-57)]	4.33	2.80-6.68 (<0.001)	0.79

Summary/Conclusion: DLBCL patients with baseline TMTV >220cm^3 and DS of ≥4 have an inferior PFS and are therefore prime candidates for new treatment strategies.

EP522 THE IMPACT OF THE GERIATRIC 8 SCORE ON OVERALL SURVIVAL IN OLDER ADULTS WITH DIFFUSE LARGE B-CELL LYMPHOMA.

K. Oiwa [1,*], S. Lee [2], K. Fujita [2], T. Morishia [3], H. Tsukasaki [4], E. Negoro [5], T. Ueda [5], S. Iida [1], T. Yamauchi [5]



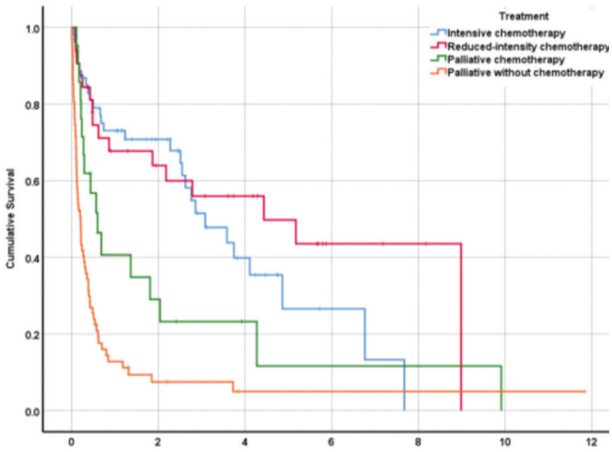
[1]Hematology and Oncology, Nagoya City University, Nagoya, [2]Hematology, Matsunami General Hospital, Gihu, [3]Healthcare Economics and Quality Management, Kyoto University, Kyoto, [4]Hematology, Fukui Red Cross Hospital, [5]Hematology and Oncology, University of Fukui, Fukui, Japan

Background: In aging society, the number of elderly patients with diffuse large B cell lymphoma (DLBCL) is increasing. The elderly patients cannot be managed in the same way as the young patients because of their various comorbidities and levels of frailty. However, the establishment of simple geriatric assessment tool to predict prognosis and management in treatment has rarely been reported in DLBCL.

Aims: The aim of this study was to verify the prognostic impact of the Geriatric 8 (G8) in elderly DLBCL patients, using a Cox hazards model with restricted cubic spline (RCS) model which is more suitable for reflecting the real-word practice.

Methods: To evaluate the usefulness of the G8, we conducted a retrospective, multicenter analysis of elderly DLBCL patients (≥65 years) who received standard therapy between 2007 and 2017 at three tertiary institutions in Japan. Patients treated with the standard regimen as first-line therapy were enrolled in this study. The exclusion criteria were transformed DLBCL, methotrexate-associated lymphoproliferative disorders, central nervous system involvement or undergoing treatment besides standard regimen. The standard regimen was defined as (R-) CHOP regimen (rituximab, cyclophosphamide, adriamycin [ADR], vincristine, and prednisolone) and (R-) THP-COP regimen (the same as CHOP including the doses, except tetrahydropyranyl adriamycin replaced ADR) in this study. The end point was the impact of the G8 on OS, which was defined as the interval from the date of the diagnosis to the date of all-cause death or the last follow-up visit. A multivariate Cox proportional hazards model was used to identify the predictors that were statistically associated with OS. Non-linear regression model with RCS was used to assess the presence of a non-linear relationship between the G8 score and OS. Diagnostic performance was assessed by receiver operating characteristic (ROC) analysis. The optimal G8 cutoff scores for OS were identified by ROC analysis using the Youden index. Survival curves for each group were estimated using the Kaplan-Meier method, and a comparison between risk groups was performed using the log-rank test.

Results: A total of 398 patients were included. With a median follow-up of 22.3 months (0-140.3), the estimated 2-year OS was 47.2%. A total of 196 patients (43.5%) died, including 127 (64.8%) of lymphoma and 10 (5.1%) of therapy-related toxicity. A multivariate Cox proportional hazards model demonstrated that the G8 was an IPI-independent prognostic predictor (HR 0.854, 95% CI 0.808-0.902, p<0.001). According to the multivariate RCS-Cox model, an obvious linear association was observed between G8 scores and mortality even though RCS model can represent in a nonlinear way (p for nonlinearity = 0.884, p for effect of the G8 <0.001). The lower the G8 score, the higher the risk of mortality. Especially, it was found that the mortality risk increases when the G8 score is below 9 to 10. The cutoff level of mortality, 9.5, in ROC analysis was considered robust, as it was consistent with the results of the Cox-RCS model. The Kaplan-Meier analysis showed that the patients with higher G8 had a significantly better prognosis than those with the lower G8 (log rank p<0.001).



Summary/Conclusion: Our research has revealed the G8 score was found to be an important prognostic predictor in elderly DLBCL patients, in that a lower G8 score proportionally exacerbated the prognosis.

EP523 DOES INTENSIVE CHEMOTHERAPY REALLY HELP OLDER DLBCL PATIENTS LIVE LONGER?

D. Gordon-Walker [1,*], C. Turner [1], D. Sparksman [2], N. Shah [3], N. Morley [1]

[1]Haematology, Sheffield teaching hospitals, Sheffield, [2]Haematology, Cambridge univerity hospitals, Cambridge, [3]Haematology, Norfolk and Norwich Hospitals, Norwich, United Kingdom

Background: Diffuse Large B Cell Lymphoma (DLBCL) is the most common type of non-Hodgkin Lymphoma (NHL) and accounts for about 40% of all NHL[1]. There are several treatment options used in the management of DLBCL in older patients (>80 years old) including curative anthracycline-based regimens and palliative regimens; however, this age group appears to be under-represented in clinical trials likely due to concerns regarding patient comorbidities and treatment tolerance. R-MiniCHOP has been shown to be safe and effective in >80 year olds[2]. We present novel data from a multi-centre UK study with a focus on survival outlooks for DLBCL in the >80 age group.
Aims: To assess wether there is any significant difference in overall survival between intensive/reduced intensity/palliative chemotherapy/palliative without chemotherapy, in the frail over 80 age DLBCL group. With an aim to try and inform future treatment decisions.
Methods: Patient demographics and survival data were retrospectively collected (N=173) from Norwich and Sheffield University Hospitals. Four treatment groups were included for analyses: intensive chemotherapy (full dose RCHOP/RGCVP/R-PMitCEBO, N=53); reduced-intensity chemotherapy (R-miniCHOP/RCVP, N=32); palliative chemotherapy (VEDEX/Chlorambucil/Etoposide, N=21) and palliative without chemotherapy (steroids/palliative radiotherapy, N=67). Overall survival (OS) by age (Spearman's correlation) and sex (Mann-Whitney U) was analysed. Median survival by treatment was calculated and a Kaplan-Meier plot was generated. We performed a multivariate analysis (Cox regression) which assessed both age and treatment in relation to OS. Post-hoc Kruskal-Wallis testing detailed specific differences between treatment groups.
Results: Age was significantly negatively correlated with OS (p=.011) whereas there was no significant difference in OS between sexes (p=.653). The overall median OS was 0.57 years. Median OS values by treatment were 1.95 years (intensive), 2.06 years (reduced-intensity), 0.57 years (palliative) and 0.21 years (palliative without chemotherapy). The subsequent multivariate survival analysis showed OS varied significantly between treatment groups (p<.001); in this model, age did not retain its significance (p=0.824). Post-hoc testing revealed treatment differences were primarily driven by palliative (without chemotherapy) conferring a significantly lower OS versus all other treatments. Figure 1 shows how OS varies by treatment group. Of note, reduced-intensity chemotherapy resulted in a higher median OS than intensive chemotherapy (2.06 years vs 1.95 years), however this finding was not significantly different and larger studies may be useful in detecting an effect.

Summary/Conclusion: To conclude, we have shown that age and treatment each significantly predict OS, but when these variables are included together in a multivariate analysis, treatment remains the only significant predictor, possibly due to patients being pre-selected into treatment groups by age. Although not significantly greater than the intensive treatment OS, the reduced-intensity OS was the largest of all treatments included. This may be due to the elderly population having difficulty tolerating intensive chemotherapy leading to treatment 'holidays', an overall decline in health and a lower OS than reduced-intensity chemotherapy - it is therefore highlighted here as a potential point of future research. Better powered analyses should further examine patient factors such as treatment tolerability, complication rates and late effects which may impact on OS in this frail study population.

EP524 PIRTOBRUTINIB (LOXO-305), A NEXT GENERATION, HIGHLY SELECTIVE, NON-COVALENT BTK INHIBITOR IN PREVIOUSLY TREATED RICHTER TRANSFORMATION: RESULTS FROM THE PHASE 1/2 BRUIN STUDY

A. R. Mato [1,*], N. N. Shah [2], N. Lamanna [3], T. A. Eyre [4], W. Jurczak [5], J. A. Woyach [6], E. Lech-Maranda [7], W. G. Wierda [8], D. Lewis [9], M. C. Thompson [1], D. Wang [10], M. Yin [10], M. Balbas [10], B. C. Nair [10], E. Y. Zhu [10], D. E. Tsai [10], N. C. Ku [10], C. C. Coombs [11]

[1]Memorial Sloan Kettering Cancer Center, New York, New York, [2]Medical College of Wisconsin, Brookfield, Wisconsin, [3]Herbert Irving Comprehensive Cancer Center, Columbia University, New York, New York, United States, [4]Oxford University Hospitals NHS Foundation Trust, Churchill Cancer Center, Oxford, United Kingdom, [5]Maria Sklodowska-Curie National Research Institute of Oncology, Krakow, Poland, [6]The Ohio State University Comprehensive Cancer Center, Columbus, Ohio, United States, [7]Institute of Hematology and Transfusion Medicine, Warsaw, Poland, [8]MD Anderson Cancer Center, Houston, Texas, United States, [9]Plymouth Hospitals NHS Trust – Derriford Hospital, Plymouth, United Kingdom, [10]Loxo Oncology at Lilly,

Stamford, Connecticut, [11]University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States

Background: Richter transformation (RT) is the development of an aggressive large cell lymphoma in the setting of underlying CLL and is a recurrent reason for treatment failure (5-15%) among patients (pts) receiving CLL directed therapy. Outcomes for pts with relapsed RT are extremely poor, with no standard treatment and overall survival estimated at 5-8 months. Pirtobrutinib is a highly selective and potent non-covalent BTK inhibitor (BTKi) with high oral bioavailability and a long half-life, resulting in robust BTK target coverage even in high-grade malignancies with high BTK protein turnover.
Aims: To evaluate pirtobrutinib safety and efficacy in previously treated pts with RT.
Methods: Pts with previously treated RT were enrolled to either the dose escalation or expansion portion of the multicenter phase 1/2 BRUIN study (NCT03740529). The primary endpoint for this analysis was ORR according to Lugano criteria. A key secondary endpoint was duration of response. Efficacy evaluable pts included all dosed RT pts who underwent their first response evaluation or discontinued therapy as of the data cut.
Results: As of 27 September 2020, 323 pts with B-cell malignancies were treated including 9 pts with previously treated RT (8 of 9 RT pts received the RP2D of 200mg QD, 1 pt received 150mg QD). All 9 pts had received at least one prior RT directed therapy, and the median number of prior RT directed therapies was 2 (range 1-5). Pts had received a median of 4 prior lines of therapy for CLL (range 0-6). Prior RT directed therapies included chemoimmunotherapy (100%, n=9), covalent BTKi (44%, n=4), anti-PD-1 or PD-L1 antibody (33%, n=3), mTOR inhibitor (22%, n=2), PI3K inhibitor (22%, n=2), CAR-T cell therapy (n=1), autologous stem cell transplant (n=1), polatuzumab vedotin (n=1), and pomalidomide (n=1). The ORR for the 8 efficacy evaluable pts was 75% with 6 PR, 1 SD, and 1 NE. These 8 pts have been on treatment for 1.6, 2.3, 2.9+, 2.9+, 3.2+, 3.7, 6.4+, and 7.1+ months (+ indicates ongoing). The remaining pt continues on treatment and is awaiting initial response assessment. No new safety signals were identified in RT pts. Since data cut, 8 additional previously treated pts with RT have been enrolled. Updated data with additional follow-up in all 17 RT pts will be presented.
Summary/Conclusion: Pirtobrutinib showed promising initial efficacy in pts with pretreated RT with extremely poor prognosis, including in pts who had received prior chemoimmunotherapy and covalent BTK inhibitors.

EP525 PRELIMINARY SAFETY DATA FROM PATIENTS (PTS) WITH RELAPSED/REFRACTORY (R/R) B-CELL MALIGNANCIES TREATED WITH THE NOVEL B-CELL LYMPHOMA 2 (BCL2) INHIBITOR BGB-11417

C. Y. Cheah [1,2,3,*], E. Verner [4,5], C. S. Tam [6,7,8,9], J. Hilger [10], Y. Gao [10], J. Huang [10], D. Simpson [10], S. Opat [11,12]

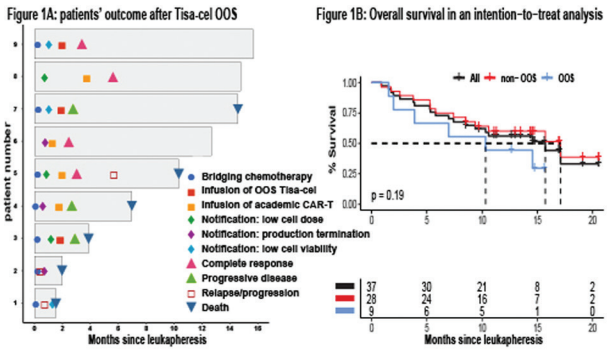
Background: BCL2, a key protein regulator of the apoptotic pathway, is aberrantly expressed in many hematologic malignancies, which can lead to pathologic cancer cell survival. Within the cell there is a delicate balance between BH3-only proteins which activate apoptosis and BCL2 which inhibits it. BH3 mimetics have been shown to be safe and effective, resulting in their approval for the treatment of pts with chronic lymphocytic leukemia (CLL) and acute myeloid leukemia. Treatment with currently approved BCL2 inhibitor venetoclax can be limited by common mild gastrointestinal toxicities, neutropenia, and the emergence of specific BCL2 mutations around the BH3-binding groove causing resistance after continued use. BGB-11417 was developed as a potent and highly selective inhibitor of BCL2 and has shown antitumor activity superior to venetoclax in human acute lymphoblastic leukemia, mantle cell lymphoma (MCL), and diffuse large B-cell lymphoma (DLBCL) xenograft models (preclinical internal data). BGB-11417 also has a favorable pharmacokinetics profile with low plasma clearance in rodents and dogs. Toxicology studies have shown a broad safety window and an excellent safety profile.
Aims: BGB-11417-101 is an ongoing first-in-human phase 1/1b study (NCT04277637) to determine the safety, tolerability, maximum tolerated dose (MTD) and recommended phase 2 dose of BGB-11417 in pts with R/R B-cell malignancies.
Methods: The study has a dose-escalation component, followed by a safety expansion. For dose escalation, pts with R/R B-cell malignancies were enrolled in 1 of 5 oral BGB-11417 dose cohorts (40, 80, 160, 320, or 640 mg once daily). All pts received a weekly or daily ramp-up to intended target dose; pts with non-Hodgkin lymphomas (NHLs) received a 2-day dose ramp-up (day 1, 25% of intended dose; day 2, 50%) before reaching the intended daily dose (day 3+, 100%). Adverse events (AEs) were reported per Common Terminology Criteria for AEs v5.0. A Bayesian logistic regression model was used to evaluate dose-limiting toxicities (DLT; assessed during dose ramp-up through day 21 at intended daily dose) rate at different doses and to determine the MTD. The first dose-escalation cohort allowed pts with R/R follicular lymphoma (FL), marginal zone lymphoma (MZL), DLBCL, or transformed NHL.
Results: As of 01-Jan-2021, 7 pts with R/R NHL across 2 dose levels had been treated. The first R/R CLL cohort had just opened with 2 pts treated. Only data from the NHL pts are reported here, including: 5 DLBCL, 1 FL, and 1 MZL with median follow-up of 2.9 mo (range, 1.7-7.7). The 40-mg (n=3) and 80-mg (n=4) dose cohorts have completed with no DLTs. The 160-mg dose cohort is currently being investigated. AEs across all dose levels occurring in >1 pt are listed in **Table 1**. Four pts have discontinued treatment (due to disease progression [n=3; 2 at 40 mg, 1 at 80 mg], or lack of efficacy [n=1 at 40 mg]) and 3 pts remain on treatment. No pt discontinued due to AEs, and no instances of laboratory or clinical tumor lysis syndrome have been observed.

Any AE in >1 Pt (N=7), n (%)	Grade ≥3	All Grade
Nausea	1 (14.3)	4 (57.1)
Constipation	0	3 (42.9)
AST increase	1 (14.3)	3 (42.9)
ALT increase	1 (14.3)	2 (28.6)
Dizziness	0	2 (28.6)
Dyspnea	0	2 (28.6)
Diarrhea	0	2 (28.6)

ALT, alanine aminotransferase; AST, asparatate aminotransferase.



Summary/Conclusion: These early phase 1 results suggest that the BCL2 inhibitor BGB-11417 is tolerable in pts with R/R NHL at dose levels tested. Preliminary activity in this pt population will be assessed with increased enrollment and follow-up. Enrollment of pts with R/R CLL is underway, and decreases in lymphocyte count have already been seen at the initial ramp-up dose of 1 mg. Evaluation of pts with MCL and Waldenstrom macroglobulinemia, and the combination of BGB-11417 and Bruton tyrosine kinase inhibitor zanubrutinib, is planned for future cohorts.

EP526 PATIENTS WITH OUT OF SPECIFICATION TISAGENLECLEUCEL CAN BE SALVAGED WITH POINT-OF-CARE CAR-T CELLS: AN OBSERVATIONAL INTENTION-TO-TREAT SINGLE-CENTER ANALYSIS

S. Fried [1,2,*], R. Shouval [1,2,3], N. Varda-Bloom [4], M. Besser [5,6], R. Yerushalmi [1,2], N. Shem-Tov [1,2], I. Danylesko [1,2], E. Jacoby [2,7], A. Shimoni [1,2], A. Nagler [1,2], A. Avigdor [1,2]

Background: Tisagenlecleucel (Tisa-cel) is an anti-CD19 chimeric antigen receptor (CAR) T-cell therapy approved for patients with relapsed/refractory diffuse large B-cell lymphoma (DLBCL). Results from the JULIET trial (Schuster, NEJM 2019) showed best overall response of 52% per-protocol and 34% in an intention-to-treat (ITT) analysis. Outcomes of patients with out-of-commercial specification (OOS) products are not well established. The availability of point-of-care anti-CD19/CD28 costimulatory domain academic CAR T-cells in our center allows us to provide rapid salvage in cases of commercial CAR T-cell production failure.
Aims: To report real-world outcomes of patients treated at a single center with Tisa-cel for DLBCL and describe outcomes in cases of OOS in Tisa-cel production.
Methods: Data of patients who underwent leukapheresis for Tisa-cel were collected and analysed. Patients received lymphodepletion with fludarabine and cyclophosphamide. Survival was calculated from leukapheresis.
Results: Peripheral blood cells were collected from 37 patients with DLBCL between May 2019 and February 2020. The median age at leukapheresis was 63 (range 28-79) years. The median number of previous treatment lines was 2 (range 2-6). Cells from 78% of the patients were collected in progressive disease. Bridging chemotherapy was given in 87% of the patients. Median time from leukapheresis to cell infusion was 1.6 (range 1.3-2.2) months. During this time, disease progression was marked in 45% of the patients. Tisa-cel CAR T-cells were infused in 29 (78%) of the patients. The median follow-up was 14.7 (IQR: 13-17) months.
In 9/37 (24%) patients, manufactured Tisa-cel did not meet specification for commercial release. Causes for OOS were production termination (3/9 [33%]), low CAR T-cells viability (<70%; 3/9 [33%]), and low CAR T-cells dose (<0.6x10^8; 3/9 [33%]). Among patients with OOS products, 3/9 (33%) received Tisa-cel, despite not meeting production standards; 2/9 (22%) did not receive Tisa-cel due to disease progression and death before salvage therapy; and 4/9 (44%) were salvaged with point-of-care academic CD19-directed CAR T-cells, at a median of 35 (range 16-92) days following the notification of production failure. Three of these four patients achieved a complete response (CR) (Figure 1A). In a univariable analysis, risk factors for OOS were ≥ 4 previous lines of treatment (p=0.04) and previous exposure to bendamustine (p=0.04). Previous bone marrow transplantation, age ≥ 65, and time from previous last therapy were not significant risk factors.
Overall response at day-28 post-CAR-T was 46% (CR 24%) and 35% (CR 24%) in per-protocol (i.e., including only patients who received Tisa-cel) and ITT (i.e., including all patients who underwent leukapheresis) analysis, respectively. One year overall survival (OS) was 65% (95% CI 50-85%) in per-protocol and 56% (95% CI 42-75%) in ITT (Figure 1B). In a multivariable ITT Cox regression, factors associated with a shorter OS were ECOG ≥ 2 (HR 6.5; 95% CI 1.9-22.5) and primary refractory disease (HR 3.3; 95% CI 1.2-9.1). Age, disease stage at leukapheresis, and LDH at leukapheresis were not significant risk factors. OOS was not statistically significant as risk factor for a shorter OS (p=0.07).

Summary/Conclusion: Our data show relatively high rates of out-of-specification products following leukapheresis for Tisa-cel. We highlight the ability to rapidly produce point-of-care CAR T-cells, facilitating immune-effector cell salvage of patients who experienced production failure of the commercial product.

EP527 DISCOVERY OF HBW-3-20, THE FIRST REVERSIBLE INHIBITOR OF BRUTON'S TYROSINE KINASE (BTK) WITH HIGH BRAIN EXPOSURE

C. Yuan [1,*], Y. Li [1], N. Lee [1], G. Liu [1], C. Yue [1]

[1]*Chengdu Hyperway Pharmaceuticals, Chengdu, China*

Background: It has been an on-demand task to develop a BTK inhibitor of significant brain exposure, a critical property for extending its usages to treat Primary Central Nervous System Lymphoma (PCNSL) and autoimmune disorders. PCNSL is an aggressive extra nodal non-Hodgkin lymphoma that exclusively invades the central nervous system (CNS). Tirabrutinib, an irreversible BTK inhibitor with limited brain exposure, is the first BTK inhibitor approved for the treatment of recurrent or refractory primary central nervous system lymphoma recently. PRN2246 is another irreversible BTK inhibitor claimed to be of brain exposure, and is currently in clinical trials for the treatment of multiple sclerosis.
Aims: Discovery of Reversible Inhibitor of Bruton's Tyrosine Kinase (BTK) with High Brain Exposure
Methods: New reversible BTK inhibitors were designed, synthesized and tested for enzymatic activities against wild-type and C481S-mutated BTK. Highly active compounds were confirmed for growth effects in diffuse large B-cell lymphoma derived TMD8 cells. Their microsomal stability and ADME properties were also assessed. Potent and bioavailable compounds were further measured for brain exposures in rats.
Results: HBW-3-20 has excellent potency against both wild-type and C481S-mutated BTK, with IC_{50} of 2.5 and 3.8 nM, respectively. Its TMD8 cellular potency is 72 nM. In a head-to-head direct comparison of brain exposure experiment, HBW-3-20, tirabrutinib and PRN2246 were all dosed at 10mg/kg orally. The brain and plasma concentration were measured after 1 hour and the data are shown in the table below. The brain to plasma ratio for HBW-3-20, tirabrutinib and PRN2246 are 58%, 11.8% and 4.2% respectively. Our results show that HBW-3-20 has much greater brain permeability than tirabrutinib or PRN2246 in rats.

Compound	tirabrutinib	PRN-2246	HBW-3-20
BTK IC_{50} (nM)	22	2.1	2.5
BTKC481S IC_{50} (nM)	na	na	3.8
TMD8 IC_{50} (nM)	158	29	72
Plasma concentration (ng/mL)	713	387	3457
Brain tissue concentration (ng/mL)	84	16.5	2009
Brain/Plasma Ratio (%)	11.8	4.2	58

Summary/Conclusion: HBW-3-20 is the first potent reversible BTK inhibitor with superior brain permeability. HBW-3-20 provides a very valuable clinical candidate for treating B-cell malignancies in brain and autoimmune disorders!

EP528 CHARACTERISTICS AND OUTCOMES IN PATIENTS WITH RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA WHO RECEIVED ≥3 LINES OF THERAPIES

M. Hamadani [1], L. Liao [2,*], T. Yang [3], J. Tang [4], L. Chen [2], C. Moskowitz [5]

[1]*Division of Hematology and Oncology, Medical College of Wisconsin, Milwaukee,* [2]*ADC Therapeutics, New Jersey,* [3]*TYStats,LLC, Marlboro,NJ,* [4]*Asclepius Analytics, New York,* [5]*Miller School of Medicine, University of Miami Health System, Miami, United States*

Background: Recent years have seen the emergence of novel treatments for Relapse/Refractory diffuse large B-cell lymphoma (DLBCL). There remains a paucity, however, of published analyses examining outcomes of patients(pts) within the evolving treatment landscape.
Aims: To address this data gap, this study examined real-world clinical outcomes among pts with R/R DLBCL who received third or subsequent line (≥3L) of therapy.
